Background: Recently, 2 large randomized controlled trials (RCTs) have been published on the efficacy of tacrolimus (TAC) in Asian LN patients. Both trials used different treatment regimens and efficacy was not consistent between the trials. Therefore, the role of TAC in the treatment of LN remains unclear. Thus, we performed a systematic review on TAC treatment for LN.

Methods: We searched multiple databases for all human studies investigating TAC treatment in LN. Then studies were selected on clinical relevance and results were analysed on renal response and adverse events.

Results: We found 26 clinical studies from which data were extracted from all controlled studies: 6 RCTs and 3 case-control studies involving a total of 888 patients. As induction treatment, TAC with steroids resulted in 82% responders of which 56% complete responders (CR). Induction with steroids, mycophenolate (MMF) and TAC resulted in 85% responders, of which 46% CR. Data from 1 RCT performed with TAC in combination with steroids as maintenance treatment, resulted in 100% responders of which 56% CR. Generally, control patients receiving induction treatment with cyclophosphamide achieved 66% response of which 29% CR. Those receiving induction treatment with MMF achieved 76% response of which 53% CR. Overall infections were observed in 20% of TAC treated patients compared to 26% of control patients treated with cyclophosphamide and 29% in MMF treated control patients. A rise in serum creatinine was observed in 5% of all TAC treated patients compared to 2% in the cyclophosphamide control group and 0% in the MMF control group.

Conclusions: This systematic review suggests that TAC-based treatments can achieve comparable renal responses in LN as conventional regimens. Currently, limitations of the available studies are the heterogeneity of TAC-based regimens, lack of studies in non-Asian LN patients and lack of long-term safety data. Altogether, these data warrant further RCTs on TAC treatment for LN.

TH-PO767
Predicting Chronic Kidney Disease (CKD) in Lupus Nephritis (LN)
Ana Malvar, Valeria Gabriela Alberton, Bruno Jorge Lococo, Haikady Nagaraja, Brad H. Rovin, Hospital Fernandez, Buenos Aires, Argentina; Ohio State Univ Wexner Medical Center, Columbus, OH.

Background: Early identification of LN patients likely to develop CKD may permit therapy to be adjusted and CKD to be avoided. Clinical and histologic parameters measured after induction and during maintenance therapy were associated with long-term chronic kidney outcomes in a cohort of LN patients to define predictors of new CKD.

Methods: Patients (n=69) with biopsy-proven class III/IV LN were induced with steroids and MMF (53%) or cyclophosphamide (44%) for 6 months, had repeat kidney biopsy (biopsy 2, 6.6±0.7 months), and were put on maintenance therapy. Long-term (median 73 months) follow-up was available on 87% of the cohort. Multivariate linear regression was used to develop a predictive model for future serum creatinine (SCr) based on clinical and histologic variables obtained after induction.

Results: Complete clinical response at biopsy 2 (CR) at last follow-up among patients who did or did not achieve a complete clinical renal response after induction (19% vs 18.4%, respectively). Among patients with complete histologic renal remission after induction, 36% had a final SCr of 1.3-2.9 mg/dl. There was no relationship between the NIH activity index at biopsy 2 and long-term kidney function. However, the median serum creatinine at biopsy 2 of patients who developed CKD was 6 (range 2-8) compared to 4 (range 0-7) in patients who did not develop CKD (p=0.02). Regression analysis showed a significant linear correlation between CI 4 at biopsy 2 and log(Scr) at long-term follow-up (R=0.36, p < 0.0001). In multivariate analysis CI and SCr at biopsy 2 were independent predictors of long-term SCr (R=0.48, p < 0.0001). For a given level of SCr at biopsy 2, a 1 unit increase of CI in the range of 4-8 corresponded to a 20% increase in last SCr.

Conclusions: Neither clinical nor histologic remission after induction predicts long-term outcome of LN patients. The combination of CI and chronic damage on induction biopsy after induction accounts for 48% of the long-term variability of renal function in those patients who reach a threshold level (CI=4) of chronic kidney damage.

TH-PO768
Clinical and Histologic Remission in Class IVG and IVS Lupus Nephritis (LN) After Induction Therapy
Ana Malvar, Bruno Jorge Lococo, Valeria Gabriela Alberton, Diego Morales, Brad H. Rovin, Hospital Fernandez, Buenos Aires, Argentina; Ohio State Univ Wexner Medical Center, Columbus, OH.

Background: The ISN/RPS classification of LN distinguishes class IV with predominantly segmental lesions (IVS) from class IV with global (IVG) lesions. It has been suggested that IVG may have a lower remission rate than IVS, possibly because it more like a vasculitis than IVG. However several studies found no significant difference in long-term kidney survival between these subclasses. We examined differences in histologic and clinical remissions between IVG and IVS in our LN cohort with serial kidney biopsies. Patients with proliferative lupus nephritis were all compared using network meta-analysis and compared to intravenous cyclophosphamide (referent).

Methods: A systematic review (CCR) was defined as normal SCr and proteinuria < 500 mg/d. Complete histologic remission was defined as an AI=0 at Bx2.

Results: Clinical outcomes and histologic data are shown in the Table. All patients were ANCA negative. Final SCr and proteinuria were determined after a mean follow-up of 54±7 months. Only 4 patients were lost to long-term follow-up.

| Bx1 | CR (n=33) | 39% | 87% | 0.32 | 0.24 | 10.3±2.9 | 3.7±2.8 | 3.5±1.9 | 4.9±1.9 |
| Bx2 | CR (n=41) | 76% | 70% | 0.32 | 0.26 | 19.5±2.2 | 3.0±1.3 | 2.6±1.8 | 4.4±0.7 |
| IVG (n=9) | 80% | 89% | 0.26 | 0.19 | 8.5±2.2 | 1.8±1.8 | 0.05 | 0.05 | 0.05 |
| IVS (n=10) | 76% | 66% | 0.34 | 1.00 | 0.43 | <0.05 | 0.05 | 0.05 | 0.05 |

Conclusions: Class IVS LN has an excellent clinical and histologic response to standard-of-care LN induction therapy. Class IVG takes longer to respond, but over time there are no differences in long-term renal outcomes between Class IVG and IVS LN as assessed by SCr and proteinuria. This suggests that these subclasses may be treated similarly. These results also raise the possibility that class IVS patients who have complete clinical and histologic remission after induction may do well with an abbreviated course of maintenance therapy.

TH-PO769
Complete Remission Rate and Outcome in Severe Lupus Nephritis: The Impact of Baseline Serum Creatinine

Background: A complete remission (CR) in severe lupus nephritis (SLN) is associated with a favorable long-term outcome. Numerous factors including level of serum creatinine (SCr) at baseline have been shown to impact on CR rate and outcome. We assess the impact of baseline SCr on CR rate and outcome in SLN.

Methods: We evaluated the 86 adult patients in the prospective, controlled trial of plasmapheresis in SLN and compared them based on SCr level at baseline (≤1.0, 1.01-1.5, 1.51-2.0, 2.01-3.0 and >3.0 mg/dl; n= 22, 23, 23, 16, 13, 12 respectively). The CR rate (defined by a serum creatinine (SCr) of ≤ 1.4 mg/dL and proteinuria < 0.33 g/day) and long-term outcomes (stable renal function, dialysis and death) were compared. Pts with a baseline SCr of ≥1.0 mg/dl were >16 times as likely (odds ratio, 16.2; 95% confidence interval, 4.2-61.5) to attain a CR and >6 times as likely (odds ratio, 6.1; 95% confidence interval, 1.9-20.5) to have stable renal function at last follow-up compared to pts with a baseline SCr of <1.0 mg/dl. The CR rate and outcome in SLN as assessed by SCr and proteinuria. This suggests that these subclasses may be treated similarly. These results also raise the possibility that class IVS patients who have complete clinical and histologic remission after induction may do well with an abbreviated course of maintenance therapy.

**Urinary Adiponectin Isorforms and Kidney Lesions in Lupus Nephritis (LN)**

Xiaolan Zhang,1 Divya Indrakanti,1 Anthony Alvarado,1 Sergey V. Brodsky,2 Hermine Brunner,2 Brad H. Rovin,1,3 1Ohio State Univ Wexner Medical Center, Columbus, OH; 2Cincinnati Children’s Hospital, Cincinnati, OH; 3CKD Biomarker Consortium.

**Background:** Human adiponectin isoforms exert different effects on inflammation. Urinary adiponectin is increased at LN flare, but the relationship between adiponectin isoforms and kidney lesions in LN has not been studied.

**Methods:** Urine and plasma total and high molecular weight (HMW) adiponectin isorforms were measured by specific ELISAs in samples from 39 normal controls and 97 biopsy-diagnosed LN patients. Urinary adiponectin levels were normalized and log-transformed, and then examined for associations with histologic lesions on kidney biopsy by ANOVA, nonparametric Wilcoxon ranked-sum testing and multiple linear regression analysis.

**Results:** The HMW to total adiponectin ratio was increased in plasma (p=0.022) and urine (p=0.0004) of LN patients compared to controls. Total and HMW adiponectin levels were highly correlated within the plasma (R²=0.91, p < 0.0001) and urine (R²=0.64, p < 0.0001) in LN, but between plasma and urine HMW adiponectin showed a correlation, and this was minor (R²=0.21, p=0.037). Urine adiponectin levels increased with the severity of ISN/PNS class. The highest total and HMW urine adiponectin levels were found in patients who had combined class III or IV + V LN. Using urine HMW adiponectin levels to differentiate between control and LN patients, and between single and combined LN classes, receiver-operating characteristic analysis showed areas under the curve of 0.96 and 0.85, respectively. Urine HMW adiponectin was significantly increased when glomerular proliferation, cellular crescents or interstitial inflammation were present on the biopsy, and HMW adiponectin correlated with the biopsy activity index (R²=0.31, p < 0.0001), but not chronicity index. Using HMW adiponectin plus urine hemopexin plus serum creatinine, an equation to predict biopsy chronicity index was constructed with R²=0.46.

**Conclusions:** Urine adiponectin isoforms increase with the severity of active kidney lesions in LN. The increase in urine adiponectin is not simply a reflection of changes in systemic adiponectin, and may be due to intra-renal processing. **Funding:** NIDDK Support

**TH-PO771**

**Significance of Serum Cystatin C as a Biomarker for Clinical Practice in Patients with Lupus Nephritis**

Hua Zhou, Di Lu, Hairong Tang, Lizi Li, Huimeng Qi, Lining Wang. Nephrology Dept, 1st Hospital of China Medical Univ, Shenyang, China.

**Background:** Serum Cystatin C (sCysC) as a novel biomarker of renal function has been studied in many primary glomerular diseases. However, sCysC was barely reported in chronic kidney disease(CKD) and hypertension.

**Methods:** 106 patients with LN proven by renal biopsy were studied. sCysC, serum creatinine (sCr), BUN, 24 hr total urinary protein (uTP), serum albumin (sAlb), systemic lupus erythematosus disease activity index (SLEDAI), C4, C3, IgG, ANA, DaDNA, C-reaction protein (CRP), and ESR were examined before and 1, 3, 6, 12, 24 months after treatment with steroid and immunosuppressants. estimated glomerular filtration rate (eGFR) was calculated by EPI-sCysC, EPI-sCr, and EPI-sCysC + sCr. The strength of correlation was compared between sCysC and sTP, sAlb, SLEDAI, and CRP before and after treatment.

**Results:** sCysC and eGFR (EPI-sCysC+sCr) showed stronger correlation with uTP, sAlb, SLEDAI, and CRP before the treatment (table). During treatment, a similar trend was seen in sCysC and eGFR (EPI-sCysC+sCr). sCysC also showed a better statistical p value than sCr/BUN in response to treatment with steroid plus either all kinds of immunosuppressants or cyclophosphamide.

**Conclusions:** sCysC and eGFR based on sCysC might be useful early biomarkers to diagnose LN and better to monitor the treatment of LN. sCysC will likely help in clinical decision making for early intervention and the timing of reducing key treatments. Prospective study is needed to investigate the effect of early treatment based on sCysC increase (sCr normal) in large cohort of LN patients. **Funding:** Government Support - Non-U.S.

**Neutrophil Membrane Blood Transcriptional Signature Is Associated with Lupus Nephritis and Its Severity in SLE**

Noemie Jourde-Chiche,1 Bertrand Gondouin,2 Stephane Burty,1 Laurent Daniel,2 Bertrand Dussol,1 Laurent Chiche.3 1Nephrology, Aix-Marseille Univ, Marseille, France; 2Pathology, Aix-Marseille Univ, Marseille, France; 3Internal Medicine, Hospital European, Marseille, France.

**Background:** Lupus nephritis (LN) is a severe complication of SLE. The aim of this study was to assess the link between blood transcriptional signatures and LN, comparatively with other pathological conditions associated with renal injury.

**Methods:** 102 patients were included: 62 SLE patients, 40 controls with various conditions (10 with crescentic GN due to ANCA-associated vasculitis (AAV), 15 with severe bacterial or fungal sepsis, 15 with non-proliferative glomerular diseases), and their matched healthy controls. SLE samples were split in those at the time of: a biopsy-proven active LN (group 1, n=24); an extra-renal flare (group 2, n=11); a clinically quiescent visit (group 3, n=34). Microarray data were generated using Illumina beadchips and analyzed using modular repertoire analyses.

**Results:** Modular repertoire analysis in SLE patients revealed, in addition to the activation of IFN-related modules, a strong upregulation of M5.15, a module of 24 transcripts annotated “neutrophil”. There was no correlation between M5.15 and SLEDAI, anti-dsDNA level or IFN modules activity. M5.15 was strongly associated with active LN (p=0.009), but not with non-renal manifestations. The neutrophil modular signature was present in 67%, 18% and 47% of patients from group 1, 2 and 3 respectively. In group 2 and 3, its presence was associated with a past history of LN or the occurrence of LN during the follow-up. M5.15 was correlated with acute renal failure (p=0.03) and serum albumin (p=0.08). In group 1, the median value of M5.15 was higher in patients with proliferative than non proliferative LN (66.7 vs 18.8 %, p=0.04). AAV and sepsis patients shared the neutrophil signature observed in SLE, but displayed no IFN signature, while those with non-proliferative GN had none of these signatures.

**Conclusions:** Modular repertoire analysis demonstrates that neutrophil signature is correlated with occurrence and severity of LN in SLE. This result could allow the design of new biomarkers in LN.

**Anticoagulation and Longterm Outcomes in Patients with Renal Artery Stenosis and Antiphospholipid Syndrome**

Alina L. Casian, Shirish Singale, Sotiria Manoustathopoulou, David D’Cruz. Lupus Unit, Guy’s Hospital, London, United Kingdom.

**Background:** Our previous data showed renal artery stenosis (RAS) is more prevalent in antiphospholipid syndrome (APS) (26%) compared to the general hypertensive population (8%), and anticoagulation with INR=3 was associated with initial reduction of chronic kidney disease (CKD) and hypertension.

**Methods:** We identified 37 patients with RAS and APS fulfilling Sapporo criteria: anticardiolipin IgG/IgM titer>40 units or >99th percentile (or lupus anticoagulant) on >2 occasions >=6 weeks apart AND vascular thrombosis (or pregnancy morbidity). RAS was diagnosed by magnetic resonance angiography (MRA).**Results:** 15 patients had APS alone and 22 APS associated with autoimmune conditions (13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had 13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had CKD and hypertension. 9/37(24%) died after a median of 10 years since RAS diagnosis. Our previous data showed renal artery stenosis (RAS) is more prevalent in antiphospholipid syndrome (APS) (26%) compared to the general hypertensive population (8%), and anticoagulation with INR=3 was associated with initial reduction of chronic kidney disease (CKD) and hypertension.

**Results:** 15 patients had APS alone and 22 APS associated with autoimmune conditions (13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had CKD and hypertension. 9/37(24%) died after a median of 10 years since RAS diagnosis. 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had CKD and hypertension. 9/37(24%) died after a median of 10 years since RAS diagnosis.

**Conclusions:** The majority of patients with RAS and APS were female, developed CKD and did not benefit from angioplasty. Anticoagulation was not associated with long-term reduction of ESRD or death, suggesting a non-thrombotic pathogenic process underlying

A Prospective Study to Investigate Mycophenolic Acid Pharmacokinetics and Its Clinical Correlations in Lupus Nephritis Patients

1Desmond Y.H. Yap, 1 Chun-Hay Tam, 1 Sunny Sze ho Wong, 1 Maggie Kam Man Ma, 1 Susan Yang, 1 Daniel Tak Mao Chan. 1 Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; 2Medicine and Geriatrics, United Christian Hospital, Hong Kong, Hong Kong.

Background: The dosing regimen of mycophenolate mofetil (MMF) in the treatment of lupus nephritis (LN) is adopted from the kidney transplant experience. The role of therapeutic drug monitoring of mycophenolic acid (MPA) level in managing LN remains under-studied.

Methods: We prospectively studied LN patients on maintenance treatment with prednisolone and MMF. Blood MPA level at 1, 2, 4, 8, 10 and 12 hours (i.e. C1, C2, C4, C8, C10 and C12) after MMF administration was measured using an enzymatic assay upon recruitment and repeated at 6-month intervals for 24 months, and at occurrence of clinically significant events, to investigate their clinical correlations.

Results: 51 patients were included, with prednisolone and MMF dose of 6.2±1.8 mg/kg/day and 1284±493 mg/d respectively at baseline. C1, C2 and C12 MPA levels were 9.9±8.7 mg/L, 8.6±6.2 mg/L, 1.9±1.4 mg/L during disease remission. C1, C2 and C12 MPA levels correlated with AUROC (r = 0.52, 0.85 and 0.77; p<0.001, <0.001 and <0.001 respectively). C12 correlated inversely with hemoglobin, white cell and platelet counts (r =−0.359, 0.226, 0.2; p<0.001, 0.010 and 0.024 respectively). There was no association between C12 and anti-dsDNA, serum creatinine or 24-h urine protein excretion (r= 0.53, 0.07 and 0.37 respectively). C1 and C2 showed no association with clinical or serological parameters. Clinically significant events included infection in 2 patients, gastrointestinal upset in 3 patients, and renal flare in 5 patients. C12 MPA level at the time of these events were 2.53±2.0, 2.53±2.0, 2.53±2.0 mg/L and 1.58±0.9 mg/L respectively.

Conclusions: C12 MPA level showed good correlation with drug exposure, and may be associated with renal flare and haematological side-effects but not infection.

TH-PO775

Long-Term Prospective Study of Tacrolimus-Based Treatment in Lupus Nephritis Patients

Kazanori Karasawa, Keiko Uchida, Yukari Asamiya, Takahito Moriyama, Mitsuyo Itabashi, Takashi Takei, Kosaku Nitta. 1 Medicine, Kidney Center, Tokyo Women’s Medical Univ, 8-1 Kawada-cho, Shinjyuku-ku, Tokyo, Japan.

Background: This study aimed to examine whether long-term maintenance treatment with tacrolimus for patients with lupus nephritis (LN) is effective and safe.

Methods: A total of 27 adult patients with LN after induction therapy were enrolled. Tacrolimus was initiated at a dose of 3 mg/day. Patients treated with other immunosuppressive agents were also switched to tacrolimus. Prednisolone doses were tapered throughout the period according to individual disease activity. Prospective data were collected. Tacrolimus was initiated at a dose of 3 mg/day. Patients treated with other immunosuppressive agents were also switched to tacrolimus. Prednisolone doses were tapered throughout the period according to individual disease activity. Prospective data were collected. Tacrolimus was initiated at a dose of 3 mg/day. Patients treated with other immunosuppressive agents were also switched to tacrolimus. Prednisolone doses were tapered throughout the period according to individual disease activity. Prospective data were collected.

Results: Four patients discontinued tacrolimus treatment due to its ineffectiveness, complications including acute myeloblastic leukaemia, or their personal intention to become pregnant or discontinue medication. A total of 23 patients (mean age 52.6±11.8 years and mean duration of LN 15.6±8.7 years) were treated with tacrolimus throughout a 5-year period and their data were analyzed. The mean urinary protein/creatinine ratio significantly decreased from a baseline of 1.12±1.47 to 0.33±0.78 at 1 year (p=0.005) and 0.40±1.54 at 5 years (p=0.016), while mean eGFR levels were unchanged throughout the 5 years of tacrolimus treatment. The mean LNDAI was significantly decreased from a baseline of 3.54±2.53 to 1.96±1.40 at 1 year (p=0.021) and 2.08±1.44 at 5 years (p=0.022). Similarly, the mean prednisolone dose significantly decreased from a baseline of 0.35±0.21 mg/kg/day to 0.22±0.15 mg/kg/day at 1 year (p=0.022) and 0.17±0.09 mg/kg/day at 5 years (p=0.001). The mean blood concentration of tacrolimus was 4.0±2.3 µg/mL only one patient experienced a disease flare, and there were no deaths during the study period.

Conclusions: Our results suggest that tacrolimus can be potentially effective for the treatment of LN; moreover, the current dosage appeared to be generally well-tolerated for most patients, and renal flare in 5 patients. C12 MPA level at the time of these events were 2.53±2.0, 2.53±2.0, 2.53±2.0 mg/L and 1.58±0.9 mg/L respectively.

Funding: Private Foundation Support

Comparison of Kidney Function and Mortality of Mexican Children versus Adults with Lupus Nephritis

Background: Childhood-onset lupus nephritis (CLN; onset before 16 years of age) has been associated with a more aggressive disease course as compared to adulthood-onset lupus nephritis (ALN). Kidney factors such as LN Class and Activity and Chronicity Indexes are related to renal prognosis. No information is available in our setting. Aims: To compare kidney function and mortality of CLN vs ALN.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

268A
expression profiles were compared at bx1 and bx2 between these CR and NR patients. Transcripts were considered differentially expressed only if they met both criteria of at least a 1.5-fold change (FC) and p-value < 0.01.

Results: At flare, 2 transcripts were differentially expressed between CR and NR. IL-28a, a type 3 interferon gene was decreased 2.6-fold (p = 0.006) and mannose-binding lectin serine peptidase 1 (MASP1), a member of the complement lectin-pathway, was decreased 1.8-fold (p = 0.009) in CR versus NR. From bx1 to bx2, 8 genes were differentially expressed in the CR group. Expression of adhesion molecule VCAM1 and macrophage regulator CEBPB was decreased while expression of TGF-β activator SMAD3, inhibitor of TLR signaling, TOLLIP, and inhibitor of IRF7 signaling, TRAF4 was increased. In NR, from bx1 to bx2, 9 genes were differentially expressed. Expression of the type 3 interferon, IL28b and the TNF-receptor TNFRSF13b (TACI) was decreased while expression of complement C2 and CFNB the TNF cytokine TNFSF8 was increased.

Conclusions: The molecular characterization of kidney biopsies at LN flare along with the change in expression after treatment identifies differentially expressed genes among patients who eventually have or do not have a CR. Some of these genes may be candidates biomarkers of long-term renal outcomes in LN.

TH-PO778
Evaluation of Healthcare Resource Utilization and Costs by Immunosuppressant Pattern of Use in Lupus Nephritis

Background: US-based treatment guidelines recommend 6 months of immunosuppressant (IS) therapy before continuing or switching regimens for class III/IV lupus nephritis (LN) patients. Literature suggested that management of LN is costly, but published data on how costs and healthcare resource utilization (HRU) may vary by IS pattern of use are limited.

Methods: We identified LN patients initiating cyclophosphamide (CYC) or mycophenolate mofetil (MMF) in 2010-2013 from a US commercial/Medicaid claims database. All-cause costs and HRU during the year post-IS initiation were examined. Comparison was made between the following four groups based on their IS utilization during the first 6 months and 7-12 months post-IS initiation: 1) patients who used the same IS continuously for at least 7 or up to 12 months (reference group), 2) patients who switched added-on IS after 6 months, 3) patients who switched/added-on IS within 6 months, and 4) patients who discontinued IS within 6 months.

Results: Final sample included 1,567 LN patients (mean age 37 years; 86% female) initiating CYC (16.1%) or MMF (83.9%). Patients who remained on the same IS throughout added-on IS after 6 months, 3) patients who switched/added-on IS within 6 months, and 4) patients who switched/added-on IS before 6 months (N=305).

Conclusions: We found encouraging results. The incidence of maternal and foetal complications during pregnancy was reduced compared to previous European studies including lupus patients. Risk factors of major maternal complications are best characterized.

Nephrotic Syndrome and Pregnancy
C. De Castro,1 J. Ashley Jefferson,2 Thomas R. Easterling,2 1Div of Nephrology, Dept of Medicine, Univ of Washington School of Medicine; 2Dept of Obstetrics and Gynecology, Univ of Washington School of Medicine, Seattle, WA.

Background: In the absence of hypertension or renal insufficiency, some consider the perinatal outcomes in pregnant women with nephrotic syndrome to be good. However, the diagnosis and management of both maternal and fetal well-being is challenging.

Methods: We describe the presentation, management, and maternal and fetal outcomes of 31 pregnancies in 24 women with biopsy proven nephrotic syndrome during pregnancy. We included patient demographic data, anticoagulant medications, anticoagulant treatment protocols, and obstetric outcomes. We excluded patients who had nephrotic-range proteinuria (>3.5g/24hr and/or >3.5g/g on spot urine protein:creatinine ratio) during pregnancy, a kidney biopsy diagnosis, and serum creatinine <1.5mg/dL at presentation.

Results: There were 24 subjects (9 primiparas) with 31 pregnancies and 32 offspring. Mean age was 27.6 years (range 16- 39 years) and mean gestational age at presentation was 18.7 weeks (range 5 - 40 weeks). Labs revealed a mean creatinine 0.85mg/dL (range 0.4-1.4mg/dL), mean serum albumin 1.97g/dL (range <1- 3.2g/dL), and mean proteinuria 8.96g/24h (range 0.2- 3.6 32g). UltraCOM data was available for 18 pregnancies. Mean cardiac output at presentation was markedly elevated at 8.38L/min. 14 of 31 pregnancies were known to have kidney disease before pregnancy. Nephrotic syndrome was newly diagnosed in 16 patients. Biopsy was performed during pregnancy in 10 subjects (median age of gestation 20.5 weeks (range 2.2-7.2 weeks) changing management in 70%. 6 were biopsied postpartum. Biopsy diagnoses were FSGS(11), IgAN(3), lupus nephritis(3), membranous nephropathy(3), and 1 case each of Fibriinny GN, MPGN, C3GN, and minimal change disease. Maternal complications included preeclampsia(10/31), acute kidney injury(3/31) and cellulitis(3/31). Mean age of gestation at delivery was 35.4 weeks (range 25-40 weeks). All delivered via caesarean section. Fetal complications included birth weight <2500g(18), IUGR(3), and 10 were admitted to NICU.

Conclusions: Pregnant women with nephrotic syndrome are at high risk for developing severe maternal and foetal complications despite the absence of significant hypertension or renal insufficiency.

Cresectic IgA Nephropathy – A Prospective Study  Krishan L. Gupta, Prabhakar Doddi, Rittambra Nanda, Raja Ramachandran. 1  Nephrology, PGIMER, Chandigarh, India; 2 Pathology, PGIMER, Chandigarh, India.

Background: Cresectic IgA nephropathy (cIgAN) carries a very poor prognosis and the initial creatinine at presentation predicts long-term outcome. The present prospective study was carried out to evaluate the clinic-pathological correlation and outcome of cIgAN.

Methods: A total of 31 patients with cIgAN were included in the study. Thirty- eight (63.33%) cases progressed to ESRD by the end of 12 months. Serum creatinine at presentation and IFI>50% and presence of fibrous crescent on biopsy was risk factor for ESRD.

Conclusions: Patients with cIgAN carries a very poor prognosis, with majority of the cases progressing to ESRD by 12 months. Serum creatinine at presentation and presence of diffuse IFTA and fibrous crescents on biopsy predicts development of ESRD.

Primary objective of the study was to evaluate percentage of patients achieving remission/ CR rate, who were examined. 39 of the above 77 patients who were observed for 3 years following subnephrotic proteinuria. Serum Gd-IgA1 levels were defined as proteinuria of less than 0.3 g/gCre and urinary erythrocytes of less than 5 high-power field.

Results: Multiple linear regression analysis adjusted by age and estimated glomerular filtration rate (eGFR) indicated that U-NAG level was significantly associated with tubulointerstitial fibrosis score (p=0.001) and the percentage of global sclerotic glomeruli (p=0.008). Multiple logistic regression analysis adjusted by age, sex and eGFR indicated that the CR rate 3 years after ST was significantly associated with tubulointerstitial fibrosis score (Odds Ratio [OR] 0.092, 95% Confidence Interval [CI] 0.009-0.914, p=0.042) and U-NAG/Gd-IgA1 (OR 0.025, p=0.007).

Conclusions: U-NAG is a potentially useful biomarker of the severity of renal tubulointerstitial fibrosis and global glomerulosclerosis percentage in IgAN. U-NAG measurement may also aid in the prediction of therapeutic response to ST in IgAN.

Beneficial Effect of Immunosuppressive Therapy for IgA Nephropathy with Moderately Impaired Renal Function

Kyung Sun Park, Jongha Park, Jong Soo Lee, Hyun Chul Chung. 1 Div of Nephrology, Dept of Internal Medicine, Dongkang Medical Center, Ulsan, Korea; 2 Div of Nephrology, Dept of Internal Medicine, Ulsan Univ Hospital, Ulsan, Korea.

Background: A variety of treatment has been attempted to slow progression of IgA nephropathy (IgAN) such as renin-angiotensin system inhibitors and adding corticosteroid for patients with impaired renal function. We compared clinical outcomes of IgAN patients who were treated with vs. without immunosuppressive therapy (IST), and explored identified risk factors associated with progression of renal dysfunction.

Methods: Patients who were diagnosed as IgAN between 2001 and 2014 were screened. Among the patients who had initial estimated glomerular filtration rate (eGFR) of 30-60 ml/min/1.73 m² and had followed up for at least 12 months were included in this analysis.

Results: A total of 92 patients were analyzed. 39 patients received IST (Group 1) and 53 did not (Group 2). Median follow-up (59 vs. 77 months) and mean age (46.6 vs. 47.4 years) were not different. In Group 1, mean arterial pressure (93 vs. 99 mmHg, P=0.019), serum creatinine (1.66 vs. 1.45 ml/min/1.73 m², P<0.003) and median amount of proteinuria (2033 vs. 1115 mg/day, P<0.001) were significantly higher, but mean eGFR (43.7 vs. 50.1 ml/min/1.73 m², P=0.001) and serum albumin (3.5 vs. 4.0 g/dL, P=0.099) were lower than Group 2 at last-visit eGFR. Three patients of Group 1 and 7 of Group 2 progressed to end-stage renal disease (ESRD). ESRD-free survival was comparable between two groups (P=0.639). For 1 year, the change of mean eGFR was significantly different between 2 groups (3.8 of Group 1 vs. -1.3 ml/min/1.73 m² of Group 2, P=0.027).

In multivariate linear regression, age at diagnosis (standardized beta, 0.212; P=0.041), MAP (standardized beta, -0.227; P=0.027), baseline eGFR (standardized beta, 0.566; P=0.007) and initial proteinuria (standard beta, 0.273; P=0.013) were independent predictors of last-visit eGFR.

Conclusions: IST may have a beneficial effect for slowing progression of IgAN with moderately impaired renal function.

Longitudinal Study of a Kindred with Familial IgA Nephropathy Reveals Stable Serum Levels of Galactose-Deficient IgA1

Hiroyuki Ueda,1 Yoshimi Ueda,2 Zina Moldoveanu,3 Stacy D. Hall,4 Karen Hart,4 Krzysztof Kiryłuk,5 Ali G. Hahvari,6 Dana Rizk,7 Bruce A. Julian,8 Jan Novak.9 Univ of Alabama at Birmingham, Birmingham, AL; The Jikei Univ School of Medicine, Tokyo, Japan; 2 Columbia Univ College of Physicians and Surgeons, New York, NY.

