Background: Veterans with CKD who live in the Hudson Valley Veterans Affair Medical Center (HVVAMC) catchment area travel to the Bronx VAMC for nephrology care. Analysis of the no-show and cancellation frequencies for these renal appointments exceeded 50%, likely due to the distance between HVVAMC and the Bronx (60 miles).

Methods: We hypothesized that patients managed via a telenephrology service, where patients visit their local VA and are evaluated remotely via videoconference by a Bronx VA nephrologist, would exhibit comparable clinical outcomes and visit compliance as patients with CKD and diabetes who received recommended medical treatment with angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, and increase the proportion of patients receiving a kidney transplant within 3 years of ESRD, moved away from the target. The remaining 2 objectives were not evaluated as they were informational with no target set. Disparities persisted by sex, race/ethnicity, and SES status.

Results: Characteristics of the groups were similar (initial creatinine [Cr], eGFR, distribution of CKD stage, urine protein) except for race and probable cause of CKD. Prior to the telenephrology service, 53.1% of scheduled visits of HVVAMC patients to the Bronx VAMC renal clinic were either cancelled or “no-shows” and this was reduced to nearly half (29.2%) after instituting telenephrology (p<0.001). Moreover, the frequency of attending appointments was greater in the telenephrology cohort (70.8%) vs. Bronx VA cohort (61.8%) which was driven by a greater frequency of cancelled visits in the Bronx VA (27.9%) vs. the telenephrology group (15.8%). The incidence of a composite outcome of doubling of Cr, ESRD and/or death was similar between both groups (Figure 1). The change in blood pressure and eGFR from baseline to 1 year was also similar.

Conclusions: Telenephrology is not inferior to in-person care for the management of CKD and may be superior for visit compliance. Application of this technology is a promising method to deliver care to CKD patients.

Engaging Urban African Americans at Risk for CKD in Discussions About Their Diet Deidra C. Cressy,1 Debra L. Roter,1 Raquel C. Greer,1 Yang Liu,1 Patti Ephraim,1 Jessica M. Ameling,1 Kimberly Gudzune,1 Lisa A. Cooper,1 L. Ebony Boulware.2 1Johns Hopkins U., Baltimore, MD; 2Duke U., Durham, NC.

Background: Patient-physician discussions about diet are recommended in primary care to decrease patients’ health risks, including CKD. However, little is known about the frequency of diet discussions or factors influencing them among African Americans (AAs) at increased CKD risk.

Methods: In a randomized trial of urban AAs with uncontrolled hypertension, we audio-recorded patients’ routine visits with their primary care physicians (PCPs) at the first visit following enrollment. We transcribed audio recordings, and quantified the frequency of patient-physician discussions about diet during visits. We marked transcripts for discussions of 36 dietary terms (e.g. sodium, weight, sweets). We also assessed patterns of patient-physician communication, including patient centeredness (degree to which the discussion focused on the patient’s psychosocial and lifestyle context), during each encounter using the Roter Interaction Analysis System. We identified factors independently associated with discussions of diet using logistic regression.

Results: Among 127 participants, mean age was 58 years and 70% were female. Average PCP visit lasted 25 minutes. Diet was discussed in 73% of visits, but only included discussion of the Dietary Approaches to Stop Hypertension (DASH) diet in 12%, weight/obesity in 36%, and cholesterol in 39% of visits. Independent predictors of diet discussions (odds ratio, 95% confidence interval) were patient centeredness score ratio (7.5, 1.3-41.9), annual income (3.8, 1.4-10.5 comparing ≥$10k vs <$10k), and visit length (1.07, 1.02-1.1 for each minute increment). Patient age, gender, literacy, comorbid disease burden, obesity, diabetes nor CKD status predicted discussions.

Conclusions: Discussions of diet in primary care were frequent, and they were more likely to occur when visits were longer, were centered on patient priorities, and were attended by patients with incomes ≥$10k. Diet discussions focused on various topics, but infrequently on the recommended DASH diet or other key aspects of dietary modification. Improvements in the content of diet discussions among African Americans at risk for CKD may be needed.

SA-PO716

Background: The Miami VA Healthcare System serves veterans in three South Florida counties: Miami-Dade, Broward and Monroe, with an estimated veteran population of 175,000. To overcome geographical barriers and facilitate the access to nephrology evaluations, we implemented Provider-Patient Tele-Nephrology using secured videoconferencing.

Methods: A retrospective and descriptive study design was used to evaluate the effect of the Tele-Nephrology clinic intervention. Multiple clinical indicators were included in the analysis: blood pressure control, stabilization of the renal function and electrolyte/metabolic control. 101 patients that were evaluated in the clinic between 2013-2015 were included and the indicators were collected retrospectively.

Results: 101 patients were included, 95% male (n=96) and 5% female (n=5). The mean age was 65.5 years. 50 patients had Chronic Kidney Disease (CKD) stage III (69.5%), 14 patients had CKD stage IV (13%), 8 patients had CKD stage II (7.9%). A one-way analysis of variance analysis (ANOVA) between subjects was conducted and showed that the effect
of the Tele-Nephrology clinic intervention reducing blood pressure was statistically significant (systolic blood pressure P-value < 0.0001). Renal function stabilized but the creatinine changes over time were not statistically significant (P-value: 0.50).

Subgroup analysis of individuals with eGFR < 30 ml/min or on dialysis reduced the differences in age and SPPB between the groups, but demonstrated no significant difference to change in SPPB over time. HRQL did not change significantly between groups. Proportion of individuals with improved PA over 1-year was 36% and 38% in EC and CG, respectively (p = 0.82).

Conclusions: In this study, an exercise counseling clinic had no significant effect physical function as measured by SPPB at 1-year, suggesting that exercise counseling alone is inadequate to improve physical function in CKD.

SA-PO718

Ideal and Actual Support of Renal Replacement Therapy Modality Selection Patients with Chronic Kidney Disease: A Nationwide Survey in Japan

Shiho Kosaka,1 Shinichi Nishi,2 Yugo Shibagaki,3 Junichi Hoshino,4 Kazuo Takahashi,5 Yukiko Katagiri,6 Chika Murayama,7 Yuka Funaki.1 1Sophia Univ; Tokyo, Japan; 2Kobe Univ Graduate School of Medicine, Kobe, Japan; 3St. Marianna Univ Hospital, Kawasaki, Japan; 4Toranomon Hospital, Tokyo, Japan; 5Fujita Health Univ School of Medicine, Toyoake, Japan.

Background: Optimal renal replacement therapy (RRT) selection supports for chronic kidney disease (CKD) patients are essential to improve post-treatment outcomes. We aimed to investigate how and when modality selection supports for patients with CKD are used by nephrologists in Japan, through a nationwide questionnaire survey of nephrologists.

Methods: A questionnaire was mailed to 1903 board-certified nephrologists of Japanese Society of Nephrology. Questionnaire items targeting support for modality selection examined the following points: establishment of an RRT modality selection (RRT-MS) clinic, ideal and actual disease stage at which RRT-MS explanation is discussed, timing of RRT initiation, and type of specialist discussing RRT-MS with patients.

Results: The valid response rate was 12.3% (234/1903). Ninety-four out of 234 responding nephrologists (40.9%) had clinics dedicated to RRT-MS. Modality selection was most frequently discussed at CKD stage 4 (55.0%), stage 3b (22.8%), and stage 3a (13.4%). Nephrologists considered stage 3b (32.5%), stage 3a (19.5%), most ideal for discussing RRT-MS, a significant difference was therefore found between ideal and actual timing of RRT-MS discussion. Timing (by eGFR) of access placement of hemodialysis (HD) and peritoneal dialysis (PD) was significantly earlier in patients of RRT-MS clinics than in those of conventional clinics (HD, 12.3/14.1; PD, 12.6/14.9 ml/min/1.73 m²). Regarding types of specialists, nurses most frequently supported patients in RRT-MS (67.1%), however, this may be partly explained by the fact that nephrologists are required to commit more specialistismo supporting patients for RRT-MS.

Conclusions: A gap between ideal and actual timing of discussion of RRT-MS with patients in Japan was identified. To promote appropriate timing of RRT-MS among CKD patients, early and multidisciplinary support systems should be structured.

Primary Care Physicians’ Perceived Barriers and Facilitators to Care of Older Adults with Kidney Failure Not on Dialysis

Helen Tam-Tham, Brenda Hemmelgarn, Chandra Mary Thomas, Karen Fruetel, Robert R. Quinn, Kathryn M. King-Shier. Univ of Calgary, AB, Canada.

Background: Primary care physicians are important care providers for older adults with kidney failure, but how they perceive and practice conservative (non-dialysis) care has not been studied. We undertook a qualitative study to describe barriers, facilitators, possible enhancements of conservative care in the community for these older adults.

Methods: Semi-structured telephone interviews were conducted with primary care physicians from southern Alberta, Canada. Participants were identified by a snowball sampling strategy and purposefully sampled based on sex, age, and rural/urban location of clinical practice. All participants managed at least 1 patient ≥75 years with kidney failure (eGFR <15ml/min/1.73m² for at least 3 months, not on dialysis) over the past year. Transcripts were analyzed thematically by conventional content analysis.

Results: Twenty-seven primary care physicians participated in this study (55.6% of participants were male, 55.6% of participants were aged 40 to 60 years, and 51.9% of participants practiced in the primary care setting for greater than 20 years). Perceived barriers to conservative care included: managing expectations of kidney failure for patients and their families, optimizing medical management of conservative care, and negotiating provider roles and responsibilities of co-management. Facilities for care included: establishing patient and their family expectations of care early, preserving continuity of care, and utilizing a multidisciplinary team approach. Primary care physicians also identified suggestions for enhancement of conservative care in the community, including direct telephone access by primary care physicians to conservative care clinicians, treatment decision aids for patients and their families, and a conservative care clinical pathway for primary care providers.

Conclusions: We found important barriers and facilitators to conservative care by primary care physicians in the community. Further investigation of potential strategies that remove barriers and enable facilitators is required to improve the quality of conservative care in the community.

SA-PO720

Background: Awareness of chronic kidney disease (CKD) is low, even among patients with advanced disease. Increasing awareness to 11.7% is a Healthy People 2020 goal. The National Health and Nutrition Examination Survey (NHANES) measures CKD awareness using the question “Have you ever been told by a doctor or other health professional that you had weak or failing kidneys (excluding kidney stones, bladder infections, or incontinence)?” The framing of this question may influence responses. We sought to compare its sensitivity/ specificity to different questions as well as to awareness of other chronic conditions.

Methods: We administered a questionnaire to 220 English, Spanish and Cantonese-speaking adults who received primary care in a public healthcare delivery system. We obtained demographic data, screened for health literacy and ascertained patient awareness about chronic health conditions, including CKD, diabetes, hypertension and hyperlipidemia. CKD awareness was measured using the NHANES question and additional ones, asking if patients had been told about “kidney disease,” “protein in the urine,” “kidney problem,” or “kidney damage”. Health conditions were verified by medical record review.

Results: In our diverse study population (9.6% White, 40.5% Black, 36.4% Hispanic, 12.0% Asian), mean age was 58, mean eGFR was 47 ml/min/1.73m2 and 47% had low health literacy. Sensitivities of each CKD awareness question were: 26.7% for “kidney damage”, 28.0% for “kidney disease”, 33.5% weak or failing kidneys” (NHANES), 36.2% for “protein in the urine” and 40.6% for “kidney problem”. Specificities ranged from 88.2% to 97.7%. Combining all 5 questions yielded a sensitivity of 61.1% and a specificity of 79.6%. This was comparable to awareness of hypertension (68.8%) but was lower than awareness for hypertension and diabetes (89.6% and 94.3% respectively). Sensitivities were lower in patients with low health literacy.

Conclusions: CKD awareness is low compared to other chronic diseases. Nevertheless, by using more sensitive combinations of questions to ascertain CKD awareness, we have likely reached the Healthy People 2020 goal.

The Effects of Age and Symptoms on Recommendations to Initiate Dialysis Michael Walsh, Rajnish Mehrotra, Carmel M. Hawley, Marcello Tonelli, Clare I. Castledine, Stephen P. McDonald, Darin Treleaven, Vicki Levioditis, K. Scott Brimble. McMaster Univ.

Background: The extent to which patient characteristics influence Nephrologists’ recommendations regarding initiation is unclear. We conducted an international survey to examine the effect of country on recommendations to initiate dialysis.

Methods: Nephrologists from Australia, Canada, New Zealand, the UK and the US were surveyed by email. The survey included clinical vignettes that varied patient characteristics. The recipient scored the likelihood they would recommend initiating dialysis on an 8-point modified Likert scale anchored at 1 (definitely would not) and 8 (definitely would). Results were analysed using mixed-effects regression.

Results: 771 nephrologists were included. The degree to which patient age was associated with recommending dialysis varied by country (p<0.001 for interaction) (Figure 1). For a given level of GFR, only nephrologists from Canada (p<0.001) and the US (p<0.001) were more likely to recommend dialysis for patients 75 years old than those aged 45. Conversely, nephrologists from Australia (p<0.001), New Zealand (p=0.001) and the UK (p=0.003) were less likely to recommend dialysis for patients aged 90 than those aged 45. All nephrologists were more likely to recommend dialysis as symptoms increased but this association was less pronounced in the US and Australia (p<0.001 for interaction). Patient comorbidities, nephrologists’ years in practice, and practice type were not associated with recommendations.

Conclusions: For patients at a given eGFR, other characteristics such as age and symptom burden influence nephrologists’ recommendations to initiate dialysis but the extent of this influence differed substantially between nephrologists in different countries. Further research is required to understand the effect of these differences on patients and health systems.

SA-PO722

The Association of Community Health Indicators with Late Nephrology Referral in Patients Reaching End-Stage Renal Disease in the U.S. Jung-In Shin, Mari Palta, Micah R. Chan, Brad C. Astor. Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Late nephrology referral in patients reaching end-stage renal disease (ESRD) is associated with inadequate preparation for dialysis and poorer clinical outcomes after renal replacement therapy (RRT). Previous studies have focused on individual-level factors to identify patients at higher risk of late nephrology referral. Environmental and socioeconomic conditions of communities in which patients live may also impact nephrology referral patterns.

Methods: We assessed the association of community health indicators with late nephrology referral in 587,574 patients reaching ESRD, using the data from United States Renal Data System (USRDS) from 2005-2012. An overall community health risk score was calculated using 35 community-level factors based on 1) health outcomes, 2) health behaviors, 3) access and quality of care, 4) socioeconomic factors, and 5) physical environment, using County Health Rankings data from University of Wisconsin Population Health Institute. Late nephrology referral was defined as the first encounter with a nephrologist occurring < 6 months before RRT initiation. Multilevel logistic regression models adjusted for individual characteristics, including demographics, cause of ESRD, body mass index, comorbidities, and insurance and employment status.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

793A
Results: The prevalence of late nephrology referral was 47.8%. A significant dose-response relationship of community risk score with late nephrology referral was found, with an adjusted odds ratio of 1.52 (95% CI: 1.36-1.71) for the highest versus lowest risk communities.

Conclusions: Higher community risk is significantly associated with late nephrology referral, independent of individual-level factors. Community risk may be an important consideration for developing interventions to improve access to pre-ESRD nephrology care.

SA-PO723
Assessment of Quality of Care Received by Patients with Predialytic CKD: Health Services, Disparities, and Prevention
Poster/Saturday

Background: In a country with limited access to dialysis and transplantation such as the Philippines, it is imperative to recognize patients with early stage CKD and aggressively intervene in a timely fashion to prevent ESRD and death. The objective of this study is to evaluate the quality of care (QoC) of patients with predialytic CKD seen at a general medicine clinic.

Methods: This was a retrospective study which reviewed the medical records of 276 patients with CKD Stages 3-4 who have at least 1 year of consult. Patients who were admitted for critical illness, and are on dialysis were excluded. For each QoC parameter, percentage of patients who received the appropriate care were reported. For the QoC study, all patients were seen at a medicine clinic.

Results: The mean QoC score for this study is 58.36% (± 23.7%) and the average annual GFR decline is 3.92 mL/min/1.73m².

Conclusions: Understanding of RRT options was poor among CKD patients participating in the US. Though the responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fail to adequately communicate key messages on RRT.

SA-PO724
Chronic Kidney Disease (CKD) Patients’ Understanding of Renal Replacement Therapy (RRT) Options: Early Findings from the U.S. CKD Outcomes and Practice Patterns Study (CKDopp)
Poster/Saturday

Background: Current KDIGO guidelines indicate that kidney failure patients should receive information on all RRT modalities, including conservative management. Even when education is provided, patients’ understanding of such a complex topic may be limited. We report the perspective of US participants in the first year of CKDopp.

Methods: CKDopp is a new international prospective cohort study that enrolls adult advanced CKD patients in national samples of nephrology clinics in the US, Brazil, France, and Germany and follows patients through the dialysis transition period. As of early 2015, 245 US participants with eGFR<30 mL/min/1.73m² completed a self-administered questionnaire including their understanding of, education on, and preferences for RRT options.

Results: The median age of patients was 71; 43% were male and 57% had diabetes. 66% of patients reported they received no education about treatment options for kidney failure; 20% said they received one-on-one education; and 14% participated in a class. 34% recalled that in-center hemodialysis (HD) was discussed as a treatment option, and less than 25% recalled their doctor discussing peritoneal dialysis, home HD, conservative management, or transplantation. 58% of participants reported they did not know if transplantation was an option for them. Nearly 3 out of 5 patients did not know what RRT option they would choose if their kidneys failed.

Conclusions: Understanding of RRT options was poor among CKD patients participating in the US. The responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fail to adequately communicate key messages on RRT.

SA-PO725
Chronic Kidney Disease (CKD) Patients’ Understanding of Renal Replacement Therapy (RRT) Options: Early Findings from the U.S. CKD Outcomes and Practice Patterns Study (CKDopp)
Poster/Saturday

Background: Current KDIGO guidelines indicate that kidney failure patients should receive information on all RRT modalities, including conservative management. Even when education is provided, patients’ understanding of such a complex topic may be limited. We report the perspective of US participants in the first year of CKDopp.

Methods: CKDopp is a new international prospective cohort study that enrolls adult advanced CKD patients in national samples of nephrology clinics in the US, Brazil, France, and Germany and follows patients through the dialysis transition period. Results: The median age of patients was 71; 43% were male and 57% had diabetes. 66% of patients reported they received no education about treatment options for kidney failure; 20% said they received one-on-one education; and 14% participated in a class. 34% recalled that in-center hemodialysis (HD) was discussed as a treatment option, and less than 25% recalled their doctor discussing peritoneal dialysis, home HD, conservative management, or transplantation. 58% of participants reported they did not know if transplantation was an option for them. Nearly 3 out of 5 patients did not know what RRT option they would choose if their kidneys failed.

Conclusions: Understanding of RRT options was poor among CKD patients participating in the US. Though the responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fail to adequately communicate key messages on RRT.

SA-PO726
Chronic Kidney Disease (CKD) Patients’ Understanding of Renal Replacement Therapy (RRT) Options: Early Findings from the U.S. CKD Outcomes and Practice Patterns Study (CKDopp)
Poster/Saturday

Background: Current KDIGO guidelines indicate that kidney failure patients should receive information on all RRT modalities, including conservative management. Even when education is provided, patients’ understanding of such a complex topic may be limited. We report the perspective of US participants in the first year of CKDopp.

Methods: CKDopp is a new international prospective cohort study that enrolls adult advanced CKD patients in national samples of nephrology clinics in the US, Brazil, France, and Germany and follows patients through the dialysis transition period. As of early 2015, 245 US participants with eGFR<30 mL/min/1.73m² completed a self-administered questionnaire including their understanding of, education on, and preferences for RRT options.

Results: The median age of patients was 71; 43% were male and 57% had diabetes. 66% of patients reported they received no education about treatment options for kidney failure; 20% said they received one-on-one education; and 14% participated in a class. 34% recalled that in-center hemodialysis (HD) was discussed as a treatment option, and less than 25% recalled their doctor discussing peritoneal dialysis, home HD, conservative management, or transplantation. 58% of participants reported they did not know if transplantation was an option for them. Nearly 3 out of 5 patients did not know what RRT option they would choose if their kidneys failed.

Conclusions: Understanding of RRT options was poor among CKD patients participating in the US. Though the responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fail to adequately communicate key messages on RRT.
Conclusion: These results suggest that the rate of prescription of statins in CKD patients is suboptimal and differs by the provider caring for the patient with CKD. Lack of CVD preventive care may impact overall CVD risk in patients with dialysis-dependent CKD.

SA-PO726

Patients’ Knowledge of Their Chronic Kidney Disease Stage and Education About Kidney Failure Prevention – The CKD-REIN Cohort

Benedicte Stengel, 1 Celine Lange, 2 Brian Con Serge, 2 Luc Frimat, 3 Denis Fouque, 4 Maurice Laville, 5 Christian Jacquelinet, 2 Bruce M. Robinson, 5 Ziad Fouque, 4 Maurice Laville, 5 Christian Jacquelinet, 2 Bruce M. Robinson, 5 Ziad Fouque, 4 Maurice Laville, 5 Christian Jacquelinet, 2 Bruce M. Robinson, 5 Ziad Fouque, 4 Maurice Laville, 5 Christian Jacquelinet, 2 Bruce M. Robinson, 5 Ziad Fouque, 4 Maurice Laville, 5 Christian Jacquelinet, 2 Bruce M. Robinson, 5 Ziad

Background: Patient knowledge about their CKD stage and how to prevent kidney failure is important to reduce ERSD risk through better adherence to treatment and lifestyle changes. We report preliminary findings about CKD knowledge among patients seen by nephrologists in France.

Methods: We used baseline data from the CKD-REIN study, a prospective cohort of patients with CKD stage 3 and 4 in a national sample of 40 nephrology clinics. Information was collected from patient interview and self-administered questionnaire. Comparisons between stages were adjusted for age and gender.

Results: Median age was 68 (59-76) and 56% were male. About 80% reported knowledge that their kidney function was low. Patients were more likely to know their creatinine level (40%) than GFR or CKD stage. For each question, knowledge increased slightly from stage 3 to stage 4. Education about how to prevent kidney failure was uncommon (10%).

SA-PO728

Getting a Diagnosis of Chronic Kidney Disease: Despite Fears, Patients Want to Know Early

Julie A. Wright Nunes, 1 Meghan Roney, 2 Eve Kerr, 3 Akinlolu O. Ojo, 1 Angela Fagerlin, 1,2 1 Internal Medicine, Univ of Michigan, Ann Arbor; MI; 2 Center for Bioethics and Social Sciences in Medicine, Univ of Michigan, Ann Arbor, MI; 3 Center for Clinical Management Research, VA Ann Arbor Healthcare System, Ann Arbor, MI.

Background: Little is known about patient perspectives related to getting a diagnosis of chronic kidney disease (CKD). This information could help providers optimize diagnosis timing and the point of care.

Methods: Using root/cause analysis and quality function deployment we conducted semi-structured patient interviews. Adult patients with established non-dialysis CKD were interviewed between January-October 2014. Interviews were audiorecorded and transcribed. Content analysis was done with Dedoose, a qualitative software package.

Results: 49 patients completed interviews. Mean (SD) age was 63 (14) years, 50% were male, 80% were Caucasian and 84% had CKD Stage 3-5. Key themes emerged from a total of 786 statements: 1) Reaction to diagnosis (160 statements) 2) Barriers to accepting diagnosis (61 statements) and 3) Expectations of diagnosis communication (122 statements). 45% of patients felt fearful after getting a CKD diagnosis-most often related to perceived threats of future dialysis and death. Barriers to diagnosis acceptance included disbelief because of lack of symptoms and lack of prior familiarity with CKD. Despite fear and denial the majority of patients (63%) desired early diagnosis communication by their providers, i.e. at earliest stages of identification. Consistent terminology and disease explanations by providers across the care continuum were perceived as critical to effective communication and diagnosis delivery, yet patients expressed frustration at inconsistent terminology/explanations.

Conclusions: Our findings emphasize that patients learning of a CKD diagnosis can experience fear, but they also prefer early communication of diagnosis. More work is needed to set uniform diagnosis terminology for patients with CKD across the care continuum.

The Cost-Effectiveness of Primary Screening for Chronic Kidney Disease in Rural and Remote First Nations

Thomas W. Ferguson, 1 Navdeep Tangri, 2 Matthew T. James, 2 Zhi Tan, 3 Claudio Rigatto, 2 Paul Komenda. 1, 2 Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; 3 Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 4 Medicine, Univ of Calgary, Calgary, AL, Canada.

Background: Chronic Kidney Disease (CKD) is a risk factor for cardiovascular disease, early mortality, and kidney failure. We have shown that the burden of CKD in First Nations (FN) populations in Manitoba is similar to that in diabetic and hypertensive populations. The cost-effectiveness of screening for CKD and subsequent treatment in FN or other high-risk indigenous populations has not yet been described.

Methods: We constructed a Markov model comparing screening in adult FN (age ≥18) for CKD by both proteinuria and estimated glomerular filtration rate (eGFR) to usual care from the perspective of the publicly funded Canadian health care payer. Patients were assigned an initial risk classification based on urine albumin-to-creatinine ratio and eGFR using the Kidney Disease Improving Global Outcomes (KDIGO) heat map. We obtained screening tests results on 1346 adult participants from the First Nations Community Based Screening to Improve Kidney Health and Quality of Life (FINISHED) initiative. Our analysis was further stratified into communities accessible by road and communities accessed by air travel. Our primary outcome of interest was the incremental cost per quality-adjusted life-year (QALY).

Results: Overall crude prevalence of CKD in FN was 26.7%. Screening for CKD was associated with an ICER of $33,500/QALY in comparison to usual care. Restricting the model to screening in the remotest air access communities (prevalence of CKD 36.0%), this ratio fell to an ICER of $16,180/QALY. In less remote road access communities (CKD prevalence of 18.4%), the ICER was $63,780/QALY. Primary model drivers included the cost of dialysis, assumed treatment effectiveness, and rates of progression towards kidney failure.

Healthcare Expenditures for Non-Dialysis Dependent Kidney Disease Compared to Other Chronic Diseases

Christina Small,1 Holly J. Kramer,1 Karen A. Griffin,1 David J. Leehey,1 Vinod K. Bansal,1 Kavitha Vellanki,1 Talar Markossian.1 1Loyola Univ Chicago; 2Hines VA Medical Center.

Background: There is a paucity of literature comparing the expenditures of kidney disease with other common costly chronic diseases in the United States. Our study compares the U.S. healthcare expenditures of non-dialysis dependent kidney diseases to several other chronic conditions.

Methods: This study used the 2012 Medical Conditions and Consolidated Data files from the Medical Expenditure Panel Survey administered by the Agency for Healthcare Research and Quality. Analyses included adults aged ≥ 21 years with one of the following conditions: kidney disease, stroke, cancer, or a combination of the three (multichronic). Non-dialysis dependent kidney disease included any ICD9 code for kidney related conditions while chronic kidney disease (CKD) included only ICD9 code “585.” Analyses of calculated healthcare expenditures accounted for the complex survey design and incorporated the sampling weights so that estimates represent healthcare expenditures for the 2012 adult U.S. population (~313.4 million). Out of pocket healthcare expenditure burden was defined as the ratio of out of pocket healthcare expenditure to total person-level income for the year 2012.

Results: The mean age for non-dialysis dependent kidney disease and CKD was 56.5 and 65.9 years, respectively. Table 1 shows the median total and out of pocket healthcare expenditure values and mean out of pocket healthcare burden for kidney disease, CKD and other chronic conditions.

Conclusions: Healthcare expenditures including out of pocket costs are higher for non-dialysis dependent CKD compared to other chronic medical conditions. Policy efforts should focus on reducing the healthcare cost burden for patients with kidney disease.

SA-PO731

Smartphone-Based Self-Management System for Chronic Kidney Disease: Results from a Single Centre Prospective Trial

Stephanie W. Ongh,1 Sarbjit Small,1,2 Holly J. Kramer,1 Karen A. Griffin,1 David J. Leehey,1 Vinod K. Bansal,1 Kavitha Vellanki,1 Talar Markossian.1 1Loyola Univ Chicago; 2Hines VA Medical Center.

Background: Following user-centric design principles we developed a smartphone-based self-management support system for patients with advanced CKD. The patient interface focuses on 4 behavioral elements over which they have direct control: monitoring BP at home, self-assessment of symptoms, managing medications and tracking laboratory results. The main objectives of this 6-month prospective study were to determine acceptability, measured by system adoption and adherence, and assess effectiveness by measuring pre and post changes in BP, medications, labs and self-management behaviors.

Methods: We tested the mobile app in 10 renal clinics at a single academic renal center in Toronto. The 47 enrolled patients were instructed at a regular clinic visit to use the mobile app. The clinical team independently received information on the mobile app system’s operation.

Results: 61% of participants were non-smartphone owners. All had more than one chronic condition and on average were on 10 to 15 medications. Most were over the age of 50 with the greatest representation in the age group 55-64. >80% of the users achieved more than the recommended 80% adherence rate to mobile app use.27% with normal clinic BP readings were discovered to have ‘masked’ hypertension on home BP monitoring. By the end of the study the SBP fell by 6.8 ± 20.4 mm Hg (p < 0.05) and DBP by 9.9 ± 9.1 mm Hg. Out of 250 medication reviews, 49% required intervention from the clinical team, such as altering drug dosing. Due to the short study duration and infrequency of lab testing, there were no changes in pre and post laboratory test results. On exit, patients and clinicians felt the mobile app helped engage and empower patients in their CKD care.

Conclusions: The mobile app was acceptable and suggests improvements in BP management and medication error prevention. This provides early evidence to supporting innovative use of mobile technology in CKD management and strongly support evaluating its use in a larger clinical.

SA-PO732

Potentially Preventable Hospitalization Among Patients with Chronic Kidney Disease and High Inpatient Use

Paul E. Ronksley, Braden J. Manns, Marcello Tonelli, James Wick, Brenda Hemmelgarn. 1Univ of Calgary, Calgary, AB, Canada.

Background: While prior studies have observed high rates of hospitalization among patients with chronic kidney disease (CKD), little attention has been given to those with high inpatient use. We explored clinical characteristics, patterns of hospital use, and potentially preventable acute care encounters among hospitalized patients with CKD.

Methods: We identified all adults (≥18 years) with an eGFR < 60 mL/min/1.73 m2 in Alberta, Canada between Jan 1 and Dec 31, 2009, excluding those with prior kidney failure. Patients with CKD were linked to administrative data to capture clinical characteristics and frequency of hospital encounters, and followed until death or end of study (Dec 31, 2012). Patients with 1 or more hospital encounters were categorized into 3 groups: persistent high use (upper 5% of inpatient use (≥3 encounters/yr) in 2 or more years), episodic high use (upper 5% in 1 year only), or non-high use (lower 95% in all years). Within each group we described patient characteristics and calculated the proportion of potentially preventable hospitalizations as defined by 4 CKD-specific ambulatory care sensitive conditions (ACSC); heart failure, hyperkalemia, volume overload, malignant hypertension.

Results: During a median follow-up of 3 years, 57007 patients had 118671 hospitalizations of which 1.7% of patients were persistent high users of hospital services, 12.3% episodic high users, and 86.0% non-high users. Persistent high users were often younger, male, First Nations, living in rural areas, and had higher levels of comorbidity compared to episodic and non-high use groups. Overall, 24804 (20.9%) CKD-related ACSC encounters were observed in the cohort. The proportion of ACSC encounters were higher in persistent high users (29.1%) compared to episodic (27.3%) and non-high users (17.3%) (p < 0.01). The majority of the encounters were attributed to heart failure and hyperkalemia in all groups.

Conclusions: A substantial proportion of hospitalizations among patients with CKD and high inpatient use are ACSC-related. These findings suggest opportunities to reduce inpatient use and cost by focusing on strategies to improve community-based care for this subset of patients.

Rapid Post-Transplant Improvement of HRQOL in Older Kidney Recipients

Kristian Heldal,1,2 Kjersti Lonning,2 Tomm Bernklev,2 Nanna von der Lippe,2 Anna Reisaeter,3 Anders Hartmann,2 Marit Helen Andersen,3 Karsten Midveldt,1 1Clinic of Internal Medicine, Telemark Hospital, Skien, Norway; 2Inst of Clinical Medicine, Faculty of Medicine, Univ of Oslo, Oslo, Norway; 3Clinic of Surgery, Surgery and Transplantation, Oslo Univ Hospital, Rikshospitalet, Oslo, Norway; 4Research Unit, Telemark Hospital, Skien, Norway.

Background: It is widely accepted that health-related quality of life (HRQOL) is significantly compromised in patients with ESRD. In adults, kidney transplantation (KTx) is known to improve HRQOL. In older recipients there is a lack of studies measuring the effect of KTx on HRQOL. The aim of this study was to measure HRQOL longitudinally in enrolled patients ≥65 years of age, from pre-transplant and until 6 months after KTx.

Methods: Patients ≥65 years listed for transplantation at our centre were asked to complete the SF36 questionnaire at enlisting and thereafter every 6 months until KTx. Post-transplant, the patients received a new SF36 form after 10 weeks and 6 months.

Results: A total of 180 patients have been included from Jan 2013. Mean age at enlisting was 76.6 years (65.0-81.8) and 68% were male. By the end of May 2015, 100 patients were transplanted and 59 of them had completed both pre- and post-transplant questionnaires. While mean time from completing the first pre-tx questionnaire to transplantation was five months. When comparing the scores for the last SF36 pre-tx with 6 months post-tx, there was a significant statistical increase in the mean scores for GH (53.71), PF (68.74), BP (64.78), VT (53.71) and MH (79.85). There was also a tendency towards improved scores for RP and RE, while the SF score was unchanged.

Conclusions: Our preliminary findings indicate that older patients report a significant improved HRQOL measured by SF36 already 10 weeks after KTx and the status remains stable after 6 months. Longer follow-up is warranted.

L-Carnitine Improves Cognitive and Renal Functions in a Rat Model of Chronic Kidney Disease

Zaher Anis Armully,1 Adel Rafik Jabbour,2 Cheuk Yee Leung,1 Alpig childhood and associated metabolic abnormalities. L-Carnitine treatment of KTx rats significantly reduced Scr and BUN, attenuated renal hypertrophy and decreased renal tissue damage. In addition, in the two way shuffle avoidance learning, CKD animals showed cognitive impairment which recovered by the administration of L-Carnitine.

Methods: We studied 178 prevalence PD patients (103 males). Cognitive impairment was screened by the 10-item Abbreviated Mental Test (AMT) questionnaire. We also determined patients’ comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Conclusions: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average AMT score was 9.3 ± 1.3. The AMT score is closely associated with age (r –

Being a Relative to Patients with Chronic Kidney Disease – Experiences of Participation in Care and Treatment

Hanne Aagholt,1 Jette Kristiansen,2 Mona Kyndal Pedersen,3 1Dept of Nephrology, Aalborg Univ Hospital, Aalborg, Denmark; 2Univ College of Northern Denmark, Aalborg, Denmark; 3Clinic for Internal Medicine, Aalborg Univ Hospital, Aalborg, Denmark.

Background: Studies concerning the lives of patients with chronic kidney disease have focused on the patients, and not the relatives. However, relatives share and are affected by the same consequences as the patient with regard to changes in everyday life, roles in the family and mutual relationship. The purpose of the study was to gain insight into and understanding of the needs of the relatives of patients with chronic kidney disease with regard to their ability to provide support in everyday life, and the expectations of the relatives of participation in care and treatment.

Methods: A qualitative study based on four focus group interviews with four to eight relatives in each group (in total 27 relatives). The groups were formed according to the age and gender of the relatives as well as their relation to the adult patient with chronic kidney disease.

Results: The study demonstrated how relatives provide substantial support to the patient both in everyday life and in care and treatment. In relation to the patient, it was a constant challenge for relatives to find the balance between supporting and taking over. They expressed a need for recognition by both the close relations and the health care professionals as well as a need for sharing their experiences with other relatives in the same situation.

Conclusions: When collaborating with the relatives with regard to care for patients with chronic kidney disease, the health care professionals should actively recognize the patient support that the relatives already provide in everyday life. Initiatives of participation in care and treatment should be based on collaboration and the needs, expectations and possibilities of both the patient and the relatives.

CKD(3-5) Affects Endurance, Strength, Balance and Fine Motor Skills which Are Not Detectable by Questionnaire

Naomi D. Clvne,1 Matthias Hellberg,1 Peter Hoglund,2 1Clinical Sciences Lund, Nephrology, Lund Univ, Lund, Sweden; 2Laboratory Medicine, Clinical Pharmacology, Lund Univ, Lund, Sweden.

Background: Physical functions are impaired in dialysis patients. It is unclear which functions are affected and how they decline in the course of CKD. This study investigated the effects of declining GFR (CKD 3-5) on measured physical functions, self perceived physical functioning and well-being.

Methods: In this cross sectional analysis 101 patients (40 women, 61 men; mean age: 67.1±13 years, median GFR: 21 (9-41) ml/min/1.73m²) were tested with 6 Minutes Walk (6-MWT), Isometric Quadriceps Strength (IQS), Functional Reach (FR) and Picking-up (PUT). Self perceived physical functioning and well-being were assessed by KDQOL-SF. GFR was measured with iohexolclearance and comorbidity by Davies’ index. Multivariable linear regression analyses were employed including the following explanatory variables: GFR, age, sex, comorbidity and the interaction between sex and age.

Results: Significant associations were found between decline in GFR and endurance (6-MWT; p=0.039), strength (IQS; p=0.035), balance (FR; p=0.024) and fine motor skills (PUT; p=0.015) as well as by the patients’ perceived domains in the KDQOL-SF™ of effects (p<0.025) and burden (p=0.016) of kidney disease and social support (p=0.006) after having taken the explanatory variables into account. There were significant associations between the KDQOL-SF™ domains role physical and emotional well-being and 6-MWT (p=0.018; p=0.018, respectively) and IQS (p=0.005; p=0.045, respectively), but these were dependent on age, sex and comorbidity but not driven by GFR.

Conclusions: Physical functions comprising endurance, strength, balance and fine motor skills were impaired relatively early in the course of CKD (3b-5), seemed to progress with declining GFR and could be detected by easy to perform physical function tests. The relationship between self perceived physical functioning and well being, respectively, with measured endurance and strength, respectively, were driven by age, sex and comorbidity but not by decline in GFR. The only domains that discriminated for GFR associated influence were effects- and burden of kidney disease and social support.
Neurocognitive Functioning and Association with Clinical Outcomes in Adults with End-Stage Kidney Disease: The COGNITIVE-HD Study Giovanni F.M. Strippoli*

On behalf of the COGNITIVE-HD Study Investigators*, 1Duaveram Medical Scientific Office; 2Univ of Bari; 3Univ of Sydney.

Background: Cognitive impairment and neurocognitive disorder have been associated with increased mortality in the general population. Whether dialysis patients have specific patterns of cognitive dysfunction, or whether cognitive function is associated with activities of daily living and durability of dialysis treatment remain poorly understood.

Methods: The COGNITIVE-HD study will provide detailed neuropsychological assessments of cognitive function among hemodialysis patients to characterize age- and education-adjusted prevalence and patterns of cognitive impairment and the associations with physical and social functioning and clinical outcomes including cardiovascular events at 12 months. The COGNITIVE-HD study is a prospective, longitudinal, population study of 751 adults conducted in 20 dialysis centers in Italy. A detailed battery of comprehensive testing for executive function, visuospatial function, language, learning and memory, personality traits, and complex attention has been carried out by a trained psychologist at baseline to assess for presence of cognitive impairment and to evaluate the pattern of cognitive deficits, and any association between cognitive impairment and activities of daily living.

Results: Preliminary analyses have been conducted on the Mini Mental State Examination (MMSE) evaluation of cognitive function among 702 participants (mean age 68.2 years, 60% men). 50% had normal cognitive function (MMSE score 27-30), 22% had mild cognitive impairment (score 26-24), 198 patients (28%) had MMSE results compatible with dementia (score <24), of whom 51%, 48% and 1% had mild, moderate and severe impairment respectively.

Conclusions: The COGNITIVE-HD is a population-based study of cognitive function involving dialysis patients that has the potential to inform candidate interventions for treatment trials of cognitive impairment in the setting of advanced kidney disease. *List of study investigators: S Palmier, M Ruoppo, A Iurillo, V Saglimbene, P Natale, O Barulli, L Giargaro, AM Muro, +C.I. Cruz, DW Johnson, M Tonelli, J Heghrent, C Wollheim, G Logroscino and GFM Strippoli.

Lower Renal Function Predicts Poorer Performance in Specific Domains of Neurocognitive Function in Older Hypertensive Men

Stephen L. Seliger, 1 Jason Kissner, 2 Jamie Giffuni, 3 Leslie I. Katzel, 1 Shari R. Waldstein.

Background: Cognitive impairment and neurocognitive disorder have been associated with common cognitive risk factors. However, across a range of GFR, lower renal function is associated with worse performance in specific domains of cognitive function.

Methods: A total of 322 children (M:F 218:104) enrolled from seven major pediatric nephrology centers of Korea from July 2010 to December 2013 were the subject of this study. Neurocognitive function and psychiatric status of pediatric CKD patients were evaluated using Wechsler Intelligence Scale for children, Child Behavior Checklist, ADHD Rating Scale-IV, State-Trait Anxiety Inventory, Child Depression Inventory and Parental bonding instrument-Korean version.

Results: Verbal, performance and full scale IQ were lower in younger age and congenital anomalies of the kidney and urinary tract as a cause of CKD. More than 10 percent of school-age children with CKD presented significant emotional distress including somatization (15%), attention problems (15%) and anxiety (12%). Impact of progression of CKD on their neurocognitive function and psychiatric status will be investigated in KNOW-PedCKD cohort study in Korea.

Conclusions: We determined that pediatric chronic kidney disease (CKD) is associated with neurocognitive impairment and psychiatric disorder from the KNOW-PedCKD cohort study in Korea.

Vitamin D Deficiency Is Significantly Associated with Depression in Chronic Kidney Disease Patients

Jung Hyeon Jhoo, Sul A. Lee, Hyung Jung Oh, Jung Tak Park, Seang Hyoeok Han, Shin-Wook Kang, Tae-Hyun Yoo. Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Recent studies have reported significant associations between vitamin D deficiency and depression in the general population. Although both vitamin D deficiency and depression are common features in chronic kidney disease (CKD) patients, the association between these two prevalent factors in this patient population remains poorly elucidated. Therefore, the association between vitamin D deficiency and depression in CKD patients was investigated.

Methods: The data from the Korean National Health and Nutrition Examination Survey between 2010 and 2012 were used. A total of 495 patients with estimated glomerular filtration rate ≤60 mL/min/1.73m² were enrolled. Vitamin D deficiency was defined as 25-hydroxyvitamin D3 [25(OH)D3] levels <10 ng/mL. Patients were dichotomized by the presence of vitamin D deficiency. Depression was determined by the EuroQOL-5D (EQ5D) questionnaire. Independent association between vitamin D deficiency and depression was evaluated by multivariate logistic regression analysis.

Results: The mean age was 71.2±9.3 years, and 257 patients (51.9%) were female. The median 25(OH)D3 levels were 17.9 (13.9-22.7) ng/mL. The prevalence of depression in CKD patients was higher compared to the general population (43.0% vs. 11.1%, P<0.01). In addition, the prevalence of depression was significantly higher in patients with vitamin D deficiency than those without vitamin D deficiency (27.9% vs. 13.3%, P<0.02). Multivariate logistic regression analysis showed that vitamin D deficiency was a significantly independent predictor of depression after adjusting for age, sex, alcohol, body mass index, hypertension, diabetes mellitus, anemia, suicidal idea, EQ5D index, and serum parathyroid hormone levels (odds ratio=6.27, 95% confidence interval=1.57-25.05, P=0.009).

Conclusions: Vitamin D deficiency was a significantly independent predictor of depression in CKD patients. Therefore, determining vitamin D levels might be helpful to predict depression in these patients.
Results: Phase 1 identified 13 common symptoms, and Phases 2 and 3 confirmed symptom selection and refined the wording used to describe them. The symptom descriptions finalised were: itching, sleep disturbance/insomnia, loss of appetite, feeling tired, pain in bones/joints, poor concentration/mental alertness, loss of libido/erectile dysfunction, loss of muscle strength/power, shortness of breath, cramp/muscle stiffness, restless legs/ difficulty keeping legs still, need to urinate more often, feeling cold. In Phase 4, 14 of 16 experts responded (87.5%). 10 of the 13 symptoms had “excellent” or “good” evaluation scores, and the content validity index of the whole questionnaire was 0.81, falling within the recommended threshold.

Conclusions: This work has provided a novel, validated symptom score for the early/pre-dialysis CKD population, which can be used as a patient reported outcome measure in both clinical management and research.

Funding: Private Foundation Support

SA-P0747

Background: Transplantation (Tx) is generally regarded as the best option for renal replacement therapy. However, few patients with CKD are listed for Tx when eligible. We examined the association between psychosocial factors in patients with advanced CKD and wait-listing for kidney Tx.

Methods: The study population includes 803 individuals with an eGFR of less than or equal to 20mL/min/1.73m² (advanced CKD) in the Chronic Renal Insufficiency Cohort study. The primary predictors were health related quality of life (HRQOL) and depressive symptoms assessed within 24 months prior to reaching the eGFR inclusion criteria using the Kidney Disease QOL (KDQOL)-56 survey and the Beck Depression Inventory (BDI), respectively. The primary composite outcome was wait-listing or transplantation (WLT). Cox proportional hazards models were used to examine the association between low HRQOL (1 SD below the cohort mean) and BDI (11) with WLT.

Results: Of the 803 subjects, 380 (47%) were wait-listed including 120 that proceeded to Tx. Compared to individuals who were not WLT, those in the WLT group were more likely to be younger, male, have no history of cardiovascular disease, and have proteinuria > 300mg/day (p < 0.01). After adjustment for demographic and clinical variables, a low Mental Component Summary (MCS) score was associated with a lower likelihood of WLT (Table). There was no association between the BDI or other QOL measures with WLT.

Conclusions: Lower MCS scores were associated with lower likelihood of WLT. Further work is needed to evaluate the impact of poor mental QOL in advanced CKD and how it might influence wait-listing.

Funding: NIDDK Support

SA-P0748

Perspectives on Pregnancy in Women with Chronic Kidney Disease Allison Tong,1 Mark A. Brown,2 Wolfgang C. Winkelmann,1 Jonathan C. Craig,3 Shilpa Jhawarson,1 1The Univ of Sydney; 2St. George Hospital; 3Baylor College of Medicine; 4Royal Adelaide Hospital.

Background: Women with chronic kidney disease (CKD) often have difficulty achieving pregnancy, and are at increased risk of adverse pregnancy outcomes. We aimed to describe the beliefs, values, and experiences of pregnancy in women with CKD, to inform pre-pregnancy counseling and pregnancy care.

Methods: Semi-structured interviews were conducted with 41 women aged 22-56 years with advanced chronic kidney disease, from two renal units in Australia. Transcripts were analyzed thematically.

Results: Six themes were identified: bodily failure (conscious of fragility, nosiness self, critical timing, suspended in limbo); devastating loss (denied motherhood, disempowered by medical catastrophizing, resolving grief, barriers to parenthood alternatives, social jealousy); intragentic guilt (disappointing partners, fear of genetic transmission, respecting donors); meaning sacrifice, medical judgment); rationalizing consequential risks (choosing survival, avoiding fetal harm, responding to family protectiveness, compromising health, decisional ownership, unjustifiable gamble); strengthening resolve (hope and opportunity, medical catastrophe, faith as determination, reticent hope); and reorientating focus (valuing life, gratitude in hindsight).

Conclusions: Decisions surrounding pregnancy in the context of chronic kidney disease require women to confront uncertainties about their own survival, disease progression, impact on their family and kidney donor, the outcomes of their offspring, and genetic transmission. Communicating the medical risks of pregnancy to women with chronic kidney disease must be carefully balanced with their values of autonomy, hope, security and family. Informed and shared decision making that is sensitive to women’s priorities as identified in this study can contribute to improved pregnancy, health and psychosocial outcomes in this vulnerable population.

SA-P0749

Nrf2 Activator, Resveratrol, Ameliorates Aging-Related Progressive Renal Injury in Mice Kim In Nam Kim, In Ae Yang, Ji Hee Lim, Min Young Kim, Buyung Ha Chung, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Yoonsik Chung, Bum Soon Choi. Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.

Background: The senescence markers of kidney have been shown to cause many changes in the energy metabolism. Two important issues in aging kidney are mitochondria dysfunction and oxidative stress. Nrf2 activator, Resveratrol may prevent inflammation and oxidative stress by activating SIRT1 and Nrf2. We examined that Resveratrol can potentially ameliorate the cellular condition, such as renal injury due to cell oxidative stress and mitochondria dysfunction caused by aging.

Methods: Male 19-month-old C57BL/6 mice were used in this study. Resveratrol (0.04%) was provided to old mice for 6month. We compared histological change, oxidative stress, and aging-related protein expression in the kidneys between Resveratrol treated-old-mice group (RSV) and vehicle-old-mice group (VH).

Results: In our study, expression of Nrf2 in nuclear (1 ± 0.1 fold vs. 2 ± 0.4 fold; p < 0.01 vs. VH) was increased in RSV. Expression of SIRT1 (1 ± 0.2 fold vs. 1.31 ± 0.11 fold; p < 0.05 vs. VH) was increased in RSV, p-AMPK/Total AMPK ratio expression (1 ± 0.1 fold vs. 1.79 ± 0.2 fold; p < 0.01 vs. VH) was increased in RSV compared with VH. RSV group displayed decreased albuminuria and Creatinine clearance increased with RSV. There were decreases in mesangial volume, tubulointerstitial fibrosis and collagen IV in RSV. Immunohistochemistry of F4/80 expression in glomerulus and tubule were decreased in RSV compared with VH. Also, TGF-β was decreased in RSV. Urate isoprostane and 8-OHdGexcretion decreased with aging. Antioxidant enzyme, HO-1 (1 ± 0.8 fold vs. 1.6 ± 0.1 fold; p < 0.01 vs. VH) and NOQO-1 (1 ± 0.06 fold vs. 1.3 ± 0.1 fold; p < 0.01 vs. VH) were increased in RSV compared with VH.

Conclusions: These results suggest that activation of Nrf2 may benefit aging-related renal injury related with SIRT1 and AMPK activation by reducing oxidative stress. Pharmacologically targeting Nrf2 signaling molecules may reduce the pathologic changes of aging in the kidney.

SA-P0750

Dual Agonist of Nuclear Hormone Receptor Farnesoid X Receptor and G Protein Coupled Receptor TGR5 Exhibits Calorie Restriction Mimetic Efffects in Aging Mice Nawaon Wang,1 Evgenia Dobrinskikh,2 Yuhuan Townsend, Peter P. Reese, Meera Nair Harhay.

Background: Previous studies have shown that calorie restriction (CR) in mice and in rats prevent age-related proteinuria and glomerulosclerosis. We have observed an age-related decrease in renal nuclear hormone receptor farnesoid X receptor (FXR, NR1H4), and G protein-coupled receptor TGR5 (GPR130 or GPR131) expression. In contrast, renal FXR and TGR5 expression are increased by CR in the aging mice. FXR and TGR5 expression are also increased in the long-lived Ames dwarf mouse. The purpose of the present study was to determine if activation of FXR and TGR5 in the kidneys of ad lib fed aging mice have similar effects to CR.

Methods: We studied 5 month old ad lib fed, 24 month old ad lib fed, 22 months old ad lib fed mice treated with the dual FXR/TGR5 agonist INT-767 for 2 months, and compared them to lifelong 24 month old CR mice.

Results: Treatment of 22 month old ad lib fed aging mice with FXR/TGR5 dual agonist INT-767 for 2 months decreases albuminuria, TGF-β expression, and fibronectin accumulation in aging mice. INT-767 stimulates mitochondrial biogenesis, increases mitochondrial DNA content, and mitochondrial transcription factors Nrf-1 and Tfam in the aging kidney. INT-767 also increases the expression of SIRT1, PGC-1α, and ERRα mRNA expression. INT-767 activation of the mitochondrial NAD-dependent deacetylase SIRT3 restores its targets MCAD and acetyl-LDH to normal levels, which are important for regulation of mitochondrial fatty acid β-oxidation as well as mitochondrial redox status. Furthermore, INT-767 increased expression of NAMPT and Nk1, enzymes involved in synthesis of sirtuins substrate NAD.

Conclusions: Our results therefore indicate that activation of FXR and TGR5 in the aging kidney reverses most of the age-related changes and the effects of FXR and TGR5 are similar to beneficial effects achieved by lifelong CR.

ESRD in Nonagenarians in the United States, 1995 Through 2010
Donald J. Sexton, Scott Reule, Robert N. Foley. Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Patients in their 90’s are increasingly being considered for maintenance dialysis, comprehensive epidemiological data could help with decision making.

Methods: We used US census data and data for patients who initiated maintenance dialysis between 1995 and 2010 (N=1,557,117) to examine trends in ESRD for those aged 90 to 99 years (N=14,289).

Results: The rate of ESRD in 1995-1996 was 0.6 per million per year in those aged 90-99 years respectively. Standardized incidence ratios (SIRs) rose between 1995 and 2010 both overall (SIR 2.8), and in individuals (males 2.89, females 2.7) white (3.1) African American (1.93) and other races (2.43).Median survival was 10.7 months.

Unspecified renal failure” was the most common reported cause of ESRD (62.6%), followed by “diabetes mellitus type 2” (15.8%), “ATN without recovery” 3.4%, “GN (not histologically examined)” 3.18%, “renal artery stenosis” 2.44% and other 12.44%.Causes of death included: Cardiac deaths 42.4%, Infection 12.07%, Withdrawal of dialysis/ uremia 10.16%, Stroke/ Intracranial Hemorrhage 3%, Cachexia 2.99%, Cancer 2.45%, Other 12.03% and Unknown 14.89%. Mortality fell over time, AHR (95% CI) 0.79 (0.72, 0.87) in 2009-2010 vs 1995-1996. Factors associated with a higher likelihood of death included: ischemic heart disease (AHR 1.13), AV graft (AHR 1.36 vs AV fistula), or venous catheter for hemodialysis vascular access (AHR 1.7 vs AV fistula), shorter pre-dialysis nephrology care (AHR 1.37), higher eGFR at dialysis initiation (AHR 1.13), serum albumin < 3.5 g/dl (AHR 1.34), cerebrovascular disease (AHR 1.21), peripheral vascular disease (AHR 1.14), cancer (AHR 1.08), inability to ambulate (1.43) or transfer (1.59), “ATN without recovery” as a primary cause of ESRD (AHR 1.11 vs “renal failure not specified”).

Conclusions: ESRD in nonagenarians has risen over the period of observation in the United States. Rising prevalence may be attributable not only to rising incidence but to falling mortality also.

SA-PO752
Impact of Geriatric Multi-Morbidity Versus Medical Multi-Morbidity on Quality of Life in Older CKD Patients
Christopher Lane, 1 2 Jason D. Fantus, 1 2 Kieran Reid, 1 2 Leslie I. Katzel, 1 Stephen L. Seliger, 1 Daniel E. Weiner, 1 Roger A. Fielding, 1 2
1Boston Univ, Boston, MA; 2Tufts Univ, Boston, MA; 3Univ of Maryland, Baltimore, MD.

Background: Geriatric conditions are constellations of signs and symptoms not always linked to a disease, such as cognitive impairment and fatigue; geriatric conditions are associated with worse quality of life (QoL). Older adults with CKD are likely to have geriatric multi-morbidity (GM), defined as ≥2 geriatric conditions. Medical multi-morbidity (MM) is also common in this population and affects QoL. We compared the impact of GM vs MM on QoL in older CKD patients.

Methods: We used baseline data from an ongoing trial of exercise in persons ≥55 years with stage 3b-4 CKD. For GM, persons were defined with 1) cognitive impairment or Montreal Cognitive Assessment ≤26, 2) poor physical function if Short Physical Performance Battery ≤7, 3) dizziness as reported by Memorial Symptom Assessment Scale; 4) fatigue if responded ≥‘good bit of time’ to feeling worn out on Short Form-36 (SF-36); and 5) chronic pain if ≥‘moderate’ pain on SF-36. For MM, hypertension, diabetes, CAD, and stroke were self-reported. Severe depression was defined as Beck Depression Inventory ≥15. QoL was measured with the SF-36. Linear regression adjusting for age, sex, race, site, BMI, and eGFR was utilized.

Results: Of 72 persons (31% women, mean age 68.6±7.8 years, mean eGFR 33.3±9.8 ml/min/1.73m²), 49% (35) had GM and 76% (55) had MM. GM was associated with lower scores in all SF-36 subscales (all p<0.05). MM was associated with lower scores in two SF-36 subscales (both p<0.05).

Conclusions: In older adults with CKD, geriatric multi-morbidity is common and likely affects QoL.

A Survey of Provider Knowledge, Attitude, and Practices Surrounding Conservative Management for Patients with Advanced Chronic Kidney Disease
Sanah Parvez, 1 Khaled Abdel-Kader, 1 V. Shane Pankratz, 1 Mi-Kyung Song, 1 Mark L. Unruh, 1 2
1Div of Nephrology, Univ of New Mexico; 2Div of Nephrology, Vanderbilt Univ; 3Adult and Geriatric Health Div; School of Nursing, Univ of North Carolina.

Background: Despite the potential benefits of conservative management (CM), discussing CM as a viable treatment option rarely occurs. Several factors might contribute to this but no studies in the U.S. have described them. The purpose of this survey was to describe nephrologists’ (NEPHs) and primary care providers’ (PCPs) knowledge, attitudes, and practices of CM for patients with advanced CKD.

Methods: We developed a survey based on the relevant literature to include items assessing knowledge, attitudes, and self-reported practices of CM for patients with advanced CKD. We then conducted a web-based cross-sectional survey between April and May 2015. We used the American Medical Association’s Physician Masterfile to identify NEPH and PCPs practicing in the U.S.

Results: 431 (67.6% NEPHs, 32.4% PCPs) providers completed the survey. The respondents were, on average, white, predominantly male, and in their 30s and 40s. A majority of both PCP (83.5%) and NEPH respondents (78.2%) reported that they were likely to discuss CM with their older advanced CKD patients. Self-reported number of patients managed conservatively was at least >11 patients for 30.6% NEPHs and 49.2% of PCPs. As shown in the figure where a higher percent demonstrates a lower barrier, the major barriers to CM discussions identified by NEPHs and PCPs significantly differed.

There were significant differences in knowledge across the groups with PCPs reporting significantly more uncertainty about survival rates with CM.

Conclusions: Both NEPH and PCP are comfortable with discussing CM with their patients. PCPs have less certainty regarding patient selection for CM and report feeling less informed about outcomes of CM.

Which Therapeutic Project for Elderly Reaching ESRD? Patient’s Characteristics and Outcomes
Corinne Fafin, 1 2 Cecile Couchoud, 1 2 Cecile M. Vigneau, 1 Olivier Moranne, 1 2 3Nephrology, CHU Nice, Nice, France; 2REIN Registry, Agence de Biomédecine, St. Denis La Plaine, France; 3Nephrology, CHU Pontchaillon, Rennes, France.

Background: The KDIGO guidelines recommend referral for planning RRT in people at risk of kidney failure. Treatment without dialysis in ESRD patient is another therapeutic option especially in elderly. The objective of our study is to describe the therapeutic projects declared by nephrologist and associated patient’s characteristics and outcomes in a prospective design.

Methods: 573 patients over 75 y/o (82±5 y/o) with eGFR below 20 (14 ± 4) were included by nephrologists in 2009 and followed 4 years (Moranne et al 2012). At baseline, we recorded social, clinical characteristics and therapeutic project declared by nephrologist and associated patient’s characteristics and outcomes of these patients according to the therapeutic projects.

Results: The therapeutic project was STAB in 234 patients (41%), DIAL in 216 pts (38%), NDne in 66 (12%) and NDpt in 55 (10%). Patients were older in ND group, with more women for NDpt and more comorbidities for NDne (dementia, active malignancy,
CVD, less physical autonomy). After 4 years follow-up, the number of death before dialysis and during the first dialysis month were 10%/85% for DIAL, 42%/34% for STAB, 67%/20% for NDpt and 95%/2% for NDN respectively. There was significantly more emergency start for the NDpt group starting nevertheless dialysis. In all groups, the main reasons declared by nephrologist to start dialysis were: eGFR level, fluid overload and weight lost.

Conclusions: In this study, we observed many patients with stable conditions and high risk mortality which anyway raises the issue of dialysis options and care organization. Although some patients expressed their willingness not to start dialysis at one point or another, it could nonetheless occur but with worst condition. On the contrary, if the dialysis options exist and retain by the nephrologists, it will not occur.

SA-PO755
Specific Prognosis Factors of Death and Dialysis Start for Elderly Patients Reaching ESRD in the Prospective PSPA Cohort Study
Hwa Liu,1 Yeda Aparecida Oliveira Souza,1 Emmanuel A. Burdmann,1 Cécile Couchoud,2 Cécile M. Vigneau,3 Olivier Moranne.1
Nephrology, CHU Nice, Nice, France; 2Agence de Biomédecine, REIN, St Denis de la Plaine, France; 3Nephrology, CHU Pontchaillon, Rennes, France.

Background: The death before dialysis start is high in elderly patients reaching ESRD and the treatment without dialysis is another option. We need to better predict the outcomes of this specific population and identify prognosis factors to improve strategies of care. The objective of our study is the identification of prognosis factors of dialysis start or death before dialysis in a multicenter prospective cohort of elderly reaching ESRD.

Methods: 573 patients over 75 yrs ([82,5] yrs) and with eGFR below 20 (eGFR14 ≥ 4 mL/min/1.73m²) were included by nephrologist in 2009-10 (Moranne et al 2012). At baseline, we recorded social and clinical characteristics, laboratory test and medications. Information about death or dialysis status is available for all patients after 4 years follow-up. Prognosis factors for dialysis start or death before dialysis were quantified with subdistribution hazard ratios using proportional hazard regression models constructed according to Fine and Gray to take account competiting risks.

Results: After 4 yrs follow-up, 274 patients (48%) started dialysis and 223 (39%) died. Compared to patients without dialysis, the patients independently associated with higher risk of death prior to dialysis are: higher age, male, diabetes, lower eGFR, behavioural disorder, less mobility, cerebrovascular disease, cardiac heart failure, active malignancy and anemia. The variables associated to higher probability of dialysis start are: lower age, male, lower eGFR, high blood pressure, hyperphosphatemia, higher proteinuria, chronic respiratory disease, cerebrovascular disease and less behaviour disorder or active malignancy.

Conclusions: We observed a higher probability of dialysis start than death before dialysis in this population. The results exclude changes independently associated by the different characteristics according to the study. We identified specific prognosis factors that could discriminate the risk of starting dialysis or died before dialysis to help organisation of the CKD 5 care in elderly patients.

SA-PO756
Ageing and Decreased GFR: A 1,249,388 Elderly Population-Based Study
Regina C.R.M. Abdulka1der,2 Mario Lucia Lebrão,1 Dirce M.T. Zanetta.1
1Div of Nephrology, Univ of Sao Paulo Medical School, Sao Paulo, SP, Brazil; 2Epidemiology, School of Public Health of the Univ of Sao Paulo, Sao Paulo, SP, Brazil.

Background: GFR decreases with ageing and so a low GFR in old people might occur due to a physiologic process instead of being a mark of a disease. However, comorbidities can superimpose on this process, and reduce GFR by a pathologic course. This study aims to assess the frequency of isolated low GFR without coincident diseases in a geriatric population in a developing country megalopolis.

Methods: A multistage cluster sampling (1,353 inhabitants) was used in order to obtain a sample representative of the elderly population of São Paulo megalopolis (1,249,388 inhabitants aged ≥50 years). Participants answered a survey on socio-demographic factors and health and had urine and blood samples collected. GFR < 60 mL/min/1.73m² (estimated by the abbreviated MDRD equation) was defined as low and presence of hematuria or proteinuria as kidney damage. Data are presented as weighted proportion or means and standard errors. Comparisons were made by chi-square with Rao-Scott correction or t-test.

Results: Individuals with GFR < 60 (19.8%) were older (75 ± 1 vs. 69 ± 1 y, p<0.001), had lower education level, more hypertension, diabetes and cardio-vascular disease and more kidney damage (35% vs 15%, p<0.001), when compared with the group with GFR ≥ 60. In the low GFR group only 25% of the individuals had no simultaneous diseases and no kidney damage.

Conclusions: Low GFR was associated with kidney damage and/or coincident chronic diseases that might affect the kidneys in this population. These data strongly suggest that in this group of geriatric individuals low GFR is indicative of renal damage. Funding: Government Support - Non-U.S (FAPESP, Ministério da Saúde, Brasil). Indoxyl Sulfate, a Representative Uremic Toxic, Suppresses Myogenic Differentiation: Implication in Uremic Sarcopenia
Chih-Kang Chang,1,2 Un Jong Ao,1 Yuan-Siao Chen,1 Shing-Hwa Liu.1 Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; 2Dept of Integrated Diagnostics and Therapeutics and Internal Medicine, College of Medicine, National Taiwan Univ, Taipei, Taiwan.

Background: Sarcopenia (or muscle wasting) is a common feature of the uremic phenotype and retards the process of sarcopenia progression. Myogenic differentiation is disturbed by the uremic toxins and contribute to sarcopenia and frailty. We hypothesized that indoxyl sulfate (IS), a representative protein-bound uremic toxin, might disturb skeletal myobute differentiation and contribute to sarcopenia and frailty.

Methods: The mouse myoblast cell C2C12 was applied to evaluate myobute differentiation and signaling. Cell viability evaluated by MIT assay. Cell morphology was observed by microscope. Hematoxylin and eosin staining morphologically analyzed the multinucleated myobute formation. The expressions of myogenic differentiation markers and related signaling proteins were determined by Western blotting.

Results: We first investigated the non-lethal concentration of IS by MTT assay, and found IS level less than 1mM without significant cellular toxicity as compared with control group. In order to development the protocol, we confirmed myobutes were visibly formed throughout 4 days of differentiation first. IS significantly attenuated the number of myobutes and the percentage of mature myobutes. Furthermore, IS significantly and dose-dependently decreased the expression of MyoD, Myogenin and myosin heavy chain, which is the representative markers of slow and fast myobute phenotype, both in translational and transcriptional level. The molecular signals of myobute differentiation were also disturbed by IS treatment.

Conclusions: These findings suggest that IS, a uremic toxic, dysregulates myobute differentiation in C2C12 cells. This is the first time to provide additional evidence that IS might contribute to the development of sarcopenia in uremic patients. Further explore would give the light to provide potential therapeutics in uremic sarcopenia.

SA-PO758
Attitudes, Experiences and Perspectives of Elderly Kidney Transplant Recipients: Thematic Synthesis of Qualitative Research
Jule Pinter,1 Camilla Sara Hanson,1 Jonathan C. Craig,1 Jeremy R. Chapman,1 Klemens Buddke,2 Fabian Halleck,2 Allison Tong.1
1Univ of Sydney; 2Charité - Universitätsmedizin Berlin.

Background: Kidney transplantation offers improved survival and quality of life in an increasing number of elderly patients with end-stage kidney disease. However, elderly kidney transplant recipients may face unique challenges due to a higher burden of comorbidity, greater cumulative risk of immunosuppression-related complications, and increasing frailty. We aimed to describe the perspectives of elderly kidney transplant recipients.

Methods: Electronic databases were searched to April 2015. Thematic synthesis was used to analyze the findings.

Results: 41 studies involving more than 120 kidney transplant recipients aged 60 yrs and over were included (29 studies did not specify number of patients aged ≥ 60 yrs). We identified 6 themes. Regaining strength and vitality meant valuing the marked physical and psychosocial improvements in daily functioning and life participation. Extending life was the willingness to accept an organ, including an extended criteria kidney, to prolong survival. Debt of gratitude entailed a need to be consciously appreciative towards their donor knowing they were unable to repay their sacrifice. Moral responsibility of maintaining health motivated adherence to medication and lifestyle recommendations out of an ethical duty to protect their gift and prolong graft survival. Disillusionsment with transplant reflected disappointment and exasperation at having to contend with side effects and adverse events such as cancer, and residual physical limitations. Finality of treatment option reflected an acute awareness that their current transplant may be their last and some would not return to dialysis if the transplant failed.

Conclusions: Kidney transplantation reverses deterioration of functioning and well-being that patients experienced whilst on dialysis. However, elderly transplant recipients may have anxieties about debilitating adverse events, comorbidities, and a sense of vulnerability that the current transplant may be their last. Addressing these concerns in the care of elderly kidney transplant recipients may improve treatment outcomes in this growing population.

SA-PO759
New Perspectives on the Evolution of Quality of Life and Depression Among Hemodialysis Patients
Christiane Hegedus Karam, Nadia Guimaraes-Souza, Adriano Luiz Ammirati, Maria C.C. Andréoli, Thais Nemoto Matsui, Fabiana Dias Carreira, Rosana Andrade, Maria Amâncio, Gean Mezzalira, Bento C. Santoso. Nephrology, Hospital Albert Einstein, São Paulo, Brazil.

Background: Hemodialysis is the most common treatment for patients with chronic kidney disease. Five to 22% of these patients have a psychiatric condition. The objective of this study was to evaluate the quality of life perception and depression symptoms in three groups of age (<65, 65-75, >65 y.o.).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: This was a retrospective observational study. Clinical and social demographic data were collected from clinical records. The Kidney Disease Quality of Life and Depression inventory were used to assess quality of life and depression symptoms.

Results: 104 patients were included. 68.3% were men, 71.2% married, 91.3% Caucasian and 44.2% were in productive life period. A relation between quality of life score and time in dialysis was observed (p=0.0118, CI -0.023; 0.0003). Patients younger than 65 y.o. showed more favorable results, such as general health perceptions, emotional well-being, fatigue, pain, and dialysis staff encouragement. Patients between 65 to 75 y.o. showed lower energy/fatigue index (11.98; CI -22.92; -1.02) and a reduction of 18.97 points (IC: -33.97; -3.98) for emotional well-being. A 15.04-point (CI -27.21; -2.87) and a 14.78-point (p<0.001; -26.46; -1.10) reduction, for patients between 65-75 y.o. and for older than 75 years, respectively, was observed in physical function. Burden of kidney disease had a reduction of 13.29 (-25.46, -1.18) and sexual function reduced 69% (27%; 87%) in 65-75 y.o. patients. Patients older than 75 years had a significant increase in quality of social interaction (17%; CI: 1%;36%) and an increase of 16% (CI 3% -30%) in social support. Depression correlated with time in hemodialysis (p = 0.0007; CI 0.14%; 0.55%). For each month an increase of 0.35% on depression symptoms was found.

Conclusions: For patients younger than 65 years hemodialysis treatment represents a rehabilitation possibility. Patients over 75 years had significant increase on social support and social interaction. Patients 65 to 75 y.o. had worse perception of quality of life.

SA-PO760
Fibroblast Growth Factor 23 and the Risk of Infection-Related Hospitalization in Older Adults: The Cardiovascular Health Study

Kristen L. Nowak,1 Traci M. Bartz,2 Lorien S. Dalrymple,1 Joachim H. Ix,1 Ian H. De Boer,3 Bryan R. Kestenbaum,2 Michael Shlipak,4 Pranav S. Gariianna,1 Michel Chonchol.1 1Univ of Colorado Denver; 2Washington University; 3Univ of California Davis; 4Univ of California San Diego; 5Univ of California San Francisco; 6Tufts Medical Center.

Background: Fibroblast growth factor 23 (FGF23) may inhibit 25-hydroxyvitamin-D-1α-hydroxylase (CYP27B1) in monocytes. We hypothesized that higher circulating FGF23 levels might lead to an increase in serious infection risk because FGF23 decreases the intracrine production of 1,25-dihydroxyvitamin D (1,25(OH)2 D), which consequently reduces production of cathelicidins.

Methods: Plasma C-terminal FGF23 concentrations were measured in 3141 Caucasian and 44.2% were in productive life period. A relation between quality of life score and time in dialysis was observed (p=0.0118, CI -0.023; 0.0003). Patients younger than 65 y.o. showed more favorable results, such as general health perceptions, emotional well-being, fatigue, pain, and dialysis staff encouragement. Patients between 65 to 75 y.o. showed lower energy/fatigue index (11.98; CI -22.92; -1.02) and a reduction of 18.97 points (IC: -33.97; -3.98) for emotional well-being. A 15.04-point (CI -27.21; -2.87) and a 14.78-point (p<0.001; -26.46; -1.10) reduction, for patients between 65-75 y.o. and for older than 75 years, respectively, was observed in physical function. Burden of kidney disease had a reduction of 13.29 (-25.46, -1.18) and sexual function reduced 69% (27%; 87%) in 65-75 y.o. patients. Patients older than 75 years had a significant increase in quality of social interaction (17%; CI: 1%;36%) and an increase of 16% (CI 3% -30%) in social support. Depression correlated with time in hemodialysis (p = 0.0007; CI 0.14%; 0.55%). For each month an increase of 0.35% on depression symptoms was found.

Conclusions: For patients younger than 65 years hemodialysis treatment represents a rehabilitation possibility. Patients over 75 years had significant increase on social support and social interaction. Patients 65 to 75 y.o. had worse perception of quality of life.

Characteristic of the Elderly Patients in the Chronic Renal Insufficiency Standards Implementation Study (CRISIS) Cohort Compared to Their Younger Cohort A Descriptive Analysis

Maharajan Raman, Darren Green, James Ritchie, Thilini Nishani Abeygunaratne, Smeeta Sinha, Philip A. Kalra. Renal Medicine, Salford Royal NHS Foundation Trust, Salford, Manchester; United Kingdom.

Background: CKD in the Elderly is associated with high mortality and slower rate of progression to ESRD. Identifying the characteristics of this phenotype and modifying their risk may reduce the burden of death but this can be challenging due to the heterogeneity of the disease in this group.

Methods: The CRISIS cohort of 2706 participants was divided into four groups based on their age. Descriptive statistical analysis was performed using SPSS and in between group significance was calculated using one way ANOVA or Chi-Square test.

Results: Essential characteristics of the cohort are shown in the table below.

Conclusions: The group aged >75 years had the highest incidence of death and accumulation of co-morbidities. We aim to develop a risk prediction model to identify the characteristics of this phenotype, which may help in modifying their risk.

SA-PO762
Muscle Strength Rather Than Muscle Mass Is More Important in Evaluating Physical Function in Elderly Patients with Predialysis Chronic Kidney Disease

Yasuhiro Taki, Koji Hiraki, Keita Uehara, Hiro Kawarazaki, Tsutomu Sakurada, Yugo Shibagaki.1 1Dept of Nephrology and Hypertension, St. Marianna School of Medicine, Kawasaki, Kanagawa, Japan; 2Dept of Rehabilitation Medicine, St. Marianna School of Medicine, Kawasaki, Kanagawa, Japan.

Background: Recently, physical function has been reported to be strongly associated with prognosis of patients with chronic kidney disease (CKD). Sarcoopenia is well described in CKD patients on dialysis especially of the elderly and is known to be associated with reduced physical function, but whether this is the case in elderly predialysis CKD is undetermined.

Methods: We enrolled consecutive 85 elderly patients (age over 60) with predialysis CKD (estimated GFR< 60 ml/min/1.73m2) in outpatient nephrology clinic at St Marianna University Hospital. We evaluated kidney functional parameters, muscle mass by bioimpedance, muscle strength by dynamometer (hand grip, knee extension) and 4-meter walking speed in these participants.

Results: Average age was 74 years old, 76% were men, 33% had diabetes mellitus (DM) and average eGFR was 28.6ml/min/1.73m2. Patients were divided into those with eGFR<30 or >30. After adjustment for age, gender and history of DM, hand grip strength (<4.36, 95%CI: -0.85–7.85), knee extension strength (-5.62, 95%CI: -2.28–8.97) and 4-meter walking speed (>0.12, 95%CI: -0.02–0.22) were significantly reduced in those with eGFR<30. However, there was no difference in muscle mass (-0.23, 95%CI: -0.68–0.23).

Conclusions: In conclusion, muscle strength and walking speed but not muscle mass decreased along with progression of CKD. Thus, it seemed more important to check muscle strength and walking speed rather than muscle mass when evaluating physical function in elderly patients with predialysis CKD.

Lower Muscle Endurance, Strength and Quality Are Associated with Greater Risk of Functional Limitations in Older Adults with CKD

**Background:** Chronic kidney disease is associated with inflammation and insulin resistance contributing to fatigue and muscle weakness. The association of muscle endurance, strength, and quality with functional limitation among persons with CKD is unknown.

**Methods:** We studied 186 participants with eGFR<60 at the year 3 Health ABC visit. Participants were excluded if unable to complete >90% of quadriceps isokinetic fatigue testing. Quadriceps endurance was defined by total work using isokinetic dynamometer. Quadriceps strength was measuring by isometric torque. Lean leg mass (legml) was measured using DXA. Muscle quality was defined by specific work (work/legml) and specific torque (torque/legml). Outcome was incident persistent severe lower extremity limitation (PSLL) based on 2 consecutive reports of having a lot of difficulty or inability to walk 1/4 mile or climb 10 steps without resting. We used competing risks regression.

**Results:** Participants had a mean age 76.2 ±3yrs, eGFR<60 of 49.2 ±10. None had mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with functional limitation among persons with CKD. The association of muscle endurance, strength, and quality with functional limitation among persons with CKD is unknown. Adjusted SHR Adjusted SHR

**Conclusions:** Among older adults with CKD free of mobility disability, lower muscle endurance, strength, and quality are independently associated with greater risk of severe lower extremity limitation.

Efficacy and Safety of Exercise Training in Patients with Predialysis Chronic Kidney Disease

Yuho Shibagaki, Koji Hiraki, Takashi Yasuda, Kenjiro Kimura. Div of Nephrology and Hypertension, St. Marianna Univ; Div of Rehabilitation, St. Marianna Univ.

**Background:** Efficacy and safety of exercise training has not been well studied in patients with predialysis chronic kidney disease (CKD). Since we have reported in elderly patients with predialysis CKD that there was a significant reduction in muscle strength and short-term exercise did not damage kidney, we conducted a randomized controlled trial to elucidate the long-term efficacy and safety of exercise in this population.

**Methods:** Study design was a randomized controlled trial. Thirty six male elderly patients with CKD stage 3-4 were studied. Patients with eGFR<60 of 49.2 ±10. None had mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with functional limitation among persons with CKD. The association of muscle endurance, strength, and quality with functional limitation among persons with CKD is unknown. Adjusted SHR Adjusted SHR

Estimated METS: Mean achieved METS was 5.6±1.8. Although there was low bias for estimated vs. achieved METS (mean difference, -0.45), precision and accuracy were poor, with only 35% of predicted values within 1 MET of achieved values, and nearly one third of estimated values >30% different from achieved.

**Conclusions:** Among older adults with CKD stage, CRF as reflected by VO2peak is markedly impaired. Lower hemoglobin, obesity, and prevalent cardiac disease are associated with worse aerobic capacity. The use of estimated METS during treadmill testing poorly estimates actual aerobic capacity.

Determinants of Impaired Cardiorespiratory Fitness in Older Adults with CKD

Stephen L. Seliger, Jamie Giffuni, Roger A. Fielding, Eamon F. Fleming, Christine Liu, Leslie I. Katzel, Kieran Reid, Sushrut S. Waikar, Andrew M. Well, Daniel E. Weiner. Medicine, U Maryland Sch of Medicine; GRECC, VA Maryland Healthcare System; Tufts Univ Sch of Medicine; Boston Univ Sch of Medicine; Brigham and Women's Hospital; Emory Univ School of Medicine.

**Background:** Chronic Kidney Disease (CKD) may be associated with impaired cardiorespiratory fitness (CRF). We examined methods of estimating CRF in CKD and identified factors associated with CRF.

**Methods:** We measured peak aerobic capacity (VO2peak) using a modified Graded Exercise Treadmill Test (GXT) in 71 older adults with CKD stage 3b-4 in an ongoing exercise clinical trial. GFR was estimated with the CKD-Epi equation. Linear regression was used to examine factors associated with VO2peak. Resting VO2 was measured prior to GXT in seated position. Metabolic Equivalents of Task (MET, oxygen consumption during exercise relative to rest) was estimated at peak exercise based on GXT stage and compared to actual achieved METS.

**Results:** Mean age was 68.4±7.7 years; 61% African-Americans; 30% women; mean eGFR was 33±11 ml/min/1.73m² and mean Hb was 12.3±1.6 g/dL. Mean VO2peak was 17.4±5.4 ml/kg/min, which was 31±17% lower than expected based on normative values (p<0.001). In a multivariate model including demographics and co-morbidity, lower hemoglobin - but not GFR - was associated with lower VO2peak (Table). Albuminuria did not correlate with VO2peak.

SA-PO766

Access to Kidney Transplantation and Outcomes of Those Listed for Kidney Transplant in Elderly

Pritika Shrivastava, Ankit Sakhuja, Diane M. Cibrik, Abhijit S. Naik. Div of Transplant Nephrology, U Michigan, Ann Arbor, MI.

**Background:** Data suggests that patients above 70 years of age (>70 y.o.) with ESRD derive a benefit from kidney transplant (KT). We report our single center experience of access to transplant and outcomes for those >70 y.o. listed for KT. We used the number of evaluations in a year and rate of acceptance after evaluation as surrogate markers for KT access in elderly.

**Methods:** We assessed the rate of acceptance for KT and its trends over the years for those >70 y.o. between 2000-2014. Linear regression was used to assess trends over time. Differences in rates of listing stratified by diabetes status, KT rates among those approved for listing by diabetes status and mortality among those transplanted vs waitlisted was assessed.

**Results:** Over 15 year period, we evaluated 612 elderly patients (pts). 25.3% of those evaluated were approved to list for transplant. There were 9 patients who were evaluated twice of those 5 were approved for listing the second time and two got transplanted. There was 300% increase in annual evaluation of the elderly from year 2000 to 2014 and trend towards increased acceptance rate of those evaluated (slope=0.82, p=0.12).

**Conclusions:** Only the advice on exercise training could increase the physical activity and muscle strength without compromising kidney function in the elderly patients with predialysis CKD.
The acceptance rate was lower in diabetics compared to non-diabetics (18.2% vs 32.0%; p<0.001). 38.0% of listed pts have been transplanted and the rate of transplant did not differ by diabetes status. Of those transplanted 59.3% had living donors. Mortality among those transplanted was 64.4% in comparison to 87.3% of those Waitlisted (p<0.001).

Conclusions: Only a fourth of those ≥70 evaluated for KT were accepted for listing, though there has been some improvement in the acceptance rate over time. Acceptance rate was significantly lower among elderly diabetics. Mortality though improved remains significantly high for transplant vs waitlisted patients.

P-Cystatin C Improves GFR Estimation in Older People  
Karin Werner,1 Anders G. Christensson,2 Mats Pihlsgård,1 Söolve Elmståhl,1 1Dept of Geriatrics, Lund Univ, Malmo, Sweden; 2Dept of Nephrology and Transplantation, Lund Univ, Malmo, Sweden.

Background: There is a need for validation of commonly used cystatin C and creatinine based formulas for eGFR (estimated glomerular filtration rate) in the older segment of the general population for all levels of kidney function.

Methods: Markers used for eGFR estimation were P-Cystatin C and P-Creatinine. Measured GFR (mGFR) adjusted to body surface area was performed by a single sample iohexol clearance in 112 participants, aged 70-100 years old from the population-based cohort “Good Aging in Skåne”. The participants were selected to cover a wide range of kidney function and to obtain an even distribution regarding sex and age. The timing of the sample depended on eGFR (eGFR >50, 25-50, and >25 at 4, 7, and 24 hours respectively). Formulas using both markers (CKD EPI combined, Lund-Malmö combined, BIS2), only creatinine (CKD EPI creatinine, MDRD) and only cystatin C (CKD EPI cystatin C) were compared. The analysis included bias (median difference: mGFR-eGFR), precision (IQR: interquartile range of the differences), accuracy (P30: percentage of estimates ±30% of mGFR) as well as accuracy (P30) above and below mGFR 45.

Results: There were 57 women and 55 men. Mean age was 82 years and mean GFR 55 ml/min per 1.73m². Results are presented in the table.

Conclusions: All the formulas that include cystatin C performed well in this Swedish cohort with a mean age above 80. This confirms that it is safe to use either of those formulas in our older patients across a wide spectrum of kidney function. However, the formulas based solely on creatinine are not reliable enough below GFR 45. Further sub-analysis can demonstrate detailed performance for males and females respectively, for all CKD-stages and for smaller age-intervals.

Differential Significance of Prognostic Factors for 6-Month and 3-Year Mortality in Elderly Patients on Hemodialysis  
Koji Harada,1 Azusa Izumiya,1 Tomohiro Kawamura,2 Juri Tsukahara,1 Koichi Sumida,3 Yukinari Yamaguchi,4 Yasuhiko Akai,5 1Dept of Nephrology, Rakunakai-Otsu Hospital, Yamashina, Kyoto, Japan; 2Center for Postgraduate Training, Nara Medical Univ, Kashihara, Nara, Japan.

Background: As the population of elderly people has been growing, the number of older chronic kidney disease patients commencing renal replacement therapy (RRT) is increasing. The survival advantage of RRT may be counterbalanced by the burden of treatment and its negative effect on quality of life in the elderly, and old age is no longer seen as a contraindication to RRT. Therefore, it is important to evaluate survival factors in this population. We conducted this study to investigate prognostic factors for mortality in elderly patients starting hemodialysis (HD) for end-stage renal disease (ESRD).

Methods: We studied 621 CKD patients≥65 years from an EMR based CKD registry linked to the USRDS data. We retrospectively analyzed factors associated with one year mortality after dialysis initiation including: age, sex, race, presence of diabetes, hypertension, BMI, stroke, CHF, COPD, malignancy, peripheral vascular disease, depression, alcohol use, smoking, presence of AVF, pre-dialysis serum albumin and potassium.

Results: In our study, 224 (36%) patients died within the first year of dialysis initiation. Results from the Cox proportional model showed that older age and CHF were associated with early deaths, while higher albumin, presence of AVF and HTN were associated with a lower hazard of early death.

Conclusions: CHF and older age in the pre-dialysis setting are associated with higher 1-year mortality after dialysis initiation. These prognostic data need to be presented to geriatric CKD patients while discussing renal replacement therapy options.

Methods: This is a single-center, retrospective cohort study from January 2009 to December 2014. In total, 90 ESRD patients commencing HD were enrolled. All the patients were aged 65 years or older. Six-month and 3-year survival rates and prognostic factors for mortality were evaluated.

Results: The mean follow-up period was 21.7±18.3 months. The 6-month and 3-year survival rate were 94.0% and 66.9%, respectively. Age, unplanned initiation of HD, presence of heart failure, high value of estimated GFR on starting HD, Charlson comorbidity index (CCI), and Eastern Cooperative Oncology Group Performance Status scale (ECOG-PS) were associated with 3-year mortality, whereas only the presence of heart failure and ECOG-PS were significant predictors of 6-month mortality. There was no significant difference in 6-month mortality rate between patients aged ≥ 80 and < 80. On the other hand, 3-year mortality rate of ≥ 80 year-old patients was significantly higher than that of < 80 (p: 53.3% vs: 80: 14.2%, p = 0.0004).

Conclusions: There is a variation of significance among different prognostic factors according to the duration of life after starting hemodialysis. The presence of heart failure and ECOG-PS predicted short-term mortality among elderly ESRD patients starting HD. These results might help clinical decision making when nephrologists considering commencing HD for elderly ESRD patients.

SA-PO770
Cumulative Cardiovascular Polypharmacy Is Associated With the Risk of Geriatric Acute Kidney Injury
Chia-Ter Chao,1 Hung-Bin Tsai.1, 2
1Dept of Medicine, National Taiwan Univ Hospital Jin-Shan Branch, New Taipei City, Taiwan; 2Department of Nephrology, National Taiwan Univ Hospital, Taipei, Taiwan.

Background: Polypharmacy is common in the elderly due to multiple morbidities. However, the effect of polypharmacy on renal outcomes is rarely recognized. We investigated the effect of cardiovascular polypharmacy on acute kidney injury (AKI) in elderly patients.

Methods: We used the Taiwan National Health Insurance PharmaCloud system to investigate the relationship between cumulative cardiovascular medications in the 3 months prior to admission and risk of AKI in the elderly at admission to general wards. Community-dwelling elderly patients (>60 years) were prospectively enrolled and classified according to the number of pre-admission cardiovascular medications. Cardiovascular polypharmacy was defined as use of 2 or more relevant medications.

Results: We enrolled 152 patients, 48% with AKI (based upon Kidney Disease Improving Global Outcomes [KDIGO] classification) and 64% with cardiovascular polypharmacy. The incidence of AKI was higher in patients taking more cardiovascular medications (0 drugs: 33%; 1 drug: 50%; 2 drugs: 57%; 3 or more: 60%; p = 0.048). Patients with higher KDIGO grades also took more cardiovascular medications (p = 0.04).

Conclusions: We found that elderly patients taking more cardiovascular medications had increased risk for adverse renal events. Interventions that reduce polypharmacy may be able to reduce the incidence of geriatric AKI.

SA-PO771
Low Bicarbonate Associates with Higher Mortality Independent of pH in Healthy Older Individuals: The Health, Aging, and Body Composition Study
Kalani L. Raphael,1 Rachel A. Murphy,1 Michael Shipkai,1 Suzanne Satterfield,3 Hunter K. Huston,1 Anthony Sebastain,1 Deborah Sellmeyer,1 Kushang V. Patel,1 Anne B. Newman,2 Mark J. Sarnak,3 Joachim H. Ix,4 Linda F. Fried.7
1Dept of Medicine, Univ Medical Center Groningen, Groningen, Netherlands; 2Univ of California San Francisco, San Francisco, CA; 3Univ of Tennessee; Johns Hopkins Univ; Univ of Washington; Univ of Pittsburgh; Tufts Medical Center; Univ of California San Diego.

Background: Low serum [HCO₃⁻] associates with higher mortality in CKD. The purpose of this study is to determine if [HCO₃⁻] associates with all-cause mortality independent of systemic pH in healthy older persons.

Methods: Data were analyzed from the Health, Aging, and Body Composition Study, an observational study of black and white adults aged 70-79 years followed from 1997-2014. Arterialized venous blood gas measurements were obtained in 2,287 individuals. Participants were grouped into one of 3 [HCO₃⁻] categories: <23.0 (low), 23.0-27.9 (reference group), and ≥28.0 mEq/L (high). Mortality hazard ratios (HR) in the low and high [HCO₃⁻] groups were compared to the reference group using Cox models adjusted for demographics, eGFR, albuminuria, COPD, smoking, and pH. Multiplicative interaction terms tested whether CKD status modified the relationship between [HCO₃⁻] categories and mortality.

Results: The mean age was 76 years, 51% were female, and 38% were black. The mean pH was 7.41, mean [HCO₃⁻] was 25.1 mEq/L, 11% had low and 10% had high [HCO₃⁻]. The mean eGFR was 82.1 ml/min/1.73m²; 12% had CKD. During follow-up (mean 10.3 years), 1,326 (58%) participants died. The adjusted all-cause mortality HR was 1.24 (95% CI, 1.02-1.49) in the low [HCO₃⁻] category and 1.03 (95% CI, 0.84-1.26) in the high [HCO₃⁻] category compared to the reference group. CKD status did not modify the association between [HCO₃⁻] and mortality (p=0.74).

Conclusions: Healthy older persons with low [HCO₃⁻] have higher mortality risk than those with normal [HCO₃⁻] independent of pH and potential confounders. High [HCO₃⁻] does not associate with higher mortality. The potential health benefits of normalizing low [HCO₃⁻] in generally healthy older persons should be investigated.

SA-PO772
Low Urinary Creatinine Excretion Is a Valid Surrogate for Frailty in Patients with Advanced Chronic Kidney Disease
Harmke Polinder-Bos,1 Hakan Nacak,2 Friedo W. Dekker,2 Stephan J.L. Bakker,1 Carlo A. Gaillard,1 Ron T. Gansevoort.1
1Dept of Internal Medicine, Univ Medical Center Groningen, Groningen, Netherlands; 2Epidemiology, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Muscle wasting is a key component of frailty, which is highly prevalent in advanced stages of chronic kidney disease (CKD). Whether low urinary creatinine excretion (UCrE), a marker of low muscle mass, is a valid surrogate for frailty in this population is unknown. We studied cross-sectional associations between frailty and a low UCrE in patients with CKD stages 4 and 5 (not on dialysis).

Methods: 2748 healthy individuals of the general population were included to define low UCrE. Low UCrE was defined as height-indexed UCrE below the age- and sex-specific 5th percentile. In a CKD population including 320 and 967 participants of the prepARE-2 and NECOSAD studies, associations of frailty, the individual components that define frailty, and frailty-associated variables with low UCrE were evaluated using multivariable logistic and linear regression models. Frailty was defined as a composite construct including self-reported poor physical functioning, exhaustion, low physical activity, and underweight.

Results: In the general population with a median age of 46 years, median UCrE was 9.8 mmol/day for women and 14.3 mmol/day for men, compared to 7.0 mmol/day and 9.5 mmol/day in CKD patients, respectively. In the CKD patients with a median age of 63 years, low UCrE was found in 38%. Frailty, and the individual components that define frailty, were associated with a low UCrE, independent of comorbidities (OR frailty = 2.19 [1.28-3.77], p=0.005). Of the frailty-associated variables, lower hemoglobin and albumin levels, and higher parathyroid hormone levels were associated with low UCrE. Adjustment for GFR attenuated the associations of frailty, and the individual components that define frailty with low UCrE, except for underweight.

Conclusions: Low UCrE is a valid surrogate for frailty, independent of comorbidities. Low UCrE is strongly determined by a lower kidney function, suggesting that reduced kidney function induces changes in muscle mass and performance leading to frailty.

SA-PO773
Oral Anticoagulation and Kidney Function in Elderly
Antonios Dousou,1 Elke Schaeffer,2 Olga Jakob,1 Reinhold Kreutz,1 Natalie Ebert.2
1Clinical Pharmacology, Charité; 2Nephrology, Charité; 3Clinical Epidemiology, Charité.

Background: In the past years new oral anticoagulants (NOACs) were approved expanding our pharmacological arsenal. Data on their utilization in elderly compared to vitamin K antagonists (VKA) are scarce and the impact of kidney function (KF) on NOAC use in a population with declining glomerular filtration rate (GFR) is of great interest. The present study investigates anticoagulant use and KF in people ≥ 70 years. Medication was assessed through personal interviews and coded using the Anatomical Therapeutic Chemical Classification System. For GFR estimation we used the CKD-EPI Cr equation. Predictor analysis was conducted via logistic regression.

Results: Figure 1 illustrates the percentage of drug use for the three NOACs and phenprocoumon, the most common VKA in Germany, over the course of 4 years.
Can Morbidity Predict Mortality in Dialysis Patients? Kathryn Dressard,1 Vijaya Sundararajan,2 Nuala Barker,1 Jodie L. Burchell,2 Robyn G. Langham.1
1Dept of Nephrology, St. Vincent’s Hospital, Fitzroy, Victoria, Australia; 2Dept of Medicine, Melbourne Univ, Fitzroy, Victoria, Australia.

Background: Symptom management and quality of life (QOL) in dialysis patients is increasingly important in determining treatment approach and outcome research. This study identified symptoms, QOL, functional status in dialysis patients, determining if symptom burden had an impact on mortality.

Methods: A single-centre cross-sectional study was undertaken in dialysis patients with median follow up time 10 months. Patients completed surveys incorporating POS-S (n=153), Phenprocoumon (n=14), Dabigatran (n=46), Rivaroxaban (n=12), Apixaban (n=12).

Results: 112 patients were recruited; 67 hemodialysis, 10 home/nocturnal hemodialysis (n=153). Pain (82%) at a rate of 10.56% was found. Poor mobility and skin changes on survival was found. Symptom burden (median POS-S score 13 (inter-quartile range (IQR 9, 22)) and reduced QOL 4 (IQR 3,4), health satisfaction 3 (IQR 2,4) and performance status 60 (IQR 50,70). A log rank analysis was performed on 104 POS-S renal responses with 8 deaths total.

Conclusions: Our data show that also in the elderly NOAC use increased over the past years. Characteristics such as age, sex or KF had an impact on the choice of oral anticoagulation.

SA-PO774

Outcomes of Cardiopulmonary Resuscitation in Maintenance Dialysis Patients Based on CPR Characteristics Haris Farooq Murad, Fahad Saeed. Cleveland Clinic Foundation.

Background: Cardiopulmonary resuscitation (CPR) is associated with high rates of mortality, especially in patients with end stage renal disease (ESRD). Previous studies have reported an in-hospital mortality rate of up to 75% in ESRD patients undergoing CPR. There are no large studies to date on how individual CPR characteristics relate to the long term outcomes in these patients. Herein, we aimed to answer this question.

Methods: By an EMR inquiry, we identified all the adult patients (>18years) who had undergone CPR from January 2006 to December 2014, and then selected patients who were on maintenance dialysis. We conducted a chart review of CPR characteristics and its association with the hospital discharge survival. We studied following variables: initial rhythm, duration of CPR, in-hospital versus out of hospital CPR and the use of hypothermia protocol.

Results: We studied a total of 497 ESRD who had undergone CPR. Sixty eight percent of our patients had expired in the hospital post-CPR. Pulseless electrical activity (PEA) was the most common initial rhythm (51.4%), followed by ventricular arrhythmias (19.6%) and asystole (19.2%). In-hospital mortality was the highest (76.8%) for patients with asystole as the initial rhythm, duration of CPR, in-hospital versus out of hospital CPR and the use of hypothermia protocol.

Conclusions: This study demonstrated high symptom burden, reduced functional status and QOL in dialysis patients. Patients with severe pain, weakness, shortness of breath, nausea, mouth problems, drowsiness, poor mobility and skin changes were more likely associated with higher mortality risk. Symptom identification and management may help predict and improve patient QOL outcomes in dialysis patients.

SA-PO775

End of Life Care Preferences in Maintenance Dialysis Patients based on CPR Characteristics Haris Farooq Murad, Fahad Saeed. Cleveland Clinic Foundation.

Background: Dialysis patients have an annual mortality rate of 20-25%. A previous Canadian study comprising mainly of Caucasian patients has shown that patients are interested in active involvement in end of life care discussions and majority would want to know their prognosis on dialysis. In this Caucasian predominant cohort, approximately 50% chose to be DNR. It is not known if patients’ preferences on end of life care are any different in a racially more diverse cohort of patients in the U.S.

Conclusions: CPR in dialysis patients is associated with high mortality rates. It is possible to predict hospital discharge survival of patients with cardio-pulmonary arrest based on the CPR characteristics.

807A
Methods: We collected data on 423 out of 440 dialysis patients from 7 dialysis facilities in the U.S. using self-reported questionnaires. 

Results: Our study included 28.1% Caucasian and 66.7% African American patients. Eighty-three percent of the patients felt that their QOL was an important determinant in their end-of-life care. We sought to introduce ACP and increase documentation of AD in older outpatient nephrology patients.

Conclusions: Multiple treatments are available to older patients with advanced chronic kidney disease. However, poor communication about available treatment options may result in a mismatch between patient preferences and treatment choice.

SA-PO777 

“So I had No Choice”: Perceptions of Dialysis Decision-Making Among Older Adults

Keren Ladin,1 Daniel E. Weiner.2 (1Occupational Therapy, Tufts Univ, Medford, MA; 2Medicine, Tufts Univ Medical School, Boston, MA.

Background: Many US dialysis patients undergo intensive procedures intended to prolong life such as mechanical ventilation, cardiopulmonary resuscitation or feeding tube placement at the very end of life. Little is known about trends over time in use of intensive procedures in this population.

Methods: We examined temporal trends in receipt of inpatient intensive procedures in the last 6 months of life by age and race among 601,942 adult Medicare beneficiaries treated with maintenance dialysis who died between January 1, 2000 and December 31, 2011.

Results: From 2000 to 2011, inpatient admissions during the last six months of life increased slightly from 89% to 90%. Among those admitted, there was a marked increase in the use of intensive procedures ranging from 38% in 2000 to 44% in 2011. Intensive procedures at the end of life were more common among black vs. white patients (50% to 57% vs. 34% to 39%) and among younger vs. older patients (50% to 61% for those < 55 years vs. 27% to 26% for those > 85 years).

Conclusions: These procedures were most common and increased most dramatically in younger patients while racial differences were most pronounced in older patients.

SA-PO780 

Will Nephrologists Implement an Advance Directives Program in Their Patients? (Quality Improvement Program)

Ali Mohammed Habeeb, Sheldon W. Tobe. Nephrology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Background: Mortality remains high among patients on dialysis. Advanced age and multiple co-morbidities are the major predictors for increasing mortality. ADs extend patients’ autonomy and are the best tool to inform patients about their preferences for health care decisions when they become unable to make such decisions. Chronic dialysis patients have been shown to want to discuss ADs in the past.

Methods: We reviewed 215 chronic in-center hemodialysis patients at Sunnybrook Health Sciences Centre from March to April 2015 by the dialysis unit social workers for any documents related to ADs (like Living wills, Substitute Decision Maker (SDM) and CPR forms). Only 2 patients had ADs in their charts (1%). When this data has presented to the Nephrologists they agreed that ADs should be discussed with their patients and that this was a quality improvement project and they started discussing ADs with their patients.

Results: As part of the process to discuss ADs, the unit’s social workers distributed a pamphlet for the patients with simple and explicit definitions and advantages of AD and also pamphlets explaining about the contents of the form pamphlets. The Staff Nephrologists were educated about the importance and advantages of ADs in their patients and were asked to start discussing the issues with their patients. The Nephrologists will also be educated about how an AD discussion might go and how to document the results of the discussion. In 3 months, a review of the patients’ charts will again look for any documented ADs. We will also study the response of individual dialysis staff and their participation in completing and discussing the ADs. We will assess the potential barriers for not completing ADs by the dialysis unit staff and by patients and attempt to address these barriers.

Conclusions: Expected Outcome: Based on the Prochaska model we are anticipating the dialysis staff are now in the contemplation stage and we are aiming to observe the progression in their behavior to more advanced stages of behavior and try to find out what are the barriers that prevent the progression.

Current Practice of Advance Care Planning in New Zealand

Background: Recent guidelines emphasise the need to improve advance care planning (ACP) for patients with chronic kidney disease (CKD). Little is known about current ACP practice in Australian/New Zealand renal centres. We aimed to describe current practice and barriers to ACP from the perspective of renal clinicians.

Methods: A cross-sectional survey was administered online to nephrology nurses, nephrologists, and social workers between 30th June and 1st January 2015. Survey questions covered the topics of experience, skills, comfort and knowledge regarding ACP, workplace policies and procedures concerning ACP, perceived barriers and facilitators to ACP, and perceived need for new CKD-specific ACP programs and materials.

Results: The 487 respondents included 41 nephrologists, 152 nurses/physician assistants, 199 social workers, and 95 dialysis center administrators. There was a significant difference by discipline in reported unmet palliative care needs for symptom management, care coordination, and family bereavement support, with administrators least likely to view these barriers (all p <.05). For example, 86% of nephrologists, 79% of nurses, and 71% of social workers reported having 4 or more symptom treatment barriers, compared to 56% of administrators. Furthermore, 71% of nephrologists, 61% of nurses, and 59% of social workers reported having 4 or more care coordination barriers, compared to 49% of administrators. In contrast, 81% of nephrologists, 75% of nurses, and 74% of social workers reported having 4 or more barriers to bereavement support, compared to 55% of administrators.

Conclusions: ACP in Australian/New Zealand renal centres is subject to health system, provider and patient related barriers. Given the volunteer effect associated with online surveys, our study may underestimate the need for ACP support. Targeted interventions are needed to improve ACP in Australian and New Zealand renal centres.

SA-P0782

Nephrology Leadership Required to Address Unmet Palliative Care Needs in Dialysis Centers

Background: Because of high symptom burden, numerous comorbidities, and shortened life expectancy, dialysis patients are increasingly recognized as appropriate candidates for early and continuous palliative care.

Methods: In 2013 the Coalition for Supportive Care of Kidney Patients conducted an online survey of dialysis professionals and administrators using ESRD Network and Renal Physicians Association email lists to determine perceptions about how well patient palliative care needs are met. Differences among disciplines were assessed by chi-squared testing and one-way ANOVA.

Results: The 487 respondents included 41 nephrologists, 152 nurses/physician assistants, 199 social workers, and 95 dialysis center administrators. There was a significant difference by discipline in reported unmet palliative care needs for symptom management, care coordination, and family bereavement support, with administrators least likely to view these barriers (all p <.05). For example, 86% of nephrologists, 79% of nurses, and 71% of social workers reported having 4 or more symptom treatment barriers, compared to 56% of administrators. Furthermore, 71% of nephrologists, 61% of nurses, and 69% of social workers reported having 4 or more care coordination barriers, compared to 49% of administrators. In contrast, 81% of nephrologists, 75% of nurses, and 74% of social workers reported having 4 or more barriers to bereavement support, compared to 55% of administrators.

Conclusions: Nephrologists report more unmet palliative care needs, barriers, and resources than the administrators who oversee dialysis centers. Because the respondents were self-selected, a study limitation, the results likely underestimate unmet palliative care needs. To better address palliative care needs, nephrologists need to lead interdisciplinary collaborations, including administrators, to implement palliative care pathways already established in evidence-based clinical practice guidelines.

SA-P0783

Hospice and Race for End-Of-Life Care in U.S. Dialysis Patients

Background: While hospice use is increasingly used for end-of-life care in dialysis patients, we hypothesized that important racial disparities may be present.

Methods: To address this hypothesis, we examined USRDS files to characterize end-of-life care for deaths occurring between 2006 and 2011.

Results: During this 5-year period, the proportion of deaths in hospice increased from 14.7% to 24.2%; grouped by age at death, the following trends were observed: 65 years-11.5% to 15.0%; 65 to 79 years-19.1% to 26.1%; 80-89 years-24.9% to 34.3%; ≥ 90 years-25.9% to 39.6%. As shown in the accompanying Table, associations of hospice use among decedents included more recent calendar year, older age and female sex. Hospice use varied substantially with race: compared to whites, adjusted odds ratios of hospice use were 0.56, 0.56 and 0.57, respectively, in patients of African American, Native American and Asian race.

Conclusions: While end-of-life care in hospice settings is growing rapidly in the US, substantial, unexplained racial disparities exist.

SA-P0784

Palliative Care Perspectives of Latinos with End-Stage Renal Disease

Background: Latinos are the fastest growing minority and have a nearly 2-fold faster progression from chronic kidney disease to end-stage renal disease (ESRD). Despite the high symptom burden and mortality suffered by patients with ESRD, there is limited palliative care research and Latinos are underrepresented in existing palliative care studies. The purpose of our study is to provide the first description of the Latino palliative care perspective.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We modified Davison’s 2010 End of Life Care Preferences and Needs Survey to include known barriers to palliative care in the Latino community. The survey was translated to 3rd grade Spanish and then back-translated to English.

Results: Participants (n=61) had a mean age of 59 years ± 12, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 months ±44.8. The majority (77%) spoke Spanish and reported limited understanding of hospice and palliative care. We found that 60 (98%) want to be informed about their prognosis and 55 (90%) want to be prepared and plan ahead; however, only 16 (26%) had discussed prognosis and only 10 (16%) had discussed end-of-life care with their nephrologist. The majority of participants stated that it was their doctor’s choice (68.8%) to start dialysis, however, few (14.7%) regret the decision to start dialysis. Participants reported a preference to have advance care planning conversations on a routine basis (86.8%), after starting dialysis but before becoming ill (85.2%), and while receiving dialysis (47.5%) or at home (37.7%). Participants want their family to have a central role in medical decision-making (93.4%) and care giving (95%).

Conclusions: Our findings provide the first description of the palliative care perspectives of a predominantly Mexican Latino population with ESRD. By understanding the palliative care perspectives and barriers experienced by Latino patients with ESRD, we can move toward a value-based and patient-centered model of palliative care.

Funding: Private Foundation Support

SA-P0785

Symptom Burden Amongst Latinos with End-Stage Renal Disease

Background: All patients with end-stage renal disease (ESRD) experience a high symptom burden. Although Latinos represent 19% of the US ESRD community, little research is available on their symptom burden. The purpose of our study was to provide the first description of symptom burden prevalence and severity amongst Latinos with ESRD.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We used Davison’s ESRA-8: renal tool which measures physical and psychological symptom distress and contains 11 symptom items on a Likert scale of 0-10. Moderate = 4-6 and severe = 7-10. We asked three questions about symptom treatment preferences.

Results: Participants (n=61) had a mean age of 59 ±12 years, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 ±44.8 months. The majority were born in Mexico (90.2%), spoke Spanish only (77%), and had a less than high school education (72.2%). Overall, Latinos experience a substantial symptom burden with a mean of 6.8 ± 2.9 symptoms of which 5.1 ± 2.8 are moderate or severe symptoms. Tiredness Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only.
was experienced by 83.5% of patients and reported as moderate or severe by 67.2%. Pain was present in 66.5% and moderate or severe in 40.1%. Depression was reported by 55.7% and anxiety by 49.1% and moderate or severe in 49.2% and 39.3%, respectively. The majority (78.6%) of patients reported lack of well-being and feeling dizzy (70.5%). With respect to medication preferences, our cohort prefers Western Medicine (77.1%) over traditional curandero (22.9%) medicine and is agreeable (77.1%) to taking a few more medications if it meant all symptoms could be controlled. Our Latino cohort prefers (88.5%) to have their physical symptoms (e.g. pain, nausea) treated by nephrology staff.

Conclusions: Latinos with ESRD suffer from a debilitating symptom burden and over half of the symptoms are amenable to symptoms directed therapy. Our findings support the early identification and treatment of physical symptoms by nephrology staff.

SA-PO786

Care of the ‘Failing HD Patient’: Role of a Supportive Care Register

Tracy Maryan, Maria Da Silva-Gane, Suresh Mathavakannan. Renal Unit, Lister Hospital, Stevenage, Hertfordshire, United Kingdom.

Background: Older dialysis patients (>70) often have significant comorbidities, that worsen with duration on HD. Continuation of dialysis often occurs at the expense of frequent illness episodes. There is a progressive decline in cognitive and physical function that exacerbates dialysis. We had introduced a Supportive Care Register (SCR) in 2012 to identify ‘failing dialysis patients’ based on their physical performance scores. We attempted to understand whether being on the SCR enabled better patient care when these patients were admitted with inter-current illnesses.

Methods: Data was collected from Patient Administration System (PAS) and Renal IT database in a large Tertiary (non-transplanting) Renal Unit serving a catchment population of 1.2 million. Data maintained in the SCR was reviewed. Total number of HD patient database in a large Tertiary (non-transplanting) Renal Unit serving a catchment population of 1.2 million. Data maintained in the SCR was reviewed. Total number of HD patient admissions to the acute renal service in 2013 were obtained with analysis of demographics, length of stay (LoS) and outcomes at discharge. Patients who were admitted were checked against the SCR entries.

Results: 287 out of the 409 total HD patients were admitted (123 F, median age 68 years, 590 episodes) with 137 of these patients being admitted more than once. The LoS was 9 days. 49 patients died in 2013 (28M; 76±16 yr; vintage 60 m; LoS 18 ±12 p<0.05). 28 patients died in hospital or at home/hospital following withdrawal of dialysis and institution of palliative care. 16 patients had died following severe acute illness. Five patients died at home. 18/28 patients were on the SCR and had discussions relating to ongoing and future dialysis therapy and advanced and preferred place of care planning prior to their last admission in the clinic setting. Seven patients had proceeded to discussions regarding resuscitation.

Conclusions: In conclusion, establishment of a SCR for dialysis patients with declining functional capacity and significant comorbidities allows for an early identification of patients at risk of physical and functional decapitation. Once identified, establishing a dialogue in the OP dialysis setting about future care needs and expectations allows for a more integrated care approach when patients decompensate to the point of being unable to continue dialysis.

SA-PO787

A Descriptive Study of Home Palliative Service Utilization and Care Trajectory Among Patients Dying on Dialysis

Dixion, Marnie MacKinnon, Sarah E. Bota, Jade S. Hayward, Erin Arthurs, Sara N. Davidson. 1Nephrology Program, Humber River Hospital, Toronto, ON, Canada; 2Inst for Clinical Evaluative Sciences, London, ON, Canada; 3Ontario Renal Network, Toronto, ON, Canada; 4Ottawa Health Research Inst, Ottawa, ON, Canada; 5Faculty of Medicine, Univ of Alberta, Edmonton, AB, Canada.

Background: Palliative care service use and outcomes among Ontario’s dialysis recipients remain uncharacterized.

Methods: We conducted a descriptive, retrospective, cohort study of 5,507 patients who died while receiving or withdrawing from chronic dialysis (hemodialysis or peritoneal dialysis) in Ontario, between January 1, 2010 and December 31, 2012. Data sources included the Ontario Renal Reporting System, the Canadian Organ Replacement Register, the Home Care database, and other linked administrative health datasets. The date of death served as the index date, and we examined patterns of service use in the prior 365 days. We present selected measures of health service use and outcomes.

Results: Cohort characteristics at death, expressed as median (IQR) or percent of cohort included: 75 (16) yrs old, 3.0 (5) yrs on dialysis, 42% female, 65% had diabetes, 14 (4) Johns Hopkins ACG (comorbidity score). Final dialysis modality was 85% centre HD, 1% home HD, 4% PD, 10% missing. During the last year of life, 11.3% received at least one palliative care service in the home, and 17.5% withdrew from dialysis in the last 30 days of life. In the last 14 days of life, 44% of patients had an emergency department (ED) visit and 65.6% an ICU visit. ED and ICU visits were less frequent among patients who had received home palliative services in the last year of life. Place of death was ICU in 33%, and acute care hospital (without ICU) in 32%, while only 3.6% of patients died at home. Patients with home palliative care services in the last year of life had a greater frequency of death at home (15 vs. 2%) compared with those who died at other places.

Conclusions: Home palliative care services may not be used optimally by dialysis patients in Ontario. Further studies are needed to understand barriers to accessing palliative care services and to improve service planning and delivery.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

SA-PO788

Ventilator Dependent Dialysis Patients

Jack Rubin, Los Angeles.

Background: We have started treating ventilator dependent patients at our dialysis unit and wish to share our results.

Methods: Chart review was done on all ventilator dependent patients treated at our unit.

Results: All data are shown mean ± sd. To date we have treated 19 patients (8F/11M) aged 71 ± 14 years with a mean time on dialysis of 90 ± 102 days. These patients were on dialysis prior to coming to us a mean 741 ± 1046 days. Seven were started within 2 months of their catastrophic event. Mean last available Kt/V 1.5 ± 0.3, weight 152 ± 41 pounds, dialysis time 194 ± 21 minutes, bun 90 ± 20, creatinine 4.5 ± 1.5 Hemoglobin 9 ± 1.2, albumin 3 ± 0.5 gm%, pre-albumin 18 ± 9 mg%, calcium 9.2 ± 0.6 mg% and phosphorus 3.4 ± 1.3 mg%. Four patients were transferred a mean of 71 ± 54 days because of insurance issues. 7 are on dialysis 97 ± 137 days and 8 have died after 94 ± 95 days on dialysis. There were no apparent differences in the parameters listed above between those transferred for insurance reasons, those who died and those still receiving treatment.

Conclusions: These non verbal non communicative patients are receiving aggressive end-of-life care fostered in some cases by Unrealistic family expectations and in other instances by state conservators who prefer treatment until death so that outpatient withdrawal of dialysis and comfort care is not a realistic option. There are two groups - vintage patients and new to dialysis patients with a catastrophic event. The goal should be to educate families on the consequences of dialysis for the patient so that they do not start or allow withdrawal of dialysis after a defined trial. Upon taking on treatment of this group of patients the dialysis unit should anticipate a lower star rating in the benchmarks as most are on catheters and are frequently admitted for infection, bedsores or pulmonary complications. To sustain these selected patients requires a dedicated staff of nurses, respiratory technicians and ambulance services.

SA-PO789

External Validation of a Prediction Model for 6-Months Mortality Risk

Adeera Levin, Brian Forzley, Helen Chiu, Lee Er, Ogjenka Djurdjev, Mohamud A. Karim, Rachel C. Carson, Gaylene M. Hargrove, Dan J. Martinussen. 1Dept of Medicine, Faculty of Medicine, UBC; 2BC Provincial Renal Agency; 3Island Health Authority, BC, Canada.

Background: End-Stage Renal Disease (ESRD) is associated with poor prognosis. Clinicians must be prepared to address end-of-life issues; hence, identifying patients at higher MR is recommended. We aimed to validate a 6-month MR prediction model for prevalent hemodialysis patients derived by Cohen et al. (2010) in a Canadian cohort and assess its clinical utility.

Methods: 375 prevalent dialysis patients in two regions of BC, Canada, were followed for 6 months. Data including serum albumin (ALB), age, peripheral vascular disease and dementia captured when the surprise question (SQ) was asked were used to validate the 6-month MR model. Model performance was evaluated through discrimination, calibration and decision-curve analysis.

Results: The observed mortality was 13.3% at 6-months. The model had reasonable discrimination (c-stat=0.67) but poor calibration (slope=0.64 [95% CI: 0.35, 0.72]) in our data. Decision curve showed added value of the model for threshold probabilities of 8%-20% (~ 12-42% fewer false-positive death), but no more beneficial to “treat-all” for probability >8% and “treat-none” for probability >20%.
SA-PO792
Charcoal Hemoperfusion in the Treatment of Pruritus in Cholestatic Liver Disease
Nephrology, Mayo Clinic, Rochester, MN.

Background: Pruritus is a distressing symptom in a considerable proportion of cholestatic patients and few of them do not respond to conventional treatment. Charcoal hemoperfusion (CH) is an extracorporeal technique to eliminate albumin-bound substances that are accumulated during cholestasis by the passage of blood through a column containing activated charcoal. Several case reports have shown significant reduction of bilirubin in mechanical jaundice and neonatal hemolytic jaundice. However, the published data of CH for the treatment of resistant pruritus in cholestatic patients is scarce.

Methods: Procedure code “Charcoal hemoperfusion” was used to identify patients who received charcoal hemoperfusion at Mayo Clinic, Rochester from 1/1/2000 to 5/1/2015.

Results: Thirty patients were identified. All patients had failed conservative treatment and 2 of them had not responded to plasmapheresis. A median of 3 (IQR 1-9) sessions for a total of 20(1-33) hours were performed. CH resulted in a significant decrease of pruritus in 19 patients (69%). 2 patients did not have significant relief and 2 patients did not pursue further treatments after having adverse reaction during the first session. Median pruritic score significantly decreased from 9/9 (10-10) to 4/10 (0-0) posttreatment (p=0.004). Duration of symptom free period ranged from 8 to 46 days (median 18 days) in 6 patients who returned for follow up. 6 patients (46%) experienced adverse reactions described in Table 1.

Conclusions: Charcoal hemoperfusion is an effective therapy for refractory cholestatic pruritus. However, the improvement is not sustainable and the short benefit should be balanced with the invasive nature of the therapy and the relatively common adverse reactions.

SA-PO793
Strict Adherence to Medicaid InterQual® Criteria Increases Adverse Events and Health Care Utilization in Undocumented Dialysis Patients
Medicine, Indiana Univ, Indianapolis, IN.

Background: Current estimates suggest there are 6000 undocumented ESRD patients in the US that may be ineligible for scheduled hemodialysis. To meet emergency Medicaid requirements, hospitals have sought creative ways to treat undocumented patients. We present data from an undocumented cohort as it progressed through a succession of three periods with different dialysis criterion.

Methods: “Renady’s” a sybiotic dietary supplement was studied in randomized clinical trials in CKD 3 and 4 and ESRD patients. Other oral therapies for removal of uremic toxins include the use of keto acids and charcoal sorbents.

Results: Our studies using Renady for “Enteric Dialysis” showed reduction in levels of various uremic toxins like lactic and indoxyl glucuronide. Levels of CRP also decreased with improved quality of life. This demonstrates the potential restoration of the gut microbiome dysisbosis with the use of specific strains of probiotics.

Conclusions: The use of a well-researched, clinically documented and safe probiotic/ prebiotic dietary supplement formulation has the potential to safely perform continuous 24h/7d uremic toxin removal and thus stabilize the gut Microbiome and its dysbiosis. Hence, the concept of “Enteric Dialysis” with continuous removal of uremic toxins may be the future key to providing an alternative HOPE for renal failure population.

811A
associated with increased adverse events with a composite OR for intubation, bacteremia, NSTEMI, ICU admit, and death of 48 (5.9-391.2) compared to P1. P2 charge estimates increased from P1 ($357,501 v $202,326 per person per year, P=0.0001).

Fig. 1 – Hospital utilization per patient per month. * = P < 0.05.

Conclusions: Strict adherence to InterQual® Criteria increases adverse events and healthcare cost per patient. We must determine better alternatives to emergent dialysis which minimize cost, while maintaining dignity, safety, and quality of life.

SA-PO794

Factors Associated with Withdrawal of Care (WOC) in Maintenance Dialysis Patients Fahad Saeed, Robert Butler, Jesse D. Schold. Nephrology, Cleveland Clinic.

Background: There is paucity of data on factors leading to WOC in dialysis patients. We studied this question by using the NIS dataset, 2005-2011.

Methods: We studied the following six major primary diagnoses: MI, cardiogenic shock, sepsis, stroke, CPR and coma. Effect of age, sex, race, hospitals’ profit status and comorbidities were assessed on WOC status. We studied 836563 dialysis patients’ admissions, and WOC occurred in 68152 patients.

Results: Male sex, African American and Latino races, smoking, obesity, psychosis and anemia carried lower odds of WOC. Primary diagnoses of CPR, coma, MI, cardiogenic shock, and sepsis; and co-morbidities such as CHF, dementia, HTN, CA, liver disease, paralysis, chronic lung disease, DM, weight loss were associated with higher odds of WOC. Odds of WOC were increased by approximately 6 % per year of patient age. Teaching hospitals had higher odds while private hospitals carried lower odds of WOC status.

Conclusions: Age, non-profit hospital status, coma, metastatic malignancy and weight loss are the most significant factors associated with WOC among dialysis patients. These prognostic data should be considered while treating such patients.

Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

Red Cell Distribution Width and Mortality in Incident Hemodialysis Patients Tania Vashistha, Elon Streja, Miklos Zsolt Molnar, Conni Rhee, Steven M. Brunelli, Hamid Moradi, Tae Hee Kim, Vanessa A. Ravel, Melissa Soohoo, Csaba P. Kovesdy, Kamyar Kalantar-Zadeh. UC Irvine; UTHSC; DaVita Clinical Research.

Background: Red cell distribution width (RDW) is a measure of red blood cell size and variability that is often used as an indicator of iron-deficiency anemia. Although RDW has recently been found to be associated with mortality in the general population, few studies have examined this association in hemodialysis (HD) patients.

Methods: We examined the association of RDW with all-cause mortality in a cohort of 109,675 incident HD patients from a large dialysis organization during 2007-2011 using Cox proportional hazards regression with adjustment for case-mix (demographics, comorbidities covariates) and markers of malnutrition and inflammation (MICS). RDW was divided into 5 categories <14.5, 14.5-<15.5, 15.5-<16.5, 16.5-<17.5, and >17.5 %.

Results: The mean age (mean/SD) of the cohort was 63.1 ±15 years old and included 44% females, 58% diabetics, and 31% African Americans. Higher baseline RDW was linearly associated with higher all-cause mortality risk in both unadjusted and fully adjusted models.

Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

Association of Pre-ESRD Hemoglobin with Early Post-ESRD Mortality Among U.S. Veterans: A Transition of Care in CKD Study Melissa Soohoo, Connie Rhee, Vanessa A. Ravel, Elon Streja, Jennie Jing, Danh V. Nguyen, Csaba P. Kovesdy, Kamyar Kalantar-Zadeh. UC Irvine; UTHSC.

Background: Patients with chronic kidney disease (CKD) are often afflicted with anemia. Previous studies have shown that low hemoglobin (HGB) is associated with pre-dialysis mortality in non-dialysis dependent CKD patients, yet the association of HGB levels in the immediate period preceding dialysis (prelude) and early post-dialysis mortality remains unknown. We hypothesized that lower HGB levels are associated with higher post-transition survival in comparison to higher HGB levels.

Methods: We investigated 18,555 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 HGB measurement during the 6 month prelude period before dialysis transition. 6 month averaged HGB was used as a continuous predictor of early post-dialysis all-cause mortality occurring in the first 3 months after initiation using restricted cubic spline models and Cox proportional hazard regressions. The models were adjusted for age, gender, race, ethnicity, region and primary cause of ESRD.

Results: The analytic cohort was a mean±SD age of 68±11 yrs, among whom 30% were African-American, 7% Hispanic and 30% had diabetes as the cause of ESRD. The 6 month prelude HGB average was 10.9±1.6 g/dL. Prelude HGB exhibited a U-shaped association with 3-month post-ESRD all-cause mortality; patients with a 6 month prelude HGB average of 11-15.5 g/dL had better survival, whereas patients with HGB measurements <9 g/dL or >13 g/dL had higher mortality (Figure).

Conclusions: The analytic cohort was a mean±SD age of 68±11 yrs, among whom 30% were African-American, 7% Hispanic and 30% had diabetes as the cause of ESRD. The 6 month prelude HGB average was 10.9±1.6 g/dL. Prelude HGB exhibited a U-shaped association with 3-month post-ESRD all-cause mortality; patients with a 6 month prelude HGB average of 10-11.5 g/dL had better survival, whereas patients with HGB measurements >13 g/dL had higher mortality (Figure).

Higher Serum Ferritin Levels Are Associated with Better Survival in the HEMO Study

Anna Jeannette Kovanyovich, 1 Eugene J. Nuccio, 2 Alfred K. Stockler 3, 4 Tom Greene, 2 Michel Chonchol, 2 Denver VA Medical Center; 2VA Salt Lake City; 4Univ of Colorado Denver; 2VA Salt Lake City; 4Univ of Utah.

Background: Ferritin is an important indicator of total body iron stores and has been shown to prevent ox-LDL induced oxidative injury in endothelial cells. Studies regarding the relationship between serum ferritin levels and all-cause mortality in chronic hemodialysis patients are conflicting. The purpose of this study was to determine the relationship between higher serum ferritin levels and death among participants in the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial.

Methods: We studied the association of serum ferritin and iron levels with all-cause mortality among 1799 subjects from the HEMO trial. Cox regression models adjusted for important confounding variables including demographics, comorbidities, treatment assignment, smoking, and albumin.

Results: Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) ferritin and iron levels were 249 (2-497) ng/ml and 50 (5-78) µg/dl, respectively. Over a mean follow-up of 2.84 years, there were 582 deaths. Among subjects with levels in the highest quartile compared to the lowest quartile, both ferritin and iron were significantly associated with reduced all-cause mortality in adjusted analyses, odds ratio (OR) 0.67 (95% CI, 0.46-0.97) and OR 0.60 (95% CI, 0.42-0.85), respectively.

Conclusions: Among subjects participating in the HEMO trial higher serum ferritin and iron levels were associated with reduced mortality. We hypothesize that ferritin may play an important role in protecting the endothelium from oxidative stress-induced damage. Funding: NIDDK Support, Veterans Administration Support.

Anemia in Chronic Kidney Disease Patients Could BeLinked to Indoxyl Sulfate Levels

Denise Mafra, 1 Natalia Alvarenga Borges, 1 Milena Barcza Stockler-Pinto, 2 Amanda F. Barros. 1 Medical Sciences Graduate Program, Federal Univ Fluminense, Brazil; 2Cardiovascular Sciences Graduate Program, Federal Univ Fluminense, Brazil.

Background: Indoxyl sulfate (IS) is a uremic toxin derived from the action of colon bacteria in dietary tryptophan. This toxin is related to many complications for chronic kidney disease (CKD) patients, including anemia. The aim of this study was to verify the relationship between IS plasma levels and anemia in hemodialysis (HD) patients.

Methods: This transversal study included 18 HD patients (50% men, 54.2 ± 11.6 yrs, BMI 26.3 ± 4.7kg/m², time on dialysis 51 (30-52) months, all patients received the same dose erythropoietin per week). Routine laboratory parameters were measured, the total IS plasma levels were quantified with high-performance liquid chromatography (HPLC) and protein C reactive (CRP) levels analyzed by Immunoenzymatic Assay. Statistical analyses were performed with SPSS version 19.0.

Results: The mean of hemoglobin was 11.0 ± 1.28 g/dL and hematocrit of 34.2 ± 3.0%. The mean of IS plasma levels was 23.9 (10.3 - 100.9) mg/L and CRP 3.1 (1.3 - 8.6) mg/dL. Multivariate linear regression analysis adjusted for age, sex, time on HD, albumin, BMI, CRP revealed that serum hemoglobin (β = -0.62; p = 0.01) was independently and negatively associated with IS levels.

Conclusions: This study provided evidence that IS seems be associate with anemia in HD patients and therapeutic strategies in the clinical care to reduce uremic toxins levels may be effective to management of anemia in HD patients. Funding: Government Support - Non-U.S.
Initially, mean Hb level was approximately 1 g/dL lower among ESA-only patients and remained 0.4 g/dL lower throughout the study. During follow-up, ESA was associated with a greater adjusted risk of mortality vs no ESA (control referent). Incidence rate ratios (95% confidence interval) ranged from 2.24 (1.93-2.60) in the 2nd quarter to 1.48 (1.18-1.84) in the 8th quarter.

Conclusions: Using a contemporarily relevant definition, ESA at a single point in time is potently and persistently associated with greater ESA utilization, lower Hb levels, and higher mortality risk.

SA-PO801
Impact of ESAs and Iron on Survival in Hemodialysis Patients: Which Is the Best, Which Is the Worth? Jacques B. Rottbourm,1 Alain Guerin.2 1Dept of Nephrology, Hôpital de la Pitié, Paris, France; 2Hemodialysis Units, Diaverium, Paris, France.

Background: Appropriate anemia management for Hemodialysis (HD) patients (Pts) is still challenging. Intravenous (IV) iron and erythropoiesis-stimulating agents (ESAs) are the main therapies, with conflicting outcomes. In the unit, pts were treated over the last seven years, cumulative doses of ESAs (darbepoetin alfa [DA]), converted in µg per session, and IV iron (iron-sucrose [IS]), converted in mg per session, were exactly constantly reported. Survival depending on the cumulative dose of each product and both products together was calculated using the Kaplan Meier methodology.

Methods: 300 incident HD pts (67% male) mean [M] (SD) age at start 59.7(16.3) years, were treated for 100,430 dialysis sessions [S], receiving all over 1,192,250 µg of DA, and 1,794,050 mg of IS. M Hb level was 11.55(0.77) g/dL, MT SAT 37.1(8.5)%, and Ms ferritin 562(322) µg/L. The M DA dose injected was 12.91(9.99) µg per S. The M IS dose injected was 20.91(11.57) mg per S. Expressing the separate doses of DA and IS received by the pts in three categories for each product, we obtained 9 categories of pts, depending on whether they received low, middle, or high doses of ESA and IS per S: M doses were [5.4(2.6), 10.8(3.4), 25.1(14.8)]/µg for ESA, [12.5(4.5), 18.4(3.4), 32.3(11.9)] mg for IV iron respectively.

Results: Survival was expressed at 1000, 2000, and 3000 days (d):

The better survival was obtained in the group of low ESA and low IV iron, the worst was high ESA and high IV iron. Survival is better with low ESA, whatever is the IV iron dose injected. High ESA dose, whatever IV iron dose is injected, seems to be worth.

Conclusions: Because the majority of patients on HD receives ESA and IS, rigorously conducted and adequately powered clinical trials studying the cumulative doses of ESA and IV iron, reflective of present-day practice, are greatly needed.

SA-PO802
Relation between Statin Prescription and Erythropoietin Stimulating Agent (ESA) Hyporesponsiveness in Hemodialysis (HD) Patients: Results from the Japan Dialysis Outcomes and Practice Patterns Study (JDOPPS) Takeshi Hasegawa,1+ Junhui Zhao,2 Douglas S. Fuller,3 Brian Bieber,4 Yun Lin,5 Jarcy Zee,5 Hal Morgenstem,6 Masami Nangaku,7 Bruce M. Robinson,8 Norio Hanafusa,9,10 Fukushima Medical Univ Hospital, Fukushima City, Fukushima, Japan; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Univ of Michigan, Ann Arbor, MI; 4Univ of Tokyo, Tokyo, Japan; 5Anemia Working Group of JDOPPS, Japan.

Background: Statins are widely used in HD patients and have pleiotropic anti-inflammatory and anti-oxidative effects, but the latest guideline is advising against starting its use in this population. Hypothesizing that statins could be used as adjuvant treatment for renal anemia, we examined the association between statin prescription and ESA hyporesponsiveness (ESAHYPO) in Japanese HD patients (pts) prescribed ESAs.

Methods: We included 3208 pts in 178 HD facilities dialyzed 3x/week for ≥4 months from JDOPPS phases 3-5. Statin Rx was reported at baseline. ESAHYPO was defined in patients on maintenance hemodialysis (MHD) as having an erythropoietin resistance index (ERI) of ≥25 U/kg/week/g/dl. Logistic regression was used to evaluate the key variables which might be independently associated with erythropoietin hyporesponsiveness in MHD patients.

Results: Mean erythropoietin resistance index (ERI) for the entire study population was 16±5 U/kg/week/g/dl. 26% patients were erythropoietin hyporesponsive. Patients were divided into two groups according to ERI: ERI<25±U/kg/week/g/dl and ERI≥25±U/kg/week/g/dl. In ERI 125±U/kg/week/g/dl cases, the proportion of female gender was higher, hemoglobin and 25(OH)D were significantly lower than that of patients with ERI <25±U/kg/week/g/dl. In addition, comparing with ERI<25±U/kg/week/g/dl patients, body mass index (BMI) and serum cholesterol were slightly lower in ERI≥25±U/kg/week/g/dl patients (p=0.05). Logistic regression study adjusted gender, dialysis periods, BMI, Kt/v, serum cholesterol, serum albumin, and alkaline phosphatase, indicating an independent association between 25(OH)D deficiency and the erythropoietin hyporesponsiveness (HR:4.590, 95%CI:1.277~16.503).

Conclusions: Erythropoietin hyporesponsiveness is prevalent among MHD patients. Female gender and malnutrition are associated with erythropoietin hyporesponsiveness. 25(OH)D deficiency is the main risk factor for erythropoietin hyporesponsiveness. Improving 25(OH)D deficiency and malnutrition may increase the response to erythropoietin treatment in MHD patients.

SA-PO803
25(OH)D Deficiency Contributes to the Erythropoietin Hyporesponsiveness in Patients on Maintenance Hemodialysis Pu Lei, Daqing Hong, Fei Deng, Li Wang, Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: The aim of this study was to identify the factors that contribute to erythropoietin hyporesponsiveness in patients on maintenance hemodialysis (MHD).

Methods: demographic data, hemoglobin, dose of erythropoietin, biochemical indicators and other related indicators of 80 MHD patients were collected and retrospectively analyzed. They were followed up for 12 months. Erythropoietin resistance index (ERI) was used to evaluate the response to erythropoietin in patients on MHD. The ERI was calculated dividing the weekly weight-adjusted (kg) dose of ESA (IU) by the hemoglobin level (g/dL). Logistic regression study was used to determine the key variables which might be independently associated with erythropoietin hyporesponsiveness in MHD patients.

Results: Mean erythropoietin resistance index (ERI) for the entire study population was 16±5 U/kg/week/g/dl. 26% patients were erythropoietin hyporesponsive. Patients were divided into two groups according to ERI: ERI<25±U/kg/week/g/dl and ERI≥25±U/kg/week/g/dl. In ERI 125±U/kg/week/g/dl cases, the proportion of female gender was higher, hemoglobin and 25(OH)D were significantly lower than that of patients with ERI <25±U/kg/week/g/dl. In addition, comparing with ERI<25±U/kg/week/g/dl patients, body mass index (BMI) and serum cholesterol were slightly lower in ERI≥25±U/kg/week/g/dl patients (p=0.05). Logistic regression study adjusted gender, dialysis periods, BMI, Kt/v, serum cholesterol, serum albumin, and alkaline phosphatase, indicating an independent association between 25(OH)D deficiency and the erythropoietin hyporesponsiveness (HR:4.590, 95%CI:1.277~16.503).

Conclusions: 25(OH)D deficiency and malnutrition may increase the response to erythropoietin treatment in MHD patients.

SA-PO804
Incidental Findings on 15 Fluorodeoxyglucose Positron Emission Tomography Along with Low Dose Computerized Tomography (FDG PET CT) Scans Among Clinically Stable Haemodialysis with Erythropoietin Stimulating Agent (ESA) Hyporesponsive Patients Kaushik V. Y. Pujari,1 Haua A. C. Fung,2 Stanley Fan,3 Neringa Vilimiene,4 Muhammad M. Yaqoob. 1Pharmaceutical Company Support - Akebia Therapeutics, 2Hasegawa Medical Hospital, J Funayama, Tokyo, Japan; 3Barts Health NHS Trust, United Kingdom.

Background: Burden of comorbidities is high among hemodialysis (HD) patient. Underlying infective focus or occult malignancy is always of concern when clinically stable patients have ESA-R (ESA resistance index of ≥6.5 U/kg body weight/mean Hgb). We started expanding malignancy to be suspected and assigned from on going living donor kidney transplant work up. 4 patients needed antibiotics and 1 had anti TB therapy. 7 patients needed appropriate invasive investigations for confirmatory diagnosis. There was no association between elevated CRP around time of scan and pathological tracer uptake (P=0.468).
SA-PO807
Oral Vitamin C Supplementation Reduces Erythropoietin Requirement in Hemodialysis Patients with Functional Iron Deficiency

Tamini Sultan, Maria V. DeVita, Michael F. Michielis. Medicine, Lenox Hill Hospital, New York, NY.

Background: Functional iron deficiency (FID) is a major cause of erythropoietin (Epo) hyporesponsiveness and persistent anemia in dialysis patients. Vitamin C acts as a reducing agent and enhances mobilization of the ferrous form of iron to transferrin thus increasing its bioavailability. High dose intravenous vitamin C has been shown to decrease the Epo requirement and improve hemoglobin levels in previous studies. This route has its downside regarding difficulty of use, higher cost and associations with increased oxalate levels and inflammatory markers. Use of oral vitamin C has been limited due to the concerns of low bioavailability and patients compliance to medication. This study assessed the effect of low dose oral vitamin C on Epo dose requirements in stable hemodialysis patients with functional iron deficiency.

Methods: This prospective study included 22 stable hemodialysis patients with functional iron deficiency defined as transferrin saturation (Tsat) <30 % and ferritin levels of >100 mcg/L with Epo requirement of ≥ 4000 u/HD. Patients received oral vitamin C 250 mg daily for three months. Epo dose was adjusted according to unit protocol depending on the hemoglobin level. Hemoglobin, iron and Tsat levels were recorded monthly. None of these participants received iron or renal vitamin supplementation during the study period.

Results: The mean Epo dose was reduced in fifteen participants by 867±1356u/HD (p=0.03). In seven responders there was 33 % reduction in Epo dose from their base line. No ill effects of oral vitamin C were observed. Despite adjustment of Epo dose, hemoglobin level significantly increased from 10±1.6 mg/dl to 10.7±0.6 mg/dl (p=0.03). There were no significant change in Tsat and ferritin levels.

Conclusions: Low dose oral vitamin C supplementation reduced Epo dose requirements in hemodialysis patients with functional iron deficiency. Despite concerns regarding oral vitamin C absorption in dialysis patients this study indicates Vitamin C is well tolerated and effective.

SA-PO808
The Greatly Misunderstood Erythropoietin Resistance Index

Yossi Chait, Sahir Kalam, Joseph Horovitz, Christopher V. Hollo, Elizabeth D. Ankens, Michael J. Germain, Ravi I. Thadhani. 1UMass; 2WNE Renal & Transplant Assoc; 3MGH.

Background: The use of erythropoiesis stimulating agents (ESAs) to treat anemia in end stage renal disease remains controversial due to reported associations with adverse events. Many studies introduce so-called ESA resistance indices (ERIs) to characterize a patient’s resistance to ESA.

Methods: We use retrospective data from a cohort study of incident hemodialysis patients (n=8924). ERI is defined as average weekly erythropoietin (EPO) dose (IU) per kg body weight (EPOwt) per average hemoglobin (Hgb) (g/dl) over a 3-month period. Linear regression was used to describe the relationship between ERI and EPOwt. Logistic (Cox proportional hazards) regression modelled the relationship between 1-year mortality (survival time) and albumin, age, and either ERI or EPOwt.

Results: ERIs were strongly linearly related with EPOwt (r=0.98) but weakly correlated with 1/Hgb (r=0.44). Associations between covariates and mortality based on two logistic regression models differing only by a single covariate, EPOwt or ERI, were almost identical (figure 1); the same was found for Cox proportional hazards models (Table 2).

Table 1: Linear regression of death on covariates albumin, age, and X, where X = log(Eري) (Model A) or log(EPOwt) (Model B). OR, odds ratio; Sens, sensitivity; Spec, specificity.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
The area under the ROC curve (AUC) was changed by <1% when covariates ERI or EPOwt were removed from the logistic regression model (AUC = 0.71, sensitivity = 0.66, specificity = 0.65).

Conclusions: ERIs are strongly linearly related to weight-adjusted EPO doses by a “universal” (i.e., not patient specific) formula, hence are merely surrogates of EPO dose. Because true resistance must depend on both the input, (EPO) and its effect (Hb increase over endogenous Hgb level), ERI appears to be a poor marker of resistance. EPO dose itself, even though a statistically significant covariate, does not substantially strengthen the association between mortality and albumin and age as assessed by logistic or Cox regression. SA-PO809
Evaluation of Iron Deposition by MRI in the Heart and Liver in End Stage Renal Disease Patients on Hemodialysis
Rhea Bhargava,1 Ibrahim Saeed,1 Joseph S. Soltys,2 Omkar U. Vaidya,3 1Dept of Internal Medicine, Univ of Missouri- Kansas City, Kansas City, MO; 2Dept of Nephrology and Hypertension, Univ of Missouri- Kansas City, Kansas City, MO; 3Dept of Cardiovascular Diseases, Mid America Heart Inst, Saint Luke’s Hospital, Kansas City, MO; 4Dept of Cardiovascular Imaging, Cardiovascular Imaging Technologies, LLC, Kansas City, MO.

Background: Anemia is highly prevalent in patients with chronic kidney disease and its management is one of the key components of treatment in this population. 2011 introduced the bundling system which led to increased use of parental iron to treat anemia in this population. There has been significant controversy regarding our current model of iron and whether this leads to iron overload and increased mortality.

Methods: Retrospective evaluation of patients with end-stage renal disease on hemodialysis who had a cardiac MRI for clinical reasons to evaluate for iron deposition in the heart and liver. Exclusion criteria: Porphyria cutanea tarda, chronic liver disease, hemochromatosis,sideroblastic anemia , thalassemia. Inclusion criteria: End stage renal disease and received a cardiac MRI after 3-5 years of hemodialysis.

Results: Average total dose of venofer dose before cardiac MRI was 3500 mg. Average ferritin level: 695 ng/mL. Average iron saturation: 34%. All patients receiving IV iron had hepatic iron deposition. No correlation was seen between ferritin or iron saturation and hepatic iron deposition. A weak relationship was noted between the total iron dose and hepatic iron deposition.

Conclusions: These data suggest that even though we still use iron markers like ferritin and iron saturation for treatment of anemia in ESRD patients, this may not have a correlation with iron deposition in the liver. Significant iron deposition was not noted in the myocardium. MRI can be a useful modality to evaluate iron overload in this population.

Paricalcitol, Klotho and Renal Anemia in Hemodialysis Patients
Miguel Uriol Riveras,1 Sheila Caballo Pelegrin,2 Gonzalez Gómez Marqués,3 Manuel Luque-Ramírez,2 1Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; 2Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.

Background: Low Klotho levels, a protein linked to aging, is associated with an increase in the etioprotein process (programmed cell death). Chronic Kidney Disease is considered as a state of Klotho deficiency. We evaluate the association between plasma sKlotho levels with iron and hematologic parameters, and the influence of paricalcitol on these.

Methods: Data were obtained from the MIR-EPO study (EudraCT: 2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use (Group A) or not (Group B). Erythropoietin-stimulating agents (ESA) and iron supplementation were administered in order to maintain hemoglobin (Hb) between 10.5 and 12.0 g/dL and transferrin saturation (TSAT) ≥ 20%. After a 3-month observation period, sKlotho was measured(month 3 and 6 of follow-up) by ELISA. The changes in sKlotho from month 3 to 6 (A) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated (Group A: 23; Group B: 8). Intact parathyroid hormone (iPTH) levels and ESA doses did not change during the study. Mean sKlotho levels decreased at month 6 compared to month 3 in the whole group of patients (527 vs 474 pg/ml, P<0.001). After adjustment for iPTH and globular sedimentation rate, mean sKlotho levels in the Group A were higher than those observed in the Group B throughout the study (537 versus 401 pg/ml, P=0.005). A sKlotho correlated with Δ serum iron (r:0.42, P=0.020) in the Group A of patients. A cubic regression model showed that Δ sKlotho strongly explained Δ serum iron in these subjects (F:9.5, R²:0.64, P<0.001). A sKlotho were also associated with changes in iron supplementation (r: -0.47, P = 0.030) in the Group A of patients. In the Group B, a direct correlation between Δ sKlotho and Δ red blood cell count was found (r:0.73, P = 0.030).

Conclusions: Soluble Klotho is associated with iron metabolism in hemodialysis patients. Higher soluble Klotho levels may be a novel beneficial effect of paricalcitol use on renal anemia.

SA-PO812
Influence of the Paricalcitol on Iron Metabolism in Hemodialysis Patients
Miguel Uriol Riveras,1 Juan Rey Valeriano,1 Aina Obrador,2 Manuel Luque-Ramírez,2 1Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; 2Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.

Background: Interleukin-6 (IL-6) and hepcidin may play a role in the pathogenesis of iron functional deficiency (IFD). The influence of the Paricalcitol in IFD is not known.

Methods: Data were obtained from the MIR-EPO study (EudraCT:2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use (Group A) or not (Group B). Erythropoietin-stimulating agents (ESA) and iron supplements were administered in order to maintain hemoglobin (Hb) between 10.5 and 12.0 g/dL and transferrin saturation (TSAT) ≥ 20%. After a 3-month observation period, plasma IL-6 and hepcidin were measured(month 3 and 6 of follow-up) by ELISA. The changes in IL-6 and hepcidin levels from month 3 to 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated (Group A: 23; Group B: 8). Intact parathyroid hormone (iPTH) and ESA doses did not change throughout the study. We found no correlation between ΔIL-6 and Δhepcidin (r:0.10, P=0.640). However, ΔIL-6 correlated with DTSAT (r:0.40, P=0.030). After adjustment for iPTH and globular sedimentation rate, mean IL-6 levels in Group A were lower than in Group B (8 versus 22 pg/ml, P=0.010). IL-6 levels decreased in the whole group of patients throughout the study, but these changes correlated with an increase in serum iron and TSAT only in the Group A. Hecidin decreased in the whole group of patients throughout the study as well. Correlation between ΔHepcidin

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

816A
and ΔHb(-0.49, P=0.010) was found in the whole group of patients. Interestingly, mean hepcidin levels were higher in Group A than in Group B (992 vs 494 pg/ml, P=0.050) during the study. In the Group A, Δhepcidin correlated with ΔHb(-r=-0.55, P=0.030).

**Conclusions:** IL-6 and hepcidin are likely related to different iron pools (functional and storage, respectively) since no correlations between their changes were found. Paricalcitol therapy showed an unexpected increase in iron availability for erythropoiesis that might be associated with changes in IL-6 and hepcidin levels.

**48 Week Open Label Safety Extension Study with Ferric Citrate Demonstrates Favorable Safety Profile in Subjects Not on Intravenous Iron: A Post-Hoc Analysis**  

**Background:** Ferric citrate (FC) is an iron-based phosphate binder approved for the control of serum phosphorus levels in patients with chronic kidney disease on dialysis. The Phase 3 pivotal trial in subjects with ESRD demonstrated FC to effectively control serum phosphorus but also significantly increased serum iron parameters. This 48-week open-label extension study to the Phase 3 pivotal trial was conducted to demonstrate long-term safety of ferric citrate. The primary data have been reported previously.

**Methods:** Subjects from the pivotal FC RCT (NCT01191255) who completed the active control period and, if eligible, the placebo control period were eligible to enroll in the safety extension trial. 79% had a time lag between participation in the RCT and this trial. The primary outcome was safety as assessed by lab data and adverse events (AE): 168 subjects enrolled. 166 received a dose of FC. The data presented are a post-hoc analysis of 98 of the 166 subjects that did not receive IV iron for the duration of the 48-week trial. Safety data regarding changes in serum iron parameters and treatment emerging AEs by system organ class are presented.

**Results:** Of the 98 subjects included in this analysis, 71 subjects were randomized to FC in the previous Phase 3 trial and 27 to the AC group. Table below shows the changes in TSAT and serum ferritin over the 48 wk period. Data presented as mean (SD).

83% of subjects experienced at least one treatment emergent adverse event with the most common being gastrointestinal disorders (40%) and infections and infestations (37%).

**Conclusions:** Subjects receiving ferric citrate and no IV iron demonstrated serum phosphorus control over the 48 wk study period, and an increase in TSAT and serum ferritin. The increase in TSAT did not exceed 45% in subjects receiving ferric citrate and no IV iron, which might suggest that ferric citrate is absorbed but the risk of excessive iron absorption is low.

**Iron Isomaltoside: A Novel Intravenous Iron Preparation for Hemodialysis**  
David Jackson, Christopher Brown, Grant Sugiuira, Rachel S. Ashcroft, Ashraf I. Mikhail. Nephrology, ABM Univ Health Board, United Kingdom.

**Background:** Diäfer® (iron isomaltoside) is newly licensed in Europe for iron deficiency anemia in CKD patients on dialysis. It is thought the controlled-release matrix minimises free iron, possibly reducing side effects. Little is known about the efficacy & safety of Diäfer in clinical practice. This study aims to assess the impact of this novel formulation on anemia parameters in prevalent hemodialysis (HD) patients previously maintained on iron sucrose.

**Methods:** Data was collected for 13 months; 6 month pre-switch (iron sucrose), 1 month crossover, & 6 month post-switch (iron isomaltoside). All patients received dialysis for ≥3 months before evaluation, excluding potential bias of iron loading doses. For both preparations, patients received intradialytic bolus doses of 100mg at frequencies dependent on individual requirements as per current practice.

**Results:**

The percentage of patients maintaining Hb target (100-120g/L) was 71% with iron sucrose & 70% with iron isomaltoside. No adverse drug reactions were observed. No metallic tastes were reported with Diäfer administration. The CRP rise during months 1-6 was imparted by 2 infections & 1 amputation.

**Conclusions:** Iron isomaltoside maintains Hb stability & adequate iron status in HD patients when incorporated into current practice. While these data suggest Diäfer may reduce ESA & iron requirements, further analyses are necessary to validate these findings. Whether the potential to reduce labile iron with iron isomaltoside impacts on clinical outcomes is yet to be determined.

**Low Iron Availability May Influence on Second Patency Rates of Vascular Access in Patients on Hemodialysis**  
Yukiko Hasu- suke, Wataru Fukao, Takeshi Nakamichi. Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

**Background:** Vascular access (VA) is essential for the patients on HD. However, VA failure is often occurred even after percutaneous-transluminal angioplasty (PTA). Iron is important for normal vascular physiology, and insufficient iron availability can lead to various vascular dysfunction. The purpose of this study was to examine the factors affecting VA patency after PTA, including iron availability and oxidative stress.

**Methods:** Blood samples were taken from 281 HD patients at the PTA. Routine blood chemistries and factors related to iron metabolism (transferrin saturation rate (TST), ferritin), oxidative stress (advanced oxidation protein products (AOPP), 8OHdG, GSH/GSSG), and inflammation (high-sensitive CRP, interleukin-6, tumor necrosis factor-a, pentraxin-3) were measured. The end point of study was the re-vascularization or re-operation of VA during the observational period after PTA. Cox proportional hazards models for the end point was used.

**Results:** 133 patients (47.3%) had native arteriovenous fistula. During follow-up period, re-vascularization was performed in 34 patients and re-operation in 31 patients. The patients with VA failure had higher numbers of leukocytes and platelet, significantly lower TST, and a tendency of higher AOPP compared with the patients without VA failure. There was no significant difference in other factors between the patients with and without VA failure. The Kaplan-Meier analysis showed lower TST (~20%) was associated with VA failure (<0.0010, (figure 1)).

Proton Pump Inhibitors and CYP2C19 Are Associated with Iron-Deficiency Anemia in Hemodialysis Patients: A Cross-Sectional Study

Aiko Nakashima, Ichiro Ohkido, Keitaro Yokoyama, Mitsuyoshi Urashima, Takashi Yokoo.

1Div of Nephropathy and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; 2Div of Molecular Epidemiology, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Hyporesponsiveness to erythropoiesis stimulating agents (ESA) is an important phenomenon in dialysis patients. As chronic proton pump inhibitor (PPI) use reduces gastric acid secretion, it seems possible that chronic PPI use might lead to iron malabsorption and anemia. In addition, PPI is mainly metabolized by cytochrome P450 enzymes, particularly CYP2C19, in the liver. The genotypes of CYP2C19 affect the pharmacokinetics and pharmacodynamics of PPI. However, there is no study investigating the relationship between PPI use and anemia status that includes the effect of CYP2C19 genotype in hemodialysis patients.

Methods: This cross-sectional cohort study analyzed 1350 hemodialysis patients. DNA was isolated from leukocytes in peripheral blood. We used polymerase chain reactions and direct sequencing to analyze CYP2C19 genotypes. We analyzed anemia status with and without PPI usage, including the association with CYP2C19 genotypes.

Results: PPI use was associated with a significantly lower mean serum hemoglobin concentration. Iron and TSAT were also lower in PPI users. ESA dosage was significantly higher in patients receiving PPIs(mean [SD] PPI): 5685 [3288] IU/week; non-PPI: 2899 [2734] IU/week; P=0.001), and multiple regression analysis indicated a significant relationship between PPI use and ESA dosage(β: 494.1 P=0.011). CYP2C19 genotypes were significantly associated with iron status and anemia. Multiple regression analysis demonstrated that CYP2C19 poor metabolizer (PM) type was significantly associated with ESA dosage in PPI users (β: 901.1 P=0.036).

Conclusions: In this study, we found that PPI use is associated with iron status and anemia in hemodialysis patients. Among the dialysis patients receiving PPIs, CYP2C19 genotype was associated with hemoglobin levels, ESA dosage, and iron status.

Background: Hyporesponsiveness to erythropoiesis stimulating agents (ESA) is an important phenomenon in dialysis patients. As chronic proton pump inhibitor (PPI) use reduces gastric acid secretion, it seems possible that chronic PPI use might lead to iron malabsorption and anemia. In addition, PPI is mainly metabolized by cytochrome P450 enzymes, particularly CYP2C19, in the liver. The genotypes of CYP2C19 affect the pharmacokinetics and pharmacodynamics of PPI. However, there is no study investigating the relationship between PPI use and anemia status that includes the effect of CYP2C19 genotype in hemodialysis patients.

Methods: This cross-sectional cohort study analyzed 1350 hemodialysis patients. DNA was isolated from leukocytes in peripheral blood. We used polymerase chain reactions and direct sequencing to analyze CYP2C19 genotypes. We analyzed anemia status with and without PPI usage, including the association with CYP2C19 genotypes.

Results: PPI use was associated with a significantly lower mean serum hemoglobin concentration. Iron and TSAT were also lower in PPI users. ESA dosage was significantly higher in patients receiving PPIs(mean [SD] PPI): 5685 [3288] IU/week; non-PPI: 2899 [2734] IU/week; P=0.001), and multiple regression analysis indicated a significant relationship between PPI use and ESA dosage(β: 494.1 P=0.011). CYP2C19 genotypes were significantly associated with iron status and anemia. Multiple regression analysis demonstrated that CYP2C19 poor metabolizer (PM) type was significantly associated with ESA dosage in PPI users (β: 901.1 P=0.036).

Conclusions: In this study, we found that PPI use is associated with iron status and anemia in hemodialysis patients. Among the dialysis patients receiving PPIs, CYP2C19 genotype was associated with hemoglobin levels, ESA dosage, and iron status.
erythropoiesis stimulating agent for at least 2 weeks were randomized to placebo or to 4 mg, 6 mg, 8 mg, 10 mg GSK1278863 once daily. The primary endpoint was Hgb from baseline at Week 4. Other endpoints included circulating levels of erythropoietin (EPO), vascular endothelial growth factor (VEGF) and hepcidin.

**Results:** A total of 97 subjects were randomized, and 88 subjects completed the study. Mean Hgb at baseline ranged from 9.68 g/dL to 9.92 g/dL across the treatment groups. After 4-week treatment, GSK1278863 produced dose-dependent increases in mean Hgb from baseline (placebo: -1.41 g/dL; 4 mg: -0.28 g/dL; 6 mg: -0.01 g/dL; 8 mg: 0.54 g/dL; 10 mg: 0.97 g/dL). A posteriori distribution from Bayesian four parameter Enamx model estimated that 2.0 mg, 3.9 mg and 8.7 mg doses would, on average, lead to achieve placebo-corrected increases in Hgb over 4 weeks of 0.5 g/dL, 1.0 g/dL and 2.0 g/dL, respectively. Dose-dependent increases in EPO and decreases in hepcidin were observed across the GSK1278863 groups, while no trends of increase in VEGF were observed in any groups. All AEs were reported as single instances in any treatment groups except nasopharyngitis, and no trends in AEs were noted. There were no deaths in the study.

**Conclusions:** This study demonstrated that GSK1278863 produced dose-dependent elevations in Hgb correction in Japanese HDD subjects across the dose range tested.

---

**SA-PO828**

A Three-Year Study of an ESA Treatment Algorithm for Patients with Renal Anemia: Stable Hb Levels Obtained with Twice-Monthly Administration of CERA (Second Report)  
Tatuhiko Mue, Shigeru Owada. Internal Medicine, Asao Kidney Clinic, Kawasaki, Japan.

**Background:** Treatment of renal anemia in hemodialysis (HD) patients requires an adequate ESA dosage to maintain stable Hb levels. Guidelines in Japan recommend determining the ESA dosage based on Hb levels measured twice a month. An algorithm for the administration of continuous erythropoietin receptor activator (CERA) has been prepared and implemented to treat patients on HD. The 2-year study results were previously reported during the ASN Kidney Week 2014 (TH-P0 820).

**Methods:** Based on the algorithm, CERA was administered for 1 year to 102 HD patients being treated with rHuEPO. After the first year, the algorithm was reviewed, and some cases of fluctuating Hb levels because of terminating and restarting CERA administration were found. Therefore, the algorithm was revised. Consequently, CERA administration was continued for another 2 years. The target Hb level was 10.5–11.0 g/dL, and Hb levels, CERA dosage, Erythropoietin Resistance Index (ERI), and iron dosage were investigated. CERA was administered once every 2 weeks, and the dosages were changed within a range of 25 g/dose based on Hb levels. The standard iron dosage was not changed during the evaluation period.

**Results:** Hb levels at baseline and 1, 2, and 3 years after the baseline measurement were 10.9 and 11.1, 11.2, and 11.2 g/dL, respectively. The corresponding CERA dosages, administered every 2 weeks, were 62 ± 13, 38 ± 25, 36 ± 23, and 33 ± 21 mg, respectively, and ERI values were 0.11 ± 0.04, 0.06 ± 0.05, 0.06 ± 0.04, and 0.06 ± 0.04, respectively. To reduce fluctuations in Hb levels to a possible extent, terminating CERA administration was avoided. Serum ferritin levels gradually decreased from 147.9 ± 122.1 at the baseline to 112 ± 95, 88 ± 67, and 67 ± 47 ng/ml in the 1st, 2nd, and 3rd years, respectively, and weekly iron dosage decreased from 13 ± 2 at the baseline to 11 ± 2.6 and 11 ± 2.4 mg in the 1st, 2nd and 3rd years, respectively.

**Conclusions:** Three years of twice-monthly CERA administration, based on the algorithm, could maintain stable Hb levels, improve ERI, and reduce iron dosage. Twice-monthly CERA administration based on the algorithm effectively controlled anemia in HD patients.

---

Continuous Erythropoiesis Receptor Activator (CERA) for the Anemia of Chronic Kidney Disease (CKD): A Meta-Analysis of Randomized Controlled Trials  
Valeria M. Saigliahbone,1 Suzetia Palmore,1 Giovanni F.M. Strippoli,1,3  
1Diaverum Medical Scientific Office; 2Univ of Otago Christchurch; 3Cochrane Kidney and Transplant.

**Background:** Targeting high hemoglobin levels with erythropoiesis-stimulating agents (ESA) leads to adverse effects in people with chronic kidney disease (CKD). Whether there are treatment differences between different ESA agents is uncertain.

**Methods:** We did a systematic review of randomized controlled trials evaluating treatment with CERA compared with other epoetins (darbepoetin alfa and epoetin alfa or beta) or placebo/no treatment, in people with CKD of any severity. We systematically searched Cochrane databases. Results were expressed as risk ratios (RR) and their 95% confidence intervals that CERA was associated with lower mortality, cardiovascular outcomes, and better cardiovascular risk factors than other ESAs.**

**Results:** 17 studies involving 5397 participants were eligible. Studies compared CERA with epoetin (n=8 studies), darbepoetin (n=5), differing frequency (n=2) and dose (n=4). Compared to epoetin and darbepoetin, CERA had similar effects on mortality, hypertension, need for blood transfusion and iron therapy.

**Conclusions:** Two studies of low-moderate risk of bias, CERA significantly improved quality of life as measured by SF-36. Data were sparse for differing frequency of administration and dose. Evidence for treatment effects of CERA was absent among children and particularly limited for kidney transplant recipients. Studies included in this review were generally at high or unclear risk of bias.

**In summary:** There is no evidence that CERA has different effects on patients-centered outcomes compared to epoetin or darbepoetin among adults with CKD. CERA may improve health-related quality of life, but further high quality trials are needed. Its effects in children with CKD and kidney transplant recipients remains poorly understood.

**Risks of Long-Term Management for Anemia, Cardiovascular Disease (CVD) Death and Risk Factors for Heart Failure in Maintenance Hemodialysis**  
Hajime Hirano,1 Haruhito Azuma,1 Hideaki Shima.1  
1Blood Purification Center, Osaka Medical College, Takatsuki, Japan; 2Nephrology, Osaka Medical College, Takatsuki, Japan.

**Background:** In this study, we evaluated the various outcome factors, the effects of improvement in anemia in patients treated with hemodialysis on the vital prognosis were evaluated focusing on changes after enrollment.

**Methods:** This retrospective study was conducted with 201 outpatients with hemodialysis at our Blood Purification Therapy Center and our other related hemodialysis facilities from March 2005 to February 2007 (24 months, 136 males and 65 females, age: male: 59.4 years old, female: 59.8 years old; overall: 59.5 years old). Using CVD death and hospitalization due to heart failure as outcomes, 2-year risk of CVD death was analyzed by logistic regression model with surviving patients. In addition, we assess anemia, changes over a long time after start of observation were evaluated.

**Results:** The multivariate analysis revealed 3 factors for CVD death risk including smoking history (OR: 9.06 [95%CI: 1.86–44.0, p=0.006]), history of ischemic heart disease (OR: 3.82 [95%CI: 1.19–12.25, p=0.024]) and hypercalcaemia. (OR: 1.77 [95%CI: 1.00–3.13, p=0.049]). Similarly, the risk factors for heart failure were smoking (OR:3.11 [95%CI:0.78–12.36, p=0.101]) and history of ischemic heart disease (OR: 5.03 [95%CI: 1.46–17.33, p=0.010]), and history of ischemic heart disease was the only significant variable in the final step.

**Conclusions:** The factors that influence the risk of CVD death included smoking, history of ischemic heart disease and hypercalcaemia. The risk factors occurring heart failure included history of IHD, and it was shown that the effects of smoking and history of IHD on prognosis were stronger than the effects of anemia. The evaluation of changes in Hb over time revealed that the low Hb sustained for a long time would increase the risk. In addition, the risk of death was high in the high-dose rHuEPO group suggesting the risk in the low HbEPO response patients.

**SA-PO825**

**Anemia Management in ESRD Patients Admitted to the Hospital Priyanka Govindan, Arjun V. Sharma. Dept of Nephrology, Univ of Washington Medical Center, Seattle, WA.**

**Background:** Anemia was twice as prevalent in people with CKD (15.4%) as in the general population (7.6%). The prevalence of anemia increased with stage of CKD, from 8.4% at stage 1 to 53.4% at stage 5. Anemia can be managed successfully with appropriate investigations and therapy in the ESRD population. The aim of the study was to see how appropriate the management of anemia was in our hospital in patients on dialysis and to identify areas for improvement.

**Methods:** Selected patients were those with ESRD on hemodialysis and peritoneal dialysis that underwent in-hospital dialysis at the University of Washington Medical Center from July 1st 2014 to Sep 30th 2014. The patients who had been undergoing dialysis for less than 12 weeks were considered to have AKI and were excluded from the analysis. In addition, the patients who underwent dialysis only in the Intensive Care units were excluded. The data was collected from the electronic medical records of the individual patient charts.

**Gender, Age, Anemia status, Lowest Hemoglobin, Iron panel, Reticulocyte count were noted in addition to treatment with iron, blood transfusions and ESA.**

**Results:** A total 145 dialysis patients were identified and 65 of them had both ESRD and anemia. 73.86% of these patients were found to be anemic by KDIGO. Patients in the 66-69 age range had the largest number of anemia with a total of 20 falling in this category. 18 patients had anemia with a Hemoglobin <7.0. Among the anemic patients 48.5% did not have an iron panel checked and 86.4% did not have a reticulocyte count checked. 40% of those with a Hb < 6 mg/dl had an iron panel checked. In patients with Hemoglobin of less than 11 31% were treated with ESA at least once during their hospital stay. 36.36% received transfusions. 50% of the patients who received blood transfusions did not have an iron panel checked.

**Conclusions:** Routine investigations for the management of anemia are being missed regularly. Worse anemia was associated with fewer investigations. We suspect that the management of anemia in patients with ESRD can be improved with more comprehensive labs and therapy. We intend to follow up with an intervention involving the EMR making it easier to work up anemia in the hospital.
SA-PO824

Variability in Hemoglobin (Hb) Levels in Hemodialysis (HD) Patients in the Current Era

**Background:** Hb variability in dialysis patients has been characterized using a number of methods. The majority of this work occurred prior to the 2011 change in CMS reimbursement policy and ESA labels. We therefore examined Hb variability and patient demographics from current data and compared the results to those obtained prior to implementation of these policy changes.

**Methods:** We used CMS ESRD data to define a cohort of chronic HD patients who were alive from Apr 1 through Dec 31, 2012. Using a method from Ebben et al. (CJASN 1:205-1210, 2006), monthly Hb values were categorized as low (L), intermediate (I), and high (H), where L and H were based on monthly Hb values below or above the 25th and 75th percentiles, respectively. Variability was then classified based on the Hb categories during a 6-month period, resulting in 6 categories of variability (see figure legend).

**Results:** This figure compares the percentage (%) of patients in each Hb variability group in 2004 compared to 2012. The 25th and 75th percentiles in the 2012 data were 10.2 and 11.5. Corresponding 2004 values were 11 and 12.5. Similar % of patients were observed in 2004 and 2012 for the LL and LH categories. A higher % of patients was consistently intermediate (II) in 2012 than 2004 (9.5% vs. 6.0%), whereas a larger % was observed for LL and a smaller % for LH. Compared to the overall 2012 cohort, II patients were older (mean=65.2), and LL or LH patients were younger (mean=58.2 and 57.8). LH had the highest % who were black (48.8%).

**Conclusions:** While Hb levels have decreased during the last few years, Hb variability is still present. The lower % of patients in the LH group is consistent with a narrowing of the overall Hb distribution. Further studies are needed to assess the association of variability with outcomes in the current era.

Prevalence and Predictors of Naturally Occurring Normal Hemoglobin Concentration in Hemodialysis Patients

**Background:** Pre-dialysis laboratory measurements of hemoglobin (Hb) are generally used for anemia management. In some clinics, bi-weekly or even weekly Hb measurements are performed for this purpose. The Crit-Line® Monitor (CLM) provides Hb non-invasively and continuously during hemodialysis (HD), but initial readings early during HD are systematically lower than pre-HD laboratory values due to hemodilution caused by the priming fluid. We present a method of correcting CLM Hb for hemodilution.

**Methods:** Pre-HD reference Hb (Hb_Spec) was measured by Spectra East Laboratories. Hb obtained by CLM (Hb_CLM) was averaged between minutes 4 and 6 after start of the HD treatment. The difference between the two (Hb_Spec - Hb_CLM) was estimated as ΔHb = (V_sal * 0.5 * (t_CLM/1.2_1_sal - V_sal) * Hb_CLM/BV, with V_sal = amount of priming fluid (saline) infused at start of HD, t_clm = time point of Hb_CLM measurement (5 min into HD), t_1/2_sal = plasma half life of infused saline (20 min, adapted from ATC Consensus Statement, 2004), VUF = cumulative ultrafiltration volume up until time point of Hb_CLM measurement, BV = pre-HD blood volume (obtained by estimating post-HD BV via Nadler equation (using post-HD weight, sex, height), then dividing by end-HD relative blood volume and subtracting V_sal). Corrected Hb_CLM was calculated as Hb_corr = Hb_CLM + ΔHb.

**Results:** 5,731 HD treatments from 952 chronic HD patients in the USA were analyzed. Without correction, Hb_CLM was found to be systematically lower than Hb_Spec by on average 0.425 g/dL (SD 0.59 g/dL). After correction for hemodilution, the difference (Hb_corr - Hb_Spec) was reduced to ~0.068 g/dL (SD 0.59 g/dL).

**Conclusions:** When applying a correction for the hemodilution caused by infusion of the priming fluid at the start of HD, the Crit-Line® Hb is nearly identical on average to the pre-HD Hb measured by a reference laboratory. More and more clinicians are employing Crit-Line® Monitors for fluid and anaemia management. Crit-Line® Hb corrected in this way may be used for anemia management, which could reduce blood draws and costs.

Hemodialysis (HD) Patients Who Can Maintain Fair Hb Level (>10g/dl) without Iron or Erythropoietin (Epo) Administration Showed Higher Serum Soluble Transferrin Receptor(sTfR) and Normal Epo, Vitamin C (VC) Levels

**Background:** HD patients have severe anemia and their Hb levels were recommended to be maintained at greater than 10g/dl using iron and Epo supplementation. Certain HD patients showed Hb level >10g/dl without iron or Epo. HD patients with fair Hb level revealed higher sTfR, %HypoHe and erythropoietic activity, of G1(30.0(22.1-36.5)nmol/L) was significantly higher than those of GN and G2. 2. MCV values were not significantly different in all three groups. 3. sTfR level, %HypoHe and VC(6.8(2.8-23.4)µg/mL) of G1 were not significantly different from those of GN, whereas significantly higher than those of G2, respectively. 4. Epo level(7.3(5.1-15.2)mIU/mL), reticulocytes(12(9-15)‰) was revealed between %HypoHe and sTfR(r=0.816, p<0.001). By multivariate analysis, %HypoHe was a predictor of sTfR(β=0.834, p<0.001).

**Results:** 1. In G1, ferritin(20(14-36) ng/ml), transferrin saturation(14(8-19)%), HPC(0/7.0(2.5-4.5)mg/ml) were significantly lower than those in both GN and G2, respectively. The percentage of hypochromic RBCs(%HypoHe) increased from (2.7(1.5-4.8)%) was higher than those of GN and G2. 2. MCV values were not significantly different in all three groups. 3. sTfR level, a marker of erythropoietic activity, of G1(30.0(22.1-36.5)nmol/L) was significantly higher than those of GN and G2. 4. Epo level(7.3(5.1-15.2)µmol/L), reticulocytes(12(9-15)%), %HypoHe and VC(6.8(2.8-23.4)µg/mL) of G1 were not significantly different from those of GN, whereas significantly higher than those of G2, respectively. 5. In G1, negative correlation was revealed between VC and %HypoHe(r=-0.437, p=0.048), whereas positive correlation was revealed between %HypoHe and sTfR(r=0.816, p<0.001). By multivariate analysis, %HypoHe was the predictor of sTfR(β=-0.834, p<0.001).

**Conclusions:** HD patients with fair Hb level revealed higher sTfR, %HypoHe and normal Epo, MCV, VC and low HPC levels. These results indicated that iron utilization of these patients was upregulated and this may participate in the maintenance of erythropoiesis.

SA-PO828

Acute Effects of Erythropoietin Administration on Blood Pressure in Dialysis Patients
Nawf Hamad Al-Gublan, Kristin M. Corapi, Ishir Bhan.
Nephrology, Massachusetts General Hospital, Boston, MA.

Background: Erythropoiesis-stimulating agent (ESA) doses are often held in patients with end stage renal disease (ESRD) because of hypertention. However, missed doses may exacerbate anemia of chronic disease. The acute effects of ESA on blood pressure are unknown. We hypothesized that ESA administration during dialysis would not be associated with a significant change in blood pressure.

Methods: With institutional review board approval, we retrospectively reviewed the medical records of 100 hemodialysis patients who were admitted to our hospital between 1/2013-4/2015. All patients in this study were prescribed, and received, ESA's during dialysis. Patients were excluded if dialyzed in the ICU, received vasoppressors, were treated for hypertensive urgency (>180/110 mmHg), initiated on hemodialysis, or only underwent ultrafiltration without dialysis. Blood pressure just prior to and 2 hours after ESA were compared using a paired t-test.

Results: The mean age was 61.6 years (±12.8), 42% were male, 66% were Caucasian, 16% African-American, and 10% Asian. Mean change in blood pressures immediately prior to ESA administration and 2 hours after are summarized.

<table>
<thead>
<tr>
<th>Pre-Dialysis</th>
<th>Just Prior to ESA</th>

</tbody>
</table>

No statistically significant increase in SBP or DBP was noted. In fact, we observed a significantly lower SBP 2 hours after ESA dosing. In a subgroup analysis of patients with an SBP > 160 immediately prior to ESA administration, an even greater decrease in SBP was noted 2 hours after ESA compared to a subgroup with an SBP < 160 (p=0.004). No significant relationship existed between dose of ESA and effect on blood pressure (SBP, p=0.52; DBP, p=0.95).

Conclusions: We demonstrated a decrease in systolic blood pressure 2 hours after ESA administration with no significant change in diastolic blood pressure. Withholding ESA during dialysis due to hypertention may be unnecessary.

SA-PO829

Serum Ferritin Predicts Mortality Regardless of Inflammatory and Nutritional Status in Incident Peritoneal Dialysis Patients
Meiyun Wu,1 Kyoung Sook Park,2 Hyung Jung Oh,2 Jung Tak Park,2 Seung Hyeok Han,2 Tae-Hyun Yoo,3 Shin-Wook Kang.1,2 1Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Serum ferritin levels have been proposed as a prognostic factor in hemodialysis (HD) patients, due to its close relationship with inflammation and malnutrition. Since iron supplementation methods and factors affecting nutritional status are somewhat different from those of HD patients, the impact of serum ferritin on clinical outcomes was investigated in incident peritoneal dialysis (PD) patients.

Methods: A prospective cohort of 408 PD patients from the Clinical Research Center for End-Stage Renal Disease was selected. Patients were divided into three groups according to tertiles of Ln ferritin concentrations (group 1: <4.69 ng/mL, group 2: 4.69-5.58 ng/mL, group 3: >5.58 ng/mL). Cox proportional hazard analysis was performed to determine the independent prognostic value of serum ferritin levels for all-cause mortality.

Results: The mean age was 52.1±13.2 years and 236 (57.8%) were male. During a median follow-up of 25 months, 46 (11.3%) patients died. Univariate Cox analysis revealed that the mortality risk was significantly higher in group 2 [hazard ratio (HR)=2.65, 95% CI=1.31-5.42, p=0.009] compared to group 1. Moreover, multivariate Cox proportional hazard models that the mortality risk was significantly higher in group 2 [HR=1.94, 95% CI=1.31-2.88, p=0.001], even after adjustment for variables representing inflammatory and nutritional status.

Conclusions: Higher serum ferritin level was a significant independent risk factor for all-cause mortality regardless of systemic inflammation and nutritional status. Therefore, determining serum ferritin levels could be a useful marker to predict clinical outcomes in incident PD patients.

Improving Anemia Therapy in Hemodialysis Patients: Interim Results
Pablo Gublan,1 Hamad Al-Gublan,2 Kristin M. Corapi,3 Ishir Bhan,4 Erika Schumann,3 Thomas Ryzlewicz,4 Franz Ferdinand Becker,4 Amelia Macdougall1
1Renal Unit, King's College Hospital, London, United Kingdom; 2Via Medis, Riesa, Germany; 3Oxyless Ltd, London, United Kingdom.

Background: An earlier pilot audit (ASN 2013, PUB200) suggested that the use of a novel bloodline (Oxylens), which reduces the contact between blood and air, could improve the efficiency of Erythropoietin Stimulating Agent (ESA) therapy by prolonging red cell survival. The aim of this investigation was to explore this effect in a larger population.

Methods: Patients (n=110; >18 years, HD ≥ 3 months via AV fistulae) were entered into an 8-month open label, single crossover audit following a 3 month Run-In. Patients reverted to control bloodlines (Nikkiso/Gambro) in the crossover phase after treatment with Oxylens. Hemoglobin (Hb) levels, IV iron sucrose and ESA doses were reported.

Results: Data analysis was conducted on 66 patients from two clinics. Twenty six patients dropped out due to transplantation and intercurrent events, death (n=14) and clinic transfers (n=4). Hb was maintained over the Treatment phase (11.22-11.34 g/dL). Mean ESA doses reduced by 34% (p=0.01) at month 8, equal to 1.09 IU/week/patient. IV iron dose did not change significantly during the audit.

Conclusions: The reduction in ESA doses observed during Treatment, and the initial reversal in the crossover, support that this novel bloodline can improve anemia therapy in HD patients. The audit design increases the confidence in the data validity. These results could have clinical and financial benefits for HD service delivery.

The Big Red Kidney Bus: Mobile Holiday Dialysis Peter G. Kerr,1 Lesley Ross,1 Jo M. Fairbairn,2 Anne C. Wilson,2 ‘Nephrology, Monash Health, Clayton, Vic, Australia; 2Kidney Health Australia, South Melbourne, Vic, Australia.

Background: The availability of hospital based hemodialysis for those wishing to travel is scarce and often results in restricted opportunities for patients on dialysis to have a holiday. The Kidney Health Australia (KHA) and Monash Health (MH) Big Red Kidney Bus Project (BRKB) offers patients the ability to dialyse on the BRKB whilst on holiday at one of a range of Victorian tourist destinations.

Methods: The aim of the BRKB Project is to provide safe, fully staffed mobile haemodialysis care, to enable people, their families and carers to take a break. KHA owns the bus, manages the bookings and markets the BRKB nationally. MH, a regional health care provider oversees the clinical assessment and treatment and provides medical supervision, dialysis nurses and renal technicians.

The BRKB is a modified bus accommodating 3 hemodialysis machines, dialysis chairs and complete water treatment. Typically, holiday dialysis on the BRKB operates across 2 sessions per day, 6 days per week duplicating the dialysis parameters of the patients’ home unit. The bus is driven to and parked at caravan parks around Victoria for 6-week periods, during which time patients may book in for dialysis sessions. Their accommodation is up to them to decide on – with the option of using cabins in the parks or local motels (or their own caravans).

Results: Since its inaugural visit in October 2014, 148 different patients have taken advantage of the BRKB. The bus has visited 6 sites around the State and has site bookings for the next 10 months. Participating holidaymakers were overwhelmingly positive about the service. They found the booking system easy to use. The dialysis service on the bus was delivered to the standard of care experienced at their home units. The professionalism of the nursing staff and friendliness was commended and all participants would recommend the service to others.

Conclusions: The BRKB is a unique project that provides patients with the opportunity to dialyse on the bus while taking a much-needed holiday.

Patient and Caregiver Values, Beliefs and Experiences when Considering Home Dialysis as a Treatment Option: A Semi-Structured Interview Study Rachael C. Walker,1 Kirsten Howard,2 Rachael L. Morton,1 Suettania Palmer,2 Mark R. Marshall,3 Allison Tong,4 ‘Univ of Sydney; ‘Univ of Otago; ‘Middledore Hospital, New Zealand; ‘Univ of South Australia.

Background: Home dialysis is associated with higher quality of life and economic benefits to health care systems compared with facility dialysis. However, little is known about the decision-making process of patients when considering home dialysis as a treatment option.

Methods: This semi-structured interview study aimed to describe patient and caregiver values, beliefs and experiences when considering home dialysis, to inform policy and practice strategies that align with patient preferences. We conducted semi-structured interviews with adults with CKD Stage 4-5D (on dialysis <1 year) and their caregivers, treated in 3 nephrology centers in New Zealand. Transcripts were analyzed thematically.

Results: 43 patients (18 pre-dialysis, 13 peritoneal dialysis, 4 home hemodialysis and 9 facility hemodialysis) and 9 caregivers participated. We identified 5 themes related to decision-making when considering home dialysis; lacking decisional power (complexity of information, limited exposure to home dialysis, feeling disempowered, deprived of choice, pressure to choose); sustaining relationships (maintaining cultural involvement, family influence, trusting clinicians, minimizing social isolation); reducing lifestyle disruption (sustaining employment, avoiding relocation, considering additional expenses, seeking flexible schedules, creating free time); gaining confidence in choice (guarantee of safety, depending on professional certainty, reassurance of peers, overcoming fears); and maximizing survival.

Conclusions: Patients feel disempowered when choosing home dialysis and make decisions that sustain their relationships, maintain lifestyle values and maximize survival. Confidence in their modality decision is gained by medical professional and peer support combined with overcoming safety concerns. Pre-dialysis programs that address this patient experiences may support home dialysis as a treatment option.

SA-PO834
Patient Experiences of Training and Transition to Home Hemodialysis: A Longitudinal Mixed Methods Study Camilla Sara Hansen,1,2 Jeremy R. Chapman,1 Jonathan C. Craig,1 David C. Harris,3 Lukas K. Kairaitis,4 Mary Ann Nicdao,3 Mary Mikhaeel,1 Allison Tong,1,3 ‘School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; ‘Centre for Kidney Research, The Children’s Hospital at Westmead, Sydney, NSW, Australia; ‘Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia; ‘Dept of Renal Medicine, Westmead Hospital, Sydney, NSW, Australia.

Background: Home hemodialysis (HD) can offer better survival and quality of life outcomes compared with in-centre HD. However, psychosocial barriers such as fears of needles and medical isolation may limit home HD uptake. This study aims to describe patients’ perspectives on training and transition to home HD; to inform strategies to optimize home HD programs.

Methods: Three semi-structured interviews were conducted prospectively with 20 patients before, during and after home HD training at an Australian renal unit. The CHOICE satisfaction survey was administered during the first and final interview. Transcripts were analyzed thematically.

Results: We identified six themes: persevering despite trepidations (intimidation of machinery, acquiring to fatal risks, reconciling censure fears, dispensing concerns of neglect, tolerating concessions); optimizing learning pathway (practicing problem solving, learning from mistakes, grasping technical complexity, minimizing cognitive overload); developing confidence (believing in own abilities, depending on caregiver partnership, faith in crisis support); interrupted transition momentum (lacking individual attention, language barriers, installation delays, illness and complications, acclimatizing to new conditions); noticing immediate gains (reclaiming normality, satisfying self-sufficiency, personalizing treatment regime); depleting resources and energy (exhaustion, draining financial reserves, imposing caregiver burden). There was no significant change in satisfaction with care after commencing home HD.

Conclusions: Individualized home HD training fosters confidence and competency in patients; however patients may face anxiety and exhaustion with medical responsibilities. Ensuring access to respite, medical assistance, and psychosocial support may alleviate treatment burdens for patients commencing home HD.

Funding: Private Foundation Support

SA-PO835
Incremental Hemodialysis, Residual Kidney Function, and Mortality Risk in Incident Hemodialysis Patients Yoshitsugu Obi,1 Elani Streja,2 Connie Rhee,1 Vanessa A. Ravel,1 Alpesh Amin,1 Csaba P. Kovesdy,2 Rajnish Mehrotra,3 Kamyar Kalantar-Zadeh,1 ’UC Irvine, ’UTHSC, ’UW.

Background: We have previously reported that an incremental hemodialysis regimen (e.g., dialysis initiation at twice weekly) was associated with more preserved residual kidney function over a year of dialysis therapy (WCN 2015, Cape Town). Here, we compared survival between the incremental vs. conventional regimen.

Methods: In a longitudinal cohort of 33,277 patients who initiated maintenance hemodialysis over four years (1/2007-12/2010) and survived the first year, 364 patients treated with the incremental regimen were matched to 4,797 patients treated with the conventional regimen on age, gender, race, the use of central venous catheter as blood access, and a history of congestive heart failure at the initiation of dialysis. The incremental hemodialysis regimen was associated with ~20% higher residual renal urea clearance (KRU) and 24-hr urine volume (UV) after 1 year of dialysis initiation. We then examined survival after the first year.

Results: Patients were 69±12 years old, 39% female, 13% non-Hispanic Black, and 66% diabetic. Median KRU and UV were 4.74 (IQR, 3.23-6.65) mL/min/1.73m² and 1,150 (IQR, 800-1,650) mL/day, respectively. Baseline KRU and UV modified the association between the incremental regimen and mortality; the incremental regimen was associated with higher mortality in patients with KRU <3.0 mL/min/1.73m² or UV <600 mL/day, but not in those with higher levels of KRU and UV.

Seasonal Trends in Dialysis Initiation and Rising Home Dialysis: Results from the USRDS
Hui Liu,1 Yang Jiao,2 Douglas Lehmann,2 Richard Hirth,3 Yi Li,1 Rajiv Saran.1 1Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; 2Dept of Biostatistics, Univ of Michigan, Ann Arbor, MI; 3Dept of Health Management and Policy, Univ of Michigan, Ann Arbor, MI.

Background: Motivated by increasing interest in home dialysis and incentive for it in the bundled payment system, we examined incident trends in home dialysis use in the United States Renal Data System (USRDS).

Methods: Using USRDS data (2007-2013), monthly counts of all new ESRD cases in the US, as well as incident home hemodialysis (HHD) and incident peritoneal dialysis (PD) patients were tracked. Incident HHD patients were those who started HHD within 90 days of entry into an ESRD program and incident PD patients who started PD as their initial modality.

Results: In 2013, over 55% of US facilities offered only in-center HD, 24.7% both HD and PD and 13.5% offered HD, PD and HHD. Figure 1 shows trends in monthly ESRD and PD utilization in the US during 2007-2013. The incidence rate of ESRD has been stable since 2010, but the number of new PD starts has risen steadily since 2009 and has somewhat further accelerated since 2011. Figure 1 also shows a seasonal trend for new ESRD and PD starts: incident ESRD cases tend to peak in the first 3 months of the year, while new PD starts tend to peak by mid-year. Rising HHD use is evident since 2007, without seasonal variation. A substantial variation in the annual growth rate of PD is notable across the states.

Conclusions: We report steadily rising home dialysis use in the US, both HHD and PD, since 2007 and 2009, respectively. This rise predates the implementation of the bundled payment system in 2011, although PD use seems to be rising faster since 2011. Research into this seasonality in ESRD incidence and the impact of rising home dialysis use are warranted.

Funding: NIDDK Support SA-PO837 Understanding Barriers to Home-Based and Self-Care In-Center Hemodialysis May L. You,1 Luis Alvarez,2 Michelle Carver,1 Geoffrey A. Block,2 Glenn Matthew Chertow.4 1Outset Medical, Inc, San Jose, CA; 2Sutter Health, Mendlo Park, CA; 4Denver Nephrology, Denver, CO; 3Stanford School of Med, Palo Alto, CA.

Background: Despite superior outcomes and lower associated costs, few patients with end stage renal disease undergo selfcare (SC) or home hemodialysis (HHD). Few studies have examined patient and physician barriers to SC and HHD and the degree which innovative technology might facilitate adoption.

Methods: We surveyed 250 in-center patients (pts) receiving hemodialysis and 51 board-certified nephrologists to identify key barriers to adoption of SC and HHD.

Results: Overall, 172 (69%) pts reported that they were “likely” or “very likely” (figure 1) to consider SC hemodialysis if they were properly trained on a new hemodialysis system designed for SC.

Patients that would consider performing self-care on a novel, patient-centered hemodialysis system

Conclusions: Nephrologists believed that pts were capable of performing dialysis-relevant tasks, including: weighing themselves (98%), wiping down the chair and machine (84%), clearing alarms during treatment (53%), taking vital signs (46%), and cannulating vascular access (41%), but thought that patients would not be willing to do the same.

Reasons that nephrologists believe pts are hesitant to pursue SC do not correspond to reasons reported by patients.

Conclusions: SC and HHD offer several advantages to patients and dialysis providers. Overcoming real and perceived barriers with new technology, and education will be required for these modalities to gain traction in the coming years.

Wessex Kidney Centre Experience of Nocturnal Home Haemodialysis Using the NxStage System One Venkat Gangaram, Amanda Jane Laird, Laura Hignell, Natalie L. Borman. Renal Medicine, Wessex Kidney Centre, Queen Alexandra Hospital, Portsmouth, United Kingdom.

Background: Wessex Kidney Centre (WKC) Portsmouth established Home Haemodialysis (HHDH) programme in 2009. In the absence of an in-house technician and limited capital the programme was set up using NxStage system one (NSO). WKC has now established a rapidly growing HHD programme using exclusively NSO, trained 97 patients to date includes nocturnal therapy.

Results: A total of 18 patients have received NHHD with mean time of 12.3 months (range 1 to 31). All patients dialyse alternate nights processing 40-60 litres using dual needleling access and a single bolus of Enoxaparin Sodium. Patients have regular transonic monitoring of their access and home visits. Two NHHD patients successfully dialyse alone. The mean age is 47.7 years (range 26 to 80), 78% male, 94% Caucasian with mean BMI 26.9. The Access used was A V fistula 56%, A V graft 22% and CVC 22% of patients. 14 patients changed from short daily HHD (SDHHD), 3 patients from in centre Haemodialysis and 1 from Peritoneal dialysis. Laboratory parameters have been favourable as shown below.

Retention has been excellent with one patient returning to in-centre HD after 25 months of HHD. Two patients switched to SD HHD as it more suited to their lifestyle and five patients have been transplanted. Pill burden has reduced, with less or no phosphorus binders (mean number of binders reduced from 6 to 2) and a 40 % reduction in antihypertensive medication.

Conclusions: Patients experience excellent, with high quality of life and with less pill burden, flexibility and more opportunity to engage in social activities.

SA-PO840
Current and Future Training of Home Haemodialysis Nurses Ruth Silvertown, 1 Philippa Catherine Brown, 1 Paul Laboi, 1 Nicola Thomas. 2 1 Department of Renal Medicine, York Hospital, United Kingdom; 2School of Health and Social Care, London South Bank Univ, United Kingdom.

Background: The UK National Institute for Health and Care Excellence recommend that >10% of dialysis patients be treated by home haemodialysis (HHHD), however only 4.1% of patients in the UK are undergoing this modality. Success with HHHD can be attributed to a supportive health policy, formal infrastructure, committed individuals and home dialysis experience; providing a patient-centred approach. Lack of nursing expertise is reported as a barrier to home dialysis for 30% of units. A 2010 survey by the Australian HOME network revealed insufficient resources in dialysis units to provide support and education to patients. A potential barrier to HHD in the UK is specific training for renal nurses on the facilitation of shared or self-care.

Methods: The extent of current training provision for dialysis nurses in order to educate patients in home therapies/shared care was evaluated via an online survey. A link to the survey was sent to the British Renal Society database and the survey was available online for 1 month. There were 63 respondents.

Results: Over 76% of respondents (n=48) had worked in renal care for >10 years, with a third (n=21) receiving more than 5 days of structured training in how to teach self care. The majority of this training (51%) was as part of an ‘in-service programme’, with just over half (53%) of all nurses surveyed feeling adequately prepared for educating patients. The preferred mode of further training was face to face at a national event (38%), with a quarter (n=14) citing e-learning as the preferred option.

Conclusions: Data from the survey highlights a lack of adequate, standardised training for HHD nurses, demonstrating the need for a structured programme that ensures up-to-date best practice. As a result, we plan to pilot a specific HHD training scheme that involves patients and carers in curriculum planning and delivery, with content including; assessment of patients’ learning styles, how to facilitate shared decision-making with patients, and how to evaluate effectiveness of the HHD programme.

Daily Hemodialysis in France: Patient’s Characteristics, Trajectories, and Treatment Modalities Adelaide Pladys, 1,2 Sahar Bayat, 1 Cécile Couchoud, 1 Cécile M. Vigneau, 1,4 1French School of Public Health, Rennes, France; 2‘Univ Rennes 1, Rennes, France; 3French Biomedicine Agency, Saint Denis La Plaine, France; 4CHU Pontchaillou, Rennes, France.

Background: Increased weekly frequency of hemodialysis (HD) sessions should have positive effects on the control of several biological data of end stage renal disease patients. However, a recent study observed contradicting results in terms of survival compared to previous ones. Patients included in this study came mainly from France where knowledge about daily hemodialysis (DHD) practices is poor. In this context, the aim of this study was to describe the characteristics of French patients in DHD, the treatment modalities and the individual trajectory before starting such a program.

Methods: We included all patients >18 y/o who started DHD between 2003 and 2012 in France. Bioclinical and treatment characteristics were extracted from the French Renal Epidemiology and Information Network (REIN) registry then described and compared by groups using Chi-square tests.

Results: 753 patients were included in the study. According to the median age (64 years), two groups of patients were distinguished: old group (≥64 years) characterized by lots of comorbidities such as diabetes (48% vs 29%, p<0.0001), active malignancy (17% vs 10%, p=0.008), 1 cardiovascular disease (80% vs 41%, p<0.0001) compared to the younger one (<64 years). At the 31/12/2013, 30.4% of the young patients underwent renal transplantation and 69% of the old ones were died. The main regimen observed was HD 6x/week with sessions’ duration of 3 hours. Among these patients, 496 started with other dialysis modality before switching to DHD (dDHD) and 257 started directly with DHD (dDHD). Before starting DHD, 81% of dDHD patients were in HD 3x/week and 5.4% had 1x1 modality change. dDHD patients initiated DHD in urgent condition for 57% of them and 92.6% underwent DHD in centre.

Conclusions: DHD in France is addressed both to old patients with lots of comorbidities who died rapidly and to young patients in better medical conditions who accessed more to renal transplantation. DHD regimens are various and depend of patients’ characteristics and previous trajectories.

In Vivo Urea Removal by Electro-Oxidation in a Wearable Dialysis Device Maarten Wester, 1 Frank Simonis, 1 Diënty Haenbrink, 1 Jaap A. Joles, 1 Karin G. Gerritsen. 1 1Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; 2Nanodialysis BV, Oirschot, Netherlands.

Background: In EU consortium NEPHRON+ a wearable dialysis device is being developed that can offer prolonged dialysis by continuous regeneration of a small volume of dialysate. A major challenge is the removal of urea, since the daily urea production is high and removal by adsorption difficult. Electro-oxidation (EO) seems attractive since electrodes are durable, small and inexpensive. Here, we studied in vivo urea removal by EO in a hemodialysis model in goats.

Methods: An EO-unit containing 10 graphite electrodes for EO and sorbent beads for K+ and PO4- removal was incorporated in a dialysate circuit in series with activated carbon (AC;25g/unit). 3 Ampère (A) was applied using 1 EO-unit (1x3A,N=7) or 2 EO-units in parallel (2x3A,N=7). Healthy goats were instrumented with a CVC, heparinized blood was pumped (110mL/min) during 3hrs over a 0.2m2 Polyflux dialyzer and dialysate was recirculated over the EO unit in counter current direction (40mL/min for 1x3A; 2x40mL/ min and 2x70mL/min for 2x3A; total dialysate volume 100mL (1 EO-unit) or 150mL (2 EO-units)). Urea was infused to achieve higher urea concentrations.

Results: Urea removal and clearance were 8.4±1.5mmol/h and 11.9±1.6 mL/min, respectively, using 1 EO unit (Fig. A,B) and remained stable during consecutive hours. Use of 2 units in parallel doubled the removal of urea and caused a 1.6-fold increase in urea.
clearance. Increase of the dialysate flow did not further increase urea removal. Urea removal was dependent on urea plasma concentrations (loglinear). Limited release of ammonia-umol was observed (0.16±0.03 mole per removed mole of urea).

Conclusions: By electro-photocatalytic reactors combined with AC showing promising urea removal in vivo. Research aimed at increasing the efficacy and biocompatibility testing is warranted.

SA-PO843
Unplanned “Crash” Home Dialysis Starts: Single Center Experience from a University Hospital in the United States
Kristen P. Tamura, 1 Jose A. Morfin, 2 Nephrology, UC Davis Medical Center, Sacramento, CA; 1Nephrology, UC Davis Medical Center, Sacramento, CA.

Background: There is a high incidence of starting dialysis from the hospital to the in-center unit, and frequently these starts are unplanned and unexpected (“crash”). To this end, we sought to implement an educational program to identify patients suitable for a home dialysis modality, unplanned home hemodialysis (UHHD) and unplanned peritoneal dialysis (UPD).

Methods: We performed an retrospective observational analyses on patients who were started on dialysis from January 2013 to April 2015 in a diverse patient population admitted to UC Davis Medical Center in Sacramento, CA. We devised a systematic and comprehensive screening educational program to provide all modality options. We identified patients suitable UHHD, and UPD, both which were transitioned to a home dialysis training program upon discharge. Clinical characteristics and outcomes were compared to groups who had a standard start home dialysis (SHHD, SPD) during the study period. Our measured outcomes include the following: average training days, interval of technique failure (patient drop out) access status and complications, infections, hospitalizations and mortality in the first 90 days.

Results: Preliminary results reveal the groups tended to have similar demographic profiles with the average age for patients starting an unplanned home dialysis 51.5 years of age, 66% non-white race, but with a trend toward more males at 59% compared to standard starts.

Conclusions: In this small representative sample, UHHD and UPD was a viable option for programs to consider for the transition of new dialysis patients from the hospital to the outpatient setting. We found similar outcomes in comparison to patients starting home dialysis training in a traditional standard way. Education and screening of home dialysis therapies should be promoted in the hospital setting.

SA-PO844
Quality of Life After 1 Year of Nocturnal Home Hemodialysis Is Comparable to Quality of Life After Renal Transplantation
Anna A. Bonenkamp, 1 Franka E. Van Reekum, 1 Marianne C. Verhaar, 2 Brigid C. van Jaarsveld. 2 Nephrology & Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; 1Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.

Background: Quality of life (QOL) is an important outcome measure for pts with ESRD. Several studies found improved QOL in Nocturnal Home Hemodialysis (NHHHD) compared to conventional HD (CHD). There are no studies comparing QOL in NHHHD vs Tx. Therefore, some pts on NHHHD hesitate whether or not to apply for a place on the renal transplant (Tx) waiting list. The aim of this study is to assess the difference in QOL between NHHHD and Tx after 1 yr of follow up.

Methods: Data were obtained from the ongoing NOCTX-study, which evaluates the 3-yr progression of coronary atherosclerosis in pts treated with CHD, PD, NHHHD and Tx. In this study, QOL was measured with the Kidney Disease-QOL SF questionnaire at baseline (<3 mo after start) and after 1 yr in NHHHD (n=22; 5:76/cr, 6-8 HD per day; all Tx-waitlisted) and Tx (n=30). Composite scores (Physical = PCS, Mental = MCS) and disease related domains were used. One yr results were analyzed with an unpaired t-test.

Results: Pts (n=52) were 50.12 yr, 67% male and median duration of RRT was 37:31mo. Baseline characteristics were comparable between the groups. PCS was 46.9 in NHHHD and 44:8 in Tx group at baseline; follow up PCS was 44:7 and 47:9 respectively (p=0.13). MCS at baseline was 53:9 vs 53:8 and 50:12 vs 52:9 after 1 yr (NS). Compared to NHHHD, Tx pts scored better on the domain “Effects of kidney disease” (75:18 vs 86:14 p=0.01). Sexual function had a remarkably good response rate (90%) and equal scores between NHHHD and Tx (69:34 vs 75:27 p=0.55). In other KQDOL domains no significance was observed.

Conclusions: This is the first study to compare QOL between Tx pts and wait-listed NHHHD patients. Physical and Mental Composite Scores were similar. In disease specific domains, Tx and NHHHD scored not significantly different except for the domain ‘Effects’. These data support an important role for NHHHD as an alternative to renal transplantation.

SA-PO845
Association of Vascular Access Type with Mortality, Hospitalization, and Transfer to In-Center Hemodialysis in Patients Undergoing Home Hemodialysis
Matthew B. Rirva, 1 Melissa Sooboo, 2 Elani Streja, 2 Miklos Zsolt Molnar, 1 Alfred K. Cheung, 1 Ronit Katz, 1 Onyebuchi A. Arah, 1 Allen R. Nissenson, 3, Joseph Himmelfarb, 1 Kamary Kalantar-Zadeh, 1 Rajnish Mehrotra. 1 Kidney Research Institute, Seattle, WA; 2Harald Simon Cyr for Kidney Dis Research & Epidemiology, Univ of California Irvine Med Ctr, Irvine, CA; 3Div of Nephrology, Univ of Tenn Health Science Ctr, Memphis, TN; 4Div of Nephrology, Univ of Utah, Salt Lake City, UT; 5Epidemiology, Fielding School of Pub Health, Los Angeles, CA; 6DaVita, Inc., El Segundo, CA; 7David Geffen Sch of Med at UCLA, Los Angeles, CA.

Background: In individuals undergoing in-center hemodialysis (HD), use of central venous catheters (CVCs) is associated with worse clinical outcomes compared to use of arteriovenous access. However, it is unclear whether a similar difference in vascular access type risk is present in patients undergoing home HD, as these patients have higher dialysis treatment frequency and lower rates of exposure to sources of nosocomial infection.

Methods: We examined the associations of vascular access type with all-cause mortality, hospitalization, and transfer to in-center HD in patients who started home HD from 2007-2011 in 464 facilities in 43 states in the United States. We analyzed the data using competing-risks hazard regression with vascular access type as the start of home HD as the primary exposure in a propensity score-matched cohort (1052 patients; 526 with CVC, 526 with arteriovenous access).

Results: Compared to arteriovenous access, CVC use was associated with increased risk for mortality (hazard ratio [HR] 1.78; 95% confidence interval [95% CI] 1.21 to 2.61) and hospitalization (HR 1.38; 95% CI 1.19 to 1.59). CVC use was not associated with increased risk for transfer to in-center HD (HR 1.07; 95% CI 0.81 to 1.40). The results of analyses in the entire unmatched cohort (2481 patients), with vascular access type modeled as baseline exposure at start of home HD or as a time-varying exposure, were similar.

Conclusions: In a large nationally representative cohort of home HD patients, CVC use was associated with increased risk for mortality and hospitalization.

Time to Transplant Associates with Home Dialysis Modality
Ritu Suri, 1,3 Gihad E. Nesrallah, 1 Leisha Li, 1 Lakshman Gunaratnam. 1 Centre de Recherche, Centre d’Hospitalisation de l’Univ de Montreal, Univ de Montreal, Montreal, QC, Canada; 2Humber River Hospital, Toronto, ON, Canada; 3Nephrology Div, Western Univ, London, ON, Canada.

Background: We recently showed that prevalent end-stage renal disease patients starting home dialysis (HDH) have reduced cardiovascular and infection-related hospitalization risk compared to those starting peritoneal dialysis (PD). As current hospitalization precludes being active on the transplant wait-list, we investigated whether HDH patients receiving home HDH would be more likely to be transplanted than those receiving PD.

Methods: We matched 2997 adults starting home dialysis (HDH) in a single US dialysis provider’s facilities from 2004-2011, to 2997 contemporaneous USRDS patients starting PD (US state and center matched scores. Demographic & insurance status, co-morbidities, complications, and outcomes were ascertained from USRDS. We used Cox regression stratified on matched sets censoring for death, and competing risk analysis using Fine’s approach for stratified data, to compare times to transplantation between groups.

Results: Baseline variables were balanced between groups after matching, with standardized differences <10%. During 12,558 years of follow-up (mean 2.1±1.4 yrs), 514 HDH and 428 PD patients were transplanted. HDH patients were 19% more likely to be transplanted than PD patients (HDH 8.2 vs PD 6.8 per 100 patient-yrs; HR 1.19, 95%CI 1.05-1.35, p=0.012). Competing risk analysis accounting for death and follow-up losses yielded a HR of 1.18 (95%CI 1.04-1.33, p=0.010). Time to waiting-list did not differ between groups (HR 0.97, 95% CI 0.90-1.06, p=0.54), but once waitlisted, PD patients were significantly more likely to be permanently removed from the wait-list (PD 14.2% vs HDH 10.2%, RR 1.39 [95%CI 1.09-1.78], p<0.008).

Conclusions: In this prevalent cohort, home HDH patients were more likely to be transplanted than matched PD patients, and less likely to be permanently removed from the wait-list during follow-up. Mean times to wait-listing were similar, suggesting that the groups were well-matched at baseline. Further study needs to determine the factors responsible for the differential transplantation rates observed in home HDH and PD patients.

Spectrum of Mutations in PKD1 and PKD2 Genes in 100 Unrelated Italian Pedigrees with ADPKD – Sanger Sequencing versus Next Generation Sequencing (NGS) Madalena Gigante,1 S. Diella,1 Matteo Accetturo;2 Paola Pontrelli;2 Giovanni Stailone;1 Giuseppe Grandaliano;1 Loreto Gesualdo.1 1 Univ of Foggia, Foggia, Italy; 2 DETO, Univ of Bari, Bari, Italy.
Background: ADPKD is caused by mutations in PKD1 or PKD2 genes. Although, clinical studies and case reports describing one or few ADPKD families have been reported in Italian population, to date a comprehensive molecular study is still lacking.
Methods: PKD1 and PKD2 genes were analyzed in 150 Italian ADPKD patients from 100 unrelated pedigrees - the largest Italian cohort analyzed to date in a single study - using Sanger sequencing and NGS. The potential pathogenicity of the newly identified variants was evaluated by combining different in silico methods.
Results: We identified the largest number of definitively and probable pathogenic mutations (n=78) reported in a single study in Italian population, achieving an overall detection rate of 90%. 55 mutations (52 PKD1 and 3 PKD2) have not been previously described, expanding the spectrum of known ADPKD mutations. We identified 12 de novo PKD1 mutations in sporadic patients without family history, providing a definitive diagnosis of ADPKD. We found the largest number of de novo mutations reported in a single study (15%) demonstrating, for the first time, that the prevalence of PKD1 de novo mutations may be underestimated. 4/32 PKD2 mutations were found in 2 unrelated Italian patients, a sign of founder effect. 20 patients were analyzed by NGS: we confirm the presence of a nonsense PKD1 mutation and the lacking of clear pathogenic mutations in 3 patients previously analyzed by Sanger, and the presence of definitively/probable pathogenic mutations in the 17 not previously genotyped patients. All NGS results have been confirmed by Sanger sequencing, achieving sensitivity and specificity of 100%.
Conclusions: Our data provide important new advances in the molecular diagnostics of ADPKD: (i) describe for the first time new potential founder mutations in Italy; (ii) report the largest number of de novo mutations identified in a single study and (iii) provide a new NGS method with a detection rate comparable to Sanger sequencing but with significantly lower cost and reduced turnaround time.

SA-PO848
The Use of Screening MR Angiography in Patient with ADPKD Claudine Christiansen, Ruben Poensen, Dirk R. Kuypers, Bert Bammens, Bjorn Meijers. Nephrology, Univ Hospitals Leuven, Belgium.
Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with the development of intracranial aneurysms and an elevated risk of hemorrhagic stroke (HIS). It is suggested that screening MR angiography reduces the incidence of hemorrhagic stroke. Current screening criteria include positive aneurysm history in relatives, neurological symptoms and planned major surgery. The efficacy of these screening criteria has, however, not been fully evaluated.
Methods: We performed a single-center retrospective analysis of all ADPKD patients followed at the University Hospitals Leuven, between January 1990 (date of the first MR angiography) and August 2014. Baseline demographics and occurrence of screening criteria, screening MR angiography, intracranial aneurysm and hemorrhagic stroke were evaluated.
Results: We identified 865 patients with ADPKD. Those who were seen at least three times (median age 51y, 49% males) were included for analysis. Mean duration of follow up was 11.6 years. In this cohort, current screening criteria were met in 183 ADPKD patients (29.2%). Of these, 136 (74.3%) had screening MR angiography. In patients with no MR angiography, presence of screening criteria was associated with an elevated risk of hemorrhagic stroke (12.8% vs. 4.0%, P=0.02). Use of MR angiography in patients with screening criteria was related with a lower risk of hemorrhagic stroke during follow-up (2.2% vs. 12.8%, P=0.01).
Conclusions: In patients with ADPKD, current screening criteria for intracranial aneurysm are associated with an 3-fold elevated risk for future hemorrhagic stroke and performing MR angiography seems effective in reducing this risk.
SA-PO849
Influence of Genotype on ADPKD Progression in the HALT PKD Cohort Christina M. Heyer,1 Kaleab Z. Abebe,1 Vicente E. Torres,2 Ronald D. Perrone,4 Marie C. Hogan,7 William E. Braun,5 Godela M. Brosnahan,2 Peter G. Czarnecki,1 Charity G. Moore,2 Peter C. Harris,1 Dana Miskulin,2 The HALT PKD Investigators.1 1 Mayo Clinic, Rochester, MN; 2 U of Pittsburgh, Pittsburgh, PA; 3 U of Colorado, Denver, CO; 4 Tufts, Boston, MA; 5 Cleveland Clinic, Cleveland, OH; 6 Brigham and Women’s Hospital, Boston, MA; 7 Carolina’s Health Care System, Charlotte, NC; 8 Sites.
Background: We assayed here the influence of the ADPKD disease gene (PKD1 or PKD3) or PKD1 mutation type (truncating or non-truncating) on the rates of renal disease progression over 5 years in the HALT PKD cohort.
Methods: PKD1 mutation type was divided into strength groups: truncating (MSG1), and more or less penetrant non-truncating (MSG2 and MSG3). Correlations were made between gene type/MSG and changes in eGFR or height adjusted total kidney volume (htTKV).
Results: PKD1 patients had a faster eGFR decline than PKD2 (3.3 vs. 1.87 ml/ min/1.73m2/yr; P=0.0001) but the rate of htTKV increase did not differ (6.44 vs. 6.81%/ yr; P=0.42). Baseline PKD1 htTKV was larger than PKD2 (733, 557 ml/m2; P=0.0001) and so PKD1 kidneys expanded to a greater extent (268, 217 ml/m2/yr; P=0.0001). Rates of change in eGFR or htTKV did not differ between PKD1 MSG2 and MSG3 (P=0.15 and 0.70), but MSG3 baseline kidneys were smaller relative to MSG1 and MSG2 (611, 753, 777 ml/m2; P<0.004) and so the volume increase was less (221, 262, 277 ml/yr; P<0.004). PKD2 patients were less likely to reach a study endpoint (death, ESRD or 50% eGFR decline; P=0.003), but there was no difference between PKD1 MSG1, 2, 3 (P=0.61). Patients with no mutation detected, had a slower increase in htTKV (4.84%/yr; P=0.008 vs. PKD1). The study showed a difference in TKV increase between the low and standard blood pressure groups (5.6 vs. 6.6%/yr; P<0.006).
Conclusions: PKD1 MSG3 kidneys are smaller but not because they grow more slowly; possibly because they have less early cysts, similar to PKD2 vs. PKD1. Since genic and allelic effects do not alter progression rates, restricting analysis by genetic factors did not improve significance.

SA-PO850
Climate Temperature Affects the Age of End-Stage Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (PKD) Marwan M. Abbas,1 Michael E. Bleyer,2 Elizabeth Swain,1 Kendra O. Kidd,1 Gregory B. Russell,2 Anthony J. Bleyer.1 Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; Biostatistical Sciences, Wake Forest School of Medicine, Winston-Salem, NC.
Background: Vasopressin receptor 2 antagonists decrease cyst size in PKD. We postulated that patients in hotter climates would have more concentrated urine, and this would affect the age of ESRD in PKD.
Methods: We obtained demographic data and cause of ESRD on 1,332,402 individuals who had their first occurrence of ESRD between ages 30 and 90 between 1971 and 2012 from the US Renal Data system (USRDS). We obtained annual mean temperatures from 1990 to 2010 for US weather stations and linked a participant’s zip code to the nearest weather center. We correlated the mean age of onset of ESRD for PKD and other causes of ESRD with 5 degree temperature intervals. We created a multivariate model for PKD patients, with the dependent variable age of ESRD and independent variables race, gender, year starting dialysis, residual GFR at start of ESRD, annual median income by patient zip code, and temperature as discrete variables in 5 degree intervals.
Results: Figure 1 shows the mean age of onset of ESRD by disease. Cold and warm temperature extremes were associated with increasing age of ESRD for PKD, but other diseases.

The multivariate model showed that temperature had a minimal effect on age of ESRD compared to other variables in the model.

Conclusions: There was a U-shaped relationship for age of ESRD according to temperature that was present in PKD and other diseases. However, in a multivariate model, climate temperature had a minimal effect on age of ESRD in PKD.

Urinary Biomarkers and Prediction of Disease Progression in Autosomal Dominant Polycystic Kidney Disease

Background: The variable disease course of ADPKD underlines the importance of predicting disease progression especially since therapeutic options are now available. Conventional risk markers (age, gender, GFR, total kidney volume (TKV)) lack sensitivity, are expensive or time-consuming to measure. We therefore investigated whether easy to measure urinary markers can predict disease progression and have additional value to conventional risk markers.

Methods: At baseline tubular damage and inflammatory markers were measured in 24-hour urine: albumin, IgG, IgM, 192mg, H-FABP, MIF, NGAL and MCP-1. Patient function was estimated (eGFR by CKD-EPI) and measured (mGFR by (125)I-iothalamate), and TKV by MRI. Disease progression was expressed as annual change in eGFR, mGFR, and height-adjusted (ht)TKV. Multivariate linear regression was used to assess the predictive ability of the markers above conventional risk markers.

Results: Included were 104 ADPKD patients, 40±11yrs, 39% female, eGFR 77±30 ml/min/1.73m², mGFR 79±29 ml/min/1.73m² and htTKV 852 (510-1243) mL/m². During a follow-up of 3.8±1.2 yrs, annual change in eGFR was -5.3±3.0, in mGFR -5.0±3.0 ml/min/1.73m² and in htTKV 0.2±5.9 yrs. B2MG and MCP-1 were associated with annual change in eGFR (Spearman β = -0.23, p = 0.02; Sβ = -0.38, p = 0.001 resp.) and mGFR (Sβ = -0.24, p = 0.03; Sβ = -0.24, p = 0.03 resp.), even when adjusted for conventional risk markers, but not with annual change in htTKV. Similar results were obtained when patients with an eGFR>60 mL/min/1.73m² were selected. Combined B2MG and MCP-1 had an added predictive ability for annual change in eGFR (R² = 0.178 vs. 0.324, p = 0.008) and in mGFR (R² = 0.134 vs 0.217, p = 0.07). The best predictive model for annual change in eGFR included age, htTKV, MIF, b2MG and MCP-1 (R² = 0.343, p = 0.025), and for annual change in mGFR, gender, b2MG, NGAL and mGFR (R² =0.411, p = 0.021).

Conclusions: Significant urinary markers can predict disease progression and had an added predictive value on top of conventional risk markers. These markers have therefore potential to serve as a predictive tool for clinical practice.

SA-PO852
The Novel Surrogate Marker of Autosomal Dominant Polycystic Kidney Disease (ADPKD) – Urinary Copeptin
Satoru Mutô1, Yu Lan1, Haruna Kawano,2 Shigeo Horie.2 1Urology, Teikyo Univ School of Medicine, Tokyo, Japan; 2Urology, Juntendo Univ, Graduate School of Medicine, Tokyo, Japan.

Background: Experimental studies suggest a detrimental role for Arginine vasopressin (AVP) in the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). Copeptin consists of the C-terminal portion of Pro-AVP and has been shown to be a reliable and stable substitute for circulating AVP concentration. In contrast to serum or plasma, urinary proteins do not undergo detectable degradation by endogenous proteases after voiding. It is unknown, however, whether urinary copeptin concentration are associated with disease severity in patients with ADPKD.

Methods: Serum and Urinary copeptin concentration were measured by immunoassay in ADPKD patients with CKD stage ≤ 4. We compared our measurements with clinical parameters including estimated Glomerular Filtration Rate (eGFR), Total Kidney Volume (TKV) and height-adjusted TKV (htTKV). Logarithmic transformation of all variables was performed to fulfill the requirement of equal distribution of the residuals.

Results: We included 50 patients in this study (24 females and 26 males; mean age: 49.3±8.2 years). The median eGFR and TKV were 55.2 ml/min/1.73 m² (interquartile range: IQR 24.9 - 68.0) and 1138.1 ml (IQR 814.7 - 2065.0), respectively. The median urinary copeptin level was 12.19 (IQR 6.91 - 22.32) pg/ml. We could show the positive-correlation between u-copeptin and plasma copeptin but without significant relationship (p = 0.198). Although there are no significant correlations between plasma copeptin and eGFR (R = -0.245, p = 0.227), there are significant correlations between plasma copeptin and htTKV (R = -0.458, p = 0.019) and TKV (R = -0.465, p = 0.017). On the other hand, Urinary copeptin/ u-Cr was statistically associated with the various markers of disease severity in ADPKD (positively with TKV (R = 0.351, p = 0.014), htTKV (R = 0.383, p = 0.008) and negatively with eGFR (R = -0.304, p = 0.036).

Conclusions: In ADPKD subjects, a higher urinary copeptin concentration is associated with disease progression, suggesting that urinary copeptin may be a surrogate marker to detect disease severity renal prognosis in ADPKD.

SA-PO853
The Burden of Tolvaptan Treatment for Autosomal Dominant Polycystic Kidney Disease (ADPKD) – Satoru Mutô1, Haruna Kawano,2 Masaki Kimura,2 Shigeo Horie.2 1Urology, Teikyo Univ School of Medicine, Tokyo, Japan; 2Urology, Juntendo Univ, Graduate School of Medicine, Tokyo, Japan.

Background: Last year, Japan became the first country in the world to approve tolvaptan for the treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD). Because tolvaptan has powerful diuretic effect, patients have to take huge amount of water and suffer from dehydration. We evaluated the burden of tolvaptan treatment on patients with ADPKD.

Methods: This study targeted Japanese patients with ADPKD on tolvaptan. An initial dose of tolvaptan was 60 mg. Estimated glomerular filtration rate (eGFR) and total kidney volume (TKV) were measured at regular intervals. The burden of tolvaptan treatment was evaluated by using clinical and laboratory analyses performed using analysis of variance.

Results: We included 40 patients (male: 28, female: 12). The median age was 46.5 ± 6.5 years (interquartile range: IQR 26.9 – 58.8) and the median baseline TKV was 1.917 mlQ (IQR 1.378 - 2.905). The median starting dosage of tolvaptan was 60 mg (IQR: 30 – 60) and the median treatment period was 8 months (IQR: 6 - 11). We observed no statistical variations in eGFR (p = 0.787) and TKV (p = 0.561) during treatment. There were no significant changes in SAP scores for general fatigue (p = 0.817), anorexia (p = 0.393), back pain (p = 0.682), and abdominal distention (p = 0.607) during treatment. Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment (P<0.003), 35% of patients did not completely sense thirst at al during treatment, and 42% (n=17) of patients spontaneously improved without any additional treatment or tolvaptan withdrawal.

Conclusions: Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment, almost third of the patients did not completely sense thirst at al from beginning of treatment, and the remaining third part of patients spontaneously improved.
Conclusions: We present the first use of texture analysis for PKD assessment. Results are promising in terms of identifying new imaging biomarkers that correlate with disease progression. This approach could function as a surrogate to more difficult imaging methods (e.g., quantitative MRI) and costly analysis (e.g., cyst segmentation). It is likely that combining texture analysis with other patient data will allow for substantial improvements to PKD prognosis.

Accuracy of Traditional and Novel Renal Filtration Markers for Estimating GFR in ADPKD Patients

Stephen L. Seliger, Charalee D. Digs, MSN, Thomas C. Dowling, Robert Christenson, Terry J. Wannick, Medicine, U Maryland Sch Medicine, Baltimore; Ferris State Univ, Pathology, U Maryland Sch Medicine, Baltimore.

Background: The best method for estimating GFR in ADPKD is unclear. Changes in tubular handling of filtration markers may affect estimating equation accuracy.

Methods: Among 51 adults with ADPKD and eGFR >20 cc/min/1.73 m², we measured GFR using iohexol plasma clearance (iGFR), serum creatinine (SCr), IDMS-traceable assay), Cystatin C (CysC, Dimension VISTA assay) and beta-trace protein (BTP, immunonephelometric assay, Siemens). We estimated GFR (eGFR) using validated equations based on SCr (CKD-Epi Cr, MDRD), Cystatin C (CKD-Epi cys, both CysC and SCr (BTP, immunonephelometric assay, Siemens). We estimated GFR (eGFR) using validated equations based on SCr (CKD-Epi Cr, MDRD), Cystatin C (CKD-Epi cys, both CysC and SCr (BTP, immunonephelometric assay, Siemens).

Results: Mean age was 51 ±12 years, 71% were female, 84% Caucasian, and mean eGFR was 68.4+/-34.2 cc/min/1.73 m². Of the 5 equations, the CKD-Epi cys was most accurate, and classification for iGFR-60 cc/min/1.73 m²) of each estimating equation.

Conclusions: Older patients with more advanced and/or severe ADPKD are more likely to be treated with statins. Placebo patients using statins progressed faster; tolvaptan slowed progression and annulled the effects of statin use.

Systems Biology of Polycystic Kidney Disease

Kelly A. George, Herve Husson, Ramya Kalyana Kumar, Vishal S. Vaidya, Jagesh V. Shah, Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA; 2 Renal Div, Brigham and Women’s Hospital, Boston, MA; 3 Genzyme Corp, Framingham, MA.

Background: Polycystic kidney disease (PKD) is a group of hereditary disease states characterized by cystic kidneys and often accompanied by other manifestations such as cystic liver and hypertension. PKD occurs in 1 in 500 people, usually resulting from a dominant mutation in one of two genes, PKD1 or PKD2. There are no treatments for PKD and it is the leading genetic cause of renal failure. Numerous studies have identified pathways that are misregulated in PKD but targeting these individual pathways has not led to a successful therapeutic intervention or molecular biomarker.

Methods: To identify potential biomarkers and develop a systems-level understanding of PKD, we are using transcriptomics, and quantitative proteomics and phospho-proteomics to evaluate the state of cystic and normal kidneys in a mouse model of PKD. Kidney cysts also induce injury to the surrounding tissues, confounding any analysis of the “cystic state”. In an effort to separate the injury signature from the cystic signature, we are also evaluating the state of the injured kidney using a folate model of acute kidney injury and fibrosis. The multi-kinase inhibitor Roscovitine has been shown to prevent cystogenesis in mouse models of PKD but its mechanism of action remains unknown. To gain insight into the mechanism(s) of Roscovitine and to identify biomarkers that change with treatment, we are also using the above “omic” strategies using kidneys from mice following treatment.

Results: From the transcriptomic experiments, we have a list of potential biomarker candidates that are currently being tested by qPCR in mouse tissue at various stages of disease progression. Phosphorylation at motifs for CK1, CK1, CaMK, and other drugs are reduced in kidneys treated with Roscovitine. The primary transcription factor family found to be suppressed with Roscovitine treatment is the E2Fs, likely a result of the loss of CDK signaling.

Conclusions: In ADPKD patients, cystatin-based GFR equations may over-estimate true GFR in contrast to the lower bias observed in the general CKD population. The SCr-based CKD-Epi equation performed best overall among 5 equations. The utility of equations utilizing beta-trace protein deserves further investigation.

Statins, ADPKD Severity and Progression in the TEMPO 3:4 ADPKD Clinical Trial

Background: In ADPKD, low HDL and high LDL cholesterol are associated with faster total kidney volume (TKV) increase and eGFR decline. A randomized controlled trial (RCT) of pravastatin in children showed lower TKV expansion without effect on renal function.

Methods: Exploratory post-hoc analysis of TEMPO 3:4 (3-year RCT of tolvaptan in relatively early but progressive ADPKD, age 18-50 yrs, TKV >750 ml, cSCr >60 ml per minute) to examine whether use of statins might have affected ADPKD progression. Linear mixed-effect models that adjust for gender, age and baseline TKV and eGFR were used to compare TKV and eGFR slopes between groups.

Results: Patients randomized to placebo using statins were older, had larger TKV and lower eGFR at baseline, and their TKV and eGFR slopes were steeper compared to statin users (Table). Similarly, patients randomized to tolvaptan and statins were older and had lower eGFR, with a non-significant trend to larger TKV compared to statin non-users; however, there was no difference between TKV or eGFR slopes of statin users and nonusers randomized to tolvaptan. Statin use did not affect a composite end point of clinically relevant ADPKD events in the placebo (HR=1.013, P=0.91) or tolvaptan (HR=0.954, P=0.65) group.

Conclusions: In ADPKD patients, cystatin-based GFR equations may over-estimate true GFR in contrast to the lower bias observed in the general CKD population. The SCr-based CKD-Epi equation performed best overall among 5 equations. The utility of equations utilizing beta-trace protein deserves further investigation.

Conclusions: These experiments will not only provide candidate biomarkers for PKD progression, but will also yield a deeper understanding of the state of the cystic kidney. Funding: Pharmaceutical Company Support - Sanofi Genzyme, Private Foundation Support

SA-PO859
Prognostic Enrichment Strategies in the TEMPO 3:4 ADPKD Clinical Trial
Maria V. Irazabal,1 Jaime Blais,2 Ronald D. Perrone,3 Ron T. Gansevoort,4 Arlene B. Chapman,5 Olivier Devuyst,6 Eiji Higashihara,7 Wen Zhou,8 John Ouyang,9 Frank S. Czerwiec,2 Vicente E. Torres,1 Mayo Clinic; 2Osaka PDC; 3Tufts MC; 4UMC Groningen; 5U. Chicago; 6U. Zurich; Kyorin U.

Background: An image classification of ADPKD based on diffuse (class 1) vs. asymmetric (class 2) cyst distribution along with estimated cyst growth determined by age and height-adjusted total kidney volume (htTKV, subclaus A-E) has been proposed for prognostic enrichment by excluding patients with a lesser risk for progression (classes 1A-B and 2).

Methods: This enrichment strategy was compared, post-hoc, to exclusion criteria used for TEMPO3:4 to examine tolvaptan effects on ADPKD progression in patients with early but progressive renal disease (38-50 year-old, TKV >750 mL, eGCL >60 mL/min).

Results: 1436 TEMPO 3:4 subjects with baseline MRIs were classified, finding only 10% class 2 or 1B and no 1A subjects. TEMPO3:4 enriched categories 1C-E (90%) compared to the published cohorts (62%, Irazabal 2014 JASN). TKV and eGFR slopes steepened from class 1B to 1E (both P<0.001, Table).

Conclusion: Tolvaptan effects on TKV and eGFR slopes was greater in classes 1C to E. Originally, tolvaptan blunted TKV and eGFR slopes from 5.51% to 2.80% and from -3.70 to -2.78 mL/min/1.73m² per year (both P<0.001), and lowered the risk for a composite endpoint (CE) of clinical progression events (hazard ratio [HR] 0.87, p=0.0095, Torres 2012 NEJM).

Methods: Removing class 1A-B and class 2 patients from the trial, marginally improved estimates of tolvaptan effects on TKV and eGFR slopes 5.78% to 2.91% and -3.93 to -2.82 mL/min/1.73 m² per year (both P<0.001), and the CE endpoint (HR 0.84, p=0.0032).

Conclusions: Prognostic enrichment strategies using kidney morphology can enhance ADPKD trials for rapidly progressing patients, increasing power and reducing costs. Refinements of imaging criteria can improve the probability of success of future clinical trials. Funding: NIDDK Support

SA-PO860
Prognostic Enrichment Design in Clinical Trials for ADPKD: The HALT PKD A Trial
Maria V. Irazabal,1 Kaleab Z. Abebe,2 Kyongtae Ty Bae,2 Ronald D. Perrone,3 Arlene B. Chapman,5 Robert W. Schrier,7 Alan S.L. Yu,4 William E. Braun,8 Theodore I. Steinman,9 Michael F. Flessner,9 Vicente E. Torres,1-5 Mayo Clinic; 2U of Pittsburgh; 3Tufts U.; 4U of Chicago; 5U of Colorado; 6Kans U.; 7Cleveland Clinic; 8Beth Israel Deaconess; NIH-NIDDK.

Background: Patients with mild ADPKD phenotype are less likely to be informative in clinical trials. An image classification into typical (diffuse cyst distribution) class 1A and atypical (asymmetric cyst distribution) class 2 has been proposed for prognostic enrichment design in clinical trials with recommendations to exclude class 1A-B and follow-up class 1B (asymmetric cyst distribution) class 2 has been proposed for prognostic enrichment design.

Methods: Post-hoc analysis of HLTK-PKD A, RCT of rigorous vs standard BP control on TKV increase and eGFR decline; eGFR=60 mL/min/1.73 m² to investigate the performance of this classification for prognostic enrichment design.

Results: 551 participants were classified by 2 raters (98.2% agreement) into class 1A (6.2%), IB (20.3%), IC (34.1%), 1D (22.1%), IE (11.8%), and 2 (5.4%). TKV increase and eGFR decline became steeper from class 1A → 1E (both P<0.0001). HALT PKD A showed slower TKV increase, faster eGFR decline in the first four months (FO-5) and marginally slower eGFR thereafter (FO-80), without a significant overall (FO-80) effect with rigorous BP control. To ascertain the ability to detect an effect of rigorous BP control on TKV increase and eGFR decline; eGFR>60 mL/min/1.73m² per year (both P<0.001), and lowered the risk for a composite endpoint (CE) to investigate the performance of this classification for prognostic enrichment design.

Methods: Examine adverse drug reactions (ADRs) of tolvaptan for up to 3 years after TEMPO in Japanese ADPKD patients.

Methods: This open-label study was conducted in 135 patients participating in the preceding TEMPO. Doses of tolvaptan were adjusted from 60 to 120 mg/day.

Results: Main ADRs, thirst (77%), polyuria (57%), polydipsia (38%), and hyperuricemia (15%) were noted during up to 3 years. In TEMPO, hepatic function-related ADRs were observed more frequently for tolvaptan than for placebo early during treatment. In this study, 8 patients (6%) experienced >3-fold increases above upper limits of normal sodium (˚SNa) >160 mmol/1, AST 3 to 9 months after tolvaptan initiation, but all recovered after tolvaptan cessation. Of these 8 patients, 7 had been allocated to placebo in TEMPO. However, the residual one patient allocated to tolvaptan similarly had shown increased serum ALT in TEMPO. None of the 8 patients met Hy’s Law criteria. No ADRs besides those seen in TEMPO were newly observed in this study.

Conclusions: Hepatic function-related ADRs occurred early during treatment and were reversible. Tolvaptan was thus indicated to be a promising drug for treatment of ADPKD for up to 6 years while carefully monitoring ADRs including hepatic function abnormalities. Funding: Pharmaceutical Company Support - Osuka Pharmaceutical Co., Ltd.

Long-Term Safety Profile of Tolvaptan in Japanese ADPKD Patients
Eiji Higashihara,7 Shigee Horie,2 Yoshiyumi Ubara,3 Satoru Muto,4 Kikuo Nutahara,4 Ichieii Narita,7 Tadashi Okada,7 ADPKD Research, Kyorin Univ School of Medicine, Tokyo, Japan; 2Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; 4Nephrology Center, Toranomon Hospital, Tokyo, Japan; 5Urology, Teikyo Univ School of Medicine, Tokyo, Japan; 6Urology, Kyorin Univ School of Medicine, Tokyo, Japan; 7Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; 8Clinical Development, Osuka Pharmaceutical Co., Ltd., Osaka, Japan.

Background: Tolvaptan was first approved in Japan for autosomal dominant polycystic kidney disease (ADPKD) based on results of the Tolvaptan Efficacy and Safety in Management of Autosomal Dominant Polycystic Kidney Disease and Its Outcomes 3-4 trial (TEMPO) to examine adverse drug reactions (ADRs) of tolvaptan for up to 3 years after TEMPO in Japanese ADPKD patients.

Methods: This open-label study was conducted in 135 patients participating in the preceding TEMPO. Doses of tolvaptan were adjusted from 60 to 120 mg/day.

Results: Main ADRs, thirst (77%), polyuria (57%), polydipsia (38%), and hyperuricemia (15%) were noted during up to 3 years. In TEMPO, hepatic function-related ADRs were observed more frequently for tolvaptan than for placebo early during treatment. In this study, 8 patients (6%) experienced >3-fold increases above upper limits of normal sodium (˚SNa) >160 mmol/1, AST 3 to 9 months after tolvaptan initiation, but all recovered after tolvaptan cessation. Of these 8 patients, 7 had been allocated to placebo in TEMPO. However, the residual one patient allocated to tolvaptan similarly had shown increased serum ALT in TEMPO. None of the 8 patients met Hy’s Law criteria. No ADRs besides those seen in TEMPO were newly observed in this study.

SA-PO862
Pregnancy Outcome in Participants in the HALT PKD Clinical Trials
Arlene B. Chapman,1 Kaleab Z. Abebe,2 Marie C. Hogan,3 Charley Ty Bae,4 Susan Spillane,2 Theodore I. Steinman,4 Kyongtae Ty Bae.2 1U of Chicago; 2U of Pittsburgh; 3Mayo Clinic; 4Beth Israel Deaconess; 5Halt Investigators.

Background: ADPKD is the most common hereditary disease. Fertility rates are not impaired in ADPKD women, however, preexisting hypertension and proteinuria associate with increased maternal and fetal complications. In the HALT PKD trials, 38 pregnancies occurred despite counseling and review with participants. We now present maternal and fetal outcomes from these pregnancies.

Methods: In a secondary analysis, data regarding maternal and fetal outcomes and complications of reported pregnancies were obtained including spontaneous abortions, delivery types and still births. Data collection relied on completion of protocol case report forms, followup of hospital discharge summaries and patient based reports if available.

Results: In Study A, 102 of 128 (80%) women were premenopausal. In all pregnancies, study medications were stopped immediately or before the pregnancy began. 36 pregnancies occurred in 30 women with experiencing 2 pregnancies. 26 women experienced 32 pregnancies in Study A (12.8%) and 4 occurred in 4 women in Study B (4.5%). In Study A, baseline TKV was 871.5+502.9 mls, and GFR was 104.3+17.5 mL/min. In Study B, baseline GFR was 51.6+9.3 mL/min. Information on pregnancy outcome was not available in 3 pregnancies (2 LTFU and 1 pregnant at the end of study). In 33 pregnancies, 58% resulted in a live birth (100% in Halt B). In the remainder, 7 spontaneous and 2 therapeutic abortions, 1 ectopic and 1 stillbirth occurred. Two C-sections, one for pre-eclampsia and one pre-term delivery was reported.

Conclusions: In this secondary analysis of HALT Study A and B, 10.3% of studied pregnancies evolved. Strategies for prognostic enrichment such as the image classification should be used in the design of RCTs for ADPKD to increase their power and reduce their cost. Funding: NIDDK Support
Renal Concentrating Capacity and Copeptin Concentration in Patients with ADPKD and IgA Nephropathy with Impaired Renal Function

**Background:** ADPKD patients have an impaired maximal urinary concentrating capacity (Unmax). This may be specific for ADPKD or may be associated with reduced renal function. Intraabdominal organ growth in ADPKD may affect Unmax. Whether this is an aspecific effect of renal function impairment, or specific for ADPKD is yet unknown. We hypothesized that ADPKD patients have a more severely impaired Unmax in comparison with non-ADPKD renal disease patients, which leads to an exaggerated vasopressin (AVP) response that may be damaging to the kidney.

**Methods:** 15 ADPKD (eGFR>60) and 15 IgA patients, matched for age, sex and eGFR underwent a water deprivation test to determine Unmax. Urine and plasma osmolality (Uosm and Posm), albuminuria (ACR) and plasma copeptin (surrogate marker for AVP in pmol/L), were measured at baseline and after water deprivation (average 17 hours). Height adjusted total kidney volume (htTKV) was measured by MRI.

**Results:** Unmax was lower in ADPKD compared with IgA patients. Upon water deprivation Posm increased in ADPKD (p=0.003), but not in IgA (p=0.1), whereas copeptin increased in both groups similarly (ADPKD: p=0.001; IgA: p=0.02). Copeptin after water deprivation was negatively associated with Unmax in both groups (ADPKD: R=-0.72, p=0.002; IgA: R=-0.70, p=0.004). In ADPKD, copeptin and albuminuria were correlated after water deprivation (R=-0.71, p=0.003), independently of eGFR or htTKV. Furthermore, htTKV in ADPKD was associated after water deprivation with Posm (R=0.52, p=0.048), copeptin (R=0.58, p=0.03) and Unmax (R=0.34, p=0.04).

**Conclusions:** ADPKD patients have a lower Unmax compared with IgA patients with similar renal function. Remarkably, this is not accompanied with an exaggerated increase in AVP. Notwithstanding, ADPKD severity was associated with stronger increases in Posm, copeptin and albuminuria during water deprivation. This suggests that in ADPKD water deprivation may be deleterious and should be avoided.

**Funding:** Government Support - Non-U.S.

Tyrosine Kinase Inhibitor Tesevatinib for Patients with Autosomal Dominant Polycystic Kidney Disease

Anjay Rastogi,1 Mitchell H. Rosner,2 Irina Barash,3 Theodore I. Steinman,3 Ziad El-Zoghby,4 Anju Yadav,1 Seth Goldberg,4 Ashraf El-Meanawy,5 Mireille El-Ters,6 Marie Roche,7 Mark S. Berger8 UCLA, 3UVA, 4Beth Israel Deaconess, 5Mayo Clinic, 6Cleveland Clinic, 7Washington Univ, 8Med College Wisconsin, 9KU Med Center, 10Kadmon Corp.; 11Mount Sinai Beth Israel.

**Background:** Tesevatinib (formerly KD019) inhibits both epidermal growth factor receptor (EGFR) and SRC. It decreases cyst growth and slows the decline in renal function in BPK mouse & PCK rat PKD models. In oncology trials the most common adverse events (AEs) were EGFR inhibitor AEs of acneiform rash and diarrhea. The 1:2:1 of approx. 60 hrs allows for schedules other than daily dosing.

**Methods:** This study evaluated the safety and tolerability of tesevatinib at several doses and schedules. Eligibility used Ravine criteria for autosomal dominant polycystic kidney disease (ADPKD) in patients (pts) aged 18-55 years with eGFR ≥ 50 mL/min/1.73 m².

**Results:** 46 ADPKD pts were enrolled into 5 dose/schedule cohorts. At 150 mg/day, 3/5 pts had moderate rash occurring during the first 28 days that was not tolerated and led to study discontinuation for 2. The tolerability of intermittent dosing schedules using 150 mg (Mon, Wed, Fri or Mon, Thu) was improved over 150 mg/day, but 1 case of severe rash occurred. QTC prolongation >485 ms occurred in 2 pts on 100 mg/day, and 1 pt on 150 mg MWF. The most common AEs overall in preclinical safety data were diarrhea (36%), rash (33%), nausea (29%), and asymptomatic CPK increase (24%). Other AEs included asymptomatic mild amylase elevations (21%).

**Conclusions:** Tesevatinib 150 mg in various schedules was associated with skin rash that was not well tolerated. A rate of QTC prolongation not acceptable for chronic use was associated with tesevatinib 100 mg/day. Tesevatinib 50 mg/day appears to be a well tolerated dose in patients with ADPKD, although some acneiform rash occurs. In order to confirm the safety profile at 50 mg/day, an additional 20 pts are being enrolled.

Total Abdominal Organ Volume Is a Major Risk Factor for Malnutrition in Ambulatory Patients with Autosomal Dominant Polycystic Kidney Disease

Hyunjin Ryu,1 Hayne C. Park,2 Hyunsuk Kim,3 Kook-Hwan Oh,4 Young-Hwan Hwang5 Currie Ahn6 Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; 7Asian Medical Center; 8Armed Forces Capital Hospital, Seongnam; 9Eulji General Hospital.

**Background:** In Autosomal dominant polycystic kidney disease (ADPKD), malnutrition may develop as renal function decreases and abdominal organ volume enlarged. In this study, we evaluated the nutritional status of outpatient ADPKD patients by using subjective global assessment (SGA) and investigated the risk factors for malnutrition.

**Methods:** In this single center, cross sectional study, anthropometric and laboratory data including serum creatinine (scr), albumin, and cholesterol were collected, and total kidney and liver volume were measured. Total abdominal organ volume was defined as the sum of total kidney and liver volume and adjusted by height (htTV).

**Results:** A total of 296 patients (47.9%) were included and mean age was 48±12 years. Mean estimated glomerular filtration rate (eGFR) was 65.3 ± 25.3 mL/min/1.73m². Mean SGA score was 6±0.6. 186 patients (53.8%) were in chronic kidney disease stage 1 or 2, 94 (31.4%) stage 3 and 21 (7.3%) stage 4. Total 21 patients (7.3%) were mild to moderately malnourished (SGA 4–5) and 63 patients(21.7%) were at risk of malnutrition (SGA 6). There was no difference in SGA score distribution with sex. Physical scores related to nutritional status in total and male were age, height, weight and body mass index. However none of these parameters were related in female. Lower hemoglobin level and relatively preserved renal function. Intraabdominal organ growth in ADPKD may affect the nutritional status independently from the renal deterioration.

**Conclusions:** The prevalence of malnutrition in this PKD population is high, and risk factors for malnutrition include low hemoglobin and relatively preserved renal function. Intraabdominal organ growth in ADPKD may affect the nutritional status independently from the renal deterioration.

**Funding:** Government Support - Non-U.S.
Renal function did not change significantly during the period that patients were on metformin. We will continue to observe these patients and accumulate more patients with PKD and diabetes but not on metformin to see if metformin is beneficial in PKD patients.

11Beta-Dichloro Inhibits Cyst Progression in an Adult ADPKD Model

Sorin V. Fedeles, Bogdan I. Fedeles, Yasunobu Ishikawa, Rachel Gallagher, John M. Essigmann, Stefan Somlo. 1 Dept of Internal Medicine, Yale School of Medicine, New Haven, CT; 2 Dept of Genetics, Yale School of Medicine, New Haven, CT; 3 Dept of Chemistry, M.I.T., Cambridge, MA.

Background: ADPKD is the most common monogenic disorder for which no effective therapy exists. We have previously shown that the novel antitumor agent 11β-dichloro specifically induced apoptosis in Pkd1 null cells (ASN 2013 FR-OR100). Administration of 11β-dichloro resulted in amelioration of cystic disease in the Pkd1fl/fl;Pkd1-Cre neonatal ADPKD model. In the current work we explored the pathways involved in the pro-apoptotic effect of 11β-dichloro and investigated whether the beneficial effect seen in the early model is also present in an adult inducible Pax8rtTA;TetO-cre; Pkd1fl/fl model which is more akin to the human disease.

Methods: Pax8rtTA;TetO-cre; Pkd1fl mice were induced with doxycycline for 2 weeks beginning at P28. 11β-dichloro was administered by IP injection at a dose of 10 mg/kg, 3 times a week for 12 weeks beginning from P42; At the end of treatment the kidneys were harvested for analysis.

Results: 11β-dichloro treated adult mice resulted in a decrease in KW/BW ratio as compared to vehicle injected controls (2.6 ±0.1 vs. 6.1 ±0.4); There was no difference in body weight between treated and control. These changes were accompanied by a decrease in the cystic index (29%±1.5 vs. 49%±1.4), BUN (41±2.4 vs. 83±2.7), and creatinine (0.18±0.007 vs. 0.37 ±0.02). 11β-dichloro specifically increased apoptosis in cyst-lining cells but not in wild-type. UPR and ROS have been implicated as potential drivers of the 11β-dichloro-dependent pro-apoptotic phenotype. We found that upregulation of the UPR marker BiP and its transcriptional targets BiP and Erdf4 was specific to the Pkd1 null cells compared with wild-type, in vitro and in vivo. Treatment with 11β-dichloro increased mRNA levels of the antioxidant genes catalase and SOD1 specifically in the Pkd1 cystic kidneys and not in vehicle-treated kidneys.

Conclusions: 11β-dichloro specifically induces UPR, ROS, and apoptosis in cystic vs. wild-type kidneys. In an adult inducible cystic model, the compound ameliorates polycystic disease progression and improves kidney function.

Outcomes of Combined Partial Hepatectomy and Cyst Fenestration for Massive Polycystic Liver Disease

Fouda T. Chebib, Yeon Soon Jung, Christina M. Heyer, Maria V. Irazabal, Marie C. Hogan, Patrick S. Kamath, Vicente E. Torres, Ziad El-Zoghby. 1 Div of Nephrology, Mayo Clinic, Rochester, MN; 2 Kosin U.

Background: PLD is the most common extrarenal manifestation in pts with ADPKD. Here we analyzed the influence of genotype and gender on the severity of PLD.

Methods: Clinical data was retrieved from electronic records in a large cohort of pts who were mutation screened, determined to be PKD1 or PKD2 and had available CT or MR liver imaging during 2000-2014 at the Mayo Clinic (n=445). Liver volumes (LV) were measured by stereoreo on axial images and adjusted to height (HxLV).

Results: Among the 445 pts, 220 (49.5%) had truncating PKD1, 153 (34.4%) nontruncating PKD1 and 72 (16.1%) PKD2 mutations. Compared to nontruncating PKD1 and PKD2, pts with truncating PKD1 were younger at time of first imaging (43.6 vs 47.6 and 50.4; p<.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<.001), had larger kidney volumes (785 vs 614 and 548 ml/m; p<.001). LV in pts with PKD1 truncating, PKD1 nontruncating and PKD2 were not different (HxLV 1039, 1076 and 1058 ml/m, respectively; p=0.53). Females had larger HxLV compared to males (1104 vs 1019 ml/m; p<.001). Annualized median liver growth rates were 1.65, 1.74 and 1.2% for truncating PKD1, nontruncating PKD1 and PKD2, respectively (p<.05). Females younger than 48 had higher annualized median growth rates compared to those older than 48 (2.65 vs 0.09%;p<.001). When adjusting for age, gender and baseline LV, growth rate remained unaffected by the ADPKD genotype.

At follow-up (mean 7.8 years), median LV was 2500 ml. Interestingly, 29 out of 61 patients with available LV2 and LV3 showed further regression in LV upon follow up (median -4.988%); while the rest showed mild growth of 9.5%. Overall volumetric comparison of preoperative to follow-up liver imaging showed sustained liver volume reduction (median 66%)

Conclusions: Sustained long-term reductions in LV in after PHCF can be achieved in selected patients with severe, highly symptomatic PLD. In our experience, liver-related death and subsequent liver transplantation are infrequent after PHCF.

SA-PO869

Effect of Genotype on the Severity and Volume Progression of Polycystic Liver Disease (PLD) in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Fouda T. Chebib, Yeon Soon Jung, Christina M. Heyer, Maria V. Irazabal, Marie C. Hogan, Peter C. Harris, Vicente E. Torres, Ziad El-Zoghby. 1 Div of Nephrology, Mayo Clinic, Rochester, MN; 2 Kosin U.

Background: PLD is the most common extrarenal manifestation in pts with ADPKD. Here we analyzed the influence of genotype and gender on the severity of PLD.

Methods: Clinical data was retrieved from electronic records in a large cohort of pts who were mutation screened, determined to be PKD1 or PKD2 and had available CT or MR liver imaging during 2000-2014 at the Mayo Clinic (n=445). Liver volumes (LV) were measured by stereoreo on axial images and adjusted to height (HxLV).

Results: Among the 445 pts, 220 (49.5%) had truncating PKD1, 153 (34.4%) nontruncating PKD1 and 72 (16.1%) PKD2 mutations. Compared to nontruncating PKD1 and PKD2, pts with truncating PKD1 were younger at time of first imaging (43.6 vs 47.6 and 50.4; p<.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<.001), had larger kidney volumes (785 vs 614 and 548 ml/m; p<.001). LV in pts with PKD1 truncating, PKD1 nontruncating and PKD2 were not different (HxLV 1039, 1076 and 1058 ml/m, respectively; p=0.53). Females had larger HxLV compared to males (1104 vs 1019 ml/m; p<.001). Annualized median liver growth rates were 1.65, 1.74 and 1.2% for truncating PKD1, nontruncating PKD1 and PKD2, respectively (p<.05). Females younger than 48 had higher annualized median growth rates compared to those older than 48 (2.65 vs 0.09%;p<.001). When adjusting for age, gender and baseline LV, growth rate remained unaffected by the ADPKD genotype.

At follow-up (mean 7.8 years), median LV was 2500 ml. Interestingly, 29 out of 61 patients with available LV2 and LV3 showed further regression in LV upon follow up (median -4.988%); while the rest showed mild growth of 9.5%. Overall volumetric comparison of preoperative to follow-up liver imaging showed sustained liver volume reduction (median 66%)

Conclusions: Sustained long-term reductions in LV in after PHCF can be achieved in selected patients with severe, highly symptomatic PLD. In our experience, liver-related death and subsequent liver transplantation are infrequent after PHCF.

Underline represents presenting author.
Conclusions: In contrast to the renal phenotype, ADPKD gene type or PKD1 mutation type were not significantly associated with the severity or growth rate of PLD in ADPKD pts. This finding, along with the demonstrated gender influence, indicates that modifiers beyond the disease gene significantly influence this phenotype.

SA-PO870

Eligibility for Renal Transcatheter Arterial Embolization in Patients with Autosomal Dominant Polycystic Kidney Disease

Tatsuya Suwabe, Yoshifumi Ubara, Junichi Hoshino, Rikako Hiramatsu, Kenmii Takaichi. Dept of Nephrology, Toranomon Hospital, Tokyo, Japan.

Background: In patients with ADPKD, massive renal enlargement is a serious problem. Renal transcatheter arterial embolization (TAE) is effective for reducing renal volume, but there is large variation of its effectiveness and the reasons remain unclear. We investigated factors influencing the renal volume reduction rate (RVRR) for one year after TAE.

Methods: All patients with ADPKD who received renal TAE at Toranomon Hospital from 2006 to 2013 were enrolled. We calculated RVRR by the calculation formula (1 - renal volume at each time after TAE/renal volume before TAE)*100, and analyzed factors affecting RVRR. We also compared sequential change of large cysts (>5cm), by classified them into four groups as cysts with wall thickening (>4mm), cyst with acute hemorrhage, normal cysts, and the others.

Results: 449 patients (228 men, 221 women, mean age: 57.0 ± 9.1 years) were enrolled. The RVRR at 1 year after TAE ranged from 3.9 to 84.8%, and the least squares mean RVRR calculated using mixed model was 45.73% (95% confidence interval [95% CI]: 44.36 to 47.10%). Multivariate analysis using mixed model revealed that large cysts with wall thickening (regression coefficient: -5.830, 95% CI: -9.410 to -2.250, p<0.0006), age (5 years): -0.847, -1.073 to -0.621, p<0.0001), dialysis duration (12 months): -0.115, -0.193 to -0.037, p<0.0009), systolic blood pressure (10mmHg): 0.283, 0.065 to 0.501, p<0.0109), and number of microcysts used for renal TAE (1.333, 0.784 to 1.882, p<0.0001) had a significant influence on the RVRR. Among large cysts, only cysts with wall thickening did not decrease in volume. Significantly more microcysts were needed to achieve complete renal artery occlusion in patients with younger age and less dialysis duration.

Conclusions: Cyst wall thickening had an important influence on cyst volume reduction. Renal TAE was more effective in patients who were younger, had shorter dialysis duration, or had hypertension, parameters that might be associated with cyst wall stiffness. Renal artery narrowing may occur in older patients or those on longer dialysis, which might contribute to renal TAE being less effective in these patients.

Patient Reported Health Related Quality of Life in ADPKD: Analysis from OUTVERTE

Dorothee Oberdhan, Arlene B. Chapman, Ronald D. Perrone, Andreas L. Serra, Jason C. Cole, Wen Zhou, Holly Krasa, Jaime Blais, Frank S. Czerwiec. 1 Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD; 2Univ of Chicago, Chicago, IL; 3Tufts, Boston, MA; 4Univ of Zürich, Zürich, Switzerland; 5PPD, San Diego, CA.

Background: Although hepatomegaly in polycystic liver disease (PLD) is common, few studies have evaluated natural history & factors associated with progression. Goal: Examine change in height adjusted liver volume (htLV) & factors influencing progression in participants in HALT-PKD-A randomized clinical trial.

Methods: Baseline PLD group (mild (htLV<1000ml;n=240) moderate (1000-1800ml; n=180; 74% female) & severe (>1800ml; n=28; 81% female)) & follow up htLVs, quality of life (QOL;SF-36), influence of telmisartan (T) vs placebo (P) on progression were assessed (n=558, age 15-49y, eGFR > 60 ml/min). We assessed factors influencing htLVs such as treatment group, age, gender, genotype (in separate models) & factors influencing progression over time were examined using linear mixed models.

Results: Annual htLV growth rates were 0.76, 0.91 & 1.08% (P<NS) in the mild, moderate & severe groups, respectively (figure 1). Neither baseline age or genotype associated with annual htLV increase. There were strong negative relationships of eGFR (p<0.02) & serum albumin (p<0.0003) with htLV. Prior pregnancy & higher parity (both age adjusted) associated with htLV but not with progression over time. Increases in BLV were associated with increased rates of fatigued/weakness (p=0.003) and declines in SF-36 physical functioning over time (p=0.02). Progression was independent of drug assignment (T 0.09% vs P 1.07% p=NS) & BP target (low 0.81 vs std. 1.15% p=NS).

**Towards Personalised Medicine – Treating a Renal Ciliopathy**

Shalabh Srivastava, 1 Simon Ramsbottom, 2 Sophie Saunier, 1 Colin Miles, 1 John Andrew Sayer. 1

1Nephrology, Inst of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; 2Laboratory of Inherited Kidney Diseases, Imagine Inst, Paris, France.

**Background:** Renal ciliopathies are genetic disorders presenting with nephronophthisis, cystic kidneys or cystic dysplasia. Pathogenesis of ciliopathies may include altered signalling or defective DNA damage response. Due to the huge genetic/phenotypic variability in ciliopathies it is pertinent to explore the most important contributor to individual phenotypes. We investigated disease mechanisms of a patient with Joubert Syndrome aiming to provide a personalised medicine approach to treatment.

**Methods:** We identified a family with 2 affected siblings with a ciliopathy phenotype. Ciliopathy gene panel sequencing followed by Sanger sequencing and segregation analysis was undertaken to provide a molecular genetic diagnosis. We established Human Urine Derived Renal Epithelial Cell (HUREC) cultures from one sibling and a control. Cultured cells where characterised and their response to therapeutic agents quantified.

**Results:** The siblings exhibited a cerebro-retinal-ciliary phenotype with renal corticomedullary cyst formation and progressive renal failure. Panel sequencing followed by Sanger sequencing confirmed a likely mutation in HURC1. Using HURECSC we have characterised, at a personalised medicine scale, the cellular defect. This data suggests that renal ciliopathies may have potential therapeutic targets and investigation through individual HUREC based model is an exciting new development.

**SA-PO875**

**Effect of Metformin on the Progression of Autosomal Dominant Polycystic Kidney Disease**

Godela M. Brosnahan, 1 Michel Chonchol, 1 John R. Holmen, 2 Eugene J. Nuccio, 3 Berenice Y. Gitomer. 1

1Univ of Colorado; 3Intermountain Healthcare, Salt Lake City, UT.

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited disorder resulting in end-stage renal disease (ESRD), without an approved treatment. In an animal model of ADPKD metformin therapy resulted in amelioration of cystic renal growth. We sought to determine whether patients with ADPKD and type 2 diabetes treated with metformin had slower progression to ESRD than similar patients treated with other antidiabetic drugs.

**Methods:** We conducted a population-based cohort study of adult patients with ADPKD and type 2 diabetes between January 1/2000 and December 31/2014. We identified 322 adults with ADPKD and type 2 diabetes, of whom 119 were treated with metformin only and 203 with other antidiabetic agents. Among these we identified 31 subjects treated with metformin only, who could be matched for age, sex, race, history of hypertension and coronary artery disease, and baseline renal function to 31 subjects not treated with metformin. The primary outcomes were incident ESRD and all-cause mortality.

**Results:** The median age of the enrolled patients was 61 years, 45% were women. Approximately 74% and 26% had a history of hypertension and myocardial infarction, respectively. The baseline MDRD-eGFR in patients receiving and not receiving metformin was 49±12 and 47±14 mL/min/1.73m2 (p=0.70). After a median follow-up of 4.5 years, incident ESRD occurred in 29% and 16% of those not exposed and exposed to metformin, respectively, with a OR of 2.13 (95% CI 1.10-3.46; p=0.02). Deaths occurred in 32% and 26% of those not exposed and exposed to metformin, with a OR of 1.37 (95% CI 0.5-2.47; p=0.60).

**Conclusions:** Metformin therapy may slow progression to ESRD in ADPKD adults with type 2 diabetes compared to other antidiabetic drugs. Because metformin has an excellent safety record, a trial to slow the progression of ADPKD in the absence of diabetes is warranted.

**Frequency and Reasons for Hospitalization Among ADPKD Patients with GFR >25 mls/min**

Dana Miskulin, 1 Kaleab Z. Abeebe, 1 Ronald D. Perrone, 1 Marie C. Hogan, 1 Frederic F. Rahbari-Oskoui, 1 Peter G. Czarniecki, 2 Susan Spillane, 1 Arlene B. Chapman, 1 Robert W. Schrier, 1 Vicente E. Torres, 1 Charity G. Moore. 1

1Tufts Medical Center, Boston, 2Mayo Clinic, Rochester; 3Emory Univ, Atlanta; 4Brigham and Women’s Hospital, Boston; 5Univ of Pittsburgh; 6Univ of Chicago; 7Univ of Colorado.

**Background:** There is a paucity of data about the frequency and causes of hospitalization in Autosomal Dominant Polycystic Kidney Disease (ADPKD).

**Methods:** We investigated disease mechanisms of a patient with Joubert Syndrome aiming to provide a personalised medicine approach to treatment.

**Results:** The siblings exhibited a cerebro-retinal-ciliary phenotype with renal corticomedullary cyst formation and progressive renal failure. Panel sequencing followed by Sanger sequencing and segregation analysis was undertaken to provide a molecular genetic diagnosis. We established Human Urine Derived Renal Epithelial Cell (HUREC) cultures from one sibling and a control. Cultured cells where characterised and their response to therapeutic agents quantified.

**Conclusions:** Metformin therapy may slow progression to ESRD in ADPKD adults with type 2 diabetes compared to other antidiabetic drugs. Because metformin has an excellent safety record, a trial to slow the progression of ADPKD in the absence of diabetes is warranted.

**Funding:** NIDDK Support
Methods: Information about hospitalizations was prospectively collected in the HALT-PKD Studies, 2 multi-center trials involving people with ADPKD and GFR 60-ml/min (Study A) and GFR 25-60 ml/min (Study B). The primary diagnosis was designated after review of discharge summaries and independently adjudicated by a committee.

Results: Total patient years (ptyrs) of follow-up in the 558 Study A patients and 486 Study B patients were 23,142 and 21,806. The incidence rates (IR) of all-cause hospitalization, in Study A and B, respectively, was 67.7 and 123.3 per 1000 ptyrs, which compares to 80.3 and 118.0, in respective age-matched general populations (CDC/NHIS National Hospital Discharge Survey, 2010). The IRs in Study A and B, respectively, for cardiovascular-related hospitalization per 1000 ptyrs were 10.5 and 11.2. For ADPKD-related hospitalization (primary diagnosis kidney or liver cyst pain, infection or hemorrhage, pyelonephritis, kidney stones or cerebral aneurysm) were 12.7 and 26.7 per 1000 ptyrs. The most common primary diagnoses are listed in the table.

Conclusions: As compared with the respective age-matched general US populations, hospitalization rates were lower in ADPKD patients with GFR 60-ml/min and higher in patients with GFR 25-60 ml/min. PKD-related complications were more common than cardiovascular related diagnoses as the primary reason for hospitalization in both Study A and B.

SA-PO877

Effect of Statins on the Progression of Autosomal Dominant Polycystic Kidney Disease (the HALT PKD Investigators) Godela M. Brosnahan,1 Kaleab Z. Abebe,2 Frederic F. Rahbari-Oskoui,3 Charity G. Moore,4 Kyongtae Ty Baec,5 Robert W. Schrier,6 Jared J. Grantham.7,8 1Univ of Colorado; 2Univ of Pittsburgh; 3Emory Univ; 4Univ of Kansas.

Background: ADPKD is the most common hereditary disease resulting in end-stage renal failure (ESRD), without an approved treatment. In a small randomized trial comparing pravastatin for 3 years (n=55) against placebo, 50 ADPKD patients age 8-22 yr, the study group experienced a slower rate of renal enlargement. No large trial has tested the effect of statins in ADPKD adults.

Methods: We performed a secondary analysis of the HALT-PKD trials, categorizing participants into 3 groups based on statin use: 1) never users, 2) less than 3 y, and 3) at least 3 y of use. For subjects in Study A (n=558, age 15-49 y, eGFR > 60 ml/min/1.73 m2) we compared the percent change in height-adjusted total kidney volume (htTKV), in height-adjusted total liver volume (htTLV) and the rate of decline in eGFR between the 3 statin use groups. For participants in Study B (n=486, age 18-64 y, eGFR 25-60 ml/min/1.73 m2) we compared time to composite endpoint of death, ESRD or 50% decline in eGFR.

Results: In HALT Study A only 59 subjects used statins for > 3y and 37 for < 3y. There was no difference in the rate of annual htTKV increase (6.41%, 7.11%, 5.97%; p=NS) or htTLV growth (1.02%, 1.15%, 0.65%; p<NS) between the 3 groups, after controlling for sex, age, and treatment arms. The rate of eGFR decline was faster in group 2 (4.07 ml/min/yr) than in groups 1 and 3 (2.93 and 2.82 ml/min/yr; p=0.015), after adjusting for the more favorable baseline characteristics of group 1 (more females, younger age, higher baseline eGFR).

In Study B 118 subjects used statins for > 3y and 76 for 3y. There was no difference in time to endpoint between the 3 groups.

Conclusions: In this secondary analysis of the HALT-PKD trials, statin therapy for 3 years did not slow the rate of renal or liver enlargement or of eGFR decline in ADPKD adults, but these results are limited by the small numbers of statin users in Study A, different statin drugs and doses, and non-randomized allocation to groups.

SA-PO878

Assessment of a Dosage-Sensitive Mutational Network for PKD in a Large Cohort of Patients with Early and Severe Forms of Polycystic Kidney Disease Carmen Bergmann,1,2 John Devane,3 Steffen Neuber,4 Eva Decker,4 Uyen Tran,4 Oliver Wessely,3 Elisabeth B. Ott. 1Center for Human Genetics, Bioscientia, Ingelheim, Germany; 2Renal Div, Univ Hospital, Freiburg, Germany; 3Cellular & Molecular Medicine, Cleveland Clinic.

Background: ADPKD patients with early and severe disease manifestations only make up a minor proportion, but are crucial for a better understanding of PKD. Affected families have a high recurrence risk for babies with a severe clinical course often resulting in perinatal death. Especially in prenatal cases the diagnostic distinction between different forms of PKD and other ciliopathies can be difficult and illustrates the need for more comprehensive genetic testing.

Methods: An accurate genetic diagnosis is crucial for genetic counselling, prenatal diagnostics and the clinical management of patients. To this end, we established a sequence capture based NGS approach targeting 95 genes for cystic and polycystic kidney disease. This includes PKD1, which - due to the presence of pseudogenes - is difficult to test. As an additional advantage over conventional Sanger sequencing we were able to detect copy number variations. The biological significance of some of the detected alleles were subsequently tested in vitro and in vivo studies using a range of animal models including zebrafish, Xenopus and mice to validate some of our findings in terms of a functionally proven dosage-sensitive network.

Conclusions: This study is the most comprehensive analysis performed so far and points towards a general and underestimated concept for the modification of disease gene expression.

SA-PO879

Determinants of Progression in Early Autosomal Dominant Polycystic Kidney Disease - Is It Blood Pressure or Renin-Angiotensin-System Blockade? The HALT PKD Trial Godela M. Brosnahan,1 Kaleab Z. Abebe,2 Charity G. Moore,3 Theodore I. Steinman,4 Frederic F. Rahbari-Oskoui,5 Susan Spillanc,6 Kyongtae Ty Baec,5 Robert W. Schrier.7 1Univ of Colorado; 2Univ of Pittsburgh; 3Beth Israel Deaconess; 4Emory Univ. Medical Center.

Background: The HALT PKD Study A (558 subjects age 15-49 years, eGFR > 60 ml/min/1.73 m2) showed that intensive control of systolic blood pressure (SBP) to 95-110 mmHg was associated with a slower rate of kidney volume growth compared to standard control (SBP 120-130 mmHg). It is unclear whether this result was due to lower BP per se or to greater blockade of the renin-angiotensin-aldosterone system (RAAS) by allowing higher drug doses in the low BP group.

Methods: In this secondary analysis of HALT PKD Study A categorizing participants into 3 groups based on losartan (L) and telmisartan (T) dosage at 4 months, after initial dose titration: 1) high, defined as ≤ 140 mg + T 80 mg daily, 2) middle (everyone not high or low) and 3) low, defined as ≤ 120 mg + T < 80 mg daily. We compared the percent change in height-adjusted total kidney volume (htTKV) and the rate of eGFR decline between the 3 groups during follow-up for 5-8 years.

Results: Participants in the high dose group (n=51) were more likely male and assigned to the low BP arm; they had higher baseline BP and lower eGFR at 4 months than subjects in the mid- (n=272) and low-dose (n=165) groups. After adjustment for age, sex, genotype, target BP (low or standard), and eGFR at 4 months, there was no significant difference in the rate of kidney growth (5.63, 6.40 and 5.83% yr) or eGFR decline (3.00, 2.94 and 3.29 ml/min/1.73 m2) between the low, middle and high dosage groups.

Conclusions: In this secondary analysis of HALT Study A in young ADPKD adults, a higher dosage of RAAS blocking drugs was not associated with a slower rate of htTKV growth or of eGFR decline, after adjustment for allocation to intensive BP control. Low BP appears to be the main determinant for reducing kidney volume growth.

The Short Term Effect of Tolvaptan for CKD Stage4 Autosomal Dominant Polycystic Kidney Disease Haruna Kawano,1,2 Satoru Muto,1,2 Shigeto Horie.1,2 1Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; 2Urology, Teikyo Univ, Tokyo, Japan; 3Endowed Course for the Study of Polycystic Kidney Disease, Juntendo Univ Graduate School of Medicine, Tokyo, Japan.

Background: In Japan, the treatment of tolvaptan, a V2 receptor antagonist, started from March 2014. Indication criteria of tolvaptan for ADPKD treatment in Japan is adult patient with more than 750ml total kidney volume (TKV) and more than about 5%year increasing rate of TKV. It is contradiction to use tolvaptan for patients with eGFR<15ml/min/1.73m². It is recommended to reduce dose of tolvaptan for patients with CCR<30ml/min. However, the treatment effect for patients with CKD stage 4 is still unknown. So, we evaluated the short time efficacy of tolvaptan treatment for patients with CKD stage 4.

Methods: Thirteen patients (5 females and 8 males, mean age; 52.5 years) with ADPKD who started tolvaptan at our hospitals from April 2014 to April 2015 were analyzed in this study. Although our standard starting dose of tolvaptan for patients with good renal function is 60mg/day, we administered 15mg/day for patients with eGFR<25ml/min/1.73m² patients. Patients were measured eGFR and TKV at the commencement of treatment and at 1.5 and 6 months later.

Results: The baseline median eGFR and TKV were 21.8 ml/min/1.73m² (range; 17.1-28.9) and 2810ml (range; 1031-5847), respectively. The change of median eGFR from baseline at 1.5 months and at 6 months were -0.36 ml/min/1.73m² (p=0.39) and -1.80 ml/min/1.73m² (p=0.04), respectively. The change of median TKV from baseline at 1.5 months and at 6 months were -132ml (p=0.39) and +12ml (p=0.93), respectively. One female patient and one male patient temporarily stopped their treatment at 3 months and at 6months because of their eGFR decreased to lower than 15 ml/min/1.73m². Hepatic toxicity, hypernatremia, and the other severe adverse events were not detected.

Conclusions: No severe adverse events were occurred and 85% of CKD stage4 patients could keep treatment for 6 months without CKD progression. Tolvaptan was safe and tolerable for ADPKD patients with CKD stage 4 in lower dose.

SA-PO881
Estimation of Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease Edwin M. Spithoven,1 Maatje D.A. van Gastel,1 A. Lianne Escobar,2 Katharina Hopp,3 Cynthia J. Sieben,4 Peter C. Harris,5 S.L. Yu,6 Jareed L. Grantham,7 Arlene B. Chapman,1 Jared J. Grantham,1 Kyongtae L. Oskoui,8 Alan L. White,9 Thomas M. Bennett,4 Edwin M. Spithoven,1 Ron T. Gansevoort,1 1Internal Medicine, Nephrology, UMC Groningen; 2On behalf of the DIPAK Consortium, Netherlands.

Background: Measuring total kidney volume (TKV) in autosomal dominant polycystic kidney disease (ADPKD) by magnetic resonance image (MRI) and manual tracing is time consuming. Two alternative MRI methods have recently been proposed to estimate TKV (eTKV ELLIPSOID and eTKV PANK) which require less time.

Methods: ADPKD patients with a wide range of kidney function were included, if they had an approved T2 weighted MRI. A test set of 10 MRI was used for assessing reproducibility, 220 for cross-sectional analyses and 48 for longitudinal analyses with a follow-up of three years. mTKV was used to assess Irazabal risk categories, reclassification was calculated for eTKV ELLIPSOID and eTKV PANK. Measured TKV (mTKV) was manually traced, eTKV ELLIPSOID was calculated as advised in literature as π/6 * (length + width + depth)/2 * length * width * depth/1000 and eTKV PANK as midslice x number of slices covering the kidney x 0.624 or 0.657 for the left and right kidney, respectively.

Results: In the test set, intra- and inter-coefficients of variation were low: mTKV 1.8% and 2.3%, eTKV ELLIPSOID 3.9% and 6.3%, and eTKV PANK 3.0% and 3.4%. Duration of analyses were respectively 55, 5 and 15 minutes. In cross-sectional analyses baseline kidney volumes (liters) were 1.96 (1.28-2.92) for mTKV, 1.93 (1.25-2.82) for eTKV ELLIPSOID and 1.81 (1.17-2.62) for eTKV PANK. The latter both significantly different from mTKV (p<0.004 and p<0.001 respectively). Bias was low and precision high for repeated mTKV (0.2%±3.2%), eTKV ELLIPSOID (1.4%±9.2%) as well as eTKV PANK (4.6±7.6%). In longitudinal analyses, no significant differences were observed between percentage change in mTKV (16±7.1%) compared to change in eTKV ELLIPSOID (19±3.1%) and eTKV PANK (17.8±16.1%). Both methods resulted in limited reclassification in Irazabal risk categories; 6.7% for eTKV ELLIPSOID and 9.8% for eTKV PANK.

Conclusions: Both methods to estimate TKV perform relatively well compared to mTKV, and detect similar changes in TKV over time. Since eTKV ELLIPSOID requires less time than eTKV PANK, we suggest this method should be preferred in clinical care.

SA-PO882
Genetic Background Radically Alters Disease Progression in the Pkd1<sup>RC/RC</sup> Model Diana L. Escobar,1 Katharina Hopp, Cynthia J. Sieben, Peter C. Harris, Mayo Clinic, Rochester, MN.

Background: Studies in ADPKD patients and PKD mouse models have shown that genetic background influences the disease phenotype. Here, we evaluated the phenotype of the inbred homozygous Pkd1: p.R3277C (RC) model in three new backgrounds: BalbC, 129S6, and F1 (C57BL6 X BalbC) and compared them to C57BL6.

Methods: To characterize the cystic disease burden, Pkd1<sup>RC/RC</sup> animals were inbred into three different strains and aged to 3 months (m). At this time point %Kidney Weight/Body W, BUN levels, kidney cyst index were used to compare disease severity.

Results: At this early stage of cyst progression (3m) genetic background significantly affects the severity of the disease in the Pkd1<sup>RC/RC</sup> model with %KW/Body significantly higher in the BalbC (3.31) and 129S6 (3.12) backgrounds compared with F1 (1.92; P<0.001). C57BL6 was 1.74; both P<0.001). However, BUN levels did not deviate from the physiological norm at this early stage of the disease in any of the backgrounds. In respect to cyst index, 129S6 (21.87%) and BalbC (19.47%) animals had a greater disease burden compared to F1 (3.71%; both P<0.001) and C57BL6 (5.24%; both P<0.001) animals. No significant difference was found between 129S6 and BalbC mice (P=0.47). Histological analysis showed a distribution of various sized cysts in the medulla and cortex in BalbC and large cysts mainly in the medulla in 129S6, which contrasted with small cysts mainly in the cortex in F1 and C57BL6 (figure 1). Immunofluorescence at 3m in all backgrounds showed the majority of cyst had a collecting duct (CD) origin, however some cysts were negative for the nephron markers LTA-AQP1 (PT), AQP2-DBA (CD).

Conclusions: This study highlights the role of genetic background in cystic disease progression in the Pkd1<sup>RC/RC</sup> model. Due to the more rapid progression and severe cystic burden, the BalbC and 129S6 models may be more suitable for PKD pre-clinical testing.

Therapeutic Effects of the Fibrokinase Inhibitor ANG3070 in Polycystic Kidney Disease
Prakash Narayan, Liming Zhang, Bin Duan, Jingsong Li, Frederic F. Rahbari, Soo Ha, Oskoui, Jessay Gopuran Devassy, Md Monirujjaman, Tamio Mayo Clinic; 7National Insts of Health; 8Legacy Good Samaritan Hospital.

Background: Aberrant receptor tyrosine kinase signaling has been implicated in cyst expansion, renal interstitial fibrosis, increased kidney volume and reduced renal function in polycystic kidney disease (PKD). We investigated the effects of a novel, orally bioavailable, small molecule fibrokinase inhibitor, ANG3070, in experimental PKD.

Methods: Male PCK rats (PCK/CrljCrl-pkhd1pck/Crl) were randomized to vehicle or ANG3070 (25 mg/kg, BID, PO) at 6.5 weeks of age following confirmation of frank disease and sacrificed at 13.5 weeks. Age-matched male Sprague-Dawley rats served as wild-type controls.

Results: ANG3070 has no effect on mean arterial pressure. In PCK rats with diseased kidneys (figure1), randomization to ANG3070 treatment was therapeutic, reducing cystic index, renal interstitial fibrosis (hydroxyproline (HYP), albuminuria and other urine biomarkers of renal injury and serum creatinine (* p<0.05).

Conclusions: ANG3070 reduces renal cyst burden and renal interstitial fibrosis in PCK rats. This oral fibrokinase inhibitor is promising as a potential therapeutic agent in human polycystic kidney disease.

SA-PO886
Alterations in Renal Oxylipins in Models of Polycystic Kidney Disease: Potential for Cyclooxygenase Inhibition for Disease Treatment
Harold M. Aukema, Jessy Gopuran Devassy, Md Monirujjaman, Tamio Yamaguchi, Amir Ravandi. Human Nutritional Sciences, Univ of Manitoba, Winnipeg, MB, Canada; CCARM, St. Boniface Research Hospital Research Centre, Winnipeg, MB, Canada; Inst for Cardiovascular Sciences, St. Boniface Research Hospital Research Centre, Winnipeg, MB, Canada.

Background: The Han:SPRD-Cy rat and the pcy mouse, prostanoid forms via the cyclooxygenase (COX) pathway are elevated, while oxylipins produced via the lipoxigenase (LOX) and cytochrome P450 (CYP) pathways are reduced. Importantly, inhibiting the formation of the elevated COX oxylipins with selective (NS-398) or unselective (aspirin) COX inhibitors reduces the progression of disease in the Han:SPRD-Cy rat, suggesting their potential use in the treatment of nephronophthisis. It is not known, however, whether renal oxylipins are altered in orthologous models of human polycystic kidney disease (PKD).

Methods: Renal oxylipins were analyzed by LC/MS/MS.

Results: The elevated renal COX oxylipins in these PKD models are consistent with the cystic kidney disease models. This suggests that COX inhibition with common drugs such as aspirin or selective COX inhibitors may be beneficial in PKD, as it is in other models of cystic kidney diseases.

Conclusions: Funding: NIDDK Support

SA-PO887
Hepatorenal Fibrocystic Diseases in Children
Ruvin Park, Yo Han Ahn, Hee Gyung Kang, Hye Won Park, Il-Soo Ha, Jae Il Cheong. Dept of Pediatrics, Seoul National Univ Children’s Hospital, Seoul, Korea; Research Coordination Center for Rare Diseases, Seoul National Univ Hospital, Seoul, Korea; Dept of Pediatrics, Seoul National Univ Bundang Hospital, Seongnam, Korea.

Background: Hepatorenal fibrocystic diseases (HRFCDs) are a group of monogenic disorders characterized by developmental abnormalities involving the liver and kidney. In this study, we performed genotype and phenotype analyses of children with HRFCDs to determine the distribution of underlying disease.

Methods: A total of 36 children with HRFCDs were recruited, with genetic tests performed in 22 patients and 14 patients diagnosed clinically as having autosomal recessive polycystic kidney disease (ARPKD).

Results: In Mx1Cre Pkd1floxflox mice with disease, renal levels of the COX metabolites, prostaglandin (PG)E2 and 6-keto-PGF1α were elevated by 35 and 59%, respectively. In Pkd2−/− mice, 11β-PGE2, PGE2, PGF2α and 6-keto-PGF1α were elevated in diseased kidneys by 43, 49, 46, 67 and 136%, respectively. In the PCK rat model of ARPKD, PGE2 and 6-keto-PGF1α were elevated by 38 and 50%, respectively. In all three models, although not as consistent as the COX oxylipins changes, LOX and CYP oxylipins were generally lower, which is similar to findings in the Han:SPRD-Cy rat and pcy mouse.

Conclusions: The elevated renal COX oxylipins in these PKD models are consistent with other cystic kidney disease models. This suggests that COX inhibition with common drugs such as aspirin or selective COX inhibitors may be beneficial in PKD, as it is in other models of cystic kidney diseases.

SA-PO888
Extended Follow-Up of the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP III): The Predictive Value of Height Corrected Total Kidney Volume (hTKV) for the Future Development of CKD Stages 3a, 3b, 4 and 5 After Ten Years Follow-Up in Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Arlene B. Chapman, Chengli Shen, Alan S.L. Yu, Michal Murg, Frederic F. Rahbari-Oskou, Vicente E. Torres, Jared J. Grantham, Michael F. Flessner, Kyongtae Ty Bae, Doug Landsittel, Peter C. Harris, William M. Bennett, U of Chicago; U of Pittsburgh; U of Kansas; Univ of Alabama Birmingham; Emory Univ; Mayo Clinic; National Insts of Health; Legacy Good Samaritan Hospital.

Background: CRISP III is a longitudinal observational cohort study of 241 ADPKD individuals now extending beyond 10 years. Measures of cyst burden by magnetic resonance imaging (MRI) provide an accurate assessment through measures of htTKV. We have shown previously that baseline htTKV predicted CKD stage 3 after 8 years. We now evaluate whether baseline htTKV can predict CKD Stage 3a, 3b, 4 and 5 after 10 years of followup.

Methods: Participants underwent protocol visits including MR imaging, iothalamate clearances and serum creatinine measurements. Baseline htTKV was evaluated in its capacity to predict later CKD stages both individually and in a multivariable model that includes age, race, gender, and baseline iothalamate clearance. Receiver operator characteristic area under the curves (AUROC) were developed for reaching CKD stage 3a, 3b, 4 or 5 after a minimum of 10 years of followup.

Results: At 10 years, 59.8%, 32.1% and 21.6% of patients had reached CKD stage 3, 4 or 5. Baseline htTKV alone predicts CKD stage 3 in 10 years with a ROC of 0.85 and an optimal TKV cut point of 470 ml/m2. Multivariable analysis assessing future CKD Stage 3a, 3b, 4 and 5 at 10 years demonstrated a ROC of 0.89, 0.87, 0.90, and 0.89 respectively.

Conclusions: HTKV is a powerful predictor of the development of all advanced stages of CKD within 10 years with an optimal htTKV of 470 ml/m2 for CKD Stage 3.

Diagnostic and Therapeutic Advances in PKD
Poster/Saturday
Identifying Genetic Modifiers in Severe Polycystic Liver Disease (PLD) by Whole Exome Sequencing (WES) 

Gema Ariceta, Carsten Young, William C. Nahas, Luiz F. Onuchic. 1

Background: PLD (sPLD) is a rare and poorly understood phenotype seen in ADPKD and ADPLD. Mutations of POLR2A or SEC63 in ADPLD reduce functional polycystin-1 dosage by decreasing endoplasmic reticulum (ER) protein-processing and aggravates cystic disease severity in vivo (Nait Genet 43: 639-647, 2011). We hypothesize that rare mutations in ER pathway genes may modify PLD.

Methods: We performed WES using Illumina HiSeq2000/2500 with SSV4/5 capture kit in 88 patients (24 affected discordant sib-pairs and 7 affected concordant sib-pairs for sPLD and 27 sporadic cases). All sPLD patients had a liver span >25 cm by CT/MRI or >5x normal liver volume. In addition to genome-wide analysis, we performed focused analysis on 168 ER genes. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare deleterious variants of high and moderate impact as predicted by PolyPhen-2, Sift, Mutation Assessor, Mammalian and Vertebrate nucleotide-level conservation, and Combined Annotation Dependent Depletion.

Results: Overall, we achieved a mean target coverage of 108X with 90% of targeted exomes having >30X read depth. We identified 4,696 rare deleterious variants that segregated with PLD disease severity in at least one family. From them, we found 7 non ER genes (TNN, DNAH10, DNAH14, HMCN2, NEB, OBSCN and ADAMTS28) with rare variants that segregate in 4 to 6 families each and 8 ER genes (WFS1, SEC63, SEC61Q, T, ATPLF, DNAH5, DNAI1, and DNAI3) with rare variants that segregate in at least one family and 3-4 sporadic sPLD cases.

Conclusions: Our results suggest extensive genetic heterogeneity with no single gene accounting for a large proportion of sPLD cases. Future studies with expanded sample size will help to identify promising candidate genes for follow-up functional studies. Identification of genetic modifiers of sPLD has the potential to improve risk prediction and treatment of this unusual complication.

TOSCA – Tuberous Sclerosis Registry to Increase Disease Awareness: Renal Manifestations of Tuberous Sclerosis Complex

John C. Kingswood, Anna C. Jensen, 1

Sussex Kidney Unit, Royal Sussex County Hospital, Brighton, United Kingdom; 2Pediatric Neurology Unit, UZ Brussel, Brussels, Belgium.

Background: Renal manifestations are the most common cause of morbidity and mortality in adult patients with tuberous sclerosis complex (TSC). The aim of the Tuberous Sclerosis Registry to increase disease Awareness (TOSCA) is to understand the various manifestations of TSC. The baseline data of renal manifestations in the overall TOSCA cohort are presented here.

Methods: Patients diagnosed with TSC were enrolled in TOSCA from 170 sites across 31 countries worldwide. Patients will be followed up for 5 up to 5 years with interim analysis performed every year.

Results: Baseline core data from 2093 patients were entered in the registry as of September 30, 2014 (cut-off date for the 2nd interim analysis). Median age at consent was 13 years (range: 0.5 – 89.5 years). 578 renal anomalies were reported in 987 (47.2%) patients. Median age at diagnosis of angiomyolipoma was 13 years (0-67). Of the 946 (95.8%) patients with ongoing renal angiomyolipomas, 396 (41.9%) had multiple and bilateral lesions, 329 (34.8%) had lesions > 3 cm, and 204 (21.6%) had growing lesions. Symptoms/signs associated with renal angiomyolipomas were reported either individually or in combination with others, were elevated blood pressure (48 [5.1%]), microscopic hematuria (35 [3.7%]), hemorrhage (47 [5.0%]), impaired renal function (36 [3.8%]), and pain (51 [5.4%]). Renal angiomyolipomas were treated in 274 (27.8%) patients; major treatment modalities included embolization in 98 (35.8%) and mammalian target of rapamycin (mTOR) inhibitors in 78 (28.5%) patients. Other renal features reported were renal malignancy (24 [1.1%]), renal cysts (477 [22.8%]), polycystic kidneys (73 [3.5%]), and impaired renal function (43 [2.1%]).

Conclusions: The prevalence of renal angiomyolipomas of 47.2% in our cohort compares with 30-85% in the literature probably reflects their young mean age. Despite this the intervention rate was high, emphasizing the need for active surveillance. This is the largest cohort of patients with TSC ever reported, thus TOSCA is a powerful tool to delineate the natural history of TSC.

Background: Autosomal recessive polycystic kidney disease (ARPKD) is the rare form of polycystic kidney disease presenting in early childhood. There is unexplained phenotypic heterogeneity. Current therapeutic approaches continue to be largely opinion-based and symptomatic.

Methods: ARegPKD is an international, mostly European, pro- and retrospective, observational study in both pediatric and adult ARPKD patients to generate a deeply-characterized ARPKD cohort. Using web-based questionnaires regarding patients’ clinical data in combination with associated biobanking and reference histology ARegPKD will characterize long-term ARPKD courses and set roots for future translational research.

Results: In June 2015 63 centers have registered and more than 130 patients have been included (67.6 % male; mean age at inclusion 7.6 ±2.4 years; number of follow-up visits up to 17). Here we present data on general patient characteristics, genetics, testing, renal and hepatic phenotype putting a special focus on the peri- and postnatal period (perinatal findings, ventilation modalities, sonographical findings, laboratory values).

Conclusions: ARegPKD aims to deeply characterize ARPKD patients in order to provide evidence base for clinical treatment decisions and contribute to the understanding of this severe renal disorder of early childhood.

The Effect of Sodium Nitrite on Central and Peripheral Hemodynamics, Vasoactive Hormones, GFR and Sodium Excretion in Healthy Subjects

Jeppe B. Hansen, Aasleiv Nielsen, Matthias H. Christensen, Frank H. Mose, Erling B. Pedersen, Jesper N. Bech. Univ Clinic in Nephrology and Hypertension, Holstebro Hospital and Aarhus Univ, Denmark.

Background: Recent research has shown that sodium nitrite is readily converted to nitric oxide (NO) by enzymes in vivo and exerts vasodilatory effects. Previous studies based on nitric oxide synthase inhibition indicates a natriuretic effect of nitrite. The purpose of the present study was to examine the effects of sodium nitrite on central and peripheral blood pressure, heart rate, fractional sodium excretion and GFR.

Methods: In a single blinded, placebo controlled dose-response study 12 healthy subjects were treated, in a randomized order, with placebo (isotonic NaCl) or one of three doses of sodium nitrite 40, 120 or 240 mg/kg/hour for two hours. Each examination was preceded by 4 days standardized diet. Subjects were supine and water loaded throughout the day. Before, during and after sodium nitrite administration we measured diastolic, systolic and mean arterial blood pressure (DBP, SBP and MAP), heart rate, plasma renin, angiotensin II and aldosterone, GFR by creatinine-creatinine clearance, fractional sodium excretion and urinary excretion rate of nitrite and nitrate (NOx).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
SA-PO093
The Spatial Distribution of Metabolites Determined by Imaging Mass Spectrometry in the Kidneys of Rats Treated with Furosemide

Background: In the kidney, metabolic processes vary among the cortex (COR), outer medulla (OM), and inner medulla (IM), and the concentrations of metabolites are different according to the kidney zones. We aimed to examine the regional differences of the significantly changed metabolites in the kidneys of rats treated with loop diuretics by exploiting the matrix-assisted laser desorption/ionization (MALDI) and imaging mass spectrometry (IMS).

Methods: Omnipine minipumps were implanted in male Sprague-Dawley rats to deliver 12 mg/day of furosemide (s.c.). Vehicle-treated control rats (n = 15) and furosemide-treated rats (furosemide rats, n = 15) were maintained in metabolic cages for 6 d on a fixed daily dose, 0.24% (±0.2) by the intermediate dose and 0.32% (0.06;0.59) by the highest dose compared to placebo. The highest dose of sodium nitrate reduced SBP by 4.5 mmHg (0.5,8.5), DBP by 3.8 mmHg (0.6,6.7), MAP by 4.0 mmHg (1.2,6.8) and increased Pr-creatinin concentration by 17.6% (2.3,32.2), P-angiotensin II by 21.8% (4.6,38.9) and urinary creatinine excretion rate by 95% (59,132) compared to placebo. There was no effect on heart rate, GFR or aldosterone

Conclusions: In supine, water loaded subjects a two hour infusion of 240 mg/kg/hour sodium nitrite exerts an antinatriuretic and BP lowering effect. The rise in urinary excretion rate of NOx suggests an increased bioavailability. The activation of the renin-angiotensin-aldosterone system (RAAS) could either be mediated directly by nitrite/NO or by baroreceptor reflex. The antinatriuretic effect might, at least partially, be mediated by the RAAS.

Bicarbonate Supplementation Improves Vascular Function in Patients with Chronic Kidney Disease: A Pilot Study

Background: Metabolic acidosis, as reflected by a low serum bicarbonate level, is associated with increased risks of endothelial dysfunction, hypertension and death. Metabolic acidosis induces inflammation and endothelin-1, both of which contribute to vascular dysfunction. Whether alkali therapy improves vascular function in patients with chronic kidney disease (CKD) is unknown.

Methods: Seven subjects (5 men and 2 women) with stage III/IV CKD and serum bicarbonate level of less than 21 mmol/L. A total of 1500 mg of sodium bicarbonate (8.3mEq) was added to three meals per day for goal serum bicarbonate of ≥ 23 mEq/L.

Results: Fractional sodium excretion were reduced by 0.25% 95%CI (0.02;0.47) by the lowest dose, 0.24% (±0.12;0.59) by the intermediate dose and 0.32% (0.06;0.59) by the highest dose compared to placebo. The highest dose of sodium nitrate reduced SBP by 4.5 mmHg (0.5,8.5), DBP by 3.8 mmHg (0.6,6.7), MAP by 4.0 mmHg (1.2,6.8) and increased Pr-creatinin concentration by 17.6% (2.3,32.2), P-angiotensin II by 21.8% (4.6,38.9) and urinary creatinine excretion rate by 95% (59,132) compared to placebo. There was no effect on heart rate, GFR or aldosterone

Conclusions: In supine, water loaded subjects a two hour infusion of 240 mg/kg/hour sodium nitrite exerts an antinatriuretic and BP lowering effect. The rise in urinary excretion rate of NOx suggests an increased bioavailability. The activation of the renin-angiotensin-aldosterone system (RAAS) could either be mediated directly by nitrite/NO or by baroreceptor reflex. The antinatriuretic effect might, at least partially, be mediated by the RAAS.

SA-PO095
Tenofovir-Related Distal Tubular Disorders in HIV Infected Patients

Background: Tenofovir disoproxil fumarate (TDF) is a nucleoside reverse transcriptase inhibitor extensively used worldwide and is now the most prescribed drug on Highly Active Antiretroviral Therapy (HAART). TDF toxicity is mainly targeted at the proximal tubule, and less often, the distal tubule. TDF toxicity may cause Fanconi Syndrome or acute kidney injury. Despite this, there are no studies evaluating other types of tubular toxicity. This study evaluated the presence of distal renal tubular acidosis (dRTA) in HIV patients on HAART.

Methods: Sixty one HIV patients older than 18 years on treatment with HAART for more than 12 months and GFR estimated by CKD-EPI equation greater than 45 ml/min/1.73m2 were evaluated. They were divided into two groups: 31 used HAART that included TDF and 30 used HAART with no current or previous use of TDF. They were submitted to fluid restriction for 12 hours and received 40mg of furosemide and 0.1mg of dDAVP subcutaneously, following a 1-hour test procedure previously described by Alkhouri et al (2007). We measured serum bicarbonate and the following parameters: hourly urine pH (4h) by potentiometry, urinary ammonium (uNH4+) by spectrophotometry and urinary titratable acidity (uTA) by NaOH (0h and 4h). The diagnosis of dRTA was established when the urinary pH was higher than 5.3 in all measurements.

Results: There was no significant difference between the groups in terms of age, gender, ethnicity, CD4 count or cGFR. The prevalence of dRTA was 6% in the group without TDF and 26% in TDF group (p<0.04). In both groups, patients without dRTA showed increase in uNH4+ (p=0.05 and p=0.009, respectively) and in uTA (p=0.06 and p=0.05, respectively), unlike patients with dRTA, who did not show increase neither in uNH4+ (p=0.44 and p=0.34, respectively) nor in uTA (p=0.52 and p=0.11, respectively). In all cases with dRTA, the serum bicarbonate was normal, featuring an incomplete presentation.

Conclusions: The prevalence of incomplete dRTA in patients using TDF was significantly higher than the group not using the drug. This is the first study suggesting a possible association between TDF and dRTA. Subsequent studies will be necessary to corroborate this hypothesis.

SA-PO096
Comparison of Acid-Base Disorder Between Patients Undergoing Ileal Neobladder and Ileal Conduit

Background: Since the 1980s, the orthotopic ileal neobladder(INB) has been as an new option by eliminating the need for a cutaneous stoma and urinary diversion appliances of ileal conduit(IC). Although this method has improved patients’ quality of life, frequent incidence of metabolic acidosis(MA) have been reported. We compared occurrence of MA in INB group to IC group, and searched for risk factors affecting MA.

Methods: We conducted a retrospective study in 95 patients who underwent radical cystectomy and urinary diversion from January 2001 to December 2014 at Hallym University Medical Center. Patients who have any illness such as severe pulmonary disorder, take any medication that could lead to MA and sepsis were excluded. Acid-base balance and renal function were measured at first hospital stay. Serum bicarbonate and the following parameters: hourly urinary pH (0h to 4h) were measured serum bicarbonate and the following parameters: hourly urinary pH (0h to 4h) were measured serum bicarbonate and the following parameters: hourly urinary pH (0h to 4h)

Results: MA was detected in 74.2% and 69.7% within 7 days(p=0.64), and in 31% and 14.8% at 1 month(p=0.1) after operation in INB and IC group. But cases on bicarbonate therapy were significantly more in INB group(p<0.02). Serum HC03 levels(p=0.05) and base excess(p=0.02) were significantly lower in INB group in spite of more cases on bicarbonate therapy. Acute kidney injury(AKI) at 1 month was higher in INB group(p<0.008). Serum creatinine concentrations were significantly correlated with bicarbonate levels. Multivariate logistic analysis showed that 1 mg/dl increase of serum creatinine level result in a 5.38-fold higher risk of MA (95% confidence interval, 1.14-25.3; P = 0.03). Patients without AKI, MA was detected in 13.5% in INB group, 12% in IC group at 1 month(p<1.0).

Conclusions: Despite there being no statistical difference, INB group may more easily develop MA compared with IC group especially in patients with elevated serum creatinine concentrations. In addition, a close association between the serum creatinine level and the degree of MA was observed in both groups.

Screening for Hyperlactatemia: Relationship Between the Anion Gap and Serum Lactate in Hypovolemic Shock

Background: In lactic acidosis (LA), a discrepancy between the increase in serum anion gap (AG) and serum lactate concentration has been noted. Previous studies evaluated patients in the Intensive Care Unit with established LA. No study has examined the relationship between AG and serum lactate within the first hour of the development of LA, specifically the sensitivity and specificity of an elevated AG for predicting hyperlactemia.

Methods: We conducted a retrospective study in 95 patients who underwent radical cystectomy and urinary diversion from January 2001 to December 2014 at Hallym University Medical Center. Patients who have any illness such as severe pulmonary disorder, take any medication that could lead to MA and sepsis were excluded. Acid-base balance and renal function were measured at first hospital stay. Serum bicarbonate and the following parameters: hourly urinary pH (0h to 4h) were measured serum bicarbonate and the following parameters: hourly urinary pH (0h to 4h)

Results: MA was detected in 74.2% and 69.7% within 7 days(p=0.64), and in 31% and 14.8% at 1 month(p=0.1) after operation in INB and IC group. But cases on bicarbonate therapy were significantly more in INB group(p<0.02). Serum HC03 levels(p=0.05) and base excess(p=0.02) were significantly lower in INB group in spite of more cases on bicarbonate therapy. Acute kidney injury(AKI) at 1 month was higher in INB group(p<0.008). Serum creatinine concentrations were significantly correlated with bicarbonate levels. Multivariate logistic analysis showed that 1 mg/dl increase of serum creatinine level result in a 5.38-fold higher risk of MA (95% confidence interval, 1.14-25.3; P = 0.03). Patients without AKI, MA was detected in 13.5% in INB group, 12% in IC group at 1 month(p<1.0).

Conclusions: Despite there being no statistical difference, INB group may more easily develop MA compared with IC group especially in patients with elevated serum creatinine concentrations. In addition, a close association between the serum creatinine level and the degree of MA was observed in both groups.

Methods: Data were obtained prospectively from adult trauma patients at a single level 1 trauma center. Venous samples were drawn prior to initiation of intravenous fluid resuscitation.

Results: 117 patients with elevated serum lactate levels (>2.1 mmol/L) were included. The sensitivity of an elevated AG (≥ 10) to reveal hyperlactatemia was only 43% whereas specificity was 84%. Sensitivity improved if the upper limit of normal AG was lowered and with increasing levels of serum lactate. (Table 1). The correlation between the AG and serum lactate level yielded an R² of 0.30 (p < 0.001) and the slope of this relationship was 0.29 ± 0.58 (95% confidence interval 0.23–0.35).

Conclusions: Within the first hour of the development of LA due to hypovolemic shock, the AG was not a sensitive indicator of an elevated serum lactate level, but it was fairly specific. The sensitivity and specificity of the AG as an indicator of hyperlactatemia is consistent with prior studies examining later stages of LA. The AG increased to a greater extent than the serum lactate and approximately 70% of the change in AG could not be explained by increases in serum lactate. Our results suggest that other anions contribute to the AG in LA.

SA-PO899

The Δ Anion Gap/Δ Bicarbonate Ratio in Early Lactic Acidosis: Time for Another Delta?

Background: The ratio of Δ anion gap and Δ bicarbonate (ΔAG/ΔHCO₃⁻) is used to detect co-existing acid-base disorders in patients with high AG metabolic acidosis. Classic teaching holds that in lactic acidosis (LA), the ΔAG/ΔHCO₃⁻ is 1:1 within the first 60 minutes of onset (despite limited human data) and subsequently rises to 1.8:1. This study examined the ΔAG/ΔHCO₃⁻ for all patients with elevated serum lactate levels (>2.1 mM) with a mean AG of 7.1, the value used to calculate subsequent ΔAG values. ΔAG/ΔHCO₃⁻ was calculated for 45 patients who had elevated serum lactate levels (>2.1 mM). The mean ΔAG/ΔHCO₃⁻ for all patients with elevated serum lactate levels was 1.36 (SD 1.40). The correlation between ΔHCO₃⁻ and AG showed a 95% prediction interval of ±6.15 (Figure 1).

Figure 1: Correlation between ΔHCO₃⁻ and ΔAG

Conclusions: The mean ΔAG/ΔHCO₃⁻ was 1.86 within the first hour of the development of LA due to hypovolemic shock, confirming a small prior human study. This contradicts the traditional belief that in LA the ΔAG/ΔHCO₃⁻ is 1:1 within the first 60 minutes. The classic 1:1 stoichiometry is based on animal models (in which lactic acid is infused into the extracellular [EC] space, facilitating EC buffering of protons by bicarbonate), while our results demonstrate a higher initial ΔAG/ΔHCO₃⁻ ratio in early endogenous LA in humans (which originates intracellularly, resulting in intracellular buffering of protons while lactate is predominantly distributed in the EC fluid). The wide 95% prediction interval suggests that ΔAG/ΔHCO₃⁻ should be used cautiously in the diagnosis of mixed acid-base disorders.

SA-PO900

Blood Lactate as a Predictor for Mortality in Sepsis Patients with Lactic Acidosis Treated Sodium Bicarbonate: A Retrospective Analysis

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 109 sepsis patients with lactic acidosis treated with sodium bicarbonate.

Results: Among the 230 patients with lactic acidosis treated with sodium bicarbonate, we finally included 109 patients (47.4%) with lactic acidosis caused by sepsis. The non-survivors had lower albumin levels (P=0.009), higher SOFA and APACHE II scores (P=0.002, P=0.047, respectively), and higher blood lactate level at 6 hours, 24 hours, and 48 hours after checking the initial lactate level (P=0.002, P=0.001, P=0.001, respectively). In particular, decrement of at least 10% in lactate clearance for the first 6 hours, 24 hours, and 48 hours of treatment were more dominant in non-survivors than survivors. Lactate clearance at 6 hours, 24 hours, and 48 hours was significantly associated with mortality after adjustment for confounding variables, including age, gender, CRP, albumin, SOFA and APACHE II scores, ventilator care, CRRT, and use of inotropic (HR: 2.201, 95% CI: 1.197–4.046, P=0.011; HR: 3.948, 95% CI: 1.269–12.281, P=0.018; HR: 4.970, 95% CI: 1.679–14.710, P=0.004, respectively).

Conclusions: Serial blood lactate levels monitoring is useful in terms of predicting mortality, which is consistent with prior studies examining later stages of LA.

SA-PO901

D-Lactate: It’s All in the Gut

Background: D-Lactic acidosis is a rare form of lactic acidosis that can occur in patients with short bowel syndrome.

Methods: 88 yo M with PMH significant for HTN and small bowel obstruction s/p subtotal small bowel resection presented to the ED with complaints of nausea, vomiting, constipation, loss of appetite, altered mental status and decreased urinary output.

On admission:

- Vitals: Blood pressure: 115/68 mmHg, Pulse: 80/min, Temperature: 98.5 F and SpO₂: 92%
- Examination: Distended abdomen with no peripheral edema.
- Imaging: CT abdomen revealed dilated bowel loops but no bowel obstruction or free air in the abdomen/pelvis.

Labs: Na: 134mmol/L, K: 4.5mmol/L, Cl: 108mmol/L, CO₂: 16mmol/L, BUN: 45mg/dL, Creatine: 1.6mg/dL and Albumin 2.3g/dL. ABGs: pH: 7.42, pCO₂: 31mmHg, HCO₃⁻: 19mEq/L. He was found to have anion gap metabolic acidosis with a non-metabolizable gap metabolic acidosis. Venous lactate: 1.11 mmol/L (Normal 0.5-2.2 mmol/L). Serum D-lactate was drawn revealing an elevation at 4.15mmol/L – thus confirming the diagnosis of D-lactic acidosis.

Treatment: Patient received IV fluids with bicarb. PO Flagyl was started and constipation was also treated. He had a normal mental status along with his acidosis subsequently improved. Diagnoses of anion gap metabolic acidosis in the setting of D-Lactic acidosis was made due to bacterial over growth because of his past history of small bowel resection.

Conclusions: The diagnosis of D-lactic acidosis should be promptly considered in patients with malabsorptive disorder such as short bowel syndrome or following a jejunocolic bypass especially when no other cause of anion gap metabolic acidosis is found. Diagnosis is confirmed by a special enzymatic test measuring serum D-Lactate. Treatment involves a low carbohydrate diet, sodium bicarbonate infusion to correct acidemia and antibiotics to minimize D-lactate producing bacteria.

Methods: Theoretical modeling has been performed using Mathematica software to determine equilibrium ion concentrations in mixed strong-weak base solutions. If these solutions have a significant proportion of strong base yet lower concentration, they are predicted to raise blood pH without generating CO₂ or producing large osmotic stress. Strong bases examined include disodium carbonate (Na₂CO₃) and sodium hydroxide (NaOH); these were mixed with NaHCO₃. Acid-base parameters were measured in acidified canine blood mixed with the base solutions in a closed system using a blood gas analyzer. Treated blood was examined using an optical microscope.

Results: A near-isotonic base solution containing Na₂CO₃;NaHCO₃, at a ratio of 3:1 is predicted to raise blood pH without increasing CO₂ or causing osmotic stress. Addition of this base to acidified blood raised blood pH while reducing CO₂. By contrast, NaHCO₃ raised blood pH, but also generated CO₂. Examination of red blood cells exposed to the former solution revealed no evidence of osmotic stress. Mixed base solutions of NaOH and NaHCO₃ are also promising as a lower sodium alternative.

Conclusions: Mixed strong-weak base solutions, rather than hyper tonic NaHCO₃, can raise blood pH and serum bicarbonate levels, minimize osmotic stress, and limit CO₂ generation. A 3:1 mixture of Na₂CO₃;NaHCO₃ well below 1 M concentration appears to be effective in this regard.

SA-PO902
Chloride Alterations in Hospitalized Patients: Prevalence and Outcome Significance Qi Oian, Charat Thongprayoon, Wisit Cheungpasitporn. Medicine/ Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Background: Chloride (Cl⁻) plays a fundamental role in the maintenance of serum osmotic pressure, acid-base balance, and cellular health. Cl⁻ channels are expressed in almost all cells in the body. Dysfunctions in the Cl⁻ channel result in a broad spectrum of diseases. Cl⁻ alterations in hospitalized patients have not been comprehensively studied in recent years.

Methods: We conducted a retrospective study of adult (≥18 years old) hospital admissions at Mayo Clinic over a period of three years (2011 to 2013). Patients without admission Cl⁻ measurement were excluded. Outcome measures included all-cause mortality, length of hospital stay and discharge disposition.

Results: 76,719 unique patients from a total of 147,358 hospital admissions were enrolled. 55,523 (72.4%) had repeat Cl⁻ measurements within 48 hours. Admission serum Cl⁻ (£24 hr of admission) were excluded. Outcome measures included all-cause mortality, length of hospital stay and discharge disposition.

Conclusions: Mixed strong-weak base solutions, rather than hyper tonic NaHCO₃, can raise blood pH and serum bicarbonate levels, minimize osmotic stress, and limit CO₂ generation. A 3:1 mixture of Na₂CO₃;NaHCO₃ well below 1 M concentration appears to be effective in this regard.

SA-PO903
A Retrospective Review of Paediatric Patients with Bartter and Gitelman Syndrome Patrick Walsh, Marc Bienias, Detlef Bockenhauer. ICH, UCL, London, United Kingdom.

Background: Bartter and Gitelman syndrome are rare autosomal recessive disorders of renal salt handling. They are characterized by disturbed electrolyte and acid-base homeostasis with potentially severe complications. Currently little is known about the long-term disease course and best treatment is controversial. We performed a retrospective case review to investigate the long-term disease course of patients with a diagnosis of Bartter/Gitelman syndrome.

Methods: Demographic and Laboratory data was recorded at presentation, and ages 1,2,3,4,5,10 and 15.

Results: 42 patients with a genetic diagnosis of Bartter/Gitelman were reviewed with a median follow up of 7.85 years (Range 0 -18 Years).

Conclusions: The overall prognosis during childhood was good. Final heights were within the normal range and no child developed ESRD. Albuninuria was common in Bartter 3, indicating the need for long-term monitoring of renal function. Interestingly, hypomagnesemia is often absent at presentation and develops over time in both Bartter 3 and Gitelman.

SA-PO904
Urinary Calcium to Magnesium Ratio Aids to Diagnose Gitelman’s Syndrome without Hypocalciuria and Receiving Intraavenous Magnesium Administration Chih-Jen Cheng,1,2,3 Shih-Hua P. Lin,1,2 Ming-Tso Yan,1,2 1Tri-Service General Hospital; 2National Defense Medical Center; 3Cathay General Hospital.

Background: Although hypocalciuria is widely used to distinguish Gitelman’s syndrome (GS) from Bartter syndrome (BS), several patients with GS actually have not hypocalciuria and may be clinically misdiagnosed as BS. Intraavenous magnesium administration to correct hypocalciurna, another distinct finding in GS can significantly enhance urine calcium excretion and unmask the preexisting hypocalciuria. Because renal Mg²⁺ wasting is characteristic in GS, we hypothesize that urine Ca²⁺/Mg²⁺ ratio may be superior in diagnosing GS.

Methods: One hundred forty three Taiwanese GS patients (M:F = 87:56, age ≥25 ± 10) with definite SLC12A3 mutations was enrolled. Nine BS patients with CLCNKB mutations and 15 healthy subjects were enrolled as disease and normal control, respectively. Intraavenous MgSO₄, was administered (elemental Mg 0.35 mmol/kg) in 8 GS patients with hypocalciuria. Relevant blood laboratory and at least two urine collection for all electrolytes excretion were determined. Hypocalciuria was defined as urine Ca²⁺/Cr ratio less than 0.1 mmol/mmol.

Results: Fourteen (9.8%) of 143 GS patients did not have hypocalciuria (Ca²⁺/Cr ratio 0.28 ± 0.09 mmol/mmol) and exhibited no significant difference in blood parameters compared with GS patients without hypocalciuria. Although their urine Ca²⁺/Cr ratio was significantly lower than that in BS (0.51 ± 0.18 mmol/mmol), there was still overlapping between them. Notably, urine Ca²⁺/Mg²⁺ ratio was significantly lower in GS than BS without overlap (0.46 ± 0.12 vs 1.57 ± 0.53 mmol/mmol, p<0.001). Acute MgSO₄ administration in GS patients markedly enhanced urine Ca²⁺ excretion (Ca²⁺/Cr ratio 0.05 ± 0.1 to 0.64 ± 0.01 mmol/mmol, p <0.001). However, urine Ca²⁺/Mg²⁺ ratio (0.21 ± 0.01 mmol/mmol) remained much lower than healthy subjects (1.35 ± 0.63 mmol/mmol, p<0.001) and BS.

Conclusions: Urine Ca²⁺/Mg²⁺ ratio may be a good index to help diagnose GS without hypocalciuria and even receiving intraavenous Mg²⁺ administration.

SA-PO905
A Blunted Response to Thiazide Diuretics Is Not Specific for Patients with Gitelman Syndrome Anneke Bech, Jack F. Wetzels, Tom Nijenhuis. Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: In Gitelman syndrome (GS), a defective sodium-chloride co-transporter (NCC) in the distal tubule classically leads to hypocalcaemia and hypomagnesemia. A challenge with thiazide diuretics, testing the functional presence of NCC, has been shown to differentiate GS from Bartter syndrome (BS) and normal controls. However, the performance of the thiazide test in renal magnesium wasting disorders other than GS and BS has not been studied.

Methods: Eleven patients who presented to our clinic between 2010-2014 with renal magnesium wasting and in whom a thiazide test was performed were included. An abnormal test result is defined as a maximal change of fractional chloride excretion (ΔFeCl) < 2.3% [Colussi 2007]. The thiazide test in eight volunteers in our clinic showed a mean maximal ΔFeCl 3.12 ± 0.48% with the lowest value being higher than 2.3%. Additional DNA mutation analyses were performed.

Results: Three patients had a mutation in SLC12A3 (GS), one patient had a compound mutation in CLCNKB and KCNJ1 (BS), 1 patient had a mutation in FXYD2 and five patients had a deletion of one HNF1β allele. The patients with GS showed a blunted thiazide test and the patient with BS showed a normal response, the patient with a FXYD2 mutation showed a blunted response and the patients with HNF1β mutations showed different responses to thiazide diuretics.

Impact of Hydration Status, Assessed by Bioelectrical Impedance Vector Analysis, on Mortality in Critically Ill Patients

**Background:** Clinical trials have shown a positive correlation between fluid overload and adverse outcomes in pts admitted to intensive care unit (ICU). Currently, there is not a non-invasive method that can provide an accurate and timely assessment of whole body hydration status.

**Objectives:** To evaluate if bioelectrical impedance vector analysis (BIVA), an ICU mortality in critically ill pts.

**Methods:** A prospective, dual-center study included 272 ICU pts with an ICU stay of 72 hrs or more. An anthropometric, medical history, and laboratory data were collected. Assessment of hydration status was performed by BIVA, using a single frequency analyzer at the baseline and daily for a period of 72-120 hrs.

**Results:** We found a significant correlation between BIVA hydration status and ICU mortality.

**Conclusions:** Further studies are needed to validate the clinical usefulness of BIVA in the general ICU setting.

**SA-PO097**

Assessment of Hydration Status by Bioimpedance Spectroscopy in Peritoneal and Hemodialysis Patients from a Single Center

**Background:** Peritoneal and hemodialysis (PD and HD) patients are at risk of fluid overload and hyperhydration. Bioimpedance spectroscopy (BIS) can be used to assess hydration status.

**Objectives:** To evaluate the hydration status of PD and HD patients using BIS.

**Methods:** We enrolled 188 pts, 120 PD and 68 HD patients. BIS was performed to assess hydration status.

**Results:** We found that measurement of SBP is not sensitive to assess the HYD in PD and HD pts. We also found that PD pts with NSBP tend to be more HH than HD pts. We suggest that SBP should not be used alone as a marker for HYD in PD and HD pts, it should always be accompanied by other tools.

**Conclusions:** The hydration status of PD and HD patients can be accurately assessed using BIS. Further studies are needed to validate its clinical usefulness.

**SA-PO098**

Sleep-Disordered Breathing Is Not Associated with Body Fluid Volume in Chronic Hemodialysis Patients

**Background:** Sleep-disordered breathing (SDB) is common in chronic hemodialysis (CHD) patients. Fluid retention may promote SDB in these patients. However, the relationship between SDB and body fluid volume is not well understood.

**Objectives:** To evaluate the relationship between SDB and body fluid volume in CHD patients.

**Methods:** Eighty-eight CHD patients in Nasu-Minami Hospital and Japanese Red Cross Koga Hospital were included in this study. SDB was assessed using overnight pulse oximetry.

**Results:** We found that SDB was not associated with body fluid volume in CHD patients.

**Conclusions:** Our findings confirm the hypothesis that SDB is not associated with body fluid volume in CHD patients.
Conclusions: SDB is associated with increased fat mass, but not body fluid volume in CHD patients. Further studies are needed to evaluate some factors that can explain the high frequency of SDB in CHD.

SA-PO909
Association Between Brain Natriuretic Peptide and Fluid Volume Imbalance Between Intra- and Extracellular Water in Patients with Chronic Kidney Disease
Yasushi Ohashi, Reibin Tai, Toshiyuki Aoki, Shizuka Kobayashi, Atsushi Aikawa, Ken Sakai. Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ; Tokyo, Japan.

Background: Malignant and elderly patients with chronic kidney disease (CKD) may be susceptible to an extracellular fluid volume overload due to a decreased intracellular fluid volume capacity. We assume that excessive fluid volume is redistributed on the basis of the baseline fluid volume balance when they are exposed to fluid accumulation.

Methods: Using bioimpedance analysis, body fluid composition was measured in 129 patients with CKD from 2013 to 2015 and was separated into three components—(a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Participants were also measured brain natriuretic peptide levels at the time of the body fluid composition measurement. The relationship between the ratio of ECW to ICW and brain natriuretic peptide was examined.

Results: Patients with higher log-transformed plasma level of brain natriuretic peptide were more likely to be older and have lower body mass index (BMI), glomerular filtration rate (GFR), and serum albumin levels and higher proteinuria. In body fluid composition analysis, the brain natriuretic peptide levels increased along with a decrease in all components of free water mass consisting of muscle, fat, and mineral (r = -0.49, P < 0.001), ICW content (r = -0.34, P < 0.001), and ECW content (r = -0.25, P < 0.01). By the steeper decreased free water mass and ICW content than the decreased ECW content in those patients, the percentage of ECW in body weight increased, and the ratio of ECW to ICW had a positive correlation with the brain natriuretic peptide levels (r = -0.58, P < 0.001). Multivariate analysis, age, BMI, GFR, and ECW/ICW ratio remained independently associated with the brain natriuretic peptide levels.

Conclusions: Brain natriuretic peptide is elevated in leaner and elderly patients with fluid volume imbalance between intracellular- and extracellular water. Fluid volume imbalance between intracellular- and extracellular water may express a reserve capacity for fluid volume overload and impact on cardiac preload.

SA-PO910
Blood Volume Estimation in Hemodialysis Patients
Doris H. Fuertinger,1 Line Malha,2 Peter Kotanko,1 David S. Goldfarb,1 Stephan Thijssem.1 Renal Research Inst, New York, NY; 2New York Harbor VAMC and NYU Langone Medical Center, New York, NY.

Background: Anthropometric formulas used to estimate absolute blood volume (ABV) are generally derived from healthy subjects. Most hemodialysis (HD) patients have an expanded ABV prior to HD, rendering these formulas inappropriate for estimation of pre-HD ABV (pre-ABV). Here, we compare the performance of several ABV formulas, used in conjunction with Crit-Line data, for assessment of pre-ABV.

Methods: We assume that post-HD ABV is closer to normal ABV, which we calculated based on height, sex and post-HD weight using several published formulas. Pre-ABV was then calculated from post-HD blood volume using pre- and post-HD HDct measured by Crit-Line®. The calculated pre-ABV was then compared to pre-ABV measured immediately before HD using 18F-labeled albumin dilution.

Results: We compared 27 formulas for ABV estimation in 21 patients (1/3; mean ± SD: age 59 ± 14.7 years, height: 170.7 ± 10 cm, post-HD weight: 82.2 ± 16.7 kg). None of the equations showed good agreement with the measured data. The Nadler formula yielded the most accurate results (Fig 1). As exemplified in Fig 1, the equations yield a systematic trend in bias, with reasonable accuracy for ABV between 5-6 L but progressive underestimation and increasing heteroscedasticity towards higher ABV (caused by fluid overload).

Conclusions: Anthropometric equations such as the Nadler formula show reasonable accuracy (unsatisfactory precision) for patients close to normal end-HD ABV, but they fail in non-euvolemic patients. Their validity in HD patients depends on the patients’ fluid status, which varies widely; hence their undifferentiated use in this population should be discouraged. More accurate and precise estimates of ABV would require a more sophisticated approach incorporating fluid status information, e.g. from bioimpedance.

SA-PO911
Impact of Hospital-Associated Hypernatremia on Outcomes in an Unselected Patient Population: A Retrospective Cohort Study
Nicolaos E. Madias, Evangelos Tsinopis, Bertrand L. Jaber. Internal Medicine, St. Elizabeth’s Medical Center, Boston, MA.

Background: Although hypernatremia has been associated with an increased risk of adverse outcomes, the majority of available studies have examined selected populations questioning the generalizability of their results to unselected patients.

Methods: The discharge data of 20,072 unselected adult patients admitted to a tertiary care facility over a 7-year period were analyzed. Based on the crude relationship between [Na+] and mortality, hypernatremia was defined as [Na+] > 142 mEq/L. Patients with community-acquired hypernatremia (CAH) and those with hospital-acquired hypernatremia (HAH) were compared to patients with normonatremia at presentation ([Na+] 138-142 mEq/L) in terms of in-hospital mortality, length of stay (LOS), and discharge disposition. Furthermore, patients with CAH in whom hypernatremia was associated with a greater increase in serum osmolality (HAggH) were compared to those without aggravation. Multivariable logistic and negative binomial regression analyses were conducted.

Results: CAH occurred in 20% of hospitalized patients and was associated with an adjusted odds ratio (OR) of 1.67 (95% confidence interval [CI] 1.38, 2.01) for in-hospital mortality, and 1.44 (95% CI 1.32, 1.56) for discharge to a short-/long-term care facility, and an adjusted 10% (95% CI, 7%-13%) increase in LOS. HAH developed in 25.9% of hospitalized patients and was associated with an adjusted OR of 3.17 (95% CI 2.45, 4.09) for in-hospital mortality, and 1.45 (95% CI 1.32, 1.59) for discharge to a facility, and an adjusted 49% (95% CI 44%, 53%) increase in LOS. HAggH developed in 8.9% of patients with CAH. Compared to patients with CAH and no further increase in [Na+]s, HAggH was associated with greater risk of in-hospital mortality (adjusted OR 1.84, 95% CI 1.32, 2.54) and discharge to a facility (adjusted OR 1.90, 95% CI 1.49, 2.41), and an adjusted 13% (95% CI 4%-23%) increase in LOS.

Conclusions: All forms of hypernatremia encountered in unselected hospitalized patients are independently associated with increased in-hospital mortality and heightened resource consumption.

SA-PO912
Utility of Urine/Plasma Osmolality Ratio for Assessing Volume Status in Hyponatremic Patients
Sho Hasegawa, Maki Shibata, Takehiro Sugiyama, Fumihiko Hinoshita. National Center for Global Health and Medicine, Tokyo, Japan.

Background: Assessing volume status is critical for managing hyponatremia. Physical examination (P/E) and laboratory data are often used for the assessment, but the utility of each parameter has not been validated in hyponatremic patients. A body composition monitor (BCM) uses bioimpedance spectroscopy and can quantify extracellular water (ECW) and volume excess or deficiency. Here, we examined which parameter is superior in assessing volume status of hyponatremic patients, using BCM data as the reference standard.

Methods: We enrolled hospitalized patients (n=41) with hyponatremia (<130 mEq/L) at our institution and conducted P/E, laboratory tests and BCM measurement. Patients with high plasma osmolality (>255 mOsm/kg) were excluded (n=5). We used %ECW/ ratio (volume excess or deficiency to ECW) derived from BCM data as the reference standard of volume status. First, patients were divided into overhydration (%ECW<0%, n=29) and dehydration (%ECW<0%, n=7) groups. Clinical signs obtained from P/E and parameters of volume status such as serum albumin (Alb), serum uric acid (UA), urine chloride, urine/plasma osmolality ratio (U/P Osm), U/NUN/BUN, U/BUN/creatinine, U/P creatinine, FENA, FEUN and FEUA were compared between the groups by Fisher’s exact test or Mann-Whitney U-test. Next, we performed univariate and multiple linear regression analyses to identify associations between each parameter and %ECW.

Results: U/P Osm was significantly higher in dehydration than in overhydration (median: 1.10 vs. 1.3, p=0.01) and carbohydrate loading case showed no significant differences. Univariate regression analysis showed that Alb (β=−7.1±3.2, p=0.04), U/P Osm (β=−11.4±3.1, p=0.001), U/NUN/BUN (β=−0.3±0.1, p=0.001) and U/P creatinine (β=−0.1±0.05, p=0.001) were associated with %ECW. Since U/NUN/BUN and U/P creatinine strongly correlated with U/P Osm, we conducted multiple regression analysis using only Alb and U/P Osm. Results showed that compared with Alb (β=−7.7±2.7, p=0.007), U/P Osm (β=−12.0±2.9, p=0.002) was more strongly associated with %ECW.

Conclusions: U/P Osm is superior to other commonly used parameters and clinical signs for assessing volume status in hyponatremic patients.

Sodium Concentrations of Body Fluid Losses: A Systematic Review

Matthew Kaptein, 1 Divya Sreeramoju, 2 John Kaptein, 3 Elaine Kaptein. 1 Nephrology, LAC+USC Medical Center, Los Angeles, CA; 2 Medicine, Presence Saint Joseph Hospital-UIUC, Chicago, IL; 3 Southern California Permanente Medical Group, Los Angeles, CA.

Background: Unexplained wide ranges and discrepancies of sodium concentrations [Na+] have been noted for different body fluids. This has led to use of “cumulative fluid balance” regardless of composition, which cannot account for specific water and sodium requirements. Appropriate water and volume management may be facilitated by an accurate and detailed knowledge of water and sodium composition of body fluid losses and gains.

Methods: We performed a systematic review of [Na+] of body fluids lost in adult humans. Particular attention was paid to gastric fluid with high and low acid states, diarrhea due to different mechanisms, and peritoneal, pleural and wound fluids. Inclusion criteria were met for 106 full-text articles.

Results: [Na+] are fluid-specific and consistent. Mean [Na+] were statistically lower for acidic (mean=SD+44+21mEq/L) than for alkaline (55+31mEq/L) gastric fluid; the difference is not clinically relevant. [Na+] are higher for bile (184+24mEq/L) or pancreatic fluid (156+3mEq/L) than all other body fluids, and similar for intact small bowel (119±4mEq/L) and ileostomy outputs (116+25mEq/L). Specific mechanisms for diarrhea are associated with different Na+. [Na+] were significantly greater for cholera (128±18mEq/L) and lower for osmotic-induced (28±16mEq/L) than all other causes. Among osmotic diarrheas, sorbitol-induced [Na+] was higher (63+17mEq/L) than for carbohydrate malabsorption (43+20mEq/L), lactulose (26+9mEq/L), Idolax (16+13mEq/L) and polyethylene glycol (13±7mEq/L). Among secretory diarrheas [Na+] for idiopathic causes (53+22mEq/L) was lower than for neuroendocrine and villous tumors (75+13mEq/L) or non-osmotic laxatives (88+33mEq/L). Pleural, peritoneal, and edema fluid had [Na+] (137±13mEq/L) similar to plasma. [Na+] for sweat was 44±17mEq/L.

Conclusions: This is the first in-depth review of verifiable sodium concentrations of body fluids most commonly lost in hospitalized patients. We propose that these losses be replaced with appropriate water and sodium content of enteral and parenteral fluids to correct and avoid dysnatremias and perturbations of volume status.

Hyponatremia in CKD: The Prevalence and Risk Factors

Masahiko Nagahama, 1 Dai-i Kobayashi, 2 Fumika Taki, 3 Takuya Fujiyama, 4 Masatada Hasegawa, 5 Yuki Heath, 6 Yasuhiro Komatsu. 1 Nephrology, St. Luke’s International Hospital, Tokyo, Japan; 2 Center for Clinical Epidemiology, St. Luke’s International Hospital, Tokyo, Japan.

Background: Kidney is a vital organ regulating water and sodium homeostasis, and it is plausible that patients with CKD are more prone to develop hyponatremia due to diminished urinary dilution ability, reduced solute intake, and/or medication which affects free water clearance. However, the prevalence and risk factors of hyponatremia among CKD patients have not been elucidated. The aim of the present study is to clarify the prevalence and risk factors contributing to hyponatremia in CKD patients.

Methods: Among 32,438 patients who visited our outpatient clinic between 2011 and 2014, 9,388 patients met the criteria of CKD, which is defined as either eGFR ≤60 ml/min/1.73m2 or proteinuria >300mg/day. We performed a systematic review of [Na+] of body fluids lost in adult humans. Particular attention was paid to gastric fluid with high and low acid states, diarrhea due to different mechanisms, and peritoneal, pleural and wound fluids. Inclusion criteria were met for 106 full-text articles.

Results: [Na+] of body fluids lost in adult humans. Particular attention was paid to gastric fluid with high and low acid states, diarrhea due to different mechanisms, and peritoneal, pleural and wound fluids. Inclusion criteria were met for 106 full-text articles.

Conclusions: The present study shows that the prevalence of hyponatremia was 8% in CKD patients, and development of hyponatremia is correlated with progression of CKD in moderate and severe CKD. Worsening CKD and Diabetes are risk factors, while RAS inhibitors are protective for hyponatremia in CKD.

SA-PO915

Mild Hyponatremia on Admission Is Associated with Sepsis and Increased Mortality in Patients Presenting with a Hip Fracture

Juan Carlos Ayus, 1 Armando Luis Negri, 1 Michael L. Morritz, 2 Nora Angelica Fuentes. 1 Hospital Italiano, Buenos Aires, Argentina; 2 Inst de Investigaciones Metabolicas, Argentina; 3 Children’s Hospital of Pittsburgh of UPMC, Pittsburgh, PA; 4 Renal Consultant 3 of Houston, TX.

Background: Hyponatremia is associated with an increased risk of falls and hip fractures in the elderly (JAMA 281: 2299-2304, 1999). Moreover, sepsis is a frequent etiology in patients with hyponatremia (AJKD 65:135-142, 2015). We assessed if hyponatremia on admission was associated with sepsis and increased mortality in patients presenting with a hip fracture.

Methods: A cohort study in adult patients admitted with a traumatic hip fracture and at least one serum Na measured at admission. Hyponatremia (H): Na <135 mEq/L, and normonatremic (N) patients were evaluated for complications occurring within 30 days of surgery, length of hospital stay, readmission rate, in-hospital mortality and mortality during 1 year follow-up. An unadjusted and adjusted odds ratio (OR) and hazard ratio (HR) were calculated for in-hospital mortality and 1 year mortality. Adjustments were made for age, gender, propensity score for hyponatremia, CVA, CHF, ischemic heart disease, arthriticms, thromboembolic disease, sepsis and dementia.

Results: 1571 patients were included of whom 366 (23.2%) were hyponatremic ( Na <124 mEq/L vs 138±3 mEq/L, <0.001). Length of stay was 8 days in H vs 7 days in N (p<0.053). There was in increased incidence of sepsis in hyponatremic patient, 9.8% in H vs. 6% in N (p<0.01) OR 1.7 (95%: 1.3-2.6). In-hospital mortality was significantly higher in H vs N patients (19 vs 14.7%; p=0.016), with an un-adjusted OR of 1.45 (95% CI 1.07-1.90) and an adjusted OR of 1.15 (95% CI 0.84-1.6). Readmissions were 15.8% for H vs 12.9% for N (p=0.14). One-year mortality was greater in H vs N patients (15.4 vs. 6.6%; p<0.001), with an un-adjusted HR of 1.8 (95% CI 1.4-2.35) and an adjusted HR of 1.45 (95% CI 1.1-1.9).

Conclusions: Mild hyponatremia on admission is associated with sepsis and increased in-hospital and late mortality in patients presenting with a hip fracture.

SA-PO916

Characteristics of Tolvaptan Trial in Korean Patients with SIADH

Background: This clinical study, a multicenter trial in 8 tertiary hospitals in Korea, was carried out to evaluate changes in serum sodium (Na) during 11 days on tolvaptan (TЛV) daily and at the 7th day after stopping TЛV in SIADH patients (pts) (<135 mEq/L). TЛV was given daily to a total of 39 pts(MF: 23/ age, 71±11.3 yrs) without neurologic symptoms were studied from Jun 1, 2013 to Dec 31, 2014. All pts received 15 mg of TЛV as the initial dose and then further increased to 60 mg/d as needed in the hospital.

Results: Serum Na (mEq/L) increased predominantly from baseline during first 24 hrs (127±13 to 131±4 mEq/L, p<0.001). It increased to day 4 (134±3.8 to 136±3.6, p<0.001), and then maintained a plateau until discontinuation of TЛV at day 11 (137±4.5). The changes in serum sodium (DNa) from the baseline were 2.8±3.3 in 4 hrs, 5.9±4.1 in 8 hrs, and 6.8±4.2 in 24 hrs, respectively. The correlation between DNa in 24 hrs and baseline Na was significant (r=-0.613, p<0.01). When hyponatremia was stratified into 3 groups, mild (I, 130-134, n=12), moderate (II, 125-129, n=18), and severe, (III, ≤124, n=9) groups, DNa in II (11.1±4.8) during first 24 hrs was significantly higher than I (6.4±2.5, p<0.05) and I (4.3±3.3, p<0.01). Also, those of DNa in 24 hrs (mEq/L) ranged from <8 to ≥21 had significantly lower baseline serum creatinine (0.56 vs. 0.73 mG/dL), Wt (53 vs 60 Kg), BMI (21 vs 23), and body surface area (1.54 vs 1.63) (all p<0.05). Then, serum Na after discontinuation of TЛV for 1 wk was similar to the baseline (127±4.3 vs 129±6.8, p=NS). All pts underwent successfully this trial more than 24 hrs, but 4 pts were withdrawn due to hypotension (1) and recurrent infection (3).

Conclusions: Tolvaptan is effective and well tolerated in Korean with SIADH. However, Korean patients, particularly those with smaller frame and severe hyponatremia (<125 mEq/L), could be vulnerable to rapid correction by usual initial dose of Tolvaptan 15 mg.

Persistent Hyponatremia at 72 Hours in Cancer Patients with Severe Hyponatremia Is Associated with Mortality Independent of Cancer Stage

Vesh Srivastava, 1 Xian Wu, 2 Edgar A. Jaimies, 2 Ilya Glezerman, 2 Lenar T. Yessayan, 2 Balazs Szamosfalvi, 2

Background: Hyponatremia is a common problem and a known independent risk factor for mortality in cancer patients. The impact of rate of correction of sodium on mortality is unknown. The study aim was to determine if the rate of correction in cancer patients with severe hyponatremia (Na < 120 mEq/L) is linked to 90 day mortality.

Methods: Patients with Na < 120 mEq/L were identified from the Memorial Sloan Kettering Cancer Center database from June 1, 2009 until June 30, 2014. 195 patients were identified. 55 patients were excluded from analysis because less than 72 hours after admission they either died (4), had no follow up data (16), were discharged (21), or made comfort care (14). The final cohort consisted of 140 patients who stayed in the hospital for at least 72 hours and had serial measurements of serum Na.

Results: The mean initial serum Na was 116.7 ± 3.0 mEq/L. The median rate of correction was 6 mEq/L with interquartile range 3.9-9 mEq/L in the first 24 hours, and the overall 90 day mortality was 32.4%. No patients with Na correction <8 mEq/L in the first 24 hours (n=54) developed osmotic demyelination syndrome. In patients who died within 90 days, the mean serum Na at 72 hrs was 128.3 ± 4.4 mEq/L compared to 130.5 ± 4.9 mEq/L in survivors (p<0.01). When adjusting for cancer stage and rate of correction in a multivariate Cox model, serum Na ≤ 130 mEq/L at 72 hrs was independently associated with 90 day mortality with adjusted HR 2.62 (1.47-4.64, p<0.001).

Conclusions: Cancer patients with severe hyponatremia are at heightened risk for 90-day mortality independent of cancer stage and rate of Na correction if their serum Na at 72 hrs is < 130 mEq/L. Based on this finding we recommend that cancer patients with severe hyponatremia should be corrected to >130 mEq/L at 72 hrs.

Hyponatremia Correction Using CRRT: Does Kinetic Modeling Avoid Overcorrection? Saurabh Dassgupta, 1 Lenar T. Yessayan, 2 Balazs Szamosfalvi, 2 Suvag Demirjian, 1 Nephrology, Cleveland Clinic, Cleveland, OH 1 Nephrology, Henry Ford Hospital, Detroit, MI.

Background: Hyponatremia is the most common electrolyte abnormality in inpatients. It must be corrected at a gradual rate of 8 mEq/L in 24 hrs to minimize the risk of central pontine myelinolysis, which can be effectively achieved in patients with renal failure by CRRT. Sodium (Na) kinetic models can predict end dialysis water. A simplified single pool fixed volume kinetic model may be applicable when net Na generation (G) is ~0 mEq/h. Our goal was to measure the correlation of predicted rate of correction by the formula to that observed in ICU patients with hyponatremia treated with CRRT.

Methods: 66 critically ill subjects with serum Na <130 at time of CRRT initiation were retrospectively identified. Median age was 60, and 52% were male. The predominant CRRT modality was CVVHD (97%), using dialysate Na of 140 mmol/L in most patients (92%) with average cumulative dose of 6L1, delivered over median duration of 23.2 hrs. Predicted Na correction in the first 24 hours was calculated using a single pool fixed volume kinetic model. The values were then compared to actual measured serum Na using simple correlation, and Bland-Altman plot.

Results: The correlation factor was calculated to be 0.49 with a p value <0.001. The Bland Altman plot (figure) showed a mean difference of 2 mmol/L between the observed and predicted delta Na values, with a trend for overestimation of Na correction as delta sodium levels increased.

Conclusions: Increasing Hb spuriously decreases dNa and increases dNa. A linear correction for this artifact can reduce the discordance between iNa and dNa, promoting their interchangeable use.

SA-PO921

HHV-6 Encephalitis Resulting in Cerebral Salt Wasting and Hyponatremia Jonathan A. Ducastel, Uday S. Nori. Internal Medicine and Nephrology, Ohio State Univ, Columbus, OH.

Background: Hyponatremia is a common electrolyte abnormality that can be associated with hypo-, hyper-, or euolemic states. Low circulating volumes secondary to extra-renal losses, fluid overload states, and syndrome of inappropriate ADH are some of the more common causes of hyponatremia. One consideration that is uncommon and often overlooked is cerebral salt wasting (CSW). CSW is defined as “renal loss of sodium during intracranial disorders leading to hyponatremia and a decrease in the extracellular fluid volume.” It occurs in the setting of cerebral injury, most commonly associated with subarachnoid hemorrhage.

Hb Category Hb mean N ANa, unadjusted ANa, adjusted
-6 5 17 1.4±0.4 1.2±0.5
-6.7-9.7 7.2 43 1.8±0.3 1.5±0.3
8.9-9.9 9.1 166 2.3±0.2 1.9±0.2
10.1-11.9 11 240 2.4±0.1 2.4±0.1
12.1-13.9 12.9 185 2.4±0.2 2.6±0.2
14.1-15.9 14.8 82 2.5±0.3 2.8±0.2
≥16 17 39 2.6±0.3 3.1±0.3

Conclusions: Increasing Hb spuriously decreases dNa and increases dNa. A linear correction for this artifact can reduce the discordance between iNa and dNa, promoting their interchangeable use.

Funding: Veterans Administration Support
hemorrhage, but also documented with other disorders of central nervous system. The mechanism of CSW is not completely understood, but is believed that a cerebral injury can lead to impairment of the sympathetic outflow causing primary natriuresis leading to hypovolemia and sodium depletion.

**Methods:** Here we describe a case of CSW in a patient with human herpes virus-6 (HHV-6) encephalitis. The patient was a 29 year old male with a history of AML who was continued on IV saline with the addition of oral salt supplements and started on foscarnet with normalization of the serum and CSF PCR within 10 days.

**Conclusions:** This case is important because the diagnosis of CSW is often confused with SIADH, as both share similar diagnostic criteria such as elevated urine sodium concentration and urine osmolality. The important clinical distinction is the patient, despite having a hypovolemic state would have polyuria and renal sodium wasting.

**SA-PO922**

**Association of 6-Month Pre-ESRD Potassium with Immediate Post-ESRD Survival: A Transition to CKD Study.** Melissa Sooho,$^1$ Connie Rhee,$^1$ Vanessa A. Ravel,$^1$ Elani Streja,$^1$ Jennie Jing,$^1$ Rajiv Saran,$^2$ Bruce M. Robinson,$^3$ Yi Li,$^2$ Danh V. Nguyen,$^2$ Csaba P. Kovessy,$^2$ Kamyar Kalantar-Zadeh.$^1$

**Background:** Previous studies of the association between serum potassium level and mortality in dialysis patients have suggested that a range of 4.6-5.3 mEq/L portends greatest survival in this population. However, the optimal potassium range in the immediate pre-ESRD period before ESRD transition (6 month-prelude) is not known. We hypothesized that a similar pre-ESRD serum potassium range is also associated with higher survival in this population.

**Methods:** We investigated a cohort of 20,404 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 potassium measurement during the last 6 month period before ESRD transition (6 month-prelude). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis episode of severe hyperkalemia. Among the different classes of antihypertensives, K-sparing diuretics had the strongest associations with both mild and severe hyperkalemia, followed by ACEis and then beta blockers, which were associated only with mild hyperkalemia (Figure).

**Results:** Potassium levels were checked ≥1 time/year in 53% of the cohort; 4% had levels checked >5 times/year. Overall, 7.4% had >1 episode of mild hyperkalemia; 0.4% had an episode of severe hyperkalemia. Among the different classes of antihypertensives, potassium sparing diuretics were protective against mild hyperkalemia but not severe hyperkalemia. There were no consistent interactions between types of antihypertensive medication for risk of hyperkalemia.

**Conclusions:** Mild hyperkalemia is relatively common and associated with the use of ACEis and K-sparing diuretics but not ARBs in this single healthcare system.

**SA-PO923**

**Antihypertensive Medications and the Prevalence of Hyperkalemia in a Large Healthcare System.** Alex R. Chang,$^1$ Yingying Sang,$^2$ H. Lester Kirchner,$^1$ Kunhiro Matsushita,$^2$ Shoshana Ballew,$^2$ Jose Corisb,$^3$ Morgan Grams,$^2$ Gessinger Health System; Johns Hopkins Bloomberg School of Public Health.

**Background:** The association of outpatient medication use with patterns and prevalence of hyperkalemia has not been rigorously examined.

**Methods:** We evaluated the association between baseline antihypertensive medications [angiotensin converting enzyme-inhibitors (ACEi), angiotensin receptor blockers (ARB), beta-blockers, loop/thiazide diuretics, and K-sparing diuretics] with the frequency and pattern of mild (K<5-5 mEq/L) and severe hyperkalemia (>6 mEq/L) over a 2 year window in 342,342 outpatients in the Gessinger Health System based on medication prescription orders. Orders of hyperkalemia were classified as: never, transient (1-time), intermittent (>1-time but ≤50% of the time), and persistent (≥50% of the time). Analyses were adjusted for demographics, eGFR, systolic blood pressure, diabetes, and history of cardiovascular disease. Interactions between medication types with hyperkalemia risk were also tested.

**Results:** There were no consistent interactions between types of antihypertensive medication for risk of hyperkalemia.

**Conclusions:** Mild hyperkalemia is relatively common and associated with the use of ACEis and K-sparing diuretics but not ARBs in this single healthcare system.

**SA-PO924**

**Wide Range in Variation in Serum Potassium in Hyperkalemic Patients with CKD, Response to a Fixed 60 mEq Potassium Diet.** David A. Bushinsky,$^1$ Martha Mayo,$^2$ Dahlia Garza,$^2$ Yuri Stavis,$^2$ Daniel J. Wilson,$^3$ Charles Dumond,$^2$ Lance Berman,$^2$ Murray Epstein,$^2$ Univ of Rochester; Relypsa, Inc; Univ of Miami.

**Background:** A wide range of inter-individual variation in s-K+ (maximum-minimum) in s-K+ at each time point for the remaining observation period to determine variation in s-K+.

**Methods:** A total of 27 pts with s-K+ ≥5.5 to ≤6.2 mEq/L were monitored in a clinical research unit. At baseline pts were fed a 60 mEq K+ diet with CKD (stage 2-4) on stable doses of RAASi, during the run-in phase of a treatment trial.

**Results:** There were no consistent interactions between types of antihypertensive medication for risk of hyperkalemia.

**Conclusions:** Mild hyperkalemia is relatively common and associated with the use of ACEis and K-sparing diuretics but not ARBs in this single healthcare system.

Best EKG Criteria for Hyperkalemia in Chronic Hemodialysis Patients

**Background:** To the date effects of hyperkalemia(HK) on the EKG of chronic hemodialysis(CHD) patients(pts) is inconsistent. We studied the EKGs of 128 consecutive CHD pts with clotted grafts or fistulas. EKGs from 46 HK pts > 5.5 mEq/L were compared to 82 pts with normal potassium (NK) levels < 5.5 mEq/L. Pts with RBBB or LBBB or cardiac events within 3 months were already excluded. There were no differences between NK and HK pts for dialysis duration, causes for ESRD, cardiac disease or serum levels of Na, Ca, HCO3, or phosphorus.

**Methods:** EKG analysis included: the height & width of the P waves, the T waves in V4 & the T waves in Lead 2, the time intervals of PR, QRS, QTc, PR/QT, PR/QTc, & slopes of ascending & descending T waves in Lead 2 & V4. For the first time ever in HK CHD pts, the EKG measurements in 32 NK pts with complete data were compared to their NK EKGs obtained 3 to 6 months from the HK EKG

**Results:** Univariate stats between the 46 HK & 82 NK pts showed 4 differences in mean values: V4 T wave height 4.0 vs 2.9 mm, Lead 2 T wave height 2.7 vs 2.0 mm, & the V4 T wave ascending (0.3 vs 0.2) and descending slopes (1.6 vs 0.3). Multivariate analysis for all clinical & EKG findings between HK & NK pts found only the increased height of the T wave in V4 was significant, p<0.05. In contrast, the EKG analysis of the HK pts to their NK EKGs revealed more differences: higher T wave height in V4, 5.0 vs 3.7 mm, higher T wave height in Lead 2, 4.0 vs 2.7 mm, shorter width of T wave in V4, 2.4 vs 4.1 ms or Lead 2, 2.1 vs 4.1 ms , longer PR 188 vs 167 ms , & steeper slopes in the T waves in Lead 2 and V4. Regression analysis of the change in potassium from NK to HK to each EKG measurement showed that the only significant correlation was the width of T wave in V4, r = 0.33, p<0.05. In these HK CHD pts T wave trending in V4 was now present in 56%.

**Conclusions:** We conclude: 1) Comparison of a NK EKG to a HK EKG in CHD pts significantly helps to confirm HK EKG changes in CHD pts. 2) A shortened width and an increased height of the T wave in V4 are the most important HK EKG changes in CHD pts.

**SA-PO0926**

Sodium Polystyrene Sulfonate for the Treatment of Mild Hyperkalemia in Chronic Kidney Disease: A Randomized Clinical Trial

**Background:** Hyperkalemia affects up to 10% of patients with chronic kidney disease (CKD). Sodium polystyrene sulfonate (SPS) has long been prescribed for this condition even though evidence is lacking on its efficacy for the treatment of mild hyperkalemia (5.0 to 5.9 mmol/L) in pre-dialysis outpatients. We randomly assigned 33 patients on stable medication to receive either SPS or placebo 30g orally once a day for 7 days. Patients had to be on stable medication to be eligible for the trial.

**Results:** SPS is superior to placebo in the treatment of mild hyperkalemia over several days.

**Methods:** The aim of this double-blind, randomized trial was to evaluate the efficacy of SPS in the treatment of mild hyperkalemia (5.0 to 5.9 mmol/L) in pre-dialysis outpatients. We randomly assigned 33 patients on stable medication to either receive SPS or placebo orally once a day for 7 days. Patients had to be on stable medication to be eligible for the trial. The primary outcome was the comparison between study groups of the mean difference of serum potassium levels between the day following the last dose of treatment and baseline.

**Results:** The mean duration of treatment was 6.9 days. SPS was superior to placebo in the reduction of serum potassium levels (mean difference between groups of -1.04 mmol/L; 95%CI: -1.37 to -0.71). A higher proportion of patients in the SPS group tended to attain normokalemia (defined as a serum potassium level of at least 3.5 mmol/L and less than 5.0 mmol/L) at the end of their treatment compared to the placebo group (73% vs 38%, P=0.07). Patients in the group treated with SPS had an increase in hyperkalemia, hypocalcemia, constipation and nausea compared to the control group.

**Conclusions:** SPS is superior to placebo in the treatment of mild hyperkalemia over seven days in CKD patients. Its use was generally well tolerated in our study population, but does require monitoring of gastrointestinal side effects and electrolytic disorders.
Conclusions: Patients with SIRS and hypoMg (<1.5 mg/dL) at the time of admission had increased risk of developing septic shock during hospitalization.

SA-PO929
Risk Factors for Calcium-Alkali Syndrome in Post-Surgical Hypoparathyroidism
Sayaka Kuroya, Masahiko Yazawa, Naoto Tominaga, Kalyani Perumal, Masanori Abe,

Background: Post-surgical hypoparathyroidism is a common complication of total thyroidectomy. Patients complicated by permanent hypoparathyroidism often require either both calcium or vitamin D supplement therapy to maintain serum calcium levels, and long-term therapy can lead to calcium-alkali syndrome (CAS). We examined the incidence rate, magnitude, and risk factors of CAS in patients being treated for post-surgical hypoparathyroidism.

Methods: We retrospectively observed 27 patients with neck tumors who had undergone total thyroidectomy with total parathyroidectomy without autotransplantation between January 2010 and October 2013 at St. Marianna University Hospital. All patients received calcium lactate and alfalcacidol. Medical records were reviewed for historical, clinical, laboratory, and imaging data. Definitions were as follows: hypercalcemia, corrected serum calcium ([cCa] >10.0 mg/dL); acute kidney disease (AKD), either or both >50% increase in serum creatinine (sCr) or >35% decrease in estimated glomerular filtration rate (eGFR); and metabolic alkalosis, difference in serum sodium (Na+) and serum chloride (Cl–) >38. Data were expressed as mean ± standard deviation (SD). For statistical analysis, the paired t-test, Student’s t-test, and chi-square test were used to compare two matched variables.

Results: Average duration between surgery and reaching peak cCa level was 392.7 ± 403.8 days, with levels peaking at 11.1 ± 0.2876 (P = 0.0033; P < 0.01). Nineteen patients (70.3%) had hypercalcemia, 9 (33.3%) had AKD, and 7 (36.9%) had metabolic alkalosis. The incidence rate was 0.2876; P = 0.244) was no obvious correlation between the body temperature rise. On the other hand, respectively in the TP concentration and the ALB concentration of 0.5 mg/dL. It was found correlated with body temperature rise after intravenous injection. In particular, a strong correlation between the ALB concentration and the increase in body temperature was observed (r = 0.8033; P < 0.01).

Conclusions: The correlation of body temperature rise after intravenous injection and IL-6 is weak, while the correlation between the corrected ALB concentration and the body temperature rise was very strong. From these results, we considered that any substance bound to the ALB or ALB itself are associated with elevated body temperature.

Effect of NBCe1 Deletion on Renal Ammonia Metabolism
J. David Weiner,1,2 Mary E. Handlogten,1 Gunars Osis,1 Hyun-Wook Lee,1 Jill W. Verlander.1 1Renal Div, Univ of Florida, Gainesville, FL; 2Nephropathy Section, NF/SVGH, Gainesville, FL.

Background: Metabolic acidosis typically increases renal ammonia excretion, but people with proximal renal tubular acidosis (pRTA), despite the associated metabolic acidosis, do not have increased ammonia excretion. Genetic forms of human pRTA typically involve the proximal tubule bicarbonate transporter, NBCe1. Based on these observations, we postulated that NBCe1 has a role in renal ammonia metabolism that is in addition to its role in bicarbonate reabsorption.

Methods: We used previously reported mice with NBCe1 deletion. Because <~5% mice have 100% mortality by d10-21, we studied mice at d8. Wild-type (WT), heterozygous (Het) and homozygous knock-out (KO) mice were generated by breeding HET male and female mice.

Results: Serum HCO3 was 26.4±1.0 mEq/L in WT, 19.8±1.9 in HET, and 10.3±0.6 mEq/L in KO mice (P<0.05). Thus, NBCe1 deletion causes metabolic acidosis at d8. Although acidosis normally increases ammonia excretion, NBCe1 deletion decreased spontaneous ammonia excretion: 275±44, 212±11 and 94±69 mmol/g creatinine in WT, HET and KO mice, respectively (P<0.01). Serum Na and K were unchanged. Urine pH was 5.3±0.2, 4.8±0.1 and 4.2±0.1 in WT, HET and KO mice, respectively (P<0.01), indicating intact urine acidification and no ongoing HCO3 loss. NBCe1 deletion did not alter urine osmolality significantly (WT, 596±74; HET, 693±51; and, KO, 726±34 mOsm/kg H2O; P=NS), which, in combination with intact urine acidification, suggests intact collecting duct function. The regulation of multiple proteins involved in ammonia metabolism was atypical of acidosis. NBCe1 deletion decreased expression of PDG and PEPCk and increased expression of the ammonia recycling enzyme, glutamine synthetase. This pattern is the exact opposite of that expected with acidosis. Expression of the TAL ammonia transporter, NKCC2, and the collecting duct ammonia transporters, RHbg and RHcg, was unchanged.

Conclusions: We conclude: 1) NBCe1 deletion significantly alters proximal tubule ammonia metabolism, leading to decreased urinary ammonia excretion; and, 2) NBCe1, in addition to its role in HCO3 transport, may have an important role in ammonia metabolism.

Assessing Urine Ammonium Concentration by Urine Osmolal Gap in Chronic Kidney Disease
Takuya Fujimaru, Yasuhiro Komatsu, Takuya Shuo. Nephrology, St. Luke’s International Hospital, Tokyo, Japan.

Background: Acidemia is one of the risk factor for end stage kidney disease and mortality for patients with chronic kidney disease (CKD). Although ammonium is the crucial component of renal acid excretion, measurement of urine ammonium concentration (NH4) is not routinely available in most hospital laboratories. To estimate NH4, urine osmolal gap (UOG = urine osmolality - [2(Na + K) + urea + glucose]) is calculated and the formula (NH4 = UOG/2) has traditionally been used. However, studies evaluating it in CKD patients are scarce. The present study aims to assess the relationship between NH4 and UOG in CKD patients.

Methods: Spot urine samples were collected from 36 patients with CKD in our hospital (24 males, age 41-96 years, serum creatinine 0.9-12.4 mg/dl). We measured urine pH, Na, K, Cl, urea, glucose and NH4. NH4 was measured by colorimetric assay (modified Fujii-Okuda method). The Bland-Altman plot was used to evaluate the agreement between NH4 and UOG/2.

Results: NH4 ranged from 0.3-45.8 mmol/l (median, 6.2 mmol/l). UOG/2 correlated positively and significantly with NH4 (r=0.92, p<0.0001).

Conclusions: UOG is an accurate method to estimate NH4 in CKD patients and can be used to assess urinary acidification ability in CKD patients.

SA-PO935
Vascular H+-ATPase Regulation by 14-3-3 Proteins
M. Soline Bourgeois, Carsten A. Wagner. Inst of Physiology, Univ of Zurich, Zurich, Switzerland.

Background: The vascular proton-ATPase (V-ATPase) is highly expressed at the apical membrane of type A intercalated cells (ICs) in the collecting duct. This pump mediates proton transport across a membrane often against a gradient. Defects in V-ATPase function can lead to renal tubular acidosis. In kidney cells we showed that the metabolic sensor AMP-activated protein kinase (AMPK) phosphorylates the V-ATPase A subunit at Ser-384. AMPK regulates some transport proteins by inhibiting their function and promoting their ubiquitination and degradation. These mechanisms are likely important for inhibition of membrane transport during cellular metabolic stress. We noticed that Ser-384 exists within a 14–3-3 binding motif. Dimeric 14–3-3 bind to phosphorylated sites on target proteins and modulate protein function. We hypothesized that phosphorylation by AMPK and an additional kinase modulate A subunit binding to 14-3-3 proteins and A subunit ubiquitination.

Methods: We used transient transfections of V-ATPase A subunit mutants in Clone C ICs, followed by immunoprecipitation and immunoblotting.

Results: We have preliminary evidence that phosphorylation at Ser-384 and a new “Site III” in the V-ATPase A subunit are required for 14-3-3 binding. For example, 14-3-3 binding to the A subunit increased when we used a phosphomimetic mutant (Ser-to-Asp) at Site III compared to the WT sequence at that site, and this binding was not dependent on the presence of the AMPK A subunit partner AICAR. Furthermore, AICAR increased A subunit ubiquitination as compared to untreated controls.

Conclusions: We propose that V-ATPase A subunit binding to 14-3-3-3s promotes its ubiquitination and degradation. These pathways are downstream of phosphorylation of the subunit at Ser-384 by AMPK and at Site III by another unidentified kinase. Our results link downregulation of the V-ATPase to metabolic depletion in kidney epithelial cells.

Albuminuria Enhances Renal NHE3 Expression via the Activation of Mitochondrial Oxidative Stress/RAS Axis
Soline Bourgeois,1,2 Yibo Zhang,1 Guixia Ding,1 Songming Huang,1 Zhanjun Jia,1,2 Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China; 2Nanjing Key Laboratory of Pediatrics.

Background: Renal sodium–hydrogen exchanger 3 (NHE3) plays a known role in the reabsorption of bicarbonate and fluid. As a result, NHE3 is thought to be important in acid base balance and vascular volume homeostasis. The present study was to investigate the role albuminuria in regulating renal NHE3 expression as well as the underlying mechanisms.

Methods: An albumin overload mouse model was established by i.p injection of albumin. The mouse kidney tissues and kidney biopsy specimens from proteinuric patients were analyzed.

Results: Following 12-day albumin overload, we found that albuminuria increased NHE3 expression by 2-fold in mouse kidneys determined by Western blotting and qRT-PCR. Considering the known role of renin-angiotensin system (RAS) in modulating renal sodium handling, we examined key components of RAS and found a striking elevation of angiotensinogen (AGT, +2.1 folds), angiotensin converting enzyme (ACE, +3.3 folds), and urinary angiotensin II (Ang II, +70%) output determined by Western blotting or ELISA. In proteinuric patients, we detected a 1.9-fold upregulation of NHE3 and 3-fold increase of ACE by immunohistochemistry in line with a 2-fold increment of urinary Ang II excretion. To further investigate the role of RAS in upregulating NHE3, we performed primary cultures of renal tubular cells and observed that albumin directly enhanced NHE3 accompanied by stimulated AGT/ACE/Ang II cascade, which was entirely abolished by ACE inhibitor captopril, indicating a key role of RAS in mediating albuminuria effect on NHE3 upregulation. More interestingly, albumin load significantly induced mitochondrial oxidative stress evidenced by reduced mitochondrial superoxide dismutase (SOD2, -60%) and elevated ROS production. Notably, a SOD2 mimic (MnTBAP) completely normalized NHE3 upregulation and activated AGT/ACE/Ang II cascade in mice with albumin overload.

Conclusions: These results suggest that albuminuria is of vital importance in upregulating renal NHE3 expression in proteinuric patients via mitochondrial oxidative stress-initiated stimulation of AGT/ACE/Ang II cascade.

SA-PO937
ATP6v1b1 Haploinsufficiency Lead to a Mild Incomplete Renal Tubular Acidosis (RTA) in Mice
Soline Bourgeois, Carsten A. Wagner. Inst of Physiology, Univ of Zurich, Zurich, Switzerland.

Background: Mutations in ATP6v1b1 gene in man is considered as an autosomal recessive disease and lead to distal RTA by dysfunction of the B1 subunit of H-ATPase in type A intercalated cells. In some transgenic models in mouse, renal failure and also distal RTA and a decrease in ammonium and alkaline urine pH.

Methods: Here we investigated on littermate mice whether ATP6v1b1+/- mice also develop acid-base disturbances during an acute and chronic acid challenge performed by 0.2 M HCl added to powdered standard food.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Results: ATP6v1b1+/+ (WT) and +/- (HET) mice exhibited no difference in their blood and urine parameters under baseline conditions. During the acid challenge, while ATP6v1b1+/+ mice (KO) developed alkaline pH and low ammoniuria with hypercalcemia, HET mice showed no difference in their urine data over the whole acid load compared to WT mice. However, even though, HET mice did not exhibit low blood pH, as KO mice, they had a lower bicarbonatemia, higher chloride, and lower pCO2 compared to WT mice at the end of the acid challenge. Both KO and HET mice drank more than WT mice over the acid load with a tendency to urinate more. After 4 days of acid load, subcellular localization of the a4 and B2 subunits of H-ATPase were not different within the 3 strains of mice and WT and HET mice exhibited the same localization of B1 subunit. However, western blot analysis of B1 and B2 expression in renal membrane fractions revealed a 2-fold decrease of B1 and B2 protein expression in HET mice compared to WT mice and no difference in the expression of B2 protein in KO mice compared to WT mice while B1 protein was totally absent from KO kidneys.

Conclusions: In conclusion, 1) HET mice developed a mild incomplete RTA during an acid challenge, undetectable regarding urine parameters. The RTA is partly compensated by the respiration and an increase in water consumption. 2) B2 subunit does not compensate for the decrease in B1 expression both in HET kidney tissues and seems to be inhibited by acid load.

Bedside Rule (pCO2=HCO3+15) Is Reliable in Predicting Respiratory Response in Metabolic Acidosis with Bicarbonate Levels of More Than 7 meq/L
Mohammad Kazem Fallahzadeh, Michael Emmett. Dept of Internal Medicine, Baylor Univ Medical Center, Dallas, TX.

Background: There is controversy about the reliability of the bedside rule (pCO2=HCO3+15) in prediction of respiratory response in metabolic acidosis. The aim of our study was to compare the accuracy of the bedside rule with Winter’s equation in predicting respiratory response in metabolic acidosis.

Methods: We extracted the measured bicarbonate and pCO2 levels of 382 patients with metabolic acidosis from the previously published articles evaluating the respiratory response to metabolic acidosis. We calculated the predicted levels of CO2 by bedside rule and Winter’s equation for each patient. Then we compared the accuracy of these formulas in predicting the respiratory response to metabolic acidosis.

Results: As demonstrated in the figure 1, the values calculated by bedside equation (pCO2=HCO3+15) appear to be a reliable predictor of respiratory response in HCO3 levels of more than 7 meq/L, as compared with the line of best fit and Winter’s equation.

Conclusions: Our results show that bedside rule (pCO2=HCO3+15) is reliable in predicting respiratory response in metabolic acidosis with HCO3 levels of more than 7 meq/L.

SA-PO939
TSS-Seq Analysis of Low pH-Induced Gene Transcripts in the Intercalated Cells of the Collecting Ducts
Yukihiro Izumi, Koji Eguchi, Kazem Kazem, Terumasa Kumamoto, Koji Eguchi, 1  Terumasa Kumamoto, 1  Koji Eguchi, 1  Michael Emmett.

Background: Metabolic acidosis is caused by acute and chronic kidney disease due to the decrease of acid excretion in the intercalated cells of the collecting duct in the kidney. Although the effect of acidosis on renal function has been examined in vivo, direct effect of low pH on the intercalated cells has not been investigated.

Methods: We employed Transcription Start Site-sequencing (TSS-Seq) to provide low pH-2.47s differentially expressed transcripts in an intercalated cell line (IN-IC cells). Two biological replicates were used for the analysis. Cells were grown in a FBS-free DMEM/F12 overnight and incubated in an isotonic solution for 24h in which pH was adjusted either to 7.4 or 7.0, then total RNA was extracted. cDNA library for CAGE (Cap Analysis Gene Expression) was constructed and deep sequencing was performed. Reads were identified. 261 transcripts were upregulated and 17 were downregulated. Among them, 225 upregulated and 13 downregulated transcripts were corresponded to known protein products. GO analysis of Biological Processes and Molecular Functions showed 9 clusters of the GO terms with high enrichment score (>1.5) in the expressed transcripts were identified. The software was used to map TSS-Seq reads. ReCLU was used to identify differentially expressed transcripts. Gene Ontology (GO) analysis was carried out using the Database for Annotation, Visualization and Integrated Discovery (DAVID).

Results: Deep sequencing of low pH-exposed IN-IC cells was carried out. The reads were mapped to the genome and gene loci were identified. The number of valid reads was 261, corresponding to 150 distinct transcripts. The GO enrichment analysis of the upregulated genes showed that they were involved in the regulation of transcription, cell cycle, and enzyme-linked receptor protein signaling pathway. The downregulated transcripts included Jak2, Pten, and Gsk3a, that are involved in renal fibrosis and urine concentration mechanism.

Conclusions: The results suggest that metabolic acidosis could regulate the function of intercalated cells and further exacerbate the renal fibrosis.

Narrowing the Gap Between the Anion Gap and the Strong Ion Gap
Keiichiro Beros, Andrew L. Lundquist,1 Nephrology, St. Elisabeth Hospital, Willemstad, Curacao, Netherlands Antilles; 2MGH Div of Nephrology, Massachusetts General Hospital, Boston, MA.

Background: Despite its importance in understanding acid-base pathophysiology, many physicians do not understand the concept of the strong anion gap. The core of the Stewart acid-base approach is the “strong ion gap” (SIG). The concept of SIG is similar to the AG, but the main difference is that Stewart uses more strong ions and the contribution of albumin and phosphate are adjusted for the pH. Because SIG gives a more precise picture of the acid-base status than the AG, one may postulate that it provides a more accurate analysis of acid-base disturbances. The exact differences, however, are not established. This paper will give insight into the difference between the anion gap and the strong anion gap and provide an adjusted formula for the anion gap to replace the need for the strong gap.

Methods: The change of the strong ion gap (SIG) and the albumin-corrected anion gap (AG) were calculated at a wide range of albumin, phosphate and pH levels.

Results: At a low albumin level of 1 to 3 g/dl and decreased pH from 6.9 to 7.3, the contribution difference of albumin in AG, and SIG will be maximally <0.97 to 0.51 meq/L. In normal human plasma (pH up to 7.6) and hypocalciuricemic (1 to 3 g/dl), the AG differs less than 2 meq/L with SIG. There is a linear relationship of the serum phosphate and the ionic contribution of SIG: at a pH of 6.9, the phosphateAg is 1.66 times higher and at a pH of 7.6, 1.86 higher. In metabolic alkalosis and moderate hyperphosphatemia, the ionic contribution to the anion gap will increase, but less than 1 meq/L.

Conclusions: SIG and AG are almost identical across a wide range of values, particularly when albumin and phosphate levels are low. The pH adjusted serum phosphate level in the SIG is about 1.76 higher, with a confidence interval of +0.5 mmol/L. The anion gap will be more precise and incorporate the major components of the SIG when using the equation: [Na+] - [CT] - [HCO3-] - 2.5 [albumin, in g/dl] – 1.76 [phosphate], with an arbitrarily set reference range of 1+5 meq/L.

SA-PO941
V-ATPase in Luminal Membrane of Renal Proximal Tubule Requires B2 Subunit and CLC-5 for Its Full Functional Activity
Nobuhiko Sato,1 Motonobu Nakamura,1 Atsushi Suzuki,1 Masashi Suzuki,1 George Seki,2 Shoko Horita,1 Nephrology, The Univ of Tokyo Hospital, Tokyo, Japan; 2Tiazu City Hospital, Shizuoka, Japan.

Background: Using an isolated rat proximal tubule (PT) primary culture system, we have previously shown that the activity of basolateral Na/H+ cotransporter (NBCc1) was preserved for 36 hours. Furthermore, gene silencing with siRNA enabled us to identify the signaling pathways involved in insulin-mediated NBCc1 stimulation (Nakamura M, Kidney Int, 2015). However, it remains unknown whether this technique is applicable to analysis of PT luminal transporters.

Methods: Freshly isolated mouse PT was attached to a glass coverslip with Cell-Tak glue and the lumen was exposed with a broken glass capillary. BCECF was used to measure intracellular pH (pHi). While the cariporide-insensitive luminal NHE activity was determined by the rates of pH decrease in response to Na removal, the bath-luminal-sensitive V-ATPase activity Na-dependent NHE activity was measured. The uncoupler 2,4-dinitrophenol (DNP) was added to the PT cultures to separate the Na-dependent from Na-independent NHE activity.

Results: The luminal NHE activity was at least partially preserved in isolated PT primary cultures (0.09+/−0.08 vs 0.89+/−0.08 pmol/min/mg protein). V-ATPase activity determined by the rates of pHi decrease in Na-dependent Na-independent NHE activity was also confirmed in the presence of Na-free solution. The experiments were also performed after PTs were cultured overnight in the presence of siRNA against V-ATPase B2 subunit or CLC-5.

Conclusions: The luminal NHE activity was at least partially preserved in isolated PT primary cultures. The mechanism behind this preservation is not clear, but it could be due to the expression of basolateral NBCc1 and CLC-5. V-ATPase activity was preserved for 36 hours. Furthermore, gene silencing with siRNA enabled us to identify the signaling pathways involved in insulin-mediated NBCc1 stimulation (Nakamura M, Kidney Int, 2015). However, it remains unknown whether this technique is applicable to analysis of PT luminal transporters.

Funding: N. Sato (PhD course) was supported by a Grant-in-Aid for JSPS Research Fellowships for Young Scientists (19J20420).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.
The Mechanistic Target of Rapamycin Regulates Solute Transport in Renal Tubules Nasir A. Shah, Davide Pietro Cina, Tuncer Onay, Vera Eremina, Robert A. Fenton, Timo Rieg, Sharon L. Barone, Kamyar A. Zahedi, Manoocher Soleimani, Thampi George, David W. Basolateral Na+/H+ Exchange Medullary Thick Ascending Limb (MTAL) Through Receptor for Advanced by inhibition of Rho. Addition of a direct Rho activator reduced basal HCO3− transporters in the renal tubular epithelium. The RAGE-Rho-ROCK1 pathway is driven, tubule-specific Mtor knockout mouse (Mtor−/−). Results: Loss of Mtor in the renal tubular epithelium resulted in increased 24-hour urine volume, diminished urine osmolality, and renal failure. Despite elevated 24-hour urinary albumin, Ca2+, and Mg2+ Mtor−/− mice were both hypercalcemic and hyperglycemic. Histologically, Mtor−/− mice exhibited generalized tubular atrophy with focal cystic dilations of the distal and cortical collecting tubules, and interstitial fibrosis. Immunohistochemistry showed decreased expression of aquaporin-2 (Aqp2), Calbindin D 28k (Cbdl), and the sodium-potassium-chloride cotransporter (Ncc2). Increased expression of the transient receptor potential cation channel subfamily V member 5 (Trpv5) was also noted. Conclusions: Taken together, our results suggest that Mtor is a key player in maintaining electrolyte balance by modifying the expression, and function of solute transporters in the renal tubular epithelium.

High Mobility Group Box 1 (HMGB1) Inhibits HCO3− Absorption in Medullary Thick Ascending Limb (MTAL) Through Receptor for Advanced Glycation End Product (RAGE)-Rho–ROCK-Mediated Inhibition of Basolateral Na+/H+ Exchange. Bruce A. Watts, Thampi George, David W. Good. Univ TX Med Branch, Galveston, TX.

Background: HMGB1 is a damage-associated molecule that is released extracellularly in response to infection or injury and plays a role in mediating kidney dysfunction in sepsis and sterile inflammatory disorders. Recently we showed that basolateral HMGB1 inhibits HCO3− absorption in perfused rat MTALs through a RAGE-dependent pathway additive to TLR4-ERK-mediated inhibition by LPS. Here we examined signaling and transport mechanisms involved in inhibition by HMGB1.

Results: Inhibition of HCO3− absorption by HMGB1 was eliminated by the Rho-associated kinase (ROCK) inhibitor Y27632 and by a specific inhibitor of Rho, the direct activator of ROCK. HMGB1 increased ROCK1 activity in dissected inner stripe of outer medulla, a preparation that accurately reproduces changes in MTAL signaling proteins. Activation of ROCK1 by HMGB1 was eliminated by the RAGE antagonist FSP-ZM1 and by inhibition of Rho. Addition of a direct Rho activator reduced basal HCO3− absorption rate and prevented inhibition by HMGB1. The Rho and ROCK inhibitors had no effect on inhibition by bath LPS. The Rho-ROCK1 pathway regulates NHE3 and we have shown that inhibition of NHE1 decreases MTAL HCO3− absorption secondary through cytoskeleton-dependent inhibition of apical NHE3. Inhibition of HCO3− absorption by HMGB1 was eliminated by bath amiloride, 0 Na+ bath, and the F-actin stabilizer jasplakinolide, three maneuvers that selectively prevent inhibition of HCO3− absorption mediated through NHE1. Bath amiloride and jasplakinolide did not affect inhibition by bath LPS.

Conclusions: We conclude: 1) HMGB1 inhibits HCO3− absorption in the MTAL through a RAGE-Rho–ROCK1 pathway coupled to inhibition of NHE1; 2) this pathway functions in parallel with the bath LPS-ERK pathway to impair MTAL HCO3− absorption. Thus, during sepsis, endogenous damage-associated molecules and exogenous bacteria-associated molecules act directly and independently to inhibit MTAL HCO3− absorption through different receptor signaling and transport pathways. The RAGE-Rho–ROCK1 pathway is a potential target to attenuate sepsis-induced renal tubule dysfunction.

Background: Identification of networks interacting proteins is crucial for all levels of cellular function. The Slc26 family of anion transporters [Slc26a3 (DRA), Slc26a5 (proxim.), Slc26a6 (PAT-1), and Slc26a9] form multi-protein complexes with cytoskeleton, anchoring proteins, PDZ adaptor proteins, CTR and/or protein kinases, which impart regulatory signals on these isoforms. No information is available on proteins that interact with pendrin (Slc26a4).

Methods: A yeast two hybrid system was employed to screen a mouse kidney cDNA library with a pendrin C-terminal fragment as bait. A total of 6 × 106 interacting clones were identified, out of which 14 clones were confirmed to be positive when screened for β-gal expression. Plasmids from these clones were purified and their interaction with pendrin was confirmed.

Results: Our experiments identified IQGAP-1 as a pendrin C-terminus binding partner. IQGAP-1 is a scaffolding protein that binds and/or stabilizes ezrin, CDC42 and RAC1, and interacts with cytoskeletal and cell adhesion molecules. In the kidney, IQGAP-1 is strongly expressed in the DCT, CNT, CCD and podocytes. IQGAP-1 has also been shown to control tight junction formation through recruitment of claudin. Our results indicate that IQGAP-1 co-localizes with pendrin on the apical membrane of B-intercalated cells. IQGAP-1 is also detected on the basolateral membrane of A-intercalated cells in CCD. Functional studies in HEK293 cells demonstrated that the co-transfection of IQGAP-1 and pendrin increased pendrin-mediated CI/HCO3− exchange activity by more than 60%. Confocal microscopy showed more abundant plasma membrane expression of pendrin in the presence of IQGAP-1.

Conclusions: These studies demonstrate the interaction of IQGAP-1 and pendrin in B-intercalated cells, as well as the stimulatory role of IQGAP-1 on pendrin activity. We propose that pendrin interaction with IQGAP-1 is important in the regulation of CED function and physiology, and that disruption of this interaction contributes to altered pendrin trafficking and/or activity in pathophysiologic states.

Regulation of Rhcg by Aldosterone in Intercalated Cells of the Collecting Ducts Koji Eguchi, Yuichiro Izumi, Terumasa Nakagawa, Yushi Nakayama, Hikedi Inoue, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.

Background: Acid-base balance is regulated by aldosterone which stimulates acid secretion in the intercalated cells of the collecting ducts of the kidney. Rhesus blood group C glycoprotein (Rhcg) is an ammonia transporter which cooperates with H^+/ATPase to secrete H^+ in the intercalated cells. In vivo experiments have shown that metabolic acidosis and hypokalemia, that change plasma aldosterone level, increases and decreases the expression of Rhcg, respectively. Direct effect of aldosterone on the regulation of Rhcg has not been examined.

Methods: We examined the effect of aldosterone on the regulation of Rhcg. Membrane fraction of the whole kidney was extracted from mice that were continuously administered aldosterone (20μg body/day) for a week. To further examine the effect of aldosterone on the regulation of Rhcg in the intercalated cells, mRNA, whole cell protein, and membrane fraction were extracted from IN-IC cells (a rat intercalated cell line) after the treatment with aldosterone (10^-4 M) for 24h. The Rhcg mRNA and protein expressions were measured by real-time PCR and Western blotting, respectively. The expression of serum and glucocorticoid-regulated kinase 1 (Sgk1) mRNA was also measured in IN-IC cells.

Results: Administration of aldosterone increased the expression of Rhcg protein in membrane fraction of the whole kidney. In IN-IC cells the expressions of Rhcg and Sgk1 mRNA were 1.3- and 3.2-fold greater, respectively, in cells treated with aldosterone (10^-4 M) than in cells with vehicle. The expression of Rhcg protein in whole cell extract was not changed by the treatment with aldosterone. However, the expression of Rhcg protein in membrane fraction was 3.2-fold greater in cells treated with aldosterone than in cells with vehicle.

Conclusions: The results suggest that aldosterone regulates membrane accumulation of Rhcg possibly through the activation of Sgk1.
Impact of Hypothermic Machine Perfusion on Outcomes following Kidney Transplantation

**Background:** Patient and allograft outcomes following deceased donor kidney transplantation (DDKT) are thought to be influenced by the intrinsic quality of the organ at procurement and any superimposed subsequent injury that occurs during cold preservation (CP). Hypothermic machine perfusion (HMP) is used in an attempt to decrease injury from CP especially for organs that have extended periods of cold ischemia. We analyzed the impact of complete, partial or no HMP use during CP on patient and graft survival following DDKT.

**Methods:** We identified 75,660 first-time adult renal transplant recipients, who received a DD kidney from 2000-2011 in SRTR. Pearson’s chi-square tests of independence and Kruskal-Wallis tests were performed to test for association between HMP and mortality, graft failure, and delayed graft function (DGF). Cox analyses, adjusting for donor factors (age, gender, creatinine, cause of death), recipient factors (age, dialysis duration, PRA, HLA mismatch), CP time, and specified effect measure modifiers, were performed to estimate the hazard of either graft failure, or DGF occurring given HMP.

**Results:** On unadjusted analyses, compared to no HMP use, kidneys that received HMP performed better (OR=0.82, p<0.001 & OR=0.77, p<0.0001) but more likely to experience allograft failure (HR=1.19, p<0.001 & HR=1.20, p<0.0001, figure 1). On multivariable analyses, the use of HMP was associated with a lower incidence of DGF(OR=0.70, p<0.001 & OR=0.59, p<0.0001) but continued to be associated with a higher risk of allograft failure even after adjusting for CIT and the lower DGF (HR=1.11, p=0.023 & HR=1.26, p=0.002).

**Conclusions:** HMP improves short term outcomes by lowering rates of DGF but is associated with reduced long-term allograft survival.

**SA-PO949**
Impact of Remote Ischaemic Preconditioning (RIPC) on the Inflammatory Response following Live Donor Kidney Transplantation
Kristin Vibeke Veyoug, Madhur P. Motwani, Jennifer Nicholas, Raymond Macallister. Weisse Kidney Unit, Portsmouth Hospitals NHS Trust, United Kingdom; UCL Centre for Clinical Pharmacology & Therapeutics, Unv College London, United Kingdom; Clinical Trials Unit, London School of Hygiene and Tropical Medicine, United Kingdom.

**Background:** Ischaemia reperfusion injury (IR) at transplantation contributes to organ damage that limits allograft longevity. Animal studies have demonstrated a reduction in circulating proinflammatory cytokines following RIPC, which may contribute to tissue protective effects. REPAIR demonstrated a trend towards improved live donor kidney function following RIPC. We investigated the effects of RIPC on serum and urinary cytokines in this study.

**Methods:** 406 adult live donor/patient pairs were recruited. Pairs were randomised using a factorial design to either: sham RIPC, early RIPC (immediately pre-surgery), late RIPC (24 hours pre-surgery) or dual RIPC. Donor and recipient received the same interventions (active or sham RIPC). Serum from donor and recipient and urine from recipients were analysed at baseline and on day 2 for pro-inflammatory cytokines IL-1β, IL-6, IFN-γ and TNFα, using multiplex ELISA. All analyses were conducted using linear regression adjusted for baseline (pre-treatment) values of the cytokine and indicator variables for early and late treatment group. Cytokine values were log transformed before analysis to account for skewed distribution.

**Results:** There was no difference in the expression of serum cytokines in donor serum or recipient serum and urinary protein baseline pre-surgery and day 2 post surgery.

**Conclusions:**
SA-PO952

Low Expression of the Messenger RNA TLRs 2-4,9 from Peripheral Blood Mononuclear Cells of the Kidney Recipients May Indicate Previous Delayed Graft Function

**Background:** The Toll-like receptors (TLR) 2-4,9 are engaged in the pathogenesis of acute renal injury. Earlier studies demonstrated that 24 hrs. after transplantation (KT), the expression of the messenger RNA (mRNA) TLR4 of peripheral blood mononuclear cells (PBMC) from patients (pts) with delayed graft function (DGF+) was lower than in recipients of kidneys without DGF (DGF-). The aim of study was to examine whether the reduced expression of TLR2,4-9 mRNA is a more permanent phenomenon associated with DGF.

**Methods:** Each of the 151 KT pts was more than 1 month after KT (from 1 to 128 months). Within this group: in 117 pts blood sample was taken for more than 3 months after KT, 45 pts experienced DGF, 13 DGF+ pts was HBcAb positive (DGF+HBc+). Control group (Con.) included 38 healthy volunteers. TLR-2,4-9 mRNA expression (expr.) from PBMC was assessed by polymerase chain reaction (real-time PCR) and analyzed in terms of DGF and clinical course.

**Results:**
- KTG+ pts had generally lower TLR2,4-9 mRNA expr. than KTG- pts (TLR2: p=0.06; TLR3: p=0.02; TLR4: p=0.07; TLR 9, p=0.027) TLR3 mRNA of DGF+HBc+ pts was: lower (p=0.046) than DGF+HBc, lower (p=0.013) than DGF-ATN- and lower (p=0.008) than Con. TLR9 mRNA of DGF+HBc+ was lower (p=0.002) than Con. In multiple regression analysis low expr. of TLR mRNA 2,4-9 was associated with the occurrence of DGF in the past.

**Conclusions:** Lower than typical expression of TLR 2-4,9 mRNA seems to be a permanent feature of peripheral blood mononuclear cells of the recipient of the transplanted kidney who experienced delayed graft function. Hepatitis B seems may be associated with additional decline of TLR3 and TLR9 mRNA expression. TLR3,4,9 mRNA expression could potentially be used as an indicator of the likelihood of delayed graft function.

**BB3, a Hepatocyte Growth Factor-Like Small Molecule, Improves Outcome in Kidney Transplant Recipients with Delayed Graft Function**

Jonathan Bromberg, 1 Matthew R. Weir, 2 A. Osama Gaber, 3 Matthew Cooper, 4 Mark Laflavi, 5 Barry Browne, 6 Bo Zhang, 7 Prakash Narayan, 8 Michael A. Yamin, 9 Izthak D. Goldberg, 7 Weizhong Cai. 7 Div of Transplant Surgery, Univ of Maryland School of Medicine, Baltimore, MD; 3 Div of Nephrology, Univ of Maryland School of Medicine, Baltimore, MD; 7 The Methodist Hospital, Houston, TX; 8 MedStar Georgetown Univ Hospital, Washington, DC; 7 Transplant Center at Erie County Medical Center, Buffalo, NY; 9 BMGC, San Diego, CA; 9 Anjion Biomedica Corp, Uniondale, NY.

**Background:** Duration of delayed graft function (DGF) portends poor short- and long-term renal function and graft survival. We studied the safety and efficacy of BB3, a small molecule with HGF-like activities, dosed starting 24 hr post-transplant (Tx) in patients with reduced urine output (UO) in a double-blind Phase 2 study.

**Methods:** Patients producing <50 cc urine/hr over 6-8 h post-Tx were randomized (2:1) to BB3 (2 mg/kg IV QD X 3 d) or placebo (PBO). An interim analysis was performed on 12 BB3- and 7 PBO-treated patients.

**Results:** BB3 was safe and well-tolerated. BB3 reduced the median time to produce 1.2L UO/24 hr from >28 d to 7.5 d, increased the % of patients reaching this UO within 28 d from 43% to 83%, increased cumulative UO (figure), decreased median duration of dialysis (figure), decreased % on-dialysis days during Days 7-28 (14.2% to 7.1%) and during Days 14-28 (10.9% to 3.6%), reduced median SCR, reduced BUN, and shortened median hospital stay (7 d to 5.5 d). BB3 reduced serum CRP and NGAL.

**Conclusions:** BB3 administered ~24 hours post-Tx significantly reduced severity of DGF in patients presenting with reduced UO. Confirmation of these results in a Phase 3 trial may translate to improved long-term outcome, decreased Tx costs, increased use of marginal organs, and a shorter waitlist.

DSA Monitoring and Treatment in Kidney Transplant Recipients
Monica Grafals,1 Alexander Gilbert,1 Olga A. Timofeeva.2

Background: The development of DSA monitoring is a new technique to detect antibodies in kidney transplant recipients. We previously showed that patients who developed de novo DSA (dnDSA) suffer a 35% graft loss. Because of this we have developed a protocol for treating patients who have developed dnDSA post kidney transplant.

Methods: Since the implementation of this treatment protocol on September 12, 2014, there have been 9 patients that have developed dnDSA after renal transplantation.

Results: Four of the patients that developed dnDSA were in the low risk category and in 3 of them the DSA has cleared. The 4th patient has a DSA against DP1 with an MFI of 1587 that has remained stable. All of these patients have a GFR>45 cc/min. Three patients were in the intermediate risk category. One of them has a creatinine of 3, BK viremia and he has a DSA against A1 with an MFI of 3150 which has been stable. Another patient in this group developed CMV viremia and his DSA became negative after treatment. The third patient just received treatment for DSA this past month and follow up DSA is not available at this time. Two patients were in the high risk category and both of them received treatment and their GFRs are >45 cc/min and their DSAs have become undetectable and weak respectively.

Conclusions: Since the development of dnDSA post kidney transplant is associated with worse graft outcomes, implementation of treatment protocols is necessary for kidney transplant patients. This preliminary data shows that treatment for dnDSA with this protocol seems to success fully treat the antibodies.

SA-PO955

On the Patterns of Early De Novo DSA Development in Kidney Transplant Recipients in the First 6 Months After Alemtuzumab Induction
Cheelesa Estrada, Yezina T Nigatu, Hecesuck Suh, Frank Darras, Mersema Abate, Edward P. Nord. Nephrology and Transplantation, Stony Brook Medicine, New York.

Background: The presence of de novo DSA (dnDSA) is associated with antibody mediated rejection and suboptimal graft outcomes. The incidence of dnDSA post renal transplantation varies according to immunosuppression protocols, screening, and detection methods, and ranges from 5-25%. A higher incidence of dnDSA after alemtuzumab (AL) has been observed. We sought to characterize the expression of early dnDSA development after AL induction in renal transplant recipients.

Methods: Consecutive kidney transplant recipients were screened for dnDSA from 7/1/14 to 4/30/15. DnDSA was detected by single antigen beads and luminex technology at months 1, 2, 3, and 6. Mean Fluorescent Intensity (mfi) >500 was considered high level. Acute ABMR and TG histology met Banff 2013 criteria. In this cohort, induction was with alemtuzumab and rapid steroid withdrawal, and maintenance immunosuppression was with tacrolimus and mycophenolate mofetil. Chi square analysis was used to assess the association between low and high levels of DSA and biopsy findings of antibody mediated injury.

Results: Fifty-three consecutive indication kidney transplant biopsies were performed from 7/1/14– 5/21/15. Of these 12 had evidence of ABMR (2 acute, 8 TG and 2 both). Six of the 8 patients with TG alone did not have DSA. At the time of biopsy, 12 class I (6 low and 6 high level) and 13 class II (3 low and 10 high level) were detected.

Conclusions: 1. The presence of high level class II DSA was significantly associated with the concurrent biopsy finding of antibody mediated injury. 2. Of greater significance, the presence of class I DSA or low level class II DSA did not correlate with pathologic findings.

SA-PO957

Characteristics of Kidney Transplant Candidates with and without Antibody against Angiotensin II Type 1 Receptor (AT1R-Ab)
Mary Carmelle Philogene, S.M. Bagnasco,2 Annette M. Jackson,1 Mary S. Leffell,1 Andrea A. Zachary.1

1Medicine, Johns Hopkins Univ, Baltimore, MD. 2Pathology, Johns Hopkins Univ, Baltimore, MD.

Background: In this study we sought to determine whether baseline characteristics of kidney transplant candidates when correlated with presence of AT1R-Ab are predictive of transplant outcomes.

Methods: 122 renal transplant recipients were tested for presence of AT1R-Ab using quantitative ELISA (CellTrend GmbH, Germany). Patient demographics were obtained from the hospital electronic record under an approved IRB.

Results: Patients were categorized according to AT1R-Ab levels: positive >17 Units/ml (30%); borderline 10-17 Units/ml (34%), negative <10 Units/ml (36%). There were fewer females (33% versus 61%, 55%) and African Americans (14% versus 24%, 16%) in the AT1R-Ab >17 Units/ml group compared to the other two groups. The presence of AT1R-Ab has been associated with development of hypertension and fibrosis; therefore, we examined AT1R-Ab among patients categorized by the following diseases: IgA nephropathy, glomerulonephritis, lupus nephritis, FSGS, and membranoproliferative glomerulonephritis. We found no correlation between these diseases and AT1R-Ab levels (38%, 29% and 30%, respectively; p=0.7). We also found no association with diagnosis of hypertension and AT1R-Ab levels (16%, 17%, 18%). The most significant difference between the three groups was a higher percentage of positive patients among those who received more than one kidney transplant (78%, 22%, 45%; p=0.001). Post transplantation, sixty-one patients were biopsied to investigate graft dysfunction. There were more patients in the borderline and positive AT1R-Ab groups who were evaluated for graft dysfunction compared to the negative group (>55%, 54% versus 34%) although this did not reach statistical significance.

Conclusions: The only pre-transplant characteristic linked to presence of AT1R-Ab in patients who are being evaluated for kidney transplantation is the incidence of previous transplant.

Effect of B-Cell Activating Factor (BAFF) Inhibition (LY2127399; Tabalumab) on Highly Sensitized Patients with End Stage Renal Disease awaiting Transplantation
Nephrology, Univ of Texas Medical Branch, Galveston, TX; 1Transplant Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; 2Bio-Medicines, Eli Lilly and Company, Indianapolis, IN; 3Nephrology, Univ of Michigan Health System, Ann Arbor, MI.

Background: B cell activation factor (BAFF) is critical in B-cell maturation. Inhibition of BAFF represents an appealing target for desensitization of highly sensitized end stage kidney disease patients.

Methods: We conducted a Phase 2a, single-arm, open-label exploratory study investigating the effect of tabalumab (BAFF inhibitor) in ESRD patients with cPRAs >50%. The treatment period had a total duration of 24 weeks. Eighteen patients received tabalumab, at a dose of 240-mg subcutaneous (SC) at Week 0 followed by 120-mg SC at 4-week intervals for 5 more months. Patients were then followed for an additional 52 weeks. Blood samples were analyzed for HLA antibodies, BAFF levels, serum immunoglobulins, T and B cell subsets at specified time intervals during the treatment and follow-up periods. Pre and post treatment tonsil and bone marrow biopsies were also performed.

Results: Significant reductions in cPRAs were observed at week 16 (p=0.043) and at week 36 (p=0.004), however the absolute reductions were small (<5%). Overall factor effect at week 76 compared to baseline was significant (p=0.04). Mean BAFF levels increased during treatment, reflecting binding to tabalumab and decreased in the follow-up period remaining slightly above baseline at week 76. Expected changes in B cell subsets and reductions in immunoglobulins were observed. Two tabalumab-related serious adverse events occurred (pneumonia and worsening of peripheral neuropathy) while the most common other adverse events were injection-site pain and hypotension. Three patients received a matched donor cadaveric transplant during the study follow up.

Conclusions: The results resulted in statistically significant, but not clinically meaningful reduction in the cPRAs from baseline. Funding: Pharmaceutical Company Support - Eli Lilly

Behavior and Impact of Donor-Specific Antibodies Before and After Kidney Transplant

Background: Pre- and post-transplant DSA increases the risk for acute rejection, humoral rejection and graft loss. Every year a 5% of patients will develop DSA but other patients turn negative. It is unclear how the behavior of pre-transplant DSA under immunosuppression and their clinical impact. This study evaluate the relationship between de novo DSA and the outcome of kidney transplantation, and whether the development of these antibodies is related to pre-transplant DSA status.

Methods: Prospective cohort study. From Jan/2004-Dec/2014 a total of 519 kidney transplant were performed. For analysis we include 412 with DSA determination plus these antibodies is related to pre-transplant DSA status.

Results: From 412 patients, 58 patients (14.1%) had pre-transplant DSA. Patients with Pos/Pos or Pos/De Novo DSA had higher and earlier AR and AMR rate, followed by Neg/De Novo-Variable and Neg/De Novo, as you can see in the figure A) and B) respectively. For graft loss only those with Pos/De Novo was higher than Neg/Neg (Figure C). Interestingly, those who are Pos/Neg had similar outcomes than Neg/Neg.

Conclusions: Staying with the same DSA or developing De Novo-DSA after transplantation, regardless what the pretransplant condition was, were associated with development of AR, AMR, and graft loss.

Course of Anti-HLA Antibodies After Induction Therapy with Rituximab in Renal Transplantation
Luuk Hilbrands, Wil Allebes, Marij W. F. van den Hoogen, Irma Joosten, Marije C. Baas.

Background: Rituximab is used to desensitize highly sensitized patients awaiting kidney transplantation. T or B cell depleting agents are known to be associated with a delayed onset of anti-HLA Ab development.

Methods: We conducted a Phase 2a, single-arm, open-label exploratory study investigating the effect of rituximab in ESRD patients with cPRAs >50%. The treatment period had a total duration of 24 weeks. Eighteen patients received rituximab, at a dose of 375-mg subcutaneous (SC) at Week 0 followed by 375-mg SC at 4-week intervals for 5 more months. Patients were then followed for an additional 52 weeks. Blood samples were analyzed for HLA antibodies, BAFF levels, serum immunoglobulins, T and B cell subsets at specified time intervals during the treatment and follow-up periods. Pre and post treatment tonsil and bone marrow biopsies were also performed.

Results: Significant reductions in cPRAs were observed at week 16 (p=0.043) and at week 36 (p=0.004), however the absolute reductions were small (<5%). Overall factor effect at week 76 compared to baseline was significant (p=0.04). Mean BAFF levels increased during treatment, reflecting binding to tabalumab and decreased in the follow-up period remaining slightly above baseline at week 76. Expected changes in B cell subsets and reductions in immunoglobulins were observed. Two tabalumab-related serious adverse events occurred (pneumonia and worsening of peripheral neuropathy) while the most common other adverse events were injection-site pain and hypotension. Three patients received a matched donor cadaveric transplant during the study follow up.

Conclusions: The results resulted in statistically significant, but not clinically meaningful reduction in the cPRAs from baseline. Funding: Pharmaceutical Company Support - Eli Lilly

Benefit of Desensitization with Rituximab from the Viewpoint of Anti-A/B Antibody Titer and Pathological Findings in ABO-Incompatible Kidney Transplantation

Background: We conducted a multicenter prospective clinical study in ABO-incompatible kidney transplantation (ABOi-KT) without splenectomy (UMIN000006635). To evaluate the benefit of desensitization with rituximab (R), we investigated the data of this study from the time course change of anti-A/B antibody (ab) titer and sequential pathological findings.

Methods: Desensitization protocol included low dose MMF and steroid started 28 days before and CNI started a few days before surgery. R 375 mg/m² was administered at day -14 and day -1. Minimum 2 sessions of plasma exchange were done for anti-A/B ab removal before transplant, and basiliximab was administered on day 0 and day 4. Anti-A/B
ab titer and eGFR were sequentially evaluated, 0 hr, 1 hr and protocol biopsies (4 weeks after transplant) were also sequentially performed as possible. Pathological specimens were centrally diagnosed by 3 pathologists.

Results: 18 pts received ABOi-KT. One-year pts and grafts survival were both 100%. The desensitization with R was well tolerated. Average anti-A/B ab (IgG) titer at baseline was 15.4x and decreased to 19.7x immediately before surgery, maintaining until the end of the study. In pts whose sequential pathological specimen available showed positive C4d deposition in 1/13 at 1 hr and 11/16(69%) at protocol biopsy. No pts developed AMR related to anti-A/B abs except for one who experienced AMR with anti-HLA ab (Banff07 type II). Her anti-A/B ab titers were slightly higher than the others (4x-32x). Pathological findings included arteriosclerosis in 8, nephrocalcinosis in 1, IF/TA (grade 1) in 1 and suspicious CNI acute nephrotoxicity in 1. Two pts showed C4d+ without other pathological signs.

Conclusions: In this series, anti-A/B ab titer were successfully decreased and no AMR occurred other than 1 caused by anti-HLA ab, whereas C4d deposition was detected in 6/13 of pts by protocol biopsy. Our desensitization protocol was confirmed both pathologically and clinically safe and effective for ABOi-KT.

SA-PO962
Post-Transplant BAFF Levels Do Not Predict the Development of Anti-HLA Antibody in Kidney Transplant Recipients. Ji Won Min,1,2 Burn Soon Choi,1,2 Cheol Whae Park,1,2 Chul Woo Yang,1,2 Yong-Soo Kim,1,2 Byung Ha Chung.1,2

Background: It is well known that pre-transplant B cell activating factor (BAFF) levels are associated with the development of de novo anti-HLA antibodies and also antibody mediated rejection post-transplant. However, the clinical significance of BAFF values at alloreactive rejection has not been determined. In this study, we investigated the clinical significance of pre- and post-transplant BAFF levels measured when indication biopsy was done.

Methods: In 130 kidney transplant (KT) recipients who required alloreactive biopsy due to an increase in serum creatinine, we checked for anti-HLA antibodies using Luminex single antigen assay, and measured BAFF levels using ELISA kits. In 78 of these patients we also measured pre-transplant BAFF and anti-HLA antibody levels. We investigated the relationship between pre-transplant, post-transplant and delta BAFF levels and the occurrence of anti-HLA antibodies.

Results: Pre-transplant BAFF levels showed significant association with pre-transplant sensitization, represented by positive PRA, high PRA, and presence of HLA-DSA. They also showed positive association with early rejection (rejection within 6 months from KT). Post-transplant BAFF levels showed significant association with post-transplant sensitization, but did not show association with anti-HLA antibodies and positive donor-specific antibodies at the time of biopsy. We did not find any association between post-transplant BAFF levels and cumulative alloreactive rejection, alloreactive biopsy results, Banff scores and microvascular inflammation scores.

Conclusions: In conclusion, pre-transplant BAFF levels are associated with pre-transplant sensitization and are useful in predicting alloreactive rejection. But post-transplant BAFF levels measured at the time of indicated biopsy are not associated with the appearance of de novo HLA-DSA, alloreactive rejection, biopsy findings and other alloreactive outcomes.

SA-PO963
Effectiveness of Bortezomib (BT) in the Treatment of Antibody Mediated Rejection (AMR) Among Pediatric Kidney Transplant Recipients (pKTx). Sarah J. Kizilbash,1 Donna J. Claes,1 Isla Ashoor,1 Ashton Chen,4 Sara E. Jandeska,1 Raed Bou Matar,1 Jason Misurac,7 Katherine Twombley,8 Priya Verghese1,3 Pediatric Nephrology, Univ of Minnesota; 2Cincinnati Children’s Hospital; 3Children’s Hospital New Orleans; 4Wake Forest Univ; 5Rush Univ; 6Cleveland Clinic; 7Indiana Univ; 8Medical Univ of South Carolina.

Background: AMR has a poor prognosis despite a number of therapeutic options. BT is increasingly being utilized in adults but there are limited data on its safety and efficacy in pKTx with AMR.

Methods: Multicenter retrospective case series including all pKTx who received BT for biopsy proven AMR, from 2008-2015, at 8 centers within Midwest Pediatric Nephrology Consortium.

Results: Twenty-four pKTx from 8 centers were treated with BT for AMR. In addition to BT, 75% were treated with rituximab, 79.2% with plasmapheresis and 91.7% with IVIG. 62.5% were males, 45.8% were white, and 41.7% were African American. Two-thirds were deceased donor recipients, and mean age at transplant was 11.1 years (SD 5.19). Obstructive urethropathy and dysplasia comprised 50% of the underlying diseases. At the time of transplant, 82.2% of patients had 0.0% panel reactive antibodies. Mean estimated GFR (eGFR) prior to AMR was 49.6 (SD 12.1). Prevalence of donor specific antibodies (DSA) and changes in eGFR are shown in table 1.

Conclusions: Even though limited by small patient numbers, this trial suggests efficacy of IA in the treatment of late AMBR.

SA-PO965
Pre-Transplant Phospholipase A2 Receptor Autoantibody Concentration Is Associated with Recurrence of Membranous Nephropathy Post-Kidney Transplantation. Hasan Fattahi,1 Gaurav Gupta,1 Dhiren Kumar,1 Luis F. Quintana,2 Anne L. King,1 Rivka Ayalon,1 Laurence H. Beck,3 Nephrology, Virginia Commonwealth Univ; Richmond, VA; 2Nephrology, Hospital Clinic de Barcelona, Barcelona, Spain; 3Nephrology, Boston Univ, Boston, MA.

Background: Idiopathic membranous nephropathy (mN) has been associated with anti phospholipase A2 receptor autoantibody (PLA2R-Ab) both in the native kidneys as well as in the setting of recurrence (rMN) post-kidney transplant (txp). Previous studies that have assessed pre-txp PLA2R-Ab for the prediction of rMN have yielded variable results. Many of these studies have been limited by the use of variable immunosuppressive regiments among patients, different ELISA assays as well as method of diagnoses (surveillance vs indication biopsies).

Results: Tubulointerstitial scarring (ci+ct) (p=0.81), microcirculation inflammation (g+p+c) (p=0.38) and transplant glomerulopathy (cg) (p=0.21) scores were similar. However, the mean total inflammation (ti) score of IA group (2.60±0.55) was significantly higher than PE (1.69±0.70) and DFPP (1.79±0.71). The rates of graft loss were as follows; PE; 13/16 (81.3%), DFPP; 10/19 (52.6%) and IA; 1/5 (25%) (p=0.03). The graft survival was significantly higher for IA than PE (p=0.01). There was a tendency of better graft survival in DFPP compared to PE group (p=0.07). Kaplan-Meier survival analysis revealed better overall survival for IA than for PE and DFPP (p=0.03).

Conclusions: Although limited by small patient numbers, this trial suggests efficiency of IA in the treatment of late ABMR.
**SA-PO966**

Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratio Predict Acute Allograft Rejection

**Methods:** Sixteen consecutive test patients with a history of IMN were tested for per-protocol PLA2R-Ab. ELISA titers (Euroimmun, NJ, USA) > 14 RU/ml were considered positive, as per manufacturer instructions. All patients received similar post-transplant immunosuppression. A receiver operating characteristic (ROC) analysis was performed after combining data from Quintana et al. (n=21; Transplantation Feb 2015) to determine a PLA2R-Ab concentration which could predict rMN.

**Results:** Six (out of 16; 37%) patients had biopsy-proven rMN at a median of 3.2 years post-txp. Of these, 5/6 (83%) had a positive PLA2R-Ab pre-txp with a median of 82 RU/ml (range=31-1500). The only patient who had rMN with a negative PLA2R-Ab was later diagnosed with non-Hodgkin’s lymphoma. 100% (n=10) patients with no evidence of rMN had a PLA2R-Ab concentration which could predict rMN.

**Conclusions:** Pre-transplant PLA2R-Ab could be a useful tool for the prediction of rMN. Patients with rMN in the absence of PLA2R-Ab should be screened for occult malignancy.

**SA-PO968**

The Pre-Transplant Ratio of T Regulatory Cells to Effector/Memory CDB+ T Cells Is Correlated with the Development of Acute Rejection

**Methods:** Single center retrospective case-control study examined all kidney transplant biopsies conducted at Einstein Medical Center from Jan 2013 through Dec 2014. Biopsies were stratified for rejection (acute cellular, borderline, negative). The NLR and PLR were calculated from routine laboratory studies obtained at various time points preceding the biopsy.

**Results:** Of the 102 “cause” biopsies, 37.3% showed clear evidence of acute rejection and 18.6% were borderline. NLR and PLR obtained within the week prior to the biopsy showed a significant reduction in NLR (p<0.001) and PLR (p<0.04) in patients with acute rejection. The AUC for NLR in NLR and PLR preceded the biopsy by 2-4 weeks suggesting a rejection prodrome. Interestingly, NLR at the time of borderline rejection accurately predicted rejection status on subsequent biopsy conducted within 8 weeks.

**Conclusions:** NLR and PLR are highly sensitive biomarkers for acute rejection which become positive prior to other clinical manifestations. Furthermore, in cases of borderline biopsies NLR accurately predict the result of subsequent biopsies. The inclusion of NLR and PLR could revolutionize allograft rejection evaluation by reducing the need for biopsies and providing additional insight in cases where the biopsy is non-diagnostic.

Quantitative Characterization of T Cell Repertoires in Kidney Transplant Patients

Houda Alachkar, 1 Martin B. Mutonga, 1 Taigo Kato, 1 Sowjanya Kalluri, 3 Vikas Vujiñi, 2 Yusuke Nakamura, 2 Nada Alachkar. 2, 3 Univ of Chicago; 4 Johns Hopkins Univ; 5 Kendall Medical Center.

Background: Acute and chronic T cell mediated rejection remains a major cause of kidney graft failure. Despite the significant decrease in early acute rejection due to current potent immunosuppressions, long-term graft survival remains unsatisfactory. Thus, characterization of the T cell repertoire and the kinetic of the expanded clones in transplant (Tx) patients may shed a light on our understanding of the T cells' role in graft rejection.

Methods: We collected blood and urine samples from (46) patients before Tx, and at sequential time points post Tx and at time of T cell mediated rejection. We utilized next generation sequencing approach to characterize T cell receptor (TCR) repertoire. Sequencing using the illumina miSeq was performed on DNA synthesized from RNA extracted from patients' samples. This approach enables to track each expanded TCR clone in the graft at 3 months post Tx, back to their first appearance in blood and urine samples obtained pre or 1 month post Tx. We also measured the RNA expression levels of CD8, CD4, FOXP3, Granzyme and Perforin in blood samples (N=43).

Results: Only patients with acute T cell mediated rejection (n=2) had TCR repertoires defined by the top 10 TCR clones appeared at any time point in blood, showed significant expansion in blood at 3 month post Tx compared with that at 1 month post Tx (P<0.01 and 0.02). CD8, FOXP3, Granzyme and perform RNA levels were significantly higher in samples obtained from patients with rejection compared to that in patients with no rejection (P<0.02).

Conclusions: Our study provides valuable comprehensive longitudinal analyses that define the kinetics of each TCR beta clone, and the changes in diversity of CDR3. This approach allows for identification of the expanded T cell clones that are possibly associated with graft rejection.

SA-PO971

Critical Appraisal of the New Banff Criteria for Chronic Antibody-Mediated Rejection in the Real Life Setting

Isabelle Houde, Isabelle Côté, Molsen Agharazii, Sacha A. De Serres. Renal Div, Quebec Univ Health Center; Laval Univ, Quebec City, QC, Canada.

Background: Significant changes in the criteria for chronic active antibody-mediated rejection (CAABMR) were made at the 2013 meeting, which is of major concern for clinical management. Here we compared the 2007 vs. 2013 criteria with regards to clinical outcomes.

Methods: Single-center, observational retrospective cohort study of all patients who received an indication biopsy between January 2006 and October 2014, during which EM evaluation, ptc scoring and C4d scoring by IH and IF was routinely performed. Patients were included if they met the criterion 1 for CAABMR: score cg1a>0, cg1b>0 or severe peritubular capillary basement membrane multilayering. GN, immune deposits, HCV+ status or suspicion of TTP-HUS were excluded. The endpoint was a composite of doubling of serum creatinine and death-censored graft loss.

Results: 123 patients were included. 18% met the full 2007 criteria, whereas an additional 18% fulfilled the full 2013 criteria. Only 25% of patients met the 2007 criterion #2-C4d, in contrast to 82% for the 2013 criterion #2-microvascular injury (MVI). 67% were C4d-positive and 55% were g’ptc positive, with substantial overlap. 45 patients experienced the endpoint at a median of 22mo post-biopsy. Overall, only a 2013 diagnosis of CAABMR was associated with the endpoint (adjusted HR=2.5 [1.2-5.0] for 2013 vs. HR=1.6 [0.7-3.8] for 2007 diagnosis). Adjusted Cox modelling revealed that the 2013 criterion #2-MVI was more strongly associated with the endpoint than the 2007 criterion #2-C4d (HR=4.0 [1.1-14.1] vs. HR=2.3 [1.0-5.3]). When the 2013 criterion #2 was dissected by component, the C4d-component was significant (HR=2.5 [1.1-5.4]), but the g’ptc (HR=1.0 [0.5-2.3]).

Conclusions: Compared to the 2007 criteria, applying the 2013 criteria here doubled the proportion of patients with CAABMR. Importantly, it improved the association with clinical outcomes.

SA-PO972

Tissue Expression of Aquaporine 2 Is Correlated to Urine Output and Allograft Function in Sensitized Kidney Transplant Patients

Luis Eduardo Becker, 1 Martin G. Zeier, 1 Christian Morath. 1 Nephrology, Univ of Heidelberg, Germany; 2 Pathology, Univ of Heidelberg, Germany.

Background: Salt and water disturbances often occur during acute kidney allograft dysfunction contributing to graft failure, but this condition has still been poorly investigated in the setting of allograft rejection. We evaluated the tissue expression of aquaporins (AQP1, AQP2) and of the epithelial sodium channel (ENaC) in kidney allograft biopsies from transplant patients with high immunological risk.

Methods: Eighty-six kidney transplant biopsies from thirty-three sensitized patients were divided into three groups according to the clinical context a possible pathological correlates as follows: time-zero/tx biopsy (N=9), protocol (N=9) and indication (N=68) biopsies. The indication biopsies were further divided into three subgroups, according to the presence or absence of acute tubular necrosis or acute rejection. Normal kidney tissue samples (N=6) served as controls. Immunohistochemical expression of AQP1, AQP2 and ENaC was analyzed with assistance of an image software.

Results: We observed a significantly lower AQP1 expression in time-zero and indication biopsies with rejection compared to controls (7.7±2.0% and 9.1±0.6% vs. 14.3±2.9% of area positively stained; P=0.03 and P=0.04 respectively). AQP2 expression was significantly lower in patients with an indication biopsy when compared to controls and protocol biopsies (21.0±2.9% vs. 4.4±0.7 and 4.0±0.5% of area positively stained, P=0.05 and P=0.005, respectively). For ENaC, a lower expression in indication biopsies compared to controls was seen (P=0.04). Both AQP1 and AQP2 tissue expressions were significantly correlated to the urine output (r=0.45 and r=0.32; P=0.001 and P=0.02, respectively), and AQP2 was correlated to the MDRD-glomerular filtration rate at the time of biopsy (r=0.23; P=0.05).

Conclusions: Our findings can partially confirm previous experimental data showing downregulation of AQP1 expression after ischemia-reperfusion injury and during rejection. AQP2 downregulation seems to be rejection-independent occurring during deteriorating or poor kidney graft function.

SA-PO973

The Utility of Protocol Biopsy in Renal Recipients: Meta Analysis and Systematic Review

Background: To evaluate the value of protocol biopsy in patients after renal transplantation.

Methods: Searches were applied to the following electronic database: Medline, Embase Database, Cochrane Library, Randomized controlled trials evaluating the value of protocol biopsy for renal allograft recipients were included. Data were extracted independently by two reviewers. The risk of bias of included studies was assessed by the Cochrane collaboration’s tool for assessing risk of bias.

Results: 5 RCTs were included. Long term graft loss was significantly reduced (RR 0.40, 95% CI 0.25 to 0.65, P=0.001 (figure 1) by protocol biopsy after renal transplantation.

Conclusions: Protocol biopsy may reduce the long term serum creatinine (WMD 38.21, 95% CI 54.83 to 21.60, p<0.00001). For renal recipients whose basal immunosuppression is CNI (tacrolimus or cyclosporine), protocol biopsy can significantly improve the long term eGFR (SMD 0.78, 95% CI 0.51 to 1.05, P=0.00001). However, for those whose basal immunosuppression is tacrolimus, this effect is not notable. Protocol biopsy seems to have no significant beneficial effect of reducing clinical acute rejection episodes.

SA-PO974

Longitudinal Biopsy Findings Among Children, Adolescents, and Young Adult Renal Transplant Recipients from a Southeastern USA Cohort

Jonathan Alexander Miles, 1 Panupong Harthsuvit, 1 Katherine D. Westreich, 2 Evan Zeitler, 2 Randall K. Detwiler, 2 Maria E. Ferris. 1 East Carolina Univ, Greenville, NC; 2 Chulalongkorn Univ, Bangkok, Thailand; 3 UNC at Chapel Hill, Chapel Hill, NC.

Background: Longitudinal procedure history in children, adolescent, and young adult renal transplant recipients needs to be characterized based on their primary cause of end-stage renal disease (ESRD). It is known that pediatric patients are a high risk group for transplant failure. Elucidating potential factors for transplant failure in this group is important for protecting vulnerable patients.

Methods: Clinical, demographic and pathological records of patients who received a renal transplant at age ≤ 30 years of age and who underwent transplant biopsies between 2000 and 2014 at the UNC Hospitals were analyzed. This cohort was classified based on
the primary cause of ESRD as either glomerular or non-glomerular. Demographics, number of biopsies (total and adjusted for graft failure), and transplant failure (rates and cause) were compared between the two groups.

Results: We enrolled 179 patients; 105 (58.7%) were male; 67 (38.3%) African American, 92 (51%) Caucasian, and 20 (11%) other race. Their mean age at transplant was 18.7 ± 8.2 years and 98 (55%) had a glomerular cause of ESRD. This cohort underwent a total of 505 graft biopsies. Comparing patients with glomerular vs. non-glomerular conditions, we found no significant differences in cellular or humoral rejections (p=0.430); mean number of biopsies (3.0 ± 1.9 glomerular; 2.7±1.9 non-glomerular; p=0.289); mean number of biopsies per year for failed transplants (p=0.702), current functioning grafts (p=0.090); time to a failed transplant (p=0.476); or age at time of transplant (p=0.136).

Conclusions: In this single institution cohort of children, adolescents and young adults, we found no statistical differences in renal biopsy findings regarding number of biopsies and transplant failure. This high risk age group shows no different longitudinal graft survival based on primary cause of ESRD. More analysis will follow.

Prospective Study of Risk Factors and Impact of Subclinical Rejection (SCR) and Acute Clinical Rejection (ACR) in Renal Transplant Recipients

Rajiv B. Mehta,1 Puneet Sood,2 Arvind Cherukuri,1 Shan Shan Chen,1 Chethan M. Puttarajappa,1 Christine Wu,1 Nirav A. Shah,1 Parmjeet S. Randhawa,2 Sundaram Hariharan.1 1Starzl Transplantation Inst, Univ of Pittsburgh Medical Center, Pittsburgh, PA; 2Dept of Pathology, Univ of Pittsburgh Medical Center, Pittsburgh, PA.

Background: The long term outcomes of subclinical rejection (SCR) remain unclear. The current study evaluated the risk factors for SCR at 3 mths and followed up renal function upto 1 year in pts with SCR, ACR and no rejection.

Methods: We prospectively followed 340 pts who underwent an ABO compatible kidney transplant between Jan 2013 and Sep 2014. Eight pts were excluded. All patients received induction therapy with either thymoglobulin (95%) or Basiliximab for induction, CNIs/MPA for maintenance therapy and rapid steroid withdrawal by day 7. Protocol biopsies were performed 3 months post transplant. Based on this, they were divided into 4 groups. Grp 1 - pts with SCR, Grp 2 - pts with normal biopsy; Grp 3 - pts with ACR; Grp 4 - pts with no biopsy. Banff classification was followed for biopsy grading. Steroids, thymoglobulin and PPI IVG were used as indicated for the treatment of rejection.