Background: Patients with IgA nephropathy (IgAN) have elevated levels of circulating galactose-deficient IgA1 (Gd-IgA1). Familial form of IgAN has been reported among people of all ancestries. Serum Gd-IgA1 levels are heritable in patients with familial and sporadic IgAN. Moreover, 50% of first-degree relatives of patients with familial IgAN have high serum Gd-IgA1 levels (≥95th percentile of healthy controls) without clinical signs of IgAN. This study performed a longitudinal follow-up of a large kindred with familial IgAN.

Methods: Pedigree includes 4 men with biopsy-proven IgAN. Members recruited in 2005 and 2014 included 2 IgAN patients, 13 relatives, and 7 genetically unrelated individuals (marry-ins). Blood samples were drawn to determine for total IgA and Gd-IgA1 levels. Gd-IgA1 was measured using lectin ELISA and expressed relative to a standard Gd-IgA1 in 100 ng of serum IgA. Spot urine sample was obtained for urinalysis and protein/creatinine ratio. Abnormal urinalysis was defined by hematuria (≥2 ×) blood and/or protein/creatinine ratio ≥0.5 g/g.

Results: Mean (± SD) ages of all IgAN patients, blood relatives, and marry-ins were 48 ±3, 43 ±6, 41 ±12 yr in 2014. Two patients had multiple kidney transplantations. Except for the 2 IgAN patients, no individual had an abnormal urinalysis. Serum Gd-IgA1 levels for marry-ins were similar to other healthy controls. Serum Gd-IgA1 levels were elevated in blood relatives and IgAN patients than in marry-ins at each sampling time (P<0.03). Serum Gd-IgA1 levels demonstrated longitudinal stability in most individuals (Intra-class correlation coefficient = 0.812; 95% CI 0.604-0.917).
Conclusions: Serum IgG-IgA levels in 22 individuals in this multiplex IgAN pedigree were stable over a 9-year period. No blood relative developed IgAN or exhibited a urinary abnormality during the 9-year follow-up period.

Childhood IgA Nephropathy with Nephrotic Syndrome (NS-IgAN) at Onset
Yuko Shimizu,1 Koichi Nakashima,1 Taketsugu Hama,1 Masashi Sató,1 Hiroko Togawa,1 Hirobue Nakamotō,1 Hiroshi Kaito,1 Kandai Nozu,1 Ryōji Tanaka,1 Kazunoto Iijima,2 Norishige Yoshikawa,2 Pediatric Medicine, Iwate Medical University, Iwate, Japan; 1Pediatric Medicine, NHIC Ilsan Hospital, Goyang, Gyeonggi-do, Korea.

Background: Although immunoglobulin A nephropathy (IgAN) is commonly considered as a lifelong disease, incidences of spontaneous remission (SR) have been occasionally reported. We investigate the incidence as well as the clinical predictors of SR in IgAN.

Methods: Medical records of biopsy-proven IgAN in Severance hospital from 2006 to 2014 were reviewed. SR was defined as complete remission reached without any treatment, defined as (1) urine RBC<3/HPF, UPCR<0.2 g/g, and estimated glomerular filtration rate (eGFR)>60 mL/min/1.73m2; (2) proteinuria<1 g/day; (3) estimated glomerular filtration rate (eGFR) ≥90 mL/min/1.73m2; (4) treated by oPSL or oPLT with our standard protocol; (5) follow-up period >1 year; (6) interval from renal biopsy to initiation of therapy ≤3 years; (7) not combined with other renal disease. We compared the clinical findings at the time of renal biopsy, histological findings, and urinary findings during the follow-up period between both groups. We defined complete remission (CR) as proteinuria <0.3 g/g, and urinary red blood cells <5 counts/HPF.

Results: After adjusting clinical findings by propensity score, each 20 patients were selected for both groups. Among these cases, there was no significant difference in clinical and histological findings between both groups (p>0.05). proteinuria>1 g/day, (3) estimated glomerular filtration rate (eGFR) >90 mL/min/1.73m2; (4) treated by oPSL or oPLT with our standard protocol; (5) follow-up period >1 year; (6) interval from renal biopsy to initiation of therapy ≤3 years; (7) not combined with other renal disease. We compared the clinical findings at the time of renal biopsy, histological findings, and urinary findings during the follow-up period between both groups. We defined complete remission (CR) as proteinuria <0.3 g/g, and urinary red blood cells <5 counts/HPF.

Results: After adjusting clinical findings by propensity score, each 20 patients were selected for both groups. Among these cases, there was no significant difference in clinical and histological findings between both groups (p>0.05). proteinuria>1 g/day, (3) estimated glomerular filtration rate (eGFR) >90 mL/min/1.73m2; (4) treated by oPSL or oPLT with our standard protocol; (5) follow-up period >1 year; (6) interval from renal biopsy to initiation of therapy ≤3 years; (7) not combined with other renal disease. We compared the clinical findings at the time of renal biopsy, histological findings, and urinary findings during the follow-up period between both groups. We defined complete remission (CR) as proteinuria <0.3 g/g, and urinary red blood cells <5 counts/HPF.

Conclusions: SR in IgAN was frequently observed. UPCR levels may be an independent predictor of SR in patients with IgAN.

approaches. In stratified analysis, a beneficial association between RASB and ESRD was observed in patients with hypertension, reduced estimated glomerular filtration rate (<60 mL/min/1.73 m²), mesangial proliferation and segmental glomerulosclerosis (P for interaction <0.05), and tended to be greater in patients with proteinuria (>1.0 g/24 h), extracapillary proliferation, and receiving methylprednisolone pulse therapy (P for interaction <0.10).

Conclusions: Treatment with RASB was associated with a lower incidence of ESRD in the real-world practice of IgAN.

TH-PO794
Remission of Urinary Protein at 2 Years After Diagnosis with Normal Renal Function and Remission of Urinary Protein at 1 Year After Diagnosis with Decreased Renal Function as an Accurate Prognostic Marker in IgA Nephropathy
Takayuki Fujii,1 Junichi Hoshino,2 Joichi Usui,2 Satoshi Suzuki,2 Yoshifumi Ubara,1 Kunihito Yamagata.1 1Seirei Sakura Citizen Hospital, Sakura, Japan; 2Toranomon Hospital, Tokyo, Japan; 3Univ of Tsukuba, Tsukuba, Japan.

Background: Level of proteinuria (UP) has a strong association with poor renal prognosis in IgA nephropathy. Recent studies reported that the level of UP, especially, remission of UP at (CR) defined as less than 0.3 g/d, during the follow-up was a more accurate prognostic factor than at diagnosis. In this multicenter study, we evaluated which post-diagnosis measurement point achieving CR strongly associated with the renal prognosis.

Methods: 1,077 patients diagnosed with IgA nephropathy between March 1991 and December 2013, and could be followed-up for at least 3 years or reached end-stage kidney disease (ESKD) were enrolled. We performed a retrospective cohort study among 2 divided groups: 638 with eGFR>60 mL/min/1.73m² (A) and 439 with eGFR<60 mL/min/1.73m² (B). The endpoint of this study was a 50% decrease in eGFR or ESKD. The annual daily UP level until 3 years after diagnosis was categorized into 2 grades: <0.3 g/d and ≥0.3 g/d and its association with the renal prognosis was investigated. The hazard ratio of the endpoint adjusted with clinical and pathological findings and treatment was examined.

Results: Regarding CR as a reference, UP<0.3 g/d was not a significant poor prognostic factor at diagnosis, but at 1 year, especially at 2 years, it became a significant factor in group A. On the other hand, in group B, UP>0.3 g/d was already shown to be a significant factor at diagnosis and the strongest factor at 1 year.

Conclusions: UP<0.3 g/d and ≥0.3 g/d were the most accurate predictors for a favorable outcome in IgA nephropathy.

TH-PO795
Copetin, a Surrogate Marker for AVP, Is Associated with Disease Severity and Progression in IgA Nephropathy Patients
Debbie Zettina,1 Jan A.G.J. van den Brand,2 Jack F. Wetzels,2 Ron T. Gansveeront.1 1Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; 2Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: The disease course of IgA Nephropathy (IgAN) is difficult to predict. Copetin, a surrogate marker for AVP, has been described to cause kidney damage in various renal diseases. We investigated therefore the associations of copeptin with disease severity and progression in IgAN.

Methods: Included were 60 biopsy proven IgAN patients from the Radboud UMC Nijmegen, of whom urine and blood samples were available. Urinary excretion of α1M, β2M, KIM-1, and NGAL and plasma copeptin were measured at baseline. Survival analyses was performed for the composite outcome death, end stage renal disease (ESRD), doubling of serum creatinine, start of immunosuppressive therapy and the individual components.

Results: In IgAN patients (male: 72%, age: 42±13 years, eGFR: 48±21 mL/min/1.73m², copeptin: 4.9±5.1 pmol/L) copeptin was associated at baseline with proteinuria in the worst way possible (p<0.003) and with start of immunosuppressive therapy (p=0.04) using a log rank test. When patients who started immunosuppressive therapy during follow up (n=14) were excluded, copeptin (continuous variable) was furthermore associated with the incidence of ESRD (p=0.01, HR=1.09, i.e. a 9% increase in risk of ESRD per 1 pmol/L increase in copeptin), doubling of serum creatinine (p=0.004, HR=1.07) and the composite outcome (p=0.003, HR=1.07) in Cox regression models, adjusting for proteinuria and sex. With additional adjustment for eGFR, which is debatable as eGFR decline could be part of the causal pathway between copeptin and outcomes, the survival analyses lost significance.

Conclusions: Copetin is a promising disease severity marker in IgAN with additive predictive value for future kidney function loss over proteinuria, but not over eGFR, the strongest predictor of disease progression in this study.

Clinical Outcomes of Nephrotic Syndrome in IgA Nephropathy
Eun Joo Jeong, Su Mi Lee, Young ki Son, Dongyeol Lee, Hansae Kim, Sung Hyun Son, Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; Dept of Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.

Background: Uncommonly, IgA nephropathy can be complicated by nephrotic syndrome. In such cases, although, corticosteroid therapy should be recommended, the response to steroid treatment has been variable, and spontaneous remission without steroid treatment can occur in some cases. Here, we report our experience of clinical outcomes of nephrotic syndrome in patients with IgA nephropathy.

Methods: Thirty-three patients with biopsy-proven IgA nephropathy with nephrotic syndrome were enrolled between March 1990 and March 2009 in Dong-A university hospital. We retrospectively analyzed the data, including demographic, clinical, and laboratory records.

Results: The mean follow-up duration were 62 ± 45 months (10-204) in 33 patients. Complete remission occurred in 10 patients with steroid treatment and 2 patients without steroid therapy. Partial remission occurred in 7 patients with steroid therapy and 8 patients without steroid therapy. There were 6 patients with progressive deterioration of kidney function during follow-up period.

Conclusions: IgA nephropathy patients with nephrotic syndrome, 36% of patients have complete remission, 45% of patients have partial remission. Steroid treatment may function during follow-up periods.

TH-PO797
Comparative Outcomes in Primary Glomerulonephritis Among a Large Diverse United States Population
John J. Sim, Michael Batech, Teresa N. Harrison, Taurino N. Avella, Aviv Hever, Nephrology and Hypertension, Kaiser Permanente Southern California, Los Angeles, CA; Research and Evaluations, Kaiser Permanente Southern California, Pasadena, CA.

Background: Glomerulonephritis (GN) remains an important cause of end stage renal disease (ESRD) in the United States and the world. Within a large diverse population of an integrated health system, we sought to evaluate rates of primary GN and then compare ESRD and mortality outcomes within different GN’s.

Methods: Retrospective longitudinal cohort study in the period 1/1/2000 through 12/31/2013 among patients within Kaiser Permanente Southern California. Patients who had biopsy proven primary GN were characterized and followed until they reached the outcome of ESRD or mortality. ESRD was defined as receiving dialysis or renal transplant.

Results: 2,849 patients were identified with biopsy-proven GN. The mean age of the cohort was 47 yrs with 48% females, 37% Hispanics, 30% whites, 17% blacks, and 12% Asians. Focal segmental glomerulosclerosis (FSGS) was the most common GN among all race/ethnic groups (36% overall) followed by membranous GN (MGN) (12%), minimal change disease (MCD) (11%), IgA nephropathy (IgAN) (10%), and others (31%). The mean follow up was 3.8 yrs. ESRD occurred in 26% (704 required dialysis and 38 had a renal transplant). Mortality occurred in 18%. ESRD occurred among 35% of FSGS, 19% among IgAN, 12% among MGN, 10% among MCD, and 29% among other GN’s.

Conclusions: Among a large racially/ethnically diverse United States population, FSGS was the most prevalent GN and was associated with the highest rate of progression to ESRD among all GN groups. This diverse cohort may give insight into characterizing and risk stratifying different GN’s which may pave the way for more optimal management strategies.

TH-PO798
A Specific Transcriptomic Profile Characterizes Peripheral Blood Mononuclear Cells (PBMCs) from Uremic Patients (pts) Treated With On Line Hemodiafiltration (OL-HDF) Compared to Those Treated with Bicarbonate Dialysis (BHD)
Simona Simona, Anna Rita Chieti, Matteo Accetturo, Roberto Corcillo, F. Rascio, Paola Pontrelli, Giovanni Stallone, Lorenzo Giussani, Giuseppina Grandi, Giovanni B. Pertosa, Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; Dept of Medical and Surgical Sciences, Univ of Foggia, Italy.

Background: Recent studies suggest that OL-HDF can reduce the progression of dialysis-related cardiovascular diseases, but the molecular mechanisms underlying this improvement are not yet known. The aim of our study was to identify, through a high-throughput approach, differences in gene expression profiles of PBMCs from pts undergoing OL-HDF compared to BHD.

Methods: The transcriptomic profile was evaluated in PBMCs isolated from 10 pts regularly dialyzed with OL-HDF (convective volume 22 l) and 10 pts treated with BHD using microarray analysis (Agilent Technologies). The results were evaluated by statistical (ANOVA test) and functional pathway analysis (Ingenuity Pathway Analysis).

Results: We observed that 868 genes were differentially expressed in the comparison between OL-HDF and BHD (fold change>1.5). Thirty-seven functional gene networks were identified and atherosclerosis signaling was the top canonical pathway associated with BHD (p=2.45x10^-10). Among the downregulated genes in OL-HDF there were PDGF (FC=-2.13) and Clusterin (FC=-2.14), involved in vascular injury and Monomime Oxidase A (MAO-A, FC=-2.43), an important source of oxidative stress and a major contributing factor to the development of ventricular hypertrophy and heart failure. Interestingly, Apolipoprotein E (Apo-E) gene, an antioxidant/anti-inflammatory protein, was upregulated (FC=+1.7) by OL-HDF. qPCR, performed in an independent testing-group [15 BHD, 15 OL-HDF] confirmed that PDGF, Clusterin and MAO-A were down-expressed in OL-HDF (p<0.01), whereas Apo-E resulted higher expressed (p<0.01).

Conclusions: The OL-HDF can contribute to cardiovascular risk reduction through the modulation of pathways involved in the progression of atherosclerotic disease. This observation could open new perspectives in the prevention of cardiovascular risk in dialysis pts.

TH-PO799
Twice-Weekly versus Thrice-Weekly Hemodialysis in Patients with or without Residual Kidney Function
Hyeon Seok Hwang, Suk young Kim, Su Hyun Kim, Yong-Lim Kim, Yon Su Kim, Shin-Wook Kang, Chul Woo Yang, College of Medicine, The Catholic Univ of Korea, Korea; Chung-Ang Univ College of Medicine, Korea; Kyungpook National Univ School of Medicine, Korea; Dept of Internal Medicine, Seoul National Univ College of Medicine, Korea; Yonsei Univ College of Medicine, Korea.

Background: Residual kidney function (RKF) accounts for large solute removal and significantly contributes to survival benefits in hemodialysis (HD) patients. However, there are no reliable outcome data suggesting that the frequency of HD might be safely reduced in patients with substantial RKF.

Methods: A total of 685 patients receiving more than 3 months HD therapy were included from the CRC registry for ESRD. The presence of RKF was defined as more than 100 ml/day of urine volume, and patients were classified into twice-weekly HD with RKF (n = 113), thrice-weekly HD with RKF (n = 137) and thrice-weekly HD without RKF (n = 435).

Results: The baseline RKF was significantly higher in twice-weekly HD patients with RKF than in thrice-weekly HD patients with RKF, and it remained higher at 12 months follow-up. The sum of weekly renal Kt/V and delivered-standard Kt/V per week was similar pattern between twice-weekly and thrice-weekly HD patients with RKF. The thrice-weekly HD patients with RKF showed significantly higher survival rate than twice-weekly HD patients with RKF or thrice-weekly HD patients without RKF (P<0.002). In multivariable analyses, compared with thrice-weekly HD patients without RKF, thrice-weekly HD patients with RKF were associated with lower risk for all-cause mortality (HR 0.11; 95% CI 0.02-0.53). However, twice-weekly HD treatment with RKF did not reduce the risk of mortality (HR 0.65; 95% CI 0.22-1.87). For hospitalization of cardiovascular events, thrice-weekly HD therapy with RKF was independently associated with lower risk, (HR 0.40; 95% CI 0.16-0.98), but twice-weekly HD patients with RKF were not associated (HR 0.80; 95% CI 0.38-1.71).

Conclusions: Twice-weekly HD patients with RKF have similar outcome compared to thrice-weekly HD patients without RKF. However, twice-weekly HD patients with RKF were more advantageous for mortality and CVE than those without RKF.
Comparison of Outcomes Between Incremental and Abrupt Initiation of Hemodialysis: A Propensity-Matched Analysis of a Prospective Cohort Study in Korea

Background:

When patients are diagnosed as end-stage renal disease (ESRD) and initiated hemodialysis (HD), thrice-weekly HD is a very common format. Recent reports suggested possible benefit from beginning HD therapy less than three times weekly and incremental increase of dialysis dose, but there are not sufficient data. We compared outcomes of thrice-weekly and incremental HD.

Methods:

A total of 1273 patients who were diagnosed as having ESRD and initiated hemodialysis from 2008 to 2014 were prospectively enrolled. The patients were classified into the abrupt initiation group (3 sessions/week) or the incremental initiation group (1-2 sessions/week). We compared HRQOL evaluated by KDQOL-SF and Beck’s depression inventory (BDI) score at 3 months and 12 months after HD, and residual renal function by daily urine volume at 12 months after HD and all-cause mortality between the groups.

Results: Before propensity score matching, the abrupt group tends to be younger and showed smaller daily urine volume, higher modified Charlson comorbidity index (mCCI), and higher serum blood urea nitrogen and creatinine level compared to incremental group. A total of 432 patients (288 for abrupt and 144 for incremental group) were selected by propensity score matching. HRQOL tends to be better in incremental group for every domain of KDQOL-SF and BDI, but none of them showed significant difference at 3 months. At 12 months after HD, only cognitive functioning domain was better in incremental group. Daily urine volume at 12 months after HD was similar in two groups. All-cause mortality was comparable between two groups before and after propensity score matching.

Conclusions: Incremental initiation of HD showed comparable results with abrupt group regarding HRQOL, residual renal function and all-cause mortality. Incremental HD might be considered as another format of initiating HD for selected ESRD patients.

Predictors of Substantial Residual Kidney Function in the First Year of Hemodialysis Treatment

Background: Residual kidney function (RFK) plays a critical role in dialysis adequacy, quality of life, and survival in hemodialysis (HD) patients. Therefore, identifying predictors related to preservation of RFK may contribute to improving patient management and developing novel strategies for preserving RFK.

Methods: In a longitudinal cohort of 18,091 patients who initiated conventional HD over four years (1/2007-12/2010), we examined the association of baseline characteristics during the first 3 months of their dialysis treatment with RFK (renal urea clearance (KRU) and urinary volume (UV)) after one year. We employed multivariable logistic regression analyses using 3 mL/min/1.73 m² of KRU or ≥300 mL/day of UV as outcomes with 2-level adjustments for case-mix variables and laboratory measurements in addition to baseline RFK values.

Results: Patients were 62±14 years old, 37% female, 29% non-Hispanic Black, and 67% diabetic. Median KRU and UV were 2.95 (IQR, 1.63-4.64) mL/min, 1.73 m² and 800 (IQR, 500-1,300) mL/day, respectively. High %lymphocyte, higher serum concentrations of albumin and calcium, and lower serum concentrations of creatinine and phosphorus were consistently associated with better preserved RFK indices irrespective of models. A history of congestive heart failure was an independent predictor for loss of RFK.

Conclusions: Better nutritional and CKD-MBD indices were associated with preserved RFK while a history of congestive heart failure were associated with loss of RFK at 1 year of hemodialysis initiation in this large national cohort. Additional studies to preserve RFK in dialysis patients are warranted.

Salt Taste Sensitivity, Sodium Intake, and Fluid Status in Hemodialysis
Panduranga S. Rao,1 Robin L. Padilla,1 Linton Cuffj,2 Tanu P. Verma,1 Debra Peterman,1 Michael Heung,1 Scott L. Hummel,1 Peter Kotanko,2 Brenda W. Gillespie,1 Rajiv Saran.1 1Univ of MI; 2Renal Research Inst.

Background: Dietary Sodium intake (SI) contributes to volume status and blood pressure (BP) control in hemodialysis (HD) patients. Salt taste sensitivity (STS) may drive sodium intake, and has not been systematically studied in HD. We sought to assess the relationship between STS, SI, fluid status (as determined by bioelectrical impedance spectroscopy (BIS)) and pre-dialysis BP in HD patients.

Methods: As part of an ongoing randomized trial involving a low sodium diet, adults receiving outpatient HD were assessed for STS using commercial taste strips impregnated with 0.1-1.5% sodium chloride (NaCl); SI was estimated from 3-day food diaries. Total Body Water (TBW) and Extracellular Volume (ECV) were estimated using whole-body and segmental ( calf-resistance) BIS, respectively.

Results: Baseline data on 33 enrolled patients (16 male, 17 black, 13 white, mean age 52+15yr) were analyzed. Mean monthly pre-HD systolic BP was 151±16 mmHg. Mean SI was 2.5±2.5; range (1.1-5.2). Mean estimated SI was 0.8±2 g/day higher in patients without STS compared to those with STS (p=0.06). Higher SI correlated with higher calf ECV (r=0.38, p=0.04), whole-body BIS-TBW (r=0.65, p=0.0005) and ECV (r=0.34, p=0.09). Mean Calf ECV was significantly lower in those with STS vs those without STS at 1.6% (0.19 vs 0.23 L; p=0.04). There was no correlation between SI and pre-dialysis BP (in-center or standardized).

Correlation of Dietary Sodium Intake with (A) Total Body Water and (B) Calf ECV BIS

Conclusions: Salt taste sensitivity and measures of hydration status by bioelectrical impedance spectroscopy are correlated with sodium intake in hemodialysis. These findings suggest that patients with low salt taste sensitivity may be particularly at risk for fluid excess. Future research should examine mechanisms of Salt taste sensitivity and its role in management of hemodialysis patients.

Arrhythmic Risk in Patients with Type II Diabetes on Hemodialysis: Preliminary Results from the Monitoring in Dialysis (MiD) Clinical Study
Prabhjot Roy-Chaudhury,1 Don E. Williamson,2 James A. Tumlin,2 David M. Charytan,3 Kowdle chandrasekhar Prakash,4 Vijay K. Kher.1 1Univ of Cincinnati; 2Nephrology Associates; 3Univ of Tennessee; 4Bigham and Women's Hospital, Boston; 5Apollo Hospitals-Chennai; 6Medanta-Medicity.

Background: 40% of the overall ESRD population has diabetes and these patients are considered to be at increased risk of cardiac events. The goal of this analysis was to describe the pattern of both clinically significant events and documented arrhythmias in a subset of patients with Type II diabetes from the Monitoring in Dialysis (MiD) study.

Methods: The MiD study is a prospective, multi-center, observational study designed to characterize the type and frequency of documented and adjudicated arrhythmias in hemodialysis patients during a 6-month period, using an implanted continuous cardiac monitoring device (Medtronic Reveal XT or Reveal LINQ). All documented arrhythmias and clinically significant atrioventricular (AV) blocks (CSA) defined as bradycardia ≤40 bpm for ≥6 sec, asystole ≤3 sec, sustained ventricular tachycardia ≥130 bpm for ≥30 sec and symptomatic arrhythmias during this period were then correlated temporarily to the dialysis cycle (first, second or third dialysis session of the week; during or after hemodialysis; how long after hemodialysis).

Results: Type II Diabetes was present in 39/66 (59%) of the MiD patients. The mean age was 62 (36-76) years, 72% male, mean years on HD 2.8 (1-15), 36% with a history of cardiac arrhythmias with a mean follow-up of 8.6 months (range 0.6-13.9). Arrhythmic risk in the Type II diabetic patients was similar to the previously reported data on the entire study population, with the highest incidence of documented arrhythmias occurring in the 12 hour period starting with each dialysis session (particularly in the 8 hours after the end of the session). The incidence then decreased, followed by a gradual rise during the rest of the interdialytic period. Interestingly, the incidence of CSA in the 12 hour period starting with the first dialysis session of the week was much greater than in the overall study population.

Conclusions: The increase in the incidence of CSA in diabetics ESRD patients suggests that these patients could be a target population for the use of the Reveal implant.

Individualising Fluid Restriction Based on Target Weight Can Prevent a High Ultrafiltration Rate Emily See, John W. MacD. Agar. Nephrology, Univ Hospital, Geelong, VIC, Australia.

Background: Fluid restriction (FR) in haemodialysis patients has traditionally been advised by residual urine output and an arbitrarily defined oral intake, commonly 750ml/ day. Surprisingly, little attention has been paid to individualising FR according to target predialysis weight (TW), despite the logical argument that smaller patients require less fluid. Excessive inter-dialytic weight gain (IDWG), when calculated as a percentage of TW (IDWG%), results in a high ultrafiltration rate (UFR) if session length (t) is constant [*UFR(ml/kg/hr) = IDWG(ml) ÷ TW(kg) ÷ (hr)]. Since a high UFR has been linked to a poor clinical outcome, these patients must be identified and targeted. We aim to determine if a high IDWG% can be predicted from TW and then be used to individualise FR.

Methods: Data were prospectively collected from 114,112 sessions in 139 patients undergoing in-centre thrice-weekly haemodialysis from Jan-Dec 2014. Mean age was 68.9yr, 56% were male. Mean TW and IDWG% were calculated every 6 weeks. Results were divided into IDWG% cohorts, within each of which an average TW was calculated.

Results: Mean IDWG% was 2.30% (range 0.1-6.4). IDWG% was inversely proportional to TW (r=−0.78).

From this data, we devised a formula that calculates an individualised FR based on the desired UFR (dUFR), the session duration (t), TW, and interval days between sessions (n). [as IDWG% = FR ÷ TW; and [IDWG% = dUFR ÷ TW] ÷ TW; therefore [FR (ml) = dUFR ÷ TW ÷ TW = n ÷ residual urine output].

Conclusions: Patients with low TW are most at risk of high IDWG% and, consequently, a high UFR. A high UFR leads to rapid intravascular volume contraction which triggers post-dialytic thirst and reinforces the inevitable cycle of further high IDWG%. As TW provides a readily accessible clinical end-point that predicts at-risk patients, we propose that FR be individualised according to TW to enable patients to remain below the desired UFR.

TH-PO807
Ultrafiltration Rate Should Be Independently Targeted as a Marker of Haemodialysis Adequacy Emily See, John W. MacD. Agar. Dept of Nephrology, Univ Hospital, Geelong, VIC, Australia.

Background: For 30 years, solute clearance has been the key determinant of dialysis adequacy. This emphasis has marginalised the critical contribution of safe rates of fluid removal to “adequate” dialysis. Ultrafiltration rate (UFR) has been proposed as an easily measurable marker of volume management (Agar 2015 HDI) and several studies have demonstrated a correlation between high UFR and poor clinical outcomes. Despite this association, UFR is not routinely targeted and the proportion of patients who meet percentage reduction in urea (PRU) but not UFR targets is unclear. While a “safe” UFR (≤25%) is yet to be conclusively defined, current literature supports an escalating clinical risk beyond a UFR of 10ml/hr/kg and an absolute risk above 13ml/hr/kg.

Results: Data were prospectively collected from patients undergoing in-centre thrice-weekly conventional haemodialysis over a 12-month study period (Jan-Dec 2014). PRU and mean UFR were calculated every 6 weeks. UFR <10ml/hr/kg was defined as “volume-adequate” and PRU >65% was considered “solute-adequate”. 720 episodes were collected from 115 patients. The mean age was 68.9yr and 56% were male. 73% of episodes met both adequacy targets (PRU+UFR+). 10% met the UFR but not the PRU target (PRU-UFR+). 16% met the PRU but not the UFR target (PRU+(UFR-)). 1% met neither (PRU-(UFR-)). In patients who met the PRU target 18% did not meet the UFR target.

As a high UFR is linked to rapid intravascular volume contraction which triggers post-dialytic thirst and reinforces the inevitable cycle of further high IDWG%, as TW provides a readily accessible clinical end-point that predicts at-risk patients, we propose that FR be individualised according to TW to enable patients to remain below the desired UFR.

BP was measured every 15 minutes on monitoring data, with a goal to increase UF tolerance without increasing IDH events. [Fresenius, Kaysville, UT]. Interventions were employed based on CV physiologic protocol required setting goal to .2 KG < dry weight OR < .2 KG last post weight with prior to protocol along with 18 txs during active monitoring and guided probing. The treatments (txs) with same staff, room, time interval. Intervention data: 36 baseline txs assisted by monitoring technology was used to assess fluid management as defined by 1) achievement of post weight within 1 kg around dry weight, 2) avoidance of IDH [SBP>90], 3) decrease in pulse pressure (PP) from pre-post dialysis.

Methods: 24 patients (16 controls, 8 intervention) were included. Control data: 18 treatments (txs) with same staff, room, time interval. Intervention data: 36 baseline txs prior to protocol along with 18 txs during active monitoring and guided probing. The protocol required setting goal to <2 KG dry weight OR < 2 KG last post weight with small goals change early in treatment, set of defined action based on CV physiologic monitoring via CVInsight™ (CVI) [Intelomed, Wexford, PA] and relative plasma volume at each treatment. Intervention were employed based on monitoring data, with a goal to increase UF tolerance without increasing IDH events. BP was measured every 15 minutes.

Results: Intervention patients demonstrated significant improvement in all three fluid management parameters during the protocol compared to preceding txs.

**Conclusion:** Adequacy of solute removal does not equate to adequacy of volume removal. When a solute marker is used as the sole determinant of dialysis adequacy, a significant number of patients undergo “volume-inadequate” dialysis. These patients were more likely to be female and have a lower post-dialysis weight. Given the potentially substantial clinical implications, we propose that UFR be independently targeted allowing composite solute and volume markers to together define truly “adequate” dialysis.

**TH-PO808**

Fluid Management with Technology-Assisted Probing **Peter B. De Orejo,** Mary Kaye Deck, Anne M. Brunfield. 

Background: Intradialytic hypotension (IDH) is associated with mortality. Rapid fluid removal is associated with cardiovascular (CV) morbidity and mortality. Decreased pulse pressure during HD is associated with improved outcomes. A focused intervention approach assisted by monitoring technology was used to assess fluid management as defined by 1) achievement of post weight within 1 kg around dry weight, 2) avoidance of IDH [SBP>90], 3) decrease in pulse pressure (PP) from pre-post dialysis.