Conclusions: 1. Incidence of SCR and ACR around 3 mths was 18.6% and 9.9% respectively 2. Significant risk variables for SCR/ACR were female recipients and DGF 3. No difference in renal function was noted between the groups at 1 year.

SA-PO976

Histological Scoring System Predicts Renal Outcome of Post Transplantation Acute Tubular Necrosis: A Single-Center Experience in Japan

Tobias Pieters,1 Lucas Falke, Tri Q. Nguyen, Marianne C. Verhaar, Roel Goldschmeding, Maarten B. Rootmaker. 1Nephrology and Pathology, UMC Utrecht, Netherlands.

Background: Acute Tubular Necrosis (ATN) is a common cause of Delayed Graft Function (DGF) after renal transplantation (RTX). Currently no histological model is available to predict renal outcome. Recovery of ATN is the result of the balance between regeneration and repair. In this study we evaluated the predictive value of immunohistochemical parameters of renal damage and regeneration and compared these to an accepted clinical prediction model for cadaveric renal transplantation.

Methods: We included 25 patients that underwent cadaveric RTX with DGF caused by ATN only, as shown in a renal biopsy 1 week after RTX. Biopsies were evaluated for histological tubular damage (atrophy, edema, casts, vacuolization), DNA damage (γH2AX staining) and apoptosis (cC3 staining). Regeneration was assessed by staining for stem cell marker CD133 and proliferation marker Ki67. Clinical parameters for renal outcome were collected as previously described in the Deceased Donor Score (DDS). The relation between these parameters and renal outcome, defined as eGFR at 6 months, was assessed using regression or one-way ANOVA. A correct analysis for regenerative markers was performed to eliminate potential confounding by the amount of renal damage.

Results: The histological damage score significantly predicted renal outcome (R= 0.52 P<0.01), whereas the DDS only tended to correlate with renal outcome (F:3.12 R: P=0.05). Neither staining for DNA damage, nor for apoptosis could predict renal outcome (R= 0.24 P=0.91 and R= 0.16 P=0.44 respectively). In addition, the investigated parameters for regeneration (CD133 and Ki67) did not predict renal outcome (R= 0.25 P=0.23 and R= 0.10 P=0.63 respectively), also not after correction for renal damage.

Conclusions: We are the first to show that histological parameters can predict renal outcome of post transplantation ATN. Importantly, our histological damage score correlated better with renal outcome than the DDS. Despite the crucial role of regeneration in recovery after ATN, no relation was found between stem cell marker CD133, proliferation marker Ki67 and renal outcome.

Histopathological Changes and Graft Survival of Long-Term Kidney Allograft in Alport Syndrome: A Single-Center Experience in Japan

Yasuuyuki Nakada,1 Izumi Yamamoto,1 Akimitsu Kobayashi,1 Yudo TAMNO,1 Hiroyasu Yamamoto,1 Masayoshi Okumi,2 Hideki Ishida,2 Takashi Yokoo,1 Kazunari Tanabe.2 1Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ of Medicine, Tokyo, Japan; 2Dept of Urology, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Patients with Alport syndrome (AS) commonly develop progressive kidney dysfunction due to a hereditary type IV collagen deficiency, which results in an abnormality in the glomerular basement membrane (GBM). Recurrent glomerulonephritis does not occur in transplanted kidneys, and the allograft survival rate in these patients is similar to that in patients with other renal diseases. Several studies have shown that the type IV collagen of the GBM originates from the recipient’s bone marrow–derived cells. Therefore, we postulated that recurrent glomerulonephritis could occur locally and should influence the long-term allograft survival. In this study, we investigated graft survival and histopathological changes in renal allograft recipients with AS, focusing particularly on whether the expression of GBM type IV collagen is altered.

Methods: We collected data on the clinical characteristics of 19 renal allograft recipients who had been diagnosed with AS. All data were obtained from a database at the Department of Urology, Tokyo Women’s Medical University. Graft survival was evaluated using the Kaplan–Meier method and compared with a control group (n = 18). We assessed the double staining of a2 and a5 using frozen specimens obtained from long-term allograft survival samples.

Results: The graft survival rate was not statistically different between patients with AS and controls (log-rank p = 0.2240). Immunoreactivity to a5 antibody in four patients exhibiting long-term allograft survival showed strong linear positivity and no GBM abnormalities. In the case of chronic active antibody-mediated rejection, the immunoreactivity to a2 antibodies increased in the mesangium and subendothelial space.

Conclusions: These results suggest that the GBM type IV collagen structure was histopathologically maintained for the long term after kidney transplantation, indicating better kidney graft survival in patients with AS.

A clinical need exists for a noninvasive method for diagnosing AMR. Endothelial cells (HMEC-1) and a monoclonal murine antibody against human HLA class II molecules were used to explore endothelial microvesicles in vitro to explore endothelial microvesicles in vitro and to explore endothelial microvesicles in vitro and to explore endothelial microvesicles in vitro and to explore endothelial microvesicles in vitro and to explore endothelial microvesicles in vitro.

**Results:**

Total number (n) and mean n of biopsies per patient performed are overall similar in both groups until mo60. N of pts with at least one rejection (as per final clinical diagnosis) was slightly higher in CNI group vs EVR group. N of pts with IFTA was higher in the EVR group especially due to mild, early acute rejections (mostly BANFF IA and IB). N of pts with histological evidence of chronic allograft nephropathy was similar in both groups (10%). CNI staining positivity was found slightly higher in the EVR group (11% EVR vs 7% CNI), however, pts with evidence of antibody mediated rejection was higher in the CNI group (2% EVR vs 4% CNI), same for CNI-induced toxicity lesions (16% EVR vs 23% CNI). The diagnosis of AMR is dependent upon pathologic examination of renal biopsy tissue. HLA on the endothelial cells activate the complement system via the classical pathway. This leads to deposition of complement split products on the cell surface (analogous to C4d deposition in biopsies from patients with AMR) and increased release of endothelial microvesicles. Consequently, Dual LCA/C4d BIC aided the evaluation quantification of inflammatory infiltrate in renal allograft rejection, possibly allowing finer and more reproducible discrimination between ptc and i scores and identifying the extent of glomerulitis. Annular detection of tubulointerstitial inflammation is unclear. We aimed the study to determine the role of CD3+CD8+Gzm-B+ cell-mediated rejection in renal transplant recipients. We evaluated a dual pan-leukocyte marker (LCA) and a vascular endothelial cell marker (CD34) immunohistochemistry and flow cytometry. Microvesicle analysis was performed using flow cytometry.

**Results:**

We have shown that W6/32 antibody binds HMEC-I cells and activates the classical complement pathway upon exposure to normal human serum. This leads to deposition of complement split products on the cell surface (analogous to C4d deposition in biopsies from patients with AMR) and increased release of endothelial microvesicles. Furthermore, anti-HLA antibody (W6/32), C3, and C4 were deposited on the surface of the microvesicles.

**Conclusions:**

Our results suggest that AMR will lead to an increase in production of microvesicles by the renal endothelium, and AMR-associated microvesicles will have surface-bound IgG and C4d. We have obtained human plasma samples from renal transplant recipients with AMR and healthy controls, and we are currently examining the potential of endothelial microvesicles as a biomarker of AMR.

**Funding:** NIDDK Support
Methods: We identified 15 normal transplant kidney biopsies without leukocyturia (Group 1) and 33 biopsies with non-specific interstitial fibrosis/tubular atrophy (IFTA) for gene expression profiling. Of the 33 biopsies with IFPTA, 24 patients had no sterile leukocyturia (Group 2) and 9 patients had sterile leukocyturia (Group 3). Biopsies with a diagnosis of acute or chronic rejection, recurrent or de novo glomerular disease, or polypoma nephropathy were excluded. Leukocyturia was defined by the presence of more than 10 leukocytes in the urine (>10/L) without bacterial growth in urine culture. The urinalysis was done within 1 month before or after the biopsy. The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: There was no significant difference in age, race, and sex, type of transplant, previous history of transplantation or acute rejection, donor characteristics, panel reactive antibody levels and immunosuppressive treatment between the Groups 2 and 3. Both groups also had similar acute and chronic Banff leukocyturia injury scores. There was a statistically significant decrease in gene expression profiles between the Group 1 and 2. When Group 3 biopsies were compared to the Group 1 and 2 biopsies, significantly increased gene transcripts were associated with cytotoxic and regulatory T cells, and macrophages (P-value for significance <0.05). There was a trend towards increased interferon-gamma and rejection associated transcripts but no statistically significant difference in expression of B-cell or natural killer cell associated transcripts.

Conclusions: The biopsies of the patients with sterile leukocyturia showed increased expression of gene transcripts associated with T cells indicating heightened inflammatory immune activity. Those patients might require close monitoring of their allograft function.

SA-PO983
Elevated Glomerular Mechano-Growth Factor and Vascular Endothelial Growth Factor in Chronic Allograft Nephropathy Is Associated with Activation of Erk1/2
Yunxiong Guo,1 Rafaat Farag Makary,2 Carmela B. Montiero,2 Leighton R. James,1 Charles W. Heilig.1 1Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL; 2Pathology, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.

Background: We previously identified increased GLUT1 glucose transporter, Mechano-Growth Factor (MGF) and Vascular Endothelial Growth Factor (VEGF) in human Chronic Allograft Nephropathy (CAN) kidneys which demonstrate glomerulosclerosis. Here we investigated a glomerular signaling pathway, Erk1/2, with potential to mediate effects of MGF and VEGF on extracellular matrix (ECM) genes. We employed IHC with specific antibodies to assess protein expression for MGF, VEGF and phospho-Erk1/2 (active Erk1/2) in human CAN kidneys vs Normal Control kidneys.

Methods: This study involving examination of archived renal biopsy samples was approved by the Institutional IRB. N = 6 for each group of renal transplant - and native kidney specimens. Immunolabelling of human CAN and Normal Control paraﬃn-embedded kidney sections was performed for assessment of selected proteins with specific antibodies, by use of immunoperoxidase stain. Scoring of glomerular immunolabelling for individual proteins was 0 – 4. Data was normalized to open glomerular tuft area. P < 0.05 was considered significant in statistical analysis.

Results: Glomerular MGF protein was increased 3.9-fold in CAN kidneys vs Normal Control kidneys, P < 0.001. Glomerular VEGF was elevated 3.0-fold in CAN vs Normal Control kidneys, P = 0.009. Both of these growth factors have potential to signal via Erk1/2 to ECM expression. Glomerular Erk1/2 activation (i.e. phospho-Erk1/2) was examined and found to be increased 4.3-fold in CAN vs Control, P < 0.0001.

Conclusions: Human CAN, characterized by excessive glomerular MGF and VEGF expression, involved enhanced activation of Erk1/2 in the glomeruli. This provides a mechanism which might induce ECM production and glomerulosclerosis. Therefore, MGF and VEGF activation of Erk1/2 may contribute to progressive glomerulosclerosis and renal failure in CAN.

Microarray Analysis of Interstitial Fibrosis/Tubular Atrophy in Kidney Transplant Recipients Using Formalin-Fixed, Paraffin-Embedded Renal Biopsy Tissue
Sanjeev Akkinsa,1 Vishal K. Varma,2 Michael J. Walsh,3 Suman Setty,4 Medicine/Nephrology, Univ of Illinois at Chicago, Chicago, IL; 1Pathology, Univ of Illinois at Chicago, Chicago, IL.

Background: Interstitial fibrosis/tubular atrophy (IFTA) is a common and complex feature of renal allograft dysfunction that is difficult to predict. Early identification of progressive IFTA (pIFTA) may lead to alternative therapies that may attenuate irreversible injury. In this study, we used formalin-fixed, paraffin-embedded (FFPE) renal biopsy specimens with microarrays to conduct differential gene expression studies to identify predictors of IFTA in kidney transplant recipients.

Methods: We identified 22 individuals with multiple protocol biopsies within the first 3 years after transplant. Glomeruli and blood vessels were removed using laser capture microdissection and the remaining tissue was used for mRNA extraction. Affymetrix PrimaGene arrays were used following standard protocols. IFTA was defined by histological image masking in Histolab to quantify the cortical interstitial fraction. pIFTA was defined as a 0.5% absolute increase in the interstitial fraction per month between serial biopsies. Data analysis was conducted using R 3.0.2 and Bioconductor 2.22. Significance was defined as an unadjusted p<5 x 10^-6.

Results: Of the 22 subjects in this study, 9 had pIFTA while the remaining 13 were considered stable IFTA (sIFTA). At baseline, the eGFR was 60.5 vs 58.5mL/min/1.73m2 (p=0.79) and log(Urine Albumin) was 3.44 vs 3.17 (p=0.072) for the sIFTA and pIFTA groups, respectively. The baseline fibrosis was higher in the sIFTA group (18%) compared to the pIFTA group (13%); p=0.04. Using linear modeling, 3 of the top 6 differentially expressed genes were metallothionein (MT1A and MT1X) and RASA1. Paired analysis of serial biopsies did not reveal any significant differences between sIFTA and pIFTA.

Conclusions: Microarray analysis of FFPE specimens show that pIFTA is associated with the differential expression of multiple genes prior to phenotypic changes. Prospective investigation of these genes is needed to determine if these are predictive of pIFTA.

Pathological Analysis for Transplant Nephropathy - 124 Consecutive Cases in a Single Center Study Over 10 Years
Masaki Muramatsu,1 Masaki Lee,1 Atsushi Aikawa,2 Carmelo Puliatti,1 Muhammad M. Yaqoob,1 Michael Sheaff.1 1Nephrology, Transplantation and Cellular Pathology, The Royal London Hospital, London, United Kingdom; 2Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.

Background: Transplant nephropathy (TNx) is performed for several indications. This study evaluates in depth histological analysis of TNx specimen.

Methods: We identified all cases at the Royal London Hospital between 2004 and 2014. The indication for TNx was divided into four groups: 47 cases with acute graft loss without significant blood flow (AGL); 44 cases of suspected ongoing rejection or graft intolerance syndrome (Rej/GIS); 24 cases with infection (INF); and 9 miscellaneous reasons (MIS). We examined the histological changes in detail and specifically looked at the artery, vein and ureter.

Results: AGL was less likely to have tubulointerstitial changes, but 74.5% had necrosis. In the AGL group, the majority of cases scored zero for t, 1, c1 and c2. Neutrophil rich arteritis at renal and small arteries was observed in 29.8% and 19.2%. Venous thrombosis was found in 61.7%. All cases in the Rej/GIS group showed c1 and c2 and 49.0% showed c3 and c4. Glomerulitis was observed in 52.3% and c2 was detected in 75.1%. Arteritis of small and renal arteries was detected in 70.5% and 59.1%. C4d expression was present in 54.1%. Nearly 70% showed ureteric inflammation. Variable cellular infiltrate comprising of lymphocytes, plasma cells and eosinophil were seen in all cases. In the INF group, 66.7% (i1-3) and 79.2% (i1-3) were observed, and c3 and c1 were detected in 66.7%. Glomerulitis was rare although allograft nephropathy was detected in 62.5%. All cases had intimal thickening of small and renal arteries but arteritis was unusual. Lymphocyte and plasma cell were common at interstitium and corticalis. In the MIS group, histological changes were minor, t3, i1-3, arteritis and venulets were not detected.

Conclusions: The histological changes were similar and specific within the TNx groups but different between the groups. A failed graft often showed substantial immunological response. In depth histological analysis may aid management of subsequent grafts.

SA-PO986
miRNAs as Novel Biomarkers for Transplant Patient’s Evolution
Esperanza Macarena Rodriguez serrano,1 Cristina Galeano,1 Edurne Ramos,1 Elisa Conde,1 Laura Martin-Gomez,1 Sara Gimenez-Moyaño,1 Maria Laura Garcia-Bermejo,1 Fernando Liano.2 1Biomarkers and Therapeutic Targets Unit, IRYCIS; 2Nephrology, Ramon y Cajal Hospital.

Background: Transplanted patients evolution and outcome is dependent on many factors including allograft function, vascular homeostasis and immunogenity. Up to this moments, apart from creatinine renal biopsy, there are no quantifiable and accurate biomarkers to predict the evolution of the allograft and the receptor, what would enable clinicians to improve the transplanted patient’s management. Our group has validated a combination of serum miRNAs as accurate biomarkers for AKI from ischemic aetiology, including: miR-127, miR-101, miR-210, miR-146a, miR-20b, miR-29a, miR-10a, miR-93 and miR-27a. Here we have determine the expression of these miRNA in serum from kidney donors and receptors and correlate this expression with clinical parameters of allograft evolution, including ATN development, delayed graft function, rejection and vascular complications.

Methods: For this purpose, serum sample from brain death donors and receptors along post-transplantation period (6h, 1, 2, 3, 4, 5, 6 and 7days and 1,3,6 months) in 30 transplanted patients form our Hospital. After RNA extraction from serum, the combination of miRNAs has been determined by qRT-PCR and correlation with clinical data has been established using SPSS.

Results: The expression of these 10 miRNAs in serum samples from donors did not exhibited significant differences among them. This combination neither correlate with immediate delay graft function because NTA or immunological rejection. However, some of the miRNAs correlate with long term evolution of transplanted patients in terms of non-optimal graft function and they also discriminate patients with also exhibited renal allograft alterations.

Conclusions: In summary we have identified miRNAs that correlates with long term evolution of transplanted patients. These information could be useful for improve transplanted patient’s evolution differentiating patients with potential renal allograft function and they also discriminate patients with also exhibited renal allograft alterations.

Plasma MicroRNA 17 Host Gene Protein level Cluster and Tumor Necrosis Factor-Alpha (TNF-α) in Patients with Renal Transplantation: Relation to Allograft Function and Survival

Havam A, El Aggan, 1 Sabah Abdel Hady Mahmoud, 2 Mohamed Mohamed Saker. 1 Internal Medicine, Faculty of Medicine, Alexandria, Egypt; 2 Medical Biochemistry, Alexandria, Egypt.

Background: Chronic allograft dysfunction (CAD) remains the leading cause of late graft loss after kidney transplantation. MicroRNAs (miR) are small (19-25 nucleotides) noncoding RNAs that regulate gene expression of diverse biological processes. The polycistronic miR-17~92 cluster is comprised of six miRs and its primary transcript may also encode for a polypeptide of 70 amino acids designated as the miR-17 host gene (MIR17HG) protein. So the aim of this work was to evaluate the plasma levels of MIR17HG protein and TNF-α levels in patients with renal transplantation in relation to renal allograft function and survival.

Methods: This study included 45 subjects; they were divided into three groups each 15, renal transplant patients with stable renal function (Group I), with CAD (Group II) and healthy subjects as controls (Group III). Quantitative determination of plasma levels of MIR17HG protein and TNF-α were performed using enzyme linked immunoassay (ELISA). Blood urea, serum creatinine and estimated glomerular filtration rate (eGFR), urinary albumin/urinary creatinine ratio and C-reactive protein (CRP) were done. Resistive index (RI) was calculated. Renal biopsy was done in patients with CAD.

Results: MIR17HG protein and TNF-α levels were significantly higher in renal transplant especially patients with CAD than the controls. In patients with renal transplantation, MIR17HG levels and TNF-α were positively correlated with each other and with serum creatinine, urinary albumin/creatinine ratio and CRP and was negatively correlated with e-GFR. The degree of fibrosis in renal biopsy was positively correlated with MIR17HG protein, TNF-α and resistive index (P<0.05).

Conclusion: MIR17HG Protein and TNF-α plasma levels can be served as circulating biomarkers for early detection of renal allograft dysfunction and follow up of patients with renal transplantation. They can act as a pro-fibrotic factor and denoting with MIR17HG protein, TNF-α levels and RI (P<0.05).

SA-PO988
Polyorphism of IL-17 and CXCL9 Genes, but Not AIF1 Gene, Affect Early Kidney Allograft Function After Transplantation

Lesznek Domanski, Karolina Kloda, Ewa Kwiatkowska, Kazimierz Ciechanowski. Clinical Dept of Nephrology, Transplantology and Internal Medicine, Pomeranian Medical Univ in Szczecin, Szczecin, Poland.

Background: Kidney transplantation outcome is determined by immunological and non-immunological factors, both the donor and the recipient dependent. There are reports suggesting that AIF1, IL-17 and CXCL9 genes polymorphisms might influence the post-transplant immune response, and thus kidney function. Therefore the aim of this study was analysis of association between 8 AIF1, IL-17 and CXCL9 polymorphisms and creatinine concentrations up to 1 year after transplantation.

Methods: The study enrolled 269 Caucasian renal transplant recipients (165 males, 104 females, mean age 47.63 ± 12.96 years). Blood samples were collected for genetic analysis and the specificity was 91.9%.

Results: The study enrolled 269 Caucasian renal transplant recipients (165 males, 104 females, mean age 47.63 ± 12.96 years). Blood samples were collected for genetic analysis and the specificity was 91.9%.

Conclusions: Polymorphisms of IL-17 and CXCL9 genes, but not AIF1 gene, affect early kidney function after transplantation. These preliminary results indicate that there is a need of genome-wide association studies scoring on genomics implicated in the immune response after transplantation.

Urinary K Cadherin Predicts Renal Allograft Dysfunction

Seema Jain, 1 Ekram Nabi, 2 Shirrose Abat, 2 Rajeshwar Ramkhelawon, 2 Sarah Yates, 1 Iain Jain, 2 Ho Lee, 1 Tae Won Lee, 2 Chun-Gyo Ihm, 3 Shin Yeong Lee, 4 Yang Gyun Kim, 2 Sang Ho Lee, 1 Da Wun Jeong, 1 Kuoyng Hee Yu hospital at Gangng; 2 Kuoyng Hee Yu hospital.

Background: To investigate whether urine and plasma Endothelial Cell Specific Molecule-1 (ESM-1) level could differentiate rejection from non-rejection in kidney transplantation (KTP) recipients, we compared ESM-1 levels according to allograft status.

Methods: We measured plasma and urine ESM-1 in 77 patients with underway KTP. The concentration of ESM-1 was analyzed by enzyme linked immunosorbent assay (ELISA). According to allograft status, Groups were divided stable, long-term good survival, immune tolerance, acute cellular rejection (ACR), acute antibody-mediated rejection (AMR) and chronic AMR.

Results: Plasma ESM-1 was not significantly different between all groups according to allograft status (p>0.42). Whereas, urine ESM-1 was significantly different between groups according to allograft status (p<0.001). Urine ESM-1 was higher in both ACR and acute AMR as well as chronic AMR than stable status. Patients with acute AMR showed significant higher level of urine ESM-1 compared with patients with ACR (p<0.05). Area under the curve (AUC) for differentiating acute AMR from ACR was 0.744 (p<0.01).

Conclusions: Urine ESM-1 may reflect endothelial injury of allograft and it could be used to differentiate the patient with acute AMR from ACR.

SA-PO998
Noninvasive Diagnostic and Predictive Value in Renal Transplant Recipients by Measurement of Urine BCA-1

Dainin Chen, 1 Kidney Disease Center; The First Affiliated Hospital, College of Medicine, Zhejiang Univ, P.R.China.

Background: To investigate the relationship between early-stage renal acute rejection and the level of BCA-1 in urine, explore the diagnostic value and noninvasive monitoring in cases with acute rejection after transplantation by measurement of urine BCA-1.

Methods: 145 patients were enrolled between January 2006 and October 2009, including 49 with biopsy-proved acute rejection, 58 patients with stable renal function and no abnormal histological findings, 9 patients with biopsy-proven acute tubular necrosis (ATN) and 30 patients with acute cellular rejection (ACR). ROC curve was constructed to determine the discriminatory power of BCA-1 levels for diagnosis of acute rejection. The area under ROC curve was 0.881 (95% CI 0.811-0.951), at a cut point of 0.23 µg/mmol creatinine, the sensitivity was 81.6% and the specificity was 87.9% (P<0.001). Patients with acute humoral rejection had significantly higher urinary BCA-1 concentration than patients with acute cellular rejection (24.2±6.68, 95% CI 5.93-34.8µg/mmol creatinine vs 2.91±0.65, 95% CI 1.64-22.4µg/mmol creatinine, P=0.0002). ROC curve was constructed to determine the discriminatory power of BCA-1 levels for diagnosis of acute humoral rejection. The area under ROC curve was 0.867 (95% CI 0.725-1.005) at a cut point of 8.3 µg/mmol creatinine, the sensitivity was 75% and the specificity was 91.9%.

Conclusions: The monitoring of BCA-1 in urine may be a new and noninvasive approach for detection acute rejection as well as useful to discriminate the type of rejection.

B Cell Attracting Chemokine 1 in Urine Is a Biomarker of Acute Humoral Rejection
Wenhan Peng, Jianghua Chen. Kidney Disease Center. The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.

Background: Presently, there are no noninvasive approaches which can be directly applied to clinical diagnosis of acute rejection (AR) or distinguish type of rejection in renal transplant recipients. The aim of this study was to construct diagnostic models of biomarkers in urine and serum from patients with AR or acute humoral rejection (AHR) in renal transplant recipients.

Methods: Concentration of nine biomarkers in urine of 81 patients with AR and 167 patients with stable renal function (No-AR) was determined by ELISA technique. Firstly, by discriminant analysis, we screened a number of biomarkers to construct the diagnostic models for AR and AHR. Secondly, another 102 patients with No-AR and AR were analysed to test the accuracy of the diagnostic model.

Results: Four biomarkers were selected to set up the diagnostic model of AR or No-AR. Based on the model of AR, 84.3% patients were correctly diagnosed. Two biomarkers were selected to set up the complementary diagnostic model of AHR. Based on the two model of AR, 100% patients with No-AR and 96.3% patients with AR were correctly diagnosed. Only B cell attracting chemokine 1 (BCA-1) was selected for the diagnostic model for AHR or acute cellular rejection (ACR). Rejectation rate of 81.5% patients with AR were correctly classified. Another 102 patients tested the accuracy of the diagnostic models. Diagnostic accuracy of AR or No-AR and AHR or ACR were 100% and 95.4% respectively.

Conclusions: Urinary BCA-1 was a valuable biomarker for determining AHR. These diagnostic models might directly identify AR and types of AR.

18FDG-PET/CT Imaging in Suspected Acute Renal Allograft Rejection
Pierre Lavrinoffέ, Laurent E. Weckx, Catherine Bonvoisin, Jean-Marie H. Krzesinski, Roland Hustinx, Francois Jouret. 1Nephrology, Univ of Liege Hospital, Liege, Belgium; 2Nuclear Medicine, Univ of Liege Hospital, Liege, Belgium.

Background: The diagnosis procedure for kidney transplant recipients (KTR) with suspected acute rejection (AR) relies on needle biopsy. Still, noninvasive tests to predict nonrejection would be useful to save selected patients from undergoing inessential biopsy. AR is associated with a recruitment of activated leucocytes into the transplant, which are characterized by a high metabolic activity and an increased uptake of glucose analog 18 fluoro-deoxy-glucose (18FDG). Thus, 18FDG-PET/CT imaging may help discriminate nonrejection, thereby avoiding unnecessary transplant biopsy in KTR with suspected AR.

Methods: From January 2013 to February 2015, we prospectively performed 32 18FDG-PET/CT in 31 adult KTR with suspected AR who underwent a biopsy. Biopsies were categorized as “normal”, “borderline”, “AR” or “others” according to Banff classification. PET/CT imaging was performed within 201 ± 18 minutes after i.v. administration of 3.2 ± 0.2 MBq/kg of 18FDG, before any modification of immunosuppression.

Results: Biopsies were diagnosed as “normal”, “borderline”, “AR” or “others” in 8, 10, 8 and 6 (including 3 polyoma-BK nephropathies) cases. AR was antibody-mediated in 1 case, whereas Type I, II and III cellular AR were found in 5, 1 and 1 cases, respectively. Mean SUV ranged 1.5 ± 0.2, 1.6 ± 0.3, 2.9 ± 0.8, 2.2 ± 1.2 in each category. Mean SUV of biopsy-proven AR was significantly higher than “normal” cases (p<0.01). No difference was found between “normal” vs. “borderline”, or between ”AR” vs. “others” histopathology. Still, a positive correlation between mean SUV and acute composite (g+i+t+v+ptc) Banff was found between “normal” vs. “borderline”, or between “AR” vs. “others” histopathology. A significant difference (p<0.01) was found in 11/18 (61.1%) patients with AR vs. “normal” cases. No difference was found in the other parameters.

Conclusions: 18FDG-PET/CT imaging may help discriminate nonrejection, thereby avoiding unnecessary transplant biopsy in KTR with suspected AR. The diagnostic model might be able to test the accuracy of the diagnostic model.

High Remnant-Like Particle-Cholesterol Is a Risk Factor of Worsening Graft Function in Japanese Kidney Transplant Recipients

Background: Many factors cause dyslipidemia after kidney transplantation. Low density lipoprotein cholesterol (LDL-C) has been focused to reduce cardiovasucular disease (CVD). However, residual risk factors such as triglyceride (TG), remnants or small dense low density lipoprotein cholesterol (LDL-C) and omega-6 fatty acid (18:2n6) has been focused to reduce CVD. We investigated whether residual risk factors affect graft function of kidney transplant function.

Methods: This study is a retrospective cohort study at a single center. Three hundred and seventy seven kidney transplant recipients (male 223) in more than six months after transplantation were enrolled. TG, Remnant-like particle-cholesterol (RLP-C), non-high density lipoprotein cholesterol (HDL-C), LDL-C, ApoB, eGFR (estimated glomerular filtration rate), Urine protein /day (UP), Body Mass Index (BMI) and other parameters at baseline were measured and we studied the association of residual risk factors with kidney function. High RLP-C is a risk factor of worsening graft function in Japanese kidney transplant recipients.

Conclusions: High RLP-C is a risk factor of worsening graft function in Japanese kidney transplant recipients.

SA-P0995
The Modification of Erythrocyte Membrane Fatty Acid Contents According to Kidney Transplantation: Prospective Study
Young Ki Son, Sung Hyun Son, Dongyeol Lee, Hyeon-Kyung Kil, Ki Geun Sohn, Sung Hyun Seo, Dongyeol Lee, Hyeon-Kyung Kil, Dongyeol Lee, Ki Geun Sohn, Sung Hyun Son.

Background: Modifications of erythrocyte membrane fatty acid (FA) contents may affect on cellular function or transmembrane receptors. The high erythrocyte membrane FA contents are related with acute cardiac syndrome. It is known that kidney transplant recipients have lower cardiovascular event than dialysis patients. Therefore, we prospectively evaluated whether erythrocyte membrane FA contents were modified after kidney transplantation (KTP).

Methods: We recruited 22 kidney transplanted recipients from September 2011 through May 2014. Blood samples were obtained just before KTP and at 6 months after KTP. The erythrocyte membrane FA contents were measured by gas chromatography.

Conclusions: The mean ages were 45.3 ±10.9 years. The erythrocyte membrane contents of omega-3 FA (10.1±3.9 vs. 5.5±3.63, p <0.001), omega-6 FA (26.6±6.2 vs. 20.7±7.7, p=0.008), arachidonic acid (11.6±4.1 vs. 7.7±4.7, p=0.001), docosapentanoic acid (1.4±0.7 vs. 0.7±0.5, p<0.001), docosahexaenoic acid (2.0±0.8 vs. 1.2±1.0, p=0.001), omega-3 index (70.3±2.5 vs. 4.1±2.7, p <0.001) were significantly higher but erythrocyte membrane contents of total saturated FAs (44.9±8.0 vs. 52.6±9.4, p=0.003), total monounsaturated FAs (17.2±1.6 vs. 19.9±2.2, p<0.001), total trans FAs (0.9±0.3 vs 1.1±0.2, p=0.011), oleic acid (15.7±1.5 vs. 18.0±1.9, p<0.001), and omega-6/omega-3 ratio (3.1±1.4 vs. 4.6±1.7, p=0.14) were significantly lower at 6 months after KTP.

Conclusions: FA contents of erythrocyte membranes including increased omega-3 FAs, decreased oleic acid and omega-6/omega-3 were significantly modified after KTP. These changes of erythrocyte membrane FA contents may effect on cellular function or transmembrane receptors. The high erythrocyte membrane oleic acid contents are related with acute cardiac syndrome.

**Diffusion Impairment Measured by Functional MRI Correlates with Allograft Fibrosis After Kidney Transplantation in Patients with Delayed Graft Function**

*Jan H. Braesen,1 Abedalrazag Ahmad Khalifa,1 Faikah Gueler,2 Frank Lehner,3 Wilfried Gwinner,4 Dagmar Hartung,1 Hermann G. Haller,2 Katja Hueper.5 Inst for Pathology, Hannover Medical School, Hannover, Germany; 6Clinic for Nephrology, Hannover Medical School, Hannover, Germany; 7Inst for Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; 8Clinic for General, Abdominal and Transplant Surgery, Hannover Medical School, Hannover, Germany.*

**Background:** Functional MRI parameters derived from diffusion weighted (DWI) and diffusion tensor imaging (DTI) correlate with renal fibrosis and cell infiltration in experimental studies. Aim of this study was to investigate these non-invasive techniques in patients with delayed graft function (DGF) and to correlate diffusion parameters with renal function and renal histology of allograft biopsies.

**Methods:** 33 patients with initial graft function between day 4 and 11 after kidney transplantation and 31 patients with DGF were examined on a 1.5 Tesla MRI. DTI and DWI sequences were acquired and apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were calculated. Kidney biopsies were available in 26 patients and analysed for acute rejection (Banff), amount of fibrosis, inflammatory infiltrates, and tubular injury as well as edema.

**Results:** ADC was significantly reduced in patients with DGF compared to patients with initial function. Similarly, FA, representing the degree of directed diffusion along anatomical structures such as tubules, collecting ducts and vessels, was impaired in DGF patients. ADC and FA positively correlated with renal function (r=0.573 and r=0.53, p<0.001) and negatively with the amount of renal fibrosis. Diffusion parameters in DGF patients did not discriminate between acute rejection and tubular injury. Histological evaluation of the allograft biopsies did not reveal any significant differences between DGF or initial function in the following parameters: leukocyte infiltration (CD4, CD8, CD15, CD20, CD68), CD31 positive peritubular capillaries or edema (interstitial tubular).

**Conclusions:** Functional MRI with diffusion techniques detects allograft dysfunction early after kidney transplantation correlating with allograft fibrosis. Biopsy is needed to verify rejection.

**Funding:** Government Support - Non-U.S.

**SA-PO997**

**Identification of Common Biological Mechanisms of Fibrosis in Transplanted and Native Kidneys with Chronic Diseases**

*Konrad S. Famluski, Jeffery M. Venner, Jeff Reeve, Philip F. Halloran. Univ of Alberta, Edmonton, AB, Canada.*

**Background:** In both primary kidney diseases and in transplants fibrosis is caused by chronic progressive diseases. Hence, we hypothesised that fibrosis has fundamental common biological pathways in native and transplanted kidneys.

**Methods:** We studied the molecular associations with fibrosis in 703 kidney transplant indication biopsies (bx) 3 days to 35 years post-transplant. The number of bx with fibrosis increased with time post-transplant and most bx with ci>1 (74%) were attributable to time-dependent diseases (ABMR, GN, TG).

**Results:** By microarrays we compared bx with ci<1 to those with little or no fibrosis (ci<1) and determined the association strength of transcripts (p-value) for ci<1. First we focused on transcripts previously associated with fibrosis: immunoglobulin, mast cells and AKI-associated transcripts. Strongest associations with ci<1 were for immunoglobulin and mast cell transcripts, but not for AKI transcripts. Because time of bx post-transplant is highly correlated with ci, we repeated the comparison of ci<1 vs. ci<1 after correcting for time. This resulted in a massive reduction in association strength for the immunoglobulin transcripts, whereas AKI transcripts were now more strongly associated with fibrosis (from 10e-9 to 10e-18). Thus time correction emphasised the injury-repair response at expense of inflammation. We then analyzed the fibrosis associated transcripts in native kidneys (CKD). 73% of CKD transcripts overlapped with our transcripts.

**Conclusions:** Fibrosis in transplants and native CKD is characterized by the same inflammatory compartment, response to injury and loss of metabolism. Some of these processes might be related to the duration of chronic disease.

**DNA Double Strand Breaks Induced Collagen Type V1 Secretion of Glomerular Endothelial Cells in Renal Allografts**

*Yuki Matsui, Norifumi Hayashi, Junko Imura, Keiji Fujimoto, Hiroki Adachi, Hiduki Yamada, Hitoshi Yokoyama. Nephrology, Kanazawa Medical Univ, Uchinada, Japan.*

**Background:** The relationship between DNA injury and glomerular fibrosis in renal allografts remains unclear.

**Methods:** We examined renal allograft specimens from 35 patients in which DNA double-strand breaks and glomerular fibrosis were detected by phospho-histone H2A.X (γ-H2AX) expression and collagen (COL) types III, IV, and VI accumulation. We also examined the in vitro relationship between DNA damage and COL accumulation by mitomycin C (MMC)-induced DNA damage in human glomerular endothelial cells (HRGEc).

**Results:** The γ-H2AX and COL type V1, which mainly accumulated in the subendothelial and mesangial regions, were positively correlated with the duration of the post-renal transplant (RT) period (r=0.691, p<0.01; r=0.760 p<0.01, respectively). In multiple regression analysis, the duration of the post-RT period and cd in the Banff’07 classification were identified as significant predictors of COL type V1 accumulation (β value=0.699 p=0.001; 5.556, p=0.035, respectively) and γ-H2AX expression in the glomerular capillaries (β value 0.700 p=0.001; 2.031, p=0.011, respectively). In addition, the γ-H2AX-positive area was also identified as a predictor of glomerular accumulation of COL type V1 (β value=0.439, p=0.028). In the immunohistochemistry examination, γ-H2AX was detected in most cells after 24 hours’ MMC treatment, whereas no γ-H2AX expression had been detected before the MMC treatment. Although COL type V1 was detected around the nuclei of the HRGEc before the MMC treatment, it was not present there after the MMC treatment. COL type V1 was detected in the cytoplasm of the HRGEc, which was secreted into the supernatant after MMC stimulation with γ-H2AX expression. The number of γ-H2AX + COL type V1 (+) cells was inversely associated with the number of γ-H2AX (+) COL type V1 (+) cells (r=0.655, p=0.001) during 24 hours’ MMC treatment.

**Conclusions:** Our findings suggested that over the long term RT may induce DNA double-strand breaks and HRGEc-secreted COL type V1 accumulation in the glomerular capillaries, which might progress to intractable glomerular fibrosis.

Imatinib Improves Interstitial Fibrosis in Deceased Donor Kidney Transplant: A Case Report

Igantius Yun-Sang Tang,1 Andres M. Acosta,2 Vishal K. Varma,2 Summy Setty.1 1Medicine, Univ of Illinois at Chicago, Chicago, IL; 2Pathology, Univ of Illinois at Chicago, Chicago, IL.

Background: Imatinib (IM) is an oral inhibitor of tyrosine kinases. Early short term PDGF inhibition with IM has been shown to prevent intestinal fibrosis and tubular atrophy in pre-clinical kidney transplantation (KT). We assess the effect of long term IM therapy on renal allograft histology in a KT recipient who received IM for gastrointestinal stromal tumor (GIST).

Methods: Patient is a 47 year old female with ESRD due to hypertension, s/p living donor KT in 2007 which failed in 2010. She was then resumed on hemodialysis. A gastric mucosa was biopsied incidentally in 2012. Fine needle aspiration showed c-KIT positive spindle cells consistent with GIST. Patient received deceased donor KT in 7/2012 with Thymoglobulin induction. Maintenance immunosuppression included tacrolimus and mycophenolic acid. Patient was started on IM 100mg daily on day 19 post-KT because of GIST. Post-KT course was complicated by biopsy proven acute tubular necrosis, requiring dialysis in the first month post-KT. Serum creatinine (CR) improved to 1.6mg/dl by 3 months post-KT when she underwent partial gastrectomy. Pathology showed low grade GIST (low mitotic count and low Ki67 labeling index). Surveillance KT biopsy was performed at 6 months, 1 and 2 years post-KT. We compared the 6-month and the 2-year post-KT biopsies for the presence of renal cortical interstitial fibrosis using the Histolab software (Microvision Instruments, France). The core sections stained with Masson trichrome were scanned at high-resolution, and divided into individual images at 200X for quantitative analysis. The software program was then run to quantify fibrosis of the selected areas.

Results: The cortical fibrosis percentage was 20.17% for the 6-month biopsy and 14.35% for the 2-year biopsy. The corresponding serum CR was 1.52mg/dl and 1.71mg/dl, respectively. Though tacrolimus levels were maintained between 5 and 7ng/ml.

Conclusions: IM reduced renal cortical interstitial fibrosis in deceased donor KT. The role of long term IM in the prevention of interstitial fibrosis in renal allograft warrants further studies.

SA-PO1000

Factors Associated with Referral, Evaluation and Listing for Kidney Transplant: A Survey of Dialysis Patients

Eric Chang, Ming Wang, Fareeha Khalil, Naman Trivedi, Nasrollah Ghahramani. Penn State Unlev College of Medicine, Hershey, PA.

Background: Kidney transplant (KT) is the treatment of choice for most patients with end stage renal disease (ESRD). Disparities in referral, evaluation, listing and transplantation have been documented. We studied factors associated with the likelihood of referral, evaluation and listing for KT.

Methods: We sent 1,283 dialysis units of. Since 2013 we invited participants who fulfilled inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent variables were demographic factors, location, and mode of education about KT. In multivariate analysis, we calculated odds ratios (OR) and 95% confidence intervals (CI) for the probability of referral, evaluation and listing for KT.

Results: Of 673 participants, 401 had been referred, 361 had been evaluated and 201 were listed. Having received 3 or more modes of education about KT was associated with higher likelihood of referral (OR:5.03;CI:2.76-9.18), evaluation (OR:5.67;CI:3.23-9.46), and listing (OR:2.70;CI:1.43-4.18). Having attended a pre-ESRD class was associated with higher likelihood of referral (OR:2.20;CI:1.44-3.35) and listing (OR:1.83;CI:1.91-2.80). A transplant center within 10 miles was associated with higher likelihood of referral (OR:1.64;CI:1.09-2.56) and listing (OR:2.17; CI:1.32-3.57). Age > 60 was associated with lower likelihood of referral (OR:0.51;CI:0.33-0.79), evaluation (OR:0.46; CI:0.30-0.72) and listing (OR:0.28; CI:0.17-0.45).

Conclusions: Many factors influence the decision about KT; a process that begins with referral. Though difficult to change, proximity to a transplant center unsurprisingly improves chances for KT evaluation. Emphasis on educating patients > 60 may improve referral and evaluation. In this study, the quantity and diversity of educational modalities are the most important contributors to the referral, evaluation and subsequent listing.

Patient Navigation Program in Kidney Transplantation: A Randomized Study

Mohana Basu,1 Dawn L. Fletcher, Lisa Petgrave-nelson, Rachel E. Patzer. Emory Univ, Atlanta, GA.

Background: We developed a patient navigation program in a kidney transplantation (KTx) clinic to improve KTx evaluation completion for patients deemed “high-risk” of not being placed on the KTx waiting list, based on known disparities in completion of KTx evaluation. We examined whether the addition of patient navigation to standard care was associated with a decrease in the number of days from a patient’s referral for KTx evaluation to KTx candidacy decision.

Methods: During evaluation scheduling at a single KTx center, patients answered questions from a risk assessment tool created using existing data; high-risk patients were randomized prior to KTx evaluation to either standard of care (control) or the additional assistance of a patient navigator (intervention). The patient navigator helped guide patients through the KTx process, serving as a point of contact and providing support and education from the time of referral for KTx evaluation through candidacy decision (patient approved for placement on waiting list or deemed “not a candidate”).

Results: From January 2013 to October 2014, 394 patients were enrolled in the study. Patient demographics were similar among intervention and control groups (80% Black, 88% female, 50% < age 55). A total of 311 (79%) accepted candidacy decision (79% of intervention and 79% of control patients) and were included in preliminary analyses. Intervention patients reached candidacy decision a median of 8 days faster than control patients (119 vs. 127 days). Shorter time to decision for intervention vs. control patients was observed in most examined subgroups, including blacks (9 days), patients who completed high school (10 days), Medicare patients (15 days), patients with BMI-35 (30 days), married (11 days) and single patients (7 days), and patients < age 55 (19 days).

Conclusions: Preliminary results support the efficacy of a patient navigation program in reducing time from patient KTx referral to candidacy decision in a KTx setting. The use of a similar program in other KTx centers may help patients who require additional assistance during the KTx process complete KTx evaluation more quickly.

Knowledge of Treatment Options in Patients Evaluated for Kidney Transplantation: iChoose Kidney Randomized Trial

Mohua Basu,1 Stephen O. Pastan,1 Sumit Mohan,2 John J. Friedewald,1 Daniela P. Ladrner5 Rachel E. Patzer.1 Emory Univ, Atlanta, GA; 3Columbia Univ, New York, NY; 5Northwestern Univ, Chicago, IL.

Background: Although kidney transplantation (KTx) provides a significant survival advantage over long-term dialysis, many end stage renal disease (ESRD) patients are not educated about KTx options. We developed a clinical decision tool (iChoose Kidney) to provide individualized risk estimates of patient survival on dialysis vs. KTx to evaluate whether use of the decision tool during KTx evaluations improved patient knowledge of the survival benefit of KTx vs. dialysis and of living vs. deceased donor KTx.

Methods: In December 2014, we began enrolling patients from three large KTx centers across the U.S. in a trial, where patients are randomized to usual KTx evaluation (control) or an appointment during which the nephrologist uses iChoose Kidney with the patient (intervention). Pre- and post-nephrology consultation, we surveyed patients on whether they believed their chance of survival was higher, lower, or the same with 1) dialysis vs. KTx and 2) living vs. deceased donor KTx. Improvement in knowledge was defined as a change from incorrect to correct post-nephrology consultation. Health literacy was measured using the Newest Vital Sign and categorized into low/moderate vs. high (0-3 vs. 4-6 correct out of 6, respectively).

Results: To date, 214 patients are enrolled (target enrollment n=450). Among 106 intervention patients, 29% improved their knowledge of the survival benefit of dialysis vs. KTx, vs. 19% of 108 control patients (p=0.07). Among patients with low or moderate literacy, 35% of intervention patients improved vs. 13% of control patients (p=0.01); this difference was not observed among high literacy patients (26% improved in each group). For knowledge of the survival benefit of living vs. deceased donor KTx, 19% of intervention patients improved, vs. 11% of control patients (p=0.17).

Conclusions: Preliminary results show that the use of the iChoose Kidney decision tool in comparing survival estimates for dialysis vs. KTx may improve patient knowledge of treatment outcomes during KTx evaluation, and the tool may be especially effective among low/literacy populations.

Hemodialysis Social Networks Facilitate the Completion of Transplant Testing and Successful Kidney Transplantation

Avrumin Gillespie,1 Alexey Uversky,2 Jonathan T. Hunt,1 Heather Marie Train,3 Sarah Bauerle Bass,3 Teri Browne,4 Zoran Obradovic.1 1Nephrology, Hypertension, and Kidney Transplantation, Temple Univ School of Medicine, Philadelphia, PA; 2Center for Biomedical Informatics, Temple Univ, Philadelphia, PA; 3School of Public Health, Temple Univ, Philadelphia, PA; 4School of Social Work, Univ of South Carolina, Columbia, SC.

Background: Hemodialysis (HD) social networks may promote access to a kidney transplant (KT). We set out to observe the formation of HD social networks and their role in completing the steps of the transplantation process in a newly formed HD clinic.

Methods: Between 8/2012 - 2/2015, 46 patients admitted to a newly formed HD clinic were enrolled, 63% were new to HD. Patients spoke either English (78%) or Spanish (22%). All eligible patients were referred for transplant evaluation and testing. Progress on each step of KT was tracked. Patients were surveyed on admission and then quarterly using a previously validated questionnaire. Social interactions and seating were recorded, this data was merged with survey data and analyzed in SPSS 21.

Results: Two thirds of patients were observed to participate in social networks. There were no significant differences in geographic, education or socioeconomic variables between patients who participated in social networks “social” vs. those who didn’t “non-social”. More social patients wanted a KT, 100% vs. 73.3% (p=0.008). Social patients reported talking to other patients about their health or KT 64.5% vs. 6.7% (p < 0.001). Social patients completed more steps, 2 steps (range 0-6) steps completed vs. 0.3 steps on average for the “non-social” group (p=0.037). In a multivariate regression analysis, only participating in a social network was positively associated with completing more steps (β 1.44 p = 0.028), and vintage was negatively associated (β -0.973, p = 0.029).

Funding: None
Kidney Transplant Referral Among Incident Georgia Dialysis Patients with and without Systemic Lupus Erythematosus: The RaDIANT Community Study

Lauren Plantinga, Rachel E. Patzer, Sung S. Lim, Cristina Drenkard, Stephen O. Pastan, Emory Univ, Atlanta, GA.

Background: Although providers often wait to start patients with systemic lupus erythematosus (SLE), shorter overall times to transplant are generally associated with more favorable transplant outcomes in SLE patients. We examined whether referral for evaluation—the first step in the often-years-long process of kidney transplantation—is delayed in dialysis patients with SLE, relative to other dialysis patients.

Methods: United States Renal Data System data on a cohort of 18,419 incident (1/1/05-9/30/12) adult (18-69 years) dialysis patients were linked to a patient referral, such as education and outreach activities targeting the patient, facility staff, and facility policy level. After the intervention, facility staff were asked to complete a 20-item questionnaire on the helpfulness (Likert scale) of each intervention activity and the likelihood (percent) of their facility continuing the activity.

Results: A total of 86 staff (51.2% social workers) at the 67 intervention facilities completed the survey. The median number of the 12 intervention activities completed by dialysis facilities was 9 (range, 0-11). Most facilities reported discussing the benefits of KT at a staff orientation (86.6%), attending monthly webinars (80.7%), and developing a referral improvement plan (76.3%) to be helpful or very helpful. The median number of prescribed intervention activities the facilities reported they would continue was 2, with the distribution of educational brochures (41.9%), a staff orientation focused on KT (41.9%), and patient and family education session (34.9%) among the most commonly cited.

Conclusions: Dialysis facility staff perceived that RaDIANT intervention activities were feasible to implement, with staff education potentially being the most helpful and sustainable component. Sustainability may be limited to intervention components that were at least as expensive and time intensive to implement. Additional ongoing support from ESRD Networks may be necessary to sustain increased KT referrals observed in the RaDIANT Community Study.

Psychosocial Differences Between Living and Deceased Donor Renal Transplant Recipients Anna Bertram, Selma Pabst, Martina De zwaa, Tanja Zimmermann, Mario Schiffer. 1Clinic for Psychosomatics and Psychotherapy, Hannover Medical School, Hannover, Germany; 2Nephrology and Hypertension, Hannover Medical School, Hannover, Germany.

Background: The specific impact of living donor (LD) as compared to deceased donor (DD) kidney transplants on psychosocial functioning has received surprisingly little attention. The present study aimed to assess whether LD and DD recipients differ in socio-demographic variables, time since transplantation, emotional variables, knowledge about immunosuppressant (IS) intake, and self-reported adherence to IS.

Methods: A questionnaire study was performed among 72 LD and 169 DD recipients who attended the kidney transplant outpatient clinic of Hannover Medical School for a follow-up visit at least 1 year after transplantation. Emotional responses were assessed using the Hospital Anxiety and Depression Scale (HADS) and the Transplant Effect Questionnaire (TEQ). Knowledge about IS (test consisting of 8 multiple choice questions, and IS adherence was measured by self-report (BAASIS), physicians’ estimates, IS trough level variability, and allograft rejection.

Results: Overall, LD recipients were younger and had a shorter follow-up since transplantation. Our results indicate that LD and DD transplantation may lead to different emotional responses with more feelings of guilt towards the donor and perceived responsibility to do well and with a generally higher anxiety level in LD recipients. LD recipients apparently had more knowledge about IS medication. However, they did not report more adherence to IS. No differences between LD and DD recipients were found for gender, educational level, depression, perceived social support, and allograft rejection.

Conclusions: Feelings of guilt and anxiety may be an important focus for interventions to improve emotional adjustment to transplantation, especially in LD recipients.

Feasibility and Sustainability of the RaDIANT Community Study Among Georgia Dialysis Facilities Jennifer C. Gandee, Leighann Sauls, Teri Browne, Laura Plantinga, Laura J. McPherson, Eric M. Gibney, Laura L. Mulloy, Stephen O. Pastan, Rachel E. Patzer. Emory Univ; 1Southeastern Kidney Council, Univ of South Carolina; 2Piedmont Hospital, Georgia Regents Univ.

Background: The Southeastern Kidney Transplant Coalition developed the randomized, dialysis facility-level Reducing Disparities In Access tokidney Transplantation (RaDIANT) Community Study to address racial disparities and low rates of kidney transplantation (KTxs) in Georgia. We aimed to evaluate the feasibility and sustainability of the RaDIANT intervention activities.

Methods: The 67 dialysis facilities that completed a 12-month intervention as part of the RaDIANT study consisted of 12 recommended activities intended to increase KTxs referral, such as education and outreach activities targeting the patient, facility staff, and facility policy level. After the intervention, facility staff were asked to complete a 20-item questionnaire on the helpfulness (Likert scale) of each intervention activity and the likelihood (percent) of their facility continuing the activity.

Results: A total of 86 staff (51.2% social workers) at the 67 intervention facilities completed the survey. The median number of the 12 intervention activities completed by dialysis facilities was 9 (range, 0-11). Most facilities reported discussing the benefits of KTxs at a staff orientation (86.6%), attending monthly webinars (80.7%), and developing a referral improvement plan (76.3%) to be helpful or very helpful. The median number of prescribed intervention activities the facilities reported they would continue was 2, with the distribution of educational brochures (41.9%), a staff orientation focused on KTxs (41.9%), and patient and family education session (34.9%) among the most commonly cited.

Conclusions: Dialysis facility staff perceived that RaDIANT intervention activities were feasible to implement, with staff education potentially being the most helpful and sustainable component. Sustainability may be limited to intervention components that were at least as expensive and time intensive to implement. Additional ongoing support from ESRD Networks may be necessary to sustain increased KTxs referrals observed in the RaDIANT Community Study.

SA-PO1005

Association of Kidney Transplantation Referral with Other Indicators of Quality Care Among Incident Georgia Dialysis Patients: The RaDIANT Community Study Lauren Plantinga, Stephen O. Pastan, Jenna Krisher, Eric M. Gibney, Laura L. Mulloy, Rachel E. Patzer. Emory Univ, Atlanta, GA; Southeastern Kidney Council, Inc., Raleigh, NC; Piedmont Transplant Inst, Atlanta, GA; Georgia Regents Univ, Augusta, GA.

Background: Dialysis facility referral of patients for kidney transplant is a potential indicator of quality care. We examined whether referral within a year of dialysis start (1-year referral) was associated with other quality indicators among incident Georgia dialysis patients.

Methods: We examined a cohort of 14,120 incident (7/1/05-9/30/11; follow-up through 9/30/12) adult (18-69 years) dialysis patients using United States Renal Data System data linked to concurrent referral data from all three adult Georgia kidney transplant centers. Multilevel, multivariable logistic regression was used to examine the association of 1-year referral with dichotomous quality indicators [pre-ESRD nephrology care, dialysis modality, permanent vascular access in place at dialysis start (HD patients only), pre-ESRD erythropoietin use, and transplant information at dialysis start], with adjustment for demographic and clinical variables and accounting for variation across clinics.

Results: Overall, 1-year referral was 24.8% and was higher among patients with other indicators of quality care: 26.0% vs. 23.8%, with vs. without pre-ESRD care (P=0.005); 27.8% vs. 24.6%, PD vs. HD (P=0.03); 28.3% vs. 22.9%, with vs. without a permanent vascular access in place at HD start (P=0.001); and 27.2% vs. 16.5%, informed vs. not informed of transplant options at dialysis start (P=0.001). With adjustment, pre-ESRD care [OR=1.34 (95% CI, 1.22-1.47)] and permanent vascular access in place [OR=1.44 (95% CI, 1.41-1.70)], and transplant information at dialysis start [OR=1.63 (95% CI, 1.45-1.85)] remained associated with higher 1-year referral.

Conclusions: These findings suggest that patients who receive quality care in multiple domains are more likely to be referred for kidney transplantation within a year of starting dialysis, independent of demographic and clinical characteristics. Interventions to increase transplant access should be targeted to patients whose care fails to meet other quality indicators.

The Difficult Road for Native Americans in Kidney Transplantation: Decreased Access and Reduced Long-Term Survival

Sarah Stith, Kristina Piorkowski, Fidel Barrantes.

Economics, Univ of New Mexico, Albuquerque, NM; Presbyterian Transplant Center, Renal Medicine Associates, Albuquerque, NM.

Background: Native Americans (NAs) have disproportionately high rates of end-stage renal disease, yet wait-listed NAs have lower rates of kidney transplantation than other racial/ethnic groups and worse long-term post-transplant survival outcomes than whites. This study evaluates these disparities across multiple medical and socioeconomic dimensions.

Methods: Using data from the Organ Procurement and Transplantation Network (OPTN), we evaluated wait list removal reasons and post-transplant survival rates from 3/1/95 to 12/31/12. We use a logistic regression model, controlling for patient, donor, match characteristics, and center and year fixed effects, along with a Blinder-Oaxaca decomposition of the results.

Results: Among registered patients removed from the wait list, NAs were less likely to receive a transplant (odds ratio, 0.71 [95% CI, 0.64-0.80]) and more likely to die on the wait list (1.88 [0.89-3.94]), compared to whites. NAs are less likely than whites to survive at least two years (odds ratio, 0.80 [95% CI, 0.70-0.92]) and at least three years (0.81 [0.71-0.94]), but these disparities become statistically insignificant with risk adjustment.

Conclusions: NAs experience higher rates of adverse wait list removal reasons than other racial/ethnic groups. Among NAs who do receive transplants, short term survival outcomes are similar to those of whites, but longer term survival outcomes are lower. The decomposition of our results indicates that the disparity in three-year post-transplant survival between NA and whites is driven primarily by the prevalence of lower quality donors among NA donors. Further investigation is required to identify source characteristics of survival disparities among NA. NAs also tend to receive transplants at centers associated with worse outcomes and would benefit disproportionately from receiving transplants at better centers.

Estimated GFR for Living Kidney Donor Evaluation

Naya Huang, Meredith C. Foster, Krista L. Lentine, Amit X. Goggio, Bertram L. Kasiske, Lesley Inker, Andrew S. Levey.

Div of Nephrology, Tufts Medical Center, Boston, MA; Div of Nephrology, Saint Louis Univ, MO; Div of Nephrology, Western Univ, London, ON, Canada; Dept of Nephrology and Hypertension, Glickman Urological and Kidney Inst, Cleveland Clinic, OH; Dept of Medicine, Hennepin County Medical Center and Univ of Minnesota, Minneapolis, MN.

Background: All living kidney donor candidates undergo an evaluation of GFR. Guidelines recommend measured GFR (mGFR) rather than estimated GFR (eGFR), but measurement methods are difficult, time consuming and costly. We questioned whether eGFR using creatinine (eGFRcre) with or without sequential cystatin C (eGFRcre-cys) is sufficiently accurate to identify donor candidates with high probability that mGFR is above or below thresholds for clinical decision making.

Methods: We combined the pre-test probabilities for mGFR thresholds <60, <70, <80 and <90 mL/min/1.73 m² in varying age, sex and race groups estimated from the National Health and Nutrition Examination Survey (NHANES) with test performance of eGFR (categorical likelihood ratios [LRs] determined from the Chronic Kidney Disease Epidemiology Collaboration) to compute post-test probabilities of meeting a given mGFR threshold.

Results: Using NHANES pre-test probabilities, we found that in some circumstances, eGFRcre and eGFRcre-cys provides high accuracy (post-test probability≥95%) in candidate donors. Using data from the Scientific Registry of Transplant Recipients, we determined that 54% and 82% of recent donors had pre-donation eGFRhigh enough to ensure ≥95% probability that mGFRwas ≥90 and ≥80 mL/min/1.73 m² respectively, suggesting a large fraction of donor candidates might not require mGFR.

Conclusions: Implementation strategies could include eGFR as a first test and possibly eGFRcre-cys as confirmatory test. If post-test probabilities are of sufficient magnitude, eGFR could be used to accept or reject donors without measurement of GFR. We will provide a web-based application.

SA-PO1012

Change of Physical Activities in Male and Female Recipients in 12 Months After Living Kidney Donor Transplantation

Makoto Tsujiita.

Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.

Background: Since renal dysfunction and immunosuppressive drugs cause muscle degeneration, physical activities decrease in CKD, dialysis patients and transplant recipients. In addition, elderly kidney transplant recipients are increasing in Japan, so improving physical activities and increasing muscle strength and volumes are important to prevent fractures and fall accident.

Methods: Consecutive 58 patients (male 33) older than 40 years were enrolled in this study from 2012. Immunosuppression basically contains steroid, cyclosporine or tacrolimus, and mycophenolatemofetil or everolimus. Hypertension, hyperlipidemia, and osteoporosis were treated as needed. Parameters of physical activities such as hand grip, SMI (skeletal muscle index) and Body fat mass using by DEXA (dual-energy x ray absorptiometry).

Results: Each year we are still growing the number of KT. The age of our recipients is diminishing and age of donors is increasing. Months before KT are also increasing lately reflecting the great number of ESRD patients. Recipient age, HLA mismatching, induction therapy use and generic drugs can explain the 13.2% of patients with Cr above 1.5 mg/dl.

Conclusions: Each year we are still growing the number of KT. The age of our recipients is diminishing and age of donors is increasing. Months before KT are also increasing lately reflecting the great number of ESRD patients. Recipient age, HLA mismatching, induction therapy use and generic drugs can explain the 13.2% of patients with Cr above 1.5 mg/dl.

Underline represents presenting author.

866A
absorptiometry), and Body mass index (BMI) were measured and compared at prior, 6, and 12 months after kidney transplantation. Recipients were encouraged to do daily exercise for 30 to 60 minutes every day.

**Results:** Mean age (years) were 52.3±10.0 in male, and 53.6±10.4 in female. In male patients, any parameter did not change after transplantation in male patients. In female patients, SMI improved in 12 months (p<0.005), and Hand grip also tended to increase with statistically difference.

![Figure 1](image)

**Conclusions:** Disturbances of bone and mineral metabolism after transplantation are prevalent and are strongly correlated with the kidney function and transplantation duration.

**Risk of Adverse Maternal and Fetal Outcomes During Pregnancy in Living Kidney Donors**

Jessica B. Kendrick,1 John R. Holmen,2 Gerard John Smits,1 Michel Chonchol,1 Univ of Colorado Denver, Aurora, CO; 2Denver Health Medical Center, Denver, CO; 3Intermountain Health Care, Salt Lake City, UT.

**Background:** A frequently asked question by potential kidney donors is risk of nephrectomy on maternal and fetal outcomes in pregnancy. Studies regarding the risks of living kidney donation and pregnancy outcomes are conflicting. The purpose of this study was to determine the risk of adverse maternal and fetal outcomes in donors vs. non-donors.

**Methods:** Using data from an integrated health care delivery system in Utah from 2000 through 2014, a total of 72 women were living kidney donors that became pregnant after kidney donation. Using a pool of 74,105 women who were not donors, we selected 1223 to use for matches for the living kidney donors. These women were matched 1:3 by age and race. Adverse pregnancy outcomes were defined as preterm delivery, delivery via cesarean section, preeclampsia/eclampsia, length of stay in the hospital and low birth weight (<2,500 g). Logistic regression analysis was used to examine the association between donation and adverse outcomes.

**Results:** Of the living kidney donors, the mean (SD) age and mean (SD) gestational age at delivery was 31.0 ±3.6 and 19.5 ±2.4 months, respectively. The mean (SD) length of stay in the hospital was 2.7 ±0.7 days. Six cases (8%) had a history of chronic hypertension. Living kidney donors did not have a higher risk of preterm delivery (OR 1.82, 95% CI 0.87–3.77), preeclampsia/eclampsia (OR 1.11, 95% CI 0.47–2.65), delivery via cesarean section (OR 1.51, 95% CI 0.85–2.66), length of stay = 3 days (OR 1.29, 95% CI 0.63–2.64) or low birth weight (OR 1.94, 95% CI 0.87–4.35) compared to non-donors.

**Conclusions:** Living kidney donation is not associated with a higher risk of adverse outcomes in pregnancy.

**Funding:** NIDDK Support

**The Quality of Life of Parents of Pediatric Kidney Transplantation**

Yuko Hamasaki,1 Miyako Tazaki,2 Yusuke Takahashi,3 Seichiro Shishido,4 Atsushi Aikawa.1 Pediatric Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan; 2Psychology, Toho Univ Faculty of Medicine, Tokyo, Japan; 3Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.

**Background:** The purpose of the study is to investigate how the Quality of life (QOL) of parents whose child had received kidney transplantation (KT) would change by delivering questionnaires four times; before, one month after, three months after and one year after KT.

**Methods:** The QOL of thirty-one parents (30 mothers and 1 father) with a mean age of 38.5 years old whose child received KT at Toho University Omoni Medical Center from May 2012 to March 2015 was measured using WHO Quality of Life (WHOQOL), Visual Analogue Scale (VAS), and General Health Questionnaire (GHQ). The mean age of the recipients was 5.8 years old (18 boys, 13 girls). Congenital anomalies of the kidney and urinary tract were the most frequent primary diseases (54.8%). Among them, twenty-two children received dialysis before KT, and nine received preemptive KT.

**Results:** Based on the results, the average WHOQOL scores show the QOL of parents decreased one month after KT (3.15) with a statistical difference compared with before KT (p=0.042), but increased at three months (3.40) (p=0.0073), and maintained until one year (3.41). The average QOL of the parents of a child with frequent infection was statistically lower than those without any infection (p=0.448) at three months after KT and one year after KT (p=0.046). The average QOL scores of nineteen donor parents had a statistically higher QOL before KT then reversed at one month after KT, but became higher again at three months after KT.

**Conclusions:** The QOL of the parents would decreased one month after KT when infection or other problems often occurred, but increased after three month when the condition of recipients stabilized and maintained until one year after KT, which became as high as before KT.

**SA-PO1013**

**Search for New Data to Predict Kidney Transplant Outcomes in the Organ Procurement and Transplantation Network Database**

Mohamed A. Sheta,1 Bertram L. Kasiske,2 Charles E. Alexander,3 Joseph Kim.4 SA-PO1014

**Background:** The Organ Procurement and Transplantation Network (OPTN) collects data used to monitor transplant program outcomes for quality assurance and regulatory oversight. It is imperative that the variables in the OPTN database used by the Scientific Registry of Transplant Recipients to determine expected outcomes after kidney transplant be reliable, complete, and up-to-date.

**Methods:** We conducted a systematic review to identify risk factors not included in current OPTN data that predict graft failure or mortality after kidney transplant. We searched for studies with publication date between Jan 1 2000-May 1 2015; at least 1000 subjects in one or more risk prediction models; multivariate analysis used to select variables predicting patient or graft survival; inclusion in the multivariate model of at least one risk factor collected before or at the time of transplant that is not already collected by OPTN, and English language. For duplicate publications we selected the most recent. For publications with overlapping but distinct cohorts, we selected the one with the largest cohort. We arbitrarily limited the search to studies including 1000 participants in at least one risk-prediction model. Although a small single-center study may convincingly show that a newly described risk factor predicts outcomes at that center, there are likely major barriers to measuring and collecting this risk factor uniformly at every program in the US.

**Results:** We identified 33 studies that met inclusion criteria; 6 (18%) were single-center, 4 (12%) were multicenter, and 23 (70%) were registry studies. Promising new variables included: myocardial infarction, coronary artery revascularization, atrial fibrillation, congestive heart failure, valvular heart disease, cerebral vascular accident, congestive heart failure, aortic aneurysm repair, ischemic leg amputation, or revascularization, tobacco abuse, alcohol and illicit drug dependence, ZIP code, and socioeconomic status.

**Conclusions:** This review provides evidence for the new OPTN Ad Hoc Data Advisory Committee to update the OPTN database.

---

**SA-PO1014**

**Prevalence of Mineral and Bone Disorders Among Living Kidney Transplant Recipients**

**Background:** Mineral and bone disorders (MBD), frequent complications of chronic kidney disease (CKD), occur frequently in kidney transplant recipients. Still, is known about its prevalence and clinical correlates in transplanted patients.

**Methods:** We conducted a cross-sectional analysis of 504 stable living kidney allograft recipients. Detailed medical history, demographic data and routine laboratory investigations, including s. creatinine, s. corrected Calcium, s. Phosphorus, serum iPTH and s. Alkaline Phosphatase (ALP) were collected. Estimated GFR was calculated using the abbreviated MDRD formula. Patients were stratified into three groups based on duration of kidney transplantation. Group I: 6 months to 1 year, group II: from 1 to 5 years and group III: more than 5 years. Correlations were done between bone minerals and all laboratory results. We also analyzed the possible relation between various immunosuppressant drugs and bone minerals, serum iPTH and serum ALP.

**Results:** The mean age was 32±8 years in group I, 45±3.7 years in group II, and 40±5 years in group III, with no significant difference between the three groups (p=0.005). There was no significant difference between the studied groups as regards of laboratory parameters (p=0.05). 115 patients had iPTH levels > 170 ng/dl, while 365 patients (72.4%) had iPTH levels >70 ng/dl. Only 24 patients had hypercalcemia, and 34 patients had hyperphosphatemia. We also found that 68 patients had hypophosphatemia. Serum iPTH and s. Alkaline Phosphatase levels were higher in group III (156±66 ng/dl; 135±54 IU respectively) when compared to group I (98±3.4 ng/dl; 120±3.3 IU) and group II (138±35 ng/dl;122±60 IU) (p<0.001). In group I, iPTH levels were negatively correlated with s.cGFR (r value = −0.37, p<0.05). Both serum ALP and iPTH levels showed significant negative correlation with s.cGFR in groups II and III (p<0.05). In all groups, bone minerals, iPTH and serum Alkaline Phosphatase levels had no statistically significant relation with the immunosuppressant agent used (p>0.05).

**Conclusions:** Disturbances of bone and mineral metabolism after transplantation are prevalent and are strongly correlated with the kidney function and transplantation duration.

Disparities in Access to Renal Transplant in Puerto Rican Children

Nilda deJesus-Gonzalez,1 Sonia M. Caraballo,1 Eduardo J. Santiago-Rodriguez,2,3 Marta P. Suarez-Rivera,1 Melvin A. Bonilla-Felix.1 1Medical School, Pediatric Nephrology Div, Univ of Puerto Rico; 2Univ Central del Caribe; 3Puerto Rico Clinical and Translational Research Consortium.

Background: Disparities in access to renal transplant have been reported in racial minorities living in US. No data is available from children with ESRD living in Puerto Rico (PR). Although PR is the largest Hispanic group in a single pediatric dialysis unit in US. We describe the pediatric population with ESRD in PR from 2003–2013, the renal transplant rates and possible barriers to receiving a graft.

Methods: Retrospective chart review of patients diagnosed with ESRD in PR from 2003–2013. Incidence, prevalence rates, means/standard deviations (SD), medians/interquartile range (IQR), frequencies and percentages were calculated and compared to national rates.

Results: From 2003–2013 99 patients, male: 52%, age:13.5yrs (8-16yrs), were diagnosed with ESRD. Congenital anomalies were the primary cause in 40%, and FGSG in 24% . Incidence of ESRD ranged from 3-14 subjects per million population/year, with prevalence per dialysis modality from 7-18 subjects per million population/year. 38% were transplanted in PR (Median age: 14yrs, IQR: 9-16); 23% from living donors. 14.1% received a transplant in the first year (National rate: 38%); 63% of these non-transplanted children had Medicare coverage. None of 9 infants diagnosed with ESRD were transplanted during infancy. 46% of the children who were not transplanted stayed at our unit for a median time of 2 yrs (IQR: 1-3). The rest was transferred to a dialysis unit outside PR (15%) or to an adult facility without being transplanted (39%). 67% of these non-transplanted children were covered by Medicare. The mortality rate during the first year of diagnosis was 3% (National rate: 4%).

Conclusions: Children with ESRD in PR face striking disparities in access to renal transplant. Lack of pediatric transplant surgeons, geographical isolation and minimal living donation are potential barriers. Medicare coverage does not appear to be a factor, as it was similar between transplanted and non-transplanted. Interventions to reduce these inequities are needed.

Funding: Other NIH Support - Supported by grant 2U54MD007587 (RCMI Clinical and Translational Research Consortium, University of Puerto Rico Medical Sciences Campus) from the National Institute on Minority Health and Health Disparities (NIMHD), a component of the National Institutes of Health (NIH).

The Case against Declining Donors with Impaired Fasting Glucose

Robert N. Foley, Naim S. Issa, Danielle M. Berglund, Arthur J. Matus, Hassan N. Ibrahim. Univ of Minnesota, Mpls, MN.

Background: The definition of diabetes, impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) have changed over time. IFG was defined in 1997 by fasting glucose 110-125 mg/dL and in 2003 the definition changed to fasting glucose 100-125 mg/dL. With the introduction of this new definition, many potential donors with fasting glucose 110-125 mg/dL and in 2003 the definition changed to fasting glucose 100-125 mg/dL. With the introduction of this new definition, many potential donors with fasting glucose 110-125 mg/dL and in 2003 the definition changed to fasting glucose 100-125 mg/dL. With the introduction of this new definition, many potential donors with fasting glucose 110-125 mg/dL.

Methods: We assessed the risk of death, new onset diabetes, hypertension, proteinuria and reduced GFR (<45 ml/min/1.73m2 or eGFR <30ml/min/1.73m2 as compared to those with FBG <100 mg/dL. In contrast, those with FBG between 110-125 mg/dL were more likely to become diabetic and hypertensive but not proteinuric or reduced GFR. Those with FBG ≥126 mg/dL were more likely to die, develop DM and HTN but not suffer any adverse renal consequences.

SA-PO1019

Psychosocial Distress and Adherence in Adolescents Post-Kidney Transplant

Jessica L. Stahl,1 Angela P. Presson,2 Chong Zhang,2 Raoul D. Nelson,1 Matthew M. Grinsell.1 1Pediatrics, Univ of Utah, Salt Lake City, UT; 2Study Design and Biostatistics Center, Univ of Utah, Salt Lake City, UT.

Background: Adolescents who are post-kidney transplant have comorbidities in medical and psychosocial arenas and high risk of non-adherence and graft loss. Limited data exists to describe the relationship between mental health and adherence in this population. Descriptive statistics were used to assess the relationship of adherence to psychiatric diagnosis, psychosocial distress, gender, and time from transplant, as well as differences in parent-child reporting.

Results: Overall, 52% reported a psychiatric diagnosis, which is significant compared to 13% in the general adolescent population (p<0.001), with 38% evidencing elevated levels of psychosocial distress on self-report and 25% elevated per parent report. 68% of adolescents reported a different distress level than estimated by their parent. The psychiatric diagnosis rate was 64% in the non-adherent group and 36% in adherent adolescents. Only 40% of the adherent group reported elevated distress versus 57% of the non-adherent group. There was a gender bias toward male non-adherence in this group with 100% of the non-adherent population being male. The mean time from transplant of non-adherent groups was 6.1 years versus 3.9 years in the adherent group. These differences were not statistically significant except as above.

Conclusions: Our population’s rate of psychiatric diagnosis was significantly elevated compared to community norms and also correlated with elevated psychosocial distress and non-adherence. Disagreement in parent and adolescent reporting was common regardless of adherence status. Our sample did demonstrate gender differences in non-adherent behavior as well. Interpretation of these results, as well as statistical significance is limited by the small sample size.

Funding: Other NIH Support - This investigation was supported by the University of Utah Study Design and Biostatistics Center, with funding in part from the National Center for Research Resources and the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant R01AT000105 (formerly U1RRO25764).
The aim of this study was to investigate the influence of body composition, and body composition affect to kidney function and other prognosis of donors in our country. Sarcopenia is the independent risk factor of hypertension. It is unclear whether obesity baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Four groups; (A) Obesity negative + Sarcopenia negative (ONSN) (B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1-year after donation.

Results: Seven patients were OPSN (11.7%), 22 patients ONSP (36.7%), and 4 patients OPSP (6.7%). Visceral fat area >100 m^2 (which is defined as central obesity in Japanese criteria) and skeletal muscle index (SMI) from the appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5 cm^2/m^2 for women and 52.4 cm^2/m^2 for men are defined as a sarcopenia)(1). We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN) (B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Conclusions: This is a retrospective single center study of 60 living kidney transplant donors from 2009 to 2014. Donors are stratified according to Body Mass Index (BMI)25kg/m^2 is defined as an obesity in Japanese criteria) and skeletal muscle index (SMI) from the appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5 cm^2/m^2 for women and 52.4 cm^2/m^2 for men are defined as a sarcopenia)(1).

SA-PO1012

Background: Currently obesity is a risk for chronic kidney disease. It is also suggested that sarcopenia is the independent risk factor of hypertension. It is unclear whether obesity and body composition affect to kidney function and other prognosis of donors in our country. The aim of this study was to investigate the influence of body composition, the findings of graft biopsy and 1-year after clinical outcome.

Methods: This is a retrospective single center study of 60 living kidney transplant donors from 2009 to 2014. Donors are stratified according to Body Mass Index (BMI)25kg/m^2 is defined as an obesity in Japanese criteria) and skeletal muscle index (SMI) from the appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5 cm^2/m^2 for women and 52.4 cm^2/m^2 for men are defined as a sarcopenia)(1). We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN) (B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Results: Seven patients were OPSN (11.7%), 22 patients ONSP (36.7%), and 4 patients OPSP (6.7%). Visceral fat area >100 m^2 (which is defined as central obesity in Japanese criteria) and skeletal muscle index (SMI) from the appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5 cm^2/m^2 for women and 52.4 cm^2/m^2 for men are defined as a sarcopenia)(1). We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN) (B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Conclusions: This is a retrospective single center study of 60 living kidney transplant donors from 2009 to 2014. Donors are stratified according to Body Mass Index (BMI)25kg/m^2 is defined as an obesity in Japanese criteria) and skeletal muscle index (SMI) from the appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5 cm^2/m^2 for women and 52.4 cm^2/m^2 for men are defined as a sarcopenia)(1). We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN) (B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Assessing Adherence Barriers in Pediatric Kidney Transplant Recipients - Charles D. Varnell,1 Kristin Loselle,1 Alina Lh Pai,2 Avani Modi,2 David K. Hooper.1 Div of Nephrology and Hypertension, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2Center for Treatment Adherence and Self-Management, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Nonadherence in pediatric kidney transplant recipients (KTRs) is associated with poor outcomes and poses a significant financial cost to society. Patient and family reported barriers to taking medications predict nonadherence, rejection, graft failure, and death. Despite their clinical importance and amenability to intervention, barriers to medication adherence are not routinely assessed in pediatric settings.

Methods: From Jan 2015 - May 2015, barriers to immunosuppressant adherence in KTRs were assessed using a standardized checklist of 14 common barriers. For KTRs≤10 y.o. the caregiver completed the assessment. For KTRs>10 y.o. both the patient and caregiver, if present, completed the assessment. Assessments were completed during routine outpatient clinic appointments.

Results: 36 pediatric KTRs [M(SD)age=13.1(4.3)years;56.7%male] and 50 primary caregivers completed a barriers assessment. At least one barrier was reported by 47% of KTRs compared to 42% of caregivers. For KTRs the most frequent barriers were forgetting(22%), hating the taste(13.9%) and running out of medicine(8.3%). For caregivers, the most frequently endorsed barriers were forgetting(20%), side effects(6.0%) and patient refuses to take their medication(6.0%). There was excellent concordance(96.2%) in dyads where both KTR and caregiver reported barriers. Assessing for barriers to adherence was easy to perform in practice and required<60 seconds.

Conclusions: Nearly half of all patients report at least one barrier to taking their immunosuppression, and there is generally consistent agreement between patient and caregiver perception of barriers. Standardizing the approach to assessing barriers to immunosuppression adherence in the clinical setting can quickly produce information that might be missed by the provider. Future research should evaluate the effectiveness of interventions delivered as part of routine medical care to overcome identified barriers and prevent known complications associated with nonadherence.

A Longitudinal Follow-Up of Hispanic Living Kidney Donors
Clarence E. Foster III,1 Pinky J. Patel,1 Hirohito Ichii,1 Madeleine V. Pahl,2 Elani Streja,3 Jonathan R. Lakey,1 Kamyar Kalantar,1 John C. Allen,2 Terence Kee Yi Shern,1 Tazeen H. Jafar,2 Sarah Stith,2 Abhijit Zadeh.
Universities of California, Irvine, Orange, CA; University of California, Irvine, Orange, CA.

Background: This is a long-term follow-up of living kidney donors (LKD) in an ethnically diverse patient population. Hispanics are known to have an increased risk of developing chronic kidney disease, associated with hypertension and obesity. The hypothesis is Hispanic living kidney donors or uninsured living kidney donors would have poorer long-term outcomes secondary to lack of access to health care and secondary to the higher risk factors for developing chronic kidney disease.

Methods: The objectives were to measure obesity, hypertension, diabetes, mean CrCl post-donation and compare to the pre-donation CrCl. LKD were contacted & invited to participate & had a questionnaire about their general health & history and physical. Analysis included a CBC, serum chemistry, a 24-hour urine collection to measure creatinine, protein and albumin. A Patient Data Visit Sheet, RAND 35 Health Questionnaire. The IRB approved this study.

Results:

Pre- and post-donation systolic and diastolic blood pressures were similar between Hispanics and non-Hispanic LKD. Non-Hispanic LKD had a greater decrease in systolic blood pressure post-donation -4.5 mmHg vs. 6.3 mmHg (p=0.0378). The decrease in CrCl post-donation was the same in Hispanic and Non-Hispanic LKD, 33 ml/min vs. 35 ml/min. None of the LKD in the study had significant proteinuria or microalbuminuria.

Conclusions: Post living donor kidney donation in our ethnically diverse patient groups are not at a higher risk for developing obesity, HTN, or CKD. Overall, our LKD feel they have a good overall quality of life including both physical and emotional realms.

Predictors of Low Estimated Glomerular Filtration Rate After Living Kidney Donation in a Southeast Asian Population from Singapore
Bo-Yu Tan,1 John C. Allen,2 Terence Kee Yi Shern,3 Tazeen H. Jafar.1 Dept of Renal Medicine, Singapore General Hospital, Singapore; 2Duke-NUS Graduate Medical School, Singapore.

Background: We aim to investigate patterns of change in kidney function and factors and associated with low estimated glomerular filtration rate (eGFR) following living kidney donation in Southeast Asian.

Methods: We retrospectively studied living kidney donors with nephrectomy performed at Singapore General Hospital between 1976 and 2012. Quantile regression analysis was performed on pre- to post-nephrectomy percent change in CKD-EPI eGFR levels. Donors were grouped according to elapsed time from donation as short-term (>6 months to <5 years after donation), medium-term (5 to <10 years after donation), and long-term (³10 years after donation), and compared on pre-nephrectomy demographic and clinical characteristics.

Results: 174 donors, predominantly female (63.8%) and of Chinese ethnicity (73%), of average age 40.6 years, were recruited. Median (range) follow-up was 7.8 (0.1–33.8) years during which 30 donors (17%) developed low eGFR, defined as <60 ml/min/1.73m2. A 5.1% (1% to 9.7%) of donors recovered to a level that is at least 75% of pre-nephrectomy eGFR levels, and 9.8% exhibited 100% recovery to pre-nephrectomy eGFR levels at 19.2 years, on average. High pre-nephrectomy eGFR was predictive of low post-donation eGFR. A pre-nephrectomy eGFR cutpoint for prognosticating low post-donation eGFR was obtained using ROC analysis.

Conclusions: In general, kidney function is well preserved following kidney donation in Southeast Asian donors. Pre-nephrectomy eGFR is a good predictor of post-donation eGFR, especially in the short-term.

SA-PO1026
Post-Kidney Transplant Follow-Up in Native American: An Opportunity for Improvement
Fidel Barrantes,1 Sarah Stith,2 B. Presbytery Transplant Center, Renal Medicine Associates, Albuquerque, NM; 2Economics, Univ of New Mexico, Albuquerque, NM.

Background: Native Americans have been shown to face decreased access to waitlisting and transplantation. We explore the possibility that Native Americans might face decreased access to high quality post-transplant care, especially in the long-run, due to a decreased general access to healthcare, as is faced by many socioeconomically disadvantaged minority populations.

Methods: Using data from the OPTN, we evaluated the quantity and type of post-transplant care received by Native Americans. We compare Native American populations with other ethnic groups from October 1, 1987 to December 31, 2012 using multivariate regression analysis, controlling for time-invariant factors affecting all patients in a given year (year fixed effects) and time-varying factors associated with a specific transplant center (center fixed effects). (Standard errors are clustered at the center level to account for heterogeneous and spatial correlation among patients in a given center).

Results: Statistically significant regression results (p<0.05) indicate that Native Americans are less likely to receive transplant program-based aftercare than other racial/ethnic groups (Black, White, Hispanic and Asian/Pacific Islander), opting instead to see other types of specialists. They also see two percentage points more likely to be lost to follow-up (mean=0.15), one percentage point less likely to participate in an immunosuppression-related research study (mean=0.03), and receive 0.3 fewer follow-up visits (mean=2.2) than whites. They face the lowest number of follow-up visits, the lowest probability of participating in a research study, and the highest probability of being lost to follow-up. They also are 13% points less likely to work post-transplant (mean=0.35) than whites.

Conclusions: The results indicate that Native Americans have reduced access to high quality post-transplant care. Further research will explore how much of the disparity in post-transplant care is related to the high correlation between being Native American and poor and between being Native American and living in a rural area, especially on tribal lands.

Medication Adherence Barrier Burden Predicts Subsequent Taking Adherence in Adolescents: A Social Media-Based Cross-Sectional Study
B. Presbytery Transplant Center, Renal Medicine Associates, Albuquerque, NM; 2Economics, Univ of New Mexico, Albuquerque, NM

Background: Longitudinal studies of objectively-measured medication adherence among high-risk adolescent kidney transplant recipients are lacking.

Methods: We aimed to determine whether the burden of perceived barriers to medication adherence predicted taking adherence (proportion of prescribed doses taken) during the subsequent 3 mo., as monitored with a multidose electronic pillbox. We evaluated the 126 participants of TAKE-IT with electronic adherence data available for the 3-mo. run-in period during which no intervention was applied. Participants (11-24 y; < 3 mo. post-transplant) were followed in 8 transplant centers (Canada and USA). Adherence barriers were assessed at baseline using the Adolescent Medication Barriers Scale (AMBS). A higher score indicates greater burden barrier (possible range 17-85). We used linear regression to estimate the association between baseline AMBS scores (total score and ingestion, disease adaptation, and cognitive/orGANization subscores) and taking adherence. Models also included sex, age, race, and time since transplant.

Results: 66% were male and 67% were white. Median age at baseline was 15.8 (IQR 13.2-17.1) y. Median time since transplant was 3.1 (0.7-7.5) y. Mean SD taking adherence for the interval was 87.0% ±28.9. Higher barrier burden (median score 38 (IQR 30-44)) was significantly associated with poorer adherence: a 5 unit higher total AMBS score was associated with 1.5% (95% CI 0.04, 3.0) lower taking adherence. Males had 7.5% (0.8, 14.3) lower taking adherence than females. The only subscale score significantly associated with taking adherence was disease adaptation: a 5 unit higher subscore was associated with 3.3% (0.4, 6.2) lower taking adherence.

Conclusions: While the absolute impact of barrier burden on adherence is small, higher burden of perceived barriers is a significant predictor of poorer adherence. Future analyses of the TAKE-IT data will determine the impact of an intervention targeting individual barriers on objectively-measured adherence.

Deceased Donor Procurement in the U.S.: Measurement of Surgical Damage Inflicted Upon the Procured Organ Tim E. Taber, 1 Nikole Neidlinger, 2 Muhammad Ahmad Mujtaba, 1 Elling E. Eidbo, 1 Anil S. Paramesh. 1

Background: Deceased organ donation provides healthy allografts for the majority of organ transplants done in this country. While there are many factors involved in determining suitability of allografts for transplantation, one of the most important is careful
determination of the organ non-transplantable. For 12 consecutive months starting in January of
2014, 36 of 58 OPOs prospectively submitted quality data regarding organ damage seen
on the weekends adversely impacts organ procurement, acceptance and transplantation.

Background: Studies of adherence to timing of medication dosing in high-risk
adolescent kidney transplant recipients are lacking.

Methods: We aimed to determine whether the burden of perceived barriers to
medication adherence predicted timing adherence (proportion of doses taken £1 h. before
to £2 h. after the prescribed dosing time) during the subsequent 3 mo., as monitored with
a multidose electronic pillbox. We evaluated the 126 participants of TAKE-IT who had
electronic adherence data available for the 3-mo. run-in-period (no intervention). Participants
(11-24 y.; ≥ 3 mo. post-transplant) were followed in 8 centers (Canada and USA). Adherence
barriers were assessed at baseline using the Adolescent Medication Barriers Scale (AMBS).
A higher score indicates greater barrier burden (possible range 17-85). We used linear
regression to estimate the association between baseline AMBS scores (total score and
ingestion, disease adaptation, and cognitive/organization subscores) and timing adherence.
Models also included sex, age, race, and time since transplant.

Results: 60% were male and 67% were white. Median age at baseline was 15.8 (IQR
17.4, 17.6). Median time since transplantation was 1.1 (0.7-7.5) y. Higher burden of perceived
timing adherence for the interval was 82.6%±32.8. Higher barrier burden (median score 38 (IQR 30-44)) was
significantly associated with poorer timing adherence: A unit higher total AMBS score was
associated with 2.0% (95% CI 0.4, 3.6) lower timing adherence. A unit higher score was
associated with 4.3% (1.2, 7.5) lower timing adherence for the disease adaptation sub-scale,
and with 5.9% (0.2, 11.6) lower timing adherence for the cognitive/organization sub-scale.
Males had 10% (2.9, 17.6) lower timing adherence than females.

Conclusions: Higher burden of perceived barriers was a significant predictor of poorer
timing adherence in this longitudinal study. Future analysis of the TAKE-IT data will
determine the impact of an intervention targeting individual barriers on timing adherence.

Funding: NIDDK Support

SA-PO1030

Background: The experience alters neither the initial impetus nor the meaning
attributed to the donation. The recommendations are to pursue the development of
laparoscopy in informing organ management completely, to better prepare the donor to the
surgical procedure, its risks and aftermath, including professional ones in younger, to
maximize the opportunity for organ transplantation.

Results: Of 93,811 donors listed in study period, 8.5 % (8012) were exposed to
coronary angiograms. From this group, 14,628 kidneys were transplanted. Statistically
significant regression results (p<0.01) indicate that patients receiving organs from donors who
were exposed to coronary angiograms are 2% points more likely to receive dialysis within the
first week after transplant (mean=0.24) and are less likely to experience a ≥25% decline in
serum creatinine in the first week of transplant (mean=0.56). These patients also face
a 61 day shorter average graft survival time and a 1% point lower probability of 6-month
post-transplant patient survival. At three years recipients from donors with contrast exposure
have 2% decrease in survival rate (p=0.005).

Conclusions: This large database analysis provided statistical power to detect an association between donor exposure to indinated contrast from coronary angiograms before organ procurement and subsequent adverse early as well as later kidney transplant outcomes. Further research into the effects of deceased-donor management strategies is warranted to expand the organ pool while decreasing adverse transplant outcomes.

Deceased Directed Kidney Donations: A Three-Year Experience at a Single OPO

**Background:** The UAGA allows for deceased directed organ donations. Our OPO has incorporated the practice of offering the option of directed donations during every donation discussion in response to routine donor family requests. However, facilitating directed donations for donor families remains a controversial topic. Opponents suggest that directing gifts is not only inequitable, but that it may encourage malfeasance in the form of organ solicitation via media or social media. In an effort to standardize the language and timing of the directed donation discussions, we retrospectively reviewed our practice and examined our results in detail. For the three-year period, 176 of our 1,056 authorized donors had a potential directed donation. Of these, 80% were directed to patients on the kidney waiting list. However, only 16% of the attempted directed kidney donations resulted in a transplant. The data illuminate that incompleteness/mismatch of potential directed kidney recipients is the most common reason that directed kidneys are not transplanted, despite the fact that directed donations are allocated ahead of highly sensitized patients, mandatory shares, and significant requestors.

**Conclusions:** Facilitating directed donations will continue as part of our routine practice. Each year approximately one in six of our donor families identified potential recipients, but transplants from these requests remained consistently less than 2% of our annual total. Future studies are planned to evaluate recipient outcomes, assess donor family satisfaction with a recipient known to them, as well as to examine our practice in detail in an effort to standardize the language and timing of the directed donation discussions.

**SA-PO1034**

**Jeevandan: Deceased Donor Transplantation Programme from a Developing Country**

**Background:** In developing country like India the prevalence of end stage organ disease is increasing. Though transplantation has been in practice in India, its been grossly inadequate in terms of actual numbers of organs and organs. The only solution for the shortage of organs is deceased donor transplantation.

**Methods:** In India the Human Organs Transplantation Act, was enacted in 1994 with the objective of promoting and regulating the transplantation of human organs like kidney, liver and heart - both live as well as cadaver there was no significant increase in cadaver transplantation over the past two decades for various reasons. India follows “opt in” system and brain death declaration is not mandatory. Andhra Pradesh and Telangana are the two most populous states in India, situated on the country’s southern coast. It is India’s fourth largest state by area and fifth largest by population. Government of Andhra Pradesh, considering the shortage of organs and burden of end stage organ failure in the state, has come up with a Government Order called “Jeevandan” to streamline the procedure for facilitating and regulating the cadaver and organ transplantations on an end-to-end basis.

**Results:** There were 129 deceased donations in 2 years. Male were 93 and female 36: male to female ratio being 1: 2.58. The mean age was 41 years (range 8 to 79). Most common Blood group was O in 51 (39.5%) donors followed by B in 39 (30.23%), A positive in 22 (18.07%), AB in 10 (7.75%) donors. Total 593 organs included. Donor organs were retrieved from 129 deceased donors; 233 kidneys, 126 livers, 7 hearts, 118 heart valves, 103 corneas , 5 lungs and 1 Pancreas. Total deceased donor renal transplantations done during this period were 24.67%. Out of 129 donors, 6.8 % kidneys and 3% livers were not utilized. Mean age of renal recipients was 44.07 years (range 13 to 72). There were 26.8% females and 73.2% males, female to male ratio being 1: 2.73. Among deceased donor renal transplant recipients, O blood group was most common, seen in 36.79% followed by B in 32.38%, A in 22.64% and AB in 8.17% patients.

**Conclusions:** Deceased donor transplantation is the solution for organ shortage and increasing demand of organ requirement.

primary failure modes. Evaluation of all transplant-related outcomes at specific follow-up
intervals will allow practitioners to assess the success of kidney transplantation and overall
recipient health and focus clinical outcome improvement efforts.

SA-PO1037
Clinical Outcome of Elderly Living Kidney Donors: A Single-Center Study in Japan
Jumpei Hasagawa, Kohei Unagami, Masayoshi Okumi, Kazuya Kwon, Hideki Ishida, Kazunari Tanabe. Urology, Tokyo Women's Medical Univ, Tokyo, Japan.

Background: Previous studies and current guidelines have suggested that elderly
persons can be living kidney donors; however, reports on elderly donors >70 years old are
limited. In order to clarify the donor safety and feasibility, we investigate the clinical outcomes of living kidney donors >70 years old after nephrectomy.

Methods: We conducted a case-series study of living kidney donations involving 48 donors aged >70 years at the time of transplantation. The kidney donations occurred between 2001 and 2014 at Tokyo Women’s Medical University in Tokyo, Japan. The primary outcomes were survival or end-stage renal disease (ESRD)-free rate and all crude event-free rates, including death, hypertension, infection, ESRD, or vascular failure rate. The secondary outcome was serum creatinine level at the end of the follow-up period.

Results: The 48 cases were followed up for a median of 4 years. The survival rate among the donors was 100% until the fifth year, and only two donors died during follow-up. The ESRD-free rate was 100% during the follow-up period. The overall event-free rate was 100% at 1 year, 85.7% at 3 years, and 75.0% at 5 years. The mean serum creatinine level was 1.18 ± 0.24 mg/dL at the time of hospital discharge and did not increase (1.18 mg/dL) at the end of follow-up.

Conclusions: Living kidney donation from elderly donors >70 years old appears to be a safe and acceptable option for patients requiring renal-replacement therapy.

SA-PO1038
Immunosuppressive Medication Adherence following Kidney Transplantation in the Military Healthcare System
Dustin J. Little, Matthew Ward, Robert Nee, Christina M. Yuan, Rahul M. Jindal. Walter Reed National Military Medical Center, Bethesda, MD; Uniformed Services Univ of the Health Sciences, Bethesda, MD.

Background: Limitations on the amount and duration of Medicare coverage of immunosuppressive medications (ISM) may contribute to ISM non-adherence and allograft failure. ISM adherence has not been reported in US patients who receive these medications at no cost. We therefore designed a prospective cohort to investigate the incidence of ISM non-adherence in Military Healthcare System (MHS) beneficiaries, who receive lifelong ISM coverage as well as prevention, identification, and treatment of depression should be prioritized for future study in order to improve outcomes following renal transplantation.

SA-PO1039
Clinical Impact of Kidney Donor Follow-Up by Nephrologists
Hee Jin Kwon, Jin Hae Kim, Jeen Eun Park, Subin Hwang, Jung Eun Lee, Woosong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Hye Ryoun Jung. Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.

Background: Compensatory and adaptive mechanisms in the remnant kidney occur immediately after nephrectomy. The adaptability in early postoperative period may affect the renal function of the remaining kidney. Since the introduction of extended criteria living donor program, the numbers of marginal donors with risk of new morbidities are increasing. The aim of this study was to evaluate the clinical impact of kidney donor follow-up by nephrologists at a donor clinic (DC).

Methods: Our study included 427 living kidney donors from January 2010 to December 2014 in Samsung medical center. Nephrologist-run donor clinic was established in January 2013. The study period was divided into pre-DC and post-DC. Primary outcomes were incidence of CKD and renal functional adaptability (%MARD = post/pre eGFR X100) at 6 months after donation. Secondary outcomes were changes in compliance and incidence of co-morbidities; hyperuricemia and microalbuminuria.

Results: A total of 215 and 172 donors were included in pre-DC and post-DC, respectively. Before donation, age, sex, proportion of hyperuricemia and microalbuminuria were similar. Preoperative eGFR in pre-DC was significantly higher than post-DC (p<0.001). After donation, poor renal adaptation (post-donation eGFR at 6 months < 60% of preoperative eGFR) was less frequent in the post-DC period compared to the pre-DC period (p=0.026). CKD development tended to be higher in pre-DC period. Donors in the post-DC period had shorter mean outpatient clinic visit intervals (p<0.001), more visits within 6 months after donation (p=0.001), earlier detection of de-novo hyperuricemia (p<0.001)

Conclusions: After establishment of kidney donor clinic operated by nephrologists, donors tended to show better renal adaptability and earlier diagnosis and treatment of hyperuricemia. In conclusion, donor clinic may be a good strategy for improving renal outcome and detecting potential risk factors of CKD in donors.

SA-PO1040
Predicting Kidney Allograft Half-Life Using a Podometric Approach

Background: Increasing donor age is a powerful predictor of worse renal allograft outcome. Podocyte depletion is part of the normal aging process (Hodgin, JASN, 2015). Recently we showed that kidney hypertrophy that occurs at time of transition from a 2 kidney to 1 kidney state (transplantation), leads to a 20% reduction in podocyte density and a 6-fold increased rate of podocyte detachment associated with transplant glomerulopathy and allograft failure (Yang, JASN, 2014). To test the hypothesis that podocyte depletion could impact allograft half-life we used a model combining age specific podocyte nuclear density decrease and rate of podocyte attrition after transplantation for comparison with actual allograft outcome data.

Methods: Podocyte density was estimated from immediate post perfusion biopsies from living and deceased donors or from non-diseased nephrectomy specimens. Projected allograft life was predicted based on modeling age-specific podocyte density and the observed attrition of podocytes. Observed data were drawn from the OPTN/UNOS STAR files as of Sep 2014, using all transplants performed between Oct 1987-June 2013. A “conditional” Kaplan Meier analysis using the “period” method was used to calculate observed half-lives at different donor ages.

Results: The podometric projected average half-life for a 40 year old donor is 15.1 years, similar to the observed average allograft half-life (15.1 years). The projected effect of increasing donor age on allograft half-life from podometric measurements is similar to the observed effect of donor age on allograft half-life at all calculated donor ages (p=NS).

Conclusions: Quantitative podometric modeling predicts both shorter-than-expected average renal allograft survival and the donor age effect, compatible with the concept that hypertrophic processes at transplantation significantly impact half-life.

Prediction of Patient Survival After Kidney Transplantation (Tx): Construction, Validation and Evaluation of Decision Models Using Data Mining Approaches
Irina Scheffner,1 Kaixun Hua,2 Dan Simovici,2 Tanja Abeling,1 Hermann G. Haller,1 Wilfried Gwinnner.1 1Hanover Medical School, Germany; 2Univ of Massachusetts.

Background: Understanding the risk factors that predispose to death is important to deliver the most appropriate therapy to Tx patients (pts). Aim of this study is to build reliable tools for the prediction in order to identify the relevant risk factors for death using different data mining approaches.

Methods: We analyzed 761 pts transplanted between 2000 and 2007 (follow-up of up to 10 years). Data included biopsy results, clinical & laboratory factors. After conventional statistical feature selection, 28 variables we build Naïve Bayesian (NB), C5.0, RPART and Random Forest (RF) models.

Results: Compared to C5.0 and RPART, NB and RF resulted in models with a higher sensitivity to predict death and a high specificity. Using different partitions for training and test set, NB models had a sensitivity of 62-65% and a specificity of 89-91% to predict death. With RF, sensitivity was 64% and specificity 96%. Because of the imbalance of the outcome groups (13% deceased pts) modeling was repeated with balanced datasets obtained by oversampling. With the balanced data, sensitivity was 82% and specificity 79% with NB. With RF, sensitivity was 83% and specificity of 68%. These models were externally validated with two separate datasets showing sensitivities of 64 and 59% and specificities of 86% and 78% for the NB models and sensitivities of 84 and 61% and specificities of 60 and 65% for the RF models. Highly important variables were recipient age, pre-Tx diabetes mellitus, peripheral arterial and coronary heart disease, cold ischemia time, graft function within the first 6 weeks and annual GFR loss, and post-Tx systolic and diastolic blood pressure, urinary tract infections, and hyperparathyroidism. Modestly important variables included donor age, time on dialysis, HLA DR mismatches, delayed graft function; the predictive value of these models is very low. The models performed well for death prediction in our dataset and can be used to identify pts on risk. Moreover, with the identified (modifiable) risk factors pts can be assigned to different treatment strata to offer each patient the optimal therapy.

The Decline of Dialysis in Northern Ireland Kathryn E. Larmour. Regional Nephrology Unit, Belfast City Hospital.

Background: The first session of haemodialysis in Northern Ireland (NI) was in 1959 for acute kidney injury. There has been an inexorably rise in the prevalent dialysis population in the province since then, with expansion of dialysis facilities to accommodate ever increasing numbers. However, in addition to inferior outcomes compared to transplantation, there are considerable costs and potential costs associated with chronic haemodialysis provision. This study considered the impact of an expansion in the living donor (LD) transplant programme on dialysis in NI and the financial implications.

Methods: The prevalence dialysis population from 1999-2011 inclusive data were retrieved retrospectively from collected data. The number of LD transplants in NI patients is prospectively recorded. The economic impact of the changes evident in our centre were studied. DN was classified as 1) donor related if present on biopsy <2 yrs from transplant and could be attributed to the donor, 2) recurrent if >2 yrs with history of pre-transplant DN, or 3) de novo if post-transplant biopsy may confer increase risk of allograft dysfunction.

Results: Underline represents presenting author.

Conclusions: Despite careful screening of transplant kidney donors, donor related DN may be missed on pre-surgical biopsy or not effectively reported and leads to renal dysfunction in the early post-transplant period. Donor related DN is a significant contributor to early allograft loss compared to recurrent or de novo DN and predicts poor long term graft survival.

SA-PO1045
Maternal and Fetal Outcomes in Living Kidney Donors in Korea Kyung Don Yoo, Hajeong Lee, Joo Yoon Park, Eunjin Bae, Jung Pyo Lee, Dong Ki Kim, Kwon Wook Joo, Youn Su Kim. Seoul National Univ Coll of Medicine.

Background: Maternal and Fetal Outcomes in Living Kidney Donors in Korea.

Methods: We tried to contact all of 417 female kidney donors. The thirty five donors who had no experience of pregnancy, and finally we could have got 253 questionnaires of kidney donors. Donors were compared in the three groups according to pregnancy pre-post kidney donation group and non-donor control group. The proportion of predonation pregnancies was 82% (370cases, Mean age 38.8 years), and postdonation pregnancies were 14% (56cases, Mean age 27.2 years). In the majority of postdonation pregnancy cases were detected in recent years from 2007 to 2014 (72.3%). There were no differences of fetal outcomes such as incidence of prematurity, low-birth weight and fetal death between the two groups. Gestational hypertension were no differences between the postdonation group and non-donor control group (5.4% vs. 5.8%). Donors with pregnancy after donation were more likely to have undergone Cesarean section (40.4%) than those with pregnancy before donation (21.9%).

Conclusions: This study revealed that maternal and fetal outcomes had little difference between the kidney donors and normal control. Further research using matched controls should be warranted.

SA-PO1046
Self-Monitoring Renal Function After Transplantation: A Clinical Trial on Safety and Usability Céline Lianne VanLint,1 Sandra Van dijk,2 Wenxin Wang,2 Mark Neerincx,3 Ton Rovekamp,3 Ton J. Rabelink,1 Paul J. Van der Net,1 Leiden, Netherlands; 2Faculty of Computer Science, Delft Technical Univ, Delft, Netherlands; 3Dept of Technology in Healthcare, Prevention and Health, TNO, Leiden, Netherlands.

Background: Kidney transplantation requires intensive monitoring which is burdensome for both patient and healthcare. With the availability of an innovative creatinine device, patients are enabled to monitor renal function at home. To investigate safety and usability of self-monitoring during the first year after transplantation an RCT was conducted.

Methods: The intervention group used a Statusensor® Xpress™ to measure creatinine at home during the first year after transplantation. Measurements were registered in a web-based system using a traffic light analogy to support interpretation of creatinine trends. Differences between groups regarding GFR were assessed at baseline (discharge) and at 1 year. Creatinine trends measured at home were compared to clinically relevant increases (>10%) measured in the hospital laboratory. A subsample of intervention patients were interviewed on self-monitoring experiences.

Results: In total 119 patients were included (intervention n=64; control n=55). GFR did not differ between groups at baseline, nor at 1 year (72.8 and 71.1 ml/min at 1 year for intervention and control group, respectively). For 34 out of 65 laboratory-based creatinine increases, sufficient home-based creatinine measurements were available for trend comparison. In 76% a similar trend was observed. Self-monitoring enhanced early detection of rejection in 3 out of 5 cases, none were missed. Satisfaction was high: 71% of the observed patients (n=26) would have liked to extend self-monitoring creatinine monitoring beyond 1 year.

Conclusions: The study revealed that maternal and fetal outcomes had little difference between the kidney donors and normal control. Further research using matched controls should be warranted.
Comparison of Heart Rate Variability in Kidney Transplantation and End-Stage Renal Disease Patients on Dialysis

**Background:** Heart rate variability (HRV) is a method for evaluation of autonomic nervous system activity by expressing the balance of sympathetic and parasympathetic tones. Some studies of HRV in patients with end-stage renal disease (ESRD) have been performed. However, few have examined kidney transplantation (KT) patients. Therefore, we investigated autonomic nervous system activity by means of HRV in patients with KT due to ESRD.

**Methods:** We compared the pattern of cardiac sympathetic and parasympathetic activity by time- and frequency-domain analyses of HRV with 24-h Holter monitoring of 23 KT and 56 dialysis patients. Patients underwent KT between January, 2008 and June, 2011.

**Results:** The mean ages of KT and dialysis patients were 54.2 ± 12.3 and 53.7 ± 12.6 years, respectively. The KT group showed increased time- and frequency-domain HRV (including HRV index), very low frequency (VLF), and standard deviation of normal R-R intervals for all 5-min segments of the entire recording (SDNNi), low frequency (LF), LP in normalized units (LFnorm), and LF to high-frequency power ratio, compared with the dialysis group.

**Conclusions:** Autonomic tone in patients with KT is higher than that in patients with ESRD on dialysis.

**Pregnancy in the Renal Transplant Recipient: Pregnancy Viability and Effects on Graft Function**

**Background:** Fertility in women is recovered few months after kidney transplantation. However, pregnancy viability and maternal complications remain unclear.

**Methods:** We studied data from patients from a kidney transplant center in Brazil from 2001 to 2012. In this retrospective study, we identified all pregnant kidney transplant recipients and collected clinical and laboratory data before pregnancy, every quarter and 12 months after delivery. Each pregnancy was considered a single event.

**Results:** We included 36 subjects and 53 events were found. The average age was 28.15 years. Pregnancy occurred 4.4±3 years after transplantation. Maintenance immunosuppression before pregnancy was prednisone, tacrolimus and azathioprine in 74% of the cases. The frequency of chronic hypertension was 38%, and 8% had preexisting proteinuria greater than 0.5g. 8 (15%) unintended termination of pregnancy (UTP) were observed in the first quarter and 4 (8%) occurred in the second quarter. Delivery was induced by medical conditions in 41% of cases. 9 (22%) premature births and 7 (17%) very premature births were observed. Two (5%) stillbirths and two (5%) neonatal deaths occurred. Maternal complications were proteinuria de novo (60%), urinary tract infection (23%), preeclampsia (9%) and high blood pressure (9%). During the follow-up period, two (6%) acute rejection and one (2%) graft loss occurred. Average baseline creatinine was compared with third quarter and 12 months follow-up creatinine and significant increase (1.17 vs. 1.46 vs. 1.59mg/dL, p<0.001) was found.

**Conclusions:** Although the sample is limited, the number of UTP was higher than the general population, with high rates of maternal complications. Besides, diagnosis of preeclampsia may be challenging because of the high frequency of hypertension and preexisting proteinuria. The sustained increase in creatinine suggests higher risk of long-term graft loss. Further research regarding the issue of pregnancy and kidney transplantation is required, in order to improve maternal safety and preserve graft function.

Kidney Transplantation for End-Stage Kidney Disease After Hematopoietic Stem Cell Transplantation Akihiro Tsuchimoto, 1 Kosuke Masutani, 1 Kei Kurihara, 2 Hidetsuya Kitada, 1 Takehiro Nishiki, 1 Morihito Oto, 3 Masayoshi Okumi, 1 Tomokazu Shimizu, 1 Hideki Ishida, 1 Kazunari Tanabe, 2 Kazuhiko Tsuruya, 1 Takanari Kitazono. 1 Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; Surgery and Oncology, Kyushu University, Fukuoka, Japan; 2 Surgery, Tomishiro Central Hospital, Okinawa, Japan; 3 Urology, Tokyo Women’s Medical University, Tokyo, Japan.

Background: Hematopoietic stem cell transplantation (HSCT) is associated with various kidney diseases. The safety of kidney transplantation (KT) for end-stage kidney disease (ESKD) after HSCT has not been established. In this retrospective multicenter study, we investigated the immunological background, immunosuppressive regimens, and outcome in the KT patients after HSCT.

Methods: We report our experience with 5 KT patients following HSCT: 4 patients received bone marrow transplantation and 1 received umbilical cord blood transplantation. Median age at the time of HSCT was 29 years old (ranged 13-54 years old), and ESKD developed after 119 months (67-307 months). The median duration of pre-transplant dialysis therapy was 18 months (7-69 months). In one patient, bone marrow and kidney were from the same donor.

Results: Median observational period was 18 (5-60) months. All patients were treated antibody-induction with basiliximab followed by triple immunosuppression consists of tacrolimus, mycophenolate mofetil and methylprednisolone. In one patient with positive complement dependent cytotoxicity cross match, we added rituximab, splenectomy and tacrolimus, mycophenolate mofetil and methylprednisolone. After KT, only one patient experienced severe diastolic hypertension (OR=4.833, P=0.048), but high mortality caused by infections, whereas we temporary gave immunosuppressive drugs. After KT, only one patient experienced severe diastolic hypertension (OR=4.833, P=0.048), but high mortality caused by infections, whereas we temporary gave immunosuppressive drugs. After KT, only one patient experienced severe diastolic hypertension (OR=4.833, P=0.048), but high mortality caused by infections, whereas we temporary gave immunosuppressive drugs. After KT, only one patient experienced severe diastolic hypertension (OR=4.833, P=0.048), but high mortality caused by infections, whereas we temporary gave immunosuppressive drugs.

Conclusions: Previous studies of KT patients after HSCT suggested low incidence of rejection and stable graft function, but high mortality caused by infections, whereas temporary gave immunosuppressive drugs. Although limited by small sample size and low event rate, our analysis suggests that pre-OLT CKD3 may have an effect on development of ESRD post-OLT. These effects if generalizable in larger cohorts are important for organ allocation.

SA-PO1052
The Risk Factors of Chronic Kidney Disease Occurrence in Patients Received Liver Transplantation Li Yuehong. Nephrology, Tsinghua Changgung Hospital, Medical Center, Tsinghua Univ, Beijing, China.

Background: Analysis the risk factors of chronic kidney disease (CKD) occurrence in patients with liver transplantation.

Methods: 190 patients received liver transplantation followed up during 2001 to 2013 were analyzed retrospectively. 40 patients developed CKD. The observation items included patients’ gender, age, primary diseases, surgical approach, postoperative complications, laboratory examinations (hemoglobin, albumin, creatinine, glomerular filtration rate), intraoperative blood loss and blood transfusion volume, postoperative complications and average serum calcium concentration (from liver transplantation to the onset of CKD). Clinical data of CKD occurrence group were compared with the non-CKD group. Chi square test, t test, and logistic regression analysis were used.

Results: The incidence of CKD in patients with liver transplantation was 21.1%. Renal pathology included IgA nephropathy, hepatitis B virus associated nephropathy, membranoproliferative glomerulonephritis, focal segmental glomerular sclerosis and cryoglobulinemia associated renal injury. 85.7% patients had tubulointerstitial damage. Univariate analysis showed that preoperative renal function, hemoglobin, intraoperative blood loss and transfusion volume, postoperative acute kidney injury, average calcium concentration in serum from liver transplantation to the onset of CKD.

Conclusions: Although limited by small sample size and low event rate, our analysis suggests that pre-OLT CKD3 may have an effect on development of ESRD post-OLT. These effects if generalizable in larger cohorts are important for organ allocation.

SA-PO1054
Pre-Transplant CKD, but Not AKI, Impacts Survival in Liver Transplant Recipients Yorg Al Aziz, Girish N. Nadkarni, Vinay Nair, Thomas Schiano, Madhav C. Menon. Medicine, Icahn School of Medicine, New York, NY.

Background: Chronic kidney disease (CKD) stage and duration of RRT pre-liver transplant (OLT) have been associated with increased risk of progression to ESRD in OLT recipients. Currently, allocation of dual organ transplantation (liver/kidney) is limited to CKD stage 4 and/or RRT > 4 weeks. The data regarding the associations of less severe pre-OLT AKI (RRT=4 weeks) and, of CKD stage 3, with ESRD post-OLT is unclear. We examined the renal outcomes of OLT recipients at our center.

Methods: We reviewed charts of OLT recipients at Mount Sinai for clinical, demographic, laboratory and outcome data from the medical record. We utilized multivariable logistic regression for analysis.

Results: We had data on 115 OLT recipients from 2008-14 (mean age 57.7 years, 66% male). 55/115(47%) patients developed AKI pre-transplant, most often from HRS (47%). Pre-existing CKD-3 was present in 26/115 patients. Pre-OLT AKI developed in 23/26 CKD-3 patients. RRT was required in 8/26 CKD-3 patients. Mean eGFR at 1- and 2-year follow-up in the CKD-3 group compared to non-CKD group were 37.4 ± 16.6 vs. 33.3 ± 23.1(p=0.01) and 59.8 ± 20.8 vs. 62.7 ± 22.9(p=0.01) respectively. At a mean follow up of 1.4 years post OLT, proportion of patients developing ESRD was higher in CKD vs. non-CKD group (23.1% vs. 2.3%,p<0.01). Although, AKI was a significant predictor of ESRD (adjusting for age, sex, race, diabetes), its effect was attenuated after adjusting for CKD. CKD3 was the strongest predictor of ESRD (OR 8.34; 95% CI 1.55 7.9=0.02) (figure 1). Overall, patient survival at a mean of 2.4 years of follow-up was lower in CKD3 vs. non-CKD groups (76.9%vs. 91%=0.08).

Conclusions: Pre-OLT CKD, but not AKI, impacts survival in liver transplant recipients. Therapy to prevent AKI should be considered to improve patient survival.
C3 Alone Is Not a Prognostic Indicator of Patient or Graft Survival in Post-Transplant Glomerulonephritis

**Background:** The prognostic implications of glomerular C3 in the post-transplant setting are not well characterized.

**Methods:** We examined the presence and graft outcomes in 71 kidney transplant recipients diagnosed with glomerulonephritis (GN). Biopsies were studied by immunofluorescence (IF) for glomerular C3 staining and divided into two categories, C3-positive or C3-negative. Primary outcomes were graft and patient survival at 3, 12, and 36 months and at last follow-up. Serum creatinine (Cr) at last follow-up was a secondary outcome.

**Results:** Thirty-three (46%) patients were C3-positive and 38 (54%) were C3-negative. Mean follow-up was 103 months for positive C3 and 117 months for negative C3 groups. There were no significant differences among groups by age, gender, type of donor, or prevalence of hypertension, diabetes, and hepatitis B or C. A total of 57% of C3-positive patients had a functioning graft at 36 months post-transplant, compared to 75.1% of C3-negative (p=0.16). A total of 88.2% of C3-positive patients were alive at 36 months post-transplant, compared to 85.7% of C3-negative (p=0.9). The mean serum Cr for C3-positive patients at 36 months was 1.59 mg/dl compared to 1.71 mg/dl for C3-negative (p=0.15). There were no significant differences in graft and patient survival between two groups.

**Conclusions:** There was no significant difference in patient or graft survival, or in serum Cr between patients with GN and C3-positive IF compared to patients with C3-negative IF.

Pretransplant Hepatitis B Viral Infection Increased Risk of Death After Kidney Transplantation: A Multicenter Cohort Study in Korea

**Background:** Outcomes in kidney transplant recipients (KTRs) with hepatitis B virus (HBV) have not been well evaluated. Here, we aimed to investigate the recent posttransplant clinical outcomes of KTRs with HBV infection compared with those with hepatitis C virus (HCV) or seronegative patients.

**Methods:** Among 3885 kidney recipients from April 1999 to December 2011, 3490 patients were enrolled whose viral hepatitis serology data was available. Numbers of patients with HBV and hepatitis C virus (HCV) were 166 (4.8%) and 55 (1.6%), respectively. We analyzed the overall mortality and graft failure (GF) among patients who had taken KT.

**Results:** Patients with HBV showed poorer patient survival (P=0.030, adjusted HR=2.296, 95% CI 1.084-4.884) than KTRs without HBV. However, HCV did not affect patient survival (P=0.763). Patients with chronic hepatitis C showed increased incidence of GF (P<0.015, adjusted HR=2.306, 95% CI 1.178-4.606). However, the GF of patients with chronic hepatitis B (CHB) was not different (P=0.066). Among causes of mortality of KTRs with HBV, hepatic failure was predominant (44.4%). The KTRs with HCV had increased incidence of acute rejection (log-rank P=0.005; crude HR=2.147, 95% CI 1.344-3.432, P<0.001). Among KTRs with HBV, mortality was significantly correlated with higher grade of inflammation in pretransplant liver biopsy (P=0.007) and lower rate of prophylactic antiviral treatment (P=0.019).

**Conclusions:** The KTRs with CHB could show poor survival due to posttransplantation hepatic complications. Serious chronic liver disease and antiviral management of KTRs with CHB patients will be needed, even if liver function is within normal range.

Does Hepatitis B Virus Impact the Outcomes in Kidney Transplant Recipients? Analysis by Phases of Infection

**Background:** In kidney transplant recipients (KTRs) with hepatitis B virus (HBV) infection, immunosuppression may increase the risk for the progression of liver disease. HBV may contribute to allograft disease and anti-HBV therapy can have nephrotoxic potential.

**Methods:** Using OPTN/UNOS database, we selected adult KTRs from 2001 - 2011 who received peri-operative operative antibody induction followed by calcineurine inhibitor/mycophenolate mofetil maintenance along with without steroid. The cohort was divided into 4 groups based on the presence/absence of hepatitis B surface antigen (HBsAg) and core antibody (HBcAb) at the time of transplantation: HBsAg+/HBcAb- (acute infection); HBsAg+ /HBcAb- (developing immune response); HBsAg+/HBcAb+ (resolving infection) and HBsAg-/HBcAb- (HBV naive). Graft and patient survivals were compared among the groups in the table by using multivariate Cox model. Donor, recipient and transplant related confounders including lamivudine therapy were adjusted in the model.

**Results:** Adjusted graft and patient survival comparisons are shown in the table.

Incidence of Hepatitis B Viral Reactivation After Kidney Transplantation with Rituximab Administration

**Background:** The efficacy of antiviral prophylaxis for rituximab (RIT)-associated hepatitis B virus (HBV) reactivation in patients with malignant lymphoma has been reported. However, the effect of single-dose RIT on HBV reactivation in kidney transplant patients with hepatitis B surface antigen-negative (HBsAg−) and hepatitis B core antigen antibody-positive (HBcAb+) results is unclear, and there is no evidence for the necessity of prophylaxis in those patients.

**Methods:** From 2001 through 2014, 1021 patients underwent kidney transplantation (KTx) at Kyushu University and Tokyo Women’s Medical University, of whom 76 (7.4%) had HBsAg−/HBcAb+. Those patients showed hepatitis C virus (HCV)-RNA-negative, hepatitis B surface antibody-positive (HBsAb+) and HBV-DNA-negative. A RIT dose of 200mg/body was administered to 49 patients, and 45 patients did not receive prophylaxis. We monitored HBV-DNA and alanine transaminase levels 1-3 months after KTx. HBV reactivation was defined as an elevation of serum HBV-DNA level to >2.1 log copies/ml.

**Results:** HBV reactivation was found in 1 of 45 patients (2.2%) without prophylaxis. In the patient with HBV reactivation, serum HBV-DNA was detected at 6 weeks after KTx, and the maximum and maximum HBV-DNA levels were 2.1 and 2.6 log copies/ml, respectively. Although the patient was not treated with antiviral therapy, the HBV-DNA disappeared at 8 months after KTx. HBV reactivation was not found in the patients without RIT, and all 4 patients who received both RIT and prophylaxis. Four (8.9%) of the 45 patients developed acute rejection, and 1 patient (2.2%) died of sepsis during the observation period.

**Conclusions:** The incidence of RIT-associated HBV reactivation in the HBsAg−/HBcAb+ patients without prophylaxis was less than 5%, suggesting that low-dose RIT might be associated with low incidence of HBV reactivation. However, sequential monitoring of HBV-DNA is necessary to prevent severe de novo hepatitis.
Direct Acting Antiviral Agents for HCV-Infected Patients Transplanted with a Kidney from a HCV Positive Donor

**Methods:**
- **HCV RNA** (±) pts on the waiting list were consented to receive a kidney from a HCV (+) donor. Acceptance of a HCV (+) kidney significantly shortened wait time. Response to DAAs appears similar to that being reported for pts with cirrhosis with a mean age of 49.4 yrs. No pts were HIV or HBV co-infected. All pts were treatment naïve, genotype 1 and non-cirrhotic. Median wait time was 30 days after consenting to accept a HCV (+) kidney. Viral clearance rates are shown in figure 1.

**Results:**
- Ten pts have started DAAs therapy (5 others pending): 6 blacks and 4 hispanics with a mean age of 49.4 yrs. No pts were HIV or HBV co-infected. All pts were treatment naïve, genotype 1 and non-cirrhotic. Median wait time was 30 days after consenting to accept a HCV (+) kidney. Viral clearance rates are shown in figure 1.

**Conclusions:**
- Treatment of HCV with pegylated interferon during dialysis results in significant improvement of patients and graft survival following transplantation as compared to untreated patients. There is also trend of decrease in serious infection in treated patients. Sepsis and liver failure are two most common cause of mortality in untreated patients.

**SA-PO1065**

Impact of Treatment of HCV Infection on Renal Transplant Outcome

**Methods:**
- Adult patients on dialysis with HCV infection treated with pegylated interferon and subject to renal transplant (RT) formed the study group. Untreated patients subjected to RT during same period served as controls. Primary end points were patient’s and graft survival and secondary end points were serious infections and NODAT. Factors which affect the outcome like age, gender, diabetes as basic disease, diabetes vintage, HBV co-infection, HCV genotype, viral load, liver biopsy grade and stage, induction and baseline immunosuppression were considered for analysis.

**Results:**
- At the time of study, 2010 RT were done in department of which 133 had HCV infection. 30 were treated with 68% SVR and 103 were untreated. In untreated group, there were more males (92% Vs 77%), less dialysis number (137 Vs 211), less HBV co-infection (0.9% Vs 10%), less use of Tacrolimus (13.6% Vs 30%). There was no difference in terms of age, diabetes, HCV genotype, viral load, liver biopsy grade and stage, use of induction, Mycophenolate mofetyl and duration of follow-up in the groups. With mean follow-ups of 59 ± 22 months (range 12- 105), there was no statistically significant difference in terms of acute rejection (23% vs 15%), NODAT (10% vs 16.7%) and overall serious infections (23% vs. 15%) between two groups. However, there were 11 deaths in untreated group (8 sepsis related, 3 liver failure and 1 coronary artery disease) while only one death related to sepsis in treated group. Patients survival (97% vs 89%) and graft survival (97% vs 84%) was significantly better (p=0.05) in treated group as compared to untreated group.

**Conclusions:**
- High dose steroid therapy in BK viremia has been tried for the management of confusing cases of BK nephropathy (±mixed cellular rejection). However, the eventual fate of renal allograft after steroid therapy in the long term is still unknown. Therefore we investigated the graft survival and the change of BK viral load after steroid therapy in patients with BK viremia.

**Methods:**
- The study population comprised 144 kidney transplant recipients with BK viremia (serum BK viral load>1x10^4 copies/mL) consecutively detected at least twice, followed by steroid pulse treatment between July 2004 and March 2013. Patients were divided into two groups based on the amount of steroid: low dose (steroid 0-2g) or high dose (steroid>2g).

**Results:**
- A total of 123 patients belonged to low dose group and 21 patients were in high dose group. There were no differences in baseline characteristics, including age, gender, and the rates of biopsy-proven BK nephropathy and acute rejection. Serum BK viral loads at the time of steroid pulse therapy were 5.3±1.10 log copies/mL in low dose group and 6.00±0.98 in high dose group (p=0.054). They were changed into 5.25±1.05 and 6.14±1.45 in each group one month after steroid treatment (p=0.03) and 4.92±1.25 and 5.86±1.74 at two months (p=0.133), respectively. From three months to one year, serum BK viral loads were not different from each group. Kaplan Meier analyses demonstrated that the incidences of further 50% decline in renal function assessed by estimated GFR and graft failure were significantly higher in the high dose group (p=0.004 and p=0.04, respectively). In multivariate regression analysis, high dose steroid treatment (p=0.002, HR 9.61, 95% CI 2.25-40.99) and log serum BK viral load at two months after high dose steroid administration (p=0.027, HR 1.72, 95% CI 1.06-2.78) were important risk factors of further 50% decline in renal function.

**Conclusions:**
- In kidney transplant recipients with BK viremia, high dose steroid therapy induced BK viral activation and subsequently resulted in poor long term graft function and early graft failure.
SA-PO1063

Donor Seroreactivity Strongly Correlates with Recipient BKV-Viremia and Nephropathy

Herman F. Wunderlich,1 Els Meijden van der Blij-de Brouwer,1 Antoine Touze,2 Marko Mallat,1 Geert Haasnoot,1 Erik Van zet,1 Eric Claas,1 Johan W. De Fijter,2 Aloys Kroes,1 Frans Claas,1 Joris I. Rotmans,1 Mariet Feltkamp.1
1Leiden Univ Medical Center, Netherlands; 2Univ François Rabelais, France.

Background: Incidence and severity of reactivating latent infections in kidney transplant (KTx) recipients are difficult to predict. In case of BK polyomavirus (BKV)-induced nephropathy, donor origin of infection is likely. Since BKV-seroreactivity reflects BKV-reactivity, we hypothesized that donor BKV-seroreactivity correlates with infectivity and predicts BKV infection of recipients.

Methods: In a retrospective cohort of 407 living donor-recipient pairs transplanted between 2003 and 2013 at LUMC, pre-KTx sera from donors and recipients were tested for presence and intensity of BKV IgG-seroresponses. Measured seroresponses were compared with recipient BKV-loads (viremia) determined post-KTxs and compared with other potential risk factors for BKV-infection.

Results: Within one year after KTx, BKV-viremia was observed in 27% of patients. Baseline BKV-serore prevalence among donors (96%) and recipients (95%) was high and not correlated with viremia. However, a strong association was observed between the strength of donor BKV-seroreactivity and occurrence of both viremia and PVAN (p=0.001). Baseline recipient BKV-seroreactivity as such was not associated. The hazard ratio of viremia was almost 10-fold higher in recipients of high compared to low seroreactive donors. In multivariate analysis, donor seroreactivity was the strongest baseline factor associated with viremia and nephropathy post-KTxs (p<0.001), outcompeting other described risk factors.

Conclusions: The strong association between donor BKV-seroreactivity and recipient BKV-infection points directly to the donated kidney as the source of BKV-induced disease and possibly reflects the BKV allograft load. Our findings warrant further research into the usefulness of BKV-serological testing prior to transplantation.

The Role of BK Viral Subtypes in BK Viral Infection After Renal Transplantation

Anike Schwarz,1 Silvia Linnweber-Held,1 Hermann G. Häller,1 Cornina Schmitt.2 Nephrology, Hannover Medical School, Hannover, Germany; 2Virology, Hannover Medical School, Hannover, Germany.

Background: Risk factors for developing BK virus (BKV) infection after renal transplantation are unresolved, including the role of BKV subtypes.

Methods: We report on 146 patients with viral replication in urine tested by quantitative PCR (Cepheid-Affigene Kit) before transplantation (29 donors and 11 recipients, spontaneous replication in urine) and after transplantation (106 infected recipients, routine recipient BKV testing). Genotyping of BKV DNA subtypes was performed. Patients were grouped as: 1) BKV-negative (n=40, group 3).

Results: Twelve patients met inclusion criteria: mean age of 60.5, 3.1 years, 8 African Americans, 6 Black non-Hispanic, 2 without race data. There were 6 liver- kidney, 4 kidney, and 2 pancreas-kidney transplant recipients. All but 1 patient received tacrolimus as their CNI. Ten of 12 patients (83.3%) achieved SVR12. Mean tacrolimus levels increased significantly by 1.5 μg/mL between week 0 and 4 (p=0.014). Five (41.7%) required a mean tacrolimus dose decrease of 2 mg during treatment. Nine (75%) required a mean dose increase of 2 mg between EOT and SVR12. The ARI scores decreased from 0.64 to 0.17 between baseline and 12 weeks of treatment, but this is not statistically significant (p=0.216). Both serum creatinine and urine protein/creatinine ratio remained stable pre- and post-treatment (p=0.260 and 0.375, respectively).

Conclusions: SVR12 was achieved in 83.3% of KTRs treated with SMV + SOF. Renal allograft function was stable during and after HCV therapy. Treatment with SMV + SOF increased CNI levels during treatment.

Inflammation and Reconstitution Injury in Resolving Polyomavirus Nephropathy: Good or Bad? Insights from a Protocol Biopsy Based Prospective Study

Harsharan Kaur Singh, A. Gasim, Volker Nickelet.1 Div of Nephrology Pathology, The Univ of North Carolina, Chapel Hill, NC.

Background: Polyomavirus nephropathy (PVN) has been extensively studied at time of disease onset and in index biopsies. In contrast, little is known about acute and chronic changes occurring during PVN resolution under low dose maintenance immunosuppression. Aim: Enhance understanding of resolving PVN.

Methods: From 1/2009-9/2014 423 adult renal transplants with an 8.5% incidence of PVN (n=37) were prospectively followed at UNC. PVC patients were monitored with the urinary PV-Haufen test and protocol biopsies collected in 9/37 patients when the test turned from positive to negative as marker for PVN resolution. Histology in index PVN (n=9), and 11 post-transplant biopsies (n=9) was compared; clinical, treatment and long-term outcome data were obtained from electronic medical records.

Results: Serum creatinine and Banff scores at time of index PVN biopsy and follow-up protocol biopsy in Table 1.

SA-PO1066

Effectiveness of Simeprevir and Sofosbuvir in the Treatment of Hepatitis C Virus in Genotype 1 Post-Kidney Transplant Recipients

Karolyn S. Horn,1 Michelle T. Martin,1 Ignatius Yun-Sang Tang.2 Pharmacy Practice, Univ of Illinois at Chicago; 2Medicine, Univ of Illinois at Chicago.

Background: The 2014 American Association for the Study of Liver Diseases (AASLD) guidelines recommended the use of simeprevir (SMV) + sofosbuvir (SOF) for the treatment of liver transplant recipients with genotype (GT) 1 hepatitis C virus (HCV). There is a paucity of data on the treatment of other solid organ recipients. We conducted a retrospective, single-center analysis of kidney transplant recipients (KTRs) who received HCV treatment.

Methods: All KTRs who received HCV treatment with 12 weeks of SMV + SOF between January and November 2014 were evaluated. The primary endpoint was the sustained virologic response at 12 weeks after the end of treatment (SVR12). Secondary endpoints included HCV PCR levels, serum creatinine, urine protein/creatinine ratio, trough calcineurin inhibitor (CNI) levels and dose changes, and AST to platelet ratio index (APRI) at week 4, end of treatment (EOT), and 12 weeks post-treatment.

Results: Twelve patients met inclusion criteria: mean age of 60.5, 5.1 years, 8 African American, 6 Black non-Hispanic, 2 without race data. There were 6 liver-kidney, 4 kidney, and 2 pancreas-kidney transplant recipients. All but 1 patient received tacrolimus as their CNI. Ten of 12 patients (83.3%) achieved SVR12. Mean tacrolimus levels increased significantly by 1.5 μg/mL between week 0 and 4 (p=0.014). Five (41.7%) required a mean tacrolimus dose decrease of 2 mg during treatment. Nine (75%) required a mean dose increase of 2 mg between EOT and SVR12. The ARI scores decreased from 0.64 to 0.17 between baseline and 12 weeks of treatment, but this is not statistically significant (p=0.216). Both serum creatinine and urine protein/creatinine ratio remained stable pre- and post-treatment (p=0.260 and 0.375, respectively).

Conclusions: SVR12 was achieved in 83.3% of KTRs treated with SMV + SOF. Renal allograft function was stable during and after HCV therapy. Treatment with SMV + SOF increased CNI levels during treatment. CNI dose adjustment is needed to maintain therapeutic levels after SMV + SOF therapy.

Differences were observed in patients with early-onset (85%, P=0.139) or combined cases. Graft survival at 4 years was inferior in patients with late-onset CMV DNAemia occurred in 18%, 25%, and 13% of the patients being asymptomatic in majority (91%) of early+late-onset DNAemia groups, respectively.

2) early-onset (<3 months) DNAemia, late-onset (³3 months) DNAemia, and 4) combined prophylaxis for 3 months was given to 132 (high-dose valacyclovir, n=87; valganciclovir year post-transplant for CMV viremia (WHO standardization) and CMI (QuantiFERON® - Nice, France, Metropolitan; 2Laboratory of Immunology, Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; 3Laboratory of Virology, Univ Hospital, Pilsen, Czech Republic; Hematooncology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic.

Background: Although occurring very often the role of cytomegalovirus (CMV) DNAemia in patients managed by preemptive therapy or by universal antiviral prophylaxis is not established. The aim of the study was to determine the impact of different types of CMV DNAemia during 4 years after transplantion. Methods: A total of 180 consecutive renal transplant recipients at risk for CMV (donor and/or recipient CMV seropositive) were included and followed prospectively. Universal prophylaxis for 3 months was given to 132 (high-dose valacyclovir, n=87; valganciclovir n=45) patients, 48 patients were managed by preemptive therapy. Based on CMV DNAemia status during the first year after transplant patients were stratified to 1) no DNAemia, 2) early-onset (<3 months) DNAemia, late-onset (3 months) DNAemia, and 4) combined early+late-onset DNAemia groups, respectively. Results: Early-onset, late-onset, and combined early+late-onset CMV DNAemia occurred in 18%, 25%, and 13% of the patients being asymptomatic in majority (91%) of cases. Graft survival at 4 years was inferior in patients with late-onset CMV DNAemia compared to patients without CMV DNAemia (73% vs. 94%, P=0.002) while no significant differences were observed in patients with early-onset (85%, P=0.139) or combined early+late-onset CMV DNAemia (96%, P=0.682). Patient survival was comparable in all groups. Most severe to severe interstitial fibrosis and tubular atrophy assessed by protocol biopsy at 36 months was not increased in early-onset (15%, P=0.05), late-onset (21%, P=0.180), and combined (29%, P=0.069) CMV DNAemia compared to no CMV DNAemia group (36%). Likewise, renal function was not different at 36 months. Conclusions: Late-onset CMV DNAemia is a risk factor for graft loss after renal transplantation.

Assessment of Cytomegalovirus-Specific Cell-Mediated Immunity for the Prediction of Cytomegalovirus Spontaneous Clearance in High-Risk Kidney Transplant Recipients with Cytomegalovirus Viremia Marie Lochouarn,1 Sylvia Benzaken,2 Laetitia Albano,1 Elisabeth Cassuto,1 Ahmed Jeribi,1 Anne Caramella,1 Valérie Giordanoen,1 Ghislaine Bernard,1 Vincent L.M. Esnault,1 Barbara Szeitz-Polksi,1,2 Nephrology and Kidney Transplantation Dept, Univ Hospital, Nice, France, Metropolitan;1 Laboratory of Immunology, Univ Hospital, Nice, France, Metropolitan;1 Laboratory of Virology, Univ Hospital, Nice, France, Metropolitan.

Background: Cytomegalovirus (CMV) is the most common virus pathogen in kidney transplant recipients (KTR) and CMV disease impacts patient and graft survival. CMV-specific CD8 T cell-mediated immunity (CMI) kinetics may help to assess the risk of CMV disease and to adapt preventive treatment strategies. Methods: High-risk KTR with CMV seropositive donor/seronegative recipient (D+R−) were longitudinally monitored after CMV prophylaxis discontinuation and during the first year post-transplant for CMV viremia (WHO standardization) and CMI (QuantiFERON®-CMV). We analyzed the ability of the CMI-test to predict subsequent spontaneous viral clearance in case of asymptomatic viremia after prophylaxis discontinuation or CMV disease recurrence after curative treatment.

Results: We enrolled 12 consecutive (D+/R−) KTR. Eleven patients developed viremia during follow-up. Spontaneous viral clearance occurred in 7 of 11 (63.6%) patients and 4 of 11 (36.4%) developed CMV disease. At viremia onset, 6 of 11 (54.5%) patients had a positive CMI-test. In those patients, the incidence of subsequent spontaneous viral clearance was 6 of 6 (100%) compared with only 1 of 5 (20%) among patients displaying a nonreactive CMI (p = 0.02). This latter patient revealed a positive CMI-test one month later. In the 4 patients who developed CMV disease, persistence of a nonreactive CMI after treatment in one patient was associated with disease recurrence, while patients whose CMI-test became positive under treatment showed no recurrence.

Conclusions: We show for the first time that D+/R− KTR with asymptomatic viremia attested by WHO standardized CMV viral load monitoring after prophylaxis discontinuation may benefit from QuantiFERON®-CMV to predict spontaneous viral clearance or CMV disease.

Prevalence of Double Stranded DNA (dsDNA) Viral Infections Among Kidney Transplant Recipients Essays Mozaffari,1 Jay Lin,2 Melissa Lingolr-Smith,1 Chimerix Inc., Mendham, NJ;1 Novosys Health, Green Brook, NJ.

Background: Management of immunosuppression following solid organ transplant is a delicate balance between preventing graft rejection and minimizing the risk of infection. Antimicrobial prophylaxis can decrease the risk of infection, while increased immunosuppression can increase these same risks. Our objective was to estimate the occurrence of opportunistic infections, specifically dsDNA viral infections, in kidney transplant recipients.

Methods: Patients who received a kidney transplant between January 2009 and September 2013 were identified from the Premier Hospital database using ICD-9-CM codes. The first transplant procedure was defined as the index event. The frequencies of opportunistic infections, documented by diagnostic codes, were evaluated during the first 12 months after kidney transplant.

Results: Of patients who received kidney transplant (n=5,402; mean age: 50.8 years) 61% were male. Most patients received transplant in urban (98%), large (≥600 beds: 61%), teaching hospitals (84%). During the 12 month post kidney transplant, 33% (1,800 patients) had a diagnostic code for 1 opportunistic infection, and among these 25% (n=448) had at least one dsDNA viral infection. Among the 448 dsDNA viral infections, 81% (n=365) were cytomegalovirus (CMV), 8% (n=36) BK virus, and 16% (n=70) other dsDNA viral infections (HSV, VZV, HHV, HPV, EBV).

Conclusions: Opportunistic infections frequently result from the immunosuppression required following kidney transplantation. In our study, one-third of the kidney transplant recipients had a discharge diagnosis for at least one opportunistic infection. One of four opportunistic infections were classified as dsDNA viral infections, with the majority caused by human herpesviruses including CMV despite the common use of anti-CMV agents. Our study also highlights the rate of BKV-related complications, which represent an unmet need given the absence of therapeutic options for this dsDNA virus and the known association with BK-associated nephropathy.

Antibiotics, Gut Microbial Diversity, and Infectious Complications in Kidney Transplant Recipients Anjali Masand,1 John R. Lee,2 Thangamami Muthukumar,1 Darshana Dadhania,1 Lilan Ling,3 Eric Pamer,1 Manikkam Suthanthiran.1 Medicine, Weill Cornell Medical College, NY, NY;2 Medicine, Memorial Sloan Kettering Cancer Center, NY, NY.

Background: Emerging data suggests that antibiotic usage can decrease gut microbial diversity and predispose patients to future bacterial complications.

Methods: We profiled serial fecal specimens by 16s rRNA deep sequencing in 26 kidney transplant recipients. Microbial diversity was assessed using the Shannon diversity index in subjects exposed to antibiotics in the 1st post-transplant month and in subjects not exposed. Based on a higher number of infections in antibiotic-exposed subjects, we conducted a retrospective study of 301 consecutive kidney transplant recipients and stratified antibiotic usage in the 1st month of transplantation and development of bacterial complications in post-transplant months 2-12.

Results: Subjects exposed to antibiotics during the 1st month of transplant had decreased gut microbial diversity and an increased number of infections in the 1st year of transplant.

Funding: Government Support - Non-U.S.
Hepatitis C infection (HCV) in kidney transplant (KTx) recipients has been shown to be an independent risk factor for decreased patient and allograft survival. Historically treatment of HCV has been interferon-alpha based, which is associated with acute rejection in KTx patients. With the development of new, oral, interferon-free directly acting antiviral (DAA) medications, treatment of HCV in renal transplant recipients is possible, but limited data exists on its safety and efficacy.

Methods: We performed a retrospective review of all KTx patients at our center with HCV on initiation of DAA. Analysis of the 9 studies (8 complete articles and 1 abstract; 1,735 patients) showed a RR of 0.58 (95% CI: 0.31-1.07) for incidence of CMV infection upon initial screening. Analysis of the 9 studies (8 complete articles and 1 abstract; 1,735 patients) showed a RR of 0.58 (95% CI: 0.31-1.07) for incidence of CMV infection in patients receiving alemtuzumab versus ATG. Other reported adverse effects in both induction groups (infections, post-transplant lymphoproliferative disorder (PTLD) and/or malignancy, decrease in estimated glomerular filtration rate , and post-transplant diabetes mellitus) were similar in both groups.

Conclusions: This study suggests that for induction therapy in kidney transplantation, the incidence of CMV infection associated with alemtuzumab is not significantly different than that associated with ATG.

SA-PO1074
Occurrence and Determinants of Antibiotic Resistance in Bacteruria After Kidney Transplantation

Background: Asymptomatic bacteriuria is often treated after kidney transplantation, which can result in the development of antibiotic resistance. Our aim was to assess the antibiotic resistance profile of gram-negative bacteria in our kidney transplant population, and to determine the factors associated with antibiotic resistance.

Methods: We performed a single center, retrospective cohort study in patients who received a kidney allograft at our center between January 1st, 2008 and June 1st, 2013. Through chart review, information on all bacteriuric episodes involving gram negative bacilli was collected during follow-up, which ended on June 1st, 2014. Bacteriuria was defined as growth exceeding 10^4 CFU/ml. Multivariable logistic regression using a generalized estimating equation (GEE) procedure was performed to identify the factors associated with resistance to antibiotics.

Results: Amongst the 318 patients studied, 629 bacteriuric episodes involving gram negative bacilli occurred in 143 patients. Resistance to TMP-SMX occurred in 336 episodes (53%), resistance to ciprofloxacin in 142 episodes (23%) and extended beta-lactamase production occurred in 30 episodes (5%). An increased risk of resistance to ciprofloxacin and/or extended spectrum beta-lactamase production was statistically associated with the number of previously treated bacteriuric episodes (2-4 previous treatments (odds ratio (OR):2.29, 95% confidence interval (CI):1.16-4.52), and ≥5 previous treatments (OR:3.05, 95%CI(1.28-7.26)), diabetes (OR:2.57, 95%CI:1.01-6.55), caucasian race (OR:0.38, 95%CI:0.16-0.91) and a longer time elapsed between bacteriuria and transplantation (OR:0.32, 95%CI:0.15-0.66, for episodes supervening >1 year post transplant versus ≤ 1 year).

Conclusions: Elevated resistance rates to TMP-SMX and ciprofloxacin were observed in our kidney transplant population, which can reduce the usefulness of prophylaxis with TMP-SMX and argue against treating asymptomatic bacteriuria, given the association we observed between the number of previous treatment of bacteriuric episodes and resistance to ciprofloxacin/ESBL production.

Carbenapenem-Sparing Antibiotic Regimens for the Treatment of Extended-Spectrum Beta-Lactamase Producing Enterobacteriaceae Infections: A Comparative Study
Tiffany Ebony Biss, Gregory Malat, PharmD, Akshay Sharna, Dong Heun Lee, Alden Michael Doyle, Pharmacy, Hahnemann Univ Hospital, Philadelphia, PA; Surgery, Drexel Univ, College of Medicine, Philadelphia, PA; Infectious Diseases and HIV Medicine, Drexel Univ, College of Medicine, Philadelphia, PA.

Background: Extended spectrum beta-lactamase producing Enterobacteriaceae (ESBL-P) has been recognized as a significant cause of mortality in solid organ transplant recipients. Carbenapenem are the considered the drug of choice for the treatment of ESBL-P infections. However, antibiotic selective pressure associated with carbenapenem use may
Glomerular Diseases following Prednisolone Free Transplant with Low Dose Rituximab and ATG Induction and Protocol Biopsies
Vivek Pathak, Nephrology, Kovai Medical Center and Hospital, Coimbatore, Tamil-Nadu, India.

Background: The purpose of this study is to document the incidence of post transplant glomerulonephritis in a steroid free protocol and other recurrent renal diseases leading to graft loss.

Methods: 883 patients, who underwent renal transplantation at our institute in nine years and eight months since July 2005 till March 2015 were studied. Thymoglobulin was used for the induction of a dose of 1.5mg/kgm 3 doses rituximab 200 mg was given before transplant to those patients who were considered to be at high risk for rejection. Maintenance immunosuppression was Tacrolimus and Mycophenolate mofetil. Prednisolone was rapidly discontinued by fifth post operative day. All patients underwent protocol biopsies at 3 months, 1 year and 5 years and indicated biopsies whenever required. The total number of biopsies was 2928. Discussion Our results show only 1% graft loss due to cumulative recurrent Glomerulonephritis at nearly 10 years. Our figures could be low due to Thymoglobulin induction therapy. We could prevent graft loss due to recurrent FSGS by achieving complete or partial remission by using Rituximab in 15/19(79%) patients.

SA-PO1079
Pre-Transplant Rituximab in Recurrent Focal Segmental Glomerulosclerosis
John Manllo, 1 Dany Matar, 1 Sami Alasfar, 1 Jochen Reiser, 2 Nada Alachkar. 1 Johns Hopkins Univ; 2 Rush Univ.

Background: Focal segmental glomerulosclerosis (FSGS) recurs in 30-40% of patients after kidney transplant (Tx). Rituximab was suggested to have cross-reactivity with podocyte sphenogomelin-phosphodiesterase-ase-like-3b (SMPLD-3b), which was found to contribute to resistance, further stressing hospital epidemiology. Our study sought to compare the effectiveness of carbapenem sparing regimens to carbapenem-containing regimens on clinical outcomes in transplant patients with ESBL-PE infections.

Methods: We conducted a retrospective analysis of 1513 renal transplants between January 1980 and December 2013, included in our database, medical records and biopsy register, collecting all patients who presented recurrence of PGN. We excluded from the study patients with secondary GN and those without biopsy study. Renal biopsy was indicated according the following criteria: impairment of renal function, proteinuria $\geq$1g/day and/or microhematuria. The analysis statistic was SPSS version 18.

Results: 414 of 1513 RT (27%) had chronic GN as underlying disease. 317 patients (260 man;57 woman) were primary GN (21%). The most frequent primary GN was IgA nephropathy (IgAGN) n=122(38,4 %); Membranoproliferative GN (MPGN), n=90(28 %); Focal segmental GN(FSGS), n= 58(15,1 %); membranous GN(MGN), n= 33(10,4 %) and rapidly progressive GN (RPGN), n=14(4,4%). Forty(12,6%) patients with primary GN recurred. IgA GN (5%), FSGS (20%), MPGN (17%), MNGN (12%) and GRNP (12%). Three MPGN patients recurred in the second RT. The mean time of recurrence was: 48.18, 33.2, 18 and 33.2 months respectively Patients with graft loss due to GN recurrence were: IgAGN (n=10;75%), MPGN (n=14;93%), FSGS(n=10,75%), MNGN(n=3,70%). No significant difference was observed between GN types(p=0.15) and graft survival. In the Kaplan Meier analysis and COX test, recurrence primary GN had low survival at 10 years (p: 0.002). No significant differences was observed at 20 years (p: 0.15).

Conclusions: Clinical Recurrence of primary GN is an important cause of graft loss. GN with most recurrence was GSF and graft lost was MPGN. We didn’t observe differences in graft survival between type of primary glomerular disease. Graft survival was higher in the group without recurrence at 10 years and no differences at 20 years.

SA-PO1082
Kaplan-Meier Analysis of Allograft Loss Due to Recurrence of Glomerulonephritis, Rejection.Death(with a Functioning Allograft) and Other Causes.
to be reduced in post perfusion biopsies of kidney Tx recipients who later on developed recurrent (rFSGS). However, the use of rituximab to prevent rFSGS remains controversial. In this study, we assessed the efficacy of pre-Tx rituximab in preventing or delaying the recurrence of FSGS.

Methods: We enrolled 56 adult patients, 50 with biopsy proven FSGS and 6 with a pre-Tx course highly suggestive of FSGS. Patients underwent kidney transplant between 2008-2014. We compared FSGS recurrence and allograft survival between recipients who received rituximab and those who did not.

Results: Mean time of follow-up was 28.6 months. 24 patients received rituximab (tx 11), 35 patients developed rFSGS (17 (48%) of them received rituximab). Of the 21 who did not develop recurrence, 7 patients (33%) received rituximab. This difference was not statistically different (p=0.26). The time from Tx to rFSGS in the patients who received rituximab was 9.3 ±3.4 vs 8.7 ±3.7 months in patients who did not receive rituximab (p=0.7). The mean and standard deviation (SD) of eGFR at the most recent follow-up in the patients with rFSGS who received rituximab was 42.2 ±28 versus 39.2 ±21 mL/min/1.73m² in those who did not receive it, respectively (p=0.74). There was no difference in allograft survival in the two groups.

Conclusions: Our data showed that pre-transplant rituximab did not decrease the incidence or delay the development of recurrent FSGS, and did not improve allograft survival.

SA-PO1080

Role of Plasmapheresis in Post-Transplant Focal Segmental Glomerulosclerosis

Sami Alasal,1 Dany Matar,2 John Manllo,1 Jochen Reiser,3 Nada Alachkar.1

1Johns Hopkins Univ, Baltimore, MD; 2McKinsey & Company, Washington, DC; 3Rush Univ, Chicago, IL.

Background: Focal segmental glomerulosclerosis (FSGS) commonly recurs after kidney transplant (Tx). This is attributed to the presence of a circulating permeability factor that may be removed or diminished by plasmapheresis (PP). In this study, we assessed the efficacy of PP in prevention and treatment of post-Tx (rFSGS).

Methods: We prospectively enrolled 56 Tx-patients with biopsy proven FSGS (50) or de novo FSGS with a pre-Tx course suggestive of FSGS (6); patients were transplanted between 2008-2014. We compared between the preventive and non-preventive PP groups.

Results: Mean time of follow-up was 28 months. Differences between the 2 groups are as following:

<table>

rFSGS developed in 35 patients (62%); of whom preventive PP was performed in 19. Out of the 21 cases that did not develop rFSGS, 7 received PP (P=0.1). Patients who received preventive PP had a shorter time from FSGS diagnosis to ESRD compared to those who did not (6.1±8.6 yr vs 10.1±9.1 yr (p 0.047)). 33 out of the 35 patients (95%) with rFSGS received therapeutic PP, and 24 also received anti-CD20 therapy. Only 5 (15%) did not respond; 2 lost their grafts. Of the 28 who responded, 14 (50%) subsequently relapsed. 71% of the relapses responded to a second course of PP; only 4 lost their grafts. Kaplan-Meier allograft survival in both groups is shown in figure 1.

Conclusions: Preventive PP does not reduce the incidence or delay the development of rFSGS. However, PP remains an effective therapy for post-transplant FSGS.

SA-PO1081

Post-Transplant Thrombotic Microangiopathy: A Single Center Experience

Cinthia Montenegro Teixeira,1 Igor Gouveia-Hopitz,2 Andre Caires Alvino Lima,1 Gianna Mastroianni-Kirschtajn,2 Laila Almeida Viana,1 J. Medina-Pestana,1,2 Helio Tedesco Silva,1,2 Hospital do Rim- Fundação Oswaldo Ramos, Sao Paulo, Brazil; 1Univ Federal de Sao Paulo, Sao Paulo, Brazil.

Background: Thrombotic microangiopathy (TMA) occurs in 1-15% of kidney transplant allografts and predicts poor outcomes.

Methods: We reviewed 35 cases of TMA in the kidney allograft diagnosed at our institution between 2011-2015.

Results: The mean age was 39.1±14 years with 18 (51%) women. Three (9%) patients were recipients of simultaneous pancreas-kidney transplant. Among the recipients of kidney transplant alone, 21 (66%) received deceased donor grafts. The cause of end stage renal disease was unknown (37%), chronic glomerulonephritis (31%), obstructive uropathy (11%), diabetes (9%), hemolytic uremic syndrome (3%) or others (9%).

Induction with thymoglobulin or basiliximab was performed in 24 (63%) patients. Maintenance immunosuppression was prednisone (PRED), tacrolimus (TAC), and azathioprine in 15 (43%), PRED, TAC and mycophenolate sodium in 12 (37%) and PRED, TAC and everolimus in 3 (9%) patients. Patients were diagnosed with TMA at a median of 71 days (range: 5-1645) from transplant, wherein 37% patients developed TMA within 1 month of transplantation and 31% after 1 year. Mean serum creatinine was 4.5±3.3 mg/dL and 13 (41%) patients needed renal replacement therapy after TMA diagnosis. TMA was renal-limited in 22 (66%) patients. Concomitant acute rejection was present in 12 (34%) cases and cellular rejection was the most common (92%) type of rejection related to TMA. Cytomegalovirus infection occurred in 5 (14%) and other infections were present in 19 (54%) patients. Following diagnosis of TMA, calcineurin inhibitor (CNI) withdrawal was the first step in the management of 22 (63%) patients and 8 (23%) also received fresh frozen plasma (FFP) and/or plasmapheresis. The mean follow-up was 375 days (range: 2-4840); 22 (62%) patients had improvement or stabilization of renal function and 11 (31%) had allograft failure.

Conclusions: High clinical suspicion is essential for early diagnosis of TMA after kidney transplant. Withdrawal of CNI and treatment of concomitant rejections and infections contribute to renal function maintenance.

Outcome After Eculizumab Therapy to Prevent Recurrence of Atypical Hemolytic Uremic Syndrome: Experience in Eleven Renal Transplant Recipients

Charlene Levi,1,2 Veronique Fremeaux-bacchi,1,2 Anne Scemla,1 Nada Alachkar,1 Julien Zuber,1 Christophe M. Legendre,1 Soussan.1

1Dept of Renal Transplantation, Assistance Publique-Hôpitaux de Paris, Hôpital Necker, Paris, France; 2Medicine Faculty, Paris Descartes Univ, Paris, France; 1Dept of Immunology, Assistance Publique-Hôpitaux de Paris, Hôpital Georges Pompidou, Paris, France.

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease with a high recurrence rate after kidney transplantation. aHUS is associated with histological lesions of thrombotic microangiopathy (TMA) that mainly leads to graft loss. The successful use of Eculizumab (Ecu) to prevent or to treat post-transplantation aHUS recurrence has been scarcely reported. In this study, we describe 11 patients who received a renal transplantation for aHUS and who were treated by Ecu after renal transplantation.

Methods: Eleven renal transplant recipients, with aHUS on their native kidney, received Ecu at our center between 2010 and 2015. Nine patients received prophylactic
Ecu at day 0. Two were treated at time of recurrence (day 6 and 25). We reviewed clinical, genetic, histological and data, and posttransplant course. Mean follow-up was 21.6±11 months.

Results: Five patients had at least one previous transplantation that failed secondary to recurrent aHUS. A genetic mutation was identified in ten patients (H factor (4); 1 factor (2), C3 (1), C4d (2), CFHR1 deletion and anti-H-factor antibody (1)). There was no graft loss and mean serum creatinine was 135± 60mmol/l at last follow-up. No patient experienced biological TMA recurrence under treatment. We found transient histological lesions in the 2 patients with later Ecu intervention. Three antibody mediated rejection (AMR) recurrences were noted during treatment including one associated with TMA lesions.

Conclusions: These data confirm that Ecu is highly effective to prevent post-transplantation aHUS recurrence, without graft loss and with a good renal function. However, Ecu doesn’t prevent AMR. The best treatment duration remains to be defined.

SA-PO1083

Recurrent of Scleroderma Renal Crisis After Renal Transplant Is Associated with Decreased Rates of Graft Survival and Earlier Graft Failure
Andrew A. Collins, Donald A. Molony. Internal Medicine, UT Health Houston, Houston, TX.

Background: The recurrence of Scleroderma Renal Crisis (SRC) after renal transplant has been previously described though its effects on outcomes and allograft survival are uncertain. Prior estimates suggest a recurrence rate of 20-50% (Pham et al, American Journal of Transplantation 2005, 5:2565-2569). Such rates of recurrence if leading to graft failure will have important implications. This study was conducted to better define the probability of recurrence and understand its impact on allograft and patient survival.

Methods: We identified cases of renal transplant recurrence for patients with SRC and all cases of disease recurrence in the UNOS database from 1987 to 2014. We analyzed the impact of recurrence on graft survival and compared this to outcomes of patients with other renal diseases: SLE, FSGS, and HUS.

Results: 11 patients were identified as having SRC as their primary diagnosis. Of those, 5.28% (26) had documented disease recurrence, which was similar to those with SLE (2.59%), FSGS (7.38%), and HUS (8.71%). Graft failure for any reason excluding death occurred in 80.8% (21) of patients with recurrence, compared to 24.5% (114) of those without recurrence (p = 0.00). Recurrent disease accounted for 11.9% (16) of graft failures in SRC, compared to 6.10% in patients with SLE as the cause of ESRD, 16.4% with FSGS, and 20.9% with HUS. The 5 year graft survival rates were similar: 68.7%, 63.2%, 67.8%, and 57.1% for SRC, SLE, FSGS, and HUS, respectively. SRC recurrence was associated with earlier graft loss; graft failure occurred an average of 628 days sooner than the recurrence group compared to non-recurrence, 1072 days versus 1700 (p = 0.021). Age, gender, and ethnicity were not associated with an increased risk of recurrence.

Conclusions: Identification of disease recurrence after renal transplantation holds prognostic significance. Both the rate and timing of kidney transplant failure is made more severe by recurrence. Post-transplant recurrence rates for SRC appear to be similar to those observed with SLE, FSGS, and HUS. Monitoring for recurrence of disease in these patients should be part of routine measures to reduce risk of allograft failure.

SA-PO1084

Clinical Characteristics of Recurrent IgA Nephropathy within the First Year After Renal Transplantation: Single Center Study
Yasuhiro Otuka, Daijo Inaguma, Yoshiklmo Watarai, Asami Takeda. Kidney Center, Nagoya Daiini Red Cross Hospital, Nagoya, Japan.

Background: There are a few studies showing that the long-term allograft survival of patients with IgA nephropathy (IgAN) is lower than that of non-IgAN, indicating that the cause of lower graft survival is recurrence of IgAN. There have been no large, prospective studies defining the risk factors contributing to the development of recurrent IgAN, and preventive therapy for recurrent IgAN is unknown.

Methods: Retrospective data was collected from 2008 to 2013 on 61 consecutive biopsy-proven IgAN patients who underwent renal transplantation (RTx) in a single center, excluding one case of medication nonadherence. Protocol biopsies were performed at one week, six months and one year after RTx. Recurrent IgAN (rIgAN) is defined as positive for IgA in mesangial area and previously negative for IgA in immunofluorescence study.

Results: Of 61 patients, 7 had rIgAN within the first year after renal transplantation. There were no significant differences between rIgAN group and NOT rIgAN group in recipient age (mean±SD) (39±11.18, 41±12.33) years, sex (63%:19, 31%:23), donor age (55±9.5, 56±9.8) years, diabetes mellitus (2, 8) cases, PEKT (5, 23) cases, living-related donor kidney (5, 53) cases, immunosuppressants, time before transplant (11, 11), cases, ABO incompatible (18, 18) cases, HLA matching, HLA alleles in recipient including HLA-B35, DR4, DR3, HLA-B8, DR5, DR3, serum IgA concentration (263±0.66, 254±1.05)mg/dl, and urinary protein (0.57±1.29, 0.07±0.13)g/day. Duration of dialysis before transplantation (months) was significantly shorter in rIgAN group (11±2.03 vs 34.8±5.94, p=0.0383, Fisher’s exact test). Urine occult blood was also significantly higher in rIgAN group (p=0.008841, Mann-Whitney U test).

Conclusions: Both PEKT was not risk factor for recurrence of IgAN in this study, short-duration dialysis before transplantation could be novel risk factor for recurrence of IgAN. Further analysis is needed to determine risk factors for rIgAN and to establish preventive therapy for rIgAN for better graft survival.
Results: 16 suspicious masses were detected (12.5%). Of these only 9 had evidence of an aggressive disease (ACD) (four or more cysts) pre-transplant. The remainder had normal pre-transplant scans showing only small contracted kidneys or less than the required number of cysts to make a diagnosis of acquired cystic disease. We are following 14 of these patients with scans every 6-12 months to detect growth in newly discovered, less than 1 cm solid lesions. We have found 2 patients in which frank renal cell cancers were discovered. We have now adopted an annual screening process for all post-transplant patients at their one-year post-transplant visit.

Conclusions: Routine screening of native kidneys post-transplant appears critical to detect renal cell carcinoma at a stage early enough to achieve a cure by nephrectomy.

SA-PO1088

Non-Melanoma Skin Cancer Mortality in Kidney Transplant Recipients

Michael Thomas Burke,1 Annie-Claire Nadeau-Fredette,1 Carmel M. Hawley,1 Elaine M. Pascoe,2 Stephen P. MacDonald,2 Sunil V. Badve,1 David W. Johnson,1 Underline represents presenting author.

Background: Non-melanoma skin cancer (NMSC) frequently occurs in kidney transplant recipients (KTRs). However, the frequency of, and risk factors for NMSC mortality in KTRs are poorly characterised.

Methods: To determine the proportion and predictors of fatal NMSC in KTRs. This cohort study included all KTRs transplanted in Australia and New Zealand between 1980 and 2013, using Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry data. A multivariable competing-risk survival analysis was used to calculate risk factors for fatal NMSC in KTRs.

Results: During the study, 21875 transplant episodes occurred in 19344 patients. Of the 6780 patients who subsequently died, 231 (3.4%) died from NMSC. Of these, 172 (74%) were male, 226 (98%) were Caucasian, 219 (95%) were first graft recipients and 213 (92%) died with a functioning graft. Amongst first graft KTRs who died from NMSC, the mean age at transplantation was 48.8 +/- 13.7 years and the mean age at death was 61.8 +/- 11.1 years. Male sex (HR 2.0, 95% CI, 1.48 -2.74); Caucasian ethnicity (HR 5.31, 95% CI, 2.15-13.11) and pre-transplant skin cancer (HR 3.79, 95% CI, 2.38-6.04) were associated with NMSC mortality. Age at transplantation and multiple kidney transplants had time-dependent associations for NMSC mortality with the 5-year post-transplant HR 1.08 per year (95% CI, 1.06-1.1) and 2.90 (95% CI, 1.39-6.05); and the 15-year post-transplant HR 1.03 per year (95% CI, 1.02-1.04) and 1.29 (95% CI, 0.66-2.35) respectively.

Conclusion: NMSC is an important contributor to mortality in KTRs. Risk factors for mortality from NMSC include male sex, Caucasian ethnicity, pre-transplant skin cancer, multiple kidney transplants and older age at transplantation.

SA-PO1089

NFAT-Regulated Gene Expression in Patients Developing Non-Melanoma Skin Cancer

Claudia Sommerer,1 Thomas Gies,2 Janina Brocke,2 Stefan Meuer,3 Martin G. Zeier.1 Nephrology, Univ Hospital, Heidelberg, Germany; Immunology, Univ Hospital, Heidelberg, Germany.

Background: After transplantation the risk of non-melanoma skin cancer (NMSC) is significantly increased. Immunosuppression with calcineurin-inhibitors (CNIs) is associated with the development of NMSC. Association to the individual immunosuppressive loads of CNIs assessed by residual NFAT-regulated gene expression was investigated in renal allograft recipients.

Methods: Renal allograft recipients from the Department of Nephrology, University Hospital Heidelberg, Germany, were included. All patients had a regular annual skin examination. Residual expression of NFAT-regulated genes (IL-2, IFNγ, GM-CSF) in PMA/ionomycin-stimulated peripheral blood was measured by quantitative real-time PCR at predose and 2h after Ciclosporin A (CsA) intake.

Results: 258 renal allograft recipients were enrolled (160 male, age 51+14y). Of these patients 75 allograft recipients developed NMSCs after renal transplantation (29.1%). The following NMSCs were histologically confirmed: 36 basal cell carcinoma, 34 squamous cell carcinoma, 33 actinic keratosis, 27 Bowen disease, 8 kerato-acanthoma. As risk factors to develop NMSC were identified: age 60 years, skin type ( Fitzpatrick 1 and 2), and load of immunosuppression. NFAT-regulated gene expression was significantly lower in patients who developed NMSCs compared to patients without NMSCs (8.3±6.5 vs. 12.7±12.8%, p<0.001). Squamous cell carcinoma and actinic keratosis were significantly associated with a high inhibition of IL-2 and IFNγ. Patients with basal cell carcinoma and Bowen disease showed a general low expression of NFAT-regulated gene expression. However, in patients with kerato-acanthoma no significant inhibition of NFAT-regulated gene expression could be detected.

Conclusions: The immunosuppressive load contributed to the risk of NMSC. NFAT-regulated gene expression was significantly inhibited in patients developing NMSCs. Monitoring of NFAT-regulated gene expression in CNI treated transplant recipients provides an individual profile of response to CNIs and is a useful tool for an individual immunosuppression with respect to safety and toxicity.
Role of Toll-Like Receptors in Aristolochic Acid Nephrotoxicity
Gem Batuman, 1 Altaf-M Khan, 1 Madlin Alzoubi, 2 Vecchi Batuman, 1, 2 Dept of Medicine, Section of Nephrology & Hypertension, Tulane Univ School of Medicine, New Orleans, LA; 3Dept of Veterans Affairs, SLVHCS, New Orleans, LA.

Background: Studies demonstrated that aristolochic acid (AA) is toxic to renal tubular epithelium and carcinogenic to renal epithelium. Although the exact extent of AA nephropathy (AAN) is unknown, case series have been reported in throughout the world and it has been implicated in the etiology of Balkan endemic nephritis (BEN) suggesting that this is a global health problem. The precise mechanisms of AA nephrotoxicity are not known. We investigated the role of Toll-like receptors (TLRs) in the pathophysiology of AAN using human renal proximal tubule epithelial cells (RPTECs).

Methods: Confluent RPTECs were exposed to AA (50 µM – 480 µM) for 24 – 48 hr and cytotoxicity was measured using lactate dehydrogenase (LDH) assay. RNA and protein were isolated from AA-exposed and unexposed RPTECs. Real-time RT-PCR was performed for various gene primers to evaluate the role of innate immunity in AAN development.

Results: At 240 µM after 48 hr exposure, AA induced significant Cytotoxicity in RPTECs as measured by LDH release in the culture medium and significant cell injury was observed morphologically. AA significantly increased mRNA expression of acute kidney injury (AKI) biomarker neutrophil gelatinase-associated lipocalin (NGAL), but at the same time significantly decreased the expression of another AKI biomarker kidney injury molecule 1 (KIM-1). AA also significantly upregulated the expression of prominent AKI-related TLRs (TLR2, TLR4 and TLR6) and their adaptor molecules (MyD88 and TICAM-1) followed by the activation of pro-inflammatory cytokines (IL-6 and TNF-α) and the tumor suppressor protein and a biomarker for apoptosis, p53, in the down-stream signaling pathways of TLRs. AA also significantly upregulated expression of multi drug resistant family gene MDR1 in RPTECs. Conclusion: AA is toxic to RPTECs and restricts cell growth. NGAL but not KIM-1 could be a diagnostic biomarker for AAN. AKI prominent TLR2 and TLR4 could be potential candidates for therapeutic target in developing new strategies for AAN and BEN treatment.

A Case of Severe Symptomatic Iatrogenic Hypermagnesemia
Rohan V Mehta, 1 Vandana Niyar, 2 Rahul Mehta. 2 Dept of Medicine, Affiliated Hospital of Nantong Univ, China; 2Dept of General Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT.

Background: Hypermagnesemia is an uncommon but a potentially life threatening condition. Symptoms may develop in patients with acute kidney injury (AKI) or chronic kidney disease with the administration of pharmacologic dose of magnesium (Mg), and with use of oral laxatives or magnesium containing enzymes.

Methods: A 30-year-old African American man with baseline Cr of 1, admitted for management of multiple fractures, subdural hemorrhage and traumatic brain injury sustained in a motor vehicle accident, suddenly became hypotensive and developed AKI. UOP declined from 2-3 ml/day on admission to 700 ml over the next 24 hours. He became areflexic and developed ARDS, with increasing FiO2 requirements. Repeat laboratory data showed Cr 3.9, hemoglobin 6.9 and Mg 9.5 mg/dL. Review of his chart revealed he had received a total of 8.75g of magnesium citrate through enemas on the previous day. Aggressive resuscitation was started, including IV calcium, but he continued to require multiple pressors.

Results: Underline represents presenting author.

Conclusions: We found histological evidence of ilium injury following both ischemia and bilateral nephrectomy. MDA and apoptosis, which was quantified by histone-associated DNA fragmentation enzyme-linked immunosorbent assay, were increased after 6 and 24 hr of renal ischemia or nephrectomy.

Serum from Rats with Acute Kidney Injury Contains Reactive Oxygen Species Generating Activity That Causes Oxidative Stress in Vitro
Tian D. Ahlstrom, 1 Zhma Hu, 1 Nicole Molin, 2 Christof Westenfelder, 2 Medicine, Univ of Utah and VA Medical Centers, Salt Lake City, UT; 2Physiology, Univ of Utah and VA Medical Centers, Salt Lake City, UT.

Background: The uremic state that is induced by acute kidney ischemia or renal failure activates oxidative stress and promotes apoptosis, and tissue damage in gut. Whether the AKI induced-gut injury by itself is sufficient to provoke systemic inflammatory response needs further investigation.

Funding: Government Support - Non-U.S.

Properdin Deficiency Enhances Renal Ischemia Reperfusion Injury in Mice
Zinh Dhevaa Zawmi, 1, 3 Nigel J. Brunskill, 1 Hans-Wilhelm Schwebele, 1 Cordula M. Stover, 1 Bin Yang, 1, 5, 6, 7, 8, 9 Infection, Immunity and Inflammation, Univ of Leicester; 7 Renal Group, Univ Hospitals of Leicester; 3College of Medicine, Univ of KwaZulu, 9 Basic Medical Research Centre, Medical school of Nantong Univ, China; 8Nephrology, Affiliated Hospital of Nantong Univ, China.

Background: Properdin is the only positive regulator of the alternative pathway of complement activation via stabilizing C3bBb convertase. Properdin has been detected on proximal tubular epithelial cells associating with proteomic renal damage. Previous studies showed that mice with combined deficiencies of properdin (Pf), DAF and CD59, the negative regulators of complement activation, had less renal ischemia reperfusion injury (IRI), 24 hours.

Methods: Pf mice (n=9) and their wildtype (WT) littermates (n=7) were used to assess the role of properdin in renal IRI. Ischaemia was induced by bilateral clamping of the renal pedicle for 30 minutes followed by 72-hour reperfusion using normal (n=2) and sham-operated mice (n=4 or 5) as controls.

Results: Renal IRI was successfully induced in the WT and Pf mice with more prominent injury in Pf mice as evidenced in renal function. Serum creatinine was significantly increased after IRI compared with the sham groups, which was further increased bilaterally nephrectomy for 24h. Ilium and blood were collected. The damage of gut mucosa was assessed by histological staining. Malondialdehyde(MDA) and apoptosis of the ilium were measured to determine the underlying mechanism of the AKI-induced gut injury.

Results: We found histological evidence of ilium injury following both ischemia and bilateral nephrectomy. MDA, an index of lipid peroxidation, increased in both the renal ischemia and nephrectomy groups, suggesting activation of oxidative stress. Ilium apoptosis, which was quantified by histone-associated DNA fragmentation enzyme-linked immunosorbent assay, were increased after 6 and 24 hr of renal ischemia or nephrectomy.
in P-ko in relation to WT mice (1.78±0.29 vs. 1.19±0.18, P=0.046) post IRI. Similarly, blood urea nitrogen in IRI mice was higher than the sham animals, with significant increase in P-ko in comparison with WT mice.

This difference was supported by histological examination, in which P-ko mice showed a worse score of tubulointerstitial damage than WT (2.67±0.26 vs. 1.94±0.22, P=0.025) post IRI.

Conclusions: This study shows, for the first time, that properdin deficiency alone causes IRI injury shown by worsened renal function and histology. The underlying mechanisms for these unexpected phenotype are under present investigation.

PUB006

Neurogenic Function of Neurons with Renal Afferents Is Altered by Lipopolysaccharides -LPS Kristina Rodionova,1 Martin Ziemer,1 Tilmann Ditting,1 Stefan Karl,1 Sonja Heinlein,1 Peter Linz,1 Peter Reeh,1 Kerstin U. Amann,2 Roland Veelken.1 1Dept of Medicine 4 - Nephrology and Hypertension, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; 2Dept of Nephropathology, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany.

Background: Renal afferent nerves (RNs) exert complex neurogenic sympathomodulatory and paracrine effects. Recently, we could demonstrate that lipopolysaccharide (LPS) sensitized TRPV1 receptors and increased the release of CGRP from afferent axons in kidney. Hence, we wanted to test the hypothesis that LPS alters firing patterns and acid induced inward currents in cultured neuron sample.

Methods: Dorsal root ganglion neurons (Thr1-1.2) of rats were incubated with LPS (E.coli O127:B8,20mg/ml) 12h before patch clamp recordings. Inward currents were assessed during stimulation of TRPV1 and ASICs with protons (pH 6.5 and 5.0). Current clamp mode was performed at physiological conditions and after 12h of LPS-incubation.

Results: Firing patterns and currents induced by acidic superfusion were studied in 246 neurons. Renal neurons (RNs) exhibited in 59% tonic firing pattern under control conditions. The number of neurons with tonic response was significantly reduced by exposure to LPS (59%vs.42%; p<0.05) under control conditions. 70.8% of RNs exhibited both sustained (i.e. sustained AP firing or phasic, i.e.<5 APs in response to current injections).

Conclusions: 1. Efficiently produce controlled releasing Curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers. Drug loading content(DLS) and encapsulation efficiency(EE) were more than other peports. Data indicated that incorporated Cur could be slow released from the core-shellstructured polymericnanoparticles. 2. Curcumin can ameliorate ischemia-reperfusionrenal injury in vitro. 3. The protective effects of Cur-NP against ischemia-reperfusion renal injurywere involved in the suppression of oxidative stress reaction.

PUB007

Protective Effect of Nitric Oxide in Aristolochic Acid-Induced Toxic Acute Kidney Injury Ines Jadot,1 Anne-Emilie Declives,2 Vanessa Colombo,1 Blanche Martin,1 Isabelle Habsch,1 Eric De Prez,2 Joelle L. Nortier,2 Nathalie Caron.1 1 Molecular Physiological Research Unit - URPHYM, Faculty of Medicine, Univ of Namur, Namur, Belgium; 2Laboratory of Experimental Nephrology, Faculty of Medicine, Un Libre de Bruxelles, Bruxelles, Belgium.

Background: Aristolochic Acid (AA) nephropathy is a pertinent example of tubulo-interstitial (TI) nephritis characterized by an early phase of acute kidney injury (AKI) leading to progressive fibrosis and chronic kidney disease (CKD). Nitric oxide (NO) has been shown to play a critical role in the AKI-to-CKD transition. Here, the AAN model was used to determine the role of NO in this process, focusing on the acute phase.

Methods: C57BL/6J male mice were randomly selected to daily i.p. injection of control solution or AA (3.5mg/kg) for 4 days and L-Arginine (L-Arg; substrate for NO synthesis) was supplemented in drinking water (5%) until mice were euthanized, 5 days after the beginning of AA injections.

Results: At day 5, AA-treated mice displayed polyuria, increased plasma creatinine levels, and tubulointerstitial (TI) nephritis. In addition, histological analyses revealed severe proximal tubular cell necrosis, renal inflammation and increased oxidative stress in AA-treated mice. These changes were associated with a significant reduction of NO bioavailability, as attested by urinary NOx and cGMP levels. L-Arg supplementation in AA-treated mice significantly improved kidney function, as reported by a significant reduction in urine volume, plasma creatinine level and proteinuria. Moreover, L-Arg treatment resulted in a significant reduction of tubular cell necrosis, renal inflammation and oxidative stress. These were concomitant to normalized NO levels.

Conclusions: Our findings demonstrated that sustaining NO bioavailability due to L-Arg supplementation improve the renal outcome of AA-induced AKI phase. Further investigations are ongoing to determine whether increasing NO bioavailability can also prevent chronic injuries in the AAN model.

The Study of Curcumin-Loaded Nanoparticles against Renal Ischemia-Reperfusion Injury Function and Mechanism Yong Xu, Lili Zhong. Dept of Nephrology, Huaian Second Hospital, Huaian, Jiang Su, China.

Background: To study the effects of curcumin-loaded nanoparticles against ischemia-reperfusion renal injury, and to investigate its mechanism.

Methods: Synthesize controlled releasing curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers and cultured renal tubular epithelial cell (cell line HK-2) in vitro. HK-2 cells were divided into four groups: Control group; Ischemia reperfusion injurygroup(IRI group); Curcumin group(Cur group); Curcumin nanoparticle group(CurNP group). In each group, HK-2 cells viability was assessed by dimethyl-thiazol-diphenyl tetrazolium bromide (MTT) test. Apoptotic Cells were measured by Flow Cytometry. HeLaF2-DA was used to detect intracellular generation of ROS. BCA were used to detect SOD activation and the Concentration of MDA. Protein levels of procaspase-3 were analyzed by Western Blot.

Results: Successfully constructed curcumin-loaded nanoparticles by amphilicmPEG-PCL block copolymers.

Conclusions: 1. Curcumin-loaded nanoparticles by amphilicmPEG-PCL block copolymers.

**Protective Effect of NDH2 Oxidase 4 Inhibition in Contrast Induced Nephropathy**

Se-Hee Yoon, Won Min Hwang, Sung-Ro Yun, Sukyung Lee, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim.

**Background:** The objective of this study was to investigate the protective effect of NDH2 oxidase 4 (Nox4) inhibition in contrast induced nephropathy.

**Methods:** HK-2 cells were incubated with iohexol (nonionic low-osmolar radiocontrast agent) at a concentration of 75 mg/mL, 150mg/mL for 2 h. Cells were pre-exposed to GKT137831, a selective Nox1&; inhibitor (Genkyo克斯, Switzerland), for 30 min before exposure to iohexol. Cell viability was measured at 0, 3, and 22 h after removal of iohexol by ATPBio assay. Apoptosis was investigated by caspase 3/7 activity assay. Nox4 protein expression level and mitochondrial ROS production was assessed by DHE assay. NDH2 oxidase activity was measured by lucigenin-enhanced chemiluminescence method, and Nox3 expression by western blot and real time PCR.

**Results:** Nox4 protein expression significantly increased at 30 min after iohexol exposure. GKT137831 pre-exposure showed significantly less cytotoxicity compared to 3 h after removal of iohexol. Caspase 3/7 activity was significantly lower in GKT137831 pre-exposed cells than only iohexol exposed cells at 22 h after removal of iohexol. ROS generation was higher with only iohexol exposed cells compared to GKT137831 pre-exposed cells.

**Conclusions:** A selective Nox4 inhibitor induced fewer cytotoxic effects on cultured HK-2 cells than iohexol along with a lower induction of Nox4-dependent ROS generation. This enzyme may represent a potential therapeutic target to prevent iodinated radiocontrast medium related oxidative stress.

**Autophagy Increased in the Early Stage of Rat Acute Kidney Injury Model**

Junyi Liu, Xing Mao, Yiwen Shen, Huijuan Wu, Aimin Xue.

**Background:** Acute kidney injury (AKI) is a major kidney disease without effective therapies, and is thus associated with a high mortality. The pathogenesis of AKI is very complex and still unclear. Recently, researches have shown the induction of autophagy in proximal tubular cells and kidneys during AKI. In the present study, we investigated the role of autophagy in the pathogenesis of rat renal ischemia-reperfusion (IR) model which causes AKI.

**Methods:** All male Sprague-Dawley rats were subjected to clamping of bilateral renal artery only for 25 min except sham group, and then they were randomly divided into four groups depended on different reperfusion time point, including 3h, 6h, 12h and 24h. The Sham group underwent surgical procedures without ischemia as the control.

**Results:** The level of blood urea nitrogen (BUN) and serum creatinine were increased from 3h after IR. By H&E staining, protein casts were found at 3h after IR, which kept increasing at 6h and 12h after IR. At 24h after IR, we found some necrotic proximal tubules. Immunohistochemistry showed the protein level of Beclin-1 and Vps34 and the ratio of LC3 II/I increasing at 6h and 12h after IR. At 24h after IR, we found some necrotic proximal tubules. Immunohistochemistry staining clearly showed an increased positive staining of Vps34 and LC3 at 3h after IR compared to the control.

**Conclusions:** Taken together, our results demonstrate the occurrence of autophagy in the very early stage of rats AKI model.

**The Previous Cardio Exercise (Exe) Normalizes Renal Function of Wistar Rats Subjected to Acute Kidney Injury by Ischemia, and Reperfusion**

Wesley Vicente Ling, Waldemar S. Almeida, Nestor Schor.

**Background:** The acute kidney injury (AKI) is characterized by acute reduction of renal function and has a high mortality rate in hospitalized patients and in severe cases may progress to chronic kidney disease (CKD). The AKI by ischemia and reperfusion (IR) causes tubular damage mainly in the proximal convoluted tubule, reducing mitochondrial activity in renal cell and increasing the reactive oxygen species (ROS). It is known that aerobic Exe lowers blood pressure (BP), slows the heart rate (HR), improves muscle aerobic capacity, increases both the number and size of muscle mitochondria, however little is known about the effects of the previous Exe in AKI. We suspect that aerobic Exe may be protective against the effects of IR.

**Methods:** We used male Wistar rats with 10 weeks of life and they were separated into two groups Sham clamp (SC) and trained control clamp (TC), moreover the TC were subjected to a prior physical training protocol for four weeks. After completed 14 weeks each group, ischemia renal injury was carry out in the two groups, the rats were given rest in 8 hours after that they were placed in metabolic cages for 24 hours. We evaluate renal function (serum creatinina and proteinuria) and renal morphological study by light microscopy and mitochondrial (number and size) by electron microscopy. Finally, we will evaluate apoptosis through caspases 3 activity.

**Angiogenin Mediates a Non-Cell Autonomous Response to Endoplasmic Reticulum Stress in the Kidney**

Nicolas Pallé, Dany Anglicheau, Eric Thervet, Iadh Mami.

**Results:** We found that 100 ng of angiogenin (ANG) when applied to the kidney cortex was sufficient to induce a marked transient increase in Nox4 protein expression at 30 min after iohexol removal. Caspase 3/7 activity was significantly lower in GKT137831 pre-exposed cells than only iohexol exposed cells at 22 h after removal of iohexol. ROS generation was higher with only iohexol exposed cells compared to GKT137831 pre-exposed cells.

**Conclusions:** A selective Nox4 inhibitor induced fewer cytotoxic effects on cultured HK-2 cells than iohexol along with a lower induction of Nox4-dependent ROS generation. This enzyme may represent a potential therapeutic target to prevent iodinated radiocontrast medium related oxidative stress.

**Sustained Infiltration of Th17 Cells Is Associated with Pulmonary Fibrosis in Rats with Salt Induced CKD Secondary to Renal Ischemia**

Purvi Mehrotra, Jason Andrieu Collett, David P. Basile.

**Background:** Acute kidney injury (AKI) is associated with high mortality rates and is a leading cause of prolonged hospitalizations. The high risk of death is due in part to distant organ damage (e.g., lungs, heart, brain). It is well established that experimental AKI induced by renal ischemia and reperfusion (IR) increases an increase in pulmonary infiltrated immune cells like T cells as early as 24 hours post surgery, which may alter endothelial barrier function in the lung. However, the long-term effect of kidney injury induced pulmonary inflammation on lung function and structure is not known. We hypothesize that T cells infiltrate into the lung post kidney injury with potential effect on pulmonary structure.

**Methods:** SD rats were subjected to a model of AKI-to-CKD in which rats are allowed to recover from unilateral IR (40 min ischemia) for 5 weeks on standard salt diet (0.4% NaCl) and then subjected to contralateral UNX and 4% NaCl diet for 4 additional weeks. Rats consistent with eEPCs infiltration of CD4+ T cells were detected as early as 24 hours post surgery in the BAL fluid, and these were shown to be predominantly Th17 cells. These cells persisted in the lungs even after 5 weeks of post surgery after resolution of kidney injury (2.5X10^6±0.3), when compared to sham (0.53X10^6±0.03). Exposure of rats to high salt diet to hasten CKD further increased the number of Th17 cells in the lungs (4.1X10^6±0.23, p<0.05). There was a corresponding increase in pulmonary fibrosis in post-AKI rats on high salt relative to sham-controls.

**Conclusions:** Taken together, these data suggest that AKI leading to CKD is associated with pulmonary fibrosis, an activity that may be due in part to the infiltration of Th17 cells into the lung and influenced by dietary salt.

The Role of Endosialin in Renal Ischemia-Reperfusion Injury
Chia-Hsiun Liu, Shui-Liong Lin. 1,2

Background: Endosialin is a glycoprotein found on hematopoietic cells and is involved in adhesion and migration to inflamed tissues. In vivo experiments have shown that endosialin-deficient mice had a reduced renal ischemia-reperfusion injury (IRI). However, the role of endosialin in acute kidney injury remains unclear.

Methods: We examined the protective effect of endosialin-deficiency on renal IRI by administering an endosialin-deficient mice model. The glomerular filtration rate (GFR) and blood urea nitrogen (BUN) were measured in wild type (WT) and endosialin-deficient (Endo−/−) mice subjected to 30 minutes of left renal artery clamping (IRI) followed by 4 hours of reperfusion (R). The kidneys were harvested for histological examination and mRNA expression analysis.

Results: The GFR and BUN of Endo−/− mice were significantly higher than those of WT mice, indicating a protective effect of endosialin-deficiency against renal IRI. The histological examination showed less interstitial edema and tubular damage in Endo−/− mice compared to WT mice. The expression of pro-inflammatory cytokines and chemokines was also lower in Endo−/− mice, indicating a reduced inflammatory response.

Conclusions: Endosialin-deficiency can protect against renal IRI by reducing inflammation and preserving renal function. Further studies are needed to elucidate the molecular mechanisms underlying this protective effect.

The Mechanism of β2-Adrenergic Receptor / Protein Kinase A Signal Transduction Pathway in Restoration of Acute Kidney Injury by Endothelial Progenitor Cells
Ying Zhou, Chen Yu. Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.

Background: Endothelial progenitor cells (EPCs) can improve renal microenvironment, stimulate endogenous repair and angiogenesis, and promote AKI recovery. However, the molecular mechanism is not well elucidated.

Methods: We investigated the role of β2-adrenergic receptor (β2-AR) and its downstream factors (protein kinase A, protein kinase C) in the restoration of AKI by EPCs. The model of ischemia-reperfusion acute kidney injury (I-R AKI) was used in vivo, while sham operation was performed in control group. Renal tissue was harvested at 7 days after IRI. Histological examination and mRNA expression analysis were performed.

Results: The expression of β2-AR and its downstream factors (PKA, PKC) was measured. The levels of β2-AR and PKA were significantly higher in I-R AKI group than in control group (p<0.05). The protein levels of PKB and PKC were not significantly different between groups. Western blotting showed that the expression of β2-AR and PKA was significantly higher in I-R AKI group than in control group (p<0.05).

Conclusions: The model of I-R AKI occurred, the mRNA levels of specific proteins on surface of EPCs increased significantly, which suggested that I-R AKI might induce EPCs homing to kidney. At the same time, the mRNA levels of β2-AR and PKA were significantly up-regulated, which suggested that β2-AR/PKA pathway may play a role in the restoration of AKI by EPCs.

Alpha Lipoic Acid and Dexamethasone Counteract Contrast Media-Induced Proximal Tubule Cell Dysfunction
Hayriye Savartiloglu,1 Ali Okuyucu,2 Abdulkarim Bedir,3 Osman Salis,2 Eser Yenen.3
1Dept of Nephrology, Ondokuz Mayis Univ Medical Faculty, Samsun, Turkey; 2Dept of Medical Biochemistry, Ondokuz Mayis Univ Medical Faculty, Samsun, Turkey.

Background: Contrast medium induced nephropathy (CIN) is one of the most common cause of hospital-acquired acute renal failure. But its pathogenesis is unclear. In this study, we observed the effect of lipoic acid, low osmolar contrast medium, on tubular cells in HK-2 cell line.

Methods: We observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line. First, we examined the effects of different doses of iopromide (10, 20, 40 and 80 mg/ml iodine) on proliferation of HK-2 cells by the real time cell analyser (RTCA). According to the results of RTCA we examined whether the non-toxic doses of iopromide (10 and 20 mg/ml iodine) is causing of the EMT by scratch assay for 20 h. We also observed whether alpha lipoic acid (0.5 mM) and dexamethasone (5 µg/ml) is preventing to EMT in this assay.

Results: We observed whether alpha lipoic acid (0.5 mM) and dexamethasone (5 µg/ml) is preventing to EMT in this assay. Although cytotoxic effect was observed for iopromide (10 and 20 mg/ml iodine) is causing of the cell migration which an indicator show any effects for HK-2 cells. In scratch assay, we observed that the non-toxic doses of iopromide (10 and 20 mg/ml iodine) is causing of the cell migration which an indicator of EMT and alpha lipoic acid and dexamethasone prevent the cell migration.

Conclusions: In conclusions, the EMT caused by contrast medium is prevented or reduced by dexamethasone and lipoic acid in HK-2 cells. This result suggest that dexamethasone and lipoic acid may be a potential treatment to prevent the development of CIN in individuals with high-risk.

PUB021

Contribution of Proliferating Endothelial Cells for Endothelial Repair After Site Specific Endothelial Injury of the Mouse Kidney
Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CCG, Dresden, Germany.

Background: Our previous studies have shown that renal endothelial cell regeneration occurs exclusively via local mechanism. To further dissect the relevance of local mechanisms for endothelial repair, we now investigated the contribution of local endothelial cell proliferation in the kidney in our model of site specific endothelial injury (ECI).

Methods: Selective ECI was induced in 9 out of 15 mice by renal arterial perfusion with Concanavalin A (ConA)anti-ConA, while 6 mice served as sham operated controls. Edu (15µg/g), a marker of proliferation, was injected starting 24hours after ECI every 12hours intraperitoneally. Kidneys were harvested on day 7 and Edu⁺ cells were analyzed using flow cytometry and histology. Endothelial cells were stained using CD31, CD105, CD44 and CD46 and hematopoietic cells were detected as CD45⁺. Inflammatory cells (macrophages, dendritic cells and neutrophils) were analyzed via GR1, CD11c, CD11b and F4/80 positivity. By histology, proliferating EC were detected as anti-ERG/Edu double positive cells.

Results: Significantly more Edu⁺ cells could be detected after ECI on day 7 (sh: 1.2%±0.7; ECI: 7.6%±4.8). Most of those Edu⁺ cells were positive for CD45 (65%±8) and 3% (sh) to 7% (ECI) were positive for EC surface markers. In diseased kidneys more endothelial cells were found (sh: 5.5%±0.7; ECI: 7.3%±0.5; p<0.01). A larger amount of Edu⁺ EC was found in injured kidney (sh: 1.5%±0.8 0160 cells; d7: 5%±1.5 O630 cells p<0.01). Histological analysis supported these findings. Gliomeruli of ECI kidneys had more ERG/Edu⁺ cells (Ø 8: 0.23±0.16; Ø 7: 1.22±0.6; p<0.01). Inflammatory cells in injured kidneys were slightly increased. Many macrophages (21%±13), neutrophils (38%±17) and dendritic cells (19%±13) were Edu⁺. The 21days was the most worst for mitochondria under EM. For the TUNEL, a lot of DNA strand breaks were detected by TUNEL in 21days. For the Edu and TUNEL, the 21days was the most worst for mitochondria under EM.

Conclusions: Enhanced endothelial proliferation was detected following ECI. Therefore EC proliferation reflects an relevant repair mechanism following site specific ECI. The further investigation of EC repair will have to dissect the contribution of the proliferative response by adult local EC from other contributors such as local progenitor cells.

PUB022

Injury of Proximal Tubular Cells in Neonate Rats with Hypoxic-Ischemia Brain Damage
Dong Li,1 Mei Han.2 1School of Medicine, Sichuan University, Chengdu, Sichuan Province, China; 2Pediatric Nephrology, West China Second Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Background: Proximal tubular cells play a critical role in renal injury. To investigate the consequence of mitochondria in renal proximal tubular cells after hypoxic-ischemia brain damage (HIBD) in rats and the apoptosis in it.

Methods: Neonatal (7 days old) Sprague Dawley rats were randomly divided into 2 groups: sham group and operation group (n=5 per group). The Rice method was used for establishment of HIBD model, proximal tubular cells Mitochondria pathology and histology were examined under electron microscope at 1 day, 7days, 14days and 21days after the hypoxic-ischemic treatment, and apoptosis was analyzed by TUNEL.

Results: After the HIBD, the mitochondria of proximal tubular cells were showed damage under EM, some membrane and ridges were broken, the mitochondria bodies were swelling, and partial cristae fragmentation were observed from the 1day till 21days after. And the 21days was the most worst for mitochondria under EM. For the TUNEL, after HIBD, it showed significant increased for 1day, 7days, 14days and 21days groups comparing with sham group, (p<0.05).

Conclusions: After the hypoxic and ischemic brain injury of neonate rats, the mitochondria were damaged in proximal tubular cells, even in 21days after HIBD. And the apoptosis maybe one of the causes of this damage.

Ex-Vivo Normothermic Perfusion (EVNP) to Repair Monoethylene Glycol Toxicity in Human Kidneys
Ivonne Palma,1 Sasha Karaan Narayan,1 Ivania Palma,1 Rajendra Ramsamojo,1 Junichiro Sageshima,1 Jakub Woloszyn,1 Nam Tran,2 Chandrashankar Santhanakrishnan,3 Richard V. Perez.1 1Surgery, Univ of California-Davis, Sacramento, CA; 2Pathology and Laboratory Medicine, Univ of California-Davis, Sacramento, CA.

Background: Monoethylene glycol (MeG), a component of radiator fluids, results in crystal-induced acute kidney injury, hypocalcemia and often death, if ingested. Utilization of kidneys from deceased donors with MeG poisoning may not be suitable for transplant. EVNP may be utilized to potentially assess/repair high-risk kidneys in this setting.

Methods: A pair of transplantable human kidneys from a brain dead 38 year old female suicide victim from MeG poisoning were discarded due extensive intratubular crystal deposition. The kidneys were placed on 3 hours of EVNP with leukocyte depleted packed red blood cells at 37°C. Oxygenation via a hollow fiber membrane oxygenator supplemented with parenteral nutrition/insulin. One kidney was given Furosamide (10 mg) at the beginning to induce diuresis and assess acute kidney injury. Hemodynamic pump parameters and urine output were monitored. Blood and urine samples were collected at the start and every 30 minutes and analyzed for pH, electrolytes, creatinine, and lactate. Wedge biopsies were collected pre & post perfusion & stained with alizarin red to measure calcium oxalate tubular deposition.

Results: Blood flow and resistance improved over time in both kidneys. EVNP reduced crystal deposition compared to baseline wedge biopsies. Kidney treated with furosamide showed slightly better hemodynamic profile and fewer crystals after EVNP.

transfusion in the perioperative period of cardiac surgery has been associated with acute kidney injury. Our purpose was to analyze the influence of transfusion of red blood cell in the incidence of acute kidney injury after cardiac surgery.

Methods: We performed a prospective cohort study carried out in a tertiary hospital specialized in Cardiology. Adult patients who had undergone elective myocardial revascularization surgery, valvular and aortic surgery and who had agreed to participate in the study were included. The primary endpoint was acute kidney injury defined by KDIGO criterion. Secondary outcomes was serious clinical complications defined according to the guidelines of the Society of Thoracic Surgeons.

Results: According to KDIGO criterion, the incidence of AKI was 46.5%. The mean age was 60±12 years old in the AKI group and 58 ± 12 in the no AKI group (p=0.145), and mostly male (56%). The surgical risk assessed by EuroSCORE was greater in the AKI Group 5 (1-25) when compared to the no AKI group 4 (2-10), (p=0.047). There were no differences between the groups for the secondary outcomes. The use of red blood cells in the perioperative period (OR=3.166, p=0.001) and the presence of prior chronic kidney disease (CKD) (OR=2.027, p=0.036) was associated with AKI postoperatively.

Conclusions: EVNP may have the potential to repair MeG acutely injured kidneys rendering them suitable for transplantation. Ex vivo administration of furomeside may be a useful tool to assess injured deceased donor kidneys being considered for transplantation.
showed acute thrombotic microangiopathy, acute tubular injury, and moderate interstitial fibrosis. The presentation suggested the diagnosis of aHUS. Eculizumab, an anti-C5 antibody, was initiated at 900 mg weekly for four weeks followed by 1200 mg every two weeks. Eculizumab therapy resulted in resolution of hemolysis. Dialysis was continued thrice weekly. Eculizumab was continued every two weeks, and LDH and platelet counts remained stable. Two weeks after initial presentation, urine output improved, lower eGFR, and interdialytic weight gains were negligible. Pre-dialysis serum creatinine was 3.9 mg/dL, and a urine collection showed creatinine clearance of 30 ml/minute. She has remained off dialysis for twenty weeks, and latest serum creatinine is 3.4 mg/dL. Screening for complement and paroxysmal nocturnal hemoglobinuria was negative.

Conclusions: Experience with eculizumab is ongoing. Most patients with aHUS have a rapid hematologic response. If they need dialysis, then recovery of renal function is usually prompt; late recovery is rare. We hypothesize that sustained control of complement activation has led to vascular improvement and all but renal remodeling and regeneration, even months later. Patients are at risk for relapse if they stop treatment. This case points out that the presumed genetic defect may require lifelong treatment, and that late recovery of renal function is possible with complement inhibition and supportive care.

PUB029
The Effectiveness of Theophylline in Preventing Cisplatin Related Nephrotoxicity in Patients with Cancer
Jamil Khavjoo,1 Derya Karademir,1 Fatma Dogrul,1 Cvet Yazić,2 Aydin Unal,1 Murat H. Sipahioglu,1 Oktay Oynak,1 Bulent Tokgoz,1 Nephrology, Erciyes Univ Medical School, Kayseri, Turkey; 2Biochemistry, Erciyes Univ Medical School, Kayseri, Turkey.

Background: Cisplatin is a potent antineoplastic agent used in treatment of many solid tumors. The major limiting side effect of cisplatin is nephrotoxicity. Theophylline is a competitive inhibitor of adenosine which has antiinflammatory and antiapoptotic activity. In this study, early detection of acute kidney injury with biomarkers such as neutrophil gelatinase associated lipocalin (NGAL) and cystatin C and investigation of the potential nephron-protective effects of theophylline were aimed.

Methods: Sixty patients who are planned administration of cisplatin for the first time were included in the study. Patients were divided into two groups as group I (n=30) (standard treatment arm) and group II (n=30) (theophylline arm). Glomerular filtration rate (GFR), NGAL, cystatin C were measured at 3rd day in all of the patients. Also, these parameters were repeated measured at the administration of cisplatin, at 2nd hour, 5th and 20th days.

Results: In both groups after the administration of cisplatin, glomerular filtration rate (GFR) showed a significant decrease within time (p<0.001). In creatinine, in spite of the decline in GFR, no significant difference was observed between groups and within time. After 2 hours of cisplatin administration, in spite of the decline in GFR, a significant decline was detected in serum cystatin C (p<0.001). Urine NGAL was significantly high after 2 hours of cisplatin administration (p<0.001). No significant difference was observed between groups. However, when the time*group effects were considered together, higher NGAL was detected in the group not receiving theophylline (p=0.025). After 5 days of cisplatin administration, urine protein levels were significantly higher in both groups (p<0.001).

Conclusions: Results showed that urine NGAL level is a superior biomarker compared to creatinine and cystatin C in the detection of early acute kidney injury. Theophylline was found not to bring a complete protection for the kidneys, but less nephrotoxicity was developed when compared to the group not receiving theophylline.

PUB030
IgA Nephropathy Presenting as RPGN After G-CSF Administration: An Interesting Case
Talal A. Khan,1 Ahmad Hassan,2 Agba Seyed Shabbir Ali,2 Hafiz Armaghan Saeed,2 Abdul Mateen Nagaria,2 Azka Arsl,1 Freeman Heath System; 3Rawalpindi Medical College.

Background: IgA nephropathy is the most common form of primary glomerulonephritis & a major cause of ESRD in the world, its pathogenesis involves lymphocyte infiltration within renal interstitium as well as glomerulus. Selectins are adhesion molecules that play very important role in leukocytes to endothelial cell attraction. G-CSF is commonly used to induce neutrophil production. It induces E-selectin expression on endothelial cells & E selectin ligand on leukocytes. We present an interesting case of IgA nephropathy presenting as RPGN after G-CSF administration.

Methods: 66-year-old male with past medical history significant for T-cell leukemia on cyclophosphamide(CY) who presented with epistaxis was found to have acute C1q, albumin, fibrinogen, & kappa and lambda light chains. There were mesangial granular deposits with IgA (3+), C3 (1+), lambda (1+); kappa was negative. The remaining stains showed no significant deposits. Patient underwent induction with CYC and pulse steroids, days 1-2, with prednisone 60 mg/ day. Renal biopsy was scheduled but patient refused and was discharged. During hospitalization in patients with CKD, hypotension, or planned surgical procedures.

Results: Among the 184 patients included, 92 patients developed AKI (age 66±13 yrs; male 52%, male 58%). Patients with AKI had a higher baseline serum creatinine (1.1±0.4 vs. 1.0±0.3, p<0.001), lower eGFR (54.10 vs. 56.7mL/min/1.73m2, p<0.03), and were more likely to have a diagnosis of CKD (40% vs.14%, p<0.001), an ICU stay (44% vs. 17%, p<0.001), a surgical procedure (34% vs. 14%, p<0.001), hypotension (24% vs. 2%, p<0.001), and concomitant loop diuretic therapy (52% vs. 36%, p<0.03). The AKI group had a longer length of stay (14±11 vs. 8±3 days, p<0.001) and a higher rate of all cause hospital mortality (8% vs. 1%, p<0.03). Factors associated with a significant increase in risk of AKI in the multivariable analysis were CKD (OR=4.3, 95% CI 1.6-9.3, p<0.001), hypotension (OR=14.2, 95% CI 3.1-65.0, p<0.001), and surgical procedures (OR=7.9, 95% CI 1.6-42.9, p=0.001).

Conclusions: Conclusion of ACEIs/ARBs during hospitalization may increase the risk of AKI in select patients. Temporary discontinuation of ACEIs/ARBs may be warranted during hospitalization in patients with CKD, hypotension, or planned surgical procedures.
Sequences of Neprilysin: Associated Lipocalin: A Novel Biomarker for Prediction of AKI Development in Critically Ill Patients

Background: Acute kidney injury (AKI) is a frequent complication in critically ill patients and is associated with high morbidity and mortality; therefore, its prophylaxis, diagnosis and intervention positively impact patient evolution. Neprilysin-associated lipocalin (NGAL) is thought to be a novel biomarker of AKI of several etiologies and is increased in both serum and urine before the increase of serum creatinine.

Methods: A prospective cohort study was conducted on 100 critically ill patients in ICU. Patients were stratified into 2 groups based on AKI development. Group I which included 50 patients who did not develop AKI, and group II which included 50 patients who developed AKI. AKI was defined based on acute kidney injury network (AKIN) classification. The Sequential Organ Failure Assessment (SOFA) scores were also calculated for all patients. Detailed medical history, demographic data and routine laboratory investigations were done. Serum NGAL was measured upon admission to ICU and upon AKI development.

Results: 60 males and 40 females were included in the study with mean age 37.52 years. As regards risks of AKI development, 9% of patients had sepsis, 15% were dehydrated, 11% had contrast exposure, 12% had rhabdomyolysis, 29% had shock and 24% had history of NSAID intake recently. On admission, there were no significant differences between the patients as regards s.creatinine, hemoglobin level and other laboratory parameters (p>0.05). Serum levels of NGAL were significantly higher in group II, before AKI development, with mean value 958.5 ng/ml, when compared with group I, mean value 272.17 ng/ml (p<0.01). Serum NGAL levels were significantly higher in group II after AKI development when compared with the levels before AKI development in the same group (1660.35 ng/ml) (p<0.01). There was no significant correlation between NGAL levels and AKIN classification stages.

Conclusions: In the absence of diagnostic increases in serum creatinine, NGAL detects patients with likely subclinical AKI who have an increased risk of adverse outcomes. Reassessment of AKI classification and stages should be considered.

Does Previous CKD Affect Renal Recovery After Acute Kidney Injury?

Maria Isabel Acosta-Ochoa, Josefina Martin, Alicia Mendiluce. Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: AKI definition includes a sharp increase of serum creatinine (Scr), essentially reversible. There is a lack of consensus of a standard definition of Renal Recovery (RR). The exact course of the repair process is subject of thorough investigation. Few studies have engaged in comparing rates of RR in patients with previous impaired vs. normal renal function.

Methods: Retrospective cohorts study, 12-months period. We defined RR as discharge Scr with maximum increment £25% over basal value, and non recovery as >25% HD persistence, and death. We studied 2 groups: AKI and Acute on Chronic Kidney Disease (AoCKD). We tested epidemiological features, Charlson Index (ChaI), and KDIGO stages. We plotted a Kapplan-Meier survival curve 24 months post-discharge.

Kaplan-Meier Curves for 2 Years Survival

Results: 270 patients, AKI=125, AoCKD=145, clinical features and KDIGO stages: see table 1.

When meta-analysis was limited only to RCTs, the pooled RR of CIAKI in patients receiving nebulol was 0.69 (95% CI, 0.38-1.15, I²=0).

Conclusions: Despite no statistical significance, there was a trend toward reduced CIAKI risk in patients receiving nebulol. This finding suggests the need for further studies on the use of nebulol in addition to standard IV crystalloid hydration in the prevention of CIAKI.

The Effect of Nebivolol on Contrast-Induced Acute Kidney Injury: A Meta-Analysis

Nephrology, Ain Shams Univ, Cairo, Egypt.

Background: Nebivolol provides protective effect on contrast-induced acute kidney injury (CI-AKI) in animal models. However, the reports on the efficacy of nebulol for the prevention of CI-AKI in human remain unclear. The objective of this meta-analysis was to assess the effect of nebulol for the prevention of CI-AKI.

Methods: Comprehensive literature searches were performed using MEDLINE, EMBASE, and Cochrane Database from inception through February 2015. Studies that reported relative risks, odd ratios or hazard ratios comparing the risk of CI-AKI in patients who received nebulol versus those who did not included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Four studies (2 RCT and 2 cohort studies) with 543 patients were included in our analysis to assess the risk of CI-AKI and the use of nebulol. Of 543 patients with contrast exposures, 30 patients (5.32%) had CI-AKI. Patients in the nebulol group had an overall lower incidence of CI-AKI (14.35%) compared to the control group (17.43%). The pooled RR of CIAKI in patients receiving nebulol was 0.66 (95% CI, 0.38-1.15, I²=0).

Conclusions: Despite no statistical significance, there was a trend toward reduced CIAKI risk in patients receiving nebulol. This finding suggests the need for further studies on the use of nebulol in addition to standard IV crystalloid hydration in the prevention of CIAKI.

Patients with Cardiovascular Diseases Are Susceptible to Acute Kidney Injury After Non-Carcid Surgery Under Preoperative Use of Angiotensin Converting Enzyme Inhibitors or Angiotensin Receptor Blockers

Hiro Masunaga, Takeshi Hamaoka, Masaru Matsui, Katsumi Morimoto, Ken-ichi Samejima, Yasuhiro Akai, Yoshihiko Saito. Nara Medical Univ, Nara, Japan; Osaka Univ, Osaka, Japan.

Background: It is unknown in which subgroups of patients the preoperative use of angiotensin converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARB) is a predictor for acute kidney injury (AKI) after non-cardiac surgery.

Methods: This is a retrospective cohort study on patients who underwent non-cardiac surgery from 2007 to 2009. After exclusion of urological surgery, missing creatinine clearance, and preoperative dialysis, the data for 2,725 patients were available. The exposure of interest was preoperative use of ACE-I/ARB. Primary outcome was postoperative AKI (AKIN criteria). The odds ratio (OR) of postoperative AKI among ACE-I/ARB users compared to non-users was analyzed using multivariable logistic regression models, adjusted for the logit of propensity score for ACE-I/ARB use. P<0.1 was considered statistically significant for interaction.

Results: Mean(SD) age was 61(16) and estimated glomerular filtration rate was 81(24) ml/min/1.73m². There were 574(21%) patients with previous impaired renal function. 36(1.3%) of postoperative AKI in ACE-I/ARB users and 97(2,265 (4.3%) in non-users. The addjusted OR of AKI were shown.
Whole Ischemia-Reperfusion Injury: The Effect of Whole-Body Cooling on Renal Function

Background: Hypothermia is able to reduce the risk of renal failure after renal ischemia-reperfusion injury in animals. In humans, Cardiac Arrest (CA) as a whole-body ischemia-reperfusion syndrome causes warm renal ischemia-reperfusion injury, similar to animal models of ischemic acute kidney injury (AKI). Induced hypothermia (IH) is a treatment potentially efficacious for post-ischemic injury. It is unclear what effect could have on renal function. The aim of the study was to investigate the development of AKI during the IH.

Methods: Between Jan 2013-Mar 2015, we performed a prospective observational study of 36 comatose pts resuscitated from CA and treated with IH performed with 2 different surface cooling devices: 1) Arctic Sun Temperature Management System (Medivance, Loviutville, CO); 2) Blanket. Temperature rate and trend, and the development of AKI during induction (0-6hrs), maintenance (24hrs), rewarming (48hrs) and normothermia (72hrs) was assessed with RIFLE and KDIGO criteria.

Results: Pts were enrolled and followed for the development of AKI during intensive care unit stay. In the induction and maintenance phase, the rate and temperature was similar; conversely, the rewarming phase was shorter with a target temperature higher in Blanket than in ArcticSun group (458 mins vs 61 min; 37.2°C vs 36.3°C). The trend and the rate of temperature, but also the development of AKI is shown in figure 1.

Conclusions: IH could be associated with development of AKI in the rewarming phase (rate 0.25 to 0.5 °C). The optimal rewarming rate is unknown. Randomized controlled trials are needed to determine the real effect of temperature on kidney, the optimal rewarming strategy and applications of this treatment for kidney in other settings.

PUB038

Decongestion-Associated Worsening Renal Function Does Not Increase Mortality of Patients with Acute Heart Failure

Background: A significant subset of patients admitted for acute decompensated heart failure (ADHF) develop worsening renal function (WRF). While there is consistent data regarding the negative impact of baseline renal dysfunction on the outcomes of these patients, the evidence on the prognostic implication of WRF during admission for decongestion is less well-understood. The aim of this study is to provide a reappraisal of the effect of decongestion on the prognostic value of WRF in patients admitted for ADHF.

Methods: Articles cited in PubMed database from 1995 to 2015 using key words "congestion," "heart failure," "worsening renal function," and "hemococoncentration" were searched. Those studies evaluating the relationship between decongestion, renal function, and ADHF in patients treated with diuretic-based conventional therapies were selected. Ultrafiltration trials were excluded. Relevant data including change in renal function, diuretic dose, change in weight, and mortality were extracted and compared.

Results: A total of 12,843 patients from 19 trials (9 retrospective and 4 prospective) with data pertaining to decongestion in ADHF patients were included in this study. The mean age of the patients was 67.1 years with follow up periods ranging from 60 days to 5.3 years. Eleven studies reported development of WRF following decongestion. The incidence of WRF was reported to be 10 to 50.1% with weight reduction ranging from 2 to 5.4 kg. Twelve studies did not observe any negative impact for WRF on the mortality of patients with ADHF unless associated with markers of persistent congestion such as lack of hemococoncentration.

Conclusions: Decongestion is associated with markers of fluid removal and WRF in the setting of ADHF. Currently available data suggest that decongestion-associated WRF does not result in increased mortality whereas persistent congestion is likely to be the driving factor for adverse outcomes in these patients. Randomized controlled trials are needed to confirm these findings as they could portend significant therapeutic implications in cardiological syndrome.

PUB039

A 13-Year Mayo Clinic Retrospective Study of the Syndrome of Rapid Onset End Stage Renal Disease (SERO-ESRD) in an Incident Hemodialysis Cohort

Background: We first described the syndrome of rapid onset end stage renal disease (SERO-ESRD) in 2010 - acute yet irreversible ESRD after AKI. However, its overall impact on ESRD outcomes in the general US ESRD population remains speculative.

Methods: A retrospective examination of SERO-ESRD among the incident Mayo Clinic ESRD population, 2001-2013 was completed in November 2014.

Results: 149 of 1461 (10%) incident ESRD patients had SERO-ESRD – M:F = 76:73, mean age 62 years (19-95), 139 (93%) native kidneys, 10 (7%) kidney transplant recipients (RTRs). Ninety-nine percent of SERO-ESRD patients’ initial vascular access was a dialysis catheter. Kidney biopsy - the commonest pathologic diagnoses were acute tubular necrosis (ATN) in 3 (25%) KTRs and in 7 (21%) native kidneys. Cardiac arrest was the leading cause of death in SERO-ESRD.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

894A
Conclusions: Among 1461 incident ESRD patients seen at Mayo Clinic Dialysis Services, Rochester, 2001–2013, 149 (10%) had SORO-ESRD. There was no gender age disparity between SORO-ESRD patients and the general ESRD cohort. Ninety-nine percent (99%) SORO-ESRD patients’ initial vascular access was a dialysis catheter. ATN was the leading pathologic diagnoses for AKI among KTRs and in native kidneys. Cardiac arrest was the leading cause of death in SORO-ESRD, similar to the general ESRD population. We conclude that SORO-ESRD contributes significantly to incident ESRD here in the USA both among KTRs and in native kidneys. Furthermore, it negatively impacts on the success of AVF-First Programs. Efforts to mitigate AKI in CKD patients must be given more attention and priority by practicing nephrologists in particular, and by physicians in general.

PUB040
Saline-Induced, Diuretics-Responsive Acute Renal Failure (ARF): Evidence that Anasarca Is Nephrotoxic and Diuresis Is Therapeutic
Grant Melzer, Kai Lau, Maria Isabel Acosta-Ochoa, Josephine Martin, Alicia Mendiluce, Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: Recent studies showed the association of fluid overload in ARDS & surgical patients and increased ventilator dependency, ICU & hospital stays, short-term mortalities, & incidence of ARF. But a cause-and-effect relationship was unproven in cross-sectional observations. In grossly edematous in-patients with unexplained ARF, we tested the hypothesis that anasarca caused the renal failure & diuresis induced recovery.

Methods: Entry criteria were fully evaluable patients, ³3 kg weight or ³3 L fluid gain, ≥50% acute loss of estimated creatinine clearance (CrCl) or ≥ 2 x rise in serum creatinine (Scre) without identifiable causes. All data were reviewed, recorded, tabulated & statistically analyzed, notably vital signs, weight, intake, output & lab. 36 qualified patients were diuresed by IV furosemide at rates keeping normotension off anti-hypertensives. Serial volume markers & renal responses were noted. Palliative care & hepatorenal syndrome were excluded.

Results: Fluid overload was due to heart failure (40%), liver failure (22%), CKD (16%), proteinuria (9%) & iatrogenic factors (10%). During 42 ARF episodes, mean weight was up 12.5 kg in 13.7d. Scre rose (4.41 vs. 1.27mg%) & CrCl fell (25 vs. 76 ml/min). Decrements in CrCl correlated with edema weight gain (p=0.02). Over 11.9, d 15.2 kg of fluid were diuresed. Renal function greatly improved in 33 patients & unchanged in 3 despite >4 kg diuresis. As an entire group, Scre fell to 1.45 mg% & CrCl rose to 67 ml/min. Increments of CrCl also correlated with diuresis volume (p=0.04). At a diuretic rate of 1.5 kg/d, no adverse events occurred.

Conclusions: 1. Our data support the hypothesis for the entity of Saline-Induced, Diuretics-Responsive Acute Renal Failure. 2. Likely mediated by reduced cardiac output, venous congestion, renal interstitial edema &/or abdominal hypertension, it is analogous to congestive kidney failure. 3. Preventable & treatable, it could cause or aggravate ARF from other etiologies. 4. Diuresis in cohorts at rates & monitored as ours should be safe & efficacious.

PUB041
Is RIFLE Classification a Good Shot for Staging Acute on Chronic Kidney Disease? Maria Isabel Acosta-Ochoa, Josephine Martin, Alicia Mendiluce, Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: 8-16% of worlds population may have CKD, which is a risk factor and prompter of AKI. We tested the performance of RIFLE and KDIGO classifications in staging severity and predicting outcomes in Acute on CKD (AoCKD) individuals. KDIGO with a 0,3mg/dL Scre increase includes patients in stage 1 category, and includes automatically in stage 3 patients with peak SCr ≥4.0 mg/dL.

Methods: Retrospective cohort study. Patients were divided in 2 groups: AKI and AcoCKD. We collected clinical data, and classified AKI severity contrasting distribution strata between groups by RIFLE and KDIGO criteria. And tested the ability of both classifications for predicting need for HD and in hospital mortality with a AUC ROC analysis.

Results: 270 patients were included, AKI=125, AcoCKD=145. Clinical features and RIFLE and KDIGO stages are listed in table 1.

Conclusions: The KDIGO staging criteria we obtain more homogeneous distribution strata. With the ROC analysis neither classification performs better in predicting adverse outcomes. We found no practical advantage when using neither classification. In the noAKI (by RIFLE) stratum no adverse event was present, so by including a 0,3mg/dL Scre increase augments sensitivity, but may not be specificity.

PUB042
Incidence of Acute Kidney Injury, Risk Factors for Acute Kidney Injury and Absence of Renal Recovery in Patients on Aminoglycosides Francois Paquette,1 Amelie Bernier-Jean,1 Veronique Brunette,1 Vincent Pichette,2 Helene Ammann,3 Stephan Troyanov,3 Josee Bouchard.3 Hospital du Sacre-Coeur de Montreal, Canada; Hôpital Maisonneuve-Rosemont, Canada.

Background: The KDIGO guidelines recommended to avoid aminoglycosides (AG) in patients at risk or with acute kidney injury (AKI). We determined the frequency of administration, incidence of AKI, and risk factors for AKI and absence of renal recovery in patients receiving AG over the last decade.

Methods: We performed a retrospective cohort study on AG administration in two university-affiliated centers, and then performed a nested case-control study, pairing AG-AKI cases to 2 controls for age and gender. AKI was defined by a 50% increase in creatinine after ≥5 days of AG up until 7 days after cessation of AG, and renal recovery, by a decrease in creatinine to within 50% of baseline creatinine over 3 weeks after cessation of AG.

Results: Between 2001 and 2015, the frequency of AG administration and drug dosing progressively decreased. Out of 562 patients, sixty-five developed AKI attributed to AG (12%). In the case-control study (n=195), age was 71 (IQR 58-81) and 46% were male. The duration of AG administration was 10.0 (IQR 7.0-15.0) days, excluding days after AKI diagnosis in AKI patients. Maximal AKI stage was 1 for 55.3%, 2 for 29.2% and 3 for 15.4% of patients. Independent risk factors associated with AKI were concomitant vancomycin administration, high trough levels, heart failure, and site of infection (endocarditis and febrile neutropenia vs. other). Only fifty-one percent (50.8%; 33/65) of patients recovered their kidney function. These patients had an AKI duration of 7.0 (IQR 4.0-11.5) days. Heart failure was associated with a lower likelihood of renal recovery, while cancer patients more likely recovered their kidney function.

Conclusions: Over the last decade, the frequency of AG administration and dosing have progressively decreased but the incidence of AKI remained unchanged. In our cohort, vancomycin administration, high trough levels, heart failure, and site of infection were independent risk factors associated with AKI. Almost half of patients did not recover their kidney function, which was more often seen in patients with heart failure.

Prairie Continuous Renal Replacement Therapy (CRRT) Study – Outcomes of CRRT in a Single Canadian Tertiary Centre

Bhau Prasad,1 Michelle Urbanski,2 Erwin Karreman,3 Nephrology, Regina Qu'Appelle Health Region, Regina, SK, Canada; 2College of Medicine, Univ of Saskatchewan, Regina, SK, Canada; 3Research and Performance Support, Regina Qu'Appelle Health Region, Regina, SK, Canada.

Background: Patients with stage III Acute Kidney Injury (AKI) requiring Renal Replacement Therapy (RRT) have the highest short-term and long-term mortality of any group with AKI. Our study aimed to prospectively follow patients with stage III AKI on Continuous Renal Replacement Therapy (CRRT) during their hospitalization in our tertiary care centre from April 2013 to September 2014.

Methods: We prospectively gathered the following: date and time of hospital admission, transfer to ICU, and starting CRRT, creatinine at admission and at CRRT initiation, weight on admission and at CRRT initiation. Duration of oliguria and anuria, exposures (sepsis,critical illness, circulatory shock, trauma, cardiac surgery, major non cardiac surgery, nephrotoxic medications, and radio contrast agents) and susceptibilities (dehydration, >65 years of age, female, pre existing CKD), APACHE score II, Inotrope support, FiO2, ECMO. Survival on CRRT, in ICU and hospital survival and renal recovery was documented.

Results: Of the 2634 patients (2201/2634) 83.6% had no AKI, and (269/2634) 10.2% had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU and 17/106 died within 24 hours of initiating CRRT. This raises a clinical concern of the benefit vs futility of initiating therapy. 5/106 patients recovered within 24 hours.

Stage III AKI needing CRRT was associated with 62% mortality in hospital. 17/106 died within 24 hours of initiating therapy. 5/106 patients recovered within 24 hours.

Conclusions: Of the 2634 patients (2201/2634) 83.6% had no AKI, and (269/2634) 10.2% had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU and 17/106 died within 24 hours of initiating CRRT. This raises a clinical concern of the benefit vs futility of initiating CRRT in specific settings.

PUB044

Urinary Liver Fatty Acid Binding Protein Predicts Acute Kidney Injury Associated with Abdominal Aortic Repair

Daisuke Ichikawa,1 Atsuko Ikemori,1 Takeshi Sugaya,1 Kenjiro Kimura,1 Yugo Shibagaki.3 Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Acute kidney injury (AKI) is common problem after cardiovascular surgery. AKI is usually diagnosed on the basis serum creatinine (SCr) and urinary output. However, SCr is of low sensitivity in patients with poor renal function. Because urinary liver-type fatty acid binding protein (L-FABP) reflects renal tubular injury, we evaluated whether periparative changes in urinary L-FABP can predict AKI.

Methods: Subjects were 68 patients who underwent EVAR and 32 patients who underwent open repair. We obtained urine samples before surgery, immediately after surgery, and on POD 1, 2, and 3 for measurement of urinary L-FABP and urinary albumin in the EVAR patients. We obtained urine samples before surgery, after anesthesia induction, before aortic cross-clamping (AXC), 1 and 2 hours after AXC, at the end of surgery, and on POD 1, 2, and 3 for measurement of urinary L-FABP and urinary albumin in the open repair patients. We obtained serum samples before surgery, immediately after surgery, and on POD 1, 2, and 3 for measurement of SCr.

Results: AKI developed in 5 (7.4%) EVAR patients and in 9 (28.1%) open repair patients with EVAR, urinary L-FABP was increased 4 hour after the procedure (P = 0.002) and it decreased but remained elevated for 3 POD (P = 0.003). With AKI, SCr increased significantly to its maximum by 2 hour after AXC (P = 0.008) and then decreased gradually over the 3 PODs (P = 0.038). The increase in urinary L-FABP was greater with open repair than with EVAR. ROC analysis showed urinary L-FABP to be more sensitive than SCr, and it decreased but remained elevated for 3 PODs.

Conclusions: Urinary L-FABP appears to be a sensitive biomarker of AKI in patients undergoing abdominal aortic surgery, especially those treated by EVAR.

PUB045

Plasma Neutrophil Gelatinase-Associated Lipocalin (NGAL) as a Biomarker for Acute Kidney Injury in Patients with Chronic Kidney Disease

Ha yeon Kim,1 Eun Hui Bae,2 Soo Wan Kim,3 Seong Kwon Ma.1 Internal Medicine, Chonnam National Univ Medical School, Gwangju, Korea.

Background: The aim of this study was to evaluate plasma NGAL levels as a predictor of early AKI in patients with with/without chronic kidney disease (CKD) and to assess whether plasma NGAL level could represent a useful marker of recovery in patients undergoing emergent renal replacement therapy (CRRT).

Methods: This was a single center retrospective observational study included 343 patients with AKI or CKD. The patients were classified into 3 groups: AKI (N=69), AKI on CKD (N=162), CKD (N=112). The cut-off values of NGAL was 200 ng/ml and those of cystatin-C was 1.0 mg/L. Study II: The retrospective observational study included 404 patients treated with CRRT. The patients were divided into 2 groups: renal recovery (N=120) vs. renal non-recovery (N=284) and survivor (N=193) vs. non-survivor (N=211).

Results: The prevalence of abnormal NGAL values was 69.0% in AKI group, 94.5% in AKI group and 91.8% in CKD group, the value of NGAL was positively correlated with aGFR (r = 0.41, p < 0.001), and cystatin C (r = 0.45, p < 0.02). The mean values of follow-up NGAL were 475.9 ± 435.9 ng/ml in AKI group, 773.2 ± 370.6 ng/ml in AKI group, 709.4 ± 401.6 ng/ml in CKD group (p < 0.001). In AKI group, the difference of NGAL (baseline NGAL – follow-up NGAL) was the highest (110.8 ± 322.0 ng/ml in AKI group, 35.7 ± 205.2 ng/ml in AKI group, 14.1 ± 203.1 ng/ml in CKD group, p < 0.001). In comparisons between renal recovery group and non-recovery group and survivors and non-survivors in CRRT patients, both baseline NGAL and follow-up NGAL were not different, but the difference of NGAL (baseline NGAL – follow-up NGAL) was increased significantly in a renal recovery and survivors group (96.8 ± 82.9 ng/ml in renal recovery group vs. 33.8 ± 53.7 ng/ml in renal non-recovery group, 129.8 ± 182.4 ng/ml in survivor group vs. 98.5 ± 162.6 in non-survivor group, p < 0.001, respectively).

Conclusions: The value of serum NGAL per se has a limitation on diagnosis of AKI in patients with underlying CKD. In patients treated with CRRT, hourly urine output and follow up of serum NGAL value may predict renal recovery and survival.

PUB046

C3 Glomerulopathy: A Pediatric Case

Luis A. Ortiz,1 Daniel Kleven,2 Harika Gorri,1 Ped. Nephrology, Georgia Regents Univ, Augusta, GA; 2Pathology, Georgia Regents Univ, Augusta, GA; 3MG, Georgia Regents Univ, Augusta, GA.

Background: C3 glomerulopathy (C3G) is characterized by C3 deposit in the glomeruli with minimal Ig deposition. C3G is described as an unregulated activation of the alternative complement pathway due to a genetic mutations in Factor H or, or acquired factors such as C3 nephritic factor, an IgG autoantibody stabilizing C3 convertase. The pattern of the injury varies from mesangio-proliferative, membranoproliferative, to endocapillary proliferative glomerulonephritis. EM finding is subendothelial and subepithelial hump shaped deposits, characteristic of acute post-infectious glomerulonephritis (PIGN). We present a pediatric case that meet the initial criteria for PIGN, but was diagnosed as C3G according the pathology.

Methods: 15 y/o AA M with Thin Basement D, HTN, asthma presented with 1 hx of sore throat, gross hematuria, facial swelling, no distal edema. Initial criteria and high Cr. PE revealed periorbital edema, no pharyngeal erythema, lung clear, abdomen with no ascites. On admission, Hb 11.6 g, Cr 3.26mg, albumin 2.5 gr, UA:50-120 BRC, UOP: 0.37 ml/hr. Despite treatment with methylprednisolone, albumin and furosemide, his Cr. increased to 15 y/o AA M with Thin Basement D., HTN, asthma presented with one Hx of sore throat, gross hematuria, facial swelling, no distal edema. Initial criteria and high Cr. PE revealed periorbital edema, no pharyngeal erythema, lung clear, abdomen with no ascites. On admission, Hb 11.6 g, Cr 3.26mg, albumin 2.5 gr, UA:50-120 BRC, UOP: 0.37 ml/hr. Despite treatment with methylprednisolone, albumin and furosemide, his Cr. increased to 15 y/o AA M with Thin Basement D., HTN, asthma presented with one Hx of sore throat, gross hematuria, facial swelling, no distal edema. Initial criteria and high Cr. PE revealed periorbital edema, no pharyngeal erythema, lung clear, abdomen with no ascites. On admission, Hb 11.6 g, Cr 3.26mg, albumin 2.5 gr, UA:50-120 BRC, UOP: 0.37 ml/hr. Despite treatment with methylprednisolone, albumin and furosemide, his Cr. increased to...
Conclusions: SRC is a serious kidney and life threatening complication of SSC. Delay in blood pressure control increases risk of ESRD in SRC patients.

PUB048

Acute Kidney Injury Risk Assessment at the Hospital Front Door: What Is the Best Measure of Risk? Aled O. Phillips,1 Dafydd Phillips,1 Mohamed Hassan,2 John Gee,2 Vikas Lodhi,3 Hermann Bolusani,1 Gareth Roberts,1 1Nephrology, Cardiff Univ School of Medicine, Cardiff, Wales, United Kingdom; 2Dept of Clinical Biochemistry, Univ of South Wales, Wales, United Kingdom; 3Dept of Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom. Background: We examined the prevalence of AKI risk factors in the emergency medical unit, generated a modified risk assessment tool and tested its ability to predict AKI. Methods: 1196 patients admitted to medical admissions units were assessed for patient associated AKI risk factors. Subsequently, 898 patients were assessed for a limited number of fixed risk factors with the addition of hypotension and sepsis. This was correlated to AKI episodes. Results: In the first cohort the prevalence of AKI risk factors was 2.1 ± 1.0 per patient, with a positive relationship between age and the number of risk factors and a higher number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI cohort 72% of the patients had ≥2 AKI risk factors compared to 43% of the cohort with no AKI. When age ≥65 yrs was added as an independent risk factor risk 84% of those with AKI had ≥2 AKI risk factors compared with 55% of those with no AKI. ROC analysis suggest that use of common patient associated known AKI risk factors performs no better than age alone as a predictor of AKI. Conclusions: Detailed assessment of well established patient associated AKI risk factors may not facilitate clinicians to apportion risk. This suggests that additional work is required to develop a more sensitive validated AKI predictive tool which would be useful in this clinical setting.

PUB049

Acute Kidney Injury, Requiring Renal Replacement Therapy – Incidence, Causes and Outcomes: One Center Experience Elena Zakharyova, Nephrology, City Clinical Hospital n.a. s.P. Botkin, Moscow, Russian Federation. Background: Acute Kidney Injury (AKI) is complex condition, associated with high mortality and morbidity. We aimed to evaluate AKI incidence, causes, risk factors and outcomes in patients, managed in nephrology unit of general hospital and urgently requiring Renal Replacement Therapy (RRT). Methods: Using electronic database for 2010-2014 (4531 admissions, 2257 patients), we searched 604 cases which met KDIGO AKI definition, and selected patients, required RRT. Results: Study group included 115 patients (19% of all AKI cases), 51 (44%) male, 64 (56%) female, median age 61 [22; 89] years. In 102 (89%) cases AKI was community acquired. Median serum creatinine prior to start of RRT was 981 [242; 2665] µmol/l, 37 (32%) patients had known CKD. Causes and susceptibilities for AKI are shown in table.

Conclusions: In our cohort incidence of AKI was 27%, proportion of patients requiring RRT constituted 19% of AKI cases. Vast majority had community acquired AKI, 1/3 developed AKI on the top of pre-existing CKD, 16% were elder than 75 years. Main trigger for RRT requiring AKI in 29% of cases was initially considered as decreased kidney perfusion, with volume-unresponsiveness due to severe underlying conditions, such as CKD, chronic heart and liver diseases, multiple myeloma, cancer, diabetes and amyloidosis. Other most frequent causes of AKI were sepsi, rhabdomyolysis, vasculitis, and interstitial nephritis. Mortality rate was 10%, ESRD developed in 23% of cases.

PUB050

Renal Manifestations in Paroxysmal Nocturnal Haemoglobinuria Rama R.,1 Dakshinamurty K.V.,2 Krishna Parasad A.3 1Nephrology, Sri Venkateswara Inst of Medical Sciences, Tirupati, AP, India; 2Nephrology, Mahatma Sri Ramachandra Centenary Memorial Hospital, Hyderabad, Telengana, India; 3General Medicine, NIMS, Hyderabad, India. Background: Paroxysmal nocturnal haemoglobinuria (PNH) is an acquired chronic disorder characterized by a triad of clinical features- haemolytic anaemia, purpura, and thrombosis. Not many reports of renal involvement in PNH are available in literature. Methods: We present a case series of PNH with renal involvement. We present the data of PNH patients attended to departments of General Medicine and Nephrology at a government run tertiary care institute in South India. The diagnosis of PNH in these patients during initial phase, between 1998 and 2004 was based on sucrose lysis and Ham’s test. After 2004, the diagnosis was based on flow cytometry to detect CD59 (MIRL), a glycoprotein, and CD55 (DAF) in regulation of complement action. The patient data was collected from 1998 to 2014. Results: There were 13 patients of paroxysmal nocturnal haemoglobinuria in this period. The mean age was 37 years and the range was 16 to 68 years. There were 7 females. Acute renal failure was noted in 5 patients. Dialysis was performed in three of them. The mean serum creatinine and urea at the initiation of dialysis was 5.4 ± 0.6 mg/dl and 64.1 ± 6.1 mg/dl respectively. The median number of haemodialysis sessions done was four. Renal biopsy was done in four patients. The indication for the biopsy was acute renal failure of more than four weeks. The median number of glomeruli was 9. The tubules showed prominent brown granular pigment within the epithelial cells. It was confirmed as hemosiderin with the Perl’s Prussian blue reaction. A few deposits of hemosiderin were also seen within the tubular lumina. The pathological diagnosis in these four patients was acute tubular necrosis secondary to hemosiderin deposition. In three patients the urinalysis and serum chemistry was suggestive of Fanconi syndrome. Conclusions: In our patients, three renal manifestations of PNH were identified. They were acute renal failure, renal vessel thrombosis and Fanconi syndrome. Chronic renal failure was not identified.
Filling the Gaps in Acute Kidney Injury Epidemiology: A Multicenter Prospective Study in Amazon

Matthew L. Howse.

Background: In some areas of developing countries, infectious tropical diseases or animal venoms may be important causes of Acute Kidney Injury (AKI). Epidemiological studies of AKI in these areas are scarce and expensive population-based studies are even scarcer.

Methods: Prospective data on all adult patients admitted in all intensive care units (ICU) in the Western Amazon region (600 square kilometers and 100,000 inhabitants) were collected for 6 months in 2014. Patients with chronic kidney disease stage 5, kidney transplant or ICU stay < 48 hours were excluded. AKI was diagnosed by KDIGO and mortality was assessed 30 days after ICU discharge. Data are presented as mean±SD or percentage.

Results: 367 patients aged 57.8 ± 19.2 years and with 39% white were evaluated. Main reasons for ICU admission were postoperative (34%), hemodynamic instability (22%) and respiratory failure (13%), with only 1% with tropical diseases. AKI incidence was 38%, but was lower in postoperative patients (28% vs 47% in non-postoperative, p = 0.005). Mortality was higher in AKI patients (53% vs 30% in non-AKI, p < 0.001). Postoperative patients who developed AKI had similar mortality to those non-operative (46% vs 56%, p = 0.302).

Conclusions: AKI has a high incidence in ICU patients of the Western Amazon area. The causes of ICU admission did not differ from those seen in developed countries. The few number of patients with the typical tropical diseases of Amazon may be due to poor access to health care. The peculiar social geographical region characteristics, with rivers that are not navigable most of the year, long rain period that difficult access to larger cities and the lack of health services in diverse areas, may be associated to the present findings.

Uncovering Complement Mediated Thrombotic Microangiopathy: Use of a Real Time Genetic Assay in the Diagnosis of Atypical Hemolytic Uremic Syndrome

Araujo Lopes de Melo,1,2 Tarcisio Andrade Souza,2 Natalia Mendes,1 Luis Yu,2 Emmanuel A. Burdnham,3 Dirce M T Zanetta.1

Background: Improved diagnostic tests and greater understanding of pathophysiology of thrombotic microangiopathy (TMA) have led to more rapid differentiation of various types of TMA. While ability to rapidly diagnose TTP (ADAMTS13 activity <5%) has improved, atypical HUS (aHUS) remains diagnosis of exclusion due to poor sensitivity, high cost, and long turnaround time (TAT) of aHUS genetic assays. We describe a patient (pt) with hypothyroidism and renal insufficiency diagnosed with aHUS, using appropriate clinical algorithms for TMA, including “real-time” aHUS genetic assay (TAT 2-5 days).

Methods: 59 y.o. female with 1-2 week (wk) history of fatigue, anemia, thrombocytopenia, renal insufficiency, and recent diagnosis of hypothyroidism with changes in CBC and creatinine (Cr) over 3 wks: hemoglobin (hgb) 13.9 to 7.1 g/dl, platelet count (pt ct) 241 to 68 X 10^9/L, and Cr 0.71 to 1.41 mg/dl (baseline Cr 0.56, BMI 19.5). Pt’s history with hypothyroidism and renal insufficiency were consistent with aHUS, using appropriate clinical algorithms for TMA, including “real-time” aHUS genetic assay (TAT 2-5 days).

Results: Pt received 11 plasma exchange (PE) treatments (txs) (hospital day [HD] 3-21). By day 4 of PE (HD 7), pt hgb 197 X 10^9/L; despite 11 PE txs, LDH remained elevated (866-2123) and Cr rose to 2.72 (3.8-4.9X higher than baseline). aHUS genetic panel (sent HD 10, results on HD 17) revealed: positive variant in CFI gene (predicted to be significant, but not previously described) and heterozygous mutations for 3 CFH polymorphisms. Pt clinically diagnosed with aHUS, received meningococcal vaccine (HD 20), and cirilloxacin (2 wk course). Induction eculizumab started and PE stopped (HD 21). After 2 months of eculizumab, pt’s Cr normalized.

Conclusions: With development of improved genetic testing (ie, increased sensitivity and speed), aHUS genetic assays may represent “real-time” diagnostic tools enabling more rapid assessment of selected TMA cases leading to more targeted treatment.

Intravenous Contrast Material Administration Increases Mortality in Patients with Acute Kidney Injury Requiring Renal Replacement Therapy

Katsuhito Igarashi, Atsuki Ohashi, Yoshiho Iida, Makiko Kubayashi, Hitomi Tanaka, Seiji Inoshita. Internal Medicine, Tokyo Metropolitan Bokutoh Hospital, Japan.

Background: Contrast material exposure is well known to induce acute kidney injury (AKI); however, it is yet unclear whether contrast material administration is related to the prognosis of AKI. We hypothesized that intravenous contrast material administration might be a poor contrast prophyaxis which was given in 2.93 mL/kg. Contrast material was administered in 50.6 % of the patients. Each the exposure group and non-exposure group included 86 and 153 patients, respectively. The 28-day mortalities of each group were 55.8 % and 36.9 % respectively. The hazard ratio in the exposure group was 2.966 [95% confidence interval (CI) 1.573-4.517] (p = 0.000) by univariate analysis. After adjustment by hypertension, sepsis, ischemia, and diuretics usage, which were the significant different confounders of the two groups, the hazard ratio was 1.987 [95% CI. 1.093-3.610] (p = 0.024).

Conclusions: Our results demonstrated that intravenous contrast material administration is an independent risk factor for mortality in patients with AKI requiring RRT.
PUB056

Dabigatran Induced Acute Kidney Injury and Management with Hemodialysis

Daren W. Grabs,1,2 Syed S. Haqiqi.1,2 1Dept of Pharmacy Practice, Albany College of Pharmacy and Health Sciences, Albany, NY; 2Dept of Medicine, Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.

Background: A 55-year-old man with a history of A Fib, cirrhosis, portal HTN, esophageal varices arrives in the ED, transferred from an outside hospital following initial presentation with multiple episodes of hematoma and melena. Medication regimen recently changed with a switch from warfarin to dabigatran 8 months prior to admission in order to avoid frequent INR checks.

Methods: On admission, initial blood work was obtained and revealed: Hg 6.3 g/dL, INR 6.9, Scr 15.6 mg/dL, and BUN 189 mg/dL. Patient was admitted to the intensive care unit for management of acute blood loss and AKI. On physical exam shows a pulse of 95 bpm and BP of 111/75 mmHg and mild hepatosplenomegaly, the physical exam was unremarkable. Dabigatran was discontinued and patient was transfused with packed red blood cells and fresh frozen plasma and administered vitamin K. Hemodialysis was initiated and continued throughout the hospital course. Kidney biopsy was performed and was consistent with ATN, chronic tubulointerstitial nephritis, and IgA Nephropathy (HAAS class I).

Results: Serum dabigatran concentration (conc) drawn on admission was 860 ng/mL. Following the initial emergent hemodialysis (HD) procedure, subsequent dabigatran conc. were determined during the second HD procedure. Predialysis and postdialysis dabigatran conc. were 130 ng/mL and 30 ng/mL, respectively. Pharmacokinetic parameters were calculated and shown in the table.

k = elimination rate constant; t1/2 = half-life; D = dialytic

Over the hospital course, patient required regular HD. Hg stabilized following transfusion and vitamin K. Patient was stable on discharge with a serum creatinine of 5.9 mg/dL and remained on dialysis.

Conclusions: Dabigatran induced AKI is rare. The mechanism of the insult in this case was unclear but acute blood loss leading to prolonged ischemic insult was largely contributive. Hemodialysis was successful in removing the offending agent with resolution of bleeding but patient remains dialysis dependent.

PUB057

Relation Between BNP And NGAL, with Bioelectrical Cardiothoracic Impedance Hemodynamics Parameters in Patients with Cardiorenal or Renocardiac Syndrome

Background: Evaluate the application of cardiothoracic bioelectrical impedance (CTBIA) in the classification of patients with cardiological or renocardiac syndrome.

Methods: We use a cohort with 18 patients (mean age years 72 SD 2.6, males 77 %) with cardiological or renocardiac syndrome. We evaluate hemodynamic parameters (cardiac output –CO, cardiac output index –COI, left ventricular work index –LVWI, and systemic vascular resistance index –SVRI) with BNP (pg/ml, limits 0-100) and NGAL (ng/ml, limits 0-4.9).

Results: Mean levels of BNP were 545.71 (SD 128.8) and mean levels of NGAL were 500.11 (SD 96.25). Only vascular resistance index was associated with NGAL (r=0.461, p=0.054). Not found associations with BNP. However we classify patients in four groups: Group 1 (BNP high, NGAL normal) (n=7), Group 2 (BNP high, NGAL high) (n=1), Group 3 (BNP normal, NGAL high) (n=7) and Group 4 (BNP normal, NGAL normal) (n=3).

The associations indicate that in Group 1 are patients with cardiac dysfunction (cardiological) and higher BNP (BNP-NGAL), with lower cardiac output and higher vascular resistance, and in group 3 are patients with renal dysfunction (renocardiac) and higher NGAL (BNP-NGAL), with higher cardiac output and lower vascular resistance.

Recovery of Renal Function After Removal of Functional Causes of Advanced Renal Failure

Maria-Elvira Roumelioti1, Faraz Khan Luni, Sandeep Vetterth, Darlene Melinda Vigel,1 Kavitha Ganta,1,3 Deepak K. Malhotra,2 Antonios Tzamaloukas.1,3 1Univ of New Mexico; 2Univ of Toledo; 3Raymond G. Murphy VA Medical Center.

Background: It is important to predict whether renal function recovers completely, early in the course of functional azotemia. We hypothesized that the level of renal function can be predicted from the early change in serum creatinine concentration ([Cr]) during treatment of functional azotemia.

Methods: Taking into account the changes in the body pool of Cr at diagnosis and Cr production during treatment, we calculated the Cr clearance ([Cr]k) between the [Cr] levels in the blood sample obtained at presentation ([Cr]k) and in the first blood sample after the initiation of non-dialytic treatment ([Cr]k) in 6 pts, 5 men with urinary retention and a woman with prerenal azotemia. The calculated Ck values was used to predict [Cr] levels corresponding to times of subsequent [Cr] measurements. We compared the predicted [Cr] levels to the corresponding measured ones.

Results: The table shows [Cr]k and [Cr]k levels, calculated Ck values, predicted and measured [Cr] levels at steady state after correction of the azotemia ([Cr]k). Predicted and measured [Cr]k values were close.

Conclusions: Computation of early Ck after removal of the cause of functional azotemia may provide estimates of post-treatment [Cr] levels reasonably close to the measured levels. More observations are needed.

PUB059

Relation of Cardiothoracic Bioelectrical Impedance Hemodynamics and Volemic Parameters with Acute Kidney Injury Prognosis

Background: Evaluate the relation of hemodynamics and volemic parameters with AKI. We evaluate hemodynamic parameters (cardiac output –CO, cardiac output index –COI, left ventricular work index –LVWI, and systemic vascular resistance index –SVRI) and thoracic volemic parameters (Thoracic fluid volumen -TFV-, Thoracic fluid volumen index –ISI), analytical parameters (creatinine –Cr, prealbumin –PRALB, albumin –ALB) and chronic health index (Karnofsky –K).

Methods: We use a cohort of 21 patients (mean age years 69 SD 2.8, 76.2% males) with AKI. We evaluate hemodynamic parameters (cardiac output –CO, cardiac output index –COI, left ventricular work index –LVWI, and systemic vascular resistance index –SVRI) and thoracic volemic parameters (Thoracic fluid volumen -TFV-, Thoracic fluid volumen index –ISI) with clinical index prognosis (severity individual index –SI), analytical parameters (c-reactive protein –CRP, prealbumin –PRALB, albumin –ALB) and chronic health index (Karnofsky –K).

Conclusions: The use of CTBIA is useful to evaluate and classify patients with cardiological or renocardiac syndrome. There are association between vascular resistance and renal tubular necrosis.
Results: Patients with lower vascular resistance and higher cardiac work have worse prognosis, associated with inflammatory state and thoracic hypervolemia, oliguria and higher renal replacement therapy requirements. But patients with higher thoracic volumes have higher risk of respiratory failure.

Conclusions: CTHBA can be used to evaluate prognosis and therapy of higher risk AKI. Patients with vasopressive state (with inflammatory origin and higher multiorgan failure risk) or thoracic hypervolemia (with higher respiratory failure and intubation risk).

PUB060

Abruptio Placenta as a Complement Amplifying Condition for Atypical Hemolytic Uremic Syndrome

Sved S. Haagc, Amro Elshoury, Daniel Sedhom, Arif Asif, Albany Medical College, Albany, NY.

Background: Endothelial injury resulting in microvascular thrombosis is the underlying pathology leading to target organ injury in aHUS. The syndrome is characterized by microangiopathic hemolytic anemia, thrombocytopenia, and ischemic injury to multiple organs including the kidney. Complement amplifying conditions often lead to the activation of complement cascade involved in the pathogenesis of aHUS. In this report, we present 33-year-old Hispanic women with abruptio placenta at 33 weeks of gestation and fetal death who underwent cesarean section. Post procedure, patient developed microangiopathic hemolytic anemia (6.7 mg/dl), thrombocytopenia (39,000/μL) and renal failure necessitating initiation of hemodialysis. Fibrinogen (267 g/dL), PT, PTT were normal while LDH was markedly elevated at 2670 IU/L haptoglobin was severely reduced at 5.8 mg/dL. Marked schistocytosis was observed on peripheral smear. ADAMTS 13 was ordered and plasma exchange was initiated. Five sessions failed to show any improvement and ADAMTS 13 activity returned at 56%. Plasma therapy was not applicable when plasma serum creatinine (sCR) is rapidly changing. Chen et al (JASN 2013) has recently proposed KeGFR formula to calculate GFR from fluctuating sCR values. The aim of this study was to compare KeGFR values with eGFR using the Modification of Diet in Renal Disease (MDRD).

Methods: We analyzed data from a cohort of 735 ICU patients screened in a prospective observational study on the incidence of aHUS from June 06 to Dec 08 at an academic center. Demographic data, comorbidities, clinical course, and laboratory parameters were recorded from ICU admission. We estimated KeGFR and eGFR for each patient during the first 48 hrs of ICU stay. We defined KeGFR = (SSPcr × CrCL/ Mean Pcr) × (0.742 if African American). We compared estimated GFR assessed by kinetic modeling with that of the Modification of Diet in Renal Disease (MDRD) equation.

Results: We analyzed data from a cohort of 735 ICU patients screened in a prospective observational study on the incidence of aHUS from June 06 to Dec 08 at an academic center. Demographic data, comorbidities, clinical course, and laboratory parameters were recorded from ICU admission. We estimated KeGFR and eGFR for each patient during the first 48 hrs of ICU stay. We defined KeGFR = (SSPcr × CrCL/ Mean Pcr) × (0.742 if African American). We compared estimated GFR assessed by kinetic formula with MDRD GFR equation.

Conclusions: Our study highlights the overestimation of renal function by MDRD equation in critically ill patients with acute kidney injury (AKI). KeGFR may be more accurate in tracking renal function changes in AKI. Further studies are needed to confirm these findings.

PUB062

Comparison of Estimated Glomerular Filtration Rate (eGFR) and Kinetic eGFR (KeGFR) in Critically Ill Intensive Care Unit (ICU) Patients

Rakesh Malhotra, Ettiene Maccio, Josse Bouchard, Ravindra L. Mehta, Albany Medical College, Albany, NY.

Background: Estimation of kidney function in critically ill patients is important for appropriate drug dosing and therapeutic strategies. However, current GFR equations are not applicable when plasma serum creatinine (sCR) is rapidly changing. Chen et al (JASN 2013) has recently proposed KeGFR formula to calculate GFR from fluctuating sCR values. The aim of this study was to compare KeGFR values with eGFR using the Modification of Diet in Renal Disease (MDRD).

Methods: We analyzed data from a cohort of 735 ICU patients screened in a prospective observational study on the incidence of aHUS from June 06 to Dec 08 at an academic center. Demographic data, comorbidities, clinical course, and laboratory parameters were recorded from ICU admission. We estimated KeGFR and eGFR for each patient during the first 48 hrs of ICU stay. We defined KeGFR = (SSPcr × CrCL/ Mean Pcr) × (0.742 if African American). We compared estimated GFR assessed by kinetic formula with MDRD GFR equation.

Contrast Induced Nephropathy Among Hospitalized South Africans – Impact of Serum Albumin

Jostor Banda, Saraladevi Naicker. Faculty of Health Sciences, Univ. of the Witwatersrand, Johannesburg, Gauteng, South Africa; Faculty of Health Sciences, Univ. of the Witwatersrand, Johannesburg, Gauteng, South Africa.

Background: Despite ranking 3rd as cause of hospital acquired acute kidney injury in hospitalized patients, contrast induced nephropathy (CIN) causes significant morbidity, mortality, and high hospitalization costs. In sub-Saharan Africa, information on rates of CIN is lacking. This study investigated the rates of CIN and influence of serum albumin on CIN.

Methods: This is an on-going prospective case controlled study conducted at Charlotte Maxeke Johannesburg Academic Hospital, in South Africa. In-patients undergoing contrast media exposure and consented to this study were consecutively recruited to the study. Ethical approval was obtained from the Human Research Ethics Committee of the University of the Witwatersrand. CIN was defined as serum Creatinine $>$250µmol/L or $>$4.4µmol/L from baseline over a 48-72 hours post exposure to contrast media. CIN clearance was calculated using the CKD-EPI. The following were exclusion criteria: age below 18years, evidence of AKI (clinical or laboratory), ESRD and prior contrast media administration.

Results: Among 285 recruited hospitalized patients, a rate of CIN was 16.9%. Serum albumin below 35g/dl positively predicted development of CIN (RR 2.3, 95% CI 1.4-4.6; p=0.020). The mean albumin was 28.4±4.6 SD and 41±2.39 SD in the CIN and non CIN groups respectively. An eGFR $<$60ml/min was associated with a 6 fold risk of developing CIN with 4±4.6 SD and 41±4.6 SD in the CIN and non CIN groups respectively. An eGFR $<$60ml/min was associated with a 6 fold risk of developing CIN (P=0.00001).

Conclusions: Rates of CIN is significantly high in developing countries and the presence of hypalbuminemia, a traditional bio-marker is significantly associated with development of CIN.

Rosuvastatin Has a Protective Effect against Hypertonicity-Induced Cell Damage

Miku Sato, Masaru Horio. Functional Diagnostic Science, Osaka Univ Graduate School of Medicine, Suita, Japan.

Background: Contrast-induced nephropathy (CIN) is one of the causes of acute kidney injury. Some studies raised a concern that statins have protective effect against CIN. Hypertonic stress in renal tubular cell is a possible factor inducing cell damage in CIN. Reactive oxygen species (ROS) can induce apoptosis. We studied the effect of rosuvastatin on hypertonicity induced cell damage in MDCK cells.

Methods: Hypertonic medium was made by addition of NaCl. Rosuvastatin was added 24 hours before the hypertonic exposure. Cell damage was assessed by LDH activity in culture medium. Apoptosis was evaluated by caspase-3 activity. Content of cellular glutathione (GSH), an important antioxidant, was measured.

Results: Hypertonicity more than 600 mOsm showed significant cytotoxic effect in MDCK cells. LDH activity in culture medium of 620, 640 and 660mOsm cells increased in osmolality dependent manner (Figure). Low concentration (0.1 and 1.0 µM) of rosuvastatin had a protective effect against the hypertonicity-induced cell damage. On the other hand, 10 µM rosuvastatin that had no significant cytotoxic effect in 300mOsm condition, stimulated hypertonicity induced cell damage.

Conclusions: Low osmolality condition is a possible factor inducing cell damage in CIN. Rosuvastatin has a protective effect on hypertonicity-induced cell damage in MDCK cells.

Anticoagulation-Free Continuous Renal Replacement Therapy: A Single Center Observation

Background: Renal failure in the ICU setting is associated with 40-60% mortality. Continuous renal replacement therapy (CRRT) is used for volume and electrolyte management in critical care units. To avoid clotting of hemofillets, patients are routinely started on anticoagulation. In literature, anticoagulation has been associated with complications of increased risk of bleeding and metabolic or electrolyte disturbances based on type of anticoagulation used. We aimed to investigate the length of cartridge use and the association of anticoagulation.

Methods: We conducted a retrospective review of 20 ICU patients who were started on CRRT over a course of 6 months for acute renal failure. We looked at the number of cartridges used per day. Prescription for CRRT was dialysate flow rate of 25-35 ml/kg/h and blood flow rate of 250 ml/h. No anticoagulation was ordered initially due to bleeding risks in this cohort. All patients were ordered 100 ml of normal saline flushes every 4 hours.

Results: Of the 20 patients, the hemofilter cartridge lasted >24 hours. 30% of the patients required more than 1 filter per day, of which only 1 patient was started on a heparin drip for anticoagulation due to multiple filter changes. We used predilution replacement fluid to reduce the blood viscosity and hemoconcentration for the patients requiring > 2 filter changes per day. Decreased requirement of filter change was noted after these changes were made. Among the patients with increased filter clotting, 33% had femoral non-tunneled dialysis catheters and 50 % had internal jugular tunneled dialysis catheters. Longer duration of dialysis was associated with increased cartridge use per pearson correlation 0.818 (p=0.000). No documentation was made in the nursing notes to distinguish between vascular access problems versus filter clotting.

Conclusions: Recurrent filter clotting leads to interruption of RRT. Frequent filter changes is not cost effective. However anticoagulation in critical care settings poses multiple potential problems. There was an association between percutameters and increased cartridge use.

Transcription Factor SRF Promotes Renal Fibrosis in IgA Nephropathy

Lijie He, Shiren Sun. Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: The role of transcription factors SRF, which regulate C4G element contained genes, in IgA nephropathy is unknown.

Methods: We carried out expression of SRF in human IgA nephropathy tissues from 10 IgA nephropathy patients with renal biopsies diagnostic of IgA nephropathy. Western blotting and qRT-PCR were used to measure SRF expression in IgA nephropathy kidney tissues.

Results: We found significant up-regulation of SRF expression in IgA nephropathy tissues in comparison to normal kidney tissues.

Conclusions: This result indicates that SRF is a potential therapeutic target in IgA nephropathy.
Conclusions: In summary, high expression of SRF associates with increased fibrosis and decreased survival in IgA nephropathy, and perhaps by enhancing TGF-β-mediated downregulation of snail and E-cadherin in HC-RBC.

PUB068
Increased Erythroid Reactive Oxygen Species Production Induced by Indoxyl Sulfate Precedes Red Blood Cell Death
Gabriela Ferreira Dias,1 Viktoria Kuntsevich,2 Lia S. Nakao,3 Fellype C. Barreto,4 Stephan Thijssen,5 Peter Kotanko,5,4 Roberto Pecoits-Filho,1 Andrea Novais Moreno-Amalar,1 Pontifícia Univ Católica do Parana, Brazil; 2Icahn School of Medicine at Mount Sinai, New York, NY; 3Univ Federal do Paraná, Brazil; 4Renal Research Inst, New York.

Background: The uremic toxin indoxyl sulfate (IS) triggers erytosis, an event characterized by phosphorylidyserine (PS) exposure on red blood cell (RBC). The aim of the present study was to evaluate whether increase in RBC reactive oxygen species (ROS) induced by IS precedes PS exposure.

Methods: RBC from healthy controls (HC) were incubated for 4, 12 or 24h with IS (free concentration 4.5 mg/L) in the presence or absence of free radicals scavenger N-acetylcysteine (NAC 0.5 mM). Flow cytometry was employed to assess erytosis (annexin-V binding) and ROS (DCFH-DA).

Results: Incubation of HC-RBC with IS over 4h did not trigger significant erytosis compared to control cells incubated without IS (4.5±1.2% vs 3.6±1.0%, p=0.67). However, 12h and 24h incubation with IS increased levels of erytosis in a time-dependent manner (10.4±3.4% and 16.6±6.1%, respectively). This IS-induced PS exposure on HC-RBC was inhibited in the presence of NAC (6.0±1.3% and 6.5±1.4%, respectively). On the other hand, ROS production by HC-RBC was increased even after only 4h of incubation with IS in a time-dependent manner (14±4.2%, 22±1.5±3 and 34±4.15% for 4h, 12h and 24h respectively) when compared to control cells (6.6±2.3%, 4.2±0.5% and 5.2±1.8%, respectively). ROS production was inhibited in the presence of NAC (6.6±3.4%, 6.3±2% and 13±4.10.5%) demonstrating the ability of an antioxidant to reverse the oxidative stress induced by IS.

Conclusions: Taken together our results suggest that IS in a high free concentration, which is in accordance with reported free toxin concentration in patients, induces ROS production in HC-RBC that precedes PS exposure. Thus, imbalance of RBC redox status induced by IS appears to be an important mechanism of elevated erytosis observed in CKD that consequently may contribute to renal anemia.

PUB069
Impact of Constitutive C-MIP Expression on Mouse T-Cell Proteome
Mario Ollero,1 Pauline Vachin,2 Cerina Chhuon,1 Kélhia Sendeyo,1 Melanie Mangier,1 Ida Chiara Guerrera,3 Andrè Pawlak,1 Djilali Sahali.1 INSERM, U955 (Eq. 21), Créteil, France; 2Plateau Protéomes Necker, Paris, France.

Background: The protein c-mip is overexpressed in lymphocytes and podocytes of MCNS patients. In order to dissect its role in INS pathogenesis, we generated a transgenic mouse expressing c-mip in peripheral mature T-cells. We aimed to evaluate the impact of c-mip expression on T-cell proteome in basal and stimulating conditions.

Methods: T-cells from transgenic (Tg) and control (Wt) mice (n=3) were purified by negative immunoselection, and subjected to anti-CD3 and anti-CD28 stimulation, to mimic T-cell activation by antigen presenting cells. At 0 and 60 min post-activation, total proteins were collected and proteins from Tg and Wt were labeled with iTRAQ and mixed in a 2:1 ratio for mass spectrometry analyses.

Results: The expression levels of 2660 proteins were compared in the four conditions. As a result, 46 proteins were found differentially expressed between Tg and Wt mice as a function of stimulation (p<0.05).

Conclusions: Our results indicate that increased c-mip expression can affect T-cell proteome in basal and stimulating conditions, which could be a valuable tool for investigating T-cell regulation mechanisms.

PUB070
An Investigation into the Prognosis of Nephrotic Syndrome and Regulatory T Cells in Elderly People
Tetsuhiro Yamano,1 Internal Medicine, Fukusuka Univ, Fukuoka, Japan.

Background: Peripheral blood flow cytometry analysis of nephrotic syndrome (NS) in children has been performed, and among T cells, regulatory T cells (Tregs) are involved in NS. Therefore, there are reports about Tregs and ANCA-associated glomerulonephritis, and the nephritic inhibitory effect of Tregs has become clear. As there has been no investigation focusing only on NS in elderly people, we conducted the analysis in this study.

Effects of 1,25-Dihydroxy Vitamin D₃ on Treg Cells, Interleukin-17, RORγt in Rats with IgA Nephropathy  

Hui Guo, Div of Nephrology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; Div of Rheumatology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China.

Background: To investigate the relationship between Treg cells, RORγt, IL-17 and rats with IgA nephropathy; to explore the intervention effect of 1,25(OH)₂D₃ on Treg cells, RORγt, IL-17 expression in rats with IgA nephropathy.

Methods: We chose Wister 52 rats, with which 8 rats were chosen in control group (group E) in random, while other 44 rats were established the IgA nephropathy group. After treatment with 1,25(OH)₂D₃, the level of Foxp3 increased significantly.

Conclusions: Treg cells, IL-17 and RORγt may participate in the occurrence/development of IgAN; 1,25(OH)₂D₃ may play a role in immune regulation by regulating the expression of Treg cells, IL-17 and RORγt directly or indirectly.

MGRS, Complement and C3 Glomerulopathy  

Yuzhou Zhang,² Fernando C. Fervenza,¹ Christopher D. Blosser,¹ Peter M. Fitzpatrick,¹ Dingwu Shao,¹ Niamh Kieran,¹ Carla M. Nester,¹ Sanjeev Sethi,¹ Nicolea Leca,² Richard J. Smith,¹ Curver College of Medicine, Univ of Iowa, Iowa City, IA;¹ Mayo Clinic, Rochester, MN;² Univ of Washington Medical Center, Seattle, WA;¹ Mayo Clinic, Jacksonville, FL.

Background: Monoclonal gammapathy of renal significance (MGRS) implies a causal relationship between clonal B cell proliferation and renal failure. By definition, these patients do not meet criteria for overt multiple myeloma/B-cell proliferation, however the significance of this disorder is not of undetermined significance. Rather, it is associated with high morbidity secondary to renal compromise induced by circulating monoclonal immunoglobulins (MIg). Recently, a subset of MGRS with dominant glomerular C3 deposition or MGRS-C3 glomerulopathy (C3G) has been reported.

Methods: Factor H (FH) autoantibodies, free light chains against FH and factor B (FB) autoantibodies were detected by ELISA. C3 nephritic factors were detected using ELISA and hemolytic-based assays.

Results: Six patients developed MGRS-C3G triggered by four different mechanisms of action. The first mechanism of action, identified in three patients, was an IgG form of MIg to FH. These FH autoantibodies compromised function of FH, the only fluid-phase negative regulator of the alternative pathway (AP) of complement. The second mechanism, identified in one patient, was a free light chain (FLC) form of MGRS against FH. The FLCs acted as min autoantibodies against the N-terminus of FH and impaired cofactor activity. The third mechanism, also identified in one patient, was an IgG form of MIg to FB as FB autoantibodies, resulting in increased activity of C3 convertase (C3bBb). The final mechanism, identified in one patient, was an IgG form of MIg, as a C3 nephritic factor that bound to and stabilized C3bBb.

Conclusions: These findings highlight the variability in autoantibodies associated with MGRS-C3G, thus mandating a comprehensive and detailed analysis of the alternative pathway in these patients. Acknowledgment: We gratefully acknowledge both the clinicians across North America who allow us to study their patients, and the patients, whose participation enhances our understanding of rare complex renal diseases.

Elucidation of Tubulo-Interstitial Injury in Chronic Kidney Ischemia by Use of Novel Renal Artery Coiling Model  

Kentarou Fujii, Kazutoshi Miyashita, Hiroiuki Inoue, Aika Hagiwara, Masanori Tamaki, Masaki Sato, Hiroshi Itoh. Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.

Background: Recent studies emphasize an essential role for tubulointerstitial hypoperfusion in the progression of chronic kidney disease (CKD) as a common pathway to end stage renal disease (ESRD). However, the mechanism of renal injury needs further to be elucidated.

Methods: Most previous animal models which aimed to simulate renal ischemia have been ischemic-reperfusion injury model, which shows major characteristics of acute kidney injury. To elucidate the progression of kidney dysfunction with chronic ischemia, we developed novel renal ischemia model by setting a coil around a left renal artery of right hemi-nephrectomy rats and reducing the kidney bloodstream by 80.5% . The coil was made of the titanium and the inside diameter is from 0.17 to 0.28 mm.

Results: After transient decline in renal function until post-operative day 14, slowly progressive renal functional decline and elevation of N-acetyl-

Toll Like Receptor 2, 4 and 9 Expression Is Enhanced in Kidneys of Patients with Anti Neutrophil Cytoplasmic Antibody Associated Vasculitis (AAV)  

Kim M. O’Sullivan, Anthony Longano, A. Richard Kitching,² Stephen R. Holdsworth,³ Dept of Medicine, Monash Univ, Clayton, Victoria, Australia;³ Dept of Nephrology, Monash Health, Clayton, Victoria, Australia;³ Pathology Dept, Monash Health, Clayton, Victoria, Australia.

Background: Toll like receptors (TLRs) may be the possible link between infection and autoimmunity. This study investigates the distribution of TLR2, 4 and 9 in human kidney biopsies from patients with AAV (40), lupus (8) and controls (with non proliferative glomerular lesions, minimal change and thin membrane disease, 10).

Methods: Biopsies were examined by confocal microscopy with immunofluorescent staining in serial sections for the cellular distribution of TLR2, 4 and 9. Mean fluorescent intensity (MFI) was measured by imaging software (Image J) and was correlated with histopathological parameters.

Results: TLR2, 4 and 9 in the AAV group, (for both MPO and PR3 patients) had significantly stronger staining than controls in glomeruli (1.5 ± 13.3AU; 0.25 ± 12.0AU, 0.7 ± 32.6AU, all P<0.05, respectively) and the interstitium (7.4 ± 63.0AU; 0.41 ± 53.8AU; 1.6 ± 59.6 AU, all P<0.05, respectively). The lupus patients also had higher remarkable changes from control kidneys and there are no findings of tissue injury and infiltration of inflammatory cells. However, the progression of tubulointerstitial fibrosis and the increase in the markers for apoptosis and oxidative stress were significant from post-operative day 28 to 84. Real-time quantitative PCR analysis in ischemic kidney revealed the progressive changes of the hypoxia-responsive gene expressions such as pyruvate kinase and hypoxia inducible factor.

Conclusions: These data suggest that the novel chronic renal ischemia model by coiling renal artery is an appropriate animal model for CKD, which shows a slowly progressive tubulointerstitial injury.

Dialysis Induces Morphological Changes and Erythropoiesis in Erythrocytes  

Grazia Maria Virzi, Sabrina Milan Manani, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco. IRRIV and Dept Nephrology Vicenza.

Background: Suicidal death of erythrocytes (erytosis) is characterized by cell shrinkage, membrane blebbing, activation of proteases, and phosphatidylserine (PS) externalization. Exposed PS is recognized by macrophages that engulf and degrade affected cells. Erytosis is a physiological mechanism under complex regulation. During their daily life, erythrocytes (RBCs) are exposed to several stressors, such as oxidative stress, osmotic shock, energy depletion. Erytosis is observed in a wide range of clinical conditions, such as CKD, malignancy, diabetes and sepsis. The aim of this study was analysed cell volume and PS abundance at the RBC surface in peritoneal dialysis (PD) and hemodialysis (HD).

Methods: 40 PD patients, 30 HD patients and 17 healthy subjects (CTR) were included in the study. All measurements were made in isolated RBCs. RBC volume and morphology was estimated from forward scatter, PS exposure at the cell surface was estimated from FITC-AnnexinV binding using flow cytometric analyses.

Results: We observed that PD and HD patients are indeed rather dramatically deranged in their morphology. Furthermore, the PS externalization on the RBC surface was significantly higher in these groups than in CTR (PD patients: 2.6%; IQR 1.6-3.7, HD patients: 2.2%; IQR 1.2-4.1 versus CTR: 0.8%; IQR 0.7-1.3; p<0.000001). We did not find significant differences in PS exposure between the PD and HD patients (p=0.47).

Conclusions: In conclusion, the percentage of erytosis has indeed been shown to be significantly higher in patients on dialysis than CTR. Our data suggest that dialysis may induce morphological changes in erythrocytes and may lead to a significant increase in erytosis, hence differences in its level were observed between PD and HD. Additional efforts will be required to define major erytosis-inducing components in uremic, PD and patients.

expression of TLR2 (4.8 AU), 4 (12.6 AU) and 7 (7.3 AU, P<0.05) compared with controls, but this difference was not significant compared to the AA V group for all TLRs (P<0.05). Cellular infiltrates contained intense staining for TLR2, 4 and 9 on macrophages and neutrophils in both glomeruli and interstitium. TLR2 and TLR4 staining was prominent on both endothelial cells and podocytes, although TLR9 was particularly evident on podocytes. In AA V glomerular TLR4 expression correlated with the % of normal glomeruli (r=0.48, P<0.05) suggesting TLR4 prominence occurs in early glomerular lesions. Glomerular TLR2 and 9 were present concurrently in more severely affected glomeruli (r=0.71, P=0.0001). TLR2, 4 and 9 were prominent in all crescentic glomeruli of AA V and lupus patients.

Conclusions: This study demonstrates that TLR expression is most prominent in AA V. Significant expression of TLRs was evident on leukocytes and intrinsic glomerular cells. TLR4 is prominent in early glomerular lesions, while TLR2 and 9 correlate with severe glomerular lesions.

Podocyte CD40 Expression in Patients with Post-Transplant FSGS

Results: Mc was detected more often in SLE patients than in controls (54.4% vs 13.6%, P<0.05). Mc was mostly fetal in origin in almost all cases. The median total number of fetal chimeric cells was significantly higher in patients than in controls (5.10^4 versus 2.510^4, P=0.048). In 50% of SLE patients with Mc, Mc originated from multiple relatives whereas in controls Mc was derived from only one relative. We found no relationship between Mc and clinical or laboratory parameters.

Conclusions: SLE patients had Mc in peripheral blood more often than controls, and at higher levels. We showed that Mc was mostly fetal in origin and, in SLE patients, could be derived from multiple relatives. Our findings substantiate the role for Mc in autoimmune diseases such as SLE.

Podocyte CD40 Expression in Patients with Post-Transplant FSGS

Recurrent Ruperto J. Maas, 1 Brigit Willensmeen, 2 Henry Jeroen Deegen, 1 Jack F. Wetzels, 3 Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: antibodies against CD40 were recently reported to predict post-transplant recurrent FSGS (rFSGS) with 78% accuracy (Delville et al. Sci Transl Med 2014). Using immunohistochemistry, the authors reported strong focal podocyte CD40 expression in glomerular lesions of two patients with rFSGS. We sought to validate this novel finding of podocyte CD40 expression as a potential marker of rFSGS.

Methods: We used formalin-fixed, paraffin embedded kidney tissue from five patients with rFSGS. Two samples were obtained from nephrectomy specimens, and three were needle biopsy specimens. All patients had nephrotic range proteinuria at the time of tissue sampling. A human tonsil was used as a positive control. For immunohistochemistry, four mm slides were cut and deparaffinized. After endogenous peroxidase block, antigen retrieval was performed by boiling in a microwave with EDTA buffer (pH 9.0). Slides were incubated with primary antibody mouse anti CD40 (clone 11E6, Abcam ab50849) diluted in PBS with 1% BSA overnight at 4°C. Detection was done with Brightvision biotin-free goat anti mouse/mouse poly HRP (Immunologic) and DAB as substrate.

Results: specificity and adequacy of the staining was confirmed by strong CD40 expression in tonsillar germinal centers (Figure, panel A). In kidney samples from patients with rFSGS, CD40 staining was found in areas of interstitial cellular infiltration, and some tubular epithelial cells (Figure, panel B). However, no glomerular CD40 was detected in any of the rFSGS samples.

Conclusions: we could not confirm glomerular CD40 staining in rFSGS with immunohistochemistry. The role of CD40 antibodies in rFSGS pathogenesis needs further study and validation.

Increased Cellular Microchimerism in Women with Systemic Lupus Erythematosus

Suzanne Wilhelms, 1 Malu Zandbergen, 1 Emile Rijnink, 1 Juan D. Diaz de Pool, 2 Mathilde M.M. Almekinders, 1 Hans J. Baelde, 1 Jan A. Rutger Maas, 1 Ingeborg M. Bajema.

1Pathology, Leiden Univ Medical Center, Leiden, Netherlands; 2Gynaecology, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Microchimerism (Mc) has been suggested to play a role in the development of systemic lupus erythematosus (SLE). We previously showed that Mc occurs twice as often in kidney biopsies of patients with lupus nephritis as in controls. Recently, it was demonstrated that the amount of Mc in lupus nephritis is associated with renal function deterioration (Tu et al. Am J Nephrol 2015). In this study, we examined the frequency, amount and origin of chimeric cells in SLE patients and controls, by using insertion-deletion polymorphisms and null alleles for the detection of Mc.

Methods: We included 11 SLE patients and 22 controls, as well as their children and mothers. A quantitative PCR for insertion-deletion polymorphisms and null alleles was used to detect Mc in peripheral blood mononuclear cells and granulocytes. The relationship between the presence of Mc and disease onset, disease activity and accumulated damage since disease onset was investigated.

Results: Mc was detected more often in SLE patients than in controls (54.4% vs 13.6%, P<0.05). Mc was mostly fetal in origin in almost all cases. The median total number of fetal chimeric cells was significantly higher in patients than in controls (5.10^4 versus 2.510^4, P=0.048). In 50% of SLE patients with Mc, Mc originated from multiple relatives whereas in controls Mc was derived from only one relative. We found no relationship between Mc and clinical or laboratory parameters.

Conclusions: SLE patients had Mc in peripheral blood more often than controls, and at higher levels. We showed that Mc was mostly fetal in origin and, in SLE patients, could be derived from multiple relatives. Our findings substantiate the role for Mc in autoimmune diseases such as SLE.

Absence of Caspase-1 Attenuates Adrenalin-Induced Nephropathy

Jinghui Luo,1 Yinghao Yang,1 J. Michelle Kahlenberg,2 Tamra J. Reed,2 Stephanie Wylie,1 Christopher Lund O’Connor,2 Jeffrey B. Hodgkin.1 1Pathology, Univ of Michigan, Ann Arbor, MI; 2Rheumatology, Univ of Michigan, Ann Arbor, MI; 1Univ of Michigan, Ann Arbor, MI.

Background: Recent studies have demonstrated a pathogenic role of caspase-1 in mediating proteinuria-associated renal injury. As a chronic proteinuric renal disease model, adrenalin-induced nephropathy (ANN) is characterized by podocyte injury followed by glomerulosclerosis (GS), tubulointerstitial inflammation and fibrosis, but the mechanisms underlying it remain poorly understood. Based on the evidence that oxidative stress stimulates inflammatory activation which subsequently contributes to renal injury, we hypothesized that abolishing caspase-1 expression in the kidney may be protective.

Methods: Male caspase-1 knockout (KO) and wildtype (WT) mice on the BALB/c background were injected with ADR (10.5 mg/kg) or saline at 8-10 weeks of age. Twenty-four-hour urine was collected and the mice were sacrificed 14 days post the injection. Creatinine, triglyceride, total cholesterol (TC), albumin and cell mitosis were determined.

Results: ADR triggered overexpression of caspase-1 and IL-1β in kidney tissue of WT mice, but not in that of KO mice. ADR induced albuminuria and GS, which was accompanied with decreased kidney weight/body weight ratio (Kw/Bw), and increased Cr and TCH levels in both KO and WT mice. Compared with WT animals, KO mice showed significantly lower ACR, reduced GS scores, increased Kw/Bw, and attenuated Cr levels (P<0.05 each). Meanwhile, elevated expression of TNF-α and INF-γ, augmented iNOS, and decreased PPAR-α, SDHA, and SOD2 levels were observed in ADR-treated kidneys, and all these changes were shown to be significantly ameliorated in KO mice. In addition, positive correlation between Cr and TCH was recognized in both KO and WT ADR-treated mice.

Conclusions: Cytokine-mediated inflammatory cascade, hyperlipidemia, and impaired mitochondrial function are all responsible for ADR-induced kidney injury. Caspase-1 may be a potential therapeutic target in proteinuric renal disease.

Glucomer H1-O1 Expression Control by Hemin: Role of Hemoxpin

Maria Detsika,1 Vasileios Atsaves,1 Emanuela Tolosano,2 Pu Duann,1 Elias A. Lianos.1,2 1Medicine, Univ of Athens, Athens, Greece; 2Medicine, Rutgers Biomedical and Health Sciences, NJ; 3Molecular Biotechnology Center, Univ of Toronto, Italy.

Background: Hemoxpin (HPX) maintains low free heme levels in serum thus mitigating heme-associated cell injury. HO-1 induction also minimizes injury by degrading heme to CO and bile pigments. In hemolytic disorders, heme scavenging by HPX is hypothesized to be sufficient. In contrast, in hemolytic disorders (HPX+/−) or HPX-deficient (HPX−/−) mice, exposure to high heme (200, 400 µM) markedly reduced HO-1. This reduction was attenuated in incubations with varying dilutions of HPX medium, and increased by 2-fold in incubations with 10% HPX+ serum. The effect of heme was added at concentrations encountered in hemolytic disorders (100-400 µM). HO-1 protein levels were assessed by western blot.

Results: HO-1 protein was reduced by 70% in hemoxy 1 and increased by 2-fold in 10% HPX+ glomeruli. HO-1 protein levels were different between 10% HPX+ serum vs serum-free media. In incubations with varying dilutions of HPX serum (1.25, 2.5, 5, 10, 100, 1000 µM) HO-1 levels in WT glomeruli progressively increased and were 2.5-fold higher with 10% HPX serum compared to 100% HPX serum. Co-incubation with 10% HPX serum and heme (200, 400 µM) markedly reduced HO-1. This reduction was attenuated in incubations with higher dilutions (2.5%) of HPX serum or with 10% HPX+ serum. The effect of heme on HO-1 levels in glomeruli incubated with HPX serum was recapitulated in GECs

Conclusions: Heme-mediated HO-1 induction in glomeruli is limited by HO-1 expression levels attained. This may serve to limit level of HO activity thereby preventing heme to CO and bile pigments. In hemolytic disorders, heme scavenging by HPX is hypothesized to be sufficient. In contrast, in hemolytic disorders (HPX+/−) or HPX-deficient (HPX−/−) mice, exposure to high heme (200, 400 µM) markedly decreased compared to Wt. In contrast, HO-1 expression and cell adhesion were all responsible for ADR-induced kidney injury. Caspase-1 may be a potential therapeutic target in proteinuric renal disease.

Glocomer H1-O1 Over Expression: Protective Effects in Secondary but Not Primary GEC Injury

Vasileios Atsaves,1 Maria Detsika, Elias A. Lianos, Medicine, Univ of Athens, Athens, Greece; Medicine, Rutgers Biomedical and Health Sciences, N. Brunswick, NJ.

Background: In contrast to tubular epithelial cells, induction of the cytoprotective enzyme, Heme Oxygenase (HO-1), in response to injury in epithelial glomerular cells (GEC) is limited or absent and this may increase their vulnerability to injury. We, therefore, expected that abolishing HO-1 expression in GEC, the protectant against primary injury, induced by puromycin aminonucleoside (PAN) or secondary injury resulting from anti-GBM Ab induced glomerulonephritis (GN).

Methods: HO-1 over expression in GEC of Sprague-Dawley (SD) rats was achieved by overexpressing aFLAG-human(h)HO-1 sequence under the control of a murine nephrin promoter using transposon-mediated gene-trap insertion mutagenesis based on a Sleeping Beauty(SB) transposon system (SB rats). GEC-targeted over expression was validated by FLAG immunolocalization and/or western blot. PAN-mediated GEC injury was induced in SD rats by a single intraperitoneal injection. GN was induced by a single intravenous injection of a rabbit anti-rat GBM Ab. At defined points following PAN or anti-GBM Ab injection, albuminuria (Ualb/Ucreat) was assessed and glomeruli were isolated to determine changes in HO-1 and nephrin expression (GEC integrity marker).

Results: In glomeruli from SB rats HO-1 levels (protein) increased compared to Wild type (Wt). Administration of either PAN or anti-GBM Ab to Wt rats increased gloomerular HO-1. In SB rats receiving PAN, HO-1 markedly decreased compared to Wt. In contrast, HO-1 protein levels were increased by 4-fold following an injection of Exogenous nephropathy (NPX) ex vivo in glomeruli from SB rats treated with PAN. In contrast, nephrin was preserved in glomeruli from SB rats treated with anti-GBM Ab. Ualb/Ucreat was significantly higher in WT compared to SB rats treated with anti GBM Ab. In contrast, there was no difference in Ualb/Ucreat between Wt and SB rats receiving PAN.

Conclusions: Augmentation of HO-1 expression in primary GEC injury is impaired. This could be yet another mechanism contributing to GEC vulnerability in primary podocytopathies.

Comparative Evaluation of Cellular Injury Models Based on Conditionally Immortalized and Primary Podocytes

Vivek C. Abraham,1 Loan N. Miller,1 Caton Brent Pulman,1 Laura Kim,2 Steve Pratt,2 Sujatha M. Gopalakrishnan,2 Andrew J. King,1 Renal Discovery, Abbvie, North Chicago, IL; 2High Throughput Screening, Abbvie, North Chicago, IL.

Background: Podocyte injury is a hallmark of proteinuric chronic kidney disease. The two podocytopathies to study the cellular level of renal reorganization, oxidative stress, de-differentiation & detachment. The purpose of this study was to compare commonly used conditionally immortalized podocytes with primary podocytes, by measuring podocyte markers and responses to injury.

Methods: Primary human podocytes were isolated and cultured from a healthy human donor kidney and compared to 1) a subclone (C5) of conditionally immortalized human podocytes (selected based on podocyte specific gene expression) and 2) conditionally immortalized mouse podocytes. Cellular phenotypes and gene expression were measured using high content screening (HCS), qPCR and western blots. For assessment of diabet onic stress the stressor used was streptozotocin and a-smooth muscle actin and 2) cytoketal and cell cycle phenotypes. C5 cells were also evaluated by comparing gene expression profiles in response to TGF-b treatment. C5 podocytes were judged to be similar to primary human podocytes based on these analyses. Current cellular models of podocyte protection often use the stressors puromycin aminonucleoside and TGF-b. We demonstrate cytoprotection by multiple reference compounds with these insults. We have also increased the disease relevance of stressors by showing that serum isolated from diabetic db/db mice differentially elicits podocyte injury across multiple parameters.

Conclusions: Our results validate the use of conditionally immortalized C5 podocytes by benchmarking against primary human podocytes. We have also enhanced the pathologic relevance of models of podocyte injury by incorporating key disease-relevant stressors and readouts.

Hypoxia Stimulates the Expression of Tissue Factor in Human Podocytes in Culture

Iwayo Narita,1 Michiko Shimada,1 Reichi Murakami,1 Masayuki Nakamura,1 Norio Nakamura,1 Moin Saleem,2 Peter W. Mathiesen,1 Hideaki Yamabe,1 Ken Okamura.1 1Nephrology, Hirosaki Univ, Hirosaki, Japan; 2Renal Academic Unit, Univ of Bristol, Bristol, United Kingdom; 3Univ of Hong Kong, Hong Kong, China.

Background: Hypoxia contributes to tubulointerstitial injury, however, the effect on podocytes and its underlying mechanisms are less well understood. Tissue factor (TF) is the initiator of extrinsic coagulation pathways and is also related to various biologic effects such as migration, proliferation, and apoptosis. We demonstrate the expressions of TF and tissue factor pathway inhibitor (TFPI) in the hypoxic conditions. We further tested the roles of known transcription factors of TF such as, nuclear-factor-kB (NF-kB) and early growth response gene-1 (Egr-1), as well as hypoxia-inducible factor-1 (HIF-1a) which regulates numerous changes in hypoxia.

Methods: Conditionally immortalized human podocytes were grown at 33°C and differentiated at 37°C. The cells were treated in normoxic or hypoxic conditions. mRNA expressions of TF and TFPI were analyzed by quantitative RT-PCR, and protein levels of TF and TFPI were assayed by western blot and found that TFPI was upregulated by HIF-1a. The expression of TF and HIF-1a were demonstrated by immunofluorescent staining. We used siRNA for the temporal knockdown of HIF-1a and Egr-1, and pyrrolidine dithiocarbamate (PDTC) for the inhibition of NF-kB.

Results: Hypoxia increased mRNA expression of TF (6h: 2.3±0.05 fold, p<0.001, 24h: 5.6±2.9 fold, p<0.001 ) compared with Normoxia. The protein levels of TF in the cell lysate were increased and TFPI in the supernatant were decreased. The TF staining was enhanced in

the cytoplasm of podocyte. As expected, HIF-1α was strongly stained in the nuclei of podocytes exposed to hypoxia for 6h. The expression of TF was not affected by HIF-1α siRNA, and neither Egr-1 siRNA. Whereas, PDTC reduced the induction of TF by hypoxia.

Conclusions: Hypoxia upregulated the expression of TF in human podocyte NF-κB dependently, and HIF-1α and Egr-1 independently. These changes may be related to the podocyte disorders and lead to proteinuria in the hypoxic condition.

PUB087

Integrity of the Mature APOL1 Protein Is Indispensable for Its Toxicity Xianan Lan,1 Hongxiu Wen,2 Aswathi Mallhotra,1 Karl Leon Skorecki,2 Pravin C. Singhal.1 1Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 2Medicine, Rambam Health Care Campus, Haifa, Israel.

Background: Several clinical reports have demonstrated that the development of higher rates of non-diabetic glomerulosclerosis (GS) amongst African Americans can be attributed to two coding sequence variants (G1 and G2) in the APOL1 gene. Recent studies indicate that the gene products of these APOL1 risk variants have augmented toxicity in kidney cells. The APOL1 protein is composed of several functional domains, including signal peptide (SP), pore forming domain (PFD), membrane address domain (MAD), and SRA-interacting domain. However, it is not clear, which domain contributes to APOL1 induced cellular toxicity. In case, specific domain is contributing to APOL1-induced cellular toxicity, it will suggest us to design therapeutic strategy to target the specific domain.

Methods: To investigate the relative contribution of each domain to cell injury, we constructed serial of expression vectors to delete each domain, we transfected these vectors into the human embryonic kidney cell line 293T, and then compared the cytotoxicity. In addition, we conducted studies in which APOL1 wild type (G0) was co-transfected in combination with G1 or G2 to see whether G0 could counteract the toxicity of the risk variants.

Results: The results showed that deleting the SP did not abrogate the toxicity of APOL1, though deletion of 26 amino acid residues at the N-terminal partially decreased the toxicity. Deleting PFD or MAD or SRA-interacting domain abolished toxicity, while, overexpressing each domain alone could not cause toxicity to the host cells. Deletion of the G2 sites while retaining G1 sites in the risk state resulted in persistent toxicity. Either deletion or exchanging the BH3 domain in the PFD led to complete loss of the toxicity in this experimental platform. Adding G0 to either G1 or G2 did not attenuate the toxicity of the either moiety.

Conclusions: These findings indicate that the integrity of the mature APOL1 protein is critical for its toxicity.

Human Podocyte Depletion: The Effects of Ageing and Hypertension Victor G. Puelle's,1 Luisa A. Cullen-McEwen,1 Jinhua Li,1 Peter G. Kerr,2 Wendy E. Hoy,2 John F. Bertram.1 1Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; 2Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia; 1Centre for Chronic Kidney Disease, The Univ of Queensland, Brisbane, Queensland, Australia.

Background: Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Many kidney diseases are more common in older age, and usually coexist with the presence of hypertension. We hypothesize that podocyte depletion develops with aging and is exacerbated by the presence of hypertension.

Methods: Kidneys from 21 adult Caucasian American males without overt renal disease were collected at autopsy in Mississippi, USA. Subjects were categorized based only on age as young adults, middle-aged adults and older adults. Subjects were also categorized based on age and hypertension as young normotensives, older normotensives, and older hypertensives. Demographic data were collected from available medical records. Design-based stereology was used to estimate individual glomerular volume (IGV), podocyte number and podocyte density. Data are presented as mean±SD.

Results: Glomeruli from young adults (22.0±2.7 years; n=6) were smaller (1.72±0.50 x10³/mm²) and contained 457±97 podocytes and 278±66 podocytes per 10³/m² of glomerular tissue. Glomeruli from older adults (60.0±8.6 years; n=7) were larger (2.94±1.41 x10³/mm²; P<0.001), contained fewer podocytes (390±105; P<0.05) and had lower podocyte density (156±65 podocytes per 10³/mm²; P<0.001). Among normotensives, older age was associated with a 15% increase in IGV (P=0.28), a 12% decrease in podocyte number (P=0.06) and a 17% decrease in podocyte density (P=0.03). Glomeruli from hypertensives and normotensives contained similar numbers of podocytes, but hypertensives had larger glomeruli (P=0.0001) and a markedly lower podocyte density (P<0.001).

Conclusions: These findings demonstrate that both aging and hypertension are independent and additive contributors to podocyte depletion in this cohort of white American men without overt kidney disease.

PUB089

Alport Nephropathy Progression Involves Altered Glomerular Mechanical Properties and Activation of the Unfolded Protein Response Addie Embry,1 Liping Liu,1 Leslie A. Bruggeman,2 Paul A. Janney,3 R. Tyler Miller.1 1Medicine, UTSW, Dallas, TX; 2Medicine, CRWRU, Cleveland, OH.

Background: Tissue and cell mechanics are important factors in the development and maintenance of tissues but are not well defined in renal disease. We determined the biophysical properties of glomeruli over the course of disease in the Col4a3−/− (Alport) mouse.

Methods: Glomerular EMod was measured with microindentation, gene transcript levels with qRT-PCR and immunofluorescence, and kidney structure with histology.

Results: Col4a3−/− kidneys have normal histology, no proteinuria, and a normal glomerular EMod (~2200Pa) through 2.0 mo of age. At approximately 4.0 mo, early interstitial and glomerular fibrosis and proteinuria appear, and the glomerular EMod decreases (~1400Pa). Glomerular softening is characterized of injured glomeruli, is associated with injured podocytes, and could lead to capillary injury even with normal hemodynamics. By 6 mo, the glomeruli regain their original EMod (~ 2200 Pa) but with increased proteinuria and more severe glomerular and interstitial fibrosis. By 7-8 mo, the glomerular EMod increases (~ 2,600 Pa) with further increases in proteinuria and glomerular and interstitial fibrosis. At 2 mo, glomerular transcripts for matrix and fibrinotic factors (CTGF, α-SMA, filamin, lysyl oxidase) are increased and remain so, demonstrating early responses of cells to alter their mechanical environment. Transcripts associated with UPR activation (BiP, CHOP, grp94) are elevated, suggesting that loss of the Col4a3 chain leads to activation of the UPR. Tunicamycin-treated glomeruli demonstrated a markedly reduced EMod (~1100Pa), suggesting that UPR activation causes glomerular injury.

Conclusions: Biophysical abnormalities occur early in the course of this Alport model, suggest that the reduced EMod of glomeruli (increased deformability) may lead to mechanical injury of capillaries even with normal hemodynamic force, that cells of glomeruli respond by producing proteins that will reduce deformability, and that glomerular or podocyte injury may be attributable to activation of the UPR.

A New Assay to Study Podocyte (De)Differentiation Frances Kindt, Karlhans Endlich, Nicole Endlich. Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany.

Background: Podocytes play an essential role in the formation and maintenance of the glomerular filtration barrier. Glomerular disease is associated with podocyte damage, frequently resulting in podocyte dedifferentiation. The loss of podocyte differentiation is poorly understood. Moreover, there are no drugs available that could halt or even reverse podocyte dedifferentiation. Since podocytes of isolated glomeruli have long been known to spontaneously lose their highly differentiated state over time, we established an assay to follow dedifferentiation of living podocyte in isolated glomeruli over time.

Methods: Using magnetic separation with dynabeads, glomeruli were isolated from transgenic mice that express cyan fluorescence protein (CFP) under control of a nephrin promoter fragment (Cui et al., "in press"-“font-family: ‘Times New Roman’; font-size: 10pt;”>). Isolated glomeruli were transferred to 35-mm tissue culture dishes with a medium containing 10% FBS, and fed with low calcium. After 72 hours, isolated glomeruli showed intact immunostaining for nephrin, and expressed high levels of CFP fluorescence as a measure of differentiation, we recorded z-stacks of several glomeruli with confocal laser scanning microscopy on each day. Mean total fluorescence intensity (CFP fluorescence) was calculated from a stack of images taken at different times.

Results: Isolated glomeruli dedifferentiated over time, as indicated by free Bowman’s capsule, exhibited diminished cell damage as assessed by propidium iodide, showed intact immunostaining for nephrin, and possessed intact interdigitating foot processes as judged by scanning electron microscopy. Isolated glomeruli were cultured for up to 9 d in RPMI containing 10% FBS. To quantify CFP fluorescence as a measure of differentiation, we recorded z-stacks of several glomeruli with confocal laser scanning microscopy on each day. Mean total fluorescence intensity per glomerulus (CFP) was calculated from z-stacks after background correction. CFP remained stable for 5 d. Thereafter, CFP gradually decreased to 10% of the initial value on day 9. Dedifferentiation of podocytes could be accelerated by treatment of isolated glomeruli with doxorubicin, strongly decreasing CFP within the first 3 days.

Conclusions: In summary, we established a new assay to study podocyte (de)differentiation. This assay may help to understand the molecular mechanisms of the loss of podocyte differentiation, and may allow to screen for compounds that stabilize podocyte differentiation.

PUB091

Methods to Selectively Remove Murine Endothelial Glycocalyx In Vivo Using Glycosaminoglycan Digesting Enzymes without Causing Non-Target Effects Karen L. Onions, Anjila Onifade, Chris R. Neal, Monica Gamez, Gavin Iain Welsh, Andy Salmon, Simon C. Satchell, Rebecca R. Foster. Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.

Background: The endothelial glycocalyx (e-GLX) is an important component of the glomerular filtration barrier (GFB), damage to which increases vascular permeability and microalbuminuria. Jeunsson and Haraldsson previously used glycosaminoglycan (GAG) digesting enzymes to study the role of the e-GLX in glomerular permeability. However, e-GLX removal was not directly quantified. The aim of this research was to confirm removal of systemic e-GLX and identify any non-targeted effects in the glomerular or coroanary microcirculation.

Methods: Mice were injected L.V with chondroitinase (Ch) and hyaluronidase (Hy) at a high (Ch: 87 mg/kg, Hy: 15 mg/kg) or low (Ch: 0.87 mg/kg, Hy: 15 mg/kg) dose. Mice
were whole body (cardiac) perfusion fixed with gluteraldehyde containing Alcian blue to stain the e-GLX. Transmission electron microscopy (TEM) was used to image the ultrastructure of the heart and glomerular microcirculation, which was quantified using an image analysis program which is augmented in response to salt deprivation.

**Results:** In summary, we developed a novel and sensitive method to monitor changes in GP using two-photon microscopy, which can be used for rodents and bigger animals.

**Conclusions:** In summary, we identified how e-GLX contributes to glomerular albumin permeability in different pathological scenarios and may highlight new therapeutic targets. This work was supported by the British Heart Foundation (FS/13/09/2957).

**A Novel Method to Measure Glomerular Permeability**

**Jin Wei, Shaohui Wang, Lei Wang, Gensheng Zhang, Jie Zhang, Byeon Cho, Kay-Pong D. Yip, Ruisheng Liu.**

**Molecular Pharmacology & Physiology, Univ of South Florida, Tampa, FL.**

**Background:** Glomerular capillaries are relatively impermeable to proteins, but in certain kidney diseases, such as diabetic nephropathy, the glomerular permeability (GP) is increased and some of the lower molecular weight (LMW) proteins, especially albumin, are filtered through the glomerular barrier into the Bowman’s space. Increased GP is a hallmark for many kidney diseases. Proteinuria is often implicated for impaired GP. However, since LMW proteins can be reabsorbed by proximal tubules, proteinuria is detected only when the GP is significantly increased. Recently, real-time quantification of GP can be visualized by two-photon microscopy, but it can only be applied to superficial nephrons, where laser can penetrate, in Munich-Wistar rats. We developed a novel method to monitor GP in C57/BL6 mice by using florescent lysine-fixable dextran conjugates without these limitations.

**Methods:** 100µl Tomato Lectin 594 (endothelial cell marker) plus 50µl 40 KD lysine-fixable dextran 488 (fluid phase marker) were injected intravenously. The kidneys were removed 1 min later and put into liquid nitrogen immediately for 10 minutes followed by fixation with 10% Formalin on ice overnight. Then 10µm thick sections were prepared using a vibratome and the florescent images were collected with two-photon microscopy. The ratio of florescent intensity in Bowman’s space over that of in glomerular capillary lumen was used as an index of GP.

**Results:** In WT mice, the GP is extremely low with a ratio of 0.16±0.08%, N=6 (figure1). In contrast, in diabetic mice induced by alloxan for 8 weeks, the GP is significantly increased with a ratio of 5.9±1.3%, N=6 (figure2).

**Conclusions:** In summary, our data are consistent with highly dynamic cellular remodeling of the renal interstitium, vasculature, glomerulus, and the proximal tubule by single progenitor cells. These results also suggest the presence of a complex nephron repair program which is augmented in response to salt deprivation.

**Vasopressin Regulates the Uptake of Extracellular Vesicles by Kidney Collecting Duct Cells**

**Wilna Oo Oo Thuzaw, 1  Jonathan Street, 1  Andrea Caporali, 1  David J. Webb, 1  Chris Gregory, 1  Matthew A. Bailey, 1  James W. Dear. 1  Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom; 2 National Inst of Diabetes and Digestive and Kidney Diseases, National Insts of Health; 3 MRC/Univ of Edinburgh Centre for Inflammation Research, Univ of Edinburgh, United Kingdom.**

**Background:** Urine contains extracellular vesicles (ECVs) originating from the circulation and all cells lining the urinary tract. ECVs are a route of inter-cellular communication along the nephron able to transfer protein and RNA. It is not known whether this is a regulated process analogous to other cell-to-cell signalling systems.

**Methods:** Kidney cortical collecting duct cells (CCDs) were stimulated with desmopressin, a vasopressin analogue, and uptake of fluorescently-loaded or microRNA-loaded ECVs was measured. In mice, fluorescently-loaded ECVs were intravenously injected before and after administration of the V2 antagonist, tolvaptan, and urinary ECV excretion was measured. By combining antibodies to nephron segment-specific proteins with nanoparticle tracking analysis we measured human urinary ECV excretion in central diabetes insipidus (DI) and after radiocontrast exposure (n=37).

**Results:** Desmopressin stimulated ECV uptake into CCDs via V2 receptor stimulation. Intra-cellular uptake of ECVs was confirmed by microRNA specific mRNA down-regulation. Mechanistically, ECV uptake in response to desmopressin required cyclic AMP production, was mediated by clathrin-dependent endocytosis and was selective for ECVs from kidney tubular cells. In mice, basally, 2.5% of injected ECV’s were recovered in urine; tolvaptan treatment resulted in a 5-fold increase. In DI, desmopressin reduced the excretion of ECVs derived from upstream glomerular and proximal tubule cells. In patients exposed to radiocontrast, urinary ECVs from the glomerulus were positively correlated with the tubular injury markers KIM-1 and NGAL.

**Conclusions:** Tubular ECV uptake is a specific, hormonally regulated process that is reduced with injury. Physiologically, ECV’s are a mechanism of inter-cellular communication; therapeutically, ECVs represent a novel vehicle by which RNA therapy could be targeted for the treatment of kidney disease.

**Systemic Hypertension and Pro-Inflammatory Cytokines**

Massimo di Cal,1 Grazia Maria Virzi,1 Alessandra Brocca,1 Salvador Roberto Lopez,1 Jose Luis Salas,1 Stefano Marcante,2 Silvia De Rosa,1 Claudio Ronco,1 1Nephrology, S.Bortolo Hospital, Vicenza, Italy; 2ICU, S.Bortolo Hospital, Vicenza, Italy.

**Background:** Cytokines produced by renal tubular epithelial cells are critical factors in inflammatory processes of renal ischemia-reperfusion injury. Increased levels of cytokines have been reported after resuscitation from cardiac arrest. Pro-inflammatory cytokines, such as IL-1β, IL-6 and IL-18, produced in the kidney during ischemia-reperfusion injury, are able to contribute to the renal damage. The purpose of this investigation was to define the proinflammatory cytokines response after resuscitation and during extended observation following therapeutic hypothermia phases.

**Methods:** We performed a prospective observational study in 36 post-cardiac arrest patients treated with Induced Hypothermia (IH) with two different cooling device: 1)Artic Sun; 2)Blanket. On Admission time and at 12, 24, and 72 hours after the start of treatment, blood and urine samples were collected. Plasma cytokines were measured by ELISA.

**Results:** During IH, we observed a decrease of IL-6, IL-1β and IL-18u levels in both groups, and an increase of inflammatory during rewarming phase. The results are showed in table.

**Impact of Different I.V. Iron Preparations on Monocyte Function and Differentiation**

Adam M. Zawada,1 Lisa H. Fell,1 Sarah Seiler,1 Martina Sester,1 Danilo Fliser,1 Gunnar H. Heine. 1Internal Medicine IV, Saarland Univ Medical Center, Homburg, Saarland, Germany; 2Dept of Transplant and Infection Immunology, Saarland Univ Medical Center, Homburg, Saarland, Germany.

**Background:** Treatment of iron deficiency with intravenous (i.v.) iron is a first-line strategy to improve anaemia and quality of life in patients with chronic kidney disease (CKD). However, in vitro and in vivo experiments demonstrated that certain i.v. iron preparations have immunological side-effects. In the present study we now investigated substance-specific impacts of different i.v. iron preparations on monocyte function and differentiation.

**Methods:** We in vitro stimulated monocytes with different concentrations (0.133 mg/ml, 0.266 mg/ml, 0.533 mg/ml) of iron sucrose (IS), sodium ferric gluconate (SFG), ferric carboxymaltose (FCM), and iron isomaltoside 1000 (IIM) and assessed monocytic adhesion and transmigration capacity. Monocyte differentiation into M1 and M2 macrophages and transmigration capacity were significantly reduced in IS and SFG stimulated monocyte derived cells. Finally, we performed ultra-deep miRNA sequencing and immunoprecipitation showed that phosphorylated CD16-CD7-nephrin interacted with wild type c-Abl indicated that the colocalization of nephrin and c-Abl showed in table.

**The Involvement of p38 MAPK in Neutrophil Bacterial Dysfunction of Hemodialysis Patients**

Yasutaka Kamikawa, Shinji Kitajima, Akinori Harahori, Norihiko Sakah, Miho Shimizu, Kengo Furuchi, Yasunori Iwata, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

**Background:** Mortality from infection has been reported to be higher in hemodialysis (HD) patients than that in healthy subjects. However, the precise mechanism causing it remains to be investigated. Neutrophils play crucial roles in host defenses against bacterial infection. Therefore, we investigated the impact of neutrophil inflammatory signal on bactericidal function in HD patients.

**Methods:** Four HD patients and six healthy subjects were recruited for this study. None of HD patients had diabetes, cardiovascular disease and cancer. Neutrophils were isolated from peripheral blood by density gradient centrifugation. The purity was tested by flow cytometry after lactofemin staining. Microarray analysis was performed to assess global gene expression in leukocytes. Neutrophil bactericidal function was evaluated by the growth rate of Staphylococcus aureus (S.aureus) after co-culture of it with neutrophils obtained from HD patients or healthy subjects. Reactive oxygen species (ROS) production and myeloperoxidase (MPO) activity were analyzed by florescence intensity.

**Results:** Microarray analysis showed the impairment of p38 mitogen activated protein kinase (MAPK) signal in neutrophils from HD patients. The growth rate of S.aureus was higher in HD patients than that in healthy subjects (490.1±147.1%, 144.5±40.4%, respectively; p=0.01) suggesting that neutrophil anti-bacterial killing function was dysregulated in HD patients. The levels of ROS from neutrophils after co-culture with S.aureus were lower in HD patients than those in healthy subjects (14±6±8.3, 32±4.1±5.4, respectively; p=0.01). On the other hand, there was no difference of MPO activity between both groups. To confirm the importance of p38 MAPK, we examined the effect of the selective pharmacological p38 MAPK inhibitor SB202190 on neutrophil bactericidal function. The treatment with SB202190 suppressed anti-bacterial killing function as well as ROS production in neutrophils.

**Conclusions:** Impaired of p38MAPK signaling pathway might contribute to the suppression of neutrophil bactericidal function in HD patients through the dysregulation of ROS production.
Nrf2 and NF-xb mRNA Expression in Chronic Kidney Disease: A Focus on Non-Dialysis Patients

Denise Mafra,1 Viviane Oliveira Leal,2 Juliana Saldanha,1 Milena Barzca Stockler-Pinto,3 Ludmila Fmf Cardo,4 Felipe Rizzetto Santos,2 Alex Sandro Duarte Albuquerque,4 Maurilio Leite.4 *Graduate Program in Medical Sciences, Federal Univ Fluminense, Rio de Janeiro, Brazil; 2Pedro Ernesto Univ Hospital, State Univ of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil; 3Graduate Program in Cardiovascular Sciences, Federal Univ Fluminense, Rio de Janeiro, Brazil; 4Div of Nephrology, Federal Univ of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil.

Background: Nuclear factor erythroid 2-related factor 2 (Nrf2), a regulator of genes encoding antioxidant and detoxifying enzymes appear to be downregulated in chronic kidney disease patients undergoing hemodialysis (HD). However, data regarding the expression of Nrf2 in non-dialysis patients are scanty. Thus, the aim of this study was to evaluate Nrf2 and nuclear factor kappa-B (NF-xb) mRNA expression in non-dialysis patients, comparing with data from HD patients.

Methods: 20 non-dialysis patients, 20 HD patients and 11 healthy subjects were enrolled. The peripheral blood mononuclear cells were isolated and processed for the evaluation of NF-xb and Nrf2 expression by quantitative real-time polymerase chain reaction.

Results: Nrf2 mRNA was significantly higher in non-dialysis when compared to HD patients but similar to healthy individuals. Inversely, NF-xb mRNA was lower in non-dialysis when compared to HD patients and also similar to healthy individuals i.e.

**Figure 1.** Nrf2 and NF-xb mRNA expression in healthy individuals, non-dialysis and HD patients.

Nrf2 mRNA was positively correlated with NF-xb mRNA in non-dialysis patients and healthy individuals. By contrast, Nrf2 mRNA was inversely correlated with NF-xb mRNA in HD patients.

Conclusions: Non-dialysis patients may conserve regular homeostatic balance between Nrf2 and NF-xb expressions, being comparable to healthy individuals. As renal disease progresses to more advanced stages, an impaired Nrf2/NF-xb balance can be observed, as in HD patients.

Chinese Herbal Medicine for IgA Nephropathy, ShenPing Decoction, Blocks Platelet-Derived Growth Factor Signaling Pathway Activated by IgA1-Containing Immune Complexes in Human Mesangial Cells

Xiaowan Zhang,1 Xi Chen,2 Zhiqiang Huang,2 Stacy D. Hall,2 Lin Wang,2 Yueyi Deng,2 Bruce A. Julian,2 Yiping Chen,1 Jane Mei. Nephrology: The First Affiliated Hospital of China Medical Univ, Shenyang, China.

Background: IgA nephropathy (IgAN) is characterized by mesangial immunodeposits containing galactose-deficient IgA1 (Gal-IgA1) usually associated with mesangial proliferation and matrix expansion. There is no disease-specific therapy of IgAN, although a herbal medicinal preparation, ShenPing decoction (SP), has been used in China for decades to effectively treat IgAN. Mesangial cell proliferation in IgAN is likely induced by Gal-IgA1-containing immune complexes (CIC) and this process may involve activation of platelet-derived growth factor (PDGF) signaling pathway. We have shown previously that SP blocks the activation of PDGF pathway induced by PDGF. In this study, we investigated the effect of CIC on PDGF signaling pathway in human mesangial cells (HMC) and assessed the effects of SP on this pathway.

Methods: CIC were isolated from sera of IgAN patients using size-exclusion chromatography. Primary HMCs were incubated with PDGF or CIC for 15 min or 24 h with or without SP. Cellular proliferation was measured by Syto60. PDGF signaling was evaluated by SDS-PAGE and Western blotting.

Results: 24-h incubation with CIC increased MC proliferation and SP inhibited this effect. Stimulation of HMC with CIC increased phosphorylation of PDGFR and ERK1/2 after 15 min and 24 h. PDGF degradation was not observed in CIC-treated group, which is different from PDGF. SP inhibited CIC- and PDGF-induced phosphorylation and degradation of PDGFR.

Conclusions: CIC induced cellular proliferation of HMC and activation of PDGF pathway by the different times group; Fluorofenidone control group; High glucose and LPS for different concentrations and different times group; Fluorofenidone intervene group.

Effects of Fluorofenidone on the Expression of Thioredoxin-Inter-Acting Protein and Thioredoxin of Human Peritoneal Mesothelial Cell in High Glucose and Lipopolysaccharide

Yicheng Chen, Jianfei Ma. Nephrology: The First Affiliated Hospital of China Medical Univ, Shenyang, China.

Background: Peritoneal dialysis is one of an important alternative therapies for end-stage kidney disease, But the occurrence of peritoneal dialysis correlation peritonitis has brought high cost and resistance for the development of peritoneal dialysis. Significance of oxidative stress in peritoneal dialysis related peritonitis has been paid more and more attention. In cells that did not receive stimulation, Txnip combined with thioredoxin, when the elevated ROS concentration inside the cell, the formation of the compounds are separated. After dissociation Tx play its functions to remove ROS, whereas Txinap participation NLRP3 activation. Objective: To observe the effects of Fluorofenidone on the Expression of Thioredoxin, Trx of HPMCs in High Glucose and Lipopolysaccharide.

Methods: The expression of CIC and Trx mRNA was measured by real-time PCR, The level of IL-6, TGF-b1 and IP-10 were measured by ELISA, Experimental groups: Control group; High glucose and LPS for different concentrations and different times group; Fluorofenidone intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of Txnip, Trx, IL-6 and TGF-b1 in a concentration and time dependent manner, all have statistically significant (P<0.05). Compared with 2.5% glucose and 10mg/L LPS group, Fluorofenidone can reduce the expression of Txnip, IL-6 and TGF-b1, increase the expression of Trx, all have statistically significant (P<0.05).

Conclusions: High glucose and LPS up-regulate the expression of Txnip, Trx, in the protein and gene levels, and increase the expression of LIF-g and TGF-b1. Fluorofenidone could reduce the increase of Trx, IL-6 and TGF-b1, and increase the expression of Trx in HPMCs that have been pre-treated with high glucose and LPS. Fluorofenidone have the effect of anti-oxidant and anti-fibrosis.

Effects of Resveratrol on NRF2 Expression in Raw 264.7 Macrophages Cells and Non-Dialyzed CKD Patients

Bruce A. Julian,2 Yiping Chen,1 Jane Mei. Nephrology: The First Affiliated Hospital of China Medical Univ, Shenyang, China.

Background: Oxidative stress and inflammation are common in CKD. Bioactive compounds as resveratrol may modulate the NRF2 expression, a transcription factor that could up-regulate cellular antioxidant systems. The aim of this study was observe NRF2 expression in macrophages cells and in non-dialyzed CKD patients treated with resveratrol.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Mouse RAW 264.7 macrophages cells were treated with 50µM of resveratrol in DMSO 1% (+/v). Nucleus and cytoplasm were separated. Western Blot (WB) was performed to quantify Nrf2. qRT-PCR was performed to evaluate Nrf2 expression. 7 non-dialyzed CKD patients (5 women; 64.0±6.5 years) were analyzed. Cellular bioenergetics were assessed with a Seahorse XF-96 extracellular flux analyzer. Intracellular ROS were produced and cell viability was reduced. Mitochondrial respiration and the cellular bioenergetic reserve capacity were decreased following glyoxylate oxidation. The expression of AGT or GR reduced the antioxidant response of glycolate metabolism to glyoxylate and oxalate. Limited mitochondrial dysfunction might be a therapeutic approach in treating PH patients.

Results: Cells treated with resveratrol showed a significant activation of Nrf2 with an increase in the ratio nucleus/cytoplasm compared to control cells i.e. p<0.02. The same was observed in qRT-PCR (p=0.02). In patients, we observed a trend to increase Nrf2 expression with resveratrol supplementation (p=0.06).

Conclusions: We concluded that both cells and patients treated with resveratrol increased Nrf2 expression. So, we suppose that supplementation with resveratrol can lead to an increase in oxidative stress and inflammatory status among CKD patients.

PUB105 Mitochondrial Implications of Glycolate Metabolism in Primary Hyperoxaluria Sonia Farque, Tanecia Mitchell, John Knight, Ross P. Holmes.

Urology, Univ of Alabama at Birmingham, Birmingham, AL.

Background: The primary hyperoxalurias (PH) are rare but severe inherited diseases characterized by an increased endogenous production of oxalate and calcium oxalate kidney stones in patients. Deficiency in alanine glyoxylate aminotransferase (AGT, deficient in PH1) or glyoxylate reductase (GR, deficient in PH2) have repercussions on the metabolism of the oxalate precursors glyoxylate and glycolate. Excessive amounts of glycolate are characteristic of PH1, through glyoxylate to glycolate cycling in the presence of glycolate oxidase (GO) and GR. Perturbations in glycolate metabolism may affect mitochondrial function in PH patients. The objective of this study is to assess how over-expression of these enzymes regulates glycolate and glyoxylate generation and mitochondrial function.

Methods: An established transformed CHO cells model was used in which cells express GO ± AGT or GR. Cells were incubated with glycolate or glyoxylate and the extracellular concentrations of oxalate and glycolate, and the induction of oxidative stress were analyzed. Cellular bioenergetics were assessed with a Seahorse XF-96 extracellular flux analyzer.

Results: The metabolism of glycolate by GO generated glyoxylate, oxalate and H2O2. Intracellular ROS were produced and cell viability was reduced. Mitochondrial respiration and the cellular bioenergetic reserve capacity were decreased following glyoxylate oxidation. The expression of AGT or GR reduced the antioxidant effects of glycolate metabolism to glyoxylate and oxalate.

Conclusions: The disruption of normal glycolate metabolism by GO, AGT and GR in a cell model of PH1 causes the production of stress related metabolites and mitochondrial dysfunction. Limiting mitochondrial dysfunction might be a therapeutic approach in treating PH patients.

PUB106 Effect of Fasudil on Response Oxidative Stress in High Glucose and Lipopolysaccharide Induced Human Peritoneal Mesothelial Cells Ye Hu, Jianfei Ma.

Nephrology, The First Affiliated Hospital of ChinaMedical Univ, Shenyang, Liaoning Province, China.

Background: Peritoneal fibrosis is a common cause of chronic peritoneal dialysis patients withdrawn from peritoneal dialysis. Research shows that there are oxidative stress exists in peritoneal dialysis patients. Rho/Rho kinase signaling pathway is involved in the regulation of multiple biological process, including inflammation, oxidative stress and fibrosis. The transcription factor Nrf2 related factor is a central regulator of cellular antioxidant responses. Rho kinase inhibitor fasudil is a Rock inhibitor which currently used in clinic and experiment, it can regulate cell proliferation, migration, adhesion and movement at the cellular level. It also can regulate a variety of factors in inflammation, thrombogenesis is, oxidation stress and fibrosis at the molecular level.

Methods: By using the method of Real Time PCR to detect the expression of RhoA, Rock1, Nrf2 and HO-1 mRNA, Western Blot to detect the expression of RhoA, Rock1, Nrf2 and HO-1 protein; chemistry fluorescence test to detect the expression of ROS protein; chemical colorometry to detect the expression of GSH-PX protein; ELISA to detect the expression of TGF-b1 protein in the human peritoneal mesothelial cell. Experimental groups: Control group; High glucose and LPS for different concentrations group; Fasudil intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of RhoA, Rock-1, ROS and TGF-b1, reduce the expression of Nrf2, HO-1 and GSH-PX in a concentration dependent manner, all have statistically significant (P<0.05). Compared with 2.5% glucose and 10mg/L LPS group, fasudil can reduce the expression of RhoA, Rock-1, ROS and TGF-b1, increase the expression of Nrf2, HO-1 and GSH-PX, all have statistically significant (P<0.05).

Conclusions: High glucose and LPS up-regulate the expression of RhoA and Rock1 but reduce Nrf2 in the protein and gene levels, and increase the expression of ROS and TGF-b1 but reduce the expression of HO-1 and GSH-PX. Fasudil could reverse the increase of RhoA and Rock-1 and the reduction of Nrf2 in HPMCs that have been pre-treated with high glucose and LPS, play the role of anti-oxidant and anti-fibrosis.

PUB107 Glucose Induces Mitochondrial Reactive Oxygen Species Through Carbonyl Stress and Respiratory Chain in Rat Peritoneal Mesothelial Cells Satoshi Shimada,1 Takefumi Mori,2 Yusuke Ohsaki,2 Ikuo Oba,1 Shinichi Sato,1 Kenji Koizumi,1 Sadayoshi Ito.1 1Nephrology, Endocrinology and Vascular Medicine, Graduate School for Medicine, Tohoku Univ, Sendai, Miyagi, Japan; 2Div of Integrative Renal Replacement Therapy, Graduate School of Medicine, Tohoku Univ.

Background: Glucose and its degradation products (GPDs) play a major role in the peritoneal injury and affect peritoneal dialysis vintage. Peritoneal mesothelial cell dysfunction has been demonstrated to involve in peritoneal injury by glucose and GPDs. GPs induced carbonyl stress has been demonstrated to induce mitochondrial dysfunction in several cell types. The present study was designed to determine the role of GPs and respiratory chain in glucose induced mitochondrial ROS in peritoneal mesothelial cells. To this end, primary rat peritoneal mesothelial (RPMC) and immortalized (RDCM) renal cells were isolated from Wistar rats. Real-time mitochondrial superoxide was monitored using a specific fluorescent indicator Mito SOX red under fluorescence microscope equipped with temperature controlled chamber. RPMC was stimulated with 90 mmol/L of glucose and compared to those of control. In separate experiments, RPMC was pre-incubated with a mitochondrial specific superoxide dismutase mimetic mitoTEMPO, respiratory chain inhibitor rotenone or carbonyl stress inhibitor pyridoxamine to determine the mechanism of glucose induced mitochondrial ROS production.

Results: 90 mmol/L glucose significantly increased mitochondrial superoxide production within 200 seconds in primary cultured RPMC (0.21±0.07 AU, n=8, P<0.05 vs vehicle). These responses were abolished when RPMC was pre-incubated with mitoTEMPO (-0.04±0.15 AU, n=5, P=0.34 vs vehicle), rotenone (0.00±0.06 AU, n=6, P=0.42 vs vehicle) or pyridoxamine (-0.34±0.34 AU, n=5, P=0.26 vs vehicle), indicating that mitochondrial superoxide production through respiratory chain and GDP.

Conclusions: The results in the present study indicate that glucose and GDP present in the PD effluent is responsible for oxidative stress in the peritoneal mesothelial cells by stimulation of mitochondrial ROS production, which could play a role in peritoneal function and injury during PD.

Background: Renal Cell Carcinoma (RCC) is a leading cause of renal cancer worldwide. The cause of RCC remains unknown, with many chemicals implicated in its development. We have developed an in vitro model of RCC using the carcinogen, potassium bromate, to investigate potential prevention and possible treatment options of RCC. Chemoprevention is the use of different chemicals, natural or synthetic, to halt, block or reverse the process of carcinogenesis. It is one of the novel approaches that is being used to control cancer and it is a good alternative to the conventional therapies that are associated with a long list of side effects and limitations. These agents have antioxidant, anti-inflammatory, antiangiogenic effects and induce phase II enzymes, apoptosis, cell cycle arrest, and differentiation. They antagonize hormones and growth factor-induced tumor proliferation. The aim of this study was to examine the functional and mechanistic effects of chemopreventative agents on chemically induced RCC using human (RPTEC/TERT1) renal cells and cancerous (AChN) renal cell line.

Methods: Morphological changes, viability and cytotoxicity assays were used to assess the toxicity of both the chemopreventatives and the carcinogen when RPTEC/TERT1 cells were exposed to them individually and in combinations. Oxidative stress was also assessed.oxidative stress...
assessed by measuring the intracellular concentration of H2O2. Oxidative stress-induced DNA damage was estimated qualitatively by measuring 8-OHdG concentrations. Western blot analysis was used to detect the changes in particular oxidative stress-induced proteins.

Results: The carcinogenic effects induced by potassium bromate were reduced by the co-administration with all of the chemopreventive agents used. Oxidative stress markers, H2O2 and DNA adduct formation, were reduced.

Conclusions: The results suggest that these chemopreventive agents show significant potential against KBrO3-induced carcinogenicity. Further analysis is being carried out to understand the functional mechanisms of this chemoprevention on the cells, in particular on the genetic and epigenetic mechanisms involved.

PUB109

The Podocyte as a Target for the Actions of Levamisole in Nephrotic Syndrome

Lulu Jiang, 1 Charles Colin Thomas Hindmarch, 1 Mark Rogers, 2 Peter W. Mathiessen, 2 Gavin Iain Welch. 1 School of Clinical Sciences, Univ of Bristol; 2 Univ of Hong Kong.

Background: Levamisole is an antihelminthic agent that has also been shown to be effective as a second line treatment for steroid-dependent or frequently-relapsing nephrotic syndrome (SD/FRNS) in children. Levamisole is able to decrease steroid dosages and reduce the relapse frequency and severity. We have recently reported the effectiveness of levamisole in a small cohort of adult patients and provided evidence which suggests that levamisole’s mode of action in SSNS is attributable to its direct effects on podocytes.

Methods: To further clarify its therapeutic effectiveness and identify the therapeutic targets of this drug, we have employed RNA-sequencing technology to profile transcriptomic changes of human podocytes in response to levamisole.

Results: We have identified a number of genes which are differentially expressed in podocytes in response to levamisole. These include genes linked to the cellular interferon response pathways and a number which overlap with those regulated by dexamethasone in podocytes. These have been validated in vitro and are now being studied in animal models of nephrotic syndrome.

Conclusions: Together, our molecular evidence strongly supports the promising use of levamisole in treating nephrotic syndrome.

PUB110

The PRIMAVERA Study: A Prospective, Randomized, Multicenter Trial Assessing the Effect of Continuous Erythropoiesis Receptor Activator (C.E.R.A.) on Renal Function in Non-Anemic Patients with Chronic Kidney Disease (CKD)

Daniel Fliess, 1 Frank Delmanno, 1 Michael Koch, 1 Jochen Seufert, 1 Oliver Witzke, 1 Affonso Weggenshaar, 1 Ingeborg A. Hauser. 1 Saarland Univ Medical Center, Homburg/Saar, Germany; 2 Center of Nephrology, Mettmann, Germany; 3 Univ Hospital of Freiburg, Freiburg, Germany; 4 Univ Hospital Essen, Essen, Germany; 5 Roche Pharma AG, Grenzach-Wyhlen, Germany; 6 Frankfurt Univ Medical Center, Frankfurt, Germany.

Background: Erythropoiesis stimulating agents (ESAs) are the mainstream of renal anemia management. ESAs may provide a beneficial non-hematopoietic effect on deterioration of kidney function in CKD, but such an effect has not been examined in a prospective controlled trial. PRIMAVERA is the first randomized study to assess whether low-dose ESA therapy can slow CKD progression in patients with near-normal hemoglobin levels (11–14g/dL) (NCT01194154).

Methods: PRIMAVERA was a single-blind, 2-year, multicenter trial which enrolled patients with type 2 diabetes or recipients of a kidney transplant, all with CKD stage 3, urinary albumin to creatinine ratio <3000mg/g or total urine protein <3000mg/24h. Patients were randomized in a 1:1 ratio to placebo or once-monthly low-dose C.E.R.A. (30-75 mg). We designed a 4 arm parallel group randomized double blind trial comparing lanthanum carbonate (1000mg tid), nicotinamide (750mg bid), neither, or both. Supported by the NIDDK CKD Pilot Clinical Trials U01, 200 participants with eGFR 20-45 ml/min/1.73 m² recruited from 7 centers across the US will be randomized: 1:1:1:1 and treated for 12 months. Main exclusions include phosphate > 2.8mg/dL, liver disease, and thrombocytopenia. The dual primary efficacy endpoints are change in phosphate and FGF23. Secondary endpoints are change in L.V mass and renal fibrosis by MRI. Enrollment began in March 2015.

Results: To date, 45 persons were screened, 33 were eligible, 26 entered run-in, and 18 were randomized. Baseline characteristics of randomized participants are shown in the table. Updated data will be available at presentation.

Randomized Patients (n) 18
Age/SD 65±14
Male, n(%) 12 (67%)
Black, n(%) 5 (28%)
Diabetes, n(%) 7 (44%)
eGFR/SD 30±9
Urinary ACR mg/g, median (IQR) 505 (48, 905)
Serum Phosphates/SD 3.9±0.6
Serum Calcium/SD 9.5±0.4
Inact PTH, median (IQR) 104 (71, 135)

Conclusions: Simultaneous blockade of NaPi2b and intestinal phosphate binding using nicotinamide and binders provides a new strategy for phosphate and FGF23 lowering in CKD, but efficacy, safety, and tolerability are uncertain. The COMBINE trial will inform us about combined therapy compared to either therapy alone, and to dual placebo in CKD 3b-4.

Funding: NIDDK Support

PUB111

A New Approach to Phosphate and FGF23 Lowering: Design of the COMBINE Trial

Joachim H. L. 1 Tamara Isakova, 2 Stuart M. Sprague, 2 Kalani L. Raphael, 1 Jennifer J. Gassman, 1 Linda F. Fried, 1 Dominic S. Raj, 6 Alfred K. Cheung, 2 Andrew N. Hoofnagle, 7 John W. Kusek, 7 Michael F. Flessner, 7 Geoffrey A. Block, 6 Myles S. Wolf, 7 The pilot clinical trials in Ckd study group. 1 UCSD, 2 Northwestern, 3 U of Utah, 4 U of Pittsburgh, 5 Cleveland Clinic, 6 George Washington U; 7 NIDDK; 8 Denver Nephrology; 9 Northshore; 10 U Washington.

Background: Elevated serum phosphate and FGF23 are associated with CVD, CKD progression, and mortality in CKD. Phosphate binders inconsistently reduce phosphate and FGF23 levels. Nicotinamide (vitamin B3) decreases active phosphate transport by down regulating Nalp2b in the gut. Whether nicotinamide alone or in combination with binders can safely and tolerably lower phosphate and FGF23 levels in CKD is unknown.

Methods: We designed a 4 arm parallel group randomized double blind trial comparing lanthanum carbonate (1000mg tid), nicotinamide (750mg bid), neither, or both. Supported by the NIDDK CKD Pilot Clinical Trials U01, 200 participants with eGFR 20-45 ml/min/1.73 m² recruited from 7 centers across the US will be randomized: 1:1:1:1 and treated for 12 months. Main exclusions include phosphate > 2.8mg/dL, liver disease, and thrombocytopenia. The dual primary efficacy endpoints are change in phosphate and FGF23. Secondary endpoints are change in L.V mass and renal fibrosis by MRI. Enrollment began in March 2015.

Results: To date, 45 persons were screened, 33 were eligible, 26 entered run-in, and 18 were randomized. Baseline characteristics of randomized participants are shown in the table. Updated data will be available at presentation.

Costly Option

Achromatoplasia

L. Raphael, 1 Guillaume Seret, 1 Jean baptiste Pain, 1 Yves Peytavin, 1 Néphrologie-Dialyse, ECHO-CMCM -Pôle Sant é Sud, Le Mans, France; 2 Gastro-enterologue, Centre Hospitalier du Mans, Le Mans, France; 3 Laboratoire de Pharmacoco-Toxicologie, Hôpital Bichat-Claude Bernard, Paris, France; 4 Biologie, Laboratoire Pôle Sant é Sud, Le Mans, France.

Background: Hepatitis C virus (HCV) infection is a serious issue in hemodialyzed patients (HD pts) and treatment is complex and rapidly evolving with the advent of newer direct-acting antivirals.

Methods: We evaluated SOF given with RBV in an 86 years old male HD pt, 90 kg, on HD since 7 years for a diabetes-related ESRD and infected by a nosocomial transmission of HCV genotype 2 overseas. SOF was given at a dose of 400 mg three times a week after dialysis session and RBV given 200 mg daily during 12 weeks. Plasma HCV RNA values were measured with the COBAS Taqman HCV Test, Roche diagnostics. Safety, efficacy and pharmacokinetics issues were studied as well as standard laboratory tests. Sustained virologic response(SVR) is evaluated six months after treatment.

Results: HCV infection was associated with cirrhosis with Fibroscan staging score of 10.3 KPa. HCV viral load at diagnosis was 7.52 log. The viral decline was < 1.18 log only 3 months after HD session and RBV given 200 mg daily during 12 weeks. Plasma HCV RNA values were measured with the COBAS Taqman HCV Test, Roche diagnostics. Safety, efficacy and pharmacokinetics issues were studied as well as standard laboratory tests. Sustained virologic response(SVR) is evaluated six months after treatment.

Conclusions: The PRIMAVERA study provides the first prospective examination of a potential effect for low-dose ESA therapy in ameliorating kidney function decline in CKD patients. Analysis of the study data is planned shortly.

The rationale and design of TREV1 TR02: A Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial of the Treatment for Uremic Pruritus in Hemodialysis Patients

Vandana S. Mathur, Michael J. Germain, Roberta Duncan, Thomas Sciascia, Mathur Consulting, Woodside, CA; Western New England Renal & Transplant Associates, PC, Hamden, MA; Trevi Therapeutics, New Haven, CT.

Background: Uremic pruritus (UP) is common in hemodialysis patients, but there are no FDA-approved treatments or "regulatory roadmap" for the development of new drugs. Nevertheless, the significant quality of life (QOL) burden of chronic itching underscores need for treatments. The striking bilateral, non-dermatomal distribution of itching and perception of non-pruritogenic skin stimuli as itch suggest that UP is centrally mediated, like neuropathic pain. Reduction in endogenous κ/µ opioid ligand ratio is hypothesized to be a mechanism. Our goal was to evaluate nalbuphine ER tablet (NAL), a κ-agonist and μ-antagonist as a treatment for UP.

Methods: The study was powered for an α = 0.05, β = 0.9 for a group difference of 1.5 (SD = 3.5) in worst itching numerical rating scale (NRS, 0-10); N = 120/arm (NAL 120 mg BID, NAL 60 mg BID, and placebo BID). Patients with NRS ≥ 4.5 (moderate to severe pruritus) were enrolled at ~45 US and 6 EU sites.

Results:

Conclusions: The trial design overcame the challenges. Unblinded results will be presented.

Funding: Pharmaceutical Company Support - Trevi Therapeutics

The Rationale and Design of Trevi TR02 Extension: A Multi-Center Open Label Extension Study of the Safety and Anti-Pruritic Efficacy of Nalbuphine HCl Extended Release Tablets in Uremic Pruritus Patients on Hemodialysis

Thomas Sciascia, Howard Hatt, Annale Havi, Roberta Duncan, Vandana S. Mathur, Trevi Therapeutics, Inc., New Haven, CT; Edenridge Associates LLC, Wilmington, DE; Havi Consulting, Ridgefield, CT; Mathur Consulting, Woodside, CA.

Background: Nalbuphine HCl is a μ agonist/kappa agonist being investigated for the treatment of pruritus in hemodialysis patients (UP). The safety and long-term benefits of Nalbuphine ER in the treatment of uremic pruritus is being investigated in this ongoing open-label extension study.

Methods: TR02ext is a 26-week multicenter open-label extension study of a double-blind placebo controlled study in which UP patients with a baseline NRS ≥4.5 were treated with Nalbuphine ER or placebo for 8 weeks followed by a 2-week washout period. At the end of study, patients that opt to roll over into the extension study, and have an NRS ≥ 2 enrolled in a 26-week Treatment Period (TP), while patients with an NRS ≤2 entered a 13-week Observation Period (OP). If a patient’s itch worsened (NRS > 2) within the OP, they entered the TP for the remainder of the study.

All patients on treatment were titrated between 30 mg QD-120 mg BID over a 3-4 week period based on reported tolerability and efficacy and then maintained their dose until end of study. Patients whose itch intensity failed to improve during the TP were discontinued from treatment.

Conclusions: Approximately 70% of the eligible patients who completed the blinded controlled study, enrolled in the extension study. Final study data will be presented once the trial is complete.

Assessing Treatment Safety and Efficacy of a New Patient-Centered Hemodialysis System

Luis Alvarez, Geoffrey A. Block, May L. Yau, Glenn Matthew Chtontow, Palo Alto Medical Foundation, Palol, CA; Denver Nephropathy, Denver, CO; Outset Medical, San Jose, CA; Stanford School of Medicine, Stanford, CA.

Background: Many studies designed and conducted for the evaluation of new technologies utilized in hemodialysis have been small, observational studies. These studies may have underestimated the rate of clinical symptoms yielding biased safety results.

Methods: We designed a prospective, multicenter, open-label, non-randomized, cross-over study where patients serve as their own control. The study was designed with novel approaches to ensuring accuracy of clinical symptom reporting both in the home and clinic setting. Up to 50 patients will be enrolled in the study for 19 weeks and will use the TeleH® Hemodialysis System for treatments 4 times/week.

Funding: Pharmaceutical Company Support - Outset Medical, Inc.

Interim Analysis of Comprehensive CKD Education Modality Choice Outcomes

Andrea K. Eason, Damitra Rotaru, Fahd Syed, Manisha Singh, Ashutosh M. Shukla, Sudhir V. Shah, Univ of Arkansas for Medical Sciences; University of Florida.

Background: Preliminary data from a study comparing telemedicine vs conventional CKD education is presented here. The primary aim is to test if patients are able to make a modality choice by the end of the third visit.

Methods: Patients are enrolled in three groups as shown in the pilot study design.

Conclusions: During each study phase, patients will record inter- and intra-dialytic symptoms for each treatment via questionnaire. Research staff will review all responses weekly to determine if an adverse event (AE) has occurred. In addition, research staff will conduct weekly visits to the dialysis clinic and to home to educate patients on AEs and to collect questionnaires. Patients will also be assessed to determine if a standardized weekly Kt/V of 2.1 has been achieved.

Results: Study enrollment is expected to begin in 2015 with results expected in 2016.

Conclusions: By utilizing patients to collect AE data both in-center and at home, we should more accurately capture AE rates due to the uniformity of the reporting mechanism. In terms of the clinical efficacy endpoint of the study, modelled clearance data suggests the majority of patients will achieve the weekly standard Kt/V target. Actual clearance data will be forthcoming at the completion of the trial.

Determination of Oxidative Stress and Inflammation Index in Patients with Different Dialysis Modalities and Analysis of Related Factors

Linsihan Jiao, Jianfei Ma.

Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.

Background: This study through the determination of serum AOPPs, GSH-PX, PTX-3, IL-6 level in ESRD patients with different treatment groups, to explore the changes and influence factors of oxidative stress and inflammation in dialysis patients.

Methods: 70 cases of ESRD patients divided into three groups: 26 cases of PD patients, 26 cases of hemodialysis patients, 18 cases of CKD5 patients. Select 14 normal persons as control group. Age, gender and other data of the four groups were matched. Get Serum of each group of subjects, using ELISA for determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in each group.

Results: 1. The concentration of AOPPs: PD Group (25.04 ± 12.18) ng/mL, MHD group (18.46 ± 10.47) ng/mL, CKD5 group (17.96 ± 8.13) ng/mL, healthy group (15.73 ± 6.68) ng/mL. PD group was statistically significant different with other groups (p < 0.05). 2. The concentration of GSH-PX: PD group (188.54 ± 112.04) U/mL, MHD group (157.12 ± 82.47) U/mL, CKD5 group (133.59 ± 65.59) U/mL, healthy group (176.03 ± 93.25) U/mL. There was no significant difference between the groups. 3. The concentration of PTX-3: PD Group (9.55 ± 5.13) ng/mL, MHD group (7.54 ± 4.79) ng/mL, CKD5 group (6.69 ± 3.12) ng/mL. The PD group was statistically significant different with other groups (p < 0.05). 4. The concentration of IL-6: PD group (123.69 ± 84.46) ng/L, MHD group (81.17 ± 72.48) ng/L, CKD5 group (64.92 ± 36.92) ng/L, healthy control group (59.08 ± 19.27) ng/L. The PD group was statistically significant different with other groups (p < 0.05). Through Correlation analysis in PD group (p < 0.05): AOPPs was positively correlated with PTX-3 (R = 0.956, P = 0.000), AOPPs was positively correlated with IL-6 (R = 0.934, P = 0.000), PTX-3 and IL-6 levels were positively correlated (R = 0.939, P = 0.000).

Conclusions: Determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in Experience group is significantly increased compared with the control group. The PD patients compared with patients in other treatment groups have more severe oxidative stress and microinflammation state. Oxidative stress is closely related to the state of inflammation in PD patients.

Impact of Type of Referral and Dialysis Start on Clinical Outcomes and Final Renal Replacement Therapy in a Multicenter Integrated Care Setting

Belden Marron, Janusz Ostrowski, Marietta Torok, Delia Timofte, Jose C. Divino-Filho, Diaverum Home Therapies, Medical Office, Diaverum, Munich, Germany; Wloclawek Diaverum Clinic, Diaverum, Wloclawek, Poland; Szeged Diaverum Clinic, Diaverum, Szeged, Hungary; Soma Diaverum Clinic, Diaverum, Bucharest, Romania.

Background: Early referral, choice of RRT modality and planned start increase patient survival, however international reports show disparities between desirable patterns and practice. Objectives: To analyze the effects of Integrated Care and education on dialysis start patterns vs. planned and RRT modality choice.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD clinics from PL, HU and RO during 2012. Scheduled initiation of dialysis with a permanent vascular or peritoneal access was considered as planned start.

Results: Population: 30% DM, mean age 64 years, 84% with previous medical care of renal disease, 49% late referral, 58% unplanned start, 92% on HD as modality. 37% of those with unplanned start had previous Nephrology follow-up. Patients (n=332) with GFR <30 ml/min were followed up mainly by “general nephrologists” (68%) and 29% in structured practice. Both RRT modality information (80% of all information expected) and general education (56%) and patient-specific education (87%) were more frequent (p < 0.001) in planned start. Half of patients were involved in therapy choice whereas informed and dialysis start consents were signed by 57% and 77%. The median time from information to dialysis start was 2 months. Unplanned start (p<0.05) correlated with nephropathy of uncertain origin, worse clinical status, shorter time from information to RRT start and less PD. Patient non-compliance (36%) and unexpected GFR loss (19%) contributed to unplanned start. “Optimal care” defined as combination of Nephrology follow-up (> 3 months), modality information and planned start occurred in 22% of the patients.

Conclusions: Despite the high rate of late referral, information and education were widely provided. Unplanned start was frequent and may underlie the low frequency of PD choice. Measures such as implementation of structured predialysis units may facilitate better and timely referral and improve well-being and planning of RRT start as well as increased PD use.

ATHENA: A Natural History Study to Observe Disease Progression, Standard of Care, and Investigate Biomarkers in Alport Syndrome Patients

Jacqui Blem, Paul C. Grint, Victoria Pratola, James F. Simon. Regulus Therapeutics Inc., San Diego, CA; Cleveland Clinic, Cleveland, OH.

Background: Alport syndrome (AS) is a rare genetic disorder caused by mutations in genes coding for type IV collagen (COL4A3), COL4A4, and COL4A5 proteins leading to hematuria, renal failure, hearing loss and eye involvement in affected patients. Patients with COL4A5 mutations develop end stage renal disease (ESRD). While there are currently no approved therapies for AS, ACE-inhibitors have been shown to delay the onset of ESRD. A better understanding of the decline of kidney function in AS is necessary to design clinical trials to enable the development of new therapeutics.

Methods: Regulus’ Natural History of Disease Study, ATHENA, is an international multi-center observational study designed to characterize the progression of renal dysfunction in up to 120 subjects that have been clinically or genetically diagnosed with AS with a measured GFR (mGFR) between 30-75cc/min/1.73m². Genetic mutation analysis is performed at enrollment. mGFR (iohexol), 24 hour urine protein excretion and serum creatinine levels are measured every 3-6 months. Serum and urine biomarkers of renal stress (microRNAs, ADMA, TGFβ, CTGF and NGAL) will also be collected.

Results: 48 subjects with clinically or genetically diagnosed Alport syndrome have been enrolled to date. The population has an age range of 20 to 67 years of age and 29% are male. Average baseline mGFR was 54.8 cc/min/1.73m². Ethnicity is reported at 91% Caucasian, 2% Hispanic or Latino, 2% African American and 5% Asian.

Conclusions: Data gathered from the ATHENA study will investigate links between genetic mutations, biomarkers of renal stress and disease progression in AS patients. The correlative data collected from the ATHENA study will provide clinically important basis for the design of the Phase 2 clinical proof of concept study to determine efficacy of RG-012 (an anti-miR targeting microRNA-21) on the decline in renal function and time to end-stage renal disease in Alport syndrome patients.

Health-Related Quality of Life in Dialysis Patients: Effect of Type D Personality

Christopher Susanto, Constantijn Konings, Jeroen Kooman. Nephrology, Ekenhovens Hospital, Eindhoven, Netherlands; Nephrology, Catharina Hospital, Eindhoven, Netherlands; Nephrology, Maastricht Univ Medical Centre, Maastricht, Netherlands.

Background: Measurement of HRQoL is a useful tool to describe the burden of illness and impact of treatment. These informations could be crucial to develop a personal care. Type D (distressed) personality is defined as a tendency to experience both negative affectivity (NA) and social inhibition (SI). The prevalence of this personality and his effect on HRQoL in dialysis patients are assessed.

Methods: Participants were from outpatient clinic. DS 14 was used. A score of 110 on both NA and SI subscales indicates that the person has a type D personality. HRQoL was measured using the Dutch version of the Kidney Disease Quality of Life. Six components of the KDQOL were the primary end points (general health perceptions, burden of kidney disease, effect on daily life, cognitive function, pain, emotional welfare).

Results: 147 patients with mean age of 71.2 (±1.7). Mean time on dialysis 37 months. The prevalence of type D personality was 30% HRQoL in patients with type D personality was lower compared with non type D. It was statistically significant in all components except for emotional welfare.
Early Stages of Chronic Kidney Disease
Potential Link Between Iron, Inflammation and FGF23 in Patients with

PUB121
Sleep Disorder and mRNA Expression Profile of Sleep-Related Gene in Peripheral Blood Cells in Patients with CKD

Conclusions: Type D personality may be an important determinant of individual differences in HRQoL and should be an important consideration in a personal care of dialysis patients.

Conclusions: These data raise the possibility that sleep related gene expression on PBC in CKD/HD patients may be associated with sleep disorder.

PUB122
Potential Link Between Iron, Inflammation and FGF23 in Patients with Early Stages of Chronic Kidney Disease

Results: There were no statistically significant associations between FGF23 and TSAT, ferritin and hsCRP. We revealed significantly higher concentrations of FGF23 in patients with type 2 diabetes (mean logFGF23: 4.0 ± 0.5 vs 3.8 ± 0.5, P<0.03) and with heart failure (mean logFGF23: 4.0 ± 0.6 vs 3.8 ± 0.5, P<0.04) in comparison to those without these diagnoses.

Conclusions: Kidney function, inflammation and iron status were the parameters affecting FGF23 in the early stages of CKD. Our data are paving the way for further studies on the role of FGF23 in cardiorenal anaemia-iron deficiency syndrome, in particular in the early stages of CKD.

PUB123
Echocardiography and Cardiovascular Risk: What’s the Relationship in the Renal Transplant Recipient?

Results: Among 107 patients (57,9% males, 50,4±13,9 years old), 7-years risk for MACE was >10% in 30,9% of patients and 7-years risk for death >10% in 56,1%. Left ventricular hypertrophy (LVH) was found in 55,1%, diastolic dysfunction in 39,3%, dilated LA in 41,2%, moderate to severe mitral regurgitation in 31,7%, and mean Ejection Fraction was 68,36±6,87%. Univariate analysis showed with statistical significance an increased risk of MACE in patients with LVH, diastolic dysfunction, dilated LA, moderate to severe mitral regurgitation. Multivariate analysis showed statistically significant on increased risk of death in patients with LVH, diastolic dysfunction, dilated LA, moderate to severe mitral regurgitation. Multivariate analysis identified an independent association between the risk of MACE >10% and valvular calcifications [OR 3.499 (1.115-10.982, P=0.032)] and high PASP [OR 7.954 (2.421-26.238, P<0.001)]. Risk for death >10% in multivariate analysis had an independent association with diastolic dysfunction [OR 3.989 (1.261-12.115, P=0.016)] and with high PASP [OR 4.319 (1.201-15.535, P=0.025)].

Conclusions: Echocardiographic abnormalities identify RTR at increased risk of MACE and death. Valvular calcifications and high PASP are significant predictors of MACE whereas diastolic dysfunction and high PASP are significant predictors of death.
PUB124

Hemodynamic Determinants of Glomerular Filtration Rate in Pulmonary Hypertension: A Prospective Cohort Analysis. Laurent Birker,¹ Cecile Payet,³ Florence Senn,¹ Turquier Segolen,² Antoine Duclos,¹,4 Vincent Cottin,²,4 Laurent Juillard,¹,4 ¹Nephrology, Hospices Civils de Lyon, Lyon, France; ²Pneumology, Hospices Civils de Lyon, Lyon, France; ³Medical Research and Statistics Dept, Hospices Civils de Lyon, Lyon, France; ⁴Univ of Lyon, Lyon, France.

Background: Up to date, renal dysfunction incidence and determinants remain unevaluated in pulmonary hypertension (PHT). We aim to assess hemodynamic and demographic factors associated with a decrease in glomerular filtration rate (GFR) in the context of PHT.

Methods: The regional center competence for PHT of Lyon (France) prospectively compiles demographic, hemodynamic and biological variables among newly diagnosed patients. We retrospectively analyzed data for patients with pulmonary arterial hypertension (PAH, group 1 of PHT classification) after exclusion of the following causes of PHT: thromboembolic, lung diseases and/or hypoxia and left heart disease. Hemodynamic variables from the right heart catheterization and estimated GFR (eGFR, CKD-EPI formula) were assessed at PAH diagnosis time.

Results: 209 patients (mean age 59.1±17.1, 63.2% women) were included from October 1998 to July 2012. 40.2% presented with systemic arterial hypertension (HT) and 12.9% with diabetes. Mean eGFR was 83.9±27.1 ml/min/1.73m² (eGFR inferior to 60 ml/min/1.73m² in 18.5% of cases). Mean values of mPAP, right atrial pressure (RAP) and cardiac index (CI) were 45±12.6 mmHg, 7.8±5.3 mmHg and 2.6±0.9 L/min/1.73m².

In multivariate analysis, age, male gender, HT, anorectic-related PAH and a CI inferior to 2.5 L/min/1.73m² were associated with a significant decrease in eGFR of 1.0 ml/min/1.73m²/year, (95% confidence interval, 0.8 to 1.2), 11.8 ml/min/1.73m² (5.8 to 17.8), 6.6 ml/min/1.73m² (0.1 to 13.2), 13.4 ml/min/1.73m² (2.3 to 24.5) and 10.1 ml/min/1.73m² (4.4 to 15.9). RAP were not statistically related to eGFR levels.

Conclusions: Renal dysfunction is frequent from diagnosis among PAH patients. A low CI is associated with a significant decrease in eGFR, whereas RAP seem unrelated. Equally, male gender, HT and anorectic-related PAH are correlated with a significant decrease in eGFR. These results should incite renal prevention in PAH patients presenting these risk factors.

PUB125

Kidney Function and Cause-Specific Mortality in Drug-Treated Older Cardiac Patients: A 10-Year Follow-Up Study. Ellen K. Hoogeveen,¹ Johanna M. Geleijnse,² Daan Kromhout,² Theo Stijnen,³ Erik Giltay,² ¹Nephrology, LUMC, Leiden, Netherlands; ²Human Nutrition, WU, Wageningen, Netherlands; ³Medical Statistics and Bioinformatics, LUMC, Leiden, Netherlands; ⁴Psychiatry, LUMC, Leiden, Netherlands.

Background: Chronic kidney disease (CKD) is highly prevalent among older (>60y) cardiac patients. The relation between CKD and cause-specific mortality among older cardiac patients who are treated with state-of-the-art pharmacotherapy is unclear.

Methods: From 2002-2006, 60-80 years old Dutch post-myocardial infarction patients were enrolled in the Alpha Omega Trial and followed until death or January 2012. We estimated Glomerular Filtration Rate (eGFR) with serum cystatin C (cysC) and creatinine using the CKD-EPI equations. Kidney function was available in 4,561 (94.3%) participants and analyzed in relation to major causes of death using Cox models and four-knot restricted cubic splines.

Results: At baseline mean age was 69y, 79% were men, 21% had diabetes, 90% used antihypertensive drugs, 85% used statins. Patients were divided into four categories of eGFR:<90 (33%; reference), 60-89 (47%), 30-59 (18%), and <30 (2%) ml/min/1.73m². Median follow-up was 6.4y. During follow-up, 973 (19%) patients died, of which 370 (42%) from cardiovascular causes, 309 (35%) from cancer, and 194 (22%) from other causes.

The hazard ratios (95%-CI) for any death according to eGFR (Q5: ≥90 (33%; reference), 60-89 (47%), 30-59 (18%), and <30 (2%) ml/min/1.73m²) were: 1 (reference), 1.4 (1.1-1.7), 2.9 (2.3-3.6) and 4.4 (3.0-6.4). For cardiovascular mortality the corresponding figures were 1.6, 3.6 and 6.0, for cancer 1.2, 2.1 and 1.6, and for other causes 1.4, 3.1 and 6.7. Similar, but weaker, results were obtained with creatinine-based eGFR.

Conclusions: We found a strong inverse graded relation between kidney function and mortality in drug-treated older cardiac patients, in particular due to cardiovascular and non-cardiovascular-non-cancer causes.

PUB126

The Association Between Serum Uric Acid and Incidence of Non-Fatal Stroke in a Community-Based Population: A Longitudinal Survey of a Nationwide Cohort in Japan. Keita Kamei,¹ Kazunobu Ichikawa,¹ Tsunuo Konto,¹ Shouichi Fujimoto,² Kunitoshi Ibeki,² Toshiki Moriyama,² Kunihito Yamagata,³ Kazuhiko Tsuruya,² Kenjiro Kimura,² Ichiei Narita,² Masahide Kondo,² Koichi Asahi,² Tuyoshi Watanabe. ¹Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan; ²Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup, Japan.

Background: Hyperuricemia is a risk for adverse renal outcomes in chronic kidney disease. This study investigated the effect of uric acid on incidence of non-fatal stroke in a community-based population.

Results: During the follow-up period 2,081 non-fatal stroke occurred (1.3%). The incidence of non-fatal stroke showed a significant J-shaped association with the increase in serum uric acid levels (P for trend <0.001, lowest [1.2%] in the 3rd quintile of uric acid [Q3: males 5.7–6.2 mg/dL, females 4.4–4.8 mg/dL] and highest [1.6%] in the 5th quintile [Q5: males ≥7.1 mg/dL, females ≥5.5 mg/dL]). After adjusting for possible confounders, the odds ratio for incident stroke was significantly higher in Q5, compared with Q3 (OR 1.21, 95%CI 1.05–1.39, P = 0.007). The odds ratio of hyperuricemia (serum uric acid ≥7 mg/dL) for incident stroke was significantly increased in total subjects (OR 1.22, 95%CI 1.05–1.39, P = 0.003).

Conclusions: This study showed that serum uric acid level is significantly associated with incident non-fatal stroke and that hyperuricemia might be an independent risk for non-fatal stroke in the general population.

PUB127

The Association Between Serum Calcium and Mortality in a Community-Based Population: The Takahata Study. Sayumi Watanabe, Keita Kamei, Kazunobu Ichikawa, Tsunuo Konto, Isao Kubota. Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan.

Background: The low intake of calcium is a risk for cardiovascular events. This study investigated the association between serum calcium and mortality in a community-based population.

Methods: This study included 1,314 participants (aged 40–87, males 45%) at local health checkup in Takahata, Japan. We divided them into 3 groups according to the tertiles of serum calcium at baseline and compared the mortality during 8-year follow-up period. Serum calcium was corrected for serum albumin.

Results: At baseline serum calcium level was 9.8 ± 0.4 mg/dL (mean ± SD). In the multivariate linear regression analysis serum calcium was positively associated with serum sodium, potassium, phosphorus, albumin, uric acid and total cholesterol, and was negatively associated with serum chloride and HDL-cholesterol, and urinary beta2-microglobulin. During the follow-up period 62 deaths, including 14 cardiovascular deaths occurred. In Kaplan-Meier analysis all-cause mortality was significantly increased along with the decrease in serum calcium (Log-rank P = 0.03). In Cox proportional hazard analysis adjusted for confounders including age, gender, smoking and drinking habits, comorbidities and other serum electrolytes, the association of serum calcium was of borderline significance with all-cause mortality (HR 2.09, 95%CI 1.94–4.75). P = 0.07, low tertile [5.6 mg/dL vs. high tertile [≥ 10.0 mg/dL]] and was significant with cardiovascular mortality (HR 6.33, 95%CI [1.13–43.7]). P = 0.04, low tertile vs. high tertile). In addition, there was a significant interaction between serum calcium and sodium on all-cause mortality (P = 0.03) and the association of serum calcium with the mortality was significant in the subjects with low serum sodium (< 150 mEq/L), but not high sodium.

Conclusions: This study showed that serum calcium was significantly associated with various environmental factors and low serum calcium was an independent predictor for the mortality in the general Japanese population.

Coronary Artery Calcification in Predialysis Diabetic and Nondiabetic CKD Patients

Sonozi Mizuri, Yoshiko Nishizawa, Kazuomi Yamashita, Michael J. Choi, Jung-hwa Kim, Ono Kyoko, Mariko Asai, Masahiro Iishine, Shigehiro Doi, Takao Masaki, Kenichiro Shiogemoto, Satoru Harada,

Methods: We examined Agatston coronary artery calcium score (CACS), BMD of T8 vertebra using MDCT, age, sex, presence of diabetes, hypertension, smoking history, statin administration, BMI, eGFR, uric acid, blood glucose, serum iron, calcium, phosphate, and triglyceride in 128 predialysis CKD patients, 82 nondiabetics, and 46 diabetics. Factors related to CACS were assessed by multivariate regression and logistic regression analyses using all of the above independent variables.

Results: Coronary artery calcification was present in 106 (82.8%) patients. Significant associations between CACS: 400H and age, diabetes, and statin administration were observed, and odds ratios were 1.1, 3.4, and 3.7, respectively, in all subjects (P < 0.05). Log CACS showed a significant association with age, diabetes, statin administration, serum phosphate, and triglyceride in all subjects (P < 0.05). Mean age and eGFR were 70.14 vs. 70.9 years (ns) and 37±20 vs. 30±19 ml/min/1.73m2 (P < 0.05), in nondiabetics and diabetics, respectively. Serum phosphate levels were not significantly different in the both groups. CACS (H) was 239±411 in nondiabetics and 942±1258 in diabetics (P < 0.001). Significant associations were observed between Log CACS and age (P = 0.0001, P = 0.042), statin administration (P = 0.01, P = 0.031), and serum phosphate (P = 0.05, P = 0.020) in nondiabetics, and between Log CACS and blood urea (P = 0.01, P = 0.55), serum iron (P = 0.01, P = 0.41), age (P = 0.01, P = 0.41), BMI (P = 0.05, P = 0.029) and smoking history (P = 0.05, P = 0.029) in diabetics. BMD showed no association with CACS.

Conclusions: Hyperphosphatemia is a risk factor for coronary artery calcification in nondiabetic but not diabetic CKD patients, and an association between CACS and BMD of T8 vertebra was not observed.

Prevalence of Hematuria and Associations with All-Cause and Cardiovascular Mortality in China

Jinwei Wang, Fang Wang, Luxia Zhang, Ming Hui Zhao. Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.

Background: Hematuria is one of the indicators of kidney damage. We aimed to estimate the prevalence of hematuria in China and evaluate its association with mortality and cardiovascular adverse outcome.

Methods: A nationally representative sample of 47,204 Chinese adults was obtained during the survey conducted between January 2009, and December 2012. Each participant’s survival status was identified through Dec 31, 2013. Causes of death in ICD code 100-199 were classified as cardiovascular disease. Hematuria was defined as ≥3 red cells per high-power field in microscopic examination. Subjects with pyuria and women undergoing menstruation were excluded from the analysis. The associations between hematuria and all-cause and cardiovascular mortality were studied by using the Cox regression model.

Results: The mean age of the participants at baseline was 49.6±15.2 years, and 42.7% of the participants were male. Altogether, 2126 (4.5%) of the population was detected with hematuria. The all-cause and cardiovascular mortality for participants with hematuria were 3.8 and 2.6 per 1000 person-years, while those for participants without hematuria were 3.4 and 1.3 per 1000 person-years. Hematuria was found to be significantly associated with increased risk of both cardiovascular mortality with the multivariable adjusted hazard ratio of 1.7 (95% confidence interval: 1.1-2.7), compared with those without hematuria. However, no significant associations were found between hematuria and all-cause mortality.

Funding: National Science Foundation, National Science Foundation of China.
Conclusions: Mortality, especially due to cardiovascular diseases, was greater among the Chinese patients with hematura. These results suggest the possible effect of hematura on cardiovascular mortality.

Funding: Government Support - Non-U.S.

PUB133
Glomerular Filtration Rate Is a Predictor of Subclinical Left Ventricular Diastolic Dysfunction in Patients with Rheumatoid Arthritis

Suad Hannawi, Khalfi Nacem, Issa Al Salmi, Medicine, MOH, United Arab Emirates; Medicine, MOH, United Arab Emirates; Medicine, The Royal Hospital, Oman.

Background: Rheumatoid arthritis (RA) is a systemic disease effecting primarily joints. Subclinical cardiovascular disease (CVD) is a leading cause of morbidity & mortality in RA & chronic kidney disease (CKD) at early stages. Left ventricular diastolic dysfunction (LVDD) is a principal pathophysiological mechanism & essential diagnostic indexes of HF with preserved ejection fraction (HFpEF).

Methods: Renal parameters correlated with echocardiographic findings in patients with RA& eGFR as estimated (MDRD equation). Doppler echocardiography was performed by pulse wave Doppler with sample volume at tip of mitral valve in apical 4-chambers view. Peak early (E) & late (A) diastolic velocities were measured as indicator of LVED pressure. Peak early (E)/late (A) diastolic velocities were measured as indicator of LVED pressure. Assessment of peak early (E′) & late (A′) diastolic mitral annular velocity was performed by pulsed wave tissue Doppler imaging (TDI) of lateral wall in apical 4-chamber view & diagnose LVDD (E/E′>8).

Results: Interim analysis: 29(3.26%) with RA diagnosed (ACR 1988), age 44+12y, CKD GFR 130+36 ml/min. Univariate regression showed a negative linear relationship of GFR & age (p<0.001, CI 2.77 -1.13, age) (RA onset p<0.001, CI 2.32-0.63, age) (RA diagnosis p=0.002, CI 0.25-0.55, -0.66) SBP p<0.032, CI 1.51-0.07, ER p=(0.005, CI 1.19-0.21, ferritin level p=0.008, CI 0.45-0.08, EE p<0.05, CI 20.76, 4.26). Multiple regression maintained a negative relationship between GFR & each of age (p<0.004, CI 2.59-0.4, EE p<0.04, CI 0.15, 0.01) &R2 was 0.54.

Conclusions: RA patient have subclinical CKD and cardiac dysfunction & eGFR independently & negatively correlated to LVDD with moderate correlation (0.54). E/E′ increased with decreasing GFR & higher than in patients GFR<90. LVDD influenced by increase LV preload due CKD progression & it’s a pre-clinical predictor of future HF & mortality. However, milder form of LVDD may stabilize or improve & subset of patients may, over time, be at risk for functional deterioration. Inflammation as a major pathological key in RA may be underlying cause for increased subclinical kidney & VD.

PUB134
The Association Between Creatinine versus Cystatin-C-Based eGFR and Cardiovascular Risk Factors in Children with Chronic Kidney Disease

Sheena Sharma,1 Ji Young Kim,3 Susan L. Furth,1 Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; 2Biosstistics Core, Clinical and Translational Research Center, Children's Hospital of Philadelphia, Philadelphia, PA.

Background: Chronic kidney disease (CKD) is an independent risk factor for cardiovascular events (e.g. stroke, myocardial infarction) in adults. Children with mild-moderate CKD have a high prevalence of cardiovascular risk factors (CRF). Higher levels of cystatin-C demonstrate a stronger predictive value for cardiovascular events compared with creatinine-based eGFR in adults. However, whether similar associations exist in children and young adults has yet to be determined. We hypothesize that cystatin-C-based eGFR will demonstrate a stronger association with CRF compared with creatinine-based eGFR in children and young adults.

Methods: We used cross-sectional data of 93 subjects aged 8-25 years with CKD and 120 healthy controls. eGFR was calculated using age-appropriate creatinine and cystatin-C based formulas. The CRF included were anemia (hemoglobin <2 standard deviations below the mean), hypertriglyceridemia (>130mg/dL) and proteinuria (urine protein/creatinine >0.2mg/dL or urine albumin/creatinine >30mcg/g). Multiple regression analysis assessed the association between creatinine and cystatin-based eGFR and each risk factor after adjusting for age, gender and race.

Results: These results suggest that creatinine and cystatin-based eGFR have similar associations with CRF.

PUB135
The Influence of Selected Demographics and Clinical Factors on Left Ventricular Function Presented by Echocardiographic Study in Patients Treated with Peritoneal Dialysis

Maria Wanic-Kossowska, Krzysztof Pawlacz, Krzysztof Schwerner, Krzysztof Hoppe. Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland.

Background: The purpose of the study was to perform a cross-sectional analysis between the selected demographics including age, sex, BMI as well as peritoneal dialysis treatment volume, volume of residual diuretics, presence of arterial hypertension, anemia, inflammatory states, malnutrition, mass of the left ventricle, problems with the contractile function of the left ventricle as well as decreased relaxation of the left ventricle in the group of patients treated with peritoneal dialysis with regard to survival prognosis.

Methods: The study was conducted on 105 patients (40 men, 56 women) treated with peritoneal dialysis with the average time of 36.1±23.7 months. The control group consisted of 30 healthy volunteers (20 women, 10 men, mean age 55.0±23.8 years). Based on general known vascular and cardiac risk factors the patients were divided into subgroups: elderly patients (<65 years of age), male, patients treated on peritoneal dialysis over 3 years, daily diuretes <500 ml, Kt/V<2.1, arterial hypertension, anemia, inflammatory states, malnutrition.

Results: Analyzing the frequency of vascular and cardiac risk factors resulting in inadequate echocardiogram results showed the inflammatory states were the most common reason for increased left ventricular mass, diastolic dysfunction of the left ventricle as well as decreased ejection fraction. In the model of logistical regression taking into account age, sex, dialysis vintage, concentration of CRP, ejection fraction of the left ventricle, left ventricle mass, and factoring E/A from the echocardiogram study only advanced age of the patient treated on peritoneal dialysis decreased survival rate.

Conclusions: Chronic low-grade inflammation and advanced age seem to be two most common negative prognostic factors decreasing life expectancy. Further research is necessary to verify the intricate relationships between demographic factors and prognosis in the group of patients undergoing peritoneal dialysis.

Ankle Brachial Index and Exertional Leg Pain Among Hemodialysis Patients without a Clinical Diagnosis of Peripheral Arterial Disease

Pranay S. Garinella,1 Lucia Kwak,2 Kunihiro Matsushita,2 Esther D. Kim,3 Michelle M. Estrella,3 Stephen M. Sozio,3 Lucy A. Mooni,3 Rulan S. Parcek,4 Bernard G. Jaac.2 Tufts Medical Center; Johns Hopkins Univ; Univ of Toronto.

Background: Exertional leg pain is considered pathognomonic for diagnosing peripheral artery disease (PAD). However, patients on dialysis may have multiple comorbidities causing or masking leg pain, potentially precluding its use to diagnose PAD. Furthermore, the utility of the ankle-brachial index (ABI) to diagnose PAD in this population is questionable due to the presence of arterial calcification. In this context, there are no data on the association of leg symptoms with ABI in dialysis patients despite having an extremely high burden of PAD.

Methods: We evaluated the cross-sectional association of exertional leg symptoms with the spectrum of ABI in 247 incident hemodialysis patients without clinical diagnosis of PAD enrolled in the Predictors of Arrhythmia and Cardiovascular Events (PACE) study. The presence of exertional leg pain was based on questionnaire and ABI was categorized as low (<0.90), borderline (0.90–1.00), normal (1.00–1.39) and high (>1.4). We used logistic regression analysis to report odds of exertional leg pain.

Results: Mean age was 54 years, 76% were black and 51% had diabetes. The prevalence of exertional leg pain was lowest in the normal ABI category and increased towards both ends of the spectrum. Compared to normal ABI, low ABI was associated with 2.8 fold higher odds of exertional leg pain, although it did not reach significance. After adjusting for age, gender and race this association was attenuated to 2.5 fold odds. Borderline and high ABI were also similarly associated with exertional leg pain.
Conclusions: Low ABI tended to be associated with higher risk of execlional leg pain. A low ABI value may be useful to identify ischemic etiology of leg pain even among dialysis patients with high prevalence of leg symptoms due to various conditions.

PUB137

Chronic Kidney Disease Is Highly Prevalent at Emergency Department and Associated with Cardiovascular Comorbidity
Jolanta Malyszko, Anna Swietochowska.
Nephrology, Medical Univ, Białystok, Podlaskie, Poland; "Emergency, Regional Hospital, Łomża, Poland.

Background: Different stages of CKD affects more than 10% of the population, while in high-risk patients, the incidence of 30-50% is reported. The aim of this work was to evaluate the prevalence of CKD in patients admitted to the non-surgical emergency department in one year, the impact of CKD risk factors, rate of hospitalization and mortality.

Methods: From 10500 patients admitted to ED, the group of patients with serum creatinine measured, i.e. 3835 (40%) patients over 18 years was selected, including 2095 (55%) patients over 70 years. Age, gender, medical history of hypertension, heart failure, ischemic heart disease, acute coronary symptoms (ACS), diabetes, inflammation, current medications, physical examination, laboratory results: creatinine, C-reactive protein (CRP), leukocyte count, hemoglobin, the alcohol level in serum, urinalysis were analyzed.

Results: 1797 patients were hospitalized (57%) mainly for cardiovascular reasons, remaining were discharged home. 561 (15%) were admitted to the ED more than once. Abnormal serum creatinine was found in 27%, while 19% have CKD stage 3 and 5% stage 4. Active urine sediment was present in 20% of studied patients. Patients and physicians were unaware of this finding. A small percentage of patients were under nephrology care. Accumulation of risk factors such as gender, age, hypertension, diabetes, results in an increased prevalence of CKD. Prevalence of hypertension in the population of patients with CKD is high (59% vs 29% in non-CKD, p<0.001), similarly to prevalence of CAD (24%), DM (15%) and CHF (16%). In CKD, 30% of patients have anemia. In-hospital mortality was 6%. Analysis of mortality of patients admitted to the emergency department and then hospitalized showed that the majority of patients were over 70, with CKD 64%, CHF (75%), DM (35%), ACS (25%) and anemia (56%). Deaths were mainly from cardiovascular causes.

Conclusions: Prevalence of CKD is high in patients admitted to ED, and associated with mainly cardiovascular disease. Education is of utmost importance to diagnose and treat CKD in a timely manner and decreased cardiovascular morbidity and mortality in this population.

Funding: Government Support - Non-U.S.

PUB138

Predictors of In-Hospital Mortality of CKD4-6 Patients with Takotsubo Cardiomyopathy
Fernando Rodrigo Aguilar, Mark Abi Nader, Wen Shen, Serban A. Dragoi, Alex Montero, Ping Li. Internal Medicine, Div of Nephrology, Medstar Georgetown Univ Hosp, Washington, DC.

Background: the pathophysiology of Takotsubo cardiomyopathy (TTC) remains poorly understood and little is known about the factors predicting mortality in these patients among those with chronic kidney disease. We aimed to study the epidemiology of TTC and predictors of mortality in these patients.

Methods: All patients with CKD 4 to CKD 6 (ICD9 585.4-585.6) diagnosed with TTC (ICD9 429.83), in the Nationwide Inpatient Sample database between 2007 and 2012, were compared to CKD4-CKD6 patients without TTC. Capturing only cases undergoing left heart catheterization (ICD9 procedure code 32.22) and excluding those receiving stent (ICD9 procedure code 90.66; 36.01 - 07.00.45.00.48) as a main treatment. Both groups were matched, using propensity matching score for chronic conditions including diabetes mellitus, hypertension, hyperlipidemia, coronary artery disease, obesity, alcohol use, smoking, heart failure and ventricular arrhythmias. Non-cardiovascular conditions were also used to match individual cases. Multivariable logistic regression analysis was performed.

Results: 143 cases of TTC were diagnosed from 2007-2012 patients having CKD4-6. Were 138 cases were matched (n to 1) and posteriorly analyzed. Among to control groups, CKD 4-6 patients with TTC was more commonly diagnosed in Women (86.23% vs 13.77 p=1.0). Alcohol, older, smoking and anxiety, were significantly more prevalent in TTC group. In-hospital mortality rate was not different among both groups even after multivariable regression analysis. Contrary to epidemiologic studies in the general population, Age, Race Stress, anxiety, smoker, Obesity and HTN did not predict mortality with TTC.

Conclusions: In CKD4-6 patients, TTC does not carry higher mortality outcome compared to the general CKD4-6 patients. Older CKD4-6 females, with anxiety disorder and smokers are at higher risk to develop TTC.

PUB139

The Importance of Evaluating Coronary Artery Disease by Multi-Director Row Computed Tomography in Advanced CKD
Masatasa Hasegawa, Daiki Kobayashi, Masahiko Nagahama, Takuya Fujimura, Yuki Heath, Fumika Taki, Miyuki Futsutayama, Yasuhiro Komatsu.
1Nephrology, St. Luke’s International Hospital, Tokyo, Japan; 2General Internal Medicine, St. Luke’s International Hospital, Tokyo, Japan.

Background: There is a growing body of evidence that CKD contributes to the severity of coronary artery disease (CAD). Although Multi-director row computed tomography (MDCT) provides valuable information about CAD, its use for patients with CKD is difficult due to the risk of contrast induced nephropathy (CIN). To our knowledge, there have been no studies to explore the association of CAD and advanced CKD. The objectives of this study are to assess the severity of CAD in advanced CKD patients by MDCT and clarify the association between CAD and renal function.

Methods: We retrospectively collected the data from 168 advanced CKD patients, stage 3b to 5, who underwent MDCT angiography at St Luke’s international hospital between 2011 and 2014. We assessed CAD by coronary artery calcification score (CASC), coronary plaque characteristics and number of vessel disease. Risk factors for CAD were sought using univariate and multivariable logistic regression.

Results: Among the 168 patients (56 females, age 60.0±17.0), 108 patients were CKD stage 3b, 42 patients were stage 4, and 18 patients were stage 5. No patient developed CIN by MDCT. On univariate analysis, patients with CASC>=100 were older (p=0.003), male sex (p=0.011), diabetic (p=0.045), and more likely to be a smoker (p=0.014). Multivariable logistic regression analysis identified age (hazard ratio = 1.08, P<0.01), male sex (hazard ratio = 2.97, P=0.013), and CKD stage (hazard ratio = 2.58, P=0.041) as independent risk factors for CASC>=100.

Conclusions: Coronary artery calcification is worsened significantly with decreasing renal function in advanced CKD. Given the high morbidity and mortality of cardiovascular disease in CKD, our study underscores the importance of evaluating CAD in advanced CKD.

PUB140

Cardiovascular Biomarkers and Coronary Calcification in CKD Patients
Joaoquin Martinique, Diana Izquierdo, Patricia Restituto, Nuria Garcia-Fernandez, Maria Fernandez Slon, Diana Lopez Espinosa, Maria Jose Meldad Higuera, Nerea Naro.
Servicio de Nefrologia, Complejo Hospital de Navarra, Pamplona, Spain; Servicio de Bioquimica, Clinica Univ de Navarra, Pamplona, Spain; Servicio de Nefrologia, Clinica Univ de Navarra, Pamplona, Spain.

Background: Cardiovascular calcification and mortality are highly prevalent in patients with CKD. Biomarkers can help to an early diagnose, like Osteoprotegerin (OPG) a glycoprotein from TNF family that has been associated with cardiovascular (CV) disease. FGF-23, a phosphaturic protein has been linked to vascular calcification, ventricular remodeling and mortality. Coronary artery calcification (CACC) measured by Agatston score (AS) by CT is associated to CV disease in CKD patients. We hypothesized that OPG and FGF-23 are abnormally elevated in CKD and are associated CACC measured with AS.

Methods: An observational study including 138 CKD 3-5patients, and 20 control subjects were included. Serum FGF-23 and OPG levels were measured by ELISA and CAC was determined by multi-detector computed tomography (AS). Biochemical regular labs (sCr, Ca, P and PTHi) were measured.

Results: Compared with control subjects, CKD patients exhibited significantly augmented serum FGF-23 (16.2 vs 304 ng/mL; p<0.001) and OPG levels (157.0 vs 711.7; p<0.05; LR=b2.48; p<0.001), and increased proportionally to CKD stage. FGF-23 and OPG were correlated to PTHi and P (p<0.001) and OPG correlated with renal function (sCr) in non-dialysis patients (p<0.05). CKD 5 patients showed significantly augmented serum FGF-23 (1380.7) compared with CKD 3 (144.3; p<0.05) or CKD 4 (527.7; p<0.05). FGF-23 and OPG were associated with AS (r=0.2-0.4; p=0.05 and r=0.37; p<0.001, respectively). Among CKD patients, high CACC (AS>800) compared to low CACC (AS<150) showed higher FGF-23 (374.9 vs 156.1; p<0.05) and OPG levels (2121.2 vs 1305.2; p<0.001).

Conclusions: CKD is related to high coronary artery calcification levels. FGF-23 and OPG are higher in CKD patients and are significantly associated to coronary artery calcification. Further investigations are needed to determine if they could promptly assess increased cardiovascular risk in CKD patients.

PUB141

Rate of Kidney Function Decline and Risk of Hospitalizations
Yan Xie, Benjamin Charles Bove, Sumitra Balasubramaniam, Ziyad Al-Aly.
Research and Development, VA Saint Louis Health Care System, Saint Louis, MO; Medicine, VA Saint Louis Health Care System, Saint Louis, MO.

Background: Risk of hospitalizations is increased in patients with chronic kidney disease (CKD). We sought to examine the association between rate of kidney function decline and risk of hospitalization in a cohort of patients with early CKD.

Methods: We built a cohort of 241,274 United States veterans with an estimated glomerular filtration rate (eGFR) between 60 and 45 mL/min on October 1, 1999 and who had at least 1 additional eGFR measurement between October 2003 and September 2004. Patients were followed longitudinally from October 2004 until September 2013. We built
survival models to examine the association between rate of kidney function decline and risk of hospitalization, and readmission. We built linear regression models to estimate the survival models to examine the association between rate of kidney function decline and risk of hospitalization, and readmission. We built linear regression models to estimate the length of hospital stay.

**Results:** Over a median follow-up of 9 years (IQR 5.42 - 9.00), compared to patients who experienced mild eGFR decline, patients with moderate and severe eGFR decline exhibited an increased risk of hospitalizations HR=1.10 (CI:1.07-1.12), and HR=1.29 (CI:1.26-1.32) respectively. The number of hospitalizations modified the association between rate of decline and risk of hospitalizations in that the risk was increasingly more pronounced with increased number of hospitalizations (p value for interaction <0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe kidney function decline had increased risk of future readmission, HR=1.16 (CI:1.10-1.21), and HR=1.47 (CI:1.39-1.55) respectively. Among patients with severe kidney function decline, the risk of readmission was increasingly stronger with increased number of readmissions (p value for interaction < 0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe decline experienced an additional length of stay of 0.91 (CI: 0.58-1.25) and 2.82 (CI: 2.43-3.20) day/year; respectively.

**Conclusions:** Our findings suggest that rate of kidney function decline is associated with future risk of increased health care utilization.

**Racial Influences on the Association of Albumin and Hemoglobin in Chronic Kidney Disease**

**Authors:** Divya Shankararanyanan, Avaneesh Jakkoju, Goutham Gudavalli, Ziad Maurice Ashkar. Dept of Internal Medicine, Louisiana State Univ, Lafayette, LA.

**Background:** In CKD, anemia is associated with reduced kidney function, female gender, diabetes, older age, African-American race (AA), iron deficiency, low albumin, renin-angiotensin blockade, and chronic inflammation. There is a paucity of studies evaluating relationship of albumin and hemoglobin(Hb) in CKD among racial groups.

**Methods:** Retrospective cross section design of 196 patients with CKD stages 2-5, in a community clinic over a 7 months period. Averages of hemoglobin, albumin, body mass index (bmi), and glomerular filtration rate (GFR) were obtained for each individual patient. Patients on dialysis and on erythropoiesis-stimulating agents were excluded. Multi-linear regression analysis (MLR) was then done between serum albumin and hemoglobin adjusting for age, sex, diabetic status, GFR, bmi and Ace inhibitors/angiotensin receptors blockers intake (ACEi) among African-Americans (AA) and Caucasians (W).

**Results:** 51% were AA. 49% were diabetics. Mean Hb was 11.7 in AA compared to 12.3 in Caucasians. Mean serum albumin was also lower (3.5 AA versus 3.8 in W). Bmi and GFR were higher in AA (36.4 and 42.8 in AA vs 32.3 and 39.9 in W respectively). Using MLR, there was a statistically significant positive association between GFR(coefficient=0.02, p<0.001), albumin (coefficient=0.77, p=0.002), and hemoglobin. AA race was negatively related to hemoglobin(coefficient= -0.68, p=0.02). When MLR was done separately among racial groups, there was a persistent positive relationship between albumin and hemoglobin among AA (coef=0.95, p<0.001). In Caucasians however there was no association between albumin and hemoglobin (p=0.181).

**Conclusions:** In CKD2-5, using multilinear regression analysis, there was a positive association between serum albumin and hemoglobin. This relationship occurs only in AA and disappears among Caucasians. It is of interest that in our sample AA had higher baseline bmi and GFR and lower serum albumin and hemoglobin. More needs to be done to understand the interplay between bmi, albumin and markers of inflammation and nutrition among African Americans with chronic kidney disease and their relationships to hemoglobin levels.

**Mircera Use in Chronic Kidney Disease Patients with Symptomatic Renal Anemia: The Real Life Setting**

**Authors:** Sai Krishna Derasingham, Suzanne H. Forbes, Muhammad M. Yaqoob. Renal and Transplantation Medicine, Baris Health NHS Trust on behalf of the Mircera Audit Consortium, London, United Kingdom.

**Background:** Randomized controlled trials have confirmed non inferiority of Mircera in the management of renal anemia when compared to other erythropoietin stimulating agents (ESAs). Many of these trials had strict exclusion criteria which perhaps confounded any benefit that may be seen in an unselected cohort of patients. This multicenter audit assessed the outcomes of Mircera use in the real life setting.

**Methods:** A prospective audit was conducted by 6 UK Renal Centers between 2009 and 2011. Demographic data, as well as haematological and biochemical parameters were longitudinally collected from 1000 adult patients requiring ESAs, over a 1 year period. A cohort of 500 patients were switched from previous ESAs to Mircera and 500 patients were excluded. Achievement of target hemoglobin (Hb) as per the National Institute of Clinical Excellence (NICE) guidelines was ascertained as the primary objective. Hb variability was reviewed as a secondary objective.

**Results:** Demographic data confirmed both cohorts were comparable. Only 11% of Mircera treated patients had their Hb maintained within range (10-12g/dl) over the entire 1 year versus 4% in the non-Mircera group (p=0.05). (If an Hb recording was out of range the patient was classified as ‘not maintained’). Parameters such as B12, folate and iron were similar in both cohorts. Hb was less variable in the Mircera group.

**Conclusions:** The results of this audit confirm that Mircera use in the correction of anemia associated with CKD is equally efficacious as other ESA therapies in this real life setting. Over a year period, Hb variability was noted to be reduced in the Mircera treated cohort suggesting a role for its use in patients with fluctuating Hb levels.

**Latent Profiles of Patient Reported Outcomes in Nephrotic Syndrome Patients**

**Authors:** Jonathan P. Troost,1 Debbie S. Gipson,1 Bryce B. Reeve,2 Patrick H. Nachman,3 Rashed A. Ghaedegisini,3 Ichuan Wang,3 Frank Medorsitzki,4 Susan F. Massengill,5 John D. Mahan,6 Howard Trachtman,7 David T. Seleowski.1 1Univ of MI; 2Univ of NC; 3Duke Univ Medical Center; 4George Washington Univ; 5New York Univ; 6Levine Children’s Hospital; 7The Ohio State Univ.

**Background:** Nephrotic syndrome (NS) can significantly impair the quality of life in children and adults. The purpose of this study was to demonstrate the feasibility and utility in using a latent profile analysis (LPA), a type of cluster analysis, to identify subgroups of patients based on their patient reported outcomes using the Patient Reported Outcomes Measurement Information System® (PROMIS®) measures as well as identifying significant predictors of these subgroups.

**Methods:** Prospective data were collected on 121 children with NS from the PROMIS-II study. Data from 55 children and 254 adults with biopsy confirmed NS from the NEPTUNE cohort were used as validation. LPA was used to identify patterns and subgroups of patients based on PROMIS domain scores. Classification was assessed using entropy statistics. Generalized multinomial logit models were used to identify predictors of profile membership as well as transitions between profiles over time.

**Results:** We identified three patient reported outcome profiles (figure1) in the PROMIS-II cohort with strong indicators of membership classification (entropy>0.86).

**Conclusions:** The models derived from the PROMIS-II cohort were also present in NEPTUNE. Reaching complete proteinuria remission, reduction in symptom number, increase in serum albumin and shorter disease duration were significant predictors of better quality of life over time.

Sex Hormone Status in Women with Chronic Kidney Disease. A Survey of Nephrologists. Sharranya Rashmi, Ellen Wells Seely, Matthew T. James, Jayna M. Holroyd-Leduc, Stephen B. Wilton, Sofia B. Ahmed, Medicine, Cumming School of Medicine; 2 Brisbane and Women’s Hospital; 3 Community of Health Sciences, Univ of Calgary; 4 Libin Cardiovascular Inst of Alberta.

Background: Chronic kidney disease (CKD) in women is often accompanied by menstrual and fertility disorders due to kidney-mediated endocrine disturbances. Whether this issue is recognized by nephrologists and discussed by them with their patients is unknown.

Methods: We electronically surveyed 111 nephrologists in Canada, identified via Canadian Society of Nephrology membership (39% response rate), regarding their impression of sex hormone loss and menstrual and fertility disturbances and the role of postmenopausal hormone therapy (HT) in women with CKD. Responses were stratified by kidney transplant nephrologist status.

Results: Fourteen percent of respondents were transplant nephrologists. There were no differences in age or sex between transplant and non-transplant nephrologists. Ninety-three percent of respondents agreed that kidney function has an important impact on regulation of sex hormones. However, only 35% reported discussing fertility, and even fewer (14%) reported discussing menstrual irregularities with their patients. Only 40% of respondents advised their patients to address these concerns with their family physician or an endocrinologist or gynecologist. Most of the of nephrologists responded that they do not know if there is a role for hormone replacement therapy in patients with CKD (48%), 23% of nephrologists disagreed with the statement. Nephrologists did not know whether the potential benefits of postmenopausal hormone therapy outweighed the risks in CKD (51%) or if the formulation (44%), route of administration (46%), and time of HRT initiation (50%) play a role in the actions of postmenopausal hormone therapy.

Conclusions: While nephrologists recognize the impact of CKD on sex hormone status in women, few address fertility and menstrual disorders with their patients. Our survey highlights the need for future studies to investigate the impact of CKD on sex hormone status and how to manage the disturbances of sex hormones in people with CKD.

Clinical and Pathological Analysis of Elderly Hospitalized Patients with Chronic Kidney Disease Fu-You Liu, Yinghong Liu. Inst of Nephrology, the Second Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: To investigate the primary disease and to examine the pathological patterns of renal in elderly patients with CKD.

Methods: Medical histories, laboratory test results and renal biopsy data were collected and retrospectively analyzed from 967 elderly patients with CKD.

Results: (1) The average age of 967 cases of elderly patients was 68.27 ± 6.41 years old. The leading cause of CKD was primary glomerular diseases (37.33%), followed by diabetes nephropathy (23.27%) and hypertension nephropathy (19.75%). (2) The left kidney was larger than the right kidney and males were larger than the females (P < 0.05). There was a positive correlation between eGFR and the left kidney width, depth, and the right kidney width, depth. (3) In 75 patients who underwent renal biopsy, the most common renal histopathology in primary glomerular disease was membranous nephropathy (MN) (48%), in patients with MN, 88.00% presented as nephrotic syndrome. (4) The prevalence of hypertension was 80.66%, eGFR was negatively correlated with systolic blood pressure levels. (5) The anemia rate of elderly patients with CKD was 77.97%, and eGFR and hemoglobin levels were positively correlated. (6) There was a positive correlation between eGFR and HDL-C, LDL-C, total cholesterol and triglyceride respectively. (7) Calcium-phosphate metabolism were mainly hypocalcemia (27.92%) and hyperphosphatemia (34.91%) eGFR was negatively related to the level of blood phosphorus and intact parathyroid hormone (iPTH), and positively related to blood calcium levels.

Conclusions: (1) This study shows that primary glomerular disease is still the leading cause of elderly patients aged 60 and above with CKD, followed by diabetes nephropathy and hypertensive nephropathy. (2) In elderly patients receiving renal biopsy, the most common renal histopathology pattern was MN in primary glomerular disease. (3) It indicated that high systolic blood pressure, renal atrophy, anemia, low HDL-C, hyperphosphatemia and secondary hyperparathyroidism may be associated with deterioration of renal function level.

Measurement of Breath Ammonia for Detection of Patients with Chronic Kidney Disease. Sebastian Beve, Evelina Mohorko, Krista Kolari, Polonca Breglez, Andrej Holobar, Daniela Kniepseis, Matej Podbrdar, Nina Hojs, Masa Knehtl, Robert Eckart, Radovan Hojs. 1 Univ Clinical Centre Maribor, Slovenia; 2 Faculty of Chemistry and Chemical Engineering Maribor, Slovenia; 3 ECHO d.o.o., Slovenes Kongice, Slovenia; 4 Medical Univ Graz, Austria; 5 Univ Clinical Centre Ljubljana, Slovenia.

Background: In a healthy individual, ammonia is converted to urea in the liver through urea and citric acid cycles. Urea is then transported through the blood stream and excreted into the urine by the kidneys. In patients with chronic kidney disease (CKD) an equilibrium concentration of ammonia and urea becomes imbalanced, concentrations exceeding physiological values and breath ammonia can be used for detecting increased ammonia wastes in the body. In our pilot study, breath ammonia was used to measure and analyze breath ammonia in healthy volunteers and CKD patients.

Methods: Six CKD patients and eight healthy volunteers were enrolled. The mean age of CKD patients was 47.2 years, mean age of healthy volunteers 61.3 years. One controlled breath sample was given to each participant immediately after the sample was collected breath gas analyzer (BA-NH3, Echo, d.o.o.). This was used for measuring breath ammonia in our participants. BA-NH3 detects breath ammonia in parts per million (ppm) and measures the electric current in milliamperes (mA). BA-NH3 was validated with reference gas current measurements prepared with a precise accredited gas mixing device (M4-1 S-2, Echo, d.o.o.) using calibrated mass flow controllers controlled with computer software.

Results: Mean serum creatinine in CKD patients was 455.17 ± 294.12 µmol/L and 62.13 ± 7.5 µmol/L in healthy volunteers. BA-NH3 detected more ppm of ammonia in breath of CKD patients (mean ± std: 2.2 ± 1.9; range: 1.26-6.33) compared to healthy volunteers (mean ± std: 0.49 ± 0.08; range: 0.38-0.64 ppm) (p = 0.003) and measured higher electric current from breath samples of CKD patients (mean ± std: 4.33 ± 0.25; range: 4.10-4.67 mA) compared to healthy volunteers (mean ± std: 4.01 ± 0.01; range: 4.00-4.03 mA) (p = 0.003).

Conclusions: Results of our pilot study show that breath monitoring of ammonia can be an useful simple, fast and noninvasive tool for detection of kidney impairment.

Minimizing Erythropoietin Stimulating Agents Requirement by Comprehensive Clinical Care
Rachita Singh Dhull, Rossana Baracco, Melissa J. Gregory, Tej K. Mattoo. Pediatric Nephrology, Children’s Hospital of Michigan, Detroit, MI.

Background: Anemia is a common problem in children with chronic kidney disease (CKD). The objective of the study was to evaluate prevalence of anemia, use of iron supplement and erythropoietin stimulating agents (ESA) in children with CKD stage 2-4, and compare the same with previous pediatric studies.

Methods: This is a retrospective chart review of children with CKD stage 2-4 (defined per KDOQI), aged between 1-18 years followed at Children’s Hospital of Michigan (CHM) in 2013. Data on transferrin saturation, hemoglobin level, use of iron supplements and ESA was collected.

Results: Total number of patients were 62. The mean age was 10.12 ± 5.52 years and 27.4% were female. The main causes of CKD were renal dysplasia (20%), obstructive uropathy (18%), reflux nephropathy (14.5%), cystic dysplasia (13%), glomerular pathology (11.2%) and others (23.3%). In our cohort, 27% patients had anemia compared to 44% in CKiD study and 43.5% in study by Wong et al. Also, only 6.5% of CKD patients were on ESA, compared to 18% in CKiD study and 19.5% in study by Wong et al. Results are elaborated in the table below.

Notes:
*Anemia as defined by hemoglobin (Hb) level < 12 g/dl or on medical management for anemia.

Conclusions: Our CKD patients had a lower prevalence of anemia and lower use of ESA compared to other pediatric studies. We maintain adequate iron stores by using iron supplements even in children with normal hemoglobins. The administration of supplemental iron prior to the development of anemia in children with CKD decreases the need for ESA.

PUB510

Validation of Urinary Biomarkers for the Diagnosis of Urothelial Carcinoma in Patients with Chronic Kidney Disease
Chin-Ching Huang,1 Che-yi Chou,1 Chao-Jun Cheng,2 and Meng-Ju Liao,1 National Taiwan University Hospital, Taipei, Taiwan.

Background: Many urine biomarkers for diagnosis of urothelial carcinoma(UC) have been published. CKD patients are prone to have UC. Most of the studies are tested in healthy controls and UC patients. Whether these biomarkers are specific to diagnose UC in CKD patients have not been studied before. AIMS: To investigate whether these urinary biomarkers are specific to diagnose UC in CKD patients.

Methods: This is a multicenter prospective case-control study, carried out at 7 tertiary medical centers in Taiwan (Taiwan UC Consortium). Subjects were healthy adults (healthy controls), patients with CKD but without UC (disease controls) and patients with ongoing UC.Urine was collected from each patient and frozen immediately after collection. We measured 9 urinary UC biomarkers: BLCA-1.HAI-1.HtrA1, NMP22, CYFRA21-1, TSCSTD2, PUB150, BTA and Midkine. Mann-Whitney Rank Sum Test was used for statistical analyses.

Results: A total of 47 UC cases, 288 CKD patients and 20 healthy controls were recruited. We selected 47 CKD control patients who were age, sex and CKD-staging best matched with 47 UC patients. Among the 9 biomarkers tested, six biomarkers, e.g. NMP22, CYFRA21-1, TSCSTD2, PUB150, BTA and Midkine showed significant increase of urinary concentrations in UC patients when compared to healthy controls. Nevertheless, only Midkine and CYFRA 21-1 had significantly increased concentrations in UC patients when compared to CKD controls. The other 4 UC biomarkers did not show significant higher concentrations in UC patients than CKD controls.

PUB515

Predictors for 30-Day Hospital Readmission in a Nephrology Ward
Carolina Melo,1 Victoria A. Wong,2 Asia Roy,2 Rachel R. Mehta,3 Michelle L. Ong,2 Jaceson J. Young,2 S. Joselynne Costanza,4 and Michele S. Clarke.1 Austin Health, Melbourne; 2Univ of Melbourne, Melbourne; 3St. Vincent’s Hospital, Melbourne; 4Sal Aqua Diagnostics, New York.

Background: Rehospitalization, particularly 30-day hospital readmission is a growing concern in health care services. In this study we searched for predictors of 30-day readmissions (including emergency department visits) and 12-months hospitalization rate in patients admitted to a nephrology ward.

Methods: A group of 144 patients admitted to our nephrology ward from 2012 to 2013 were randomly selected. Their medical records regarding demographic and clinical-laboratorial data were collected. The statistical analysis was performed using univariate and multivariate logistic regression, and poisson regression.

Results: Median age was 66yos (IQ 56-81), with 63% of male patients. The majority of the patients had an emergent admission (63%) and regular hospital follow-up (55%). The median length of hospital stay was 7 days. The readmission rate was 23% and the median length until readmission was 13 days. The prevalence of chronic kidney disease was 89%, with 30% of these patients undergoing chronic intermittent hemodialysis and 11% peritoneal dialysis. The median Charlson Comorbidity Index (CCI) was 7 points (IQ 4-11). In the univariate analysis we found a significant association between diabetes mellitus (OR =2.45, p <0.05), lower (<3.5 g/dL vs ≥ 3.5 g/dL) albumin level (OR=8.73, p =0.006), higher (>8 vs ≤ 8) CCI score (OR=2.94, p =0.02) and 30-day hospital readmission. In the binary logistic regression only albumin level kept its significant association (OR=7.9, p=0.01), with diabetes mellitus maintaining a tendency for significance (OR=2.97- p=0.09). The rate of rehospitalizations at the first year adjusted for gender was 2.6 vs 6.4 rehospitalizations/100 patients-month in the lower and higher CCI score groups, respectively (p=0.01). The rate of emergency department episodes adjusted for gender was 29 versus 75 episodes/100 patient-month in the lower and higher CCI score groups, respectively (p=0.001).

Conclusions: The Charlson Comorbidity Index and albumin level may be valuable predictors of hospital readmission risk in patients from a nephrology ward.

PUB512

Urinary Protein Fragment Excretion in Diabetic Patients with Chronic Kidney Disease
Michele V. Clarke,1 Elif Ekinci,1,2 Nicholas J. Radcliffe,1,2 Richard J. Mac slaac,3 George Jerums,1 Wayne Comper.1 Austin Health, Melbourne; 2Univ of Melbourne, Melbourne; 3St. Vincent’s Hospital, Melbourne; 4Sal Aqua Diagnostics, New York.

Background: Albuminuria is an established marker for the development of diabetic nephropathy. Normal renal handling of albumin involves endocytosis by proximal tubule cells through a lyososomal pathway. This returns small albumin fragments, undetectable by standard clinical assays, to the tubular lumen. Albuminuria has been shown in patients with type 1 diabetes to be associated with an impaired degradation pathway, and urinary peptides have been shown to be reduced in patients with macroproteinuria. However, urine peptide excretion studies have not controlled for changes in estimated glomerular filtration rate (eGFR) in patients with diabetes.

Methods: Patients with diabetes and eGFR <60ml/min were stratified into normo- (<20mg/min, n=9), micro- (20-200mg/min, n=12) or macroalbuminuric (>200mg/min, n=9) groups. 24 hr urines were passed through a 10kDa protein filter, and the <10kDa and >10kDa fractions were assayed separately using the BCA protein assay to detect peptide bonds.

Results: Macroalbuminuric patients had a reduced proportion of peptide fragment excretion (<10kDa compared to micro- and normalalbuminuric patients (81.1% vs 89.0%, p=0.08 and 86.8%, p=0.001 respectively), however there was no difference between micro- and normalalbuminuric groups (Figure 1). Mean fragment concentrations were lower in micro- and macro- groups compared to normalalbuminuric patients, (338g/ml and 348g/ml vs 4396g/ml) but did not reach statistical significance.
In patients with diabetes and reduced renal function, we have demonstrated a reduction in peptide fragment proportional excretion in macroalbuminuric patients. These findings are consistent with the hypothesis that albuminuria is linked to defects in the renal tubule resorption and fragmentation pathways.

**Conclusions:** In patients with diabetes and reduced renal function, we have demonstrated a reduction in peptide fragment proportional excretion in macroalbuminuric patients. These findings are consistent with the hypothesis that albuminuria is linked to defects in the renal tubule resorption and fragmentation pathways.

**Clinical and Pathological Features of Idiopathic Membranous Nephropathy in Young Adults**

Chenxi Gao, Jing Xu, Wen Zhang, Xiaoxia Pan, Xiao Li, Nan Chen. Nephrology, Rajiin Hospital, Shanghai Jiaotong Univ, Shanghai, China.

**Background:** Membranous nephropathy (MN) is a common pathological type in elderly nephrotic syndrome (NS) patients. Few researches focus on the young idiopathic MN population.

**Methods:** 583 patients hospitalized between Jan 2009 and Dec 2014 in our department, with biopsy-proved MN eliminating secondary causes, are enrolled. All patients were divided into 3 groups: 150 patients (25.1%) in young adult group (44 yrs), 202 (34.7%) in middle-aged group (45-59 yrs) and 231 (39.6%) in elderly group (60 yrs). We collected and compared their clinical and pathological data as well as therapy strategies.

**Results:** 310 male and 273 female enrolled. The young adult group had a lower rate of NS (P<0.02), higher serum albumin (P<0.01), estimated-GFR (P<0.01) and hemoglobin level (P<0.01), and lower fast blood glucose level (P<0.01).

**Table 1. Clinical features in three groups**

There’s no significant difference in the disease staging or immunofluorescences staining. However, the young adult patients had fewer mesangial, interstitial, tubular and arteriolar lesions, and fewer inflammatory cells infiltration as well (P<0.01). For the therapy, the number of ACE/ARB regimen applied in the three groups was 72/95/75, while corticoid associated with immunosuppressive agents regime was 66/92/140 (P<0.01).

**Conclusions:** About a quarter of all IMN patients are young adults. They had fewer cardiovascular risk factors, higher serum albumin level and better renal function. Their pathological lesions were milder. ACE/ARB regimen is more widely applied in young adults patients.

**Effect of Glycemic Control on Estimated Glomerular Filtration Rate by Cystatin C**

MasaHiro Horio,1 Enyu ImaI,2 Yoshinari Yassuda,3 Tsuyoshi Watanabe,4 Hitoshi Yokoyamaa,5 Seichi Matsu,6 1Osaka Univ Graduate School of Medicine, Osaka, Japan; 2Nakayamaderia Imai Clinic, Takarazuka, Japan; 3Nagoya Univ Graduate School of Medicine, Nagoya, Japan; 4Fukushima Medical Univ, Fukushima, Japan; 5Kanazawa Medical Univ School of Medicine, Kanazawa, Japan; 6Okayama Univ Graduate School of Medicine, Okayama, Japan.

**Background:** Cystatin C has been proposed as an alternative marker for estimating glomerular filtration rate (GFR). But, some factors other than GFR affect the accuracy of estimated GFR (eGFR). Some studies raised a concern that poor glycemic control may cause inaccuracy of estimation of GFR. We studied the effect of glycemic control on eGFR based on serum cystatin C (cGFR).eGFR.

**Methods:** eGFR was measured by inulin clearance (Cin). Estimated GFRs were calculated by CKD-EPI equation (CKD-EPI) and Japanese GFR equation (J-Eq) based on standardized cystatin C. Glycemic control was evaluated by serum glycated albumin (GA). Three hundred and forty five Subjects with normal GA (12.4±6.3%) and 126 subjects with high GA (>16.3%) were included. Effects of age, gender, BMI, GA and serum albumin on eGFR/Cin ratio was analyzed by multiple regression analysis.

**Results:** Cin, eGFRcys(J-Eq) and eGFRcys (CKD-EPI) in normal GA were 57.9±34.0, 56.1±31.7 and 57.9±33.9 ml/min/1.73m², respectively. Cin, eGFRcys(J-Eq) and eGFRcys (CKD-EPI) in high GA were 36.2±28.9, 36.7±27.5 and 36.7±28.5 ml/min/1.73m², respectively. There was no significant difference among Cin, eGFRcys(J-Eq) and eGFRcys (CKD-EPI) in both subjects. Slopes (95% CI) of the regression lines with zero intercepts in subjects...
with high GA were 0.989 (0.944-1.033) in J-Eq and 0.966 (0.922-1.009) in CKD-EPI. The slopes were not significantly different from 1.0, suggesting that eGFReqs performed well in subjects with high GA. Multiple regression analysis showed that age, gender, BMI, GA and serum albumin were not significant factors affecting both eGFReqs(CKD-EPI) /Ctin and eGFReqs(Eq)/Cin.

Conclusions: Estimated GFR based on cystatin C performed well in subjects with high GA.

PUB157
Renal Hyperfiltration and Outcome in HIV-Infected Subjects
Gianni Cappelli,1 Elisabetta Ascione,1 Giovanni Guaraldi,2 Andrea Malagoli,2 Elisabetta Rubbianti,1 Antonio Bellasi.1 1Univ Hospital of Modena, Nephrology Dialysis and Renal Transplantation Unit, Modena, Italy; 2Univ Hospital of Modena, Metabolic Clinic, Infectious and Tropical Diseases Unit, Modena, Italy; Azienda Ospedaliera S. Anna, Como, Dept of Health Sciences, Univ of Milan, Nephrology and Dialysis Unit, Como, Italy.

Background: Although highly active antiretroviral therapy (HAART) improves life expectancy of HIV-infected subjects, it is also associated with numerous comorbidities. Evidence suggests that renal hyperfiltration (RFH) is associated with various lifestyles, clinical conditions and portends poor prognosis in the general population. We sought at determining prevalence of RFH and its associations with traditional and HIV-related risk factors as well as all-cause mortality in a large cohort of HIV-infected subjects.

Methods: Retrospective study of 3875 HIV-infected patients attending at the “Modena Metabolic Clinic”. The Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) was used to estimate glomerular filtration rate (eGFR). Linear regression was used to model eGFR against age and sex. RFH was defined as eGFR with residuals above the 95th percentile. Anova, Chi-square, logistic regression and survival analyses were used to identify factors and the risks associated with RFH.

Results: Overall, we investigated middle-age (44.5±7.5 years) men and women (male 65.1%) with preserved renal function (eGFR 94.5±17.1 ml/min/1.73 m²). RFH was inversely associated with age (Odds Ratio 0.93), hemoglobin (OR 0.8), WBCs (OR 0.93) and positively associated with HIV-infection (OR 1.07). Of interest, no association with HAART was noted. Over mean follow-up of 7 years, 75 persons died. RFH was associated with all-cause mortality independently of potential confounders (Hazard ratio: 4.17, 95%CI: 1.81 - 9.6; p<0.001).

Conclusions: RFH is influenced by HIV infection duration independently of established factors and is related with the risk of all-cause of death. Future efforts are needed to clarify what are the mechanisms that link RFH with poor prognosis and if RFH modulation improves survival in HIV-infected subjects.

PUB158
Bioelectrical Impedance Analysis as a Screening Tool for Chronic Kidney Disease
Anita Saxena, Amit Gupta. Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.

Background: Chronic Kidney Disease (CKD) has a latent period during which the disease is present but asymptomatic. With increasing incidence of hypertension and diabetes, incidence and prevalence of CKD is on increase. Bioelectric impedance analysis (BIA) is a noninvasive method for estimation of body composition in clinical setting but it has not been used for CKD screening. Purpose: To evaluate applicability of BIA as a screening tool for presence of kidney disease in general population with creatinine clearance and glomerular filtration rate (GFR).

Methods: A pilot cross-sectional CKD screening study on randomly selected 52 subjects from general population. Maltron BIOSCAN analyzer 915/916 was validated with Hume etal’s equation for estimation of total body water. BIA derived GFR was validated with 99mTc-DTPA nuclear scan derived GFR, a study done on voluntary healthy kidney donors.

Results: There was no significant difference between total body water estimated with BIA and Hume etal’s equation and BIA derived GFR and DTPA nuclear scan GFR. Mean serum creatinine for males was 0.94 ± 0.14 mg/dl and 0.91 ± 0.84 mg/dl for females. BIA derived creatinine clearance was 97.39%: 28.98 in males and 107.60%: 34.03 in females. GFR was 74.1±25.98 ml/min/1.73 m² in males and 65.17±21.14 ml/min/1.73 m² in females. Based on GFR subjects were classified into CKD. Out of 52 subjects 8 were in CKD stage 1 (15.5%), 23 (44.2%) were in CKD stage 2, 18 (34.6%) were in CKD stage 3, 1 (1.9%) patients were in CKD stage 4 and CKD stage 5 respectively. Incidentally, 15.5% were diabetic, and 65.8% were hypertensive. Mean blood pressure was 133.90±80.82/76.7±27.79 mmHg in males and 132.10±16.20/83.46: 7.85 mmHg in females. Based on American Heart Association classification for hypertension, 19 (36%) patients had normal blood pressure, 8 (15.3%) were in prehypertension stage, 20 (37.7%) patients were in hypertension stage 1, 6 (11.5%) were in hypertension stage 2 and 2 had crisis hypertension.

Conclusions: Population-based CKD screening programs can identify people with renal injury for early intervention. BIA can be used for screening CKD in general population. It can also be a routine test as 99m-Tc-DTPA scan for estimation of GFR.
Evaluation of Chronic Kidney Disease Epidemiology Collaboration Equation (CKD-EPI), Modification of Diet in Renal Disease (MDRD) and Cockcroft-Gault (CG) Equations to Assess Glomerular Filtration Rate (GFR) in Kidney Cancer Patients

**Background:** Equations used to estimate GFR were not validated in kidney cancer patients. The aim of this study was to assess the performance of CKD-EPI, abbreviated (a) MDRD and CG equation in these patients.

**Methods:** Prospective evaluation of 124 outpatients with kidney cancer admitted to treatment at São Paulo State Cancer Institute between September 2012 and February 2015. Estimated (e) GFR was calculated using CG, aMDRD and CKD-EPI equations and compared to "true" GFR via radiotopic (r) clearance. The bias was given as the mean difference between the eGFR and rGFR values and the precision as the SD of the differences. Accuracy was described as the number of eGFR studies within 10 and 30% of the rGFR values.

**Results:** Patients were 59.0 ± 10.3 years old, 50.2% were women, rGFR (mL/min/1.73 m²) was 78.7 ± 24.6 and eGFRs (mL/min/1.73 m²) using the CKD-EPI, aMDRD and CG (mL/min) equations were respectively 80.7 ± 22.1, 83.4 ± 25.3 and 87.8 ± 26.5. Equations bias is detailed on table 1.

The accuracy of eGFR equations within 10% of rGFR were 31.4%, 27.4% and 19.4% with CKD-EPI, aMDRD and CG, respectively. Within 30% of eGFR, the accuracy of eGFR equations were 75.8%, 78.2% and 68.5% with CKD-EPI, aMDRD and CG, respectively.

**Conclusions:** CKD-EPI equation showed smaller bias and satisfactory accuracy when compared with the GFR assessed by "true" GFR in this group of kidney cancer patients.

Impacts of Chronic Kidney Disease on Other Non-Communicable Chronic Diseases – The Burden in the Health System of China

**Background:** The spread of non-communicable diseases (NCDs) presents a global crisis, and accumulating evidence based on individual disease reveals that major NCDs including heart disease and stroke have a worse prognosis in the presence of chronic kidney disease (CKD). However, there is neither large-scale study quantitatively evaluating the burden of CKD on various NCDs, nor studying the burden of CKD with other NCDs, especially among low- and middle-income countries like China.

**Methods:** A national in-patient database involving 19.5 million patient-records was used. Diagnoses of CKD and other major NCDs, including hypertension, coronary heart disease, stroke, chronic obstructive pulmonary diseases, and cancer, were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. The effect of CKD on costs, length-of-stay, and hospital mortality were analyzed for each NCD. Then the effect of CKD on those outcomes was compared with other major NCDs.

**Results:** For each NCD, the presence of CKD was associated with increased length-of-stay and in-hospital mortality. And the costs were also increased by 0.1-20.3%, except for coronary heart disease and diabetes. Among those NCDs, CKD was associated with the highest length-of-stay, and with in-hospital mortality only lower than that of cancer.

**Conclusions:** Using database with large sample size and broad geographic coverage in China, we found that the presence of CKD was associated with substantial increased healthcare resources utilization and increased risk of in-hospital mortality.

Funding: Government Support - Non-U.S.
comparatively analyzed adjusted for age, sex, race and center. The asking questions revealed comfort asking questions was independently associated with higher confidence / empowerment, β = 0.23 (95% CI: 0.04, 0.45), p < 0.02. Our 10-item confidence / empowerment measure showed excellent internal reliability (Cronbach alpha = 0.89).

Discussion: Patients in a multi-disciplinary CKD clinic reported being comfortable asking their doctor questions and rated confidence and empowerment as high. Comfort asking the doctor questions was positively associated with patient confidence and empowerment in care. More work is needed to compare patient-centric quality measures across care models and assess changes over time.

PUB166
Factors Affect Use of Healthcare Services Among Different Ethnicities
Enchi K. Chang,1 Li-Li Hsiao,2 Harvard College, Cambridge, MA; 2Renal, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Use of healthcare services by medically underserved minority populations varies by ethnicity and cultural factors. Healthcare providers may address ethnicity-specific barriers to healthcare service usage to decrease disparities in healthcare use. Through free community health screenings provided by the Kidney Disease Screening and Awareness Program (KDSAP), we seek to elucidate ethnicity-specific differences and sociocultural barriers to healthcare service use.

Methods: A questionnaire available in English, Chinese, and Spanish was administered to KDSAP participants in Massachusetts, New Jersey, and Toronto from 2012 to 2014. Participants were asked to provide their ethnicity, health insurance, primary care physician, and difficulties and alternatives to receiving care.