Methods: 24 patients (16 controls, 8 intervention) were included. Control data: 18 treatments (txs) with same staff, room, time interval. Intervention data: 36 baseline txs prior to protocol along with 18 txs during active monitoring and guided probing. The protocol required setting goal to <2 KG dry weight OR < 2 KG last post weight with small goal change early in treatment, set of defined actions based on CV physiologic monitoring via CVInsight™ (CVI) [Intelomed, Wexford, PA] and relative plasma volume (RPV) via Crit-Line III® [Fresenius, Kayville, UT]. Interventions were employed based on monitoring data, with a goal to increase UF tolerance without increasing IDH events. BP was measured every 15 minutes.

Results: Intervention patients demonstrated significant improvement in all three fluid management parameters during the protocol compared to preceding txs.

**Conclusion:** Adequacy of solute removal does not equate to adequacy of volume removal. When a solute marker is used as the sole determinant of dialysis adequacy, a significant number of patients undergo “volume-inadequate” dialysis. These patients were more likely to be female and have a lower post-dialysis weight. Given the potentially substantial clinical implications, we propose that UFR be independently targeted allowing composite solute and volume markers to together define truly “adequate” dialysis.

Increased Mortality Associated with Higher Dialysate Sodium Concentrations Is Not Due Solely to Higher Interdialytic Weight Gains and Blood Pressure **Ambreen Gul,** Dana Miskulin, Leonard A. Arbeit, Srima Narisupur, Susan Paine, Ronald Schrader, Philip Zager, DCI, Albuquerque, NM; UNM, Albuquerque, NM; Tufts, Boston, MA; SUNY, Stony Brook, NY; SUNY, Syracuse, NY.

Background: There is ongoing controversy regarding the optimal dialysate sodium concentration (DNA). Many investigators have urged the use of DNA of 134 to 138 mEq/L, to limit interdialytic weight gain (IDWG) and improve control of hypertension and mortality. Unfortunately, throughout this debate, little attention has been paid to how closely delivered DNA matches ordered DNA.

Methods: We studied 333 hemodialysis (HD) patients at 4 DCI facilities. We sampled dialysate from the arterial dialyzer port prior to the start of HD for measurement of DNA. Units 1 and 2 used Fresenius 2008 K and 2008 K machines and Fresenius Granuflo® Dry Acid and Naturalyte® mixed onsite from dry concentrates. Units 3 and 4 used Gambro Phoenix machines and pre-mixed acid concentrates obtained from Rockwell and bicarbonate cartridges from Baxter or Gambro. The online clearance feature was off.

Results: Measured DNA was usually higher than ordered DNA. The magnitude of difference varied by clinic (p < .0001).

**Conclusion:** Although reducing DNA to < 140 mEq/L may have only a modest impact on IDWGW and predialysis SBP it has the potential to significantly decrease mortality.

**TH-PO810**

Comparison of Ordered versus Measured Dialysate Sodium Concentrations **Ambreen Gul,** Dana Miskulin, Leonard A. Arbeit, Srima Narisupur, Susan Paine, Ronald Schrader, Philip Zager, DCI, Albuquerque, NM; UNM, Albuquerque, NM; Tufts, Boston, MA; SUNY, Stony Brook, NY; SUNY, Syracuse, NY.

Background: There is controversy regarding the optimal dialysate sodium concentration (DNA). Many investigators have urged the use of DNA of 134 to 138 mEq/L, while others have cautioned that low DNA may be associated with increased hospitalization and mortality. Unfortunately, throughout this debate, little attention has been paid to how closely delivered DNA matches ordered DNA.

Methods: We conducted a retrospective observational study of 26,000 chronic hemodialysis (HD) patients in 4 DCI facilities. We sampled dialysate from the arterial dialyzer port prior to the start of HD for measurement of DNA. Units 1 and 2 used Fresenius 2008 K and 2008 K* machines and Fresenius Granuflo® Dry Acid and Naturalyte®, mixed onsite from dry concentrates. Units 3 and 4 used Gambro Phoenix machines and pre-mixed acid concentrates obtained from Rockwell and bicarbonate cartridges from Baxter or Gambro. The online clearance feature was off.

Results: Measured DNA was usually higher than ordered DNA. The magnitude of difference varied by clinic (p < .0001).

**Conclusion:** Although reducing DNA to < 140 mEq/L may have only a modest impact on IDWGW and predialysis SBP it has the potential to significantly decrease mortality.
Least squares mean differences (95% CI) were larger at Clinics 1 [-3.27 (-4.02, -2.53) mEq/L] and 2 [-3.77 (-4.49, -3.05) mEq/L] vs. with Clinics 3 [1.144 (2.16, -0.78) mEq/L] and 4 [-1.78 (-2.47, -1.10) mEq/L]. The percentages of measured DNA concentrations within ± 2 mEq/L of the ordered DNA at Clinics 1, 2, 3 and 4 were 47, 25, 71 and 77%, respectively.

**Conclusions:** Measured DNA concentrations were often significantly higher than ordered DNA in facilities using Fresenius machines and dialysate concentrates mixed onsite. Routine measurement of DNA should be incorporated into facilities’ QAPI programs. Future studies looking at clinical outcomes associated with differences in prescribed DNA should include measurements of delivered DNA concentrations.

**Successful Use of Bivalirudin Protocol to Prevent Extracorporeal Thrombosis in Hemodialysis Patients with Heparin Induced Thrombocytopenia**

**Malcolm A. Finkelman,1 Sreedhar A. Mandayam,2 Enric Vilar,3 Abdullatif Abdullah,1 Hadi Saafi,4,5**

**Background:** Heparin Induced Thrombocytopenia (HIT) patients have a variable prevalence of 1-13%. There have been few reports using Lepirudin, Argatroban and Danaparoid in the management of extracorporeal thrombosis (ECT) during dialysis in these patients as heparin is contraindicated. We are reporting use of Bivalirudin to prevent ECT.

**Methods:** Our study was done in Fahd Bin Jassim kidney Center in Doha, Qatar (a large outpatient HD clinic of 300 patients). All patients diagnosed with HIT were included. HIT was diagnosed by ELISA method.

**Results:** 8 patients had confirmed positive HIT AB, 2 were receiving warfarin for atrial fibrillation with no ECT events and were excluded. One patient had a negative repeat test for HIT AB with no ECT events so he was excluded too. 5 patients with HIT AB and recurrent ECT events during dialysis were included. 3 patients had fistula and 2 had permanent catheter. A protocol was developed to start and adjust Bivalirudin based on activated partial thromboplastin time (APTT) value. Table 1 summarizes patients dosing and protocol.

**Bivalirudin Infusion Protocol for HIT in Hemodialysis Patients**

<td>increase dose by 20% and repeat APTT after 2h.</td>
</tr>
<tr>
<td>&gt;4.6</td>
<td>hold therapy until APTT ratio &lt; 3.5 then restart at a reduced dose and repeat APTT after 2h.</td>
</tr>
</tbody>
</table>

**Conclusions:** We are reporting a successful use of Bivalirudin protocol to prevent ECT in HD patients with HIT. It provided a simple dosing initiation with easy adjustment based on weight, aPTT and ECT events. The protocol provided excellent safety where no bleeding complications occured in these patients throughout the study.

**Intracranial Fluid Shifts During Hemodialysis Measured Using VIPS (Volumetric Integral Phase-Shift Spectroscopy) Is Influenced by Osmolarity, Sodium and Less So by Urea Nitrogen**

**Sreedhar A. Mandayam,1,2 Jose Ignacio Suarez,3**

**Background:** End Stage Renal Disease (ESRD) patients undergoing hemodialysis (HD) experience a drop in serum osmolality. This may result in cerebral edema. Cerebral edema has been measured by invasive monitors or imaging studies. We used Volumetric Integral Phase-Shift Spectroscopy (VIPS), a non-invasive technology that detects fluid-induced phase shifts in low-energy radio waves transmitted through the brain.

**Methods:** The protocol was approved by the IRB of Baylor College of Medicine. ESRD on HD subjects without intracranial illnesses were enrolled. VIPS monitoring was performed pre, intra and post HD. Measured and calculated serum osmolality (osm) and mini mental state examination was performed pre and post HD.

**Results:** 19 patients (12 males) were enrolled. Median age was 50 years, 1 patient withdrawn. Of the 31 HD runs, 21 complete data sets were analyzed. There was a mean increase of 10.6% in the total Intracranial fluid (ICF) value from baseline corresponding to an average of 7 mOsm reduction. The ICF change measured by VIPS correlated with osm changes (r=0.31), best with change in Sodium change [Post HD – pre HD](r=0.51), less so with the BUN change (r=0.14) and least with glucose (r=0.01). Subjects with sodium < 135 at baseline had a tendency to develop lower ICF change (3% n=5) as compared to euvarenic subjects (12%, n=16, p=0.22).

**Conclusions:** VIPS provides real-time non-invasive monitoring of intracranial fluid shifts. Subjects develop serum osmolal reductions during HD, which potentially be a model for studying cerebral edema. Sodium shifts had a higher correlation to ICF change in our study. Further research to confirm our findings are warranted.

Online Hemodiafiltration Using Citrasate® Dialysis Solution – An Alternative to Systemic Anticoagulation?  

**Background:** Citrasate® is a dialysis solution using citrate (contrary to more common acetate) as the acidifying buffer compound. According to recently published data, its application could decrease or even obviate the need for systemic anticoagulation in hemodialysis (HD) patients. Particularly so during online hemodiafiltration (HDF) as in this setting predilution should provide yet higher in-dialyzer citrate concentrations resembling regional citrate anticoagulation (RCA).

**Methods:** In a prospective, randomized, cross-over study, 10 long-term HD patients were enrolled during 4h HDF procedure using Citrasate® (0.8 mmol/l citrate) in a predilution setting without additional systemic anticoagulation. Standard HDF procedure using acetate-buffered solution together with fractionated heparin was applied as a control. Along the session, blood and dialysate were sampled to enable analysis of thrombogenicity, acid base balance, calcium metabolism, and dialysis efficacy. Data are given as means ±SD; statistical significance was calculated by ANOVA.

**Results:** No HDF session was terminated prematurely though the semiquantitative dialyzer clotting score showed increased clotting under citrate solution (p = 0.001). At the same time, procedure efficacy assessed by spKt/V, as well as serum calcium, bicarbonate and pH did not differ significantly. While in controls the thrombin-antithrombin (TAT) and fibrinogen levels were examined during 4h HDF procedure using Citrasate® (0.8 mmol/l citrate) in a predilution setting without additional systemic anticoagulation. Standard HDF procedure using acetate-buffered solution together with fractionated heparin was applied as a control. Along the session, blood and dialysate were sampled to enable analysis of thrombogenicity, acid base balance, calcium metabolism, and dialysis efficacy. Data are given as means ±SD; statistical significance was calculated by ANOVA.

Hypertension in Hemodialysis Patients: Dialysis Techniques and Hormonal Regulation

**Background:** Hypertension in hemodialysis patients has a prevalence of 50-80% and is associated to increased cardiovascular mortality. Endogenous osinoid (EO), a digitalis-like cardiotonic steroid produced by adrenal glands, in hemodialysis patients is associated to left ventricular mass, volume and eccentric hypertrophy remodeling. N-terminal pro-B-type natriuretic peptide (NT-proBNP) is associated with heart failure and fluid overload. Hemodiafiltration (HDF) improves cardiovascular survival than bicarbonate hemodialysis (HD). The aim is to explore the relationship between BP values, hormonal regulation (EO and NT-proBNP) and hemodialysis techniques.

**Methods:** We enrolled 93 chronic hemodialysis patients; we performed ABPM of 24 hours of blood and effluent dialysis fluid analysis. 42 patients were treated with HDF, 51 with HD.

**Results:** NT-proBNP is directly associated with SBP of 24h and indirectly with EF of left ventricle; it is removed by HDF by convective clearance (decrease of 57%), as medium molecular weight compounds, and not by HD (increase of 21%). EO is directly associated with interdialytic weight gain and interventricular septum; it decreases with dialysis session independently of dialysis technique (decrease of 20%). Patients with cardiopathy have higher EO plasma levels than patients without cardiopathy. Beta-2 microglobulin is directly associated with NT-proBNP and SBP of 24h.

**Conclusions:** These data show that NT-proBNP is an index of hypertension and heart failure, while EO is linked to fluid overload and left ventricular hypertrophy. NT-proBNP is removed by convection, while EO decreases independently of dialysis technique (by ultrafiltration determine the decrease?). Convective clearance, expressed indirectly by beta-2 microglobulin, may influence BP control through the modulation of NT-proBNP.

---

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.**
No systemic heparin was used. Primary endpoint was non-inferiority for clotting events of the combination of a heparin-grafted membrane plus citrate-containing dialysate vs. RCA, with a prespecified non-inferiority margin of 10%.

Results: We included 25 patients, receiving 1285 study dialysis sessions in total, 636 in the study arm and 649 in the control arm. Both anticoagulation strategies were safe. Overall, clotting rates were low: 37/636 (5.82%) in the study arm and 42/649 (6.47%) in the control arm. The primary endpoint of non-inferiority was met (P < 0.0001). In secondary analysis, using Cox proportional hazard analysis, time to clotting did not differ between study arms (P 0.62).

Conclusions: Combination of a heparin-grafted dialyzer with citrate-containing dialysate is non-inferior to conventional RCA. The procedure is easy to perform without additional pumps or calcium measurements. Combination of a heparin-grafted dialyzer and citrate-containing dialysate is a valid alternative to RCA in patients requiring heparin-free dialysis.

Effect of L-Carnitine on Markers of Mineral Bone Disease in the CARNIDIAL trial

Lecie Myerwald,1 Michel Chonchol,2 Messaoud Ouizilia,3 Christine Fumeron,4 Aude Servais,5 Sophie Tezenas du montcel.6

Background: Previous studies suggested that L-carnitine in hemodialysis patients decreases intact parathyroid hormone levels (iPTH). We studied the effects of L-carnitine on markers of mineral bone disease (MBD), including fibroblast growth factor (FGF23) in a randomized, double-blind trial.

Methods: We evaluated the effects of 1 g of intravenous L-carnitine after each dialysis session for 1 year when compared to placebo in a randomized and double-blind trial. C-terminal FGF23 (cFGF23) were measured at baseline, every 3 months and end of study in 91 chronic hemodialysis patients. Serum calcium, phosphate and iPTH were available at similar time points.

The effect of L-carnitine on serum calcium, phosphate, iPTH and cFGF23 was evaluable in 83 patients. L-carnitine treatment slightly increased serum calcium and phosphate (β calcium: 0.007; β phosphate: 0.005) and negatively correlated with EPO dose (β -0.41; p<0.0001) and adenine nucleotide translocator (ANT) expression (r=-0.31; p=0.041). Multivariate logitic regression analysis showed that the injectable group was also significantly associated with better survival than oral group (HR, 0.33, 95% CI, 0.13–0.83).

Conclusions: Treatment with injectable L-carnitine has a favorable impact on the infectious mortality compared to oral VDRA in the real-world practice of hemodialysis patients.

TH-PO823

Aldosterone Levels in Patients on Hemodialysis/Relationship with the Metabolic Syndrome

María José Fernandez Reyes,1 Manuel M. Heras,1 Maria Gonzalez,2 Olaia Rodriguez fraga,3 Ramiro Callejas,1 Álvaro Molina,1 Vanesa Lopes-martin,2 Maria astrid Rodriguez gomez,2 Leonardo Calle.1 Nephrology, Hospital General Segovia, Segovia, Spain; Biochemistry, Hospital Univ La Paz, Madrid, Spain.

Background: Recently it has been shown that serum aldosterone (SA) levels are correlated with several components of the metabolic syndrome (MSyn). OBJECTIVE: to establish SA levels on hemodialysis (HD) patients and its possible association with insulin resistance (homeostasis model assessment of insulin resistance HOMA-IR), excess body fat and/or serum adipocytokines levels.

Methods: 44 stable patients on HD, not taking ACE inhibitors/angiotensin receptor blockers. Mean age: 72.5±12.5years; 52.3% men; 34.1% diabetics. Mean time on HD:43.2±49 months. 28 patients were anuric. All measurements were done prior to the midweek HD session.

Results: SA levels were above the normal range (1.17-23.6 ng/dl) in 63.6% of patients. Plasma Renin Activity (PRA) was above the normal range (0.23-3.32 ng/mL/hour) in 27.3% of patients. Median: 31.15 (p25: 5.25; p75: 411 ng/dl). PRA median: 1.14 (p25: 0.04; p75: 20.9 ng/mL/hora). There were not statistically significant difference (Student’s t) in SA levels between anuric and non-anuric; male and female; presence and absence of myocardialopathy or diabetes. There were not statistically significant correlations (Spearman) of SA levels or PRA with urine volume; residual renal function; dose or length of time on HD; age; or Charlson Comorbidity Index. SA levels were positively correlated (Spearman) with ARP (r= 0.72; p=0.0001); body fat mass in kg/m2 (r=0.32; p=0.045); serum leptin levels (r=0.30; p=0.05); HOMA-IR (r= 0.36; p=0.017) and negatively with serum adiponectin levels (r=- 0.31; p=0.041). Multivariate logistic regression analysis showed that SA levels above its median level were independently associated to PRA and HOMA-IR.

Variables Independientes | Odds ratio | 95% CI | Valor de p
--- | --- | --- | ---
HOMA-IR | 1.236 | 1.025-1.492 | 0.01
Plasma Renina Actividad | 2.664 | 1.136-6.248 | 0.024

Conclusions: SA levels are elevated in a high percentage of HD patients and such elevation is associated with PRA and several components of MSyn (insulin resistance; body fat mass; and serum levels of adipocytokines). Funding: Government Support - Non-U.S.
TH-PO824
Dialysate Calcium Concentration Was Significantly Associated with Cardiovascular Diseases in Diabetics and Patients with High Body Mass Index among Hemodialysis Patients  
Mihoko Tagawa,1 Takayuki Hamano,2 Shinichi Sueta,3 Seiji Hashimoto,2 Satoshi Ogata.2 1Nara Medical Univ, Nara, Japan; 2Patient Registration Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; 3Kyoto Univ, Kyoto, Japan.

Background: Previous studies showed that higher dialysate calcium (Ca) concentration was positively associated with cardiovascular (CV) diseases. Which patient characteristics modify this association has not been studied.

Methods: This was a longitudinal study based on the Japan Renal Data Registry (JRDR) from 2008 to 2009. Predictor variables were dialysate Ca concentration (3.0 mEq/L vs. 2.5 mEq/L). Primary outcome was CV composite event (either myocardial infarction, stroke, amputation, or CV death). Statistical analyses were performed using multivariable logistic regression model, adjusted for potential confounders.

Results: Among 300,660 patients on JRDR database, data for 38,697 patients were available for analyses after excluding patients with missing data. Serum albumin corrected Ca was significantly higher (9.27±0.77 vs. 9.18±0.79 mg/dL) and intact parathyroid hormone (iPTH) was significantly lower (135±65 to 236±164 [85-274] pg/ml) among high dialysate Ca users compared with low dialysate Ca users. The odds ratio of CV composite outcome among high dialysate Ca users was higher among diabetics and patients with higher body mass index (BMI) (p for interaction 0.02 and 0.01, respectively).

Conclusions: Higher iCa was also associated with higher HRV. The association of iCa with QTc interval and HRV remained significant in the repeated measures analysis. Associations with serum K, Mg, dCa, and dK were not significant at baseline or over follow-up. Serum-to-dialysate Ca gradient, but not K gradient was associated with higher HRV at baseline and over follow-up (β=0.3(0.0, 0.6) and 0.3(0.0, 0.6) respectively).

TH-PO825
Association of Serum and Dialysate Electrolytes with Arrhythmic Risk in Incident Hemodialysis  
Jacqueline Watt,1 Esther D. Kim,2 Larisa Tereshchenko,3 Stephen M. Sozio,3 Bernard G. Jaar,3 Lucy A. Meoni,2 Michelle M. Estrella,3 Rulan S. Parich1,2 1McMaster Univ; 2Univ of Toronto; 3Johns Hopkins Univ.

Background: Arrhythmias and sudden cardiac death (SCD) may occur during or shortly after receiving dialysis treatment. The extent to which serum and dialysate concentrations of potassium (K) and calcium (Ca) are associated with the risk of arrhythmias in incident hemodialysis is unclear.

Methods: In 402 patients from the Predictors of Arrhythmic and Cardiovascular Risk in End Stage Renal Disease (PACE) study, we analyzed the association of serum (ionized Ca[iCa]), K, magnesium [Mg]) and dialysate (dCa and dK) electrolyte concentrations with prolonged QTc interval (Bazett’s formula) and heart rate variability (HRV). Outcomes were measured by a 5-minute signal-averaged ECG. Prolonged QTc was defined as ≥460ms in women and ≥440ms in men. Baseline associations were examined using linear and logistic regression, and repeated measures were analyzed using mixed-effects models.

Results: At baseline, 86.3% had QTc prolongation, of whom 68.5% had persistent QTc prolongation at the follow-up visit. In the baseline analysis, higher iCa was associated with a shorter QTc interval and lower odds of having QTc prolongation, independent of demographic and cardiovascular risk factors, CRP, and pH.

TH-PO826
Phosphorus Kinetics During Hemodialysis: Further Validation of a Pseudo-One Compartment Model  
J. Ken Leveyold,3 Baris U. Agar,2 Alfred K. Cheung,1 Angelito A. Bernardo,1 Medical Products (Renal), Baxter Healthcare Corporation, Deerfield, IL; 3Medical Products (R&D), Baxter Healthcare Corporation, Round Lake, IL; 3Nephrology, Univ of Utah, Salt Lake City, UT.

Background: A pseudo-one compartment model has been proposed to describe phosphorus kinetics during hemodialysis (HD) and postdialysis rebound. This model suggests that phosphorus mobilization from tissues is proportional to the difference between the predialysis serum (C_0) and instantaneous serum concentration. The current study evaluated the ability of a pseudo-one compartment model to describe the kinetics of phosphorus in two short HD treatments on the same day separated by a 1-hr inter-treatment period without dialysis. The latter is the postdialysis rebound period for the first treatment.

Methods: Serum was collected frequently during both HD treatments and the inter-treatment period to assess phosphorus kinetics in 21 chronic HD patients. Phosphorus mobilization clearance (C_m) and predialysis central distribution volume (V_c) were estimated for each patient during the first HD treatment and the inter-treatment period. Assuming those kinetic parameters remained constant for each patient, phosphorus concentrations during the second HD treatment were used to estimate the driving force concentration (C_d) for phosphorus mobilization during that treatment.

Results: Treatment times (117±14 vs. 117±14 min), dialyzer phosphorus clearance (55±25 vs. 140±32 ml/min) and net fluid removal (1.44±0.74 vs. 1.47±0.76 L) were similar during both HD treatments. Phosphorus concentration at the start of the second HD treatment (3.3±0.9 mg/dL) was lower (P<0.001) than at the start of the first or C_0 (5.4±1.9 mg/dL). K_c and V_c were 98±44 ml/min and 11.0±4.2 L, respectively. Calculated C_m was 4.9±2.0 mg/dL, not significantly different from 5.0±1.3 mg/dL (P=0.12). C_d and C_m were correlated (R=0.72, P<0.001).

Conclusions: The results from this study demonstrate that the driving force concentration for phosphorus mobilization during HD is constant and equal to that predialysis, consistent with a fundamental assumption of the pseudo-one compartment model.

Funding: Pharmaceutical Company Support - Baxter Healthcare Corporation
Conclusions: SA and poor sleep quality were common among hypertensive HD patients. Short sleep duration and poor sleep efficiency, but not the severity of SA, were associated with higher LVM indices.

THI-PO828
Role of Nicotinic Acid as Phosphate Lowering Agent in End Stage Renal Disease Patients on Maintenance Hemodialysis
Khaliq Taher1, Hafiz I. Ahmad1, Syed Rizwan Bokhari1, Syed A. Khalid,1 AnF Asif.2
1Dept of Nephrology, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan; 2Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.

Background: Hyperphosphatemia is associated with higher risk of mortality and morbidity in End Stage Renal Disease (ESRD) patients. Use of Nicotinic Acid as phosphate lowering agent has been studied in many countries but available data is sparse and limited. We conducted a study to determine the mean decrease in serum Phosphorous level with Nicotinic acid use in dialysis patients.

Methods: Nicotinic acid, in a dose of 250 mg twice a day with food for 4 weeks, was given to 45 ESRD patients with serum Phosphorous level more than 5.5 mg/dl. Serum phosphorus level was measured at the start and then at the end of study. Data was analyzed for decrease in serum phosphorus level with Nicotinic acid use.

Results: Mean age of 45 patients was 44.6 ± 13.9 years and 57.8% were male. Serum Phosphorus level before treatment was 5.6 ± 10.8 mg/dl (mean 6.91 ± 1.33 ) and after treatment for one month it was 2.60 ± 8.70 mg/dl (mean 5.82 ± 1.40). Mean decrease in phosphorus level with Nicotinic acid after one month of treatment was 1.08 ± 1.16 mg/dl (p value < 0.001).

Conclusions: Nicotinic acid is an effective and cheaper phosphate lowering agent in dialysis patients. Further larger and Randomized Controlled Trials are needed to establish the role of this cheaper phosphate lowering agent.

Cerebral and Cognitive Effects of Short- and Long-Term Hemodialysis – A Pilot Study
XiuFeng Li1, Yelena Slinin,2 Gregory J. Metzger,1 Lynn E. Eberly,1 Donald R. Dengel,1 David Tupper,1 Anne M. Murray,3 1Univ of Minnesota, MN; 2Veterans Affairs Medical Center, MN; 3Hennepin County Medical Center, MN.

Background: The short- (≤6 months) and long-term (³12 months) effects of conventional hemodialysis (HD) on brain structure, cerebral blood flow and cognitive function are not well understood.

Methods: We conducted a small longitudinal pilot study to investigate the effects of HD initiation on brain MRI and cognitive function in 4 HD patients by obtaining pre- and post- initiation brain MRIs and cognitive testing. The MRIs were obtained at 3-6 months and 12 months after HD initiation. The Modified Mini-Mental State Examination (3MSE) was performed within one month of the baseline and 12 month MRI examinations. MR diffusion tensor imaging (DTI) measured white matter (WM) fractional anisotropy (FA) (connectivity), and pseudo-continuous arterial spin labeling (PCASL) imaging was used to evaluate grey matter (GM) cerebral blood flow (CBF). A two-tailed paired t-test was used to compare pre- and post- initiation results. Patients provided written informed consent to participate in the IRB- approved protocol.

Results: Progressive and significant declines in frontal and temporal WM FA (Fig. 1), prefrontal CBF (Fig. 2), and cognitive function (Fig. 3, left) were found following HD initiation (Table 1 for p values). The decline in frontal WM FA on MRI was correlated with the 3MSE decline (R= 0.42)(Fig. 3, right).

Conclusions: Our results suggest that HD may adversely alter cerebral vascular function and progressively induce cerebral structural abnormalities and associated cognitive decline.

THI-PO830
Patient and Dialysate Temperature Characteristics in Incident Hemodialysis Patients: Results from a Large U.S. Population
Xiaoqing Ye1, Len A. Usyaty,2 Yue Jiao,2 Peter Kotanko,3 Franklin W. Maddux.2 1Renal Research Inst, New York, NY; 2Fresenius Medical Care North America, Waltham, MA; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In chronic hemodialysis (HD) patients the use of dialysate at a temperature below the patient’s core temperature (“cool” dialysate) has been associated with improved outcomes in observational and prospective randomized studies [Odudu et al., CJASN 2015; Eldehni et al., JASN 2015; Selby, Sem. Dial 2008]. Little is known about temperature profiles in large US populations.

Methods: We include a subset of incident HD patients who were treated in Fresenius Medical Care North America facilities from 1/2010 to 12/2014 and who survived the first year of HD. Pre- and post-HD body temperatures were measured with thermometers. The dialysate temperature was measured by the HD machine. The dialysate-to-patient temperature gradient was computed as dialysate temperature minus patient temperature.

Results: We studied 20,360 incident HD patients (age 62.5 (SD 14.5) years; 57.6 % males; 68.1% White, 29.2 Black, 2.7% others). The vast majority (83.8%) had a dialysate temperature above body temperature at the start; and at the end (80.6%) of HD.

281A
The prescribed dialysate temperature was 36.87 ± 0.31 °C. We observed a small yet significant rise in body temperature during HD.

**Conclusions:** Delivered dialysate temperature exceeds the body temperature in majority of patients. This may provide potential opportunities for dialysate temperature reduction to improve intradialytic stability and outcomes.

**Effect of a Single Hemodialysis Session on Visual Evoked Potentials**

Savas Sipahi,1 Ahmed Bilal Genc,1 Yalcin Solak,1 Nephrology, Sakarya Univ Research and Training Hospital, Sakarya, Turkey; 2Neurology, Sakarya Univ Research and Training Hospital, Sakarya, Turkey.

**Background:** Some studies have shown that visual evoked potentials (VEPs) may be a marker of dysfunction in visual pathways in uremic subjects. However, data are scarce regarding effect of hemodialysis procedure on VEPs. We aimed to compare VEPs of hemodialysis patients with healthy volunteers and in particular to assess the impact of a single hemodialysis session on VEPs.

**Methods:** Thirty hemodialysis patients were included in the study. We also recruited 30 age and gender matched control subjects. Patients with diabetes mellitus, cataracts, glaucoma, and stroke were excluded. Demographic characteristics, midweek predialysis recordings. Bias was defined as the mean difference in BP (pre-HD, intra-HD, post-HD) measure Bias, average HBPM was subtracted from each of these three index BP intradialytic device was used for the patient at home. Patients were instructed to bring the device to the dialysis. Patients with symptomatic hypotension during dialysis were excluded. To measure Bias, average HBPM was subtracted from each of these three index BP intradialytic recordings. Bias was defined as the mean difference in BP (pre-HD, intra-HD, post-HD) compared with HBPM.

**Results:** 192 patients, mean age 63.8 ± 14.8 y.o. (70% male), of 11 HD clinics of Fresenius Medical Care of Spain were included, 33% diabetic. All patients were on thr ee times weekly HD. The mean time on HD was 46 ± 57 months.

**Conclusion:** Reduction of tissue sodium content by hemodialysis treatment differs in skin and muscle tissue. While bound sodium content in muscle was unaffected by hemodialysis, bound sodium content in skin tissue could be mobilized by HD.
End-Dialysis Overweight and Chronic Inflammation: A Dangerous Association—A 36-Month Prospective Observational Study
Ezio Movilli, U.O. of Nephrology, Spedali Civili and Section of Nephrology Univ of Brescia, Brescia, Italy.

Background: Attaining dry body weight is paramount in dialysis practice, but this goal is not always reached. We hypothesized that the amount of end-dialysis overweight (edOW), could be associated to increased chronic inflammation and mortality. Aim of the study: to evaluate the effect of edOW on serum C-reactive protein (hsCRP) concentrations and on survival in a cohort of 182 prevalent HD patients (pts) followed for 36 months.

Methods: In 182 pts (117 men, age 65±12 years, vintage 48 months; range 6-336), edOW was present in 98/182 (54%) pts. Mean value was 0.4±0.2 Kg (range: 0.1-1.4). In the 98 pts with edOW (Group 1) and in the other 84 (Group 2) we evaluated: Ultrafiltration rate (UFR), hsCRP/day body weight (dBW), Kt/V, protein catabolic rate (PCRn), interdialytic weight gain (IDWG), mean arterial pressure (MAP). Unpaired Student’s t was employed to compare groups, linear regression analysis to test correlations, log-rank test and Kaplan-Meier curves to evaluate survival.