Results: Of 3730, 30% were African-American, Hispanic, and 50 Caucasian participants were surveyed. Participants lacking health insurance comprised 29.1% of Asian and 45.1% of Hispanic participants, compared with 17.3% of African-American and 8% of Caucasian participants. 25% of Asian and Hispanic participants reported language barriers with their healthcare provider compared with 6% of African-American and Caucasian respondents. 50% of Asian and Hispanic participants were prevented from seeking care due to lack of insurance, and as an alternative, 51% of Asian participants would ignore the problem. African American participants without insurance primarily reported seeking emergency care (51%), and Hispanic participants reported seeking free clinics (40.5%) as an alternative to emergency care (37.8%).

Conclusions: Culture and ethnicity-specific barriers to receiving care affect use of healthcare resources for medically underserved populations. Asian and Hispanic populations experience greater difficulty accessing healthcare services and are less likely to have health insurance compared to African-American and Caucasian populations, suggestive of linguistic and sociocultural barriers to healthcare for immigrant populations. Healthcare services targeting medically underserved communities must address ethnicity-specific sociocultural differences to reduce healthcare disparities between ethnic populations.

Trends in Access to Care in Adults with Kidney Disease, United States 2002-2011
Mukoso N. Ozieh,1 Kinfe Gebreegziabher Bishu,2 Rebekah J. Walker,2 Leonard Egede,2 Nephrology, MUSC, 2‘Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.

Background: Access to healthcare is essential in order to attain health equity in the US. Studies on access to healthcare in kidney disease (KD) are scant and there are no studies on national trends in access to healthcare in people with KD. This study aims to evaluate trends in access to healthcare, prescription medication and factors associated with access to healthcare in people with KD.

Methods: Data on 4,399 adults with KD aged ≥18 from the Medical Expenditure Panel Survey were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157-acute/ unspecified renal failure; 158-chronic renal failure; 160- acute or chronic renal failure and 161 - other diseases of kidney and ureters. Access to healthcare was defined as having a usual provider, ability to get necessary medical care and no delay in getting medical care. Assess to prescription medications was defined as ability to get necessary prescription and no delay in getting prescription. We used unadjusted and adjusted logistic regression to examine factors associated with access to care overtime. Covariates included demographics and comorbidities.

Results: Of the 4,399 adults with KD, 81% and 97% reported having access to medical care and prescription medications respectively. Access to medical care was stable while access to prescription improved over time in people with KD. Factors associated with increased access to medical care were age ≥65, higher income, high income, region, sociability-hypertension while marital status, being uninsured, regional community and comorbidity- joint pain were associated with decreased access to medical care. Factors associated with increased access to prescription were Hispanic race, age ≥65 and 4+ college degree while being uninsured, regional region and comorbidities – diabetes and joint pain were associated with decreased access to prescription medication.

Conclusions: Access to medical care has remained stable and access to prescription medication in people with KD has improved over time. Further studies on access to healthcare in people with KD compared to the overall US population are needed.

PUB168
Patient-Centered Care in United States Adults with Kidney Disease
Mukoso N. Ozieh,1 Kinfe Gebreegziabher Bishu,2 Rebekah J. Walker,2 Leonard Egede,2 Nephrology, MUSC, 2‘Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.

Background: Patient-centered care is a quality of personal, professional, and organizational relationships. There is no studies on factors associated with patient-centered care in patients with kidney disease (KD). This study examines trends in and factors associated with patient-centered care (PCC) in people with KD.

Methods: Data on 3,868 adults with KD aged ≥18 from the Medical Expenditure Panel Survey (MEPS) Household Component were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 160 - acute or chronic renal failure and 161 - other diseases of kidney and ureters. Patient-centered care was ascertained if the usual care provider asked about prescription medications and treatments other doctors may give them; showed respect for mental, traditional, and alternative treatments that the patient is happy with; asked the person to help make decisions between a choice of treatments; presented and explained all options to the person; and spoke the persons language or provided translator services if person is uncomfortable speaking in English. We used unadjusted and adjusted poison regression to examine the association of patient-centered care overtime. Covariates included demographics and comorbidities.

Results: Of the 3,868 adults with KD, 3%, 7%, 22%, 63% and 4% reported a positive response to 1, 2, 3, 4, and 5 out 5 questions on patient-centered care respectively. Patient-centered care was significantly reported in 2010/2011. Hispanic race was significantly associated with increased while residence in the west was associated with decreased patient-centered care. Compared to 2002/2003, year 2004/2005 and 2010/2011 were significantly associated with increased patient-centered care in the poison regression analysis.

Conclusions: Patient-centered care in people with kidney disease has improved in recent years. Prospective studies examining the impact of patient-centered care on kidney disease outcomes especially end stage renal disease is imperative.

PUB169
Hypertension and Correlating Factors in a Minority-Rich Population
Andrew A. Lin,1 Jennie Kuo,2 Li-Li Hsiao,2 Harvard College, Cambridge, MA; 2Renal, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Analysis of demographic variations in hypertension (HTN) in minority-specific populations presents a major opportunity for understanding the factors that influence chronic kidney disease (CKD). This study analyzes the influence of various factors in BP control in a minority-rich population.

Methods: Data from 417 participants from minority populations in the Boston area (38.4% Black; 17.6% White; 5.0% other race) was sampled via Kidney Disease Screening and Awareness Program screenings from 2012-2014. Participants were assessed via questionnaire for awareness of their BP, healthcare, insurance, and an assessment of their own health as well as their race, gender, age, and education. Participants then had their systolic (SBP) & diastolic (DBP) blood pressure measured, which was in turn classified according to American Heart Association guidelines & analyzed via T-tests & one-way ANOVA.

Results: Of the 417 participants, 28.8% had normal BP, 47.2% were pre-HTN (130 ≤ SBP < 140 or DBP < 90), 18.5% had stage 1 HTN (140-160/90-100), & 5.5% had stage 2 HTN (>160/100). Participants aware of their HTN had higher SBP (p=0.001) & DBP (p=0.007) than those who self-reported HTN. Men had significantly higher SBP & DBP than women (p=0.002, p=0.003, respectively), & individuals with little/no education had higher SBP than those with college (p=0.005) or post-graduate degrees (p=0.001). Younger age groups (below 30 years: mean BP 125/76) had significantly lower BP than older age groups (60-69+: years: mean BP 136/81); p<0.0001 & p<0.037 for SBP & DBP. Notably, no significant differences in SBP among ethnicities emerged.

Conclusions: Our results revealed that awareness of HTN status, gender, education level & age influence BP variations in minority communities. Services tailored to these factors may help reduce HTN prevalence in minority communities. Services tailored to these factors may help reduce HTN prevalence in minority communities.

Veterans Affairs (VA) eKidneyClinic: A Freely-Available Online Tool to Help Close the Chronic Kidney Disease (CKD) Patient Education Gap
Devasinna Choudhury,1 R. Brooks Robey,2 Rosemary M. Pries,3 Dorian R. Schatell,1 Susan T. Crowley.4 VA eKidneyClinic (http://ckd.vacloud.us). This freely-available, Veteran-centered, virtual health literacy, and varied, fragmented presentation of patient education materials (PEMs) compound the gap in understanding CKD.

Methods: To address these deficiencies, VA developed a comprehensive web tutorial, VA eKidneyClinic (http://ckd.vacloud.us). This freely-available, Veteran-centered, virtual...
Leveraging Predictive Modeling to Improve the Participant Identification Process for Transition to Dialysis Support Programs

**Background:** Evidence demonstrates that renal care management is beneficial to patients suffering from late-stage chronic kidney disease (CKD) and end-stage renal disease (ESRD), especially around the time of transition to dialysis. Integrated care management solutions provide assessment, education, and care coordination. Engagement in these programs improves health outcomes, including compliance with dialysis schedules and vascular access, and also reduces costs.

**Methods:** Traditionally, patients are identified for renal care management programs via a qualified estimated glomerular filtration rate (eGFR) lab value of $<20\text{mL/min/1.73}\text{m}^2$. However, since eGFR is not always available, there may be a gap in identifying people who could benefit from this type of support. A predictive model (PM) was developed to identify candidates for a transition to dialysis program. The PM identifies individuals with CKD over the prior 12 months and determines their likelihood of starting dialysis within the subsequent 12 months. It is based on claims, demographics, and lab and consumer data.

**Results:** 630 CKD patients with DM attending CKD clinic at our trust were identified. 195/630 (31%) of patients had diabetic nephropathy. 54.6% (100/195) had progressive CKD, but only 57% (37/100) of these patients attended a diabetic clinic. Conversely, 45.4% did not have progressive CKD, potentially representing a group of patients who could be safely monitored by general physicians. Patients with progressive diabetic nephropathy were more proteinuric than those with stable CKD (161 vs.46mg/mmol, p=0.004) but did not significantly differ in terms of age, weight, glycemic control or BP. 9.2% (58/630) were lost to follow-up from nephrology services, 31% (18/58) of this subset of patients continued to attend the diabetic clinics and 69% (40/58) were lost to follow-up from both diabetic and renal services.

**Conclusions:** Not all patients with diabetic nephropathy develop progressive CKD. Identifying patients (e.g. low-level proteinuria) who could be safely monitored by general physicians may relieve pressure on CKD clinic and reduce hospital visits for patients. However, many patients with progressive CKD were not being monitored in a diabetic clinic, potentially missing out on specialist interventions. Development of a joint diabetic-renal clinic could streamline care and improve management for these patients.

926A
There is a positive correlation between IL6 and all oxidative stress markers and an inversely correlation with eGFR (all, p<0.05). We divided CKD patients in CDK1-2 (n=10) and CKD3-5 (n=15): a significant higher level of oxidative stress was observed in CKD3-5 (p<0.008).

Conclusions: CKD is characterized by ROS and RNS disequilibrium and inflammation that promote additional damage to the kidney and to distal tissues with development and progression of concomitant diseases. This pilot study demonstrates the significantly heightened presence of dual oxidative stress pathway induction in CKD patients that increase with the progression of CKD: each stage of CKD could be characterized by differing levels of ROS/RNS disequilibrium. Our findings indicate that oxidative stress is a potential therapeutic target, as it promotes inflammation by ROS/RNS-linked pathogenesis. Future research should focus on interventions that aim to reduce oxidative stress and inflammation in patients with various stages of CKD and slow the progression of CKD during its early stages.

Comparative Biomarker Analysis Reveals Serum and Urine sTNFR1 Correlates with eGFR and Albuminuria in Man

Diana L. Donnelly-Roberts, Marian T. Namovic, Mark T. Houser, Murali Gopalakrishnan, Timothy A. Esbenshade. Renal Discovery, Abbvie, North Chicago, IL.

**Background:** It has been demonstrated that soluble tumor necrosis factor receptors (sTNFR1 & sTNFR2) are elevated in serum of patient cohorts with various renal disease etiologies with a strong association to early renal decline with or without proteinuria. The current study was designed to gain further insight into the relationship of renal function to sTNFR1 and sTNFR2. Serum and urine samples from a recently completed clinical study in high risk subjects undergoing non-cardiac surgery. A subset of baseline serum and urine samples from patients with and without CKD (mean age of 70, 64% male, mean eGFR of 58 ml/min/1.73 m², and mean total urinary protein concentration 70 g/l) were evaluated to assess sTNFR1 and other select BMs reflective of progression of DN, CV risk, inflammation, fibrosis or renal injury.

**Methods:** Samples were selected based on medical history (DM, DN, other CKD, or no renal disease) and stratified for analysis based on eGFR values. All samples examined were from baseline/pre-dose collections prior to drug administration or surgery and analyzed in blinded manner.

**Results:** In serum, several BMs correlated with eGFR with sTNFR1 (P <0.0001) and uromodulin (P =0.0004) being significant but moderate for FGF-23 (P<0.01), and ADMA (P<0.01). In urine, results revealed that several BMs correlated with eGFR with a strong significance for sTNFR1 (P<0.0001) as well as complement C9 (P=0.011) and IC3b (P=0.013). Significant correlations were also observed for qualified biomarkers such as NGAL (P=0.01), albumin (P<0.001), and cystatin C (P=0.05). sTNFR1 in urine also strongly correlated with albuminuria (P=0.0002) and UACR (P<0.0001).

**Conclusions:** Our studies demonstrate that sTNFR1 correlates with renal functional decline across a wide eGFR range (22 to 116 ml/min/1.73 m²) regardless of renal disease, which was assessed in both serum and urine. Limitations of this preliminary study are small sample size and use of static eGFR values. Additional correlation analyses in longitudinal cohorts can shed further light into the relationships of sTNFR1 and other BMs to CKD.

The Association of Plasma Uric Acid with Renal Vascular Lesions and Intertstitial Fibrosis in Biopsy-Confirmed Kidney Disease

Anand Allegretti, 1 Venkata Sabbisetti, 1 Isaac Ely Stillman, 1 Helmut G. Rennke, 2 Sushrut S. Waikar. 1

1Renal Div, Brigham & Women’s Hospital, Boston, MA; 2Dept of Pathology, Brigham & Women’s Hospital, Boston, MA; 3Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA.

**Background:** Elevations in plasma uric acid (PUA) have been hypothesized to play a pathogenic role in the development of chronic kidney disease (CKD) through multiple mechanisms, including mitochondrial dysfunction, oxidative stress, endothelial dysfunction, vascular smooth muscle proliferation, and intra-renal inflammation.

**Methods:** We measured PUA in plasma samples obtained from 272 patients on the day of native kidney biopsy at three tertiary care hospitals in Boston, MA. We compared PUA against measures of kidney function and pathology, including estimated glomerular filtration rate (eGFR) and adjudicated semi-quantitative measures of kidney pathology using Spearman correlation coefficients. Arterial and arteriolar sclerosis/hyalinosis were classified as none (0), mild (1), moderate (2), or severe (4). Fibrosis was classified as 0% (1), 1-10% (2), 11-25% (3), 26-50% (4), and > 50% (5) of cortical volume.

**Results:** The primary indications for kidney biopsy were proteinuria in 61%, hematuria in 33%, abnormal eGFR in 35%, and nephrotic syndrome in 14% (sum exceeds 100% due to multiple indications). Mean age was 51.2 ± 16.0 yrs, 53% were women, 18% were black, and median eGFR was 50 (IQR 30–80) ml/min/1.73 m². Median PUA was 6.3 (IQR 5.1-7.5) mg/dl, and was inversely correlated with eGFR (r=-0.43) and positively correlated with arterial sclerosis (r=0.21), arteriolar hyalinosis (r=0.23), and interstitial fibrosis (r=0.28) (p<0.05 for all). The association between PUA and fibrosis was observed and no longer statistically significant after adjustment for eGFR. Findings were generally consistent in subgroup analyses of those with diabetes, glomerulonephritis, vascular disease, and tubulointerstitial disease.

**Conclusions:** We found no independent associations between PUA and semi-quantified measures of kidney pathology. The cross-sectional associations of PUA with renal vascular lesions and interstitial fibrosis appear to be confounded by eGFR.

Association of Plasma Sphingomyelins and Ceramides with Chronic Kidney Disease and Glomerular Filtration Rate

Maria Lourdes Gonzalez Suarez, 1 Vesa D. Garovic, 1 Norman James Haughey, 2 Veera Venkatat Ratnam Bandaru, 2 Susan Resnik, 2 Luigi Ferrariu, 2 Michelle M. Mielke. 3

1Div of Nephrology, Mayo Clinic, Rochester, MN; 2Dept of Neurology, Johns Hopkins Univ School of Medicine, Baltimore, MD; 3Dept of Psychiatry, Johns Hopkins Univ School of Medicine, Baltimore, MD; 4Intramural Research Program, NIA/NIH, Baltimore, MD; 5Dept of Health Sciences Research, Mayo Clinic, Rochester, MN.

**Background:** Sphingolipids are a class of bioactive lipids linked to insulin resistance and diabetes. Ceramides have been implicated in acute renal failure and diabetic nephropathy. We cross-sectionally examined the associations of plasma ceramides and sphingomyelins (SM) with glomerular filtration rate (GFR) and Chronic Kidney Disease (CKD).

**Methods:** Baltimore Longitudinal Study of Aging participants (N=486) with plasma ceramides, SM and GFR were included (median age 63, 58% men); 23 had CKD defined as GFR <60 ml/min. Ceramides and SM were quantitatively measured using a HPLC-coupled electrospray ionization tandem mass spectrometer. Logistic regression was used to determine the association between the log transformed sphingolipids and odds of CKD, adjusting for age, sex, and race. Among participants without CKD, linear regression was used to examine the association between the sphingolipids and GFR adjusting for age, sex, race, BMI, and hypertension.

**Results:** Higher levels of all SM were associated with increased odds of CKD: each log unit increase in SM C18:1 was associated with six-fold increased odds of CKD (OR=6.92, p=0.002). Among individuals without CKD, higher SM were also associated with lower GFR. This association was most pronounced among the 290 individuals without diabetes or pre-diabetes: each log unit increase in SM C18:1 was associated with lower GFR (b=-8.40, p=0.002).

**Conclusions:** These results suggest that elevated plasma SM are associated with CKD. Likewise, among those without CKD, elevated SM are associated with lower GFR. The cross-sectional study design limits specific conclusions on the mechanisms and temporality of these associations but suggests that further research is warranted.

Clinical and Pathologic Predictors of Progression to End Stage Renal Disease following Renal Biopsy

Andrew S. Allegretti, 1 Ivy A. Rosales, 1 A. Bernard Collins, 1 Nina E. Tolko-Rubin, 1 Robert B. Colvin, 2 Isaiah Bhan, 1 Julia Beth Wenger, Joshua Wibecan, Rex Neal Smith. 1

1Div of Nephrology, MGH, Boston, MA; 2Dept of Pathology, MGH, Boston, MA.

**Background:** The value of renal biopsy in prognosis of chronic kidney disease remains unclear. Irreversible, chronic changes such as interstitial fibrosis and glomerulosclerosis are thought to provide prognostic information. We sought to define the relative prognostic value of biopsy pathology and clinical factors for predicting progression to end stage renal disease (ESRD).

**Methods:** Retrospective, single center review of renal biopsies performed between 2004-2014 in four kidney diseases. Cox regression was used to evaluate nine pathologic findings on light microscopy and 21 clinical variables as potential predictors of progression to ESRD.

**Results:** 231 cases were reviewed (34% IgA nephropathy, 29% focal segmental glomerulosclerosis, 19% tubulointerstitial disease, 18% diabetic nephropathy). 83/231 (36%) subjects progressed to ESRD within 5 years follow-up. Median estimated glomerular filtration rate (eGFR) at time of biopsy was 32 [IQR: 18, 54] ml/min. Median percent interstitial fibrosis was 20% [IQR: 10%, 40%]. In multivariable Cox regression adjusting for pathologic diagnosis and eGFR at the time of biopsy, independent predictors of progression to ESRD by 5 years of biopsy were: interstitial fibrosis > 20% (HR 1.94 [95% CI 1.09, 3.44]; p=0.02), presence of endocapillary inflammation (HR 2.35 [2.12, 4.53]; p<0.01), and presence of arteriosclerosis (HR 2.50 [1.01, 5.05]; p=0.05), history of liver disease (HR 1.55 [0.95, 2.53]; p=0.08) and congestive heart failure (HR 1.85 [0.99, 3.49]; p=0.06).

Lower Dietary Intake of Magnesium Is Associated with Faster Decline in Kidney Function: The Healthy Aging in Neighborhoods of Diversity Across the Life Span Study

Background: Lower dietary magnesium intake has been associated with higher prevalence of chronic kidney disease (CKD). We hypothesized lower dietary magnesium intake would be associated with more rapid decline in kidney function.

Methods: Participants with estimated glomerular filtration rate (eGFR) ≥ 60mL/min/1.73 m² at baseline (2004-2008) of the population-based, Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study were followed for a median of 4.7 years. Baseline dietary magnesium intake was calculated from two 24-hour dietary recalls. eGFR was calculated from serum creatinine using the CKD-EPI equation. We defined rapid decline as eGFR decline ³3% per year. The association between dietary magnesium intake and eGFR decline was evaluated using Cox regression.

Results: Among 1,326 participants, those with lower dietary magnesium intake (tertile 1 vs. 3) were significantly younger (mean age of 46 vs. 49 years), more likely to be African-American (67% vs. 48%) and male (45% vs. 31%); had lower mean body mass index (BMI, 29 vs. 30 kg/m²), higher mean baseline eGFR (99 vs. 94 mL/min/1.73 m³) and lower prevalent diabetes (10% vs. 18%); p<0.05 for all. In the overall study population, eGFR was stable without any decline (mean change: 0.1 mL/min/1.73 m³) while 189 participants experienced an eGFR decline ³3% per year. Lower dietary magnesium intake was associated with higher risk of eGFR decline ³3% per year (tertile 1 vs. 3, hazard ratio 1.9, 95% confidence interval: 1.1, 3.3) adjusted for socio-demographics, baseline eGFR, prevalent diabetes and hypertension status, BMI, serum magnesium, total energy intake, and dietary intake of calcium, potassium, and phosophorus.

Conclusions: Among persons with preserved eGFR, we detected a significant association between lower dietary Mg intake and increased risk of rapid kidney function decline independent of traditional CKD risk factors. These results highlight the importance of magnesium intake in the overall diet for the preservation of kidney function.

PUB181

Renin-Angiotensin System: A Possible Mechanism for AKI-CKD Continuum

Background: Based on many clinical observations and studies, acute kidney injury (AKI) was now regarded as an important risk factor causing chronic kidney disease (CKD). Not only does CKD lead to end-stage renal disease (ESRD), but also increases the risk of cardiovascular disease or even death. Clinical studies often disclose that the higher the AKI severity of a patient is, the more likely her/his kidneys progress into CKD. To this end, the mechanism underlying the progression of kidneys into CKD after AKI remains illusive. Since the higher severity of the AKI leads to more reduction of nephron numbers, we propose that activation of renin-angiotensin system (RAS) may be involved in the progression to CKD after recovery from AKI.

Methods: Severe AKI was induced in male adult CD-1 mice by right uni-nephrectomy (Nx) followed by ischemia-reperfusion injury of left kidney 2 weeks later. Drinking water was replaced with a type 1 angiotensin II receptor blocker losartan or direct vasodilator hydralazine administered to mice from 4 weeks after surgery. Mice with Nx only were served as the control.

Results: Compared to Nx group, AKI mice showed acute rise of plasma creatinine levels on day 2 after Nx+1RI surgery, which decreased to baseline on day 7. Moreover, elevated systolic blood pressure and increased urinary ACR were noted since 4 weeks after Nx+1RI surgery. During the 4-month experimental period, progressive increase of urinary ACR and plasma levels of creatinine were noted. On the contrary, systolic blood pressure, urinary ACR and plasma creatinine level were normalized in mice administered with losartan since 4 weeks after Nx+1RI surgery. However the increase of urinary ACR and plasma creatinine level were not prevented in mice administered with hydralazine despite similar normalization in blood pressure.

Conclusions: These data suggest that RAS activation may underlie the mechanism for development of CKD in mice after recovery from AKI. Future studies are needed to explore the effect of RAS blockade in prevention of CKD and its pressure in patients recovered from AKI.

PUB182

The Renal Effects of Neprilysin Inhibition in Heart Failure and Hypertension

Background: Neprilysin inhibitors (NEPi) represent an emerging therapeutic option for treatment of hypertension (HTN) and heart failure (HF) through enhancement of natriuresis. While these agents have shown promising results with regards to lowering blood pressure (BP) and HF events, their impact on the kidney remains largely unknown.

The aim of this study is to evaluate the currently available evidence on the effect of NEPi use on kidney-related parameters in patients with HTN or HF.

Methods: A search of articles cited in PubMed database from 1995 to 2015 using key words “neprilysin”, “heart failure” and “hypertension” found 237 articles. Animal studies were excluded. Those studies containing kidney-related parameters such as serum creatinine, glomerular filtration rate (GFR), or ACR were selected. Relevant data including changes in renal function, blood pressure and mortality were extracted and compared.

Results: A total of 42,487 patients from 12 randomized controlled trials with data pertaining to NEPi use were included (8 in HTN and 4 in HF). Seven studies used NEPi combined with ACE-inhibitors andARB, and 1 with endothelin converting enzyme inhibitors. The follow up periods ranged between 7 days and 27 months. All studies in HTN (including 27,401 patients) reported significantly better BP lowering effect for NEPi compared to control group, while 94% of the patients in the HF studies presented with improvement in left ventricular remodeling. Although most studies did not reach endpoint, all HF studies (including 15,086 patients) showed less frequent renal impairment (expressed as increase in plasma creatinine and ACR) in NEPi group compared to placebo group (12%).

Conclusions: Current evidence suggests that in patients with HF, NEPi can lower HF-related events and mortality while potentiating favorable impact on renal function. In patients with HTN, although NEPi have been shown to reduce BP, there is no conclusive evidence of their role in improvement of renal function in this setting.
The Differences of Renal Protective Effect by Hyperuricemia Treatment Using Febuxostat in Various CKD Subgroups
Akinori Yamaguchi, Makoto Harada, Yousuke Yamada, Koji Hashimoto, Makoto Higuchi, Yuji Kamiyo. Dept. of Nephrology, Shintei Univ, Mutsuno, Nagano, Japan.

Background: We often experience the CKD cases exhibiting the attenuation of eGFR decline by hyperuricemia treatment using febuxostat. However, renal protective effect by the hyperuricemia treatment has not yet been established. We hypothesize that the therapeutic response of febuxostat treatment might differ among various subgroups of CKD patients.

Methods: To investigate the difference of the therapeutic response in CKD patients, 272 outpatients with hyperuricemia who were treated by febuxostat from May 2011 to March 2015 were enrolled. Patients undergoing hemodialysis and/or peritoneal dialysis treatment, and patients lacking essential clinical data were excluded. Finally, 178 patients were analyzed. Correlation coefficient between the average of serum uric acid level and the eGFR variation during 6 months after the treatment were statistically investigated in various clinical subgroups.

Results: In all patients, significant correlation between the average of serum uric acid levels and the eGFR variation was detected (Brockman’s correlation coefficient r=-0.163, p=0.019). This significant correlation was also detected in each patient groups as follows: male patients (n=121, r=-0.211, p=0.020), non-elderly (below 70 years old) patients (n=107, r=-0.261, p=0.007), patients whose systolic blood pressure were below 130 mmHg (n=72, r=-0.238, p=0.044), patients without dyslipidemia (n=133, r=-0.316, p=0.005) and non-diabetic-nephropathy patients (n=133, r=0.184, p=0.034). However, the significant correlation was not detected in each opposite subgroups.

Conclusions: The current study suggest that therapeutic response of febuxostat treatment might be well in each CKD subgroups, including male, non-elderly, non-hypertension, non-dyslipidemia and non-diabetic-nephropathy. It is possible that various risk factors of atherosclerosis conceal the beneficial renal protective effects of hyperuricemia treatment using febuxostat.

Urinary RBP as an Independent Predictor of “Hard Composite Outcome” in Albuminuric Diabetic Nephropathy
Gesime Fernandes Tavares, Roberto Zatz, Silvia M. Titan. Renal Div. Dep. Clinical Medicine, Faculty of Medicine, Univ. of Sao Paulo, Sao Paulo, Brazil.

Background: The current search for new biomarkers in CKD is intense, with particular emphasis on hard end-points, such as ESRD, creatinine duplication and cardiovascular and overall mortality. In this analysis, we sought to evaluate which baseline clinical and laboratory variables were related to ESRD/mortality in 56 patients with albuminuric diabetic nephropathy after mean follow-up time of 5 years.

Methods: Baseline clinical and laboratory data of 56 participants of a clinical trial were evaluated as predictors of major outcomes (primary outcome: PO: ESRD, creatinine duplication or mortality). Mann-Whitney and chi-square tests were used for univariate analyses. Several univariate and multivariate COX regression models were built on the risk of PO. Kaplan-Meier curve and LOG rank test were also performed.

Results: PO occurred in 39 participants after a mean follow-up time of 5 years (70%). In univariate analyses, sex, creatinine clearance, 24h proteinuria, uRBP, urinary VEGF and serum TGF-beta were related to the event group. In univariate COX regression models, sex, proteinuria, creatinine clearance, VLDL, cholesterol, ferritin, PTH, RBP and uMCP-1, uVEGF and uTGF-beta were significantly associated to the risk of PO. However, after adjustments for creatinine clearance and proteinuria, only uRBP and uMCP-1, uTGF-beta and uVEGF remained significantly associated to PO. In a stepwise model, only creatinine clearance (HR 0.98, 95%CI 0.97 - 1.00, P=0.06) and uRBP (HR 1.13, 95%CI 1.07 - 1.20, P=0.0001) were left as independent predictors of PO in this population. KM curve for uRBP is shown in figure 1.

Conclusions: Urinary RBP is an independent predictor of PO in albuminuric diabetic nephropathy. Its role as a risk biomarker should be further explored in larger studies of CKD patients.

Association Between Urinary RBP and Renal and Cardiovascular Risk Factors in a Population with CKD: The Progredir Study
Maria Alice Muniz Domingos,1 Alessandra C. Goulart,2 Paulo Lotufo,2 Isabel M. Bensoner,2 Silvia M. Titan.1 Renal Div. Dep. Clinical Medicine, Faculty of Medicine, Univ. of Sao Paulo, Sao Paulo, Brazil,2 Clinical Research Center, Univ Hospital, Sao Paulo Univ, Sao Paulo, Brazil.

Background: Urinary RBP (uRBP) has been related to the risk of ESRD in glomerulonephritis and renal transplant. However, its role in CKD is not well established.

Methods: Baseline clinical and laboratory data on 454 participants of the Progredir Study was analysed. uRBP was measured by an immunoenzymatic assay with monoclonal antibody. Descriptive data is presented according to tertiles of uRBP, and correlation coefficients were calculated. Several univariate and multivariate linear regression models were built. Lastly, binary regression models were built on the risk of presenting more advanced CKD (class IV-V versus class II-III).

Results: In the descriptive data, the tertiles of uRBP were significantly related to sex, diabetes, renal function, SBP, glcated hemoglobin, HDL, proteinuria, WHR, phosphorys, acidosis, albumin, pulse-wave velocity (PWV), left atrium diameter (LAD), systolic and diastolic left ventricular diameters and ejection fraction. These results were confirmed by correlation. In the univariate regression models, diabetes, SBP, WHR, renal function, proteinuria, phosphorus, albumin, lipids, glycated hemoglobin, PWV and echography variables remained related to uRBP. However, after adjustments, only renal function, proteinuria, SBP, bicarbonate and LAD remained associated to uRBP.

Table: Stepwise multivariate linear regression models on log of urinary RBP.

Conclusions: Urinary RBP is independently related to cardiovascular risk factors in the CKD population. Its role as a biomarker of hard clinical end-points should be further explored.

Treatment of Subclinical Hypothyroidism and the Progression of Chronic Kidney Disease
Padmavathi Mali,1 Sudheer Muduganti.2 Internal Medicine, Marshfield Clinic, Marshfield, WI.1 Nephrology, Univ of Wisconsin Hospitals and Clinics, Madison, WI.

Background: Evidence suggests that treatment of subclinical hypothyroidism may slow the progression of chronic kidney disease (CKD) and delay or prevent development of end stage renal disease (ESRD). The goal of this study was to provide additional evidence regarding the same.

Methods: Patients with subclinical hypothyroidism and CKD stages 3 or 4 were identified by retrospective chart review over a period of 6 years. Subjects were grouped based on L-thyroxine treatment. Subjects treated with L-thyroxine before first elevated thyroid stimulating hormone (TSH) were excluded. Index date was defined as the date of first L-thyroxine for treated patients. Index dates for untreated patients were assigned by random sampling of dates for treated TSH and serum creatinine values were captured from the electronic medical record. Change in eGFR (glomerular filtration rate) over time in treated and untreated patients was assessed using a linear random coefficients model in the subset with two or more eGFR results spanning a period of at least 6 months, both before and after the index date.

Results: A total of 258 patients meeting inclusion criteria were identified; 181 were treated with L-thyroxine and 77 were not. Treatment initiation began after the first elevated TSH in the study period for 110/181 subjects. Upon analysis, before the index date, eGFR showed a significantly decreasing trend (p<0.001) that was not significantly different

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
between treated and untreated patients (p = 0.593). After the index date, the rate of gFR changes showed a similar trend (p = 0.017) for a gradual increase, but again this was not significantly different between groups (p = 0.522).

Conclusions: The similar results in the two groups, regardless of L.

### PUB87

**Effect of Hyperuricemia on the Blood Pressure-Dependent Proteinuria in Non-Nephrotic Chronic Kidney Disease**

Kentaro Kojiiura, 1,2 Ryo Yamamot, 2

**Background:** Patients with chronic kidney disease (CKD) are suggested to be highly susceptible for hypertensive renal damage due to disrupted autoregulation system in different arteriole. We reported that hyperuricemia was associated with renal arteriolar hyalinosis in the CKD patients. However, effect of hyperuricemia on a relationship between blood pressure (BP) and proteinuria is unknown in CKD patients.

**Methods:** A total of 288 consecutive patients who underwent renal biopsy at our department between 2003 and 2007 were considered for the study. We excluded patients receiving renin angiotensin inhibitor and nephrotic CKD patients defined as serum albumin equal or more than 3 g/dL, leaving us with 117 patients (57 men and 60 women) for analysis. Arteriolar hyalinosis were assessed by semi quantitative grading for arterioles. We compared the relationship between systolic BP and log-transformed urine protein (g/gCr) in the patients with or without hyperuricemia.

**Results:** The mean ± standard deviation values for age, BP, estimated glomerular filtration rate (eGFR), and uric acid were as follows: 63 ± 18 years, 126 ± 20/75 ± 12 mmHg, and 84 ± 37 ml/min/1.73 m², respectively. In the patients with hyperuricemia (n=63), systolic BP was significantly correlated with log-transformed urine protein (r=0.45, p=0.004). In contrast, there was no significant correlation between them in the patients without hyperuricemia (r=0.07, p=0.60). In the multiple regression model (R²=0.25, p=0.01), systolic BP was significantly correlated with log-transformed urine protein β(0.33, p=0.02) independent of age, sex and classical risk factors in the patients with hyperuricemia. However, its statistical significance was disappeared after additional adjustment with urinary hyalinosis.

**Conclusions:** These results suggested that hyperuricemia might potentiate the susceptibility for hypertensive glomerular damage via disrupted autoregulation in non-nephrotic CKD patients.

### PUB88

**HCV Independently Affects Kidney Function Among HIV Co-Infected Individuals**

Maya Balanac, 1 Richard A. Teran, 1 Joseph G. Timpane, 1 Jason G. Uman, 2 Princy N. Kumar, 1 Seble Kassaye, 1 Georgetown Univ Medical Center, Washington, DC; 2 Georgetown Howard Univ Center for Clinical & Translational Science, Washington, DC; 3 MedStar Health Research Inst, Hyattsville, MD

**Background:** Predictors of chronic kidney disease (CKD) include increasing age, hypertension and diabetes. Hepatitis C (HCV) infection has also been associated with increased risk for CKD. We sought to determine the relative contribution of HCV vs other co-morbidities on kidney dysfunction among individuals with HIV.

**Methods:** We analysed data from HIV-positive patients enrolled in the DC HIV Clinical Cohort study at Georgetown University Hospital (2011-2014). Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI formula. Analyses were conducted stratified by HCV status. Chi square, Cochran–Mantel–Haenszel and Breslow Day Test statistics were performed to determine factors associated with normal kidney function (eGFR > 90 ml/min/1.73 m²), compared with participants with decreased kidney function, stage 2 and 3 (≥30 eGFR <89) using SAS v9.4.

**Results:** Among 771 participants, median age was 48, 73.4% male, 50.3% black, median CD4+ T cell count 546.5 cells/μL, and HIV RNA <20 copies/μL 93 (12.1%) had HCV co-infection. There was significantly higher prevalence of stage 2-3 kidney dysfunction with HIV/HCV co-infection than HIV mono-infection (35% vs. 19%, p=0.0016; OR, (95% CI) 2.1 (1.3-3.6)). Prevalence of hypertension, diabetes, hyperlipidemia and chronic Hepatitis B was similar between HIV and HIV/HCV co-infected groups. Presence of these co-morbidities was not a confounder in the increased risk for CKD with HIV/HCV (Mantel-Haenszel chi-square OR, (95% CI) 2.1 (1.3-3.6) for hypertension, 2.18 (1.3-3.6) diabetes and 2.2 (1.3-3.6) hyperlipidemia (Breslow Day test p values<0.05 for each co-morbidity).

**Conclusions:** We identified a strong association between HIV/HCV co-infection and reduced kidney function independent of co-morbidities usually associated with kidney dysfunction in this group with well controlled HIV. Further investigation is needed to study the mechanisms by which HCV affects kidney function.

### PUB89

**Vitamin D Deficiency Is a Cause and a Result of Renal Dysfunction in Rheumatoid Arthritis**

Suad Ma Hanaww, Issa AL Salmi.

**Background:** Asymptomatic kidney dysfunction is common in RA. Low vitamin D levels increase susceptibility to development of RAA disease activity. Sequential hydroxylations occurs in liver & kidney to form active 1,25-VD & patients with kidney failure are often resistant to VD & suffer from 2

**Methods:** A total of 475 patient (25-VD level & GFR calculated by MDRD at Rheumatology clinic visit. Univariate linear regression analysis carried out to determine the relationship between 25-VD and eGFR, other renal parameters & RA inflammatory markers.

**Results:** In univariate analysis of 52 RA(475M) with mean age 46±13 years(46±12, M±SD), 25-VD level is 40±29 mmol/l(INR:50-80) & GFR is 134±49 ml/min/1.73 m². Univariate linear regression showed a negative relationship between 25-VD level & eGFR (p=0.041,CI 0.23, 0.01), micro-albuminuria(p=0.046, CI 0.63, 0.01), CRP (p=0.01,CI 1.16, 0.16), neutrophil count (p=0.03,CI 1.67, 0.11). A positive linear relationship between GFR & weight (p=0.03,CI 0.06, 0.14), HSA(p=0.02, CI 0.11, 0.19) & BMI(p=0.009,CI 0.65 4.05), Ca(p=0.003, CI 7.24, 13.12 mmol/l).

**Conclusions:** Negative relationship between eGFR&25-VD, indicating a higher 25-VD as failure to convert to active form as GFR decreases. Extra-reformation of active VD requires a lower level of 25-VD>78 mmol/L & is necessary for maximal extra-renal production of 1,25VD. 1,25-VD is one of the most potent regulators of cellular growth & very effective modulator of the immune system. RA patients are present in most cells & tissues including body including activated T and B lymphocytes. Surveillance for VD deficiency, should be part of follow up as it may be linked to underlyng kidney dysfunction in RA. On the other hand, reduced VD might worsen RA & hence, increase the possibility of renal deterioration. VD supplementation may be needed early in management for prevention of kidney dysfunction & to reduce RA severity.

### PUB90

**Associations Between the Progression of Chronic Kidney Disease and Patient Demographics**

Daniele Xu, 1 Mark Stuart, 1 Barbara Cannon, 2 Chad Sowers, 1 John W. Larkin, 1 Sophia Rosen, 1 Carly R. Van Zandt, 1 Len A. Usvyat, 1 Yoongeun Oh, 1 Terry Ketchersid, 2 Dugan Maddux, 2 Franklin W. Maddux, 2 Unit of California, Santa Barbara; 2 Fresenius Medical Care North America; 3 Acumen Physician Solutions; 4 Frenova Renal Research.

**Background:** It is not well known if demographic factors are related to the progression of chronic kidney disease (CKD). We aimed to investigate whether age, sex, race, marital status and geography are associated with significant changes in kidney function determined by linear slopes of mean annual glomerular filtration rate (GFR).

**Methods:** We analyzed data from 90,240 CKD patients (Pts), who had significant declines in GFR, in the Fresenius Medical Care CKD Data Registry. Annual average decline in GFR was estimated on a per pt basis using linear regression with time as the predictor and GFR as the outcome variable. Univariate linear models were fitted for age groups (15-30, 31-40, 41-50, 51-60, 60-65, 65-75, 76-80, 80+ years), sex (female vs. male), race (African American, Caucasian, or other), marital status (married, unmarried) and geography (10 divisions of zip codes); a multiple linear regression model was utilized to investigate associations in mean annual GFR slope and demographics.

**Results:** In this analysis identifies significant associations between mean annual GFR slope and Pt demographics. CKD Pts age 15-30 years old were found to decline faster in GFR versus older Pts in all other age groups (p<0.001). Males were observed to decline slower in GFR versus females (p<0.001). Pts with a race of “other” were seen to decline slower in GFR versus Pts of African American or Caucasian race (p<0.001). The geographical location of Pts by zip code was observed to be associated with differences in GFR slope (p<0.001). The marital status of Pts was not found to be related to differences in slopes of GFR (p=0.218).

**Conclusions:** This study identifies that during the progression of CKD, younger Pts tend to have faster declines in GFR, as compared to older Pts; males have slower declines in GFR, as compared to females; Pts with a race of “other” have slower declines in GFR, as compared to Pts of African American or Caucasian race; and declines in GFR are related to Pt geography.

### PUB91

**Correlation of Increased Th17 to Treg Cell Ratio with Endoplasmic Reticulum Stress in Chronic Kidney Disease**

On Tan.

**Background:** The study aimed to investigate the relationship between the regulatory immune network and endoplasmic reticulum stress (ERS) in patients with different stages of chronic kidney disease (CKD).

**Methods:** A total of 91 patients diagnosed with CKD were divided into different groups according to the stage of disease. Routine blood and biochemical tests were performed in parallel in healthy controls (n = 20). The frequencies of T helper type 17 (Th17) and regulatory T (Treg) cells in the overall T cell population was measured by flow cytometric analysis. Levels of Th17 cell (IL-17) and Treg cell (IL-10) cytokines and the ERS markers

---

930A
CHOP and GRP78 were measured by ELISA in serum samples collected from controls and patients. Correlations between each parameter and serum creatinine, an indicator of renal function, were analyzed by Spearman’s rank correlation and regression test.

**Results:** CKD stage showed a positive correlation with serum creatinine level, and increased levels of CHOP and GRP78 increased with advancing CKD stage. These correlations were most pronounced in patients in the CKD5 group, who also had the poorest response to hemodialysis and peritoneal dialysis treatment, compared with CKD5 patients in the non-dialysis group. Correlation analysis showed that serum levels of CHOP and GRP78 were independently and positively correlated with the ratio of TH17/Treg cells.

**Conclusions:** We have found that an increased TH17/Treg cell ratio and increased serum levels of ERS markers correlate with the progression of CKD. Our results indicate that the interplay between the immune network and management of ERS is closely associated with the pathogenesis of CKD. Although hemodialysis and peritoneal dialysis treatment manage chronic kidney conditions and prevent further deterioration of renal function, they have limited effects on improving the immune disorder and relieving ERS.

**Metabolic Phenotyping in Thin Basement Membrane Nephropathy**

**Background:** Thin basement membrane nephropathy (TBMN) is the commonest cause of familial microscopic hematuria in children and adults, usually associated with benign clinical presentations and normal renal function. In a Greek-Cypriot cohort of TBMN patients, 35% of patients were shown to develop ESRD by age 70-years while ~50% of patients over 50-years developed CKD of variable degree. 40% of TBMN patients inherit heterozygous mutations in the COL4A3/A4 genes. What predisposes these TBMN patients to an adverse outcome and chronic kidney function decline during aging is presently unclear. Using Metabolic phenotyping techniques (NMR and mass spectrometry) our study should provide new biological insights in the development of extreme conditions in adult TBMN patients.

**Methods:** Spot urine samples from 81 patients with the same founder mutation, COL4A3-G1334E. Patients were classed; Severe (S) (n= 55): proteinuria >500 mg/day and CKD, irrespective of age. Mild (M) (n=26): normal kidney function with no proteinuria, regardless of age. It is expected that some will progress to CKD on follow-up. Samples were analysed by 600 MHz 1H NMR spectroscopy (detecting predominantly small molecules >1μM) and UPLC-MS (detecting water-soluble molecules >0.05 μM). Multivariate analysis (MVA) was used to elucidate class differences.

**Results:** MVA of M vs S samples revealed significant metabolic differences between the groups. From the UPLC-MS 15 MS features discriminate M and S. Among the discriminating metabolites discovered using NMR: citrate, glycine and creatinine were negatively correlated with M. Metabolite identification is ongoing, as well as application of additional metabolic profiling technologies.

**Conclusions:** Urine metabolic profiling may prove useful to classify renal disorders such as in the M and S cases of TBMN by their specific renal metabolite signatures and lead to the discovery of novel molecular disease biomarker profile patterns.

**Uric Acid and Its Association with Glomerular Filtration Decline Rate in an Incident Pre-Dialysis Population**

Pedro Viestra, Miguel Goncalves, Gil Silva. Nefrologia, Hospital Central do Panchal, Panchal, RAM, Portugal.

**Background:** Hyperuricemia is highly prevalent and there is cumulative evidence based on experimental models of its likely detrimental role in multiple pathologies, namely hypertension, vascular and renal diseases. Given hyperuricemia’s high occurrence on chronic kidney disease patients, we have tried to assess the association between uric acid basal levels (UABL) in an incident pre-dialysis population with renal function decline rate.

**Methods:** We have randomly selected incident patients with chronic kidney disease stages IV-V, referred to low clearance nephrology assessment from 2010 to 2014. We kept follow up until dialysis initiation, death or lost of follow up. Results: Sixty-six patients were selected with mean UABL of 8.15 (±2.10) mg/dl and a mean glomerular filtration rate of ~40ml/min/1.73m²/year. Of notice that by each unit increase in UABL an added variation of ~1.41 ml/min/1.73m²/year on glomerular filtration decline rate was observed (CI 95%, p=0.039). Adopting a linear mixed model analysis on UABL impact on glomerular filtration decline rate, despite adjustment for multiple demographic confounders and comorbidities, statistical significance (p<0.006) was conserved.

**Conclusions:** High UABL were associated, with statistical significance, to enhanced deterioration of kidney function.

**PUB194**

**Soluble α-Klotho in HIV-Infected Patients and Kidney Dysfunction**

Clara Dias, Sara Maia, Fernando G. Pereira, Pedro Pereira Campos, Ana Luisa Papoila, Alberto Ortiz, Sofia Pereira, Karina Soto.

**Background:** Chronic kidney disease is common among HIV-infected patients. Klotho is a new endocrine protein that exerts modulation of kidney solute transport and nephroprotection in AKI and CKD. We aim to explore whether levels of serum soluble α-Klotho are related with CKD progression in HIV-population.

**Methods:** As a part of an ongoing prospective study of HIV-infected patients, a cross-sectional analysis was performed. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation being Early Kidney Disease (EKD) when <90 ml/min/1.73m². Fractional excretion of phosphate (FePi) was also assessed and serum soluble α-Klotho was quantified by ELISA.

**Results:** A total of 169 HIV patients were included, 66% men, 75% non-Black, 55yo (48-62). Median values Klotho: 957 pg/mL (717-1213) and FePi: 21% (14-25). Klotho/FePi ratio was negatively correlated with eGFR when <75 ml/min/1.73m² (Spearman r=0.213, p=0.024), while the correlation was positive if eGFR>75 (Spearman r=0.410, p=0.002).

**Key:** - TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

931A

No direct relation between Klotho and eGFR was found, while FePi was only related with eGFR<75 (Spearman r=0.396, p=0.002).

**Conclusions:** In HIV-infected patients, the association between Klotho and CKD progression has only significance when normalized by FePi levels. This association differed in opposite directions between patients with EKD and with normal kidney function, or in very early CKD stages. Of note, Klotho/FePi ratio seems to be better biomarker of EKD than Klotho itself.

**Association of hsCRP and Kidney Damage Indicators in 5667 Adults Receiving Physical Examination**

Hao Zhang, Juan Mao, Bin Yi, Guo Xu, Wei Li. The Third Xiangya Hospital of Central South Univ.

**Background:** Chronic kidney disease and cardiovascular disease share many risk factors. Injury to the vascular endothelium, measured by elevated levels of serum high-sensitivity C-reactive protein (hsCRP), may play a role in kidney disease. We therefore examined the association of hsCRP with kidney damage indicators (ACR, eGFR) among 5667 participants receiving physical examination in the Third Xiangya Hospital.

**Methods:** We conducted a cross-sectional analysis of 5667 adults who received healthy physical examination in 2014. Spearman correlation analysis, multiple linear regression and multivariable logistic regression analysis were used to assess the correlation between hsCRP and uACR, eGFR. ROC curves was drawing to explore the statistically significant intercept point of hsCRP in predicting the occurrence of albuminuria and declining in eGFR. Multivariable logistic regression analysis was used to calculate the ORs for albuminuria, declining in eGFR according to the quartiles of hsCRP levels and other risk factors.

**Results:** Spearman correlation analysis showed that uACR was positively correlated with serum hsCRP (r=0.233, p=0.01). While hsCRP showed negative correlation with hsCRP (r=-0.135, p<0.01). Multiple linear regression analysis showed that hsCRP was independently correlated with uACR (B=0.205, p=0.156, P<0.01). While hsCRP didn’t enter the multivariate linear regression model of eGFR. Multivariable logistic regression analysis showed that male, central obesity, hypertension, diabetes and high hsCRP levels were independent risk factors for albuminuria. Based on the ROC curve, the 0.85mg/L of hsCRP was the best numerical value to predict the risk of albuminuria. Multivariable logistic regression analysis showed that the risk of albuminuria significantly increased in male, central obesity, hypertension, or diabetes combined with high hsCRP levels.
Conclusions: HoCRP was correlated with kidney damage indicators, and HoCRP was an independent risk factor of albuminuria. The 0.85μg/L of CRP was the best numerical value to predict the risk of albuminuria. Male, central obesity, hypertension, diabetes accompanying high serum CRP levels are more likely to have albuminuria.

PUB196
Serum Non-Protein Bound Homocysteine Levels Are Related with Chronic Kidney Disease Progression in HIV-Infected Patients Clara Dias, 1 Nelson Casimiro, 1 Nuno Coelho, 1 Ana R. Lemos, 1 Pedro Pereira Campos, 2 Ana Luisa Papolla, 3 Sara Maia, 1 Karina Soto, 1 Soﬁa Pereira. 1 Centro de Estudos de Doenças Crônicas, NOVA Medical School/Faculdade de Ciências Médicas (NMS/FCM), Univ Nova de Lisboa; 2Centro de Estatística e Aplicações da Univ de Lisboa (CEAUL); NOVA Medical School/Faculdade de Ciências Médicas, Univ Nova de Lisboa; 3Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal.

Background: Homocysteine (Hcys) is present in serum in two major forms: disulﬁde protein-bound (PB) (70-80%, mostly albumin) and non-protein-bound (NPB) (20-30% combined thiol dimers + 1 % thiol free). Only the NPB-fraction of Hcys is able to enter into the cell and accumulates in both kidney failure and HIV-infected patients, hyperhomocysteinemia is a common feature. The present study was aimed to explore the relationship of Hcys NPB-fraction and chronic kidney disease (CKD) progression in HIV-infected patients.

Methods: As a part of an on-going prospective study of HIV+ population, a cross-sectional analysis was performed in a cohort of HIV-infected patients under combined antiretroviral therapy. Serum NPB-fraction of Hcys was quantiﬁed by HPLC with ﬂuorescence detection. Glomerular ﬁltration rate (eGFR) was estimated by CKD-EPI equation. The fractional excretion of phosphate (FePi) was also assessed.

Results: A total of 141 HIV-infected patients were included, 65% men, 73% non-Black, 52% non-smokers, 44% current smokers, 41% with previous smoking, 57% with antiretroviral therapy and 84% with CD4 cell counts over 200. Median values of eGFR and FePi were 85 ml/min/1.73m² in Renal Function infected patients.

Conclusion: These data add strength to the hypothesis that an active diabetic foot ulcer may contribute to a decline in renal function, particularly when associated with an episode of AKI. This decline may also be under-estimated due to loss of muscle mass and subsequent over-estimation of eGFR in the post hospitalisation period. These results support additional prospective epidemiological and mechanistic studies to further explore the relationship between diabetic foot ulcers, AKI and CKD progression.

PUB198
Gender – An Additional Cardiovascular and Chronic Kidney Disease Risk Factor in an Apparently Healthy Population Attilio Di Benedetto, 1 Annalisa Cioltola, 2 Fabrizio Cerino, 3 Annamaria Colao, 2 Daniele Marcelli, 1 Bernard J. Canaud, 3 NephroCare Italy, Naples, Italy; 3Medicina Clinica e Chirurgia, Univ Federico II, Naples, Italy; 4Fresenius Medical Care, Bad Homburg, Germany.

Background: Cardiovascular disease (CVD) is on the rise, presenting signiﬁcant social and economic burden. Early detection of CVD and chronic kidney disease (CKD) risk factors may prevent related complications. We report results of a CVD and CKD risk factor screening program in an apparently healthy population.

Methods: Participants and spectators of the “Prevention Races” held in 2013/2014 in Naples/Salerno (Italy) were screened for CVD and CKD risk factors by different specialists, including nephrologists. Parameters assessed were: systolic blood pressure (SBP), diastolic blood pressure (DBP), weight, height, waist circumference, BMI, and body composition. Lean (LTI) and Fat (FTI) tissue indexes and overhydration were evaluated by Body Composition Monitor (Fresenius Medical Care, Bad Homburg, Germany) using multi-frequency bioimpedance spectroscopy at 50 different frequencies.

Results: 701 subjects (38.5% m; 61.5% f) were evaluated. Mean age was 54.54 ± 15.6 (m) and 50.06 ± 15.2 (f). 3.7% m and 6.8% f had dyslipidemia; 5.9% m and 3.0% f were diabetics; 18.6% m and 11.4% f were hypertensive; 2.2% m and 0.7% f had heart disease; 0% m and 3.5% f had hypothyroidism; 1.5% m and 1.2% f had CKD. Gender differences were significant in SBP, DBP, overhydration, FTI, LTI and BMI (Table).

Conclusions: In a large sample of apparently healthy persons, males had more CVD and CKD risk factors than females, such as SBP, overhydration, and FTI. In association with other CVD risk factors, these increase morbidity and mortality. Evaluation of body composition is important in the general population for identiﬁcation of CVD and CKD risk.

PUB199
Potential Effect of Treatment of Metabolic Acidosis on Reducing the Risk of End Stage Renal Disease in Chronic Kidney Disease Solomon Daleman, Candace D. Grant, Vladimir Liberman, Alejandro Pepen Romero, Shayan Shirazian, Nobuyuki (Bill) Miyawaki, Joseph Mattana. Medicine, Winthrop-Univ Hospital, Mineola, NY.

Background: There is increasing evidence that low serum bicarbonate levels impact adversely on the progression of chronic kidney disease (CKD) to end stage renal disease (ESRD). It is plausible that treatment could result in a signiﬁcant reduction in ESRD incidence though the potential impact in a CKD population and number needed to treat (NNT) are incompletely understood. We carried out the present study to estimate the potential impact of treatment of metabolic acidosis on the incidence of ESRD in a population of CKD patients.

Methods: We evaluated a cross section of 623 Stage 3 and 4 CKD patients at our institution. Their risk of developing ESRD at 2 and 5 years was estimated using the method of Targarini et al (JAMA 2011;305:1553-1559) which incorporates age, gender, eGFR, uric acid to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. ESRD risk was then recalculated after assuming correction of all serum bicarbonate levels to 28 mEq/L.

Results: The population had a mean serum bicarbonate level of 24.3 mEq/L, with 79.5% having levels below 28 mEq/L. When ESRD risk was calculated following correction of low serum bicarbonate levels to 28 mEq/L, 16 fewer patients were predicted to develop ESRD at 2 years and 27 fewer at 5 years (relative risk reductions of 0.31 and 0.23 respectively). This effect was greatest for patients with CKD stage 4, accounting for 13 fewer ESRD patients predicted at 2 years and 20 fewer at 5 years. For the population as a whole, the NNT to prevent one case of progression from CKD to ESRD was 40 and 23 at 2 and 5 years respectively, while for those with CKD stage 4 the NNT was only 16 and 11.

Conclusions: Our findings suggest that in a population of CKD patients correction of metabolic acidosis could potentially result in a substantial reduction in the number who reach ESRD given the large numbers of patients with low serum bicarbonate levels. Prospective studies are needed to determine whether sodium bicarbonate therapy in populations of CKD patients could prevent many cases of ESRD.

The Impact of Vascular Disease on Risk of Development of End Stage Renal Disease in Patients with Chronic Kidney Disease

Vladimir Liberman, Sairah Sharif, Candace D. Grant, Alejandro Pepen Romero, Shanza Mujeeb, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, Joseph Mattana. Medicine, Winthrop-Univ Hospital, Mineola, NY.

Background: Patients with chronic kidney disease (CKD) are not only at higher risk for development of end stage renal disease (ESRD) but also suffer disproportionately from vascular disease (VD), with associated high cardiovascular mortality. VD can plausibly impact progression of CKD and increase the risk of ESRD. However, VD also shortens survival, and may therefore reduce the risk of ESRD by increasing the competing risk of death. In the present study we evaluated the relationship between VD and the risk of development of ESRD in patients with CKD.

Methods: We carried out a retrospective cross sectional study of 623 CKD patients and recorded demographic, clinical and laboratory variables. We divided them in two groups based on presence or absence of VD and stratified them into different age groups. We estimated the risk of ESRD progression using the method of Tangri et al (JAMA 2011;305:1553-1559) and compared the risk levels between each group.

Results: Out of 623 patients with CKD 285 had VD (coronary artery disease and/or peripheral vascular disease) documented in the record. Patients with VD were significantly older than patients with no VD (76 vs 70 years), had lower serum albumin (4.0 vs 4.1 g/dL) and lower eGFR (33.8 vs 36.4 ml/min/1.73 m²). We found that older patients with VD had significantly higher risk of developing ESRD. For the 70 to 79 year age group the 2 year risk was 2.45 vs 1.50 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03) in patients with and without VD. For patients ≥80 years the 2 year risk of developing ESRD was 2.18 vs 1.35 (p=0.029) and 5 year risk of developing ESRD was 6.80 vs 4.31 (p=0.03).

Conclusions: Our findings suggest that older patients with VD may be at increased risk for the development of ESRD despite the higher competing risk of death. This may be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD progression. If validated in an ongoing prospective study this finding would suggest that VD should be considered a risk factor predisposing to an increased risk of developing ESRD.

Management of Renal Artery Stenosis Post-ASTRAL and CORAL: Outcome of Patients with Radiologically Confirmed Atherosclerotic Renal Artery Stenosis Treated Conservatively

Moheen Mohammed Ahmed, Nicholas John Railton, Abdelgalil Abdelrahman Ali, Anthony Chan. Renal Medicine, Mid Essex NHS Trust, Chelmsford, United Kingdom; Radiology, Mid Essex NHS Trust, Chelmsford, United Kingdom.

Background: Following the publications of ASTRAL and CORAL trials, the use of percutaneous renal artery angioplasty and stenting (PRAS) in the treatment of atherosclerotic renal artery stenosis (ARAS) has fallen dramatically. We report the outcomes of patients with radiologically confirmed diagnosis of ARAS who did not undergo PRAS and were managed medically.

Methods: Retrospective review of all patients undergoing CT/MRI angiography for suspected ARAS from 2008-2014 in Broomfield Hospital, Essex. Patients with more than >50% stenosis in a renal artery who were medically managed and did not undergo PRAS were included in analysis. They were followed for blood pressure control, renal events and mortality.

Results: 29 patients were identified, all Caucasians with a median age of 78 (49-85 years) of which 59% were males. None underwent PRAS. They were followed up from diagnosis till December 2014 or date of death with a mean period of 51 months. Systolic BP at end of study was <140 mmHg in 48%, 140-200 in 48% and >200 in 4% of patients. 69% were on 3 or more antihypertensives with 34% on renin angiotensin system blockade. 20 patients were CKD 3 and 8 with CKD 4 at baseline, with 3 patients progressing from stage 3 to 4 and 1 to stage 5 CKD, requiring dialysis.

Conclusions: From this study of patients with ARAS not indicated for PRAS, only a small number progressed to higher grades of CKD. Blood pressure control appeared adequate in a significant proportion of patients. This is in keeping with the findings from ASTRAL/CORAL trials and may be of significant benefit in terms of cost and reducing patient morbidity.
Factors Influencing Initiation and Choice of Immunosuppressive Therapy in Primary FSGS

Louis-Philippe Laurin, 1  Bethany J. Foster, 2  A. Gasim, 3  Caroline J. Pouillon, 1  J. Charles Jennette, 4  Ronald J. F actively, 5  Patrick H. Nachman, 6
6  Dip of Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 7  Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 8  Dip of Nephrology and Hypertension, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 9  Dip of Nephrology, McGill Univ Health Center, Montreal, QC, Canada.

Background: The treatment of patients with primary focal segmental glomerulosclerosis (FSGS) may include immunosuppressive therapy in patients not responding to conservative treatment or considered at high risk of progression to renal failure. We sought to determine the patient and disease characteristics associated with choice of therapy early in disease course.

Methods: Inception cohort of biopsy-proven patients with primary FSGS diagnosed between 1980 and 2012. Factors influencing choice of therapy were identified using multiple logistic regression; we report odds ratios (OR) with 95% confidence interval (CI).

Results: 458 patients met inclusion criteria; 183 had FSGS not requiring immunosuppressives; 173 treated with glucocorticoids [GC] alone; 90 with calcineurin inhibitors [CNIs] ± GC; 12 with other immunomodulatory agents.

Conclusions: Presence of tip lesion, preserved renal function at baseline and more severe hypoalbuminemia are associated with immunosuppressive therapy in primary FSGS, but only tip variant appears to influence choice of GC alone over CNIs.

Uric Acid Is Independent Risk Factor for Progression of Renal Dysfunction in IgA Nephropathy Female Patients

Yasuyuki Nagasawa, 1  Ryoho Yamamoto, 2  Maki Shizawa, 2  Sayuri Kawada, 2  Katsuyuki Nagatoya, 1  Aritoshi Kida, 1  Tatsuya Shoji, 1  Yukiko Hasume, 1  Terumasa Hayashi, 1  Takahiro Kuragano, 1  Atsushi Yamatani, 2  Yoshitaka Isaka, 2  Takeshi Nakanishi. 2  Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; 3  Dept of Nephrology and Geriatric Medicine, Osaka Univ, Suita, Osaka, Japan; 4  Dept of Internal Medicine, Osaka Rousai Hospital, Sakai, Osaka, Japan; 5  Dept of Nephrology, Osaka General Hospital, Osaka, Japan.

Background: IgA nephropathy is one of common primary glomerulonephritis. Hyperuricemia could be caused by reduced renal function. Therefore, it was difficult to distinguish hyperuricemia from the factors which promote renal dysfunction. Recently, several reports indicated that hyperuricemia might be independent risk factor for renal worsening, but there was little information about the effect of hyperuricemia itself upon progression of kidney diseases, especially in IgA nephropathy patients. Aim is to reveal effect of uric acid upon renal prognosis in IgA nephropathy patients.

Methods: This study is retrospective cohort study. Subjects were 923 IgA nephropathy patients who had not been treated uric acid lowering drugs, from 1001 IgA nephropathy patients who were diagnosed by renal biopsy, and over 15 years old in Osaka University Hospital, Osaka general medical center, Osaka Rosaki Hospital. Outcome was 1.5 times of serum creatinine. Exposure is uric acid at renal biopsy. Explanatory variables included sex, age, BMI, blood pressure, baseline eGFR, proteinuria, smoking status.

Results: Mean age was 34[23-46] years, proteinuria was 0.40[0.18-0.89] g/day. Uric acid was 6.5±1.3mg/dl in male patients, and 4.8±1.3mg/dl in female patients. Multivariate Poisson regression analysis revealed that uric acid was significant risk for progression of renal disease [Hazard Ratio 1.30[1.01-1.65] UA per 1mg/dl] in female patients along with proteinuria(g/day) [HR 1.27[1.08-1.47],p<0.001], Creatinine (mg/dl) [HR 2.73[1.34-3.74]]. In male patients, uric acid was not independent risk factor.

Conclusions: Hyperuricemia is independent risk for progression of kidney disease in female IgA nephropathy patients.

Kidney Inst, Gilbert, AZ.

Background: Long-term treatment with H.P. Acthar® Gel (repository corticotropin injection, Questa Pharmaceuticals, Inc., Hayward, CA), an FDA-approved treatment for remission of proteinuria associated with nephrotic syndrome, was examined in a patient with biopsy-confirmed idiopathic membranous glomerulopathy (mM).

Methods: A retrospective clinical record review examined Acthar Gel treatment over 2 years and 8 months in a patient with mM who received prescription-based treatment in a clinical practice. Outcomes included proteinuria level (mg/g), serum creatinine (SCr), serum albumin and treatment-related side effects. Complete remission was defined as proteinuria <500 mg/g. Partial remission was defined as ≥50% reduction in proteinuria from baseline and proteinuria 500-3500 mg/g.

Results: The 54-year-old Vietnamese patient with mM was treated over 7 years. At diagnosis, the patient’s proteinuria was 8000 mg/g, SCr 0.7 mg/dL, and serum albumin 2.1 g/dL. Initial treatment included prednisone, cyclosporine, mycophenolate mofetil, tacrolimus, and rituximab over 4.5 years. The patient showed partial complete remissions followed by relapse. At Acthar Gel initiation, proteinuria was 3400 mg/g, SCr 0.6 mg/dL, and serum albumin 4.2 g/dL. The patient did not tolerate 80 U twice weekly but did tolerate 40 U twice weekly. At 4 months, she showed complete remission (proteinuria <150 mg/g). Dose reduction to 20 U twice weekly resulted in relapse 7 months later (proteinuria 2300 mg/g). Dose increase to 40 U twice weekly led to complete remission 4 months after that. Loss of insurance and cessation of Acthar Gel for 4 months led to relapse (proteinuria 7700 mg/g). Acthar Gel was re-started at 32 U twice weekly followed by 24 U twice weekly. Partial remission occurred 4 months later (proteinuria 2100 mg/g) with greater improvement at 10 months (proteinuria 500 mg/g). The patient has maintained partial remission (proteinuria 970 g/g) 4 months post-therapy. Side effects over the course of Acthar Gel therapy included fatigue, myalgia, hyperglycemia, and weight gain.

Conclusions: Long-term treatment with H.P. Acthar® Gel may help meet an important treatment need in patients with treatment-resistant and frequently-relapsing mM. Funding: Pharmaceutical Company Support - Funding for editorial support provided by Mallinckrodt Pharmaceuticals.

Outcome of Steroid Dependent (SDNS) and Frequent Relapsing Nephrotic Syndrome (FRNS) in Children

Isabel Roberts, Shefali Vyas. Children's Kidney Center, Saint Barnabas Medical Center, Livingston, NJ.

Background: Management of SDNS and FRNS in children can be frustrating. With the goal of minimizing steroid toxicity while achieving a sustained remission multiple regimens have been used with variable results. We reviewed our cases of SDNS/FRNS who had kidney biopsy (BX) during the past 12 yrs. Methods: Charts of children with BX due to SDNS or FRNS (after failure of MMF) were reviewed. Congenital and secondary causes of NS were excluded. Demographics, medications, side effects and response to therapy were studied. IV cytoscan (CYP) was considered in non-FSGS cases with suspected non-adherence (800 mg/m2/dose monthly
x 3). Others received tacrolimus (TAC) (0.1mg/kg BID; trough up to 6 ng/ml). Rituximab (70mg/m² x 2 doses IV) was given if child became TAC dependent or resistant. Response to therapy was classified as: complete remission (CR), partial remission (PR), infrequent relapse (IR)(<2/yr), failure (F).

Results: 32 children had kidney biopsy (Bx) for primary SDND/FRNS. 14 females; 14 CH, 6 AA, 2 other race. Age at presentation: 2-14 yrs (median= 3 yrs). Bx: 15 MCNS (4 diagnosed later with FSGS), 9 IgMN, 5 FSGS, 3 C1QN, 1 idiopathic immune mediated GN. All children had normal GFR at the time of the bx.

MCNS (4 diagnosed later with FSGS); 9 IgMN, 5 FSGS, 3 C1QN, 1 idiopathic immune mediated GN. All children had normal GFR at the time of the bx.

Follow-up time as CYP had a failure rate 60% (p<0.01), including 4 cases with MCNS. However, those children who had CR were significantly higher for TAC (87.5%) and rituxan (100%) (4 had initial diagnosis MCNS but later bx had FSGS); 7 received rituxamab: all had CR (5 IR). The rates of CR were significantly higher for TAC (87.5%) and rituxan (100%)

24 children received TAC; 21 CR (13 became TAC dependent with IR), 2 PR, 1 IR, 15 received CYP: 6 CR, 9 F, 3 IR (2 before diagnosis MCNS but later bx had FSGS); 7 received rituxamab: all had CR (5 IR). The rates of CR were significantly higher for TAC (87.5%) and rituxan (100%) as CYP had a failure rate 60% (p<0.01), including 4 cases with MCNS. However, those who had CR from CYP didn’t have further relapses. Rate of IR among those who initially had CR was similar between rituximab and TAC. Follow-up time: 2-12 yrs (median= 4 yrs), including 6 discharged due to stable CR and 3 ESRD (all with FSGS).

Side effects: 4 AKI with TAC (reversible), 2 respiratory distress/allergy in rituximab group (IV D/C).

Late TAC resistance was seen in 3 patients.

Conclusions: Children with SDND/FRNS despite failure to respond to MMF had an excellent outcome. Some reported sequential use of tacrolimus and rituximab after failure of CYP with a rate of CR:IR=88% with minimal side effects.

PUB208

Granulomatosis with Polyangitis (GPA) versus Sarcoaidosis

Sruhti Jinna,
Samir S. Zarouk.

Methods: His BUN was 18 mg/dl, and creatinine 1.33 mg/dl. Urinalysis showed 3+ blood, 2+ protein, over 100 RBCs, 10 WBCs. Serology for Hepatitis B and C, HIV, EBV and CMV were negative. Antinuclear antibody, anti-neutrophil cytoplasmatic antibody, anti dsDNA antibody, smith antibody, RNP antibody, myeloperoxidase antibody, proteinase 3 autoantibody, anti SSA antibody, anti SSB antibody, and complement levels were negative. An angiotensin converting enzyme (ACE) level was 81 U/L (8-52). A chest Computed Tomography scan showed mediastinal, hilar lymphadenopathy, and multiple pulmonary nodules.

Results: Suspicion for relapsing GPA prompted renal biopsy. It showed 3 out of 13 glomeruli with pauci-immune crescentic glomerulonephritis. There were extensive non-caseating granulomas in the interstitium and associated tubular atrophy. No microorganisms were noted on AFB and PAS stained sections. Nalas septum biopsy showed non-necrotizing granulomatous inflammation. Medialastinal lymph node biopsy showed necrotizing granulomatous lymphadenitis. These 3 biopsy sites were consistent with sarcoidosis.

Conclusions: This case highlights the difficulty in differentiating between ANCA negative GPA versus sarcoidosis as both can cause granulomatous lesions. Glomerular involvement in sarcoidosis can show membranous glomerulonephritis, FSGS and rarely a crescentic glomerulonephritis. In our opinion, a TAC level combined with extensive presence of non-caseating granulomas in the nasal septum, mediastinal nodes and renal interstitium are more characteristic of sarcoidosis. He responded well to steroids and his weight loss in the last two months.

PUB209

Epidemiology of Glomerulonephritis in Southern Arizona

Benjamin Kweisi Sarsah, Irfan K. Moinuddin, Bijn Thajudeen, Amy Nicole Sussman, Pradeep V. Kadambi.

Nephrology, Univ of Arizona, Tucson, AZ.

Methods: Renal biopsy specimens from adult patients above the age of 18 years with glomerular renal disease were included. Renal transplant biopsies showing glomerulonephritis and biopsies showing co-existing diabetic nephropathies were excluded. Histological diagnoses were grouped into one of the following 8 categories: minimal change disease, FSGS, membranous nephropathy,membrane-proliferative glomerulonephritis, pauci-immune glomerulonephritis, IgA nephropathy, lupus nephritis and others. Demographic parameters were systematically collected from the medical records archive.

Results: The most common histopathological diagnosis was FSGS followed by membranous nephropathy and IgA nephropathy. There were male predominance in all histological variants except IgA nephropathy, lupus nephritis and pauci-immune glomerulonephritis. The race distribution was uneven, and all histovariantal diagnoses except minimal change disease and lupus nephritis were more commonly seen in whites. In separate analysis of the histological pattern in Hispanics, lupus nephritis was found to be the most common pathology followed by FSGS. In American Indian population the most common pathology was IgA nephropathy followed by FSGS. Bar diagram represents frequency of each glomerular disease

PUB210

Use of Rituximab to Induce Remission in Frequently Relapsing Pediatric Nephrotic Patients

Jason Peter Thomas, Teri L. Crumb, Alejandro Quiroga.

Pediatrics, Helen DeVos Children’s Hospital, Grand Rapids, MI; Pediatric Nephrology, Helen DeVos Children’s Hospital, Grand Rapids, MI.

Background: Rituximab has been shown to be effective in patients with frequent relapsing nephrotic syndrome (NS) with a reported 82% response rate. We evaluated the clinical response of pediatric nephrotic patients for induction of remission following one dose of rituximab.

Methods: This is an IRB approved, prospective clinical research trial. Informed consent was obtained from each family. Four pediatric patients with NS were enrolled prior to their clinically indicated rituximab infusion. Urine Protein/Creatinine ratio and albumin blood levels were collected.

Results: Urine Protein/Creatinine ratios obtained post infusion of rituximab decreased between 37-93% from pre infusion levels. 50% of patients identified had resolved edema noted on physical exam post infusion.

Conclusions: Rituximab may be an effective agent for inducing remission for pediatric patients with frequently relapsing nephrotic syndrome. 50% of patients had clinical response on physical exam post infusion and 100% of our patients had a decrease in the amount of protein excreted in their urine. The use of rituximab for the induction of remission is a novel and innovative treatment option for children with frequently relapsing nephrotic syndrome, warranting further investigation.

Lupus Nephritis: An Exploration of Management Style

Abhishek NANDAN.

Huzefa J. Syed, Christen Vagts, Jason M. Kidd.

Internal Medicine, Virginia Commonwealth Univ Medical Center, Richmond, VA.

Background: We aim to evaluate the differences and rationale behind the diagnostic and therapeutic approaches to proliferative lupus nephritis (LN) among nephrologists and rheumatologists.

Methods: A de-identified, multiple-choice survey was distributed to nephrologists and rheumatologists. The survey consisted of a demographic questionnaire and two case vignettes exploring the decision of when to biopsy, management of ISN Class III LN, and management of refractory ISN Class IV LN.

Results: There were 38 respondents to our survey: 12 rheumatologists and 26 nephrologists. Work setting: 81% academic, 19% non-academic. Management of abnormal UA findings in an asymptomatic lupus patient: 33% of rheumatologists versus 76% of nephrologists chose to biopsy. Induction regimen of ISN Class III LN: 79% of all providers chose MMF and 21% chose IV cyclophosphamide.

Choice of Induction Regimen in ISN Class III LN per Specialty

Maintenance regimen of ISN Class III LN: all surveyed rheumatologists chose MMF as a sole maintenance agent compared to 32% of nephrologists who elected the addition of low-dose corticosteroids to MMF. Choice of an adjunctive agent in refractory ISN Class IV LN: 68% of providers chose rituximab, 14% chose tacrolimus, 5% chose CTLA-4 Ig, and 14% elected not to add any agents listed.

Conclusions: The results of this survey suggest a significant difference among rheumatologists and nephrologists on the decision to perform initial kidney biopsy and maintenance long-term treatment with glucocorticoids.

**Background:** The clinical impact of the immune complexes in pauciimmune GN is not well studied. The purpose of this study was to evaluate the long-term prognosis after achieving a complete or partial remission among patients with iMN presenting with heavy proteinuria.

**Methods:** In this study, 25 patients with iMN with heavy proteinuria defined as ≥ 6 g/d were evaluated for the effect of a partial remission (50% reduction in baseline proteinuria to ≤ 3 g/d and ≤ 25% increase in baseline creatinine) and complete remission (proteinuria ≤ 0.5 g/d and serum creatinine ≤ 123 µmol/l) on renal outcomes compared with patients who did not attain a remission. Worse renal outcome was defined as doubling of the baseline serum creatinine value or development of end stage renal disease.

**Results:** Complete remission was attained in 7 (28%) patients, a partial remission in 12 (48%) patients, and no remission in 6 (24%) patients. The worse renal outcome was not observed in all patients who achieved complete remission, but it was seen in 16.7% of the partial remission group and in 66.7% of the no remission group. (P value 0.14).

**Conclusions:** Achieving a complete or partial remission compared to no remission in patients with iMN is associated with a significantly better renal outcome.

**PUB214**

**Eosinophilic Pneumonia with Renal Involvement** Geddie Goldet,1 Rachel Hung,1 Michael Sheaff,2 1 Basildon and Thurrock Univ Hosp; 2 Pathology, Barts and the London School of Medicine.

**Background:** Eosinophilic pneumonia is a rare condition and a well-established cause of pulmonary symptoms. It is often associated with eosinophilic pneumonia or eosinophilic granulomatosis with polyangiitis (EGPA). The clinical presentation can be varied, ranging from asymptomatic disease to severe respiratory failure. The diagnosis of eosinophilic pneumonia is often challenging due to the variable presentation and the need for a multidisciplinary approach toward renal and lung disease.

**Results:** In this case series, we report the outcomes of 7 patients with eosinophilic pneumonia and renal involvement, including 4 patients with interstitial nephritis and 3 patients with Goodpasture syndrome.

**Conclusions:** Eosinophilic pneumonia with renal involvement is a rare but important disease that requires a multidisciplinary approach to achieve better outcomes for patients.
Comparison of Short- and Long-Term IgA Nephropathy Clinical Remission Rates Between Tonsillectomy plus Consecutive and Intermittent Steroid Pulse Therapies

Div. of Nephrology, Iwate Prefectural Central Hospital, Morioka, Iwate, Japan.

Background: Tonsillectomy (Tx) plus steroid pulse therapy (TSP) is widely performed across Japan for clinical remission (CR) of IgA nephropathy (IgAN) but treatment protocol lacks a consensus. We used both TSP (methylprednisolone 0.5 g/day iv for 3 days)* thrice/3 consecutive weeks (TSP-C) and intermittent pulse (⋆) thrice/4 high-power field.

Results: Before treatments, there were no significant clinical [TSP-C (n = 57) vs. TPS-I (n = 33): age, 31.0 ± 11.2 v. 34.0 ± 11.9 years; male/female, 17:40 v. 17:21; eGFR, 82.2 ± 29.9 vs. 77.4 ± 28.7 mL/min; blood pressure, 121 ± 17/72 ± 12 vs. 120 ± 17/76 ± 13 mmHg; urinary protein, 0.41 (0.18, 1.19) v. 0.79 (0.20, 1.08) g/L; and positive occult blood, 91.2 ± 90.9%] and histological grade stratification differences between the groups. At TPS-I cessation, short-term CR rates were equivalent between the groups (TSP-C vs. TPS-I: 1 year, 78.9 (n = 19) vs. 80.0% (n = 10); 3 years, 73.6 (n = 19) vs. 66.7% (n = 6)]. CR continuation between the groups [TSP-C vs. TPS-I: 1 year, 64.1 (n = 39) vs. 59.1% (n = 22); 2 years, 74.2 (n = 25) vs. 80.1% (n = 10); 3 years, 76.6 (n = 19) vs. 66.7% (n = 6)] and histological grade stratification differences between the groups. At oPSL electrophoresis should be routinely performed in the patients with renal failure.

Conclusions: Multiple myeloma patients diagnosed by nephrologist did not show the diagnosis, but had not been treated accordingly.

A Case Series on the Treatment of Nephrotic Syndrome with Natural Adrenocorticotropic Hormone Gel in an Office Setting

Marco A. Bonilla, Xavier F. Panida, Mario A. Henriquez.
Nephrology, Bronx Nephrology-Hypertension, Bronx, NY.

Background: ACTH is a promising treatment for the nephrotic syndrome, associated with significant improvement in proteinuria and relatively few adverse effects. We present our experience using natural ACTH gel for nephrotic syndrome in patients with diverse diagnosis.

Methods: Retrospective case series of 7 Adults patients with nephrotic syndrome, treated with ACTH gel. Data was gathered by chart review, from the clinic EMR and paper based records. ACTH was given in the form of ACTHAR gel 80 USP units/ml SC twice a week for 6 months. Complete remission defined as stable or improved renal function with final proteinuria ≤500 mg/day; partial remission as stable or improved renal function with ≤50% reduction in proteinuria and final proteinuria 500 to 3500 mg/day. Failure to meet this criteria was classified as treatment failure.

Underline represents presenting author.
Very few studies have reported on the prognosis of anti-GBM antibody-positive GN. Anti-GBM disease (GBM) is a renal vasculitis characterized by the formation of immune complexes in the glomerular basement membrane (GBM). Anti-GBM antibodies are directed against the alpha 3 chain of type IV collagen, a major component of the GBM. The hallmark of anti-GBM disease is rapidly progressive renal failure, which is often accompanied by proteinuria and hematuria. The prognosis of anti-GBM disease is influenced by several factors, including the type of GBM, the level of proteinuria, and the presence of hypertension. The presence of hypertension is associated with a worse prognosis, as it can lead to further damage to the kidneys. The disease is often treated with immunosuppressive agents, such as steroids, to reduce inflammation and the formation of immune complexes. However, the prognosis of anti-GBM disease remains guarded, and the outcomes for patients with this condition continue to be monitored closely.
The Clinical Predictors for Outcome of Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis Patients with Renal Involvement

Guisen Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: Primary anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are chronic multisystem autoimmune diseases and result in dysfunctions of multisystem. Renal involvement is the most common manifestation and is closely associated with the outcome of patients with vasculitis. We investigated the clinical determinants of the early mortality of patients with vasculitis-related renal injury followed up 2 years in a single west Chinese center to study the factors associated with patient outcome.

Methods: A total of 123 consecutive patients with AAV-related renal injury diagnosed in our center were recruited. Clinical and laboratory data were collected retrospectively. All the patients were followed up for 2 years after diagnosis. The predictive values of variables associated with mortality were analyzed.

Results: During 2 years follow up duration, 54 (43.9%) died, of whom 41 diedwithin the first year after diagnosis. Compared with surviving patients, the deceased patients had higher BVAS scores and higher incidence of pulmonary hemorrhage. They also had higher serum creatinine and ESR, lower hemoglobin and complement C3, more patients accepting renal replacement therapy than surviving patients during hospitalization. Higher BVAS scores and serum creatinine>400μmol/L were the predictors of death in patient with AAV-related renal injury independently.

Conclusions: The incidence of early mortality in patients with AAV-related renal injury was higher. Prudent monitoring and therapy should be given to patients with active vasculitis and serious renal dysfunction to reduce adverse events.

Significance of Resistive Index in Renal Arterial Ultrasonography as a Clinical Parameter for Tubulo-Interstitial Nephropathy

Kazuyuki Takayagami,1 Taisuke Shimizu,1 Hiroaki Hara,1 Nobuyuki Onizawa,1 Koki Ogawa,1 Yuka Tanaka,1 Kunihiko Yasuda,1 Tomonari Ogawa,1 Akihiko Matsuda,2 Hajime Hasegawa.1 1Nephrology and Hypertension, Saitama Medical Univ; Saitama, Japan; 2Ishikawa Kinenkai Kawasaki Ekimae Clinic, Kawasaki, Saitama, Japan.

Background: Renal arterial ultrasonography (RA-US) has been principally applied to evaluate the stenosis of the renal artery and the indication of catheter intervention by the measurement of peak systolic velocity (PSV). Resistive index (RI) is calculated as PSV/EDV (PSV: where EDV indicates end-diastolic velocity, and is reported to be related to the renal function. In this study, we aimed to investigate the possible clinical benefit of RI for the assessment of tubulo-interstitial nephropathy (TIN).

Methods: We studied 51 patients (51.6±2.3 years old) who underwent RA-US and sufficient laboratory tests for the analysis in the past 10 years in our hospital. PSV and RI were measured at both main renal arteries (RA-measurement) and intra-renal arteries roughly corresponding to the inter-lobar arteries (IRA-measurement). NAG index (urine excretion ratio of N-acetylglucosaminidase (NAG) to creatinine) was used as a conventional clinical parameter for the assessment of TIN.

Results: Stratified analysis by median value of RI (0.69) showed significant difference in eGFR in the RA-measurement (43.4±4.7 vs 60.3±4.2), but not in the IAR-measurement. In contrast, the analysis showed significant difference in NAG index in the IRA-measurement (median: 11.6 vs 5.4), but not in RA-measurement. When the patients showing NAG index ≥ 15, indicating advanced renal insufficiency, would be excluded from the analysis, NAG index significantly correlated with RI of IRA-measurement (R=0.50, p<0.05), but not RA-measurement. In addition, ROC analysis revealed that the cut-off value of RI to NAG index was 0.65.

Conclusions: In addition to the previous report showing the relevance of RI to the histological severity, the present study demonstrated the correlation of RI with the conventional parameter of TIN, NAG index. Particularly, for the assessment of TIN, RI value measured at intra-renal artery would be more beneficial.

Recovery of Renal Function with Eculizumab in a Girl with Dense Deposit Disease and Normal Soluble C5b-9 Levels

Martin Könighoff,1 Arjan Diepstra,2 Marc Maj Seelen,3 Coen A. Stegeman,1 Valentina Gracchi.1 1Pediatrics, UMCG, Groningen, Netherlands; 2Pathology, UMCG, Groningen, Netherlands; 3Nephrology, UMCG, Netherlands.

Background: Dense Deposit Disease (DDD) is a rare glomerulopathy characterized by electron-dense deposits in the glomerular basement membrane (GBM) and glomerular complement deposition. 50% of patients progress to ESRD and have recurrences after kidney transplantation. Dysregulation of the alternative complement pathway plays a key role in the pathogenesis. Increased soluble C5b-9 in blood is considered to predict response to eculizumab, an anti-C5 monoclonal antibody.

Methods: We report the case of a previously healthy 15-year-old girl who presented with acute kidney injury, hypertension, nephrotic syndrome (10.8 gr protein /24 hours) and microscopic hematuria.

Results: Biochemical (C3 &4, sC5b-9, factors H & I, C3 nephritic factor and anti-FH) and genetic workup of the complement system (CFI, CFB, C3 and MCP) showed normal results, except for a slightly increased C3d and a risk allele in the CFH gene. Renal biopsy showed cellular crescents and electron-dense deposits in the GBM. Glomerular C3 and C5b-9 immunofluorescence staining was positive. Despite escalating therapy, including methylprednisolone pulses followed by oral prednisolone, cyclophosphamide and plasma exchange (PE), the renal function further deteriorated and hemodialysis was started. Eculizumab was administered. This led to a rapid improvement of renal function (discontinuation of dialysis and increase of endogenous creatinine clearance from 11 to 53 ml/min/1.73m²). Three months later the girl is in a good clinical condition but proteinuria is still in the nephrotic range (3.6 gr/24 hours). Treatment with eculizumab is ongoing. Up to now no side effects have been observed.

Conclusions: Response to eculizumab in DDD cannot be predicted merely on the basis of levels of sC5b-9 in blood.
Manifestations of IgAN vary widely. The mainstay of therapy consists of supportive measures, which the majority of our cohort received. Immunosuppressive regimens are reserved for a select group, and in our cohort both mycophenolate and steroid based regimens yielded a reduction in proteinuria.

**Conclusions**: Manifestations of IgAN vary widely. The mainstay of therapy consists of supportive measures, which the majority of our cohort received. Immunosuppressive regimens are reserved for a select group, and in our cohort both mycophenolate and steroid based regimens yielded a reduction in proteinuria.

**Effect of Rituximab on Immunoglobulin Levels and Infection Risk in ANCA Associated Vasculitis**

*Shivani Shah,*1 *M-Hafizur Rahman,*2 *Duvuru Geetha.*1

1Div of Nephrology, Dept of Medicine, Johns Hopkins Hospital, Baltimore, MD; 2Bloomberg School of Public Health, Johns Hopkins Univ, Baltimore, MD.

**Background**: Rituximab (RTX), a B cell depleting anti-CD20 monoclonal antibody, is approved for treatment of ANCA associated vasculitis (AAV). Low immunoglobulin (Ig) levels are a consequence of RTX treatment. The association between the degree of Ig deficiency and infection risk is unclear in AAV patients.

**Methods**: AAV patients treated with RTX in a single center with available serum Ig measurements were included. The rates and types of infection after RTX administration were correlated with Ig level using correlation matrix and logistic regression analysis.

**Results**: Our cohort of 27 patients had a median age of 68 years, eight males, 15 GPA patients, and 17 with a new diagnosis of AAV. Twenty five received four doses of RTX 375 mg/m² weekly and two received RTX 1000 mg biweekly for two doses. Nine received concomitant cyclophosphamide. Twenty three patients had low serum IgG levels (<751 mg/dL) greater than one month following RTX treatment. Ten out of these 23 developed infections over the median follow up time of 338 days. Pneumonia was the most common infection. The odds of having an infection with IgG level ≤500 mg/dL is 3.6 times higher than with IgG level between 501-750 mg/dL, though p = 0.26. There is a significant association between infection and IgM level ≤20 mg/dL (p = 0.047).

**Conclusions**: Severely low Ig levels due to RTX therapy may increase the risk of infection in AAV patients, and these patients may benefit from IVIG therapy. Further investigation is warranted given our study is limited by small sample size, concomitant cyclophosphamide use, and variable timing of Ig measurement.

**Lipoprotein Glomerulopathy**

*Hostensia M. Beng,* Basema I. Dibas,* Hsiao Ling Lai,* Guillermo Hidalgo.*Pediatrics, ECU, Greenville, NC.

**Background**: Lipoprotein glomerulopathy has been associated with mutations in the Apolipoprotein E (APOE) gene. The average age of reported cases is 32 years and the youngest patient described to date is 4 yrs old. Here we present the first case of a 3 years old AA male with right hemihypertrophy, malignant hypertension, severe proteinuria & lipoprotein glomerulopathy, with a heterozygous mutation on APOE gene.

**Methods**: A 3 year old African American male presented to pediatrician complaining of hemihypertrophy, short stature, polydipsia & hypertension. Physical examination remarkable for right leg soft tissue hemihypertrophy. Echocardiogram revealed left ventricular hypertrophy likely secondary to chronic hypertension. Hypertension and proteinuria persisted despite adequate treatment. Renal US showed persistent echogenic kidneys. Kidney biopsy showed Lipid vacuolization of podocytes, endothelial cells, tubular epithelial cells, and glomerular capillary lumens. Labs & imaging studies AFP and abdominal US have been normal with exception of proteinuria and increased lipid profile. Patient currently on a trial treatment with fibrin acid and dietary modification.

**Results**: eGFR is stable at 60 ml/min/1.73 m², proteinuria has improved from a ratio of 2.1 to 0.8 mg/mg and lipid profile has significantly improved.

**Conclusions**: APOE is an important LDL in transporting cholesterol to the liver for processing. Four main alleles of the APOE gene located on chromosome 19 have been described and different alleles have been associated with various medical conditions. Mutations of the LDL bind domain of the APOE gene coexist and may be associated with certain kidney diseases. Renal biopsy shows lipid deposits and thrombi which results in glomerular damage and glomerular sclerosis. No effective preventative or curative treatments have been identified for apolipoprotein glomerulopathy. In our patient a trial of fibrates to lower cholesterol, Gemfibrozil and effective management of hypertension has resulted in some improvement but it is uncertain if these medication can effectively lower lipid and prevent long term progression of kidney disease. More research to find more effective treatment and management strategies of this disease in children.

**Proliferative Lupus Nephritis (LN) – 60 Month Evolution of an Argentinian Cohort**

*Gabriel Pedro Alvarez,*1 *Marcelo Alejandro De Rosa,*2 *Luis Alberto Togneda.*1 Hospital San Martin, La Plata, Buenos Aires; 2Univ of Buenos Aires, Argentina.

**Background**: Remission of proteinuria predicts good evolution in many glomerular diseases; we describe the behavior of the proteinuria, renal function and flare up in a group of patients with proliferative LN in a 60 month period.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline represents presenting author.**
Methods: Data from 55 patients were obtained. Proteinuria and Creatinine were shown to be significant at 0 (time of the biopsy), 6 and 60 months; renal biopsies were classified using ISN-RPS criteria among patients with and without vasculitic lesions, only tubular atrophy was predictive of future decline in renal function (p=0.007). In this cohort, 21% reached ESRD within a mean follow up of 7 yrs which highlights the aggressive nature of this disease process.

Results: Significant differences (p=0.05) was between concentrations of cytokines EGF, G-CSF, GM-CSF, GRO, IFN, IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-12(p70), IL-13, IL-15, IL-17, IL-1Ra, IL-1a, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IFN-α2, TNF-α, TNF-β, VEGF, scCD40L, RIL-2RA) using MILLIPLEX®-MAP Human Cytokine/Chemokine-Magnetic-Bead-Panel-Premixed 39 Plex.

Conclusions: Significant differences in plasma samples of these molecules may be considered.

PUB234
Clinical Outcomes of IgA Nephropathy with Necrotizing and Crescentic Lesions in Inner City Hospital

Nephrology, John H Stroger Jr. Hospital of Cook County, Chicago, IL.

Abstract: IgA nephropathy is the most common cause of glomerular disease worldwide. Segmental necrosis and crescents are seen only in small subset of patients and literature regarding their clinical outcomes is sparse.

Methods: Retrospective analysis of cases with primary IgA nephropathy from Stroger Renal biopsy database from January 2005 to May 2015 was performed. Demographic and clinical information was obtained from medical charts. Study was approved by IRB.

Results: Of 66 cases of IgA nephropathy, 10 (15%) had lesions with segmental necrosis and/or crescents. These patients responded well to cyclophosphamide based therapy with improvement in creatinine and proteinuria after a mean follow up of 4.6 years. However, patients without vasculitic lesions had a progressive decline in renal function despite immunosuppressive therapy. This group had longer follow up period (median 7.1 yrs) and 21% required dialysis.

Conclusions: Segmental necrosis and crescents in IgA nephropathy are not rare but not well understood. This study provides new insights into the natural history of this disease.

Plasma Cytokines and Chemokines Profile in Patients with Systemic Lupus Erythematosus: Its Potential Use as Biomarkers of Kidney Damage

Gustavo Aroca Martinez,1,2 Lisandro Pacheco,1 Elkin Navarro Navarro;1 Yirys Diaz,1 Henry J. Gonzalez torres,1,2 Gloria Garavito,1 Eduardo Egea bermejo,3 Eduardo J. Navarro,3 Liseth Almendrals,4 Antonio De Jesus Iglesias-Garrama.5

Background: Systemic lupus erythematosus is an autoimmune disease in which the innate and adaptive response plays a significant role, mainly mediated by cytokines. Lupus nephritis-LN is the most severe complication associated with SLE. Objective: To identify differential expression of cytokines profiles and circulating chemokines in plasma of SLE patients with different degrees of Caribbean region.

Acute Tubulo-Interstitial Nephritis (ATIN): Predicting Long Term Outcomes
Victoria C. Robins,1 Aravind Cherukuri,2 Padmini Prasad,1 Richard J. Baker.1, 2SUH; 3Pittsburgh.

Background: ATIN is a relatively common potentially reversible cause of acute kidney injury. It has become clear over the last 2 decades that the disease is not always reversible, particularly in the elderly. We present a large contemporary single centre retrospective series concentrating on factors that predict poor outcomes.

Methods: 62 cases retrospectively diagnosed histologically via pathology records as primarily ATIN were included. An experienced histopathologist, blinded to outcomes, graded biopsies according to the presence, absence and degree of 8 different parameters: Interstitial inflammation, tubular atrophy, eosinophilia, plasma cell infiltration, chronic vascular lesions, hyalinosis, granulomas + oedema. Patients were classified as a poor outcome if eGFR (variable MDRD) after 12 months was less than 30 ml/min/1.73m² or they died.

Results: 62 patients with biopsy proven ATIN were identified. 15 had a poor outcome. Baseline demographics are presented in Table 1.

Aetiology was difficult to definitely ascertain but consisted of drug induced, infectious, sarcoid or sjogrens. Parameters significantly associated with poor outcomes include higher creatinine at presentation & 6 months, presence of granulomas and chronic vascular lesions on biopsy at diagnosis. The effect of steroid treatment was difficult to assess since most patients were treated at the outset.

Conclusions: ATIN usually carries a good prognosis but some patients experience poor outcomes. Poor renal function at diagnosis and the presence of granulomas and chronic vascular lesions are predictive of poorer outcomes.

Cotreatment of Olmesartan and Caterpillar Fungus Attenuate Albuminuria in Patients with Glomerulonephritis
Hua Zhou, Ye Zhang, Ya Li, Hairong Tang, Congcong Jiao, Lining Wang. Nephrology Dept, 1st Hospital of China Medical Univ, Shenyang, China.

Background: Angiotensin II receptor blockers (ARBs) were demonstrated to reduce proteinuria since a decade ago. However, proteinuria still remains as the top of clinical symptoms in glomerulonephritis (GN). We aim to investigate the effect of cotreatment with olmesartan (Olm), an ARB and caterpillar fungus capsule (CF) on proteinuria in patients with GN.

Methods: 491 patients with GN were retrospectively studied. GN was diagnosed by their medical records, including the date of diagnosis and the approximate date of the first symptoms in 194 patients. We have also analyzed data related to ANCA subtype in each patient. The cotreatment with CF showed an increased statistical p value.

Results: Of the 209 patients, 160 (76.7%) were MPO-positive, 28 (13.3%) were PR3 positive and 21 (10%) were ANCA negative. Regarding the onset of symptoms, we found a greater number of cases in the months of January, February and March, compared with the rest of the year. This data correlates positively with the higher incidence of the symptoms in Barcelona between 2009 and 2013.
Considering the date of diagnosis we found a greater number of cases in two periods of the year; the months of May, June and July, and the months of October, November and December.

Conclusions: In our population, predominantly ANCA-PMO-positive related vasculitis, we found a higher incidence of the disease in the winter months, being diagnosed more frequently in May, June and July or October, November and December. One potential environmental factor, influenza disease, may explain this finding.

PUB239
Mycophenolate Mofetil for the Treatment of Idiopathic Nephrotic Syndrome: A Meta-Analysis of Randomized Controlled Trials Bin Zhu, Yongjun Wang. Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (Guangxing Hospital) Affiliated to Zhejiang Chinese Medical University, Hangzhou, Zhejiang, China.

Background: This meta-analysis was performed to investigate the efficacy and safety of mycophenolate mofetil (MMF) in treating idiopathic nephrotic syndrome.

Methods: We searched MEDLINE, EMBASE, the Cochrane Library database, the Database for Chinese Technical Periodicals, Wanfang, Chinese National Knowledge Infrastructure and the Chinese Database of Biology and Medicine for randomized controlled trials compared MMF with the other immunosuppressive agents for the treatment of idiopathic nephrotic syndrome. Weighted mean difference (WMD) and summary estimates of relative risk (RR) reductions with 95% CIs were calculated.

Results: We identified 36 trials that included 2007 patients, mainly on membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS) and refractory nephrotic syndrome without clearly pathological diagnosis (RNS). Overall, MMF therapy significantly reduced proteinuria (WMD=-462.31mg/d, CI: -219.69 to -704.92 P<0.001), increased the likelihood of complete remission (RR: 1.15, CI: 1.09 to 1.22, P<0.001) compared with the other immunosuppressors. The subgroup analyses shown that MMF was superior to other immunosuppressors, particularly than cyclophosphamide.

Conclusions: MMF seems superior to the other immunosuppressive regimens for the treatment of idiopathic nephrotic syndrome with mild adverse effects, particularly in MN, FSGS and RNS. High-quality large-sample trials are still required to reliably define the balance of efficacy and safety.

PUB240
A Retrospective Analysis of Acute Kidney Injury in Adult-Onset Minimal Change Disease Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.

Background: Minimal change disease (MCD) is a major cause of primary nephrotic syndrome in adults, accounting for 10 to 25 percent of cases. In terms of treatment, steroid therapy is very effective, however in some cases an acute onset of moderate to severe decline in kidney function is seen, occasionally requiring transient dialysis. To the best of our knowledge, the risk factor for acute kidney injury (AKI) and clinical course of cases with AKI had not been fully elucidated.

Methods: This study is a single-center, retrospective observational study. The clinical records of adult (older than 18 years old) who had biopsy-proven MCD and who were followed at Tokai University Hospital from 2000 to 2015 were retrospectively analyzed. The diagnosis of AKI was based on KDIGO criteria, namely, serum creatinine changes ≥ 1.5 times baseline within 7 days and a 0.3 mg/dl increase in serum creatinine within 48 hours.

Results: 57 patients were enrolled, and AKI occurred in 24 patients at presentation or subsequently, among whom five patients underwent hemodialysis. Patients with AKI showed lower level of serum albumin and higher rates of use of diuretics, renin-aldosterone system (RAS) inhibitors, and NSAIDs. Logistic-regression analysis showed that use of these drugs before presentation at our institution could predict the development of AKI (odds ratio, 2.8, 95% CI, 2.2 to 3.2). Furthermore, use of these drugs could determine the time to remission (Hazard ratio, 2.4, 95% CI, 1.8 to 3.0), as well as the initial serum creatinine. All cases were initially treated with steroid, and there was no difference in the time to remission between oral and parenteral administration of steroid.

Conclusions: There is a high incidence of AKI in adult-onset MCD. The use of several drugs such as diuretics could influence the onset of AKI and clinical course of MCD.

PUB241
Expression of HLA-G Molecule in Crescentic Glomerulonephritis and Its Clinical Significance Guixue Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chongdu, Sichuan, China.

Background: In recent years, human leukocyte antigen-G (HLA-G) was found to be an important immune-regulatory molecular. Our purpose of this study is to assay the concentrations of serum soluble HLA-G (sHLA-G) in patients with CGN and to analyze its clinical significance.

Methods: 48 patients with CGN from 2009 to 2014 were involved in this study. The clinical data were collected, include demographic characteristics, laboratory parameters, pathological examinations, prognostic information and immunosuppressive therapy. Analyze if oliguria or anuria, serum creatinine levels, the crescent formation ratio and therapy would affect the prognosis of patients.22 patients with CGN, 15 patients with MCD, and 30 healthy adults in control group were enrolled with serum levels of HLA-G measured by ELISA. The relationship between the clinical or pathological features and sHLA-G was studied and the value of the HLA-G in crescentic glomerulonephritis was analyzed.

Results: 3-years kidney survival rate was only 38% with one case of death. Cox regression analysis showed higher serum creatinine was associated with the patients with a poor prognosis (HR=4.04,95%CI:1.548-10.544, P=0.004). Serum level of HLA-G in CGN was significantly higher than in healthy control(2198.81 ± 1294.77pg/ml vs 1311.86 ± 448.84pg/ml, P=0.048), while higher than in MCD, (2198.81 ± 1294.77 pg/ml vs. 1181.33 ± 320.10 pg/ml, P=0.023). Kaplan Meier survival analysis showed elevated levels of HLA-G was associated with poorer patients.

Conclusions: High serum creatinine level(>5mg/dl) at admission is an independent risk factor for the development to be ESRD. sHLA-G was significantly elevated in the serum of patients with CGN, and the level of sHLA-G had relationship with the prognosis of the patients with CGN. sHLA-G may be used as a new biomarker in CGN with clinical value in the early diagnosis and prognosis.

PUB242
A Treatment of Nutcracker Syndrome Leads to a Resolution of Unexplained Proteinuria Badamkhand Baatarkhuu, Raymond Raut, Winston Y. Shih, Panupong Lisawat. Nephrology and Hypertension, WCHN Danbury Hospital, Danbury, CT.

Background: The nutcracker syndrome is rare and can be a cause of unexplained proteinuria. We report a case of nutcracker syndrome related proteinuria and resolution of the proteinuria is observed after the entrapment was surgically corrected.

Methods: This is a 22-year-old male with a history of unexplained proteinuria since he was 17 years old. He has moved to a new location and presented to our clinic with proteinuria. The patient’s initial work up at an outside hospital revealed 1.4g proteinuria per 24 hours. A left kidney biopsy showed mesangial hypercellularity and preserved foot processes. The patient at that time was treated with prednisone, cyclosporine and lisinopril. His proteinuria decreased to 196 mg per 24 hours. Due to intolerance, lisinopril was stopped and urine protein subsequently rose. At the time of evaluation, the patient’s 24 hour urine protein was 700 mg and the autoimmune and infectious work up was negative. Upon reviewing the medical record from 2 years ago, he had inferior venacavagram as a part of varicocele treatment. It showed compression of the left renal vein between the aorta and superior mesenteric artery. Nutcracker syndrome was suspected. Subsequently, he was referred to vascular surgery, and underwent an open reconstructive surgery. Postoperatively the patient remained off lisinopril and repeated 24 hour urine protein was down to 20mg.

Conclusions: Nutcracker syndrome can cause significant proteinuria. Although it is rare, an early recognition could lead to a definitive treatment, help avoid unnecessary medications and invasive procedure such as a kidney biopsy.
A 14 year old girl underwent a cadaveric renal transplant due to end-stage renal disease from obstructive uropathy and developed Parvovirus B19 viremia and graft dysfunction. Renal biopsy showed de novo immune complex glomerulonephritis with Parvovirus B19 DNA detected in renal tissue by PCR. We herein review of B19-associated glomerular diseases.

Methods: A search of the English-language medical literature was conducted. PubMed, Medline, and Google scholar were used. Adult and pediatric cases were included. Sources included case reports and series, including prior reviews. Articles were evaluated for design, sample size, the definition of primary MN, pathology, and clinical outcomes. We report the incidence of Parvovirus B19-DNA in renal tissue from patients with combined MN and FSGS, the percentage of patients with combined lesions showed higher stages of MN, no cellular variant on FSGS classification and more common (100%) tubulointerstitial injury than both primary MN and primary FSGS patients. The patients with combined lesions, 80% had circulating anti-PLA2R antibody and 68.4% had IgG4 predominant deposition in glomeruli, which were comparable to primary MN. No circulating antibody or IgG4 deposition was detected in primary FSGS patients. The patients with combined lesions had significantly lower urinary subPAR concentration, compared to the primary FSGS patients (315.6±302.0 vs. 691.3±1223.5pg/ up, P<0.01), but similar to primary MN patients (275.7±253.4pg/ml in MN).

Conclusions: We conclude that patients with combined MN and FSGS may share the same underlying pathogenesis with primary MN. The FSGS lesion might be secondary to primary MN.

Glanzmanns Thrombasthenia: A Coagulation Antithrombin Disorder Causing Glomerular Injury

Methods: A case of a 53 year old female whose known past medical history included only hypertension who presented to the outpatient clinic with arthralgias, pancytopenia, alopecia, proteinuria and skin rash to this point had included an elevated ESR of 115, negative ANA, neg HIV, Hep B, and Hep C serology. She was then lost to followup until presenting to the hospital with anisocoria and acute kidney injury. Her further workup confirmed a negative ANA but also revealed positive Anti-SSa, and anti-SSb. Her platelet count during this time was decreased to 43 and 46 respectively. She had a renal biopsy performed revealing focal proliferative and membranous lupus nephritis, Class III-V. The patient was started on mycophenolate, plaquenil, and prednisone.

Conclusions: Once a byproduct of a technically variable laboratory test, the entity of ANA-negative Lupus has been decreasing.

Methods: We report a case of a 35 year old female whose known past medical history included only hypertension who presented to the outpatient clinic with arthralgias, pancytopenia, alopecia, proteinuria and skin rash to this point had included an elevated ESR of 115, negative ANA, neg HIV, Hep B, and Hep C serology. She was then lost to followup until presenting to the hospital with anisocoria and acute kidney injury. Her further workup confirmed a negative ANA but also revealed positive Anti-SSa, and anti-SSb. Her platelet count during this time was decreased to 43 and 46 respectively. She had a renal biopsy performed revealing focal proliferative and membranous lupus nephritis, Class III-V. The patient was started on mycophenolate, plaquenil, and prednisone.

Conclusions: Once a byproduct of a technically variable laboratory test, the entity of ANA-negative Lupus has been decreasing in its frequency. The adoption of the human epithelial substrate has brought standardization to this assay and also increased its sensitivity. The incidence of ANA negative Lupus has been decreasing.

Acute Renal Failure in Thrombotic Microangiopathy and C3 Glomerulopathy? Tiziana Stellato, 1 Paolo Fabbrini, 1 Sonia Sirtori, 2 Andrea Stefl, 1, 2 Dept of Nephrology, San Gerardo Hospital, Monza, Italy; 1 Univ of Milano Bicocca, Milan, Italy.

Background: Thrombotic microangiopathy is a rare disease characterized by arteriolar and capillary thrombosis with endothelial damage. Clinical manifestations include renal involvement, such as focal segmental glomerulosclerosis and proteinuria and hypertension.

Methods: We report a case of a 75 years old man without past medical history that referred to us with oliguric acute renal failure diagnosis-diplopia. Laboratory work up revealed creatinine of 7.5 mg/dl, prolonged activated partial thromboplastin time (APTT) in order to 2.2 Ratio, normal serum creatinine (56 mg/dl) with normal proteinuria, VES augmented, positive low titer anti-cardiolipine and anti-beta2 glicoprotein1 antibodies, positive LAC screening. Urinalysis showed microhematuria and proteinuria 2.5 g/24 h, ANA, ANCA, antinuclear are negative. A renal biopsy was performed and showed mesangial proliferative glomerulonephritis associated to thrombotic microangiopathy with subendothelial and mesangial C3 deposits. Considering the clinical history, the laboristic tests and the biopsy result, suggestive of antiphospholipid syndrome (APS), we start treatment with plasma-exchange (total 4 sessions) with plasma sostitution and corticosteroids (500 mg IV methylprednisolone for 3 days, followed by 0.5 mg/Kg/die oral prednisone). So with plasma-exchange (total 4 sessions) with plasma sostitution and corticosteroids (500 mg IV methylprednisolone for 3 days, followed by 0.5 mg/Kg/die oral prednisone). So with plasma-exchange (total 4 sessions) with plasma sostitution and corticosteroids (500 mg IV methylprednisolone for 3 days, followed by 0.5 mg/Kg/die oral prednisone).

Conclusions: Our case represents an unusual finding of RBC casts in myoglobinuric ATN. We purpose then recovered with residual CKD.

Acute Renal Failure is a reversible kidney damage that can revert with a specific diagnosis and treatment. Kidney biopsy was always gold standard and a combination of clinical data and renal databases.

Idiopathic Cryoglobulinemic Crescentic Glomerulonephritis – A Rare and Atypical Case
Pedram Joseph Kohan, 1 Akshatha Rao, 2 Sandeep Aggarwal. 1 Internal Medicine, Drexel College of Medicine/Hahnemann Univ Hospital, Philadelphia, PA; 2 Nephrology, Drexel College of Medicine/Hahnemann Univ Hospital, Philadelphia, PA.

Background: Cryoglobulinemic glomerulonephritis is an exotic entity, manifesting in middle-aged females. We report an atypical case of cryoglobulinemic crescentic glomerulonephritis in an 18-year-old African American Male without an identifiable viral, autoimmune or lymphoproliferative etiology.

Methods: Our case is an 18 y/o AAM with no significant PMH who presented for an incidental herniating and proteinuria. Patient did not complain of edema, recent illness, joint pains, rash, night sweats or weight loss. No history of IVDA, BP was 114/72, without significant physical exam findings. Urine microscopy: cellular casts and dysmorphic RBCs. Serum creatinine was 1.27 mg/dL.

Results: The primary outcome was reached in 24 patients, 16 with IgA and 8 with IgA+IgG (p=0.82). The incidence of renal replacement therapy, death, OR doubling of serum creatinine (SCr). The change in estimated GFR (eGFR) was also assessed. Covariates were age, sex, race, SCr and proteinuria at biopsy, length of follow-up, treatment, Oxford score, and presence of crescents.

Conclusions: This cohort was 64% male, 69% Caucasian and 14% Asian. IgA+IgG deposits were seen in 25 of the patients. There was no difference between IgA and IgA+IgG with respect to any of the covariates or between initial and follow-up proteinuria. There was a tendency for more endocapillary hypercellularity to be seen in IgA+IgG biopsies (p=0.08). The primary outcome was reached in 24 patients, 16 with IgA and 8 with IgA+IgG (p=0.82). Using multivariate modeling the change in eGFR over time was not different between IgA and IgA+IgG.

Conclusions: In this cohort of IgAN patients the presence of IgG co-deposits in the mesangium did not affect clinical outcomes.

Background: IgAN is characterized by IgA dominant or IgA+, 1 Isao Kurihara, 1 Sayuri Suzuki, 1 Shintaro, 1 Akshatha Rao, 2 Sandeep Aggarwal. 2

Methods: We experienced a case of ChRCC with adrenal pheochromocytoma in a 69-year-old Japanese female. We noticed that iodine-123 MIBG scintigraphy showed uptake in ChRCC in addition to RCC. It is not cytotoxic, uptake is not observed in other cases of clear cell carcinoma. As a candidate transporter that mediate iodine-123 uptake in ChRCC, we determined the expression of pendrin, a Cl-/HCO3- exchanger expressed in the kidney cortex. The pendrin messenger RNA (mRNA) expressions, and protein expressions were analyzed in 4 cases of ChRCC and 3 cases of clear cell carcinoma.

Conclusions: The protein expression of pendrin, the candidate transporter, which related to iodine-123 uptake, was highly detected in ChRCC compared with clear cell carcinoma. Moreover, the mRNA expression was also exclusively increased in ChRCC.

Conclusions: The uniqueness of this case is underscored by a variety of factors: clinical presentation, laboratory, serologies, and pathology. Laboratory and serologic studies in cryoglobulinemia generally follow a characteristic pattern, detection of circulating cryoglobulins, low levels of complement, viral, autoimmune or lymphoproliferative etiology - yet a limited number of cases have presented with normal serological results, similar to the case presented here.

Development of a Clinicopathologic Kidney Biopsy Database Using Billing and Diagnosis Codes: A Descriptive Study
Nosayaba Enok, 1 Anju A. Oommen, 1 Jason Cobb, 1 Jose E. Navarrete, 1 Demilade Adesinewo, 1 Oluwatobiloba A. Osikoye, 2 Helen B. Fevrier, 3 Frederic F. Rahhari-Oskou, 4 Alton Brad Farris, 1 Laura Plantinga, 1 Titilayo O. Background: A growing kidney disease population coupled with expanded use of electronic medical records (EMR) presents a unique opportunity for regional translational clinical research. We developed a comprehensive registry of all native renal biopsies at a major hospital in Southeastern US and described the pattern of glomerular diseases.

Methods: We identified all native percutaneous renal biopsies (n=2,245) performed at OhioHealth (18) between 2000 and 2011 using CPT and ICD-9 billing codes (50200 and 55 23). Transplant biopsies (V42.0) and cytopathology were excluded. Renal pathology reports were reviewed by at least two independent clinical nephrologists. Clinical, laboratory and demographic data were extracted and validated by independent chart review. A clinicopathologic diagnosis was subsequently entered. Descriptive and bivariate statistics were used to analyze patient characteristics at biopsy.

Results: Patients in the registry had a mean age of 44.2 years; approximately half were male and majority were African American (40%). Overall, lupus nephritis (n=278, 12.4%) was the most prevalent renal clinicopathologic diagnosis. Among primary glomerular diseases, FSGS (136, 9.2%) was the most prevalent, followed by IgA nephropathy (123, 8.3%), membranous glomerulonephritis (GN) (69, 4.6%), membranoproliferative GN (24, 1.6%) and minimal change disease (27, 1.8%). Diabetic nephropathy was the second most common secondary GN (97, 6.5%) followed by ANCA-associated vasculitis (31, 2.1%). Other diagnoses were all less than 2%.

Conclusions: We successfully established a kidney biopsy registry at our center, which will be instrumental to studying outcomes in this rare group of diseases, the most prevalent of which were lupus nephritis and FSGS.
Is There Clinical Significance of IgM and Complement Staining in Idiopathic Focal Segmental Glomerulosclerosis?  

Lilian M. Pereira, 1 Alicia Imada, 1 Alexander J.M. Darding, 1 Rudolphe De Sevaux, 1 Ron T. Connor, 1 2 3 4

1Nephrology, Barts & The London NHS Trust, London, United Kingdom; 2Pathology, Barts & The London NHS Trust, London, United Kingdom.

**Background:** Experimental evidence suggests that focal segmental glomerulosclerosis with complement deposits is associated with poor outcome. Whether this is transferrable or relevant in human disease is unclear.

**Methods:** We performed a proof-of-concept observational study on all patients with a diagnosis of idiopathic focal segmental glomerulosclerosis (fSGS) native renal biopsies from January 2004 to December 2014. A total of 40 renal biopsies were identified. Clinical outcome data were obtained to seek an association with complement deposits (CD) and outcomes. Immunosuppression administered was according to the local trust policy which included prednisolone and cyclophosphamide or calcineurin inhibitor.

**Results:** See Table 1

CD was present in approximately 50% of the biopsies, but there was no significant association between CD and baseline clinical or demographic characteristics, furthermore, there are no association between CD and markers of disease progression (change in proteinuria, serum albumin or GFR between baseline and 1 year follow up). IgM staining was strongly co-associated with CD.

**Conclusions:** Our results indicate that, unlike animal models of fSGS, IgM and complement deposition does not alter outcomes. However, these findings will need to be confirmed in a larger study.

**PUB258**

A Case of Intra-Ocular Lucentis (Ranibizumab) Induced Minimal Change Disease  
Ashwin Reddy Ganta, Dept. of Nephrology, Archbold Memorial Hospital, Thomasville, GA.

**Background:** Intravitreal monoclonal antibodies like Lucentis (Ranizibumab) , Eylea and Avastin are being increasingly used for the treatment of Wet Age-related Macular Degeneration (wAMD) and Diabetic Macular Edema (DME) of the eye. Though the systemic toxicity of these VEGF inhibitors is well known, not much is known about the renal toxicity profile of these agents when administered intravitreally.

**Methods:** A 78 y/o WM presented with worsening shortness of breath and anasarca. His Scr was 1.5 (0.9-2.0) mg/dl and platelet count was 12 (57) x 10^9/L. Given his h/o cancer with almost 3 gms of proteinuria, MCD (Minimal Change Disease) was high in the differential. Serology for HIV, SPEP, Hep C, SIEP, ANA and ANCA was negative. Given his h/o cancer with almost 3 gms of proteinuria, MCD (Minimal Change Disease) was high in the differential. Serology for HIV, SPEP, Hep C, SIEP, ANA and ANCA was negative. His PMH was significant for Afib, h/o Lung Cancer s/p RLL resection 8 years ago and he was receiving Lucentis intravitreal shots for his AMD and had just had his 5th monthly dose a few days ago. His urine showed 3+ protein with some RBCs and we were consulted for worsening renal function with a Scr of 2.4 mg/dl, up from a baseline of 1.0 mg/dl. Given his h/o cancer with almost 3 gms of proteinuria, MCD (Minimal Change Disease) was high in the differential. Serology for HIV, SPEP, Hep C, SIEP, ANA and ANCA was negative. His Scr continued to worsen and reached a peak of 4.6 and he had to undergo Diabetic kidney disease. Renal Biopsy performed showed 9 g/gm with no evidence of IC, double medullary bluing or MCD pattern confirmed on EM. He was started on high dose steroids and discharged with a diagnosis of MCD 2/2 Lucentis. He was taken off HD after he started showing signs of renal recovery in a few weeks and he was gradually tapered of Steroids over the next 4 months. His proteinuria has completely subsided and his Scr is back to his baseline.

**Conclusions:** Systemic use VEGF inhibitors and their renal toxicity is well documented. Now, they are currently being used to treat wAMD and DME. However, there is some evidence that intravitreal use may result in systemic absorption, with the potential for AKI. We report the first case to our knowledge of a patient who developed severe AKI needing HD with MCD pattern of injury after 5 intravitreal injections of ranibizumab that was successfully treated with cessation of Lucentis and Steroids. Because of the increasing use of these agents, ophthalmologists and nephrologists should be aware of the associated risks.
Methods: Multiplex ligation-dependent probe amplification (MLPA) kits have been developed for genetic analysis using proprietary MLPA technology. We obtained informed consent from nine patients (mean age, 45 years) and collected 8 mL of blood from each patient for analysis of genetic mutations in PKD1 and PKD2 genes using the MLPA method.

Results: In case 1 (a 39-year-old man), we found deletions in exons 3 and 39 of the PKD1 gene. The kidney was extracted due to enlargement and cyst infection. Dialysis was initiated when the patient was 39 years of age. The kidney capacity was 5013 mL. In case 2 (a 32-year-old woman), we found a deletion in exon 3 of the PKD1 gene. Renal function was maintained, and the serum creatinine level was 0.7 mg/dL. She has hope of the delivery. Tolvaptan does not have the safety about the dosage to a pregnant woman. Tolvaptan was administered after delivery.

Case 1

Case 2

No mutations were identified in the other subjects.

Conclusions: Genetic screening of the PKD1 and PKD2 genes using the MLPA method may decrease cost and labor. Indeed, the MLPA method was especially useful in cases exhibiting juvenile onset and rapid kidney enlargement.

The administration of tolvaptan significantly reduced body weight, eGFR, TBW, ICW and ECW in whole body and TBW in limbs. However, TBW in trunk were sustained (Table).

</table>

HtTKV at baseline correlated with rate of ICW in trunk and TBW in whole at baseline (r=0.39, P=0.049). There were no significant correlation between eGFR decrease and rate of change in body weight (r=0.02, P=0.46). Rate of TBW in limbs and TBW in whole at baseline correlated with rate of change in eGFR (r=0.45, P=0.028). These results suggest that cyst fluid might be measured as ICW by InBody720®. TBW in limbs can predict eGFR decline.

Conclusions: Measuring body water balance by InBody720® could be useful as predictors of HtTKV and eGFR decline in short term after administration of tolvaptan in ADPKD patients.

On admission biochemical tests;urea 132 mg/dl,creatinine 4.7 mg/dl,potassium 4.7 mmol/L, pH 7.32,HCO3 18.4.Urinary output was satisfactory,no uremic symptoms were present.Renal ultrasonography revealed bilateral renal cysts with normal size and parenchymal thickness.Histopathology of the Shagreen patch revealed dense collagen bundles in the dermis.Due to the skin lesions and renal cysts the patient was diagnosed as TS.Other manifestations of TS were not present.Renal biopsy was suggested but she did not accept the procedure.

Conclusions: As stated in diagnostic criterias,physical examination has a strong impact on diagnosis of TS.Hypomelanotic macules (~3),Shagreen patch,forehead plaque,non traumatic periumbilical fibromas,adenoma sebaceum,facial angiofibromas should remind the physicians TS.Kidneys are involved in almost 50-80% of the adult patients.Most frequent renal lesions in TS are angiomyolipomas.Bilateral and multiple characteristics of angiomyolipomas are pathognomonic.They may progress to end stage renal disease.However in some rare cases frank renal lesions may be absent.With a detailed inspection it is possible to recognize these specific dermatological signs,marking the Tuberous sclerosis diagnosis and taking these patients under nephrological follow up.

Use of Antidepressant Medications During the HALT-PKD Randomized Trials Vicente E. Torres,1 Kaleab Z. Abebe,2 Theodore I. Steinman,1 Charity G. Moore,3 Ronald D. Perrone,4 Arlene B. Chapman,5 Robert W. Schrier,6 Alan S.L. Yu,7 William E. Braun,8 Kyongtae Ty Bae,9 Peter C. Harris,10 Charity G. Moore,11 Michael F. Flesner,12 The HALT PKD Investigators,13-15 Mayo;16 U. Pittsburgh;17 BIDMC;18 Tufts U.;19 U. Chicago;20 U. Colorado;21 KS U. Med. Ctr.;22 Cleveland Clinic;23 NIH;24 Multi-Ctr.

Background: Depressive disorders are highly prevalent in a general population and are associated with poor outcomes. The use of antidepressants (ADs) has been associated with inappropriate release of vasopressin and hyponatremia. Since vasopressin exposure for less £30% and exposure for >30% of the time:

Conclusions: Measuring body water balance by InBody720® could be useful as predictors of HtTKV and eGFR decline in short term after administration of tolvaptan in ADPKD patients.

Conclusion: Tolvaptan does not have the safety about the dosage to a pregnant woman. Tolvaptan was administered after delivery.
five topics/outcomes (surgical management of cysts, patient education about end-stage kidney disease, psychosocial impact of diagnosis, need for dialysis, knowledge). Many more topics (33) and outcomes (44) were identified as priorities by health professionals than consumers. Six themes reflected reasons for consumer choices: clarifying ambiguities, resolving debilitating pain, concern for family, preparedness for the future, taking control, and significance of impact.

Conclusions: Although there was considerable concordance between the priority topics and outcomes of health professionals and consumers for guidelines of ADPKD, there was also important discordance with consumers focused on fewer but particularly on lifestyle, psychosocial support, pain management, and quality of life and renal outcomes.

PUB268

Urinary AQP2 Is One of the Candidates for a Surrogate Marker in the Treatment of ADPKD Patients by Tolvaptan

Kenichi Akitaiguchi, Toshihiko Mochizuki, Miki Nishida, Masayo Sato, Hiroshi Katoita, Hidekazu Sugira, Ken Tsuchiyi, Kosaku Nitta. Medicine IV, Tokyo Women’s Medical Univ, Shinjyuku, Tokyo, Japan.

Background: Tolvaptan, arginine vasopressin (AVP)/V2 receptor antagonist is accepted for autosomal dominant polycystic kidney disease (ADPKD) patients in Japan since 2014. TEMPO study showed tolvaptan from 60 to 120 mg per day slowed renal cyst expansion and renal function decline. Tolvaptan dose is decided by preliminary study (TEMP01), which showed the maximum dose that meet both urinary osmolality (Uosm) under 300 mOsm/kg and patient’s tolerance. So that adequate dose for individual patient has not been suggested. Moreover, tolvaptan cause polyuria, thirsty, polydipsia due to aquaresis. Thus, it is necessary to find surrogate markers for determine the maximum effects and minimum side effects for long-term administration.

Methods: Seventeen ADPKD patients initiated tolvaptan of 60 mg were investigated. Physical data, plasma osmolality (Posm), Uosm, AVP, urine cyclic AMP (UCAMP), and urine AQP2 (UAQP2) were assessed. UCAMP was measured by radioimmunossay (Yamasa corp.), and UAQP2 was measured by a sandwich enzyme-linked immunosorbent assay method (Otsuka Pharmaceutical Co. Ltd.).

Results: After initiation of tolvaptan, average urinary volume was 862±1 m/L/day and daily weight loss was -1.42 kg/day on day 1. One month after, AVP increased from 3±3 to 7.3±11.2 pg/mL (p < 0.001). Uosm decreased from 367±349 to 243±436 mOsm/kg (p < 0.001). Posm and UCAMP were not statistically associated. UAQP2 decreased from 0.029±0.068 to 0.012±0.028 pmol/MgCr (p < 0.001). In our preliminary data (n=5), the serum copeptin, a precursor of vasopressin, was shown to be no consistent level.

Conclusions: It has been reported that 3% of total production of AQP2 excreted into the urine, it reflected directly the intracellural action of AVP. Thus, UAQP2 is likely to be one of surrogate markers of tolvaptan effect, moreover it could provide additional information of determination of individual dosage and monitoring for long-term usage.

PUB269

Abnormalities in the Radius of Patients with Autosomal Dominant Polycystic Kidney Disease Measured by High-Resolution Peripheral Quantitative Computerized-Tomography Imaging

Danielle Diarra, Janina M. Patsch, Claudia Schuemel-Weidemann, Michael Weber, Arastoo Nia, Gere Sunder-Plassmann. 1Dept of Medicine III, Medical Univ of Vienna, Austria; 2Dept of Radiology, Medical Univ of Vienna, Austria; 3Dept of Medicine II, St. Vincent Hospital, Medical Univ of Vienna, Austria.

Background: ADPKD is a multi-organ disorder and the most common of all cystic kidney diseases. Mutation of the PKD1 or -2 gene causes epir- and endothelial cell proliferation, which lead to the dysfunction of various organs. Animal studies show that primary cilia are present in osteoblasts of mice and point mutation of the osteoblastic KIF7 gene induces osteopenia.

Methods: In this pilot-study, we examined the bone structure in 6 ADPKD patients in comparison to 6 matched patients with glomerular disease (GD), both in CKD stages I-II, by HR-pQCT of the radius and the tibia. The aim of the study was to identify microarchitectural target parameters for a subsequent larger study in patients with ADPKD.

Results: Demographic data see Table 1.

We found reduced cortical and trabecular microstructural parameters by HR-pQCT, mainly affecting the radius. The outer trabecular density, the cortical thickness and the total density of the radius showed the biggest differences between the two groups, see Figure 1.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

949A
The total density of the radius was the best parameter to distinguish between the bone structure of ADPKD in comparison to GD patients (AUC = 0.861).

Conclusions: We provide evidence of microstructural bone deterioration in the radius in patients with ADPKD. We thus hypothesize that ADPKD is associated with microstructure bone changes in men.

PUB270

An Accurate Formula for a Quick Estimate of Total Liver Volume in Polycystic Liver Disease Patients

Background: Polycystic liver disease (PLD) appears in two disorders; autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (ADPLD). The primary aim of treatment of PLD is reduction of total liver volume (TLV) as patients often suffer from hepatomegaly. The gold standard to assess TLV is CT volumetry which involves manual delineating of the liver outline. Unfortunately this is a time-consuming method (45–60 minutes per CT scan) and requires a certain level of expertise. An easily accessible and fast method to estimate TLV in routine clinical practice is needed. Therefore we aimed to develop an accurate formula for quick estimation of TLV.

Methods: We collected a cohort of PLD patients in whom CT scans were available. Manual delineation of TLV served as gold standard. PLD patients were distributed in 2 cohorts, a development cohort (N=80) and a replication cohort (N=50). We measured anterio-posterior (AP), transverse (T) and cranial (CC) distance (in meters) of the liver on CT. TLVs were logarithmically transformed as data were not normally distributed. R² was measured as it indicates the goodness of fit of the prediction model. The prediction model was tested in a replication cohort.

Results: Median liver volumes in the development and replication cohort were 4749 mL and 4810 mL respectively. All three diameters significantly correlated with TLV (p<0.0001). Linear regression analysis resulted in the following formula: Logarithm of TLV = 5.240 + T*0.680 + CC*2.522 + AP*0.041. Our model predicted TLV accurately in the development cohort (R²=0.898). The correlation in the development cohort was R²=0.848 and validation in the replication cohort resulted in a correlation of 0.937.

Conclusions: Our model accurately and quickly (<2 minutes) predicts TLV in PLD patients based on three liver dimensions.

**Lipid Alterations in Murine Models of Polycystic Kidney Disease**  
**Christine Podrin,1 2 Isaline Rowe,2 Marco Chiaravalli,2 Alessandra Boletta,2\*  
\*Univ Vita-Salute San Raffaele, Milan, Italy; 2Dibit San Raffaele Scientific Inst, Milan, Italy.

### Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disorder characterized by massive bilateral renal cyst formation. ADPKD results from mutation in the PKD1 or PKD2 genes, encoding Polycystin-1 (PC-1) and 2 (PC-2) proteins respectively. Previous studies have suggested that the mTORC1 cascade might play an important role in PKD. Further, mTORC1 regulates the activity of SREBP which regulate the expression of genes required for the synthesis of fatty acids and cholesterol. However, the regulation of fat synthesis in ADPKD remains poorly understood. In this study, we seek to understand the relationship between fatty acid regulation and defective PKD1 function.

### Methods: We analyzed newborn kidneys of Ksp-Cre/Pkd1flox/+ mice and detected an increased expression of SREBP1 and its target genes including fatty acid synthase (FAS) and steroyl-CoA desaturase (SCD) when compared to control, non-cystic kidneys (Ksp-Cre/Pkd1flox/+ or Pkd1flox/flox).

### Results: As expected the increased expression of SREBP1 also correlated with increased transcript levels of SREBP2 concomitant with an increased transcript levels for sterol biosynthesis mevalonate kinase (MVK) and acetyl-CoA synthase (ACSL). Next, we performed a lipidomic profiling of Ksp-Cre/Pkd1flox/+ kidneys compared to controls Ksp-Cre/Pkd1flox/flox collected at P4 using shotgun lipidomics technology. The profiles confirmed the alteration of some lipid classes, particularly sphingolipids and sterol esters (cholesterol).

Of interest both have been implicated in regulating membranes trafficking and they may cross-talk to mTORC1 in response to altered nutrient/fatty acid signals. Notably, some of the lipid alterations that we observed appear to be gender-specific.

### Conclusions: We are currently characterizing this aspect further and trying to determine which lipid alterations might be dependent and/or independent of mTORC1 upregulation.

**Reactive Hyperaemic Index in Early Disease Stages of Autosomal Dominant Polycystic Kidney Disease**  
**Adebowale Olavinka Adekoya,1 Andrew J. Streets,1 Albert C. Ong.1**  
1Academic Nephrology Unit, The Medical School, Univ of Sheffield, Sheffield, South Yorkshire, United Kingdom; 2MRC Centre for Developmental and Biomedical Genetics, Univ of Sheffield, Sheffield, South Yorkshire, United Kingdom.

### Background: ADPKD is the commonest inheritable cause of ESKD. Cardiovascular complications are the commonest cause of death in ADPKD. Endothelial dysfunction (ED) has been reported to precede CVE events. In our pilot study of sixty ADPKD patients in the late stages of disease (CKD 3 and above), ADMA and 8 isoprostane were found to be increased suggesting ED. The aim of this study is to investigate ED in the ADPKD patients in early stages of the disease (CKD 1 and 2) and to identify factors associated with its severity.

### Methods: This is a single centre cross sectional study of ADPKD patients in the early stages of disease. Individuals with HBP, DM, CKD 3 and above, ADMA and 8 isoprostane were found to be increased suggesting ED. The aim of this study is to investigate ED in the ADPKD patients in early stages of the disease (CKD 1 and 2) and to identify factors associated with its severity.

### Results: The mean age of the patients was 40.80 ± 14.18 years. M:F was 1:2.3. Prevalence of lifestyle counseling was moderate as ascertained by chart review of our electronic medical record. Discussion of exercise recommendations was low. Nephrologists could consider focusing more attention on offering lifestyle counseling to individuals with ADPKD.

### Conclusions: The Cysts volume is useful to predict prospectively the EPO requirement in ADPKD in stage 4-5 CKD.

**A Novel Method to Determine Glomerular Volume Distribution from Few Serial Sections on a Single Slide**  
**Mohan C. Abraham,1 Rishi Singh,2 Krishnamurthy P. Gudeokta,1 Jose A. L. Arruda,1 Ashok K. Singh,2,3**  
1Div of Nephrology, John H Stroger Hospital, Chicago, IL; 2Hektoen Research Inst, Chicago, IL; 3Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL.

### Background: Estimating glomerular volumes is important in understanding pathogenesis of glomerular diseases. Some methods are convenient but give a single mean volume for the entire kidney and do not provide volume profiles. Methods for volume profiling are too laborious for routine use. We describe here a new method to obtain glomerular volume profiles from few serial sections. The method uses the formula, R^2 = r_1^2 + (r_1^2 - r_2^2)/2h^2, where R is the radius of a sphere and r_1, r_2 are the radii of two parallel circular planes cut across the sphere h distance apart.

### Methods: To validate our method we compared glomerular volumes between normal (n=5) and STZ diabetic rats (n=4) by measuring 100 random glomeruli from each group. Three (or four) serial sections each 5µm apart were obtained on the same slide. Sections were stained with H&E and glomerular diameter was measured at four points to arrive at a mean diameter and radius r. The same glomerulus was identified on the third (h=10 µM) (or fourth; h=15 µM) section to similarly determine r_1, R was calculated by the formula to obtain the glomerular volume (4/3 π R^3).

### Results: The mean glomerular volume (10^5 µM^3) of normal rats was 1.04 ± 0.06, a value very close to that determined by MRI recently (Heilmann et al 2012). The mean glomerular volume of diabetic rats was 1.48 ± 0.06, which was 45% higher (P<0.03) than normal, confirming glomerular hypertrophy. While the volume distribution in normal rats was Gaussian, the distribution of glomerular volumes in diabetic rats was skewed towards higher volumes (42% glomeruli >1.4 X 10^5 M^3 compared to 12% in normals), suggesting that not all glomeruli but only a population of glomeruli hypertrophied in diabetic rats.

### Conclusions: Precise glomerular volumes can be conveniently determined by our method using a few serial sections of the kidney, making it possible to obtain glomerular volume distribution from experimental as well as human kidney biopsies.

Amniotic Fluid Stem Cells Transplantation in Fetal Kidney to Regenerate Nephrons Loss
Kathleen Labarbe,1 Sebastien Sammut,2 Mehrak Hekmati,2 Agnieszka Anna Ksiazek,2 Benedikt Weber,1 Luc Behr.1 1Necker Hôpital-Paris5 Univ, Paris, France; 2IMMR, Paris, France; 3Swiss Center for Regenerative Medicine, Univ Hospital, Zurich, Switzerland.

Background: Amniotic fluid stem cells (AFSC) harbour the potential to differentiate toward renal lineages and contribute to the development of primordial kidney structures. To investigate whether AFSC can improve prenatal renal compensatory growth, cells were transplanted in a model of subtotal nephrectomy (5/6NX) in the fetal sheep.

Methods: Using AFSC labelled with GFP were selected using c-kit. In absence of LIF, AFSC formed embryonic bodies which cultured in an optimized medium generated a renal epithelial progenitor population (oAFSCd), expressing Pax-2. 5/6NX was performed at 70 days of gestation in 10 fetal lambs; 5 were injected with oAFSCd in the kidney poles. Sham-operated did not receive oAFSCd (SHAM, n=8). At 134 days of gestation, fetuses were euthanized, kidneys removed and processed.

Results: Body weight did not differ significantly among the groups and no morphologic abnormalities were observed, in spite of a severe reduction in amniotic fluid in 5/6NX vs 5/6NX+oAFSCd. Compensatory renal growth of the remaining kidney was observed in all 5/6NX, but in spite of oAFScd injection, catch-up kidney growth was similar in both 5/6NX groups: SHAM: 2711±644.7 g vs 5/6NX+oAFSCd: 5341±1499.7 g. Glomeruli number/section was similar in all groups: SHAM: 27±64.2 vs 5/6NX+oAFSCd: 25.5±1.4 KW/BW. Glomeruli number/section was similar in all groups: SHAM:27±1;237;5/6NX:2155±694;5/6NX+oAFSCd:1962±199. In 5/6NX+oAFSCd, GFP cells were present in renal proximal tubules, and proximal tubule hypertrophy was observed.

Conclusions: Transplantation of oAFSCd predifferentiated toward renal epithelial progenitor cells during nephrogenesis increases proximal tubule mass but has no effect on the number of glomeruli in 5/6NX and do not restore fully kidney damage. Funding: Private Foundation Support

Low Birth Weight Impairs Renal Development and Function

Background: Low birth weight (LBW) results in a significant risk to the newborn, with many of these babies developing acute kidney failure and dying soon after birth due to underdeveloped vascular and renal systems. Surviving LBW neonates are also susceptible to a variety of health problems later in life during adulthood including hypertension, diabetes and chronic kidney disease with an associated 70% increased risk of end-stage kidney failure.

Methods: Using a maternal malnourished mouse model, we examined the causes of vascular and renal underdevelopment and impaired function in the LBW neonate. Parameters measured in the LBW offspring included nephron development, stem cell levels, apoptosis, gene expression, circulating cyto-/chemokines, renal blood flow and renal function.

Results: Within 24 hours after birth, LBW male offspring had 40% reduced weight, while only 49% of LBW neonates survived the first week after birth. Within the first week after birth, LBW neonates had an up to 40% reduction in renal blood flow and elevation of serum creatinine up to 3.0 mg/dl. Nephrogenesis was impaired in the LBW neonates with a 75% reduction in renal vesicle formation and a significant downregulation of Wnt9B (which induces differentiation of progenitor cells into tubular epithelium) at day E17.5, which ultimately resulted in a 30% reduction in glomeruli at the conclusion of nephrogenesis. During nephrogenesis, six2-positive nephron progenitor cells were reduced by up to 70% in the LBW embryonic kidney, which was accompanied by 6-fold increase in apoptosis. At birth, the LBW neonate had significantly elevated circulating levels of proinflammatory IL-1beta. Using explanted embryonic kidneys, we observed IL-1beta dramatically reduces six2+ cell populations and their ability to aggregate and form renal vesicles during kidney development.

Conclusions: LBW impacts vascular and renal function due to underdeveloped renal and vascular systems that result from enhanced IL-1-beta, increased apoptosis, altered Wnt9B expression, and reduced six2 nephron progenitor cells in the embryonic and neonate kidney. Increasing Podocyte Number in Neonatal Kidney Reduced Renal Injury in Adulthood
Jianyong Zhong,1 Ji Ma,2 Taiji Matsusaka,1 Agnes B. Fogo,2 Valentina Kon,2 Haichun Yang.1 1Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; 2Pediatric Nephrology, Vanderbilt Univ, Nashville, TN.

Background: Preterm birth increases the risk of hypertension and renal disease, which has been linked to decreased podocyte number. We previously found that paronycin injection in mice at birth impairs glomerular maturation, and has renal pathology phenotype which is similar to that observed in human preterm births. In the present study, we tested the hypothesis that increasing podocyte number during glomerular maturation can rescue glomerular loss and thus reduce renal injury in adulthood.

Methods: We targeted podocin-rTA with TRE-SV40RT with mouse to generate double-transgenic mice (RS), in which podocyte proliferation can be activated by doxycycline (Dox). rTA mice (R) served as controls. After a single paronycin injection, doxycycline was given at P1 until P8. At 12 weeks of age, mice underwent uninephrectomy (UNx) and were started on a high salt diet. At 14 weeks of age, angiotensin II (Ang II) was given by minipump for the next 8 weeks. All mice were sacrificed at week 22.

Results: At week 3, there were more WT1 positive glomerular cells in RS than R mice (RS 10.3±0.41 vs. R 8.1±0.58 X10^4mm^2, p<0.05), while glomeruli in superficial cortex were less mature (RS 2.1±0.05 vs. R 3.2±0.06, maturase scale 1-3; p<0.05). At week 6, glomerular number increased in RS (RS 9097±2442 vs. R: 6932±12447/ kidney, p<0.05). Glomerular volume and albuminuria did not differ between groups at week 3 and 6. At week 22, after UNx, high salt and Ang II, blood pressure, albuminuria and glomerular number were similar in RS and R. However, RS mice had lower KW/BW ratio (RS 0.97±0.143 vs. R 1.62±0.041, p<0.05) and less mesangial expansion (0-4 scale) (RS 0.72±0.10 vs. R 1.14±0.14, p<0.05).

Conclusions: We conclude that increasing podocyte number in developing kidney rescue paronycin-induced reductions of glomerular growth, which in turn reduces renal injury following a second hit in adulthood.
Results: Restricted deletion of Ebf1 from podocytes did not result in any observable developmental changes as assessed at the functional and histological levels. The glomerular number, and glomerular development were unchanged regardless of genotypic. The mice were followed for up to 6 months. During this time renal function did not decline in the mice with podocyte-specific deletion of Ebf1, and in fact baseline proteinuria was reduced in Podocin-cre−/−, Ebf1−/− animals compared to littermate controls. To examine if Ebf1-deficient podocytes harbored differential response to injury 3 months old mice animals were subjected to BSA-overload and exhibited reduced proteinuria.

Conclusions: Taken together these results suggest that Ebf1 regulates nephronepithelial development through other cell types than the podocyte. While Ebf1 does not control glomerular development through its actions in the podocyte, it appears to participate in proper damage response by podocytes as its removal appears to be protective.

Possible Renoprotective Effects of Acetazolamide Administration in Obese Diabetic Mice with Nephropathy

Yushi Nakayama, Koji Eguchi, Terumasa Nakagawa, Tomonari Onoue, Yuichiro Izumi, Hideki Inoue, Yutaka Kakizoe, Takashige Kawabara, Masashi Mukoyama. Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.

Background: Administration of carbonic anhydrase inhibitors (CAI) is thought to decrease glomerular filtration rate (GFR) by activation of the tubuloglomerular feedback (TGF) system. Acetazolamide (ACZ), a major CAI, has been shown to decrease urinary albumin excretion in the patients of type 1 diabetes with nephropathy. Previously, we showed that ACZ treatment in mice could ameliorate the onset of diabetic nephropathy due to the reduction of intraglomerular pressure by activating the TGF system.

Methods: In the current study, we treated obese diabetic mice (KK-Ay/Tacl) with ACZ for 14 weeks, and evaluated the long-term effects on urinary albumin excretion and glomerular hyperfiltration.

Results: The blood glucose levels were significantly higher in KK-Ay/Tacl mice compared to the control mice (BALB/cAe1) at 14 weeks. The blood glucose levels were significantly reduced in KK-Ay/Tacl mice treated with ACZ (547±37 vs 250±75 mg/dL). Interestingly, urinary glucose excretion levels in the ACZ group were not significantly different compared to the non-treated group. Creatinine clearance was higher in KK-Ay and ACZ group, while not changed by ACZ (0.73±0.07 vs 0.69±0.15ml/min) (Figure A). Urinary albumin excretion was reduced with ACZ treatment by 29% (Figure B). The plasma renin activity was not reduced by ACZ in this model.

Conclusions: These results suggest that the long-term oral treatment with ACZ may exert renoprotective effects in obese diabetic model with nephropathy, not due to activation of the TGF system but to better glycemic control.

Inhibition of miR-34a Reduces Podocyte Apoptosis by Targeting Bel-2 and Autophagy

Yang Liu, Ruixi Li, Wai Han Yiu, Hui-Jia Wu, Dickson W.L. Wong, Joseph C.K. Leung, Loretta Y.Y. Chan, Kar Neng Lai, Moin Saleem, Peter W. Mathiesen, Sydney C.W. Tang. Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong, China; Dept of Medicine, Academic and Children’s Renal Unit, Univ of Bristol, Bristol, United Kingdom.

Background: Podocyte apoptosis is a key event in the pathogenesis of diabetic nephropathy. MiR-34a has been reported to be involved in cell proliferation and apoptosis, but its potential roles in podocytes under the diabetic condition remains unknown.

Methods: Type 2 diabetic nephropathy was established by uninephrectomy (Unx) in nine-week-old db/db mice. In cultured human podocytes, expression of miR-34a was reduced by transfection with anti-miR-34a and increased by transfection with anti-34a. Western blot was used to observe the expressions of TGFβ, Smad1 and Smad3. Autophagy was detected by immunofluorescence assay using the autophagy marker LC3-II.

Results: In the current study, we treated obese diabetic mice (KK-Ay/Tacl) with ACZ for 14 weeks, and evaluated the long-term effects on urinary albumin excretion and glomerular hyperfiltration.

Conclusions: These results suggest that the long-term oral treatment with ACZ may exert renoprotective effects in obese diabetic model with nephropathy, not due to activation of the TGF system but to better glycemic control.
Increased Iron Deposition Is Associated with Decreased α-Klotho and Vitamin D Receptor Expression in the Renal Proximal Tubules in Ob/Ob Mice

Arianne van Koppen,1 Roel Baobao Wang,2 Yasunori Iwata,1 To explore this possibility, we performed genome-wide transcriptional profiling in human umbilical vein endothelial cells (HUVEC), which were stimulated by high glucose (HG) with/without EPO treatment and detected the expression of inflammation associated genes.

Methods: To explore this possibility, we performed genome-wide transcriptome profiling in human umbilical vein endothelial cells (HUVEC), which were stimulated by high glucose (HG) with/without EPO treatment and detected the expression of inflammation associated genes.

Results: Hierarchical clustering and principal component analysis showed the different pattern of mRNA expression in HG stimulated HUVEC with/without EPO. While inflammatory cytokines/chemokines mRNA expression were increased, the HG stimulation in HUVEC, Th2 related cytokine receptors and intracellular signaling molecules showed the reduced mRNA expression levels. EPO treatment reduced inflammatory cytokines/chemokines mRNA expression and increased Th2 related cytokine mRNA expression levels. Real-time PCR analysis confirmed the increased expression of inflammatory related genes, those were decreased in HG stimulated HUVEC with EPO treatment. Moreover, EPO stimulation increased mRNA expression of EPO receptor and b-common receptor. EPO signaling affect neither cell proliferation nor cell death.

Conclusions: Taken together, EPO signaling might protect high glucose induced cell injury by the regulation of immune balance.

Ob control mice

Iron enhanced with DAB

Ob/mice

Klotho

VDR

Cyp27b1

Conclusions: In ob/ob BTBR mice, increased iron deposition in the renal PCT is associated with a decreased in klotho expression, vitamin D hormone synthesis and VDR signaling in the PCT. These changes together contribute to the progression of diabetic renal injury in these mutant mice, and future treatments.

Erythropoietin Protects Endothelial Cells from High Glucose Induced Injury

Haruka Yasuda,1 Yasunori Iwata,2 Takashi Wada,1 1Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; 2Div of Infection Control, Kanazawa Univ, Kanazawa, Japan; 3Div of Nephrology, Kanazawa Univ, Kanazawa, Japan; 4Div of Blood Purification, Kanazawa Univ, Kanazawa, Japan.

Background: Diabetic nephropathy (DN) is a major complication in metabolic syndrome/diabetes patients. We have developed a metabolic syndrome mouse model characterized by non-alcoholic steatohepatitis and atherosclerosis upon high fat diet feeding. These animals show mild renal changes, but don’t progress to moderate DN. Therefore, we investigate whether inducing hypertension on top of metabolic syndrome leads to progression of DN.

Methods: Male LDLr−/− mice (8 wk old) received high fat (45%) + high salt (6%) diet for 6 wk. To induce hypertension, combinations of several pro-hypertensive components were used (eninemproprionate (UNX), angiotensin II (ANGII), DOCA and a vasorestrictor), for an additional 10 wk. At regular intervals, systolic blood pressure (SBP), 24h diuresis and albumin/creatinine ratio (UACR) were assessed. 17 wk after start diet, mice were terminated and renal injury was scored. We used age-matched chow fed animals as controls.

Results: Cholesterol and diuretics were significantly elevated in all groups vs chow from wk 5 onwards. ANGII induced a 20 mmHg increase in SBP at wk 13 vs. chow. At wk 8, UACR was significantly increased by ANGII in combination with HFD+HS (264±303 μg/mg) and UNX+HFD+HS (438±781 μg/mg) vs chow (62±24 μg/mg). At wk 13, ANGII further elevated UACR in HFD+HS (593±377 μg/mg) but decreased it in UNX+HFD+HS (187±230 μg/mg). Combining ANGII and UNX induced a strong increase in UACR (717±585 μg/mg) at wk 5 but also caused fatal thoracic bleedings. This group was terminated at wk 11. Renal injury score showed glomerular hypertrophy, mesangium expansion, nodular glomerulosclerosis, mild hyalination and micro-aneurysms.

Conclusions: We show that LDLr−/− mice on high fat diet + HFD+HS and ANGII induces hypertension and mild progressive DN, in addition to NASH and atherosclerosis in a single high glucose induced the aberrant immune balance remains to be explored. Therefore, we hypothesized that EPO modulated high glucose induced injury via the regulation of inflammatory and anti-inflammatory balance.

Methods: To explore this possibility, we performed genome-wide transcriptome profiling in human umbilical vein endothelial cells (HUVEC), which were stimulated by high glucose (HG) with/without EPO treatment and detected the expression of inflammation associated genes.

Results: Hierarchical clustering and principal component analysis showed the different pattern of mRNA expression in HG stimulated HUVEC with/without EPO. While inflammatory cytokines/chemokines mRNA expression were increased, the HG stimulation in HUVEC, Th2 related cytokine receptors and intracellular signaling molecules showed the reduced mRNA expression levels. EPO treatment reduced inflammatory cytokines/chemokines mRNA expression and increased Th2 related cytokine mRNA expression levels. Real-time PCR analysis confirmed the increased expression of inflammatory related genes, those were decreased in HG stimulated HUVEC with EPO treatment. Moreover, EPO stimulation increased mRNA expression of EPO receptor and b-common receptor. EPO signaling affect neither cell proliferation nor cell death.

Conclusions: Taken together, EPO signaling might protect high glucose induced cell injury by the regulation of immune balance.

Hypertension Results in Moderate Diabetic Nephropathy in a Mouse Model of Metabolic Syndrome

Reinout Smeets,1 Arnaud van Koppen,2 Pavel Goldschmeding,2 1MHR, TNO, Leiden, Netherlands; 2Pathology, UMCU, Utrecht, Netherlands.

Background: Diabetic nephropathy (DN) is a major complication in metabolic syndrome/diabetes patients. We have developed a metabolic syndrome mouse model characterized by non-alcoholic steatohepatitis and atherosclerosis upon high fat diet feeding. These animals show mild renal changes, but don’t progress to moderate DN. Therefore, we investigate whether inducing hypertension on top of metabolic syndrome leads to progression of DN.

Methods: Male LDLr−/− mice (8 wk old) received high fat (45%) + high salt (6%) diet for 6 wk. To induce hypertension, combinations of several pro-hypertensive components were used (eninemproprionate (UNX), angiotensin II (ANGII), DOCA and a vasorestrictor), for an additional 10 wk. At regular intervals, systolic blood pressure (SBP), 24h diuresis and albumin/creatinine ratio (UACR) were assessed. 17 wk after start diet, mice were terminated and renal injury was scored. We used age-matched chow fed animals as controls.

Autophagy Activation in Proximal Tubular Epithelial Cells in Diabetic Nephropathy Acts as a Renoprotective Role Ying Xu, Lei Liu, Wei Xin, Xu Zhao, Liyong Chen, Qiang Wan. Renal Div, Shandong Provincial Hospital Affiliated to Shandong Univ, Jinan, Shandong, China; ‘Shandong Provincial Hospital Affiliated to Shandong Univ, Jinan, Shandong, China; ‘Shandong Provincial Qianfoshan Hospital Affiliated to Shandong Univ, Jinan, Shandong, China.

Background: Previous studies revealed that lipotoxicity participated in epithelial-to-mesenchymal transition (EMT) of proximal tubular epithelial cells (PTECs) under diabetic conditions. Based on evidences that autophagy and lipid metabolism are closely related, the aim of the present study was to investigate autophagy under diabetic conditions and its role in lipotoxicity and EMT.

Methods: HK-2 cells were cultured in normal (5.5 mmol/L glucose) and high glucose medium (30 mmol/L glucose). At 6h, 24h, 48h, and 96h, autophagy activity was evaluated by western blot of LC3II/I, Beclin1 and p62. Next, the inhibition of autophagy was achieved by chloroquine diphosphate (CQ), 3-methyladenine (3-MA), or Atg5 knockdown using siRNA transfection. Rapamycin, which is a mammalian target of rapamycin (mTOR) receptor specific inhibitor and a known autophagy activator, was used to induce autophagy in HK-2 cells. Lipid accumulation was detected by Oil-Red O staining; EMT was estimated by western blot of vimentin and E-cadherin.

Results: In high glucose cultured HK-2 cells, Beclin1 and LC3-II were elevated, while p62 was decreased. These results indicate that autophagy activity was elevated under diabetic conditions. Autophagy deficiency induced by autophagy inhibitors, CQ and 3-MA, or by Atg5 siRNA transfection exacerbated lipid accumulation and EMT. Treatment of rapamycin attenuated high glucose induced lipid accumulation and EMT. The Atg5 silence counteracted the protective effect of rapamycin.

Conclusions: In conclusion, these results demonstrate that autophagy activity in PTECs is elevated under diabetic conditions and the elevated autophagy activity acts as a renoprotective response.

Insulin Sensitivity Before and Six Months After Kidney Transplantation Morten Baas Jorgenesen, 1 Mads Hornum, 1 Gerrit van Hall, 2 Claus Bistrup, 1 Jesper Hansen, 3 Bo Feldt-Rasmussen, 1 Dept of Nephrology, Rigshospitalet, Denmark; 2Clinical Metabolomics Core Facility, Rigshospitalet, Denmark; 3Dept of Nephrology, Odense Univ Hospital, Denmark; 4Dept of Nephrology, Herlev Univ Hospital, Denmark.

Background: Severe uremia is a known cause of insulin resistance. We aimed to investigate the effect of kidney transplantation (Tx) on peripheral and central insulin sensitivity.

Methods: Nine non-diabetic patients awaiting living related kidney Tx were examined prior to Tx (Pre-Tx) with an oral glucose tolerance test (OGTT) and a 3h hyperinsulinaemic euglycaemic clamp. The clamp was repeated six months after Tx (Post-Tx). Nine age, gender and BMI matched individuals with normal kidney function were examined once under euglycaemic clamp. The clamp was repeated six months after Tx (Post-Tx). Nine age, gender and BMI matched individuals with normal kidney function were examined once under euglycaemic clamp.

Results: Two patients had pre-Tx prediabetes whereas all other had both normal fasting plasma glucose and normal glucose tolerance. The amount of glucose utilized during clamp was non-significantly lower in patients before Tx (Pre-Tx: 15.1 [11.2–19.0], Ctrl: 20.2 [13.4–27.0], P = 0.17) but significantly reduced after Tx (Post-Tx: 9.8 [6.7–12.9], P = 0.01). The suppression of EGP were comparable before Tx (Pre-Tx: 7.0 [5.4–8.5], Ctrl: 7.0 [3.1–12.7], P = 0.097) but was significantly improved after Tx (Post-Tx: 9.4 [7.8–11.1], P = 0.04). Gd were comparable both prior to and after Tx (Pre-Tx: 18.1 [13.6–22.5], Ctrl: 22.3 [15.1–29.5], Post-Tx: 17.1 [13.4–20.8], P = 0.22). The suppression of glycolate rate of appearance were comparable before Tx (Pre-Tx: 11.0 [9.1–14.1], Ctrl: 11.0 [6.6–21.1], P = 0.96) but significantly improved after Tx (Post-Tx: 2.0 [1.0–3.8], P = 0.04).

Conclusions: The reduced insulin sensitivity after kidney Tx is characterized by a central insulin resistance with impaired suppression of endogenous glucose production, impaired suppression of lipolysis and comparable peripheral insulin sensitivity.

Renal Functional and Morphological Changes Related to Obesity and Hyperglycemia in Göttingen Minipigs Rikke Lindgaard Thomsen, 1 Berit Østergaard Christoffersen, 1 Trine P. Ludvigsen, 2 Rikke Kaæ Kik, 2 Jonas Kildegård, 2 Lisa Timdan Fuchs, 1 Pall Leifisson, 1 Henrik D. Pedersen, 1 Lisbeth Hoier Olsen, 1 Dept of Veterinary Disease Biology, Univ of Copenhagen, Frederiksberg, Denmark; 2Nordov Nordisk A/S, Malsvau, Denmark.

Background: Obesity and diabetes, two major health problems worldwide, both lead to renal functional and morphological changes, with diabetic nephropathy being the leading cause of end-stage renal failure. A large animal model displaying human-like features of obesity-related and diabetic nephropathy would be very valuable to study pathogenesis and effects of new drug candidates on these syndromes. The aim of the present study was to evaluate renal function and morphology in diet-fed obese, atherosclerotic Göttingen minipigs with or without mild diabetes.

Methods: Male castrated Göttingen minipigs, aged 8 weeks at study start, were fed normal chow (n=6) or high-fat, high-cholesterol diet (n=6) for 43 weeks. Mild diabetes was induced in 11 pigs after 18 (n=6) and 25 (n=5) weeks of diet-feeding, using streptozotocin (125 mg/kg IV) preceded by nicotinamide (67 mg/kg IV). The study included two cohorts. Parameters of interest were: Body fat percentage (BF) estimated by dual-energy X-ray absorptiometry, inulin clearance (IC), kidney resistive index (RI), plasma fructosamine reflecting plasma glucose (FRA), plasma urea, plasma creatinine (PCr), plasma total cholesterol (TC), uric acid excretion (proteinuria (UPC) and albumin (UAC)) adjusted for creatinine. Glomerulus area and number of nuclei/glomerulus area were estimated post mortem. Influence of BF, TC and FRA on in vivo kidney function and post mortem kidney changes was evaluated using ANOVA with cohort as fixed covariable. Glomerulus BF was positively associated with urea (P=0.01), IC (P<0.05), Glomerulus area (P=0.001) and UPC (P=0.05), and negatively with PCr (P<0.001). FRA was positively associated with UACr (P<0.05) and number of nuclei/glomerulus area (P=0.05). RI was not associated with BF, TC or FRA.

Conclusions: In conclusion, functional and histological renal changes were found in diet-fed obese, atherosclerotic Göttingen minipigs with and without mild diabetes. The changes were associated with obesity and hyperglycemia.

Activation of Toll-Like Receptors Through Fetuin-A Leads to an Inflammatory Response in Podocytes and Exacerbates Palmitic Acid-Induced Cell Death Jana Orellana, 1 Kapil Dev Kampe, 1 Andreas Werner 3 Dept. of Biomedical Sciences, Aarhus University Hospital, Aarhus, Denmark; 2Novo Nordisk A/S, Maaloev, Denmark; Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland; 3Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland.

Background: Inflammation participates in the pathogenesis of type 2 diabetes and contributes to diabetic nephropathy (DN). There is growing evidence that chronic elevated free fatty acids (FFAs) contribute to this chronic inflammatory milieu. Studies in pancreatic β-cells suggest that the inflammatory response mediated by FFAs depends on toll-like receptor (TLR) 4 and IL-1 receptor (IL-1R). The signaling pathways of TLRs and IL-1R involve activation of the transcription factor nuclear factor-κB (NF-κB) which induces a wide range of cytokines/chemokines including monocyte-chemoattractant protein-1 (MCP-1), and IL-1. Here, we addressed whether fetuin-A together with FFAs leads to an inflammatory response in podocytes and whether this exacerbates palmitic acid-induced podocyte death.

Methods: Conditionally immortalized murine podocytes were used. Murine and bovine fetuin-A were used alone or in combination with palmitic acid complex to BSA. MCP-1 was measured by ELISA. Podocyte death was determined by flow cytometry (annexin V and propidium iodide staining).

Results: Palmitic acid alone did not, but fetuin-A induced MCP-1 in podocytes and this was further increased by palmitic acid. The MCP-1 release was prevented by CI095 (TLR4 blocker). Fetuin-A or LPS exacerbated palmitic acid-induced podocyte death, and CL095 as well as the IL-1 receptor antagonist anakinra or an anti IL-1β antibody attenuated cell death.

Conclusions: Fetuin-A alone and in combination with palmitic acid leads to an inflammatory response in podocytes and promotes palmitic acid-induced podocyte death. As inhibition of IL-1R as well as II-1β prevents these effects, both pathways are promising targets to attenuate the progression of DN.

IL-1β Mediates the High Glucose Induced Endothelial-to-Mesenchymal Transition in Human Aortic Endothelial Cells Dongelang Zhu, Rui-ning Tang, Kun Ling Ma, Bi-Cheng Liu. Zhong Da Hospital, Southeast Univ Medical School, Nanjing, Jiangsu.

Background: Studies have shown that endothelial-to-mesenchymal transition (EndMT) induced by high glucose (HG) contributes to cardiac fibrosis. Additionally, proinflammatory cytokine interleukin-1β (IL-1β) has been implicated as one of the dominant players in the development of fibrosis and diabetic heart. In vitro studies, retinal endothelial cells (ECs), human intestinal ECs and human dermal ECs have been reported to undergo EndMT by

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 955A
IL-1β stimulation. Interestingly, most IL-1β immunoreactivity was localized to endothelial cells and interstitial macrophages in an animal model of cardiac hypertrophy. However, the potential role of IL-1β in high glucose induced EndMT remains unknown. Here, we hypothesize that IL-1β might mediate the process.

Methods: Primary human aortic endothelial cells (HAECs) were divided into three groups: a normal glucose (NG) group, an endothelial phenotype, wherein increased microvascular proliferation and a rounded endothelial cell phenotype were observed in the cytoplasm. The expressions of FSP1 and a-SMA were significantly increased in the HG group, and these changes were inhibited by anti-interleukin1β antibody or IL-1β siRNA treatment.

Results: The treatment of HAECs in the HG group resulted in significant increases in the expressions of FSP1 and a-SMA and IL-1β in dose- and time-dependent manners. The incubation of HAECs with FGF-23 induced a fibroblast-like phenotype, wherein increased microvascular proliferation and a rounded endothelial cell phenotype were observed in the cytoplasm. The expressions of FSP1 and a-SMA were significantly increased in the HG group, and these changes were inhibited by anti-interleukin1β antibody or IL-1β siRNA treatment.

Conclusions: These findings suggest that IL-1β mediates the HG-induced EndMT, which was inhibited by anti-interleukin1β antibody or IL-1β siRNA treatment.

PUB296

Serum Bilirubin and Asparaginase Aminotransferase Concentrations Predict Loss of Renal Function in Type 2 Diabetes

Kevin M. Wheelock,1 Guđeta D. Fufaa,1 Miranda Man,1 2 William Knowler,1 Madhumita Sinha,1 Frank C. Brosius,2 Robert G. Nelson.1 NIDDK, Phoenix, AZ; 1Univ of Michigan, Ann Arbor, MI.

Background: Higher serum bilirubin concentration is reported to slow the progression of nephropathy in type 2 diabetes. We examined associations of serum bilirubin and asparaginase aminotransferase (AST) concentrations with renal function loss (RFL) in a post-hoc analysis of a clinical trial of renoprotection with losartan in Pima Indians with type 2 diabetes (ClinicalTrials.gov number, NCT00340678).

Methods: Serum bilirubin and AST were measured at baseline in 168 subjects who underwent annual measurement of GFR by the urinary clearance of inulinodulose. RFL was defined by ≥40% decline in GFR from baseline. Cox regression was used to compute hazard ratios (HRs) for the association of a 1 standard deviation (SD) increment in bilirubin and AST concentrations with RFL adjusted for age, sex, treatment group, HbA1c, GFR, and urinary albumin/creatinine ratio (ACR). The sum of standardized AST and bilirubin was standardized to create a liver index variable with mean=0, SD=1.

Results: Participants (73% female, mean age 42±11 years, bilirubin 0.6-0.2 mg/dL, HbA1c 9.3±2.2%, GFR 103±63 ml/min, and median AST 19 U/L (IQR=13-31.5 U/L), ACR 31 mg/g (IQR=12-77 mg/g)) were followed for a median of 7.0 years (IQR=4.5-9.9 years); 73 subjects (43%) developed RFL. After multivariable adjustment, serum bilirubin and AST were independent predictors of RFL (HR=1.52). The combination of these liver function tests provided the strongest prediction (HR=1.52).

Conclusions: Higher serum bilirubin and AST concentrations predict loss of renal function in Pima Indians with type 2 diabetes.

Baseline Data from the Multinational Prospective Cohort Study in Patients with Type 2 Diabetes for Validation of Biomarkers (PROVAILD)

Gert J. Mayer,1 Susanne Eder,1 Laszlo Rosvall,2 Peter Voros,3 Hiddo Jan Lambers Heerspink,1 Dick de Zeeuw,1 Beata Czerwiec,1 Andrzej Wieczek,1 Diianne Z. Hill,1 Patrick B. Murr,1 George Heinz,1 Peter Rosling1, Internal Medicine IV, Medical Univ Innsbruck, Innsbruck, Austria; 2Inst of Pathophysiology, Semmelweis Univ, Budapest, Hungary; 3Egyetemist Szent Istvan es Szent Laszlo Korhaz, Budapest, Hungary; 4Dept Clinical Pharmacy and Pharmacology, Dept of Nephrology, Medical Center Groningen, Groningen, Netherlands; 5Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ Silesia, Katowice, Poland; 6Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; 7Section for Clinical Biometry, Medical Univ Vienna, Vienna, Austria; 8STENO Diabetes Center, Gentofte, Denmark.

Background: We recruited 4065 subjects at the primary healthcare level in Austria, Hungary, Netherlands, Poland and Scotland, who will be treated according to local practise and followed for 4 years to compare the incidence and progression of renal and cardiovascular disease between the countries. Additionally extensive biobanking is performed.

Methods: We will determine the cumulative incidence of progression of albuminuria, doubling of serum creatinine, and end stage renal disease as well as fatal and non-fatal cardiovascular events. Exclusion criteria are active malignancy and age <18 years.

Results: The mean age of the population was 62 years, mean duration of diabetes as 9.9 years. 9% of the patients had eGFR values <45 and 22% <60 ml/min/1.73m2. Baseline data from the “lowest” country “highest” country

PUB298

FGF-23 and Magnesium Are Independent Risk Factors for an Increased Albumin-to-Creatinine Ratio in Type 2 Diabetes with Chronic Kidney Disease

F. Brito Mendes,1 Ana Paula Silva,1 André Fragoso,1 Nélio Santos,1 Teresa M. Jeronimo,1 Ana Pocinho Pimentel,1 Pedro L. Neves,1,2 Centro Hospitalar do Algarve- Hospital de Faro, Portugal; 2Univ of Algarve, Portugal.

Background: Microalbuminuria is the earliest sign of glomerular involvement in diabetes mellitus. The multiple physiological mechanisms involved are complex and not completely understood. Recently, it appeared that fibroblast growth factor-23 (FGF-23) and magnesium play a role in the emergence and maintenance of albuminuria in type 2 diabetes. The aim of this study is to investigate the role of FGF-23 and magnesium in relation to the urine albumin-to-creatinine ratio in type 2 diabetes with chronic kidney disease (CKD) stages 2-4.

Methods: In a cross-sectional study we included all eligible type 2 diabetic patients with CKD stages 2-4, followed in our outpatient Diabetic Kidney clinic. We included 150 patients, f=53–57, with a mean age of 66.6±7 years (40-85) and a mean follow-up of 76 months. We used descriptive statistics, the Student’s t and the chi-square tests. We also divided our population according to the pulse pressure (G I <50 mmHg and G2 ≥ 50 mmHg), and compared these groups regarding the several biological and laboratory parameters analyzed. We employed a multiple regression model to identify risk factors of increased urine albumin-to-creatinine ratio. In this model we used the urine albumin-to-creatinine ratio as the dependent variable and as independent ones age, duration of type 2 diabetes, systolic blood pressure, HbA1c, eGFR, HOMA-IR, malonialdehyde, hs-CRP and 1,25(OH)D3 levels.

Results: The patients in G2 displayed a lower eGFR (p=0.001) and magnesium (p=0.004) levels, as well as higher levels of FGF-23 (p=0.043) compared to patients in G1. The magnesium and FGF-23 were found to play a role in the urine albumin-to-creatinine ratio (β=0.006, p=0.002), and the magnesium (β=−0.016, p=0.001) are independent risk factors for increasing the urine albumin-to-creatinine ratio.

Conclusions: The present study shows that a dysregulation of mineral metabolism, reflected by altered levels of magnesium and FGF-23, correlates with an increased urine albumin-to-creatinine ratio in type 2 diabetic patients with CKD stages 2-4.

FGF-23 and Klotho Influence the Pulse Pressure in Diabetic Patients with Nephropathy

Ana Paula Silva,1,2 Filipa Brito Mendes,1 André Fragoso,1 Teresa M. Jeronimo,1 Ana Pocinho Pimentel,1 Pedro L. Neves,1,2 Centro Hospitalar do Algarve- Hospital de Faro, Portugal; 1Dept of Biomedical Sciences and Medicine, Univ of Algarve, Faro, Portugal.

Background: The last decade have shown that FGF23 and Klotho may have relevant independent actions on the renal and CV systems. They interfere with vascular functions and may play a role in vascular calcification, atherosclerosis and arteriosclerosis. Their interactive activities may also have direct and indirect effects on interdependent renal and CV pathophysiology. The aim of this study is to investigate the relationship between FGF-23 and Klotho with pulse pressure in type 2 diabetic with chronic kidney disease (CKD) stages 2-3.

Methods: In a cross-sectional study we included 107 type 2 diabetic patients (67 males, 62.6±11 years), a mean age of 66.6±7.9 years and CKD stage 2-3. We used descriptive statistics, the Student’s t and the chi-square tests. We also divided our population according to the pulse pressure (G 1<50 mmHg and G2 ≥ 50 mmHg), and compared these groups regarding the several biological and laboratory parameters analyzed. We employed a multiple regression model to identify risk factors of increased pulse pressure (PP). In this model we used as dependent variable the pulse pressure, and as independent ones age, metabolism and albuminuria-to-creatinine ratio, insulin resistance, oxidative stress and eGFR.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: We found that G2 patients showed higher age (p = 0.017), phosphorus (p < 0.001), iPTH (p = 0.001), urine albumin-to-creatinine ratio (p = 0.001), Homa-IR (p = 0.001), FGF-23 (p = 0.001) and OxLDL (p = 0.001) and lower levels of eGFR (p = 0.001), Klotho (p = 0.001) and 1.25(OH)2D3 (p = 0.001). In the multivariable linear regression model we found that FGF-23 (β=0.377, P=0.047) and the Klotho (β= - 0.567, P=0.023) are independent risk factors for increasing the pulse pressure.

Conclusions: In conclusion, in a population of type 2 diabetic with chronic kidney disease stages 2-3, the Klotho and FGF-23 levels are independently associated with PP. Further studies with more patients are warranted to confirm whether an increase in Klotho and a decrease in FGF-23 would reduce the PP and consequently the cardiovascual risk of our patients.

PUB300

Prediction of Renal Outcome in Type 2 Diabetic Dephropathy by Estimating GFR from a Combination of Serum Creatinine and Cystatin C

Yu Pan, Song Jiang, Dandan Qiu, Yu An, Yongchun Ge, Honglang Xie, Zhihong Liu. National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.

Background: serum cystatin C is an alternative to serum creatinine for estimating glomerular filtration rate (GFR), however, the utility of estimated GFR from combination of serum creatinine and cystatin C as marker to predict long-term renal outcome is uncertain, particularly in the Type 2 diabetic nephropathy (DN).

Methods: A total of 501 patients (The National Clinical Research Center of Kidney Diseases, 2003-2011) were recruited in prospective cohort study. Follow-up was 5-year. Renal outcome was defined by eGFRcre-cys<15 ml/min per 1.73m² or renal replacement therapy.

Results: The distributions of standardized serum cystatin C with eGFRcre and eGFRcre-cys are shown in. Kaplan-Meier curves showed significantly increased renal endpoints with higher quartile of cystatin C (p < 0.001) and lower eGFRcre-cys (p < 0.001). The highest AUCs for eGFRcre-cys was predicting the renal endpoint compared with eGFRcre or eGFRcre-cys. The best cut-off value for predicting the renal endpoint was 29.28% decline in the 24-month, which value showed 79.6% sensitivity and 82.6% specificity. Cox regression models with restricted cubic splines were shows a change of -30% in eGFRcre-cys was a precision, and accuracy marker in the predicting the renal output and 30% decline of eGFRcre-cys over 2 years was strongly associated with the risk of ESRD, suggesting it could be used as an alternative endpoint in T2DN.

PUB301

Prevalence and Prognostic Role of Uncontrolled Risk Factors in Diabetic CKD (DM-CKD) Treated in Nephrology Clinics

Roberto Minutolo, 1 Michele Provenzano, 1 Paolo Chiordi, 1 Giuseppe Conte, 1 Luca De Nisola. 1Nephrology, Second Univ, Naples, Italy; 2Med Stat, Second Univ, Naples, Italy.

Background: Knowledge of prognosis of DM-CKD mainly derives from RCTs and cohorts followed in the dialysis setting. Epidemiologic features are less defined in patients with overt disease managed in renal clinics.

Methods: We studied 763 DM-CKD patients derived from 3 prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from 26 months in 40 different renal clinics. Endpoints were ESRD (chronic dialysis-transplant) and first major cardiovascular (CV) events (fatal and non fatal) assessed through 12/2014. Uncontrolled risk factors were defined as high blood pressure (BP=140/90 or >130/80 if proteinuria >0.150 g/24h), HbA1c >7.5%, hemoglobin <10.5 g/dL, serum phosphorus (P) >4.5 mg/dL, LDL-C >100 or 70 mg/dL according to ESC 2012 guidelines, proteinuria (Uprot) >0.5 g/24h.

Results: HbA1c was 6.9%, (95% CI 6.6-7.2), Uprot 0.5 g/24h (95% CI 0.4-1.4), P 3.9±0.8 mg/dL, Hb 12.3±1.7 g/dL and BP 142±19/78±11 mmHg. During follow-up (43 months, IQR 21-56), 171 ESRD and 170 CV events occurred (incidence rate 6.4 and 6.9/100 pts/y). Multivariable Cox analyses for ESRD and CV risks (HR, 95% CI) stratified by the Table in the text.

Conclusions: eGFRcre-cys was a precision, and accuracy marker in the predicting the renal outcome and 30% decline of eGFRcre-cys over 2 years was strongly associated with the risk of ESRD, suggesting it could be used as an alternative endpoint in T2DN.

Prevalence of Proteinuria, Albuminuria and Associated Factors in Obese Patients Undergoing Bariatric Surgery

Background: Obesity is associated with proteinuria. But the exact prevalence of proteinuria or albuminuria with and without additional risk factors in obese patients is unclear.

Methods: Consecutive patients undergoing bariatric surgery were included in study. Participating patients had a urine sample for protein creatinine ratio and albumin creatinine ratio prior to their surgery. We defined a positive protein to creatinine ratio as greater than or equal 300 mg and a positive albumin to creatinine ratio as greater than or equal to 30 mg. Associated factors such as diabetes mellitus (DM), hypertension (HTN), body mass index (BMI), and ACE/ARB use were collected.

Results: One hundred forty-three patients were included. The mean age was 43 years (SD: 12). Twenty five percent of the patients had DM, 50% had HTN, and the mean BMI was 44.7 (SD: 9.8). The prevalence of proteinuria and albuminuria was 8.5% (95% CI 4.5-14.4%) and 21% (95% CI 14-30%) respectively. Sixty six percent of the patients with proteinuria had DM as did 43% of the patients with albuminuria. Eighty three percent of patients with proteinuria had either DM or HTN. Seventy eight percent of patients with albuminuria had either DM or HTN. One renal failure with neither DM nor diabetes mellitus (DM), hypertension (HTN), body mass index (BMI), and ACE/ARB use were collected.

Conclusions: The majority of patients with proteinuria and albuminuria had diabetes and/or hypertension and there was a much lower prevalence of proteinuria/albuminuria in patients without these risk factors. Patients who had proteinuria had a higher BMI than patients who did not have proteinuria, though for albuminuria the BMI did not differ.

Risk Factors for Renal and Cardiovascular Events in Type 2 Diabetic Patients with Biopsy-Proven Nephropathy in Japan

Akihito Hara, Kengo Furuichi, Miho Shimizu, Yukio Yuzawa, Hiroshi Kitamura, Hiroshi Sato, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Japan; Dept of Nephrology, Fujita Health Univ Hospital, Japan; Dept of Pathology, Clinical Research Center, National Hospital Organization Chiba East National Hospital, Japan; Clinical Pharmacology and Therapeutics, Tohoku Univ Graduate School of Pharmaceutical Sciences.

Background: Standardized pathological classification is an essential tool in the evaluation of disease progression and/or efficacy of clinical management. In this nationwide, multicenter, retrospective study, we examined pathological findings as risk factors for renal and cardiovascular events in Japanese patients with type 2 diabetes. The observational period was 76.3 months and the observation period was 2264 person-year in total. Nine glomerular lesions, two interstitial lesions, and two vascular lesions were classified and evaluated as pathological predictors.

Methods: One hundred sixty nine composite renal events (dialysis and doubling of serum creatinine or death) in 13 centers in Japan. The median follow-up period was 76.3 months. We then identified 9902 patients with type 2 diabetes who met the diagnostic criteria of the Japan Diabetes Clinical Practice Guidelines of 2011. The aim was to determine if similar relationships exist in adolescents with T1D, analyzed on the basis of low GFR and lower renal blood flow in adults with type 1 diabetes (T1D). Our overall aim was to determine if similar relationships exist in adolescents with T1D, analyzed on the basis of lower GFR and lower renal blood flow in adults with type 1 diabetes (T1D). Our overall aim was to determine if similar relationships exist in adolescents with T1D, analyzed on the basis of lower GFR and lower renal blood flow in adults with type 1 diabetes (T1D).

Results: Sixty eight diabetic patients undergoing maintenance hemodialysis (6 men and 2 women; mean age, 64.4±11.9 years; mean dialysis period, 4.0±5.0 years; 2 insulin users, 6 nonusers) were instructed in CBGFM with BCC and followed for 3 months to assess changes in their predialysis blood glucose (BG), hemoglobin A1c (HbA1c), Hemoglobin HbA1c, triglycerides (TG), Potassium (K), Phosphorus (P), albumin (Alb), total cholesterol (T-Ch), high-density lipoprotein-Chol (HDL-Chol), low-density lipoprotein-Chol (LDL-Chol), protein catabolic rate (PCR), dry weight (DW), body mass index (BMI), and the Geriatric Nutritional Risk Index (GNNR).

Conclusions: The results demonstrated that the CBGFM with BCC is a useful method of dietary management for glycemic control that can be applied independently of, but concurrently with, the control of potassium and phosphorus intake in dietary therapy for diabetes patients.

The Clinical Effects of Renoprotection with DPP-4 Inhibitors

Koichi Kanzawazaki, Saeo Sato, Yoshimi Okada, Hiroaki Haru, Minoru Hatanou, Nobutada Onizawa, Takatsugu Iwashita, Tomonori Ogawa, Hajime Hasegawa. Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kagawa, Saijina, Japan.

Background: Recently, not only animal models of diabetic nephropathy, but also non-diabetic neprhopathy models, DPP-4 inhibitors could be used to develop renoprotective effects that improve albuminuria or tissue damage, through inhibition of oxidative stress, inflammation, and fibrosis. The aim of this study is to clarify the mechanisms of renoprotective effect by DPP-4 inhibitors in diabetic nephropathy models, DPP-4 inhibitors (DPP-4i) are reportedly associated with the change rate of UACR (p=0.03). MDA-LDL (34 mU/L (p<0.01), decreased from 7.49±0.18 to 5.97±0.12 (p=0.01)). DPP-4 inhibitors were investigated in 128 patients with type 2 diabetes (G1-3a, A1-2), either 1,5-anhydro-d-glucitol (1,5AG) was increased from 11.0±15.0 to 15.3±15.0 (p<0.01), carotid-femoral pulse wave velocity (Car-Fem PWV) were measured in 65 HC, 64 low-, 74 middle- and 50 high-tertile T1D participants from normo- to microalbuminuria and albuminuria groups with lower GFR and higher values for BP and arterial stiffness in T1D adolescents but not HC.

Conclusions: We proposed that the CBGFM with BCC is a useful method of dietary management for glycemic control that can be applied independently of, but concurrently with, the control of potassium and phosphorus intake in dietary therapy for diabetes patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

958A
Conclusions: In DMN, DPP-4i have oxidative stress relief and renoprotective effect, by the improvement of short-term blood sugar fluctuations, also by oxidative stress reduction which independently of the improving glycemic control.

PUB309
Fibrinogen: A Potential Predictive Factor for the Progress of Diabetic Kidney Disease
Wenbo Zhao, Hui-juan Li, Zhenda Zheng. The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, Guangdong.

Background: To evaluate the potential of fibrinogen as a predictor of the progress of proteinuria in diabetic kidney disease.

Methods: For a Cross-Sectional Study, collecting 1121 type 2 diabetes patients without or with microalbuminuria or massive proteinuria were treated during January 2008 to January 2013. Proteinuria was negative in 755 cases, 285 cases with microalbuminuria, and 181 cases with massive proteinuria. We analyzed the correlation factors of the negative protein urinal group and the microalbuminuria group; the correlation factors of the microalbuminuria group and the massive proteinuria group. Fibrinogen levels were compared between three groups.

Results: Retinopathy, hypertension grading, SBP, Fibrinogen levels, serum albumin, serum creatinin were the related progress factors of Microalbuminuria; Diabetes course, retinopathy, waist to hip ratio, Fibrinogen levels, serum albumin levels, serum creatinin, C, serum creatinine were the related progress factors of the massive proteinuria; Except fibrinogen, other factors had been known relating to the progress of diabetic kidney disease. There were differences in the levels of three groups of fibrinogen (P < 0.05), which were 3.43 + 0.91 g/L, 4.15 + 1.31 g/L, 5.16 + 1.44 g/L.

Conclusions: Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. The conclusion needs to be confirmed by further study.

PUB310
Interaction of HDLc, Iron, and Diabetes on Kidney Function
Baqiyyah, 1 Tina Costacou, 2 John M. Arthur. 3 Epidemiology, West Virginia Univ; 2Epidemiology, Univ of Pittsburgh; 3Univ of Arkansas for Medical Sciences.

Background: The effect of HDL cholesterol (HDLc) on kidney function has recently received attention, partly due to the finding of increased hemoglobin (hb) inside of the HDL protein in persons with high risk haplotgbin (hp) genotypes. Such hb w/in the HDL protein may lead to iron induced lipid peroxidation products. These lipid peroxidation products may lead to iron-induced kidney damage. We have recently shown an interaction between HDLc and iron w/ kidney function (eGFR) in persons with diabetes that after controlling for hb, higher serum iron levels were associated w/ reduced eGFR but only in those w/ HDLc levels above the median for the population. Because of the diabetes-specific association of increased hb inside the HDL protein in those w/ high risk hp genotypes, we hypothesize that this interaction between HDLc and iron w/ kidney function varies by diabetes status. To test this hypothesis, we examined the inter-relationship between HDLc, iron, and diabetes status w/ eGFR in approximately 55,000 individuals in West Virginia and Ohio.

Methods: Data on adults aged ≥20 years were obtained from the C8 Health Project. eGFR was estimated using the CKD-EPI formula. Linear regression analysis was used to test the relationship between HDLc, serum iron, and diabetes status, and their interactions, with eGFR.

Results: Mean age was 57.8 in those w/ diabetes and 45.1 in those w/out diabetes. In multivariable analyses controlling for age and sex, iron was positive related w/ eGFR in those w/ (p<0.03) and inversely in those w/out diabetes (<0.0001), while HDLc was positively associated w/ eGFR only in those w/out diabetes (p=0.97 in diabetes; p<0.001 in those w/o diabetes). As previously reported, an interaction existed between HDLc and iron in diabetes (p=0.04). However we report that this relationship was even stronger in those w/out diabetes (interaction p=0.0008). A significant 3-way interaction existed between HDLc, serum iron, and diabetes status w/ eGFR (p=0.008). Controlling for hb, the interaction between iron and HDLc disappeared in those w/ diabetes but remained robust in those w/out diabetes.

Conclusions: The divergent relationship between iron and HDL on the eGFR by diabetes status needs further investigation.

PUB311
Molecular-Selective Plasma Exchange in Acute Kidney Injury due to Multiple Myeloma
Mamoru Kanda, Satoru Satoda, Shintaro Mizuno, Shu Yamakage, Mitsuhiro Sato, Yoshio Taguma, Toshinobu Sato. Nephrology, Japan Community Health Care Organization Sendai Hospital, Sendai, Miyagi, Japan.

Background: Benefit of plasma exchange in overall survival of patients with multiple myeloma (MM) remains to be determined, however, it is evident that lowering free light chain (FLC) reverses renal function in acute kidney injury (AKI) due to MM. High cut-off hemodialysis is recommended to remove FLC as an initial treatment for MM related AKI, which is different from traditional plasma exchange (PE) in preventing loss of large size molecules. As another option, we show the effect of molecular-selective plasma exchange to remove FLC, which enables target size removal without losing other size molecules.

Methods: A 49 year male with Bence-Jones type M protein was admitted with AKI; serum creatinine rose from 3.8 to 7.9mg/dL in 1 month. Past history included bone fracture and anemia. Serum FLC lambda was elevated to 29800 mg/dL. MM was confirmed by plasma cells in the bone marrow. The patient was treated with sequential molecular-selective plasma exchange (Evacure) and on-line HDF every other day combined with Bortezomib.

Results: PE was performed 6 times and removed 43.1% of FLC each on average without losing small and large size molecules.

Conclusions: Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. The conclusion needs to be confirmed by further study.

PUB312
Preliminary Evaluation of a New CRRT Machine: Kibou™
Mauro Neri, Francesco Garzotto, Anna Lorenzin, Silvia Guggia, Alessandra Brendolani, Federico Nalesso, Monica Zanella, Claudio Ronco. IRRIV and San Bartolo Hospital, Vicenza, Italy.

Background: Kibou™ (Asahi Kasei Medical Co., Tokyo, Japan) is a new multifunctional automatic machine for Continuous Renal Replacement Therapy (CRRT) system (figure 1).

Methods: Based on the traditional experience of International Renal Research Institute of Vicenza (IRRIV), in vitro and in vivo test evaluations of Kibou and related disposables have
been conducted. 12 treatments were performed. Machine’s usability and accuracy has been evaluated by the staff through scores table. The measurement of fluid balance accuracy was even performed.

**Results:** Based on score given by the staff (engineers, nurses and physicians), the machine hardware results compact and well organized, with 3 well separated compartments (dialyzer replacement, blood and effluent) that facilitate the preparation phase. Automatic priming function allows short priming time. The interface is user friendly in all the modalities (SCUF, CVVH, CVVHD, CVVHDF, TPE, both for adults and pediatrics). The measured fluid balance error was always lower than 0.3%. On the contrary CVVHDF pre-infusion and pre-pump infusion are not performable. For pediatric treatment the continuity of the flow of blood pump need to be maintained and improved.

**Conclusions:** Kibou is a promising CRRT machine that can perform multiple continuous therapies with just one platform. In particular, we evaluated a highly accurate gravimetric fluid balance control system and a user friendly interface. Kibou is one of the first machines of the new frontier of CRRT devices: the fourth generation of CRRT machines.

### PUB313

**The Effect of MySleeve on Fluid Restriction Adherence in Hemodialysis Patients**

Prima Health Analytics, 1Prima Health Analytics; 2Dialysis Center of Lincoln; 3Medicine, Div of Nephrology, Maastricht Univ Medical Center, Maastricht, Netherlands.

**Background:** In hemodialysis patients, non-adherence to fluid restriction is associated with high interdialytic weight gain (IDWG) and adverse outcomes. Monitoring drinking behaviour and direct feedback to the patient can lead to better adherence. We developed the MySleeve, a device that can be wrapped around a drinking glass to monitor fluid intake throughout the day. The MySleeve will also provide a subtle vibration on the glass when the amount drunk exceeds target. The information about drinking behaviour can be found in the accompanying application on a mobile phone. In this study, we investigate the effect of direct feedback and information to the patient on fluid restriction adherence measured by the IDWG.

**Methods:** We will include prevalent, anuric hemodialysis patients from the Catharina Hospital Eindhoven, The Netherlands in a randomised controlled trial. Patients in the intervention group are provided a MySleeve device, a mobile phone and an activity tracker. BCM measurements are performed weekly and IDWG will be calculated before every dialysis session. The patients in the control group will continue with regular hemodialysis.

**Results:** We expect that by providing patients insight in fluid intake, there will be an increase in fluid restriction adherence and an increase in activity levels and better quality of sleep. Due to less IDWG, patients will experience less discomfort of fluid overload.

**Conclusions:** Introducing a MySleeve device to provide direct insight into drinking behavior will help the patients to adhere to their fluid restriction, leading to less IDWG and better quality of life measured by daily activity and better sleep.

### PUB314

**A Time and Motion Study of Erythropoiesis Stimulating Agent Administration in United States Dialysis Centers**

Mark Stephens, 1Larry C. Emerson, 1Leslie A. Spry, 1John P. Caloyeras, 1Ernest R. Anderson, 1John Reitan, 1Akhtar Ashfaq, 1Prima Health Analytics; 2Dialysis Center of Lincoln; 3Amgen, Inc.; 4RJM Group.

**Background:** Previous research suggests that ESA administration in dialysis is a time-consuming task and switching to less frequently dosed ESAs may offer opportunities for more efficient and effective patient care. This study estimated the time required for activities involved in the ESA process at US dialysis centers using epoetin alfa (EPO) or darbepoetin alfa (DPO), and examined potential time savings of switching from EPO to DPO.

**Methods:** Time and motion study conducted from 10/2014 to 1/2015 to assess activities involved and staff time required to prepare, administer and document ESA doses. A sample of 11 dialysis centers using either 3 times-per-week (TIW) EPO or once-weekly (QW) DPO were selected in pairs (one EPO, one DPO), where possible, from the same organization or nephrology practice to help control for patient management protocols and staffing patterns. ESA-related tasks were timed by trained nurse observers. Time savings were calculated from switching from TIW EPO to QW DPO were estimated. Staff were interviewed about alternate patient-focused activities that could be accomplished if time were saved in the ESA process.

**Results:** 200 administrations were observed (81 DPO, 119 EPO). A mean of 2.3 (95% CI: 2.1-2.5) minutes per dose were required for ESA-related activities. RNs performed 95% of tasks; LPNs 5%. ESA process time did not vary significantly between EPO and DPO (p>0.83). Staff time savings would accrue due to fewer ESA administrations using QW DPO: 10-20 minutes per nurse/day. For an average facility, the total monthly nurse time would be reduced substantially in de novo conversion.

**Conclusions:** Switching from TIW EPO to QW DPO for anemia management in dialysis patients can result in time savings and opportunities to redirect nurse time towards activities aimed at improving patient care while still offering the ability to respond to changing clinical circumstances to effectively manage anemia.

**Observational Study on the Use of Darbepoetin Alfa in Hemodialysis Patients in Central Eastern Europe – ANREG Final Analysis**

Tomasz Jezrywicz, 1Alena Patrikova, 2Alexander Selyutin, 3Botond Csiky, 4Jaroslav Rosenberger, 5Igor Rus, 6Kinga Jedynasty, 1Dept of Nephrology/ENDO, MSW Hospital, Katowice, Poland; 2Dept of Nephrology, Inst for Clinical and Experimental Medicine, Prague, Czech Republic; 3B Braun Avitum, Orenburg, Russian Federation; 4FMC Dialysis Center, Pécs, Hungary; 5Nephrology and Dialysis Center Fresenius, Kosice, Slovakia (Slovak Republic); 6Dept of Hemodialysis/Nephrology, General Hospital Jesenice, Jesenice, Slovenia; 7CEE Headoffice, Amgen GmbH, Vienna, Austria.

**Background:** This study observed anemia treatment patterns in HD patients (pts) treated with darbepoetin alfa (DA) in clinical practice in CEE.

**Methods:** Multicenter observational study in HD pts treated with DA. From 2007 to 2014, 14 cohorts were observed for 6 months (mo) each. Primary outcome: % pts maintaining an average Hb >at 11 (cohorts 1/2 enrolled prior to label change in 02/2008) or 10-12 g/dL (cohorts 3-12) during mo 4-6. Secondary: conversion versus de novo pts, Hb trends, ESA and iron use, adverse drug reactions (ADR).

**Results:** Of 2923 enrolled pts (n=1101 de novo; n=1822 converted from other ESAs), 2647 (91%) completed 6 mo of DA, 276 (9%) discontinued (155 [5%] due to death). At baseline (BL) 83% received iron.

**Conclusions:** Patients receiving DA achieved target Hb (HR:0.25, P=0.04), and patients with normal TSAT (20-30%) were significantly lower risk for adverse events (fatal: intracranial hemorrhage; myocardial infarction, death).

**Funding:** Pharmaceutical Company Support - Amgen

### PUB316

**Dysutilization of Iron for Erythropoiesis Is a Significant Predictor for Adverse Events and Survival in Maintenance Hemodialysis Patients**

Takahiro Kuragano, Takeshi Nakanishi. Dept of Internal Medicine Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

**Background:** Patient with high serum ferritin and low transferrin saturation (TSAT) levels could be considered as dysutilization of iron for erythropoiesis. Long-term safety and iron administration to these patients has not been well studied.

**Methods:** Study design was the observational multicenter study for period of 3 years. In 805 patients with maintenance hemodialysis (MHD), we evaluated Hb, ferritin, TSAT levels in each 3 months, and high sensitive C reactive protein (hsCRP) and b2microglobulin (MG) levels every 6 months. We defined dysutilization of iron for erythropoiesis as the patients with lower TSAT (<20%) and higher ferritin (100 mg/mL) levels. The association between dysutilization of iron for erythropoiesis and adverse event was investigated with the time dependent cox hazard model.

**Results:** Compared with low TSAT (≤20%) level, patient with normal TSAT (20-30%) was significantly lower risk for cerebrovascular and cardiovascular disease (CVVD) (HR:0.25, P=0.04), and patients with higher TSAT (>30%) were significantly lower risk for death (HR:0.12, P=0.01). In multivariate logistic regression analysis, male, younger patients, without diabetes, low hsCRP and low b2MG were selected as significant predictors of high TSAT, but iron administration or ferritin were not. Compared with low ferritin (<100 ng/mL) and high TSAT (>20%), patients with high ferritin (100ng/mL) and low TSAT (<20%)
Inflammatory and Metabolic Syndrome Biomarkers Analysis of Vascular Outcomes in End-Stage Renal Disease

Vinod K. Bansal,1 Patrick Sweigert,2 Debra Hoppensteadt,2 Jennifer Saluk,2 Daneyal Syed,2 Jawed Farzad.2
1Nephrology, Loyola Univ Medical Center, Maywood, IL; 2Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: The relevance of some biomarkers of inflammation and metabolic syndrome to vascular outcomes in end stage renal disease (ESRD) is not clear. To study these relationships, biochip array technology method was used to profile the complex plasma biomarkers in the setting of various comorbid outcomes such as Stroke or Transient Ischemic Attack (TIA), Acute Coronary Syndrome (ACS), Congestive Heart Failure (CHF), and Coronary Artery Disease (CAD).

Methods: Plasma samples were collected from 83 ESRD patients (mean age 65) prior to hemodialysis and were profiled using biochips for metabolic and inflammatory biomarker levels. Inflammatory cytokine and Metabolic Syndrome arrays were used to profile C peptide, ferritin, insulin, leptin, resistin, TNFα, PAI-1, IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, VEGF, EGF, IFNG, and MCP1. Retrospective review was performed to group patients based on history of Stroke or TIA, ACS, CHF, and CAD.

Results: Of the 83 ESRD patients, 25 (30.1%) were found to have history of Stroke/TIA, 14 (16.9%) were found to have history of ACS, 30 (36.1%) were found to have history of CHF, and 39 (47.0%) were found to have history of CAD. Stroke/TIA patients were found to have decreased plasma IFNG levels (p=0.042) and elevated plasma resistin, IL-1α, and leptin levels (p=0.008, 0.021, 0.026; respectively) when compared to patients without Stroke/TIA. ACS patients had elevated plasma IL6 levels (p=0.040) when compared to those without ACS. CHF patients had decreased plasma leptin levels (p=0.031) and elevated plasma IL1β levels (p=0.042) when compared to patients without CHF. CAD patients had elevated plasma IL1α levels (p=0.049) when compared to ESRD patients without CAD.

Conclusions: Profiling of multiple inflammatory and metabolic syndrome biomarkers may aid in the risk stratification of ESRD patients for cerebrovascular and cardiovascular disorders. These studies demonstrate that biomarker profiling of vascular comorbidity levels in ESRD may provide useful diagnostic and prognostic information in the management of ESRD patients.

Individualized Anemia Management in Pediatric Nephrology Patients

Adam E. Gaweda,1 Jason Misurac,2 Michael E. Brier,1 Jeffrey D. Leiser.2
1Medicine, Univ of Louisville, Louisville, KY; 2Nephrology, Riley Hospital for Children at Indiana Univ, Indianapolis, IN.

Background: Anemia management in pediatric patients on dialysis poses a great challenge to the nephrologist. In this study, we tested the hypothesis that individualized approach anemia management, previously demonstrated successfully in adult patients, improves hemoglobin maintenance within target range in pediatric dialysis patients.

Methods: We performed prospective evaluation of Clinical Decision Support System “Smart Anemia Manager” (SAM) in pediatric dialysis patients at Riley Hospital for Children at Indiana University. SAM was implemented as a stand-alone software on a desktop computer used by the nurse anemia manager and connected to a database containing Hemoglobin (Hgb) and ESA dose data. The anemia manager was allowed to override dose recommendations from the system and each override was documented. The followup period was 10 months, including 4 month washout period. We compared the hemoglobin distribution within 9–12 g/dL range during 6 months immediately before SAM implementation and 6 months after the washout period. Only patients who received ESA and had at least 4 Hgb values within each period were included in the analysis.

Results: 13 patients satisfied the inclusion/exclusion criteria. The percentage of monthly Hgb within target range varied between 82% and 92% in 6 months prior to deployment of SAM and between 69% and 100% during 6 months after SAM deployment. Quarterly Hgb distribution varied between 86% to 87% prior to SAM deployment and 87% to 95% after. There was a significant decrease in low Hgb numerix after SAM deployment, but no change in high Hgb levels, compared to the period before SAM deployment.

Conclusions: Individualized anemia management in pediatric patients improves distribution of Hgb within the target range, compared to a standard population-based protocol approach.

Funding: NIDDK Support

Extracorporeal Ultrafiltration Therapy for Acute Decompensated Heart Failure

Neeraj Pourashkar, Ashkan Karimi, Amir Kazory. Medicine, Univ of Florida, Gainesville, FL.

Background: There has been a renewed interest in the use of ultrafiltration (UF) for management of patients with acute decompensated heart failure (ADHF). While a number of studies reported on the efficacy of this therapy and lack of any significant adverse impact, the more recent trials have challenged its safety. The aim of this study is to provide a reappraisal of the current evidence on the use of UF in ADHF.

Methods: Articles cited in PubMed database from 2000 to 2015 using key words “ultrafiltration” and “heart failure” were searched. Those randomized and non-randomized trials using recent portable devices dedicated for UF were selected. Case reports, and case series were excluded. Relevant data such as renal function, cardiac status, and weight change were extracted and compared.

Results: A total 940 patients from 15 trials (7 randomized and 8 non-randomized) that used dedicated UF devices were included. Eleven studies reported either no change or non-significant decrease in serum creatinine, while 4 found worsening renal function after UF therapy; these studies had included patients with more severe renal dysfunction at baseline. Concerning weight, a reduction of 2 to 9 Kg was reported that was similar to conventional therapies in 9 studies but was significantly lower with UF in 6 trials. Length of stay was evaluated in 5 studies, 2 of which showed a significant reduction. Three studies showed fewer re-hospitalizations in the UF group at 30 days, 90 days, and 1 year follow ups. None of the studies evaluated long-term outcomes of patients undergoing UF therapy.

Conclusions: Based on the currently available data, UF is efficient for management of volume overload in ADHF. However, these studies do not support any beneficial impact for this therapy on renal function, and suggest that it might be associated with suboptimal renal outcomes if used for patients with more severe renal dysfunction at baseline. Currently there is no data on the effect of UF on long-term outcomes of patients with ADHF. Whether this would translate into a lack of effect for UF on these outcomes needs to be elucidated by future studies.

Ultra-Sensitive Troponin I Predictive Value in Remote Ischemic Preconditioning in Hemodialysis: A Randomized Double Blinded Clinical Trial

Marcelo Bacci,1 Lívia Yadova Vasconcelos, Felipe R. Bruniera, Filipê Moreira Ferreira, Neif Murad, Antonio Carlos palandri Chagas, Fernando Luiz yffonso Fonseca. ABC Medical School, Brazil.

Background: Remote ischemic cardiopreconditioning(RIPC) is a procedure that generates a brief period of ischemia followed by reperfusion Areas submitted to RIPC in the experimental ischemia models have less occurrence of necrosis. RIPC role in protecting myocardial ischemia during hemodialysis is not established yet.The aim of the study was to evaluate RIPC as myocardial protection achieved by ultra sensitive I troponin in hemodialysis outpatients.

Methods: It is a double blind randomised trial with two groups: intervention,submitted to RIPC with external compression in the right arm with sphygmomanometer with 200mm/Hg of pressure with three-5 minute rounds alternating with deflation totalising 30 minutes and control group without RIPC.Intervention group received RIPC in three consecutive hemodialysis sessions.Blood samples were taken before and after each session. Randomization was made by a software stratified by sex and age.BUN for calculation of single pool Kt/V and ultra sensitive I troponin were measured to evaluate dialysis adequacy and myocardial injury.

Results: A total of 47 patients were randomized.About 60.8% were men and 54% diabetic.The mean single pool Kt/V was 1.51 in the intervention group and 1.49 in control.
Racial Differences in the Evolution of Subclinical Cardiovascular Disease from CKD to ESRD: The CRIC Study  
Nisha Bansal,1 Jason Roy,2 Hsiang-Yu Chen,2 Alan S. Go,3 Martin Keane,4 Rajat Deo,5 Elyse Foster,1 Sankar D. Navaneethan,6 Jiang He,7 Mahboob Rahman,1 Mirela A. Dobre,8 John W. Kusek,9 Michael J. Fischer,10 Emile Mohler,11 Chi-yuan Hsu,12 1 UW; 2 UPenn; 3 Temple; 4 UCSC; 5 Case Western; 6 Tulane; 7 UH; 8 NIDDK; 9 UIC.

Background: Studies have reported that black incident dialysis patients have better survival compared with white dialysis patients, even after accounting for adverse profile of comorbidities among blacks. We hypothesized that differences in subclinical cardiovascular disease (CVD) may explain this paradox.

Methods: We studied incident dialysis patients in the CRIC study who had a research echocardiogram performed before and after the initiation of dialysis. Left ventricular mass index (LVMi) and ejection fraction (LVEF) were measured at CKD (mean eGFR 24 ml/min/1.73 m2) and at dialysis initiation (median 7.9 months after initiation).

Results: Of 316 participants, 74% were black and 26% were white. After initiation of dialysis, there were 88 deaths. In multivariable models, black (vs. white) race was independently associated with a 38% (95% CI: 1%, 61%) lower risk of mortality. From CKD to incident dialysis, mean LVEF worsened in whites (51±10% to 47±11%; p-value for change <0.0001) and blacks (52±9% to 48±10%; p=0.0001). LVMi trended worse in whites (54±16 g/m2 vs 57±15 g/m2; p=0.1) and significantly improved in blacks (61±16 g/m2 vs 58±15 g/m2; p<0.004). Adjusting for LVMi, change in LVMi, LVEF and change in LVEF did not change the association between black race and lower risk of death.

Conclusions: In CRIC, black dialysis patients had better survival than whites. This association was not explained by differences in subclinical CVD at incident dialysis or by differences in the evolution of CVD from CKD to ESRD. Further studies are needed to understand mechanisms underlying the differential survival by race among dialysis patients.

Whole Blood Viscosity at Low Shear Rate Is Associated with Cardiovascular Mortality in Patients with Hemodialysis  
Jong-Hwan Jung,1 Dong Hwan Lee,2 Young I. Choi,3 Kyung Pyo Kang,1 Sik Lee,3 Sung Kwang Park,1 Won Kim,4 1Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea; 2Dept of Mechanical Design Engineering, Engineering College, Chonbuk National Univ; Jeonju, Republic of Korea; 3Dept of Mechanical Eng. and Mechanics, Drexel Univ, Philadelphia, PA.

Background: The change of whole blood viscosity (WBV) may increase risk of major atherosclerotic events, including congestive heart failure, myocardial infarction, and stroke. However, there is few report about the relationship between WBV and mortality rate due to atherosclerotic vascular disease. The objective of the present study was to investigate correlation between values of WBV at shear rates of 1, and 5 S⁻¹ before and after hemodialysis in patients with end-stage renal disease (ESRD) and mortality, especially cardiovascular or cerebrovascular mortality.

Methods: Forty three patients with ESRD receiving maintenance hemodialysis had initially participated in this study. In a prospective observational study, we examined the effect of WBV in pre- or post-dialysis on cardiovascular or cerebrovascular mortality in dialysis patients for approximately 5.8 years.

Results: Twenty seven patients among total 43 patients died and 2 patients had received transplantation of kidney within period of this study.Cerebrovascular deaths occurred in 8 patients among 27 patients, and cerebrovascular deaths occurred in 5 patients among the 27 patients. The hazard ratios for overall survival in the patient with hemodialysis according to increase of predialylic diastolic WBV at low shear rate of 1 S⁻¹ in an univariate Cox proportional analysis were 1.585 (95% CI, P=0.382) in the group of moderate blood viscosity and 2.351 (95% CI, P=0.128) in the group of high blood viscosity. However, pre-DBV1 was not still statistically significant after adjustment for covariates. In addition, the HRs for overall survival according to increase of pre-DBV5 were 1.357 and 1.930 in each moderate and high blood viscosity group. In Kaplan-Meier’s survival analysis, when pre-DBV1 increased, cumulative mortality relatively showed rising tendency, but, unfortunately there was no statistical significance.

Conclusions: These results suggest that the diastolic low-shear WBV may impact on cardiovascular or cerebrovascular mortality in hemodialysis patients. New prospective and large-scaled studies to more exactly evaluate the correlation between WBV and mortality will be needed in the future.
Survival of Patients Over 75 Years Old in a Chronic Hemodialysis Program
Adriano Luiz Ammirati, Maria C.C. Andreoli, Fabiana Dias Carneiro, Thais Nemoto Matsu, Nadia Guimaraes-Souza, Bento C. Santos. Dialysis, Albert Einstein Hospital, São Paulo, Brazil.

Background: The intensity of medical care for people over 75 years of age has increased over the past decade. In this surrounding context is increasing the number of individuals with this profile that has clinical indication starting renal replacement therapy. Published studies have shown that survival of patients after initiation of hemodialysis (HD) according to the presence of comorbidities. The aim of this study was to evaluate the survival of elderly patients with chronic kidney disease on regular HD.

Methods: From analysis of medical records was assessed the rate of survival of incident patients starting HD in the months of January to December 2000 to 2010. Demographic and clinical data were collected. It was made a comparison, based on these data, among the elderly (over 75 years old) and non-elderly groups who died.

Results: During the study period, 158 patients started HD program, 69% male and 46% over 75 years old. The average age of patients was 60 years, all patients were adults. The overall mortality rates at 6 and 12 months were, respectively, 7.5% and 17%. Considering only the elderly, mortality rates at 6 and 12 months were respectively 14 and 27%. The median survival of these patients was 33 months. Considering only patients younger than 75 years mortality rates at 6 and 12 months were, respectively, 2% and 8%. Comparing elderly patients with non-elderly, we observed that the first group had a higher proportion of diabetic and hypertensive patients and with a history of cardiovascular disease and cancer. Considering only the patients who died, there were no important significant differences in the presence and score of comorbidities, when the elderly was compared with the non-elderly.

Conclusions: Patients over 75 years in HD had a mortality rate two times higher than younger patients and the presence of comorbidities may be a contributing factor to the age to explain this data.

Prevalence of Abnormal Ankle – Brachial Index in Haemodialysis Patients in Mexico and its Association with Other Cardiovascular Risk Factors
Laura E. Izguerra Ochoa, Heriberto Reyes López. Nefrología, Regional General Hospital #46, Guadalajara, Jalisco, Mexico.

Background: Abnormal Ankle-Brachial index (ABI), defined as ≤ 0.9 or ≥ 1.3, is considered an independent predictor of mortality in hemodialysis patients, in other countries abnormal ABI is found between 35% and 80% of hemodialysis patients. In Mexico the prevalence of abnormal ABI has not been reported. The aim of the study was to determine the frequency of abnormal ABI and its association with other cardiovascular risk factors.

Methods: Prevalent hemodialysis patients over 16 years old were included; data were obtained from medical records and interviews. ABI was measured by oscillometry (Model HEM-705CPINT) and classified as a normal result between 0.91 - 1.3 (NABI), ≤ 0.9 (LABI) or ≥ 1.3 (HABI). NAVI was considered as the control group and the data were analyzed using descriptive and inferential statistics, using T Student and Chi2.

Results: Of the 119 patients analyzed abnormal ABI was present in 36 (30%); 26 (21.9%) with HABI. The mean age was 44.9 years, 68% were male, duration of dialysis of 7.1 years. In univariate analysis ABI was significantly associated with smoking history (p<0.003), smoking history (p<0.001), diabetes (p<0.04), lower creatinine (p<0.001) and albumin (p<0.001) and higher calcium (p<0.01); HABI was significantly associated with lower age (p<0.01), smoking history (p<0.05), lower systolic blood pressure (SBP) (p<0.02), higher levels of sodium (p<0.04) and calcium (p<0.01). No differences were found between normal ABI and history of hypertension, dyslipidemia, heart disease, stroke; there were no differences with the dose of calcium carbonate or calcitriol, the value of Kt / V, the type of vascular access and serum phosphorus.

Conclusions: Abnormal ABI was less prevalent than in other populations, among these HABI is the most common. LABI was associated with older age, DM, smoking history, high calcium and low creatinine and albumin (probably associated with poor nutritional status). HABI patients were younger, with smoking history, lower SBP, high serum sodium and calcium levels.

PUB329
A Lower Serum Uric Acid Is Associated Not Only with All-Cause Mortality but Also Cardiovascular Mortality Among Patients Receiving Hemodialysis in Japan
Naoki Sugano, 1 Yukio Maruyama, Keitaro Yokoyama, Koki Takane, Yasuhiro Takahashi, Chisa Kobayashi, Shinichiro Nishio, 1 Daikusei Takahashi, Satoshi Kidoguchi, Kosuke Honda, 1 Northiko Morisawa, Gorou Tokudome, Iwao Ohno, Tatsu Hoosyota, Takashi Yokoo, 1 Takashi Shigematsu, Kunitoshi Iseki, 1 Ikuto Masakane. 2 1Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; 2Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.

Background: High level of serum uric acid is prevalent in chronic kidney disease (CKD), however it has a controversy whether high or low serum uric acid level appears to be a risk factor of cardiovascular event and mortality in the patients of receiving renal replacement therapy.

Methods: We collected the baseline data of 222,434 patients receiving HD thrice weekly (males: 63.0%, 66 ±12 years, median HD vintage of 60 months, females: 68 ±13 years, median HD vintage of 72 months) extracted from a nationwide dialysis registry at the end of 2011 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2012.

Results: During one-year follow-up, 18775 (8.4%) died of all causes including 8094 (3.6%) cardiovascular death. All-cause mortality and cardiovascular mortality were lower in the line with the increase of baseline uric acid. In a multivariable logistic regression analysis, patients of the highest quartile of uric acid had lower all-cause, and cardiovascular mortality compared with those of the lowest quartile (males: OR, 0.745; 95% CI, 0.673 to 0.8207, females: OR, 0.833; 95% CI, 0.726 to 0.9366, and males: OR, 0.720; 95% CI, 0.6266 to 0.8278, females: OR, 0.8375; 95% CI, 0.7029 to 1.0462, respectively).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: In this large observational cohort study, lower levels of serum uric acid were independently associated not only with all-cause mortality but also cardiovascular mortality among Japanese HD patients. Close monitoring of serum uric acid is thought to be necessary for the management of HD patients.

*Post Stroke Disability Deterioration and Mortality of Hospital Onset Stroke in Patients with and without End-Stage Renal Disease*  Tomoko Usui,1 Norio Hanafusa,1 Hideo Yasunaga,2 Masaomi Nagakuni.1 1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, the Univ of Tokyo, Japan.

**Background:** Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including diastolic treatment and disability deterioration and mortality during the hospital stay of hospital onset stroke.

**Methods:** The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age ≥20 years old, hospital-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Deterioration of disability was defined as an increase in disability level. The odds ratio (OR) for in-hospital deterioration of disability and mortality was calculated using a logistic regression model.

**Results:** Out of 26,834 patients, 593 (2.2%) had diastolic therapy. The median length of stay was 39 and 33 days for patients with and without diastolic, respectively. During the hospital stay, there were 7,655 (28.5%) disability deterioration and 3,851 (14.4%) death. The patients with diastolic had higher disability deterioration (47.9%) and mortality rate (31.3%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antithrombotic, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of diastolic for disability deterioration was 2.88 (95%CI: 2.40-3.45), and in-hospital mortality was 3.57 (95%CI: 2.94-4.33).

**Conclusions:** Diastolic treatment was an independent risk factor for in-hospital disability deterioration and mortality of hospital onset stroke.

*Role of Bioimpedance as Tool for Fluid Management in Hemodialysis Patients*  Maria Cecilia Recalde,1 Manuela Bello,1 Cecilia Arruabarrena,2 Alvaro Herou,1 Fabian Cano,1 Laura Sola,1,2 1Hemodialysis Unit, CASMU, Uruguay; 2Preventive Medicine, Univ of the Republic, Uruguay.

**Background:** Fluid management in hemodialysis patients is difficult, hypertension and fluid overload is frequent as well as hypotensive episodes leading to cerebral and cardiac injury and increased mortality risk. The objective of the study is to evaluate if bioimpedance could be a tool to optimize fluid management in hemodialysis patients.

**Methods:** Patients were included after giving informed consent when fulfilled inclusion and exclusion criteria. Were recorded age, gender, diabetes status, dialysis vintage, body mass index (BMI) estimated dry weight, and mean in previous month: systolic blood pressure and was prescribed more number of other antihypertensive drugs than control group. After matching, there were no differences in age, sex, dialysis modalities, comorbidities and number of other antihypertensive medications. Before PSM, patient survival was significantly better in the RAAS group using the Gehan-Wilcoxon test (P=0.001), however, this difference disappeared after matching (P=0.450). Cardiovascular event-free survival was not different between RAAS group and control group before and after PSM analysis.

**Conclusions:** RAAS blockade did not affect all-cause mortality and MACE-free survival in the Korean ESRD patients. Further researches such as randomized control study will be needed.

**PUB333**

*Effect of Renin Angiotensin Aldosterone System Blockade on Clinical Outcomes in Patients with End-Stage Renal Disease: A Prospective Cohort Study in Korea*  Kyung Don Yoo,1 Jung Pyo Lee,1 Jung Nam An,1 Yun Kyu Oh,1 Shin-Wook Kang,1 Chul Woo Yang,1 Yong-Lim Kim,1 Chun Soo Lim,1 Yon Su Kim.1 1Seoul National Univ College of Medicine; 2Yonsei Univ College of Medicine; 3The Catholic Univ of Korea College of Medicine; 4Kyungpook National Univ School of Medicine.

**Background:** Adequate blood pressure control plays a key role in the management of patients with end-stage renal disease (ESRD). Although renin angiotensin aldosterone system (RAAS) blockade is known as the best treatment option for chronic kidney disease with hypertension, there is debate in the ESRD patients maintaining dialysis.

**Methods:** A total of 5,223 patients in the Clinical Research Center for ESRD (CRC for ESRD) prospective observation cohort from Aug 2008 to Dec 2014 were enrolled in this study. We compare overall survival and major cardiovascular event (MACE)-free survival between RAAS group and control group for using 1:1 propensity score matching (PSM) analysis. We defined the RAAS group as using ACE inhibitor or angiotensin receptor blocker more than 3 months.

**Results:** Before matching, the RAAS group was younger; however, had more comorbidities such as diabetes and cardiovascular disease. The RAAS group had higher systolic blood pressure and prescribed more number of other antihypertensive drugs than control group. After matching, there were no differences in age, sex, dialysis modalities, comorbidities and number of other antihypertensive medications. Before PSM, patient survival was significantly better in the RAAS group using the Gehan-Wilcoxon test (P=0.001), however, this difference disappeared after matching (P=0.450). Cardiovascular event-free survival was not different between RAAS group and control group before and after PSM analysis.

**Conclusions:** RAAS blockade did not affect all-cause mortality and MACE-free survival in the Korean ESRD patients. Further researches such as randomized control study will be needed.

*Hemodynamic Changes in Maintenance Hemodialysis Patients with Intradialytic Hypotension*  Meijun Meng, Hong Ye, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

**Background:** Intradialytic hypertension (IDH) is a common complication in patients undergoing maintenance hemodialysis (MHD) which leads to high mortality. This study is to explore the hemodynamic changes in MHD patients with IDH.

**Methods:** Thirty-seven patients were included in our study. IDH were defined as a decrease of systolic blood pressure (SBP)<20mmHg or the lowest SBP below 90 mmHg during dialysis. Twenty-three patients were diagnosed with IDH. Among them, 13 were...
asymptomatic while the other had the hypotensive symptoms, such as abdominal discomfort, sighing, nausea, vomiting, muscle cramps and restlessness. All of them underwent a noninvasive hemodynamic evaluations before, during and after dialysis.

Results: Compared to the patients without IDH, the dialysis age was longer and the prevalence of diabetes was higher in the patients with IDH. There were no difference in age, amount of ultrafiltration, pre-dialysis cardiac index (CI), systemic vascular resistance index (SVRI) and thoracic fluid capacity (TFC) between these two groups. During dialysis, CI decreased while SVRI increased generally especially in patients with IDH. At the end of dialysis, ΔCI was markedly higher in patients with IDH. However, there was no significant difference in the change of CI, SVRI and TFC ten minutes before and after hemodialysis between these two groups. Meanwhile, the hemodynamic changes were analyzed in IDH patients with or without symptoms. It was found that there were no difference of change values and absolute values of CI and SVRI in these subgroups.

Conclusions: It was found that CI decreased while SVRI increased during hemodialysis. In the mid and later period, the CI decreased much more in patients with IDH. It was suggested that CI might be an indicator of IDH.

Dual Relationships of Serum Leptin on Heart Rate Variability in Patients with Stage 5 Chronic Kidney Disease Ningning Wang, Yao Jiang, Jingjing Zhang, Changying Xing. Nephrology, First Affiliated Hospital of Nanjing Medical Univ; Nanjing, China.

Background: Leptin regulates nutrition, bone metabolism and cardiovascular function. Lower heart rate variability (HRV) in chronic kidney disease (CKD) predicts higher risk of cardiovascular disease (CVD). Relationships between leptin and HRV in CKD is obscure.

Methods: This study included cross-sectional observation and longitudinal follow-up on parathyroidectomy (PTX) patients.

Serum leptin/BMI is transformed using natural logarithm (ln [leptin/BMI]).

Results: In PTX/BMI showed no difference between stage 5 CKD and controls. However, quartile 2 of ln [leptin/BMI] level in CKD patients prone to have higher HRV indices

PUB336

Association of Geriatric Nutritional Risk Index and Responsiveness to Erythropoiesis-Stimulating Agent in Mortality of Chronic Hemodialysis Patients Kosaku Nitta, Ken Tsuchiya. Dept of Medicine, Tokyo Women’s Medical Univ, Shinjuku-ku, Tokyo, Japan.

Background: Responsiveness to erythropoiesis-stimulating agent (ESA) may be associated with mortality in hemodialysis (HD) patients. The aim of the present study was to assess the effects of geriatric nutritional risk index (GNI) and responsiveness to ESA in outcome in HD patients.

Methods: The ESA response index (ERI) was determined as the weekly weight-adjusted dose of ESA divided by hemoglobin concentration. Patients were divided into four groups by quartiles of ERI. Odds ratios were estimated using a Cox proportional model for the association between GNI and ERI and mortality, adjusting for potential confounders. Patients were divided into four groups by quartiles of ERI.

Results: Of the 298 subjects enrolled, 51 died with 31 cardiovascular deaths during the follow-up period of 34.6 ± 6.1 months. The ERI was inversely correlated with the GNI (r = 0.287; p < 0.0001). Age, gender, serum total cholesterol, phosphorus, total phosphorus, and albumin were independent predictors of ERI. Older age, female gender, serum total cholesterol, transferrin saturation and GNI were independent predictors for ESA hyporesponsiveness. Receiver operating confidence intervals for the cut off values of GNI and ERI for mortality were 94.9, 13.5, respectively. When subjects were stratified by ERI and GNI value into four groups, those who had low GNI and high ERI were associated with the highest risk of mortality among the four groups (log-rank p < 0.001).

Conclusions: High ERI and low GNI were associated with an increased risk of all-cause mortality.

PUB337

A Multidisciplinary Approach Is Required to Reduce Hospitalizations for Cardiovascular Disease in Maintenance Hemodialysis Patients David L. Epstein,1,2 Thomas Parker,1,2 Daniel Levine,1,2 Jeffrey I. Silberzweig,1,2 Medicine, The Rogosin Inst, New York, NY; Medicine, Weill Cornell Medical College, New York, NY.

Background: Patients receiving maintenance hemodialysis have hospital admissions rates significantly greater than patients with other chronic diseases.1,2 Approximately 40% of the hospital admissions are related to cardiovascular disease including both acute events and pulmonary edema.1 We sought to assess the contribution of fluid weight gains to hospital admissions.

Methods: We compared inter-dialytic weight gains as a percentage of target weight and changes in blood pressure for the approximately 1200 patients receiving maintenance hemodialysis in our seven dialysis clinics in New York City between January and April 2015. We compared these data to total and cardiovascular hospital admissions using t-tests.

Results: Greater relative weight gains were significantly associated with pre-treatment systolic blood pressure (2.7 mmHg increase in BP per 1% increase in weight; p < 0.0001) and hospitalizations for cardiovascular complications (p = 0.03). In contrast, neither greater relative weight gain nor pre-treatment systolic blood pressure was significantly associated with all-cause hospitalization (p > 0.5). The clinic with both the greatest relative weight gains and the highest rate of hospitalization for cardiovascular disease was without a full-time dietitian for the months of the study.

Conclusions: In our population of maintenance hemodialysis patients, we report a statistically significant association between relative weight gains, hypertension and hospitalization for cardiovascular disease. We suggest that this relationship may be related to the absence of a full-time dietitian leading to a lack of a true multidisciplinary team approach to fluid management in these patients. Acute Effects of Cinacalcet on Arterial Stiffness and Ventricular Function in Hemodialysis Patients Mohsen Agharazii,1 Kosaku Nitta,2 Carolina Marin-Blanco,1 INTRODUCTION Chestnut P, Emery C, Leslie K, Billings J, Parent L, Timmons B, York E, Wu J, Chu C, Asano M, Families, Fondation, Children, M. CHU de Quebec Research Center, Dept of Medicine, Tokyo Women’s Medical Univ, Shinjuku-ku, Tokyo, Japan. A Multidisciplinary Approach Is Required to Reduce Hospitalizations for Cardiovascular Disease in Maintenance Hemodialysis Patients...
m/s, p<0.139). In 14 subjects, who underwent echocardiography, there were no significant changes in cardiac output, stroke volume and ejection fraction. However, left ventricular end-systolic volume (52 ± 22 versus 57 ± 25 ml (p=0.20) and end-diastolic volumes (92 ± 35 versus 97 ± 17, p=0.08) were numerically higher under cinacalcet, but not statistically significant. There were no significant changes in the parameters of diastolic dysfunction.

Conclusions: In this short term study, there were no detectable effects of cinacalcet on aortic stiffness and diastolic dysfunction despite the expected reduction in serum calcium concentration. The numerically higher left ventricular volumes with cinacalcet, may need to be investigated. Clinical trials: NCT01250405.

Kidney Transplantation and Cardiac Repolarization Descriptors

Dimitrios J. Poulikakos,1 Debashish Banerjee,2 Marek Malik,1 Renal, Salford Royal, United Kingdom; St. George’s Univ of London, United Kingdom; Imperial College, London, United Kingdom.

Background: Selected descriptors of cardiac repolarization derived from the computerized analysis of electrocardiogram (ECG) can predict cardiac risk in hemodialysis (HD) patients. Kidney transplantation improves cardiovascular survival. The aim of the study was to investigate the impact of kidney transplantation on these descriptors.

Methods: The study was conducted in two phases. In phase 1, Holter ECGs were obtained during HD sessions and repeated 5 times at 2-weeks intervals in stable HD patients. The repolarisation descriptors QRS-to-T angle (TCRT) and T wave morphology dispersion (TMD) were calculated in overlapping 10 second ECG segments and averaged over the first hour of recordings. In phase 2, continuous 1-hour ECG recordings were obtained in patients who received a kidney transplant minimum three months after transplantation and if they were stable with EGFR>30 ml/min/1.73m2. Average values of post transplant repolarisation descriptors were compared with average values over the first hour of HD using Wilcoxon test and t-test was used for baseline comparisons.

Results: In 80 HD patients in phase 1 both descriptors showed intrasubject stability and exhibited extreme values in subjects that suffered major arrhythmic events. During a period of 35.9±3 months 10 eligible transplanted subjects were recorded and although TMD and TCRT improved 7 months following kidney transplantation (see table) the difference did not reach statistical significance (p=0.05). However these subjects had better baseline TCRT and TMD values compared to the study population (TCRT 0.463 vs. 0.078 p < 0.05 and TMD 17.9 vs 32.4 p>0.05).

Conclusions: In transplant recipients with healthier baseline repolarisation profiles the improvement did not reach statistical significance in the early post transplant period. Larger studies with longer follow up are needed.

PUB340

Prognostic Significance of Cardiopulmonary Exercise Test and 6-Minute Walk Test in Chronic Dialysis Patients

William Dziubek,1 K. Bulinska,2 B. Ochman,1 Ukasz Rogowski,1 Mariusz Kuształ,2 Tomasz Golebiowski,2 D. Markowska,1 A. Zembron-Lacny,1 Marian Klinger,3 M. Wozniewski,3 Imperial College, London, United Kingdom; Univ School of Physical Education, Wroclaw, Poland; 3Non-Public Medical College of Wroclaw, College, Wroclaw, Poland; 4Nephrology and Transplantation Medicine, Wroclaw Medical Univ, Wroclaw, Poland; 5Physical Education, Univ of Zielona Gora, Zielona Gora, Poland.

Background: Dialysis patients (pts) are burdened by significant morbidity and the majority of deaths result from cardiovascular causes. Identifying patients with an increased risk of ominous prognosis is of essential clinical relevance. The aim of the study was to evaluate prognostic value of cardiopulmonary exercise test (spiroergometry) and 6-minute walk test (6MWT) in chronic dialysis pts.

Methods: In prospective study 90 pts receiving high-flux dialysis (12h/week) were examined by means 6MWT and spiroergometry (VO2max, VE, VO2CO2, METS). After 3 years of follow-up data were evaluated in term to assess prognostic value of physical performance tests. Patients were divided into 2 groups: survivors and non-survivors (died within 3 years).

Results: Mortality at 3 years was 22.2% (20 pts) – non-survivors. They showed significantly lower values in cardiopulmonary exercise test and achieved shorter distance in 6 MWT compared to survivors – table. In multivariable analyses controlling for age, and sex and low dided distance in 6 MWT was significantly correlated with all lower measures of spiroergometry (r=0.5-0.6). VO2max and 6 MWT were independently (from age) associated with death within 3 years.

Adaptive Servo-Ventilator Therapy Improves the Cardiac Dysfunction in Hemodialysis (HD) Patients with Sleep-Disordered Breathing

Fumiko Fukuuchi,1 Ken Tsuchiya,2 Kosaku Nitta.3 Nephrology, Komagome Kyuritsu Clinic, Bunkyo-ku, Tokyo, Japan; 2Medicine II, Tokyo Women’s Medical Univ, Shinjyuku-ku, Tokyo, Japan.

Background: Cardiac dysfunction is a very serious problem in HD patients. Sleep Disordered Breathing (SDB) is considered to cause cardiac dysfunction. Dialysis patients have a disordered respiratory center and a high prevalence of central apnea. Adaptive Servo-Ventilator (ASV) is automated modality used to treat heart failure patients with SDB, especially central apnea. The aim of this study is to explore the relationship between sleep apnea and cardiac dysfunction, and to evaluate the effects of ASV therapy in HD patients.

Methods: Sleep study was performed using a portable sleep test device (Sleeptester LS-300, Fukuda Denki Co., Ltd, Japan). We measured the variables of cardiac function by echocardiogram. The relation between apnea index and the echocardiogram indicates was evaluated. We also collected baseline information on demographics, lab tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Results: The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) were included in this study. Out of them, echocardiogram, SDB indications showed a connection. The obstructive apnea hypoxemia index was related to the left ventricular posterior wall thickness (LVPWT) (r=0.49, p=0.02). Seven patients received ASV therapy. There has been improvement of overall of their cardiac function with significant increase of ejection fraction (p=0.02) 1 year after ASV introduction.

Conclusions: In this study, we demonstrated the efficacy of ASV therapy in hemodialysis patients with SDB. Near future, ASV is possible to be one of attractive devices for HD patients, with aging, several complications, to improve their poor prognosis.

PUB342

Endovascular Renal Denervation: Effects on Dyslipidaemia and Vascular Inflammation in Dialysis Patients

Neil A. Hove,1 J. Christopher Baldi,1 David L. Jardine,1 John B. Scholllum,1 Gerard T. Wilkins,1 Luke C. Wilson,2 Robert J. Walker,1 Dunedin School of Medicine, Univ of Otago; 2Christchurch School of Medicine and Health Sciences, Univ of Otago.

Background: Endovascular renal denervation (RDN) reduces arterial and effluent sympathetic nerve activity. Its effects on vascular inflammation and cholesterol levels in dialysis patients are unknown. We hypothesized RDN would reduce sympathetic activity, resulting in improvement in biomarkers of vascular inflammation and dyslipidaemia.

Methods: Nine dialysis patients with uncontrolled office BP (>140/90mmHg despite two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA) and venepuncture. Bilateral RDN was undertaken with an EnligHTN™ catheter.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Background: Hemodialysis practice varies based on health system, payer practice, patient choice and socioeconomic environment. We analyzed the practice pattern and characteristics of non survivors and survivors among twice weekly hemodialysis patients across 9 centers in India.

Methods: Retrospective study of patients on HD between July 1, 2013 to Dec 31, 2014. Inclusion criteria: > 30 days of HD & 1.8 - 2.3 HD sessions/week. Demographic data, the use of OAC, were included in the study. Thyroxine-3 (T3), free thyroxine-4 fT4, Thyroid Stimulating Hormone (TSH), and Thyroid Peroxidase Antibodies (TPO-Ab) were measured. Data was presented as non survivors vs survivors: Hospitalizations: 42.6% vs 25.8% (<0.01), DM: 65.2% vs 34.5% (<0.01), CAD: 17.5% vs 6.4% (<0.05), CV A: 1.8% vs 2.3%; HCV: 1.8% vs 10.9% (p<0.05), Office Systolic BP (mmHg) 90±17 vs 76±13, Office Diastolic BP (mmHg) 173±19 vs 173±23, Total Protein (g/L) 66±6.1 vs 68±8.2, CRP (mg/L) 27±28 vs 20±20, Albumin (g/L) 3.8±5.0 vs 3.9±6.3, Chol (mmol/L) 4.1±0.9 vs 4.1±1.0, HDL Chol (mmol/L) 1.2±0.3 vs 1.2±0.2, LDL Chol (mmol/L) 2.2±0.7 vs 2.4±0.9, Triglycerides (mmol/L) 1.4±0.8 vs 1.2±0.6. Conclusions: RDN in dialysis patients improves office systolic BP, impacts uraemic dyslipidaemia and possibly reduces vascular inflammation. Further controlled studies are warranted.

PUB343

Management of Subclinical Thyroid Dysfunction Can Reduce Cardiovascular Events in Patients with End-Stage Renal Disease on Hemodialysis Hong Joo Lee, Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Republic of Korea.

Background: Normal thyroid function influences basal metabolic rate and general body metabolism and thyroid dysfunction is often associated with dyslipidemia and increased cardiovascular risk in general population. It is known that about 25% of patients with end-stage renal disease (ESRD) on hemodialysis had subclinical thyroid dysfunction. We investigated that subclinical hypothyroid dysfunction associate with dyslipidemia and cardiovascular event in hemodialysis patients. Hence, we conducted our study to elucidate whether subclinical thyroid dysfunction treated or not in ESRD patients.

Methods: All hemodialysis patients in Red Cross Hospital within a period of one year were included in the study. Thyroxine-3 (T3), free thyroxine-4 fT4, Thyroid Stimulating Hormone (TSH) and lipid profiles in the serum were estimated and death from all causes and CV events served as outcome variables over a median follow-up period of 12 months. Participants were divided into groups based on the thyroid function. Statistical analysis was carried out by using SPSS.

Results: Among the 92 cases, 28.2% of the patients were having thyroid disorder. In which 21.2% were of hypothyroid, 13.7% were of subclinical hypothyroid, and 0.8% were of hyperthyroid, 11.6% were of subclinical hyperthyroid. We observed negative correlation between T3 & T4. Total cholesterol was raised in hypothyroidism in comparison to euthyroid ESRD patients. However, thyroid function didn’t have significant association with lipid profiles. Cardiovascular disease significantly often occurred in subclinical thyrotoxic patients than other groups.

Conclusions: Our results show that the blood thyroid hormone level isn’t affected by dyslipidemia but affected by occurrence of CVD. Therefore, the management of subclinical hypothyroidism in hemodialysis patients should be considered.

Non survivors were significantly older, had lower number of total sessions, lower albumin and Hb. But dialysis adequacy and UF were comparable. Short duration of follow up may limit the ability to study other factors influencing outcomes.

PUB344

New Anticoagulant Free Strategy for Non Valvular Atrial Fibrillation in Hemodialysis Patients Teresa Arcidiacono, Patrizio Mazzone, Marco Simonini, Donatella Spotti, Maria Teresa Sciarri Alibrandi, Rita Quartagno, Marco Melandri, Stefano Tenitori, Giorgio Slaviero. San Raffaele Scientific Inst, Italy.

Background: Vascular calcification in patients with CKD-5 is associated with increased cardiovascular morbidity and mortality. An excessive calcification of coronary arteries and of aortic valve has been reported during Warfarin treatment. In addition use of oral anticoagulation (OAC) seems to be an important risk factor for calciphylaxis. Atrial fibrillation (AF) is the most frequent reason for OAC use in CKD patients.

Methods: An alternative to OAC could be the percutaneous Left Atrial Appendage Closure (LAAC) closure. With this technique an implantable component is permanently fixed in the LAA to prevent thrombus embolization. Different studies demonstrated that this procedure is not inferior to systemic anticoagulation with OAC in prevention of thromboembolic risk. We reported our clinical experience with the use of this technique in haemodialysis patients with non valvar AF.

Results: In the last few months seven (7) haemodialysis patients were treated with percutaneous LAA closure. Bleeding and stroke risks were evaluated by HAS-BLED score and CHA2DS2-VASc score: HAS-BLED score was 4.5±0.58 (equal to 9%/±0.11 yearly risk of major bleeding); and CHA2DS2-VASc score was 4.1±0.81 (equal to 4.47%/±1.5 yearly risk of stroke). This procedure was well tolerated by each patient. OAC treatment was interrupted after the procedure and doubled antiplatelet therapy was introduced for a month. At this moment median of 9 months of follow-up was archived (IQR 3-12); no adverse events has been assessed.

Conclusions: To the best of our knowledge this is the first consecutive series of LAA closures in haemodialysis patients. This procedure represents a real clinical alternative to the use of coumarin derived drugs. Our experience leads the way to the possible routine use of this procedure in CKD-5 patients. As well as this procedure could be used in those patients with contraindications to OAC, even more this treatment should be used in haemodialysis population, in which the use of OAC should be avoided for both increased risk of life-threatening bleeding events and well known negative cardiovascular effects.

PUB345

Results: Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, total cholesterol-HDL ratio increased along with a falling trend in CRP and rising trend in albumin, all novel findings.

Conclusions: MSNA may impact on arterial stiffness and cardiovascular disease. This study further adds to the evidence that office BP and ABPM are different, with ABPM being the better predictor of cardiovascular disease.
Effect of Altitude on All-Cause Mortality in End-Stage Kidney Disease Patients Ongoing Hemodialysis in Peru

Katia Bravo-Jaime,

Vicky Y. Sunicion,

Jose Ernesto Rojas,

Christian R. Mejia,

Sandra C. Schult.

Medicine, Univ of Rochester Medical Center, Rochester, NY; Medicine, Jackson Memorial Hospital, Miami, FL; Inst de Investigaciones de Altura, Univ Peruana Cayetano Heredia, Lima, Peru; Asociacion Medica de Investigacion y Servicios en Salud, Lima, Peru; Pediatrics, Inst Nacional de Salud del Niño, Lima, Peru.

Background: Worldwide, end-stage kidney disease (ESKD) prevalence has tremendously risen. Previous studies suggested that receiving hemodialysis (HD) at high altitude confers mortality benefits; however this effect has not been proved above 2000 m or in developing countries.

Methods: This historical cohort study analyzed medical records from six HD centers of the Peruvian Social Security System. Adult ESKD patients who started HD between 2000 and 2010 were included. Patients were classified into two strata (< 2000 m and > 2000 m). The outcome variable was death from any cause. Cox proportional hazards models were built and patients were censored by year and death from any cause. Stratification by year was included. Patients were classified into two strata (< 2000 and > 2000 m). The period prevalence for the patients undergoing renal dialysis was 52 patients per 100,000. The mortality rate for the same period of time was four patients per 100,000. The expenditure on these 380 patients in 2014 was 6.5 million dollars. However, to determine the size of the burden, we need a comprehensive study covering the whole country of Oman and we need to receive data from neighboring countries to compare with.

Conclusions: In Peru, patients receiving HD at high altitude do not experience mortality benefits. In fact, diabetics have higher mortality rates at > 2000 m (p = 0.003), independently of age.

Conclusions: In Peru, patients receiving HD at high altitude do not experience mortality benefits. In fact, diabetics have higher mortality rates at > 2000 m.

Follow up in years

p = 0.001

Results: 723 patients were enrolled, including 248 women (38.2%). The mean age was 52.8 ±16.9 years. 166 patients lived > 2000 m (22%). In first years after follow-up, survival rates were lower in the group > 2000 m, however after 8 years of follow-up this trend reversed. Age and gender were not significantly associated to mortality at altitude levels > 2000 m. Patients with diabetes had higher mortality rates at > 2000 m (p = 0.003), independently of age.

Conclusions: In Peru, patients receiving HD at high altitude do not experience mortality benefits. In fact, diabetics have higher mortality rates at > 2000 m.

Depression Is Associated with Frailty and Malnutrition but Not Comorbidity Load in Chinese Peritoneal Dialysis Patients Cheuk-Chun Szeto,1 Shin Man Choy.2 1Dept of Medicine & Therapeutics, The Chinese Univ of Hong Kong, Shatin, Hong Kong; 2Dept of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.

Background: Depression is common amongst patients with chronic kidney disease and is associated with excessive mortality in dialysis patients. This study determines the prevalence and risk factors of depression in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalent PD patients (103 males). Depression was screened by the 15-item self-reported Geriatric Depression Scale (GDS). We also determined patients’ comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average GDS score was 4.9 ± 4.4. GDS score is closely associated with the frailty score (r = 0.692, p < 0.0001), malnutrition inflammation score (r = 0.406, p < 0.0001), and subjective global assessment score (r = -0.386, p < 0.0001). GDS score also has a modest but significant correlation with Charlson’s comorbidity index (r = 0.164, p = 0.028) and serum albumin level (r = -0.192, p = 0.019), but not with patient age, vintage of PD, dialysis adequacy, or residual renal function. When defined as a GDS score ≥8, 50 patients were introduced in multivariate analysis: HD/HDF*, vintage, age*, weight, CCI*, use of EA.

Results: Table 1 shows the association between depression and various parameters.

Conclusions: In an aged Western dialysis population, treatment with HDF did not improve all-cause mortality compared to high-flux HD. Mortality seems to be determined by comorbidity rather than by clinical practice patterns.

Trends in anemia management with Darbepoetin Alfa on Maintenance Hemodialysis Robert H. Yenchek,1 Anne C. Beaubrun,2 Jeffrey Petersen,3 David G. Dalpiaz,4 Alfred K. Cheung.1 1Univ of Utah, Salt Lake City, UT; 2Ameren, Inc., Thousand Oaks, CA.

Background: In the US, darbepoetin alfa (DA) is primarily used to treat anemia in patients receiving treatment in hospital-based dialysis centers. Epoetin alfa (EA) doses and hemoglobin (Hb) levels declined in response to recent regulatory and reimbursement events but little is known about trends in anemia management with DA in the US maintenance hemodialysis (HD) population receiving treatment in free-standing dialysis centers (FSDCs). We describe herein anemia management in FSDCs within the University of Utah (UU) Dialysis Program who switched from the use of EA to DA program-wide in 2005.

Methods: We included ~650 adults (age ≥18 yrs) with ≥1 months on HD between 2008-2013 in 18 FSDCs within the UU Dialysis Program. We summarized quarterly inpatient and HD and iron dose use, and dialysis transferrin saturation (TSAT) and ferritin levels.

Results: 70-78% of patients received DA over the study period. Mean Hb levels among patients who received DA fell from 12.2 g/dL in 2008 before leveling around 10.3 g/dL from Q4 2011 to 2013 (Figure). The mean monthly DA dose was 209 mcg in Q1 2008, reached a peak of 256 mcg in Q1 2010, and decreased to ~105 mcg in 2013. Iron dose use rose from 52% in 2008 to 67% of patients in 2013. Iron dose also rose from 129 mg in Q4 2008 to 194 mg in Q4 2010, but declined to 163 mg in Q4 2013. Mean serum TSAT levels remained relatively constant at ~30% between 2008-2013 but serum ferritin levels increased from 449 ng/mL in Q1 2008 to 770 ng/mL in Q4 2013.

Conclusions: Trends in anemia management parameters among patients on HD treated with DA within FSDCs in the UU Dialysis Program were consistent with national reports of patients treated with EA.
A Prospective Study of Routine Heparin-Free Hemodialysis (HFD) with Streamline® Bloodlines (SL) in a Large Tertiary Acute Care Inpatient Practice Sami Safari,1 Mary Ann Ryan,2 Amanda L. Severson,3 Scott Klarenbach,1 Anita Molzahn,1 Mark Haykowski,1 Anita Lloyd,1 Marcello Tonelli,2 1Univ of Alberta, Edmonton, AL, Canada; 2Univ of Calgary, Calgary, AB, Canada.

Background: Intradialytic exercise (IDE) is associated with improved dialysis adequacy and amelioration of dialysis-related symptoms. However, the uptake of IDE is limited by knowledge gaps on efficacy—what type of exercise to prescribe to optimize outcomes, and on feasibility. The results of this pilot will inform the design of a full-scale efficacy study evaluating two types of IDE (aerobic and resistance) and will also provide research users with practical information on IDE.

Methods: In this single center, randomized, factorial (2 x 2) study, chronic adult hemodialysis patients were randomized to one of four IDE groups: cycling, resistance, cycling and resistance, or stretching (an attention control). Exercise was semi-supervised by a kinesiologist. Outcomes focused on a priori feasibility criteria: recruitment, fidelity to the protocol, and participant and unit staff response to IDE. As a secondary outcome, we evaluated the main effect of cycling and weights each compared with control on quality of life and physical performance at baseline and 12-weeks. To better understand feasibility, we conducted interviews with users.

Results: We exceeded targeted accrual of 28 people over 12 weeks. Of 100 patients screened, 51 were enrolled (36 did not meet inclusion criteria, 33 declined participation); 16% dropped out after randomization. Fidelity to the intervention was high: of 1,039 training sessions offered, 87% were delivered. Participant response to the intervention was favorable: 92% of participants continued exercising after the trial. There were no crossovers and no reported contamination. Dialysis staff were not consistently available to assist with implementation, so staff were necessary to deliver IDE. Secondary outcomes were not statistically significant.

Conclusions: This pilot study demonstrated feasibility of high patient acceptability, and low risk of contamination. However, IDE will not be feasible in the long term unless dialysis staff assist with implementation. This will need to be addressed before executing a definitive trial.

Patterns of Oral Disease in Adults with Chronic Kidney Disease Treated with Long-Term Hemodialysis: A Multinational Ecological Study Giovanni F.M. Strippoli,1,2,3,4,5 On behalf of the ORAL-D Study Investigators;2 Diaverum Medical Scientific Office; 3Univ of Bari; 4Univ of Sydney.

Background: Oral disease is a potentially treatable risk factor for premature death and impaired quality of life. However, the oral disease burden and candidate preventative strategies are uncertain in the dialysis setting.

Methods: ORAL-D was a prospective study in 4726 adults treated with hemodialysis in Europe and Argentina recruited from a convenience sample of 80 dialysis clinics within a treatment network. Oral disease was assessed using standardized WHO methods. Participants self-reported oral health practices and symptoms. Socio-demographic and clinical factors associated with oral diseases were assessed within nation states.

Results: Of 4726 eligible adults from 80 dialysis units, 4205 (88.9%) participated. Overall, 20.6% were edentulous (95% CI, 19.4-21.8). Participants had on average 22 (21.7-22.2) decayed, missing or filled teeth while moderate to severe periodontitis affected 40.6% (38.9-42.3). Oral disease patterns varied markedly across countries. Participants in Spain, Poland, Italy and Hungary had the highest mean adjusted odds of edentulism (2.31, 1.90, 1.90, and 1.54) whilst those in Poland, Hungary, Spain and Argentina had highest odds of ‘14 decayed, missing, and filled teeth (23.2, 12.5, 8.14, 5.23). National levels of tobacco consumption (R²=0.79), diabetes (R²=0.49), and child poverty (R²=0.66), were associated with edentulism within countries.

Conclusions: Oral disease in adults on hemodialysis is very common, frequently severe, and highly variable among countries, with much of the variability unexplained by patient characteristics or oral practices. Given the substantial variation among countries and high burden of disease, strategies to improve oral health in hemodialysis patients will require national strategies.

PUB356
Low Serum Albumin Is a Risk Factor for In-Hospital Mortality Among Hemodialysis Patients Hospitalized with Infectious Diseases: A Multicenter Retrospective Cohort Study in Japan Shun Minatozumi,1,2 Hideaki Shimizu,1,2 Takaya Ozeki,1 Daisuke Uchida,2 Hiroko Kawarazaki,1 Hiroti Nishiwaki,2 Takahiro Imaizumi,2 Yoshito Fujita,2 Yugo Shibagaki,2 1Nephrology, Chubu Rosai Hospital, Nago-yama, Ichinomiya, Japan; 2TOMEI Nephrology Group for Clinical Research, Japan.

Background: Serum albumin is the known marker of nourishment and inflammation. Several studies in the past have shown the relationship between low serum albumin and long-term mortality among dialysis patients. However, there is insufficient data on the

Funding: Pharmaceutical Company Support - Medisystems, a NxStage Company
The relationship between serum albumin levels and short-term mortality among chronic dialysis patients who are hospitalized with infectious diseases. This multicenter retrospective cohort study in Japan evaluated if serum albumin levels at the occurrence of infection is a risk factor for in-hospital mortality among hemodialysis patients.

Methods: From June 2011 to July 2013, a total of 418 hemodialysis patients who took blood cultures were reviewed retrospectively in five tertiary dialysis units participating in "TOMEI Nephrology Group for Clinical Research" study. After exclusion of 232 patients diagnosed with non-infectious diseases, 186 patients diagnosed with infections were analyzed. Patients were divided into two groups according to the serum albumin level at hospitalization (median 3.5 g/dL), lower serum albumin (Serum albumin<3.5 g/dL), or not. Outcome measured was in-hospital mortality. For statistical analysis, cox proportional hazard model was used.

Results: Among 186 patients with infectious diseases, there were 117 patients (62.9%) in low albumin group, and 69 patients (37.1%) in normal albumin group. During hospitalization (median 19 days, interquartile range 10-37), 29 patients (15.5%) died, 25 of 117 (21.4%) in low albumin group, and 4 of 69 (5.8%) in normal albumin group. The cox proportional hazard model revealed that low serum albumin and bacteremia were associated with in-hospital mortality. The hazard ratio of in-hospital mortality among low albumin group was 4.203 (95% CI: 1.36-13.55).

Conclusions: Although low serum albumin is a known risk factor for long-term mortality, this study showed that low serum albumin strongly predicts short-term mortality among hemodialysis patients hospitalized with infectious diseases.

PUB357
Usefulness of High-Frequency Wave-Length Ultrasonography as a Diagnostic Tool for Carpal Tunnel Syndrome in Hemodialysis Patients Tadashi Yamazaki,2 Tokie Hayasaka,2 Tetsuo Saito,2 Shuichi Tsuruoka.1 1Nephrology, Nippon Medical School, Tokyo, Japan; 2Dialysis Unit, Moka Hospital, Moka, Tochigi, Japan.

Background: Carpal tunnel syndrome (CTS) is a common complication in dialysis-induced amyloidosis. In orthopedics, high-frequency wave-length ultrasonography (US) with improved resolution is recently used for diagnosing disorders of the upper extremities. We aimed to determine the value of US for diagnosing CTS in hemodialysis (HD) patients, through a cross-sectional analysis.

Methods: All maintenance HD patients (N ~ 150) at our hospital were recruited after providing written informed consent. Patients with apparent paralysis or pain in the upper extremities due to causes other than CTS were excluded. Longitudinal scan of the median nerve around the carpal tunnel area was performed with US (Toshiba Viamo TM, 12-MHz probe) during HD, and the compression rate (CR) of the nerve was calculated as (1 - shortest diameter/longest diameter of the nerve around the carpal tunnel area). The CTS symptoms were evaluated with the visual-analogue scale (VAS) of pain around the index finger area and the quick form of the Disabilities of the Arm, Shoulder and Hand (Quick-DASH) questionnaire. Pinch strength was also measured. Serum C-reactive protein (CRP) and b2-Mg concentrations, and medical histories related to CTS or dialysis-induced amyloidosis were extracted from the patients’ records.

Results: Total 250 wrists from 125 patients (Mean age = 65.6±10.6 years) were studied. The mean CR was 11.8±7.0 and the cut-off values of CR from ROC curve for history of carpal tunnel release was 25.7% (sensitivity 0.80, specificity 0.91). Multivariate analysis revealed that CR was significantly positively correlated with dialysis career, VAS and carpal tunnel release was 25.7% (sensitivity 0.80, specificity 0.91). Multivariate analysis of Korea; 2Dept of Internal Medicine, Wonkwang Univ College of Medicine School of Medicine, Ewha Womans Univ Mokdong Hospital, Seoul, Republic

Conclusions: CR significantly correlated with symptoms and factors associated with dialysis-induced CTS.

Technique Failure in Korean Incident Dialysis Patients: A National Population-Based Study Shina Lee1, Hyunwoo Kim2, Seung-Jung Kim1, Duk-Hee Kang1, Kyu Bok Choi1, Dong-Ryol Ryu1, 1Dept of Internal Medicine, School of Medicine, Ewha Womans Univ Mokdong Hospital, Seoul, Republic of Korea; 2Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanhon Hospital, Gunpo, Republic of Korea.

Background: Technique failure is an important issue for dialysis patients. In this study, we aimed to analyze a detailed technique failure rate and to determine the predictors for technique failure in Korea.

Methods: We identified all patients who had started dialysis between January 1, 2005 and December 31, 2008 in Korea, using the Korean Health Insurance Review and Assessment Service database. A total of 32,357 eligible patients [24,743 hemodialysis (HD) patients and 7,614 peritoneal dialysis (PD) patients] were included, and the median follow-up was 26.7 months.

Results: The crude incidence rates of technique failure among HD patients and PD patients were 3.4 and 5.1 per 1000 patient-years, respectively. When comparing technique survival rate between HD and PD in both Kaplan-Meyer analysis and competing risks analysis, it was significantly higher in patients on PD than those on PD. The gap of technique failure incidence between HD and PD was exaggerated in Kaplan-Meier analysis compared to competing risks analysis. In multivariate analyses, diabetes mellitus and Medical aid as a crude reflection of low socioeconomic status were independent risk factors in both Cox proportional hazard model and Fine and Gray subdistribution model.

Conclusions: Technique failure in PD is higher than that in HD, and it is major concern in patients initiating dialysis in Korea. The results of our study offer a basis for risk stratification and customized care for technique failure.

PUB359
Frequency of Not Achieving Target Weight in Hemodialysis Patients and the Reasons Behind It Tine Malha,1 Frank Modersitzki,1 Lada Beara Lasic,2 1Internal Medicine, Div of Nephrology, New York School of Medicine, New York, NY; 2Internal Medicine, Div of Nephrology, New York Harbor VA Healthcare System, New York, NY.

Background: Volume overload and volume depletion have both been associated with morbidity and mortality in patients with end stage kidney disease (ESKD) on hemodialysis (HD). A recent study demonstrated an increased mortality risk when post HD weight is more than 2kg above or below the prescribed estimated dry weight (EDW) for >30% of HD sessions. Our aim was to determine the frequency of sessions with weight difference (WD)≥2kg, determine the prevalence of patients WD≥2kg for >30% of sessions and identify the possible reasons in our outpatient chronic HD population.

Methods: 32 outpatients on chronic HD at the New York Harbor VA Healthcare System in Manhattan were monitored for 2 months. Data for 631 sessions was obtained. Charts and HD nursing notes were reviewed every 2-4 weeks for: weight, prescribed EDW, ultrafiltration (UF) rate, intradialytic complications (hypotension with systolic BP<90, dizziness, cramping, administration of intravenous fluids). Sessions with a missing documented EDW or post HD weight were excluded. 502 sessions were used in the analysis.

Results: The mean WD for all sessions was 0.67±1.64 kg with a majority (83.7%) of HD sessions ending with post HD weight within 2kg of EDW which is consistent with the literature. 6 out of 31 (19.3%) patients had WD≥2kg for >30% of the evaluated sessions. The inability to achieve post HD weight within 2kg of EDW was most commonly (51.2%) associated with an elevated UF rate (defined as >875ml/hour). Possible reasons for not achieving EDW included cramps (4.9%) and hypotension (2.4%).

Conclusions: Failing to achieve EDW within 2kg range is most commonly associated with high UF rates, indicating high weight gains between treatments. Proposed strategies to continue aiming at achieving EDW while compensating for the constraints of elevated UF include: decreasing intradialytic weight gain, increasing treatment frequency or treatment time. Further studies identifying the best strategies to achieve this goal are needed.

PUB360
Comparative Effectiveness of Dialyzers: A Longitudinal Propensity Score-Matched Study Scott Sibbel,1 Abigail Hunt,1 Suzanne Laplante,2 Werner Beck,2 Mary Gellens,2 John Alan Laich,1 Steven M. Brunelli.1 1DaVita Clinical Research, Minneapolis, MN; 2Baxter Healthcare Corporation, Deerfield, IL.

Background: Differences in dialyzer design may affect systemic inflammation and extracorporeal blood sequestration and thereby impact anemia management and control. We evaluated the comparative effectiveness of commonly used dialyzers with respect to longitudinal hemoglobin (Hb) levels, and ESA and IV iron utilization.

Methods: Patients included in the analysis received hemodialysis between 01 Jan 2009 and 31 Dec 2013 and were new users of Revaclear, Optiflux 160, or Optiflux 180 dialyzers. Patients were followed for 1 year or until end of study or censoring for dialyzer switch, modality change, or loss to follow up. For each comparison, eligible patients were propensity score-matched 1:1 on a range of demographic, comorbidity history, and baseline laboratory parameters. Outcomes were assessed using linearized mixed models including fixed effects for dialyzer type, time, and their interaction term.

Results: Matched patient pairs (21,551 for Revaclear-Optiflux 160 comparison; 21,008 for Revaclear-Optiflux 180 comparison) were assessed. ESA doses evolved differently over time among Revaclear patients versus both Optiflux 160 and Optiflux 180 patients (p interaction=0.001 for both). Differences in ESA dose were significant from month 3 for Revaclear versus Optiflux 160 (range, 173-483 U/treatment) and at all time points for Revaclear versus Optiflux 180 (range, 120-392 U/treatment) and at all time points for Revaclear versus Optiflux 180 (range, 120-392 U/treatment). Hb levels were equivalent between Revaclear and Optiflux patients at all times. IV iron dosing was lower for Revaclear patients than Optiflux 160 and 180 patients (p=0.001 for each) but differences were small (≤1 g/dL iron/month).

Conclusions: Use of Revaclear versus Optiflux dialyzers was associated with lower ESA doses, modestly lower IV iron doses, and equivalent Hb concentrations.
PUB362

Fluid Overload Predicts Mortality Risk in Maintenance Hemodialysis Patients
Carlo Donadio, Valentina Vigo. Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.

Background: Maintenance hemodialysis (MHD) patients have a high mortality rate, mainly due to cardiovascular disease and malnutrition. The aim of this study was to evaluate the efficacy of the analysis of body composition by bioimpedance (BIA) to predict the mortality risk in hemodialysis patients.

Methods: Observational longitudinal study lasting six years on 78 prevalent MHD patients (68% male, mean age 65 ± 14 years; dialysis vintage 7 ± 7 years). Every two years, starting from the baseline, we collected clinical, laboratory and BIA data, including vectorial analysis (BIVA) and hydration scale, that is the hydration as percentage of extracellular body mass. We compared the BIA data of patients dead during the study period (n = 45; 65%) with those of survivors (n = 24; 35%). The significance of the differences between the mean values of the two groups at the baseline was evaluated.

Results: Nine patients moved to another hemodialysis facility. The patients dead at different times during the six years had significantly higher values of BMI (28 ± 6 vs 24.8 ± 3.1 kg/m², p < 0.01) and fat mass index (11.2 ± 4.1 vs 8.4 ± 2.8 kg/m², p < 0.003) compared to the survivors, while there were no significant differences for body cell mass (BCM) index (7.1 ± 1.7 vs 7.9 ± 1.8 kg/m²) and serum albumin (4.1 ± 0.4 vs 4.1 ± 0.1 mg/dl). Furthermore, deceased patients had lower values of reactance (53.5 ± 11.7 vs 67.3 ± 13.7 Ohm, p < 0.000003), phase angle (5.1 ± 0.9 vs 5.9 ± 0.8 degrees, p = 0.000003) and the percentage of extracellular water was higher (50.6 ± 5.2 vs 46.1 ± 3.6%, p < 0.00003). Finally the BIVA analysis confirmed that the hydration was significantly higher in the deceased (73.3 ± 1.8 vs 71.2 ± 3.3%, p < 0.000006). In summary survivors had normal values of BMI and fat mass, a smaller reduction in BCM and less fluid overload than deceased patients.

Conclusions: The survival of HD patients is influenced by the nutritional status. In particular, fluid overload and decrease in muscle mass play a decisive role on survival. Fluid overload, low values of electrical resistance and phase angle predict mortality risk in MHD patients.

A Single Center 2-Year Experience with Haemodialysis Care in Nigeria
Bala Waziri,1 Isah Alhaji Umar.2 Dept of Medicine, IBB Specialist Hospital, Minna, Niger State, Nigeria; 2Dept of Medicine, IBB Specialist Hospital, Minna, Niger, Nigeria.

Background: In Nigeria, sustaining maintenance haemodialysis while awaiting renal transplantation is largely being hampered by high cost of care. Furthermore, the scarcity of dialysis units, lack of government funding or subsidy on haemodialysis have made survival very difficult for patients with End Stage Renal Disease in Nigeria. Thus the aim of this study was to share our experience with the challenges of providing maintenance haemodialysis in a developing country.

Methods: We retrospectively reviewed records of all the patients with ESRD who had haemodialysis at our dialysis facility over a period of 24 months. Data on their demographic characteristics, etiology of Chronic Kidney Disease, types of vascular access for dialysis, frequency of haemodialysis, history of blood transfusion and patient outcomes were collected.

Results: This study included 64 patients on maintenance haemodialysis. The mean age was 43.9±18.1 years, and there were 39 males (60.9%) and 25 females (39.1%). The underlying presumed etiology of Chronic Kidney Disease were hypertension (73.4%), diabetes mellitus (31.3%) chronic glomerulonephritis (1.6%) and (21.0%) was unknown. Their mean haemoglobin level at the time of commencing dialysis was 7.2±2.2 g/dL, with 17.5% receiving 3-4 pints of blood transfusion. The mean systolic and diastolic blood pressure were 169±37.6mmHg and 103.3±15.5mmHg respectively. A significant inverse correlation between haemoglobin level and serum creatinine was observed (r= -0.413, p<0.001). A predominant proportion of the patients (68/93.8%) were dialyzed via femoral access for dialysis, frequency of haemodialysis, history of blood transfusion and patient outcomes were collected.

Conclusions: The high mortality in this study, is likely due to a combination of inadequate dialysis with other predictors of cardiovascular events such as anaemia and uncontrolled hypertension as demonstrated in our results.

PUB364

Characteristics and Patient Survival in Nursing Home Residents on Maintenance Dialysis
Robert Nee,1 Lawrence Agodoa,2 Kevin C. Abbott.3 1Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; 2NIDDK, National Insit of Health, Bethesda, MD.

Background: There is limited data on the growing nursing home (NH) population with end-stage renal disease (ESRD) in the United States. We evaluated the characteristics and predictors of mortality of NH patients on dialysis.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 782,161 patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2013, followed until 31 May 2014. Covariates include age, gender, race, dialysis modality, body mass index, serum albumin, indicators

972A
of poor functional capacity and other co-morbid conditions from the Medical Evidence Form 2728. We conducted both Kaplan-Meier and Adjusted Cox regression analyses with death as the outcome variable.

Results: 56,194 (7.18%) were identified as nursing home residents upon initiation of dialysis. Among NH patients, 50.53% were female, 69.92% were white, and 99.49% were on hemodialysis and the mean age was 71.1 ± 12.1 years. The overall incidence rates of death of NH vs. non-NH patients were 51.8/100 and 17.6/100 patient-years, respectively (p<0.001). The unadjusted 1-year mortality was 50% in NH patients (vs. 20% in non-NH patients, p<0.001). Adjusted Cox analysis showed that NH patients were at significantly higher risk of death when compared to non-NH patients (adjusted hazard ratio [AHR] 1.37; 95% confidence interval 1.35-1.38). Within this NH cohort, age (AHR 1.02; 95% CI 1.02-1.03), inability to transfer (AHR 1.25; 95% CI 1.22-1.29), inability to ambulate (AHR 1.08; 95% CI 1.05-1.11), cancer (AHR 1.15; 95% CI 1.12-1.19) and other co-morbid conditions were significantly associated with death.

Conclusions: NH patients on dialysis have a high mortality rate, even when compared to the broader ESRD population. Further studies on modifiable risk factors of mortality in this particularly high-risk ESRD population are warranted. [Disclaimer: The views expressed in this paper are those of the authors and do not reflect the official policy of the Department of the Army, the Department of Defense, or the United States government.]

PUB365

Background: Protein-energy malnutrition (PEM) is prevalent in the hemodialysis (HD) population and is associated with a high morbidity-mortality burden. Metabolic acidosis and PEM are closely related. Protein intake, which constitutes an acid load, is an important factor of pH regulation in end-stage renal disease patients. Therefore, a higher bicarbonate serum level could be the result of insufficient protein intake and be a useful marker of malnutrition?

Methods: We conducted a retrospective study in our HD service using a computer database with measurements obtained simultaneously for all 342 patients. Correlation between pre-HD session bicarbonate, albumine, prealbumine and normalized protein catabolic rate (nPCR) was assessed by the use of Pearson’s and Spearman’s correlation test. Subgroup analysis were realised for patients with negative C-Reactive Protein (CRP < 5) and patients classified as clinically stable.

Results: We found a significant, negative and moderate, correlation between bicarbonate and nPCR, (spearman’s r = -0.27, p<0.001). Subgroup analysis showed similar results, (spearman’s r: -0.28; p<0.001) for 196 clinically stable patient and (spearman’s r: -0.24, p<0.05) for 144 patients with a negative CRP. There was no association between albumin (spearman’s r: -0.06, p=0.1511) or prealbumin (spearman’s r: -0.08, p=0.1511) and bicarbonate in any group.

Conclusions: A higher serum level of bicarbonate is associated with a lower nPCR, reflecting of poor protein intake, but not with a malnutrition state defined by albumin or prealbumin criteria. These patients are at risk to develop a clinically apparent malnutrition state after a prolonged period.

PUB366
Scope and Consistency of Outcomes Reported in Randomized Trials of Hemodialysis Gabrielle J. Williams, Allison Tong, Jonathan C. Craig. School of Public Health, Univ of Sydney, Sydney, NSW, Australia.

Background: Inconsistent outcome selection and reporting in clinical trials may limit their capacity to inform evidence-based decision making and the ability to combine findings in systematic reviews. Aim: We aimed to assess the scope and consistency of outcome selection and reporting in trials included in systematic reviews of interventions for patients on hemodialysis (HD).

Methods: The Cochrane Database of Systematic Reviews was searched from 1999 to January 2015 for published systematic reviews of interventions for patients on chronic HD. The description and frequency of outcomes reported within the source randomized controlled trials were assessed.

Results: The 18 systematic reviews included 282 trials that reported over 518 outcomes. There was considerable heterogeneity among the outcomes reported. Across all trials, 320 outcomes were measured, and the units and threshold changes that defined an outcome. For example, blood pressure was reported as pre-dialysis, post-dialysis, maximum, difference in pre and post dialysis, intermittent, resting, rise, and time to restore.

Conclusions: A wide array of outcomes are reported in trials of interventions in HD, with large heterogeneity in timing of measurements, units of measure, and threshold changes that define an outcome. This highlights the need for a well-defined set of standardized core outcomes to improve the comparability of trial findings in meta-analysis and to provide greater confidence around treatment decisions for patients undergoing HD.

PUB367
Blood Pressure and Cognitive Decline in Hemodialysis Patients Sarah M. Duncan,1 Hocine Tighiouart,2 David A. Drew,3 Tammy Scott,2,1 Daniel E. Weiner,4 Mark J. Sarnak,5 1Tufts Medical Center, Boston, MA; 2Tufts Univ, Boston, MA.

Background: Cognitive impairment is common in hemodialysis (HD) patients; however, the relationship between measures of blood pressure (BP) and longitudinal decline in cognitive function is unknown in this population.

Methods: 314 participants in the Cognition and Dialysis Study underwent an annual comprehensive battery of cognitive tests. Using principal components analysis (PCA), we reduced individual test results to two domains representing memory and executive function. Adjusted joint mixed models accounting for death, transplant, and drop-out were used to explore the association of blood pressure (systolic [SBP], diastolic [DBP] and pulse pressure [PP]) with change in cognitive function over time.

Results: Mean (SD) age was 63 (16) years, 47% were women, 22% were African American, and 44% had cardiovascular disease (CVD). Mean (SD) SBP, DBP, and PP were 141 (21), 73 (12) and 68 (13) mmHg, respectively. Median follow-up time was 1.8 years (IQR 1.0-3.4). Mean slopes of PCA memory and executive were 0.03 (95% CI -0.01, 0.07) and -0.11 (95% CI -0.15, -0.06) per year, respectively. Lower DBP and higher PP were associated with decline in measures of both memory and executive function. There was no association between SBP and cognitive decline.

*Adjusted for baseline BP measure, age, sex, race, education, vascular access and CVD. Negative coefficients are associated with worse scores except on Trials Tests. Bold results are significant.

Conclusions: Lower DBP and higher PP are associated with faster rate of cognitive decline, in particular that related to executive function. Because impairment in executive function is a manifestation of vascular disease and lower DBP and higher PP are associated with CVD in HD patients, our results suggest that cognitive decline may be mediated by vascular disease in this population.

High Ferritin Levels Achieved with Ferric Citrate as a Phosphate Binder Do Not Associate with Adverse Events Udavan Y. Bhatt,1 Kausik Umanath,2 Mohammed Sika,3 Mark Koury,3 Robert M. Nicastro,2 Barbara A. Greco,3 Dana G. Niewold,1 Wiktoria J. Chang,3 Emmanuel Stephen Z. Fadem,2 Molly McFadden,1 Julia Lewis,1 Jamie P. Dwyer,2 The Collaborative study group.4 1Ohio State; 2Henry Ford Hosp; 3Vanderbilt; 4CSC; 5Baystate Med Ctr; 6U of VT; 7Western Neph; 8U of Utah; 9Baylor College of Med.

Background: Ferric citrate (FC) as a phosphate binder increases Fe stores and reduces IV iron/ESA use while maintaining hemoglobin. This analysis compares effects of higher achieved ferritin levels in subjects on FC to those in subjects on sevelamer carbonate and/or calcium acetate (active control, AC).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Data were obtained from the 52-wk active control period of the FC pivotal trial. Subjects with a baseline ferritin 100ng/mL or TSAT:50% were excluded from the trial. We randomized 292 subjects to FC and 149 to AC. Any subjects who developed ferritin level ≥1500ng/mL at any time over 52ks were identified. CV, ID, and dialysis access related adverse events (AE) occurring at any time over the 52-wk period were tabulated. Results: 57 subjects (19.8%) in the FC group and 14 subjects (9.5%) in the AC group had at least a single ferritin≥1500ng/mL (p=0.021) during the 52 ks. CV events including MI, CHF, and arrhythmias, occurred in 12.3% of the FC group compared to 21.4% of the AC group. ID AEs occurred in 42.1% of FC and 50% of AC. Dialysis access related AE occurred in 15.7% of FC and 13.5% of AC. IV administration was statistically significant (p=0.003) for the FC group (2.95±3.7mg/wk) than the AC group (6.20±3.64mg/wk), consistent with the full cohort that saw a significant reduction in IV iron use. Cumulative ESA dosing was 1016±906 Units/wk FC and 1781±1756 Units/wk AC (p=0.256).

Conclusions: It was suggested that the adjustment of serum BNP by strictly managing the weight reduced pruritus in hemodialysis patients but it was difficult to improve long-term QOL.

PUB371

The Mechanisms Study on Neointimal Hyperplasia of Autogenous Arteriovenous Fistula in Maintenance Hemodialysis Patients 
Nanmei Liu, Jimin Hospital of Shanghai.

Background: To evaluate the influence and the possible mechanism about neointimal hyperplasia of autogenous internal arteriovenous fistula in hypertensive nephropathy and diabetic nephropathy patients which was going maintenance hemodialysis and provide possible theory about how to prevent from intimal hyperplasia, extend the life of AVF in clinic.

Methods: Collecting cephalic vein when the hemodialysis patients had the surgery of AVF angioplasty and reconstruction. Vascular tissues were divided into chronic glomerulonephritis group, hypertensive nephropathy group and diabetic nephropathy group.

Immunochemistry was used to detect the expression of vascular smooth muscle actin (a-SMA). Selecting the control group and fistula vascular tissue which the useful life was 12-18 months, basic fibroblast growth factor (bFGF), insulin-like growth factor 1 (IGF-V), matrix metalloproteinase2 (MMP2) and matrix metalloproteinase9 (MMP9) were to detect expression change by immunochemical staining.

Results: Compared with chronic glomerulonephritis group, intima thickness of hypertensive nephropathy and diabetic nephropathy were significantly increased and the increase was more significant in diabetic nephropathy. Hyperplasia intima was eccentric hypertrophy and the hyperplasia intima showed obvious inflammatory cells infiltration and vascular degeneration. Immunochemical staining showed that compared with the group of chronic glomerulonephritis, hypertensive nephropathy and diabetic nephropathy groups’ a-SMA, bFGF, IGF-1 and MMP9 expression levels were significantly increased, expression of VEGF was significantly reduced, MMP2 was no significant change (P<0.05). Univariate regression analysis revealed that the expression levels of a-SMA was positively correlated with bFGF, IGF-1 and MMP9 negatively correlated with the VEGF. AVF intimal hyperplasia mainly dominated by the vascular smooth muscle cells (VSMC) proliferation. Hyperplasia intima showed evident inflammation. A possible hypothesis was that neointimal hyperplasia, shorten the life of fistula and diabetes promote intimal hyperplasia more significant. This study provides a theory and therapeutic targets for the prevention and treatment on intimal hyperplasia of AVF in dialysis patients.

Association of Nutritional Status with Depression and Sleep Disorders in Elderly Hemodialysis Patients 
Pavan V B., Enrue Turlut., 2 Nephrology, Afyonkarahisar State Hospital, Afyonkarahisar, Turkey; 2Nephrology, Basant University Hospital, Ankara, Turkey.

Background: The relationship between depression, sleep quality, and malnutrition in an elderly population in maintenance hemodialysis is very complex and not yet fully understood. We aimed to determine the association between nutritional status and psychological factors such as depression and sleep disturbance in elderly dialysis patients.

Methods: Seventy three dialysis patients (41 female, 32 male; aged, 72±5.60 years) older than 65 years of age were enrolled in the study. Nutritional status was determined by Subjective Global assessment (SGA). Beck Depression Inventory (BDI) questionnaire was used to measure presence and degree of depression. Quality of sleep was measured using the Pittsburgh Sleep Quality Index (PSQI). Demographic and biochemical parameters and Charlson Comorbidity Index and frequency of infection in previous year period of all patients were recorded.

Results: In our elderly patients 15 (%20.5) had sleep disorder and 24 (%32.9) had mild to moderate depression and 11 (%15.1) had moderate to severe depression. When the well nourished group had higher albumin levels (4.28±4.56) vs 3.97±3.97 (p=0.009), lower CRP levels (7.51±4.23 vs 16.02±19.45), better quality of sleep (3.50±0.82 vs 5.56±1.73) and better depression scores (6.08±2.75 vs 16.28±4.56) than malnourished group. By multivariate analysis when factors affecting nutritional status were taken into consideration the nutritional status and depression scores were the present independent parameter.

Association Between Employment Status and KDQOL Scores in Dialysis Patients 
Duan Du,1 Deborah S. Evans,1 Elizabeth J. Jones,1 Caroline Hann,2 Rich Metu,2 Allen R. Nissenson,1 Deborah A. Benner.1 DaVita HealthCare Partners Inc, Denver, CO; 2Apx Health Innovations, Simi Valley, CA.

Background: Emunemployment negatively impacts dialysis patients’ quality of life (QOL).1 QOL can be quantified and low scores on the Kidney Disease Quality of Life (KDQOL) survey are associated with poor outcomes.2 Our study examines employment/unemployment status and KDQOL scores.

Methods: We collected employment status data on 122,166 adult patients at a large dialysis organization from Nov 2014-Apr 2015. Patients were grouped as either employed (received pay or in training), unemployed (including retirees and those on long- or short-term disability or Workers Compensation) or other (involved in work/activity but not paid). Data were matched with patients’ most recent KDQOL scores.

Results: The employed group (n=16,216) had the highest KDQOL scores in all categories compared to the unemployed (n=98,014) and other groups (n=7936) [Table]. A clinically meaningful difference (6.8) in Physical Component Score was found between categories, followed by the other (n=7936) and unemployed groups (n=98,014) [Table]. A reduction of pruritus in hemodialysis patients by adjustment of serum BNP.

Conclusions: More studies are needed to better understand the factors influencing KDQOL scores among dialysis patients. More studies are needed to better understand the factors influencing KDQOL scores among dialysis patients.
Conclusion: Depression and sleep disorders are important factors influencing the nutritional status and could be an independent risk factors for malnutrition in elderly patients receiving maintenance dialysis. Psychological assessment should be mandatory in the follow up of these patients to identify depression and sleep disturbance because many of them are reversible.

PUB373
Predialysis Hyponatremia and Mortality in Elderly Patients with Incident Maintenance Renal Replacement Seung Ho Ha, Sung Woo Lee, Shin-Young Ahn, Sejoong Kim, Ki Young Na, Dong-Wan Chae, Ho Jun Chin. Internal Medicine, Seoul National Univ Bundang Hospital, Republic of Korea.

Background: Predialysis hyponatremia recently have been reported to be associated with mortality in incident hemodialysis patients. However, little is known about whether predialysis hyponatremia is associated with unfavorable outcomes in elderly patients.

Methods: We retrospectively assessed mortality in 397 (mean age 73.0 year, male 226(171) patients aged ≥65 years with non-diabetic end-stage renal disease (ESRD) who initiated renal replacement therapy (RRT) at a tertiary university hospital between 2000 and 2010. 1 year survival, 2-year survival and multivariate mortality (ACM) was analyzed in relation to predialysis serum sodium (sNa). We divided subjects into 3 groups according to sNa: Group1, < sNa 125; Group 2, sNa 125-134; Group 3, sNa ≥ 135 mEq/L. Patients with sNa levels >145mEq/L were excluded.

Results: The median value of sNa was 137 mEq/L (interquartile range 133-140 mEq/L).

1. Chronic comorbidities included congestive heart failure (r = -0.215, P < 0.001) and liver cirrhosis (r = -0.174, P < 0.001), and lower estimated glomerular filtration rate (r = -0.150, P < 0.001) and albumin (r = -0.175, P < 0.001) and higher white blood cell count (r = -0.136, P = 0.006) were associated with lower sNa levels in elderly patients after full adjustment. One hundred and five (26.4%) patients had died at the 1-year follow up. Higher sNa level was associated with lower adjusted ACM in a continuous model (HR 0.433, 95% CI 0.261-0.718, P = 0.001). Group 1 had a higher mortality than normonatremia group in a categorical model (reference group: normonatremia, Group 1: hyponatremia, Group 2: hypernatremia). The associations of sNa and mortality difference was not observed between group 2-3 (reference group3). HR 1.511, P=0.161).

Conclusions: Predialysis hyponatremia was associated with increased 1-year mortality in elderly ESRD patients who initiated RRT. However, the higher mortality was only observed in elderly patients with severe hyponatremia (sNa < 125 mEq/L). These findings suggested that compared to adults <65 years, other comorbidities or factors rather than sNa may affect mortality in elderly.

PUB374
Observation of the Correlation Between the Uremic Toxins with Clinical Feature in Uremia Patients Mei Li,1, 2 Gong-Li Yin,1 Zhenda Zheng,1 Cai-Lian Cheng,1 Xun Liu,1 Cheng-Gang Shi.3 1VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; 2Cardiovascular Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; 3Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.

Background: To investigate the correlation between the uremic toxins with age, dialysis duration and the different blood purification techniques on removal uremic toxins with hemodialysis (HD) and hemodiafiltration (HDF).

Methods: 72 cases of maintenance hemodialysis patients were observed, age 28~80 years (mean age 64±13.6), duration 4~20 months (34.4±39.15). HD group (n = 50), HDF group (n = 22) (once 1~2 weeks). Before each conventional HD and HDF therapy, blood was sampled for small molecule water-soluble toxins BUN with automatic biochemical analyzer, Middle molecular and macromolecular toxins (MMS) with Ultraviolet spectrophotometry, pentosidine (PENT) with enzyme-linked immunosorbent assay methodfrom ALD Company, USA. Protein-bound toxins, indoxyl sulfate(IS) with high performance liquid chromatography method.

Results: For HD versus HD, there was no significant differences between BUN, MMS, pentosidine and IS. There was low positive correlation between MMS, PENT, IS and the age of the patients (r being 0.322, 0.263 respectively, P<0.05). MMS, PENT and IS were positively related with dialysis months (r being 0.406, 0.427, 0.742 respectively, P<0.05).

Conclusions: HD and HDF therapy may not good enough in clearing middle molecular toxins and protein-bound toxins, which results in their accumulation in patient’s body with the increase of dialysis course. It is recommended that better dialysis methods be adopted for patients who have received hemodialysis for a long time.

PUB375
Parathyroid Hormone Response in Chronic Hemodialysis Patients Converted from Intravenous Doxercalciferol to Oral Calcitriol Three Times a Week Anna Jeanette Jovanovich,1,2 Annegret Howe,2 Morgan E. Marceculi,3 Michel Chonchol.1 1Denver VA Medical Center; 2Freensien Medical Care; 3Univ of Colorado Denver.

Background: The purpose of this study was to characterize serum calcium, phosphorus and intact parathyroid hormone (iPTH) level response during the initial 24 weeks following conversion from intravenous doxercalciferol to oral calcitriol three times a week in a real world setting.

Methods: Data was collected by a retrospective chart audit of end stage renal disease patients on hemodialysis in an outpatient chronic dialysis unit. We identified 33 chronic hemodialysis patients that had a record of treatment with intravenous doxercalciferol (6 months to 3 years prior to conversion to oral calcitriol) and 19 patients (28~80years(59.75 ± 9.36)) with eGFR ≤ 5 and > 5ml/min upon initiation. The comparisons achieved statistical significance (p < 0.03 for all). 48% of patients were on calcinacel during each of the treatment periods. The median (IQR) change in iPTH increased slightly among those patients receiving oral calcitriol and sevelamer (3132 to 4797 pg/ml) while iPTH decreased among patients receiving oral calcitriol and other non-sevelamer binders (41029 to 155 pg/ml; P = 0.173).

Conclusions: This small retrospective study suggests that conversion from intravenous doxercalciferol to oral calcitriol using a conversion algorithm maintains iPTH within KDIGO recommended targets and does not appear to cause hypercalcemia or hyperphosphatemia. The clinical significance of other iPTH values among those treated with oral calcitriol and sevelamer needs further study.

PUB376
Pregnancy and Chronic Kidney Disease – A Case Study Morgan E. Lindsay, Syed S. Haqqie, Arif Asif. Albany Medical College.

Background: For women with underlying renal disease, pregnancy remains high risk. Case series have provided guidance on the interdisciplinary management of these patients. Herein, we report one institution’s management of five patients requiring dialysis in pregnancy. The present case series includes patients with chronic kidney disease secondary to lupus nephritis (n=2), cystinosis (n=1), malignant hypertension (n=1), and diabetic nephropathy (n=1). All five patients, one of whom was on dialysis prior to pregnancy and the rest were CKD 5 were placed on six-times weekly dialysis upon the presentation with pregnancy. Three of the patients, two with Lupus and one with Malignant HTN delivered infants with whom they were able to discharge home after NICU stays, two patients one with cystinosis and one with DM delivered infants who subsequently died in the NICU secondary to prematurity. All 5 patients post-delivery continued on maintenance hemodialysis. Although improving, maternal and fetal outcomes in those with chronic kidney disease remain variable. Our experience adds to the growing literature on dialysis for chronic kidney disease in pregnancy.

Methods: Restrospective study of patients at one institution.

Results: Out of five pregnancies three had successful outcome with intensive dialysis.

Conclusions: Pregnancy complications in dialysis patients and outcomes are generally poor. There are improved results with intensive dialysis and multidisciplinary approach to the management.

PUB377
When Shall the Advanced Chronic Kidney Disease Patients Start Dialysis? Lee Ying Yeol,3 San Yoon Paik, Hae Min Hong, Sung Min Lee, Hye-Eun Lee, Ji-Hye Lee, Ji-Young Lee, Ji-Hyun Jang, Ji-Won So, Ji-Sung Hahn, Joonkeun Shin, Jung-Kyung Kim, Soon-In Kang, Su Young Park, Seung Hoon Kim, Ji-Woo Jang. Jovanovich,1,3 Jovanovich,2 1Denver VA Medical Center; 2Fresenius Medical Care; 3Albany Medical College; 4Albany, NY.

Background: Recent guidelines suggest dialysis should be initiated when estimated glomerular filtration rate (eGFR) drops below 10-12ml/min. The aim of the present study was to analyse outcomes of those initiating dialysis at very low eGFRs.

Methods: A single center, prospective study of new ESRD patients who were initiated on dialysis between 2012–2014 and dialysis was performed for >90 days. The patients were categorized into 2 groups according to eGFR ≤ 5 and > 5ml/min upon initiation. The patients with incomplete data, and those who underwent transplantation were excluded.

Results: A total of 251 patients were included with mean age of 59.0 ± 11.9 years, mean eGFR of 5.4 ± 2.9ml/min; 57% were males and 51.4% were Chinese. Majority started on hemodialysis (81.7%) and 69.7% were unplanned. The survival rate till May, 31 2015 was 88.4%; 61% were initiated when eGFR ≤ 5 (mean 3.6±1.1 ml/min) and 39% with eGFR >5 (mean 8.3 ± 2.6 ml/min). Dialysis vintage was shorter in the group with eGFR ≤5 (18.2 ± 9.5 vs. 21.7 ± 11.1 months). The patients with eGFR < 5 had lower Charlson Comorbidity Index (4.0 ± 1.3 vs. 4.7 ± 1.2), and hemodialysis was preferred (90.9% vs. 67%). The death burden was significantly lower in the group with eGFR ≤5, including diabetes mellitus (72.1 vs. 88.7%), ischemic heart disease (23.4% vs. 37.1%) and peripheral arterial disease (4.5% vs. 12.4%). However, there were trends showing that these patients were younger, had higher serum albumin and shorter hospitalization for index admission. Underlying diabetes, ischemic heart disease, mortality selection and dialysis vintage remained significant after adjusted. Mean survival for both groups were comparable (36.3 months, 95% CI, 34.4-38.2 vs. 34.5 months, 95% CI 32.0-37.0). Among the patients who survived, 97.7% remained on their initial modality.

Conclusions: Our study suggests that the ESRD patients without significant morbidities may be able to delay dialysis initiation without significant short term adverse outcomes. Further studies are required.
The Incidence and Type of Cancer in Patients with End-Stage Renal Disease: A Prospective Cohort Study for End-Stage Renal Disease in Korea

Background: In patients with end-stage renal disease, urinary tract cancer is known to be related to the general population. However, the incidence and type of cancer is affected by variable factors such as age, gender, ethnic differences. Moreover, the causality of dialysis and cancer incidence in certain type of cancer is still needed to be clarified.

Methods: A total of 5,225 patients in the clinical research center for ESRD cohort were reviewed from Aug 2008 to Dec 2014. The primary outcome here is to compare the cancer incidence rate of ESRD patients with the general population. We obtained cancer incidence data from National Cancer Information Center Registry in healthy counterpart.

Results: A total of 2,200 incident and 3,035 prevalent dialysis patients was included the study. The mean follow-up duration was 22.5 months, and 116 (2.3%) patients were diagnosed with cancer during the observation periods. ESRD with cancer group was significantly older, longer dialysis duration and more comorbidity than control group. The incidence rate of cancer in prevalent dialysis patients was higher than that in incident dialysis patients (2.5% vs 1.3%, p=0.002). The proportion of primary organ was highest in digestive organ (33.6%) followed by urinary organ (25.3%) and others. The MSPSS (social support) is positively correlated with the incidence of cancer from dialysis initiation was 58.6 months in digestive cancer, 52.0 months in urinary tract cancer. The standardized incidence ratio (SIR) of overall cancer was 0.94 [95% CI: 0.72 –1.19]. Urinary tract cancer showed the highest SIR (4.7, 95% CI: 4.2– 8.19) and had the shortest duration (16.1%). Interestingly, the highest frequency (33.1%) of digestive organ cancer showed no difference in the incidence of cancer compared to the general population [SIR: 0.607, 95% CI: 0.36– 0.94].

Conclusions: Further research was needed to compare the organ-specific cancer incidence of ESRD patients with the general population. The screening test could be necessary for digestive and urinary tract cancer.

The Role of Social Support in Hemodialysis Patients

Background: A number of patients with End-Stage Renal Disease (ESRD) have significant impairment in social support. Social support is the major determinant of health-related quality of life in chronic renal failure. Social support is the major determinant of health-related quality of life in chronic renal failure. The aim of the current study was to identify the clinical and psychosocial factors including social support, the MSPSS (social support) of dialysis patients and to compare those to the general population.

Methods: The 101 participants on HD from the Daegu Catholic University Medical Center were assessed from September 2013 to September 2014. Patients on HD for acute kidney injury were excluded from this study. Multidimensional Scale of Perceived Social Support (MSPSS) was used for evaluating patients’ social support. Analysis was done to identify significant risk factors of social support of dialysis patients. Multivariate logistic regression with backward selection was performed.

Results: The mean score of MSPSS (social support) was 56.3 ± 9.1. In subgroup of social support, the MSPSS-family, MSPSS-friend, and MSPSS-medical team scores were 41.2 ± 11.3, 29.8 ± 9.1, and 16.4 ± 9.2, respectively. The variables showed the significant association with social support were quality of life (r=0.332, p=0.001), depression (r=-0.290, p=0.003), anxiety (r=-0.372, p=0.001), and serum creatinine (r=-0.270, p=0.007). Multiple regression showed that quality of life (95% CI: 0.615–0.799, p=0.037) and serum creatinine (95% CI: -1.543–0.319, p=0.003) were independent predictors of impaired social support.

Conclusions: This study explored the determinants of high susceptibility to the impaired social support in HD patients. We found that the impaired social support is associated with the quality of life and serum creatinine. Further study will be needed because of the possibility of different result depending on culture and ethnicity. As well as, we should consider the psychosocial interventions to improve the impaired social support.

Use of Portable Fundoscopic Photography to Screen for Diabetic Retinopathy in the Hemodialysis Unit

Background: Over 40% of dialysis patients have diabetes, yet only 25% get annual eye exams. Due to the frequency and duration of visits to dialysis centers, patients on dialysis likely have increased barriers to receiving eye exams and other recommended preventive care. This study evaluated the need for ophthalmic care, barriers to care, and prevalence of diabetic retinopathy (DR) in this population.

Methods: Prospective cohort study at two dialysis centers (1 urban, 1 suburban). A patient survey (measuring eye care utilization, barriers to eye care, and self-reported visual functioning) and eye screening (visual acuity test and non-mydriatic fundus photos) was conducted at baseline and every 3 months. Other variables were obtained from medical records and included demographics, duration of diabetes, co-morbidities, and insurance type. Descriptive analyses examined barriers to eye care and presence of DR. Cox regression data on satisfaction with eye screening were also obtained from both staff and patients.

Results: 58 patients (79.5% of diabetics at the two sites) were screened. Of the readable fundus photos, 50% had DR and only 10% had no ocular abnormalities. The majority (64%) had diabetic retinopathy and 8% had advanced DR. Only 11% of patients reported that getting an annual eye exam is a priority. The most commonly reported barriers to eye care were cost (89%) and transportation difficulty (82%). Qualitative data indicated that staff and patients were overall very satisfied with the program.

Conclusions: There is a significant under need for ophthalmic care among diabetics receiving dialysis. Since cost and transportation were reported as main barriers to eye exams, providing the screening at dialysis centers could improve adherence to eye care thereby improving ophthalmic and other health outcomes.

Recent Diabetic Beginning Is a Mortality Predictor for In-Patients

Background: Acute kidney failure occurs in 5% of hospital admitted patients. Dialysis need during patients stay in hospital is associated with higher mortality risk. The main objective was to evaluate patients profile in our dialysis center and the impact in the outcomes.

Methods: Prospective observational study. A check list was applied for every patient or who required intensive care or who died. The data was analyzed from 01/2010 to 10/2014. The main outcome was to evaluate the patients' profile in our dialysis center and the impact in the outcomes.

Results: The study shows about 64% of our participants believe that there is a paucity of information and awareness regarding organ donation in general population. The study was conducted to see the knowledge and beliefs towards organ donation programme in chronic kidney disease patients in western india.

Methods: The author conducted a cross sectional study among 85 CKD patients to evaluate the knowledge about and attitude towards organ donation at a large tertiary academic hospital in western india. The author used a questionnaire that included items on knowledge, attitude and demographics.

Results: Age of respondents participated in study ranged from 15 to 75 years. Around 2/3rd participants were males. About eighty-two percent belonged to hindu religion. All were aware of term organ donation and cadaveric organ donation. About 47% of people heard about organ donation through hospital or from doctor. The audiovisual media such as television (21%) followed by newspaper/magazines (14%) were the major source of information about organ donation. Strikingly, radio was not the source of information to any of the respondents. All respondents believed in medical colleges/government institutions should make awareness about organ donation. All respondents felt that the organs should go to the needy irrespective of the relationship. Almost 67% of patients were aware of term organ donation through hospital or from doctor. The aesthetic media such as television (21%) followed by newspaper/magazines (14%) were the major source of information about organ donation. All respondents believed in medical colleges/government institutions should make awareness about organ donation. All respondents felt that the organs should go to the needy irrespective of the relationship. About 64.70% believe that there is a danger that donated organs could be misused, abused or misappropriated. There seem to be paucity of information and awareness regarding organ donation among CKD patients.

Conclusions: The study shows about 64% of our participants believe that there is a paucity of information and awareness regarding organ donation among CKD patients. Mass media, religious and political leaders may be involved to maximize awareness about organ donation.
**Enhancing Patient Engagement in Future Clinical Trials – The Effects of Age and Ethnicity**

_Territa Santhakumaran, Kieran McCafferty. Renal, Royal London Hospital, London, United Kingdom._

**Background:** Increasing patient engagement from ethnic minority populations is crucial to the widespread applicability of research findings, but this represents a challenge in nephrology clinical research. Ethnicity, socio-cultural and language barriers along with a lack of understanding and awareness of clinical trials are potential factors that affect patient involvement in clinical trials.

**Methods:** We developed a patient survey in English, Urdu and Bengali to represent our ethnically diverse population in East London to explore the attitudes and understanding of clinical research. The surveys were offered to all patients attending the haemodialysis and renal outpatients department over a 2 week period.

**Results:** 151 forms were completed, 145 in English, 7 in Bengali and 1 in Urdu. 41% of respondents were from patients who attended transplant clinic and 31% from patients who attended for haemodialysis. Overall there was a strong message that patients wanted more trials in nephrology and felt that taking part in trials would help them take a more active role in their health. They also felt there was a lack of information on how to access research opportunities. Of those who completed the survey there was no significant ethnicity differences in their attitudes and understanding of clinical research, however transplant patients who identified themselves as White British were significantly more likely to take part in the survey (p<0.01). Patients who identified themselves as Black British were significantly less likely to take part in the survey (p<0.02). In the dialysis cohort, patients who identified themselves as White British were significantly more likely to take part in the survey (p<0.01). Whereas patients who identified themselves as Bangladeshis were significantly less likely to take part in the survey (p<0.01). Age did not appear to have an effect on patients' perception and understanding of clinical trials.

**Conclusions:** From our work it is clear that there is a patient led demand for greater engagement in translational research. However, challenges remain in engaging ethnic minority cohorts in clinical research.

**Deferred Educational App Personalization Increases Registration Completion**

_Daniel Schwartz,1 Chan Kruse.2 1Faculty of Medicine, Univ of British Columbia, Vancouver, BC, Canada; 2QxMD, Vancouver, BC, Canada._

**Background:** ‘Read by QxMD’ (http://qxd.md/read) is an app that curates the nephrology literature and personalizes reading recommendations based on a clinician’s or researcher’s interests. In order to provide highly accurate recommendations, the app must collect content preferences such as preferred journals and topics. In addition, it must collect email address and personal identifiers in order to complete registration and offer CME. When the registration process is too onerous, mobile app users may not complete registration. If the registration process fails to collect necessary user data, this may negatively impact the educational value of the app. We hypothesized that allowing users to delay providing personal information until after they set their preferences would increase registration completion.

**Methods:** We randomly assigned all users registering on the Android version of Read to two different registration processes. In version 1, “upfront personalization”, users are asked to provide personal identifiers prior to setting their preferences, while in version 2, “deferred personalization”, users set preferences first and after this has been completed are asked for personal identifiers. The Leamplum SDK was used to implement and automate the randomization of alternate registration pathways. The primary outcome was completion of registration.

**Results:** Between April 6, 2015 and June 1, 2015, a total of 5660 users who registered using the Android version of Read were randomized with 2834 users randomized to upfront personalization and 2836 to deferred personalization. Upfront personalization yielded a 47.4% (95% CI 46.0 to 48.8) registration completion rate versus 50.7% (95% CI 49.0 to 52.4) with deferred personalization (p < .05).

**Conclusions:** A strategy of deferred collection of personal identifiers yielded slightly higher completion rates. To maximize user registration when onboarding users to educational medical apps, consider deferring the collection of personal information until after user preferences have been provided. Further research is required to maximize app registration when data requested is extensive as in ‘Read’.

**Onconephrology Abstracts Trends in ASN Kidney Week 2012-2014**

_Jyotsana Thakkar, Rimda Wanchoo, Kenar D. Jhaveri. Nephrology, Hofstra NSLIJ School of Medicine._

**Background:** Onconephrology is an emerging new specialty of nephrology. The ASN created a forum dedicated to the field of Onconephrology in 2011 to improve collaborative care for cancer patients with kidney disease. One of the aims was to allow for collaborative research strategies in the field of onconephrology. However, the number of onconephrology related abstracts accepted to be presented at ASN Kidney Week (ASN-KW) 2012-2014 is not known.

**Methods:** We reviewed the abstracts presented in the ASN-KW over past 3 years from 2012-2014 which were related to Onconephrology. Search terms used to identify abstracts included cancer, myeloma, chemotherapy, tumor lysis, paraneoplastic syndrome and hypercalcemia. They were then categorized into: basic science, chemotherapy, myeloma, epidemiology, electrolyte disorders, AKI, tumor lysis, GN, paraneoplastic syndromes and obstructive uropathy. Abstracts were also categorized based on study design.

**Results:**

Figure above breaks down the total number(s) of abstract(s) Y axis) in the last 3 years presented at ASN-KW by category. There has been an increase in the number of onconephrology abstracts over last 3 years. A total of 175 abstracts were reviewed. In 2012, there were 50 onconephrology related abstracts, increased to 54 in 2013 and 71 in 2014. Abstracts related to basic science(16%), chemotherapy toxicities(16%), myeloma(16%) and epidemiology (16%) dominated most of the accepted abstracts. Of the clinical abstracts, > 50% were case reports, 41% were retrospective studies, 4.5% database studies and <1% RCT.

**Conclusions:** Over the last 3 years, we have seen a growing trend in the number of abstracts submitted in the ASN-KW related to the field of onconephrology. We suggest creating a separate section dedicated to onconephrology in the ASN meetings to allow for collaborative research and greater understanding of cancer related nephrology, leading to improved patient outcomes.

**Patients-Initiated Educational Research in a Digital Age**

_Chavakrit Krittanawong,1 Zhen Wang,2 Sakkarin Chirapongsathorn,3,4 Hua Ann Jenny Lu.1 1Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; 2Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; 3Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; 4Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; 5Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA._

**Background:** The emergence of web-based technology in the digital age has become popular in the healthcare industry, particularly in the educational research field. A web-based technology can bridge the educational gap between researchers and patients.

**Methods:** We aimed to develop a user-friendly interface between a virtual community that is driven by patients and researchers and a preliminary knowledge-building activity. Wikiheart is a web research environment that creates a real-time community between researchers and patients without geographical restrictions.

**Results:** On patients have registered for free, the system allows these users to write their own articles or to edit other articles, which often leads to thought provoking medical research questions. Wikiheart also demonstrates a novel approach to population science that is based on huge databases with multiple cloud servers that reach the web research community. Nowadays Wikiheart has more than one million visitors, and serves as an educational web technology that provides its users with both a variety of learning methods, and several areas of research focus.

**Conclusions:** Wikiheart is an innovative web-based program for conducting educational research in the digital community. It is an excellent tool for researchers and patients to generate new hypotheses via the scientific method in an online environment.
DB-2 fell 2 to 7 days after folic acid injection, supporting tubules as a site of SLIT2 synthesis. In a separate experiment, mice were given folic acid, then recombinant human SLIT2 i.p. on days 2, 4, and 6. Kidney function measured directly as GFR or indirectly via BUN 14 days after injection was not significantly improved by SLIT2 treatment.

Conclusions: Folic acid induced injury increased expression of SLIT2 in proximal tubules, followed by detection of SLIT2 in the urine, which points to SLIT2 as a candidate urine biomarker for tubular injury. Amelioration of injury with systemic SLIT2 treatment was not observed, suggesting better utility as a marker than a mediator.

PUB390

Dept of Medicine and Clinical Science, Okayama Univ Graduate School, Okayama, Japan.

Background: Trefoil factor 3 (TFF3) is a small peptide involved in mucosal protection. TFF3 is widely expressed in multiple tissues including kidney. Previous studies have suggested that serum and urinary TFF3 significantly increases in patients with chronic kidney disease and that urinary TFF3 level decreases in rats with acute kidney injury. However, it is unclear whether serum or urinary TFF3 is associated with human renal tissue injury. The aim of this study is to elucidate the relationship between serum and urinary TFF3 levels and the degree of renal tubulointerstitial injury.

Methods: The total study population included 52 patients (tubulointerstitial nephritis: 31, minor glomerular abnormalities and thin basement membrane disease as controls; 21) who underwent renal biopsy. The serum and urinary TFF3 concentrations were determined by a specific ELISA. The degrees of tubulointerstitial cell infiltration and fibrosis were semiquantitatively graded in biopsy specimens and defined by the inflammation score and the fibrosis score, respectively. An immunohistochemical analysis was performed to reveal the localization of the TFF3 protein.

Results: The median serum and urinary TFF3 levels of the disease group were significantly higher than those of the controls (p=0.002 and p=0.008, respectively). A statistically significant positive correlation was observed between the urinary TFF3 level and the fibrosis score in the disease group. However, there was no correlation between the serum or urinary TFF3 level and the renal inflammation score in disease group. TFF3-positive cells were observed in the renal tubular epithelium.

Conclusions: The data indicate that serum and urinary TFF3 levels are significantly increased and, in particular, that urinary TFF3 could reflect renal tissue fibrosis in patients with tubulointerstitial nephritis. Further studies are required to elucidate the precise distribution of renal TFF3 protein and mRNA, and the mechanism underlying the contribution of TFF3 to renal fibrosis.

PUB391

Induction of Epithelial-to-Mesenchymal Transition and Fibrosis Signals via AKT and Peroxisome Activator-Receptor Pathway in Renal Tubular Cells Induced by a Plasticizer Di(2-ethylhexyl) Phthalate Shing-Hwa Liu, Li-Chen Huang, Bo-Lin Chen, Chih-Kang Chiang.

Dept of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; 1DIDT, NTUH, Taipei, Taiwan.

Background: Di(2-ethylhexyl)phthalate (DEHP) is a plasticizer and a probable genotoxic and reproductive carcinogen. More than 300 million tons of DEHP were used each year worldwide. Recent studies have suggested that DEHP has potential adverse effects on the liver, kidney, and reproductive system. It could also cause carcinogenicity and developmental toxicity. DEHP exposure might exacerbate kidney progression. Tubular epithelial-to-mesenchymal transition (EMT) is recognized to play pivotal role in the process of renal fibrosis. However, the mechanisms of nephrotoxicity induced by DEHP remain unclear. Here, we investigated whether DEHP could induce renal fibrosis via EMT process.

Methods: A rat renal proximal tubular cell model (NRK-52E cells) was used to evaluate EMT and fibrosis signaling. Cell morphology was observed by microscope. Cell viability evaluated by MTT assay. The molecular signals of EMT and fibrosis were analyzed by flow cytometry, confocal laser scanning microscopy, immunocytochemistry, and Western blotting.

Results: Treatment with DEHP (5-25 μM) for 72h caused the change in renal tubular cell morphology shifting to spindle-like shape. DEHP did not induce cell apoptosis, but significantly induced G2/M cell cycle arrest. Moreover, the expressions of vimentin, α-SMA, and CTGF, which are the markers of the mesenchymal phenotype, were significantly increased. The expressions of E-cadherin, a maker of epithelial cells, was significantly decreased by DEHP. DEHP could also inhibit the expression of peroxisome proliferator-activated receptor (PPARα) and γ. The phosphorylation of Akt and Smad 2/3 was also significantly increased by DEHP. Notably, treatment with MK2206 (an Akt inhibitor) significantly inhibited DEHP-induced phosphorylation of Akt and EMT. Further investigation revealed that MK2206 suppressed the expression of Akt downstream proteins (NF-κB and GSK3).

Conclusions: These findings suggest that DEHP is capable of inducing the EMT process through AKT and PPAR signaling pathway, which may lead to renal fibrosis.

Discussion: The B Thalassemia is a hereditary disorder of hemoglobin synthesis in the B-globin gene that present clinically with microcytic hypochromic anemia, erythrocytosis ineffective, normal reticulocyte counts or slightly elevated and high levels of A2 hemoglobin. In the kidneys can cause tubular injury and GFR decline. Developing glomerulosclerosis and fibrosis. We can not rule out that CKD is secondary to B-thalassemia, a genetic study would be necessary. It is an uncommon diagnosis in Latin America, but should be considered in patients with CKD and microcytic hypochromic anemia refractory to conventional treatment.

**PUB397**

**Empirical Antifungals in Peritoneal Dialysis Patients with Bowel Obstruction: Time to Reconsider?** Ravinder Pal S. Bhatti, Elwaleed Elnagar, Dumitru Rotaru. Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.

**Introduction:** Intestinal obstruction, even without perforation or ischemia, predisposes patients on peritoneal dialysis (PD) to peritonitis by gut commensals including fungi. Fungal peritonitis (FP), with (Secondary) or without (Primary) prior antibiotic use, is associated with increased mortality and technique failure. This raises the question of empirical antifungal use in PD patients with bowel obstruction. We present our experience with such a patient.

**Case Description:** A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for the past four years with his prescription being 5 exchanges of 2 liters of 1.5% and 2.5% dialysis with a last fill of 2 liters of icodextrin, presented with worsening abdominal pain. His dialysate was clear and had just 3 leucocytes. His CT abdomen showed small bowel obstruction (SBO) with conservative management pursued. Over the next few days, the SBO resolved and dialysate cell counts remained unremarkable. On day 5, he became hypotensive. Examination was notable for increased abdominal tenderness and a cloudy dialysate. Repeat dialysate studies were sent and intraperitoneal vancomycin and cephaloprim were started. Imaging suggested SBO. He responded appropriately to the antibiotics over 48 hours. His CT abdomen showed small bowel obstruction (SBO). With a high risk for both primary and secondary FP, these patient should be suspected in patients with HIV presenting with unexplained hematuria, and renal biopsy should be performed as soon as possible for early diagnosis and therapy. Current management recommendations are similar to those with idiopathic IgA, including ACE inhibitors or ARB for control of proteinuria (>1 g / day) or hypertension.

**Discussion:** Several reports have evaluated the predictive value of peripheral blood eosinophilia as a simple noninvasive diagnostic marker for ACR of transplanted kidneys and of acute cellular rejection. However, peripheral blood eosinophilia was not evaluated as a possible test predicting renal ACR. In a case report, Baradhin et al, described the etiology of AKI following treatment with armodafinil for narcolepsy. They indicated that both (AIN and ACR) has similar biopsy characteristics. However, our patient had no clinical features to suggest AIN, including no new medications. We conclude that leukocytosis and peripheral blood eosinophilia could represent signs of impending acute cellular rejection of transplanted kidneys.

**PUB399**

**A Case of IgA Nephropathy in an HIV-Positive Patient** Hermes Garcia-Sanchez, Vandana Niyyar, Thomas E. Rogers. Nephrology, Emory Univ, Atlanta, GA.

**Introduction:** IgA nephropathy has been described in patients infected with HIV. Though IgA levels are commonly elevated in HIV, these patients may also develop IgA antibodies against specific HIV antigens. Renal lesions may result from HIV antigen-specific immune complexes that are derived from the circulation and from in-situ complex formation.

**Case Description:** We present a case of a patient with HIV/AIDS, on highly active antiretroviral therapy (HAART), who was evaluated for microscopic hematuria and worsening renal function. The patient’s only complaint was early morning peri-orbital edema. On examination, BP was 103/72 mm Hg with a BMI 23 kg/m². Labs showed normal electrolytes, serum creatinine 1.7 mg/dL (baseline 0.7mg/dL), urine protein/creatinine ratio of 2.5 grams/dL. Other serologies were negative. HIV VL was undetectable, and CD4 count was 183. Renal US showed bilateral enlarged, echogenic kidneys. Renal biopsy revealed sclerosing glomerulopathy with IgA immune type deposits on immunofluorescence. The patient was initiated on an ACE inhibitor and a low salt and protein diet, with resolution of his proteinuria to 0.7 Grams/dL. His renal function stabilized, with a creatinine of 1.6 mg/dL.

**Discussion:** In conclusion, IgA glomerular disease arising in HIV positive patients has clinical and pathologic aspects similar to idiopathic IgA nephropathy. IgA nephropathy should be suspected in patients with HIV presenting with unexplained hematuria, and renal biopsy should be performed as soon as possible for early diagnosis and therapy. Current management recommendations are similar to those with idiopathic IgA, including ACE inhibitors or ARB for control of proteinuria (>1 g / day) or hypertension.

**Calcium Channel Blocker Toxicity: Management Strategies and Considerations** Sreesh G. Iyengar, Mark I.C. Hong, Seyed-Ali Sadjadi. Nephrology, Loma Linda Univ, Loma Linda, CA.

**Introduction:** Calcium channel blocker overdose is rare but carries a high mortality due to cardiovascular complications. Generally the management is supportive with use of vasopressors, IV fluids, cardiac pacing, and insulin therapy. There are reports of CVVHDF, hemodialysis or hemofiltration alone and charcoal hemoperfusion for the treatment of CCB overdose. Effective management strategies are needed to improve outcomes.

**Case Description:** Here we describe a patient who presented to the ER after a suicide attempt with ingestion of Norvasc. On arrival to the ER he was awake but later he was intubated. The patient developed acute kidney injury and became anuric. Patient was started on CVVHDF that lasted 48 hours. Unfortunately after two days the patient continued to decompensate and expired.

**Discussion:** Amdioline is a CCB of the dihydropyridine group acting primarily on vessel walls whereas the non-dihydropyridines act more on cardiac muscle and pacer cells. In our case it was clear Norvasc selectively took its effect on the vasculature with profound hypotension with preserved systolic function and no arrhythmia. The case was complicated with ARDS related to diffuse pulmonary edema, a well known complication with CCB overdose. In our case renal failure was likely related to severe hypoperfusion leading to ischemia. There was development combined respiratory and metabolic acidosis. The metabolic acidosis was attributed to renal failure but it is possible that CCB induced inhibition of insulin secretion leading to ketoacidosis may also have contributed. In terms of management of CCB overdose, if recent ingestion then GI decontamination is reasonable with activated charcoal or whole bowel irrigation. The use of high dose insulin therapy has been tried and its role may include increasing ionized calcium levels, improvement of hyperglycemic acids, and improved myocardial function. Most case reports, though
few, have shown little benefit from hemofiltration or hemodialysis theoretically due to high protein binding, bioavailability, rapid metabolism, and low lipid solubility of the drug. One case report did show some promise when multiple therapies were used including IV lipid emulsion, CVVHDF and charcoal hemoperfusion.

**PUB401**

**A Rare Case of IgG1-Heavy Chain Deposition Disease Using Oral Prednisone and Therapeutic Plasmapheresis**

**Sachi Baldeosinh, Madhu Kandarpa. Internal Medicine, Kettering Medical Center.**

**Introduction:** Heavy chain deposition disease (HCDD) is rare, especially without light chain deposition and when causing non-amyloid tissue deposits. **Case Description:** A 75-year-old male with chronic kidney disease (CKD) stage 3 (baseline creatinine 2.3 mg/dL) and right single lung transplant for idiopathic pulmonary fibrosis in 2008 presented with extremity edema and decreased urine output. He has no history of diabetes or uncontrolled hypertension. Admission labs showed BUN 77 mg/dL, creatinine 4.37 mg/dL, and subtherapeutic tacrolimus levels at 3.9 mg/mL. Urine protein/creatinine ratio was 6.6. A 24-hr urine protein collection revealed 5822 mg/24hr. Serum protein electrophoresis showed hypalbuminemia, but no monoclonal proteins were identified. Urine protein electrophoresis was negative for Bence Jones proteins or monoclonal proteins. Urine protein concentration was 713 mg/dL, consisting of 57.8% albumin and 42.2% globulins. C3 and C4 complement levels were low at 46.5 mg/dL and 8.92 mg/dL respectively. Antinuclear antibodies (ANA), anti-streptolysin O (ASO), anti-neutrophil cytoplasmic antibodies (C-ANCA and P-ANCA), and cryoglobulins were negative. Renal ultrasound showed multiple renal cysts without hydropnephrosis. Renal biopsy revealed nodular sclerosing glomerulopathy and IgG1-heavy chain deposition disease. Immunohistochemical study showed negative foci for multiple myeloma. The patient was placed on oral prednisone and therapeutic plasmapheresis in an effort to prevent further renal damage and delay hemodialysis. The patient underwent eight plasmapheresis treatments, however still required hemodialysis for fluid overload.

**Discussion:** Histological and functional plasma cell proliferative disorder characterized by tissue deposits of heavy chain fragments which can lead to renal disease. In HCDD, deposits do not have a fibrillary structure and do not stain positive with Congo red such as with heavy-chain amyloidosis. The rarity of the disease and limited data on evidence-based guidelines for treatment make HCDD challenging to treat. We describe a rare case of IgG1 HCDD with no plasma cell dyscrasia. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCDD renal dysfunction.

**PUB402**

**Cocaine-Induced Vasculitis**

**David Aravapong. Nephrology, Univ of New Mexico, Albuquerque, NM.**

**Introduction:** An increasing number of cases of Cocaine-induced vasculitis are being found among cocaine users in the United States which is due to the use of Levamisole laced cocaine. It is estimated that about 70% of the cocaine used here in the US is contaminated with Levamisole. **Case Description:** We describe a 65 year old male, with a 20 year history of cocaine abuse, who presented with a 1 month history of a progressively worsening, non-painful rash on his trunk and extremities. He denied fever, weight loss and myalgias. He also denied history of otitis media and sinusitis. He reported increased cocaine use during this time. On physical examination he was found to have violaceous plaques with central necrosis on the trunk and extremities. These plaques showed 10% of glomerulitis and interstitial fibrosis and tubular atrophy involving approximately 70% of the specimen. **Treatment:** Mainly abstinence and supportive. •The clinical course of patients is difficult to assess due to the fact that few patients are able to abstain from cocaine use. Our patient was able to abstain from cocaine use for about 30 days and that almost resulted in complete resolution after 30 days of being cocaine-free (Fig. 5). •Although in the setting of worsening skin lesions and ongoing cocaine use, some patients have been treated with anticoagulation or thrombocytopenia, immunosuppression and corticosteroids with varying degrees of success, robust evidence lacking.

**Discussion:** With more than 2 million Americans using cocaine, occurrences of levamisole-induced vasculitis will increase Levamisole exposure should be included in the differential of patients with purpuric vasculitis, neutropenia and cocaine.

**PUB403**

**Morbidity Associated with Uremic Ascies Among Emergent Dialysis Patients**

**Shobana Sivan, Rajeev Raghavan. Nephrology, Baylor College of Medicine.**

**Introduction:** Patients with end-stage renal disease (ESRD) on emergent dialysis often develop complications of inadequate dialysis such as pleural effusion, ascites and pericardial effusion. Uremic ascies is characterized by exudative ascites with SAAG usually <1.1 and is diagnosed after excluding liver, cardiac, infectious and malignant causes. The incidence of uremic ascies in standard dialysis population was described as 0.7-20%. We believe that emergent dialysis patients with uremic ascites have higher morbidity and mortality.

**Case Description:** Total of 463 emergent dialysis patients, who were initiated on dialysis between July 2010 and April 2015 were analyzed. Among 36 patients with Ascites of unknown etiology, 12 patients were included in the study group of uremic ascites. A cohort of 36 patients without ascites was randomly selected for comparison. Two groups were compared based on demographics and morbidity indicators.

The mean age was 50 years with predominance of Hispanic male in both groups. The serum creatinine in the uremic ascites group and the cohort group was 2.6±0.4 and 3.29±0.2 respectively. The mean emergency center (EC) visits and hospital admissions in uremic ascites and cohort group were 79.6, 9 and 63.4, 5.2 respectively. Volume overload and abdomen pain were the major reasons for admissions in the study group. They underwent paracentesis and frequent dialysis during the hospital course.

An Unusual Case of Anticoagulant-Like Nephropathy in a Non-Anticoagulated Patient

Elyas Safar,1 Apurv Khanna.1

Introduction: Anticoagulant-related nephropathy is a well-known cause for Acute Kidney Injury (AKI), which was first described in Coumadin anti-coagulated patients, usually with excessive anticoagulation (INR >4). It was also reported to be associated with other Anticoagulants such as direct thrombin inhibitor Dabigatran. We report a case of Anticoagulant-related Like Nephropathy in a Non-anticoagulated patient.

Case Description: A 71-year-old male was admitted to the VA medical center for shortness of breath and hemoptysis. Past medical history was significant for Non Small cell Lung Cancer, cryoprecipitate liver cirrhosis and COPD. CT chest, showed no pulmonary emboli. He was treated with Vancomycin and Zosyn for Pneumonia. The patient reported gross hematuria initially, which resolved spontaneously. His admission creatinine was 1.1 mg/dl, (baseline 0.6 mg/dl), and went up to 2.4 mg/dl. The patient had another episode of gross hematuria and his creatinine went up to 3.5 mg/dl. The patient remained non-oliguric throughout the course of his AKI. Kidney biopsy showed Tubular epithelial cells injury with red cell casts, but no inflammatory changes and no Immune complexes by Immunofluorescence. The histopathologic pattern shown by the kidney biopsy was consistent with Anticoagulant-related nephropathy. However, the patient was not anticoagulated with Coumadin, Heparin, or any other Anticoagulants. His Pro-thrombin time (PT) was 13.1 seconds (normal 9-12 seconds) and INR 1.2. His PTT was 20.1 seconds (normal 25-34 seconds). He had a low platelets count between 55-100K/ mm3, due to liver cirrhosis.

The findings in this case, suggest a role for Thrombocytopenia in liver cirrhosis, in causing anticoagulant like intra-glomerular hemorrage, which may result in an AKI.

Discussion: Thrombocytopenia and likely Platelets dysfunction in Liver cirrhosis can cause intra-glomerular Hemorrhage and results in Anticoagulant-like Nephropathy, even in the absence of excess coagulopathy as evidenced by a normal PTT & near normal INR. To our knowledge, there has not been a reported case of Anticoagulant-like Nephropathy in Non-Anticoagulated patients.

Smoking Related Idiopathic Nodular Glomerulosclerosis with Crescents

Tahir Zaman,1 Frederic Clayton,2 Josephine Abraham.1,2

Introduction: Idiopathic nodular glomerulosclerosis (ING) is a rare but important cause of nephrotic syndrome. There have been case series reported in the literature regarding the association of ING and smoking.

Case Description: A 57-year-old female with a history of rheumatoid arthritis (RA) presented to the hospital with cough and hemoptysis. Her RA treatment consisted of leflunomide, prednisone and folic acid. Her social history is pertinent for a history of smoking (20 pack-years). Urine analysis was with dysmorphic hematuria and proteinuria (spot protein/creatinine ratio 3.2gms). Serologic workup was unremarkable. Renal biopsy revealed nodular glomerulosclerosis with sparse crescents. Due to sparse crescents, hemoptysis, and AKI the patient was started on high dose steroids which exacerbated patient’s nephrotic syndrome. Ultimately steroids were discontinued which lead to an improvement in proteinuria. Smoking cessation was encouraged.

Discussion: ING with crescents has not been described in the literature. In a case series reported by Markowitz et al, patients with ING had renal failure with a mean sCr of 2.4 mg/dl and proteinuria. The main clinical predictors of progression included lack of angiotensin II blockade and continued smoking.1 In retrospect, it is likely the severity of her intra-glomerular pressures which lead to proteinuria was exacerbated with steroid treatment and resolved with discontinuation.

Charcot Foot Syndrome in a Nondiabetic Hemodialysis Patient

Werner Kizogbas,1 2 Behabat Sat,1 Barbara Klein,2 Andreas Westhoff,2,3 Frank Dellanna,1,2 Gerd R. Hetzel.1,2 1MVZ Davita Karlstrasse, Duesseldorf, Germany; 2Univ Med Zentrum Duesseldorf, Germany; 3Heinrich-Heine Univ, Duesseldorf, Germany.

Introduction: The prognosis is very poor for diabetic hemodialysis (HD) patients with foot lesions. Foot lesions are associated with risk of systemic inflammation and cardiovascular (CV) morbidity. Severe cases of diabetic foot with neuropathic arthropathy, microvascular changes from mediasclerosis, and alteration of foot architecture are known as Charcot Foot Syndrome (CFS). Since diabetic and nondiabetic HD patients may experience changes in calcium and phosphate metabolism and secondary hyperparathyroidism, the question arises whether CFS can occur in HD patients in the absence of diabetes.

Case Description: Presented was a decade-long case study of a male HD patient (DOB 1961) who was treated since Dec 1999 for biopsy-proven nephrotic syndrome due to glomerulosclerosis. The patient began thrice weekly HD in Sept 2005 without prior treatment for diabetes mellitus (A1C 4.9%). In Apr 2012 he presented with a painless inflammatory acute foot syndrome, then presented in Apr 2013 with a planar ulceration. After conservative wound management, prophylactic shoes were prescribed. In clinical examination he showed signs of chronic CFS and arthropathic changes in osa metatarsals 2 and 3 with osteolysis and luxation of tarso-metatarsal joints. Lab results indicate secondary hyperparathyroidism: parathyroid hormone 465 pg/mL, phosphate 6 mg/dL, and calcium 2.2 mg/dL.
Discussion: We believe this is the first description of chronic CFS in a nondiabetic HD patient. Acute CFS diagnosis is important because its symptoms (red warm skin, foot edema) are similar to those of phleghmon and osteomyelitis, and thus may be considered a differential diagnosis. Further investigations are necessary to determine whether this is an authentic entity of a foot syndrome, and if it’s associated with CV morbidity.

**PUB410**

**Introduction:** Crescentic GN is usually manifested by features of active glomerular disease in the urine and by progressive rapid loss of significant renal function. SLE can present as predominantly crescentic GN often as Class III or IV lupus nephritis (LN) usually resulting in rapid deterioration of renal function requiring RRT.

**Case Description:** 18 y/o female recently diagnosed with SLE, on Plaquenil presented to ER with nausea, vomiting and epigastric pain after consuming “tiny tea” and was found to have serum creatinine (Scr) 4.5 mg/dL, which further increased to 4.74 with 3+ protein (2.5g/day), 3+ blood and RBC casts on urinalysis. Other relevant lab data: ANA 1:600, negative dsDNA, positive RNP, anti-SM Ab and normal complements. She was initiated on IV fluids and Scr normalized within 2 days. Renal biopsy showed Pauci immune Crescentic GN, class IV-S (A/C) with minimal IF staining. The clinical course was complicated by seizures; the diagnostic considerations included lupus cerebritis vs. PRES. She was put on valproate to be started on immunosuppression as outpatient. She was admitted a week later with acute liver failure due to valproate and Tylenol at which time she was pulsed with IV Solu-Medrol and discharged on oral steroids with a plan to start MMF after normalization of LFTs.

**Discussion:** Crescentic and focally necrotizing GN can be infrequently present in the spectrum of diffuse proliferative LN. Such cases are generally ANCA negative. Normalization of SCR after hydration in this case suggest pre renal as the likely etiology which poses a treatment dilemma for biopsy proven crescentic GN. While there is not much literature available regarding the treatment of lupus with crescentic GN and normal SCR, a retrospective case series reported that even <50% crescents portend a significant renal risk despite clinically evident preserved renal function. We believe that intense immunosuppression should be used in patients with crescentic GN and preserved renal function, despite the absence of any controlled studies. Our patient was started on MMF and prednisone with improvement in proteinuria from 2.6 gm to 150 mg with normal SCR.

**PUB411**

Anti-Thymocyte Globulin Induced Non Cardiogenic Pulmonary Edema Jaya Kaia, Amit Lahoti. Nephrology, Univ of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** Anti-Thymocyte globulin (ATG) is used in treatment of hematologic malignancies and solid organ transplantation. Immediate local and systemic reactions are known. There has been only one reported case of non cardiogenic pulmonary edema (NCPE) caused by ATG.

**Case Description:** Our patient was a 59-year-old man with Marginal Zone Lymphoma which had progressed to diffuse large B cell lymphoma. Despite Hyper CVAD and Rituximab his disease continued to progress. He received Matched Unrelated Bone marrow transplantation after conditioning with ATG and rituximab. The next day he was admitted to the ICU with respiratory distress and bilateral lung infiltrates initially thought to be pulmonary edema. He was started on Lasix drip but did not improve. His CVP was 5, and his echocardiogram showed normal ejection fraction. Based on these findings he was diagnosed to have NCPE. Bronchoscopy revealed pulmonary hemorrhage. His condition worsened and he was intubated and started on Continuous Renal replacement therapy. He was given additional doses of steroids but without improvement. His died due to respiratory failure after two days of ICU stay.

**Discussion:** Non cardiogenic pulmonary edema is a clinical syndrome characterized by presence of severe hypoxemia, bilateral alveolar infiltrates on chest radiograph without evidence of left atrial hypertension, fluid overload or congestive heart failure. Drug related NCPE is usually diagnosed after other causes of pulmonary infiltrates such as gastric aspiration, sepsis and pneumonia are excluded. The presence of normal echocardiogram and pulmonary hemorrhage within a day of administration of ATG, pulmonary infiltrates which did not resolve after intense attempts of volume removal indicated that the patient had NCPE. ATG is known to cause acute respiratory distress syndrome, alveolar hemorrhage and rapidly progressive interstitial fibrosis likely secondary to Cytokine release syndrome. Providers need to be aware of such complications as even though rare these cause increased morbidity and mortality. It is beneficial to give ATG infusions slowly and accompanied by high dose systemic steroids.

**PUB412**

Hypomagnesemia After Treatment with Pertuzumab Lilian Saro-Nunez,1 Tiffany A. Traina,2 Karen A. Cadoo,1 Teresa Gilewski,3 Ilya Glezerman,4 1Nephrology, NYP-Well Cornell Medical Center, New York, NY; 2Breast Medicine Service, Memorial Sloan Kettering Cancer Center, New York, NY; 3Gynecologic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY; 4Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

**Introduction:** Hypomagnesemia is a known side effect of epidermal growth factor receptor (EGFR) inhibitors such as cetuximab and panitumumab. Pertuzumab blocks HER (human epidermal growth factor receptor) 2 dimerization with HER3 and EGFR, and is used in HER2+ breast cancer. We present two cases of hypomagnesemia with pertuzumab use.

**Case Description:** Case 1 58 year-old woman with history of breast cancer treated with trastuzumab (T), docetaxel, pertuzumab (two doses of 840mg and one dose of 420mg) and carboplatin (AUC6). Patient developed hypomagnesemia with serum magnesium (Mg2+) 0.7 (1.7-2.6) mg/dl and symptomatic hypomagnesemia of 5.9 (8.5-10.5) mg/dl. Since initiation of chemotherapy she experienced diarrhea controlled with loperamide. Fractional excretion of magnesium (FeMg) was 2%. Parathyroid hormone (PTH) was 309.2 (12-88) pg/ml. Pertuzumab and carboplatin were stopped. Mild hypomagnesemia persisted 6 months later.

Case 2 56 year-old woman with history of breast cancer on treatment with T, paclitaxel and pertuzumab (one dose of 840mg and 2 doses of 420mg) was admitted with Mg2+ of 0.3 (1.4-2.2) mg/dL and corrected calcium of 6.1 mg/dL. She complained of chronic diarrhea which improved with loperamide and was receiving proton pump inhibitor (PPI). FeMg was 3%, PTH was 16.1 (12-88) pg/ml. PPI was stopped but patient received another dose of pertuzumab (840mg). She remained hypomagnesemic and required IV supplementation until her death from progression of disease 22 months later.

**Discussion:** Although there were other confounding factors that could have caused hypomagnesemia including diarrhea, PPI and carboplatin, hypocalcemia (a manifestation of hypomagnesemia) did not develop until patients were started on pertuzumab. Carboplatin has been associated with hypomagnesemia but not with the degree of hypomagnesemia seen in these two patients. We postulate that pertuzumab may interfere with reabsorption of Mg2+ similar to EGFR inhibitors.

Acute Renal Infarction: Case Series Yelda Delipozbuddyagci,1 Rumeyza Kazancioglu,2 1Nephrology, Bezmialem Vakif Univ, Istanbul, Turkey; 2Nephrology, Bezmialem Vakif Univ, Istanbul, Turkey.

**Introduction:** Acute renal infarction (ARI) occurs from interruption of kidney’s blood supply either partially or totally. Causes of renal infarction include: thromboembolism (usually from injured or replaced heart valves, congenital heart defects etc.) vasculitic disorders, trauma to the kidneys or hypercoagulable state. We present five cases of ARI with different etiologies.

**Case Description:** Description of Cases : Two female, three male, mean age 52 (range 26-72) patients presented to the emergency department between 2013 and 2015 in a university based hospital setting. Presenting complaint was severe flank pain lasting 2 to 5 days for all of them. At initial examination all patients had costo-vertebral angle tenderness at the affected side. Contrast enhanced abdominal tomography was useful for showing renal artery occlusion and also renal infarction. Trans thoracic echocardiography were all normal and were not adequate in identifying patients having had heart defects, trans esophageal echocardiography was obviously superior in finding cases with possible paradoxical embolism. All patients were treated with enoxaparin therapy. During follow-up there was neither further complication nor kidney damage.
A Rare Case of Kidney Amyloidosis Caused by Heroin Abuse

Nilson D. Feliz, Roberto L. Collazo

A 40 y/o AA man with no past medical history just 20 years of IVDA. Is a condition characterized by deposition of insoluble fibrils in various organs; most commonly the liver and kidneys.Occurs as a result of chronic inflammatory states such as RA, IBD, chronic osteomyelitis, or familial Mediterranean fever.Kidney involvement in amyloidosis is a significant source of morbidity as it can progress to CKD.

**Case Description:** A 40 y/o AA man with no past medical history just 20 years of IV heroin abuse presented to the ED with the CC: Worsening lower extremity edema and a weight gain of 20 lbs. in the past few months. Patient denied any other medical problems or complains. On PE, afebrile, normotensive, with clear lungs, normal heart at auscultation. He was placed on ethacrynic acid and atovaquone because of a sulfa allergy. His albumin remained < 1.5 mg/dL. Renal function worsened, developed Clostridium difficile diarrhea. He was placed on ethacrynic acid and atovaquone. The UA showed >600mg/dL of protein and no hematuria. A 24 hour urine protein collection was >3 g/day. The creatinine level increased to 3.3 mg/dL, from 1.2 mg/dL on arrival. The UA showed >600 mg/dL of protein and no hematuria. A 24 hour urine protein collection was >3 g/day. The creatinine level increased to 3.3 mg/dL, from 1.2 mg/dL on arrival. The UA showed >600 mg/dL of protein and no hematuria. A 24 hour urine protein collection was >3 g/day. The creatinine level increased to 3.3 mg/dL, from 1.2 mg/dL on arrival.

**Diagnosis:** The UE showed 600 mg/dL of protein and no hematuria. A 24 hour urine protein collection showed 50 g of proteinuria and serum albumin 2.1 g/dL. Cholesterol 232 mg/dL, LDL 192 mg/dL, and Trig 189 mg/dL. The patient was started on prednisone and cyclosporine. The patient was referred for biopsy-proven FSGS with high-dose prednisone and cyclosporine.

**Discussion:** ARI usually is a hidden disease, which can easily be missed without any specific suspicion for patients presenting with flank pain. It should be kept in mind that there is no specific biochemical test for ARI and diagnosis process must involve evaluation of cardiac pathologies preferably with trans esophageal echocardiography.

**PUB414**

Disseminated Cryptococcal Infection in a 24-Year-Old Man with Primary Focal Segmental Glomerulosclerosis

Jordin J. Wilber, Caitlin Dugdale, George P. Bayliss, Rhode Island Hospital, Providence, RI; Miriam Hospital, Providence, RI; Aperio Medical School, Providence, RI.

**Introduction:** Focal segmental glomerulosclerosis (FSGS) is commonly treated with biopsy-proven FSGS with high-dose prednisone and cyclosporine.

**Case Description:** Our patient initially responded to prednisone 80 mg daily with proteinuria reduced to 37 mg/g from 3.5 g/y, but then suffered frequent hospitalizations for infection necessitating interruption of immunosuppression, now with decreased responsiveness to prednisone. Cyclosporine was added but interrupted after he developed classical symptoms of SLE and her ANA was only mildly positive at 1:40. Biopsy of the kidney revealed predominant immunofluorescent staining for IgG and C1q with mesangial deposits of C1q. There was no clear evidence of focal segmental glomerulosclerosis to portend a worse prognosis. Her decision to pursue pregnancy prompted further inquiry into the effects of pregnancy on her renal disease.

Review of existing literature, limited as it may be, suggested that C1q autoimmunogenicity may be associated with normal placentation and development in the context of hormonal changes.

**Discussion:** Therefore, interpretation of typical parameters, including urinary protein excretion alone, may not be sufficient in determining disease status. This case demonstrates the importance of renal biopsy in defining the underlying pathology in young women with evidence of glomerular disease who wish to become pregnant as it can help guide prognosis.

A Rare Case of Kidney Amyloidosis Caused by Heroin Abuse

Ravina Patel, Nilson D. Feliz, Roberto L. Collazo-Maldonado. Nephrology, Dallas Methodist Medical Center, Dallas, TX.

**Introduction:** Secondary(AA)Amyloidosis nephropathy is a rare manifestation of AA amyloidosis nephropathy is a rare disease that can present in a variety of ways. We present the case of a 26 year-old female with PCOS and borderline diabetes who developed non-nephrotic-range proteinuria with preserved renal function who wished to become pregnant.

**Case Description:** Her serologic workup was unremarkable. She did not have any classical symptoms of SLE and her ANA was only mildly positive at 1:40. Biopsy of the kidney revealed predominant immunofluorescent staining for IgG and C1q with mesangial deposits of C1q. There was no clear evidence of focal segmental glomerulosclerosis to portend a worse prognosis. Her decision to pursue pregnancy prompted further inquiry into the effects of pregnancy on her renal disease.

Review of existing literature, limited as it may be, suggested that C1q autoimmunogenicity may be associated with normal placentation and development in the context of hormonal changes.

A Case of Adult-Onset Segmental Membranous Glomerulonephritis
Mao Watanabe, Toshiyuki Imasawa, Takehiko Kawaguchi, Takafumi Yamakawa, Maiko Nagata, Moritoshi Kadomura, Hiroshi Kitamura. Internal Medicine, National Hospital Organization Chiba East Hospital, Chiba, Japan.

Introduction: Generally, adult-onset membranous glomerulonephritis (MN) has diffuse and global glomerular changes. We experienced a rare case of segmental MN (SMN).

Case Description: A 66 years old Japanese male was firstly noted proteinuria in an annual health check-up. Serum creatinine was 0.76 mg/dl, urine protein excretion was 2.1 g/gCr, and 10-19 red blood cells/high-power field were observed in the urine sediment. A percutaneous renal biopsy revealed segmental spike formation on the glomerular basement membrane (GBM) and segmental subepithelial deposits in all glomeruli. Granular deposits of IgG, IgM, IgA, C3, C1q were segmentally positive with granular patterns at the same regions. In electron microscopy, electron dense deposits were also found segmentally. The glomerular tufts with deposits included inflammatory cells (mainly macrophages). Any autoimmune disease, malignancies, and infections were detected by further examinations. Because urine protein decreased less than 1g/gCr during the hospitalization, only temocapril hydrochloride has been prescribed from 67 years old. He has never taken immunosuppressive drugs. In 68 years old, because urine protein increased to 3g/gCr, the second renal biopsy was performed. Similarly to the first biopsy, segmental spike formation on GBM and segmental staining of immunoglobulins and complements were observed. The percentage of glomeruli with subepithelial deposits decreased to 60% (6/10) compared with 100% (20/20) at the first biopsy.

Discussion: Adult-onset SMN was rarely reported in spite of 30% of MN cases in childhood. Here, we firstly reported the sequential pathological changes of adult-onset SMN without any immunosuppressive therapy. We will also discuss about the pathogenesis about SMN.

A Case of Hydronephrosis due to Bilateral Retroperitoneal Fibrosis
Zachary Freestrong, Akron M. Shaaban, Josephine Abraham. Nephrology, Univ of Utah, Salt Lake City, UT.

Introduction: Retroperitoneal fibrosis is characterized by inflammatory and fibrous retroperitoneal tissue. It is believed to be due to an exaggerated inflammatory reaction to aortic atherosclerosis resulting from an immunologic trigger. Retroperitoneal fibrosis can be classified as primary or secondary. Secondary causes include medications, malignancy, infection, radiotherapy, and trauma. Patients diagnosed with retroperitoneal fibrosis should undergo thorough evaluation for infectious causes and malignancy.

Case Description: A 55 year old male presented to the clinic with a chief complaint of left side flank and groin pain. He had additional symptoms of night sweats, left leg edema, and weight loss. He was referred to our clinic after initially presenting to the emergency department and receiving a CT scan of the abdomen identifying left side hydronephrosis and a retroperitoneal mass. His past medical history included melanoma 4 years prior and cutaneous follicular lymphoma of the right mandible one year prior. Repeat ultrasound prior to initiation of therapy showed new left sided hydronephrosis. The patient was started on monotherapy with prednisone 1 mg/kg/day. Imaging after initiation of therapy showed improvement in fibrosis with resolution of ureteral obstruction. The patient’s serum creatinine improved from 1.93 to 1.2 after initiation of therapy.

Discussion: Retroperitoneal fibrosis can present as obstruction of the ureters. It is often idiopathic, but secondary causes should be ruled out. Secondary causes include malignancy, infection, and medications. Recommended therapy includes decompression of obstruction if renal function is compromised. If the cause of the disease is idiopathic, then immunosuppressive therapy is recommended. If the disease is due to secondary causes, the underlying cause should be immediately addressed.
she developed new onset BK viruria. One month later, she had a new onset BK viremia and worsening BK viruria up to 3 million and 67.5 billion copies/mL, respectively (Figure 1). Concurrently, she had AKI with a serum creatinine (SCr) of 4mg/dL from a baseline of 1.4mg/dL. Ultrasound showed moderate hydronephrosis (Figure 2). Allograft biopsy revealed acute tubular injury with negative SV40. A percutaneous nephrostomy (PCN) tube was placed and antegrade nephrostogram showed high-grade ureteral strictures (Figure 3). A ureteral stent was placed. FK and MPA target levels were decreased to 5-7ng/mL and 2-4mg/L, respectively. One week later, a repeat nephrostogram showed no obstruction and PCN tube was removed. SCr trended down to 1.2mg/dL. Ureteral stent was removed 6 weeks later. BK viremia became undetectable 6 months posttransplant with low-level BK viruria. The high-level BK viremia but negative SV40 in the kidney biopsy in the context of ureteric obstruction suggested that there was extensive BK replication within the urothelium leading to ureteral stricture and mechanical obstruction. The obstruction improved with resolution of BK viremia following reduction in immunosuppression.

Discussion: Medical management of BK virus with lowering immunosuppression can be an effective treatment to reverse ureteral obstruction due to BK virus infection, while surgical intervention is used to temporarily relieve obstruction.

Impact of Cannulation Technique on Access-Related Complications in Hemodialysis Patients

A 39-year-old woman with a history of lupus nephritis (class V) for 19 years was treated with methylprednisolone and mycophenolate sodium, with recovery of renal function. After being transplanted with a kidney, she developed complications including infection, pain, bleeding, and aneurysm. The incidence of access-related complications (i.e. pain, infection, bleeding, and aneurysm) were extracted from 70 articles, of which 6 RCT were reviewed and 5 were included in the analysis.

Case Description: Articles cited in PubMed database from 2000 to 2015 using key words “hemodialysis”, “cannulation”, and “buttonhole” were searched. Original articles evaluating hemodialysis access cannulation techniques were reviewed; randomized controlled trials (RCT) were selected.

Relevant data including primary outcomes and access-related complications (i.e. pain, infection, bleeding, and aneurysm) were extracted and compared.

Impact of Cannulation Technique on Access-Related Complications in Hemodialysis Patients

A total of 70 articles were found, of which 6 RCT were reviewed and 5 were included in this study (1 duplication). There were a total of 472 patients (BHCT 227 and RLCT 245) with follow-up periods ranging from 2 to 12 months. Two studies reported more pain with RLCT while it was similar in 2 studies and one found more pain with BHCT. Importantly, there was a significant tendency for infection with BHCT compared to RLCT in all 4 studies that could evaluate this complication and included 73% of the patients; the overall rate of infection being too low in one trial to be conclusive. Bleeding complications were similar in 4 studies while 1 found higher risk with BHCT. Only 2 studies reported higher tendency for increase in the size of the access in the RLCT group while 3 did not report any increase. Two studies reported higher incidence of access-related complications (i.e. pain, infection, bleeding, and aneurysm) were extracted from 70 articles, of which 6 RCT were reviewed and 5 were included in the analysis.

Acute Interstitial Nephritis Associated with Probiotic Use

A 44-year-old man was found to have a stable baseline Cr of 1.4mg/dL with a measured Cr of in the normal range. 42 d later, to treat infrequent loose bowel movements (2x/wk), he consumed a probiotic regimen of 10 billion cells of Lactobacillus GG bid for 14 d. There was no diarrhea, fever, rash, blood in the stool, or exposure to NSAIDs, antibiotics, herbs, or other medications. 11 d after probiotics use, during routine physical, he was found to have an increase in his Cr to 1.66 mg/dL (an increase of .5mg/dL in 52 d). There was no proteinuria or hematuria, and an ANA was negative. A renal sonogram revealed echogenic, normal-sized kidneys. His Cr remained 1.4-1.6 mg/dL and did not return to baseline. 135 d after exposure to probiotics, a renal biopsy was performed. The biopsy revealed patchy tubular atrophy and interstitial fibrosis affecting 10% of the cortical area with a few monoclonal inflammatory cells and focal mild lymphocytic tubulitis, consistent with resolving AIN.

Discussion: This case, the temporal association between the use of probiotics with kidney injury and the absence of other causes of AIN implicates the probiotic Lactobacillus GG as the etiologic agent. The mechanisms by which probiotics could potentially cause AIN include manipulation of intestinal microbial communities, immunomodulation, alteration of

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
responsiveness of intestinal epithelial and immune cells, and altering the immunogenicity of degraded enteric antigens. Given the frequent over-the-counter use of probiotics, multiple potential coexisting etiologies for aIN, the often indolent nature of this disease, the rarity of this association, and the need for a renal biopsy to establish the diagnosis, the association between probiotics and aIN may be under-recognized.

PUB426
Decision-Making for the Critically Ill Un-Befriended Patient
Aparajita Mattoo, Jennifer S. Scherer.
Nephrology, NYU School of Medicine, New York, NY.

Introduction: The “un-befriended” patient is one that lacks decision-making capacity & a surrogate decision-maker (SDM). Nephrologists encounter un-befriended patients often, yet limited literature exists to guide decision-making for these vulnerable patients. This case describes an organized approach to caring for a critically ill un-befriended patient.

Case Description: Mr. S was a 74-year-old wheelchair bound nursing home (NH) resident who underwent an urgent right hemicolectomy for a perforated colon. His post-operative course was complicated by septic shock & multi-organ failure including AKI due to ATN. During this time his serum Cr increased from 0.8 to 3.6 mg/dl, with a urine output of <50cc/day. Mr. S was obtunded & had diffuse anasarca. He lacked advance directives & any SDM. The primary service believed that dialysis (HD) should be withheld given his overall poor prognosis. The consulting renal service utilized the four-topic approach to ethical decision-making to guide their recommendations. An estranged sister was asked to partake in an inter-disciplinary team (IDT) family meeting with renal, palliative care, bioethics, & the primary service to explore Mr. S’s values. It was established that Mr. S cherished his life in the NH & would have appreciated time there even if on HD. Under provisions of the NY State Family Health Care Decisions Act (FHCDA), it was determined to be ethically appropriate to withhold HD & transition Mr. S to comfort care.

Discussion: Utilizing the four-topic approach to decision-making, established legal policies, & an IDT, nephrologists can manage un-befriended patients within an organized, legally sound, & ethically sensitive framework.

PUB427
Persistent Kidney and Alveolar Damage in Patients with Goodpasture's Disease and Negative Anti-GBM Antibodies
Giovanna Y. Arteaga Muller, Lilia Maria Rizo Topete, Elisa Maria Guerrero Gonzalez, Concepcion Sanchez Martinez, Jesus Cruz Valdez, Gabriela Alarcón Galván.
Nephrology, Univ Hospital José E. González UANL, Monterrey, Mexico; 2Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.

Introduction: Goodpasture’s disease is characterized by the presence of basement membrane antibodies which act against type 4 collagen in the glomerular basement membrane (GBM) and alveoli, it represents 20% of all crescentic glomerulonephritis. In patients with positive anti-GBM antibodies, the effective addition of a second potassium-sparing agent to ATN is logical. Despite prompt initiation of therapy with fomepizole and renal replacement therapy, rare cases of central hypotension have been reported.

Case Description: 21-year-old old woman, with anemic syndrome presenting Hb 4.33g/dl, Cr 0.8mg/dl, receiving a red cell transfusion. Is readmitted 15 days later Hb 2.7g/dl and Cr 1.9 mg/dl, whereby three globular packages were transfused and she was referred to our hospital. On admission, the patient was hypertension, lower limb edema and gross hematuria, Hb 11g/dl, Cr 1.7mg/dl, negative ANA's and ANCA'S and positive anti-GBM antibodies. Renal biopsy showed crescentic glomerulonephritis and linear staining deposits of IgG in GBM (4+).

Direct immunofluorescence technique (400X). Linear glomerular basement membrane staining for IgG.

Immunosuppressive therapy begins with methylprednisolone and CYCLOPS protocol. Later hemoptysis which improves with plasmapheresis, negative control anti-GBM antibodies. After presented sudden hypoxemia, bronchoscopy with abundant hemosiderin-laden macrophages, whereby plasmapheresis is performed again together with methylprednisolone, cyclophosphamide and rituximab. Currently the patient is in chronic hemoptysis, with negative anti-GBM antibodies.

Discussion: In patients with positive anti-GBM antibodies renal involvement may occur alone or associated with pulmonary hemorrhage, our patient despite having negative anti-GBM antibodies presented pulmonary hemorrhage. The literature recommends confirm the sustained absence of anti-GBM antibodies and signs of recurrence every 6 months.

PUB428
Gitelman Syndrome: Use of Dual Potassium-Sparing Agents in Refractory Hypokalemia
Maria Bernadette Yballe, Sandeep Aggarwal.
Div of Nephrology, Drexel Univ, Philadelphia, PA.

Introduction: Hypokalemia is one of the most frequently encountered electrolyte disturbances. Chronic hypokalemia with hypomagnesemia should prompt further investigation to include rare genetic disorders such as Gitelman syndrome. Despite the appropriate diagnosis, treatment can be challenging.

Case Description: We present a case of a 49-year-old non-hypertensive Caucasian female who presented to our outpatient clinic for an evaluation of her polyuria, chronic hypokalemia and hypomagnesemia. Her polyclia testing revealed the first distinct heterozygous missense autosomal recessive mutations of the SLC12A3 gene from Athena Diagnostics: c. 1315G>A; p.Gly439Ser and c. 2221G; p.Gly741Arg. She was continued on spironolactone 25mg twice daily along with potassium and magnesium supplements. Despite supplementation, she often required hospital visits which prompted magnesium and potassium infusions. Addition of amiloride improved her electrolyte levels, decreasing the need for hospitalizations and supplementations.

Discussion: Gitelman syndrome occurs in only ~1% of the Caucasian population which presents as chronic, sometimes severe and symptomatic hypokalemia, hypomagnesemia, hypocalciuria, and normotensive aldosteronism. The existence of 2 unique recessive alleles inherited by two siblings makes this case even more of a rarity. Our case also demonstrates the effective addition of a second potassium-sparing agent such as amiloride in ameliorating the need for more supplementation.

PUB429
Cerebral Ethylene Glycol Toxicity Despite Prompt Renal Replacement Therapy
Maria Bernadette Yballe, Sandeep Aggarwal.
Div of Nephrology, Drexel Univ, Philadelphia, PA.

Introduction: Acute cerebral edema is a rare consequence of ethylene glycol toxicity. Despite prompt initiation of therapy with fomepizole and renal replacement therapy, rare case reports of central hypotensions on CT imaging with neurologic abnormalities have been reported.

Case Description: We present a case of a 38-year-old female with PMH of HTN and anxiety who was brought in for agitation. One hour later, the patient became obtunded with significant respiratory distress requiring intubation. Home medications included bupropion. It was unclear if she ingested any toxins but the patient did have a history of marijuana use. On physical examination, the patient was hypertensive 210/114 mm Hg with reactive pupils. She was found to have high anion gap metabolic acidosis with a pH of 6.808, a serum bicarbonate of 4, an osmolal gap of 68, and a lactate acid of 5.6. Levels of ethanol, acetaminophen, phenobarbital, salicylate, and valproic acid levels were undetectable while urine drug screen was only positive for THC. Head CT did not reveal any acute
pathology. Urine microscopy revealed multiple ovoid colorless crystals in rosette formation consistent with monohydrate calcium oxalate crystals. Fomepizole was immediately started and intermittent dialysis initiated promptly within 10 hours of ingestion. However, due to hemodynamic instability, RRT had to be converted to a continuous veno-venous hemodialysis. After 2 days, patient then experienced an acute hypertensive episode with a BP of 172/100 mm Hg from a radial arterial line with pinpoint pupils and a repeat head CT revealing cerebral hypodensities in the basal ganglia, thalami, and brainstem along with surrounding vasogenic edema. Initial serum toxicology screen suggested ethylene glycol toxicity. The patient was intubated and intermittent dialysis initiated promptly within 10 hours of ingestion. However, there was significant focal edema in the basal ganglia with no other electrolyte abnormalities. Toxicology was negative for ethanol or salicylates. 

Discussion: Despite prompt initiation of dialysis, rare case reports of acute cerebral edema from ethylene glycol toxicity have been reported. It is unknown whether these abnormalities are due to direct cellular toxicity or deposition of crystals in the cerebral vasculature causing ischemia and subsequent edema and inflammation. Our case demonstrates a rare neurologic sequela of ethylene glycol toxicity despite appropriate prompt treatment.

**Encapsulating Peritoneal Sclerosis – Case Reports**

**Introduction:** Encapsulating Peritoneal Sclerosis (EPS) is a rare but serious and potentially lethal complication in peritoneal dialysis (PD), first described in 1980. Intestinal obstruction, serious malnutrition and sepsis are the causes of death for this uncommon condition. The exact incidence is unknown.

**Case Description:** We described outcomes of 6 cases followed in a referral service of PD between 2010 and 2015.

**AM Tolvlantop to Avert Hypotensive Seizures in a Patient with Primary Polydipsia and New Mildly Impaired Free Water Excretion**

**Introduction:** A former pilot with a history of primary polydipsia PP (past urines >6 l/day) complicated by confusion. Plasma (P_on) and urine sodium were 123 and 37 mEq/l, and plasma (P_off) and urine osmolalities were 251 and 207 mOsm/kg H2O. With cessation of Prozac and advised fluid restriction (FR) P_on corrected. Interim P_on was 286 mOsm/kg and urine SG 1.005. Following multiple surgeries (decompensatory laparotomy, subtotal colectomy, ileostomy, feeding gastrostomy), for complex postoperative syndrome/pancreatitis, AM Tolvlantop was avert hypotensive seizure (HS). No cause for impaired free water excretion (iFWE) was found. Her PP made FR difficult, as she was thirsty at P_on <125 mEq/l, and caused repeat HSs.

**Case Description:** After her 4th seizure, we replaced FR and salt tablets with AM Tolvlantop. This normalized PNa, abolished her recurrent HSs, and was tailored to her new dreadful PP/SIADH combination.

Indeed, since thirst is constant in DI but only diurnal in PP, the AM tolvlantop-induced daytime DI allowed her to quench her thirst without fear of HSs, if since WE were required by us, when the drug effect wore off, and her PP abided. She was reluctant giving up this diurnal/nocturnal PP/DESIADH, for fear of seizures.

**Discussion:** Given the high capacity for FWE, a syndrome of inappropriate antidiuresis (SIAD) or impaired diuresis-aquaresis (SIDA), due or not to ADH (SIAD/H or SIDA/H) must coexist in PP, for HS to occur; conversely some PP or other source of free H2O must exist in the SIAD/H – SIDA/H spectrum of iFWE to cause HS, since FR alone increases the low P_on and prevents HS despite depot ADH in man, or chronic diAVP infusion in rats. This is the first report of successful compassionate off label use of AM tolvlantop, instead of FR, to prevent HS in a patient where PP is the culprit. However FR instead of vaptans is the first line treatment of low P_on in SIAD/H, yet here ADH is the culprit. In that PP and SIAD/H (or iFWE state) must coexist to cause HS, and that ADH, as assessed by sensitive assays is rarely totally suppressed, resolves this paradox.

**PUB432**

**Atypical Presentation of Calcium Oxalate Nephropathy**

**Introduction:** Ethylene glycol ingestion can cause multi-organ dysfunction including acute kidney injury (AKI) and death. The diagnosis can be made based on history, a high anion gap metabolic acidosis with an elevated osmol gap, oxalate crystalluria and an elevated ethylene glycol level. The diagnosis may be challenging with the concurrent use of other substances such as cocaine as it causes vasomotor AKI or ANCA vasculitis. To elucidate the diagnosis, a renal biopsy may be required. Herein, we present a patient with biopsy proven calcium oxalate nephropathy who presented with unexplained AKI likely related to unintentional low dose regular ethylene glycol use. She did not have any symptoms or classic biochemical features of ethylene glycol intoxication.

**Case Description:** A 57-year-old homeless woman with a history of rheumatoid arthritis, COPD presented with a productive cough and dyspnea and was found to have a Cr of 3.9 mg/dl, elevated from a recent baseline of 0.9 mg/dl. Her anion gap was 17, with no other electrolyte abnormalities. Toxicology was negative for ethanol or salicylates. Her BP was 157/77 mm Hg and physical exam was unremarkable. Her last use of cocaine was 3 days prior to admission. She was initially given normal saline and maintained an adequate urine output, but her Cr continued to rise to 13.0 mg/dl. Urine sediment showed a few isomorphic RBCs only. A renal ultrasound revealed normal sized kidneys. Serological tests for autoimmune, post-infectious and dysproteinemic causes of AKI were normal or negative. Renal biopsy revealed acute tubular injury with calcium oxalate deposition. An in depth history did not reveal a high oxalate diet nor a medical history predisposing her to hyperoxaluria, however she admitted to the regular ingestion of “juiced” street alcohol. She did not require dialysis. Her follow-up Cr was 1.8 mg/dl two months later.

**Discussion:** In conclusion, a thorough history is required when encountering unknown AKI, in patients with a history of drug abuse or homelessness, while keeping a high index of suspicion for drug intoxications including ethylene glycol.

**PUB433**

**Thrombotic Microangiopathy (Hemolytic-Uremic Syndrome) Induced Acute Kidney Injury Associated with Brucella Infection**

**Introduction:** Thrombotic microangiopathies (HUS, TTP and DIC) have been associated with a host of infectious agents. Its association with Brucellosis is uncommon.

We present a case of a patient who developed TMA associated with a case of Brucellosis.

**Case Description:** 52-year-old woman with minimal past medical history presented to the hospital with abdominal pain, fever/chills and general body aches. History was significant for intermittent bloody diarrhea approximately 2 weeks prior to ED presentation. Physical examination revealed epigastric and right upper quadrant tenderness to palpation and patient was started on broad-spectrum, empiric IV antiobiotic therapy with...
Vancomycin, Piperacillin-Tazobactam, and Ciprofloxacin. Shortly thereafter, her clinical status continued to deteriorate resulting in acute respiratory failure requiring intubation and mechanical ventilation. CBC was notable for a white blood cell count of 27,000, hemoglobin of 7.3 g/dL and a platelet count 80,000. Other labs were notable for total bilirubin 2.3 mg/dL, LDH 509 U/L, lactate dehydrogenase less than 10, procalcitonin 5.7 nmol/L and elevated transaminases. Peripheral Smear was notable to be positive for numerous schistocytes. Patient was anuria and Nephrology consulted to begin CRRT in setting of sepsis requiring three vasoressors.

Patient had a rapid improvement in symptoms after initiation of sepsis protocol and was weaned off all vasoressors by 72 hours. Initial workup including abdominal imaging and blood cultures were negative for a source of infection. Patient had remarkable spontaneous clinical recovery and was later found to be positive for Brucellosis by immunoglobulin assay.

Discussion: Brucella infection has uncommonly been associated with the development of Hemolytic Uremic Syndrome. In addition, clinical course is widely variable, ranging from spontaneous recovery, as occurred with this patient, to disease requiring long-term renal replacement therapy.

**PUB434**

**Patient with Clinical Diagnosis of Scleroderma Presenting with Sjögren’s Associated Renal Disease:** Aasim Jaberi, Javvinder S. Bhatia. Nephrology, Boston Medical Center, Boston, MA.

**Introduction:** Overlap rheumatologic syndromes occur in a substantial number of patients with renal disease. The clinical manifestations often favor one diagnosis over another, which can make diagnosing and treating the renal disease very challenging.

**Case Description:** 69-year-old female with no known history of previous rheumatologic disease presented with cough, fever and AKI and was diagnosed with mCTD-related pneumonia. Initial laboratory tests revealed a creatinine level of 2.2 mg/dL and persistent non-anion gap metabolic acidosis. On further history, she complained of long standing heartburn and Raynaud’s symptoms in her fingers. Her physical examination disclosed telangiectasias on palms and skin thickening of the face and PIP joint. These features were consistent with systemic sclerosis, which prompted a rheumatologic work-up. Serologies were significant for a positive ANA and SSA antibody as well as hypocomplementemia. Urine sediment revealed many WBCs with no casts and some non-dysmorphic RBCs. A decision was made to proceed with kidney biopsy to identify the cause of her renal disease since the sediment was not supportive of Scleroderma associated renal disease. She was commenced on corticosteroid therapy and two months post-initiation, her renal function has stabilized.

**Discussion:** This case demonstrated the importance of kidney biopsy in elucidating a diagnosis in a challenging case of overlap syndrome. The rapid diagnosis of interstitial nephritis was particularly important in this patient since most cases of renal associated Sjögren’s go unrecognized until significant renal dysfunction has occurred. It has been proposed to consider kidney biopsy findings of tubulointerstitial disease as additional supportive criteria in the classification of Primary Sjögren’s syndrome, which is a sentiment we also support.

**PUB435**

**Introduction:** Acute post infectious glomerulonephritis (APIGN) most frequently be expected in just over half of patients, and prognosis is dismal in those with underlying diabetic glomerulosclerosis.

**Case Description:** A 69-year-old male with medical history of uncontrolled diabetes, Hypertension and chronic alcohol abuse presented to the emergency department due to shortness of breath and swelling of his legs since one week. Patient was afibrile, blood pressure 200/102 mm Hg. On exam he had clear signs of fluid overload. Pitting edema was seen over the lower extremities bilaterally, up to the shins. He also had an oval ulcer on his right leg anteriorly measuring 2 cm discharging pus. The remainder of the physical exam was grossly normal. Relevant laboratory results potassium of 6.4 meq/L, BUN 51 mg/dl, Creatinine 1.7 mg/dL (Baseline unidentified) and Albumin 2.8 g/dL. Arterialization: protein 300 mg/dL, blood MOD, WBC 61/hpf, RBC 87/hpf, Hyaline casts 7/hpf. Urine eosinophils present. Urine 24 Hr Protein: 6.7 g. Wound cultures positive for Beta Hemolytic Streptococcus Group A. Complement C3: 10.950 <10, C4:34 Antistreptolysin O:400 <200 IU/ml Anti DNAs B Titre: 967. Kidney biopsy results: acute post-infectious glomerulonephritis superimposed on background changes of moderate nodular diabetic glomerulosclerosis.

Discussion: Most children with APIGN recover completely, but there is general agreement that the prognosis is more guarded in adults. Full recovery of renal function can be expected in just over half of patients, and prognosis is dismal in those with underlying diabetic glomerulosclerosis.

**PUB436**

**Two Cases of Kidney Injury Induced by Anti-VEGF Therapy for Carcinoma** Yudai Isozaki, Youse Okagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.

**Introduction:** Anti-vascular endothelial growth factor (VEGF) agents have been widely used in the treatment of various types of advanced-stage malignant tumor, including lung carcinoma and renal cell carcinoma. Although these agents are generally well tolerated, there are increasing reports of renal adverse events, especially proteinuria.

**Case Description: Case 1: A 69 year-old male started chemotherapy including bevacizumab (monoclonal antibody of VEGF) with a diagnosis of advanced lung adenocarcinoma of left upper lobe. The completion of four-course chemotherapy resulted in reduction of tumor volume, and then converted to bevacizumab monotherapy. At one year after the start of therapy, proteinuria with renal insufficiency developed. He was referred to our service for further evaluation and management. Renal biopsy demonstrated microthrombi in the loop wall with duplication of GBM, which was consistent with thrombotic microangiopathy (TMA). Thereafter, with cessation of anti-VEGF agent, proteinuria was gradually ameliorated to less than 1.0 g/day and renal function returned to normal range. Case 2: A 56 year-old male with renal cell carcinoma, who had undergone nephrectomy and diabetes. After the introduction of therapy, he exhibited progression of kidney disease with nephrotic-range proteinuria in a short time. In addition to the cessation of sutinib, hemodialysis was initiated because of fluid overload. After several times of dialysis, urine output was gradually increased and renal function returned to the baseline level.

**Discussion:** The renal adverse effects of anti-VEGF agents are supposed to arise from inhibition of podocyte-endothelial VEGF signaling pathway. VEGF signaling pathway plays an essential part in glomerular development and endothelial maintenance. We need to pay attention to renal adverse effects with anti-VEGF therapy.

**PUB437**

**Concurrent Development of Eculizumab (ECU) (Anti-C5 Antibody) - Responsive Atypical Hemolytic Uremic Syndrome (aHUS) and Siltuximab (SLT) (Anti-IL-6 Antibody) -Sensitive Multicentric Castleman Disease (MCD): Evidence for the Pathogenic Role of Inflammatory Cytokines Joe Ghata,13 Abdulmawla Albiniri,1 Kai Lau.

**Introduction:** The literature has a few cases on the association of MCD with thrombotic microangiopathy (TMA), but the pathogenesis & therapy are unknown.

**Case Description:** We describe a 29-year-old previously healthy man initially presented with non-specific symptoms of what later proved to be MCD. Diagnosis was delayed due to explosive full-blown systemic & biopsy-proven renal TMA, producing dialysis-dependent ARF, severe thrombocytopenia & transfusion-dependent hemolytic anemia tail eculizumab (ECU). The appearance of diffuse lymphadenopathy 8 weeks after acute renal failure (ARF) led to node-biopsy proven MCD diagnosis & therapy with SLT. We postulate MCD was the trigger for TMA & full resolution needs both ECU & SLT directed at the etiology.

10 days before ARF, patient had abdominal pain, treated as cholecystitis by cholecystectomy. Mild splenomegaly & trace ascites were overlooked. Day 7 after ARF, bilateral pleural & peri-cardial effusion & moderate ascites emerged but overlooked as serum creatinine rose.
Severe Hypercalcemia Presenting During Recovery Phase of Ischemic Acute Kidney Injury
Buthavna A. Dinari,1 Fazel Dinari,1 Lavinia A. Negrea.1

Introduction: AKI is frequently complicated by multiple electrolyte abnormalities, including hyperkalemia, hyperphosphatemia, and hypo/hypercalcemia. Hypercalcemia is often seen in the recovery phase of rhabdomyolysis associated AKI, can be severe, including mobilization of calcium deposits out of the recovering muscles, secondary hyperparathyroidism, increase in calcitriol, and resolution of hyperphosphatemia. Immobilization during the oliguric phase he developed severe symptomatic hypercalcemia. Improved with volume replacement and administration of calcitonin, and bisphosphonates are some of the methods used for its treatment.

Case Description: A 31 yo Caucasian male with recently diagnosed Type I DM. A case of hyponatremia from adrenal insufficiency mimicking SIADH

Kappa and lambda light chain staining was negative.1 mg/kg metilprednisolone therapy was initiated and given for 1 month. No regression was observed and hemodialysis therapy was continued. After 2 months steroid therapy was reintiated again but there was no clinical and biochemical response. On follow-up, after 7 months from renal biopsy hypercalcemia, anemia, high sedimentation rate, hypergobulinemia and lytic bone lesions were detected. 16% monoclonal plasma cells were present in bone marrow. With further examinations MM diagnosis was made.

Discussion: Renal biopsies revealing acute tubulointerstitial nephritis pattern which are unresponsive to steroid therapy should always be deeply investigated for alternative diagnoses. MM may have obscure presentations.

Sleep Disturbances in an ESRD Patient Soon After Initiation on Hemodialysis: An Atypical Presentation of ESRD-Related Sleep Disorders
Desiree Garcia Anton, Franco H. Cabeza Rivera, Alexandre Abreu, Marco A. LodinoAvellaneda. Nephrology, Univ of Miami, Miami, FL.

Introduction: Sleep disorders including obstructive sleep apnea (OSA), restless legs syndrome (RLS) and insomnia are highly prevalent in ESRD patients undergoing dialysis, however, these remain stable or tend to improve after initiation of dialysis. There is scarce evidence of new-onset sleep complaints or disorders after initiation of dialysis.

Case Description: We present a case of a 64 year-old male with HTN, DM, ESRD and no previous sleep problems who developed insomnia, RLS, sleepwalking and other sleep disturbances within a month after initiation of continuous hemodialysis. He presented to the nephrology clinic with secondary complications from uncontrolled diabetes (neuropathy, retinopathy and nephropathy); he had been followed by the nephrology service for 4 years before requiring dialysis for uremia and volume overload. Intermittent HD was well tolerated during first month of treatment, achieving good metabolic clearance and volume control; his Kt/V was 1.16, phosphorus was controlled at 4.6 mg/dl and his anemia improved to a hematocrite of 30%. Despite clinical and laboratory improvement, disabling sleep symptoms were reported and he was referred to the Sleep clinic for further evaluation. On his initial actigraphy, a bedtime or rise time pattern was unable to be determined as it showed continuous movements 24 hours per day for the 14 days monitored. Overnight Polysomnography (PSG) revealed normal size kidneys without hydronephrosis. Renal biopsy was compatible with acute tubulointerstitial nephritis.

Reduced Serum Anion Gap due to Lithium Overdose
Tanmoy Sahai,1 Josef Bautista.1 Internal Medicine, Roger Williams Medical Center, Providence, RI; 2Nephrology, Brown Univ/Rhode Island Hospital, Providence, RI.

Introduction: This case demonstrates the clinical presentation and corresponding laboratory results of lithium overdose as well as further discuss management of overdose with intermittent hemodialysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Case Description: A 32-year-old man with a history of bipolar disorder came to the hospital with altered mental status and worsening lethargy. He was subsequently intubated for airway protection. Patient’s lithium level was ~20 mmol/L. CT head showed no injury. The rest of the toxicology screen was negative. His basic metabolic panel (including calcium and albumin) was within normal limits however his bicarbonate was 32 mmol/L and anion gap was elevated. Patient was intubated 24 hours later as patient was awake, alert and arousable with dramatic improvement in mental status. Creatinine also trended down to 0.9 after 48 hours. Patient was extubated 48 hours after initial presentation.

Discussion: Lithium has a narrow therapeutic window and therefore in cases of overdose toxicity have many symptoms including altered levels of consciousness as seen in this patient. Low anion gap is a diagnostic clue to lithium intoxication however other causes include hyperkalemia, hypermagnesemia, and monoclonal gammopathies. Although serum osmolality was not measured in our patient, this can also be a helpful indicator noted in previous case reports. Elevated osmolar gaps with low anion gaps are useful in diagnosing lithium overdose. The standard management for lithium overdose is intermittent hemodialysis and maintaining water balance. The theory behind using intermittent hemodialysis versus continuous venovenous hemodiafiltration is that higher clearance of lithium can be achieved from faster blood flow rates in intermittent hemodialysis if it can be tolerated hemodynamically.

PUB443
Episodes of Hypertensive Crises in a Tetraplegic Dialysis Patient due to Catheter-Associated Endocarditis
Martin Russoorum, Joachim Hoyer, Ivica Gregic, Dept of Internal Medicine and Nephrology, Philips-Univers Marburg, Marburg, Germany.

Introduction: Hypertensive emergencies are a life-threatening condition associated with organ damage including acute heart failure, seizures and coma. Pre-existing arterial hypertension and non-adherence to anti-hypertensive treatment as well as volume overload particularly in dialysis patients are considered major triggers of HC. ESRD patients have a high prevalence (>70%) for hypertension and are at high risk for the development of cardiovascular disease and related complications. Early assessment and treatment of hypertensive states including HC is therefore imperative.

Case Description: Here, we report a case of a 34-year-old patient with sudden onset of repeated episodes of hypertensive emergencies on dialysis. The first episodes of spiking blood pressure of >240/120 mmHg occurred several weeks prior to admission and had become increasingly difficult to manage forcing early termination of dialysis sessions. The patient had been on hemodialysis, via tunneled catheter, for one year. Laboratory findings showed elevated inflammation parameters. Blood cultures were positive for gram-negative rods which were later identified as Pseudomonas aerugiiosa (Pa.). We performed transesophageal echocardiography which showed echodense masses at the tip of the catheter and right cardiac atrium. Hemodialysis via an alternative vascular access instantly resulted in normal blood pressures during dialysis. Subsequently, the patient underwent heart surgery. The tunneled catheter and a large (5.2 x 3.5cm), PA-infected thrombus were removed from the right atrium and the patient put on a targeted antibiotics. Following recovery, a forearm fistula was created and used without major complications.

Discussion: To our knowledge, there is no report in the current literature of hypertensive crises associated with CAE infection. While one may question whether or not it is theoretically possible that the infected catheter may have led to transient bacteremia triggering hypertensive episodes via an unclear mechanism. This case demonstrates that catheter-associated infections should be included in the differentials of causes and triggers of HC.

Funding: Government Support - Non-U.S.

PUB444
Adipsic Nephrogenic Diabetes Insipidus a Possibility? Nivin Haroon, Zeenat Youssuf Bhat. Dept Nephrology, Wayne State Univ, Detroit, MI.

Introduction: Adipsic diabetes insipidus (DI) is a rare syndrome where the patient has central DI and lack of thirst response due to presence of central lesion. We describe a patient who developed nephrogenic DI following a contrast exposure and acute kidney injury (AKI).

Case Description: The patient is a 47 yr old African American female with significant past medical history of mild diabetes mellitus. Her baseline kidney function was stable with a creatinine of 1.0 mg/dl. She had developed progressive non-infarctive inflammatory breast cancer. She completed 2 cycles of paclitaxel and doxorubicin and cyclophosphomide. During this time she was admitted to the hospital following incision and drainage of a rectal abscess and treated with vancomycin and zosyn. Patient had received contrast exposure from computed tomography imaging for the abscess. Two days later the patient started to have rise in Cr with level going from 0.7 to 1.5. Nephrology was consulted for the same.

There was no overt septic shock or blood pressure fluctuation. Urine microscopy was bland and ultrasound showed no pathology. Acute kidney injury was possible from the contrast exposure due to the time to Cr bump within 48 to 72 hour period and history of other overt evidence. Along with the AKI patient was found to have rise in sodium levels. She was having increased urine output in the range of over 4 Liters every day. Sodium was going up from baseline 140 up to 152. Initially patient was not having increased thirst response to give a 5% glucose in D5W (DDAVP) challenge test with no change in the urine output. An MRI imaging of brain was negative for pathology. She was instructed to drink water to match her urine out even if not thirsty. Initially the sodium levelled off and later trended down along with AKI.

Discussion: The case is very much as the contrast injury resulted in nephrogenic DI. The patient lack of thirst response and rise in sodium was even more peculiar as the DI was clearly nephrogenic due to lack of response to DDAVP. It is still unclear why the thirst response in this patient was affected. More studies in future will unravel the complex relation between thirst response and osmolarity.

PUB445
Frailty Modifies the Association Between Age and Dysnatremia in Community-Dwelling Adults
Amanda Jean Miller, 1 Susan E. Howlett, 2 Kenneth John Rockwood, 2 Karthik K. Tennankore. 1 Nephrology, Dalhousie Univ, Halifax, NS, Canada; 2Geriatrics, Dalhousie Univ, Halifax, NS, Canada.

Background: Frailty represents a state of increased risk to adverse health outcomes, reflecting some combination of increased damage and compromised repair processes. Dysnatremia is more common with age and can occur in many settings, suggesting that it may reflect not simply a specific renal problem, but a more general imbalance in damage and repair. The aims of this study were to establish whether frailty severity is associated with a higher rate of dysnatremia and to determine whether frailty explains the previously established association between age and dysnatremia.

Methods: The relationship between age, frailty severity and dysnatremia was investigated across the adult life course in 8898 respondents from the 2003-2004 and 2005-2006 cross-sectional National Health and Nutrition Examination Survey (NHANES) datasets. Respondents were assigned a frailty index (FI) and assessed for dysnatremia (a deviation of serum sodium from the 135-144 mmol/L normal range). The coefficient of variation in serum sodium was used as a systems measure of the response repertoire.

Results: In the overall population, there was a significant positive association between increasing frailty severity and the proportion of patients with dysnatremia (chi-square trend p = 0.001). Increasing frailty severity was also associated with more variability in serum sodium. There was a significant association between advancing age and dysnatremia (p < 0.001); however after stratifying by frailty (FI <0.100, 0.100-0.199, 0.200-0.299, 0.300-0.399, >=0.400), the association between increasing age and dysnatremia became non-significant in all categories.

Conclusions: Increasing frailty severity is associated with dysnatremia and greater variability in serum sodium. Furthermore, frailty appears to modify the earlier association between age and dysnatremia.

PUB446
Approach to Hyponatremia in Congestive Heart Failure: A Survey of Canadian Physicians and Trainees
Amanda Jean Miller1, Bonnie Kuehl, 2 Karthik K. Tennankore. 1 Nephrology, Dalhousie Univ, Halifax, NS, Canada; 2Research, Scientific Insights Consulting Group Inc., Mississauga, ON, Canada.

Background: Hyponatremia is a complication of congestive heart failure (CHF) and is associated with reduced survival, however there are no consensus guidelines for the treatment of hyponatremia in CHF. The aim of this study was to determine the approach to hyponatremia in CHF among Canadian Nephrologists, Cardiologists, Internists and trainees in each of two domains; pathophysiology and management. Management topics included use of diuretic therapy, hypertonic saline, oral urea tablets, vasopressin receptor antagonists (vaptans) and rate of sodium correction. Correct answers were determined by an expert panel of Canadian Nephrologists and Cardiologists.

Methods: Respondents completed 15 multiple-choice style questions surrounding three cases of hyponatremia complicating CHF using an online survey on UKiN.com between December 2012-May 2013. Results were summarized as the proportion of correct/ incorrect responses among Canadian Nephrologists, Cardiologists, Internists and trainees in each of two domains; pathophysiology and management. Management topics included use of diuretic therapy, hypertonic saline, oral urea tablets, vasopressin receptor antagonists (vaptans) and rate of sodium correction. Correct answers were determined by an expert panel of Canadian Nephrologists and Cardiologists.

Results: There were 1097 responses to survey questions among 455 Canadian respondents. Pathophysiology governing hyponatremia in CHF was correctly identified in 68.7% of responses (n = 380). Overall, hyponatremia was managed inappropriately in 53.6% of responses (n = 759). The proportion of incorrect responses among specialists and trainees is depicted in Figure 1. Importantly, an incorrect rate for sodium correction was selected 61.1% of the time (n = 211).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Sorafenib Induced Hyponatremia

Evan Gorshein,1 Catherine K. Wei,1 Jasmeet S. Bajaj,2 Internal Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; 2Critical Care Unit, Univ Medical Center of Princeton at Plainsboro, Plainsboro, NJ.

Background: Sorafenib treats unresectable hepatocellular carcinoma (HCC). It is a multi-targeted tyrosine kinase inhibitor (TKI), which prevents tumor cell proliferation. Their use, however, has been limited by adverse events. Hyponatremia has been reported as one of the most common adverse events associated with sorafenib.

Methods: A 58 year-old female presented with lethargy and edema. Patient was diagnosed with HCC 6 months earlier. She underwent transcatheter arterial chemoembolization and was noted on repeat imaging to have metastatic disease. Patient began sorafenib two weeks prior to admission, with a dose of 200 mg daily. A week later, the dose was increased to 200 mg twice daily. Three days later, the patient increased her dose to 400 mg in the AM and 200 mg in the PM. A day thereafter, patient became lethargic, with generalized swelling. The serum sodium was 106 mmol/L, with a baseline of 134 mmol/L three weeks prior to admission. Urine osmolality was 542 mOsm/kg, and the urine random sodium was less than 25 mEq/L. Patient’s TSH was 6.82, with a normal FT4. AM cortisol was measured at 20.2. Her total protein and lipid profile were normal.

Conclusions: TKI agents may enhance the effects or increase the action of ADH. Time to onset of hyponatremia may be within ten days. Our patient took sorafenib for two weeks. Upon admission, her serum sodium was 106. It was noted that she had a prolonged diuresis and fluid restriction, her sodium reached 128. Other etiologies of hyponatremia were excluded. Sorafenib has been associated with hyponatremia, which may be related to the syndrome of inappropriate antidiuretic hormone (SIADH) secretion. We present a case of sorafenib induced hyponatremia.

PUB447

Current Trends in Etiologic Factors Responsible for the Development of Hyponatremia in Hospitalized Patients

Sandor Win,1 Maria V. DeVita,1 Diana Dreyer,2 Samuel J. Wahl,2 Sandor Win,1 Maria V. DeVita,1 Diana Dreyer,2 Samuel J. Wahl,2 Internal Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; 2Critical Care Unit, Univ Medical Center of Princeton at Plainsboro, Plainsboro, NJ.

Background: Hyponatremia remains the most common electrolyte disorder seen in hospitalized patients. The prevalence has been reported to range from 5% to 15% and to be as high as 29.6% depending on the hospital setting.

Methods: New data were obtained on 2 separate days to evaluate the prevalence and etiologies of hyponatremia in hospitalized patients in a large metropolitan hospital. Hyponatremia was defined as less than 135mmol/L.

Results: Hyponatremia was recognized in 41 of 879 patients (4.6%). The mean serum sodium level in the hyponatremia group was 132.0±3.2 mmol/L. Eighty-five percent of the patients exhibited a serum sodium level of <130 mmol/L. Individuals aged 65 years old or greater made up 58.5% of the patients. Etiologic factors identified in the total number of hyponatremic patients included 9.7% with ESRD, 4.8% post op, 14.6% dehydration, 24.3% with pulmonary disorders, 26.8% with a diagnosis of cancer. The majority of patients were noted, however, to be receiving related drug therapies 63.4%. They were distributed between diuretic therapy (36.6%) and psychiatric drug therapy (26.8%).

Conclusions: This study suggests that hyponatremia often is mild, is commonly associated with drug therapy, affects a significant number of younger patients, and now includes novel conditions such as patients receiving renal replacement therapy.

PUB449

Development of Metabolic Acidosis After Neobladder Replacement in Korea

Shina Lee,1 Dong-Ryeeol Ryu, Kyu Bok Choi, Suk-Hae Kang, Seung-Jung Kim. 1Department of Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea.

Background: Metabolic acidosis frequently develops in patients after neobladder replacement. However, the incidence of metabolic acidosis in patients with neobladder and the factors associated with the development of metabolic acidosis have not been well elucidated. We aimed to investigate the incidence and the potential predictors for the development of metabolic acidosis after neobladder replacement with intestinal segment.

Methods: We included all patients who underwent neobladder replacement using intestinal segment at Mokdong Hospital between January 1, 2005 and December 31, 2014. Metabolic acidosis was defined as serum CO2 below 22 mEq/L at any visit during the follow up period. Patients’ biologic data was presented using t-test and student t test. Subgroups according to the time of metabolic acidosis occurrence was further analyzed in order to characterize predictors for metabolic acidosis by ANOVA tests and multiple regression.

Results: Metabolic acidosis was encountered in 79.4% of patients with neobladder during follow up period. When patients were divided into 2 groups according to anion gap (AG), total CO2(18.9±2.1 mEq/L vs. 20.9±1.3 mEq/L, p<0.001) and chloride(106.6±4 mEq/L vs. 109.4±3.6 mEq/L, p<0.001) were significant different between groups with AG<12 and AG≥12 respectively. Furthermore, when patients were divided into 3 groups; patients with metabolic acidosis at post operative day 1; within a 14days; after 14days, there was significant difference of postoperative laboratory findings among the those subgroups.

Conclusions: Our study showed the rate of development of metabolic acidosis in patients underwent neobladder replacement and the difference between patients with metabolic acidosis and those without metabolic acidosis after neobladder replacement for the first time in Korea. In the future, well designed prospective study will be needed to prevent metabolic acidosis after neobladder replacement.

PUB450

Potassium Abnormalities and Acute Kidney Injury Are Common Complications After Colectomy

Lindsay M. Smith,1 Robert M. Perkins,2 Andrea Lynn Berger,1 H. Lester Kirchner,3 Morgan Grams,1 Alex R. Chang,1 Geisinger Health System; 2Bayer Healthcare; 3Johns Hopkins Bloomberg School of Public Health.

Background: Patients undergoing colectomy may be predisposed to disturbed potassium homeostasis, since the colon has a role in potassium excretion, and volume depletion due to diarrhea occurs frequently after colectomy.

Methods: We examined the frequency of incident mild (<5 mmol/L) and severe hyperkalemia (>6 mmol/L), mild (<3.5 mmol/L) and severe (<2.5 mmol/L) hypokalemia, and impaired AKI, stratified by estimated glomerular filtration rate (eGFR) using creatinine only and potassium (impaired/outpatient) data from 1,762 patients who underwent colectomy surgery at Geisinger Health System between 2004-2013. Results: Median age was 66 and mean baseline eGFR was 79 ml/min/1.73m2. Colonic conditions included inflammatory bowel disease (8%), bowel obstruction (8%), incontinence (2%), diverticulitis (23%), and colorectal cancer (20%). During the surgery hospitalization, post-operative AKI occurred in 32% of patients ; mild and severe hyperkalemia occurred in 18% and 3% of patients. Over a median of 4.0 years post discharge after colectomy, mild and severe hyperkalemia occurred at a rate of 13.4 events/100 person-years and 1.8 events/100 person-years; mild hyperkalemia and severe hyperkalemia occurred at a rate of 15.4 events/100 person-years and 0.7 events per person-years. Rates of impaired AKI after discharge were high (9.1 events/100 person-years). Risks for AKI, mild and severe hyperkalemia increased as eGFR declined (p-values<0.001, Table). Conclusions: Patients who undergo colectomy are at high risk for hyperkalemia, hypokalemia, and AKI, particularly when eGFR is decreased. Comparison to a control group is needed to determine whether the high incidence of hyperkalemia is related to removal of the colon or frequent AKI episodes.

Identify the Causes of the Chronic Hypokalemia: Importance of Urinary Sodium and Chloride Excretion

Chi-Hsien Sung, Kun-Lin Wu, Chih-Jen Cheng, Yu-Juei Hsu, Sung-Sen Yang, Shih-Hua P. Lin

Methods: The patients referred for evaluation of chronic hypokalemia in a medical center were enrolled prospectively for five years.

Results: Ninety-nine patients with chronic hypokalemia (serum K⁺: 2.8±0.4 mmol/L) were enrolled. The major presentations were diziness, fatigue, palpitation, abdominal fullness and muscle weakness/weakness. The plasma renin activities were increased in all patients along with normal-to-high serum aldosterone level. The main imaging findings were nephrocalcinosis/renal stones (n=25). Although Gitelman’s/Bartter’s syndrome (n=32/13) and renal tubular acidosis (n=10) were major renal tubular disorders, forty-four patients were identified with anorexia/bulimia nervosa (n=24), surreptitious use of laxatives (n=10) and diuretics (n=10). The urinary K⁺ excretion rates in patients with renal versus non-renal tubular disorders were significantly overlapped for making the diagnosis alone. Of note, unparalled urinary sodium (Na⁺) and chloride (Cl⁻) excretion with normal Na⁺/Cl⁻ ratio are unique to non-renal tubular disorders. Furthermore, body mass index, serum bicarbonate and magnesium levels, and urine pH were also helpful for the differential diagnosis.

Conclusions: Chronic hypokalemia due to non-renal tubular disorders is emerging and often clinically indistinguishable from those with renal tubular disorders. The integrative interpretation of urine electrolytes excretion rates, especially Na⁺ versus Cl⁻, is important to make a prompt and accurate diagnosis.

Effect of Arterial pH and Bicarbonate Level on Survival of Lactic Acidosis

Disorders of Plasma Sodium in Hospitalized Patients and Effect of Total Plasma Protein Concentration on Its Measurement
Pedro J. Labrador, Silvia Gonzalez S, Santiago Polanco Candelario, Elena Davin Carrero, Jesus P. Marin, Ines Castellano, Juan R. Gomez-Martino. Nephrology, San Pedro de Alcantara Hospital, Cáceres, Spain.

Background: The aim of the study was the analysis of the prevalence of hyponatremia in hospitalized patients, and the effect of total plasma protein concentration on plasma sodium measurements.

Methods: We registered all biochemical analysis from in-hospital patients during one year. Data from age, sex, and department was recorded. Plasma Na was measured by an indirect ion selective electrode measuring system (Cobas 8000 analyzer, Roche Diagnostics). Hyponatremia was defined as plasma Na concentration lower than 135 mmol/L. Hyponatremia was classified based on plasma Na concentration. Mild hyponatremia was defined as 130-134 mmol/L, moderate as 125-129 mmol/L and profound as lower than 125 mmol/L. When TPP was measured, plasma Na concentration was corrected according to: Plasma Na (mmol/L) = Na (mmol/L) / [1 + 0.7 x (TPP concentration)] and by Plasma Na – indirect Na = 0.7 x (TPP concentration – 10).

Results: Our hospital is a 520 in-hospital beds. Plasma Na was measured in 26,904 biochemical analyses from 6,873 patients. Median age was 67 (IQR 50-79). 55.9% were men. Median plasma Na measurement was 5 (IQR 2-11). Hyponatremia was present in 1,514 patients (22%), mild hyponatremia 1,114 (16.2%), moderate 287 (4.2%) and profound 113 (1.6%). Plasma Na could be corrected to TPP in 3,122 patients, using the first formula hyponatremia was present in 29.4% (mild 19.6%, moderate 6.8% and profound 3%) while using the second one, 27.9% (mild 18.7%, moderate 6.4% and profound 2.8%).

Conclusions: Hyponatremia is present in one fifth of in-hospital patients. Correction of plasma Na concentration according to TPP concentration increase hyponatremia diagnostic up to 25%.

An Unusual Cause of Hyponatremia
Mohanad A. Hanounah, James F. Simon. Internal Medicine, Cleveland Clinic, Cleveland, OH; 2Glickman Urologic and Kidney Inst, Cleveland Clinic, Cleveland, OH.

Methods: A 59-year-old woman presented as a self-referral for a second opinion regarding hyponatremia. She had long-standing resistant hypertension currently treated with a diuretic and calcium channel blocker. Medical history included hypertension, type 2 diabetes, and hyperlipidemia.She had been treated for depression and developed depression complications during this hospitalization. She had chronic kidney disease along with mild hyponatremia. She was admitted due to possible hypokalemic polydipsia. She denied any use of diuretics, lithium or diuretic abuse, the last of which was most likely in this clinical situation. Suppression of both renin and aldosterone secretion after IVF confirmed the initial abnormalities were due to volume depletion.

Conclusions: Diuretic abuse should be considered when patients present with hyponatremia and hyponatremia. This case provides a rare insight into physiologic response of the renin-angiotensin system to diuretic abuse and volume resuscitation.
mortality adjusted for patients' characteristics and co-morbid conditions. We used random effects meta-analysis to derive pooled estimates of effect in medical, surgical and mixed admission settings.

Results: We evaluated 135 full text publications from 2,105 reviewed abstracts, of which 32 studies met the inclusion criteria (19, 13, and 5 reported aOR, proportion and both respectively). Patients with hyponatremia were at increased risk of hospital mortality (OR=2.59, 95% CI 1.5-4.47, P=0.001).

Figure 4: Mean serum Na levels before and after the activity.

Conclusions: Admission with serum Na of ≥145 mg/dl is significantly associated with twice the odds of hospital mortality. Protocols towards increasing awareness of hyponatremia and studies evaluating the efficacy of early intervention are warranted.

PUB446

Diagnostic Workup of Hyponatremia in Hospitalized Patients: Does Education Have an Impact? Farai Karimol. Ladan Golestaneh. Dept of Nephrology, Montefiore Medical Center, Bronx, NY.

Background: Hyponatremia is associated with poor outcomes. Studies show that hospitalized hyponatremic patients seldom get adequate diagnostic workups. This study tests the effects of a CME activity on physician’s behavior in the diagnostic workup of hyponatremia.

Methods: This is a cross-sectional analysis of patients admitted to the Internal medicine department at Montefiore Medical center between 05/01/2014 and 12/01/2014. Demographic and clinical data were collected retrospectively. Patients were included if they were admitted under the service of 24 hospitalist attendings. These attendings were implemented to improve hyponatremia workup as defined by the frequency of the following tests: serum osmolality, urine osmolality, and urine sodium. Hyponatremia was defined as the earliest serum sodium less than 135 mEq/dL. There was further subclassification into three groups based on the severity: mild- 130-135 mEq/dL, moderate- 125-130 mEq/ dL and severe: less than 125 mEq/L. Frequency of the diagnostic orders was stratified to be calculated after the activity.

Results: There were 358 patients with hyponatremia: 176 hyponatremia admissions occurred before the live lectures and 182 occurred after. Average age was 63±17, average length of stay was 5.2 days ± 2.9. The severity of hyponatremia was 82%, 14% and 3.4% for mild, moderate and severe, respectively. Forty eight percent of all patients who had hyponatremia at admission were discharged with hyponatremia. There was an increase in serum sodium between admission and discharge with a mean difference of 3.06 (95%CI, 2.63-5.5mg/dL). The mean duration of the 3 orders was 3.2, 19% and 50% in the pre-activity compared to 5.6% in the post-activity. The p value was <0.0001. The effect of activity was 130-135 mEq/dL, moderate- 125-130 mEq/ dL and severe: less than 125 mEq/L.

PUB465

Characteristics and Initial Outcomes of a Multidisciplinary Renal Genetics Clinic (RGC) Andrew John Mallett,1,2,3 Helen G. Healy,1,2,3 Julie M. McQuaughan,1,3 Melissa H. Little,1,3,5 Chirag Patel,1,3,5 ‘Kidney Health Service & Conjoint Kidney Research Laboratory, Royal Brisbane & Women’s Hospital, Brisbane, QLD, Australia; ‘School of Medicine, The Univ of Queensland, St Lucia, QLD, Australia; ‘School of Population Health, The Univ of Queensland, St Lucia, QLD, Australia; ‘Genetic Health Queensland, RBWH, Brisbane, QLD, Australia; ‘Murdoch Children’s Research Inst, Melbourne, VIC, Australia.

Background: Genetic Renal Disease (GRD) accounts for 10% of adults and 50% of children with end stage kidney disease. Advances in molecular genetic diagnostic testing and multidisciplinary renal clinic models suggest opportunities for clinical redesign. Here we describe the initial characteristics, experience and outcomes of the first Australian multidisciplinary RGC.

Methods: A retrospective audit was undertaken of the RBWH Adult Conjoint RGC (1st year of operation; Aug 13-Jul 14). Each encounter involved a nephrologist, clinical geneticist and genetic counselor.

Results: 278 patients (56%) encountered had a known GRD, 9/48 (19%) had a suspected GRD and 12/48 (25%) had an unknown GRD with positive family history (FHs). Patients were most commonly referred by nephrologists (66%). The most common GRD category & diagnosis were cystic kidney disease (49%) and Autosomal Dominant Tubular Aldosteronism (42%). The impact of clinical genetics was associated with GRD in 12/26 (48%). During consultations differential diagnoses were explored (54%), management

OTC Medication Leading to Chronic Salicylate Toxicity. Muhammad Deen, Roozi Khan. Nephrology, CHI St. Luke’s Health, Houston, TX.

Background: OTC medication containing salicylate leading to intoxication.

Methods: 60 YO F with PMH significant for chronic migraines, PUD s/p partial gastrectomy, presented to the ED with complains of nausea, vomiting, AMS, confusion and lethargy with headaches, timmness and decreased bilateral hearing. Patient was found to be tachyphic, diaphoretic with respiratory alkalosis and anion gap metabolic acidosis with normal renal function.

Vitals: BP 114/67mmHg, Pulse 90/min, Temp 97.6 °F, RR 22/min and SpO2 100%.

Examination: Unremarkable examination except AMS.

Figure 3: Admission with serum Na of ≥145 mg/dl is significantly associated with twice the odds of hospital mortality. Protocols towards increasing awareness of hyponatremia

Figure 4: Mean serum Na levels before and after the activity.

Conclusions: Admission with serum Na of ≥145 mg/dl is significantly associated with twice the odds of hospital mortality. Protocols towards increasing awareness of hyponatremia and studies evaluating the efficacy of early intervention are warranted.
advice provided (83%) and genetic counseling undertaken (79%). A genetic test was requested in 58.3%, most commonly being induced by combined diagnostic and genetic counseling reasons (78.6%). Of 12 returned genetic test results, 7 were positive and 1 was a variant of uncertain significance. Two negative results have prompted additional genetic testing. Of 27 patients referred with a known GRD, 6 now have a new suspected GRD. The majority of those referred with either a suspected (69) or unknown GRD diagnosis (10/12) now have a new suspected or confirmed GRD.

Conclusions: These findings demonstrate the early successful operation of this RGC model including diagnostic and genetic counseling benefit. Future assessment of clinical outcomes and expansion to telehealth and paediatric settings is anticipated.

PUB466
Characteristics and Clinicopathological Analysis of Japanese Nephronophthisis Patients Keisuke Sugimoto, Tomoki Miyazawa, Takuji Enya, Hitomi Nishi, Kohei Miyazaki, Hidehiko Yanagida, Mitsuura Okuda, Tsukasa Takeamura, Pediatrics, Kindai Univ Faculty of Medicine, Osaka, Osaka, Japan; 2Pediatrics, Kindai Univ Faculty of Medicine, Medulla Osaka, Osaka, Japan; 3Pediatrics, Kindai Univ Faculty of Medicine, Sakai, Osaka, Japan.

Background: Nephronophthisis (NPHP) accounts for 4 to 5% of end-stage renal disease (ESRD) occurring in childhood. Disease subtypes include infantile NPH1, which progresses to ESRD around the age of 3 years; juvenile NPH, which develops from early childhood to school age and usually progresses to ESRD by an age of 13 14 years; and adolescent NPH, with development of ESRD at an average age of 19 years. Juvenile NPH is reported to be the most common subtype.

Methods: We investigated clinical, histologic, and genetic features in 35 Japanese patients clinically and histologically suspected to have NPHP, aiming to promote early diagnosis. We studied many exons as many as 13 NPHP genes. Since such genetic analysis involves significant cost and time, we also screened biopsy specimens by immunohisto metric methods employing antibodies against relevant peptides.

Results: NPHP occurred fairly uniformly throughout Japan irrespective of region or gender. In 3 families, NPHP affected siblings. The median age of patients was 12.5 years. Renal abnormalities attributable to NPHP discovered through mass screening, such as urine tests in school, however, NPHP accounted for less than 50% of children with abnormal findings, including incidentally discovered renal dysfunction during evaluation of extrarenal symptoms or during routine check-ups. Typical extrarenal manifestations led to discovery including anemia and delayed physical development. The urine often showed low gravity specific density and low-molecular-weight proteinuria. Renal frequent histologic findings included cys tic dilation of tubules, mainly in the medulla, and irregularity of tubular basement membranes. Genetically abnormalities of NPH1 were not common, with large deletions found in heterozygotes showing single abnormalities in each of NPH1, NPH3, NPH4 were observed.

Conclusions: Our findings resemble those reported in Western populations.

PUB467
The Functional Role of the ARHGAP32 L405V Mutation on Cytoskeleton Guisun Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, China.

Background: A site-directed mutagenesis for ARHGAP32 was developed to whether the mutation of ARHGAP32 has the effect on the related factors of cytoskeleton in vitro and to understand the functional role of ARHGAP32 in FSGS.

Methods: 1. Blood DNA of 110 FSGS patients proved by renal biopsy were sequenced and screened for the mutation of ARHGAP32. 2. Total exons sequencing were performed in 28 DNA samples to find out whether mutation of ARHGAP2and other genes were existed. 2.1 site-directed mutagenesis primers of ARHGAP32 was designed and amplified by PCR, obtaining the mutations of ARHGAP32 plasmids. 2.2 Transform the wild type and mutant plasmids of ARHGAP32 into Escherichia Coli respectively, sequenced the plasmids to identify whether the site-directed mutagenesis of ARHGAP32 was successful constructed. (3) Transfected the mutated plasmid of ARHGAP32 into 293T cells and real time RT-PCR. 3.1 Detected the expression of ARHGAP32 in FSGS, IgAN, MN, normal change disease and diabetic disease by IHC. 2.2) (2) The expression of ARHGAP32 in FSGS, IgAN, MN, minimal change disease and diabetic disease by IHC.

Results: 1. No mutation of ARHGAP32 was detected while 6 candidate genes were selected by sequencing all exons. 2. (1) ARHGAP32 gene was expressed mainly in glomerular in kidney tissue by IHC. 2. (2) The expression of ARHGAP32 and β-catenin by real time RT-PCR and western blots in 293T cells which were transfected with the wild type and mutant plasmids of ARHGAP32. 2.2) (2) The expression of Cdc42 and -catenin by real time RT-PCR and western blots in 293T cells which were transfected with the wild type and mutant plasmids of ARHGAP32.

Conclusions: 1. No mutation was detected in sporadic FSGS currently. 2. The mutation of ARHGAP32 had effect on the distribution of cytoskeletal protein of F-actin.

PUB468

Background: Hyponatraemia is the commonest electrolyte abnormality found in elderly hospitalized patients defined as a serum sodium concentration <135 mmol/L with a mean prevalence of 5%. (NDT 2003; 18: 2466). It is a risk factor for fractures due to unsteady gait as well as osteoporosis and bone fragility. Fractured necks of femurs (NOF) are a significant cause of morbidity and mortality in the elderly with an estimated 24% mortality at 1 year (JAMA 2001; 285: 2736).

Methods: Retrospective analysis of 501 patients from fractured NOF database from 1/1/2014 to 31/12/2014 to identify the incidence and severity of hyponatraemia, Chronic Kidney Disease(CKD) Stage and mortality at 30 days and 1 year.

Results: Mean age was 83 years and M:F ratio of 1:3. Mild-moderate hyponatraemia was found in 48% of patients (serum sodium of 126-134mmol/L) with only 3% suffering with severe hyponatraemia (< 126mmol/L). 31% of patients had CKD Stage 3, 5% Stage 4 and 2% Stage 5. 30-day and 1-year mortality was 7% and 18% respectively. Patients were separated into 3 groups based on natrema status.

Natraema status (mmol/L) 1 year survival (%)
<126 (severe) 0.643
126-134 (mild-moderate) 0.809
≥135 (normal) 0.841

Kaplan-Meier survival functions were calculated looking at 1-year mortality.

Those with hyponatraemia at the time of presentation appeared to have a worse 1-year survival. Log-rank test was performed. Using a chi-squared value of 3.521, a p value of 0.172 was obtained (not significant).

Conclusions: From our analysis it is clear that nearly half of patients on admission with fractured NOF have at least mild hyponatraemia with evidence to suggest reduction in 1-year survival. We propose more rigorous investigation of this subtle electrolyte disturbance in primary care which carries with it a significant morbidity and mortality.

PUB469
The Effect of Age on Mitochondrial Protein Levels in Rat Kidney Cortex and Medulla Marianna J. Zamauskis-Tucker, Natalya Mezenina, Cameron M. Behringer. Physiology & Health Science, Ball State Univ, Muncie, IN.

Background: The present study was undertaken to determine the effect of rat age on total protein levels in mitochondria from kidney cortex and medulla.

Methods: Young (3 months of age) and Old (22 months of age) female Lewis rats were used. The kidneys were harvested from anesthetized rats after being perfused with isotonic saline via a catheter in the abdominal aorta. The kidneys were separated into cortical and medullary sections and homogenized in isotonic saline. Differential centrifugation was used to isolate the mitochondrial pellet. The mitochondrial pellet was dissolved in distilled water and spun again at 10,000 rpm to isolate the mitochondrial protein pellet. The mitochondrial protein pellet was dissolved in 1 ml of 0.1 M sodium hydroxide. The protein concentration of the sodium hydroxide solution was measured using the Lowry Protein Assay. The protein concentration was expressed as mg protein/g kidney wet weight. Differences were evaluated using a Student’s t test.

Results: A significant decrease in the total mitochondrial protein level was observed in kidney cortex from Old rats. The total mitochondrial protein level in kidney medulla from Old rats was not significantly decreased.

Conclusions: Total mitochondrial protein levels decrease in the cortex but not in the medulla of the rat kidney with age.

PUB470

Background: Prior research suggests that functional status in ESRD patients declines after initiation of dialysis, implicating the dialysis process in contributing to functional decline. We evaluated a dialysis-specific risk factor of intradialytic change in blood pressure (BP) in relation to changes in physical performance, a component of functional status.

Methods: We enrolled 29 dialysis patients aged ≥50 years. Participants completed a 4m timed walk to measure gait speed both pre and post predialysis and a Falls Efficacy Survey, a measure of concern for falls. Dialytic variables included BP measurements from pre, post and during dialysis along with ultrafiltration rate. Demographics and comorbid data was collected. Analysis evaluated for association between dialytic BP variables and change in gait speed and score on Falls Survey. Multivariate analysis was done to adjust for age, race, sex, diabetes and congestive heart failure.

Results: 28 participants completed the study. The mean age was 62.7 (12.3) years. The majority were male (70.4%) and hypertensive (86.2%). Diabetes was present in 55.2%. The mean (SD) change in gait speed from pre to post dialysis was -0.10 (1.01) m/s. The mean (SD) change in systolic and diastolic BP from pre to post dialysis was -10.6 (25.8) mmHg and -4.6 (10.5) mmHg, respectively. Participants with diabetes had greater intradialytic change with mean (SD) change of SBP + DBP of -26.9 (23.5) and -7.9 (11.3) and -4.6 (10.5) mmHg, respectively. Univariate analysis showed that every 10mmHg decrease in systolic BP and every 5mmHg decrease in diastolic BP was associated with a change in gait speed of -0.01m/s (p = 0.02) and -0.02m/s (p = 0.01), respectively. This association was no longer significant in multivariate analysis, likely due to correlation of change in BP with diabetes status. There was no association between BP change and Falls Survey score.

Conclusions: Decline in physical performance, as measured by gait speed, can be seen post dialysis and is associated with hemodynamic changes during dialysis. Patients with diabetes may be most susceptible to hemodynamic changes. Improving dialytic hemodynamic stability may be a way to reduce the significant functional impairment that occurs post-dialysis.

PUB471
Sirtuin1 Expression in Kidney Tissue Specimens in Patients with IgA Nephropathy. Cetin Ozemre,1 Izret Hakki Arıkan,2 Ceren Ozcan,2 Derya Guler,2 Serhan Tuglular,2 Finlife Denizli.1 *Internal Medicine, Marmara Univ Hospital, Istanbul, Turkey; Nephrology, Marmara Univ Hospital, Istanbul, Turkey; Pathology, Marmara Univ Hospital, Istanbul, Turkey.*

Background: SIRT1 immune expression in renal biopsies samples of the patients with IgA nephropathy were evaluated to identify the possible role of SIRT1 on the pathogenesis of SIRT1 in IgA nephropathy.

Methods: Twenty eight patients 28 patients (16 women, mean age 37±13.8 years) were included. Biopsy specimens of the patients were evaluated according to Oxford Classification. Immunexpression of SIRT1, TNF-α, IL-10 and TGF-β were evaluated on kidney tissue specimens by immunohistochemical staining.

Results: Older age, and higher serum creatinine and uric acid levels were the predictors of a greater decline of the kidney function. There was a positive correlation between mesangial hypercellularity and uric acid levels. TGF-β (nuclear) and IL-10 (cytoplasmic) expressions were shown in 20 (71.4%) and 25 (89.3%) of the patients, respectively. Expression of the IL-10 was higher in patients who had a high average mesangial score. Tubular and weak (+) SIRT1 expression was present only in 7 patients.

Conclusions: A positive correlation was shown between mesangial hypercellularity with uric acid levels in the first time. These results suggest that SIRT1 does not play a direct role in the pathogenesis of IgA nephropathy.

PUB472
Response of Human Primary Renal Proximal Tubular Epithelial Cells to Different LPS Strains. Hong Wang, Margaret M. O’Neill, Carine Boustany, Steven S. Pullen. *CardioMetabolic Diseases Research, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.*

Background: Toll-like receptors are expressed on leukocytes and renal tubular epithelial cells where they regulate immune responses. Recent evidence has implicated renal TLR4 signaling in the pro-inflammatory response in diabetic nephropathy. Ligands for TLR4 include lipopolysaccharide (LPS) and HMGB1. We sought to explore the response of renal proximal tubular epithelial cells (PTEC) to different strains of LPS and HMGB1 as well as modulation by TLR4 antagonists.

Methods: The HK-2 human proximal tubular cell line was stimulated with 3 strains of LPS (S. minnesota, E. coli K12, E. coli 0111:B4) and HMGB1. Primary human PTEC were stimulated with 5 strains of LPS (S. minnesota, E. coli 0111:B4, E. coli 055:B5, E. coli K12, S. typhosa) and HMGB1. Supernatants were harvested and IL-1β, IL-6, IL-8, TNFα, and MCP-1 were detected. TLR4 antagonists EX 76233 and EX 76824 were tested for the ability to modulate cytokine production induced by LPS stimulation.

Results: In HK-2 cells, LPS from E. coli 0111:B4 induced IL-6 and IL-8 production, whereas, S. minnesota and E. coli K12 did not stimulate cytokine production. In PTEC, IL-6 and IL-8 production increased upon S. typhosa, and S. minnesota stimulation. Other strains of LPS did not stimulate production of IL-6 and IL-8 in PTEC. There was little detectable production of IL-1β, TNFα or MCP-1 under the conditions tested in both PTEC and HK-2 cells. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not produce any of the cytokines or chemokines tested upon HMGB1 stimulation. The TLR4 antagonists EX 76233 and EX 76824 blocked cytokine production stimulated by S. typhosa in PTEC. EX 76824 inhibited IL-6 and IL-8 production stimulated by E. coli 0111:B4 in HK-2 cells.

Conclusions: Primary PTEC have unique responses to different strains of LPS, and this response profile differs from that of the HK-2 cell line. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not respond to HMGB1 stimulation. These results highlight a limitation of using the HK-2 cell line in lieu of primary PTEC for interrogating the role of TLR4 in renal inflammation.

PUB473
Assessment of Serum Transforming Growth Factor-Beta 1 in Patients with Diabetic Nephropathy. Om Prakash Kalra,1 Avanish Shukla,1 Ashok Kumar Tripathi,1 Alpana Raizada.2 *Medicine, UCMS & GTB Hospital, Delhi, India; 1Biochemistry, UCMS & GTB Hospital, Delhi, India.*

Background: Diabetes mellitus is the leading cause of chronic kidney disease (CKD) worldwide. The pathogenesis and initial molecular events leading to diabetic nephropathy are still elusive. Chronic low grade inflammation plays an important role in pathogenesis of diabetic nephropathy. Ubiquitous cytokines like transforming growth factor-beta (TGF-β) function in an autocrine or paracrine fashion to elicit extra cellular matrix (ECM) accumulation and cellular hypertrophy in several cell types. TGF-β may play an important role in the pathogenesis of diabetic nephropathy by influencing ECM accumulation.

Methods: This was a case control, cross sectional study. 75 subjects aged 30 – 65 years of either sex were recruited and divided into three groups: Group I: healthy controls (n=25), Group II: patients of T2DM without nephropathy (n=25), Group III: patients of T2DM with nephropathy (n=25). Detailed history, complete physical examination, routine investigations, urine albumin creatinine ratio (ACR) estimation was done. Serum levels of hs-CRP and TGF-β1 were estimated by ELISA.

Results: A statistically significant difference in serum TGF-β1 and hs-CRP levels was observed between all the 3 groups (p<0.001), where highest levels were found in group III and lowest in group I. A positive correlation was observed between serum TGF-β1 and duration of diabetes, FBs, PPBS, HbA1c levels, serum creatinine, urinary ACR and serum hs-CRP. Similarly serum hs-CRP levels positively correlated with the duration of diabetes, FBs, PPBS, HbA1c levels, serum creatinine, and urinary ACR. Serum TGF-β1 and serum hs-CRP showed negative correlation with eGFR.

Conclusions: Overall, TGF-β1 and hs-CRP levels were significantly higher in diabetics as compared to non-diabetic subjects. They were higher in diabetic subjects with nephropathy as compared to those without nephropathy. Serum TGF-β1 and hs-CRP levels in diabetic subjects appear to be dependent on duration of diabetes, glycemic control and degree of renal dysfunction. Thus cytokines like TGF-β1 may play a role in the etiopathogenesis of diabetic nephropathy.

Daptomycin Antibiotic Lock Therapy for Hemodialysis Patients with Gram-Positive Bloodstream Infections following Use of Tunneled, Cuffed Hemodialysis Catheters. Retropective Single Center Analysis Hsung-Wen Yen, Szu-yuan Li. Dept of Medicine, Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Catheter-related blood stream infection (CRBSI) is a major complication in hemodialysis patients. We assessed the efficacy of systemic daptomycin (DPT) plus DPT antibiotic lock therapy (DPT-ALT) for catheter-salvage in patients with gram-positive CRBSI.

Methods: Study Design: Retrospective study of hemodialysis patients with tunneled, cuffed hemodialysis catheters. Setting & Participants: All patients were from a single institution in Taipei and received systemic DPT plus DPT-ALT for treatment of gram-positive CRBSI. Outcome: Successful resolution of CRBSI. Measurements: Resolution of fever within 48 h, negative result of repeated blood cultures after resolution of fever, no clinical evidence of CRBSI relapse, and no need for catheter removal.

Results: Fifteen hemodialysis patients received DPT-ALT for CRBSI, 9 with coagulase-negative Staphylococcus (CONS), 2 with methicillin-resistant Staphylococcus aureus (MRSA), 3 with methicillin-sensitive Staphylococcus aureus (MSSA), and 1 with polymicrobial infections. Systemic DPT plus DPT-ALT cured 11 patients (73.3%). Treatment failed in all 3 MRSA cases (2 with MRSA and 1 with MRSA + Enterococcus faecalis).

Conclusion: Daptomycin antibiotic lock therapy (DPT-ALT) appears to be a promising treatment for CRBSI from CONS and MSSA, but not for MRSA CRBSI. Systemic DPT plus DPT-ALT should be considered for patients with CRBSIs caused by certain species.

The Association of the Type of Vascular Access and Erythropoietin Dose in Maintenance Hemodialysis Patients with Targeted Hemoglobin Level Fanoping Lu.1 Nephrology, First Hospital of Tsinghua Univ, Beijing, China; 2Blood Purification, Beijing Chaoyang Hospital, Beijing, China; 3Nephrology, The Third Hospital of Beijing Hospital, Beijing, China.

Background: Arteriovenous Fistula (AVF) is considered to be the preferential access for patients needing hemodialysis. It is called the “line of life” for these patients. Complications may occur even in autologous AVF or grafts (PTFE). Stenosis is the most frequent complication. Therefore thrombolysis is used for high morbidity, mortality, hospitalization, interruption of the treatment and access loss. The patient must go to angiography study immediately. We want to show that endovascular percutaneous technique with transluminal angioplasty through trans radial access (TRA) results in quick recovery, particularly in AVF thrombosis.