Results: Mean UFR was 11.7±2.8 Kg/hour, dBW 64±12 Kg, hsCRP 6.6 (0.2-36) mg/L, Kt/V 1.27±0.09, PCRn 1.06±0.10 g/Kg/day, IDWG 2.8±0.4 Kg, MAP 97±6.5 mmHg. edOW and hsCRP were directly and significantly correlated (r= 0.67; p<0.0001). Comparison between pts with (Group 1) and without (Group 2) edOW showed significant differences in: UFR (12.7±2.6 vs 10.9±2.6 ml/Kg/hour; p<0.0001), hsCRP (13.0±2.6 vs 10.9±2.6 mg/L, p< 0.0001), and PCRn (1.03±0.09 vs 1.08±0.10 g/Kg/day; p<0.0004). 98 pts (54%) died during follow-up for cardiovascular complications in 69% of cases. Survival curves showed significantly greater mortality in Group 1 vs Group 2 in relation to the amount of edOW, and hsCRP (p<0.0001).

Conclusions: edOW and chronic inflammation are directly correlated in HD pts, and both are associated to a greater long-term risk of mortality.

Suicidal Erythrocyte Death in Hemodialysis Patients

Background: Even though anemia in ESRD results mainly from the lack of erythropoietin, compelling evidence points to the contribution of accelerated erythrocyte death/eryptosis, which is characterized by phosphatidylserine (PS) exposure at the cell surface. PS exposure might be stimulated both by uremic toxins and the mechanical stress induced by hemodialysis (HD). We investigated the possible differences in terms of eryptosis levels between healthy subjects and HD patients before and after HD session.

Methods: We enrolled 15 patients (4F, mean age 65±16yrs, 33% with diabetes) undergoing chronic HD and 15 healthy subjects (CTR). Blood samples were collected prior to and after 4h standard HD session. Measurements were made in isolated erythrocytes (RBCs). PS exposure was estimated from AnnexinV binding in flow cytometer.

Results: The percentage of AnnexinV reflecting the percentage of RBC’s exposing PS at RBC surface was significantly higher (more than twice) in HD patients than CTR (2.2%; IQR 1.2-4.1 versus 0.8%; IQR 0.7-1.3; p<0.05). The average forward scatter reflecting cell volume was significantly higher in RBCs from HD patients than in CTR. There was no statistically significant relationship between baseline levels and eryptosis in HD patients. The percentage of AnnexinV and cell volume were measured prior to and after 4h of HD: no significant differences were observed between pre and postdialytic eryptosis.

Conclusions: Our data suggest that HD may lead to a significant increase in eryptosis, but no differences in the level were observed before and after HD session. Although the procedure is known to be responsible for cytokines and inflammatory mediators release, because of the interaction between blood and circuit lines and filters, it does not seem to induce eryptosis. Further studies are needed to compare different types of HD treatments.

Deployment of a Dialysis Hospitalization Reduction Program Is Associated with Lower Hospitalization Rates
Hanjie Zhang, Dugan Maddux, Karen G. Butler, Len A. Usvyat, Yue Jiao, Brian Scott Ash, John W. Larkin, Terry Ketschersid, Peter Kotanko, Franklin W. Maddux. Renal Research Inst, New York, NY; Fresenius Medical Care North America, Waltham, MA; Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The aim of this study was to investigate the potential effect of a Dialysis Hospitalization Reduction Program (DHRP) on hospital admissions.

Methods: We deployed DHRP to 69 patients between 1/1/2014 and 5/5/2015 in a network of Fresenius Medical Care North America (FMCNA) dialysis clinics. These patients were identified as being at high risk for hospitalization based on FMCNA’s data driven predictive modeling efforts and clinical assessments. The DHRP encompasses multiple interventions, targeting malnutrition, non-compliance, mental status issues, fluid overload, and others. Each patient is identified to have one or more “clinical tags”; 88 tags were identified for 69 patients. Interdisciplinary teams were deployed to design and implement interventions. Hospitalization rates were measured 90 days before and after the program.

Results: DHRP was associated with a reduction of all-cause hospitalization from 7.5 to 4.4 per patient year (ppy) (-42 %) (Figure 1A). Interventions targeting patients with “malnutrition” tag were associated with a reduction of hospitalizations from 9.3 to 4.1 ppy (-56%) (Figure 1B).

The Long Inter-dialytic Period Is Not Associated with Inferior BP Control in Stable Hemodialysis Patients

Background: 3-day-a-week hemodialysis (HD) involves one long (72hr) and two short (48hr) inter-dialytic periods (IDP) with higher death risk after the long IDP. We investigated BP and CV biomarker patterns in clinically stable HD patients to determine whether BP control during the final 24 hrs of the long IDP is inferior to that of the short IDPs.

Methods: In an initial retrospective study, in-center BP readings over 1 month were analyzed for 81 adult HD patients with stable regimen and medical status for ≥ 3 mths. Next, 23 patients completed a prospective study in which ambulatory BP monitoring was performed for the final 24hrs of the long and one short IDP in the same week. Blood was collected for CRP, Troponin T, BNP following each ABPM.

Results: In the retrospective study, mean pre-dialysis systolic and diastolic BP (SBP/DBP) did not differ for the long and short IDPs despite greater weight gain during the long IDP. This observation was confirmed in the ABPM study and applied to both day- and night-time readings. Pre-dialysis CV biomarkers were not significantly higher following the long IDP. Inter-dialytic weight gain showed no correlation with BP indices.

Conclusions: Our data suggest that HD may lead to a significant increase in eryptosis, but no differences in the level were observed before and after HD session. Although the procedure is known to be responsible for cytokines and inflammatory mediators release, because of the interaction between blood and circuit lines and filters, it does not seem to induce eryptosis. Further studies are needed to compare different types of HD treatments.
Conclusions: In stable HD patients, BP control and CV biomarkers were similar during long compared to short IDP despite greater fluid gain. The adverse influence of excessive inter-dialytic fluid gain is unlikely to be mediated directly through a hypertensive effect.

Notch Signaling in Bone Marrow-Derived FSP-1+ Cells Mediates a Phenotypic Change in Smooth Muscle Cells Leading to A VF Failure
Jinlong Luo, Sonia Bhati, Nikhil Grandhi, Ashish Verma, Amanda B. Ravi S. Shah, Jizhong Cheng, William E. Mitch, Yechong Cheng, Medicine, Baylor College of Medicine, Houston, TX; *Nephrology, Guangzhou Medical University, Guangzhou, Guangdong, China.

Background: sociological and economic costs of failed arteriovenous fistulas (AVF) are well known but mechanisms of AVF losses are controversial. We have shown that smooth muscle cells (SMCs) from anastomosed artery compose of ~50% of neointima cells in AVF. Arterial anastomoses are also infiltrated by bone marrow (BM)-derived FSP-1+ cells, potentially linking FSP-1+ cells to SMC activation. However, whether Notch/RBP-JK signaling involves in BM-derived FSP-1+ cells activation has not been studied. We propose that Notch/RBP-JK activation in BM-derived FSP-1+ cells causes a phenotype-switch of SMCs, resulting in SMC translocation from the artery to the venous anastomosis, forming neointima.

Methods: we created CKD and AVFs in wild type and Notch knock out mice. The role of Notch signaling in activation and function of BM-derived FSP-1+ cells was explored. Activated SMCs were characterized by a loss of differentiation markers plus a gain in proliferation (PCNA+). Using BM transplantation, we examined if FSP-1+ cells lacking RBP-JK or CKD mice would suppress SMC phenotype switch and neointima formation in AVFs.

Results: BM-derived FSP-1+ inflammatory cells in AVFs from CKD mice were 45% greater vs. results in pair-fed, control mice. In the artery anastomosis, increased infiltration of FSP-1+ cells led to loss of SMC differentiation markers, SM22, SM-22a and SMA-α. Activation of Notch signaling (NICD+ and RBP-JK+) raised expression of cytokines (IL-1), MCP-1 and growth factors (PDGF-BB, bFGF and TGF-β1) in FSP-1+ cells. The cytokines and growth factors caused a SMC phenotype switch (characterized by loss of SMC differentiation markers), resulting in SMC migration and proliferation. RBP-JK KO in BM-derived FSP-1+ cells significantly decreased the production of cytokines and growth factors, suppressed SMC activation of and neointima formation in AVFs.

Conclusions: Thus, Notch signaling in BM-derived FSP-1+ cells can induce a phenotype switch in SMCs stimulating neointima growth. Targeting Notch signaling in FSP-1+ cells could improve AVF function.

Cytooglobin Is Upregulated in Failed Arteriovenous Fistula from Hemodialysis Patients and Exerts Survival Functions in Medial Smooth Muscle and Neointimal Cells
Lam Poon, Jizhong Cheng, Frances L. Jourd'heuil, David Jourd’heuil, 1William E. Mitch, 1Yechong Cheng, Medicine, Baylor College of Medicine, Houston, TX; *Nephrology, Guangzhou Medical University, Guangzhou, Guangdong, China.

Background: Arteriovenous fistulae (AVFs) suffer significant problems with high incidence of both early and late failures. Interventions that may prolong access patency are still very limited and require strategies that may impair or regress neointimal hyperplasia. In the cardiovascular system, globins such as hemoglobin are thought exclusively to regulate O2 and nitric oxide (NO) levels. However, recent studies suggest that this model might be incomplete and that non-canonical mammalian globins including cytooglobin (CYGB) have survival functions independent of the regulation of O2 and NO. Our goal was to understand the function of CYGB in the hyperplastic response associated with AVF failure.

Methods: Histomorphometric, immunostaining, and protein analysis were performed on protein extracts. sections. Molecular analyses were performed on RNA extracts from these venous segments and protein analyses were performed on protein extracts.

Results: CYGB was upregulated in revision compared to primary placement veins with significant expression in both smooth muscle and neointimal cells. Injury-induced neointimal formation in vivo was attenuated by CYGB deficiency and associated with increase apoptosis and medial VSMCs loss. Human venous medial and neointimal SMCs derived from failed AVFs maintained high levels of CYGB in culture in contrast to medial SMCs from placement veins. Molecular strategies to modulate CYGB expression levels were validated that CYGB promotes SMC cell survival by inhibiting the mitochondrial apoptotic pathway.

Conclusions: Our results challenge the current dogma on globin functions and demonstrate a role for CYGB in regulating venous VSMCs survival. Strategies aimed at regulating CYGB anti-apoptotic functions might represent important therapeutic options to control for AVF maturation and limit stenosis.

Identification of Ca2+/CaM-Dependent Protein Kinase (CaM KKII) Isoforms and Their Selective Regulation by NADPH Oxidases in Failed Arteriovenous Fistula from Hemodialysis Patients
Jinlong Luo, Sonia Bhati, Nikhil Grandhi, Ashish Verma, Amanda B. Ravi S. Shah, 1Jizhong Cheng, William E. Mitch, Yechong Cheng, Medicine, Baylor College of Medicine, Houston, TX; *Nephrology, Guangzhou Medical University, Guangzhou, Guangdong, China.

Background: Placement of an arteriovenous fistula (AVF) provides vascular access for lifesaving hemodialysis to patients with severe and chronic kidney disease. A significant percentage of AVF’s initially mature; serve as successful hemodialysis access points; but fail at some later time due to neointimal hyperplasia that occludes the vein. The causative underlying molecular, biochemical, and cellular factors that contribute to AVF failure are incompletely understood. CaM KKII is a positive regulator of VSM cell proliferation and migration that results in occlusion of carotid arteries in both mice and rats. Currently, there is little known regarding the role of CaM KKII in either physiological or pathophysiological venous function.

Methods: Cephalic veins from patients prior to AVF placement and after AVF failure were obtained. Immunochemistry analyses were performed on OCT embedded frozen sections. Molecular analyses were performed on RNA extracts from these venous segments and protein analyses were performed on protein extracts.

Results: Our results indicate that there is an increase in CaM KKIIId and CaM KKIIg expression in failed AVFs as compared to cephalic vein prior to AVF placement. CaM KKII activity is regulated by both phosphorylation and oxidation, NADPH oxidases (Noxs) generate reactive oxygen species (ROS) that increases CaM KKII activity. Analysis of failed AVFs shows an upregulation of Nox5 and Nox5. Further studies show an increase in CaM KKII activity. Interestingly, our data indicates that only a subset CaM KKII isoforms are oxidized under these conditions.

Conclusions: These findings lead us to conclude that increases in [Ca2+] and [ROS] after AVF placement may result in increases of CaM KKIIId and CaM KKIIg expression and sustained activity that contribute to AVF failure. They also identify CaM KKII as a rational target for therapeutic manipulation to prevent AVF failure.

TH-PO841
Combined RNA seq and gDNA Methylation Analysis for AVF Maturation

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction. In order to understand the cellular and molecular mechanisms involved in early AVF failure we evaluated the gene methylation profile (epigenetics) in conjunction with the gene expression profile (RNA Seq) from venous tissue samples obtained at the time of AVF creation. This approach allows us to identify genes that have altered expression (RNA Seq analysis) as a result of epigenetic changes (DNA methylation). The latter can be induced by different factors, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD).

Methods: Genomic DNA (gDNA) and RNA were isolated from venous segments collected at the time of AVF creation. We divided the samples into 2 groups, THICK (n=5) and THIN (n=5), based on a histological evaluation of the amount of neointimal hyperplasia. Deep sequencing technologies were then used to identify differentially regulated levels of gene expression between the THICK and THIN groups, that also had significant differences in DNA methylation. Standard bioinformatic techniques were used to identify/interrogate these changes.

Results: We were able to identify a number of genes that were differentially regulated, either at the level of the transcriptome or at the level of DNA methylation (epigenetics) between the THICK and THIN groups. However, we were not able to identify individual genes that had changes in both the RNA Seq and DNA methylation analyses, at a high level of statistical significance.

Conclusions: While we were unable to identify differences in both gene expression and methylation of DNA methylation for individual genes, between our two groups (perhaps because of a small sample size), we do believe that these techniques and technologies could be used in larger studies, to dive deep into the mechanisms of AVF failure at a molecular and genetic level.
Computational Fluid Dynamic Analyses in a Uremic Mouse Model of AVF Stenosis: Of Surgery, Techniques and Computation
Begoña Campos,1 Yang Wang,2 Yong He,2 John M. Pearce,1 Richard Scott Dunn,3 Keith Louis Saum,1 Janaka Wansapura,1 Charles L. Dumoulin,1 Scott A. Berceli,1 Prabir Roy-Chaudhury,1 Univ of Cincinnati; 2Univ of Florida; 3CCHMC.

Background: Although arteriovenous fistulae (AVF) are the preferred form of vascular access for hemodialysis patients, over 50% of AVFs fail to mature (inability to increase blood flow and diameter adequately to support dialysis). Work performed in our laboratory suggests that AVF maturation failure is due to an interaction between “upstream hemodynamics” and “downstream vascular biology”. In order to better elucidate the mechanisms involved in both these processes, we herein describe the techniques needed to develop a shear stress profile within a uremic mouse AVF.

Methods: In order to create a uremic mouse model, C57Bl/6 animals underwent an initial cauterization of the left kidney followed 2 weeks later by a contralateral nephrectomy. Four weeks later AVFs were created in the neck. In order to generate different shear stress profiles, we created AVFs between the carotid artery and jugular vein in the following surgical configurations (a) end of carotid artery to end of jugular vein (b) end of jugular vein to end of carotid artery and (c) end of carotid artery to side of jugular vein. Mice were then perfused with a silicone rubber casting agent (Microfil). Fistulae were harvested, stored in 4% paraformaldehyde, and treated with Lugol solution as a micro-CT contrast agent. Each AVF was then scanned using micro-CT imaging to create a 3D reconstruction of AVF geometry. In order to obtain blood flow parameters we have developed an MRI technique that allows us to quantify blood flow within the carotid artery. We then use software to develop a complete shear stress profile in the mouse AVF.

Results: We have described for the first time a hybrid surgery-fluid dynamics approach, which could allow us to identify the differential impacts of different surgical configurations, with or without the impact of uremia on AVF fistula functionality (with the promise of also being able to use genetically manipulated animals in the future).

Conclusions: We firmly believe that teasing out the relative roles of upstream hemodynamics and downstream uremic vascular biology will allow us to identify target(s) for future therapeutic interventions.

Biodegradable Stents Improve Arteriovenous Fistula (AVF) Maturation
Begoña Campos, Yang Wang, Zhangzhang Yin, Keith Louis Saum, Diego Celdran-Bonafonte, Mark J. Schulz, Vesselin Shanov, Prabir Roy-Chaudhury, Univ of Cincinnati.

Background: Arteriovenous fistula (AVF) maturation failure is currently a huge clinical problem with no effective therapies. At a pathogenetic level the three main causes of AVF maturation failure are (a) small veins (b) abnormal non-laminar flow profiles and (c) abnormal local endothelial function. We therefore, hypothesize, that the placement of a biodegradable magnesium based maturation enhancing stent (bMES) within the venous segment, at the time of surgical AVF creation would dilate small veins, optimize the anatomical configuration, and serve as a conduit for the future delivery of therapies to improve local vascular biology during the critical initial 4-8 week period with an absence of long term side effects (no stent after 4-8 weeks).

Methods: bMES were fabricated using pure Mg foil (125 mm) and Mg-Zn alloy wire. Bilateral AVFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and diallated to 8mm. A control AVF was created on the contralateral side. CT angiograms and ultrasounds were performed to document blood flow and diameter for the control and stented AVF.

Results: Preliminary data documents almost complete degradation of the bMES at 4-8 weeks with an initial increase in diameter of the stented AVFs on CT angiograms at 2 weeks (Figure). Histological examination performed on both the stented and control AVFs did not reveal any evidence of necrosis or inflammation.

Conclusions: These initial results clearly demonstrate technical feasibility and safety for the bMES, and also provide us with an efficacy signal based on our CT angiogram data (Figure). We believe that this technology could significantly reduce the huge morbidity and mortality associated with AVF maturation failure and also expand the patient population considered to be suitable for AVF placement in the future.

Association Between Clinical Outcomes and Type of Vascular Access in Elderly End-Stage Renal Disease Patients Initiating Hemodialysis
Kyoung Sook Park, Mi Jung Lee, Tae-Hyun Yoo, Shin-Wook Kang. Dept of Internal Medicine, Yongui Univ College of Medicine, Seoul, Korea.

Background: Although dialysis initiation via arteriovenous fistula (AVF) is the best strategy in incident hemodialysis (HD) patients. Elderly patients with HD are compelled to use HD catheter (HC) due to maturation failure after AVF operation. Therefore, we investigated the association of vascular access (VA) type and clinical outcomes in elderly incident HD patients.

Methods: A prospective cohort of incident HD patients from the Clinical Research Center for End-stage renal disease in Korea between 2009 and 2013 was used. Patients who were 65 years or older were defined as elderly. The patients were classified into three groups according to VA type at HD initiation. Since the hazard ratio (HR) according to type of VA was not proportional, time-dependent Cox regression analysis was performed to determine all-cause mortality.

Results: Among the 511 enrolled patients, 303 (59.3%) were male and the mean age was 72.3±5.4 years. HD was initiated with AVF, arteriovenous graft (AVG), or HC in 86 (16.8%), 36 (7.0%), and 389 (76.1%) patients, respectively. During a median follow up of 12 months, all-cause death was observed 12 (14.0%) in AVF, 13 (36.1%) in AVG, and 107 (27.5%) in HC. Multivariate time-dependent Cox regression analysis demonstrated that AVG as reference, HR=1.719, 95% confidence interval [CI]=1.274-2.319, P<0.001 and HC (HR=1.304, 95% CI=1.036-1.640, P=0.023) were significant risk factors for all-cause mortality after adjustment of age, sex, diabetes mellitus, previous cardiovascular disease, tumor referral to nephrologist, hemoglobin, serum albumin, and C-reactive protein levels.

Conclusions: Patients with successful AVF were associated with better survival compared to those with AVG or HC. In addition, survival was comparable between elderly patients initiating HD with AVG and HC. Although vascular problems are common in elderly patients, AVF may be the best strategy to improve clinical outcomes in this population.

International Variability in Arteriovenous Fistula Maturation and Placement: The Dialysis Outcomes and Practice Patterns Study (DOPPS) findings demonstrate international variability in vascular access practices, and association with outcomes. Here we describe international practices in arteriovenous fistula (AVF) placement and predictors of AVF maturation.

Methods: We studied 2,230 patients with an AVF created during DOPPS phases 4-5 (2009–2015) in North America, Europe/Australia-New Zealand (ANZ), and Japan. AVF maturation was defined as access use ≥ 30 days. Generalized estimating equations with a logit link were used to assess predictors of AVF maturation adjusting for country, phase, patient characteristics, and accounting for facility clustering.

Results: No significant association was found between many patient characteristics (e.g., age, diabetes, peripheral vascular disease) and AVF maturation. AVF maturation was more likely for males vs. females (OR = 1.49 [95% CI = 1.25–1.79]) and for AVFs placed in the upper vs. lower arm (OR = 1.40 [95% CI = 1.15–1.70]). Even though upper arm AVFs were more common in North America, AVF maturation was lowest in this region (Figure).
Conclusions: There is large international variability in site of AVF placement and AVF maturation. Differences in blood flow used (much higher in the US vs. Europe and Japan) may lead to different interpretation of the term ‘maturation’ internationally, and may influence maturation rates.

Vascular Access in Acute Kidney Injury: Results from the ATN Study
Kavitha Ganta, Yue-Harn Ng, Herbert T. Davis, Mark L. Unruh. Department of Internal Medicine, Univ of New Mexico, Albuquerque, NM.

Background: Acute kidney injury requiring renal replacement therapy (RRT) portends a poor prognosis. Currently, the decision regarding catheter placement is based solely on physician discretion. Limited data exist to guide catheter placement. The Acute Renal Failure Trial Network (ATN) study was a multicenter, prospective, randomized trial on the effects of dialysis dose on mortality in critically ill patients. Using data from this study, we assessed the complications rates and the adequacy of dialysis based on different catheter locations.

Methods: Baseline characteristics were gathered. The outcomes of interest included catheter related infections, cardiac arrhythmias, excessive bleeding, local thrombosis and dialysis adequacy. Categorical variables were analyzed using Chi-square test while continuous variables were analyzed using the Student T test. The SAS software was used for all analyses.

Results: There were 242 (11.7%) subclavian (SC), 951 (46.1%) internal jugular (IJ) and 861 (41.7%) femoral (FC) catheters inserted. The baseline characteristics based on catheter location is shown in Table 1.

The rate of bacteremia was comparable between the 3 groups. (5.4% (SC) vs 3.5% (IJ) vs. 3.5% (FC); p = 0.34) The IJ group experienced more cardiac arrhythmias (2%) compared to SC (0.8%) and FC (0.5%) group (p = 0.01) while the FC group had more venous thrombosis (0.7%) compared to none in the SC and IJ group (p = 0.02). Overall, complication rates were low. There was no clinically significant difference in the adequacy of dialysis between the 3 groups.

Conclusions: There was no significant differences in complication rates amongst the 3 catheter locations hence decision on catheter location should be based on operator experience and comfort level.

TH-PO848
Vascular Access at Dialysis Initiation in the United States Renal Data System (USRDS): Strong Agreement Between CMS 2728 Medical Evidence Form and CROWNWeb
Purna Mukhopadhyay, Jeffrey Pearson, Kenneth J. Woodside, Sarah Bell, Ronald L. Pisoni, Douglas E. Schaubel, Kaitlyn Ratkowicki, Rajiv Saran.1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2 Univ of Michigan, Ann Arbor, MI; 3 Biostatistics, Univ of Michigan, Ann Arbor, MI; 4 Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: The USRDS has long reported vascular access (VA) at the start of hemodialysis (HD) using the CMS-2728 Form. In 2012, CMS rolled out the CROWNWeb (CW) system to collect clinical treatment and laboratory monthly data for all dialysis patients. As CW data are fully integrated into the USRDS database, it is critical to evaluate the level of completeness and consistency between these two data sources.

Methods: We compared VA used at the first HD session reported on the CMS-2728 form for new ESRD patients in 2013 (n = 96,936) in USRDS database with VA used at the end of the 1st month of HD reported through CW. To evaluate the potential for data lag, we also compared to the 2nd month of HD reported through CW. Completeness and consistency was assessed at the patient level by 2x2 tables. The level of agreement was evaluated by kappa statistics. Logistic regression models were fit to identify patient characteristics associated with the level of agreement.

Results: 89% of patients had at least one monthly VA report in CW among which 0.23% was missing VA data from the CMS-2728 and 32.8% did not have a VA reported in CW for their 1st month of HD. However, completeness of CW data improved when either 1st or 2nd month of HD was considered as only 12.6% of patients did not have a VA reported. Among patients with VA reported from both data sources, kappa statistics was 0.88 using the 1st month of ESRD and 0.84 using first two months of ESRD. Agreement was highest for catheter (97.98%) and lowest for graft (78.81%). Age, sex in race were associated with the level of agreement; Hispanic ethnicity and cause of ESRD were not.

Conclusions: Our analysis confirms the large CVC burden among pediatric HD pts. Conversion to AVF were observed over the first year in an incident cohort where nearly 50% of pts transitioned to PD or TX. Further study will assess the impact of CVC dependence among pediatric ESRD pts with respect to future VA options and patient outcomes.

In Search of an Optimal Screening Program for Containing Graft Thrombosis
Nicola Tessitore, Giuseppina Pessolano, Valeria Bedogna, 4 Arbor Research Collaborative for Health, Ann Arbor, MI; 3 Univ of Michigan, Ann Arbor, MI; 1 Emodialisi Borgo Roma, Verona, Italy; 2 Dept Public Health, Verona, Italy.

Background: K DOQI guidelines recommend regular screening for ‘50% stenosis (ST)’ in graft by surveillance (access blood flow (Qa) & static venous pressure ratio (vVR) or Duplex Ultrasound to reduce the risk of thrombosis. Analysis of the literature suggests that the best predictor of thrombosis is sVR>0.5, with an area under curve (AUC) of 0.81[95%CI:0.75-0.85] significantly higher than that of Qs<400 ml/min (0.72[95%CI:0.68-0.77]) & ST (0.49[95%CI:0.45-0.53]), but no study has compared vis-a-vis all of the tools.

Methods: To identify an optimal screening program, in 2013 we compared the diagnostic performance of the available tools for incipient thrombosis (within 3 mo) in the same population of 42 grafts (5 forearm loop & 37 straight upperarm), that underwent 18 thrombotic episodes.

Results: Qa by Ultrasound Dilation proved to be the best screening tool (AUC:0.81[0.69-0.93]) optimal thresholds between Qa<400 ml/min prevalence[SE], 18% false positive[FPR] & Qs<1200 ml/min (83% SE, 27% FPR). Its AUC was higher than that of (ST (0.69[95%CI:0.54-0.84]: 78% SE, 39% FPR), monitoring (0.62[95%CI 0.45-0.79]: 33% SE, 9% FPR), & VAPR (0.58[95%CI:0.42-0.74]:VAPR:0.82% SE, 58% FPR). At GLM analysis Qa was the only significant predictor of thrombosis, with 18%[95%CI 7-29%] lower risk for each 100 ml/min above a Qa 400 ml/min.

Conclusions: CW data has VA information for the vast majority of patients; however, coverage is not complete and may be lowest at start of ESRD. However, there is very strong agreement in VA reported on the CMS-2728 and in CW. This study also demonstrates near completeness of CMS Form 2728 with respect to VA information at start of HD.

Funding: NIDDK Support
2014 onward we adopted a monthly Qa screening program using a Qa=1000 ml/min for stenosis repair & a drop inQa>25% for detecting & repairing restenosis. This led to a significant drop of thrombosis rate from 0.70 [95%CI 0.41-1.11] (during the 2012-2013 period in which screening was based on bimonthly VAPR and quarterly Qa measurements and stenosis repair triggered as per guidelines, by a VAPR:0 or a Qa=600 ml/min) to 0.11 [95%CI 0.01-0.40] event/graft-y (p=0.005), at a comparable elective angioplasty rate (0.71 [95%CI 0.46-1.04] vs 0.77 [95%CI 0.43-1.27] event/graft-y, p=ns).

Conclusions: Our comparative study suggests that QA is the best predictor of graft patency & QA surveillance using a QA=1000 ml/min threshold allows for appropriate and timely stenosis repair & may contain the risk of thrombosis.

TH-PO851
The Impact of eGFR at Pre-HD Access Surgery on the Likelihood of Starting Hemodialysis with a Mature Vascular Access
Alain Albalas, Timmy C. Lee, Michael Allon. Nephrology Dept, UAB, Birmingham, AL.

Background: The optimal timing of pre-dialysis vascular access surgery is uncertain. If the access is placed too late, it may not be ready for use; if it’s placed too early, it may not be needed. The optimal timing may differ for AVF vs AVG. We evaluated the association of eGFR at access placement with (1) likelihood of starting HD, and (2) likelihood of a mature access at HD initiation.

Methods: We retrospectively queried a prospective computerized access database to identify patients with pre-HD access surgery (301 AVF and 64 AVG placed between 2006-12) with an eGFR recorded on the surgery date. Patients were stratified into 4 eGFR groups (<10, 10-14, 15-19, >20 ml/min). For each patient we determined (1) whether dialysis was initiated within 2 years, and (2) whether the permanent access was used on the first HD session.

Results: Overall, 208 (or 69%) of pts with pre-HD AVF surgery initiated HD within 2 years, but the proportion varied by eGFR at surgery (90, 81, 64, and 47% for eGFR <10, 10-14, 15-19, and >20 ml/min).

Conclusions: There are tradeoffs in the timing of pre-HD AVG surgery. A higher eGFR is associated with a lower likelihood of initiating HD in 2 years, but a higher likelihood that the AVF will be used on the first HD session. The optimal balance is achieved at an eGFR of 15-19 ml/min. In contrast, the optimal timing for pre-HD AVG surgery is an eGFR of 10-14 ml/min. Late placement of an AVF may be a catheter-sparing strategy.

TH-PO852
Economic Burden to Dialysis Providers of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients
Steven M. Brunelli,1 Wendy Turenne,1 Scott Sibbel,1 John Alan Laich,1 Antony E. Pfaffle.2 1DaVita Clinical Research, Minneapolis, MN; 2Internal Medicine, Dept of Internal Medicine, Kidney Research Inst, Anyang, Korea; 1Internal Medicine, Shamyook Medical Center, Seoul, Korea.

Background: Complications of CVCs may have economic consequences for dialysis providers derived from opportunity costs for missed dialysis treatments and increased use of bundled medications. We sought to quantify this financial burden among incident patients at a large dialysis organization (LDO).

Methods: We considered patients who began HD via a CVC between Jan 2013 and Dec 2014. In parallel analyses, patients who developed BSI (N=3269) or occlusion (N=676) during the first 6 months of dialysis were matched to control CVC-HD patients who did not. Missed HD treatment rates and medication utilization were considered from date of BSI/occlusion (or corresponding date for controls) for 180 days or until censoring for death, morbidity, or loss to follow up. Costs were derived using payer-specific remuneration rates (missed treatments), LDO acquisition costs (IV iron, ESA) and average wholesale prices (antibiotics, thrombolytics). Differences were estimated using linear mixed models including fixed effects for exposure status and month, adjusted for covariates that were imbalanced at baseline.

Results: CVC-related BSI was associated with significantly greater ESA utilization (59.33 vs 49.85 U/month, cases vs controls), IV antibiotic use (41.8% vs 6.0%) and missed HD treatment rate (1.95 vs 1.36 missed treatments/patient-month). This translated to a mean incremental cost of $5397 per patient per month. CVC occlusion was associated with increased thrombolytic use (10.9% vs 4.2%) but no significant difference in costs.

Conclusions: CVC-related BSI is a potent cost driver for dialysis providers with incremental costs of ~$400/month over a 6-month time horizon. No appreciable economic consequences of CVC occlusion were observed.

TH-PO853
Obesity Related Decrease in Intraoperative Blood Flow Is Associated with Maturation Failure of Radiocephalic Arteriovenous Fistula
Jwa-kwang Kim,1 Sun Ryoung Choi.1 1Internal Medicine, Dept of Internal Medicine, Kidney Research Inst, Anyang, Korea; 1Internal Medicine, Shamyook Medical Center, Seoul, Korea.

Background: Significant arteriovenous fistula (AVF) maturation is often challenging in obese patients. Optimal initial intraoperative blood flow (IOBF) is essential for adequate AVF maturation. This study was conducted to elucidate the effect of obesity on IOBF and radiocephalic AVF maturation.

Methods: Patients who newly created radiocephalic AVF were included (n=252). Obesity was defined as a baseline BMI>25 kg/m², and primary maturation failure was defined as the failure to use AVF successfully by 3 months after its creation. IOBF was measured immediately after construction of AVF using a VeriQTM system.

Results: The mean BMI was 24.1±3.9 kg/m², and the prevalence of obesity was 31.3%. Particularly, 8.3% (21 patients) were BMI > 30 kg/m². Primary maturation failure occurred in 100 (39.7%) patients and an IOBF < 190 mL/min was closely associated with the risk of maturation failure (relative risk, 3.05; 95% CI, 1.52–6.11). Compared to non-obese patients, obese subjects had a significantly higher prevalence of diabetes and elevated hs-CRP levels, whereas diameters of vessels were similar. When the patients were further divided into 3 groups as the BMI ≤25, 25-29.9, and ≥30 kg/m², patients in higher BMI groups had significantly lower IOBF and higher maturation failure rate. According to multivariate analysis, the statistically significant variables that determined maturation failure were obesity, previous vascular disease, increased hs-CRP levels, and IOBF < 190 mL/min.

Conclusions: Obese patients had a significantly lower IOBF, and both obesity and low IOBF contributed to the primary maturation failure of AVF. Obesity-associated inflammation and atherosclerosis might play roles in this association.

TH-PO854
The Impact of Vascular Access on Hemodialysis Patient Survival and Risk Analysis
Ping chin Lai,1 Le mei Yeh,1 Yue hsiu Chiu,1 Ling yin Chiu.1 1Renal Dept, Chang Gung Memorial Hospital, Taoyuan, Taiwan; 2Health Care Management, Chang Gung Univ, Taoyuan, Taiwan.

Background: Hemodialysis is the most common dialysis modality worldwide. However, the impact of different types of vascular access on hemodialysis patient survival has not been investigated in a large scale study. Therefore, we retrospectively reviewed the survival of hemodialysis patients in our center and analyzed the impact of vascular access on their survival. Other potential risk factors were also studied.

Methods: From 2001 to 2010, patients, who aged more than 40 years old and received regular hemodialysis in our center for at least 3 months, were included into this study. A total 916 patients were enrolled. The mean followed up interval were 4.4± 2.5 years. Among them, 51.1% were male, while 48.9% were female. These patients were divided into three groups according to their vascular access. Group A: patients used either native arteriovenous fistula or arteriovenous graft at the all time and dialysis catheter had never been used during the whole study period. Group B: patients used either native arteriovenous fistula or arteriovenous graft as their vascular access most of the time but they had used dialysis catheter at least once during study period. Group C: patients used dialysis catheter as their vascular access and arteriovenous shunt had never been established during the study period. Other survival associated factors were analyzed by using univariate and multivariate factor analysis.

Results: The results showed that group C patients had significantly worst survival rate (P<0.0001). The group B patients also had significantly worse survival rate when compared to group A and group C.
with group A patients (P = 0.0001). The hazard ratio was 1.71 (1.31-2.24) for group B and 3.56 (2.08-6.05) for group C when compared to group A patients. Multivariable analysis showed that the associated risk factors for patient survival were male sex, diabetes mellitus, low albumin, high hsCRP, and abnormal AST level.

**Conclusions:** The use of dialysis catheter imposed high risk for patient mortality on top of other associated risk factors. Early establishment of vascular access can eliminate this risk factor and improve patient outcome.

**TH-PO855**

Early Experience with a Novel Device for Ultrasound-Guided Management and Cannulation of Hemodialysis Vascular Access

William D. Paulson, 1 Deborah J. Brouwer-Maier, 2 Lillian A. Pryor, 3 John Jason White, 1 Laura L. Mulloy, 1 Lu Y. Huber, 1 Matthew J. Diamond, 1-4 Charlie Norwood VAMC & Georgia Regents Univ, Augusta, GA; 1,4 Fresenius Medical Care, Waltham, MA.

**Background:** The vascular access continues to be the Achilles Heel of dialysis. Methods that facilitate easier management and cannulation of accesses are needed. We describe early experience with a novel ultrasound device.

**Methods:** The Sonic Window (Analogic Corp, Peabody, MA, USA) is designed to assist management of vessels in a variety of contexts. It differs from conventional ultrasound in that it provides a coronal view of vessels that yields determination of characteristics such as depth and luminal diameter, and assists in cannulation for dialysis. We have initiated a program in 4 FMC dialysis units which is designed to identify its role and limitations.

**Results:** Two experts in the use of the Sonic Window have trained dialysis staff in the 4 FMC units. Staff have successfully cannulated 33 AV fistulas and synthetic grafts. Set up and use of the device generally adds an extra 1-3 minutes to cannulation time. Staff are able to easily visualize advancement of dialysis needles into the vessel lumen (figure).

**Conclusions:** Our early experience supports the concept that Sonic Window is a significant advance in managing and cannulating accesses in both routine and difficult situations.

**Funding:** Pharmaceutical Company Support - Fresenius Medical Care

Modifiable Risk Factors Affecting the Outcome Hemodialysis Graft

Jee eun Park, Jin Hae Kim, Subin Hwang, Do Hee Kim, Hye Ryoun Jang, Jung eun Lee, Woo Seong Huh, Yoon Goo Kim, Ha Young Oh, Dae Joong Kim. Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.

**Background:** Arterio-venous graft (AVG) for hemodialysis has poorer outcome than arterio-venous fistula (AVF) with its frequent stenosis and thrombosis. We investigated modifiable risk factors affecting the outcome of AVG.

**Methods:** A single-center cohort of 254 patients (pts) receiving AVG for hemodialysis access from Sep 2010 to Oct 2014 were included. Demographics, laboratory data, comorbidities, and medications were collected from the medical records. Surgical factors related to AVG operation including the type and diameter of connected vessels, graft site, and type of operation (elective or emergent) were also recorded. End points was the interval from initial access formation to any intervention intended to restore patency (primary patency, days) and the total access survival duration (secondary patency, days).

**Results:** Data of 225 pts were analyzed. During the follow-up period, 139 (62%) pts received intervention and 45 (20%) pts underwent permanent failure. Survival analyses using Kaplan-Meier method was shown in the figure. In multivariate analysis, primary patency duration was associated with RAS inhibitor (hazard ratio [HR] 1.67, 95% confidence interval [CI] 1.37-2.06), and upper arm graft (HR 0.62, 95% CI 0.40-0.94). Secondary patency duration was associated with serum albumin level (HR 0.28, 95% CI 0.13-0.61), diastolic blood pressure (BP) (HR 0.93, 95% CI 0.89-0.98) and warfarin (HR 5.80, 95% CI 2.04-16.46).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.

Vascular Access Outcomes following Peritoneal Dialysis to Hemodialysis Transition
Timmy C. Lee, Mae Thamer, Qian Zhang, Yi Zhang, Michael Allison. 1 Univ of Alabama at Birmingham; 2 Medical Technology and Practice Patterns Inst.

Background: Few studies have evaluated vascular access (VA) use following transition from PD to HD. Our goal was to examine short-term VA utilization following PD to HD transition.

Methods: Using USRDS and Medicare claims data from July 2010-December 2012, we identified 3,565 incident Medicare-insured PD patients who were >18yrs and initiated dialysis between July 2010-June 2011. Patients had at least one dialysis claim within 90 days of dialysis initiation and were followed for 1 year until one of the following events: switched to HD, kidney transplant, death, or end of follow-up. We used Cox-regression models to examine the association of risk factors and switching to HD, with death and transplantation used as competing events.

Results: 991 (27.8%) patients switched from PD to HD during the 1 year follow-up. Of these, 46% switched to HD within 90 days of dialysis initiation and 66% by 6 months. The median switch time was 114 days (IQR: 32-226). Patients with cardiovascular disease (Adjusted Hazard Ratio (HR) 1.25, 95% CI 1.10-1.43), COPD (HR 1.29; 95% CI 1.01-1.66), and without pre-dialysis nephrology care (HR 1.46; 95% CI 1.21-1.76 versus those with >12 months nephrology care) were more likely to switch from PD to HD. After switching from PD to HD, 89% used a catheter, 6.6% AVF, and 1.9% AVG. 90 and 180 days after switching to HD, 71% and 50% of patients, respectively, who remained on HD still used a catheter as their VA.

Conclusions: The majority of patients transitioning from PD to HD initiate HD with a catheter. 50% dialyze with a catheter at 6 months. This highlights the need for VA planning in patients with failed PD to ensure timely transition to permanent VA.

TH-PO859
Temporal Trends in Pre-Hemodialysis Vascular Access Creation in Elderly Patients with CKD
Timmy C. Lee, Mae Thamer, Qian Zhang, Yi Zhang, Michael Allison. 1 Univ of Alabama at Birmingham; 2 Medical Technology and Practice Patterns Inst.

Background: Optimal timing of pre-dialysis vascular access (VA) creation remains unclear. Elderly CKD patients with high co-morbidity are more likely to die before starting HD, so deferring VA creation may be reasonable. We assessed whether nephrologists have started selecting healthier elderly patients for pre-HD VA surgery.

Methods: Using Medicare claims data we identified 3418 elderly patients (aged ≥70 years) with CKD undergoing pre-HD VA creation in 2004 to 2009, and divided them into 3 time cohorts (2004-05, 2006-07 and 2008-09). For each temporal cohort, we assessed the likelihood of initiating dialysis during 2 years of follow-up after VA surgery. We collected data on cardiovascular co-morbidities and cardiovascular events prior to VA surgery and after dialysis initiation to determine if there were significant changes in these variables during the 3 time cohorts.

Results: During the 3 consecutive time periods, the proportion of patients dying before initiating HD decreased by 28%, the proportion surviving without HD increased by 31%, whereas the proportion initiating HD remained constant (p<0.005).

Concomitantly, during the 3 consecutive time periods there was a progressive decrease in patients with history of PVD (66.5 to 59.7%, p<0.005), CHF (47.0 to 35.8%, p<0.005), and prior MI (6.5 to 3.3%, p<0.0001). Among patients who initiated dialysis, there was a progressive decrease in the proportion of patients with a CHF (38.8 to 26.0%, p=0.001) or MI (5.4 to 2.6%, p<0.01) event in the first year after dialysis.

Hemodynamic Changes in Arteriovenous Fistula During Dialysis
Mary S. Hammes,1 Vikash Kumar Sinha,1 Tom Bilcharski,1 Michael Boghosian,2 Jane E. Hines,1 Sydeeka Watson,2 Kevin Cassel,2 S.M. Javid Mahmoudzadeh A,2 Medicine/Nephrology, Univ of Chicago; 3 Dept of Mechanical, Materials and Aerospace Engineering, Illinois Institute of Technology; 4 Dept of Public Health Sciences, Univ of Chicago.

Background: Optimal blood flow velocity (BFV) in arteriovenous fistulas (AVF) to prevent neointimal hyperplasia is yet to be determined. We have hypothesized that changes in BFV and diameter in a brachiocephalic fistula (BCF) are affected by fistula maturation and blood flow induced during hemodialysis.

Methods: Eight subjects with primary BCF participated. Doppler BFV was measured pre-dialysis and during dialysis at 250, 350 and 450 mL/min blood flow for up to 14 months. BFV was measured in the straight portion of the cephalic vein 10 cm proximal to the cephalic arch. The relationship between BFV and diameter was examined using a linear mixed effects model. Computational modeling using venography was performed at 3 and 12 months.

Results: The change in measured diameter and BFV showed an inverse relationship with a significant association at baseline (p=0.0074) and 350 mL/min dialysis blood flow (p=0.0092). The computational model of the cephalic arch in one subject showed a 4 fold increase in Reynolds number with a dramatic recirculation region shown by a swirling eddy at the upper elbow of the arch.

Conclusions: From 2004-2009, there has been a progressive decrease in cardiovascular co-morbidities in elderly CKD patients undergoing pre-HD VA surgery, and this has been associated with a decrease in patients dying before HD and in patients with cardiovascular events after starting HD. Clinicians are becoming more selective in pre-HD placement of VA in this patient population.

TH-PO861
Arteriovenous Fistula (AVF) Maturation Among Hemodialysis (HD) Patients: Results from the USRDS Rajiv Saran,1 Sarah Bell,1 Brett W. Plattner,1 Douglas E. Schaubel,1 Sudipta Dasmunshi,1 Purna Mukhopadhyay,2 Jeffrey Pearson,2 Ronald L. Pisoni,3 Kenneth J. Woodside,4 Univ of Michigan; 5 Arbor Research Collaborative for Health.

Background: AVF are considered the gold standard for HD vascular access, but require time to mature and may not adequately develop, resulting in prolonged central venous catheter (CVC) use. We describe AVF survival from placement until time to first use for prevalent HD patients in the US.

Methods: We examined HD patients with new AVF placements during 2013 using Medicare claims. Failure of maturation was identified by non-use following placement using CROWNWeb (CW) where patient access use is reported monthly by the facility. Patients were followed until end 2014. We assessed the relationship between patient characteristics and time-to-first-use of AVF with a Cox model.

Results: In 2013, 51,561 AVF were placed among 42,160 HD patients followed through 2014. No subsequent evidence of use occurred in 44.3% of the placements. Of successfully used AVF, median time to first use was 113 days. Older age groups were incrementally associated with lower probability of using AVF. Pts in the 0-21 and 22-44yr groups (HR=1.23 [95% CI=1.06-1.44], and 1.06 [1.03-1.11], respectively), were more likely to use AVF’s compared to the 45-64yr group (ref). Sex (Female; Fig. 1a), race (e.g., Black; Fig. 1b), comorbidity (cardiovascular disease, peripheral artery disease, diabetes, needing assistance or institutionalized status), vintage <1year, CVC and/or AV Graft use at incidence, were also associated with lower probability of AVF use.

This region, present at baseline and 3 months is much deeper at 12 months and with increased dialysis blood flow rate of 450 mL/min.

Conclusions: In patients with BCF, as the AVF matures and with increased dialysis blood flow, an increase in diameter of the cephalic vein with subsequent decrease in BFV is observed. Increased blood flow during hemodialysis evokes recirculation eddy’s which may result in endothelial damage and subsequent intimal hyperplasia unless the arterialized vein is able to adapt and remodel to the pressures and flows that are generated during hemodialysis.

This dataset is intended for research purposes only and is not intended for commercial use. All information is provided "as is" without warranty of any kind. Use of the data is subject to the terms of use and data use policy. The data provider reserves all rights.
Conclusions: We have characterized AVF maturation in a national US sample and identified important associations with multiple patient-level factors. Research is urgently required into the importance of patient, region and practice factors that could improve AVF placement and maturation, decrease CVC use, to improve patient outcomes and experience.

Eldest Age Does Not Affect Long-Term Survival of Non-Transposed and Transposed Upper Extremity Arteriovenous Fistulae

Neville R. Dosslabhoy,1 Peter Van,1,2 Renu Gupta,1,2 Clifton Frilot,2 *Nephrology, Veterans Affairs Medical Center, Shreveport, LA; 1LSU Health, Shreveport, LA.

Background: The Fistula First initiative has successfully increased the placement of arteriovenous fistulae (AVF) for vascular access. Some authors have suggested that there is a higher failure rate of AVFs in elderly patients. The purpose of this study was to determine if elderly age influences the overall survival of transposed brachial-basilic fistulae (TBBF) and non-transposed AVFs (NT) placed in the upper extremity (UE).

Methods: Our prospective, computerized clinical database was queried retrospectively to identify the survival outcomes of all upper extremity (UE) fistulae placed in CKD and ESRD patients over a 6-year period at our VA hospital. All fistulae were placed by a single surgeon, hence eliminating inter-operator variability. Patient demographics and comorbidity conditions were noted from the electronic record. The primary end point was permanent failure of the access. Kaplan Meier survival analysis was performed using SPSS.

Results: 230 UE fistulae were placed, which were categorized into two groups by patient age at the time of AVF placement: < 75 years and 75 years and older. The table shows the distribution by access type and age.

<table>
<thead>
<tr>
<th>Age</th>
<th>Type of AVF</th>
<th>TOTAL NUMBER OF AVFs</th>
<th>TOTAL NUMBER OF FAILED AVFs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 75 years</td>
<td>NT</td>
<td>124</td>
<td>40</td>
</tr>
<tr>
<td>&lt; 75 years</td>

<td>NT</td>
<td>15</td>
<td>6</td>
</tr>
<tr>
<td>≥ 75 years</td>
<td>TBBF</td>
<td>19</td>
<td>5</td>
</tr>
</tbody>
</table>

The figure shows that there was no difference in the Kaplan-Meier survival curves for the two age groups when NT and TBBF were analyzed collectively (P=0.833). Furthermore, there was no statistical difference between the survival curves when each group above was analyzed separately (P=0.996).

Conclusions: In conclusion, overall survival was similar for TBBF and NT AVF in our study and was not influenced by elderly age. This finding is contrary to popular opinion and some other reports.

TH-PO863

Peripherally Inserted Central Catheter (PICC) Placement in Hemodialysis Patients with Central Venous Catheters (CVC)

Rita L. McGill, Robin Ruthazer, Klemens B. Meyer, Dana Miskulin, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

Background: PICC insertion threatens opportunities for AVF creation and may reduce achievement of AVF. Accordingly, we evaluated the incidence of PICC placement in ESRD patients after starting dialysis and in the 2 years prior to starting dialysis, and recognizing that AVF rates are lower in women, whether PICC rates differed by sex.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all PICCs placed during the 2 years before HD initiation and up to 12/31/2012 in the subset of adult HD patients entering USRDS in 2010 or 2011 with CVC as sole vascular access. Accounting for censoring due to death and ESRD modality treatment change, and using Poisson regression to adjust for age, race, BMI, diabetes and peripheral vascular disease, we calculated sex-based incidence ratios (IRR) using PICC per 100,000 patient months.

Results: PICC were placed in 2437 (14.6%) of women and 2250 (12.2%) of men.

<table>
<thead>
<tr>
<th></th>
<th>Women</th>
<th>Men</th>

<td>1330</td>
</tr>
<tr>
<td># PICC placed after first year of HD</td>
<td>567</td>
<td>532</td>
</tr>
<tr>
<td># PICC TOTAL</td>
<td>3988</td>
<td>3331</td>
</tr>
</tbody>
</table>

Compared to men, crude and adjusted IRR of PICC for female sex were 1.35 [1.28-1.41] and 1.34 [1.27-1.41]. Multiple PICC (range = 2 to 14) were placed in 648/2260 (29%) men and 803/2437 (33%) women who had any PICC.

Conclusions: Despite persuasive indications for PICC avoidance, people dialyzing via CVC frequently receive one or more PICC before and even after starting dialysis. The PICC rate was 35% higher in women, a difference not attenuated by adjustment for demographic and clinical factors. More frequent PICC placement may explain some of the lower fistula rate in women. Eliminating frequent PICC placements in patients with CVC may improve achievement of AVF.

Arteriovenous Fistula Outcomes in an Elderly UK Population

Agnes Masenga,1,2 Jennifer B. Hanko,1 Alexander P. Maxwell,1,2 *Regional Nephrology Unit, Belfast City Hospital, Belfast, County Antrim, United Kingdom; 2Nephrology Research Group, Queen’s Univ Belfast, Belfast, County Antrim, United Kingdom.

Background: The merit of placing arteriovenous fistulas (AVFs) in the elderly is debated in the literature. We sought to investigate AVF outcomes in the population aged ≥ 65 years in our region.

Methods: The Northern Ireland Vascular Access Database incorporates vascular access data on patients with chronic kidney disease stage 4 and 5. The database includes information on all patients ≥ 65 years who had an AVF created during January 2009-December 2014 and had a functional outcome by the 1st March 2015. Functional AVF patency was defined as sustained 2-needle use on haemodialysis for at least 6 sessions. Failure to mature (FTM) was defined by either clinical examination or failure to sustain 6 sessions of 2-needle dialysis.

Results: During the study period 344 patients ≥ 65 years had an AVF created. One AVF failed immediately, three AVFs were ligated due to steal, 56 patients had not started dialysis by the study end-point and records were incomplete for 50 patients. A total of 254 patients (98% White) remained included for functional AVF patency analysis. Table 1: Clinical Characteristics of Patients ≥ 65 years with AVF Patency Outcomes (n=254)

<table>
<thead>
<tr>

<tr>
<td>Ischamic heart disease</td>
<td>102 (40)</td>
</tr>
<tr>
<td>Lower arm AVF</td>
<td>134 (53)</td>
</tr>
</tbody>
</table>

A total of 150 AVFs (59%) achieved functional patency and 105 (41%) FTM. Binary logistic regression revealed that a lower arm AVF in this elderly population was associated with FTM (p < 0.001, OR 0.23, CI 0.13–0.40).

Conclusions: Given their shorter life-expectancy, the goal of vascular access creation in the elderly should be to create one functional AVF using the best vessels identified. The greater risk of FTM with lower arm AVFs may mean preferential creation of an upper arm AVF if these vessels are better on clinical and ultrasound assessment.

Type of Vascular Access and Mortality in Japan

Toshihiko Ozeki, Shun Minatoguchi, Hideaki Shimizu, Yoshito Fujita, Daijo Inaguma.

Background: The National Kidney Foundation (NKF) Kidney Disease Outcome Quality Initiative (KDOQI) guidelines have recommended the use of AVF at dialysis initiation of dialysis. However, it has been reported that the dialysis environment has been significantly different between Japan and the United States, and there are few people who continue hemodialysis with CVVs in Japan. The aim of this study is to examine the association between type of vascular access at dialysis initiation and mortality in Japan.

Methods: This study is retrospective, multicenter, cohort study which data was collected by “Aichi Cohort study of Prognosis in Patients” (AICOPP) newly initiated into dialysis. 18 tertiary care centers in Japan participating in the “AICOPP”. This study enrolled 1,525 patients who started maintenance dialysis between October 1, 2011 and March 31, 2014. After exclusion of 129 patients who started peritoneal dialysis or without data, 1396 (87.1%) patients were enrolled. Cox regression was used to determine the effect of access type on total mortality. Type of vascular access was divided into four categories: AVFs, AVGs, CVVs changed to AVF during the course (CAVF), CVVs changed to AVG during the course (CAGV).

Results: This research showed prevalence of type of blood access in Japan.

Under multivariate analysis, CAVGs had a higher risk of mortality compared with AVFs group [hazard ratio (HR): 2.408, p value: 0.003]. No significant differences were observed compared AVFs with AVGs [hazard ratio (HR): 1.466, p value: 0.219] and CAVFs [hazard ratio (HR): 1.222, p value: 0.389].

Conclusions: As it is known, high AVF use was seen in Japan. Compared with AVFs, using CVVs changed to AVG during the course is associated with higher risks of mortality.

TH-PO866

Comparison of Arteriovenous Fistula and Arteriovenous Graft on Patient Survival and Access Patency in Non-Elderly versus Elderly Population

Hoon Hoon Minatoguchi, 1 Hideaki Shimizu, 1 Naoto Kakita, 2 Takeshi Nakanishi. 1 Div of Nephrology, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; 2 Vascular Access Center, Tanaka-Kitanoda, Japan.

Background: Arteriovenous fistula (AVF) is generally known to be the ideal option as a vascular access. However, this consensus can be challenging in elderly population.

Methods: From August in 2008 to April in 2014, 1452 adult incident hemodialysis patients were included from Clinical Research Center registry for ESRD prospective cohort, from 31 centers in the South Korea.

Results: In the whole population, AVF vs. AVG use was associated with the better patient survival only in male (p < 0.001) and DM (p = 0.004) patients. Multivariate Cox regression analysis showed AVG (vs. AVF; odds ratio [OR] 2.308, 95% confidence interval [CI]: 1.013–4.829; p = 0.026), catheter (vs. AVG; OR 10.659, 95% CI: 5.379–21.119; p < 0.001) and age (OR 1.035, 95% CI: 1.012–1.058; p = 0.003) were significantly associated with poor patient survival. In the elderly patients (≥ 65 years old), the survival benefit by AVF use also existed in only male (p = 0.001) and DM (p = 0.009) patients, but AVG compared with AVF showed better access patency only in female (p < 0.001) and DM (p = 0.01) patients. Multivariate Cox regression analysis in the elderly population showed AVF (vs. AVG; OR 3.158, 95% CI: 1.080–9.238; p = 0.036), male (vs. female; OR 3.941, 95% CI: 1.031–15.066; p = 0.045) and the presence of peripheral vessel disease (OR 4.659, 95% CI: 1.389–15.626; p = 0.013) were significantly associated with poor patient survival.

Conclusions: As it is known, high AVF use was seen in Japan. Compared with AVFs, using CVVs changed to AVG during the course is associated with higher risks of mortality.

TH-PO867

Abnormality of Fibrinolysis as well as Coagulation Were Associated with Second Patency Rates of Vascular Access in Hemodialyzed Patients

Yukiko Hasuiku, 1 Naoto Kakita, 2 Takashi Nakanishi. 1 Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; 2 Vascular Access Center, Tanaka-Kitanoda, Japan.

Background: Vascular access (VA) is essential for the HD patients. However, VA is often occluded even after the percutaneous-transluminal angioplasty (PTA). There is increasing evidence indicating the importance of the fibrinolysis system (i.e., plasminogen activator-inhibitor-1 (PAI-1) level) in the progression of vascular disease. We intended to clarify whether coagulation and fibrinolysis might be associated with VA failure after PTA.

Methods: Blood samples were taken from 262 HD patients at the PTA. Thrombin/anti-thrombin (TAT) as a marker of coagulation, D-dimer, FDP and of fibrinolysis system, and laboratory data were measured. Blood flow volume of VA was evaluated by Doppler ultrasonography before PTA. The end point was the re-vascularization or re-operation of VA during the observational period after PTA. The results were analyzed using univariate and multivariate Cox regression analyses.

Results: Age of patients was 70.6±9.7 years, and 121 patients (46.2%) have native arteriovenous fistula (AVF). During follow-up period, re-PTA was performed in 33 patients and re-operation in 28 patients. Native AVF, higher blood flow volume (≥500 ml/min), lower TAT (<3 mg/ml), and higher PAI-1 (≥7 ng/ml) were associated with good patency rates. The Kaplan–Meier analysis showed both higher TAT (p=0.0026) and lower PAI-1 (Figure 1) were significantly associated with VA failure. Cox regression analysis revealed that higher TAT (HR 2.140, 95%CI 1.288–3.556, p=0.0033) and lower PAI-1 (HR 2.322, 95%CI 1.390–3.800, p=0.0013) were related to VA failure event.

Conclusions: The present research indicates that VA failure after PTA might be associated with abnormality in the fibrinolysis system as well as activated coagulation.

TH-PO868

Early Hemodynamic and Geometric Changes in Brachiocephalic Fistula Graft

Matthew S. Hammel, Kevin Cassel, Michael Boghosian, Jane E. Hines, Syedaekwa Watson, M. Javid Mahmoudzadeh. 1 Medicine/Nephrology, Univ of Chicago; 2 Dept of Mechanical, Materials and Aerospace Engineering, Illinois Inst of Technology; 3 Dept of Public Health Sciences, Biostatistics Laboratory, Univ of Chicago.

Background: An arteriovenous fistula is the optimal vascular access for hemodialysis. A brachiocephalic fistula (BCF) is often placed in the upper arm to provide effective dialysis, but unfortunately cephalic arch stenosis (CAS) commonly develops leading to access failure. We hypothesized that a contribution to fistula failure is low wall shear stress (WSS) resulting from changes that occur in the cephalic arch because of alteration in post-fistula creation hemodynamics.

Methods: Twenty-two subjects with advanced renal failure had BCF placed. The following procedures were performed at mapping (pre-operative) and fistula maturation (8-32 weeks post-operative): venogram, Doppler to measure venous blood flow velocity, and whole blood viscosity. Geometric and computational modeling was performed to determine stress (WSS) resulting from changes that occur in the cephalic arch because of alteration in post-fistula creation hemodynamics.

Results: Blood flow velocity, venous diameter, and regions of low WSS were shown to increase in subjects by the time of maturation (p < 0.05). The percent of low WSS was linearly related to an increase in blood flow velocity (p < 0.01). Although the mean global measures in curvature and asymmetry remained unchanged from baseline to time of maturation, the change fell for shorter time to maturation and rose for longer time to maturation (p = 0.52; p = 0.01), across the regression line at 15–16 weeks.

Conclusions: The maturation process of an AVF introduces geometric effects in arch curvature and asymmetry. Hemodynamic changes increase the percentage of low WSS between parameters was examined using univariate (Kaplan-Meier methods) and Cox regression analyses.
Dilator-Assisted Banding and Beyond: Proposing an Algorithm for Managing Dialysis Access-Associated Steal Syndrome

Showwen Wang, AKDHC Access Centers, Arizona Kidney Disease and Hypertension Center; Phoenix, AZ.

Background: Dialysis Access-associated Steal Syndrome (DASS) is a major complication of arteriovenous dialysis accesses and its proper management is of critical clinical importance. However, the reported approaches are diverse and general consensus is lacking. Guided banding approaches have gained popularity, as they are minimally invasive. This report analyzes the clinical outcome of Dilator-assisted Banding (DAB), a simple technique initially described by the author for managing DASS.

Methods: This study included 30 patients that underwent DAB for DASS due to excessive dialysis access flow.

Results: Of the 30 patients: 29 had upper arm fistulas or grafts and 1 had a forearm fistula; 23 had arteriogram - 3 of which required angioplasty ± stent for feeding artery stenosis. The DAB procedures included: intraluminal DAB (12/30), extraluminal DAB (14/30) and open fistula revision plus DAB (4/30). After DAB, the average severity scores of ischemic symptoms was reduced from 2.8 ± 0.4 to 0.2 ± 0.4 for the fistula group (n=24, p<0.001) and from 3.0 ± 0.0 to 1.2 ± 1.2 for the graft group (n=6, p=0.041). Of the 24 patients with fistula, 19 had resolution of ischemic symptoms and 5 had minimal residual symptoms while 3 had finger necrosis that healed after DAB. Of the 6 patients with graft, 2 had resolution, 2 had minimal residual and 2 had no change of ischemic symptoms. These two DAB-ineffective patients underwent proximalization of arterial inflow (PAI) revisions that resulted in resolution of ischemic symptoms. During follow-up of 18.7 ± 14.5 months (range 1-50), all dialysis accesses remained functional. At 24-month post-DAB, the primary patency, primary-assisted patency and secondary patency rates of the fistula group were 72%, 91% and 100%, respectively.

Conclusions: DAB is a simple, effective and versatile approach for managing DASS due to excessive flow, especially in patients with fistula. In patients with failed banding, PAI can be effectively used for rescue. Based on the data in this study and the literature, an algorithm is proposed for managing DASS.

Outcomes of Vascular Access Creation in Incident Hemodialysis Patients in Singapore

Nicholette Geh,1 Chieh-shuai Tan,2 Shaan Achudan,1 Yi Liang Tan,1 Kian Guan Lee,1 Hui-Lin Choong,2 Tze tce Chong,3 National Univ of Singapore; 1Renal Medicine, Singapore General Hospital; 3Vascular Surgery, Singapore General Hospital.

Background: Hemodialysis is the main modality of renal replacement therapy for end-stage renal disease (ESRD) patients in Singapore. Vascular access is critical for effective therapy. This study evaluated the impact of pre-operative vein mapping on vascular access creation in patients newly initiated on hemodialysis in Singapore General Hospital.