Methods: A 81-year-old man with a left brachiocephalic AVF for 5 years visited the ER with uremic symptoms, and right upper arm swelling, and pain. There was a thrombus in the brachiocephalic vein. Results: Successful cannulation was not possible through the arm. TRA was carried out with a 6Fr sheath and a 0.035” guide wire. A 6F sheath was used to perform an angiography which showed an AVF thrombosis. A 6F sheath was used for the TRA, a 2.5/8 mm angioplasty balloon was used, and it was inflated twice. There was no further AVF thrombosis. The patient was discharged 5 days later with improved symptoms.

Conclusion: Trans Radial Access for Percutaneous Treatment of Arteriovenous Fistula Thrombosis – 2 Cases

Incidence and Risk Factors for Cather Related Infections (CRI) and Their Antibiotics in Hemodialysis Patients – A South Indian Study Shruti Gupta,1 Shikara P. Mallya.2 1Microbiology, SGPJIMS, Lucknow, India; 2Microbiology, KMC, Mangalore, India.

Background: Bacterial infections particularly Staphylococcus species often complicate the vascular access in dialysis patients. This study was aimed to determine the incidence and associated risk factors for catheter related infections in patients on maintenance hemodialysis in a tertiary Hospital in South India.

Methods: Eighty-seven hemodialysis patients (56 M; 31 F) were enrolled in the study. After insertion of dual lumen catheter, patients were followed up till its removal. Nasal swabs were also collected before insertion. At each dialysis session, catheters were examined for any evidence of local infection or sepsis. In case of suspicion, the catheter tip was sent to microbiology laboratory and patients were empirically administered vancomycin. Data obtained was examined for relationship of CRI with clinical and socio-demographic risk factors.

Results: Fifty-three catheters (61%) showed colonization (<15 CFU). Twenty-four (45.2%) catheter tips were found to be colonized by S. aureus, 9 (17%) by P. aeruginosa, 5 (9%) by Acinetobacter, 4 (7.5%) by Enterobacter, 3 (5.6%) by Klebsiella, 2 (3.7%) each by E. coli and Citrobacter spp and one (1.9%) each by S. epidermidis, S. maltophilia, S. marcescens and C. albicans. Bacteremia was positive in 18(20.7%) patients and P. aeruginosa was the organism isolated in 17 (73.8%) episodes. Staphylococcal nasal carriage was seen in 60 (69%) patients, and 36 (41.4%) of these isolates were MRSA. Positive Statistically significant factors associated with CRI included history of bacteremia, presence of diabetes mellitus, long duration (>15 days) of catheterization and antibiotic use within 3 months (p < 0.05 for all). However, the age, gender and staphylococcal nasal carriage did not correlate with increased rate of infection.

Conclusion: P. aeruginosa is the most common organism in catheter related bacteremia which may have a bearing on our current antibiotic policy. Also, early initiation of hemodialysis through fistula may help reduce the CRI rate.
Analysis of Risk Factors of Death in Patients of Maintenance Hemodialysis with Tunneled Cuffed Venous Catheter

Li Zhou, Min Shi, Ping Fu
Nephrology/Medicine, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Background: To analyze the causes of death in patients of maintenance hemodialysis with tunneled cuffed catheter, and explore the risk factors of death.

Methods: All patients of maintenance hemodialysis with tunneled cuffed venous catheter starting hemodialysis from January 1, 2009 to December 1, 2014 in West China hospital were included and observed until June 1, 2015. The patients were divided into observation (death) and control group (survival). Multivariate logistic regression analysis was used.

Results: In total 94 hemodialysis patients who met the inclusion criteria, 24 cases died in the study period. The median age of dead patients was 73.4 years (51.5–96.4). The median time of hemodialysis was 19.20 months (3.17–56.27). Just 1 case replaced tunneled cuffed catheter for twenty three times in total. The main primary causes of renal disease were: CGN 54.3%, JDK 25.7%, HTN 43.3%, polycystic kidney disease 4.3%. Multivariate logistic regression analysis showed that elder age, infection, low serum albumin were risk factors of death. Replacement of tunneled cuffed catheter was not the risk factors for death.

Conclusions: The main causes of death of patients with maintenance hemodialysis by tunneled cuffed venous catheter were cardiovascular and cerebrovascular diseases and infection. Elder age, infection, lower level of serum albumin were risk factors of death in patients of maintenance hemodialysis with tunneled cuffed venous catheter. Replacement of DM (38.3% vs. 58.4%; p = 0.01), more AKI rather than ESRD as a cause of catheter insertion (42.6% vs. 25%; p = 0.02). The immediate complication rate including suturing at exit site for bleeding control was higher in the exchange group (19.1% vs. 8.7%; p = 0.03), but the late complication rate including infection and catheter dysfunction was higher in the de novo placement group (21.6% vs. 8.5%; p = 0.04). The catheter survival rates between two groups were comparable (p = 0.58) and multivariate Cox regression analysis for catheter survival showed the development of late complication was the only risk factor (odds ratio [OR] 1.391, 95% confidence interval [CI]: 1.017–1.901; p = 0.039) rather than the exchange procedure was not a risk factor (OR 0.878, 95% CI: 0.554–1.393; p = 0.582).

Conclusions: The exchange over the guidewire from a previous tunneled catheter to a new one should be positively considered and performed when the new tunneled catheter placement is required.

Exchange Technique Using Previous Venotomy Site Over the Guidewire From Non-Tunneled to Tunneled Hemodialysis Catheter Can Be Performed without Compromising Catheter Long Term Patency

Woo Jeong Kim, Min Seok Choi, Hoong Soh Park, Sung Jun Kim, Byeong Ha Chung, Hyoung Wook Kim, Bum Soon Choi, Cheol Whee Park, Chul Woy Yang, Dong-Chan Jin
Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ. Korea.

Background: The exchange from non-tunneled HD catheter to tunneled one over the guidewire using previous venotomy site does not require time for hemostasis for a new tunneled catheter insertion after its removal. It also does not require a new venipuncture so that it can prevent additional vessel wall injury. However, some concerns that it may be associated with increased risk of infection and bleeding after procedure prevention is required.

Methods: From March in 2009 to March in 2013, 47 cases where the exchange from non-tunneled to tunneled catheter and 310 cases with de novo placement groups were respectively assigned to exchange and de novo placement groups and they were compared.

Results: Compared with the de novo placement group, the exchange group over the guidewire had a higher hemoglobin level (10.6 ± 1.6 g/dl vs. 10.3 ± 1.7 g/dl; p = 0.001), more females (69.6% vs. 48.1%; p = 0.006), more ESRD rather than AKI as a cause of catheter insertion (95.7% vs. 74.8%; p = 0.002). Both immediate complication rate including suturing at exit site for bleeding control (19.6% vs. 8.7%; p = 0.02) and late one including infection and catheter dysfunction were higher in the exchange group (21.6% vs. 8.5%; p = 0.04). The catheter survival rates between two groups were comparable (p = 0.58) and multivariate Cox regression analysis for catheter survival showed the development of late complication was the only risk factor (odds ratio [OR] 1.391, 95% confidence interval [CI]: 1.017–1.901; p = 0.039) rather than the exchange procedure was not a risk factor (OR 0.878, 95% CI: 0.554–1.393; p = 0.582).

Conclusions: The exchange over the guidewire from a previous tunneled catheter to a new one should be positively considered and performed when the new tunneled catheter placement is required.
Utility of Arterio-Venous Fistula Flow and Doppler Ultrasound in the Prevention of Thrombosis of the Vascular Access

Background: A Multidisciplinary Unit for attention to the vascular access was established in our hospital in December 2010. The main role of the nephrologist consists in monitoring the functioning of the vascular access by determining the arterio-venous flow (AVF) and undertaking the doppler ultrasound. The objectives for initiating this program were to reduce the thrombosis rate by diagnosis and treatment of a non clinically detected pathology and to decrease the percentage of patients with a tunnelled catheter.

Methods: The prevalence of haemodialysis patients on 31st December 2014 was 65 patients in the Hospital Unit and 90 patients in the Dialysis Center. In the Hospital Unit we supervise the functioning of the vascular access by measuring the AVF flow and we perform a Doppler ultrasound study if the flow is less than 500 ml/min, if there are significant decreases in comparison with previous controls or if there is any clinical dysfunction. The Dialysis Center uses first generation methods for monitoring (increase in venous pressure, pump flow decrease, recirculation) and requests the Hospital Unit to undertake a Doppler ultrasound study whenever there is any type of dysfunction.

Results: We have observed differences in the results between both centers: 1° Incidence of patients with a tunnelled catheter was lower in the Hospital Unit (14 vs 22%). 2° Thrombosis rate was 40% lower in the Hospital Unit (7.9 vs 12/100 patients-year). 3° Doppler ultrasound detected 25 patients with haemodynamically significant stenosis, confirmed by radiologic study, which were successfully treated.

Conclusions: The combined use of AVF flow measuring and doppler ultrasound studies for monitoring the vascular access is an efficient method for reducing the rates of thrombosis and the number of tunnelled catheters due to the early detection of stenosis and its preventive treatment.

Females Have Less Arteriovenous Fistula and More Grafts Compared to Men: Data from the Slovenian Renal Replacement Therapy Registry

Background: The aim of our study was to compare prevalence of arteriovenous fistula (AVF) and graft in female and male chronic haemodialysis (HD) patients.

Methods: Data on vascular access in prevalent HD patients on December 31, from 2009-2013, were analyzed, in addition to sex, age, dry body weight and blood flow (QB) during HD, from database of the Slovenian Renal Replacement Therapy Registry. The use of preoperative ultrasonography mapping before AVF and graft construction in standard practice in the country.

The difference between percentage of AVF comparing females and males is persistent and highly significant during the observation period (p<0.001), with females having less AVF. Females had persistently slightly more grafts. Males had higher mean dry body weight (77.1±11.6 kg vs. 64.7±14.7 kg, end of 2013, p<0.001). Although absolute blood flow during HD was higher in males, females had higher blood flow when standardised to body weight (4.41±1.03 vs. 3.83±0.83 ml/min/kg, p=0.001, end of 2013).

Conclusion: Females chronically have significantly less arteriovenous fistula and slightly more grafts compared to males, with the difference being persistent during five years. Blood flow during HD, when standardised to body weight, was significantly higher in females than in males. Potential clinical consequence of higher blood flow during HD in females is the lack of unexplained variation which is increasingly had seen in patients on AVF where we are waiting to intervene.

Waiting Too Long to Intervene

Background: A number of patients with newly created arteriovenous fistulae (AVF) require tunnelled dialysis catheter (TDC) for dialysis until their AVF is deemed mature. Although data have emphasized that the AVF maturation period is 4-6 weeks long, providers often wait up to 6 months hoping the AVF will eventually mature. During this maturation period if dialysis is required, patients frequently use TDC and can experience complications associated with these devices. This retrospective study evaluated 43 ESRD patients with a maturing AVF who were dialyzing with a coexisting TDC placed within 3 months of AVF creation. The patient population was divided based on dual access (DA) duration: DA<42 days (n=10), DA=42-90 days (n=13), and DA>90 days (n=20). An analysis of DA duration and follow-up visits were performed. All patients had surgical follow-up at least once within the first 42 days of AVF placement regardless of DA duration. Additionally, patients with a DA duration greater than 90 days were evaluated consistently by a surgeon once within the first 42 days of AVF placement regardless of DA duration. Despite this, patient with DA period of greater than 42 days had increasing propensity to undergo avoidable exposure to the risks of prolonged TDC use (p<0.01). Specifically patients with DA>42 days, DA=42-90 days, and DA>90 days were unnecessarily exposed to the risks of dual access for an additional 2.5, 11.7, and 46 days, respectively (p<0.01). This discrepancy between regular surveillance and delayed TDC removal raises concerns that there is a lack of timely intervention after assessment. A more thorough documentation of reasons for prolonged TDC use and analysis of such data are required to verify this hypothesis and get a better idea of etiology of delayed TDC removal.

Methods: Retrospective collection of data from outpatient dialysis units on patients who have AVF/Graft and TDC.

Results: The delayed TDC removal in patients with AVF/Graft the risk of infection in these patients with both devices.

Conclusions: TDC should be removed at an appropriate period once AVF/Graft are mature enough to be used.

Gene Methylation Profile of Human Vein Tissues Taken at the Time of Surgery: Correlation with AVF Maturation

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction and a major impediment to the Fistula First initiative. Despite the magnitude of the clinical problem, there are currently no effective therapeutic interventions for early AVF failure. In order to better understand the cellular and molecular mechanisms involved in early AVF failure we have evaluated the gene methylation profile of venous segment tissue samples obtained at the time of AVF creation. DNA methylation of Cpg islands (regions of the genome that are rich in cytosine and guanine sequences), influences gene expression (turns off the gene). An increasing number of diverse factors are now known to epigenetically regulate genes, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD). In this study we compare the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that are able to support dialysis.

Methods: gDNA was isolated from venous segments collected at the time of AVF creation. Deep sequencing technologies were used to identify genes with the greatest differences in methylation between the two groups. Gene networks focused on inflammation, oxidative stress and endothelial dysfunction were evaluated. Standard bioinformatic techniques were used to identify/interrogate both the gene list and the network analyses.

Results: We were able to identify approximately 300 genes that were significantly different in the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that were able to support dialysis.

Conclusions: Our results suggest that epigenetic regulation (DNA methylation) could play an important role in AVF maturation, and also in the identification of novel druggable targets. This latter point could result in the development of novel therapies for dialysis vascular access dysfunction as a whole.

Development of a Uremic Pig Model of Arteriovenous Fistula Stenosis (AVF): A Surgical Approach

Background: AVF stenosis remains an important cause of hemodialysis vascular access dysfunction for which there are no truly effective therapies. We and others have previously described well characterized large animal models of AVF stenosis. An important flaw in these models is that the pigs are not uremic, which is an important factor in the pathogenesis of AVF stenosis.

Methods: Chronic renal insufficiency was created by initially removing one of the kidneys through a midline incision. Following this the contralateral kidney underwent a dissection of the renal vasculature to expose all the major branches of the renal vasculature. A selective ligation of the renal vasculature in the pelvis,
which allowed for the viability of less than 20% of the renal mass on one side was then performed (upper figure = a, b, c). Of note the differential backbleeding/motting of the kidney following ligation of vessels in the renal pelvis, allows us to perform a real time assessment in terms of the amount of viable renal tissue. BUN and creatinine estimations were then made biweekly for 6 weeks.

Results: The described surgical technique has allowed us to achieve a stable creatinine of 4 mg/dL over a four week period (lower figure = d). This stable period of uremia will allow us test out the impact of “downstream uremic vescular biology” on AVF maturation.

Conclusions: We have developed a unique, innovative and surgically created pig model of uremia with potential logistic and financial benefits. The availability of this animal model will put us in a unique position to be able to tease out the relative contributions of hemodynamics and uremia to AVF stenosis both in our experimental pig model and also in CKD and ESRD patients.

Multimedia Education Tools for Dialysis Vascular Access Monitoring

Tushar J. Vachharajani, 1 Claudia L. Poole, 2 Victoria L. Cash, 2 Joseph A. Vassalotti, 1 Nephrology, W. G. (Bill) Hefner VAMC, Salisbury, NC; 2Fistula First Catheter Last Workgroup Coalition, ESRD National Coordinating Center; 1Nephrology, Icahn School of Medicine at Mount Sinai & National Kidney Foundation, NY.

Background: From 2005 to 2012, the Fistula First Breakthrough Initiative (FFBI) of the Centers for Medicare & Medicaid Services focused on improving the arteriovenous fistula (AVF) rate in the hemodialysis (HD) patients. Since the transition to Fistula First Catheter Last (FFCL) in 2013, the workgroup has created multimedia tools to help dialysis facilities and clinicians reduce the use of central venous catheters (CVCs) and further increase AVF use. The key focus for FFCL remains access planning, access monitoring (physical examination) and the multidisciplinary dialysis care team (DCT) with the ultimate goal of achieving freedom from CVC. Two separate toolkits available on the FFCL website (http://esrdncc.org/ffcl) highlight patient-level and DCT-level education.

Results: The multimedia toolkits are interactive and easily accessible from any mobile device. Conventional handout/poster formats are also available. The impact of these educational tools will be evaluated once these resources are widely utilized in clinical practice. The primary goal is to develop and disseminate tools to educate and create awareness to increase AV fistula utilization to 68% of appropriate patients, decrease the use of long term catheters (<90 days) to <10%. FFCL is currently collecting metrics on professionals that are aware and using these tools.

Conclusions: The purpose of this presentation is to achieve wider dissemination of these tools and increase awareness among patients/professionals.

Multimedia Access Planning Tools to Attain Catheter Freedom

Tushar J. Vachharajani, 1 Claudia L. Poole, 2 Victoria L. Cash, 2 Joseph A. Vassalotti, 1 Nephrology, W. G. (Bill) Hefner VAMC, Salisbury, NC; 2Fistula First Catheter Last Workgroup Coalition, ESRD National Coordinating Center; 1Icahn School of Medicine at Mount Sinai & National Kidney Foundation, NY.

Background: From 2005 to 2012, the Fistula First Breakthrough Initiative (FFBI) of the Centers for Medicare & Medicaid Services focused on improving the arteriovenous fistula (AVF) rate in the hemodialysis (HD) patients. Since the transition to Fistula First Catheter Last (FFCL) in 2013, the workgroup has created multimedia tools to help dialysis facilities and clinicians reduce the use of central venous catheters (CVCs) and further increase AVF use. The key focus for FFCL remains access planning, access monitoring (physical examination) and prevention of access infection.

Methods: Why the need for change? FFBI Change Concepts over the past decade resulted in an increase in the AVF rate in the prevalent HD population from 23% to 61% of eligible patients. The impact on the incident HD population has remained suboptimal, with >78% HD patients initiating dialysis with a tunneled CVC. Moreover, the percentage of patients in the prevalent HD population with CVCs in use for 90 days or longer has remained stagnant. Access planning tools: FFCL tools are created to educate the patient and the multidisciplinary dialysis care team (DCT) with the ultimate goal of achieving freedom from CVC. Two separate toolkits available on the FFCL website (http://esrdncc.org/ffcl) highlight patient-level and DCT-level education.

Results: The multimedia toolkits are interactive and easily accessible from any mobile device. Conventional handout/poster formats are also available. The impact of these educational tools will be evaluated once these resources are widely utilized in clinical practice. The primary goal is to develop and disseminate tools to educate and create awareness to increase AV fistula utilization to 68% of appropriate patients, decrease the use of long term catheters (<90 days) to <10%. FFCL is currently collecting metrics on professionals that are aware and using these tools.

Conclusions: The purpose of this presentation is to achieve wider dissemination of these tools and increase awareness among patients/professionals.
There was a steep relationship between weekly Kt/V and B2M in all three modalities. The steepness of this relationship was similar between HD and SF across RRF values, but differed for RRF=4ml/min in LD. At any given level of Kt/V the B2M level depended on RRF and dialysis modality.

Conclusions: Weekly B2M Kt/V, a simple measure of middle molecule dialysis adequacy, tracks middle molecule exposure in conventional and daily dialysis. The interpretation of a given Kt/V value requires knowledge of RRF in all dialysis modalities. Future studies should determine whether RRF, diaclytic Kt/V or both are predictors of survival in daily dialysis.

A Test Battery to Establish Changes in Physical Performance and Protein Energy Wasting in Nocturnal Hemodialysis: The DiapriFIT Study

Manouk Dam,1 Floor Neeleman,1 Caroline E Douma,2 Brigit C van Jaarsveld.2 1Nutrition and Dietetics, YU Univ Medical Center, Amsterdam, Netherlands; 2Nephrology; YU Univ Medical Center, Amsterdam, Netherlands.

Background: Nocturnal hemodialysis (NHD) improves volume control and phosphate and middle molecule removal. Observational data show increases in body weight and protein intake upon switching to NHD. Other aspects of protein energy wasting (PEW) remain underexplored and also little is known about functional outcomes, such as physical performance and muscle strength. Therefore, the aim of this study is to investigate whether physical performance improves and PEW decreases in patients who change from conventional hemodialysis (CHD) to NHD, compared to patients who continue their treatment on CHD.

Methods: The DiapriFIT study plans to include 25 patients on CHD (2-4x/wk, 3-4 hours) and 25 patients on CHD who switch to NHD (3-4x/wk, 8 hours) with 1-year physical performance and PEW as endpoints. They were submitted to a Visual Appetite Score (VAS), Handgrip Strength (HGS), upper arm circumference (UAC), Short Physical Performance Battery (SPPB) and 6 minute walk test (6MWT), baseline results are reported here. As in NHD weight increases, we tested associations of the outcome parameters with dry weight.

Results: At present, 23 patients were included, aged 58.3±16.0 years, 30.4% males, with a dry weight of 87.6±17.2 in males and 74.3±17.2 in females. Mean VAS was 7.3±2.3, HGS 22.7±5.6 cm, UAC 8.0±2.3, SPPB 8.0±1.9 and 6MWT 576±328 meters. Only HGS and UAC were correlated with HD dry weight (r 0.43, p<0.05 for HGS, r 0.79, p<0.001 for UAC).

Conclusions: The DiapriFIT Study measures a great variety of parameters regarding physical performance and PEW. As some, but not all parameters correlate with HD dry weight, we expect them to differentiate between CHD and NHD during follow-up of the study. Other results of physical performance and PEW, such as subjective global assessment, physical activity, sleep, and QOL-questionnaires, activity monitoring, body composition measurement, nutritional diary, DEXA and lab tests will provide additional information on these patient-relevant outcomes of NHD.

Anti-Thymocyte Serum Nephritis Rats Developed Augmented Circadian Rhythm of the Intrarenal Renin-Angiotensin System

Rats were sacrificed every 6 hour and the levels of the intrarenal RAS components were evaluated.

| protein expression levels of intrarenal AGT, AngII and AT1R proteins were made| increased in A group compared with C group and attenuated in AO and AH group (Peak trough ratios of AGT in C: 1.13, A: 1.47, AO 1.24, AH 1.17, AngII in C: 1.03, A: 1.26, AO: 1.14, AH: 1.17 and AT1R in C: 1.36, A: 1.51, AO: 1.37, AH: 1.26). However, renal function, proteinuria and augmentation of intrarenal RAS components were attenuated only in AO group. The protein expression levels of intrarenal renin and protein were the same tendency as AGT, AngII and AT1R, though fluctuation of them was attenuated in AO group. The protein expression levels and fluctuation of angiotsin converting enzyme and (pro)renin receptor were not different among groups.

Conclusions: Intrarenal AGT, AngII and AT1R proteins were increased and the amplitude of oscillations of these proteins was augmented in ATP-knell nephritis rats. Furthermore, renal damage may be linked to the activation of the intrarenal RAS independent of amplitude of its oscillation and BP.

Background: Recent data suggest that the KCNQ family of voltage activated K+ (K7) channels represents a new therapeutic target in cardiovascular disease. We used KCnq1-/- mice to determine whether KCNQ1 (K7.1) play a role in the regulation of arterial tone.

Methods: Wire-myography, pharmacology approach and patch-clamp techniques were used.

Results: We found that R-L3 produces similar concentration-dependent relaxations (EC50 =1.6 µM in wild-type (Kcnq1+/+) and KCnq1-/- arteries pre-contracted with either phenylephrine or 60 mM KCl. This relaxation was not affected by 10 µM chromanol-B293, 10 µM HMR1556, 30 µM XE991 or 500 µM 4-aminopyridine. Chromanol-B293 and HMR1556 did not affect the anti-contraction effects of perivascular adipose tissue (PVAT). The anti-contraction effects of PVAT were normal in Kcnq1-/- arteries. Whole-cell recordings showed normal peak K, currents, capacity and their blockade by XE991 in Kcnq1-/- VSMCs. The pan KCNQ2-5 opener retigabine lead to a similar relaxations in Kcnq1-/- and wild-type vessels.

Conclusions: We conclude that KCNQ1 channels are apparently not involved in the control of arterial tone by alpha, adrenergic vasoconstrictors and PVAT. R-L3 is an appropriate pharmacological tool for studying the function of native vascular KCNQ1 channels in mice.

The Role of Renal AT1 Receptor-Associated Protein in Salt-Sensitive Blood Pressure Regulation

Hiromichi Waku,1 Kouichi Tamura,1 Ryu Kobayashi,1 Kazuaki Ueseda,1 Masato Ohawa,1 Toru Dejima,1 Akinobu Maeda,1 Yoshiyuki Toya,1 Kotoro Haruhara,1 Satoshi Umemura.1 1The Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan; 2Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: The intrarenal renin-angiotensin system plays a role in the regulation of renal hemodynamics and the maintenance of water electrolyte balance, and is also involved in the pathophysiology of hypertension and target organ damages. We previously identified an angiotensin II type 1 receptor-associated protein (ATRAP), which interacts with the C-terminal domain of angiotensin II type 1 receptor (AT1R) and attenuates AT1R-mediated pathological responses. The present study was designed to investigate the putative functional role of ATRAP in the blood pressure regulation by high salt loading in vivo.

Methods: We generated transgenic mice expressing ATRAP dominantly on renal tubules on a C57BL/6J background. Renal ATRAP transgenic mice and their wild-type littermate mice on a normal salt diet at baseline were subjected to dietary high salt loading for 7 days. Results: In renal ATRAP transgenic mice, the development of high blood pressure was suppressed when salt loaded, thereby suggesting ATRAP to be an interesting target in hypertension.

**Carbonic Anhydrase II Inactivation Confers Salt Appetite and Elicits Salt Sensitive Hypertension**

Mujian Varashteh kia, Sharon L. Barone, Saeed Alishahrami, Marybeth Brooks, Kaymar A. Zahedi, Jie Xu, Manoocher Soleimani, Center on Genetics of Transport, Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; Research Services, VA Medical Center, Cincinnati, OH.

**Background:** Salt appetite or salt intake in excess of physiological needs is a major health problem and a risk factor in the pathogenesis of hypertension, which consequently can lead to heart disease and stroke. Few genetic factors are implicated in the pathogenesis of salt appetite.

**Methods:** Wild-type and CAII null mice were given a choice of regular water or 140mM NaCl dissolved in their drinking water. Balance studies were performed and blood pressure was measured via the CODA tail cuff system. Western blots and Northern Hybridizations were performed.

**Results:** Our results indicate that CAII null mice display significant salt appetite as judged by their preference for salted water (140 mM NaCl) over regular water, when both options are provided. In age and gender matched mice (n=4 per each group), daily salted water intake was 2.89 ml in WT vs. 5.71 ml in CAII null mice, while daily regular water intake was 5.05 ml in WT and 3.6 ml in CAII null mice. Kidney renin expression and blood creatinine concentration were comparable in WT and CAII null mice. When given only salted water, CAII null animals showed a robust increase in their daily salt intake (12.21ml in CAII null vs. 7.80ml in WT mice) and urine volume (4.62ml/day in CAII null vs. 2.62ml/day in WT mice). Expression of sodium and water absorbing channels, ENaC and AQP-2, increased by ~100 to 200% in both cortex and medulla in CAII null vs. WT mice in response to salt intake for 10 days. Consequently, CAII null mice developed hypertension (systolic BP of 155 +/- 3.9 in CAII null vs. 138 +/- 3.2 in WT, p<0.003). The protein expression levels of ENaC in taste buds were not different between the two genotypes. Male CAII null mice exhibited a remarkable propensity toward salted water intake vs. regular water intake as compared to female null mice.

**Conclusions:** We propose that CAII plays an important role in regulating salt intake and its inactivation can cause salt appetite, specifically in male animals, and provoke salt sensitive hypertension.

**Ambulatory Blood Pressure in Chronic Kidney Disease: An International Collaborative Study**

Paul E. Drazner, Luca De Nicolia, Naohiko Fujii, Francis B. Gabbai, Jennifer J. Gassman, Satoshi Iimuro, Roberto Minutolo, Robert A. Phillips, Luis M. Ruijope, Raymond R. Townsend, Mahboob Rahman, Div of Renal Diseases & Hypertension, Univ of Minnesota; Italian Cohort; CKD-JAC; AASK; Spanish Cohort; CRIC.

**Background:** In chronic kidney disease (CKD), ambulatory blood pressure (BP) is a better measure of hypertension related risk for cardiovascular disease and ESRD than clinic BP. The International Ambulatory Blood Pressure in Chronic Kidney Disease Collaborative Group is a collaboration among investigators from different countries interested in ambulatory BP in patients with CKD. The main aims of the research facilitated by this collaboration will be to evaluate: 1) the clinical and demographic characteristics associated with elevated ambulatory BP, 2) the prognostic role of ambulatory BP on cardiovascular and renal outcomes, and 3) ethnic and geographic differences in these associations.

**Methods:** This group will establish a large database derived from individual databases in the various countries to allow for powerful individual participant data meta-analyses of the relationship between clinical and demographic characteristics, CKD severity, ambulatory BP, and clinical outcomes.

**Results:** Investigators from 5 cohort studies have already agreed to participate. Characteristics of the cohorts are shown below.

**Conclusions:** This multi-national collaboration will provide greater insights than possible from within-country analyses into the etiology and consequences of high risk ambulatory BP profiles. This information will be instrumental in helping us design prospective international large scale multicenter trials aimed at reducing renal and cardiovascular events in patients with CKD.

**Clinical Study of Pregnancy Related Kidney Injury**

Yumei Liu, Ying Fan, Yang Fei, Hongda Bao, Yajuan Huang, Niansong Wang, Nephrology and Rhenumatology, Shanghai Jiao Tong Univ Affiliated Sixth People’s Hospital, Shanghai, China; Obstetrics and Gynecology, Shanghai Jiao Tong Univ Affiliated Sixth People’s Hospital, Shanghai, China.

**Background:** The diagnosis and treatment of pregnancy related kidney injury is a complicated clinical problem for obstetricians and nephrologists. However, information regarding this topic in China is insufficient.

**Methods:** Totally 18589 women hospitalized between August 2004 and January 2013 from Obstetric and Nephrology Department in Shanghai Jiao Tong University Affiliated Sixth People’s Hospital were screened. 569 women were enrolled for the pregnancy related kidney injury, including 494 cases from 2008 to 2013 and 75 cases from 2004 to 2007. The inclusive criteria was women with a history of kidney disease or Scr >= 70mmol/L or proteinuria >= 0.3g/24hour before the termination of pregnancy, or the diagnosis of kidney disease made during or after 6-month delivery.

**Results:** The prevalence of pregnancy related kidney injury was 3.1%. The incidence of kidney injury caused by obstetric disease was 3.1%, with the most common reason for pre-eclampsia (88.9%). The incidence of chronic kidney disease women with pregnancy is 0.74%, with the most common reason for chronic glomerular nephritis (36.2%). The incidence of kidney disease onset related to pregnancy was 1.5%. The incidence of proceeding to end stage renal disease for pregnancy was 0.21%. Kidney injury in pregnant women with obstetric disease may be more severe than that in pregnant women with kidney disease (with higher maternal blood pressure and proteinuria, lower birth weight and higher proportion of pre-term babies, P<0.05). Most women with pregnancy related kidney injury underwent cesarean section (>60%). Their proportion of stillbirth, pre-term and low birth weight babies were higher than healthy parturient, and the proportion of follow-up was low (9.9%). Neonatal death rate was 0.63% and pare-natal death rate was 2.1% in all.

**Conclusions:** Prevalence of pregnancy related kidney injury increases due to the foundation of Shanghai First-Aid Center for High-risk Pregnant Women in 2007. Serum creatinine, proteinuria and blood pressure have different indication for maternal condition and pregnancy outcome.

**A New Vasculo-Renal Marker Enhances Accuracy of Hypertensive Nephropathy Recognition**

Arkadiusz Lubas, Robert Ryczek, Grzegorz Kade, Stanislaw Niemczyk, Dept of Internal Diseases, Nephrology and Dialysis, Military Inst of Medicine, Warsaw, Poland; Dept of Cardiology, Military Inst of Medicine, Warsaw, Poland.

**Background:** Latent and slow beginning of chronic kidney disease (CKD) coexisting with well tolerated, usually not recognized previously hypertension makes difficult to recognize hypertensive nephropathy (HN) from CKD of others origins. The aim of the study was to investigate the best marker helpful in differentiating HN from other causes of CKD.

**Methods:** Forty patients (4; 36 M; age 52.7 ± 14.4) with stable CKD (CKD-EPI 53.1 ±27.6 ml/min/1.73m2) and a history of hypertension (26 with HN) were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), NT-pro brain natriuretic peptide (NTproBNP), Troponin 1 (TNI) and urinary albumin to creatinine ratio (UACR) were tested. Renal function was estimated according to Cre and Cys based CKD-EPI formula. Echocardiographic examination, carotid Intima-Media Thickness (IMT), ABPM, Renal Resistive Index (RRI) were performed. Vasculo-Renal Index (VRI) was calculated as IMT to UACR ratio.

**Results:** Groups with HN and CKD of other origins did not differ in renal function (CKD-EPI 46.2 vs 57.1 ml/min/1.73m2, p =0.22), NTproBNP: TNI, left ventricular (LV) ejection fraction, LV mass index and mean arterial pressure. Patients with HN were older (56.4 ±15.1 vs 45.9 ±14.1; p <0.039), had lower UACR (0.264 ±0.484 vs 0.814 ±0.564 mg/mg; p=0.001), but higher IMT (0.858 ±0.217 vs 0.652 ±0.380; p<0.009) and VRI (m. 28.8 ±0.36; 1030.00) vs m. 0.78 ±0.34; 12.50 ±0.0001). In ROC analysis VRI ≥ 1.91, UACR ≤ 0.199, and IMT ≥ 0.87 could recognize HN with sensitivity of 85%, 73% and 62% respectively, specificity of 79%, 93% and 86% and of accuracy of 82.5%, 80% and 70% (AUC 0.874, 0.849 and 0.749; p<0.05).

**Conclusions:** A new Vasculo-Renal Index recognizes HN more accurately, but UACR and IMT are not significantly worse.

Graduate School of Medical Sciences, Kyusu Univ, Fukuoka, Japan.

Background: In patients with chronic kidney disease (CKD), impaired urinary sodium excretion (UNa) may cause nocturnal hypertension and pressure natriuresis to compensate for daytime sodium retention. The aim of this study was to determine the renal histological lesions which associated with nocturnal blood pressure (BP) and UNa in patients with CKD.

Methods: We analyzed patients biopsyed in our institutions from Sep 2010 to Apr 2014 (Forty Iga nephropathy, 6 Purpura nephritis, 4 membranous nephropathy and 14 the others). During the same hospitalization period of renal biopsy, ambulatory BP monitoring and evaluation of UNa were performed simultaneously. The association of histological findings such as global sclerosis (%GS), arteriolar hyalinosis (%hyaline), and interstitial fibrosis (IF), with nocturnal BP and night/day ratio of UNa were assessed using linear regression analysis.

Results: Twenty three patients were male, mean age was 40.5 ± 15.9 years, and mean estimated glomerular filtration rate (eGFR) was 79.0 ± 28.9 ml/min/1.73m². Both nocturnal BP and night/day ration of UNa positively associated with %GS, %hyaline, and IF, and negatively associated with eGFR. Multiple regression analysis adjusted for age, sex, eGFR, and usage of antihypertensive drugs showed that %GS was significantly associated with nocturnal systolic BP (β = 0.38, p = 0.012), nocturnal diastolic BP (β = 0.34, p = 0.031) and night/day ratio of UNa (β = 0.52, p = 0.005).

Conclusions: We found that night/day ratio of UNa and nocturnal BP closely related to the percentage of global sclerosis. These findings could be the morphological evidence that increase in the number of functioning glomeruli causes increase in nocturnal UNa to compensate for daytime sodium retention resulting in elevation of nocturnal BP in patients with CKD.

Conclusion: This meta-analysis suggests that the bedtime dosing regimen drug therapy benefits CKD patients in terms of hypertension especially those with non-diaper BP pattern.

The Impact of Glomerular Collapse in Hypertensive Emergency Patients Tukafumi Yamakawa, Yoshihiko Imasawa, Takeliko Kawaguchi, Mao Watanabe, Maiko Nagata, Hiroki Kitamura. Dept of Internal Medicine, National Hospital Organization Chiba East Hospital, Chiba City, Japan.

Background: The prognosis of kidney disease with hypertensive emergency (malignant glomerulosclerosis) is still worse compared with benign nephrosclerosis. Here, further to assess the reasons of worse prognosis and to reconsider more appropriate therapy for malignant nephrosclerosis, we compared pathological parameters between malignant and benign nephrosclerosis.

Methods: 8 patients diagnosed as hypertensive emergency with acute renal failure were performed renal biopsies from October 2005 to May 2015. We selected all patients with benign nephrosclerosis (n=20), who were performed renal biopsies during same period, as controls. We compared changes in clinical and pathological data using the paired t-test and the Mann-Whitney U-test.

Results: All 8 patients with hypertensive emergency had characteristic pathological changes of malignant hypertension, such as fibrinoid necrosis, onion-skin thickening and edematous-appearing matrix in arterioles. These changes were never observed in benign nephrosclerosis. The rates of global sclerosis and segmental sclerosis had no statistical differences between these two groups. Interestingly, when glomerular collapsing rate was counted by GCR (GCR=number of glomerular collapse/ total number of glomeruli), GCR scores were much higher in hypertensive emergency cases compared with those in benign nephrosclerosis cases (42.9 ± 23.8 vs. 6.5 ± 7.4 %; p < 0.05). These patient's clinical characteristics showed a high level of plasma renin activity (PRA) (14.9 ± 5.8 ng/ml/h) and a high level of aldosterone (263 ± 256 ng/dl).

Conclusions: Glomerular collapse and hyper-renin mean glomerular hyperperfusion. Therefore, if therapy accelerate this glomerular hyperperfusion, it might affect renal outcome. We should reconsider the way of therapy, such as the selection of anti-hypertensive drugs, and the speed of declining blood pressure and volume control by thinking glomerular hyperperfusion.
Conclusions: This study shows that high dosage ACEI and super high dosage ACEI all can decrease blood pressure, reduce proteinuria, depress the expressions of TGF-β and PAI-1 protein in SHR, and delay glomerulosclerosis. But super high dosage ACEI can not reverse glomerulosclerosis in SHR.

PUB505
Hemolytic Uremic Syndrome Associated with Scleroderma Renal Crisis: The Challenge for Timely and Accurate Diagnosis
Amro Elshoury, Syed S. Haqiqie, Daniel Sedhom, Arif Asif. Albany Medical Center, Albany, NY.

Background: Scleroderma renal crisis (SRC) is a rare cause of atypical hemolytic uremic syndrome (aHUS) and differentiating it from other causes of thrombotic microangiopathies can be challenging. A 53-year old Caucasian male, with no past medical history was found unresponsive. BP was elevated to 207/141 mm Hg. Skin examination showed diffuse telangectasia and edema of his extremities with bilateral sclerodactyly (Figure 1). Fundoscopy revealed bilateral retinal hemorrhage and exudates. Labs showed a hemoglobin=5gm/dl, platelet=25×10^9/μl, creatinine=6mg/dl. LDH=1122U/L, bilirubin=1.6mg/dl, haptoglobin<5%, reticulocyte count<10.4% and schistocytes. ANA and anti-RNA Polymerase III antibody were positive (C3 and C4, coagulation profile, fibrinogen were normal; Coombs negative). CT head showed severe microvascular changes throughout the white matter of the cerebrum and MRI showed evidence of punctuate chronic micro-hemorrhages in the left thalamus and cerebellar tonsils. The presence of MAH, acute renal failure and thrombocytopenia raised suspicion for possible aHUS/TPP. Serum ADAMTS 13 was ordered. Because of the possibility of SRC, the patient was started on caprornil. A dramatic improvement in BP, hemoglobin and platelets count along with the normalization of LDH and schistocytes disappearance was observed. However, there was no improvement in kidney function requiring hemodialysis. ADAMT-13 activity returned at 40% (cut-off for TTP is <5%). Patient did not pursue eculizumab therapy. A significant portion of patients with Scleroderma can develop aHUS. In this case, hypertension might have served as a complement amplifying condition.

Methods: Clinical presentation/course of the patient.
Results: Despite therapy with ACEI inhibitors patient ended up on RRT.
Conclusions: Patient presenting with Malignant HTN and MAH was found to be in scleroderma crisis.

PUB506
The Impact of Neck Irradiation on Baroreceptor Reflex and Hypertension

Background: Only a few studies with a very limited sample size have evaluated the impact of neck irradiation on baroreceptor reflex failure and blood pressure (BP) abnormalities. We investigated 60-patients, with head/neck cancer, who received neck irradiation between 2005 to 2010. IRB approval was obtained. Median for age was 61.5 years (range 24-90 years). We used the same cohort of patients, before they received neck irradiation between 2005 to 2010. IRB approval was obtained. Median for age was 61.5 years (range 24-90 years). We used the same cohort of patients, before they received neck irradiation between 2005 to 2010. IRB approval was obtained.

Results:
Blood pressure before and after radiation showed no increase.

Conclusions: The study suggests that carotid baroreceptors might not have been damaged by radiation or baroreceptors.

PUB507
Sympathetic Nervous System Activity Reflected by Renalase and Catecholamines in Different Aged Patients with and without Chronic Kidney Disease
Edyta Zbroszlav, Dominika Maciorowska, Ewa Koc-Zorawska, Jolanta Malczewska, 1 2nd Dept of Nephrology and Hypertension with Dialysis Centre, Medical Univ, Bialystok, Poland; 1 1st Dept of Nephrology and Transplantation, Medical Univ, Bialystok, Poland.

Background: Sympathetic nervous system activity is elevated in patients with chronic kidney disease (CKD) as well as in older persons. It contributes to hypertension and cardiovascular diseases. It is due to a reduction of catecholamines clearance and in elderly also to an increased sympathetic discharge from different organs. Renalase may play a role in the regulation of catecholamines degradation. The aim of the study was to assess the sympathetic nervous system activity, according to serum renalase and catecholamines concentration in a cohort of 211 patients with hypertension and or with chronic kidney disease.

Methods: The study group was divided according to age below and above 65 years. The older persons (61) was also divided into group with (75%) and without CKD stage 5. The serum renalase, dopamine and norepinephrine concentration as well as pressure control, residual renal function rate and echocardiography were assessed.

Results: The older group had higher renalase (p=0.02) and dopamine (p=0.001) concentration and it was elevated in patients with CKD comparing to those without. They also had advanced abnormalities in echocardiography, like thicker interventricular septum (p=0.03) and lower ejection fraction (p=0.001) as well as CKD patients comparing to those without CKD – pronounced left ventricular hypertrophy (p=0.007) and lower ejection fraction (p=0.004). They more often suffered from coronary artery disease. The residual renal function was less in older patients with CKD. The main used hypotensive drugs in studied group were beta-blockers. There was the significant correlation between age and renalase, norpinephrine and dopamine concentration.

Conclusions: The advanced aged especially combined with chronic kidney disease is associated with elevated renalase and dopamine level. It may reflect the sympathetic nervous system hyperactivity due to impaired kidney function and reduction of residual diuresis. It may have an impact on the development of cardiovascular complications.

PUB508
Heart Rate Variabilities During Day and Night Can Alter the Circadian Blood Pressure (BP) Rhythm
Toshinuki Miura,1 Michio Fukuda,1 Yoshiaki Ogizama,2 Ken Kiyono,3 Junichiro Hayano,3 Nobuyuki Ohte.1 1 Nagoya City Univ, Japan; 2 Osaka Univ, Japan; 3 Tokoyo Univ, Japan.

Background: We previously reported in patients with chronic kidney disease (CKD) that the circadian rhythms of BP and urinary sodium excretion (Un/Ur) were both impaired into non-dipper pattern as renal function deteriorated. Elevated salt-sensitivity of BP and inappropriate activation of the renin-angiotensin-aldosterone system and the sympathetic nerve system play important roles in high BP and the high incidence of cardiovascular diseases in patients with CKD.

Methods: In 39 patients with CKD, we analyzed HRV in 24-h electrocardiography, BP monitoring and urine collection, separately for daytime and nighttime. Patients, who took antihypertensive agents, were excluded. We evaluated the relationship between systolic blood pressure (SBP) and Un/Ur, the Non-Gaussianity index of HRV(Un), which reflects the probability of intermittent large deviations of heart rate (HR) from the trend, and the power of high frequency (HF, 0.15–0.40 Hz) obtained by frequency domain analysis of HRV as well as GFR was reduced.

Results: In 39 patients with CKD, we analyzed HRV in 24-h electrocardiography, BP monitoring and urine collection, separately for daytime and nighttime. Patients, who took antihypertensive agents, were excluded. We evaluated the relationship between systolic blood pressure (SBP) and Un/Ur, the Non-Gaussianity index of HRV(Un), which reflects the probability of intermittent large deviations of heart rate (HR) from the trend, and the power of high frequency (HF, 0.15–0.40 Hz) obtained by frequency domain analysis of HRV as well as GFR was reduced.

Conclusions: Our study clearly demonstrated that as renal function deteriorated, sympathetic nerve activity is activated during the day, and vagal activation was impaired during the night, both of which can contributes to high BP in patients with CKD. However, the type of circadian BP rhythm was associated with the circadian Un/Ur rhythm rather than sympathetic or vagal nerve activity, even though the sympathetic activity can stimulate tubular sodium reabsorption.

PUB509
The Effects of the Insight Meditation Practice on Blood Pressure Reduction in Buddhist Exemplary People
Kriengsak Vareesangthip,1 Jutamas Vareesangthip,2 1 Dhamma Communication Div, Graduate School, Mahachulalongkornrajavidyalaya Univ, Bangkok, Thailand; 2 Renal Div, Dept of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

Background: Hypertension (HTN) is a leading risk factor for preventative cardiovascular disease, with over one in five adults affected worldwide. Lifestyle modification is an important strategy for the prevention and treatment of HTN. Contemplative interventions are associated with greater cardiovascular risk, and stress management is a recommended intervention for hypertension. For many patients, maximal medical therapy is insufficient.
to adequately treat refractory hypertension. Lifestyle modification remains an important approach in management. Buddhist meditation encompasses a variety of meditation techniques that aim to develop mindfulness, concentration, and insight.

Methods: We aimed to study whether Buddhist Insight Meditation (IM) Practice, composing of Walking Meditation and Sitting Meditation, could reduce the level of blood pressure in the Buddhist Exemplary People. 65 exemplary people were divided into 3 groups according to the schedule they performed IM Practice. Group 1 (n=25) performed 30 minutes of the Walking and 30 minutes of the Sitting Meditation, group 2 (n=20) performed 45 minutes in each Meditation and group 3 (n=20) performed 60 minutes in each Meditation. Their blood pressures (BP), pulse pressures (PP) and pulses (P) were measured before and after Walking and Sitting Meditations.

Results: The results clearly showed that systolic BP, PP and P were significantly decreased after the Walking Meditation at 30-45-60 minutes. After IM Practice schedule, an artsy-duced decrease was significantly increased in all 3 groups, PP has been significantly decreased in group 2 and systolic BP has been significantly reduced in group 3.

Conclusions: In conclusion, the Buddhist IM Practice could meaningfully reduce the sympathetic activities including systolic BP, PP and P. Therefore, this Buddhist Practice should be added to be one modality of the standard hypertensive treatments.

**ENA as a Novel Mechanism for Hypertension and Volume Expansion in Type 2 Diabetes**

Mark L. Unruh,¹ V. Shane Pankratz,¹ Evan C. Ray,¹ Rebecca P. Hughey,² Thomas R. Kleyman.³ Div of Nephrology, Univ of New Mexico; ²Renal-Electrolyte Div, UPMC.

Background: Renal Na retention and extracellular fluid volume expansion are hallmark features of type 2 diabetes. There is evidence that this occurs even in the absence of activation of hormones that are known to stimulate renal Na transporters. Recent studies suggest that plasmin-dependent activation of ENA may be responsible for renal Na retention in the setting of nephrotic syndrome. We hypothesized that the ENA inhibitor amiloride would be an effective therapeutic agent in inducing a natriuresis and lowering blood pressure in individuals with macroscopic proteinuria.

Methods: We conducted a pilot double-blind randomized cross-over study comparing the effects of daily administration of either oral amiloride (10 (low dose) followed by 20 (high dose) mg/d) or HCTZ (Na,Cl co-transporter inhibitor) to patients with type 2 diabetes and macroscopic proteinuria. We examined safety and feasibility of amiloride by monitoring kidney function, adherence, blood pressure, weight, urinary Na excretion and serum electrolytes during diuretic administration.

Results: 9 subjects were enrolled in the trial. Systolic blood pressure (SBP) decreased in both treatment groups, but there was not a significant difference between HCTZ and amiloride (p=0.53). Amiloride treatment was associated with a 1.1±0.4 kg decline in weight (p=0.02), and a 0.78 ± 0.18 mmol/L greater increase in serum potassium (p=0.002) over the low dose portion of the study. 2 subjects developed acute kidney injury and hyperkalemia when treated with amiloride. 5 subjects had readily detectable levels of urinary plasminogen/plasmin, and 4 did not. Among those receiving amiloride, the low plasmian group experienced a change of 1.1±4.6 mmol/L in SBP and the high plasmian group experienced a change of -13.9±8.7 mmol/L, although there was insufficient evidence to conclude that there were differential treatment effects by high/low plasminogen status (p=0.113).

Conclusions: Among patients with type 2 diabetes, normal renal function, and proteinuria, there was suggestion of increased natriuresis for those treated with amiloride vs. HCTZ. However, acute kidney injury and severe hyperkalemia was a safety concern.

**Serum Phosphorus Control and Reduced Phosphate Binder Pill Burden Among Hemodialysis Patients Who Switched from Sevelamer to Sucroferric Oxyhydroxide**

Vidhya Parameswaran, Lin Ma, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossman. Fresenius Medical Care North America, Waltham, MA.

Background: Clinical management of hyperphosphatemia among hemodialysis (HD) patients (pts) can present challenges. A retrospective database analysis was conducted to study the effectiveness of sucroferric oxyhydroxide (SO) among in-center HD pts who switched from sevelamer to SO as part of routine clinical care.

Methods: Pts who switched from sevelamer and had 1 serum phosphorus (sPshos) measured during SO treatment were included. Changes in sPshos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and pill burden were assessed at baseline (3-months prior to SO) and at follow-up (3-months during SO treatment).

Results: Pts (n=1487) were, on average, 54 years old, with dialysis vintage of 4.4 years and hyperphosphatemia (baseline sPshos=6.94 mg/dL). Figure shows sPshos distribution at baseline and follow-up. Pts with in-range sPshos (3.5-5.5 mg/dL) increased from 12% to 20.1% (68% increase). Mean sPshos decreased from 6.94 to 6.7 mg/dL (p<0.001) and mean sCa decreased from 9.3 to 9.25 mg/dL (p<0.001). There was a significant decrease (4.7 pills/day, p=0.001) in pill burden (8.5 to 3.7 pills). No significant change in iPTH levels was seen in Baseline 1 to 67.6 pg/mL). TSAT and FER significantly increased (p=0.001) from 33.7% to 35.3% and 98.3 to 105.1 ng/mL, respectively. In pts not receiving IV iron (n=149), there were no significant changes in TSAT (36.3% to 35.9%) or FER (1221.5 to 1177.4 ng/mL).

An Investigation of the Inverse Relationship Between Fractional Excretion of Phosphate and the Tubular Maximum for Phosphate per Volume of Filtrate

Kenneth R. Phelps,¹ Darius Mazon.² ² Strattion VAMC, Albany, NY; ³Albany Medical College, Albany, NY; ⁴Albany College of Pharmacy and Health Sciences, Albany, NY.

Background: The serum P concentration ([P]) is the sum of urinary excretion and tubular reabsorption rates of [P] per volume of filtrate (E_P|C_rx and Tm_P/C_rx). The two ratios could determine fractional excretion of P (FEP) [Clin Nephrol 85:167] and E_P|C_rx is approximately proportionally to the concentration of [P] (P) in the cortical distal nephron (CDN) [Clin Nephrol 82:191]. Maximal TR_P/C_rx (i.e. Tm_P/GFR) exceeds actual TR_P/C_rx when FE_P is < 20%; as FE_P falls, Tm_P/GFR and (Tm_P/GFR - FEP) rise [Clin Chim Acta 26:15]. We investigated these phenomena.

Methods: We measured [cr] and [P] in fasting serum (s) and urine (u), and [PTH]1-84 (Scantibodies) and intact [FGF23] (Immunotops) in plasma from 28 subjects without renal or parathyroid disease. We calculated E_P|C_rx as [P] [cr] / [cr] and TR_P/C_rx as [P] - E_P|C_rx and FE_P as ([P] - [cr]) / [cr]. We then determined Tm_P/GFR from the Walton-Bijvoet nomogram.

Results: All x-variables correlated inversely with FEP, Tm_P/GFR correlated directly with TR_P/C_rx but was unrelated to E_P|C_rx. Other x-variables correlated inversely with E_P|C_rx but were unrelated to TR_P/C_rx. None of the y-variables correlated with [PTH] or [FGF23].

Observational Study at the Mexican Institute for Social Security and Services for State Worker’s National Medical Center 20 de Noviembre Nephrology Department Outpatient Clinic Using Cinacalcet as Renal Replacement Therapy for Secondary Hyperparathyroidism Caused by Chronic Kidney Disease poster

Elvira González, Jesús Alejandro Nava Martínez, Juana Eugenia Amador Sánchez, Edgar Alejandro Fragoso, LM Valeria Espinosa, CRISCUA, Hospital General, Mexico, D.F., Mexico, Nephrology, CMN 20 de Noviembre, Mexico, D.F., Mexico.

Background: Secondary hyperparathyroidism is a highly prevalent clinical condition in persons with advanced chronic kidney disease (CKD). It can be seen in the early stages of the disease and consists of disorders in bone metabolism.

Methods: A descriptive, retrospective observational study was done using patient records at the Institute for Social Security and Services for State Worker’s (ISSSTE) National Medical Center 20 de Noviembre Nephrology outpatient clinic, located in Mexico City, Mexico. 50 cases of adult patients with advanced chronic kidney disease were reviewed in renal replacement treatment, dentopetalal dialysis and/or hemodialysis who were managed with Cinacalcet for Secondary Hyperparathyroidism, with PTHi > 300 pg/ml.

Results: The baseline level of serum parathyroid hormone of the 42 patients was 137.1 pg/ml prior to the use of cinacalcet, with a percentage reduction of 33% per month and 6 months of treatment 55% with a mean of 1133 pg/ml and 615.48 pg/ml respectively. A total of 42 patients; 19 (45%) achieved targets at the end of the 6-month study. 36 patients underwent to scintigraphy of parathyroid gland, because they did not obtain parathyroid hormone decreased over 30% at the 3rd month of treatment; 5 patients showed hyperplasia and 11 parathyroid adenoma.

Conclusions: Cinacalcet combined with conventional treatment succeeds in reaching goals compared to standard treatment only. Hypocalcemia is a common side effect however when administered together with calcium salts and/or vitamin D or its analogues decrease side effects According to previous studies cinacalcet it increases the achievement of goals in mild hyperparathyroidism. In our study was more important for the response time in the RRT than the severity of hyperparathyroidism.

PUB514
“Binder Reminders” for Persistent Hyperphosphatemia in Hemodialysis Patients: A Fellow’s Quality Improvement Project poster

Divyakam Jammalamadaka, N. Stanley Nahman, John Jason White. Medicine, Georgia Regents Univ, Augusta, GA.

Background: Despite regular quality improvement (Qa) processes, control of mineral metabolism remains poor. One root cause is patient non-adherence to phosphate (Pho) binders. Evolving data suggest SMS/text reminders improve medication adherence in a wide range of chronic illnesses. Here, we report our initial experience with text reminders on Pho control in HD patients.

Methods: 40 patients with Pho > 5.5 mg/dL for 2 of last 3 months, and possessing cell-phones with texting capabilities were studied. We randomly assigned 20 to receive the phrase “Binder Reminder” at mealtimes x 7 days prior to their monthly lab draw. The remaining 20 received usual care. Group assignment and messaging was communicated by a nephrology fellow, not part of the multidisciplinary team. Patients were excluded if they declined participation, missed any dialysis sessions during the 7 day period, or if they were unable to obtain their binders. Pho level after intervention was the primary outcome.

Results: After exclusions, 13 patients received the intervention and were compared to 14 controls. Pre-intervention Pho levels were 6.81 +/- 0.88 and 6.60 +/- 0.93 mg/dL (Mean +/- SD) in the control and intervention groups respectively. After intervention, Pho levels declined in the intervention group to 6.00 +/- 1.2 mg/dL (P= 0.10). Pho also declined in the control group to 6.19 +/- 0.76 mg/dL. Hence there was no difference between the groups (P = 0.76). Each group had 8 patients with improved Pho levels, and 5 patients at goal.

Conclusions: Our initial QA project utilizing SMS/text messaging appears to have no effect on short-term Pho control in a group of HDs patients with chronic hyperphosphatemia. A major drawback is the small number of patients and the number excluded (33%). However, this study does provide useful preliminary data for the planning of a larger pilot project, highlights the importance of contemporary control groups in QA to exclude the Hawthorne effect, and, given its simplicity, may be a model for fellow-driven QA projects and education.

PUB515
Niacin Improves Cardiac Function in Alport Mice with Progressive Chronic Kidney Disease and Hyperphosphatemia poster

Kelly Ambell1, Evgenia Dubovy2, Veronica A. Hogg-Correa1, Xiaoxiong Wang3, Yuhan Liu1, Jason R. Stubbs2, Moshe Levi1,1 University of Colorado Denver, 2Univ of Kansas Medical Center.

Background: Increase in serum phosphate (Pi) level (hyperphosphatemia) is a common clinical problem in chronic kidney disease (CKD). Systemic Pi homeostasis is balanced through three major mechanisms: intestinal uptake, retention or release from bone, and renal reabsorption. Sodium-phosphate co-transporter type 2b (NaPi2b) is a major phosphate transport system in the small intestine. Alport syndrome is a genetic disorder characterized by CKD, hearing loss and cardiac dysfunction.

Methods: By 9-10 weeks of age Alport mice, which have a mutation in a COL4A3 gene on the SvEv129 background, develop signs of CKD and hyperphosphatemia.

Results: We have found by western blot that there is an increase in intestinal NaPi2b protein abundance and Evcertel Sac studies showed increased NaPi transport in the Alport Helem compared to the WT littermate controls. Cardiac echo studies revealed that Alport mice have decreased ejection fraction (EF: 67±2% compared to 75±3% in the WT littermate) and diastolic dysfunction (mitral Doppler flow E/A ratio: 1.2±0.1 compared to 1.6±0.1 in the WT littermate, p<0.05), which could be corrected by treatment with Niacin (intestinal phosphate uptake inhibitor). In the treated Alport mice EF increased to 78±2% (p<0.05) and E/A ratio improved to 1.3±0.1 (p<0.05). In addition, there were significant decreases mRNA relative expression in β-MHC (0.08±0.02 in control vs. 2.19±0.34 in Alport, p<0.001, vs. 0.2±0.001 in Alport+Niacin, p<0.05), PAI-1 (0.12±0.01 in control vs. 1.05±0.15 in Alport, p<0.05, vs. 0.15±0.05 in Alport+Niacin, p<0.05), and TGF-β (0.03±0.01 in control vs. 0.77±0.23 in Alport, p<0.01, vs. 0.07±0.23 in Alport+Niacin, p<0.01), markers of heart failure and cardiac fibrosis.

Conclusions: Inhibition of intestinal phosphate transport with Niacin therefore improves systolic and diastolic cardiac dysfunction in CKD.

Establishing Regulatory Networks of Phosphorus Metabolism in HD Patients – A New Path of Treating Hyperphosphatemia poster

Mengjing Wang,1 Panpan Wang,2 Yulin Zhang,1 Li Ni,3 Minmin Zhang,1 Jing Chen.1 Nephrology, Huashan Hospital, Shanghai; 2MOE Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan Univ, Shanghai.

Background: The clinical efficiency of current treatment of hyperphosphatemia in HD varies widely on different patients. We assume that it is due to phosphorus regulation in vivo. In physiological conditions, phosphorus is regulated by a biological network consisting of interacting hormones and minerals. In HD, the networks change dramatically and affect serum phosphorus. This study aims to establish the regulatory networks of phosphorus in HD and identify the key factors that may have a causal effect on circulating concentrations of phosphorus.

Methods: 50 HDH patients were enrolled and divided into three groups (n=10, PTH≤300 ng/ml; n=10, 300 ng/ml<PTH≤600 ng/ml; n=10, PTH>600 ng/ml). Predialysis blood samples were obtained on the mid-week dialysis day for detection of PTH, FGF23, 25(OH)D3, Klotho, and Ca every week for 12 weeks every patient. Caused adherence, we would used process of concluding a causal connection, was adopted to establish the regulatory networks of phosphorus metabolism within different PTH levels.

Results: The networks show that when PTH≤600 ng/ml, FGF23 can stimulate the increase of serum Pi, Ca, and PTH, in turn, serum Ca and Pi can also stimulate the increase of FGF23. When PTH>600 ng/ml, FGF23 becomes the stimulator of only serum Ca, and serum Pi has a positive causal effect on PTH, besides, the rise of PTH increases serum Pi level, too. Serum Pi is affect by FGF23 when PTH>600 ng/ml and by PTH when PTH>600 ng/ml. Since FGF23 promotes the increase of PTH when PTH>600 ng/ml, FGF23 becomes the key factor in disorders of phosphorus metabolism. The figures also shows that Klotho and 25(OH)D3 may be not important in the therapy of hyperphosphatemia.

Conclusions: Reducing FGF23 levels might contribute to the control of phosphorus.

PUB517
Evolution of Renal Calcium Excretion Throughout Chronic Kidney Disease poster

Carmen Gonzalez Corvillo1, Paula Batalla-Castano,2 Silvia Ros-Ruiz,2 Fernando Callejo,3,4 José G. Heras,5 Mercedes Salgueira Lazo,5 Nephrology, Hospitales Virgen Macarena-Rocio, Sevilla, Spain; 4Nephrology, Hospital Regional, Malaga, Spain; 5Nephrology, Hospital Puerto Real, Cadiz, Spain; 6Nephrology, Universidad, Granada, Spain.

Background: Chronic kidney disease(CKD)patients have a normal serum calcium(Ca) concentration until the end of renal disease(ESRD).The decrease of VitaminD levels, and that a percentage of patients develops hypocalcemia at ESRD, lead us to think that our Ca networks change dramatically in vivo. In physiological conditions, phosphorus is regulated by a biological network consisting of interacting hormones and minerals. In HD, the networks change dramatically and affect serum phosphorus. Since Klotho and 25(OH)D3 may be not important in the therapy of hyperphosphatemia.

Methods: Observational multicenter,retrospective and transversal study,with the participation of Hospitales 63 patients were included,in different stages of disease(66,7%men,mean age 66years).None on renal replacement therapy. Variables:blood,urine analysis and treatment. The sample was stratified by stage of the disease and urine Ca(>or<100 mg/dl).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: Sample:6,3%/CKD1,4,8%/CKD2,28,6%/CKD3,38,1%/CKD4 and 22,2%/CKD5. Mean serum Ca: 4,77 mg/dl mean serum phosphate(P): 3,77 mg/dl PTH level 1749 dl/ul M0: 27mg/ml Mean Ca excretion: 126mg/day Mean P excretion:477mg/d/day was on Ca based binders, 22,2% on calcium, 12,7% on calcium and 28,6% on paricalcitol. 70% of the sample had Ca excretion<100mg/d. When classifying by stages of the disease, increases the amount of patients with Ca excretion<100 mg/d CKD1 25%, CKD2 50%, CKD3 50%, CKD4 80%, CKD5 83%, decreasing the mean Ca excretion. The group of patients with lower Ca excretion had a higher PTH level (155 vs 111 pg/dl) p<0,05. 94% of patients treated with Ca based binders had a Ca excretion<100 ng/dl, with no difference in serum Ca. Patients on calcium carbonate, paricalcitol or calcium had lower Ca excretion than those without treatment.

Conclusions: According to our results, patients within CKD show a decrease in renal Ca excretion that become exacerbated as the renal disease progresses. Supplementation with hypercalcemic drugs is not balanced out with the expected increase of renal Ca excretion. Therefore, we think that CKD patients are exposed to a chronic Ca overload, sometimes underestimated, with the resulting negative impact in morbidity and mortality.

PUB518

Effect of Parathyroid Hormone on Serum Magnesium Level: The Neglected Relationship in Hemodialysis Patients with Secondary Hyperparathyroidism Bing Tang, Li Fang, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Chronic kidney disease–mineral and bone disorder (CKD–MBD) is an important complication in patients with end-stage kidney disease which is associated with cardiovascular morbidity and mortality. Since recent studies have shown that serum magnesium play an important role in secondary hyperparathyroidism, vascular calcification and in cardiovascular mortality, the interest on magnesium has grown.

Methods: This cross-sectional study was conducted on 111 patients with end-stage renal disease on maintenance hemodialysis who was hospitalized for secondary hyperparathyroidism. The interventional study was conducted on 23 patients underwent total parathyroidectomy.

Results: In our study, hypermagnesaemia (>2.5mg/dl) occurs in up to 44% of cases and hypomagnesemia did not present. No significant correlations were found between serum magnesium and parathyroid hormone (r = 0.143, p = 0.134). Correlation analysis and logistic regression analysis suggested that the derangement of magnesium homeostasis was correlated with the derangement of calcium/phosphate homeostasis. After parathyroidectomy, serum magnesium levels dropped immediately and reached the lowest level at one day after surgery; however, it gradually restored three days later. The changes of serum magnesium after surgery was positive correlated with the changes of serum phosphorus (r=0.558, p=0.003).

Conclusions: The effect of PTH on magnesium metabolism could not be neglected, especially in hemodialysis patients with secondary hyperparathyroidism. The role of magnesium metabolism and therapeutic strategies to achieve optimum serum magnesium levels in CKD-MBD should take into account the varying stages of disease development.

Calciphylaxis in Patient with Chronic Renal Disease Not Dialytic and Multiple Myeloma Patricia Junqueira Freitas, Aline Lourencio Baptista, Clovis Antonio lopes Pinto, Joubert Araujo Alves, Pedro Caruso, Benedito Jorge Pereira, Germana Alves Brito. Nephrology, AC CAMARGO, Sao Paulo, Brazil.

Background: Calciphylaxis, also known as calcifying uremic arteriolopathy, is a rare medical condition, which is normally diagnosed in patients with terminal CKD who are already in renal replacement therapy (RRT). Objective: report the presence of calciphylaxis in patients with chronic renal disease which is associated with end stage renal disease on maintenance hemodialysis who was hospitalized for secondary hyperparathyroidism.

Methods: The presence of calciphylaxis was diagnosed in a patient with chronic renal disease who was not on dialysis, and multiple myeloma, with a reduced renal function and a hyperparathyroidism. The diagnosis of calciphylaxis was based on the presence of calcific plaques, necrosis, of acute and progressive installation. It must be paid attention to its presence even in non dialytic stages of CKD as happened in the described case.

Calcium Binders Are They All Equal? Comparison Calcium Acetate (CA) versus Carbonate Calcium (CC) in CKD 5D: Multicentric Study Philippe Brugere, David Attaf, Laurent Juillard. 1Nephrology - Dialysis, Conception Hospital, Marseille, Bouches-du-Rhône, France; 2Dialyse, Fresenius, Paris, IDF, France; 3Nephrology - Dialysis, Edouard Herriot Hospital, Lyon, Rhone, France.

Background: CA’s phosphate binder is available since 2010 in France. A monocentric study indicates that CA is equivalent to CC based on phosphatemia reduction while reducing calcium intake by 60%. This study compare CA to CC in different dialysis centers i.e different CKD MBD protocols.

Methods: 28 hemodialysis centers are involved. CC is switched to CA at M6 with 6 months follow up (M0, M6). We compared M0’s, biologic data with M6’s data.

Results: 293 patients (70+/14 y) in 28 centers. At M0, CA dosage was 3.8 +/- 2 pills/day. Demographic characteristics are consistent with our National French registry. At M6 mineral values are similar to M0 : Ph mEq/l (1.54 +/- 0.55 vs 1.52 +/- 0.65, NS), Ca mM (2.23 +/- 0.17 vs 2.21 +/- 0.15, NS), PEx mg/dl (221 +/- 204 vs 262 +/- 217, NS), Vit. D (75 +/- 32 vs 79 +/- 24, NS), % pts with no calcium binder (43 vs 49, NS), % pts w. Ca > 2.6 mM (2 vs 1, NS), % pts w. Ph > 1.5 mM (39 vs 38, NS). The only difference is related to a decrease of Calcium Intake (g/d) from M0 (1.51 +/- 1.13) to M6 (0, 63 +/- 0.31, P<0.05).

Conclusions: At M6, Calcium intake is reduced by 57% vs M0 while Ph is similar vs M0. Mean serum calcium is not altered. The frequency of Ca > 2.60 mM and Ph > 1.5 mM are not modified at M6. Calcium based binders had a Ca excretion<100mg/d with no difference in serum Ca. Patients on calcium carbonate, paricalcitol or calcium had lower Ca excretion than those without treatment.

PUB521

Hemodynamic Changes in Maintenance Hemodialysis Patients with Hypotension After Parathyroidectomy Meijuan Meng, Bing Tang, Hong Ye, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Parathyroidectomy (PTX) is applied to treat secondary hyperparathyroidism in hemodialysis patients. Some patients suffered from hypotension after PTX although hypocalcemia was corrected. The aim of this study was to demonstrate the hemodynamic changes in hemodialysis patients after PTX.

Methods: Twelve patients were included in this study. Among them 4 have hypotension after PTX (Group 1) and the other have their blood pressure remained after PTX (Group 2). Before PTX, systolic blood pressures (SBP) of all the 12 patients were above 90 mmHg. Noninvasive hemodynamic evaluation was performed before, during and after dialysis.

Results: Comparing with group 2, cardiac index (CI) was higher (P=0.252) while systemic vascular resistance index (SVRI) was lower (P=0.05) in group 1. The mean thoracic fluid capacity (TFC) of the two groups were similar (P=0.424) before dialysis. Serum Ca, PTH, ALP, ventricular ejection fraction and vascular calcification score of thoracic aorta, abdominal aorta and heart valve before PTX, as well as the weight of the removed parathyroid glands, serum Ca, ALP, hemoglobin after PTX of the patients were determined. No statistical differences were found. However, the phosphorus level was lower in group 1 both before and after PTX. CI, SVRI and TFC were similar in both groups during hemodialysis.

Conclusions: Patients with hypotension after PTX have a lower systemic vascular resistance index and a higher cardiac index, which might be associated with serum phosphorus level.

PUB522

Cost of Medications Used in the Management of Secondary Hyperparathyroidism (SHPT) in Patients with End Stage Renal Disease (ESRD)  1  Leigh Darryl Quarles, 2  Vasily Belozeroff, 1  Kerry Cooper, 1  Jonathan D. Campbell. 3  Amgen Inc., Thousand Oaks, CA; 4  Univ of Tennessee, Memphis, TN; 5  Univ of Colorado, Aurora, CO.

Background: Management of SHPT associated with ESRD is complex, typically requiring combinations of medications. Eighty-two percent of the ESRD population is covered by Medicare with detailed drug expenditures reported annually by the US Renal Data System. For the remaining 18% covered by commercial health plans, drug expenditure information is unknown. The purpose of this study is to estimate the cost of medications used in the management of SHPT in ESRD patients from the US commercial health plan perspective.

Methods: Economic analysis with one-year time horizon to estimate per-member-per-month (PMPM) cost for SHPT related medications: calcium and non-calcium-based phosphate binders, calcitriol or active vitamin D analogs, and calcimimetics. Input parameters include: prevalence of ESRD in commercial health plans (MarketScan®); medication utilization and non-adherence (IMS Health for oral medications and Outcomes Plus for intravenous [IV] medications); and medication wholesale acquisition costs (WAC) (AnaSource.com) with one-way sensitivity analysis.

Results: The total PMPM (2014 US Dollars) cost of SHPT-related medications is $0.34: cinacalcet $0.06, phosphate binders $0.16, oral vitamin D $0.02, and IV vitamin D $0.10.

Figure 1. Total PMPM Cost Breakdown

Results are most sensitive to variation in ESRD prevalence and cinacalcet WAC parameters.

Conclusions: Results indicate that the collective cost of medications for the management of SHPT in commercial health plans is substantial with the cost of cinacalcet being lower compared to phosphate binders and IV vitamin D, but higher compared to oral vitamin D.

Medullar Compression by Bone Tumor: Case Report  1  Cinthia Sobral Vieira, Nicole D.T. Carvalho. 2  Nephrology Unit-Cliniefero, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: The presentation of vertebral tumors may have different kinds of manifestation. They can mimic neoplastic, inflammatory and congenital diseases. The presentation of vertebral tumors may have different kinds of manifestation. They can mimic neoplastic, inflammatory and congenital diseases. The presentation of vertebral tumors may have different kinds of manifestation. They can mimic neoplastic, inflammatory and congenital diseases. The presentation of vertebral tumors may have different kinds of manifestation. They can mimic neoplastic, inflammatory and congenital diseases.

Methods: A 66 years old masculine patient, with chronic renal disease in hemodialysis for 5 years, non-adherent to treatment or diet, had his levels of phosphate, calcium/phosphorus, alkaline phosphatase and parathyroid hormone (PTH) elevated in the last year. He did not take the medication prescription: Calcitriol and Sevelamer. The patient came to the ER of a general hospital referring constipation and abdominal distention. During the hospitalization, he started to refer paresthesia in inferior members with progressive march dysfunction. The neurological exam showed ataxic/calcaneal gait and strength reduction (4+/5+) in the inferior members.

Results: At first, an angiotomography study of the mesenteric vessels were made, thinking of the possibility of mesenteric ischemia, but the exam showed multiple lytic lesions in the corps of lumbar vertebrae and in the hipbones, mimicking secondary implants. The bone MIR demonstrated one lytic bone lesion at the level of D6 and D7 causing medullar compression. The bone scintigraphy was suggestive of a metastatic bone disease and the parathyroid scintigraphy showed a hyperfunctioning tissue, in the parathyroid left pole. The patient was submitted to a compressive laminectomy, the biopsy revealed a Brown Tumor. Then, it was indicated a parathyreodectomy. The pathological result showed no evidence of malign disease. Nowadays, the patient is still in hemodialysis, receiving calcium and under physiotherapy to recover muscle strength, already walking.

Conclusions: Brown Tumor or osteoclastoma is a rare bone lesion, an incidence of 1.4 to 13% in chronic renal patient due to a secondary hyperparathyroidism and less than 5% in primary hyperparathyroidism. It is more frequent in women. The vertebral involvement is uncommon. This case report has its importance for calling attention to importance to include brown tumor as a differential diagnosis in compressive spine lesions especially in chronic renal patients.

PUB524

Rescue-Therapy with Lanthanum-Carbonate (LC) in Uncontrolled Hyperphosphatemia in Dialysis  1  Nicola Giotta, Angela maria Marino. 2  Dept of Medicine, Nephrology and Dialysis Unit, Cardinal Massaia Hospital, Asti, AT, Italy.

Background: Control of hyperphosphatemia in hemodialysis provides an approach based on changes in diet, dialysis efficiency improvement, and use of phosphate binders. The latter, however, in some patients do not prove effective, conditioning the indirect increase of mortality and morbidity of the subject on dialysis. The objective of this study was to evaluate the difference in efficacy of a regimen of lanthanum carbonate plus standard therapy (LTS) compared to standard therapy alone (TS) in the treatment of patients with persistent hyperphosphatemia, as rescue-therapy.

Methods: We conducted an observational study of data on consecutive patients in hemodialysis who have presented more than four phosphorus values greater than 6 mg/dL in three months. Patients treated with TS, have varied therapeutic scheme introducing LC. Patients treated with sevelamer have outstanding this therapy and were treated with LC. The data analysis has been done considering a retrospective phase (FR) of three months and a prospective phase (FP) of six months, for each subject analyzing the effectiveness of therapy before and after enrollment.

Results: In a cohort of 163 patients on hemodialysis, we have selected for the study, 14 patients who had a mean age of about 65 years and length of dialysis than 6 years. The combination of LC plus TS produced a significant increase in the proportion of patients achieving the therapeutic targets as defined by the K/DOQI Guidelines. Reduction of 2.12 mg/dL (-32.7%) than the average of the P phase prospective (4.55 mg/dL) than the retrospective phase (6.27 mg/dL), was statistically significant (p < 0.01), associated with the reduction of 19:21 mg2/dl2 (-32.9%) of the average value of CaXP in the prospective phase (39.07 mg2/dl2) compared to the retrospective phase (58.28 mg2/dl2), also statistically significant (p < 0.001). The patients at the target of the FP accounted for 92.31% for P and 100% for the CaXP, respectively vs. the 7.14% and 50% of FR.

Conclusions: The introduction of the LC-as rescue therapy in the treatment of hemodialysis patients with uncontrolled hyperphosphatemia resulted very effective allowing more easily reach the therapeutic objectives.

PUB525

Glucocorticoid-Induced Osteoporosis in Renal Patients  1  Gabrielle Goldet, George Greenhall,2  Alan D. Salama. 3  Basildon and Thurrock Univ Hospital; 4  Royal Free Hospital, London; 5  Royal Free Hospital, London.

Background: Glucocorticoid-induced osteoporosis (GIO) is associated with severe morbidity due to fragility fractures as well traumatic fractures and 50-90% of patients on long term steroids are affected by GIO. GIO is relevant in the renal context as steroids are widely used to treat renal disease and as part of immunosuppression in transplant. Also, renal patients are already at higher risk of fractures in association with renal bone disease.

Methods: We designed and undertook an audit to assess screening and management of GIO in nephrology outpatients in a university hospital in London, using national guidelines as a benchmark for our performance. We then presented the results at a local meeting, produced posters and leaflets on GIO to be placed in the outpatient waiting area for patients so as to raise awareness of this issue and provided a simple algorithm to be followed by clinicians in all the clinic rooms. We then re-audited after 6 months.

Results: 100 patients were audited in each audit cycle. Measures audited were a) whether all patients over 65 were treated with bone-sparing agents (BSA); b) whether all patients with documented fragility fracture were treated with BSA; c) whether all patients under 65 without fragility fracture underwent DXA scan; d) whether all patients with T-score below -2.5 were treated with BSA; e) whether all patients with T-score 0 to -1.5 underwent repeat DXA within 3 years; f) whether BSA was prescribed for all patients where indicated; g) whether all patients were managed according to national guideline (cycle 1: 29%; cycle 2: 41%). See table for breakdown of results.

Conclusions: Our intervention has improved performance as measured against national guidelines, though the rate of GIO screening remains low. Many patients could potentially benefit from bone protection, though larger studies would be needed to demonstrate an effect on fracture incidence.

The Kidney Stone and Increased Water Intake Trial in Steel Workers: Results from a Pilot Study
Hakam Gharbi,1 Yair Lotan,2 Jodi Antonelli,2 Inmaculada Buendia Jimenez,3 Allison Ahrens Beaver,4 Aphril Dennis-Barrie,4 Dendra K. Von merveldt,5 Suzie Carter,3 Adam B. Cohen,2 John Pointdexter,6 Orson W. Moe,7 Margaret S. Pearl.1 1Urology, Dallas, TX; 2Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX; 3Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX; 4Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX; 5Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX; 6Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX; 7Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX.

Background: Preventing dehydration in subjects at risk may provide a means of primary prevention of kidney stones. The purpose of this pilot study was to assess the hydration status of an at-risk group of steel plant workers based on end-of-shift ("post-shift") spot urine osmolality and 24-hour urinary stone risk parameters.

Methods: 100 volunteers were recruited from Gerdau Midlantic steel mill in Texas on 11/14/14 and 12/5/14. Clinical data was recorded and a post-shift spot urine sample was obtained for measurement of urine osmolality. In addition, participants were invited to submit a 24-hr urine sample within 4 weeks of enrollment.

Results: Mean age was 41 and 95% were men. The majority of subjects were white (75%), followed by 10% Hispanic and 9% Black. Mean body mass index was 30.1 kg/m2 and overall 16% had past history of stone disease. Mean post-shift urine spot osmolality was 704.5 mOsm (169-1165 mOsm) and was >800 mOsm and >700 mOsm in 39% and 57%, respectively. Among 59 24-hour urine samples, mean volume was 1.89 ± 0.92 l/day, with 56% <2 liters and 17% <1 liter. Elevated levels of urinary analytes were found in 29% of subjects for calcium (>250mg/TV), 39% for uric acid (>700 mg/TV), 25% for oxalate (>45mg/TV) and 50% for sodium (>200 meq/TV).

Conclusions: The prevalence of stone disease in this population of steel workers is higher than the published prevalence of stone disease in the general population. A significant number of workers had concentrated post-shift and 24-hour urines and elevated levels of urinary analytes.

chronic renal pain in medullary sponge kidney
Giovanni Gambaro,1 Jackie Hirsch,2 Rocco Baccaro,1 Nicole Topilow,2 Matteo Bargagli,1 David S. Goldfarb,3 Pietro Manuel Ferraro.1 1Nephrology, Catholic Univ, Rome, Italy; 2NY Univ, School of Medicine, New York, NY.

Background: MSK usually occurs with recurrent stones; less frequently it is asymptomatic; very rarely the main manifestation is severe chronic flank pain. Often these pts are accused of seeking pain medications. Because of the rarity of such a presentation it is not clear whether pain is due to intense lithogenic activity or is independent of it, something like a form of the “loin pain hematuria syndrome”. Three Facebook support groups exist for North American patients with MSK and chronic pain. Their cooperation allowed us to investigate chronic pain in MSK.

Methods: An ad hoc questionnaire and the Brief Pain Inventory were administered through a dedicated web site; 92 patients (89 females) participated after verification of the diagnosis of MSK (imaging and diagnosis certified by a nephrologist or urologist).

Results: Mean age of patients was 39.8y (range 24-66). Age at onset of manifestations and MSK diagnosis were 23y (4-47) and 31y (7-57), respectively. Manifestations at onset were: flank pain (31%), reno-ureteric colic (RUC) (26%), hematuria (19%), cystitis (14%), pyelonephritis (10%). 71% of pts had daily pain, 76.5% have taken painkillers in the past week and 69.1% needed them at the time of questionnaire administration; 58% take them 1 time/day. The strong pain (5.4 in a scale from 0 to 10), jeopardizes general activities, mood and sleep. Only 4.6% of pts have RUC like pain; in 52.9% it is non-radiating flank pain with manifestations of possible UTI or stone passage (painful micturition, urgency, frequent uriination, hematuria, fever); in 42.5% it is non-radiating lumbar pain without other manifestations (however only in 3 cases the pain was a unilateral flank pain). Pain is frequently associated with stone (67%) or sand passage (46%), hydronephrosis (42%), hematuria (42.4%).

Conclusions: Although in these MSK pts the chronic pain that dominates the clinical manifestations is usually associated with some of the typical symptoms of stone passage, in a fraction of pts this is not the case and pain is not associated with lithogenic activity. The etiology of this pain syndrome remains uncertain and merits investigation.

Funding: Government Support - Non-U.S.

Difference in Vitamin D Level Between Older and Younger Kidney Transplant Recipients
Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Ali. Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.

Background: Vitamin D deficiency is more common in older than younger people. In kidney transplant recipients, vitamin D deficiency has a high prevalence of up to 80% according to recent studies. We compared vitamin D status in older versus younger patients with kidney transplant.

Methods: We reviewed all available record of kidney transplant recipients that came to our clinic at Hamad General Hospital in Qatar between September 1st 2013 and March 1st 2014. We recorded background data and laboratory tests. Patients divided into 2 groups younger and older (below and above 60 years old respectively). All patients were receiving vitamin D supplement.

Results: 102 patients were included. 52 patients in the younger group and 50 patients in the older. Age was 68.6±5.9 years in the older versus 41.9±10.4 years in the younger group. Table (1) compare laboratory values between the two groups. Vitamin D status was classified (normal above 30, mild 20-29, moderate 10-19 and severe below 10 ng/mL) figure (1).

Conclusions: In a comparative study, we found that older transplant recipient group had more male patients (pValue<0.05), lower alkaline phosphatase and higher intact parathyroid hormone (not statistically significant) but similar vitamin D, calcium and phosphorus level. There was a trend towards milder vitamin D deficiency in the older group that could be due to better compliance with vitamin D supplement. Despite vitamin D supplement protocol and long sunny days in Qatar we still found high rate of vitamin D deficiency in transplant recipients (81.4%).

Efficacy of Low Dose, Alternate Day Cinacalcet for Treatment of Secondary Hyperparathyroidism in Hemodialysis Patients: A Randomized Controlled Trial
Pongsathorn Gojaesi, Dolnapa Pattarathitnan, Kolasm Pokchaton, Anutra Chittinnanda. Medicine, Bhumibol Adulyadej Hospital, Royal Thai Air Force, Bangkok, Thailand.

Background: Secondary hyperparathyroidism (SHPT) is common in hemodialysis patients and has been associated with increased mortality. Cinacalcet, a modulator of calcium-sensing receptor, effectively reduced serum parathyroid hormone (PTH) in clinical studies. We tested whether prescription of low dose, alternate day cinacalcet could be an option for treatment of SHPT.

Methods: An open-labeled, randomized controlled trial enrolled hemodialysis patients with severe secondary hyperparathyroidism (intact PTH > 550 pg/ml). Patients were randomized to received low-dose cinacalcet (25 mg alternate day) or standard-dose (25 mg daily) for 16 weeks. At 8 weeks, doses of cinacalcet could be increased to achieve KDIGO PTH target of less than 585 pg/ml. The primary outcome was the difference in percentage of patients achieving KDIGO target at 16 weeks. The changes of serum iPTH, other biochemical data were also tested.

Results: Between July 2014 and January 2015, a total of 30 hemodialysis patients (15 females, 15 males) were randomly assigned to a treatment group: 16 to low-dose and 14 to standard-dose. Baseline iPTH in low-dose and standard-dose group was 1,065.9 ± 477.7 and 1,211 ± 466.5 pg/ml respectively (p = 0.409). During study period, 4 patients (2 from each group) were dropout from study due to adverse events. Intention to treat analysis showing that the percentage of patients who achieving KDIGO PTH target was not different (38.5% in low-dose group compared with 30.8% in standard-dose group, p = 1.0). Serum iPTH reduction during 16 weeks of study period in low-dose and standard-dose group was 253.5 ± 316.1 and 330.6 ± 698.2 respectively (p = 0.731). The adverse events were not different between both groups except hypocalcemia that tend to be higher in standard-dose (38.5% vs 13.3%, p = 0.274).

Conclusions: Among patients with SHPT, cinacalcet 25 mg alternate day may be sufficient effectively decrease serum iPTH levels with low incidence of hypocalcemia. The role of low dose cinacalcet in SHPT should be determined in large-scale, adequately powered randomized controlled trials.

Parathyroid Hormone Stability in Hemodialyzed Patients: Comparison on Non-Centrifuged EDTA and Serum Samples with 2nd and 3rd Generation Assays

Pierre Delanaye,1 Pierre Delanaye,2 Etienne Cavalier.1 Clinical Chemistry, Univ of Liege, CHU Sart-Tilman, Liege, Belgium; 3Nephrology, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.

Background: PTH stability is of importance. Many studies have shown divergent results between EDTA and serum, mainly linked to differences in protocols or cut-offs used to decipher whether PTH remained stable or not. No studies have yet compared PTH as measured by 2nd and 3rd generation assays on the same samples in hemodialyzed (HD) patients.

Methods: Five pairs of samples (EDTA and gel tubes) were obtained in 10 HD patients before session. One pair was centrifuged and run immediately to establish the “T0”. Two pairs were kept at -4°C and +25°C. They were centrifuged after 4 and 18 hours. Supernatant was kept at -80°C for one week. Then, all samples were measured in a single batch, on Roche Cobas andDiaSorin XL. 2nd and 3rd generation PTH assays. Samples were considered as stable if 90% of subjects had a decrease lower than a total change limit (TCL) that takes both analytical and biological variability into consideration. All determinations were run in duplicates.

Results: At T0, no difference was observed between plasma and serum for any of the methods. PTH decreased in all samples and degradation was the same with 2nd or 3rd generation assays, whatever the method used. Percentages of decrease were systematically lower in EDTA plasma compared to serum and none of our subjects presented a decrease higher than the TCL with EDTA plasma. In serum, PTH was not considered as stable, but only when kept at 25°C for 18 hours.

Conclusions: PTH stability is of paramount importance for correct interpretation of the results. Many studies have tried to evaluate this stability but are not free from criticism, mainly due to a poorly defined T0 and questionable acceptance limits. In this study, we used an unfrozen T0 and decision limits based on analytical and biological variations. Moreover, we tested 2nd and 3rd generation PTH on two automated platforms. Our results show that, if PTH is basically more stable in EDTA plasma than in serum, this advantage is only clinically significant when samples are stored for a long period (18h) at +25°C.

Conclusion: Vitamin D insufficiency is highly prevalent in patients on dialysis and in hypertensive controls, and only partially resolves after kidney transplantation.

Vitamin D Metabolism Is Incompletely Restored After Kidney Transplantation

Thomas F. Hiemstra,2 Stephen M.S. Ting,1 Ragada El-Damanawi,1 Kenneth Lim,1 Martin Kauffmann,3 Glennine Jones,1 Daniel Zehnder.1 1Univ of Warwick, United Kingdom; 2Univ of Cambridge, United Kingdom; 3Massachusetts General Hospital, Boston, Queen’s Univ, Kingston, Canada.

Background: Vitamin D deficiency is widely reported in patients with renal impairment and is associated with adverse outcomes. The extent and rate of recovery of vitamin D metabolism after kidney transplantation is uncertain.

Methods: We enrolled 175 dialysis patients (HD) listed for kidney transplantation, and 85 hypertensive but otherwise healthy controls (HTN). We determined blood markers of mineral metabolism including intact FGF23 and vitamin D metabolites at entry (or immediately pre-transplantation), and 2 months. As a surrogate for vitamin D deficiency, we assessed the 25(OH)D3: 24,25(OH)2D3 ratio (D-ratio, normal 5-25).

Results: Of 175 dialysis patients, 76 were transplanted (TXR) during the study. TXR were younger with a lower BMI than controls. FGF23 was higher in HD patients than HTN at baseline, but normalised after 12 months (p=0.13). At baseline, vitamin D insufficiency (defined as 25(OH)D <30 ng/mL) was present in 82 of subjects and did not differ between groups. However, vitamin D deficiency (defined as 25(OH)D <10 ng/mL) was more common in dialysis (15% versus 4%, p=0.49). The baseline D-ratio was higher in HD (48, IQR 27-67) than in HTN (16, IQR 14-18, p<0.0001) patients. Transplantation resulted in significant reduction in D-ratio after 2 and 12 months compared to HD (p=0.0008 and p=0.005 respectively). The slope of D-ratio vs 25(OH)D3 increased after transplantation, but remained lower than for HTN controls, suggesting reduced expression or activity of the cataboly CYP24A1 (25-OH-D3-24-hydroxylase) in kidney failure.

Conclusion: Low TA-iPTH levels during the first 12 months after initiation of dialysis (group 1: <65pg/ml, group 2: 65 to 300 pg/ml, group 3: >300pg/ml). Cox regression analysis was performed to determine the prognostic value of TA-iPTH on overall mortality and MACCEs.

Results: The mean age was 56.5 + 14.5 years and 222 patients (53.8%) were male. During a median follow-up of 50.8 months, 49 patients (11.9%) were dead and MACCEs were occurred in 55 patients (13.3%). Multivariate Cox regression analysis demonstrated that low TA-iPTH level was an independent risk factor for both overall mortality [group 2 as reference; group 1, hazard ratio (HR)=2.08, 95% confidence interval (CI)=1.2-3.85, P=0.02] and MACCEs (HR=1.88, 95% CI=1.04-3.40, P=0.04) in incident dialysis patients after adjusting confounding factors.

Conclusion: This study demonstrates that low TA-iPTH is an independent risk factor for overall mortality and MACCEs in incident dialysis patients.

Combined Analysis of Hypercalcemia and PTH Levels as Clue to Unveil Persistent Transplant Hyperparathyroidism

Melan Custodio,1 Maria Julia C.L. Araujo,1,2 Wagner Dominguez,1 Rosa M.A. Moyzas,1,2 Elías David-Neto,1 Vanda Jorgetti,1 1Nephrology Div, Unio de Sao Paulo; 2Transplant Unit, Unio de Sao Paulo; 3UNINOVE, Sao Paulo, Brazil.

Background: Mineral and bone metabolism disorders in chronic kidney disease (CKD-MBD) are not always corrected after kidney transplantation (TxR). The persistence of hyperparathyroidism may have a negative impact on patient and graft outcome. Our objective was to evaluate the evolution off CKD-MBD and the incidence of hyperparathyroidism after 12 months of TxR.

Methods: In this study, we included all consecutive patients submitted to a TxR during the period between Jan 2010 and Dec 2014 in a University based center. We excluded patients with a PTH <300 pg/ml before TxR, multi-organ transplants, patients with an eGFR<30mL/min and those who underwent parathyroidectomy after TxR. Twelve-month eGFR, plasma levels of total calcium (Ca), phosphorus (P), alkaline phosphatase (AlkP), magnesium (Mg), parathormone (PTH), and 25-hydroxy vitamin D (25-OH vit D) were compared to baseline values. A PTH >100pg/mL and a total calcium >10.2mg/dL were considered abnormal. We defined high PTH, with or without hypercalcemia as the primary endpoints for the analysis.
Results: During the observation period, 408 patients were evaluated. There was a significant increase in gFR and in calcium levels 12 months after the TxR. Compared to the baseline, PTH, AlkP, and P significantly decreased. 25-OH VitD did not change during the period. Fifteen percent of patients presented both PTH and Ca above the reference levels, while 37% presented isolated high PTH and 8% hypercalcemia only. Multivariate analysis disclosed that post-TxR hyperparathyroidism was dependent on pre-transplant PTH (OR 1.001; CI 95%: 1.001-1.002) and Ca (OR 1.23; CI 95%: 1.036-1.468).

Conclusions: Monitoring Ca and PTH before and after TxR may be important to detect patients at high risk of persistent hyperparathyroidism, and to identify patients in need of treatment to prevent its complications.

PUB534
Predictors of FGF23 and Soluble Klotho in HIV Infection Rubin Wang,1 Michael Shlipak,2 Joachim H. Ix,1,2 Michelle M. Estrella.1 Johns Hopkins Univ: 1UCSF, 2UCSD.

Background: In the general population, FGF23 and its co-receptor, soluble klotho (sKlotho), have been implicated in the aging process. HIV+ individuals are at higher risk of age-related comorbidities compared with HIV- persons. We evaluated whether FGF23 and sKlotho levels differed by HIV status and determined clinical factors associated with each hormone in HIV+ men.

Methods: 384 HIV+ and 225 HIV- men in the Multicenter AIDS Cohort Study (MACS) were randomly selected for FGF23 and sKlotho measurements from samples stored in 2008-2010. We compared FGF23 and sKlotho levels by HIV status, adjusted for age and race. Multivariable linear regression models were used to determine predictors of FGF23 and sKlotho levels among HIV+ men.

Results: Mean age was 53±20 years; 34% were black; median eGFR was 35.7 mL/min/1.73m². FGF23 levels were 94 [73–141] RU/mL. FGF23 did not change significantly after adding either HCT (99 [74–148] RU/mL) or low sodium diet (98 [57–135 RU/mL]) to HIV- counterparts. Among HIV+ men, clinical predictors associated with FGF23 differed from those associated with sKlotho. Mechanisms by which HIV treatment and co-morbidities impact these hormones need further study.

Conclusions: HIV+ individuals had similar FGF23 but higher sKlotho levels compared to HIV- counterparts. Among HIV+ men, clinical predictors associated with FGF23 differed from those associated with sKlotho. Mechanisms by which HIV treatment and co-morbidities impact these hormones need further study.

PUB535
Response of Fibroblast Growth Factor 23 to Sodium Interventions in Diabetic Nephropathy and Arterial Hypertension Jolmer K. Humalda,1 Sahoo Arjun,2 Veggeloe,2,3 Gunnar H. Heinc;2 Martin H. De Borst.1 Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; 2Nephrology and Hypertension, Saarland Univ Medical Center, Homburg, Germany; 3Nephrology, VU Medical Center, for NiGrAm, Amsterdam, Netherlands.

Background: Fibroblast growth factor 23 (FGF23) rises progressively in chronic kidney disease (CKD) and is associated with adverse cardiac outcomes. Both CKD patients with diabetic nephropathy (DN) and patients with hypertension are vulnerable to the effects of excess sodium. We hypothesized that renin-angiotensin system (RAS) inhibition (ACEi) with four 6-week trial in 45 DN patients on background ACE inhibition would inhibit tubular phosphate reabsorption. Chronic kidney disease (CKD) leads to FGF23 excess and deficiency of sKlotho. Mechanisms by which HIV treatment and co-morbidities impact these hormones need further study.

Methods: We performed a post-hoc analysis of a randomized controlled 2x2 crossover trial in 45 DN patients on background ACE-Inhibition (ACE) with four 6-week treatment periods with add-on hydrochlorothiazide (HCT) or placebo, combined with regular (RS) or low sodium (LS) diet. Plasma C-terminal FGF23 was measured by ELISA (Immutopics). Additionally, FGF23 was measured in 12 patients with arterial hypertension but without overt CKD before and after 4 hours of intravenous administration of 2 liters sodium-chloride 0.9%. Changes in FGF23 were assessed by Friedman’s test and Wilcoxon Signed Rank test as appropriate.

Results: DN patients were 65±9 years old (mean±SD). During ACE+RS eGFR was 65±25 mL/min/1.73m², HbA1c 7.1±0.8% and albuminuria 649 mg/d median [1st- 3rd quartile: 230-2008 mg/d]. FGF23 levels were 94 [73–141] RU/mL . FGF23 did not change significantly after adding either HCT (99 [74–148] RU/mL) or low sodium diet (99 [75–135 RU/mL]) or both HCT and low sodium diet (111 [81–160] RU/mL) P=0.15. The FGF23 response with arterial hypertension were 45/13 years old with an eGFR of 101±18 mL/min/1.73m². Sodium-chloride infusion did not affect FGF23 (before: 68 [58–97] RU/mL, after: 67 [57–77] RU/mL, P=0.4).

Conclusions: Chronic and acute changes in sodium status did not materially change FGF23 in DN and hypertensive patients, respectively. Our data thus do not support a direct feedback loop between volume status and FGF23 in diabetic nephropathy or hypertension.

PUB536
Hypocalcaemia Management Post Parathyroidectomy in Renal Patients – On Experience and Change in Practice Rajkumar Chirnadhar, Maharajan Raman, Constantin Chrysochou, Smeeta Sinha. Dept of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom.

Background: Hypocalcaemia is common post parathyroidectomy in renal patients with secondary hyperparathyroidism due to hungry bone syndrome with an incidence as high as 51%. Hypocalcaemia can be prevented by effectively preloading patient with Vitamin D supplements and close monitoring of calcium levels post operatively. Currently there is no clear guidance on the preloading dose of one-alcacidol in literature. Our current practice is to preload all patients with 2 mcg one-alcacidol for 5 days pre operatively. Our aim was to study the management of hypocalcaemia post parathyroidectomy in renal patients and factors influencing length of hospital stay (LOS). To identify if any changes in current practice could improve outcome.

Methods: Retrospective observational study of all renal patients who underwent parathyroidectomy under a single surgeon over 6 years (April 2008 to September 2014). Data was collected from the Electronic Patient Record. Data were analysed using Stats direct and Fisher Exact test was used for testing statistical significance.

Results: 72% of our sample (n = 25) were male with a mean age of 54. Of the 25 there were 13 transplant, 9 haemodialysis and 3 CKD patients. The mean hospital stay was 5 days shorter than quoted in the literature (5.6 Days). 3 of 25 patients were not preloaded with one-alcacidol and 3 had secondary hyperparathyroidism due to hungry bone syndrome with an incidence as high as 51%. Hypocalcaemia can be prevented by effectively preloading patient with Vitamin D supplements and close monitoring of calcium levels post operatively. Currently there is no clear guidance on the preloading dose of one-alcacidol in literature. Our current practice is to preload all patients with 2 mcg one-alcacidol for 5 days pre operatively.

Conclusions: Insufficient preloading was identified as a major risk factor for hypocalcaemia, which significantly increased LOS. Further to consensus between renal and surgical teams we have increased the preloading dose of one-alcacidol to 5 mcg for 5 days pre operatively. A follow up study is planned in 12 months to observe the outcome of this change.

PUB537
Links Between Urinary Phosphate Handling, FGF23 and Klotho: An Australian Single-Centre Cross-Sectional Study Sven-Jean Tan,1,2 Edward Robert Smith,1 Stephen G. Holt,1,2 Tim Hewlton,1,2 Nigel David Toussaint.1,2 1Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; 2Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.

Background: Aim: To examine the links between measured phosphate parameters and regulators of phosphate homeostasis (fibroblast growth factor-23 [FGF23] and soluble α-klotho [sKlotho]). Background: FGF23, via the FGF-Receptor/Klotho complex, reduces expression of sodium-phosphate co-transporters thereby inhibiting tubular phosphate reabsorption. Chronic kidney disease (CKD) leads to FGF23 excess and deficiency of sKlotho. Elevated serum phosphate (sP) results as remaining function nephrons are unable to compensate for reduction in total phosphate excretion. Complex relationships between these parameters in health and disease, and the impact on phosphate handling, are not fully understood.

Methods: Blood samples and spot and 24-hour urine were collected from patients with CKD (Stages 1-5) and healthy volunteers. Serum and urine biochemistry, intact FGF23 and sKlotho were analysed. FGF-23 and sKlotho were log-transformed (Ln). Fractional excretion of phosphate (FEp) and maximal tubular phosphate reabsorption (TmP) were calculated. Pearson correlation coefficients were used to assess correlation between phosphate handling and regulatory hormones.

Results: 116 participants (77 CKD and 39 controls) were recruited. 74 (63.8%) were male. Median (IQR) age of all participants was 61 (49-71) years. FGF23 and FEPi were higher, while sKlotho and TmP were lower, in CKD compared to controls (all p<0.005). Adjusting for eGFR, LnFGF23 correlated with FEp (R=0.22, p=0.026) and sP and FEp (R=0.26, p=0.003). Notably, higher FEp was associated with lower sKlotho (R=-0.328, p=0.001) and sP (R=0.309, p=0.002). There was no association between LnFGF23 and LnKlotho.

Conclusions: Disruption of phosphate regulatory mechanisms is characteristic of CKD. In this small cohort, we established that FGF23 contributes to phosphate excretion. However, sKlotho may provide insight into a greater physiological role of Klotho in regulating TmP at a cellular level. Causal relationships should be explored further in vitro.

**PUB538**

**Fibroblast Growth Factor 23 Can Predict the Progress of Aortic Artery Calcification in Dialysis Patients**  
Zijin Chen, Xiaonong Chen, Xiaobo Ma, Bei Ding, Huawei Ling, Nan Chen.  
Department of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; Department of Radiology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

**Background:** To investigate the factors associated with progress of aortic artery calcification in maintenance haemodialysis (MHD) patients and to determine whether plasma FGF23 level is related to progress of aortic artery calcification.

**Methods:** MHD patients from Ruijin Hospital from July 1st 2011 to July 31th 2011 were involved in our study. Follow up 36 months. Aortic artery calcification (AAC) was detected by a lateral lumbar X-ray plain and read by two radiologists.

**Results:** 120 MHD patients were enrolled and followed up for 36 months. To July 2014, a total of 67 MHD patients finished the study. Among 67 patients, 32 were male, mean age 53.9±13.1 years old, mean dialysis vintage 44.1±31.8 months, median FGF23 level 48052 (11372-35750.4)Ru/ml, LgFGF23 3.79±0.83. In July 2011, 53.7% of patients had visible calcification in the abdominal aorta and mean involved segment was 1.42 with mean AAC scores(AACS) 3.96. In July 2014, 73.1% had AAC and mean involved segment was 2.34 with mean AACS 10.7. There are significant differences between two AAC involved segments and AACS (both P<0.001). Age, dialysis vintage and FGF23 level had significant difference between AAC progress group and no AAC progress group (P = 0.007, <0.001 and 0.020, separately). Logistic analysis showed that the independent parameters associated with AAC progress were age (OR=1.114, CI:1.045-1.186) and LgFGF23 (P = 0.007, <0.001 and 0.020, separately). The severity of vascular calcification progress yearly in maintenance haemodialysis patients. Age and FGF23 are independently associated with the progress of AAC. FGF23 level could predict the progress of AAC in MHD patients.

**Funding:** Government Support - U.S.

**Conclusions:** The severity of vascular calcification progress yearly in maintain haemodialysis patients. Age and FGF23 are independently associated with the progress of AAC. FGF23 level could predict the progress of AAC in MHD patients. Funding: Government Support - Non-U.S.

**Could FGF23 Be a Regulator of Hepcidin in Liver Cells?**  
Justine Bacchetta, Nathalie Domencheaux, David Duranent. Hospices Civils de Lyon and INSERM, Univ Claude Bernard Lyon 1, Lyon, France.

**Background:** Hepcidin is a 25-amino-acid protein synthesized in hepatocytes and macrophages that acts as a post-translational inhibitor of ferroportin, the only receptor known to export iron from intracellular compartments to systemic circulation. Thus, higher hepcidin levels are associated with greater intracellular sequestration of iron, and increased risk of anemia. Vitamin D is an inhibitor of hepcidin expression; the working hypothesis is that FGF23 could be an “inverse” regulator of iron metabolism in comparison to vitamin D, with a stimulation of hepcidin expression, an increase of intracellular ferritin and an inhibition of ferroportin expression on the cell membrane, leading to a further intracellular sequestration of iron.

**Methods:** Three different types of liver cells were used: HepG2, HepaRG and primary human hepatocytes (PHH). Cells were exposed to FGF23 (1, 10 or 100-ng/mL), at different time points (0, 24, 48, 72 h). Cultures were performed in triplicates, and qRT-PCR in duplicates (StepOne Plus Real-Time PCR). Western Blots were also performed (Erk and Akt phosphorylation pathways, FGF1, FGF2, ferritin).  
**Results:** In HepG2, even though FGF1-expression was found by Western blot analysis, FGF23 did not modify hepcidin expression by qRT-PCR, and Erk/Akt pathways were not activated by FGF23. In HepaRG cells, hepcidin expression was modified with FGF23 by qRT-PCR, i.e. increased at 6 hours and decreased at 24 hours.

**Prevalence of Hyperparathyroidism and Its Correlates in a Large Cohort of Hemodialysis Patients**  
Pusquale Esposito, Fabio Malberti, Elena Caramella, Marta Calatroni, Edoardo La Porta, Marina Foramitti, Rosanna Coppo, Antonio Dal Canton. Department of Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy; Department of Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy; Department of Nephrology, Regina Margherita Children’s Hospital, Turin, Italy.

**Background:** Beyond experimental setting of randomized trials, little is known about the occurrence of mineral bone disorders (MBD) in the real-life clinical practice of hemodialysis (HD). This is the reason why we designed this observational study to define the prevalence of hyperparathyroidism (HPT) and its correlates in a large cohort of HD patients.

**Methods:** We enrolled HD prevalent patients from 38 Dialysis Units collecting data on: clinical information, dialysis parameters, biochemical and instrumental evaluations and pharmacological therapy. According to the KDIGO guidelines we divided the patients in: patients affected by HPT (i.e. PTH> 9 the upper reference limit of each laboratory) vs patients on target.

**Results:** Out of 495 patients, 34 (6.8%- 59.9±15.5 years, 53%M) presented HPT with mean PTH of 1064±536 pg/ml, while 461 patients resulted OT (93.2%- 66.9±13.7 years, 66%M), mean PTH 242±151 pg/ml (p<0.0001). HPTs were younger than OT (59.9±15 vs 69.9±13.7 years, p=0.008), with a longer HD history (126.2±125 vs 64.3±69.4 months, p=0.0003). There were not significant differences in both clinical and dialysis parameters. Similarly, there were not differences in laboratory examination except from serum ALP that resulted higher in HPTs (194.8±142 vs 144.1±108 U/l, OT, p<0.01). Moreover, there were not differences in the use of phosphate binders, whereas a significantly higher percentage of HPTs was taking paricalcitol and calcimetics and the prescribed vitamin D doses (both as calcitriol and paracalcitriol) were significantly higher in HPT patients.

**Conclusions:** The prevalence of HPT in our population was surprisingly lower, compared to that reported in previous studies. This finding could be due to the general application of KDIGO guidelines, which recommend more permissive PTH levels compared to the previous K-DQOI guidelines, especially those to the availability of effective drugs, probably used more appropriately than in the past.

**Effect of Vitamin D Receptor Activators on Glomerular Filtration Rate: A Meta-Analysis and Systematic Review**  
Qian Zhang, Jing Chen. Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.

**Background:** Vitamin D receptor activators (VDRAs) can protect against mineral bone disease, but they may also elevate serum creatinine and reduce glomerular filtration rate (GFR).

**Methods:** We conducted a systematic review and meta-analysis of randomized clinical trials (RCTs) to evaluate the effect of VDRAs on kidney function and adverse events. MEDLINE, EMBASE, the Cochrane Controlled Trials Register were searched for RCTs that evaluate vitamin D receptor activators (alfacalcidol, calcitriol, doxercalciferol, falcalcitriol, maxacalcitol and paricalcitol) up to March 2015.

**Results:** We included 31 studies, all of which were performed between 1976 and 2015, which enrolled 2621 patients. Patients receiving VDRAs had lower eGFR (weighted mean difference WMD -1.29 mL/min/1.73m², 95% CI -2.42–(-0.17) and elevated serum creatinine (WMD 7.03 μmol/L, 95% CI 0.61–13.46) in sensitivity analysis excluding studies with dropout rate more than 30%. The VDRAs and control groups had no significant differences in all-cause mortality (relative risk RR 1.41, 95% CI 0.58–3.80), cardiovascular disease (RR 0.84, 95% CI 0.42–1.71), and severe adverse events (RR 1.15, 95% CI 0.75–1.77). Episodes of hypercalcemia (RR 3.29, 95% CI 2.02–5.38) were more common in the VDRAs group than in the control group.

**Conclusions:** Although administration of VDRAs slightly reduced the eGFR, all-cause mortality and severe adverse events were comparable between the groups. Future RCTs with larger sample sizes are needed to assess whether the mild reduction of eGFR is of clinical significance.
This study was an one-year intervention study for hemodialysis patients with hypovitaminosis D. During the first six months, patients received 3,000 IU of cholecalciferol after each hemodialysis (9,000 IU/week), thereafter, they stopped taking supplements. Serum levels of 25(OH)D and 1,25(OH)₂D, and other biological variables were measured every 3 months for one year. We investigated the effects of cholecalciferol supplementation on the biological variables and inflammatory markers. In addition, the effective factors on the levels of 25(OH)D and 1,25(OH)₂D after cholecalciferol supplementation were assessed by multivariate regression analysis.

Results: Twenty-nine patients with hypovitaminosis D participated in our study. During cholecalciferol supplementation, the 25(OH)D and 1,25(OH)₂D concentration significantly increased from baseline to six months (9.9 to 34.3 ng/mL, p = 0.001 and 19.7 to 22.9 ng/mL, p = 0.05, respectively). At 6 months, 65.5% of the patients had 25(OH)D levels within the target range [30 ng/mL] with a low dose of cholecalciferol supplementation. Also, serum calcium and phosphorus levels did not increase above the normal range. However, the inflammation markers, hsCRP, e-selectin, VEGF-A, were not shown significant effects of cholecalciferol supplementation on the biological variables and inflammatory markers. In addition, the effective factors on the levels of 25(OH)D and 1,25(OH)₂D after cholecalciferol supplementation were assessed by multivariate regression analysis.

Conclusions: The low dose cholecalciferol supplementation was effective in correcting serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, 6 months of low dose cholecalciferol supplementation in these patients did not improve the levels of inflammatory markers.

Funding: Government Support - Non-U.S.
Methods: We performed a cross sectional study in 80 Tx (5510.5;49M/31W) with CKD stage 2-4 (GFR 47±16 ml/min). 30 healthy subjects (3412;43;30GFR95±19 ml/min) were the control group. We evaluated in all patients SOST, Ca, P, PTH, FGF23 and Alkaline Phosphatase (AP).

Results: SOST was not different between Tx and controls (27.6±10.2; 10.1±0.8; 3.0±0.7; 178.65±59; 51; 26±1 142±17 45.73±28.8). Serum levels of FGF23 were increased compared to controls (473±28.8 vs 30.31;00;0 pg/ml; p<0.05). SOST showed a negative correlation with AP (R=-0.75; p<0.05) and a positive correlation with FGF23 (R=0.23; p<0.05) and 25D (R=0.23; p<0.05). No correlation existed with other parameters.

Conclusions: eGFR does not seem to affect serum levels of SOST in Tx. The negative correlation with AP indicates that SOST maintains its modulatory role of osteoblastic activity in this population. The correlation with FGF23, which is in agreement with low FGF23 in SOST null mice, suggests modulatory effects of both proteins on osteoblastic direct, through Wnt inhibition, for SOST, indirect, through effects on 1,25D, levels for FGF23. Serum SOST may be an additional marker of bone metabolism, useful to understand metabolic pathways in normal subjects and in CRF.

PUB547

Comparison of Cholecalciferol Supplementation Dosing with a Bolus Dose Versus Daily Administration in Chronic Hemodialysis Patients

Background: The aim of this study was to assess the safety profile of bolus cholecalciferol supplementation and compare its effectiveness to daily oral administration in hemodialysis (HD) patients.

Methods: This 6-month prospective, intervention study enrolled 60 stable HD patients with 25-hydroxyvitamin D [25(OH)D] levels <30ng/ml, who received cholecalciferol 25,000 IU once or twice monthly (n=30) or 700 IU daily (n=30). Differences in biochemical parameters, including 25(OH)D, calcium, phosphorous, parathyroid hormone (PTH), alkaline phosphatase and C-reactive protein levels, were analyzed monthly. Primary outcome was 25OHD3 level at 6 months. For safety purposes, in the subgroup of patients with hypertension, hypokalemia, metabolic alkalosis and low plasma renin and aldosterone levels, were low. Given the clinical picture and autosomal recessive inheritance pattern, a provisional diagnosis of AME was made. 24 hour urinary cortisol and cortisone estimation was unavailable. We decided to confirm the diagnosis using next generation gene sequencing.

Methods: Whole blood was collected from the parents and the affected members after informed consent. 30 ng of the isolated high quality DNA was used to prepare library and sequencing. Sequencing was performed using the Illumina HiSeq platform. Variations were called using the GATK Unified Genotyper and analysed using ANNOVAR and annotated ClinVar.

Results: Analysis revealed the presence of homozygous variation p.R337C in HSD11B2 gene annotated to be pathogenic in ClinVar and confirmed to be deleterious using Sanger sequencing of the amplicons, confirming the diagnosis. All the patients were negative for GCKR gene which is known to be associated with hyperglycemia. In addition, the patient was not found to be positive for CYP2C9 and CYP2C19 which are known to be associated with drugs metabolism. The patient showed normal serum levels of vitamin D and calcium, consistent with the diagnosis of AME. The patient was treated with a combination of glucocorticoids and mineralocorticoids and the patient showed an improvement in his symptoms.

Conclusions: A homozygous mutation (p.R337C) variation in the HSD11B2 gene was demonstrated in the family using whole-exome sequencing. This is the first genetically demonstrated case of AME in an Indian population. Our study underscores the utility of next generation sequencing in the diagnosis of rare inherited diseases.

Genetics of Thrombotic Microangiopathies – The Viennese TMA Cohort

Background: Thrombotic microangiopathies (TMA) classified as hemolytic uremic syndrome (HUS) are characterized by acute kidney injury (AKI), mechanical hemolysis and thrombocytopenia, caused by an excessively activated alternative pathway of the complement cascade. The pathogenesis of TMA is still not fully understood. The aim of this study was to identify genetic variations associated with the risk of TMA in the Viennese population.

Methods: A total of 150 patients with TMA were enrolled in this study. Whole-exome sequencing was performed using Illumina HiSeq 2500 platform. Variations were called using the GATK Unified Genotyper and analysed using ANNOVAR and annotated ClinVar.

Results: Analysis revealed the presence of homozygous variation p.R337C in HSD11B2 gene annotated to be pathogenic in ClinVar and confirmed to be deleterious using Sanger sequencing of the amplicons, confirming the diagnosis. All the patients were negative for GCKR gene which is known to be associated with hyperglycemia. Under-Diagnosis of Alport Syndrome in First-Degree Relatives of Affected Individuals Clifford E. Kashtan, 1,2 Theresa F. Cassidy, 1,2 Michelle N. Rheault, 1,2 1Pediatrics, Univ of Minnesota, Minneapolis, MN; 2Alport Syndrome Treatments and Outcomes Registry (ASTOR).

Background: Alport syndrome (AS) is an important inherited cause of progressive renal disease. Hematuria, the cardinal feature of AS, is highly penetrant in affected individuals. Urinalysis is a sensitive method for detecting AS in relatives of AS patients. This report describes a cohort of at-risk individuals (first-degree relatives of known AS patients) who underwent a first urinalysis as part of a clinical trial feasibility study.

Methods: For a study entitled “Multi-center Controlled Clinical Trials in Alport Syndrome – A Feasibility Study” (R21 DK91480, Clinicaltrials.gov #NCT01696253) conducted during 2013-14, first morning urine collection kits were sent to 104 people registered with ASTOR who carried a diagnosis of AS or were first-degree relatives of people known to have AS. 45/104 participants (43%) had been classified as unknown because a urinalysis had not been performed previously.

Results: 17/45 unknowns did not return the urine kit. Of the 28 who returned a urine kit, 11 had hematuria and 17 had normal urinalyses. Of the 11 who were reclassified from unknown to affected, 6 were siblings of a known affected child, 3 were sons of a known affected mother and 2 were mothers of known affected children. 3/11 had microalbuminuria (urine microalbumin:creatinine ratio > 30 mg/g); none had overt proteinuria.

Conclusions: The results are consistent with the following conclusions: 1) it is not unusual for first-degree relatives of known AS patients to have never been screened by urinalysis; 2) screening of first-degree relatives of known AS patients frequently identifies individuals affected individually (39% [11/28] of those who returned urine kits) who may benefit from early intervention. Early initiation of ACE-inhibitor therapy appears to slow renal disease progression in AS (Gross et al, Kidney Int 2012). It is recommended that treatment be initiated when urinary protein is >100 mg/day (n=5), hypertension (n=2), surgery, diabetes and renal transplantation (each n=1). Thirteen and 3 showed a CHF-1 and a MCGPigaac risk haplotype, respectively; potentially disease-causing mutations were identified in 22 patients (7 CFHI, 6 CD46, 3 CFI, 4 C3, 2 CF1, 1 THBD; 4 of them with more than 1 mutation); 7 showed wild-types and no data existed for 1 patient.

Conclusions: In our cohort of TMA patients we identified 30 cases of aHUS. In 22 patients (74%) we identified a mutation within genes of the complement regulatory proteins CFB, thrombomodulin (THBD) and C3, and medical history for triggering factors were analyzed.

Results: Out of 92 patients with TMA we classified 30 as atypical HUS (aHUS), 1 as typical HUS, and 61 as secondary HUS. At onset of disease patients with aHUS had a mean age of 25 years (range: 1-47), 20 were female (65%), and 13 (43%) were kidney transplant recipients. First presentation of 24 patients was AKI, 3 showed hemolysis, 2 had pre-eclampsia and 1 HELLP-syndrome. Distinct triggering factors in 20 patients were: UTIs (n=10), infections (n=5), hypertension (n=2), surgery, diabetes and renal transplantation (each n=1). Thirteen and 3 showed a CHF-1 and a MCGPigaac risk haplotype, respectively; potentially disease-causing mutations were identified in 22 patients (7 CFHI, 6 CD46, 3 CFI, 4 C3, 2 CF1, 1 THBD; 4 of them with more than 1 mutation); 7 showed wild-types and no data existed for 1 patient.

Conclusions: In our cohort of TMA patients we identified 30 cases of aHUS. In 22 patients (74%) we identified a mutation within genes of the complement regulatory proteins CFB, thrombomodulin (THBD) and C3, and medical history for triggering factors were analyzed.

The DS3 Scores and Quality of Life in Japanese Patients with Fabry Disease Nobuhito Hiraga, Keisuke Yatsu, Sanae Saka, Gen Yasuda, Satoshi Umemura. 1 Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; 2 Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.

Background: Fabry disease (FD) is the lysosomal storage disorder, caused by the deficiency of lysosomal hydrolase alpha-galactosidase A activity. Various symptoms associated with renal disease, heart lesion and cerebrovascular disease occur in Fabry disease patients. Thus, the quality of life (QoL) would be altered with the disease progressed. We evaluated the clinical severity and the QoL in a sample of Japanese patients with Fabry (FD) disease using the Disease Severity Scoring System (DS3) and the SF-36 survey in male and in female.

Methods: Observational cross-sectional study. The DS3 and SF-36 survey was administered to the patients of the hospitals, which belong to the research group of Kanagawa enzyme replacement therapy. Participants were treated with agalsidase-alpha or agalsidase-beta. Disease activity was assessed by the Disease Severity Scoring System (DS3). The QoL was measured by Short form-36 (SF-36) and the Kidney Disease QoL. Short Form version 1.3 (KDQoL).

Results: Fifteen patients were included in the study. Mean age was 45 years (M/ F=10/5), and all patients were receiving ERT. The mean serum Cr was 2.9 mg/dl. The DS3 scores were follows; mean assessment score: 26.5 +/- 10.1, average domains: 10.5 +/- 9. The renal domain and the cardiac domain showed relatively high score compared to PNS and CNS scores. The QoL scores of the FD patients were lower than those of general population, but the scores were better than the previous reports of FD from U.S. or EU. The mental component summaries of women were similar to those of the general population. The physical component summaries of QoL were negatively associated with the age (r=-0.545, p<0.001).

Conclusions: Japanese patients with FD receiving ERT had a relatively good QoL beyond anticipation. DS3 score is useful for assessing disease severity, and may predict some components of QoL.

PUB556

Two Cases of Fabry Disease in Women with Proteinuria Diagnosed by Molecular Analysis of α-Galactosidase A Gene and Kidney Biopsy Jong Oh Yang, Eun-Young Lee. 1 Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea; 2 Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea.

Background: Fabry disease is a X-linked lysosomal storage disorder caused by deficiency of α-galactosidase A. This abnormality in enzyme results intracellular accumulation of globotriaosylceramide and leads to severe painful neuropathy with progressive renal, cardiovascular, and cerebrovascular dysfunction and early death. We report 52 and 55 year-old women with proteinuria and hematuria, which were proven to be due to Fabry disease.

Methods: A52 and 55 year-old women was admitted to the hospital due to proteinuria. They denied previous histories of hypertension, diabetes mellitus, pulmonary tuberculosis, and hepatitis. Their sister and cousin diagnosed fabry disease. Physical examination revealed nonspecific findings. On admission, blood pressure 110/60 mmHg, heart rate 64/min, respiratory rate 16/min, body temperature 36.5°C. Lungs were clear and heart was normal. The extremities showed no edema, cyanosis or skin rashs. The laboratory data showed the WBC 3650/mm², Hb 13.2 g/dL, Platelet 212,000/mm², BUN 10.2 mg/dl, serum creatinine 0.7 mg/dL. Urinalysis showed pH 5.0 SG 1.023 protein 2+ RBC 5-9/HPF WBC 5-9/HPF. 24-hour urine protein was 533 mg. Abdomen & Pelvic CT and echocardiography were normal. The serologic study was normal. The kidney biopsy showed expansion of mesangial matrix and glomerular hypertrophy. The cytoplasm of podocytes was vaculoated, which consisted of multiple, variable-sized, concentric electron-dense lamellated structures, by electron microscopy.

The DS3 Scores and Quality of Life in Japanese Patients with Fabry Disease Nobuhito Hiraga, Keisuke Yatsu, Sanae Saka, Gen Yasuda, Satoshi Umemura. 1 Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; 2 Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.

Appetite was average 14.46%±4.13% poor 9.7%±18.18%, anorexic 13.2%±7.4% in males and females. Income correlated with BMI (p<0.001), dietary protein (p<0.001) energy (p<0.001), and carbohydrate (p<0.001). Appetite correlated with creatinine (p<0.01), dietary energy, protein, carbohydrate, and fat (p<0.001). BMI correlated (p<0.001) with fat, carbohydrate, energy and creatinine clearance. Anova showed significant difference among baseline appetite groups in energy, protein, fat, carbohydrate, and creatinine clearance (p<0.001) and serum albumin (p<0.01) in severely malnourished (SGA 1-2, C) and creatinine clearance (p<0.038) between BMI groups. Based on income there was significant difference between groups in BMI (0.001), energy (p<0.019), protein (p=0.031), albumin (0.001).

Conclusions: With decline in renal function, appetite worsened and nutritional intake decreased. Energy intake was significantly deficient. 84% patients had reduced appetite and 69.2% had PEW. Low income is a risk factor for PEW in CKD.

PUB589
Study on Correlation Between Serum Creatinine, Cystatin-C, Uinary Albumin Creatinine Ratio and Body Composition Xuemei Li, Jie Ma.

Background: Based on an epidemiological study in Peking, China, to study the correlation between serum creatinine, Cystatin-C and urinary albumin creatinine ratio (ACR) and body composition.

Methods: Residues over the age of 35 of the Beijing Pingshu District by random sampling method. Laboratory test: taking morning ACR, blood samples were taken for blood routine, kidney function. Test body composition after emptying the bladder by using INBODY-720 machine.Use SPSS 17.0 software for data statistical analysis, count data were analysed by using multivariate linear regression .

Results: A total of 9283 people participated in the survey, which 4324 males, age 54.7±10.7 years, 4599 females, age 53.4±11.2 years. Male: 1) Human body cell mass (BCM) and ACR, Cystatin-C, no correlation, was positively correlated with height (B=0.43, P<0.01), and serum creatinine was that positive correlation (B=0.01, P<0.01). 2) Lean body mass (FFM) and ACR, serum creatinine, Cystatin-C, no correlation. 3) Skeletal muscle content and ACR, serum creatinine, Cystatin-C, no correlation. 4) Body fat mass and ACR, no correlation, and Cystatin-C was positively correlated with (B=0.79, P < 0.01). Female: 1) Human body cell mass (BCM) with height and cystatin-C, no correlation, but positively correlated with serum creatinine (B=0.035, P<0.01), and ACR was negative correlation (B=−0.005, P<0.05). 2) Lean body mass (FFM) and ACR, Cystatin-C, no correlation, and serum creatinine were positively related (B=0.035, P<0.01). 3) Skeletal muscle content and ACR, Cystatin-C, no correlation, and was positively correlated with height (B=0.031, P<0.01), and serum creatinine were positively related (B=0.035, P<0.01). 4) Body fat mass and ACR was negative correlation (B=−0.01, P<0.05). Cystatin-C were positively correlated (B=12.3, P<0.01), and age negatively correlated (B=0.13, P<0.01), and serum creatinine was negative correlation (B=−0.092, P<0.01).

Conclusions: There was a positive correlation between serum creatinine and the human body cell mass (BCM), lean body mass (FFM) in men, and skeletal muscle content, body fat weight in women, but the correlation is not strong. The blood cystatin-C and body fat weight was positively correlated.

PUB560
Worsening Nutritional Status Assessed Is an Independent Predictor of All-Cause Mortality in Incident Dialysis Patients Jong Hyun Jhee, Young Eun Kwon, Tae-Hyun Yoo, Shin-Wook Kang.

Department of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Malnutrition is closely associated with mortality in end-stage renal disease (ESRD) patients. However, little is known whether improvement or deterioration of nutritional status after dialysis initiation affects clinical outcome. This study was aimed to elucidate the association between the changes of subjective global assessment (SGA) after dialysis initiation and mortality in ESRD patients.

Methods: Data were collected from the Clinical Research Center for ESRD cohort. SGA score was measured by trained investigators at the time of dialysis initiation and after 12 months. Nutritional status was defined as well-nourished (SGA 6-7, A), mildly to moderately malnourished (SGA 3-5, B), or severely malnourished (SGA 1-2, C). Severely malnourished patients (SGA C) were excluded due to small sample size. The patients were divided into four groups according to the change of SGA: group 1, A to A; group 2, B to B; group 3, A to B; and, group 4, B to B.

Results: A total of 911 patients were enrolled. The mean age was 54.6±14.1 years, 554 patients (60.0%) were male. During a median follow-up duration of 30 months, 109 patients (12.0%) died. Survival rate of group 1 were the highest, and that of group 4 was the lowest (group 1, 1.77%; group 4, 7.41%; P<0.001). Worsening nutritional status was a significant risk factor for mortality (group 3 vs. 1, HR=3.15, CI=1.51-6.54, P=0.002), while baseline nutritional status at dialysis initiation was not (group 1 vs. 2, P=0.063; group 3 vs. 4, P=0.107).

Conclusions: Improvement of nutritional status after dialysis initiation could be beneficial for patient outcomes regardless of baseline status, suggesting that intervention to improve nutritional status after dialysis initiation might be a strategy to reduce mortality in ESRD patients.

Background: This study was performed to evaluate whether increasing hemoglobin before ascent by prophyactic erythropoietin injections prevents acute mountain sickness (AMS).

Methods: This open label, randomized, controlled trial involved 39 healthy volunteers with hemoglobin £15.5g/dl who were divided randomly into erythropoietin (n = 20; control (n = 19) groups. Epoetin alpha 10,000 IU injections were given weekly for four consecutive weeks. On day 1, and 7 days after the last injection (day 29), oxygen saturation (SatO2), and hemoglobin were measured. The subjects departed Seoul on day 30 and arrived at Annapurna base camp (ABC, 4,130 m) on day 34. AMS was diagnosed when headache and Lake Louise score (LLS) of ± 3 were present. Immediate descent criteria followed US Army recommendations.

Results: Two groups differ in hemoglobin levels on day 29 (15.4 ± 1.1 vs 14.2 ± 1.0 g/dl, P<0.001). At ABC, erythropoietin group had a significantly lower mean LLS, AMS incidence, and number of subjects who met immediate descent criteria. Multiple logistic regression analysis showed that SatO2<87% and control group, but no hemoglobin<15.0 g/dl, independently predicted satisfaction of immediate descent criteria.

Erythropoietin-related adverse effects were not observed. In conclusion, erythropoietin may be an effective prophylaxis for AMS.

PUB562
Nutritional Assessment for the Chronic Dialysis Patients with/witout Sarcopenia Miho Suzuki, Yuya Sakai, Ikuto Masakane. Tabuki Hospital.

Background: A recent arising problem of chronic dialysis patients is sarcopenia closely related to malnutrition. Muscle loss deteriorates daily activities of dialysis patients and ultimately worsens the QOL and prognosis of the patients. The aim of this study was to clarify the relationship between the nutritional status and sarcopenia and to analyze the status of nutrient intake in these patients.

Methods: 90 chronic hemodialysis patients were enrolled to the current study. (age 62.8yrs. Men were 76%, DM 41%).Skeletal muscle mass (SMM) was estimated by bioimpedence analysis and a low muscle mass was defined by the SMM index (SMI: SMM [kg]/ height [m]2 as < men: 7.0kg, women: 5.7kg).Muscle function was evaluated by grip strength and walking speed as the Timed up and go test (TUG).A low grip strength was defined as less than 26 kg (men) or 18 kg (women). TUG less than 11 second was diagnosed as a low walking speed.Malnutrition was defined as by the Malnutrition-Inflammation Score(MIS):<36point), GNRI(<92) and the criteria of protein energy wasting (PEW).The dietary assessment was performed by the food frequency questionnaire.

Results: Sarcopenia was identified in 22% of the subjects. The sensitivity to detect sarcopenia was not sufficient as 35% in MIS, 50% in GNRI and 10% in PEW. In the patients with sarcopenia, the average of total energy intake and protein was significantly lower than those in non-sarcopenia, 1618±122kcal vs 2041±165kcal in energy, 52±4g vs 68±2g in protein. The intake of fishes and meats (110±15g vs 153±8g),beans (313±11g vs 61±6g ),confectionery, beverages and sugar (126±77g vs 306±41g ) were significantly lower in sarcopenia than non-sarcopenia.

Conclusions: Malnutrition-related sarcopenia was only 10-50% among sarcopenia. It is important to measure muscle mass and muscle function regularly for dialysis patients because it is not enough to screen sarcopenia only by nutritional measurements. Sufficient protein and energy intake are essential for the prevention of sarcopenia. If patients don’t have appetite,confectionery or a beverage or sugar may be acceptable for the prevention of muscle loss.
Stomach Acid Reducers May Predict Nutritional Deficiency in Dialysis Patients

**Methods:** This is a cross sectional study of 103 patients undergoing chronic hemodialysis in Budapest, Hungary at a university hospital based dialysis unit. The patients’ nutritional indicators such as serum albumin, phosphorus, nPCR and whether they were on dialysis, chronic kidney disease (CKD) stage were evaluated. The study group included patients who did not take an acid reducing agent, such as a Proton Pump Inhibitor (PPI) or H2 blocker.

**Results:** Six patients were excluded because data were incomplete or the patients had not been on dialysis for more than 2 months. Of the 96 patients 44.9% took an acid reducer on a daily basis. The serum albumin (3.76±0.02 mg/dL vs. 3.56±0.01 mg/dL; p=0.008); phosphates (1.88±0.49 mmol/L vs. 1.64±0.54 mmol/L; p=0.04) and nPCR (1.00±0.20 vs. 0.91±0.25: p=0.06) were lower among PPI takers. PPI takers were much more likely to be taking cholecalciferol measured 25-OH-vitamin D deficiency (1.8% vs. 18.1% p=0.01). While PPI takers were older (59.7±16.2 years vs. 65.7±13.3 p=0.04), there was no difference in the two populations in the presence of a AV Fistula, delivered Kt/V, calcium or serum bicarbonate.

**Conclusions:** We conclude that taking PPI’s or H2 Blockers in dialysis patients may be an indicator of being at risk for malnutrition.

---

Impact of the Potassium Additives on the Total Content of This Element in Processed Foods

**Results:** Processed foods contained high potassium values than expected from the food label were, beverages 102.6 to 125.3; type of cream cheese 80.3 to 194.4; margarine 21.6 to 37.3; tomato powder 253.3 to 258.2; salad dressing 78.5 to 128.4; powdered juices 33 to 240.8. Processed food that had higher potassium values than expected included beef jerky, milk beverages, yogurt, a type of cream cheese, margarine, tomato sauce, salad dressing, powdered juices, and had potassium sorbate or others potassium salts. The concentration of potassium (mg K/100g of food) was determined by flame photometry according to the Adolfo Lutz Institute methodology, and in triplicate. The comparison of the potassium obtained with the expected potassium was based on two national reference tables.

**Conclusions:** Processed foods with potassium additives contain higher levels of potassium than those listed in reference tables.

---

Differences in Eating Patterns Between Maintenance Hemodialysis Patients from the U.S. and the UK

**Results:** Patients from the US consumed more energy on DD (24.9±2.1 vs. 18.5±1.1 kcal/kg/d; p=0.004) and HDD (24.5±1.5 vs. 20.5±1.2 kcal/kg/d; p=0.048) than US patients. Additionally, US patients had lower energy intake on DD than HDD (p=0.007), while there were no differences in UK patients. UK patients consumed more dairy products and breads, whereas US patients consumed more energy from beverages, entrees, and deli items.

**Conclusions:** HD patients from the US had lower energy intake on DD and HDD compared to UK patients. Furthermore, US patients had lower dietary intake on DD. This might be in part due to US clinics’ restrictive policy on eating during dialysis. Furthermore, there were differences in food pattern consumption and food insecurity. These differences may help explain global differences in nutritional status and outcomes. Further studies are needed to assess the contribution of eating patterns and socioeconomic status on clinical outcomes in HD patients.
Obese Donors: The Multidisciplinary Approach in Improving Outcomes
Giselle Guerra,1 Ian Thomas,1 Panagiotsis Tryphonopoulos,2 Linda J. Chen,2 Gaetano Ciancio.2 1Department of Medicine, Miami Transplant Inst, Miami, FL; 2Department of Surgery, Miami Transplant Inst, Miami, FL.

Background: Living donation appears safe over the years but concerns still exist long-term. Small analyses under similar nephrectomies have resulted in proteinuria and slight decrease in renal function (eGFR) if patient tended to be obese; thus raising a concern for accepting living kidney donors (LKD) with body mass index (BMI) greater than 30 but less than 35: Aim: determine the outcomes of obese LKD with BMI greater than 30 but less than 35.

Methods: A single center retrospective analysis was performed at transplant center during the period January 1, 2010 – November 30, 2014. LKD ages 18-65 were assessed: 1. Study Arm (SA): obese LKD with BMI>30 who were enrolled into a nutritional program; and 2. Control arm (CA): non-obese living donor candidates at the time of referral. Weight loss prior to surgery and afterwards, surgical complications, loss of kidney function (eGFR), and proteinuria (spot urine protein/spot urine creatinine ratio) after 6 months from donation were reviewed.

Results: Patient demographics - SA: 15African Americans (AA), 13 Hispanics (H), 7 White, 1 Other, 3 Unknown versus CA: 55 H; 49 Whites; 20 AA; 5 Other [figure1]. In the SA, 24/40 had BMI>35 at time of referral and placed in nutritional program; 8/24 dropped BMI to less than 35 prior to surgery and 3/24 pending surgery now; 4/24 ruled out due to medical issues & (8/24) were non-compliant. Surgical complications 1/8: Parasthesia. After donation in SA, blood pressure remained stable, 2/8 gained weight. Kidney function at 6 months: 47% of obese donors had a decrease in eGFR at 6 months of 40% or greater. The mean decrease in eGFR was 33.9% in the study arm. In the control arm: 55 Hispanics; 49 Whites; 20 AA; 5 Other. 15% had a decrease in eGFR at 6 months 40% or greater and the mean decrease in eGFR was 28.9.

Conclusions: Obesity among donors needs careful analysis especially in minority populations since there is a trend to have a greater loss in kidney function after donation. Donor nephrectomy is possible but strict nutritional and guidelines and medical evaluation need to persist for the wellness of these patients long-term.

PUB569
The Role of Renal Pharmacist in Prescribing Immunosuppressant Medication for Renal Transplant Patients to Improve Safety
Israr Vieira, Preetham Boddana. Pharmacy Dept, Gloucestershire Hospitals NHS Foundation Trust, Gloucester, Gloucestershire, United Kingdom.

Background: This paper describes the safe and efficient repatriation of renal immunosuppressant prescribing from General Practitioners (GPs) to secondary care using hospital Pharmacist Independent Prescribers (PIPs).

Methods: From March 2015 the UK commissioner NHS England required all renal immunosuppressant medication, which was traditionally prescribed by GPs following nephrologists’ advice, to be prescribed by hospital renal prescribers. Gloucestershire hospitals NHS Foundation Trust decided to use Pharmacist Independent Prescribers to implement this change and provide the ongoing service using commercial Homecare Companies. All Patients were initially sent detailed information about the changes and asked to consent. On receipt of the completed consent form the PIP wrote the initial homecare prescription which was then processed by the pharmacy homecare team. Patients continued to be reviewed at regular intervals by their nephrologists. Details of these consultations were documented using a central renal database which included graft function, drug levels and communication with GPs. The Pharmacist Prescribers subsequently reviewed the renal database prior to generating the homecare prescriptions and, when necessary, contacted the nephrologist for clarification and interventions.

Results: This service reconfiguration has resulted in safe and robust pathway. The use of Pharmacist Independent Prescribers has insured the whole pathway is efficient and closely monitored. Patients are satisfied with the new homecare service and clinicians value the pharmacists’ input. Pharmacist prescribers have made a number of interventions which have included patient compliance issues, changes to doses in response to serum drug levels and appropriate brand changes to improve cost effectiveness.

Conclusions: The use of Pharmacist Independent Prescribers to prescribe and manage the renal immunosuppressant homecare service at Gloucestershire Hospitals NHS Foundation Trust has been shown to be safe and efficient.

PUB570
Tools for Adverse Events Prevention in a Hemodialysis Facility: A Local Experience
Cinthia Sobral Vieira,1 Cassiana G. Prates.2 1Nephrology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil; 2Hospital Epidemiology and Manager Risks Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: After the publication “To err is human” there has been a new approach to prevent risks in health system. According to the International Patient Safety Goals there are six steps to be followed like patient identification, proper communication, right surgery in the right side, fall prevention, high alert medication and infection prevention. The goal is to show how a hemodialysis unit, for ambulatory and hospitalized patients leads with adverse event prevention.

Methods: This experience happens in a hemodialysis unit with 101 patients, 3 shifts of 4 hours. It is located in a general hospital in Porto Alegre, south Brazil.

PUB571
Zinc Deficiency Correction and Phosphaturia in Children with CKD – A Pilot Study
Vladimir Belostotsky,1 Stephanie A. Atkinson,2 Michelle N. Rasiah,3 Steven Arora,1 Ji Cheng,1 Joanne Grimmier,2 Guido Filler.1 1Pediatrics, McMaster Children’s Hospital, Hamilton, ON, Canada; 2Pediatrics, Children’s Hospital, London Health Sciences Centre, London, ON, Canada.

Background: There are no guidelines for correction of Zinc (Zn) deficiency in Chronic Kidney Disease (CKD). Experimental data (Morishita 2001) suggests that Zn modulates the phosphaturic effect of parathyroid hormone and can potentially increase phosphatase. Aim: To identify Zn deficiency and determine whether 3 months of oral Zn therapy normalizes Zn status in children with CKD. To assess feasibility of conducting a clinical trial similar to Morishita’s in mice and gather information on clinical outcomes and relationship between Zn status and correction of Zn deficiency and phosphatase (P) excretion.

Methods: 40 patients (pt) 4-18 yr with primary CKD and CKD due to declining graft function were enrolled from 2 tertiary pediatric nephrology centers. Plasma Zn was measured by High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry at baseline and at 3 months with routine blood and urine parameters. Pt with Zn<11.5 mmol/L were treated for 3 months with Zn citrate tablets (10mg Zn/day for 4-8 yr and 20 mg/day for 9-18 yr). Statistical analysis was done using nonparametric methods and relative risk ratio.

Results: Of 21 pt (M-13, F-8) with completed data, Zn deficiency was found in 10. Stages of CKD were: 2-11 pt, 3-5 pt, 4-5 pt. One pt was hyperphosphatemic. 2 Zn deficient pt had abdominal discomfort whilst taking Zn. Plasma Zn improved in 8 out of the 10 treatment pt (4.4 times more frequently than in control pt) after 3 months of Zn therapy. Zn therapy over 3 months did not change serum P (median 1.23 mmol/L to 1.25 mmol/L) or its fractional excretion (median 24.08% and 21.71%).

Conclusions: Zn deficiency occurred in about 50% of CKD pt. Preliminary analysis indicates that 3 months of oral Zn supplementation is likely beneficial in Zn deficient pt but a larger sample size is required to evaluate the impact of correction of Zn deficiency on other metabolic parameters. Correction of Zn deficiency does not alter P excretion in pt with normal blood P. Similar studies are feasible to perform in hyperphosphatemic pt.

PUB572
Proteinuria as a Marker of Severe Unilateral Ureteral Obstruction in Infants
Mariselas Rosa-Sanchez, Janetly Chandar, Wacharee Seehurungvon, Chryso P. Katsoufis, George N. Sfakianakis, Rafael Gosalbez, Andrew Labbie, Guido Filler.1 Peds, Pediatrics, Pediatric Urology, Holtz Children’s Hospital/Univ of Miami, Miami, FL.

Background: Unilateral ureteral obstruction (UUO) is a common congenital anomaly in infants. Controversies remain regarding clinical indications for timely surgery. The objective was to compare the radiologic and laboratory parameters of a cohort presenting with significant unilateral hydronephrosis that were managed either conservatively or surgically.

Methods: This retrospective analysis included 81 infants during a 10 year period with high grade hydronephrosis designated by renal ultrasound. Further assessment included renal function by nuclear scintigraphy and proteinuria. Proteinuria was determined by random urine total protein to creatinine ratio (U/pr) and albuminuria by random urine albumin to creatinine ratio (U/alb). Receiver operator characteristic (ROC) area under the curve (AUC) statistics were applied to U/pr and U/alb cr ratios with determination of likelihood ratios (LR) for requiring surgery.

Results: In this cohort, 22/81 (27%) were operated, including 21 pyeloplasties and 1 nephrectomy for severe UUO. Initial proteinuria was significantly greater in UUO patients who underwent surgery compared to those without surgery (p=0.02). ROC-AUC demonstrated that both U/pr and U/alb cr predicted the presence of severe UUO requiring surgery (U/pr: AUC=0.71; p=0.01 and U/alb cr: AUC=0.75; p=0.02). U/pr and U/alb cr was similar in normal control infants and those with non-surgical UUO.
Conclusions: Proteinuria and albuminuria were significantly elevated in UUO infants who required surgery compared to normal term infants and those with non-surgical UUO. Although both were sensitive markers of renal injury, albuminuria was superior in predicting who required surgery compared to normal term infants and those with non-surgical UUO.

PUB574
Familial Lecithin-Cholesterol Acetyltansferase Deficiency Masquerading as Membranous Nephropathy in Childhood

Anita R. B. Koziell, Katrina Soderquest. Experimental Immunobiology, King’s College London, London, United Kingdom.

Background: Familial Lecithin-cholesterol acetyltransferase (LCAT) deficiency is a rare autosomal recessive disorder of lipid metabolism characterised by severely reduced HDL concentrations and impaired esterification of cholesterol. It is characterised clinically by glomerulopathy and mild haemolytic anaemia presenting in adulthood leading to ESRD by the fourth decade of life through the deposition of abnormal lipoproteins in the renal stroma. Paediatric cases are rarely described.

Methods: 2 siblings aged 8 and 11 years presented with asymptomatic non-nephrotic range proteinuria detected on routine testing. There was no family history of renal disease, although parents were consanguineous. Initial screens revealed normal renal function and normal serum albumin. Other investigations demonstrated raised lipid profiles but in keeping with nephrotic syndrome. A renal biopsy was performed in view of escalating protein and albumin creatinine ratios.

Results: Renal biopsy initially demonstrated light microscopic features of membranous nephropathy. However, electron microscopy demonstrated inclusions that were not typical of the adult form of the disease but clearly lipid filled (Figure 1). Confirmation of the diagnosis was by demonstration of significantly reduced HDL-cholesterol, and detection of a novel LCAT gene missense mutation G54V as well as reduced LCAT enzyme activity on assay.

Conclusions: LCAT deficiency may present with mild symptomatic proteinuria in childhood. Although rare, it should be considered in a differential in paediatric membranous nephropathy. However, electron microscopy demonstrated inclusions that were not typical of the adult form of the disease but clearly lipid filled (Figure 1). Confirmation of the diagnosis was by demonstration of significantly reduced HDL-cholesterol, and detection of a novel LCAT gene missense mutation G54V as well as reduced LCAT enzyme activity on assay.

Insulin-Like Growth Factor/Growth Hormone and Insulin-Like Growth Factor Binding Proteins in Normal Height and Short Children with CKD

Methods: 232 children in CKD (206 normal height: 26 short stature; none on GH therapy) were matched by gender, age and GFR. Short stature = Height Standard Deviation Score (SDS) < -1.88. GH, IGF-1, and IGFBP-1 and 3 were determined by chemiluminometer and ELISA.

Results: Normal height CKD children had higher serum IGF-1/GH, higher IGF-1/IGF-1 BP1 and similar IGF-1/IGF-1 BP3 compared to short CKD children.

Conclusions: Differences in IGF-1, IGF-1/GH, and IGF-1/IGFBP-1 may explain some variance in growth in CKD children. Height is more highly correlated to IGF-1 in normal height than short children. Analyses in paired subjects may provide further evidence to explain and/or predict growth in children with CKD.

PUB579

Acute Lymphoctic Leukemia with Bilateral Renal Masses Masquerading as Nephroblastomatosis

Background: While leukemia has a wide spectrum of presenting features, renal involvement in the presentation of disease is relatively rare. We report a case of acute lymphocytic leukemia (ALL) with bilateral renal masses that presented as nephroblastomatosis.

Methods: A 4 year old boy was presented with low grade fever and abdominal pain for few days. A complete blood count (CBC) and abdominal CT scan were done to rule out appendicitis. WBC of 8.1 K/UL, hemoglobin of 13.3 g/dL, Platelets of 170 K/UL, neutrophils 22%. Lymphocytes of 68.9% and absolute neutrophil count of 1.8 K/UL. CT scan showed bilateral renal enlargement with multiple hypodense lesions in the corticomedullary regions. Blood urea nitrogen of 7 mg/dL and creatinine of 0.38 mg/dL. The patient was diagnosed with viral gastritis and sent home on supportive treatment. CT scan was later interpreted as nephroblastomatosis by pediatric radiologist as an incidental finding advised follow up with the pediatric nephrologist. After 14 days he again had low grade fever with abdominal pain. CBC showed WBC of 3.5 K/UL, hemoglobin of 11.1 g/dL, platelets count of 21 K/UL, neutrophils 6% and lymphocyte 85% Absolute neutrophil count was 351 and ESR of 71 mm/hr. The pediatric oncology service was consulted for possible malignancy. Peripheral blood smear showed the presence of abundant immature lymphoid cells representing 90% of the total white cells. Bone marrow aspirate and biopsy, flow cytometry and cytogenetic studies showed early B cell leukemia. Treatment was initiated following the guidelines of COG AALL1092. After one week of induction therapy, the CT scan showed a complete interval resolution of all renal hypodense lesions.

Conclusions: Renal involvement in leukemia is challenging to diagnose due to its variable presentation on imaging. On CT scan, it may present as enlargement of kidneys (unilateral or bilateral), or a low-attenuation focal parenchymal. These focal lesions can be difficult to distinguish from nephroblastomatosis which has a similar radiological picture on CT scan.

PUB577

Assessment of Cochlear Sensitivity of the Pediatric Chronic Kidney Disease and Hemodialysis Patients

Conclusions: UAH links an adverse and/or competitive intrauterine environment with nephrogenesis independent of GA. An enhanced umbilical artery muscle area reflects an increased renal mass while increased vascular collagen parallels decreased renal mass in discordant twins and singletons of PE mothers.

Funding: Private Foundation Support

PUB578

Percutaneous Renal Biopsy at OPD Level

Background: Renal biopsy is a prerequisite procedure for the final diagnosis and to evaluate the treatment effect or to determine the prognosis, however due to serious complication of the procedure, should be done by nephrologist and has been performed at admission state.

Methods: Our center performed percutaneous renal biopsy 3,000 cases without major complications during last 30 years, when patients were admitted for 3 days. During last 18 months, we performed percutaneous renal biopsy at OPD level under the ultrasound guide (LOGIQ E9).

Results: The youngest one is 1 year old male and the oldest was 64 years old. Mean age was 26 years old. Male to female ratio was 3:2. Mean glomerular numbers were 31. We used disposable kidney biopsy needle (TSK ASECUT). We checked ultrasound 3 times after renal biopsy for checking AV fistula, hematoma formation during 6 hours hospital stay. Of the 100 case 8 cases received follow up biopsies. Among 100 samples renal medulla was not detected. Two patients(2%) among 100 biopsies showed small(less than 1cm) hematomas. No AV fistula were detected. All patients went home 6 hours after renal biopsy without any problems. Renal biopsy results showed IgAN(23%), Non_specific GN(21%), Diffuse mesangial proliferative GN(17%),JSSP(6.7%),MGN(5.6%),FSGS(5.6%).Others were Alport,Lupus nephritis,DM nephropathy,MPGN type I,Thin GBM nephropathy.

Conclusions: In conclusion, percutaneous renal biopsy under the ultra-guide sound at OPD level with 6 hour ABR is safe and effective if performed at renal cortex level.
Malodity of Treatment of Pediatric Patients with Diarrheal HUS in Acute Renal Failure Does Not Affect Long Term Outcome and Survival

Sonia Solomon, Julia W. Tzeng. Pediatrics, Valley Children’s Hospital, Madera, CA; Pediatrics, Univ of California, San Francisco - Fresno, Fresno, CA.

Background: Diarrheal HUS is a disease process usually resulting from infection by E. coli H7:0157 and leading to the development of microangiopathic hemolytic anemia, thrombocytopenia, and acute renal failure. Acute renal failure typically follows in five days from presentation, with resolution of the majority of the renal replacement therapy (RRT) in the first week. Long-term studies have demonstrated that these patients are at risk for long-term renal insufficiency and end-stage renal disease. Indications to start dialysis and the mode of dialysis vary from institution to institution. There is no current study comparing which mode of dialysis, hemodialysis or peritoneal dialysis, has better benefit and less complications. The aim of this study is to compare dialysis modalities and determine whether one modality will result in less complications and better outcomes.

Methods: This is single center, retrospective review. We studied a total of 102 patients from January 2010 to 2014. We compared the number of complications and the types of complications from each modality. Long-term outcomes were measured by each patient’s CKD staging at least one year after diagnosis. EGFR was calculated using the Schwartz formula. Fisher’s exact statistical test was used to assess statistical significance.

Results: No statistical significance was found between the mode of dialysis and associated complications (p>0.4). There was also no statistical significance between kidney and long term outcome (p>0.9). Complications of PD were catheter malfunction (p=0.6), peritonitis (p=0.5), and the need to switch to HD or CVVHDF (p=0.3). Complications of HD included central line infections (p=1).

Conclusions: PD and HD are equally effective in treating patients with diHUS in renal failure and have comparable long term outcome and risks for complications. An important complication to consider for patients on PD is the potential need to switch to HD or CVVHFH; this exposes the patient to an additional surgical procedure that may result in further complications.

Self-Reported Health Care Transition Readiness Among Mexican Adolescents with Chronic or End-Stage Kidney Disease

Guillermo Cantu,1 Ana Catalina Alvarez-Elias,1 Saul Valverde,2 Maria E. Ferris,3 Mara Medeiros.2 1Univ Panamericana, Mexico, DF, Mexico; 2Univ of North Carolina at Chapel Hill, NC; 3Hospital Infantil de Mexico Federico Gomez, Mexico, DF, Mexico.

Background: 90% of pediatric patients with chronic disease live more than 20 years after being diagnosed. When pediatric patients are transferred to adult-focused health services, generally they do not have the skills and abilities to manage their disease. Adolescents tend to have poor adherence to treatment, and there is a period when there may be complications and increased morbidity-mortality. Performance on self-reported health care transition readiness (HCTR) needs to be assessed in patients with chronic or end-stage kidney disease. The aim of the study was to measure self-reported HCTR using the STARs (Self-management and Transition to Adulthood with Rx=Transition) Questionnaires, among adolescents in the Nephrology Service at Hospital Infantil de Mexico Federico Gomez. The Spanish version of the STAR, Questionnaire was translated and back translated for validity. The tool evaluates adolescents with chronic or end-stage kidney disease in the outpatient nephrology department over a 9-month period. The 18-question tool diagnoses difficulties in the transition, and end-stage kidney disease differs by sex and treatment modality.

Methods: The Spanish version of the STAR, Questionnaire was translated and back translated for validity. The tool evaluates adolescents with chronic or end-stage kidney disease. The aim of the study was to measure self-reported HCTR using the STARs (Self-management and Transition to Adulthood with Rx=Transition) Questionnaires, among adolescents in the Nephrology Service at Hospital Infantil de Mexico Federico Gomez.

Results: We enrolled 68 adolescents (53% males) who had a mean age of 15.75 years (± 1.87). Patients who received hemodialysis in the past 22 (34%). Females had significantly greater scores than males in the “action” category. Those who received hemodialysis in the past had greater knowledge about the disease (p=0.013).

Conclusions: The self-reported HCTR among Mexican adolescents with chronic or end-stage kidney disease differs by sex and treatment modality.

Funding: Government Support - Non-U.S.
A retrospective database study on the real-world effectiveness of sucroferric oxyhydroxide (SO) use among peritoneal dialysis (PD) patients (pts) who self-selected as Black or African American (AA).

**Methods:** A retrospective database analysis was conducted on a cohort of AA PD pts who were prescribed SO as part of standard care at FMCNA clinics. Pts had 1 serum phosphorus (sPhos) measured while using SO and had been on sevelamer, calcium-based phosphate binders or had no phosphate binder specified prior to SO treatment. Differences in sPhos, pill burden (PB), serum calcium (Ca), ferritin, transferrin saturation (TSAT), and intact parathyroid hormone (iPTH) were noted between baseline (BL; 3 months prior to SO) and follow-up (SO-TX; 3 months during SO).

**Results:** 117 AA PD pts (mean age=50 years, dialysis vintage=4.2 years) were included. At BL, 37% were on sevelamer, 31% on calcium-based phosphate binders, 2% on dual phosphate binders or had no phosphate binder specified. Figure shows increase in pts who have in-range sPhos (20% to 31.6%, 58% increase). Mean sPhos dropped from 6.55-6.38 mg/dl (p=0.06). A significant decrease in PB was observed (4.5 pills/day; p<0.001) between BL (8.8 pills) and SO-TX (4.3 pills). No significant differences were observed between BL and SO-TX for sCa (BL=9.1 mg/dl, SO-TX=9.1 mg/dl), ferritin (BL=861.9 ng/ml, SO-TX=870 ng/ml), TSATs (BL=34.7%, SO-TX=36.8%) and iPTH (BL=729.5 pg/ml, SO-TX=696.4 pg/ml).

**Conclusions:** In a cohort of African American peritoneal dialysis patients who were prescribed sucroferric oxyhydroxide as part of routine clinical care, there was a 58% increase in the number of patients with serum phosphorus levels in-range (p<0.006). Furthermore, there was a significant reduction in pill burden (4.5 fewer pills, p<0.001).

**Peritoneal Dialysis Patients Who Switch Phosphate Binders from Sevelamer to Sucroferric Oxyhydroxide As Part of Routine Clinical Practice: A Retrospective Database Study**

**Background:** A retrospective database study on the real-world effectiveness of sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), in a cohort of adult peritoneal dialysis (PD) patients (pts) was conducted. This analysis examines PD pts from that cohort who switched from sevelamer (SEV) to SO (n=183).

**Methods:** All pts were prescribed SO as part of routine clinical practice at FMCNA clinics. Pts eligible for analysis had 1 serum phosphorus (sPhos) during SO and the most recent PB used during the 3 months before SO was SEV. Changes in sPhos, serum calcium (Ca), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed 3-months before starting SO (baseline) and 3-months during SO treatment (follow-up).

**Results:** Pts (n=183) were, on average, 53 years old with a dialysis vintage of 3.9 years. Pts with in-range sPhos increased from 14.8% to 25.7% (74% increase). There was a significant reduction in sPhos (6.8 to 6.5 mg/dl; p=0.005), sCa (9.2 to 9.1 mg/dl; p=0.02), and PB pills per day were assessed 3-months before starting SO (baseline) and 3-months during SO treatment (follow-up).

**Conclusions:** Our single-center experience demonstrated similar PD catheter survival rate and a better 2-year survival for catheters placed by peritoneoscopy. Our predominant use of the curvy PD catheters suggests no significant difference in outcome compared to the straight catheters.

**Peritoneal Dialysis for Management of Refractory Heart Failure**

**Background:** Refractory heart failure (RHF) is associated with significant morbidity and mortality. There is growing interest in the use of peritoneal dialysis (PD) for management of patients with RHF. In this study, we explored the currently available data on the safety and efficacy of PD in this setting.

**Methods:** A search of PubMed database using key words “peritoneal dialysis” and “‘heart failure’” from 1985 to 2015 was performed by two of the authors independently and found 763 articles, from which those including at least 20 patients who had initiated PD for cardiac indication were selected. Relevant data on efficacy and safety such as changes in the quality of life and cardiac function as well as the rate of hospitalization were extracted and compared.

**Results:** Seven studies (4 prospective and 3 retrospective) met the inclusion criteria with a total of 398 patients and a mean age of 70.4 years. PD was associated with improvement in functional status (1 to 2 NYHA class reductions) in 5 of the 7 studies (not reported in 2) as well as an increase in the ejection fraction in 6 studies. A variety of PD regimens were used that in general showed efficacy in removal of fluid as suggested by notable reduction in patients’ weight in 6 studies by up to 8.3 kg (unavailable in 1). It was also shown to significantly reduce the number of days of hospitalization for acute HF in 6 studies by up to 90%. Five studies reported increase in responsiveness to diuretics as well as perceived improvement in the quality of life. The PD-related complications were found to be minimal in 6 studies while one reported 0.75 episode/patient/year of peritonitis.

**Conclusions:** Currently available evidence suggests that PD is an efficacious option for management of patients with RHF that can result in significant improvement in their functional status, hospitalization rate, and the quality of life. Based on the findings of these studies PD is safe in this population and its related morbidity does not replace HF-
associated morbidity. Larger controlled trials are warranted to explore the potential impact of PD on the mortality of patients with RHF and to define those subgroups most likely to benefit from this therapy.

PUB888

Procalcitonin, Is It a Useful Biomarker for Peritoneal Dialysis Peritonitis? Shinshan Song, Hyeyeon-Chool Park, Jae Seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.

Background: Peritonitis is a common complication in peritoneal dialysis (PD). Procalcitonin is a peptide hormone which has been used as a biomarker for the diagnosis of bacterial infection. We aimed to investigate the usefulness of procalcitonin in the patients with PD peritonitis.

Methods: This study included 33 episodes of peritonitis in 27 patients for follow-up period of 450 days. In addition, we collected samples of PD effluents from 7 PD patients without peritonitis to compare with those of peritonitis. We investigated clinical characteristics, serum and PD effluent levels of procalcitonin at the time of initial visit and discharge.

Results: The mean value of dialysis vintage of patients with peritonitis was 1774 days, incidence of total peritonitis for period of PD maintenance: 4.3 times, interval from symptom onset to visit: 13.6 hours, duration of intraperitoneal antibiotic treatment: 8.2 days, and interval from clinical improvement to recurrence: 80.7 days. Initial serum procalcitonin increased to 0.97 ± 3.67 ng/mL (mean ± standard deviation) compared with reference values (healthy <0.05, PD patients <0.50 ng/mL), and PD effluent procalcitonin also increased compared with the subjects without peritonitis, but not significantly (0.07 ± 0.19 vs. 0.01 ± 0.01 ng/mL, p=0.505). The serum procalcitonin decreased to 0.33 ± 0.54 ng/mL with clinical improvement but not significantly (p=0.308), and the PD effluent procalcitonin also showed the decreased level of 0.03 ± 0.08 ng/mL, but not the statistical significance (p=0.360). Pearson’s correlation analysis showed that the serum and PD effluent procalcitonin did not have relationships with existing inflammatory markers such as ESR, CRP. Lastly, procalcitonin could not predict recurrence and mortality of peritonitis.

Conclusions: Collectively, procalcitonin showed the tendencies corresponding to the clinical course of PD peritonitis, but not statistical significance. We believe that procalcitonin is not superior biomarker in PD peritonitis compared with other existing markers.

PUB889

Epidemiological Survey of Maintenance Peritoneal Dialysis in China Xiang-Mei Chen, Xueying Cao, Delong Zhao, Guangyan Cai. Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.

Background: To analysis epidemiology and trend of peritoneal dialysis during 2011 - 2014 in China.

Methods: Patient-reported outcome data from the peritoneal dialysis centers were collected online during the study.

Results: (1)By the end of 2014, there were 55373 cases of maintenance peritoneal dialysis patients in China, had increased by 17% per year over this time period. The annual incidence rate was 5.81/100 million people. The prevalence was 34.3/100 million. (2)The average age was 53 years. Male to female ratio was 1.2:1. The average age at initiation of dialysis was about 30 years old. The average residual renal function was 3ml/min. The average dialysis time was 2 years. The primary causes were primary glomerular disease 54%, diabetic nephropathy 16%, hypertensive renal damage 14%. (3)In 2014, DOR fell to 6.6%. TOT was 27.2 months. The death patients accounted for about 51.3% of exit patients. The average death age was 64.8 years. The average therapy time was more than 28.6 months. The cause of death was the cardiovascular and cerebrovascular events (4) Peritoneal dialysis access was the two cufis, no gooseneck, straight. 78% patients were the continuous ambulatory peritoneal dialysis patients. The therapeutic dose was 6L to 8L. High peritoneal transport type was the largest. (5)PD patients with hemoglobin 100g/L ratio was raised every year. The albumin level in plasma was greater than or equal to 35g/L in peritoneal dialysis (PD) patients. We studied the effects of chlorhexidine-impregnated patches (Biopatch), which are used as central-line dressings or drain site dressings, on PD catheter exit site infection and tunnel infections.

Conclusions: In a cohort of PD patients who switch from calcium-based binders to sucoraf er oxyhydroxide as part of routine clinical practice, there was a 78% increase in patients achieving in-range serum phosphorus (p=0.003). Additionally, phosphate binder pill burden was lessened from 7.4 to 3.6 pills per day (3.7 fewer pills, p=0.001).

PUB890

Peritoneal Dialysis Patients Who Switch from Calcium-Based Binders to Sucroferric Oxyhydroxide as Part of Routine Clinical Practice: A Retrospective Database Study Linda H. Fioceciello, Vidhya Parameswaran, Phaneth Keo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. Fresenius Medical Care North America (FMCNA), Waltham, MA.

Background: A retrospective database study on the real-world effectiveness of sucorfer oxyhydroxide (SO), an iron-based phosphate binder (PB), was conducted in a cohort of adult peritoneal dialysis (PD) patients. This analysis examines pts who switched from a calcium-based phosphate binder (CaPB); either calcium acetate (n=95) or calcium carbonate (n=35) to SO.

Methods: All pts were prescribed SO as part of routine clinical practice at FMCNA clinics, had 1 serum phosphorus (sPhos) measured during SO, and the most recent PB used was a CaPB. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), % transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed 3-months before starting SO baseline and 3-months during SO treatment (follow-up).

Results: Pts who had in-range sPhos increased from 12.5% to 22.3% (78% increase) between baseline and follow-up (Figure). There were significant reductions in sPhos (7.1 to 6.8 mg/dL, p=0.004) and PB pills per day (7.4 to 3.6 pills, p<0.001). Minimal change in sCa (8.9 to 8.95 mg/dL, p=0.5) and iPTH (519.2 to 544.4 mg/mL, p=0.4) was observed. There was significant change in FER (708.5 to 788.5 mg/mL, p=0.008, but not TSAT (35.8 to 35.5%, p=0.8) when pts treated with IV iron were included. There was minimal increase in FER (733.6 to 735.0 mg/mL, p=0.98) or TSAT (38.0 to 39.1%, p=0.61) in pts not administered IV iron (n=45).

Serum phosphorus during baseline compared to sucorfer oxyhydroxide[SO]-treated follow-up for patients who switched from calcium-based binders to SO (N=130)

Conclusions: In a cohort of PD patients who switch from calcium-based binders to sucorfer oxyhydroxide as part of routine clinical practice, there was a 78% increase in patients achieving in-range serum phosphorus (p=0.003). Additionally, phosphate binder pill burden was lessened from 7.4 to 3.6 pills per day (3.7 fewer pills, p=0.001).

PUB891

Effects of Chlorhexidine-Impregnated Patches on Catheter Exit Site and Tunnel Infections in Peritoneal Dialysis Patients Chiiki Kawabata, General Internal Medicine, Japanese Red Cross Kaminomoto Hospital, Kaminomoto, Japan.

Background: Exit-site infections and tunnel infections are major causes of catheter loss in peritoneal dialysis (PD) patients. We studied the effects of chlorhexidine-impregnated patches (Biopatch), which are used as central-line dressings or drain site dressings, on PD catheter exit site infection and tunnel infections.

Methods: A retrospective review was conducted of 45 patients whose PD catheter exit site was made between January 2007 and December 2014. We compared acute exit site infections, chronic exit site infections, and tunnel infections of the two groups, (the Biopatch Group and the Non-Biopatch Group), 6 months after the exit site was created.

Results: The Biopatch was used until the exit site had healed perfectly. The mean time of using the Biopatch was 63±26 days. The two groups had no significant differences in age (49.6±12.0 years vs 52.3±16.3 years), diabetes mellitus co-morbidity or pattern of peritoneal dialysis. There were no statistical differences in acute exit site infections [15.4% vs 6.1% (p=0.27)]. chronic exit site infections [0% vs 9.1% (p=0.28)] or tunnel infections [15.4% vs 15.2% (p=0.901)] during the 6 months. A cohort Using the Biopatch until the exit site has healed perfectly does not reduce either exit site infections or tunnel infections.

When to Remove the Peritoneal Dialysis (PD) Catheter After Renal Transplantation? (RT) 

Results: 108 patients transplanted from PD, 32 women/76 men with a mean age at the time of transplantation 58.0±13.3 years were analyzed. Two patients received RT due to a tunnel infection by Staphylococcus aureus or Pseudomonas aeruginosa. The withdrawal was delayed in 91 patients (84%) and 8 has not yet been removed. The average withdrawal time was 4.1±2.7 months. The indication of withdrawal was: stable renal function in 85 (93%), stable pancreatic and renal function in 4 and exit site infection in 2 (2%). Mean survival at the time of withdrawal was 2.1 months and 4.1 months for catheters were removed surgically under local anesthesia. The mean duration of hospitalization was 2.1±0.8 days (0-12). Four patients (3.7%) had complications during withdrawal (one hemotoma, two hemorrhagic shock and one surgical wound infection). 18% patients shared complications before withdrawal: 13 exit site infection, one peritonitis associated with urinary fistula and one spontaneous peritonitis.

Conclusions: In our experience the removal of the peritoneal catheter may be delayed until renal graft function were stabilize since the rate of complication is low compared with another studies.

When to Remove the Peritoneal Dialysis Catheter (PD) Catheter After Renal Transplantation? (RT) 

Saul Enrique Fontan, 1 Estefania Yerovi, 1 Nuria Rodriguez mendiola, 1 Sara Jimenez alvaro, 1 Cristina Galeano, 1 Fernando Liano. 1 Nephrology, Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Urology, Hospital Universitario Ramon y Cajal, Madrid, Spain.

Background: There seems to be consensus that the time of removal of the peritoneal catheter after RT may be delayed until renal function and the patient is stabilized, but there are few publications about.

Methods: We analyzed retrospectively patients on peritoneal Dialysis Unit (PD) who have received a RT between May 1995 and March 2015 gathering medical history data relating to the peritoneal catheter removal and complications.
Conclusions: The combination of serum albumin, hs-CRP, and BMI at the time of PD commencement was a significant independent risk factor for the composite outcome of all-cause death and unplanned hospitalization in incident PD patients. 

Funding: Government Support - Non-U.S.

PUB597

Background: Learning proper device use and clinical concepts of care must be internalized by patients to successfully perform PD at home. With increasingly diverse patients going on PD and increasing adoption of urgent start PD, there is a need for simpler techniques. Enhancing the user educational environment with methods including visual, graphical and voice will improve the educational experience leaving the patient with better understanding of the procedure.

Methods: Automated PD training was undertaken at a university based home dialysis program using a novel APD device (AMIA). 5 patients were trained on the device in a 1:1 nurse to patient ratio. The cyclers provided on screen instructions using a touch screen interface with voice guidance, text instructions and animation. Each patient was trained according to standardized outlines and sequential training progression from CAPD to APD techniques. Training included RN demonstration followed by patient direct interaction with the device. Instruction was displayed on a touch screen.

Results: Patient training completion required consistency of error free setup.

5 patients aged 30-68 yrs (mean 47), 80% female with a minimum of HS education completed training. Device training ranged from 2-3 days for urgent start patients and 4-5 days for routine start patients.

Conclusions: From our experience, training times were similar or reduced using the AMIA cycler and allowed the ability to efficiently train urgent start patients. Observed advantages of the new cycler included: 1) less need for memorization 2) distinction of a beginner vs advanced mode 3) online alarm troubleshooting 4) presence of an air detector in the device. Instruction was displayed on a touch screen.

PUB598

Peritoneal Dialysis-Related Peritonitis in a Single Center: 10 Years Experience Patricia O. Costa, Carla M V Melo, Jardordon P. Oliveira, Flavia A. Nobrega, Jandson P. Oliveira, Kleyton Andrade Bastos. Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.

Background: Peritonitis remains as the main Peritoneal Dialysis (PD)-related complication. It is estimated that it contributes directly to 20% of dropout and is related to 16% of all deaths. This study proposes to evaluate episodes of PD-related peritonitis and describe its incidence, causative organisms and possible predictors in patients belonging to a DP program from a reference center in Aracaju-Sergipe-Brazil.

Methods: Retrospective cohort study that evaluated 565 patients who stayed for at least 30 days in the technique, between 01/01/2003 and 12/31/2012, with a mean age of 54 ± 19 years, 55% male, 62% less than 8 years of regular study and 88% with monthly income less than 5 national minimum wages. They remained in DP by an average of 713.5 days. Among the 565 patients, 348 had at least an episode of peritonitis, resulting in 494 episodes of peritonitis, with an incidence of 8.7 episodes/100 patient-months.

Body Composition and Cardiovascular Outcomes Using Continuous Automated Peritoneal Dialysis – A Prospective Cohort Study Carlos Alberto Garza, Gabriela Leal, Bernard Moguel. Dept of Nephrology, National Inst of Cardiology, Mexico City, Federal District, Mexico.

Background: Fluid overload (FO) due to compliance in Continuous Ambulatory Peritoneal Dialysis (CAPD) is common. Efforts to achieve dry weight and avoid cardiovascular outcomes (CO) are lessen from inaccurate body composition (BC) estimations despite best clinical assessment.

Methods: We’ll follow BC, multiple frequency bioelectrical impedance (InBody S10, InBody Co), standard laboratories and CO, in all new patients to continuous Automated Peritoneal Dialysis (APD) previously in a CAPD. Measurements at baseline (CAPD), 1 month and every visit to the dialysis clinic thereafter (APD) for a 5 year period.

Results: These are the first data of BODY cohort study. Initial 10 subjects are described, 4 men and 6 women, median age 27 years (17-46), height 159.5cm(146-166), baseline and first follow up variables are in Table 1. Wilcoxon rank test for related samples was performed. We found that PD modality switch to APD, at 1 month, reflected a body composition transition with statistical significance (P<0.05), within the EBW/TBW ratio at expense of trunk compartment. Most likely from improved dialysis adherence

**"not statistically significant**
Conclusions: We consider that APD, on the ground of increased, uninterrupted and rigorously performed therapy, is an appropriate and effective treatment to optimize FO and aim for dry weight in PD. Further recruitment of patients and follow up of the BODY Cohort study is expected to confirm this hypothesis.

PREVENTION OF PD GROWTH USING MODIFIED PET

PB601

The Changes in Bicarbonate Level and Ionized Ca/Corrected Ca Ratio of Patients Receiving Peritoneal Dialysis Using Bicarbonate/Lactate-Buffered Solution Emi Kimoto, Nanae Matsuo, Masamitsu Morishita, Mami Nakamura, Yukio Maruyama, Yuayuki Nakada, Masatsugu Nakao, Yudo Tanno, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yokoi. Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Recently, PD solution which contains 25mEq/L bicarbonate and 10mEq/L lactate (Bicarbonate/Lactate-buffered peritoneal dialysis solution; B/L solution) is developed in Japan. Because of high concentration of lactate (40mEq/L) of conventional peritoneal dialysis (PD) solution, patients have generally higher serum bicarbonate level than those of patients receiving hemodialysis (HD). The new B/L solution is expected not only its biocompatibility but also improving excess correction of acids. Under the metabolic alkalosis environment, we reported that PD patients have lower levels of ionized Ca (iCa) at the same corrected Ca (cCa) levels. Thus, we hypothesized that iCa / cCa ratio increased after switching PD solution from Lactate-buffered to B/L solution.

Methods: We recruited 28 patients (55 ± 13 years, male 82%, PD duration 42 ± 21 months) who switched from Lactate-buffered to B/L solution, and investigated changes in serum bicarbonate, iCa, and cCa levels.

Results: After switching solution, serum bicarbonate decreased (26.7 ± 3.2 vs 24.8 ± 2.5, P<0.01), and cCa did not change (9.3 ± 0.5 vs 9.3 ± 0.5, P=0.63). Neither iCa nor iCa/cCa ratio increased significantly (1.12 ± 0.09 vs 1.11 ± 0.09, P=0.48; 0.12 ± 0.007 vs 0.119 ± 0.006, P=0.54, respectively).

Conclusions: Conversion to B/L solution from lactate solution was associated with lower serum bicarbonate. Unfortunately, iCa did not change. Further investigations are needed to confirm the utility of the monitoring of iCa for the management of chronic kidney disease - mineral and bone disorder (CKD-MBD) in PD patients.

Road to Success: One Academic Medical Center’s Experience Building a Peritoneal Dialysis Clinic Yazar M. Ali, William A. Schlueter, Erwin E. Morales, Maria A. Gavino, Shubhada N. Ahya, Robin E. Watson. Nephrology, Northwestern Memorial Hospital, Chicago, IL.

Background: Peritoneal Dialysis (PD) is an option for renal replacement therapy. The US Renal Data System 2012 Annual Report states that the annual per-patient HD cost is approximately $87,500 whereas for PD it is $66,750. In addition, studies have demonstrated that some aspects of quality of life are improved in PD patients compared with HD patients. Despite this, PD is underutilized in the US. Northwestern Medicine’s PD Program was initiated in 01/2014 with 4 nephrologists and 10 patients who transferred from a neighboring PD Unit. From 02/2014 to 04/2015, Northwestern’s Peritoneal Dialysis Clinic grew to 50 peritoneal dialysis patients.

Methods: We included all patients who started on PD (or transferred to PD) in PD Clinic between the periods of 2/14 and 4/15. Patients excluded from this analysis stopped PD within this period for the following reasons: switched to HD, expired, recovered kidney function, or underwent transplantation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

1028A
Results: There were significant differences between group B and A (Hazard Ratio: 2.611, \(p = 0.016\), 95% CI: 1.223-6.009), group B and C (Hazard Ratio: 6.031, \(p = 0.001\), 95% CI: 2.975-13.53), group C and A (Hazard Ratio: 2.390, \(p = 0.009\), 95% CI: 1.33-4.09). In addition, these groups were analysed by adjustment factor such as age, sex, blood pressure, hemoglobin, Ca, P, whole PTH, TC with multivariable analysis. The results proved that there were tended to be correlation between group B and A (Hazard Ratio: 1.963, \(p = 0.09\), 95% CI: 0.901-4.61). There were significant differences between group B and C (Hazard Ratio: 4.00, \(p = 0.003\), 95% CI: 1.866-9.35), group C and A (Hazard Ratio: 2.037, \(p = 0.002\), 95% CI: 1.165-3.63).

Conclusions: Low level of albumin increases the mortality of PD patients gradually. Therefore we may decrease mortality of PD patients by improving nutritional condition and infection control when PD patients are introduced.

PUB605

The Effect of Neutral pH versus Conventional Peritoneal Dialysis Solutions on Peritoneal Permeability

Atsushi Ueda, Kei Nagai, Toshiaki Usui, Joichi Usui, Kunhiro Yamagata, Chie Saito. Univ of Tsukuba, Tsukuba, Japan.

Background: Biocompatible peritoneal dialysis (PD) solutions have been anticipated to reduce oxidative stress against peritoneal PD solutions. However, previous reports suggested peritoneal permeability have not been changed. This study was undertaken to investigate the peritoneal transport status from PD initiation, using biocompatible or conventional PD solutions.

Methods: We employed retrospectively 101 patients who started PD and divided into three groups. Group A was consisted of 76 patients who used only conventional low pH solutions, and neutral pH group was consisted of 19 patients who used only biocompatible neutral pH solutions during the subsequent two years. The rest of six patients used low pH solutions at the initial phase of PD, then switched to neutral pH solutions. The ratios of diolysate to plasma creatinine concentration at 4 hour (D/Pcre) in peritoneal equilibration test were measured at every year. We evaluated D/Pcre levels at the initiation and two years after between acid and neutral pH groups, and also the D/Pcre movements before and after switching PD solutions of the six patients.

Results: There was no significant difference on the D/Pcre values between at the start and two years after in the acid and neutral pH groups respectively. D/Pcre change between at the start and two years after in the acid group was not significant different compared to that of the neutral pH group. However, D/Pcre declined significantly one year after switching PD solutions from acid to neutral pH.

Conclusions: It was not observed obvious beneficial effects of neutral pH solutions on peritoneal permeability within two years PD duration. However, the transient effect in decreasing peritoneal permeability was found, and suggested that biocompatible solutions may preserve peritoneal functions compared to conventional solutions in a long time period.

PUB606

Predictive Power of Serum Cystatin C Assessing Residual Renal Function in Patients on Peritoneal Dialysis

Jung Min Park,1 Song-Hoon Song,1 Eun Young Seong,1 Harin Reeh,1 Ihm Soo Kwak,1 Il Young Kim,1 Dong Won Lee,1 Soo Bong Lee,2 Woo Jin Jung,1 Su Min Park,1 Min Jung Kim,2 Joo Hui Kim.1 1Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea; 2Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea.

Background: Residual renal function (RRF) is of considerable importance for patient survival on peritoneal dialysis. In clinical practice, the RRF is usually measured by assessing the urine concentrations of urea and creatinine and total urine output and the process is cumbersome and time consuming. Cystatin C has proposed to be used in place of RRF measurement. This study aims to investigate the predictive power of serum cystatin C in peritoneal dialysis patients.

Methods: This study included 54 patients on peritoneal dialysis who had evaluated RRF, serum cystatin C and serum creatinine. RRF was measured using the 24-hour urea-creatinine clearance method and cystatin C based glomerular filtration rate (eGFRcysC) was estimated using the Hoek’s formula. RRF and cystatin C were followed up for 6 months at least. The rate of RRF decline and slope of serum cystatin C were assessed by regression.

Results: Patients were on peritoneal dialysis for a median of 30 months and average serum concentrations of cystatin C was 5.41 ± 1.06 mg/L. Among the 54 patients, sixteen was anuric and seven became anuric during follow up. The patients with RRF had significantly lower cystatin C levels (\(p = 0.001\)). RRF was correlated with cystatin C (\(r = -0.687\), \(p < 0.01\)). In simple linear regression, RRF was associated with cystatin C (\(r = 0.687\), \(p < 0.001\), eGFRcysC (\(r = 0.741\), \(p < 0.001\)) and creatinine (\(r = 0.662\), \(p < 0.001\)). The slope of serum cystatin C was correlated with the rate of RRF decline (\(r = 0.616\), \(p < 0.001\)) during follow up. The overall small loss of RRF group had a higher level of serum cystatin C at the point of dialysis initiation (\(p = 0.017\)).

Conclusions: Serum cystatin C level might be convenient parameter for estimating the RRF and serum cystatin C at the point of dialysis initiation might be a predictive marker of preservation of RRF. Further studies about the cystatin C based equations are required to replace creatinine/urea clearance measured RRF.

PUB607

Peritoneal Dialysis: A Decade Experience at a Reference Centre in Brazil

Patricia O. Costa, Carla M.V. Melo, Flavia A. Nobrega, Jordanno P. Oliveira, Jандson P. Oliveira, Kleyton Andrade Bastos. Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.

Background: Peritoneal Dialysis (PD) is underutilized in most countries. The Brazilian prevalence is around 9%. This study aims to describe the ten years experience on PD in a dialysis center in Northeast of Brazil (Aracaju-Sergipe). Unlike other national programs, negative selection for DP is not an attribute of this dialysis unit.

Methods: Retrospective cohort study that evaluated the sociodemographic and clinical profiles, comorbidities, peritonitis, hospitalizations and death causes of 565 patients who remained in PD for at least 30 days from 01/01/2003 to 12/31/2012.

Results: Patients were mostly men (55%), living outside Sergipe’s capital (56%), had a mean age of 54 ± 19 years old when started on dialysis, were illiterate or had less than 4 school years (62%) and had a family income less than 5 national minimum wages per month (88%). The etiology of nephropathy was identified in 54% of cases, diabetic nephropathy (46%) and hypertensive nephrosclerosis (22%) were the most prevalent. Hypertension was associated with immobility (77%), diabetes (29%), D/Pcre was the initial dialysis modality for 53% of patients, mainly as an emergency (58%), and only 9% of patients had undergone peritoneal dialysis care for at least six months. Patients remained in PD by an average of 710.5 ± 714.2 days, and 61% of them also underwent hemodialysis (HD) at some point during their dialysis treatment. 676 peritoneal catheters were implanted (1.19 patient), 75% by trocar, by nephrologist, mostly Tenckhoff (58%). The main cause of dropout were infectious complications related to therapy (17%). The peritoneal index was 1 episode every 27.03 months, and S. aureus was the most prevalent etiological agent (22%). There were 1045 hospitalizations during follow up, most frequently due to infections (48%). The cause of death was identified in 64% of cases, mostly from cardiovascular diseases (50%).

Conclusions: In this study, patients had predominantly low socioeconomic status and did not have access to predialysis treatment, however, peritonitis rates and catheter complications are similar to those reported in other international series. HD and PD are shown as complementary techniques.

Implementation of Clinical Practice Guidelines on Antimicrobial Prophylaxis in Peritoneal Dialysis Patients

Denise Campbell,1 Fiona Brown,2 Jonathan C. Craig,1 Martin P. Gallagher,4 David W. Johnson,4 Geoffrey S. Kirkland,4 Subramanian K. Kumar,4 Wai Hoi Lim,3 Dwarakanathan Ranganathan,4 Walaa W. Saweirs,6 Germaine Wong,7 David Mudge. 1School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; 2Nephrology, Monash Univ, Clayton, Victoria, Australia; 3Renal Medicine, Auckland City Hospital, Auckland, New Zealand; 4Renal and Metabolic Div, George Inst for Global Health, Sydney, New South Wales, Australia; 5Nephrology, Princess Alexandra Hospital, Wooloongabba, Queensland, Australia; 6Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia; 7Renal Unit, Gosford Hospital, Gosford, New South Wales, Australia; 8Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; 9Nephrology, Royal Brisbane & Women’s Hospital, Herston, Queensland, Australia; 10Renal Unit, Whangarei Hospital, Whangarei, New Zealand.

Background: Despite the existence of international guidelines, peritoneal dialysis (PD)-related infections vary widely across Australia and New Zealand units, with multiple units reporting suboptimal rates and variable practice.

Methods: The current practice and barriers to guideline uptake were evaluated in eight PD units located in Australia and New Zealand in 2011. A multifaceted intervention was developed which included case report forms, a patient diary, a ‘Preventing Peritonitis Checklist’, an Emergency Department flyer, a letter to the patient’s general practitioner, a medical card, and a poster summarizing ISPD and KHA-CARI guidelines.

Results: At baseline (1 Jan-31 Dec 2011), exit-site infection (ESI) rates ranged from 0.06-0.53 episodes/patient-year; peritonitis from 0.31-0.86 episodes/patient-year; and fungal peritonitis from 0.00-0.50 episodes/patient-year. After implementation (9 Dec 2013-8 Dec 2014), the ESI rates were 0.00-0.22 episodes/patient-year; peritonitis was 0.06-0.53 episodes/patient-year; and fungal peritonitis was 0.00-0.14 episodes/patient-year.

Conclusions: Implementing the various tools resulted in improvement in the ESI and peritonitis rates but the difference was not statistically significant (P=0.15 and P=0.08). There was no statistically significant difference in the fungal peritonitis rate (P=0.64).

Survival Analysis of 326 Continuous Ambulatory Peritoneal Dialysis (CAPD) Patients  

Hao Zhang, Liu Li, Bin Yi, Wei Li. The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: This study aimed to identify clinical outcomes and risk factors that may affect potential prognosis of ESRD (end-stage renal disease) patients who receiving continuous ambulatory peritoneal dialysis(CAPD) in Southern China.

Methods: A total of 326 CAPD patients were initiated Cycler in the Third Xiangya Hospital, Central South Univ, from August 1st 2002 to Mar 31st 2015. The patients were divided into two groups according to the baseline PET. Gender (r = 0.299, p = 0.299), serum albumin (r = 0.199, p = 0.199) and TG level (r = 0.140, p = 0.140) were correlated with the baseline PET respectively. Multiple stepwise linear regression analysis showed that gender (β = 0.085), serum albumin (β = -0.005, p = 0.005) were associated with baseline PET independently. Multivariate Logistic analysis showed that men (OR = 3.314, p = 0.001), hypoalbuminemia (OR = 2.552, p = 0.001) and TG levels (1.11±0.62 mmol/L vs 1.28±0.57 mmol/L, p = 0.047) compared to the low baseline PET. Gender (r = 0.299, p = 0.299), serum albumin (r = 0.199, p = 0.199) and TG level (r = 0.140, p = 0.140) were correlated with the baseline PET respectively. The high transport rate is a contributory factor in low serum albumin levels. This result is similar to what several large studies had reported in the literature. For diabetic PD patients, PET should be carefully evaluated and accordingly the prescription of short dwells, which have found their natural application in APD, should be kept in mind as a treatment option. The high transport rate is a contributory factor in low serum albumin levels.

Results: A total of 326 CAPD patients (199 male and 127 female) were identified in this study. The mean age was 50.73±14.99 years, median dialysis vintage was 46(2-144) months. Primary glomerulonephritis was the most common cause of ESRD (50.6%). The overall 1-, 3- and 5- patient survival rate were 95.4%, 79.3% and 46.2%, and 1-, 3- and 5- technique survival rates were 78%, 62% and 42% respectively. Technique survival rates were 64%, 52% and 24% respectively. Only 10% of the patients could perform their PD therapy without the assistance of any family member or nurses. Only 70% of the patients were on APD among those using CAPD. Albumin levels were significantly associated with the commencement were independent risk factors for technique survival in diabetic patients on peritoneal dialysis (PD).

Conclusions: Our data suggest that diabetic PD patients tend to be significantly high transporters with worse prognosis in terms of patient and technique survival.

Factors Influence the Baseline Peritoneal Transport Status  

Hao Zhang, Bin Yi, Cuiling Hou. The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: Baseline peritoneal solute transport rate (PSTR) is an independent risk factor for total and cardiovascular (CV) mortality in the PD (peritoneal dialysis) population. The determinants of PSTR in incident PD patients are still under debate. Our objective was to explore the influence factors of baseline PSTR.

Methods: (1) 205 incident PD patients who had a standard peritoneal equilibration test (PET) within 3 months after commencing PD and without peritonitis history were enrolled. Pre-dialysis clinical parameters and biochemical indexes were assessed. 205 individuals were divided into two groups according to the baseline PET. High transport group: PET > 0.65, Low transport group: PET < 0.65. (2) Pre-dialysis serum advanced oxidation protein products (AOPP) and dialysate AOPP, GPx, hsCRP, IL-1beta, TGF-beta1 and eGFR were collected from medical records. Outcome of death or technique failure from any causes were selected. All-cause mortality and survival rate were analyzed using variance analysis and COX regression.

Results: A total of 326 CAPD patients (199 male and 127 female) were identified in this study. The mean age was 50.73±14.99 years, median dialysis vintage was 46(2-144) months. Primary glomerulonephritis was the most common cause of ESRD (50.6%). The overall 1-, 3- and 5- patient survival rate were 95.4%, 79.3% and 46.2%, and 1-, 3- and 5- technique survival rates were 78%, 62% and 42% respectively. Technique survival rates were 64%, 52% and 24% respectively. Only 10% of the patients could perform their PD therapy without the assistance of any family member or nurses. Only 70% of the patients were on APD among those using CAPD. Albumin levels were significantly associated with the commencement were independent risk factors for technique survival in diabetic patients on peritoneal dialysis (PD).

Conclusions: A strong adherence to PD method in all 15 patients. All patients were educated 2-3 weeks after the start of acute PD regimen and we observed a strong adherence to PD method in all 15 patients.

Causes of Failure in Chronic Peritoneal Dialysis Catheters  

Elizabeth Huerta calistis. Nephrology, Hospital Angeles Puebla, Puebla, Mexico.

Background: One of most common treatment of end stage kidney failure is peritoneal dialysis. Encapsulating peritoneal sclerosis is a complication in wich the osmotic capacity of the peritoneal barrier is lost, mainly due to infections. This pathology has different clinical presentations that oblige to use different diagnostic and therapeutic methods.

Methods: I was a survey conducted retrospective, descriptive and cross that included June 1, 2008 to May 30, 2014 in nephrology department of Angeles Hospital.

Results: Clinical and imagine presentation in three different patients, we analyze each separately as well as their solutions. These include delimitation of the affected zone, sterilization of the cavity and its collapse, even the renal transplantation.

Conclusions: Different clinical presentations of the encapsulating peritoneal sclerosis oblige to design evaluation and treatment for each patient in particular, using all the imagine and laparoscopic methods.

Take on Characteristics of Incident PD Patients in a Multicentre Multinational Integrated Care Setting  

Belen Maroni, Marieta Torro, Delia Timofio, Janusz Ostrowski, Jose C. Divino-Filho. 1 Diaverum Home Therapies. Medical Office, Diaverum, Munich, Germany; 2 Segged Diaverum Clinic, Diaverum, Szeged, Hungary; 3 Sena Diaverum Clinic, Diaverum, Bucharest, Romania; 4 Wloclawek Diaverum Clinic, Diaverum, Wloclawek, Poland.

Background: Our institution as a Renal Service provider is committed to integrated care, offering all types of RRT and focusing in patient’s choice. Objectives: To analyze HD and PD take on and its relationship with the type of previous referral and provided care. Methods: A retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD clinics in 2012. Early referral (ER) considered if patient known ≥3months in Nephrology, and scheduled initiation of dialysis with a permanent access was considered planned (P).

Results: Population: 30% diabetes, mean age 64 years, 84% with previous medical care of renal disease, 49 % late referral, 80% modality informed, 58% unplanned start, 11% PD (3% early switch from urgent HD). PD therapy in non-planned start applied in 5/59 PD patients. No differences in HD/PD take on were observed for gender, diabetes, initial renal and predialysis follow up, at structured units or in elapsed time between early

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
follow up and dialysis start. PD patients (p=0.02) received more modality information than HD (92% vs. 78%) and were mainly under 50 years (p = 0.001). Incidence varied according with different studied groups

Conclusions: Despite commitment to offer PD/HD as complementary treatments, PD incidence is still low. Optimal care provision is important to improve outcomes but also to involve patients in their therapy choice.

PUB615

The Adsorption Kinetics Profile of Aminoglycoside Antibiotics During Lixelle S-35 Cartridge Hemoperfusion

Marco Sartori, 1,2 Angela Casas, 1 Silvia De Rosa, 1 Mirella Zancato, 1 Leopolda Zampieri, 1 Davide Giavarina, 1 Claudio Ronco. 1 Internal Medical Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy; 2Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.

Background: The bactericidal activity against Gram(-)-to of Tobramycin(TOB)and Gentamicin(GEN)is concentration-dependent. It is therefore fundamental achieving the maximum drug plasma levels. Lixelle-S-35 is a physiological hydrophilic interaction liquid chromatography (HILIC)-tandem MS/MS. A small volume (150mL) of plasma spiked with six drugs was diluted with 350mL of acetonitrile containing 0.1% formic acid. After centrifugation, 100uL of the clear supernatant was directly injected into the HILIC-MS/MS, without any solvent evaporation and reconstitution step. The chromatographic separation of the AG AMBs was achieved on Unison UHPLC-HILIC column (50m x 3mm i.d., particle size 3um) with a linear gradient elution system composed of 0.1% formic acid and acetonitrile.

Methods: We performed mock direct hemoperfusion (DHP;Q B =1.06mg/L; n=3) then it was circulated into the system. Samples were taken from arterial(Cpin) and venous(Cpout) lines at 5, 10, 60, 120 min. Sample levels were measured by TOBR and GENT Flex methods (Siemens). The adsorption kinetics profiles were calculated. Results: The mob mass adsorption was 37.20% whereas GEN was 46.20%.

Conclusions: Our in vitro study indicates an high adsorption rate for both aminoglycosides. This should be considered when TOB or GEN are used in pts treated with Lixelle S-35 cartridge. A supplemental dose may be needed to maximize efficacy.

PUB616

Analysis of Some Aminoglycoside Antimicrobials in Human Plasma by HILIC-MS/MS

Shinya Omika, 1,2 Xiao-Piao Lee, 1 Takeshi Kumazawa, 1 Keiko Sato, 1 Kyoko Inui, 1 Tomoki Miyazaki, 1 Yoshitivo Inoue, 1 Ashio Yoshimura, 1 Daichi Medicine, Div of Nephrology, Showa Univ Fujigaoka Hospital, Kanagawa, Japan; 2Dept of Legal Medicine, Showa Univ School of Medicine, Tokyo, Japan.

Background: Aminoglycoside(AG) antimicrobials(AMBs) have been used for a treatment of bacterial infections especially by acid-fast bacteria. However, their acute overdose or chronic abuse can cause serious side effects, such as difficulty in hearing, interstitial nephritis resulting in renal failure and even sudden death from anaphylactic shock. In such cases, there is a great need to identify and quantify AG AMBs in the blood from patients or cadavers. We earlier reported an analytical procedure for nine AG AMBs in human serum by capillary HILIC mass spectrometry (MS). Although this method works well for identification of the drug, it is semi-quantitative unless a suitable isotopic internal standard is used.

Methods: A simple, rapid, sensitive and quantitative method is presented for the analysis of six AG AMBs (streptomycin, ribostamycin, kanamycin, amikacin, dibekacin, arbekacin) in human plasma samples by hydrophilic interaction liquid chromatography (HILIC)-tandem MS/MS. A small volume (150mL) of plasma spiked with six drugs was diluted with 350mL of acetonitrile containing 0.1% formic acid. After centrifugation, 100uL of the clear supernatant was directly injected into the HILIC-MS/MS, without any solvent evaporation and reconstitution step. The chromatographic separation of the AG AMBs was achieved on Unison UHPLC-HILIC column (50m x 3mm i.d., particle size 3um) with a linear gradient elution system composed of 0.1% formic acid and acetonitrile.

Results: All drugs showed base peaks due to [M+H]+ ions by HILIC-MS with positive ion electrospray ionization, and the product ions were produced from each drug ion as a product ion by HILIC-MS/MS quantification was made by selected reaction monitoring. The data obtained from actual determination of the AG antimicrobials in human plasma after their oral or intramuscular administration are also presented for validation of the methods.

Conclusions: This method would seem to be useful in clinical and forensic medicine because of its ability in both identification and quantification of the drugs.

PUB617

Prevalence of Chronic Musculoskeletal Pain Among Hemodialysis Patients

Magdy F. Elshankawy, 1 Cherry Reda, 1 Haitham Ezzat, 1 Amr Mohab. 1 Nephrology Dept, Ain Shams Univ, Egypt.

Background: Chronic musculoskeletal pain is common in patients with end stage renal disease (ESRD) undergoing hemodialysis; however information regarding its frequency and prevalence is relatively scarce.

Methods: A cross-sectional study was conducted on 100 ESRD patients on maintenance hemodialysis three times per week for at least 3 months. Chronic musculoskeletal pain was evaluated using the VON KRAEEFUHRENS scale for grading the severity of musculoskeletal pain. Correlation was done between chronic MS pain and physical findings of motor and sensory systems examination. In addition, correlation was also done between chronic MS pain and intact Parathormone (PTH), serum corrected calcium, serum phosphorus, serum alkaline phosphatase, serum albumin and hemoglobin level.

Results: Mean age was 57.46 years. Mean dialysis duration was 3.80 years. 42% were females and 58% were males. In our study, 37% of the patients had low disability low intensity of pain i.e. little affection on the daily, social & work activity (grade 1), 37% of the patients had low disability high intensity of pain (grade 2) while 26% of them had high disability high intensity of pain i.e. moderate limitation of the daily, social, recreational & work activities (grade 3). Chronic musculoskeletal pain showed positive correlation with muscle state, tenderness and power (p<0.001, p<0.001, p=0.001 respectively). Grade 3 disability patients had the highest level of serum Ca and PTH which were significantly different from grade 1 and 2 patients (p<0.001, p=0.013 respectively). While serum albumin level was lowest in grade 3 patients (p=0.025).

Conclusions: Chronic MS pain is common in ESRD patients. Disturbed mineral metabolism is strongly associated with chronic MS pain in long-term HD patients. Musculoskeletal system involvement remains a common problem that limits the physical function of patients with ESRD.

PUB618

Practice Patterns of United States Nephrologists in Blood Pressure Medication Use when Transitioning Patients to Dialysis

Mary C. Mallapalli, 1 Steven Fishbane, 2 Rimda Wanchoo, 2 Andrea Roche-Recinos, 1 Subodh J. Saggi, 2 Moro O. Salifu. 1 Internal Medicine: Div of Nephrology, SUNY Downstate School of Medicine, Brooklyn, NY; 2Internal Medicine -Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.

Background: As there is no standard approach to transitioning a patient in chronic kidney disease (CKD)-5 to CKD5-Dialysis in regards to adjustment of diuretics, BP medication, optimal frequency of medication reconciliation (MR) and determination of dry weight (DW) we conducted a survey to determine how US nephrologists transition a patient from CKD5 to CKD5-D in these aspects.

Methods: We designed an anonymous electronic survey with 39 questions and sent it to practicing nephrologists in the US after IRB approval.

Results: 120 US Nephrologists replied to the survey; 60% were in Nephrology for more than 10 years. (79%) used furosemide in CKD5 (66%) used a combination of furosemide and metolazone. The first choice of diuretics in CKD5 was furosemide (79%), in CKD5-D was torsemide (9%) and torsemide (9%) (p=0.005). In CKD5, 45% used diuretics daily, 29% on non-dialysis days and 26% discontinued them(p<0.002). In CKD 5, 63% would continue ACEI or ARB. In CKD5D, 84% of responders had at least 30% of patients on ACEI/ARB and most (64%) would not stop these medications despite hyperkalemia. The majority (79%) did not change ACEI to those that were not dialyzed out. The perceived most effective BP medication in CKD5 decreasing order: Nifedipine/mladipine (36%), ACEI/ARB (29%), beta blockers (17%), diuretics (13%) and others (4%); (p=0.0005). Most responders (79%) prescribed BP medication on non-dialysis days only and 88% thought that BP should be monitored with ultrasound in the first month. The first choice of BP medication in CKD5 was monthly (78%), weekly (12%) and as needed only (8%). DW was determined in the first week (31%) and the first month(52%). Of those surveyed, 59% felt HTN in CKD5 had multiple causes.

Conclusions: Transitioning patients from CKD5 to CKD5-D continues to remain challenging in terms of adjustment of BP medication. Variations in practice regarding the frequency of medication use may benefit from guidelines.
First Dialysis Prescription and Access Use: A Survey of United States Nephrologists  
Mary C. Mallapallil,1 Steven Fishbane,2 Rinda Wanchoo,2 Andrea Roche-Recinos,1 Subodh J. Saggi,1 Moro O. Salifu.1 1Internal Medicine-Nephrol, SUNY Downstate School of Medicine, Brooklyn, NY; 2Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.

Background: As there is no standard approach to initiate renal replacement therapy in CKD5 patients in regard to location of first treatment, access and dialysis prescription we conducted a survey of US nephrologists to better identify current practice patterns.

Methods: We created an anonymous electronic survey with 39 questions that was validated then approved by the IRB. Aggregate data was analyzed using descriptive statistics, avoiding duplicate responses.

Results: 120 US nephrologists replied to the survey, 60% were in nephrology practice for more than 10 years. The first hemodialysis (HD) treatment was as inpatient (22%), outpatient (29%) or either (49.5%). At the first HD, most nephrologists (92%) used a blood flow (BF) >300 mL/min. 65% would use lower than usual dialysate flow rates (DFR) and 47% would use another access. Ninety six percent prescribed less than twice the usual dose, even with blood area nitrogen less than 100 mg/dL. About 45% replied that only 10-50% of patients meeting criteria for peritoneal dialysis were actually started on this modality (p<0.005). Of the participants 47% noted that only 10-50% of patients who were eligible for transplant were listed, and the majority of responders noted less than 10% of their patients got a preemptive transplant (p<0.0005). A patient educator was available to educate 64% of the participants. First dialysis with a permanent access was noted among 30-60% of patients by 43% of responders and in more than 60% of patients by 22% of responders. Of the participants 73% replied that the majority (>60%) of their patients got vein mapping before access creation. The time between vein mapping and access creation was one week to one month (61%) and more than one month (26%), (p<0.005). The number of angioplasties that were acceptable prior to primary access failure was noted as 2, (25%) or more than 4 (24%).

Conclusions: There is variation in practice in several areas in regard to the initial dialysis session in CKD5 which may benefit from guidelines.

Association Among Calcium, Phosphorus, and Parathyroid Hormone with Aortic Ring Calcification in a Cohort of Hemodialysis Patients  
Arturo Reyes Marin. Nephrology, Hospital Juzre de Mexico, DF, Mexico.

Background: The prevalence of vascular calcification in dialytic therapy is 40-92%, values increased in serum levels of calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) have been associated with high calcification progression and cardiovascular mortality. It has been described association among serum levels of Ca, P, Ca-P product and PTH with aortic ring calcification in patients with chronic renal disease (CRD). We did an observational and descriptive study, in the nephrology department of Hospital Juzre de Mexico, with a cohort of 95 hemodialysis patients, the aim of study was to evaluate the association among aortic ring calcification by torax radiography with the serum levels of Ca, P and PTH.

Methods: Adult patients in hemodialysis were included, patients with severe malnutrition, cancer and mental abnormalities were excluded. We used 2 scales (torax radiography), in order to assess the aortic ring calcification and we did correlation coefficient among Ca, P, PTH and 2 scales. We used Pearson correlation coefficient for analysis and Bland-Altman test for analysis of concordance among Ca, P, PTH and 2 scales.

Results: They were 95 adult patients: 50 (52%) men and 45 (48%) women, average age was 40.7 years old. We found weak negative correlation between Ca and PTH (r = -0.21, p > 0.05), weak positive association was found between P and PTH (r = 0.30, p < 0.05), correlation between PTH and CaSP (r = -0.36, p > 0.05), PTH and 2 scales (r = 0.5, p < 0.05). In the scales that we used to evaluate vascular calcification (torax radiography) showed high scores, however the intraclass correlation coefficient between scales and PTH, Ca and P (0.33) showed not statistical significance.

Conclusions: Despite that vascular calcification was high by torax radiography, the association among scales (torax radiography) and serum levels of Ca, P and PTH was not statistical significant. There are other important factors that can explain the progression of vascular calcification and the traditional markers for calcification: Ca, P and PTH are not enough for explain it.

How to Dialyze a Patient with Left Ventricular Assist Device in a Chronic Dialysis Unit? A Practical Protocol  
Sadiq Ahmed,1 Debbie Baker,2 1Univ of Kentucky; 2Univ of Padua, Padua, Italy.

Background: To provide chronic HD treatments to ESRD patients with LVAD in a chronic unit in the community is a challenge and a relatively new experience for nephrologists. As LVADs have revolutionized the treatment of advanced heart failure there are rising numbers of these patients developing ESRD need for HD in the community. Development of a practical, simple and safe protocol is needed to dialyse these patients in the chronic units.

Methods: This protocol and safety check list is developed to provide routine HD treatment for patients with LVAD and successfully implemented in a chronic dialysis unit in the community setting. The special policy and procedure relevant to this protocol, safety check list and standing orders for the dialysis nurses were approved by the governing body in the community setting. The special policy and procedure relevant to this protocol, safety check list and standing orders for the dialysis nurses were approved by the governing body in the community setting.