Methods: Data of ESRD patients initiated on hemodialysis from January 2010 to December 2012 were retrospectively collected from electronic medical records. 708 patients (mean 62.8 ± 12 years old, 61% male, 71.3% Chinese) who underwent surgical creation of their first vascular access were followed up for a mean of 2.3 ± 1.2 years.

Results: 694 (98%) arteriovenous fistulae (AVF) and 14 (2%) arteriovenous grafts (AVG) were created. Successful AVF cannulation was established in 543 patients (78.2%). After 6 months, 511 (73.6%) remained patent with 43.5% (295/694) primary and 30.1% (208/694) secondary patency. 216 upper arm and 478 forearm AVF were created. Upper arm AVFs had significantly higher maturation rates (85.0% vs 76.4%, p = 0.011). Pre-operative vein mapping was performed in 42.5% (295/694) of patients. The mean vein diameter was 2.44 ± 0.82mm. Maturation rates with and without vein mapping were 72.2% and 82.7% respectively (p = 0.001). Between vein diameters <2 mm and 2mm, there was no statistical difference in maturation rates (71.3% vs 72.6%; p = 0.887) or median maturation time (66.5 ± 77 days; p = 0.280). There was no statistical difference in maturation rates between veins of <2 mm and 2 mm in both forearm (p = 0.676) and upper arm AVF (p = 0.722). On univariate analysis, male gender (p = 0.001) and the presence of good post-operative thrill (p = 0.001) were associated with successful maturation in newly created AVF. AVF created by trainees also had better maturation rates compared to consultants (83.5% vs 76.2% p = 0.027).

Conclusions: In conclusion, successful vascular access creation can be accomplished in majority of ESRD patients. This is independent of vein size or the need for pre-operative vein mapping.

Uremia Induced Gene Expression in a Mouse Model of Arteriovenous Fistula Stenosis

Background: Arteriovenous fistula (AVF) non-maturation remains a huge clinical problem resulting in significant morbidity and mortality. Unfortunately most animal models of AVF stenosis do not incorporate uremia. As a result, the molecular mechanisms by which uremia contributes to AVF dysfunction remain unknown. The aim of this study was to assess the impact of uremia on the expression of genes associated with the pathogenesis of AVF dysfunction using a uremic mouse model of AVF stenosis.

Methods: Mice were made uremic by cauterity of one kidney, followed by contralateral nephrectomy. After weeks, an end to side anastomosis was created between the jugular vein and carotid artery. Contralateral vessels served as controls. Vessels were harvested after 14 days, and RNA isolated from the AVF venous segment. Gene expression of different mediators was measured with qPCR. Data was analyzed from control vein; uremic vein; veins of non-uremic AVFs; and veins of uremic AVFs.

Results: Significant upregulation in the expression of monocyte chemotactic protein-1 (MCP1), NAPDH Oxidase (NOX4), and E-Selectin were found within the veins of AVFs compared to wild-type control vessels (P<0.017 for each gene). Compared to normal vein, MCP1 expression was increased 4.4, 14.0, and 49.1 fold in uremic vein, the non-uremic AVFs, and uremic AVFs respectively. Paradoxical increases in Krüppel-like factor-2 (KLF-2) were also seen in uremic vessels compared to wild-type veins (P<0.017).

Conclusions: In summary, marked upregulation of the proteins MCP-1, NOX4, and E-Selectin were seen with uremia, and some of these (MCP-1) were further elevated within the AVF. Of note, the flow sensitive gene KLF2 was also elevated in uremia, but was attenuated in the setting of an AVF. These preliminary findings suggest key pathways by which uremia could exacerbate AVF dysfunction and future targets for the prevention and treatment of AVF maturation failure.
In-Patient Permanent Access Is Associated with Reduced Catheter Time for Emergent Start Hemodialysis Patients  Catherine A. Moore,1 Richard E. Wing,1 Scott E. Liebman.1 Medicine-Nephrology Div, Univ of Rochester; Rochester, NY; 1Aurora Medical Group, Marinette Menominee Clinic, Marinette, WI.

Background: Hemodialysis initiation with a tunneled catheter carries increased risk of morbidity and mortality. Conversion from a hemodialysis catheter to permanent access at any time is associated with improved outcomes. This study investigates whether a strategy of placing permanent dialysis access in incident HD patients without permanent access while still hospitalized is associated with reduced exposure to hemodialysis catheters.

Methods: We conducted a retrospective cohort study of ESRD patients initiating Hemodialysis with a catheter while hospitalized at a single University Hospital Medical Center from October 2010 through June 2013. Patients were divided into two groups: those with permanent access placed during the hospitalization (N = 22) vs. those discharged without permanent access (N = 67). Our primary endpoint was removal of the hemodialysis catheter.

Results: Subjects who underwent permanent access placement while still hospitalized had a median catheter exposure time of 114 days compared with 241 days for those who did not. The median time with HD catheter in place was shorter by 127 days in the group who did not. The median time with HD catheter in place was shorter by 127 days in the group who did not. The median time with HD catheter in place was shorter by 127 days in the group who did not.

Conclusions: The practice of placing permanent access while the patient is still admitted to the hospital is associated with greater likelihood of hemodialysis catheter removal.

Factors Affecting Haemodialysis Arterio-Venous Fistula Maturation

Hannah R. Wilson, Salman Ahmed, Joseph Russell, Nicola Ding, Maggi Steele, Ayeshra Irtiza-Ali, David Makanjuola, Nihil Chitalia. Renal Unit, St. Helier Hospital, Surrey, United Kingdom.

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD). Many AVFs however, fail to mature. We investigated the factors affecting maturation of AVFs in order to identify any characteristics which were predictive of AVF maturation.

Methods: All AVFs created between 2006 and 2014 were reviewed. Data analysis was performed using GraphPad. AVFs were deemed to have failed to mature if by 90 days post-creation, it was not possible to use them for HD. The patients were divided into 2 groups – those who had the AVF created pre-emptively (group 1) and those already on HD at the time of AVF creation (group 2). Characteristics reviewed were age, gender, ethnicity, co-morbidity score, diabetes status and site of AVF.

Results: There were 1876 AVFs created. 954 in group 1 and 922 in group 2. In group 1, 597 patients started HD; 469 (79%) used their AVF for the 1st HD session. In group 2, 330 (36%) used their AVF within 90 days from creation. Group 1 AVFs were more likely to mature than those in group 2. Co-morbidity scores, age, diabetes status and ethnicity had no impact on AVF maturation rates.

*p < 0.0001 for percentage of mature AVFs in pre-emptive vs non-pre-emptive groups.

Conclusions: Our data show that the timing of AVF creation is important; those formed pre-emptively are more likely to mature than those created when the patient is on dialysis. It is possible that the presence of a dialysis line might delay maturation, especially if it is isplanted to the AVF.

It highlights the importance of prompt referral to nephrology services so that AVFs can be created in a timely manner.

Hand Held Ultrasound Device Solves Vascular Access (VA) Cannulation Problems

Beth Adams, Vivek Soi, Jerry Yee, Lalathaksha Murthy Kumbar. Henry Ford Hospital, Detroit, MI.

Background: The Fistula First Catheter Last workgroup coalition identifies VA cannulation as a fundamental “failure” point in optimizing arteriovenous fistula (AVF) usage. Infiltration from cannulation difficulties result in significant morbidity including loss of VA and cost. Cannulation success is reliant on cannulators’ skill and VA characteristics. Surface marking of VA to aid cannulation is frequently used but lacks real time information. Traditional ultrasound devices are expensive and need skilled operators rendering inapt for routine use in hemodialysis units. Sonic Window© (Analogic Ultrasound) is a coronal mode ultrasound device (CMUD) approved for VA cannulation. We present our early experience in using this novel hand held CMUD for real time guidance of VA access.

Methods: Three patients with cannulation failure defined as inability to achieve 3 needle cannulations leading to tunnel cuffed catheter (TCC) removal were identified. AVF was evaluated initially for 1-2 dialysis sessions with CMUD for course, depth from skin, optimal site for cannulation, needle length and size. Infiltration rates, subsequent procedures and hospitalizations were noted before and after CMUD use and cannulation failure days (days from initial VA clearance for use to TCC removal).

All 3 AVF were successfully cannulated leading to TCC removal within 21 days of CMUD guidance. CMUD usage resulted in no cannulation related complications and no subsequent revision procedures.

Conclusions: CMUD guided cannulation of dialysis access is feasible and safe. Real time ultrasound guidance mitigates cannulation failure and catheter removal.

Reaching First Dialysis Quickly and Unassisted with Sirolimus Treated Fistulae – Serial Ultrasound Results and Clinical Outcomes

Maria V. DeVita,1 Eric S. Chemla,2 Konstantine B. Kipiani,3 Nutsa K. Beridze,3 Sriram Iyer;3 1Nephrology, Lenox Hill Hospital, New York, NY; 2Vascular Surgery, St. George’s NHS Foundation Trust, London, United Kingdom; 3Vascular Surgery, Georgian Center of Angiology and Surgery, Tbilisi, Georgia; 4Vascular Therapies Inc, Cresskill, NJ.

Background: Neointimal hyperplasia (NH) resulting in a flow limiting stenosis within the juxta-anastomotic segment (JAS) of an AV Fistula (AVF), impairs increase in upstream vein diameter (VD), often requires supplementary procedures and prolongs time to 1st cannulation for dialysis (D). Sirolimus delivered locally to the vessel wall can suppress NH and preserve lumen patency ("sirolimus effect").

Methods: 30 pts (29 on D) undergoing AVF surgery (22 Radiocephalic (RCF), 8 Brachiocephalic fistulae (BCF)) received a Sirolimus eluting collagen implant at and around the JAS. 1st cannulation was based on clinical evaluation.

Results: 18 males, mean age 50.8y, 20% diabetic. Analysis excludes 4/22 RCF that thrombosed 2wks; 18/22 RCF (88%) and all 8 BCF maintained Primary Patency (PP) prior to 1st cannulation (mean 49 days); 13 AVF were cannulated ≤6wks, 74% AVF maintained suitability for D with PP at 12mos. Table shows serial Ultrasound results.

Economic Burden to Medicare of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients

Scott Sibbel,1 Steven M. Brunelli,1 Abigail Hunt, Wendy Turemne,2 Antony E. Paffie;3 1DaVita Clinical Research, Minneapolis, MN; 2CorMedix Inc, Bedminster, NJ.

Background: Episodes of CVC-related BSI and occlusion in HD patients result in hospitalizations and vascular access-related procedures, with attendant increases in costs. We sought to quantify this burden to the payor among Medicare-enrolled patients at a large dialysis organization.

Methods: Patients received HD via CVC during 2011 and were enrolled in Medicare Parts A and B. In parallel analyses, patients who developed BSI (N=1413) or occlusion (N=793) were matched with controls who did not, on the basis of entry month and incident/prevalent dialysis status. Outcomes were assessed from date of BSI/occlusion (or corresponding date for controls) for 6 months or until censoring for modality change, transfer of care, loss of Medicare benefits or death. Comparisons were made using linear (or corresponding date for controls) for 6 months or until censoring for modality change, transfer of care, loss of Medicare benefits or death. Comparisons were made using linear

Results: CVC-related BSI was associated with greater rate of hospitalization (incidence rate difference [IRD], 1.07 events/patient-year) and vascular-related procedures (IRD, 2.87 events/patient-year). Mean per patient per month (PPPM) costs were $2262.40 higher for BSI patients versus controls, driven primarily by increased inpatient costs. CVC occlusion was associated with modestly greater rate of hospitalization (IRD, 0.29 events/patient-year), but substantively greater rate of ambulatory procedures (IRD, 4.00 events/patient-year). Mean PPPM costs were $2354 greater for occlusion patients versus controls, driven by higher ancillary service and procedure costs.

Conclusions: CVC-related BSI and occlusion are potent cost drivers for Medicare. Risk mitigation strategies to prevent BSIs and occlusions should prove to reduce systemic health care costs.

Arteriovenous Fistula Maturation and Medial Collagen Organization Assessed by Second Harmonic Generation Microscopy

Yan-Ting E. Shiu,1 Michael Allon,2 Daniel Pike,1 CS Jason Tey,1 Silvio H. Litovskiy,3 Alfred K. Cheung,1 1U of Utah; 2U of Alabama; 3VASLCHCS.

Background: Arteriovenous fistula (AVF) maturation entails vascular dilation to allow increases in AVF blood flow. The required vascular wall distention is likely affected by its microstructure. We hypothesized that the organization of collagen fibers in the medial layer affects vascular dilation and hence AVF maturation. State-of-the-art second harmonic generation (SHG) microscopy and image-analysis algorithms were used to visualize and assess collagen-fiber organization.

Methods: Arteries and veins used for anastomosis were sampled during AVF creation from 128 participants with chronic kidney disease (CKD). Collagen SHG signals in unstained paraffin-embedded tissue sections were acquired under a two-photon microscope at 850 nm excitation, and analyzed for fiber pattern, anisotropy index (AI) and dominant orientation (DA) by 3 independent observers blinded to AVF outcomes. AI ranged from 0 (random radial pattern) to 1 (perfectly aligned fiber network). DA ranged from 0° (parallel to lumen) to 90° (perpendicular to lumen).

Results: Arterial and venous medial collagen fibers demonstrated a total of 5 patterns: parallel to lumen, perpendicular to lumen, track, web, or random (Fig. 1). The parallel and perpendicular patterns had a similar AI (~0.3) which was higher than the AI of the other patterns. However, the parallel pattern had a smaller DA than the perpendicular pattern in arteries (18° vs 70°, p=0.001). AVF non-maturation rate was lower in patients with venous DA >30° vs DA <30° (17 vs 36%, p=0.03).

Conclusions: We have characterized novel vascular medial collagen fiber organization in CKD patients. Moreover, these patterns appear to be associated with the likelihood of AVF maturation.

Impact of DPP-4 Inhibitors on Hemodialysis Vascular Access Dysfunction

**Background:** Autoimmune arterio-venous fistulae is an optimal vascular access for haemodialysis. Arterio-venous fistula is not faultless and up to 40% of fistulae never mature. In patients with no possibilities to create effective native arterio-venous fistulae haemodialysis with using a proper prostheses gives a chance to avoid a central venous catheter (CVC).

The aim of the study was to evaluate of usefulness polyurethane prosthesis as an emergency vascular access for haemodialysis.

**Methods:** The study involved 23 patients, 18 men and 5 women, at 29 – 83 years. Eight patients were in predialysis period, for 17 patients (2 in predialysis) it was a secondary procedure. All patients had implanted AvFlo prosthesis (Nicast, Israel). There were 5 loops in the forearm and 18 straight segments in the arm. Six patients underwent an urgent operation, because of lack of any vascular access. For others it was an elective operation.

**Results:** The longest observation period was over 36 months. Twenty one grafts were used for hemodialysis within 1-42 days, one prosthesis was removed due to infection, one patient died before initiation of dialysis. All grafts implanted for urgent indications were successfully cannulated within 24 hours. No differences were observed between diabetic and non-diabetic patients.

**Conclusions:** Implantation of polyurethane prosthesis provides an effective vascular access for dialysis and enables avoidance of CVC. Low infection rate improves the final outcome.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: There are 1002 haemodialysis patients; 412 dialyse via a CVHC.

- Total uses / total patients (%) = 94 / 74
- Repeat Alteplase, same CVHC n (%) = 20 / 23
- Median age of CVHC (BQR) = 147 days (77-300)
- Indication (occlusion / Poor Qb) n = 31 / 83

CVHC age was statistically different depending on the indication; occluded CVHC age was 124 ± 22 vs 244 ± 27 days for low Qb (p<0.01). Rescued CVHC age was significantly lower than those in whom the alteplase was unsuccessful (147 ± 18.4 vs 269 ± 35.8, p<0.004). In 48% of patients with an occluded CVHC, flow was restored; the remaining 52% required further intervention. Low Qb CVHC success rate was 60% compared to 38% requiring further intervention, 2% were removed (arteriovenous fistula or transplant). There was no significant difference between success rates depending on the indication (p<0.34).

Alteplase infusion significantly increased litres processed in subsequent dialysis sessions, in whom the indication was low Qb (6.2 ± 1.16 litres, p<0.0001). Overall of all infusions undertaken; 1 month patentity was 56%, 3 months 45% and 6% removed. No patient had an adverse bleeding event as a result of the alteplase infusion.

Conclusions: Alteplase infusion use is common; approximately once a week in our centre. Interestingly, complete occlusion of CVHC occurs early, possibly suggesting rapid growth of fibrin following insertion. Total litres processed improves after an alteplase infusion in over half of patients. This study demonstrates the safety and success rates of an alteplase infusion, providing evidence for its role prior to replacing the CVHC and importance in saving resources.

TH-PO883

Temporal Evolution of Parameters Before and After Initiation of Hemodialysis

Jochen Raimann, John L. Larkin, Carly R. Van Zandt, Lyan A. Usvyat, Jerson Koonman, Frank van der Sande, Barbara Cannon, Chad Sowers, Mark Stuart, Terry Ketchersid, Dugan Maddux, Peter Kotanko, Franklin W. Maddux, 1 Renal Research Inst; 2 Fresenius Medical Care North America; 3 Maastricht Univ Medical Center; 4 Icahn School of Medicine at Mount Sinai.

Background: Little is known about the dynamics of clinical and laboratory parameters during the transition between pre-dialysis chronic kidney disease and end stage kidney disease (ESKD). The goal of our research was to explore the temporal evolution of albumin (Alb), systolic blood pressure (SBP) and serum sodium (SNa) by analyzing monthly data before and after hemodialysis (HD) initiation.

Methods: We analyzed all available data from the de-identified Fresenius Medical Care CKD Data Registry to understand progression of clinical and laboratory markers before and after HD initiation. Average values of Alb, SBP and SNa were compared for 12 months prior and after HD initiation using t-test. To estimate the trends of the average values, we fitted a linear regression function through monthly averages.

Results: We studied 136846 patients (64±14 years, 56% male) over 48 months. Average SBP increased prior to HD initiation (1.2 mmHg/year), immediately decreased following HD initiation, and remained lower for the following 12 months (142±22.8 vs 136.1±23.2 mmHg; P<0.05). Before starting HD, Alb was found to be relatively unchanged, but increased after HD initiation (average Alb increased by 0.14 g/dL per year, levels were slightly higher 12 months after HD initiation [3.7±0.5 vs 3.8±0.4 g/dL; P<0.05]). Average SNa pre-ESKD had a declining trend (-0.5 mEq/L per year) and was lower compared to SNa pre-ESKD had a declining trend (-0.5 mEq/L per year) and was lower compared to 0.4 g/dL; P<0.05). Average values of Alb, SBP and SNa were compared for following HD initiation. Average values of Alb, SBP and SNa were compared for the following 12 months (142.4 ± 11.6 vs 136.1 ± 11.6; P<0.05). Overall of all infusions undertaken; 1 month patentity was 56%, 3 months 45% and 6% removed. No patient had an adverse bleeding event as a result of the alteplase infusion.

Conclusions: Alteplase infusion use is common; approximately once a week in our centre. Interestingly, complete occlusion of CVHC occurs early, possibly suggesting rapid growth of fibrin following insertion. Total litres processed improves after an alteplase infusion in over half of patients. This study demonstrates the safety and success rates of an alteplase infusion, providing evidence for its role prior to replacing the CVHC and importance in saving resources.

TH-PO884

Accelerated Arterial Stiffening in Vitamin-K-Antagonist Treated Hemodialysis Patients

Christian D. Peters, Krista D Kjaergaard, J. Dam Jensen, Bente Jespersen, Dept. of Renal Medicine, Aarhus Univ Hospital, Aarhus, Denmark.

Background: Many hemodialysis (HD) patients are treated with vitamin-K-antagonists (VKA) in order to prevent thromboembolic events. A potential side effect to VKA treatment is an increase in soft tissue calcification due to the inhibitory effect of VKAs on the central (liver) and peripheral (e.g. vascular) carboxylation cycle synthesis of several vitamin K-dependant calcification-inhibiting factors. The aim of the present study was to investigate the impact of VKA-treatment on arterial stiffness in a longitudinal, prospective comparative study.

Methods: Seventy-five HD patients from the SAFIR study with urine output >300 mL/day and HD-vintage ≤1 year were divided into controls (n=67) and VKA-treated (n=8) and followed for one year. The groups were well matched according to age, sex, comorbidity, and intervention (placebo/irbesartan). Arterial stiffness was assessed with carotid-femoral pulse wave velocity (PWV) and pulse wave analysis using the SphygmoCor device.

Results: Blood pressure (BP), PWV, and glomerular filtration rate (GFR) were similar at baseline (controls/VKA-treated) systolic BP: 148±20/145±17 mmHg; PWV: 11.6±3.2/11.0±3.9 m/s; GFR: 53±3±3.5 mL/min/1.73m2. Dialysis treatment and BP-medication were also similar. During follow up, GFR decreased similarly in both groups (P=0.2). There was no significant difference in BP between the two groups over time although BP tended to decrease more in the controls. PWV decreased in the controls -0.9(-1.4; -0.3) m/s; P=0.004 and increased in the VKA-treated 1.6(0.3; 3.2)m/s; P=0.05. Mean difference 12 months between the groups (DUPWV) was: 2.5(0.7; 4.2) m/s; P=0.006. DPWV 3.9 m/s; increased significant after adjustment for ∆GFR, ∆MAP, age at baseline, and ∆BP-medication: 2.2(0.4; 4.0) m/s; P=0.02. Mean differences after 12 months between the groups in heart rate adjusted augmentation index and time to pulse wave reflection were: 7(-2; 15) %; 8(-27; -2) ms; P=0.03 (TR).

Conclusions: Our findings indicate that VKA-treatment increases arterial stiffening significantly. We speculate that vitamin K-dependant calcification-inhibiting factors in HD patients may be inadvertently affected by VKA treatment.

TH-PO885

Associations of Kt/V with Mortality in Hemodialysis Patients by Heart Failure Status

Parta Hatamizadeh, Brian Bieber, Keith McCullough, Bruce M. Robinson. 1 Dept of Internal Medicine, Univ of Michigan, Ann Arbor; MI; 2 Arbor Research, Ann Arbor, MI.

Background: Kidney failure and heart failure (HF) frequently coexist, a condition called cardiorenal syndrome (CRS). Though HF patients on maintenance hemodialysis (mHD) have high risk of poor outcomes, there is a paucity of data to guide their care. Given the role of uremic toxins in the pathogenesis of CRS, we hypothesized that mortality for mHD patients is lower at higher Kt/V targets.

Methods: Cox regression was used to estimate associations of baseline Kt/V with all-cause mortality (ACM) and cardiovascular mortality (CVM) in phases 1-4 of the Dialysis Outcome and Practice Patterns Study (DOPPS), an international prospective cohort study of mHD patients. Separate models for patients with and without HF (by clinical diagnosis) were stratified by county and DOPPS phase and adjusted for age, gender, race, diabetes and hypertension as comorbidities, dialysis vintage, serum albumin, pre-dialysis systolic blood pressure, and weight. SAS 9.4 was used for analyses.

Results: Among 51,678 mHD patients, mean age was 62.5±14.8 yrs, 41.3% female and 32% had HF. In non-HF patients, Kt/V was inversely associated with ACM and CVM, followed a monotonic pattern. In HF patients, the association was similar for ACM but generally flat for CVM. A sensitivity analysis of Kt/V by sex showed a monotonic decline in both groups for ACM (p<0.001) and a monotonic decline in the controls (p<0.001). Overall of all infusions undertaken; 1 month patentity was 56%, 3 months 45% and 6% removed. No patient had an adverse bleeding event as a result of the alteplase infusion.

Conclusions: Contrary to our hypothesis, higher dialysis adequacy was not associated with longer survival in HF patients. Confounding by health status (patients with more advanced HF) may achieve lower Kt/V because they tolerate dialysis poorly. Further investigation is needed to identify ways to improve outcomes for this high-risk patient population.
TH-PO886

Different Impact of Malnutrition-Inflammation and Metabolic Syndrome on Long-Term Mortality and Cardiovascular Events in Hemodialysis Patients

Naoki Nakaawag, Renal Div, Dept of Internal Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.

Background: Malnutrition syndrome confers an increased risk of cardiovascular disease (CVD) in the general population. The relationship between adiponectins, and clinical outcomes in hemodialysis patients remains controversial. We investigated whether adiponectins, biomarkers of inflammation, nutrition status and clinical features predict the mortality of hemodialysis patients for 6 years.

Methods: We measured baseline plasma total and high-molecular-weight (HMW) adiponectins, tumor necrosis factor (TNF-α), serum high sensitivity C-reactive protein (hsCRP), and clinical characteristics including visceral fat area (VFA) and the Geriatric Nutritional Risk Index (GNRI) in 133 hemodialysis patients.

Results: During the 6-year follow-up period, 41 (30.9%) patients died (heart failure, n = 13; acute myocardial infarction, n = 11; stroke, n = 2; infection, n = 10; and malignant cancer, n = 5). The deceased patients were significantly older, had more prior CVD and diabetes, higher TNF-α and hsCRP levels but lower GNRI, VFA, and total and HMW adiponectin did not significantly differ between the two groups. TNF-α and hsCRP levels and GNRI score were significant for predicting all-cause and cardiovascular mortality in receiver operating curve analyses. The present ROC curve analysis for all-cause 6-year mortality found the predictive value of GNRI for mortality was 96. When stratified by a GNRI score of 96, Cox proportional hazards analyses identified TNF-α as a significant predictor of all-cause mortality (hazard ratio [HR] 1.23, P = 0.038) and hsCRP as a significant predictor of all-cause and cardiovascular mortality (HR 2.32, P = 0.003; HR 2.20, P = 0.012, respectively) after adjusting for age, sex, diabetes mellitus, and prior CVD only in malnourished patients.

Conclusions: These results demonstrate that malnutrition and the inflammatory markers TNF-α and hsCRP, but not metabolic markers, including VFA and adiponectins have a significant impact on 6-year all-cause and cardiovascular mortality in hemodialysis patients.

TH-PO887

Associations of the Malnutrition-Inflammation Complex Syndrome with Depression Symptoms, Kidney-Disease Targeted Quality of Life Measures and Mortality in a Hemodialysis Population of Predominantly African Descent

Marcelo Barreto Lopes,1 Raisa B. Peixoto,1 Priscila S. Carvalho,1 Jean M. Monteiro,1 Jessica S. Fernandes,1 Pedro Guimarães Silva,1 Luciana Ferreira Silva,2 Gildete Barreto Lopes,1 Antonio Alberto Lopes,1 Univ Federal da Bahia;2 Univ do Estado da Bahia, Salvador, BA, Brazil.

Background: The malnutrition-inflammation score (MIS) has been used to assess protein-energy wasting (PEW), also named malnutrition-inflammation complex syndrome, in maintenance hemodialysis (MHD) patients. Higher MIS has been associated with poorer outcomes in MHD patients but remains unclear if MIS expands the predictive power for outcomes in relation to its ten components and if the published results may be generalized for populations not targeted by previous investigations. We assessed associations of MIS and its components with mortality and patient-reported outcomes, i.e., health-related quality of life (HRQOL) and depression symptoms in a MHD population predominantly of African descent.

Methods: Prospective cohort (PROHEMO) of 632 MHD patients (92% Black or mixed race) treated in Salvador, Brazil. The predictor was MIS (range: 0-30, higher worse) and GNRI score of 96, Cox proportional hazards analyses identified MIS as a significant predictor of all-cause mortality (hazard ratio [HR] 1.23, P = 0.038) and hsCRP as a significant predictor of all-cause and cardiovascular mortality (HR 2.32, P = 0.003; HR 2.20, P = 0.012, respectively) after adjusting for age, sex, diabetes mellitus, and prior CVD only in malnourished patients.

Conclusions: These results demonstrate that malnutrition and the inflammatory markers TNF-α and hsCRP, but not metabolic markers, including VFA and adiponectins have a significant impact on 6-year all-cause and cardiovascular mortality in hemodialysis patients.

Funding: Government Support - Non-U.S.

TH-PO888

Non-Traditional Risk Factors Predict Atherosclerotic Events in Haemodialysis Patients – Post-Hoc Analyses of the AURORA Trial

Marti D. Solà,1,2 Geir Møjen,1 Patrick B. Mark,1,3 Hallvard Holdaas,1 Bengt C. Follstrem,3 Alan G. Jardine,1,4 Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom;1 Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway;1 Dept of Nephrology Ullevål Univ Hospital, Oslo, Norway;2 Renal and Transplant Unit, South Glasgow Univ Hospital, Glasgow, United Kingdom;3 Dept of Transplantation Medicine, Oslo Univ Hospital Rikshospitalet, Oslo, Norway;4 Div of Nephrology, Uppsala Univ Hospital, Uppsala, Sweden.

Background: Patients on haemodialysis are at high risk for cardiovascular events, but heart failure and sudden death dominate and atherosclerotic events are less common. The AURORA trial was designed to assess the effect of rosvustatin on myocardial infarction (MI) and death from any cardiac source in haemodialysis patients. We studied predictors of the atherosclerotic, and not all cardiovascular, events in AURORA.

Methods: We re-adjudicated all deaths and presumed myocardial infarctions according to stricter criteria to separate atherosclerotic from non-atherosclerotic cardiovascular events. The readjudicated atherosclerotic endpoint included non-fatal myocardial infarction, fatal coronary heart disease, non-fatal and fatal non-haemorrhagic stroke, revascularisation procedures and death from ischaemic limb disease. Baseline predictors were assessed for the 27% participants of the AURORA trial, and step-wise Cox regression analysis was applied.

Results: During a mean follow-up of 3.2 years, 716 patients experienced a readjudicated atherosclerotic event. Baseline phosphate (HR 1.33; 95% CI 1.16-1.53 per 1 mmol/L increase), albumin (HR 0.93; 95% CI 0.91-0.96 per 1 g/L increase) and high sensitive CRP (HR 1.07; 95% CI 1.00-1.14 per mg/L increase) were significant predictors in addition to female sex, age, prevalent diabetes and cardiovascular disease. LDL-cholesterol was not a significant risk factor.

Conclusions: Even with the use of strict criteria for endpoint definition, non-traditional risk factors, but not lipid disturbances, predicted atherosclerotic events in haemodialysis patients.

Proteomic Studies of Blood Plasma Using 2DE and Mass Spectrometry for Deeper View into the Mechanisms Involved in Atherosclerosis in Chronic Kidney Disease

Maria Wanja-Kosowska,1 Dorota Formanowicz,1 Elzbieta Pawlczak,1 Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland;1 Dept of Clinical Biochemistry, Poznan Univ of Medical Sciences, Poznan, Poland.

Background: The exact participation and association of particular risk factors and specific mechanisms that promote cardiovascular complications (CVD) in patients with chronic kidney disease (CKD) remain unclear. The close relationship between CVD and CKD is most likely due to the co-existence of both traditional and novel risk factors. To gain insight into better recognition of the mechanisms of CKD-related accelerated atherosclerosis, a comparative proteomic analyses have been performed.

Methods: Blood samples were taken from 90 patients (CKD1-2, CKD3-4, CKD5), 30 patients with CVD, but without CKD and 30 healthy volunteers. Plasma samples were depleted using affinity chromatography and divided into three fractions: high-abundance protein, low-abundance protein and low molecular weight protein. The first two fractions were analyzed by two dimensional gel electrophoresis and mass spectrometry, the last one has been subjected to direct MS/MS analysis. Differential accumulated proteins were confirmed by selected reaction monitoring analysis.