Results: The protocol and safety check list is developed to provide routine HD treatment for patients with LVAD and successfully implemented in a chronic dialysis unit in the community setting. The special policy and procedure relevant to this protocol, safety check list and standing orders for the dialysis nurses were approved by the governing body in the community setting.

Conclusions: This protocol to provide incenter HD to patients with LVAD in a chronic unit is simple & safe. It can be implemented in a chronic HD unit.

Does Dialysis Influence Treg Cells? A Meta-Analysis  Carlotta Caprara, 1 Gilbert R. Kinsey, 1 Wenxin Xin, 1 Jennie Z. Ma, 1 Valentina Corradia, 1 Elisa Scalzotti, 1 Francesca K. Martino, 1 Mark D. Okusa, 2 Mitchell H. Rosner, 2 Fiorenza Ferrara, 2 Claudio Ronco, 2 1International Renal Research Inst Vicenza (IRRV), Dept of Nephrology, Dialysis & Transplantation, St. Bortolo Hospital, Vicenza, Italy; 2Medicine, Univ of Virginia, Charlottesville; 3Public Health Sciences, Univ of Virginia, Charlottesville.

Background: The immunological state of patients with ESRD is dysregulated. Regulatory T (Treg) cells comprise a small proportion of the total lymphocyte population yet regulate key immune responses across a variety of disease settings. Contrasting results have been reported about the influence of dialysis on Treg cells. Our aim is to determine whether the available literature support a positive or negative influence of dialysis on Treg cells.

Methods: After screening 84 published studies (PubMed and Web of Science) we included 10 that evaluated Treg cells in ESRD patients. Of these, 5 studies included comparable healthy controls (HCs) and hemodialysis (HD) patients and used similar criteria for determining the percentage of Treg cells in total CD4 T cells were subjects included to a meta-analysis.

Results: A total of 99 HD patients and 88 age-matched HCs were included in these 5 studies. Using the fixed effect model a significant difference in the percentage of Treg cells in total CD4 T between HD and HCs was observed (P<0.001). The mean difference in Treg percentage was -2.34% in HD patients vs. HCs. Several discrepancies were noted between studies that may be due to the lack of consistent criteria for Treg cell identification and use of different type of dialysis membranes which was not specified in all articles.

Conclusions: The available literature comparing Tregs in HD patients and HCs suggested HD is associated with a reduction in Tregs. A limitation is that only a few articles consider uremic patients (ESRD not on dialysis) as a control group for HD. Furthermore, no studies have investigated Treg cells in the same patient before and then after initiating dialysis. This type of study will be critical to understanding the influence of dialysis on Treg cells. Furthermore, the clinical significance of these changes in Treg cell numbers will need to be elucidated.

More Nephrologist Visits Are Associated with Lower Cost of Care for Dialysis Patients  Hao Hang, Jane Brzozowski, Sheetal Chaudhuri, John W. Larkin, Mahathi Mothali, 1 Len A. Usvyat, Terry Ketchersid, Franklin W. Maddux. Fresenius Medical Care North America, Waltham, MA.

Background: Medicare patients with end stage renal disease (ESRD) are treated by nephrologists, primary care providers (PCPs), cardiologists and other specialists on a regular basis. We investigated the relationship of visits to these providers and total costs of care.

Methods: Medicare 100% ESRD data for patients with evidence of dialysis at any time during January 1, 2010 through December 31, 2011 were analyzed. Nephrologist, PCP and cardiologist visits were determined by specialty codes of Part B claims including both in- and out-patient visits. All data was aggregated at the Metropolitan Statistical Area level (MSA). We computed a ratio of nephrologist visits to PCP visits per MSA as well as nephrologist visits to cardiologist visits per MSA during the above period (visits were calculated on a per patient per month basis). Total costs of care (per member per month [PMPM]) were determined by aggregating Medicare Part A and B costs. Comparisons of ratios were performed using t-tests for quartiles of PMPM for two specialty visit ratios.

Results: Claims for 368,711 patients were analyzed. Patients in the lower quartiles of total cost had significantly more nephrologist visits relative to PCPs and cardiologists.

PUB626

Prediction of Non-Adherence to Hemodialysis Treatment Regimens  Yue Jiao, 1 Daniel E. Geary, 2 Theresa J. Hetzel, 1 Sheetal Chaudhuril, 1 Mahathi Mothali, 1 Terry Ketchersid, 1 Dugan Maddux, 1 John W. Larkin, 1 Peter Kotanko, 1,2 Brian Scott Ash, 2 Len A. Usvyat, 1 Franklin W. Maddux. 1Fresenius Medical Care North America, Waltham, MA; 2Renal Research Inst, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Non-adherence with hemodialysis (HD) treatment regimens is known to be associated with increased morbidity and mortality. The aim of this project was to develop a predictive model (PM) to identify HD patients who will likely have unexcused no shows to routine dialysis treatments within the next week.

Methods: Using data between 1/1/2014 and 12/31/2014 from the Fresenius Medical Care Knowledge Center and 2014 weather data from the National Oceanic and Atmospheric Administration’s National Centers for Environmental Information, PMs were designed and developed for prediction of unexcused no shows in patients not residing in a nursing home. Various PMs were investigated and included the generalized linear model, partitioning and regression trees, artificial neural networks, and generalized additive model (GAM). In all, 1,554,833 records stratified in weekly intervals on 60 variables from 172,854 patients were utilized. Variables included data on the patient’s history of unexcused no shows, demographics, comorbidities, laboratories, holidays, sporting events, and weather. A multi-tier prediction process was performed with respect to the availability of data. The area under the curve (AUC), sensitivities and specificities were investigated to determine the model with the highest performance.

Results: Best performing model had AUC of 0.87 for the multi-tier PMs utilizing a 30% test dataset. A small pilot test on 860 patients for three weeks utilizing optimal Yoden index as the cutoff value to predict the high probability of the unexcused no show events achieved an average sensitivity of 0.57 and specificity of 0.95.

Conclusions: These results indicate that higher ratios of nephrologist visits to cardiologist/PCP visits are significantly associated with decreased cost on a MSA level. Taken that nephrologist visits tend to be constant (due to the monthly capped payment), these results may be reveling a “sicker” and therefore more expensive population of patients on a MSA level that require more medical attention from a cardiologist or PCP, likely due to hospitalizations. Adjustments for underlying disease should be considered.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America
Conclusions: This pilot test of the developed modeling demonstrates that PM can assist in identifying patients with a high probability for unexcused missed HD treatments. Additional studies are needed to further analyze the potential of predictions for and interventions associated with reducing unexcused no show events.

PUB627
Factors Influencing Residual Renal Function Decrease in Hemodialysis Treated Patients

Bobby C. Lee, 1 John Duffy, 2

Background: We have shown in previous studies that maintenance of residual renal function in hemodialysis treated patients is conditioned by the number of weekly sessions, and is better in patients who start treatment with a twice weekly schedule. The aim of this study is to analyse the influence of other variables in the preservation of residual renal function.

Methods: Of the 174 consecutive patients who started hemodialysis treatment in the hospital, 98 began with 2-weekly sessions (2HD group), and 76 with 3-weekly sessions (3HD group). Residual renal function was measured every two months (mean urea and creatinine clearance).

Results: Decrease in residual renal function was lower in the 2HD group (median 0.19 vs 0.46 ml/min/month, p=0.005). In both groups the residual renal function decrease was higher in the patients from the transplant program than in those from predialysis: 2HD group: median 0.93 vs 0.17 ml/min/month, p=0.003; 3HD group: median 0.76 vs 0.32 ml/min/ month, p=0.005. Neither the initial schedule, sex or etiology of the renal disease influenced the decrease in residual renal function in either of the two groups of patients. Moreover we found no correlation between the decrease in residual renal function with age, the residual renal function at the start of dialysis or with the Charlson comorbidity index. Of the 98 patients who began with the 2HD schedule, 45 went on to dialysis three times a week when the residual renal function was less than 3 ml/min: these patients had a mean of 10.8 months on the 2HD schedule. The length of time on this model was not influenced either by age, sex, etiology of the nephropathy, comorbidity index, scheduled start or basal renal function.

Conclusions: The decrease in residual renal function in the patient treated with hemodialysis depends basically on the number of weekly sessions with which the dialysis treatment was started. Of the variables analysed only the return to dialysis due to graft loss conditioned a higher decrease in residual renal function in both groups of patients.

PUB628
Circadian Blood Pressure Behaviour in Hemodialysis Patients

Dimitrios Petras, 1 Kyriakos Dimitriadis, 2 Panagioti E. Giannouli, 1 Eirini Andrikou, 2 Konstantinos Tsioufs. 2

Background: Blood pressure (BP) evaluation and management in haemodialysis (HD) patients is often a matter of debate. During HD hypotension as well as a paradoxical rise in BP pattern are at high risk for coronary artery disease, especially if other comorbidities are present. The riser pattern is high and further increases during the interdialytic period. Patients with this BP pattern are at high risk for coronary artery disease, especially if other comorbidities coexist. Ambulatory BP monitoring in ERSD patients is a promising non-invasive technique for the recognition of future heart disease.

PUB629
In Vitro Dialysability of SNF472, a Novel Inhibitor of Vascular Calcification, Using Conventional Hemodialysis and Hemodiafiltration

Joan Perelló, 1 Miquel Gomez Humbert, 2 Nestor Yesid Rodriguez, 2 Carolina Salcedo, 1 Miquel D. Ferrer, 1 Juan Manuel Buaides, 3 Maria de mar Perez, 2 Eva Martin Becerra, 4 Francisco Maduell, 1 Sanijet, Palma, Spain; 2Nephrol. and Renal Transpl., Hosp. Clinic, Barcelona, Spain; 3Nephrol., Hosp. Son Llàtzer, Palma, Spain; 4Kürol, Madrid, Spain.

Background: SNF472 is being developed for the treatment of calciphylaxis and cardiovascular calcification in end stage renal disease patients on hemodialysis. The intended use of SNF472 is intravenous infusion during dialysis; therefore our aim was to assess its possible dialyzability and its effects on calcium (Ca) chelation.

Methods: Dialysability of SNF472 was assessed using online hemodiafiltration (OL-HDF) and conventional hemodialysis (HD) systems. The interaction of SNF472 with Ca was studied under bypass conditions (dialysis in off-mode). One liter of heparinized fresh blood spiked with 8 mg/dl creatinine was introduced in a container maintained at 37 ºC and a one hour dialysis session was simulated. 66.6, 30 and 10 ml/liter SNF472 were infused during the first 20 minutes of dialysis. Samples were obtained at different time points and creatinine, total and ionized Ca and SNF472 levels were quantified.

Results: No dialyzation of SNF472 was detected at 30 and 66.6 mg/liter neither in OL-HDF nor in HD systems. Dialyzation was measured at 10 ml/liter SNF472 both in OL-HDF and in HD, with an estimated clearance (Cl) of 30 and 18 ml/min, respectively. Creatinine showed a Cl of 231 and 220 ml/min, respectively. In bypass conditions, blood Ca was chelated during the 20 minutes of SNF472 infusion when added at 66.6 mg/ml. However, when the system was switched to the dialysis mode, the Ca in the dialysis bath compensated the chelating effect of SNF472 and Ca levels remained unaltered.

Conclusions: SNF472 dialyzes with a low Cl. SNF472 levels increase in blood during infusion and dialysis does not prevent from attaining potentially therapeutic levels. As SNF472 will be infused during the whole dialysis session, this low Cl is not expected to affect systemic exposure. The chelating effects of SNF472 on Ca are compensated by the Ca in the dialysis bath, so no hypercalcemia is expected. Supported by REDINREN RD012/0021 and RETOS COLABORACIÓN RTC-2014-2460-1 grants.

PUB630
A Simple and Cost Effective Approach to Ultra-Pure Dialysate

Anthony M. Valeri, 1 Bobby C. Lee, 2 John Duffy, 3 Robin Ferrer, 4 Ronald Villota, 5 Greg C. Riccardi, 5 Edmond P. Wong. 3

Background: Ultrapure dialysate has been shown to reduce inflammation and improve nutritional and anemia parameters in patients on chronic maintenance hemodialysis. The Nephros 9 HDU (Dual Stage Ultrafilter, Nephros Inc, River Edge, NJ) has been shown to reduce bacterial counts and endotoxin levels by at least a 5 log order of magnitude.

Methods: We performed an observational trial of this filter in a hospital-based acute dialysis facility in the USA.

Results: There were 23 chronic stable hemodialysis outpatients treated during the 6 month period after the installation of the filters to the preceding 6 months, there was an increase in the mean hemoglobin level of 0.5 g/dl (p=0.010) with a reduction in the mean weekly darbopoietin dose of 14.6 mcg or 40% (P<0.001) translating to a reduction in the ESA resistance index (weekly ESA dose/hemoglobin level) of 1.52 (p<0.001). During this time period, indirect inflammatory markers showed a reduction in the mean WBC count from 7,000 to 6,600 x 10³/ L (p=0.008) and an increase in serum albumin from 3.6 to 3.7 (p=0.024). The mean sPκt/V was unchanged during the 2 time periods (from 1.699 to 1.607, p=0.30).

Conclusions: In conclusion, the use of the Nephros® DSU filter to further reduce endotoxin exposure in chronic hemodialysis patients can result in improved ESA responsiveness and a lower ESA dose.
**PUB631**

Care Delivery Models for End Stage Renal Disease: A Systematic Review
María Lourdes Gonzalez-Suárez,1 Priya Ramar,2 Sagar Chawla,2 Adriano Luiz Ammirati, Thais Nemoto Matsui, Maria C.C. Andreoli, Fabiana Dias Carneiro, Ana C M S Ramos, Bento C. Santos. Dialysis Center, Hospital Israelita Albert Einstein, Brazil.

**Background:** Reimbursement for dialysis care has led the way for the broader transition to a value-based payment model. As payment policy for dialysis evolves, a better understanding of the evidence regarding care delivery models that optimize outcomes and increase the value of care for dialysis patients is essential. Limited evidence exists about which care delivery models are most effective.

**Methods:** Multiple databases were searched for comparative studies of care delivery models. Included were studies published between 2000 and 2014. The intervention had to include >5 dialysis patients over age 18 years and receiving treatment; >6 months follow up, and reported patient important outcomes i.e. mortality, important clinical outcomes, hospitalizations and quality of life. Data was abstracted by reviewer pairs; study quality was evaluated using Cochrane and Newcastle-Ottawa criteria: a) diagnosis of cognitive dementia, b) survival rates, c) hospitalization rates, d) quality of life.

**Results:** 1841 abstracts were screened, 59 full text articles were reviewed, and 23 studies with 87,281 patients were included for final analysis. The interventions included nutritional care (n=4), multidisciplinary care (n=6), satellite programs (n=3), home dialysis (n=3), access monitoring (n=2), physician contact (n=4), and nocturnal dialysis (n=1).

Most were observational studies of decent quality with representativeness and incomplete follow up being the main potential sources of bias. Two randomized studies on home dialysis and pharmacist care, had attention as the main risk of bias. Most interventions showed positive effect raising concern of publication bias. Overall, hospitalizations were significantly lower in the intervention group despite large heterogeneity: RR: 0.824, 95% CI 0.781, 0.868, p=0.001, I²=95.96%.

**Conclusions:** Multiple interventions have the potential to improve the outcomes of dialysis patients but have not been compared in terms of safety and effectiveness. Limited evidence is available to inform dialysis practice redesign to adapt to new payment structures. Further studies are needed to define best delivery models for dialysis care.

**PUB632**

Symetrical Dimethylarginine (SDMA) Is Poorly Cleared by Standard Hemodialysis
Mirela A. Dobra,1 Peter B. De Oro,2 Timothy W. Meyer,3 Thomas H. Hostetter.1 Case Western Reserve Univ; 2Centers for Dialysis Care, Cleveland; 3Stanford Univ School of Medicine.

**Background:** High SDMA levels have been associated with an increased risk for cardiovascular disease in patients with normal or reduced renal function. The effect of hemodialysis on SDMA has not been thoroughly studied.

**Methods:** We measured SDMA levels and its handling by hemodialysis and by the normal kidney in subjects with ESRD on chronic hemodialysis (n=7) and in normal controls (n=6).

**Results:** The mean (SD) SDMA levels in ESRD were six times higher than in normal controls, 3.350(6.5) vs 0.530(2.5) μM, p<0.001. For comparison pre-dialysis BUN levels was 44.123(1 ml)/dl in ESRD, and 14.9(3.2) mg/dl in controls. The fractional reduction of SDMA was significantly lower than that of urea, 47.4(1.5)%, vs 76.7(4.7), p<0.001; and the volume of distribution was much higher 58.5(14.5) ml vs 35.10(4) ml. For urea. Also the urinary clearance of SDMA 17.82(33.5) ml/min in normal controls was higher than that of urea 55.2(13.7) ml/min. SDMA production rates were similar 46.7(9.4) vs 52.3(13.9) mmole/day, ESRD vs normals, p<0.05.

**Conclusions:** In summary, SDMA circulates at high levels in hemodialysis patients due at least in part to its relative high clearance by the high kidney, relative to urea, and its larger volume of distribution. The latter suggests that SDMA is likely to be localized in the intracellular compartment, and therefore less available for clearance by standard hemodialysis.

On-Line Hemodiafiltration Is Efficient for Inflammation and Phosphorus Control
Nadia Guimaraes-Souza,1 Thais Nemoto Matsui, Adriano Luiz Ammirati, Maria C.C. Andreoli, Fabiana Dias Carneiro, Ana C M S Ramos, Bento C. Santos. Dialysis Center, Hospital Israelita Albert Einstein, Brazil.

**Background:** High efficiency on-line hemodiafiltration is the best method for middle molecules and phosphorus removal. Many studies have demonstrated the efficiency of this method in mortality reduction. The main objective of this study was to compare the three filters available for on-line HDF comparing the ability to remove urea, phosphorus and beta2-microglobulin.

**Methods:** Prospective cross-over study including four patients and three available filters for hemodiafiltration. All section of on-line hemodiafiltration was made with high efficiency (23-25%). Filters HDF 100, FX100 and HDF80COR were compared. Urea, phosphorus and beta-2-microglobulin were collected before and after first use of each filter A reduction ratio was computed for each.

**Results:** 95% surveys of the total population comprised 111 patients were taken; of which 85 are for patients undergoing hemodialysis and 10 patients on CAPD. By studying the “General Satisfaction” in all aspect of the service that is offered to the patients responses they expressed their overall dissatisfaction. Prospective, descriptive study conducted at the Dialysis Unit of the Military Hospital Córdoba, conducted between 15/11/2014 to 15/12/2014. Methods: All patients attending the service, who received some form of dialysis (hemodiafiltration) in the period. Exclusion criteria: a) diagnosos of cognitive dementia, b) Carrying less than three month of treatment c) not be psychological and physical conditions to answer the survey. A qualitative survey, structured ajar, applied voluntary and anonymous.

**Conclusions:** FX100 and HDF100 filter were similar for urea remotion ratio. There were no differences for other molecules.

**PUB635**

Satisfaction of Patients on Dialysis Unit
Jorge Nicolas Abadla. Nephrology, Militar Hospital, Cordoba, Capital, Argentina.

**Background:** The assessment of the satisfaction of patients in Dialysis, is a useful tool to meet patient needs; axis on which the care service is based.In turn it allows to identify the deficient areas.

**Methods:** Objective 1) To know the views of patients about the service that is offered in each of the areas of focus. 2) To analyze the profile of satisfaction of patients they expressed their overall dissatisfaction. Prospective, descriptive study conducted at the Dialysis Unit of the Military Hospital Córdoba, conducted between 15/11/2014 to 15/12/2014. Methods: All patients attending the service, with received some form of dialysis (hemodiafiltration) in the period. Exclusion criteria: a) MSN diagnostic of cognitive dementia, b) Carrying less than three month of treatment c) not be psychological and physical conditions to answer the survey. A qualitative survey, structured ajar, applied voluntary and anonymous.

**Conclusions:** FX100 and HDF100 filter were similar for urea remotion ratio. There were no differences for other molecules.

Correlation Between Calcium Phosphorus Product and Hypertension in ESRD Patients on Maintenance Hemodialysis
Shoua Islam1, Hafiz I. Ahmad1, Syed Rizwan Bokhari2, Arif Asif1. 1Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; 2Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.

**Background:** Increased levels of serum calcium, phosphorus and product of serum calcium and phosphorus (Ca x P) in end stage renal disease (ESRD) patients has been shown to be associated with increased mean arterial blood pressure (MAP). The available data is limited and no study has been done in Pakistan. We conducted a cross sectional study to determine the correlation between mean arterial blood pressure (MAP) and serum calcium-phosphorus product in our ESRD patients on hemodialysis.

**Methods:** Blood Pressure of all the prevalent ESRD patients in a single dialysis center was recorded and mean arterial blood pressure (MAP) was calculated pre and post dialysis. All patients were clinically euvalmic. Serum calcium and phosphorous levels were measured and Calcium-phosphorus product (CaP) was calculated. The product above 50 and the MAP above 93 were taken as high.

**Conclusions:** High efficiency on-line hemodiafiltration is an efficient method of reduction of reactive C protein and may reduce costs due to reduced doses of erythropoietin analogs.

Behavior of Ankle-Brachial Index During Hemodialysis: Effect of Calcium Dialysate Concentration. Zaida Noemy Cabrera Jimenez,1 Rosa M. A. Moyes,1,2 Bruno C. Silva,1 Luciene dos Reis,1 Wagner Dominguez,1 Fabiana Gracioli,1 Rosilene M. Elias.1 Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil; 2Univ de Nole Juho-UNINOVE, Sao Paulo, SP, Brazil.

Background: Ankle-brachial index (ABI) is a simple way to access cardiovascular risk. Both low (<0.9) and high (>1.3) ABI are associated with increased mortality risk in patients on hemodialysis (HD). However, little is known regarding the acute variation of ABI (from pre to post hemodialysis), and also whether the calcium dialysate content [Ca] may interfere with this variability. We aimed to investigate the impact of [Ca] 3.5 vs. 2.5 on the variability of ABI during HD.

Methods: Incident patients on HD for up to 90days were included. ABI was evaluated pre- and post-HD in the midweek session of two consecutive weeks with [Ca] 3.5 and 2.5, respectively. Biochemical variables, electrical bioimpedance and non-invasive hemodynamic (Finapress®) were assessed.

Results: 17 patients (10 men) aged 42 ± 17 years were included. ABI pre- and post-HD with [Ca] 3.5 and 2.5 were 1.2 ± 0.1, 1.1 ± 0.1, 1.1 ± 0.2, and 1.2 ± 0.1, respectively. Although the mean ABI values were within normal range, there was a great variability in the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing

Conclusions: ABI presents great variability during a conventional HD. However, whether an acute decrease in ABI by using a [Ca] 2.5 may impact the long-term mortality deserves further investigation.

Variation in the Intracranial Pressure During Hemodialysis in a Patient with Subdural Hematoma on Propofol. Rho-Phe Bhargava,1 Omkar U. Vaidya.1,2

1Dept of Internal Medicine, Univ of Missouri-Kansas City, Kansas City, MO; 2Dept of Nephrology and Hypertension, Univ of Missouri-Kansas City, Kansas City, MO; 3Dept of Critical Care, Saint Lukes Hospital, Kansas City, MO.

Background: Disseminated intravascular coagulation (DIC) is a rare but potentially serious complication of hemodialysis. Pathophysiology of this disorder is explained by the ‘reverse urea effect’. This can be difficult to detect in patients in the neuro-intensive care unit given their compromised CNS status. However it is imperative to diagnose DIC especially in this population as intracranial pressure (ICP) instability during hemodialysis can lead to microcirculatory defects.

Methods: 60 y/o male with ESRD admitted for left frontal subdural hematoma, underwent evacuation with ventricular drain placement. He was intubated and sedated, BP 142/69 mmHg, Pulse 122 bpm, Temp of 37.3 °C, RR of 34 and SpO2 100%. The remaining physical examination was unremarkable. Hemodialysis (HD) was performed on 3 contiguous days. ICP and the changes in cerebral perfusion pressure (CPP) were monitored every 15 minutes during hemodialysis. Sedation with propofol which was started on Day 1, was weaned off completely by the session on day three. The patient seized after the third hemodialysis session. CT scan of the head was unremarkable. He was eventually discharged on day 14 and made full recovery.

Conclusions: ICP and CPP during hemodialysis decreased in the first 30 minutes and maximum variation was between 45-120 minutes. Peak ICP pressure during HD: Day 1: 5 mmHg; Day 2: 1.5 mmHg and Day 3: 25 mm Hg. Maximum change in CPP from baseline during HD: Day 1: 20 mm Hg; Day 2: 22 mm Hg and Day 3: 47 mmHg.

Cerebrovascular disease is a major cause of hospital death in patients with ESRD. Therefore it is vital to prevent and manage the ICP during HD. In this case, the acute variation in ICP and CPP makes it feasible to perform HD while monitoring the physiological parameters.
**Methods:** PBMCs were isolated from blood of patients with Delay graft function (DGF) and early graft function (EGF, n=10) at T0 and T24h from transplant. Gene expression profiles of PBMCs from both groups were assessed by Affymetrix technologies. Results were evaluated by statistical analysis and functional pathway analysis and validated by confocal analysis on a swine model of IR injury. Renal I was induced in 5 pigs by arterial clamping for 30 min and tissues were analyzed at different time points after R (T15, 30′ , 60′).

**Results:** Microarray analysis (FDR<5% and a FC>1.5) revealed that the expression of PTX3 and C3 were downregulated in EGF compared to DGF patients. On the contrary, the gene CR1 was upregulated in DGF. Furthermore, in the pig model, confocal laser microscopy showed that deposits already present at 15 R, localized at peritubular (7.7±1.1;p=0.005) and glomerular (8.2±2.5;p<0.03) capillary levels. We found a significant increase in infiltrating interstitial leucocytes such as CD163+/PTX3+ monocyte-macrophages (6.2±1.2;p=0.05) and SWC3a+/PTX3+ dendritic cells (3.7±0.5;p=0.05) compared to T0. Finally, we identified tubulo-interstitial FSP1+/PTX3+ myofibroblasts (4.1±1.3;p=0.04). Co-localization between C5b-9/PTX3, PTX3/C1g and PTX3/MBL clearly demonstrated the activation of Classical and Lectin Complement pathways in presence of PTX3 deposits.

**Conclusions:** Our data would suggest a key role of PTX3 synthesized by peripheral blood mononuclear cells (PBMCs) during DGF leading to an early activation of complement in transplant kidney.

**The Effect of Combined Treatment of Dipeptidyl Peptidase Inhibitor and Metformin in Sirolimus-Induced Diabetes Mellitus** Long Jin, Jian Jin, Sun WOo Lim, Byung Ha Chung, Chul Wooy Yang. **Transplant Research Center & Div of Nephrology, Dept of Internal Medicine, Seoul, St Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.**

**Background:** Optimal treatment of post-transplant diabetes mellitus is still controversial. This study was performed to evaluate whether the combined treatment of DPP IV inhibitor with metformin (MET) is effective in sirolimus (SRL)-induced diabetes mellitus.

**Methods:** SRL-induced diabetes mellitus was made by treating SRL (0.3 mg/kg) for 3 weeks in rats, and then started to treat DPP IV inhibitor (LC15-0444[Lc], 5 mg/kg), and/or MET (200 mg/kg) for further 3 weeks. The effect of combined treatment of LC and MET on SRL-induced diabetes mellitus was evaluated by IPGTT and islet size. The oxidative stress was evaluated by measuring 8-OHdG, 4-HHE, M3SOd, and catalase in samples. Insulin secretion capacity was evaluated by glucose-stimulated insulin secretion (GSIS) test using normal isolated rat islets treated with SRL, exendin-4 and/or MET.

**Results:** SRL treatment for 6 weeks decreased body weight and increased water intake and urine volume compared with vehicle group. SRL treatment significantly increased AUCG from the values obtained during the IPGTT, but LC or MET treatment recovered these value compared with the SRL treatment alone. Combined treatment with LC and MET has more significantly decreased blood glucose level than LC or MET treatment alone. Combined treatment with LC and MET showed higher insulin level than exendin-4 or MET treatment alone.

**Conclusions:** Combined treatment with LC and MET exerts better glucose control by decreasing oxidative stress by SRL. This provides the rationales of the combined use of DPP IV inhibitor and MET in SRL-induced diabetes mellitus.

**Incidence and Outcomes of Hyponatremia Early Post Lung Transplantation** Ekamol Tantisattamo, 1 Aneesa Shetty, 1 Bing Ho, 1 John J. Friedewald, 1 Opas Traitannon, 1 Sangeeta Bhorade, 2 Alexander Haynes, 2 Amber Nieland, 2 Lorenzo G. Gallon. 1 *Div of Nephrology and Hypertension; Pulmonary and Critical Care, Dept of Medicine, Northwestern Univ Feinberg School of Medicine.*

**Background:** Outcomes of in-hospital hyponatremia in lung transplant recipients are unclear. The aim of this study is to describe the frequency of hyponatremia and outcomes associated with hyponatremia during the early postoperative period.

**Methods:** We performed a retrospective chart review of all lung transplant recipients at Northwestern Memorial Hospital since the first case performed in July 2014 until May 2015. The severity of hyponatremia was defined as mild, moderate, and severe with serum sodium of 135 to 130, 120 to 125, and less than 120 mEq/L, respectively.

**Results:** A total of 13 lung transplant recipients were included. Age at the time of transplantation was 61.5±2.2 (SEM) years and 69% was female. The most common indication for transplantation was severe COPD (54%). Serum creatinine at the time of transplantation and at hospital discharge was 0.8±0.6 and 1.1±0.2 mg/dL, respectively. Seven out of 13 lung transplant recipients developed acute kidney injury (AKI) with AKI severity ranging from Stage 1 to Stage 3. Co-morbidities like chronic obstructive pulmonary disease (COPD) (66%) and hypertension (67%) were common. Hyponatremia was present in 6 (46.2%) recipients at time of discharge. Table 1. Of the 6 recipients with hyponatremia, the incidence was up to 46% at the time of discharge (Table 1). Almost half of the patients had persistent hyponatremia during month follow-up.

**Conclusions:** Lung transplant recipients commonly develop hyponatremia during the immediate postoperative period and are more likely to be readmitted with hyponatremia. The incidence of hyponatremia remains high up to 1 month post transplantation. AKI is also a risk for readmission and predicts longer length of hospital stay.

**Motivations, Challenges, and Attitudes to Self-Management in Kidney Transplant Recipients: A Systematic Review of Qualitative Studies** Nathan Jamieson, 1,2 Camilla Sara Hanson, 1,2 Michelle A. Josephson, 1,2 Elisa J. Gordon, 1,2 Jonathan C. Craig, 1,2 Fabian Halleck, 1,2 Klemens Budde, 1 Allison Tong, 1,2 1 Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, New South Wales, Australia; 2School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; 2Dept of Medicine, The Univ of Chicago, Chicago, IL; 1Centre for Healthcare Studies and Comprehensive Transplant Centre, Northwestern Univ Feinberg School of Medicine, Chicago, IL; 2Dept of Nephrology, Charite, Universitaetsmedizin Berlin, Berlin, Germany.

**Background:** Kidney transplantation offers superior life expectancy and quality of life outcomes compared to other renal replacement therapy modalities. However, the complex and ongoing medication and self-management regimes impose a treatement burden on patients, and non-adherence remains a leading cause of graft loss.

**Methods:** MEDLINE, Embase, PsycINFO, and CINAHL were searched from database inception to October 2014. We used thematic synthesis to analyse the findings.

**Results:** Fifty studies involving 1238 participants aged from 18 to 82 years across 19 countries were included. We identified five themes: empowerment through autonomy (achieving mastery, tracking against tangible targets, developing bodily autonomy, routinisng and problem-solving, adaptive coping), prevailing fear of consequences (inescapable rejection anxiety, aversion to dialysis, minimising future morbidity, trivialisation and denial, defining acceptable risks), burdensome treatment and responsibilities (frustrating ambiguities, inadvertent forgetfulness, intrusive side-effects, reversing ingrained behaviours, financial hardship), over-medicalising life (dominating focus, evading patienthood, succumbing to burnout), and social accountability and motivation (demonstrating gratitude towards medical team, indebtedness to donor, peer learning).

**Conclusions:** Self-efficacy and social accountability are motivators for self-management, but ongoing adherence can be mentally and physiologically taxing. Multi-component interventions that incorporate education, psychosocial support, decision aids, and self-monitoring tools may foster self-management capacity and improve transplant outcomes.

**Characteristics of Patients with Vitamin D Deficiency After Kidney Transplantation in Qatar** Mohamed Amin Elesawy, 1,2 Abdullah Hamad, 1,2 Fadwa S. Al-Ali. Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.

**Background:** Vitamin D deficiency is common among normal people and in patients with chronic kidney disease including dialysis patients. Vitamin D deficiency continues to be prevalent after kidney transplantation (studies showed prevalence of 50-80%) especially with immunosuppression use and sun protection needed for elevated risk of skin cancer. We studied characteristics of kidney transplant patients with vitamin D deficiency in Qatar.

**Methods:** We reviewed all available records of kidney transplant patients presented to our clinic at Hamad General Hospital in Doha, Qatar between 1/9/2013 and 1/3/2014 and have vitamin D level less than 30 ng/mL. Background data and laboratory tests of patients were obtained. All patients were receiving vitamin D supplements and prednisone within the immunosuppression per institution protocol.

**Results:** We studied 83 patients. Mean age was 55.5 ± 16.1 years. There were 55 males (66%) and 28 females (34%). Vitamin D deficiency was severe (level than 10 ng/mL) in 15 patients (18%), moderate in 38 (45.7 ng/mL) and mild in 30 patients (20)-9 ng/mL). Duration of transplant was 7.9 ± 2.5 years. Glomerular Filtration Rate was 65.5 ± 20.6 ml/min. We found no correlation between vitamin D and PTH levels or between vitamin D and GFR levels. Table 1 summarize bone mineral panel in our patients.

### Conclusion:
In a study of kidney transplant patients with vitamin D deficiency in Qatar, we found that they were predominantly males, had normal calcium, phosphorus, and alkaline phosphatase levels, while they have variable degree of elevated PTH with no correlation to vitamin D level. Most patients have mild to moderate vitamin D deficiency (82%) despite receiving vitamin D supplement although the supplement could have decreased the number of patients with severe vitamin D deficiency (18%). Further study could help to evaluate the role of vitamin D supplement in improving vitamin D level in kidney transplant recipients.

**Methods:** We reviewed the medical records of 86 renal transplant recipients, 45 patients with 51 acute graft rejection episodes and 41 patients with 54 AGPN episodes, at the Univ of College of Medicine, Seoul, Republic of Korea.

**Funding:** This work was supported by the Ministry of Health and Welfare of Korea (H11011008001-09), the Ministry of Science, ICT, and Future Planning (2010-0028874), and the National Research Foundation of Korea (2011-0019406).

A DNI value of 2.7% was selected as cut-off value for AGPN, and renal transplant recipients with a DNI ≥ 2.7% were found to be at a higher risk of infection than those with a DNI < 2.7% (odd ratio [OR] 40.50; 95% CI 8.68-189.08; P <0.001). In a multivariate logistic regression analysis, DNI was a significant independent factor for predicting AGPN after adjusting age, sex, log WBC count, log neutrophil count, log lymphocyte count, DNI value, CRP concentration and procalcitonin concentration (OR 4.32; 95% CI 1.81-10.34, P = 0.001).

Conclusions: The present study demonstrated that a DNI value above 2.7% was an independent predictive marker for AGPN and an effective marker to differentiate between AGPN and acute graft rejection. Thus, these finding suggest that DNI may be a useful marker in the management of these patients.

PUB652

Effect of Pre-Transplant Dialysis Modality on Outcomes of Living-Donor Kidney Transplantation Recipients Chiaki Kawabata, General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.

Background: There are few studies on living-donor kidney transplantation that compare the outcomes after pre-transplant dialysis modality. We examined the short-term outcomes of living-donor kidney transplantation recipients after peritoneal dialysis (PD) and hemodialysis (HD), respectively.

Methods: 112 patients have undergone living-donor kidney transplantation procedures in our hospital between January 2001 and May 2014. We studied 40 patients, under 40 years of age, with dialysis durations of less than 5 years. We compared 13 PD patients with 27 HD patients and investigated the short-term outcomes.

Results: These two groups showed no significant differences as regards baseline characteristics including dialysis duration, body mass index, type of calcineurin inhibitor or ABO blood type compatibility. The PD group was younger than the HD group as regards dialysis duration, body mass index, type of calcineurin inhibitor or ABO blood type compatibility (data not shown).

Intravenous Immunoglobulin in the Management of Pneumocystis Pneumonia: A Case Series Musab Elgaali, Muhammad Inman, Matthew Edey. Hull Royal Infirmary, Hull, United Kingdom.

Background: Pneumocystis pneumonia (PCP) is a well-recognized complication of renal transplantation. We present 2 cases of severe PCP treated successfully with intravenous immunoglobulin (IVIg), trimethoprim-sulfamethoxazole (TMP-SMX) and withdrawal of immunosuppression. Graft function was maintained despite a high baseline immunosuppression.

Methods: Case A: A 32-year-old woman presented 2 years post-transplant with acute cellular rejection treated with steroids. 2 months later she was admitted with respiratory failure due to PCP. She required intubation and ultimately oscillatory ventilation. CMV DNA was detected at low levels in bronchoalveolar lavage (BAL) fluid. IVlg 30g on alternate days (10 doses) was added, in addition to withdrawal of immunosuppression and hydrocortisone replacement. She made a full recovery, with preservation of transplant function. She was discharged on prednisolone, mycophenolate and tacrolimus. 9 months later she was admitted with respiratory failure and Pneumocystis jirovecii in BAL. She required invasive ventilation and inotropic support. She was treated with intravenous TMP-SMX, but her clinical condition deteriorated with acute kidney injury (AKI) requiring hemofiltration and escalating ventilator requirements. She received IVlg 25g/day for 5 days, replacement hydrocortisone and immunosuppression was withdrawn. Her AKI resolved and later she became ventilator-independent. Graft function was at baseline on discharge. Maintenance immunosuppression was recommenced.

Conclusions: It is understood that immunity against Pneumocystis jirovecii is both B- and T-cell mediated. This pooled immunoglobulin might be expected to have some anti-Pneumocystis activity. It is also recognized that IVlg has immunomodulatory properties. In both cases the administration of IVlg allowed withdrawal of immunosuppression apart from replacement steroid without graft rejection despite high immunological risk. Both patients survived life-threatening PCP. We suggest adjunctive therapy with IVlg be considered in severe PCP.
A 12/20 (60%) were on statin therapy. Almost all (6/7 = 85.7%) of patients with vascular risk clinically, however, further analysis will be required to determine whether valid reasons exist to support decisions to omit statins or renin inhibitors. Significant proteinuria (uPCR >50) was not common (6/68 = 8.8%), but of these patients (63.6%) have not had a follow up HbA1c. 20/69 (29.0%) of patients were calculated to have a >20% cardiovascular risk on the basis of comorbidities or using JBS2. Of these only 9/12 (75%) achieved target HBa1c of <48 mmol/mol. Prescription of statins, antihypertensives and aspirin were audited against guidelines from the UK Renal Association (RA) and KDIGO. Cardiovascular risk management of all transplant patients in our region by comparing new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation. Our sample consisted of 140 doctors from Mumbai (Age Range=21-80 years, M=38.1, SD=17.95, Males=44.3%, Females=55.7%). A questionnaire, presenting ethical issues related to kidney donation/transplantation, in an agree/disagree format with supporting reasons was employed. The research design was exploratory; data was analyzed quantitatively and qualitatively.

Cardiovascular Risk Management of Renal Transplant Patients

Joseph C. Newton, Thalakunte M. Muniraju, Dumfries and Galloway Royal Infirmary, Dumfries, United Kingdom.

**Background:** There is a high burden of cardiovascular disease amongst renal transplant recipients, and it is the most common cause of death with a functioning graft. We have assessed the medical management of all transplant patients in our region by comparing regular monitoring of glycaemia, blood pressure and serum lipids, with appropriate prescription of medicines based on their cardiovascular risk.

**Methods:** Using the electronic health record information was collected on detergent dysfunction in patients with CAD. Notably, taurine was increased in serum after the initiation of dialysis. Nephrologists should prepare patients to PKT rather than to dialysis.

**Funding:** Private Foundation Support

**Results:**

- among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers. To explore this hypothesis, we recruited individuals with stable allograft function (n=20), chronic allograft dysfunction (n=20) and healthy controls (n=10), and analyzed their metabolomic profile by ex vivo liquid/gas chromatography-mass spectrometry (LC/MS-MS) of serum and urine in vivo two dimensional correlated spectroscopy (2D-COSY) of the kidney graft.

**Results:** LC/MS-MS revealed serum and urine abnormalities of amino acids, biogenic amines and acylcarnitines in individuals with worse allograft function (T3) compared to preserved graft function (T1). Novel potential theranostics targets have been identified with an unbiased

Preemptive Transplantation Is Associated with Improved Graft Survival: Results from the French Transplant Database

Mathilde Revist,1,2 Christian Comec,2 Jerome Haraamb,2 Christian Jacqueline,2 Pierre Merville,2 Lionel Couzi,2 Karen Leffondré,1 INSERM U897, Bordeaux School of Public Health, Bordeaux, France; 1Nephrology and Transplantation, Bordeaux Univ Hospital, Bordeaux, France; 2Agence de la Biomedecine, Paris, France.

**Background:** Kidney transplantation (KT) is the treatment of choice for end-stage renal disease. In France, preemptive kidney transplantation (PKT) should be considered when glomerular filtration rate is under 20 ml/min/1.73m² but European reports on the results of PKT are scarce. Our objective was to evaluate the impact of PKT on graft and patient survival.

**Methods:** We analyzed all first kidney-only transplants performed in adults in France between 2002 and 2012. A Cox multivariable model was used to study the impact of PKT on the hazard of graft failure defined as death, return to dialysis, or retransplantation, whichever came first.

- among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers.

Novel Potential Theranostics Targets in Individuals with Kidney Allograft Dysfunction

Roberto Bassi,1,2 Monika A. Niewczas,1 Nirmala Almeida,1 Karen Almeida,1 Alan F. Almeida,2 1LifeSupporters Inst of Heath Sciences; 2Human Development, Nirmala Niketan College of Home Science; Psychology, Mumbai Univ; 1Nephrology, PD Hinduja Hospital, Mumbai, India.

Ethical Issues Related to Kidney Donation/Transplantation: Perspective of Indian Doctors

Richard S. Fernandes Almeida,1 Nirmala Almeida,1 Karen Almeida,1 Alan F. Almeida,2 1LifeSupporters Inst of Heath Sciences; 2Human Development, Nirmala Niketan College of Home Science; Psychology, Mumbai Univ; 1Nephrology, PD Hinduja Hospital, Mumbai, India.

**Background:** Dearth of kidneys for transplantation has provoked the need to evaluate new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation.

**Methods:** The sample consisted of 140 doctors from Mumbai (Age Range=21-80 years, M=38.1, SD=17.95, Males=44.3%, Females=55.7%). A questionnaire, presenting ethical issues related to kidney donation/transplantation, in an agree/disagree format with supporting reasons was employed. The research design was exploratory; data was analyzed quantitatively and qualitatively.

**Results:**

Preemptive Transplantation Is Associated with Improved Graft Survival: Results from the French Transplant Database

Mathilde Revist,1,2 Christian Comec,2 Jerome Haraamb,2 Christian Jacqueline,2 Pierre Merville,2 Lionel Couzi,2 Karen Leffondré,1 INSERM U897, Bordeaux School of Public Health, Bordeaux, France; 1Nephrology and Transplantation, Bordeaux Univ Hospital, Bordeaux, France; 2Agence de la Biomedecine, Paris, France.

**Background:** Kidney transplantation (KT) is the treatment of choice for end-stage renal disease. In France, preemptive kidney transplantation (PKT) should be considered when glomerular filtration rate is under 20 ml/min/1.73m² but European reports on the results of PKT are scarce. Our objective was to evaluate the impact of PKT on graft and patient survival.

**Methods:** We analyzed all first kidney-only transplants performed in adults in France between 2002 and 2012. A Cox multivariable model was used to study the impact of PKT on the hazard of graft failure defined as death, return to dialysis, or retransplantation, whichever came first.

**Results:** Between 2002 and 2012, 22 288 patients received a first KT, including 3112 (14%) who had a PKT. Mean recipient age at KT was 50 ± 13.4 years, 61% were men. Median follow-up was 4.7 years. In addition, 493 patients were recruited for the UK Renal Association (RA) and KDIGO. Cardiovascular risk management of all transplant patients in our region by comparing new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation.

**Results:**

- among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers.

Good Patient and Graft Survival in Recipients of Kidney Transplantation due to Diabetic Nephropathy  
Amjad E. El Agroudy. Internal Medicine Dept, College of Medicine and Medical Sciences, Arabian Gulf Univ, Manama, Bahrain. 

Background: Compared with non-diabetic subjects, patients with type 2 diabetes and end-stage renal disease (ESRD) have seldom been selected for renal transplantation. The aim of this study is to compare patient and graft outcome in kidney transplant patients with diabetes mellitus. 

Methods: We retrospectively studied 358 patients who underwent kidney transplantation between 1979 and 2014, including 88 with diabetic ESRD (DM group) (type 1, n = 8; type 2, n = 80) and 270 with non-diabetic ESRD (NDM group). Mean follow-up was 92 ± (1.389) months. 

Results: Mean age was higher in the DM group (52.8 ± 44.6 years; P < .0001), and there was no significant difference in recipient gender, donor age or donor source. At the end of follow-up, there was no difference between the groups in terms of blood pressure (DM 139 ± 16.7/81 ± 7.376 vs NDM 138 ± 15.7/82 ± 1.81 mmHG; P = 0.83 ± 0.80) and renal function (creatinine, 115±4.71 vs 133±4.80 μmol/L, P = 0.18; calculated creatinine clearance, 66±24 vs 68±42 ml/min/1.73 m², respectively, P = 0.9). In total, 26 patients had acute transplant rejections [8 patients with diabetes vs 18 patients without diabetes, P = 0.11]. There was no significant difference in post transplant surgical complications as wound dehiscence or infections. There was a significant high incidence of the urinary tract infection rate in DM group (17 vs 32 patients; P = 0.02). Four out of 22 patients died (18.2%) in the DM group and 10 out of 47 patients died (21.3%) in the NDM group died from cardiovascular disease (P = 0.17). The 1-, and 10-year patient survival rates in the DM and NDM groups were 97.5% vs 99% (ns), and 56.8% vs 58.8% (ns), respectively. The 1- and 10-year graft survival rates were 97.5% vs 70.7% (ns) and 58.9% vs 66.1% (ns), respectively. 

Conclusions: Renal transplantation in diabetic ESRD patients yields good results in terms of patient survival and complications, suggesting that renal transplantation can be performed in these patients and should become a more established treatment option. 

PUB660 
Impact of Pre-Transplant Peritoneal Dialysis Compared with Hemodialysis on the Incidence of Delayed Graft Function in Kidney Transplant Recipients with Lupus 
Gabriel Contreras, Javier Pagan, Antonio A. Armstrong, Jorge M. Diego, Ian Thomas, Patricia Marie Byers, Alberto J. Sabucedo, Jair Munoz Mendoza, David Roth. Univ of Miami Miller School of Medicine. 

Background: Delayed graft function (DGF) increases the risk of allograft failure in recipients of kidney transplants. 

Methods: In this study we assessed the impact of pre-transplant peritoneal dialysis (PD) compared with hemodialysis (HD) on the risk of DGF in patients with lupus using logistic regression models. 

Results: Three hundred-fifty three of 2513 (14 %) recipients transplanted between 3/22/1994 and 9/27/2006 with complete records in the United Network for Organ Sharing files had DGF. The incidence of DGF was lower in recipients who used PD (68.6±13.1%) compared with HD (285/1900 = 15%) prior to transplantation (P = 0.013). After adjusting for donor and recipient age, gender and race-ethnicity, type of donor, recipient education and insurance, time of dialysis prior to transplantation, panel reactive antibodies (PRA), human leukocyte antigen (HLA) mismatch, and ABO blood type compatibility, the lower risk for DGF associated with the use of PD compared with HD remained significant (Odds-ratio 0.70 [95% confidence interval 0.53-0.94]; P = 0.015). Donor age (1.01 [1.00-1.02] per 1 year), deceased donor transplantation (1.64 [2.59-9.12] living donor as reference), HLA mismatch (1.08 [1.01-1.15] per 1 antigen mismatch), and PRA (1.01 [1.00-1.01] per 1%)) were also independently associated with DGF. 

Conclusions: In lupus recipients of kidney transplants, the use of PD compared with HD is associated with lower risk of DGF after adjusting for important predictors.

Association Between Dipstick Proteinuria and Allograft Outcomes in Living Donor Kidney Transplant Recipients 
Joon-young Park, Joon Wook Choi, Chang Hyun Lee, Gang-Hyun Kim. Dept of Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea. 

Background: Proteinuria is one of the important factors suggestive of kidney function impairment. Previous epidemiologic studies had demonstrated that greater than trace amounts of protein on a casual urine dipstick may be an important predictor of long-term clinical outcomes in general population. In kidney transplant (KT) recipients, there were few data concerning it. 

Methods: We retrospectively analyzed 238 living donor KT recipients to investigate impact of dipstick proteinuria on allograft outcomes. All KT recipients were divided into 2 groups according to dipstick proteinuria: control group (n=190); negative; case group (n=48), ≥ trace. Cox’s proportional hazard model with time-dependent covariates was used to encompass compounding effect of covariates that change over time, including vintage and allograft survival time.

While cytomegalovirus (CMV) infection is associated with Guillain-Barré syndrome (GBS), the development of CMV disease shortly after transplantation was not expected. This vignette details a case of CMV disease in a renal transplant recipient, focusing on the clinical presentation, diagnosis, and management.

**Background:**

BK nephropathy (BKN) is a relevant cause of graft dysfunction in kidney transplantation. mTOR inhibitors (mTORi) have been suggested as the best immunosuppression in BKN. However, CMV-free therapy could increase the risk of rejection. Since 2009 in patients with BKVN we conducted a protocol discontinuing Mycophenolate and decreasing Tacrolimus (TAC) dose in association with mTORi, both with target levels of 5 ng/mL.

**Methods:**

From 2007 to 2013 we diagnosed 22 BKVN. Patients diagnosed since 2009 (n = 14, group 1) were treated beginning mTORi and decreasing TAC dose. The others 8 patients suffered significant reduction of immunosuppression (group 2). We analyze renal function, plasma quantitative BK PCR, antiHLA antibodies, reactions and dialysis mortality. We calculate follow-up.

**Results:**

22 patients were identified. The BKVN was diagnosed at 7 months after transplantation (range 2-55). The medium duration of follow-up was 53 months (685). Baseline characteristics and evolution are listed in table 1.

<td>Patients with negative plasma BK viral load at final follow-up</td>
<td>78.6% (11)</td>
</tr>
<tr>
<td>Acute rejection after BKVN</td>
<td>0%</td>
</tr>
</tbody>
</table>

Although group 1 had a greater immunologic risk and a higher plasma BK viral load at diagnosis, the renal function during follow-up was more favorable than patients from group 2. No rejection episodes were diagnosis in group 1. Only one patient in each group started chronic dialysis at the end of the follow-up (52 and 85 months after BKVN diagnosis).

**Conclusions:**

An immunosuppression regimen based in TAC and mTORi is an effective treatment for BKVN. This treatment reduces viral load and increases graft survival without increasing the rejection risk.

**PUB665**

A Rare Case of Guillain-Barré Syndrome Associated with Cytomegalovirus Disease in a Renal Transplant Patient

Jessica Bian, George P. Bayliss, Medicine, Rhode Island Hospital, Providence, RI.

**Background:**

While cytomegalovirus (CMV) infection is associated with Guillain-Barré syndrome (GBS) in the general population, there are few reports of GBS associated with CMV disease in the renal transplant patients. We describe the case of a renal transplant patient who developed GBS after treatment for documented CMV disease.

**Methods:**

The patient is a 62-year-old woman with ESRD from polycystic kidney disease status post deceased donor renal transplant (CMV donor positive/recipient seronegative) on tacrolimus and prednisone. She developed ascending motor weakness, sensory loss, and areflexia without progression to respiratory compromise, improving with IVIG therapy. She was started on treatment with CMV disease (serum CMV PCR 2200 copies; CSF CMV PCR undetectable) and prednisone. Fourteen days after stopping valgancyclovir, she presented with fevers, chills, and myalgias, consistent with GBS. She developed ascending motor weakness, sensory loss, and areflexia. CSF studies were notable for albuminocytologic dissociation. MRI brain showed T2-weighted hyperintensities, consistent with GBS. She was started on treatment with CMV disease (serum CMV PCR 2200 copies; CSF CMV PCR undetectable) and prednisone.

**Results:**

She returned 7 days later with compartment syndrome of her right arm due to deep venous thrombosis of her right subclavian, axillary, and brachial veins with associated hematoma requiring emergent fasciotomy and hematoma evacuation. This was attributed to recent IVIG therapy, as thromboses may occur even in the absence of other risk factors (US boxed warning). She was bridged to warfarin prior to discharge. Of note, she maintained excellent alloreactive function throughout this complicated course.

**Conclusions:**

This vignette details a case of CMV-associated GBS after renal transplantation. The case is notable for the development of CMV disease shortly after cessation of valgancyclovir prophylaxis in a CMV donor positive/recipient negative renal transplant despite only being on only being on a two-drug immunosuppressive regimen. This may support a longer course of CMV prophylaxis in donor positive/reipient negative renal transplants.

Clinical Significance of Pre-Transplant 25-Hydroxyvitamin D Levels on Acute Rejection and Infection in Kidney Transplant Recipients

Jessica Kiberd, 1
decision of Nephrology, Dalhousie Univ, Halifax, NS, Canada; 2Medicine, Div of Nephrology, Univ of Toronto, Toronto, ON, Canada; 3Dept of Surgery, Multi-Organ Transplant Program, Dalhousie Univ, Halifax, NS, Canada.

**Background:**

It is well known that vitamin D shows immune modulating effects. However, vitamin D levels in transplant serum 25(OH)D levels are independent predictor of acute rejection or infection in kidney transplant recipients.

**Methods:**

We included 174 kidney transplant recipients with low immunologic risk between 2011 and 2013. We measured 25(OH)D levels right before transplantation, and investigated whether the level of 25(OH)D predicts the development of acute rejection or infection in kidney transplant recipients.

**Results:**

During the first year after the KT, a total 27 cases of biopsy proven acute rejection was detected. 25(OH)D levels showed significant association with the development of acute rejection within the first year from KT. In the high tertile, the rate of acute rejection was 6.9 % (p=0.012). It was significantly lower incidence toward the high tertile. There was significant distinction between each tertile (low and second, p=0.032; second and high, p=0.002). For the prediction of infectious complications, after the 1 year predictive limits of 25(OH)D levels were dissipated. During the first year after KT, a total of 62 (47.5%) cases of infectious complications were detected. Most common causes were 23 (33.2%) cases of CMV and UTI respectively. 25(OH)D levels did not show significant association with either the overall or different types of infectious complications.

**Conclusions:**

Clinical transplant serum 25(OH)D levels are independent predictor of acute rejection after the first year from kidney transplantation. However, they were not associated with infectious episode.
Mammalian Target of Rapamycin Inhibitors Withdrawal in Kidney Transplant Recipients: Risk Factors and Related Transplant Outcomes

Lee-Moay Lim, Mei-Chuan Kuo, Hung-Tien Kuo, Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.

Background: With its antiproliferative and antineoplastic properties, Mammalian Target of Rapamycin Inhibitors (MTORi) potentially have important long-term therapeutic consideration in kidney transplantation. Treatment cessation frequently occurs following its unique adverse effects. The objective of this study was to investigate the risk factors for MTORi withdrawal and its impacts on transplant outcomes.

Methods: This retrospective observational study consisted of kidney transplant recipients followed up from January 1999 till May 2015. We examined the risk factor for MTORi withdrawal using multivariate logistic regression analysis. The impacts of MTORi withdrawal on transplant outcomes were analyzed using multivariate Cox regression and logistic regression. P<0.05 was considered as statistically significant.

Results: A total of 111 kidney transplant recipients who received MTORi treatments were included, with 46 patients withdrew (41.0%). The risk factors for MTORi withdrawal included initial proteinuria (adjusted OR=4.61, P=0.007), higher initial serum creatinine (per 1mg/dl increment, adjusted OR=2.73, P=0.035), and glomerulonephritis as primary renal disease (adjusted OR=5.00, P=0.035). MTORi withdrawal was associated with an increased risk of graft failure (adjusted HR=3.79, P=0.027), but not with patient survival (adjusted HR=0.61, P=0.595).

Conclusions: MTORi withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for MTORi withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for MTORi conversion in order to optimize transplantation outcomes.

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Cohort

Jee Eun Park, Do Hee Kim, Hye Ryoun Jung, Jun Eun Lee, Da Joong Kim, Yoon-Goo Kim, Ha Young Oh, Wooseong Huh, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.

Background: The use of steroid withdrawal protocols after kidney transplantation has been increasing because of well-known adverse effects of steroids and the introduction of new effective immunosuppressants. Long-term efficacy and safety of tacrolimus plus mycophenolate mofetil (TAC) group compared with cyclosporine A plus MMF (Csa group) for 10 years were analyzed in renal transplantation patients with low immunologic risk who underwent steroid withdrawal at 6 months after transplantation.

Methods: Overall 10-year follow-up data of patients who underwent their first living-donor renal transplantation at Samsung Medical Center between September 2000 and August 2003 were retrospectively analyzed. Patients were randomized to CsA or TAC groups and underwent steroid withdrawal at 6 months after renal transplantation. End points were patient and graft survival, and the incidence of acute rejection and post-transplant de-novo comorbidity such as diabetes mellitus.

Results: A total of 117 patients who successfully discontinued steroid treatment were included (55 in Csa group vs. 62 in TAC group). The 10-year patient survival was 96.2% in the Csa group and 98.4% (61/62) in the TAC group (p=0.495). The 10-year graft survival rate did not differ between groups (81.3% in Csa vs 91.2% in TAC; p=0.412). The cumulative incidence of acute rejection for 10 years after transplantation was 24.5% and 15.6% in the Csa and TAC groups, respectively (p=0.201). The incidence of post-transplantation diabetes mellitus was higher in the Csa group compared to the Csa group (10.0% vs 23.3%, respectively; p=0.046).

Conclusions: Long-term graft and patient survival, and the incidence of acute rejection were similar between CsA- and TAC-based regimens combined with MMF in low immunologic risk patients who underwent steroid withdrawal 6 months after kidney transplantation.

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Cohort

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: 10 CV events occurred in the overall group, and 7 events in the post KT bacterial group, and 3 events in the post KT viral group. All affected CV events of these group were diabetes, high body mass index (BMI) and high baPWV. Overall arterial stiffness measured by baPWV after KT showed significant improvement (1417.5 ± 234.5 cm/s) compared to those of before KT (1503.5 ± 252.2 cm/s) (p=0.05 vs after KT).55 out of 79 patients (69.6%) showed improvement of baPWV after KT, but 24 patients did not. Between two groups, improvement group showed higher pre-transplant baPWV than no-improvement group (1561.0 ± 263.9 vs. 1371.6 ± 177.1), and multivariate analysis revealed that gender and BMI, degree of decrement of calcium level were an independent risk factor of change of baPWV.

Conclusions: We could expect CV event risk in KT recipients by diabetes, BMI and baPWV, and these were very strong prediction marker of CV event. Arterial stiffness in ESRD patients improves after transplantation, and lower BMI, the amount of calcium decreased, gender affected the improvement of baPWV. PUB673

The Correlation of Donor:Recipient Body-Mass Index (BMI) Ratio and 6-Month Post-Transplant Kidney Function in Known End-Stage Renal Disease (ESRD) Patients

Joseph Justin Hipolito Regaldado, Internal Medicine, Cardinal Santos Medical Centre (CSMC), San Juan, Metro Manila, Philippines.

Background: Kidney Transplant (KT) is the preferred treatment for ESRD. The challenge rests in finding appropriate donors. Donor-recipient size mismatch was shown to correspond to donor-recipient nephron supply mismatch, affecting prognosis. Matching nephron supply to recipient needs was proposed to improve outcomes. Patients with a higher BMI relative to their donors were shown to have poorer post-KT graft function. Determining whether measures such as BMI are valid predictors of outcomes is a legitimate area of study. This research sought to determine the association and correlation between Donor-Recipient BMI Ratio and the 6-month post-KT creatine (crea).

Methods: A review of patients who underwent KT in 2005-2014 at the CSMC was done. Inclusion criteria were Filipinos aged 18 years and above with a graft, coming from a Living Donor, functioning for at least 6 months post-KT (25 Donor-Recipient pairs). Association using Chi-Square and correlation using Multiple Regression analysis between Donor-Recipient BMI and renal function based on 6 months post-KT crea were determined.

Results: Data showed no statistically significant association (p=0.64) and correlation (p=0.77) between Donor-Recipient BMI ratio and post-KT crea. Statistically significant correlations (p<0.10) were noted between the post-KT crea and the recipient and donor BMI. For every 1.00-point increase in post-KT crea per 1 point increase in the donor BMI, and a 13.51umol/L decrease in post-KT crea per 1 point increase in recipient BMI.

Conclusions: The data support two schools of thought on donor-recipient selection in improving outcomes. First, recipients are to lose weight to improve BMI before KT due to the increased risk of graft damage from hyperfiltration and lipotoxicity. Second, donors with larger BMI’s are better due to a higher nephron reserve. It could be surmised from the study that the donor and recipient BMI’s influence the 6-month post-KT crea. The appropriate mathematical instrument defining the relationship between these measures predicting KT outcomes more accurately, however, is yet to be universally established.

PUB674

Incidence of Malignancies in Kidney Transplant Patients – Report from Eastern Province of Saudi Arabia

Abdul Raazek Amir,1 Nephrology, Internal Medicine, Johns Hopkins Aramco Healthcare, Dhahran, Eastern, Saudi Arabia; 2Internal Medicine, Univ of Danmann, Danmann, Eastern, Saudi Arabia.

Background: Renal transplant patients have a higher incidence of malignancies due to the use of immunosuppressive medications and concomitant infections.

Methods: Based on the follow up of a single center in Saudi Arabia, the incidence of malignancies patients who underwent kidney transplantation was analyzed.

Results: During the 15 years study period, a total of 221 patients underwent renal transplantation. Eleven patients developed post-transplant malignancies with an average incidence of 4.9%. Two patients had Kaposi sarcoma (0.9%) and two developed Non-Hodgkin lymphoma (0.9%). One case was reported to have transitional cell carcinoma of the bladder (0.45%), one had breast cancer (0.45%), one had cervical cancer (0.45%), one developed angiosarcoma (0.45%), and one had hepatocellular carcinoma (0.45%). In addition, two patients developed renal cell carcinoma, one in the native kidney (0.45%), and the other in the transplanted kidney (0.45%). The duration to cancer development ranged from 6-120 months. Mortality rate in renal transplant patients with cancer was higher (55%) than those who did not develop cancer. Risk factors that determined cancer development included patient age, gender, duration of the transplantation and type of immunosuppression. Type of transplant was not found to be a determining factor of cancer development.

Conclusions: The incidence of malignancies in post renal transplant patients in the Kingdom of Saudi Arabia is evidently comparable to that reported in literature. In addition, the data highlights the importance of long term close follow up of renal transplant patients.
seen more in non-desensitized patients at 3 months, but significance was not sustained after 3 months (Table). The leukopenia effect was not significant when adjusted for steroid. There was no difference in eGFR in either group, however mean eGFR was higher in those desensitized. Incidence of rejection was very low in both groups (5% vs 8%). When living donor recipients from both groups were compared, the eGFR and leukopenia effect was similar in both groups, and there was no significant difference in BK Viremia.

Conclusions: Desensitization with IV Ig appears to be safe and effective. The lower incidence of leukopenia in desensitized group can be explained by greater use of steroids.

PUB678

Results of Chinese Renal Transplant Recipients with Post-Transplant Malignancies Lihui Ou, Hong Jiang, Jianghua Chen. The Kidney Disease Center, The First Affiliated Hospital, Medical College, Zhejiang Univ, Hangzhou, Zhejiang, China.

Background: Malignancies are a severe complication of immunosuppressive therapy among renal transplant recipients, representing an important cause of long-term morbidity and mortality.

Methods: A retrospective study of 2700 recipients who underwent renal transplantation between July 1977 and July 2013 was carried out. 51 patients developed the following malignancies at a mean of 55.2 months (range = 1–207) after kidney transplantation. According to the regimen of immunosuppressive agents, all the recipients occurred malignancies were divided into azathioprine group (Aza group, n = 21) and mycophenolate mofetil group (MMF group, n = 30). The recipient age, gender, interval from renal transplantation to tumor development, long term survival of patient and graft and the ratio of converting to rapamycin of patients were made a comparison in detail between two groups.

Results: 29 patients survived without a recurrence including 28 with graft function (Survival group, n=29), and 22 patients died of malignancies including 21 with graft function (Death group, n=22). In the survival group, only one patient lost the graft after 26 months after immunosuppressant adjustment due to chronic rejection. Renal graft function remained stable in all other patients from diagnosis throughout follow-up. Moreover, 10 patients in the survival group were switched from calcineurin inhibitor-based immunosuppression to rapamycin after the diagnoses of malignancy, otherwise no patient in death group switched to rapamycin. At a mean follow-up of 34.0 months (range: 4–74), all the 10 patients are cancer-free and survived with functional graft. The incidence of death was similar in the Aza group and MMF group.

Conclusions: Our results demonstrate that the incidence of malignancy in renal allograft recipients is much higher than normal population, closely related to the long term use of immunosuppressant. Treating cancer thoroughly and maintaining the function of the transplanted kidney can decrease the risk of death with functional graft. Rapamycin-based immunosuppression blocks the recurrence of nonmetastatic tumors.

PUB679

Background: Basiliximab is widely used in clinical practice for induction therapy of renal transplant recipients, expecting to reduce the incidence of acute rejection and improved graft function without increasing adverse events. We evaluate the impact of induction therapy using Basiliximab on relevant clinical outcomes: graft and patient survival, incidence of acute rejection (AR) and incidence of infectious or malignancy complications.

Methods: This retrospective study included all renal allograft recipients who were transplanted between January 2010 and April 2014 and who received Basiliximab as induction therapy. We collected the baseline characteristic of recipients, type of donor, donor’s age, HLA matches and immunosuppression at the time of transplantation. The clinical outcomes were evaluated at the first year of transplantation and include: AR incidence, infectious or malignancy complications, serum creatinine and estimated glomerular filtration rate (eGFR) using the 4-variable MDRD formula, as well as graft and recipient survivals.

Results: The demographic characteristics of recipients and donors are in Table 1. Among 662 renal transplant recipients including in this study, only 10.6% (n=70) experienced AR during the first year follow up. The incidence of infectious complications in the first year after transplantation was 32.3%, mostly urinary tract infection (82%). No episode of malignancy was reported. Graft and patient survival rates were 96.9% and 98.5% respectively.

Conclusions: Our findings support previous studies, with similar incidence of AR episodes during the first year, and less incidence of infectious and malignant complications, similar patient and graft survivals at 1 year follow up. We can conclude that basiliximab is associated with excellent graft and patient survival and low rates of AR episodes.

PUB680

Background: A successful kidney transplant improves the quality of life and reduces the risk of death in most patients when compared with staying on dialysis, however, the survival of transplant patients is lower than general population patients of the same age. In our analysis we calculated, the causes of death and characteristics of deceased patients were identified.

Methods: This was a retrospective observational study that included all kidney transplant patients between January 1, 2010 to April 30, 2014, at HE-CMNO, IMSS, Guadalajara, Jalisco, Mexico. The follow-up time was one year. Mortality was calculated, the causes of death and characteristics of deceased patients were identified.

Results: During this time 1,047 transplants were performed. 30 deaths (2.86%) were recorded during the first year after transplantation. Regarding the type of donor: 12/102 (11.76%) patients with brain death donor died, and 18/945 (1.9%) patients with living donor died. The causes of death were 20 (66.6%) infections, 6 (20%) cardiovascular events, 2 (6.6%) related to graft rejection event and 2 (6.6%) unknown. The average time of transplantation to death was 2 months 27.4 days with a SD of ± 2.9 months 21.9 days; 70% of deaths occurred in the first 3 months after transplantation. The average time in dialysis was 5 years, with a SD ± 3 years 4.4 months; 83.3% of patients had more than two years on dialysis. Most patients who died had thymoglobulin induction, but patients were older, had more comorbidities, more time on dialysis, increased immunological risk and they had a brain death donor. Finally, 76.7% of patients who died had functional graft.

Conclusions: In our hospital, 1 year mortality postkidney transplantation is low, but there are many individual patient factors that contribute to the risk of mortality increases significantly in them and there we could intervene.

PUB681

Granzyme B Level and Acute Kidney Allograft Rejection: Impact on One Year Survival in Mexican Population Perlà Edith Simancas Ruiz,1 Caridad Aurea Leal,2 Benjamin Gomez-Navarro.1 1Nephrology and Transplant, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; 2Surgical Research, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.

Background: Exposure to insufficient levels or discontinuation of immunosuppressants often increases the risk of rejection. Granzyme B is the most useful test to monitor graft function. However, it is a poor predictor of rejection and often raises only after significant damage has occurred to the allograft. Granzyme B has been tested as a marker of acute rejection, with high specificity and sensitivity in different types of sample and has also enabled the identification of subclinical
rejection. The elevation of both the mRNA and protein has been associated with a worse prognosis.  

Methods: Kidney recipients transplanted between January 2008 and March 2009. Donors (n=38) and healthy subjects (n=6) were also included. The relation of granzyme B levels determined by ELISA with graft function and rejection was studied.

Granulocyte levels in patients (n=43) was 12.5 pg/mL while the reference group (n=6) was 1.5 pg/mL (p<0.001). Comparison between patients with rejection (n=14) and non-rejection (n=20) was not statistically significant, nor the development of interstitial fibrosis year. The correlation between creatinine, GFT and granzyme level showed a trend to significance (n=66, r=0.30, p=0.06).  

Conclusions: The level of granzyme B was not associated with one year post-transplant rejection. However immune system activation is suggested by the higher level of granulocyte in patients vs control group. Continuous analysis of patients.

Prediction of Recipients Survival in Deceased Donor Kidney Transplant Using Korean Network for Organ Sharing Database  

Kyung Don Yoo,1 Junhyung Noh,2 Hajeong Lee,3 Dong Ki Kim,3 Chun Soo Lim,3 Young hoon Kim,1 Yon Su Kim,1 Gunhee Kim,3 Jung Pyo Lee.1  

1Seoul National Univ College of Medicine; 2Seoul National Univ College of Engineering; 3Univ of Ulsan.  

Background: The Korean Network for Organ Sharing (KONOS) was founded in 2000 for organ allocation in Korea. It has been allowed medical doctors and researchers to fully access the national population-based raw data about KT recipients. We propose a novel prediction approach of recipient survival based on machine learning techniques using KONOS data.  

Methods: Our dataset is collected from 2000 to 2014 by the KONOS. We design a novel prediction model that uses all of the follow-up recipients’ data including censored ones, on which estimated death risks are weighted accordingly. We compare this approach with the baseline model that uses only uncensored data by the CART (Classification And Regression Trees) modeling.  

Results: We analyze 5,430 recipients’ records with more than 10 attributes, among which we use 15 independent attributes to learn our models. The proposed weighted algorithm leads a better performance when predicting survival rates of transplant recipients within 6 years, but fails to show any significant difference from the baseline for those more than 7 years after transplantation. Using the decision-tree models, we find that the inotropic agent usage of donor management is the most important predictor, which estimates in 51.3% of 10-year mortality. In the age ≥51.5 group, non-diabetes recipients, waiting period < 4years, and donor age < 23.5 years show significant associations with better 10YRS. The results are consistent with our hypothesis that poor donor status, recipients’ longer waiting time and advanced age are associated with poor prognosis.

PUB685

Perforin Expression in Renal Allograft Biopsies  

Michele T. Rooney,1 Ping L. Zhang,2 Dilip Samarapungavan,3 Randolph Alexander Henningar.3  

1Incyte Diagnostics, Spokane, WA; 2Anatomic Pathology, William Beaumont Hospitals, Royal Oak, MI; 3Nephrology, William Beaumont Hospitals, Royal Oak, MI; 4Nephropathology Associates, Little Rock, AR.  

Background: Perforin is a cytotoxic protein in effector lymphocytes that facilitates targeted cell killing and it has an established role in allograft rejection. A diagnostic value has not been delineated. We examined perforin expression in renal transplant biopsies by immunohistochemistry (IHC) and found that positive lymphocytes are confined largely to the microvasculature in cases of active cellular rejection (ACR). The goal of this study is to investigate whether perforin IHC is a useful metric in identifying and classifying acute rejection in renal transplant biopsies.  

Methods: Renal transplant biopsies accessioned over a one-year period were selected to include cases showing no acute rejection, acute tubular injury, BK nephritis, ACR types 1 and 2, and C4d+ antibody-mediated rejection (AMR), according to the 2013 revised Banff Classification. IHC using a mouse monoclonal anti-perforin antibody was performed on each case. Perforin positive cells/10 high power (400X) fields (hpf) were counted from slides identified by number only.  

Results: Most rejection-negative cases had < 10 perforin-positive cells/10 hpf. Biopsies showing type 1 ACR, excluding one outlier, did not exhibit a significant increase in perforin-positive cells relative to rejection-negative cases. In contrast, cases of type 1B and 2 ACR, and C4d+ AMR displayed significantly increased perforin-positive cells (p < 0.0001) with most showing > 40/10 hpf. Cases of AMR contained the highest number of perforin-positive cells (p < 0.052). Cases of BK nephritis varied widely from < 10 to > 50/10 hpf. 2 of 3 cases with > 50 had a recent history of ACR developing BK infection upon increasing immunosuppression, raising the possibility of coexisting BK and rejection.  

Conclusions: Further study is needed, but our data suggests that increased numbers of perforin-positive lymphocytes correlate with more aggressive forms of rejection, and that perforin IHC may be a useful ancillary test for acute allograft rejection of type 1B or higher.

PUB638

Impact of Hemoglobin Concentration on Mortality After Renal Transplantation  

Vitoria C. Vilela,1 Marcos A. Meniconi,1 J. Medina-Pestana,1 Miguel Cendoroglo Neto,2 Miguel A Goes,1  

1Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil; 2Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.  

Background: Kidney transplant recipients have chronic anemia, irrespective of the time from transplantation. Objective: To assess the impact of hemoglobin concentration on mortality in renal transplantation.  

Methods: A total of 233 patients who underwent renal allograft biopsy between January 2010 to January 2014, for graft dysfunction, proteinuria or active urinary sediments. All protocol biopsies were excluded from the study. Graft biopsies were evaluated by light microscopy and indirect immunofluorescence study. Out of 285 graft biopsy biopsies 242 were taken into study. Biopsies showing evidences of glomerulonephritis were further evaluated for incidence of individual types of glomerulonephritisand their outcome at the end of one year post diagnosis.  

Results: Based on biopsy findings among 242 renal allograft biopsies taken in study 42(17.35%) had post-transplant glomerulonephritis. Further the incidence of individual types of glomerulonephritisand their outcome at the end of one year post diagnosis.

Conclusions: In this study, we show that the proposed machine learning based models with weights of estimated-death risks can present more accurate and flexible than baseline models for predicting in long-term survival rates of kidney transplant recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Due to TS were identified. Incidence rates and standardized incidence ratios (SIR) were computed using Poisson distribution and standardized using 2001-2002 as reference. Hazards ratios adjusting for age, sex, race and ethnicity (AHR) were calculated for outcomes.

Results: In 2001-2002, the overall incidence rate of ESRD due to TS was 1 per 10 million person years (MPY) and the SIR remained largely unchanged over the observation period. Of those with ESRD due to TS were more likely to be < 40 years (23.2% vs 9.2%), white ethnicity (81.5% vs 65.5%), and lack diabetes (81.2% vs 48.1%). Compared to those with ESRD due to other causes, odds ratios adjusted for age, sex, race and ethnicity (AOR) were highest for females (1.83) and those with eGFR > 15mL/min/1.73. Factors associated with ESRD included age 40-64 years (0.29), age ≥ 65 years (0.25), and black race (0.33). Over the study period, 53.7% of TS patients died, 27.3% were listed and 10.6% were transplanted. The AHR for outcomes demonstrated those < 40 years of age were more likely to be listed for renal transplant, receive renal transplant and survive.

Conclusions: The incidence of ESRD due to TS remained largely unchanged from 2001 through 2010. Our results indicated gender and racial differences in the odds of ESRD due to TS.

PUB689

The Impact of Hepatitis C Virus Infection on the Clinical Course, Short-term and Long-term Outcome in Renal Transplant Recipients – A Retrospective Study

Pratik Das, Rohit Rungra, Santosh Kumar. Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.

Background: Hepatitis C infection is common in patients of end stage renal disease with increased morbidity and mortality post-transplant. The aim of the study was to find out the impact of HCV infection on graft and patient outcome and compare it with the non HCV infected post-transplant cohort.

Methods: We retrospectively analysed patient and graft survival of HCV infected (after virological remission) post renal transplant patients from 2008 to 2014 with a median follow up of 24 months and compared them with our HCV negative statistically matched cohort.

Results: Outcome analysis was done at 6, 12, 18 and 24 months in terms of liver dysfunction, acute rejections, infections, hospitalization and death. Results were further tabulated as shown.

Conclusions: HCV infected end stage renal disease patients may undergo renal transplantation safely after virological remission and outcome is not different from other renal transplant recipients.

PUB690

Patient and Graft Survival in Pediatric Kidney Transplantation: A Single-Center Experience According to Transplant Era

Marta Monteverde, Juan Carlos Lopez,1 Gerardo Nyman,1 Liliana Briones. 1Nephrology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina; 2Urology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina.

Background: Improvements in the management of kidney transplantation has improved in the last 20 years. However the long term results in terms of graft survival and morbidity still require more research.

Methods: We evaluated 744 pediatric renal transplants (RTX), 551 with deceased donor (DD) and 222 with living-related donor (LRD), between 1988-2015. We divided this time into 2 periods: 1988-2000 and 2001-2015. Patient and graft survival were calculated for each period for LD and DD recipient. We analyzed causes of mortality, causes of graft failure and risk factors for graft loss. Mean age at RTX was 3.6 y (r: 0.5-19.5). Mean time of follow-up was 54.5 months (IQR: 22.4-90.1) months.

Results: Patient and graft survival for DD have significantly increased in the recent era (p=0.0002; p=0.0013 resp). Chronic rejection was the first cause of graft loss in both eras (43.9% vs 61.1%). Vascular thrombosis decreased (14.9% vs 5.5%; p=0.001), and also Death with a Functioning Graft (15.8% vs 8.3%; p=0.001). Acute rejection during the first 30 days post RTX + relapse of the original disease increased (0% vs 7.1%). First cause of death in both eras was bacterial infection (77% vs 66%). No death due to PFTD were seen in 2001-2015. Independent Risk factors for graft loss for DD recipients were: FSGS

VARIABLES
HCV positive patients
HCV negative patients

Patient(s) 51
2. Induction with ATG 26(50%) 700(50.68%)
3. Tacrolimus 34(66.67%) 1196(86.9%) <0.05
4. Cyclosporin 17(33.3%) 185(13.1%) <0.05
5. Infection 05(9.8%) 117(8.5%) NS
6. Abnormal LFT 08(15.6%) NA
7. 1 year patient survival 96.1% 97% NS
8. 2 year patient survival 92% 93.2% NS
9. Hospitalization 24 episodes 621 episodes NS

Results were found not to be statistically different from non HCV infected renal allograft recipients.

Conclusions: HCV infected end stage renal disease patients may undergo renal transplantation safely after virological remission and outcome is not different from other renal transplant recipients.

PUB686

Is It Safe to Transplant Sensitized Patients? Analysis of 1,002 Consecutive Kidney Transplants

Anna Rita Aguirre, Patricia Soares Souza, Fabiana Agena, Daisa R.S. David, Flavio Jota Paula, Elias David Neto, Maria Cristina R. Castro. Renal Transplant Service, Hospital das Clinicas - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background: From 2009-13, 24% of kidney recipients in our center had antiHLA antibodies (aHLA abs). Obj: To compare the risks of rejection, patient and graft survival when transplant recipients were performed with or without aHLA abs and with or without DSAs. To compare morbidity between patients transplanted with aHLA abs to mortality in the waiting list.

Methods: Retrospective study, which included all isolated kidney Tx in patients older than 18 and performed between 2009 and 2015. We analysed the incidence of TCMBR and ABMR in the first year after Tx. Median follow-up time was 32mo. Graft and patient survival were evaluated by Kaplan Meyer estimates.

Results: In 741 Tx (74%), no aHLA abs were detected (AHR=0) and 261(26%) had PrA+ with or without DSAs (AHR=0). Tx with PrA+ and DSA(6.6%, 129(86.6%; 0.11%) did not have rejection, 16(11%) had TCMBR and 7(4.7%) had ABMR. In Tx with PrA-0 with DSA(91, 56:10.2%) did not have rejection, 7(5.5%) had TCMBR and 3(33.4%) had ABMR. ABMR was more frequent when there was a DSA(p=0.001).

Graft survival did not differ according to ARP or DSA in groups with no rejection. TCMBR and ABMR. There were more graft losses in the whole sample when a DSA was detected(p<0.0001) or when Rama occurred, in comparison to no rejection(p=0.001) and TCMBR(p 0.0143). Regarding patient survival, there was no influence of aHLA abs and DSAs, nor influence of TCMBR or ABMR. In recipients with aHLA abs, mortality was 11% in 32mo, or 4.12% per year, smaller than in the waiting list in our state, which was 5.6% in the same period.

Conclusions: There was no difference in patient survival after 32 mo between patients with or without aHLA abs or DSAs, or even between patients with or without ABM.

However, there were more graft losses in recipients with aHLA abs and with ABM.

Mortality after Tx among sensitized patients hasn’t been larger than in the waiting list. We conclude that transplanting the sensitized patient does not increase mortality risk.
as cause of ESRD (HR: 3.1; CI 95%: 2.4-4.8), DGF (HR: 2.8; CI 95%: 2.4-4.8) and Receiving no induction therapy (HR: 2.1; CI 95%: 1.3-3.5). For the recipients: DGF (HR: 5.2; CI 95%: 2.9-9.3) and Age at RTX = 12y (HR: 2.2; CI; 0.9-1.3-2.9).

Conclusions: Patient and graft survival has significantly improved for DD in the recent era. Chronic rejection remains a major cause of graft failure. No death from malignancy were observed in the recent era.

PUB691
Impact of Rituximab Induction on Short Term Outcome of Kidney Transplant Recipients

Background: Rituximab (rATG) induction has proven efficacy. However, it remains unclear what is the best dosing regimen.

Methods: From August 8th, 2014 immunosuppression protocol was changed at our institution to induction with single dose thymoglobulin to all deceased donor kidney transplant recipients. This retrospective study evaluated the incidence of acute rejection (AR) in deceased kidney transplant recipients with delayed donor graft function (DDGF) before and after the adoption of a new induction protocol.

Results: Pre-protocol Group 1 - 96 patients transplanted between 12/31/2013 and 08/08/2014: Standard criteria deceased donors (SCD) (without induction, tacrolimus 0.1-0.3 mg/kg or prednisone and methylprednisolone) or expanded criteria (EC) (induction with thymoglobulin 6mg / kg, tacrolimus 0.05 mg/Kg/dose, prednisone and mycophenolate sodium) versus Group 2 (new protocol), 87 patients transplanted between 08/08/2014 and 03/31/2015, subdivided in the same way, receiving the same maintenance therapy and thymoglobulin induction 3mg/kg single dose. In both groups, the population was overwhelmingly male (63% vs. 55%), young (47 vs 46 years) and low immunological risk. The incidence of AR in G1 vs. G2, SCD subgroup was 13%, vs. 4% (p = 0.09). When compared ECD recipients, the incidence of rejection was similar between G1 vs. G2 (15% vs. 15%, respectively), respectively. Inclusions: In the SCD kidney transplant recipients, the incidence of AR was numerically lower in the group that received induction with single dose rATG 3mg/kg and induction with a reduced dose of rATG was not inferior in the ECD group.

PUB694
Cardiovascular Changes After Kidney Donation
Fernando H. Marquis, Nefrologia y Transplante Renal, Hospital General de Agudos Cosme Argerich, CABA, Buenos Aires, Argentina.

Background: The aim of our study is to investigate the changes in cardiovascular structure and endothelial function after donation in kidney donors.

Methods: Fourteen living kidney donors (both genders) without history of kidney disease, diabetes, cardiovascular events or hypertension, who participated in the donor screening protocol with subsequent donation, were included. Office blood pressure (OBP), ambulatory blood pressure monitoring (ABPM), left ventricular mass index (LVMI), arterial stiffness (AS) and endothelial function (EF) were measured before and one year after the donation. AS was assessed from the left index finger using a digital photoplethysmograph (Pulse Trace; Micro Medical), that uses a simplified analysis of the digital volume pulse stiffness (AS) and endothelial function (EF) were measured before and one year after the donation. AS was assessed from the left index finger using a digital photoplethysmograph (Pulse Trace; Micro Medical), that uses a simplified analysis of the digital volume pulse.

Results: Reduced nephron mass (0.7; 0.9, P<0.001), mean BMI (27.1 ± 4, P<0.001), mean SBP (127 ± 8, P<0.001), mean DBP (80 ± 10, P<0.001), mean OBP (88.6 ± 7, P<0.001), mean LVMI (76.3 ± 13.7, P=0.004), mean OBP (90 ± 10, P=0.004), mean DBP (61.4 ± 4, P=0.004), mean OBP (71 ± 9, P=0.004), mean DBP (41 ± 10, P=0.004). The isolated estimated glomerular filtration rate levels by MDRD 4 formula at 1 year (57.4 ± 12ml/min/1.73 m², P<0.001) were significantly increased as compared to baseline (26.4 ± 3; 85 (76, 92) and 0.78 (0.74, 0.97), respectively). The estimated glomerular filtration rate levels by MDRD 4 formula at 1 year (57.4 ± 12ml/min/1.73 m², P<0.001) were significantly decreased as compared to baseline (82.8 ± 10 ml/min/1.73 m²). We did not find significantly differences in mean 24hs ABPM (84.8 ± 15 mmHg, P=0.940), mean LVMII (6.6 ± 1.7 mm, P=0.727), mean AS (7.7 ± 2.3 m/s, P=0.210) and median EF (5.1% ± 18.3, P=0.374) compared to baseline (85 ± 7 mmHg. 99.8 ± 31 ml/g; 9.03 ± 2.3 m/s and 10% ± 1.6, 34.6), respectively.

Conclusions: Our study demonstrated that after an year, reduced nephron mass because of kidney donation was not associated with changes in cardiovascular structure and endothelial function.

Funding: Government Support - Non-U.S.
viral, fungal and bacterial cultures. Cytologic and serologic studies were unremarkable. Flow cytometry analysis of the spinal fluid showed no evidence of lymphoma. A brain biopsy was performed revealing non-specific perivascular lymphoplasmocytic infiltrate with no evidence of lymphoma or infection. Additionally, myelain stain was positive ruling out demyelinating disease. Our patient was started on high-dose steroids with remarkable improvement of his symptoms. Diagnosis of CLIPPERS was made.

Conclusions: CLIPPERS is a rare and poorly recognized CNS inflammatory condition. To our knowledge, this is the first case reported after renal transplantation. More studies are needed to determine the pathophysiology of CLIPPERS in immunosuppressed patients and whether it could represent a pre-malignant state. Duration of treatment and follow up is yet to be determined. In this case, treatment with steroids has led to symptomatic improvement over a month and close follow-up continues.

PUB696
The Impact of Post-Transplant Hemoglobin and Creatinine Level on Renal Allograft Survival
Luis Fernando Christiani, Fernanda Paula Feres Rios Da Costa, Ana Flavia Baldoni, Alicia Imada, Kelly Rodrigues, Maria Izabel Neves de Holanda Barbosa, Géssika Marcelo Gomes, Cláudia Fagundes. Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.

Background: Anemia is a common finding after kidney transplantation. The roll and the prevalence of Posttransplantation anemia (PTA) in predicting renal allograft outcomes still vary between different studies. In this study, we aim to assess the prevalence of anemia at one and six months post transplant and its correlation with 1 year renal allograft survival.

Methods: Anemia was defined by an absolute level of hemoglobin less than 11 g/dL. Hemoglobin and creatinine level were assessed at one, six and twelve-month after transplantation.

Results: We included 261 consecutive patients who underwent renal transplant from January/2010 to June/2012. Mean recipient age was 42±10 years and 56% were male. Prevalence of anemia was 42% at 1 month, 16% at 6 months and 9% at 12 months. Hemoglobin and creatinine level at first month of transplantation were 11.2±1.0 and 56% were >2.25 mg/dL. Hemoglobin and creatinine level were assessed at one, six and twelve-month after transplantation.

Results: We included 261 consecutive patients who underwent renal transplant from January/2010 to June/2012. Mean recipient age was 42±10 years and 56% were male. Prevalence of anemia was 42% at 1 month, 16% at 6 months and 9% at 12 months. Hemoglobin and creatinine level at first month of transplantation were 11.2±1.0 and 56% were >2.25 mg/dL. Hemoglobin and creatinine level were independently associated with poor graft survival at 12 months. The best cut-off selected by receiver operating characteristic curve analysis was 10.8 g/dL for Hemoglobin level, (AUROC 0.74 (0.63-0.86), p: 0.001), and 2.25 mg/dL, for serum creatinine (AUROC 0.77 (0.62-0.91), p: 0.001). Combining the best points of those two variables could identify patients at risk of graft loss. Patients who met both criteria ( Hb < 10.8 g/dL and Creatinine ≥2.25 mg/dL) had 59% graft survival at 1-year, whereas allograft survival was 98.5% for patients without any criteria ( Hb ≥10.8 g/dL and Creatinine < 2.25 mg/dL).

Conclusions: Prevalence of anemia was high in the first month after transplant and persisted in a substantial proportion of functioning kidney transplant recipients. Early (1-month) hemoglobin and creatinine level can predict 1-year graft survival.

PUB697
Examining Adverse Weight Gain After Kidney Transplantation
Birah Workeh,
1 Linda W. Moore,
2 William E. Mitchell.
3 Medicine/Nephrology, Baylor College of Medicine, Houston, TX; 4Transplant Medicine, Houston Methodist Hospital, Houston, TX.

Background: Between 15,000-17,000 patients with end-stage renal disease (ESRD) receive a kidney transplant in the United States every year. Among the most consequential complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent complications to these patients are adverse weight gain and the development of diabetes. The impact of post-transplant reveals there is significant gain in adipose weight gain in all cases.

Methods: We are conducting a longitudinal study in ESRD patients anticipating receiving a live donor kidney transplant. We are studying subjects before kidney transplant, at 12 weeks and 1 year after they have received living donor kidney transplant to measure changes body composition and other indices. Body composition was characterized by DEXA as well as total body potassium (a gold standard measure of muscle mass).

Results: Results from 5 subjects who completed baseline assessment and 3 months post-transplant reveals there is significant gain in adipose weight gain in all cases.

Additionally, we discovered there is significant loss in skeletal muscle mass (p=0.032) measured by total body potassium.

Conclusions: We have not studied enough to conclude whether changes in energy expenditure and diet contribute to adipose weight gain and whether there is acute nitrogen (muscle) loss peroperatively. Ultimately, methods to identify patients at high risk for adverse weight gain and related metabolic disorders before transplant are greatly needed.

Funding: Private Foundation Support

PUB698
Effect of Mycophenolate Mofetil Dose on BK Virus Infection in Kidney Transplant Recipients
Ledran Pasara,1 Danica Gallesic Ljubanovic,2 Madlen Knotek.1 1Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Hospital, Zagreb, Croatia; 2Dept of Pathology, Univ of Zagreb Medical School, Dubrava Univ Hospital, Zagreb, Croatia.

Background: Intensity of overall immunosuppression is a risk factor for BK virus infection (BKVI). However, the exact impact of exposure to tacrolimus and mycophenolate mofetil (MMF) to BKVI is unclear. The aim of this study was to determine if BKVI in kidney transplant (KT) recipients is associated with drug exposure to MMF.

Methods: This prospective randomised controlled clinical trial (NCT01860183) included 36 KT who underwent KT from May 2013 to February 2015 at Clinical Hospital Merkur. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF±steroid maintenance. KTR were randomized in two groups, with respect to MMF dose (2g or 3 g daily). Urine cytology for decoy cells was performed at prespecified time-points posttransplant. KTR were followed up to 12 months post KT. Graft biopsy was performed per protocol at 2, 6 and 12 months, or in case of graft dysfunction. Kaplan-Meier analysis with log-rank test was used to assess graft survival. A Cox regression was used to determine variables associated with graft survival.

Results: 13 (37.1%) KTR had decoy cells in urine, 4 (11.1%) KTR had biopsy-proven BK virus-associated nephropathy (BKVAN). The mean time-to-occurrence was 4.8 months for decoy cells and 4.3 months for BKVAN. Cumulative one-year overall graft survival was 93.5%. Incidence of decoy cells, BKVAN, or acute rejection was similar in the two MMF groups. Rejection was not a risk factor for decoy cell positivity or for BKVAN.

Conclusions: MMF dose may not increase risk for BKVI after kidney transplantation.

Malignancy following Renal Transplantation
Louloures de la Vara Iniesta,1 Francisco Llamas Fuentes,2 Inmaculada Lorenzo Gonzalez,2 Carmen Gomez Roldan.2 1Virgen de la Luz Hospital, Cuenca; 2Univ Hospital of Albacete, Albacete.

Background: There is retrospective experience in many reports about the association between the intensity of immunosuppression and the higher frequency of malignancy. Objective: Analyse and describe our centre’s experience.

Methods: 275 transplant patients were analyzed. A record was made of the frequency, anatomic-pathological diagnostics, location, the mean interval between transplantation and diagnosis (latency time), follow-up time, use of antilymphocyte-antibodies, affection by cytomegalovirus, rejection and immunosuppressive therapy.

Results: Of 273 patients, 9.52% (26) were diagnosed of cancer. The majority, 93.43% (24), corresponded to De novo malignancy. 7.7% (2) were recurrences of pre-existing disease. The mean age at diagnosis was 63.19±9.43 years. The most frequent malignancies were skin cancers, predominantly Basal-cell and Squamous-cell carcinomas. The incidence of other tumors was similar to the general population. The most common causes of chronic renal failure was the glomerular and interstitial disorders.

Conclusions: Of 273 patients, 9.52% (26) were diagnosed of cancer. The majority, 93.43% (24), corresponded to De novo malignancy. 7.7% (2) were recurrences of pre-existing disease. The mean age at diagnosis was 63.19±9.43 years. The most frequent malignancies were skin cancers, predominantly Basal-cell and Squamous-cell carcinomas. The incidence of other tumors was similar to the general population. The most common causes of chronic renal failure was the glomerular and interstitial disorders.
Conclusions: Our experience is similar to what is reported in the literature. The incidence of cancer is higher than expected in the general population and increases according to the duration of the immunosuppression. Skin cancers were the most frequent malignancies. Unlike other studies, there was a low incidence of lymphoproliferative disorder and Kaposi’s sarcoma, and the incidence of other solid malignancies being similar to that of the general population. To reduce the development of malignancies must be one of our objectives.

PUB700
Lipidapheresis in 3 Sisters with Familial Hypercholesterolemia
Claudia Teoman, 1 Andreu Schlume, 2 Thomas Meissner, 2 Lutz Thorton Weber, 2
1Pediatric Nephrology, Univesity Hospital of Cologne, Cologne, Germany; 2Dept of Pediatrics, Neuroradiology and Cardiology, Univesity Hospital of Duesseldorf, Duesseldorf, Germany.

Background: Familial hypercholesterolemia (FH) is the most common monogenic form of hypercholesterolemia. It carries the risk of premature coronary heart disease. As the atherosclerotic burden is dependent on the degree and duration of exposure to raised LDL-cholesterol levels, early diagnosis and effective treatment are imperative. Statins are the mainstay in the management of these patients. Lipoprotein-apheresis becomes recently more established in patients with severe dyslipidemia. Together these treatments improve the prognosis of FH. Most children fail to attain targeted lipid goals owing to persistent shortcomings in diagnosis and treatment.

Methods: Three siblings with a LDLR mutation (p.Trp577Arg) being on statins (20 mg/d Atorvastatin) and Ezetimib (10 mg/d) for 12 months with still LDL-C plasma concentrations of above 300-500 mg/dl started once a week a double filtration plasmaphoresis (DFPP) with with a single plasma volume to be treated.

Results: After each LDL-apheresis LDL-C concentration of 100-150 mg/dl could be reached. (66-70% reduction). After 6 months plasma volume to treat was doubled because of a rebound within 7 days with LDL-C concentration up to 300-350 mg/dl. But though after each session LDL-C concentration decreased to 50-100 mg/dl the rebound was still evident after 7 days of therapy pause. With a treatment regime with twice plasma volume every 3-4 days the children finally attained a stable pre-treatment LDL-C concentration of 120-170 mg/dl. Another 2 months later statin therapy was stopped because of underlying mutation with assumed non receptor function. Neither the effectiveness of each apheresis nor the LDL-C concentration after 4 days showed any change.

Conclusions: In pediatric FH patients with high levels of LDL-cholesterol plasma concentration it might be necessary to treat instead of conservative medication with apoaferesis in high frequency and with high plasma volumes to reach a durable decrease in LDL-cholesterol plasma concentration. The use of cholesterol uptake-inhibitors should be considered.

PUB702
Cadmium Induces Matrix Metalloproteinase-9 Expression via NADPH Oxidase/Ros-Dependent Egfr Signals in Human Endothelial Cells
Nam ho Kim. Internal Medicine, Chonnam National Univesial Hospital, Gwangju, Korea.

Background: Cadmium, a widespread cumulative pollutant, is a known human carcinogen, associated with inflammation and tumor. Matrix metalloproteinase-9(MMP-9) plays a pivotal role in inflammatory reaction and tumor metastasis, however, the mechanisms underlying MMP-9 expression induced by cadmium remains obscure in human endothelial cells.

Methods: Here, cadmium elevated MMP-9 expression and enzyme activity, as well as MMP-9 promoter-driven luciferase activity, in a dose and time dependent manner in ECs. Moreover, cadmium activated phosphorylation of EGF, Akt, Erk1/2, JNK1/2, P38MAPK and promoted NF-kB and AP-1 binding.

Results: Specific inhibition and mutation studies show that EGFR, Akt, Erk1/2, JNK1/2 and transcription factor NF-kB and AP-1 were related to cadmium-induced matrix metalloproteinase expression in ECs. Furthermore, cadmium increased ROS production and the ROS-producing NADPH oxidase. Cadmium translocates p47phox, a key subunit of NADPH oxidase, to the cell membrane. The exogenous H2O2 increased MMP-9 mRNA expression. And that, inhibition of ROS by ROS scavenger (NAC) or NADPH oxidase inhibitor (DPI) attenuated EGF, Akt, MAP/ERK1/2,JNK1/2,p38MAPK activation, and MMP-9 expression. Likewise, inhibition of EGFR phosphorylation prevented the activation of AKT,MAP/ERK1/2,JNK1/2,p38MAPK activation, and MMP-9 expression. These findings provide further insight into the molecular mechanisms in the carcinogenesis effect of cadmium.

PUB703
Exosomes from Activated Kidney Fibroblast Have Ambivalent Potential Effects on Atherosclerosis
Fumitoshi Nishio, Noritoshi Kato, Yoshio Funahashi, Takuji Ishimoto, Tomoki Kosugi, Naotake Tsuobi, Shoichi Maruyama, Seichi Matsuo. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi-Pref., Japan.

Background: Exosomes are small (50-140nm) membrane vesicles of endosomal origin that contain host cell’s proteins, mRNAs, and microRNAs (miRNAs). The body of the cell secretes vesicles or exosomes which have been biologically active, and had roles in intracellular communication. Especially tumor-derived exosomes has been intensively explored and proven to be associated with distant metastasis. On the other hand, it is well known that CKD patients are at risk of cardiovascular diseases, but the mechanism of this distant organ crosstalk is not fully understood. Under the hypothesis that exosomes are involved in cardiovascular correction (CRS), the aim of this study is to explore the role of exosomes from kidney fibroblasts, which are activated in diseased kidney, on cardiovascular endothelial cells.

Methods: We isolated Exosomes from culture media of TGF-β stimulated rat kidney fibroblasts line (NRK-49F), by ultracentrifugation technique. Cured vascular endothelial cells (RAOEC; Rat Aortic Endothelial Cells) were stimulated by these exosomes or exosomes from unstimulated fibroblast. Then we evaluated the expression of genes, which associated with atherosclerosis by qPCR.

Results: RAOE-C stimulated with exosome from TGF-β activated kidney fibroblasts (RAOE-T) showed higher expression of PIGF and lower expression of FB-1, ABCA-1 than control (RAOE-C). This expression pattern is compatible with atherosclerotic change. On the other hand, RAOEC-T showed reduced expression of adhesion molecules such as ICAM-1/VCAM-1 and E-selectin compare with RAOE-C.

Conclusions: So far, CRS is supposed to caused by uremic factor, RAS system, chronic inflammation, and so on. From this study, we showed that exosomes from activated kidney fibroblasts have ambivalent roles in atherosclerosis by modulating the expression of adhesion molecules, metabolic factor, and VEGF system on endothelial cells. Further studies are needed to elucidate the contribution level of exosomes on CRS.

PUB704
Prevalence of Metabolic Syndrome in Patients with End Stage Renal Disease: Relevance of Biomarkers Vinod K. Bansal, Jennifer Sakl, Debra Hoppensteadt, Danyal Syed, Schubaatraz Abro, Jawed Fareed. Nephrology, Loyola Univ Medical Center, Maywood, IL; Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: Since the metabolic syndrome (MetS) and chronic kidney disease (CKD) share many of the same risk factors and similar inflammatory pathogenesis, many studies have suggested a correlation between CKD and MetS, and that patients with MetS are more likely to develop CKD. The purpose is to investigate metabolic biomarker levels in ESRD patients to evaluate their relevance to ESRD and to provide insight into the pathological ESRD processes and the development of associated comorbidities.

Methods: Plasma samples were retrospectively collected from 89 ESRD patients prior to maintenance hemodialysis. Normal human plasma samples (female & male, 18-35 years old) were purchased from George King Biomedical Inc. (Overland Park, KS).
were stored at -80°C. Biochips were purchased from RANDOX (Co. Antrim, Northern Ireland) to test C peptide, ferritin, IL-6, resistin, insulin, TNFα, IL-1α, leptin, PAI-1. These biomarkers were tested on 82 ESRD and 17 normal samples.

Results: All biomarkers, except insulin, were significantly elevated in Patients with ESRD compared to normal (p values are 0.05 - 0.0001). MetS patients with ESRD, as compared to non-MetS Patients with ESRD, had significantly elevated Leptin (P=0.002), and the correlation between MetS and Leptin levels was significant (P=0.0001, r=0.43). All other biomarkers showed no significant difference between ESRD+MetS and ESRD-MetS patients. Furthermore, when leptin levels for Patients with ESRD were broken down into ESRD+MetS and ESRD-MetS, ESRD+MetS vs. normal was significant (P=0.003), but ESRD-MetS vs. normal was not (P=0.6).

Conclusions: Elevated biomarkers suggest an ongoing inflammatory process in ESRD patients. Insulin levels were not significantly elevated in ESRD patients, possibly attributable to the high Leptin levels, which can interfere with insulin secretion and signaling. ESRD+MetS and ESRD-MetS populations are not statistically different for all other biomarkers. This suggests that biomarker elevation is due to ESRD pathogenesis, rather than due to MetS as a comorbidity.

PUB705
Decreased Mitochondrial Membrane Potential in Monocyte Subsets from Patients with Chronic Kidney Disease Ying Wang,† Eric Joseph Lai,† Annie Febus,† Yuan Zhang, Linda Vernocchi,† Anjali Ganda,† 1 Div of Nephrology, Dept of Medicine, Columbia Univ Medical Center, New York, NY; 2 Dept of Biostatistics, Mailman School of Public Health, Columbia Univ, New York, NY.

Background: Particular monocyte subsets are associated with future cardiovascular events in patients with chronic kidney disease (CKD), and the underlying mechanisms require further investigation. Previous studies have suggested impaired mitochondrial function in patients on dialysis, while little is known about mitochondrial functionality in monocyte subsets from non-dialyzed patients with CKD. Given that mitochondrial dysfunction has been linked to atherosclerosis, we hypothesized that non-dialyzed patients with CKD would have mitochondrial dysfunction in monocyte subsets which could accelerate atherosclerosis in patients with CKD.

Methods: Monocyte subsets from 18 adult CKD patients (eGFR<30 ml/min/1.73 m²) and 26 matched controls (eGFR ≥60 ml/min/1.73 m²) were freshly analyzed by flow cytometry. Mitochondrial membrane potential (ΔYm), as a measure of mitochondrial functionality, was determined by the mean fluorescence intensity (MFI) of TMRM (tetramethylrhodamine methyl ester).

Results: ΔYm was significantly reduced by 10% in patients with CKD vs. controls in total monocytes (P<0.05). Interestingly, the intermediate monocyte subset (CD14++CD16+), which has the highest ΔYm among all the monocyte subsets and has been shown to predict accelerated atherosclerosis in patients with CKD.

Conclusions: Patients with CKD demonstrate mitochondrial dysfunction in total monocytes and monocyte subsets. Mechanistic and prospective studies are needed to examine the relationship between monocyte mitochondrial dysfunction, atherosclerosis, and future cardiovascular events in CKD patients.

PUB706
Paricalcitol Uregulates Renal Klotho and Restores Uremia-Induced Endothelial Integrity Disruption Marc Vila Cuéllar,1 Robert H.j. Beelen,† Marc G. Vervloet.† 1 Molecular Cell Biology & Immunology, YU Univ Medical Center, Amsterdam, Netherlands; 2 Nephrology, YU Univ Medical Center, Amsterdam, Netherlands.

Background: Klotho deficiency in chronic kidney disease (CKD) is associated with the disruption of the endothelial integrity. Active vitamin D induces klotho expression. Hence, active vitamin D may limit endothelial layer disruption.

Methods: Male wistar rats were assigned into one of four groups: Control; Vitamin D deficiency, induced with Vitamin D deficient diet; Uremic, developed after ½ nephrectomy; Uremic + Vitamin D deficiency. Animals were treated with Paricalcitol or vehicle control during 7 weeks. Serum samples were analyzed for 25D and 1,25D. Evans Blue was injected for estimation of the endothelial thoracic aorta and lung permeability and quantified using spectrophotometry. To determine the levels of Klotho, qPCR and WesternBlot was performed in kidney tissue.

Results: Average 25D levels were 9.83 nmol/L while 1,25D levels were below the detection levels (20pmol/L) after the induction Vitamin D deficiency. mRNA and protein levels of Klotho in the kidney were decreased in Vitamin D deficient and uremic rats and restored after Paricalcitol treatment. Aortic Evans blue leakage increased in all uremic rats regardless of vitamin D level, compared with the control group and restored after Paricalcitol treatment (p<0.03). Uremia did not induce pulmonary leakage, but paricalcitol lowered it compared to control and uremic condition (p<0.04). Figure shows uremic without D-deficiency together.

PUB707
Altered Intra-Aortic Expression of the Renin-Angiotensin System Is Associated with Arterial Aging in Mice Hye Eun Yoon,‡ Eun Niam Kim,† Min Young Kim,† Ji Hee Lim,‡ Cheol Whee Park,‡ Bum Soon Choi.‡ 1 Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; 2 Internal Medicine, Incheon St. Mary’s Hospital, Incheon, Korea.

Background: Aging is the major risk factor of cardiovascular disease and results in progressive decline in physiological function and structural abnormalities of vasculature. The renin-angiotensin system (RAS) is the key player in cardiovascular diseases. This study evaluated whether the change in the RAS is associated with arterial aging.

Methods: Histologic changes and expressions of angiotensin, angiotensin converting enzyme 1 (ACE1), angiotensin II type 1 receptor (AT1R), angiotensin II type 2 receptor (AT2R), and antioxidant enzymes, superoxide dismutase 1 (SOD1) and superoxide dismutase 2 (SOD2), were measured in the thoracic aortas from 2-month-old, 12-month-old, and 24-month-old C57BL/6 mice.

Results: Twenty-four-month-old mice showed significantly increased aortic media thickness compared to 2-month-old mice (1.6-fold). The aortic expression of angiotensin was increased in 12-month-old (1.2-fold) and 24-month-old mice (1.6-fold) compared to 2-month-old mice. Similarly, the expression of ACE1 was increased in 12-month-old (1.2-fold) and 24-month-old mice (3-fold) compared to 2-month-old mice. The AT1R/AT2R ratios were increased in 12-month-old (1.3-fold) and 24-month-old mice (1.5-fold) compared with 2-month-old mice. The expressions of SOD1 and SOD2 were decreased in 12-month-old (0.8-fold and 0.6-fold, respectively) and 24-month-old mice (0.6-fold and 0.5-fold, respectively) compared with 2-month-old mice.

Conclusions: Age-related intra-aortic activation of the RAS was associated with reduced antioxidant enzymes and hypertrophy of the aorta. These results suggest that the altered expression of the RAS contributes to the increased susceptibility to vascular injury in the elderly population.

Funding: Government Support - Non-U.S.

PUB708
Upregulation of Microparticles, Tissue Factor, Adhesion Molecules, Nitric Oxide and Adiponectin in End Stage Renal Disease Vinod K. Bansal,† Daneyal Syed,† Debra Hoppensteadt,† Jawed Fareed.† 1Nephrology, Loyola Univ Medical Center, Maywood, IL; 2Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: End stage renal disease (ESRD) represents the final stage of chronic kidney disease characterized by kidney failure (GFR <15 ml/min/1.73 m²). To understand the pathophysiology of ESRD, we measured the circulating levels of microparticles (MP), tissue factor (TF), adhesion molecules, such as p-selectin (P-select), soluble ICAM (s-ICAM), nitric oxide (NO) and adiponectin (AD).

Methods: Plasma samples were collected from 119 ESRD patients undergoing maintenance hemodialysis to profile various inflammatory biomarkers. 100 normal plasma samples were collected from healthy individuals. MP levels were measured using an annexin

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

1051A
binding method (Hyphen Biomedical, Paris, France). NO was measured using a kit from R&D systems (Minneapolis, Minnesota) and ELISA methods for TF, P-Sel, s-ICAM and adiponectin were obtained from R&D systems. A chromogenic substrate method was used to measure heparin.

Results: MP levels were elevated in the ESRD group (28.1nm ± 6.1nm vs. the control 8.9nm ±1.3nm). Tissue factor levels were found to be increased in the ESRD group (20.4±1.6 ipg/ml vs the control (11.9±2.8ipg/ml). The nitric oxide level was markedly higher in the ESRD group (32±17μM) vs the controls (7±3μM). The p-selectin levels were elevated in the ESRD group (46±20ng/ml) vs the control (31±3ng/ml). The soluble ICAM levels were higher in the ESRD group (250±112ng/ml) vs the control (180±19ng/ml). Interestingly, the adiponectin levels were also increased in the ESRD group (19.2±11.2ug/ml) vs the control (11.2±9.3ug/ml). The nitric oxide level was markedly higher in the ESRD group (46 ± 20 ng/ml) vs the control (31 ± 3 ng/ml).

Conclusions: These studies suggest that MP, TF, NO, P-selectin and s-ICAM levels are increased in the ESRD patient. It is of interest to note that despite that a significant number of ESRD patients were diabetic; the AD levels were increased. These results also suggest that while ESRD represents a pro-inflammatory/ hypercoaguable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance.

PUB709
Coronary Artery Calcification and All-Cause Mortality in RRT Patients with Diabetes: 5 Year Survival Analysis
Ramin Tolouian, 1 Sean M. Connery, 2 Kyari Sumayin Ngamdu. 2 Internal Medicine, Eastern Virginia Medical School, Norfolk, VA; *Internal Medicine, Texas Tech Univ HSC El Paso, El Paso, TX.

Background: Vascular calcification is a significant sequela of ESRD. A Coronary Artery Calcification (CAC) Agatston score ≥ 300 has been associated with adverse cardiovascular events & increased mortality. The purpose was to evaluate all-cause mortality rates in patients with diabetes.

Methods: 113 diabetic pts undergoing RRT had CAC scoring by sub-second gated helical CT standard Agatston scoring system, slice thickness 3mm. Patients were categorized into 3 groups according to CAC score: 0, 1-299, ≥ 300 (Low, Medium, High Risk). Survival of 3 groups was calculated using Kaplan-Meier curves for all-cause mortality for 5 year period after CAC. Unadjusted and risk-factor adjusted for age & length of time on dialysis Cox proportional hazard modeling was used to estimate time to all-cause mortality.

Results: 5 year survival was 92%, 60%, 46% for Low, Medium, High Risk CAC groups.

Conclusions: There was a statistically significant difference between survival curves, Gehan-Breslow p = 0.031, but no difference between Medium & High Risk curves pairwise multiple comparison procedures Holm-Sidak method (p=0.1). Adjusting for covariates of age & length of time on dialysis at time of scan did not make a significant difference in survival curves, Age HR = 1.034 (0.99-1.0795% CI), time on dialysis HR = 1.004 (0.99-1.0195%).

PUB710
Elevated Toll Like Receptor 4 Expression and Macrophage Infiltration Is Found in High Dose Vitamin D-Induced Non-Uremic Vascular Calcification
Jianpeng Zhou, 1,2 Yuan Min Wang, 1 Helen Williams, 1 Anne M. Durkan, 1 Geoff yu Zhang, 1 Huiling Wu, 1 Andrew Sawyer, 1 Stephen I. Alexander, 1 David C. Harris, 1 Vincent W.S. Lee. 3 *Centre for Kidney Research, Children’s Hospital at Westmead, NSW, Australia; 3Centre for Transplantation and Renal Research, Univ of Sydney at Westmead Millennium Inst, Westmead, Sydney, NSW, Australia; 2 Vascular Biology Research Centre, Surgery, Univ of Sydney, Westmead Hospital, Sydney, NSW, Australia; 4 Transplant Research Group, Royal Prince Alfred Hospital, Sydney, New South Wales, Australia.

Background: Vascular calcification is strongly associated with cardiovascular morbidity and mortality. Several studies have suggested that monocytes/macrophages are involved in arterial vascular calcification, while the involvement of the TLR4 pathway in vascular calcification has also been proposed.

Methods: Male C57BL/6 mice aged 8 weeks were injected with a high dose of vitamin D (50000IU/kg/day) subcutaneously for 3 days at 0, 24 and 48 hours. All mice were sacrificed 3 days after the final administration of vitamin D. Kidneys were assessed histologically. Whole aortas were dissected. Macrophage infiltration and TLR4 expression was assessed by immunohistochemistry and histology and vascular calcification by Von Kossa staining.

Results: High dose vitamin D treatment did not induce kidney fibrosis or injury in C57BL/6 mice within the short time frame, as assessed by GT fibrosis score and PAS tubular damage score. High dose vitamin D treated mice demonstrated significantly higher calcium deposition in the aortic arteries (17.45% of vessel area) compared to controls (1.2% p<0.05). This was accompanied by a greater level of macrophage infiltration and TLR4 expression in these arteries compared to controls.

Conclusions: Accelerated vascular calcification was induced in mice with high dose vitamin D treatment. These data also identify a potential role for macrophages and the TLR4 pathway in vascular calcification.

PUB711
Lack of Correlation of Pyrophosphate Levels with Survival and Coronary Artery Calcification in Hemodialysis Patients
Ramin Tolouian, 1 Sean M. Connery. 1 *Internal Medicine, Div of Nephrology, Eastern Virginia Medical School; *Internal Medicine, Texas Tech Univ HSC El Paso.

Background: Vascular calcification is an important predictor of cardiovascular mortality in ESRD. Decreased levels of inorganic pyrophosphate (PPi) are thought to increase vascular calcification. The purpose of this study was to evaluate the association of PPi & coronary calcification scores in maintenance HD patients and all-cause mortality over 5 years.

Methods: 98 maintenance HD patients were studied (mean ± SD): Age (yr) 57 ±10.7, HD vintage (month) 36 ±37.6. Platelet free plasma PPi was measured by radiometric, enzymatic method as described by Tolouian. Coronary arterial calcification score (CACS) was measured by sub-second gated helical computed tomography with an Imatron C-150 XL ultra fast CT scanner using a standard protocol for vascular calcification. Patients were categorized into 3 groups according to their CAC score: 0, 1-300, and > 300.

The covariate PPi had no significant effect on the hazard rate, log rank p=0.61. After adjusting for covariates of PPi, age, length of time on HD at time of measurement the log rank statistic for the survival curves is not great enough to exclude the possibility that the difference is due to random sampling variability; there is not a statistically significant difference (P = 0.614).
Conclusions: The difference in 5 year survival rate in dialysis patients based on the severity of vascular calcification is not influenced by pyrophosphate levels. This supports the multi-factorial nature of vascular calcification.

PUB712

Aortic Artery Calcification and Cardiac Valve Calcification Is Associated with Mortality in Chinese Hemodialysis Patients: A 3.5 Year Follow-Up

Xiaonong Chen, Zijin Chen, Xiaobo Ma, Bei Ding, Huwei Ling, Zhongwei Shi, Nan Chen. Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; Radiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; Cardiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China.

Background: Aim to investigate the relationship among aortic artery calcification (AAC), cardiac valve calcification (CVC) and mortality in maintenance haemodialysis (MHD) patients.

Methods: The study included 110 MHD patients. All MHD patients were treated in Shanghai Ruijin Hospital in July 2011. Follow-up these patients for 42 months.

Results: Totally 110 MHD patients were involved in this study, 64(58.2%) patients were male, and the mean age was 55.2±15.0 years old, the mean dialysis duration was 41.7±38.1 months. 25.5% patients had cardiac valve calcification, while 61.8% had visible calcification. After 42 months follow-up, 26(22.7%) patients died, including 16 cases death from cardiovascular events, 5 cases respiratory failure, 3 cases tumor metastasis, 1 case deep venous thrombosis and 1 case abandon treatment. Kaplan-Meier analysis showed that patients with AAC or CVC had a significant greater number of all-cause and cardiovascular deaths than those without. In multivariate analyses, the presence of AAC was a significant factor associated with all-cause mortality (HR 3.149, P=0.025) in addition to lower albumin level and lower 25(OH)D level. The presence of CVC was a significant factor associated with cardiovascular mortality (HR 3.800, P=0.029) in addition to lower albumin level and lower 25(OH)D level.

Conclusions: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

PUB713

Beneficial Effect of the Vasopressin AV1a and AV2 Receptor Blocker Conivaptan (C) on the Renal Alterations Resulting from Mild Heat-Induced Dehydration (MHID) and Rehydration with a 10% Fructose (F) Beverage

L. Gabriela Sanchez-Lozada, Fernando E. Garcia-arroyo, Monica Gabriela Bias-Marron, Jose Pedraza-chaverrí, Cecilia Zazueta, Magdalena Cristobal, Edilia Tapia. Renal Physiopathology, INCICh, Mexico City, DF, Mexico; Biology, UNAM, Mexico City, DF, Mexico; Cardiovasc BioMed, INCICH, Mexico City, DF, Mexico.

Background: The aims of this study were: 1. To define a possible synergistic effect between fructose and vasopressin during MHID, and 2. To evaluate the potential therapeutic benefit of C (3mg/kg BW) on this condition.

Methods: Six groups of male Wistar rats were MHID (37°C/1 h/day) and rehydrated with the selected beverage during 30 days: Water (W)+Veh, W+C, F+Veh, F+C, Stevia (S)+Veh and S+C. A group of normal control (NC) rats was studied as reference. After 30 days plasma and urine parameters were evaluated, renal cortex mitochondria were isolated and respiratory control rate (RCR) was evaluated with malate/glutamate (M/G) and succinate/rotenone (S/R) substrates.

Conclusion: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

Funding: Government Support - Non-U.S.

Oxpro: oxidized protein; *p<0.05 vs V; **p<0.01 vs V; ***p<0.001 vs V; ****p<0.0001 vs V.

Conclusions: These data suggest a crosstalk between F and vasopressin on this particular condition. In addition, C treatment prevented renal and mitochondrial alterations induced by rehydration with F.

Lack of Aquaretic Effects of the Kappa Opioid Agonist Nalbuphine following Multiple Ascending Oral Doses in Healthy Volunteers

Amale Hawi, Thomas Sciscia, Vandana S. Mathur, Haiw Consulting, Ridgefield, CT; Trevi Therapeutics, New Haven, CT; Mathur Consulting, Woodside, CA.

Background: Nalbuphine is a mixed µ-antagonist and κ-agonist opioid drug that may suppress thirst in hemodialysis patients with pruritus following oral administration of nalbuphine HCl extended release (ER) tablets. However, as a class, kappa opioid agonists have aquaretic effects in both animals and humans, which can be treatment-limiting. In this Phase 1 study, the potential of nalbuphine to induce aquaretic effects was explored in healthy subjects.

Methods: Healthy male and female subjects (n=9) were administered oral doses of nalbuphine escalating every 2-3 days from 30 mg QD on Day 1 to 30 mg BID, 60 mg BID, 180 mg (Day 10, PM) to 180 mg QD on Day 13.

Results: There was no evidence of an aquaretic effect at nalbuphine oral doses up to 180 mg BID in healthy subjects, the most sensitive population in which such effects have been reported to selectively contain renal functional proteins, including AQP2. In this study, we examined whether the level of urinary exosomal AQP2 excretion was altered in pcy mice.

Conclusions: Urinary volume in pcy mice was not altered at 7 weeks of age, those significantly increased at 16 and 21 weeks of age in comparison with age-matched control mice. Urine osmolality was significantly decreased in pcy mice at all ages examined in this study. Urinary exosomal AQP2 protein levels in pcy mice were dramatically increased at 16 weeks of age, whereas those at 7 and 21 weeks of age were not significantly increased. Similarly, a transient increase in urinary excretion of exosomal tumor susceptibility gene 101 protein (TSG101), frequently used as an exosome marker protein, was observed in pcy mice at 16 weeks of age. The levels of renal AQP2 protein in pcy mice at 16 weeks of age or older were significantly higher than those in the control mice.

Conclusions: Urinary exosomal AQP2 protein excretion was transiently increased in pcy mice and this increase appeared to be related to both the number of exosomes excreted into the urine and its renal abundance.

PUB716

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide and accounts for 10% of patients with end-stage renal disease in the United States. Vasopressin is a known detrimental factor in disease progression and cyst enlargement.

Methods: This randomized controlled trial examined the effect of a novel approach of combining low osmolar diet and adjusted water intake on vasopressin, measured by change in urinary osmolality, and total daily urinary solute in 34 patients with early ADPKD. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of 280 mOsm/kg versus no intervention for two weeks duration, with equal (1:1) allocation. Permutated block randomization was performed within strata of age and sex.

Results: Baseline characteristics of the two groups were similar. Compared with baseline, the mean urine osmolality significantly declined from 426 (±193) to 258 (±110) mOsm/kg (P=0.007) but not in the control group. At 2 weeks, levels significantly differed between groups (P=0.04).

Crispr-Cas9-Mediated Deletion of Myosin Light Chain Kinase in Cultured Collecting Duct Cells

Viswanathan Raghuram, 1,2,3 Naoyuki Otani, 1 Promsuk Jutabha, 1 Motoshi Ouchi, 1 Naohiko Anzai. 1

Background: Regulation of osmotic water transport in the renal cortical collecting duct by vasopressin is in part dependent on membrane trafficking of aquaporin-2 (AQP2) to the apical plasma membrane of the principal cells. It is known that trafficking of AQP2 is in part dependent on changes in AQP2 phosphorylation. We previously proposed that AQP2 trafficking is dependent on the protein kinase Myosin Light Chain Kinase (MLCK; gene symbol: Mylk). Here, we test the role of MLCK in AQP2 phosphorylation and trafficking, utilizing Crispr-Cas9-mediated gene editing to mutate the catalytic region of the Mylk gene. Clones were generated with 4 different guide RNAs and were characterized by genomic sequencing and immunoblotting. Effects of the deletions were assessed by immunoblotting and immunofluorescence immunocytochemistry of AQP2.

Results: Multiple clones with mutations in the catalytic domain of MLCK were generated. Western blots showed absence of MLCK protein in MLCK-deleted clones. Controls were clones that express MLCK without mutations in the catalytic domain, but may contain off-target modifications. AQP2 protein abundance varied over a broad range, among all MLCK-deleted (n=4) and control (n=4) lines, but, on average, was not affected by the deletion. Immunocytochemistry showed that vasopressin stimulates redistribution of AQP2 to the apical plasma membrane in both control cells and MLCK-deleted cells. Vasopressin-dependent phosphorylation of AQP2 at Ser256 and Ser269 was not significantly reduced in MLCK-deleted AQP2 clones.

Conclusions: The results demonstrate the feasibility of Crispr-Cas9-mediated genome editing in mouse mpkCCD cells. Our experiments in mouse cultured collecting duct cells provide evidence that vasopressin-induced phosphorylation of AQP2 and redistribution of AQP2 to the apical plasma membrane can occur independently of myosin light chain kinase.

The PDZ Domain-Containing Protein Harmonin Is a Binding Partner of Sodium-Coupled Monocarboxylate Transporter 2

Naoyuki Otani, 1 Promsuk Jutabha, 1 Motoshi Ouchi, 1 Hajime Hasegawa, 2 Naohiko Anzai. 1

1Dept of Pharmacology and Toxicology, Dokkyo Medical University School of Medicine, Hitawari, Tochigi, Japan; 2Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.

Background: Lactate is freely filtered and extensively reabsorbed in the proximal tubule to prevent the loss of this valuable metabolite from the body. Sodium-coupled monocarboxylate transporters SMCt2 (SLC5A12) mediates the transport of pyruvate, lactate, and lactate (Gopal et al., BBA. 2007). In contrast to its well characterized transport properties, less information is available on the regulatory mechanism of SMCt2.

Methods: We used Crispr-Cas9-genome-editing to mutate the catalytic region of the Mylk gene. Clones were generated with 4 different guide RNAs and were characterized by genomic sequencing and immunoblotting. Effects of the deletions were assessed by immunoblotting and immunofluorescence immunocytochemistry of AQP2.

Results: The catalytic domain of SMCt2 was exposed to the cytoplasmic compartment and contains thePDZ domain, one of the famous protein-protein interaction modules, suggesting that it may interact with PDZ proteins.

Methods: We used the yeast two-hybrid screening to investigate the putative SMCt2-associated proteins that modulate its transport function. Using the SMCt2 C-terminal tail (SMCt2-CT) as bait, we performed a yeast two-hybrid screen of a cDNA library constructed from the human adult kidney. Next, to further confirm the interaction between SMCt2 and harmonin, we performed a co-immunoprecipitation study using anti-harmonin antibodies.

Results: In the yeast two-hybrid screening, 34 positive clones were obtained from a total of 1.2 × 107 independent colonies screened. Of these, 8 yielded an identical sequence encoding the gene for the PDZ protein PPDK1 (manuscript in preparation), and 1 yielded an identical sequence encoding the gene for the PDZ protein Harmonin. Deletion of C-terminal PDZ motif abolished the interaction with harmonin in the yeast two-hybrid system. Furthermore, co-immunoprecipitation studies revealed that the SMCt2 interacted directly with harmonin.

Conclusions: Harmonin was identified as the binding partner for SMCt2. The elucidation of these interactions may further our understanding of the function and regulation of monocarboxylate (e.g., lactate) transport in the human kidney.

Stimulation of V1a Receptor Increases Renal Uric Acid Clearance via Abcg2 Transporter - Insight into Hypouricemia in SIADH

Yoshifuru Tamura, Shigeru Shibata, Shunya Uchida. Dept of Internal Medicine, Teikyo Univ School of Medicine, Ithabashi, Tokyo, Japan.

Background: Hypouricemia seen in the subjects with syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is pathogenicomicohthe mechanism of hypouricemia remains to be clarified. V2 receptor agonist ‘desmopressin’ induced hyponatremia but not hypouricemia in human unlike SIADH (G Decca, JASN, 1996). Therefore, we hypothesized that V1 receptor but not V2 receptor may play a role in inducing hypouricemia. In the present study, we examined the changes in serum uric acid, urinary uric acid excretionand expression of uric acid transporters in response to V1a receptor agonist ‘terlipressin’.

Methods: Terlipressin was subcutaneously infused by osmotic mini pump to 7-weeks-old male Wistar rats (n = 9). Control rats were infused with normal saline (n = 9). The rats were sacrificed to obtain renal cortical tissues at 3 days.

Results: Serum uric acid significantly decreased and the excretion of urinary uric acid significantly increased in the terlipressin group. Thus, fractional excretion of uric acid increased from 1.20% ± 0.28% to 3.10 ± 0.56% (P < 0.001). The expression of ATP-binding cassette transporter, sub-family G, member 2 (ABCG2) significantly increased in the terlipressin group. Other uric acid transportersdid not significantly change.

Conclusions: These results suggest that stimulation of V1a receptor increases renal uric acid clearance probably via upregulation of ABCG2, leading to hypouricemia seen in SIADH patients.

Fluorescein Angiography and the Kidney: Friend or Foe?

Background: Fluorescein angiography (FA) is an indispensable tool for diagnosis and management of diabetic retinopathy (DR). However, safety of fluorescein sodium on renal functions is not fully understood.

Methods: 100 type 2 diabetic patients presenting to the ophthalmology outpatient clinic at Alexandria main university hospital were included in our study. Serum creatinine and cystatin-C were measured just before and 2 days after FA. Urinary NGAL as a tubular biomarker was measured also before and 4 hours after FA. Renal injury was defined as 25 % increase in serum creatinine or cystatin-C.

Results: The mean of serum creatinine was 0.99 ± 0.36 mg/dL and 1.0 ± 0.36 mg/dL before and after FA respectively with no statistically significant change (P=0.061). Only one patient (out of 100) experienced more than 25% rise in serum creatinine from baseline. Cystatin-C and urinary NGAL increased significantly after FA (P<0.001). Mean of serum Cystatin-C was 0.89 ± 0.34 mg/L and 0.95 ± 0.36 mg/L before and after FA respectively. 11 patients experienced more than 25% rise in serum cystatin-C from baseline. Mean of urinary NGAL was 21.78 ± 23.90 ng/ml and 27.15 ± 28.17 ng/ml before and after FA respectively.

Conclusions: Using ordinary renal biomarkers as serum creatinine, FA was thought to be kidney friendly. Nevertheless, using more sensitive early biomarkers as serum cystatin-C and urine NGAL, FA is not as innocent as previously thought. A creatinine negative, biomarker positive change may implicate a form of subclinical AKI.

Transcultural Adaptation and Validation of the Mexican Version of the Kidney Disease Questionnaire KDQOL-SF36 Version 1.3

Edgar Dehesa Lopez, 1 Ricardo Correa-Rotter, 2,3 David Olvera, 2,4 Carlos Gonzalez Parra, 3 Rafael Bazaldua, 2,4 1Dept of Nephrology, Research and Teaching Center in Health Sciences (CJIDOC), Culiacan, Sinaloa, Mexico; 2Dept of Nephrology, National Inst of Medical Sciences and Nutrition Salvador Zubiran, Mexico, D.F, Mexico; 3Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico; 4Department of Nephrology, Christus Merguez UPAEP, Puebla, Mexico; 1Dept of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.

Background: The evaluation of health-related quality of life through the application of efficient, reliable and simple instruments is a relatively new concept in the practice of nephrology. The aim of the study was to translate the Kidney Disease Quality of Life Short Form 36 (KDQOL-SF36) into the Spanish language, to adapt it culturally and to validate it in the Mexican population.

Methods: The translation, transcultural adaptation and validation of the Mexican version of KDQOL-SF36 was performed according to the recommendations of RAND Health. The validity was evaluated using Cronbach’s α. The test-retest reliability was evaluated using interobserver and intraobserver intraclass correlation coefficients (ICCs).

Results: The questionnaires were applied to 194 Mexican patients with end stage chronic kidney disease in chronic hemodialysis. The average age was 54±16 years and 54.6.1% were males. The Mexican version proved reliable with intra-and interobserver ICCs ≥ 0.7 in most of the dimensions evaluated, with a range between 0.5 and 0.9. The validity of the questionnaire was acceptable, with an internal items-dimensions consistency between 0.4 and 0.9, dimensions-total of 0.725 and items-total of 0.921.

1055A
AKI was a frequent diagnosis on hospital admission or during the hospitalization. The epidemiological characteristics and prognosis of patients with AKI and H-AKI have not been thoroughly studied.

Methods: A total of 192 patients admitted to internal medicine service were studied. AKI was diagnosed and classified at time of admission (C-AKI) or posteriorly during hospitalization. AKI was defined according to the Acute Kidney Injury Network (AKIN) criteria and serum sCr. The etiology, severity and evolution of the AKI episodes were compared among patients with C-AKI and H-AKI.

Results: C-AKI incidence was 22.4% (n=43) and H-AKI was 5.7% (n=11), giving an overall incidence of 28.1%. AKI stage 1 was present in 51.7%, AKI stage 2 in 12.9% and AKI stage 3 in 35.4%. Renal factors were the most frequent etiology of AKI in 55.6%, preterminal in 38.9% and obstructive in 5.6%. Oliguric AKI was observed in 75.9% of cases, among them 34.5% required dialysis, 24.1% reached the third stage of AKI and 31.8% were referred to additional treatment after ICU discharge. Eleven (9%) patients died and 63.6% of them developed AKI. The bivariate analysis showed that age (p = 0.006) and APACHE II score (p = 0.003) had a higher median among patients who developed AKI compared to those who did not develop AKI. In the logistic regression, the number of medications (OR: 1.15; 95% CI: 1.05 to 1.26) presented a statistically significant correlation with the development of AKI.

Conclusions: These results demonstrate that the identification of factors associated with AKI in ICU patients is very important for the early identification of renal dysfunction induced by drugs, providing conditions for appropriate prevention and treatment of the extent of kidney damage.

Clinical, Dialytic and Laboratorial Factors Associated with Poor Health Related Quality of Life in Mexicans Hemodialysis Patients

Edgar Dehesa Lopez,1 David Olvera,2 Carlos Gonzalez parra,3 Rafael Baizabal.4
1Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico; 2Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico; 3Dept of Nephrology, IMSS, Puebla, Mexico; 4Deparment of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.

Background: The evaluation of health related quality of life (HRQOL) in hemodialysis patients has recently gained great importance because it has proven to be an independent predictor of clinical outcomes.

Methods: Cross-sectional study. The validated Mexican version of the KDQOL-SF36 v1.3 questionnaire were applied to 194 adult patients with ESRD on hemodialysis in different regions of Mexico. According to the global score of questionnaire, patients were grouped in: patients with poor HRQOL (global score below the median) and patients with good HRQOL (global score greater than the median). Logistic regression was used to investigate the effects of clinical, dialytic and laboratorial factors on HRQOL.

Results: The average age was 54±16 with 54.6.1% male. Comorbidities were: hypertension in 86.6%, diabetes mellitus 2 in 57.2% and dyslipidemia in 7.2%. The vascular access was a catheter in 55.2% and fistula in 44.8% of the cases. Diabetes mellitus and the use of catheters as vascular access were more frequent in patients with poor quality of life. On the other hand, phosphorus >5.5 mg/dl and albumin >4g/dl were more frequent in patients with good quality of life. There were no differences in age, Kt/V, hemoglobin and calcium between groups. Table 1 shown the clinical, dialytic and laboratorial factors studied in the multivariate logistic analysis.

Table 1-Multivariate logistic regression analysis of clinical, dialytic and laboratorial factors associated with poor HRQOL.

Empagliflozin and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Chronic Kidney Disease
Christopher Wanner, 1 John M. Lachin, 2 David H. Fitchett, 3 Silvio E. Inzucchi, 4 Maximilian von Eynatten, 5 Michaela Matthaeus, 6 Odd Erik Johannsen, 7 Hans-Juergen Woerle, 8 Uli Christian Broedl, 9 Bernard Zinman, 10 1 Dept of Medicine, Wurzburg Univ Clinic, Wurzburg, Germany; 2 The Biostatistics Center, The George Washington Univ, Rockville, MD; 3 St Michael's Hospital, Div of Cardiology, Univ of Toronto, Toronto, Canada; 4 Section of Endocrinology, Yale Univ School of Medicine, New Haven, CT; 5 Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; 6 Boehringer Ingelheim Norway KS, Asker, Norway; 7 Lunenburg-Tannhaeuser Research Inst, Mount Sinai Hospital, Toronto, Canada; 8 Div of Endocrinology, Univ of Toronto, Toronto, Canada.

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at high risk of cardiovascular (CV) events and premature death. Empagliflozin is a sodium-glucose co-transporter (SGLT)-2 inhibitor used in the treatment of T2D.

Methods: In EMPA-REG OUTCOME®, we explored long-term CV outcomes with empagliflozin vs placebo when added to standard of care in 7020 T2D patients with established CV disease. Inclusion criteria included eGFR ≥30ml/min/1.73m². Patients (mean age 63 years, male 71%, mean HbA1c 8.1%) were randomized 1:1:1 to empagliflozin 10mg, 25mg or placebo.

Results: Most patients had impaired kidney function (52.2% stage 2, 17.8% stage 3a, 7.7% stage 3b CKD) while 28.7% and 11.0%, respectively, had moderately (30-300mg/g) or severely (>300mg/g) increased urine albumin to creatinine excretion. At a median follow-up of 3.1 years, the primary outcome (first occurrence of non-fatal myocardial infarction, non-fatal stroke, or CV death) occurred in a lower percentage of patients on empagliflozin (10.5%) than placebo (12.1%) (HR 0.86 [0.74-0.99]; p=0.04). This result was driven by a 38% reduction in CV death vs placebo (HR 0.62 [0.49-0.77]; p<0.001), with no difference in the risk of heart attack or stroke. Empagliflozin reduced hospitalization for heart failure by 35% (HR 0.65 [0.50-0.85]; p=0.0017). Pre-defined subgroup analyses on CV outcomes in patients with T2D and CKD will be presented.

Conclusions: Empagliflozin reduces CV morbidity and mortality in patients with T2D and various degrees of CKD.

HI-OR02

High Dose Perioperative Atorvastatin and Acute Kidney Injury Following Cardiac Surgery
Federic Tremaine Billings, Chad E. Wagner, Patty Hendricks, Yaping Shi, Michael R. Petracek, Nancy J. Brown. Vanderbilt Univ, Nashville, TN.

Background: Hydroxy-methylglutaryl-coenzyme A reductase inhibitors (statins) affect several mechanisms underlying acute kidney injury (AKI), a common and dangerous complication after cardiac surgery. We hypothesized that short-term high-dose perioperative atorvastatin would reduce AKI following cardiac surgery.

Methods: We randomized elective cardiac surgery patients, stratified by chronic kidney disease (CKD), to atorvastatin or matching-placebo starting the day prior to surgery until 14 days following surgery, or new dialysis in the 30 days following surgery. Patients, care givers and outcome-assessors were blinded to allocation. Acute kidney injury was defined as ≥2.50% or ≥26.5 mmol/l increase in the postoperative serum creatinine concentration from the preoperative concentration in the 14 days following surgery, or new dialysis in the 30 days following surgery.

Results: Methylprednisolone (n=3,647) vs placebo (n=3,639) did not alter the risk of acute kidney injury (40.9% vs 39.5%, respectively; relative risk 1.03 [95% CI, 0.96 to 1.11]). Results were consistent with multiple alternate continuous and categorical definitions of acute kidney injury, and in the subgroup with baseline chronic kidney disease.

Conclusions: Amongst patients undergoing cardiac surgery with cardiopulmonary bypass, the use of corticosteroids during the perioperative period did not alter the risk of acute kidney injury. Trial Registration: NCT00427388

Funding: Government Support - Non-U.S.

HI-OR04

The NEFILGAN Trial: NEFCON, a Novel Targeted Release Formulation of Budesonide, Reduces Proteinuria and Stabilizes eGFR in IgA Nephropathy Patients at Risk of ESRD
Benet C. Feliu-strom, 1 Rosanna Coppo, 2 John Feehally, 3 Jürgen Floege, 4 Johan W. De Fijter, 5 Alan G. Jardine, 6 Francesco Locatelli, 7 Bart D. Maes, 8 Alex Merce, 9 Fernanda Ortiz, 10 Manuel Praga, 11 Soren Schwartz-Sorensen, 12 Vladimir Tesar. 13

Background: In IgA nephropathy (IgAN) nephropathy, patients at risk for end-stage renal disease (ESRD) are often treated with oral corticosteroids. However, the frequent side effects of long-term corticosteroid therapy limit their use. NEFCON is a novel targeted release formulation of budesonide which allows for sustained release of drug directly to the glomerulus, effectively reducing proteinuria with minimal systemic glucocorticoid side effects.

Methods: A double-blind, placebo-controlled study in 150 patients (62 sites, 10 EU countries) with primary IgAN, proteinuria (UPCR >0.5 g/G or urinary protein >0.75 g/d) and eGFR ≥30ml/min/1.73m² randomized to NEFCON (n=75) vs placebo (n=75). Primary endpoint was renal function at 12 months.

Results: At baseline, patients in the NEFCON and placebo groups were well matched with comparable baseline characteristics, and mean UPCR was 4.77±1.73 mg/dl. Mean UPCR decreased to 1.09±0.79 mg/dl in the NEFCON group compared to 1.13±0.75 mg/dl in the placebo group (p=0.0036), after 12 months of follow-up. NEFCON was generally well-tolerated.

Conclusions: NEFCON reduced proteinuria in IgAN patients with a risk of transitioning to ESRD, with minimal systemic glucocorticoid side effects. NEFCON is a promising new treatment for IgAN.

Randomized Trial on Efficacy of Mycophenolate Mofetil versus Tacrolimus in Maintaining Remission in Children with Steroid Resistant Nephrotic Syndrome

Aditi Sinha, Arvind Bagga. All India Inst of Medical Sciences, New Delhi, India.

Background: Since prolonged therapy with tacrolimus (Tac) causes nephrotoxicity, this RCT examined non-inferiority of mycophenolate mofetil (MMF) to Tac in maintaining remission in patients with steroid resistant nephrotic syndrome (SRNS).

Methods: Following approvals, 84 patients with SRNS (1-18 yr; minimal change 48, FSGS 36) & eGFR >60 ml/min/1.73m2 were randomized to Tac (0.15 mg/kg/d; trough 4-8 ng/ml) for 6 months. Stratifying for histology & type of response, patients with complete (Up/Uc <0.2 mg/mg) or partial remission (Up/Uc 0.2-2, albumin >2.5 g/dl) were randomized to continue Tac or receive MMF (0.75-1 g/m2/d), prednisone & enalapril. Primary outcome, at 12-mo, was proportion with remission or infrequent relapses. Therapy failure was recurrent SRNS, frequent relapses or >1 SAE. Enrolment was closed after interim intention-to-treat analysis of outcome in 1/2 sample.

Results: Baseline features were similar. Therapy with MMF led to significantly higher treatment failure, prednisone dose & SAE; eGFR change was similar. On multivariate regression, hazards of treatment failure were high with MMF (HR 9.7, adjusted for histology, type of resistance & remission; P<0.0001).

Prevention of Bone Mineral Density Loss in De Novo Kidney Transplant Recipients with Twice-Yearly Denosumab: A Randomized Controlled Trial

Rudolf P. Wuthrich,1 Diana P. Frey,1 Jens Günther Brockmann,2 Thomas Feih,1 Thomas F. Mueller,1 Lanja Saleh,3 Arnold von Eckardstein,4 Nicole Graf,5 Marco Bonanni.1

Div of Nephrology; 2Div of Visceral and Transplantation Surgery; 3Inst of Clinical Chemistry, Univ Hospital, Zurich, Switzerland; 4Graf Biostatistics, Winterthur, Switzerland.

Background: Kidney transplantation is associated with bone loss and an increased risk of fracture. Since current therapeutic options to prevent bone loss are limited we assessed the efficacy and safety of Receptor Activator of Nuclear Factor k B Ligand (RANKL) inhibition with denosumab to improve bone mineralization in the first year after kidney transplantation.

Methods: We enrolled 108 kidney transplant recipients and randomized 90 patients two weeks after surgery in a 1:1 ratio to receive denosumab (subcutaneous injections of 60 mg denosumab at baseline and after 6 months) or no treatment. The primary endpoint was the percentage change in bone mineral density (BMD) measured by DXA at the lumbar spine at 12 months.

Results: After 12 months, the primary outcome of total lumbar spine BMD increased by 4.6% (95% CI 3.3-5.9%) in 46 patients in the denosumab group and decreased by -0.5% (95% CI -1.8-0.9%) in 44 patients in the control group (between-group difference 5.1%, 95% CI 1.7-8.5%, p=0.001). Denosumab also significantly increased BMD at the total hip by 1.9% (95% CI 0.1 to 3.7%; p=0.035) over that in the control group at 12 months. HR-pQCT in a subgroup of 24 patients showed that denosumab also significantly increased BMD and cortical thickness at the distal tibia and radius (p<0.05). Biomarkers of bone resorption (β-Cr, urine deoxypyridinoline) and bone formation (P1NP, BSAP) markedly decreased with denosumab (p<0.0001). Episodes of cystitis and asymptomatic hypocalcaemia occurred more often with denosumab, whereas graft function, rate of rejections and incidence of opportunistic infections were similar.

Conclusions: Antagonizing RANKL with denosumab effectively increased BMD in de novo kidney transplant recipients, but was associated with more frequent episodes of urinary tract infection and decreased calcium.

Funding: Government Support - Non-U.S.
Methods: This international, randomised, double-blind, placebo-controlled trial examined whether 3 months therapy with w3FA (Ag/day) reduced primary AVF failure at 12 months after AVF creation. AVF failure was defined as AVF thrombosis and/or abandonment and/or cannulation failure. A subset of patients received aspirin (100mg/day) or matching placebo in addition to w3FA or placebo in a factorial design (n=388).

Results: The 567 randomised participants had a mean age of 55 years, 63% were male and 46% diabetic. AVF failure occurred in 128/270 (47%) participants assigned to w3FA compared with 125/266 (47%) assigned to placebo (relative risk adjusted for aspirin use [RR] 1.03, 95% confidence interval [CI] 0.86-1.23, p = 0.78). Regarding each component of AVF failure, w3FA did not reduce the risk of thrombosis (22% vs 23%, RR 0.98, 95% CI 0.72-1.34, p=0.90), AVF abandonment (19% vs 22%, RR 0.87, CI 0.62-1.22, p=0.43) or cannulation failure (40% vs 39%, RR 1.03, 0.83-1.26, p=0.81). A subgroup difference was observed for diabetes mellitus (interaction p=0.038; RR 1.30 v.0.78; diabetics vs non-diabetics) but not for age, gender, AVF site, dialysis modality and cardiovascular disease. There was no difference in any serious adverse event (AE) (9.2% vs 13.0%, p=0.14; bleeding, 8.1% vs 10.9%; p=0.26, or gastrointestinal AE, 4.9% vs 5.4%; p=0.86. The risk of AVF failure was similar (45% vs 45%, RR 1.05, 95% CI 0.95-1.15) in the subset of participants randomised to aspirin or placebo-aspirin as part of the factorial design.

Conclusions: Three months of w3FA intake was ineffective in reducing primary AVF failure at 12 months. Aspirin may be similarly ineffective. There was no increased risk of bleeding. Neither w3FA nor aspirin increased the proportion of useable de novo AVF.

SA-PO1091
The Remote Ischemic Preconditioning in Cardiac Surgery Trial (Remote IMPACT) Michael Walsh,1,2 McMaster Univ; 3Population Health Research Inst.

Background: Cardiac surgery is frequently complicated by ischemia-reperfusion injury which can lead to kidney and myocardial injury. Preoperative Remote Ischemic Preconditioning (RIPC), cycles of brief ischemia to a limb alternating with reperfusion, may reduce the frequency or severity of organ injury after cardiac surgery.

Methods: We randomly allocated 258 patients at high risk for death after cardiac surgery to receive either RIPC or a sham procedure immediately after induction of anesthesia. RIPC consisted of 3 cycles of thigh tourniquet inflation to 300 mmHg for 5 minutes followed by 5 minutes reperfusion. The sham group tourniquets were inflated to 15 mmHg. Patients and care providers were blinded. The main clinical outcomes were change in creatinine over the first 4 postoperative days and the peak CK-MB within 24 hours of surgery. Other outcomes were assessed 30 days after randomization. Analyses were performed according to the intention-to-treat principle.

Results: We randomized 128 patients to RIPC and 130 to sham. No patients were lost to follow-up. There was no significant difference in postoperative change in creatinine (p=0.79) or peak CK-MB (p=0.18) (Figure 1). We found no significant differences in the frequency of acute kidney injury (34% vs 31%), myocardial injury (24% vs 24%), stroke (4% vs 3%) or mortality (6% vs 5%) at 30 days.

Figure 1. Mean and 95% confidence intervals of creatinine over time for the RIPC (green diamonds) and sham (blue circles) groups.

Conclusions: In this trial RIPC did not affect markers of kidney and myocardial injury. These results fail to provide proof-of-concept that RIPC may impact clinically important outcomes in the cardiac surgery setting.

SA-PO1092
Nephrotoxicity of Invasive and Noninvasive Coronary Angiography: Randomized Controlled Study of Intracoronary and Intravenous Contrast Agent Administration Eva Schönberger,1 Patricia D. Bady,2 Peter Martus,2 Elke Zimmermann,2 Michael Laule,3 Marc Dewey,4 Anesthesiology, Charité, Berlin, Germany; 2Radiology, Charité, Berlin, Germany; 4Inst for Clinical Epidemiology and Applied Biostatistics, Eberhard Karls Univ, Tübingen, Germany; 5Cardiology, Charité, Berlin, Germany.

Background: Intradialytic contrast agent administration is known to cause nephrotoxicity. We compared the effects of intracoronary contrast agent administration (ICA) vs intravenous contrast agent administration (CTA). We hypothesized that ICA will cause less nephrotoxicity than CTA.

Methods: We randomly assigned patients with suspected coronary disease to either intracoronary contrast agent for invasive coronary angiography (ICA) or an alternative diagnostic test (CTA). The 302 patients were randomised to receive either ICA or CTA. In ICA group, the intracoronary contrast agent was used for ICA and CTA. Blood samples were taken before and at two time points after ICA and CTA (18 to 24 hours and 46 to 50 hours) to identify contrast-induced acute kidney injury defined according to the KDOQI definition of at least 0.5 mg per deciliter or 25%.

Results: 218 patients of whom 10 and 4 dropped out from the ICA and CTA group, respectively, leaving 161 and 165 patients who underwent ICA and CTA until September 8, 2015. Baseline creatinine levels in the ICA group (0.85±0.19) and the CTA group (0.87±0.21 mg per deciliter) were similar (P=0.34). Follow-up creatinine was not available in 3 and 5 patients in the ICA and CTA group, respectively. Twenty-one of the 158 patients in the ICA group (13%) had an increase in creatinine of at least 0.5 mg per deciliter or 25%, as compared with 9 of the 160 patients in the CTA group (6%; P=0.05). In patients without coronary disease on ICA or CTA, such a creatinine increase was found in 17 of the 134 patients in the ICA group (13%) and 6 of the 139 patients in the CTA group (4%; P<0.05). No patient without coronary disease in the CTA group had an increase in creatinine according to the KDOQI definition of at least 0.5 mg per deciliter or 50%, but 6 of the 134 patients in the ICA group (4%; P<0.05).

Conclusions: Nephrotoxicity may be more likely after intracoronary than after intravenous contrast agent administration.

Efficacy and Safety of Bosutinib in Autosomal Dominant Polycystic Kidney Disease: A Phase 2, Randomized, Double-Blind, Placebo-Controlled Study Ewa Rzepczynska,1 Katarzyna Biechowicz,1 Marcin Wronski,1 Barbara Truszczyńska,2 York P. Ingwersen,3 Andreas L. Serra,4 Pomeranian Medical Univ, Szczecin, Poland; 3Charles Univ, Prague, Czech Republic; 4Univ Health Network, Toronto, Ontario, Canada; 5Ichsan School of Medicine at Mount Sinai, New York, NY; 2Pfizer Inc, San Diego, CA; 3Pfizer Inc, Cambridge, MA; 7Sanofi US, Bridgewater, NJ; 8Roche Pharma Research and Development, Basel, Switzerland; 9Inst for Allgemeine Inneren Medizin und Nephropathie, Suisse ADPKD Hirslanden, Zurich, Switzerland.

Background: Src overactivation has been linked to the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). We assessed efficacy and safety of bosutinib (BOS), an oral dual Src/Abl tyrosine kinase inhibitor, in ADPKD patients (pts).

Methods: In this phase 2, multicenter study (NCT01233869), ADPKD pts with estimated glomerular filtration rate ≥60 mL/min/1.73 m2 and magnetic resonance image (MRI) confirmed total kidney volume (TKV) ≥750 cc were randomized 1:1:1 to placebo (PBO), 200 mg/d, or 400 mg/d of oral BOS for ≥24 mo. The primary endpoint was annualized TKV % change. Pts treated for ≥2 wk who had an MRI after a 30-d washout period were included in the modified intent-to-treat (mITT) analysis.

Results: 169 of 172 enrolled pts received ≥1 dose of treatment. 24 pts who initially received 400 mg/d BOS were later reduced to 200 mg/d BOS per protocol. 88 pts (52%) were in the mITT population (200 mg/d, n=27; 400 mg/d, n=7; 400 mg/d to 200 mg/d, n=21; PBO, n=33) after discontinuations (unrelated to study drug, 27%; study drug-related adverse events, 17%; consent withdrawal, 14%). Annual rate of kidney enlargement was significantly reduced for pooled BOS vs PBO (0.84% vs 4.74%, respectively, 95% CI for difference in annualized rates [2.02-5.74]; p<0.0001) and was 65.2% lower for BOS 200 mg/d vs PBO (1.63% vs 4.74%, respectively, 95% CI [0.93 to 5.27]; p<0.005). Gastrointestinal (GI) effects were dose-dependent for BOS; the overall safety profile, including GI toxicities, was consistent with the known profile of BOS.

Conclusions: BOS reduced the annual rate of kidney enlargement vs PBO in ADPKD pts, and the safety profile was consistent with the BOS label.

SA-PO1094
Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD: A Randomized Controlled Trial Osama W. Amro,1,2 Jessica K. Paulus,2 Farzad Nourbary,1 Ronald D. Perrone.3 Nephrology, Tufts Medical Center, Boston, MA; 2Tufts Univ School of Medicine.

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide. Vasopressin promotes disease progression.

Methods: This randomized trial examined the effect of combining a low osmolar diet and adjusted water intake on vasopressin as measured by change in plasma copeptin, and

underline represents presenting author/disclosure.
urinary osmolality in 34 ADPKD patients. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of ≥280 mOsm/L versus no intervention for two weeks.

**Results:** Change from baseline to two weeks between intervention and control groups was statistically significant for the primary outcome of copeptin and urinary osmolality (-3.86 ±1.3 pmol/L versus +0.39 ±1.2 pmol/L; p=0.009) and -167±264 mOsm/L versus +20.80 mOsm/L (0.007) respectively. Mean plasma copeptin and urinary osmolality declined from 6.2 ±0.5 to 5.3 ±2.5 pmol/L (p=0.3) and from 426 ±193 to 258 ±117 mOsm/L (p=0.003) respectively in the intervention group compared to a non-significant increase from 4.7 ±3.6 to 5.07±5.4 pmol/L (p=0.7) and from 329 ±159 to 349 ±139 mOsm/L (p=0.6) in the control group.

Total urinary solute decreased only in the intervention group and significantly differed between groups at week one (p=0.03) reducing mean water prescription from 3.2 to 2.6 liter/day.

**Conclusions:** We developed a step wise dietary intervention that led to significant reduction in vasopressin in ADPKD patients. Furthermore, this intervention led to reduction in water required for vasopressin suppression. Long-term studies are needed to determine if vasopressin suppression slows ADPKD progression.

**Funding:** Other NHI Support - Dr. Amro is supported by NIH 5T32DK007777 institutional training grant. This project was performed and Dr. Perrone were supported in part by the National Center for Advancing Translational Sciences (NCATS), National Institutes of Health (NIH), Grant Number UL1 TR001064.

**A Phase 2, Double-Blind, Randomized Study of Fresolimumab or Placebo in Patients with Steroid-Resistant Primary Focal Segmental Glomerulosclerosis**

**James A. Tumlin,1 Flavio Vincenti,2 Fernando C. Fervenza,3 Kirk N. Campbell,4 Montserrat M. Diaz Encarnacion,5 Manuel Praga,6 Denysie Thibeau-Brown,7 Francisco Verissimo Veronese,8 Beverly Accamando,9 Sara Enstrang.8 Steven R. Ledbetter,10 Julie Lin,18 John F. Neylan,16 UT Coll. of Med., Chattanooga, TN; 2UCSF, San Francisco, CA; 3Mayo Clinic, Rochester, MN; 4Icahn Sch. of Med. at Mt. Sinai, New York, NY; 5Fundacion Puigvert, Barcelona, Spain; 6Hospital 12 de Oct., Madrid, Spain; 7Univ of Alabama at Birmingham, AL; 8Hosp. de Clínicas de Porto Alegre, Brazil; 9Sanofi, Cambridge, MA; 10Formerly Genzyme, Sanofi.

**Background:** Steroid-resistant primary FSGS confers substantial risk of morbidity & progressive kidney failure. Fresolimumab (freso), a neutralizing mAb to all 3 isoforms of TGF-β, is a potential new treatment.

**Methods:** 36 pts with biopsy-proven nephrotic-range FSGS randomized to freso 1mg/kg (n=14) v 4mg/kg (n=12) v placebo (PL) (n=10) for D112, allowed immunosuppressives (IMM). IMM-patients with an eGFR >60 ml/min/1.73m² received a non-stereoid (NSI) IMM. All 7 remission (>50% Up/c decrease from BL to <3mg/mg): 3 pts, 1mg/kg; 2 pts, 4mg/kg; 1 pt, PL; 1 additional pt on 1mg/kg had steep & consistent Up/c decline from 17–4mg/mg. All 7 freso responders were Black/Hispanic. Mean Up/c changes at D112: -18.5% (1mg/kg, PL; 1 additional pt on 1mg/kg had steep & consistent Up/c decline from 17–4mg/mg. All 7 freso responders were Black/Hispanic. Mean Up/c changes at D112: -18.5% (1mg/kg, +10.5% (4mg/kg, P=0.008), +10.5% (4mg/kg, P=0.02), +9.0% (PL, P=0.91). eGFR showed nonsignificant trend for stability in freso v decline in PL. Freso was generally well tolerated with no significant difference in AEs in low v high doses.

**Conclusions:** In steroid-resistant FSGS, freso may be associated with proteinuria remission. Black & Hispanic pts may have higher response rates. Freso merits continued evaluation in FSGS.

**Effects of Sustained-Release Beraprost Sodium in Patients with Primary Glomerular Disease or Nephrosclerosis: The CASSIOPEIR Study**

**Toshiro Fujita,1 Xueqing Yu,2 Suhyngwon Kim,3 Hidetomi Ogita,3 Hajimu Kurumurata,4 Takashi Kiriyama,5 ’The Univ of Tokyo, Tokyo, Japan; ’The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; ’Seoul National Univ Hospital, Seoul, Korea; ’Saitama Medical Univ, Saitama, Japan; ’The Univ of Toyama, Toyama, Japan; ’Toray Industries, Inc, Tokyo, Japan; ’Astellas Pharma Inc., Tokyo, Japan.

**Background:** No single treatment, except RAS inhibitors, can delay progression of CKD. TRK-100STP, a sustained-release tablet of an orally-active prostacyclin analogue, beraprost sodium, is suggested to suppress worsening of renal filtration function. We aimed to demonstrate superiority of TRK-100STP over placebo in patients with CKD, either as primary glomerular disease or nephrosclerosis; determine the recommended dose of TRK-100STP; and evaluate its safety profile.

**Methods:** We performed a randomized, double-blind, placebo-controlled, parallel-group comparative study at 160 sites in seven Asian-Pacific countries and regions (CASSIOPEIR: CRF Asian Study with Oral PG2; Derivative for Evaluating Improvement of Renal Function). Patients entered a run-in phase with oral administration of placebo twice daily for two to eight weeks. Patients meeting the inclusion/exclusion criteria at the end of the run-in period (n=892) were randomized to TRK-100STP 120 mg, TRK-100STP 240 mg, or placebo for a treatment period of two to four years. The primary efficacy endpoint was the time to first occurrence of a renal composite endpoint: doubling of Scr or occurrence of end-stage renal disease. ClinicalTrials.gov identifier: NCT01090037.

**Results:** No significant differences were evident observed in renal composite endpoints between TRK-100STP and placebo (2-sided 5% significance level, P=0.5674). The overall incidence of adverse events and adverse drug reactions was comparable between the two treatment arms.

**Conclusions:** TRK-100STP did not demonstrate superiority over placebo, and the recommended therapeutic dose for patients with CKD either primary glomerular disease or nephrosclerosis was not determined. However, no findings raised safety concerns in the comparison between TRK-100STP and placebo.

**Corticosteroid Monotherapy versus Combined Immunosuppression in IgA Nephropathy: Insights from the STOP-IgAN Trial**

**Jürgen Floege,1 Thomas Rauen,1 Frank Eitner,1 Christina Fitzner,2 Ralf-Dieter Hilger,2 ’Nephrology, RWTH Aachen Univ, Aachen, Germany; ’Biostatistics, RWTH Aachen Univ, Aachen, Germany; ’Bayer AG, Wuppertal, Germany; ’For the STOP-IgAN Investigators.

**Background:** In high-risk IgA nephropathy (IgAN) the value of immunosuppression is controversial.

**Methods:** We recently reported a randomized, controlled trial in IgAN patients (STOP-IgAN trial). Following 6 months of optimized supportive treatment 162 trial participants, who still displayed a proteinuria ≥0.75 g/d, entered a 3 year study phase and were randomized to continue on supportive therapy (SUT) or to receive additional immunosuppression (IMM). IMM-patients with an eGFR ≤60 ml/min/1.73 m² received a 6-month corticosteroid monotherapy (“Pozzi-protocol”). Patients with an eGFR of 30 to
59 ml/min/1.73m² received cyclophosphamide for 3 months, followed by azathioprine, plus oral prednisolone (“Ballardie protocol”). Primary endpoints were (i) full clinical remission (proteinuria < 0.2 g/g and eGFR loss of < 5 ml/min) and (ii) eGFR loss >15 ml/min from baseline to trial end.

Results: Here we report a secondary analysis of the two IMM subgroups versus corresponding SUP patients matched for eGFR. The intention-to-treat (ITT) analysis assuming a worst-case scenario at 3 years is shown in the table.

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>GFR &gt;60 ml/min/1.73m²</th>
<th>GFR 30-59 ml/min/1.73m²</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMM vs. SUP (n = 55 vs. 54)</td>
<td>OR 5.23 (95%-CI 1.29-21.15), p=0.020</td>
<td>OR 2.77 (95%-CI 0.38-22.29), p=0.319</td>
</tr>
<tr>
<td>IMM vs. SUP (n = 27 vs. 26)</td>
<td>OR 0.65 (95%-CI 0.27-1.56), p=0.333</td>
<td>OR 1.62 (95%-CI 0.49-5.61), p=0.428</td>
</tr>
</tbody>
</table>

eGFR loss >15 ml/min

Patients treated with the Pozzi protocol had a transient decrease in proteinuria after 12 months and significantly less microhematuria at trial end compared to matched SUP patients. In the group with the low eGFR range, there were no significant differences between both arms. Compared to supportive care, more patients receiving immunosuppression developed severe infections, impaired glucose tolerance and weight gain in year one.

Conclusions: Our secondary analyses provide little evidence for a stabilization of renal function with immunosuppression in the group with an eGFR >60 ml/min and no evidence for a benefit in patients with a lower eGFR.

SA-PO1098
A Randomized Trial of Rituximab in Advanced IgA Nephropathy
Richard A. Lafayette,1 Pietro A. Canetta,2 Brad H. Rovin,3 Gerald B. Appel,4 Marie C. Hogan,5 Stephen B. Erickson,1 Fernando C. Fervenza,1 Stanford Univ, Stanford, CA;4 Columbia Univ, New York, NY;3 Ohio State Univ, Columbus, OH;1 Mayo Clinic, Rochester, NY.

Background: IgA nephropathy (IgAN) frequently leads to progressive renal dysfunction. Present immunosuppressive treatment remains uncertain in terms of benefit and risks side effects. B cells are an attractive target in IgAN so we performed a pilot trial of rituximab in subjects at high risk of progression.

Methods: Patients with biopsy proven IgAN, more than 1 g/d of proteinuria despite RAASi (or 0.5 g/d if on dual RAASi), well controlled blood pressure (BP) and eGFR <90ml/min were randomized to 1 year of rituximab therapy (4g total) vs ongoing BP control, fish oil and use of RAASi. They were followed for B cell depletion, effects on proteinuria and changes in eGFR. Safety signals were also followed.

Results: 14 patients were randomized. Baseline serum creatinine was 1.5±0.5 mg/dl and proteinuria was 2.1, 0.6-5.5 g/dl. There was no change in BP during the study. Treatment with rituximab resulted in significant B cell depletion and was generally well tolerated. There was no change in renal function during the study in either group. Rituximab treatment had no significant effect on proteinuria compared to baseline or control patients, and 3/17 patients in each group experienced a ≥50% reduction in proteinuria during the study.

Figure 1: Proteinuria (A) Control vs. (B) Rituximab Groups. The heavy weight red line represents median data.

Conclusions: In this small study, rituximab therapy had no influence on renal function or proteinuria in subjects with advanced disease due to IgA nephropathy. There were numerically greater reductions in proteinuria, but this did not reach significance. Few patients had substantial responses in either group. These results do not support the use of rituximab as treatment for patients with IgA nephropathy.

SA-PO1099
Establishing Endpoints for Lupus Nephritis Clinical Trials: Progress by the Kidney Health Initiative/Lupus Nephritis Trials Network Collaboration
Brad H. Rovin,1 Meggan Mackay,2 Joanna Stein,3 Kenneth Kalunian,4 Martin L. Lesser,5 Melissa West 5 Ohio State Univ;3 Feinstein Inst;3 Univ Calif San Diego;4 Univ Calif San Francisco;3 American Society of Nephrology.

Background: There are no universally accepted endpoints for lupus nephritis (LN) clinical drug trials. To obtain approval of new therapies a uniform endpoint that can be applied to future LN trials is needed. The optimal endpoint is a short-term measurement that accurately reflects long-term kidney survival. The present work was undertaken to define LN trial endpoints.

Methods: Clinical data at LN flare (baseline) and during serial follow-up (minimum 22 months) from 751 patients were analyzed. Clinical variables at baseline and after 6 and 12 months were tested as predictors of adverse long-term renal outcomes, in this case time to new chronic kidney disease (CKD), defined as a sustained increase in serum creatinine (Scr) ≥30%. Multivariable Cox regression analysis was used to model time to CKD.

Results: After accounting for missing data 507 patients were included in the final analysis. This cohort was 89% female, 56% White, 20% Asian and 14% Black. The average baseline serum creatinine was 1.2±0.7 mg/dl, proteinuria was 4.1±3.4 g/d, and eGFR by CKD-MDRD was 81.35 ml/min. Median follow-up was 42 months (range: 22-147 months). By univariate analysis urine RBCs, race, complement C3, C4, eGFR and proteinuria were potential significant predictors of time to CKD. By multivariate modeling the significant predictors of future CKD were: Scr at 12 months (p=0.0005, Hazard Ratio (HR) 1.8 (95%-CI 1.3-2.5)); proteinuria at 12 months (p=0.0001; HR 1.6 (1.3-1.8)); and an increase in eGFR>10% from baseline to 12 months compared to no change in eGFR (p=0.0001; HR 0.4 (0.3-0.6)).

Conclusions: We have identified 3 highly significant predictors of time to CKD in LN patients that can be measured during the first 12 months of treatment for flare. These were developed into a composite endpoint for future LN therapeutic trials. Unexpectedly, small improvements in eGFR appear to predict renal survival. Also, because urine RBCs do not appear to predict time to CKD, it may be possible to exclude urinalysis as an endpoint component in future clinical trials.

Grazoprevir (GZR)/Elbasvir (EBR) Treatment of Hepatitis C Virus (HCV) Infection in Patients with Chronic Kidney Disease Stage 4/5: Final Results of the C-SURFER Phase 3 Study
David Roth,1 Annette Bruchfeld,2 Paul Martin,1 David R. Nelson,2 Marcelo Silva,4 Howard Monsour,1 Laurent Alric,3 Shuyan Wan,1 Beth Jackson,1 Bach-Yen Nguyen,1 Janice Wahl,1 Eliav Barr,1 Wayne L. Greaves.7 Univ of Miami, Miami, FL; Karlolinstit Ut, Stockholm, Sweden;7 Univ of Florida, Gainesville, FL; Hospital Univ Austral, Pilar, Buenos Aires, Argentina;7 Houston Methodist Hospital, Houston, TX;5 Hôpital de Purpan, Toulouse, France;3 Merck & Co., Inc., Kenilworth, NJ.

Background: Limited options are available for treating HCV infection in patients with advanced kidney disease. C-SURFER is the first randomized, placebo-controlled phase 3 study to evaluate an all-oral, ribavirin-free regimen in CKD 4/5 patients.

Methods: 224 patients with HCV genotype (G1 and CKD 4/5 ± hemodialysis (HD) were randomized to GZR/EBR 100/50mg (Immediate Treatment Group, ITG; n=111) or placebo for 12 weeks. Placebo subjects (deferred treatment group, DTC, n=113) received GZR/EBR after placebo therapy. 11 additional subjects received GZR/EBR with intensive pharmacokinetic (PK) sampling. The primary safety comparison was GZR/EBR vs. placebo. The primary efficacy endpoint, sustained virologic response (SVR) 12 weeks post-therapy in the ITG vs PK group, was reported previously. Here we report the final results, including data from subjects who received GZR/EBR after placebo.

Results: In the placebo-controlled phase, serious adverse events (AEs) occurred in 16 (14%) GZR/EBR and 17 (15%) placebo subjects; discontinuation due to an AE in GZR/EBR and placebo subjects was 0% and 4%. SVR12 in all subjects who received GZR/EBR was 94.6% (ITG) vs. 94.3% [115/122, DTG after placebo. 95.0% [96/101]). 12 subjects failed to attain SVR12: virologic relapse, n=3; discontinuation for AE, n=1; admin reason, n=8. Excluding subjects who discontinued for reasons unrelated to study drug, overall SVR12 was 98.6% (211/214). PK data indicate no need for dose adjustment in HD patients (geometric mean ratio [HD/non-HD] ranged from 0.67-0.85 for GZR and 1.43-1.67 for EBR).

Conclusions: Once-daily GZR/EBR for 12 weeks was highly effective with a low rate of adverse events in patients with advanced kidney disease and HCV G1 infection.

Long-Term (52-Week) Efficacy and Safety of ZS-9 in the Treatment of Hyperkaemia: Interim Results From a Phase 3 Open-Label, Multi-Center, Multi-Dose Maintenance Study

James A. Tumin,1 Mikhail Kosiborod,2 Pablo E. Pergola,1 Wajeh Y. Quinlivan,1 David K. Packham,1 Simon D. Roger,1 Edgar V. Lerman,1 Steven Fishbane,1 Henrik S. Rasmussen,2 Bruce S. Spinowitz,1,2 U of Texas Health Science Center, TX; 3Mayo Clinic, Rochester, MN; 4Renal Associates PA, TX; 5U of Texas Health Science Center, TX; 6Melbourne Renal Research Group, Australia; 7Renal Research, Gosford, Australia; 8U of Illinois, IL; 9North Shore U. Hospital, NY; 10ZS Pharma, Inc., TX; 11Weill Medical College, NY

Background: Hyperkalemia (HK) is a common and potentially lethal electrolyte disorder, often induced with the use of renin-angiotensin-aldosterone inhibitors (RAASi). Currently, the use of RAASi is prevented by HK and thus the potential for cardiac and renal protective effects of these agents is limited. In previous studies, ZS-9 (sodium zirconium cyclosilicate), a selective K+ ion trap, significantly lowered serum K+ and maintained normokalemia (NK) for up to 28 days. We present the results to date of the largest ever phase 3 trial examining the efficacy of ZS-9 in treating HK patients for up to 52wks.

Methods: ZS-9 (target N=750) is a multicenter, ongoing, open-label study evaluating ZS-9 treatment for 52wks in ambulatory pts with HK (K+ ≥5.1 mEq/L) with or without concurrent RAASi therapy. In the acute phase (AP), pts with HK received 10g ZS-9 TID over a 24-72hr period until NK (K+ <5.5 mEq/L) was achieved. Pts achieving NK were enrolled in a 52wk maintenance phase (MP) starting at 5g ZS-9 QD. There were no restrictions on diet and ZS-9 could be titrated to maintain NK. Primary outcomes were proportion of pts with mean K+ ≤5.1 mEq/L during AP and safety of ZS-9.

Results: To date, 583 pts with a mean baseline K+ of 5.6 mEq/L (15% ≥6.0 mEq/L) entered the study. Overall, 575 (99%) normalized K+ in AP and transitioned to the MP. To date, K+ was maintained at ≤5.1 and <5.5 mEq/L in 87% and 99% of patients, respectively. The incidence and severity of adverse events were similar to that of previous studies.

Conclusions: ZS-9 acutely reduced K+ levels in pts with HK and maintained NK for up to 52wks irrespective of RAASi use. ZS-9 may control HK, both emergent and long-term, while allowing continued use of cardio- and renoprotective RAASi.

Interleukin-1 Inhibition and Vascular Function in Patients with Chronic Kidney Disease (CKD): A Randomized Controlled Trial

Krisen L. Nowak,1 Michel Chonchol,1 Talat Alp Ikizler,1 Heather Farmer,1 Natjolie Salas,2 Rafia I. Chaudhry,2 Wei Wang,1 Gerard John Smiths,1 Adriana Hung,1,2 1Univ of Colorado Denver; 2Vanderbilt Univ; 1VA Tennessee Valley Healthcare System

Background: Vascular endothelial dysfunction and increased arterial stiffness contribute to increased cardiovascular risk in CKD patients who exhibit chronic systemic inflammation. As chronic inflammation is a key mechanism contributing to vascular dysfunction, blocking inflammation may reduce cardiovascular risk in CKD.

Methods: In a two-site, double-blind trial, n=42 patients with stage 3-4 CKD were randomized to receive either the interleukin-1 (IL-1) trap rilonacept (subcutaneous injection; loading dose of 320 mg followed by 160 mg/wk) or placebo for 12 weeks. All patients were receiving optimal treatment of hypertension, diabetes, and/or hypercholesterolemia, with 64% and 62% receiving a statin and an ACE inhibitor or ARB, respectively. The co-primary endpoints were change in aortic pulse-wave velocity (aPWV) and transitioned to the MP. To date, K+ was maintained at ≤5.1 and <5.5 mEq/L in 87% and 99% of patients, respectively. The incidence and severity of adverse events were similar to that of previous studies.

Conclusions: ZS-9 acutely reduced K+ levels in pts with HK and maintained NK for up to 52wks irrespective of RAASi use. ZS-9 may control HK, both emergent and long-term, while allowing continued use of cardio- and renoprotective RAASi.

SA-PO1104

Impact of Vitamin D Supplementation on Endothelial and Vascular Function in Patients with Chronic Kidney Disease: A Randomized, Double Blind, Placebo-Controlled Trial

Vivek Kumar,1 Ashok Kumar Yadav,1 Vinod Sharma,1 Manphool Lal,1 Debasish Banerjee,1 Vivekanand Jha,1 Nephrology, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; 2Radiodiagnosis, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; 3Nephrology, St. George’s Univ Hospitals NHS Foundation Trust, London, London, United Kingdom.

Background: Vitamin D deficiency is associated with mortality in CKD patients. We investigated the effect of Vitamin D supplementation on endothelial and vascular function in patients with non-diabetic CKD stage 3-4.

Methods: In a prospective, randomized, double blind, placebo-controlled trial, 120 patients with non-diabetic CKD stage 3-4 and vitamin D deficiency [serum 25(OH)D <20ng/ml] aged 18-70 years were randomized (1:1) to receive either two directly observed oral doses of 300 IU of cholecalciferol at 0 and 8 weeks or matching placebo. The pre-specified primary outcome was 40% change in endothelium dependent brachial artery flow mediated dilation (FMD) at 16 weeks. Secondary outcome measures included changes in pulse wave velocity (PWV), augmentation index (AI), and serum biomarkers.

Results: Baseline FMD was identical in both arms (7.6±2.24% vs 7.8±2.34%). Intervention arm showed a significant increase in serum 25(OH)D (+ 24.9 ng/ml, 95% CI: 21.8 to 28.06, p=0.0001), and the number of subjects meeting the primary end point (70% vs 5%, p=0.0001). FMD change was 5.42% (95% CI: 4.44 to 6.40%) in the intervention arm and -0.72% (95% CI: -0.30 to -0.58%) in placebo arm. Intervention led to favorable changes in PWV (-0.94 m/s, 95% CI: -1.30 to -0.58, p=0.0001), E-selectin (3.68 mg/ml, 95% CI: 8.1 to 0.7 p=0.01), IL-6 (-2.96 to 0-p=0.01), FGF-23 (-14.7 pg/ml, 95% CI -28.5 to -1.0 p=0.036) and 1,25(OH)D (+ 15.5 pg/ml, 95% CI: 5.4 to 25.5, p=0.003). These did not change significantly in the control group. No changes were observed in AI, sPWV and hs-CRP in either group.

Conclusions: In non-diabetic patients with stage 3-4 CKD and vitamin D deficiency, vitamin D supplementation leads to improvement in endothelial function, markers of inflammation and arterial stiffness.

Effect of Cholecalciferol versus Calcitriol on Vascular Endothelial Function in CKD: A Randomized Active-Controlled Trial

Jessica B. Kendrick,1,2 Gerard John Smiths,1 Emily Decker,1 Heather Farmer,1 Michel Chonchol,1 1Univ of Colorado School of Medicine, Aurora, CO; 2Denver Health Medical Center, Denver, CO.

Background: Epidemiological studies have shown that vitamin D is associated with decreased cardiovascular morbidity and mortality, but effect of vitamin D administration on patient outcomes in chronic kidney disease (CKD) are lacking. We conducted a prospective, double-blinded, randomized trial to determine the effects of oral cholecalciferol vs. calcitriol on vascular endothelial function over 24 weeks in patients with CKD stage 3-4.

Methods: 128 patients with CKD stage 3-4 (estimated GFR 15-44 ml/min/1.73m²) with vitamin D deficiency, defined as serum 25-hydroxyvitamin D level (25(OH)D) <30 ng/mL, were randomly assigned to receive either cholecalciferol (4000 IU daily x 4 weeks then 2000 IU daily x 20 weeks) or calcitriol (0.25 mcg daily x 4 weeks then 0.5 mcg daily x 20 weeks). The primary endpoint was change in brachial artery flow mediated dilation (FMDa) over 24 weeks. Secondary endpoints included changes in parameters of mineral bone disease and plasma concentrations of inflammatory cytokines (C-reactive protein and interleukin-6).

Results: 115 patients completed the study. The mean (SD) age and eGFR was 58.1 ± 12.4 years and 33.1 ± 10.2 ml/min/1.73m², respectively. In the cholecalciferol group, mean 25(OH)D levels increased from 22.7 ± 7.5 ng/mL to 33.5 ± 7.9 ng/mL. There was no change in 25(OH)D levels in the calcitriol group. Parathyroid hormone levels decreased significantly in the calcitriol group compared to the cholecalciferol group (p=0.001). At 24 weeks, the change in FMDa did not differ significantly between treatment groups (cholecalciferol group -0.72%, 95% CI -1.97 to 0.54 vs calcitriol group 0.29%, 95% CI -0.72 to 1.29, p=0.44). There was no significant change in C-reactive protein or interleukin-6 concentrations between the two groups. Episodes of hypercalcemia were more frequent in the calcitriol group (n=4) compared with the cholecalciferol group (n=1).

Conclusions: Twenty-four week therapy with cholecalciferol or calcitriol did not improve vascular endothelial function or reduce inflammation in patients with CKD.

SA-PO1106

Vitamin D Receptor Activation and Dietary Sodium Restriction to Reduce Residual Albuminuria in Chronic Kidney Disease

*Martin H. De Borst,1 Charlotte A. Keyzer,1 Fenna van Breda,2 Marc G. Vervoet,3 Gozewijn Dirk Laverman,3 Marc H. Hemmelder,1 Wilbert M. Janssen,2 Hildo Jan Lambers Heerink,3 Stephan J.L. Bakker,4 Gerjan Navis,1 1UMC Groningen,1 2VUMc Amsterdam,2 ZGT Almelo,2 MC Leeuwarden,3 Martini Hospital Groningen, Netherlands.

Background: Reduction of residual albuminuria during single-agent RAAS-blockade is associated with improved cardioress outcomes in CKD. Both vitamin D receptor activators (VDRA) and dietary sodium restriction reduce residual albuminuria. Previous data suggested that sodium restriction is not required for optimal albuminuria reduction by VDRA. We studied the individual and combined effects of paricalcitol and sodium restriction on residual albuminuria during optimally dosed ACEi in CKD.

Methods: In a multi-center, randomized, placebo-controlled cross-over trial, 45 patients with non-diabetic CKD stage 1-3 and residual albuminuria >300 mg/24h despite ramipril 10 mg/d and BP ≤140/90 mmHg were treated during four 8-week periods with paricalcitol (PARI, 2 µg/day) or placebo (PLAC), each combined with a low (LS, 2.5 gr Na+/d) or regular sodium (RS, 4 gr Na+/d) diet, in random order. Linear mixed-effect models for repeated measurements were used to determine treatment effect.

Results: In the intention-to-treat analysis, albuminuria was 1,060 [778 to 1,443] (geometric mean [95% CI]) mg/24h (-12.5% [-26.0% to 26.3%] vs. RS+PLAC, P=0.2). LS+PARI reduced albuminuria to 717 [512 to 1,005] mg/24h (-25.4% [-52.6% to -2.3%] vs. RS+PLAC, P=0.001). LS+PARI provided the strongest albuminuria reduction to 683 [502 to 929] mg/24h (-31.7% [-55.0% to -0.9%], P=0.001 vs. RS+PLAC, although the additional reduction by PARI beyond the effect of LS was non-significant (P=0.6). However, in a per protocol analysis (≥95% compliance, N=34) PARI did reduce residual albuminuria beyond the effect of LS (P=0.04).

Conclusions: The combination of paricalcitol and moderate dietary sodium restriction provided the strongest reduction of residual albuminuria during optimal ACEi; the effect was mainly driven by sodium restriction. Our findings underline the relevance of sodium restriction, possibly combined with paricalcitol, to optimize albuminuria reduction.

Vascular Function and Uric Acid Lowering via Allopurinol in Stage III CKD: Results of a Double-Blinded Randomized Placebo-Controlled Study

Diana I. Jalal,1 Emily Decker,1 Loni J. Perrenoud,1 Nina Bispham,2 Tapan Mehta,2 Gerard John Smits,3 Richard J. Johnson. 1UMC Groningen, 2VUMc Amsterdam, 3ZGT Almelo.

Background: Observational studies suggest that asymptomatic hyperuricemia associates with vascular disease in chronic kidney disease (CKD). A recent study suggested that lowering serum urate with allopurinol improves endothelial function in elderly adults with stage III CKD. It remains unknown if lowering serum urate improves endothelial function in adult subjects with stage III CKD.

Methods: 80 adult subjects (18-70) years of age with stage III CKD and asymptomatic hyperuricemia (>7 mg/dL in men and >6 mg/dL in women) were randomized to receive placebo or allopurinol (100 mg tablets) for 12 weeks. The study was double-blinded and subjects were instructed to take 1 tablet for 1 week, 2 tablets for another week, and 3 tablets thereafter. Changes (from baseline) between both groups were compared by Wilcoxon rank-sum test.

Results: No significant differences existed between both groups at baseline. After 12 weeks, allopurinol lowered serum urate significantly. FMD increased in the allopurinol group compared to placebo; but this was not statistically significant. NMD increased with allopurinol but decreased with placebo; p value = 0.14. These data are shown in Table 1. There were no significant differences between allopurinol and placebo for systolic or diastolic blood pressure, markers of inflammation, or markers of oxidative stress. 10 subjects withdrew from the study. A few adverse events were noted in both groups including 1 gout attack in each group. 1 subject died during the study due to a cardiac event.

<tr>
<td>NMD (%change)</td>
<td>-1.29(5.33)</td>
<td>0.97(6.05)</td>
<td>0.14</td>
</tr>
</tbody>
</table>

Conclusions: Allopurinol effectively and safely lowered serum urate in adults with stage III CKD and asymptomatic hyperuricemia but this did not improve endothelial function significantly. There was tendency towards improved NMD suggesting that hyperuricemia may negatively impact vascular smooth muscle function in stage III CKD.

Podocyturia Is an Earlier and Superior Predictor of Cardiovascular Outcomes Than Is Albuminuria

Assaad Antoine Eid,1 Robert Habib,2 Kamal F Badr.3 1Anatomy, Cell Biology and Physiological Sciences, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon; 2Internal Medicine, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon.

Background: Increased urinary albumin excretion rate (AER), a predictor of cardiovascular events, results from abnormally increased albumin filtration accompanying injury to glomerular endothelial and epithelial cells (“podocytes”). Since AER is modified by renal proximal tubule albumin filtration, we hypothesized that urinary podocyte shedding, podocyturia, would be a more relevant and earlier biomarker of endothelial injury (and CVD) than moderate albuminuria.

Methods: In 106 Type II diabetic subjects (mean age: 46/60 men/women) with normal AER (<2.26 mg/mmol (20 µg/mg) creatinine) and free of overt cardiovascular disease (CVD) were enrolled. AER and podocyte-specific proteins (podocin and nephrin) mRNA were measured at baseline (visit 1), 3-4 years later (visit 2) and at 7 years (visit 3). Development of cardiovascular diseases VD - defined as coronary disease, cerebrovascular disease and/or peripheral vascular disease (can be removed to fit words counting) was collected as outcome. 7-year Kaplan-Meier time-to-event (log rank) data were compared in baseline biomarker tercile groups (low, intermediate, high).

Results: All three biomarkers increased significantly between visits (P<0.001). ARExhibit similar time to CVD (P=0.127), which was in contrast with the step-wise and substantial increase in CVD events with increasing podocin and nephrin levels (P<0.001). Considering all three biomarkers as continuous factors, the covariate-adjusted hazard ratios (95% confidence intervals) [HR] were highest for podocin mRNA [HR=15.9 (6.1-41.8); p<0.001], intermediate for nephrin mRNA [HR=7.61 (3.75-15.5); p<0.001] and lowest for ARE [HR=1.17 (1.01-1.36); P=0.041].

Conclusions: Compared to traditional ARE, podocyturia predicts more accurately and a longer time point the presence of silent systemic vascular injury, that manifests as overt cardiovascular events.

Empagliflozin Reduces Microalbuminuria and Macroalbuminuria in Patients with Type 2 Diabetes

David Cherry,1 Soren Sogaard Lund,1 Bruce A. Perkins,1 Per-Henrik Groop,2 Mark E. Cooper,3 Stefan Kaspers,4 Susanne Crowe,5 Hans-Juergen Woerle,6 Maximilian von Eynatten.7 1Toronto General Hospital, Univ of Toronto, Canada; 2Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; 3Mount Sinai Hospital, Univ of Toronto, Canada; 4Univ of Helsinki and Helsinki Univ Hospital, Folkhalsan Research Center, Helsinki, Finland; 5Baker IDI Heart and Diabetes Inst, Melbourne, Australia.

Background: Reductions in HbA1c, systolic blood pressure (SBP), and weight with the highly selective SGLT2 inhibitor empagliflozin in patients with type 2 diabetes (T2D) may favorably impact albuminuria.

Methods: Using data pooled from 5 Phase III, randomized clinical trials, we assessed the effect of empagliflozin 10 or 25 mg for 24 weeks on urine albumin to creatinine ratio (UACR) in patients with T2D and prevalent microalbuminuria (UACR 30–300 mg/g; n=636) or macroalbuminuria (UACR >300 mg/g; n=215) at baseline.

Results: Empagliflozin reduced UACR vs placebo in patients with T2D and microalbuminuria (-32%; p<0.001) or macroalbuminuria (-41%; p<0.001) after controlling for baseline log (UACR), HbA1c, SBP, estimated glomerular filtration rate (MDRD), region, study and treatment (Figure). Adjusted mean (SE) changes in HbA1c, weight, SBP and diastolic BP with empagliflozin vs placebo were -0.50 (0.07) %, -1.6 (0.2) kg, -4.4 (1.1) mmHg and -2.3 (0.6) mmHg, respectively, in patients with microalbuminuria (all p<0.001), and -0.53 (0.13) %, -1.8 (0.4) kg, -6.3 (2.0) mmHg and -2.2 (1.1) mmHg, respectively, in patients with macroalbuminuria (all p<0.05). Linear regression analyses showed that changes in HbA1c, weight and SBP accounted for a maximum of half the UACR-lowering effect.

Conclusions: Empagliflozin reduced microalbuminuria and macroalbuminuria in patients with type 2 diabetes (T2D) and may favorably impact albuminuria.

Vadadustat, a Novel Oral Treatment for Anemia of Chronic Kidney Disease, Maintains Stable Hemoglobin Levels in Dialysis Patients Converting from Erythropoiesis-Stimulating Agents

Methods: A multi-center, open-label, 16-week trial was designed to assess Hb response, safety, and tolerability of vadadustat. The trial enrolled 94 hemodialysis patients (Hb 9 - 12 g/dL), who were maintained on erythropoiesis-stimulating agents (ESAs) prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD; or 450 mg three times weekly (TIW). The primary entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD; or 450 mg three times weekly (TIW). The primary

Vadadustat safely and effectively maintained Hb levels in dialysis patients who were converted from injectable ESAs.

Funding: Pharmaceutical Company Support - Boehringer Ingelheim and Eli Lilly and Company

Conclusions: SGLT2 inhibition with empagliflozin reduced UACR by >30% in patients with T2D and prevalent microalbuminuria or macroalbuminuria, independent of its known metabolic and hemodynamic effects.

SA-PO1112
Monitoring in Dialysis (MiD) Study: Exploring the Timeline and Etiology of Increased Arrhythmias in Hemodialysis (HD) Patients

Methods: We present initial results from 3 ongoing open label ascending dose studies of TARGT in patients with anemia due to CKD undergoing either Hemo or Peritoneal Dialysis.

Results: Thus far 14 patients were enrolled in all protocols. Follow up is ongoing with the first implanted patient being followed with stable EPO secretion and stable Hb for over 14 months from a single implantation without the need for rHuEPO or blood transfusion. Concentrations of serum EPO levels revealed significantly lower Cmax compared to rHuEPO and an order of magnitude less overall EPO exposure as calculated by Area Under the Curve which may confer significant clinical benefit. No treatment related serious adverse events have been reported.

Conclusions: TARGT™ is a promising novel therapy for the treatment of anemia of CKD and potentially for other protein deficient diseases.

Funding: Pharmaceutical Company Support - Medgenics Inc.

SA-PO1111
Autologous Erythropoietin Production by the TARGT Gene Therapy Platform Maintains Stable Hb for 6-12 Month in ESRD Patients without the Need for ESA Administration

Background: Recombinant human erythropoietin (rHuEPO) administration to iron replete patients corrects anemia in most patients with ESRD, but doses result in supra-physiological peak serum concentration (Cmax) of EPO that may cause thromboembolic complications. The Transduced Autologous Restorative Gene Therapy system (TARGT™) is an ex-vivo gene therapy, providing autologous, continuous protein therapies at physiological ranges that was used encoding for the human erythropoietin gene (TARGT™) for these studies. Patient dermal tissue biopsies (MOs) are transduced with a Helper-Dependent Adenoviral Vector containing the EPO gene and then re-implemented subcutaneously to deliver the required EPO dose.

Methods: We present initial results from 3 ongoing open label ascending dose studies of TARGT in patients with anemia due to CKD undergoing either Hemo or Peritoneal Dialysis.

Results: Thus far 14 patients were enrolled in all protocols. Follow up is ongoing with the first implanted patient being followed with stable EPO secretion and stable Hb for over 14 months from a single implantation without the need for rHuEPO or blood transfusion. Comparative analysis of serum EPO levels revealed significantly lower Cmax with TARGT compared to rHuEPO and an order of magnitude less overall EPO exposure as calculated by Area Under the Curve which may confer significant clinical benefit. No treatment related serious adverse events have been reported.

Conclusions: TARGT™ is a promising novel therapy for the treatment of anemia of CKD and potentially for other protein deficient diseases.

One subject in the 300mg QD cohort had a single Hb excursion to 13.1 g/dL. Adverse events were balanced across the 3 cohorts. Serious adverse events (SAEs) were reported in 13 subjects (13.8%), which was within the expected range (13 – 17 subjects). No drug-related SAEs, nor deaths, were reported.

Conclusions: Vadadustat is a novel, oral agent that stimulates erythropoiesis by stabilizing hypoxia-inducible factor (HIF). Prior studies in patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) have shown that vadadustat results in metabolic and hemodynamic effects. The trial enrolled 94 hemodialysis patients (Hb 9 - 12 g/dL), who were maintained on erythropoiesis-stimulating agents (ESAs) prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD; or 450 mg three times weekly (TIW). The primary

All patients were iron replete at baseline and throughout the study; IV iron use was allowed.

Results: Vadadustat maintained stable Hb levels in all 3 dose cohorts during the 16 week treatment period following conversion from ESA.
Conclusions: These data establish linkages between intra-dialytic CSA and the long interdialytic period, and also identify a unique interaction between fluid removal and K in the generation of RCA. This suggests for the first time, that future data driving targeted of these parameters might reduce CA and potentially SCF in HD pts.

The Occurrence of Cardiac Arrhythmias in Hemodialysis Patients is Linked to the Hemodialysis Procedure and to Electrolyte Abnormalities as Recorded by Implantable Loop Recorders

Christian Combe, 1 Antoine Benard, 1 Hélène Savel, 1 F. Sacher, 1, 2 CHU & Univ: Bordeaux, Bordeaux, France; 2 Rhythmical Study Group.

Background: Sudden cardiac death (SCD) is the most common mode of death among hemodialysis (HD) patients (pts). Little is known about the terminal arrhythmic events in these pts. Our objective was to identify the mechanisms which may lead to SCD in HD pts by using an implantable loop recorder (ILR, Reveal XT®, Medtronic).

Methods: Pts from 9 HD centers have been included in the study. Continuous monitoring of the cardiac rhythm has been performed using the remote monitoring capability of the ILR device (CardiLink®). Clinical, biological, and technical HD parameters and medications have been recorded for at least 1 year. General joint frailty model for recurrent event data were used to analyze associations between these parameters and the occurrence of cardiac rhythm events.

Results: 72 pts (65 18±6.6 yrs, 52M) have been included. Causes of ESRD were diabetes (n=32) and hypertension (n=19). 22 pts had an ischemic cardiomyopathy. In multivariate analyses, the occurrence of conduction abnormalities (n=64) was associated to diabetes (n=32) and hypertension (n=19). 22 pts had an ischemic cardiomyopathy. In SA-PO1114

SA-PO1115

Comparison of the Efficacy and Safety of Intravenous (IV) Etecalcetide (AMG 416) and Oral Cinacalcet (CIN) in Patients on Hemodialysis (HD) with Secondary Hyperparathyroidism (sHPT)

Kevin J. Martin, 1 Geoffrey A. Block, 2 Sunifa Cheng, 1 Bastian Dehmel, 3 Reshma Kewalramani, 3 David M. Spiegel, 4 Hao Wang, 1 Glenn Matthew C terrct, 1 St Louis Univ SOM, St Louis, MO; 2 Denver Neph, Denver, CO; 3 Amgen; 4 Relypsa.

Background: Approximately 40% of US hemodialysis (HD) patients experience moderate-to-severe itching, which negatively affect their mental and physical health (e.g., sleep loss, depression, higher antibiotic and cytotoxic side effect and increased mortality). The etiology of this condition is likely multi-factorial, including immune system dysfunction and imbalance of mu/kappa endogenous opioids. CR845 is a novel and well-tolerated kappa opioid receptor (KOR) agonist with limited central nervous system entry, thereby preferentially activating peripheral KOR on immune and skin cells and reduces itch.

Methods: In this Phase 2 double-blind, randomized (1:1), placebo-controlled clinical study, 65 prevalent US HD patients with persistent (~5 years) moderate-to-severe pruritus (baseline V AS ~68 mm, 0=no itch; 100 mm =worst itch) were treated with 1 mcg/kg intravenous CR845 or placebo following each HD session for 2 weeks. Antihistamines were discontinued 1 week prior to the study.

Results: The primary endpoint was VAS change in worst itch intensity from Baseline to Days 1-15, with a significant difference in itch intensity between placebo and CR845-treated patients (p<0.01). CR845-treated patients had a 50% mean reduction in itch intensity from baseline. The 1st secondary endpoint was also met with a significant improvement in Skindex-10, a validated patient-reported outcome measure of pruritus-related quality of life (p <0.003). Furthermore, a trend for a sleep improvement was observed (SLEEP).

Conclusions: Short-term treatment with CR845 significantly reduced itch intensity and improved quality of life in HD patients with moderate-to-severe pruritus. Thus, CR845 appears to have substantial potential to alleviate the symptoms and consequences of this frequently incapacitating condition for which existing treatments have often provided little or no relief. These data also support the opioid/immune etiology of this condition.

The ASSertID Study: Feasibility Randomised Controlled Trial of Drug Treatment for Depression in Patients on Haemodialysis

Ayan Gunuguri,1,2 Michael K. Almond,3 Joseph Chilcot,4 Andrew Davenport,5 Clara Day,2 Naomi Fineberg,2,3 Karin Friedli,6 Benjamin Spencer,1 David Wellsted,1 Ken Farrington,1 1East & North Hertfordshire NHS Trust, United Kingdom; 2Univ of Hertfordshire, United Kingdom; 3Hertfordshire Partnership Univ NHS Trust, United Kingdom; 4Southend Univ Hospitals NHS Trust, United Kingdom; 5King’s College London, United Kingdom; 6Royal free London NHS Trust, United Kingdom; 7Univ Hospitals Birmingham NHS Trust, United Kingdom.

Background: Major Depressive Disorder (MDD) is common in patients on Haemodialysis (HD) but there is little evidence of benefit from antidepressants. Hence we undertook a multicentre feasibility Randomised Controlled Trial (RCT) of sertraline versus placebo.

Methods: A screening phase identified patients with Beck Depression Inventory (BDI-II) score ≥16. Those meeting eligibility criteria, underwent psychiatric assessment (Mini International Neuropsychiatric Interview). Consenting patients with mild to moderate MDD and Montgomery-Åsberg Depression Rating Scale (MADRS) score ≥18 were randomised to sertraline or placebo. Follow-up by study psychiatrist/week 2, month 2, 4 and 6 and monthly by study nurses. Initial dose was 50 mg with titration to 100 mg if required.

Results: Of 1355 patients approached, 715 consenting for screening. BDI-II ’16 was present in 231(32.3%), 58 (25.1%) were ineligible due to current treatment for MDD. Sixty-three underwent psychiatric assessment. MDD was diagnosed in 37; 30 consented to the RCT (mean age 61±15; 71% male; 60% white). Twenty-one (70%) completed the trial, 8(15) on sertraline and 13(25) on placebo. Over 6 months, BDI-II and MADRS scores decreased ((17±6; t=3.001 and (20(±11.3, t=0.001 respectively). There was no reliable difference between the sertraline and placebo groups. Fewer on sertraline completed (6 withdrawals and one death versus 2 withdrawals on placebo (22±3.97, p=0.046)). There was a trend towards a greater fall in MADRS scores by month 2 on sertraline (effect size 0.37; lower bound 0).

Conclusions: This feasibility study is the largest RCT investigating the use of anti-depressants in HD patients with MDD. Similar significant improvement in MDD occurred over both groups. Recovery may have been quicker on sertraline.

The Effects of Normal Saline and an Acetate-Buffered Crystalloid Solution on Hyperkalemia in Deceased Donor Renal Transplantation: A Randomized Blinded Trial

Laura Elisabeth Harris, Peter F. Mount, Francesco L. Ierino, Laura Legendre, Stephen J. Chadban, J. Grinyo, Nizam Mamode, Gunnar Tufveson, Lionel Couzi, P. Riggoti, 1Y. Lebranthu, S. Sandrini, W. Marks. 1Hôpital Saint-Louis, Paris, France; 2Royal Free Hospital, London, United Kingdom; 3Hôpital Saint-Louis, Paris, France; 4Alexion Pharmaceuticals, Inc., Chesire, CT; The International Eculizumab Transplant Study Group.

Background: Complement activation by preformed DSA is the major mechanism of acute antibody-mediated rejection (aAMR) in sensitized, kidney transplant recipients (SKTR). In a previous interim study report, the C5 inhibitor eculizumab (Ec) appeared effective in preventing aAMR in deceased donor (DD) SKTR compared to historical controls. We now report 12-mo efficacy and safety data from a Sept 2015 update of this ongoing, open-label, single-arm, phase 3 clinical trial.

Methods: SKTR defined as current DSA->3000MF detected by SAB; or Br- or T-cell flow cytometric crossmatch <300 and ≤500 mean channel shift; or historical positive complement-dependent cytotoxicity crossmatch to donor HLA. All recipients received Ec 1200mg perioperative day (POD) 0 prior to reperfusion. 900mg on POD 1, 7, 14, and 28, and 1200mg at wks 5, 7, and 9. Recipients received Rabbit ATG for induction and corticosteroids, tacrolimus, and mycophenolate for maintenance immunosuppression. Plasmapheresis was not allowed following Post- transplant week 9. The primary composite endpoint was clinically significant, biopsy (bx)-proven aAMR grade II/III (Banff 2007, based on centrally read bx), graft loss, death, or loss to follow-up at 9wks. Graft and patient (pt) survival were estimated by K-M.

Results: 80 pts were transplanted (48 F, 32 M); median age 52y (range, 24–70). 7 of 80 SKTR had aAMR (8.8%) compared to 30% expected for historical controls. 11.8 SKTR met the 9wk composite primary endpoint based on local bx (13.8% [95% CI 7.1–23.3]). Graft survival at 6 and 12mwo was 93.7% and 88.7%, respectively; pt survival at 6 and 12mwo was 97.4%. SCR levels (mg/dL) at baseline, 1 and 12mwo were 7.43 (±2.51), n=79; 1.86 (±0.9), n=79; 1.86 (±0.9), n=79. (p=0.37)

Conclusions: Ec appeared to be effective in reducing aAMR in SKTR. Pt and graft survival and kidney function at 12mwo were similar to those expected for non-sensitized KET. Ec was well tolerated. Funding: Pharmaceutical Company Support - Alexion Pharmaceuticals, Inc.

Impact of De Novo Donor Specific Antibodies on Graft Outcomes in Kidney Transplant Recipients following Early Switch from Calcineurin Inhibitor to Everolimus: Analysis of the ELEV ATE Trial

Johan W. De Fijter, Wolfgang Hubdass, Patricia M. Lopez, Peter Bernhardt, Zailong Wang, Frans Claas, Wolfgang Arns, Josep M. Cruzado, Markus van der Giet.

Background: Development of de novo donor specific HLA-antibodies (dnDSA) after kidney transplantation (KTx) is associated with an increased risk of antibody-mediated rejection (AMR) and graft failure. The ELEVATE study evaluated the impact of early conversion from CNIs to everolimus (EVR) after KTxs and prospectively explored the status and development of DNAs.

Methods: In this 24 month (M), multicentre study KTx recipients were randomized at 10–14 weeks post-Tx to convert from CNI to EVR (n=366: C0 6–10 ng/mL) or continue CNI (n=373: C0, tacrolimus 5–10 ng/mL, ciclosporine 100–250 ng/mL); all received enteric-coated mycophenolate sodium (MPS) + corticosteroids. Blood samples were collected at

baseline, randomization (RND), M12 and M24 or at time of rejection episodes and analysed by Luminex/SAB assay in one central lab. dnDSA was defined by a MFI value $\geq 500$ any time post-RND in patients with MFI $\geq 500$ at RND.

**Results:** Baseline characteristics were comparable between groups. Incidence of preformed DSA (MFI $\geq 500$ at baseline) against HLA class-I or -II was low (table A). Overall, incidence of dnDSA HLA class-I was higher with EVR/MPS treatment vs CNI/MPS at M12 and M24. The incidence of dnHLA Class-II antibodies was dominated by anti-DQ in the CsA/MPS [lrm]group (table B). No association between de novo (either HLA class-I or -II) antibodies and a diagnosis of AMR or tBPAR was evident in this population up to M24 (table C, D).

**Conclusions:** Early conversion to EVR at 3M post-Tx did not increase the risk of dnDSA formation vs CNI continuation. Moreover, no association was observed between development of dnDSA and AMR or tBPAR, even with the lowest detection thresholds.

**Donor-Derived Cell-Free DNA in Plasma Increases with Rejection and Decreases after Treatment in Kidney Transplant Recipients**

Marica Grskovic,1 Brian Christie,1 David Hilles,1 Robert Woodward,1 Jim Yee,1

Flavio Vincenti.2 1CareDx, Inc., Brisbane, CA; 2UCSF, San Francisco, CA.

**Background:** Donor-derived cell-free DNA (dd-cfDNA) is an emerging biomarker of acute cellular rejection in organ transplant recipients. The utility of determining plasma levels of dd-cfDNA aimed at diagnosing rejection and evaluating treatment response was assessed in kidney transplant recipients in a longitudinal observational trial.

**Methods:** Clinical status, biopsy grade (performed in response to elevated serum creatinine) and plasma were collected at 326 routine surveillance visits from 101 patients. Samples from nine patients assigned a biopsy grade I, II or III (NIH criteria) were classified as rejection (R). Samples from seventeen patients assigned a biopsy grade 0 were classified as quiescent (Q). cfDNA extracted from plasma was amplified at targeted SNPs and analyzed using a sensitive and accurate Next Generation Sequencing assay to quantify dd-cfDNA levels without the need to separately genotype the donor. Standard statistical measures of significance were used.

**Results:** dd-cfDNA levels were significantly higher ($p=0.029$) in patients with biopsy-confirmed rejection (R, mean 4.23%) compared to quiescent patients (Q, mean 0.96%). Creatinine levels were not significantly different between R and Q patients ($p=0.69$; mean 4 and 3.1 mg/dL, respectively). Longitudinal sample analysis from 15 patients showed increased dd-cfDNA levels following transplant (mean 2.8%) with reduction to levels below 1% by two weeks post transplantation. In 3 cases with clinically treated biopsy-confirmed rejection and 2 serial samples following the rejection, levels of dd-cfDNA decreased following rejection treatment.

**Conclusions:** dd-cfDNA shows promise as a biomarker of rejection that may be used for non-invasive surveillance of kidney allograft status and treatment response. The ongoing measurement of cfDNA may allow clinicians to better personalize care and improve patient outcomes.