Results: 49 proteins (13 high and 36 low molecular mass) showed differences in accumulation levels. The proteomic profiles in CKD5 and CVD patients differed in the accumulation of four LAPs the relative accumulations of alpha -2-macroglobulin, second isoform of alfa 1 microglobulin and were higher in CKD5 compared with CVD; fold changes 1.77, 4.14, 2.68 and 1.79, respectively. Moreover, the relative abundances of these proteins were up-regulated in CKD3-4 compared with CVD. CKD1-2 and CVD group differed in the accumulation of apolipoprotein A-4 and apolipoprotein A-1.

Conclusions: Our results definitely indicated similar proteomic profiles in CKD1-2 and CVD patients, in contrast to CVD and CKD5 patients, suggesting that mechanisms of CVD acceleration may be different in initial and advanced stages of CVD. It seems that it is related to chronic inflammation and immune disturbances, typical for CVD.

Hemodialysis-Induced Release of Microparticles

Liina Vassål,1 Inga Soveri,1 Fariborz Mobarez,1,2 Nora Almqvist,1,3 Bengt C. Follstrem,1 3Dept of Medical Sciences, Uppsala Univ, Uppsala, Sweden;2 Dept of Medicine, Karolinska Inst, Stockholm, Sweden;3 Dept of Clinical Sciences, Danderyd Hospital, Karolinska Inst, Stockholm, Sweden.

Background: Microparticles (MPs) are 0.1-1.0 μm vesicles that are released from cells upon activation or during apoptosis. MPs are believed to be involved in the pathophysiology of atherosclerosis and thrombosis. Patients with cardiovascular risk factors have significant MP elevation. Measurements of MPs may uncover new insight into mechanisms behind the severe increased cardiovascular disease (CVD) risk in hemodialysis (HD) patients. The aim was to study whether a hemodialysis session affects MP formation and release.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Plasma samples from 20 HD patients were drawn before and 1h after the start of a HD session. MPs derived from platelets (CD62a+), monocytes (CD14+), endothelial cells (CD31+), and their expression of phosphatidylserine (PS) and tissue factor (CD142) were analyzed using flow cytometry. P-selectin (CD62P) and CD40 ligand (CD154) were measured on platelet-MPs. In addition, Klotho and the receptor for advanced glycation end products (RAGE) expression were measured on MPs. Paired t-test was used.

Results: Mean age was 73.6 years (range 54-91). 5 patients were female, 14 had central dialysis catheter, 8 patients had diabetes and 14 had CVD.

The Monocyte Subset of CD14+CD16+ Cells Plays a Key Role of Promoting Atherosclerosis in Hemodialysis Patients

Miki Nishida,1 Minoru Ando,2 Yusuke Iwamoto,2 Minoru Inoue,1 Ken Tsujiuchi,1 Kosaku Nitta,3 Dept. Medicine, Kidney Center, Tokyo Women’s Medical Univ, Tokyo, Japan; Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; 'Saitou Memorial Hospital, Tokyo, Japan.

Background: Atherosclerosis is closely associated with morbidity and mortality in hemodialysis (HD) patients. The scavenger receptor CD16 plays a key role in promoting foam cell formation by binding and internalizing oxidized low-density lipoprotein. In addition, heterogeneity of monocytes and macrophage-colony stimulating factor (M-CSF) may facilitate the atherosclerotic process by SR over-expression.

Methods: Subjects included 62 HD patients and 30 healthy controls. Peripheral monocytes were isolated using magnetically labeled Whole Blood CD14+ micro-beads. Transcriptional levels of CD16 and SR-A were measured in monocytes by quantitative real-time RT-PCR, using the comparative threshold (Ct) method. The gene expressions were measured within HD patients and controls, and between HD patients who had cardiovascular disease (CVD) and those who did not. Plasma concentration of M-CSF was measured with M-CSF ELISA kit. Additionally, CD16 protein expression was analyzed by a flow cytometry.

Results: SR-A gene expression was higher in monocytes from HD patients than in those from controls (2.35 vs 1.29, P=0.0006). Moreover, it was higher in HD patients with CVD than in those without (2.79 vs 1.64, P=0.0023). Plasma concentration of M-CSF was 8-fold higher in HD patients than in controls (1173±5173 vs 152±551 pg/ml, P<0.0001). It was significantly correlated with the gene expression of SR-A (r=0.129, P<0.0001). The CD16 gene expression was higher in CD14+ monocytes from HD patients than in those from controls (1.28 vs 1.17, P=0.0310), and was significantly correlated with the gene expression of SR-A (r=0.051, P=0.0467). In a flow cytometry, the proportion of CD14+CD16+ cells was 2.2-fold higher in HD patients than in controls (34.60 vs 15.85, P=0.0034). In addition, this proportion was related with M-CSF (r=-0.354, P=0.0118) and SR-A gene expression (r=0.540, P=0.0240).

Conclusions: The CD14+CD16+ cells are important subset of monocytes in HD patients, which may prime and increase SR expressions.

TH-P0892

Active Ghrelin Enhances the Association Between BMI and Clinical Outcome in Hemodialysis Patients Irrespective of Appetite Ilia Beberashvili,1 Inna Sinuani,2 Ada Azar,3 Leonid Feldman,1 Leonid Feldman,1 Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel;2Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea;3Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.

Background: Ghrelin, a gastric orexigenic peptide, and BMI are known as inversely associated to each other and have both been linked to cardiovascular (CV) risk and mortality. Interestingly, the orexigenic effect of ghrelin does not seem involved in described interaction.

Methods: Serum ghrelin, BMI, appetite, circadian rhythm of ghrelin, sympathetic nerve activity, and heart rate variability were measured in 261 maintenance HD patients (39% women, mean age of 68±13.6 years). The majority of MP levels increase significantly after the start of a HD session. Whether this is driven by patient or dialysis specific factors remains unclear. The clinical significance of MP release during HD needs to be evaluated.

Funding: Government Support - Non-U.S.

TH-P0893

Serum Procollagen Type I Carboxy-terminal Propeptide Is Associated with Left Ventricular Hypertrophy and Dysfunction, and May Predict Cardiovascular Event in Incidential Dialysis Patient Sung Jun Kim,1 Hye Eun Yoon,2 Sungjin Chung,2 Seok Joon Shin,3 Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Incheon, Korea; 'Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Korea.

Background: Serum procollagen type I carboxy-terminal propeptide (PICP) is a marker of myocardial fibrosis in hypertensive heart disease. However, the clinical significance of this marker in patients who are not determined to be on regular dialysis remains unknown. The aim of this study was to evaluate the association of predialysis serum PICP levels with echocardiographic markers in ESRD patients.

Methods: Serum PICP, albumin, CRP, ITPH levels were obtained from predialysis blood samples of 123 incidentally detected ESRD patients. Echocardiographic parameters were measured before the start of the HD session. The left ventricular mass index (LVMI) and ejection fraction, ratio of peak early transmural flow velocity to peak early diastolic annular velocity (E/A ratio), ratio of early transmural flow velocity to peak late transmural flow velocity (E/A ratio), and mitral valve-deceleration time (DT).

Conclusions: Serum procollagen type I carboxy-terminal propeptide (PICP) is associated with left ventricular hypertrophy and dysfunction, and may predict cardiovascular event in incidental dialysis patient.

TH-P0894

Associations of Soluble Receptors for Advanced Glycation End Products and Serum Procollagen Type I Carboxy-terminal Propeptide with Mortality in Long-Term Hemodialysis Patients J Yong Jung,1 Eul Sik Jung,1 Byunghoo Choi,2 Yun Jung Oh,2 Chungsik Lee,2 Ae jin Kim,1 Han Ro,2 Jae Hyun Chung,1 Hyun Hee Lee,1 Wooyoung Chung.1 'Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; 'Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.

Background: Hemodialysis (HD) patients have been associated with vascular calcification and ultimately with high mortality rates. Formerly, we reported association of soluble receptor for advanced glycation end products (s-RAGE) and S100A12 (EN-RAGE) with vascular calcification. We extended our observation whether those biomarkers could be proposed for predicting cardiovascular morbidity and mortality in these subjects.

Methods: This is a prospective observational cohort study in 199 HD patients from extended analyses of our previous study. Serum S-RAGE, S100A12, comorbidities, and other traditional risk factors were evaluated. The Cox proportional-hazards regression was used for Cox proportional-hazards regression were evaluated in multivariable analyses. A mean observation period was 29 months.

Conclusions: The patients were 57 ± 13.7 years of age; 54.3% were male, 49.2% were diabetic, and 36.2% had a history of cardiovascular disease. During the observation period, 27 patients (13.6%) were died. Univariate analysis demonstrated that S100A12 was correlated with diabetes (P = 0.04) and hs-CRP (P = 0.01). In multivariable analyses, serum s-RAGE (HR [hazard ratio], 1.16; 95% CI [confidence interval], 0.61-2.19; P = 0.65) and S100A12 (HR 1.05; 95% CI, 0.62-1.77; P = 0.87) were not associated with mortality in hemodialysis patients, though traditional predictors for mortality including age, history of cardiovascular diseases, serum albumin and serum high-sensitivity C reactive protein (hs-CRP) were related to mortality. Powerful predictors for mortality were age, previous cardiovascular disease and serum albumin level.

Conclusions: Serum S-RAGE and S100A12 may be weak surrogate markers to predict all-cause mortality in patients receiving hemodialysis, even though S100A12 was partly related with diabetes and inflammation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Impact of Sodium-Dependent Phosphate Co-Transport, Pit-1, in Peripheral Blood Mononuclear Cells on Cardiac Calcification in Maintenance Hemodialysis Patients

Minwon Ding, Mengjing Wang, Minmin Zhang, Jing Chen. Huashan Hospital, Fudan Univ.

Background: Vascular calcification (VC) is an important risk factor for cardiovascular disease in MHD patients, however, the mechanisms of which are still under investigation. The aim of this study was to explore the risk factors of VC in MHD patients, and to identify the expression of sodium-dependent phosphate co-transporter (Npt) in peripheral blood mononuclear cells (PBMCs) and assess its association with cardiac calcification and its possible impact factors.

Methods: This is a cross-sectional analysis of adult MHD patients who received at least 6-month regular MHD in our dialysis center. The coronary artery calcification (CAC) was measured by cardiac MSCT. The gene expression of Npt in PBMCs was measured by Real-time PCR and we tested serum TNN-I and IL-6 by ELISA. Multivariate logistic analysis was used to determine the risk factors of CAC. Correlation between the gene expression of Npt and other parameters was examined by Pearson relativity analysis.

Results: 1,685 eligible patients were enrolled. 2. Three kinds of Npts were detected in PBMCs of MHD patients. They were typeIINpt, Npt2b, type III Npt, Pit-1 and Pit-2, among which Pit-1 mRNA expression was significantly associated with extent of CAC. 3. The results of the logistic regression analysis were listed in Table 1. 4. Pearson relativity analysis showed phosphor-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus (r=0.43, P=0.002), CAC score (r=0.63, P<0.001) and Pit-2 mRNA expression of PBMCs (r=0.53, P=0.001).

Table 1. Multiple logistic regression analysis of factors associated with CAC score tertile in MHD patients

Conclusions: Our result showed that longer dialysis vintage, diabetes, higher concentration of serum TNN-I and Pit-1 mRNA expression of PBMCs are the risk factors of CAC in MHD patients. Pit-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus, CAC score and Pit-2 mRNA expression of PBMCs.

TH-P0895

HDL Not as Predictive as apoA-1:apoB Ratio of Dialysis Patients in Predicting Death

Sato1, Akihiro Fukuda. 2,3

Background: Chronic kidney disease is a common disease associated with high cardiovascular risk. Recent studies have suggested that HDL not LDL may play the more important role in the progression of atherosclerosis in CKD patients. HDL from CKD patients was shown to become dysfunctional, lose its vasoprotective properties and begin to promote endothelial dysfunction and inflammation.

Methods: The aim of this study was to investigate the association between the apolipoprotein profile and the incidence of death in chronic dialysis patients.

Results: Of the 194 deaths recorded, 82 were of CVD origin. For the regular lipid markers (HDL, non-HDL, and TG), +1 digit of the apoA-1:apoB ratio was significantly associated with both categories of death when compared with the lowest quarters by multivariable Cox analysis.

Conclusions: Although controversies persist regarding whether lipids affect the prognosis of dialysis patients, our data revealed that the apoA-1:apoB ratio was significantly associated with all-cause and CVD mortality in dialysis patients. 

Funding: Government Support - Non-U.S.

TH-P0897

HDL Subfractions in End-Stage Renal Disease (ESRD) Patients

Anna Gluba-Brazokza, Beata Franzyk-Skora, Jacek Rysz. Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Poland.

Background: Chronic kidney disease is a common disease associated with high cardiovascular risk. Recent studies have suggested that HDL not LDL may play the more important role in the progression of atherosclerosis in CKD patients. HDL from CKD patients was shown to become dysfunctional, lose its vasoprotective properties and begin to promote endothelial dysfunction and inflammation.

Methods: The aim of this study was to investigate the association between the HDL subfractions and the incidence of death in chronic dialysis patients.

Results: When participants were divided into quartiles, the highest quartiles of the apoA-1:apoB ratio were significantly associated with both categories of death when compared with the lowest quartiles by multivariable Cox analysis.

Conclusions: Although controversies persist regarding whether lipids affect the prognosis of dialysis patients, our data revealed that the apoA-1:apoB ratio was significantly associated with all-cause and CVD mortality in dialysis patients.

Galeano-3 Does Not Correlate within Markers of Cardiac Structure and Function on Cardiac MRI: A Study in Haemodialysis Patients

Lisa E. Crowley,1 Aghogho Odudu,1 Saoirse O’Sullivan,1 Christopher W. McIntyre,1* 1Dept of Renal Medicine, Royal Derby Hospital, United Kingdom; 2Div of Medical Sciences, Univ of Nottingham, United Kingdom; 3Kidney Clinical Research Unit, London Health Sciences Centre, London, Canada.

Background: End-stage renal failure patients undergoing haemodialysis (HD) suffer disproportionately rates of death due to heart failure. Accurate tools to help predict those highest risk are therefore desirable. Galeano-3 is a soluble β-galactoside binding protein secreted by activated macrophages that promotes cardiac fibroblast proliferation, collagen deposition and as a result ventricular dysfunction. Galeano-3 is the only FDA approved test for assessing prognosis in chronic heart failure. Our study explored the relationship between Galeano-3 and cardiac structure and function in a dialysis population.

Methods: We measured Galeano-3 (G3) levels in a multiplex assay (Merck Millipore) in HD patients enlisted in a clinical trial. Results were correlated with tagged cardiac magnetic resonance imaging to assess left ventricular structure and function.

Results: A total of 65 patients had G3 levels taken. The mean age of the cohort was 60±24 years. The overall mean G3 level was 17.7±10.07. The mean Left Ventricular Mass Index was 77.09±21.04, mean ejection fraction 57.47±.11 and mean End-diastolic volume 143.4±24 years. The whole cohort had no significant correlation between G3 levels and any of the measure of left ventricular structure and function including LVMi (r=0.22 p<0.04), LVEF (r=0.08 p=0.65) or LVEDV (r=0.012 p=0.94). The previously reported upper limit of normal for G3 levels is 17.7ng/mL. 32 patients had a G3 level greater than this. In this group the mean G3 level was 23.2±ng/mL, however there remained no significant correlations with age (r=0.10 p=0.38), LVEF (r=0.23 p=0.26), LVEDV (r=0.01 p=0.95), LVMi (r=0.11 p=0.59) or global peak diastolic and systolic strain rates (r=0.3 p=0.14 and r=0.16 p=0.41).

Conclusions: In HD patients, Galeano-3 is not associated with structural and functional markers of systolic dysfunction seen on tagged cardiac MRI. Our results suggest that Galeano-3 does not have a role in risk stratification of this patient group.

Galeano-3 is not associated with arterial stiffness in CKD patients.

TH-P0901

Association of Klotho and FGF23 with Frailty in Patients Initiating Hemodialysis

Sahar Kourbari1 Esther D. Kim,2 Dorry L. Segev,3 Stephen M. Sozio,1 Larisa Tereshchenko,2 Lucy A. Moe,2 Rulan S. Parekh,2 Michelle M. Estrella,1 Johns Hopkins Univ; 1Univ of Toronto; 2Univ of Oregon.

Background: At dialysis initiation is associated with higher mortality. Both FGF23 and its co-receptor, klotho, have been implicated in the development of frailty. We aimed to evaluate the independent association of FGF23 and soluble klotho (sKlotho) with frailty in hemodialysis (HD) patients.

Methods: We conducted a cross-sectional study of incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Events in ESRD (PACE) Study. Frailty was defined by 3 of the following: unintentional weight loss ≥10 lbs in prior year, self-reported exhaustion, weakness (by hand grip strength), slowness (by walking distance) and self-reported low physical activity. Logistic regression was used to examine the associations of sKlotho and FGF23 with odds of frailty and frailty subcomponents.

Results: Of 336 individuals, 71% were black; 59% were male. Mean age was 55y. All had hypertension and 56% had diabetes, 38% CAD, and 37% obesity. Median sKlotho level was 364.4±ng/mL (IQR 272.5-494.6); mean FGF23 level was 656.2±U/mL (SD: 498). 40% of participants were frail. Adjusting for demographic factors, obesity, Charlson Comorbidity Index, hsCRP, serum albumin and Kt/V, higher sKlotho was associated with lower odds of frailty (Table).

Conclusions: In HD patients, sKlotho, but not FGF23, was inversely associated with odds of frailty and frailty subcomponents. This remained robust after also adjusting for FGF23. Conversely, FGF23 was not associated with frailty. In adjusted analyses of the frailty subcomponents, higher sKlotho was only associated with self-reported exhaustion (OR=0.54, 95%CI: 0.30-0.95) while higher FGF23 was only associated with unintentional weight loss (OR=0.93, 95%CI 0.88-0.98).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.

TH-P0902

Differential Association of Fibroblast Growth Factor-23 and Soluble Klotho with Left Ventricular Hypertrophy

Tanya S. Johns,1 Esther D. Kim,2 Tessa Kimberly Novick,2 Lucy A. Moe,3 Stephen M. Sozio,3 Bernard G. Jaar,1 Larisa Tereshchenko,4 Rulan S. Parekh,2 Michelle M. Estrella,3 Albert Einstein College of Medicine; 1Univ of Toronto; 2Johns Hopkins Univ; 3Univ of Oregon.

Background: Fibroblast growth factor-23 (FGF23), a phosphaturic hormone, has been implicated in the pathogenesis of left ventricular hypertrophy (LVH) among patients with chronic kidney disease. Whether FGF23 co-receptor, klotho, is independently associated with LVH is unclear.

Methods: To determine whether soluble klotho (sKlotho) is independently associated with LVH among incident hemodialysis patients, we conducted a cross-sectional study among participants who underwent baseline 2D echocardiograms in the Predictors of Arrhythmia and Cardiovascular Events (PACE) Study. Multivariable logistic regression models with FGF23, sKlotho, and both as primary predictors were constructed to estimate the odds of LVH (defined as LV mass index ≥116 g/m² in men and ≥104 g/m² in women).

Results: Of 391 participants who underwent echocardiogram, 371 and 387 had sKlotho and FGF23 levels available, respectively; 72% had LVH. Mean age was 54 years and 72% were black. All participants had hypertension with mean systolic BP 154 mm Hg. Median parathyroid hormone (25 pmol/l, IQR 13-56 versus 3.8 pmol/l, IQR 3-5, p<0.001) and parathyroid hormone (25 pmol/l, IQR 13-56 versus 3.8 pmol/l, IQR 3-5, p<0.001). PWV was elevated in patients with CKD (8 m/sec, IQR 6.9-6.9 vs. 7.0 m/sec, IQR 6.8-8.4, p=0.0002). In a regression model adjusted for known predictors of PWV, FGF23 did not predict PWV (p=0.15, p=0.063), but was positively associated with the presence of CKD (p=0.009), age (p=0.001), mean arterial pressure (p=0.001) and heart rate (p=0.001).

Conclusions: In this prospective cohort study, FGF23 did not predict arterial stiffening beyond known risk factors of age, mean arterial pressure, heart rate and the presence of diabetes. Our findings suggest that the excess cardiovascular mortality observed with elevated FGF23 in CKD is not primarily driven by effects on arterial stiffening.

TH-P0911

FGF23 is Not Associated with Arterial Stiffness in Patients with CKDSD

Kenneth Lim1,2 Stephen M. Ting,3 Daniel Zehnder,4 Thomas F. Hiemstra.1 1Div of Nephrology, Massachusetts General Hospital, Boston, MA; 2Dept of Medicine, Heart of England NHS Foundation Trust, Birmingham, United Kingdom; 3Div of Nephrology, Univ Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; 4Div of Metabolic and Vascular Health, Warwick Medical School, Coventry, United Kingdom; 5School of Clinical Medicine, Univ of Cambridge, Cambridge, United Kingdom.

Background: Arterial stiffening is thought to be a key determinant of excess Cardiovascular mortality in CKD patients. In CKD, the bone-derived phosphatonin fibroblast growth factor (FGF) 23 is elevated and has been implicated in the development of Cardiovascular disease. In this study, we sought to determine whether FGF23 is a predictor of arterial stiffness in dialysis-dependent CKD patients.

Methods: In this cross-sectional study, we enrolled 352 patients with advanced CKD and 150 healthy controls. Pulse wave velocity (PWV) was recorded by application tonometry, and blood pressure and biochemical parameters including plasma intact-FGF23 concentrations determined.

Results: Patients with CKD were significantly younger than controls (46±14 versus 49±11 years, p<0.02), had a higher blood pressure (MAP 97±14 vs 94±10 mmHg, p<0.003), and were more likely to be male (61% versus 49%, p<0.008). CKD patients had significantly higher FGF23 (3095 pg/ml, IQR 12-17276 versus 40 pg/ml, IQR 33-49, p<0.001) and parathyroid hormone (25 pmol/l, IQR 13-56 versus 3.8 pmol/l, IQR 3-5, p=0.001). PWV was elevated in patients with CKD (8 m/sec, IQR 6.9-6.9 vs. 7.0 m/sec, IQR 6.8-8.4, p=0.0002). In a regression model adjusted for known predictors of PWV, FGF23 did not predict PWV (p=0.15, p=0.063), but was positively associated with the presence of CKD (p=0.009), age (p=0.001), mean arterial pressure (p=0.001) and heart rate (p=0.001).

Conclusions: In this prospective cohort study, FGF23 did not predict arterial stiffening beyond known risk factors of age, mean arterial pressure, heart rate and the presence of diabetes. Our findings suggest that the excess cardiovascular mortality observed with elevated FGF23 in CKD is not primarily driven by effects on arterial stiffening.
Predictors of Arterial Stiffness in Incident Hemodialysis Patients

**Background:** Premature vascular aging and arterial stiffening characterize CKD progression to ESRD and are associated with increased cardiovascular (CVD) morbidity and mortality. We identified predictors of arterial stiffness over time in HD patients.

**Methods:** In 339 incident HD patients in the Predictors of Arthrythmic and Cardiovascular Risk in ESRD (PACE) study, we examined the associations of baseline age, sex, race, comorbidities, CVD medications, and dialysis characteristics with longitudinal vascular stiffness measured by carotid-femoral pulse wave velocity (PWV) using generalized estimating equations. Annual change in PWV for up to 3 years was analyzed using linear regression.

**Results:** Mean age was 54, 58% male, 74% African-American, mean (SD) baseline PWV 10.7 (3.4) m/s, and annual PWV change 0.2 (1.6) m/s. Several factors were associated with higher PWV in univariate and multivariate longitudinal models. None were associated with PWV change.

P-value: <0.05
<0.01
<0.001

**Conclusions:** Although PWV did not change significantly over time in incident HD patients, age, male sex, diabetes, and pulse pressure were independently associated with higher PWV. It may be difficult to modify PWV after HD initiation and clinical factors should be optimized prior to starting HD.

**TH-PO904**

Differences in Risk Factors for Coronary Artery Calcification Between Non-diabetic and Diabetic Hemodialysis Patients

**Background:** The differences in risk factors for coronary artery calcification between non-diabetic and diabetic hemodialysis (HD) patients have not been fully explored.

**Methods:** We examined Agatston coronary artery calcium score (CACS) using MDCT, age, sex, presence of diabetes, dialysis vintage, smoking history, administration of phosphate binders, geriatric nutritional risk index (GNNRI), Hba1c, serum calcium, phosphate, iPTH, CRP, B2MG, LDL-cholesterol and triglyceride (TG) in 355 HD patients: 242 nondiabetics and 113 diabetics. Factors related to CACS were assessed by multivariate regression analysis using all of the above independent variables. Differences in the above parameters according to quartile (Q) of CACS were also assessed.

**Results:** Mean age (years), dialysis vintage (months), (CACS) and serum phosphate (mg/dl) were 63.14 vs. 66.12 (ms), 125.5 vs. 171.50 months (P<0.01), 1651.2173 vs. 21772.2533 (P<0.005), and 5.3±1.53 vs. 5.0±1.14 (ms) in nondiabetics and diabetics, respectively. Patients with CACS Q4 showed higher prevalence of diabetes (40 vs. 19%), age (68±12 vs. 58±14 years), and CRP (0.7±1.3 vs. 0.2±0.4 mg/dl), but lower iPTH (146±133 vs. 193±131 pg/ml) levels than patients with CACS Q1 (P<0.05), and other parameters were not significantly different except HbA1c. Significant associations were observed between CACS and age (P<0.001, β: 0.21), female (P<0.001, β: -0.21), dialysis vintage (P<0.001, β: 0.31), CRP (P<0.05, β: 0.16), TG (P<0.05, β: 0.13) in nondiabetics. However, CACS was significantly associated only with age (P<0.05, β: 0.30) and HbA1c (P<0.05, β:0.26) in diabetics.

**Conclusions:** Risk factors for coronary artery calcification differ between non-diabetic and diabetic HD patients, and poor glycosic control is the main factor in the latter.

**TH-PO905**

Hemodialysis and Hemodiafiltration Improve Serum Calcium Propensity

**Background:** Calciprotein particles (CPPs) may play an important role in the calcium propensities in CKD patients. The calcium propensities of serum (T 250) is highly predictive of all-cause mortality in chronic kidney disease patients. Whether T 250 is therapeutically improvable, by hemodialysis (HD) or even further by hemodiafiltration (HDF), has not been studied yet.

**Methods:** We designed a cross-sectional single center study, and included prevalent patients on HD or HDF. Patients were divided into two groups based on dialysis modality. We included patients on a thrice-weekly schedule, with a dialysis vintage of ≥3 months and vascular access providing a blood flow rate of >300 ml/min. Calcium propensities of serum was measured by the time of transformation from primary to secondary CPP (T 250 test), by time-resolved nephelometry.

**Results:** In total 64 patients were included and, T 250 was measured in 376 pre- and post-dialysis samples of all in-center dialysis sessions during one week. T 250 levels improved in both the HD and HDF group with pre- and post-dialysis (mean (SD) of 244±46-301±57, and 253±55-304±61) mm respectively (P=0.43). The mean improvement of T 250 was 26.29% in the HD group and 21.97% in the HDF group (P=0.01). The delta values (A) of calcium, phosphate (P) and albumin were equally improved in both groups. The DT 250 was mostly improved by DP (P=0.280, P<0.01 HD and r=0.235; P=0.02 HDF).

**Conclusions:** HD and HDF patients present with same baseline vascular calcification risk values pre-dialysis. Calcium propensities is significantly improved during both HD and HDF. T 250 might be a useful guide to optimize renal replacement strategy to improve the individual calcification risk in dialysis patients.

Association of Circulating Biomarkers with Vascular Stiffness and Coronary Artery Calcium in Incident Hemodialysis

**Background:** Vascular calcification and stiffness are associated with higher mortality in hemodialysis. Studies examining the role of circulating biomarkers – specifically, FGFR23, desphospho-uncarboxylated matrix GlA protein (dpucMGP), Fetuin A, osteoprotegerin (OPG), and C-reactive protein (CRP) – in vascular calcification have reported contradictory findings, and the independent association of the biomarkers remains inconclusive.

**Methods:** In 392 incident hemodialysis patients in the Predictors of Arrhythmic and Cardiovascular Risk End Stage Renal Disease (PACE) study, we examined the associations of baseline FGFR23, dpucMGP, Fetuin A, OPG, and CRP with total coronary calcium score (Agatston) at baseline and vascular stiffness (pulse wave velocity [PWV]) at baseline and over 4 years visits. Baseline associations were determined using linear regression and repeated measures over visits were examined using mixed-effects models.

**Results:** At baseline, higher OPG was associated with increased odds of having a high coronary calcium score (>257), independent of other biomarkers (OR=1.11, 95% CI: 1.06, 1.15).
1.6). The remaining biomarkers were not associated with high coronary calcium. Higher OPG was associated with higher PWV, and higher FGF23 was associated with lower PWV after adjusting for demographic factors, body mass index, comorbidity index, calcium phosphorus product, systolic blood pressure, and albumin.

**Association of Arterial Stiffness with Cognitive Impairment in Incident Hemodialysis Patients**

**Methods:** This study included 390 incident hemodialysis patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease (PACE) study. Arterial stiffness was measured using aortic pulse wave velocity (PWV) and augmentation index (AIx). Cognitive function was measured using time to complete Trail making tests A and B (TMT A and TMT B) and the modified mini-mental state exam (3MS) score. Log-linear, Tobit, and logistic regression models were used to examine the baseline association of PWV with TMT A, TMT B, and 3MS, respectively. Changes in 3MS score. Log-linear, Tobit, and logistic regression models were used to examine the relationship between arterial stiffness and cognitive function in dialysis patients.

**Results:** At baseline, higher PWV was associated with longer time to complete TMT A after adjusting for demographic factors, reading comprehension score, comorbidity index, systolic blood pressure, and atrial fibrillation (%TMT A=3.12, 95% CI: 0.37-5.87). In the repeated measures analysis, higher PWV was still associated with longer TMT A time (%TMT A=2.05, 95% CI: 0.00-4.11), and higher AIx was associated with longer TMT B time (β=0.80, 95% CI: 0.01-1.58).

**Conclusions:** Vascular stiffness was associated with longer time to complete TMT A and TMT B suggesting that arterial stiffness may lead to subclinical cerebrovascular events and decline in executive function among incident hemodialysis patients.

**Close Relationship Between Vascular Endothelial Function and Serum Uric Acid Level in Hemodialysis Patients**

**Background:** Vascular endothelial function (VEF) impairment is often detected in hemodialysis (HD) patients and has been associated with atherosclerosis and cardiovascular disease (CVD). Although avoidance of VEF impairment is therefore desirable in preventing such complications, the precise factors that influence VEF remain unknown. The present study evaluated VEF for associating factors in HD patients.

**Methods:** We enrolled 48 patients undergoing maintenance HD at Ueda Kidney Clinic in Japan. No patient had a history of CVD. Reactive hyperemia index (RHI) was evaluated by Endo-PAT (Itamar Medical, Ltd., Caesarea, Israel) was used to assess VEF, whereby a higher RHI was indicative of better function. We also assessed for correlations between the natural logarithm of RHI (LnRHI) and clinical parameters.

**Results:** The median age of our patients was 67 years, the male-to-female ratio was approximately 2:1, and median LnRHI was low at 0.36. Analysis of Spearman’s rank correlation coefficient revealed a significant positive correlation between serum uric acid level (sUA) and LnRHI (r=0.37, p=0.009). As sUA is influenced by diet, inflammatory cytokines, and dietary intake, we also performed multivariable linear regression analysis adjusted by age, body mass index, index of dietary efficiency by Kt/V, and normalized protein catabolic rate, and observed that sUA was significantly related to LnRHI (β=0.042, 95% CI: 0.007-0.078, p=0.009). We also assessed for correlations between the natural logarithm of RHI (LnRHI) and clinical parameters.

**Conclusions:** The current study suggests that VEF is closely associated with sUA in HD patients. Although the precise mechanism is unknown, a marked decrease in sUA might be correlated with VEF impairment and should be avoided in individuals undergoing HD.

**Ambulatory Arterial Stiffness Index: An Early Marker of Cardiovascular Disease in Young Hemodialysis Patients**

**Background:** Cardiovascular disease (CVD) is the leading cause of death in pediatric hemodialysis (HD) patients. Ambulatory arterial stiffness index (AASI) may be an earlier measure of vascular compliance in young patients than pulse pressure (PP). Our objective was to evaluate AASI as a marker of increased vascular stiffness in young HD patients and to compare it with other non-invasive indicators of CVD risk.

**Methods:** Retrospective review of 24-hour ambulatory blood pressure monitoring (ABPM) was performed in 11 pediatric patients on chronic HD (mean±SD: 16±3.6 yrs) and dialysis vintage of 32±18 months. AASI was calculated as 1-regression slope of the diastolic over systolic BP. Echocardiogram and bilateral carotid artery ultrasound were performed to assess left ventricular mass index (LVMI) and carotid intimal medial thickness (cIMT). Cardiac artery stiffness indices included distensibility coefficient (DC), stiffness index-β (SI-β), SI, and PP. AASI was used as a marker of increased vascular stiffness in young HD patients and compared to other non-invasive indicators of CVD risk.

**Results:** AASI was significantly increased in HD patients compared to controls (0.42±0.1 versus 0.20±0.2, p=0.01). When matched to controls with similar BP's and PP's, the AASI detected increased vascular stiffness independent of PP, cIMT, LVMI, and DC were also significantly increased in HD patients (p<0.01).

**Conclusions:** Young HD patients demonstrate early surrogate markers of CVD including increased LVMI, cIMT, and decreased vascular compliance. Increased AASI detected vascular stiffness that was independent of BP's and PP's. AASI may be an early non-invasive marker of vascular disease in young HD patients that merits further investigation.
Effects of Music and Exercise during Hemodialysis on the Cardiac Autonomic Nervous System Activity

**Evaluating the Cardiac Effects of a Combined Protocol during Hemodialysis**

- **Methods:**
  - Nine dialysis patients with uncontrolled office BP (>140/90 mmHg despite two or more agents at maximal tolerated dosages) were recruited into this feasibility study. (Page 380)
  - Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA). Echocardiography was performed at baseline and three months. (Page 381)

- **Results:**
  - Mean heart rate (HR), standard deviation of NN intervals (SDNN), root mean square (RMSSD) (pNN50), and very low frequency (VLF) were: mean heart rate (HR); standard deviation of NN intervals (SDNN); root mean square (RMSSD) (pNN50) and very low frequency (VLF).
  - There was a correlation between change in office systolic BP and ventricular dilatation (R=0.255) or dysfunction (R=0.034), suggesting BP-independent effects.
  - Conclusions: RDN in dialysis patients improves office systolic BP and leads to a BP-independent improvement in ventricular dilatation and probably dysfunction. Further controlled studies are warranted in this population.

**Temporal Loss of Bone Mineral Density Is Associated with Cardiovascular Diseases in Japanese Patients Starting Renal Replacement Therapy**

- **Background:**
  - High mortality in dialysis patients may be related to reduced clearance of cytokines with conventional dialysis membranes. Attempts to provide a better clearance with high cut-off membranes also leads to albumin loss. A new Medium-Cut-Off membrane with better permeability for molecules up to 45 kDa but with limited permeability for albumin was tested clinically. (Page 318)

- **Methods:**
  - 50 patients were dialyzed with MCO and conventional high-flux (HF) membranes for four weeks following a randomized cross-over design. After the second phase, another 12-week-period was conducted to test for long-term effects. Serum samples were tested for inflammatory effects and cytokine concentrations. Support was granted by the German Federal Ministry of Education and Research (FKZ 13N11796-99).

- **Results:**
  - The primary end point mRNA content of TNF-α in leukocytes was reduced to a higher degree and significantly better after 4 weeks on MCO compared to HF membranes (p < 0.001). Interleukin-6 mRNA was markedly reduced with MCO (p < 0.001). After a significant drop after four weeks of MCO dialysis, albumin concentrations stabilized after 12 weeks.

**Endovascular Renal Denervation Ameliorates Pathological Left Ventricular Dilatation in Patients with Dialysis-Related Hypertension**

- **Background:**
  - Endovascular renal denervation (RDN) ameliorates left ventricular hypertrophy and improves contractile function in resistant hypertension. Its cardiac effects on a dialysis population are unknown. We hypothesized that RDN would improve blood pressure (BP) control and sympathetic overload, resulting in improved ventricular function.

- **Methods:**
  - Patients with end-stage renal disease (ESRD) were enrolled and followed for a median of 3.8 years (range 1-5.8 years). Bone mineral density (BMD) of the lumbar spine was measured by dual X-ray absorptiometry at baseline and after 1 year.

- **Results:**
  - Baseline BMD, median value 1.05 (0.67-1.56) g/cm2, negatively correlated compared to age (r=-0.28, P = 0.015) and JTF (r=-0.14, P = 0.0002). When dividing patients into two groups according to delta BMD (defined as baseline - 1 year), those with high delta BMD had an increased mortality risk (Log rank 6.36, P = 0.012) and time from dialysis initiation to the first CVD event appeared, although not significant, shorter in patients with high delta BMD (Log rank 2.81, P = 0.094). Patients with high delta BMD had a significantly increased relative risk (RR: Cox hazard model) of mortality (10.9, 95% CI; 1.34-250.6) even after adjustments for age, gender, diabetes and smoking, compared with those with low delta BMD. RR of the first CVD event was 5.52 (95% CI; 1.15-73.8) with adjustment for age and gender.

- **Conclusions:**
  - Progressive loss of BMD associated with an increasing risk of CVD and mortality. Whereas in end-stage renal disease patients, BMD may have limited value as predictor of a fracture risk, temporal changes of BMD, potentially reflecting bone-vascular interactions, may be useful as a marker of a CVD risk.

**First in Man: Reduction of Inflammation with Medium Cut-Off (MCO) Membranes**

- **Background:**
  - Interleukin-6 and C-reactive protein are strongly associated with an increased risk of cardiovascular disease (CVD) in dialysis patients.
  - Inflammation is a predictor of mortality and morbidity in chronic kidney disease (CKD) patients. The use of an MCO membrane could reduce inflammatory mediators and thereby reduce the risk of CVD and all-cause mortality.

- **Methods:**
  - 50 patients were dialyzed with MCO and conventional high-flux (HF) membranes for four weeks following a randomized cross-over design. After the second phase, another 12-week-period was conducted to test for long-term effects. Serum samples were tested for inflammatory effects and cytokine concentrations.

- **Results:**
  - Interleukin-6 mRNA was markedly reduced with MCO (p<0.001). After a significant drop after four weeks of MCO dialysis, albumin concentrations stabilized after 12 weeks.

Vitamin D and Cardiac Autonomic Tone in End-Stage Kidney Disease: A Blinded, Randomized Controlled Trial

Sofia B. Ahmed, 1 Michelle C. Mann, 1 Brenda Hemmelgarn, 1 David A. Hanley, 1 Tanvir Chowdhury Turin, 1 Jennifer M. MacRae, 1 David C. Wheeler, 2 Sharanya Ramesh, 1 Darlene Y. Sole, 1 Derek Exner, 1 1 Univ of Calgary, Canada; 2 Univ College London, United Kingdom.

Background: Importance: End-stage kidney disease (ESKD) patients are at high cardiovascular (CV) risk. Vitamin D deficiency is associated depressed heart rate variability (HRV), a risk factor for CV death. Both vitamin D deficiency and depressed HRV are highly prevalent in ESKD.

Methods: Objective: To determine the effects of activated vitamin D (conventional) compared to activated and nutritional vitamin D (intensive) on HRV (low to high frequency spectral ratio; LF:HF) in patients with ESKD on hemodialysis (HD). Design: 2x2 crossover, blinded, randomized controlled trial in outpatient HD units. Fifty-six patients were randomized 1:1 to begin either conventional (0.25mcg alfacalcidiol and placebo 3 times/week) or intensive vitamin D therapy (0.25mcg alfacalcidiol 3 times/week and 50000IU ergocalciferol weekly for 6 weeks). Main Outcomes: HRV is a surrogate index of cardiac autonomic nerve function and independently predicts CV mortality. The primary outcome was the change in LF:HF from the 1st to 6th week HD session. Secondary endpoints included individual changes in LF and HF, parameters of mineral metabolism and renin angiotensin system (RAS) activity.

Results: There was no difference in LF:HF from baseline to 6 weeks for either vitamin D treatment (conventional p=0.9; intensive p=0.07). There were no significant changes in any other measure of HRV, mineral metabolism or RAS activity. On exploratory subgroup analysis, participants who remained vitamin D deficient (25-hydroxyvitamin D<50nmol/L) after treatment had a significant increase in LF:HF (conventional: n=13, p<0.001 vs. insufficient and sufficient groups; intensive: n=8, p=0.001 vs. sufficient group).

Conclusions: Six weeks of treatment with conventional or intensive vitamin D did not alter LF:HF in ESKD patients. However, improved LF:HF was observed in the vitamin D-deficient subgroup. This finding may translate into decreased CV risk and should be considered hypothesis-generating and deserving of further study. Trial Registration: ClinicalTrials.gov NCT01774812. Funding: Private Foundation Support.

The Validity of Left Ventricular Mass as a Surrogate Endpoint for Mortality Outcomes in Chronic Kidney Disease

Suni V. Badve, 1,2 Suetsuna Palmer, 1,2 Giovanni F.M. Strippoli, 3 Matthew A. Roberts, 3 Armando Teixeira-Pinto, 3 Neil Bell, 3 Alan Cass, 7 Carmel M. Hawley, 12 Susan J. Hiramatsu, 12 Elaine M. Pascoe, 1 Vlado Perkovic, 9 Gillian A. Whalley, 3 Jonathan C. Craig, 3 David W. Johnson, 1 1 Univ of Queensland; 2 Princess Alexandra Hospital; 3 Univ of Otago; 4 Univ of Bari; 5 Monash Univ; 6 Univ of Western Australia; 7 Menzies School of Health Research; 8 Univ of Ottawa; 9 The George Inst for Global Health; 10 Unitec Inst of Technology; 11 Univ of Sydney.

Background: Left ventricular mass (LVM) is increasingly used as a surrogate endpoint in trials involving chronic kidney disease (CKD) patients, as intervention-induced reductions in LVM, a risk factor for cardiovascular disease (CVD), is often indicated in dialysis patients. Methods: The aim of this systematic review was to determine the validity of LVM as a surrogate endpoint for all-cause and CV mortality in CKD. Randomized controlled trials evaluating pharmacological and non-pharmacological interventions with follow-up >3 years were included. The outcomes of interest were LVM change from baseline to last measurement and all-cause and CV mortality. Standardized mean differences (SMDs) in LVM change and relative risk of mortality were estimated using random-effects models. Correlations between LVM change and mortality endpoints were summerized across all trials.

Methods: The primary endpoint was the correlation between change in LVM and relative risk of mortality. The secondary endpoints were correlation between change in LVM and relative risk of all-cause mortality, and correlation between change in LVM and relative risk of CV mortality. Results: Seventy trials (6420 participants) were eligible. Among 23 interventions, only erythropoiesis-stimulating agents (SMD -0.13, 95%CI -0.23 to -0.03), renin-angiotensin-aldosterone-system inhibitors (SMD -0.28, 95%CI -0.44 to -0.11) and isosorbide mononitrate (SMD -0.43, 95%CI -0.72 to -0.14) were associated with changes in LVM and relative risk of mortality. There were weak associations between LVM change and all-cause mortality (30 trials, 4749 participants, correlation coefficient [r] 0.28, 95%CI -0.15 to 0.60) and CV mortality (13 trials, 3272 participants, r0.23, 95%CI 0.60 to 0.75).

Conclusions: In CKD, it is uncertain whether an intervention-induced LVM change correlates with reduced mortality. Evidence for LVM as a valid surrogate endpoint in CKD is currently lacking.

Non-Invasive Left Ventricular End-Diastolic Pressure (LVEDP) Measurement in Hemodialysis Patients: A Pilot Study

Tariq Shaif, 1 Bernard G. Jaar, 1 Luis F. Gimenez, Alison G. Abraham, Chloe F. Knight, Naya El Hage, Paul J. Scheel, Josef Coresh, Harry A. Silber. Johns Hopkins Univ.

Background: Optimal volume status in dialysis patients is difficult to assess. The Val saliva maneuver is recognized as an bedside marker of central volume overload. A novel handheld device that combines finger photoplethysmography with Val saliva maneuver can reliably estimate LVEDP (normal: <12mmHg). (Silber H, PMID: 22389389). The goal of our pilot study is to determine the role of this non-invasive LVEDP measurement in managing volume in hemodialysis patients.

Methods: The LVEDP-Guided Volume Management Study is being conducted at 2 dialysis centers in Baltimore. Baseline data collected includes demographics, medical history, KDQOL-36, NYHA dyspnea scale, intra/post dialysis symptoms, predialysis metrics [LVEDP, bioimpedance, blood pressure (BP) and echocardiogram]. We assessed the cross-sectional association of predialysis LVEDP with dyspnea symptoms and intradialytic hypotension (IDH, defined as ≥20mmHg drop in systolic BP + nursing interventions).

Results: In the first 28 participants (mean age 56 years, 71% male, 82% black), median (25%, 75% percentiles) for predialysis LVEDP was 14mmHg (12, 19), interdialytic weight gain (IDWG) was 1.7kg (0.9, 2.9) and systolic BP was 150mmHg (133, 164). LVEDP was significantly higher in patients with dyspnea vs. those without. (Mean, 19 vs. 14.6; p<0.03). IDH occurred in 5 (18%) patients and all had LVEDP £14mmHg (Table). The unadjusted odds ratio for IDH per SD decrease in LVEDP was 4.37 (p=0.08). There was no significant association between IDH and predialysis systolic BP or IDWG.

Conclusions: Non-invasive LVEDP measurements can identify hemodialysis patients with volume overload associated with symptoms (high LVEDP) and patients at risk for IDH (low LVEDP). Our ongoing study may help confirm these initial findings and define the role of this measurement for volume management in dialysis patients.

E/e’ Calculated by Tissue Doppler Echocardiography and Cardiovascular Outcome in Incident Dialysis Patients

Jongha Park, 1 Jongmin Lee, 1 Kyung sun Park, 4 Sang Hyun Son, 1 Shin-Jae Kim, 1 Jong Soo Lee, 1 Hyun Chul Chung, 1 1 Ulsan Univ Hospital, Ulsan, Republic of Korea; 2 Dongkang Medical Center, Ulsan, Republic of Korea; 3 BHS Han-Sea Hospital, Busan, Republic of Korea.

Background: The ratio of early diastolic peak mitral flow velocity (E) to early mitral annular velocity (e’), called E/e’, is a less volume dependent, non-invasive index to estimate left ventricular (LV) filling pressure. However, the prognostic value of E/e’ has not been evaluated sufficiently in patients with end-stage renal disease (ESRD).

Methods: The patients who newly started maintenance dialysis therapy between 2009 and 2012, had survived for at least 3 months after dialysis initiation, and had E/e’ data, were analyzed. E/e’ was calculated by pulse and tissue Doppler echocardiography. Cardiovascular (CV) composite endpoint comprised hospitalization for heart failure (HF), acute coronary disease (ACD) requiring intervention, ventricular arrhythmia, cerebral infarction or hemorrhage, and CV death. The patients were followed up until 2013.

Results: A total of 206 patients were analyzed (mean age 55.0±13.7 years old, female 51.5%). Median follow-up duration was 29.2 months (range 3.1-61.3). Forty-two CV events occurred during follow-up (15 HF, 17 ACD, 1 cerebral infarction, and 9 CV deaths). Mean E/e’ was 13.6±5.4 (range 5.3-39). After adjusting age, sex, diabetes, mean arterial pressure, LV ejection fraction, hemoglobin, serum albumin, C-reactive protein and volume status, one unit increase in E/e’ ratio was associated with 7% increase in the risk of CV composite endpoint (hazard ratio 1.07, 95% confidence interval 1.02-1.13, p=0.009). Adjusted hazard ratio linearly increased above 15 of E/e’ in Cox regression with cubic splines.

Conclusions: A higher E/e’ ratio, reflecting high LV filling pressure which is the main physiological finding of diastolic HF, may be associated with a higher CV risk in patients with ESRD.

Tallium-201 Washout Rate of Single Photon Emission Computed Tomographic Myocardial Perfusion with Pharmacologic Stress as a Predictor of Mortality in CKD Patients Undergoing Hemodialysis: An Observational, Follow-Up Study

**Toshihide Hayashi, Nobuhiko Joki, Masaki Iwasaki, Ai Matsukane, Takasuke Asakawa, Yuri Tanaka, Hiroki Hase.** Div of Nephrology, Toho Univ Ohashi Medical Center, Tokyo, Japan.

**Background:** Tallium-201 (201Tl) washout rate of single photon emission computed tomography (SPECT) has been reported to correlate with coronary flow reserve which is an index of myocardial microcirculation and be useful to detect coronary artery disease and evaluate the severity. However, the evidence for its use in chronic kidney disease (CKD) has been lacking, and the association between 201Tl washout rate and mortality is unknown. Therefore, a hospital-based, prospective, cohort study was conducted to evaluate the predictive ability of 201Tl washout rate for mortality in CKD patients undergoing hemodialysis.

**Methods:** A total of 156 patients who had been started on maintenance hemodialysis undergoing pharmacologic stress tallium-201 SPECT within 1 year, 107 men and 49 women, with a median age of 67 years, were studied. The endpoint was defined as all-cause death. The Cox proportional hazards model was used to calculate hazard ratios (HR) and 95% confidence intervals (CI).

**Results:** During the mean follow-up period of 3.2 ± 2.4 years, 30 (19.2%) deaths occurred. The median (interquartile range) of 201Tl washout rate was 45.1 (37.4 - 50.8)%. Cumulative survival rates at 5 years after starting dialysis, with 201Tl washout rate levels above and below the median, were 76.7% and 63.8% (p = 0.992, log-rank test), respectively. Overall, the multivariate Cox regression analysis revealed that 201Tl washout rate remained an independent predictor of death after adjusting by confounding variables (HR 0.95, 95% CI 0.90 to 0.99).

**Conclusions:** Among CKD patients undergoing hemodialysis, 201Tl washout rate seems to be useful for predicting death.

**TH-PO919**

Research Cardiac Magnetic Resonance Imaging in Chronic Kidney Disease – Incidence, Significance and Implications of Unexpected Incidental Findings

**Elaine Rutherford, Jonathan Weissmuller, Rajan K. Patel, John Gruene Houston, Giles Roditi, Allan Struthers, Alan G. Jardine, Patrick B. Mark.** Div of Cardiovascular & Diabetes Medicine, Univ of Dundee; 1Dept of Cardiovascular & Medical Sciences, Univ of Glasgow.

**Background:** Left ventricular (LV) mass on cardiac magnetic resonance imaging (CMR) is a common end point of clinical trials in nephrology. Incidental findings (IF) on CMR. A suitably trained radiologist should prospectively review all CKD CMR research and reviewed their impact on patient care.

**Methods:** Among CKD patients undergoing hemodialysis, 201Tl washout rate seems to be useful for predicting death.

**Results:** During the mean follow-up period of 3.2 ± 2.4 years, 30 (19.2%) deaths occurred. The median (interquartile range) of 201Tl washout rate was 45.1 (37.4 - 50.8)%.

**Conclusions:** Among CKD patients undergoing hemodialysis, 201Tl washout rate seems to be useful for predicting death.

**TH-PO920**

A Significance of Cardiothoracic Ratio for Mortality in Hemodialysis Patients: The Q-Cohort Study

**Ryuji Koyama, Masahiro Eriguichi, Shigeru Tanaka, Masatomo Taniguchi, Hideki N. Hirakata, Kazuhiko Tsuyama, Takanari Kitazono.** 1Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; 2Dept of Integrated School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 3Dept of Integrated School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 4Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.

**Background:** Cardiothoracic ratio (CTR) of chest X-ray is commonly used to determine the volume status in hemodialysis (HD) patients. Thus, the present study was conducted to evaluate the significance of CTR in terms of longitudinal prognosis of HD patients.

**Methods:** A total of 3,437 Japanese HD patients aged ≥18 years were followed for 4 years. Patients were divided into four groups according to quartiles of CTR levels by sex. Risk estimates were calculated by a Cox proportional hazards model, adjusting for potential confounders. We investigated stratified analysis by sex, age, etiology of end-stage kidney disease, history of major adverse cardiac events (MACE) and blood pressure for subanalysis.

**Results:** The median values (interquartile range) of CTR were 0.49 (0.46–0.53) in male and 0.52 (0.48–0.56) in female. During the follow-up period, 564 patients (16%) died from any causes and the 4 years survival rate decreased significantly with higher CTR levels (p trend <0.001). Compared with the lowest CTR quartile, the multivariable-adjusted hazard ratios (HRs) for all-cause mortality were 0.89 (95% confidence intervals, 0.66–1.21), 1.41 (1.07–1.86), and 1.52 (1.17–2.00) in subjects with low–intermediate, high–intermediate and highest quartile, respectively. Furthermore, the combination of higher CTR levels and history of MACE or lower blood pressure before HD (systolic blood pressure <140 mmHg and diastolic blood pressure <90 mmHg) synergistically increased the risk of all–cause mortality.

**Conclusions:** A higher CTR level is closely related to increased mortality in HD patients. This association is more remarkable in patients with history of MACE or without high blood pressure.

High Convection Volumes in Postdilution Online Hemodiafiltration (HDF) Are Feasible in the Vast Majority of ESKD Patients

**Camiel L.M de Roij van Zuidewijn, Isabelle Chapdelaine, Men Ju Jeub, Peter J. Blankenstijn, Constantijn Konings, Tonnis K. Kremer Hovinga, Neelke C. Van Der Weerd, Pieter M. Ter Wee, Muriel P. Grooteman.** 1Nephrology, VU Med University Center Amsterdam; 2Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; 3Internal Medicine, Martini Hospital, Groningen, Netherlands; 4Nephrology, Academic Medical Center, Amsterdam, Netherlands.

**Background:** Available evidence suggests a survival benefit for patients treated with high volume postdilution HDF (hvHDF) when compared to HD. Since these studies are limited by an observational design, we investigated whether hvHDF (>2L/session) is feasible in the majority of patients (>75%).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: A prospective, multicenter study was performed (NCT01877499). HD(F) patients (n=1784) were eligible for analysis. Non-participating eligible patients formed a reference group to examine the representativeness of the study group. Treatment-related determinants of the convection volume were optimized in a stepwise fashion (treatment time [TT] up to 4 hours, blood flow rate [BFR] up to 400 mL/min and filtration fraction [FF] up to 33%). At the end of this protocol (T0) and 4 (T4) and 8 (T8) weeks thereafter, the convection volume was determined.

Results: Baseline characteristics were comparable in participants (n=86) and references (n=58). At T0 and at T4, 79/86 (92%) and 68/79 (89%) patients achieved hvHDF (mean 26.5±3.56 and 26.3±3.36L/session, resp). Hereafter, 2 patients died and 1 was transplanted. 83 patients remained; 66 (80%) reached hvHDF (mean 25.9±3.5L/session, fig 1). Study discontinuation (n=9), TT <4h (n=4) or BFR £300 mL/min (n=4) caused a convection volume <22L/session.

Conclusions: hvHDF is feasible in the vast majority of ESKD patients. As TT remained virtually unaltered, these findings were mainly due to a higher BFR and FF. Funding: Pharmaceutical Company Support - Fresenius Medical Care

Physical Activity Among Patients with End-Stage Renal Disease: Use of the Exercise Vital Sign  Shavna L. Henry, Yi-Lin Wu, John J. Sim, Michael K. Gould. 1 1 Dept of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA; 2 Dept of Nephrology, Kaiser Permanente Southern California Los Angeles Medical Center, Los Angeles, CA.

Background: Exercise has been shown to improve physical functioning among ESRD patients. However, ESRD patients report exceedingly low levels of physical activity (PA) with only 13-34% engaging in recommended levels of PA. Although ESRD is characterized by substantial barriers to PA, low PA puts patients at risk for serious complications and higher mortality. Within Kaiser Permanente (KP), patients are administered the Exercise Vital Sign (EVS) – self-reported weekly minutes of PA – during each office encounter. The EVS has been validated in multiple KP regions, with roughly one-third each of the membership reporting no, insufficient, and sufficient PA, or >150 minutes exercise/week. Although the relationship between EVS reports and cardiometabolic status has been examined, levels of PA reported by ESRD patients using the EVS have not yet been explored.

Methods: EVS reports of all KP patients with a diagnosis of ESRD between January 2013 and July 2014 (N=8,187, Female=3,534, Mean Age=63.3 years) were assessed.

Results: Patients were 25% White, 38% Black, 23% Hispanic, 12% Asian, and the remainder Other, consistent with the regional patient catchment; just over 50% were married. The majority (88%) had comorbid HTN, 65% had comorbid DM, and 37% comorbid CHF. On average, patients had four other comorbid illnesses. During the study period, patients presented for 135,562 encounters. The mean reported PA frequency was 1.4 times per week (SD=2.2), for a mean 12.3 minutes/bout (SD=22.4), or an average of 49.9 minutes/week (SD=103.2) and a median zero minutes/week. The majority of ESRD patients did not achieve sufficient levels of PA during this period; 75% of the sample exercised for <50 minutes/week.

Conclusions: Self-reported rates of PA among ESRD patients at KP are critically low. Implications of low PA for cardiovascular and other outcomes as well as for interventions to improve rates of PA in this diverse population will be discussed.
Conclusions: Patient prioritized outcomes are focused on maintaining a quality lifestyle above the usual outcomes in HD trials i.e. death, adverse events, and biological markers. Researchers need to consider interventions that could improve these outcomes, and measure and report patient-relevant outcomes in trials.

TH-PO925

Medicare Advantage (MA) Is Associated with Lower Rates of Mortality versus Medicare Fee-For-Service (MFFS) Among Incident End-Stage Renal Disease (ESRD) Patients

Steven M. Brunelli,1 Carey Colson,1 Scott Bibel,1 Abigail Hunt,1 Allen R. Nissenson,2 Mahesh Krishnan.1

1DaVita Clinical Research, Minneapolis, MN; 2DaVita HealthCare Partners Inc, Denver, CO.

Background: Patients with ESRD have a high burden of comorbid illness and are complex to manage and may therefore benefit from programs like MA that facilitate care coordination. Currently, ESRD patients are barred from enrolling in MA after onset of ESRD; however, those already enrolled at the time of ESRD onset may remain enrolled. To understand the potential impact of MA among ESRD patients, we compared mortality rates among patients who began dialysis enrolled with MA versus MFFS.

Methods: Adult patients initiating hemodialysis (HD) or peritoneal dialysis (PD) between 01 Jan 2009 and 30 Jun 2011 and who were enrolled with MA or MFFS as of ESRD onset were considered. MA patients were matched 1:1 to MFFS controls based on initial modality, access type, and propensity score (based on 26 demographic and clinical variables). Patients were followed from dialysis initiation until death, transplant, lost to follow up, change in benefits status, or end of study (31 Dec 2011). Mortality rates were compared using negative binomial models. Sensitivity analyses considering early and latent follow up, change in benefits status, or end of study (31 Dec 2011). Mortality rates were compared using negative binomial models. Sensitivity analyses considering early and latent effects were performed using piecewise methods.

Results: Compared to MFFS, MA was associated with lower rates of mortality (64.3 vs 70.7 deaths/100 patient-years; incidence rate ratio, 0.91). Mortality effects were limited to the first 24 months of dialysis and were attenuated after the first 24 months of dialysis.

Conclusions: Enrollment in MA was associated with substantially lower rates of mortality during 2009-2011.
laboratory measurements and dialysis-related information. We used logistic regression and 10-fold cross validation to identify and validate a model of significant predictors. The Model discrimination and calibration were measured by c-statistic and Hosmer-Lemeshow goodness-of-fit respectively. A point system was created based on regression coefficients of predictors in the final model.

**Results:** 2,211 patients initiated dialysis, of whom 386 (17.4%) died within 6 months. Significant predictors of 6-month mortality were: age ≥80, vascular access with central venous catheter, baseline eGFR 10-14.9 or >15mL/min/1.73m², normal proteinuria, atrial fibrillation, lymphoma and congestive heart failure (CHF). Model discrimination (C-Statistic: 0.73) and calibration (Hosmer-Lemeshow c²: 6.09; p=0.64) were good. A 40-point scale for 6-month mortality was created based on model coefficients with points assigned based on strength of each predictor as specified in Table 1.

**Conclusions:** We derived and internally validated a clinical risk prediction tool for 6-month mortality for older adults initiating dialysis, using age, vascular access, eGFR, proteinuria, atrial fibrillation lymphoma and CHF as predictors. The results require external validation prior to use in clinical practice. A tool such as this can guide decision making for older adults with kidney failure.

**TH-PO929**
Coping Strategies and Outcomes Among Hemodialysis (HD) Patients in the DOPPS

**Methods:** Patients from 6 DOPPS countries completed the Coping Strategies Inventory-Short Form (CSI-SF), which we found to be reliable and valid in those countries for measuring 4 coping strategies: problem-focused engagement (PFE) and disengagement (PFD), and emotion-focused engagement (EFE) and disengagement (EFD); and summary measures of engagement (actions to confront stressors) and disengagement (avoiding exposure to stressors). Outcomes were QoL (from SF-12 and KDQoL-SF), depression symptoms (from CES-D), and all-cause mortality. Mixed linear and logistic models were used to estimate coping effects, adjusting for country and potential confounders.

**Results:** The sample included 2,062 HD patients from the US, UK, Australia/New Zealand, Canada, and Sweden in DOPPS4 (2009-11). In general and whatever the instrument, both engagement coping strategies and the summary score were positively associated with better QoL scores and inversely associated with depression symptoms. In contrast, disengagement strategies were inversely associated with better QoL scores and positively associated with depression symptoms. The PFE score was inversely associated with mortality (HR =0.78 per 4 points higher score; 95% CI: 0.66-0.9).

**Conclusions:** Engagement strategies appear to be beneficial and disengagement detrimental for HD patients. A better understanding of the coping strategies used by patients may have prognostic implications and may help to improve disease management by providing tailored care for each patient.

**TH-PO930**
Intradialytic Aerobic Cycling Exercise Improve Inflammation Status, Endothelial Progenitor Cells and Bone Density in Patients with End Stage Renal Disease (ESRD) on Maintenance Hemodialysis

**Introduction:** End-stage renal disease (ESRD) on maintenance hemodialysis (HD) and osteodystrophy (OD) are crucial health issues. HD patients show reduced physical function and greater risk of arteriosclerosis because of hypertension, metabolic disturbances, and vascular calcification. Meanwhile, exercise training in hemodialysis patients improves fitness, physical function, quality of life, and markers of cardiovascular disease such as arterial stiffness. This study aimed to determine whether aerobic training and electrical stimulation to skeletal muscles for 12 weeks could improve physical function and dialysis efficacy in patients with end-stage renal disease (ESRD).

**Methods:** This was a multicenter trial. A total of 35 ESRD patients on three occasions (20 males, 15 females; age: 70±11.7 years) were randomized to receive 12 weeks of aerobic training exercise during hemodialysis session (Ex-group: n=19), electrical stimulation to the lower limbs (ES-group: n=6), or no specific intervention (Cont-group: n=10). The Borg

---

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
scale was used to control the intensity of training. At baseline and study completion, the primary outcome measures were grip strength, quadriceps strength, workload time, activities, dialysis efficacy, HDL, LDL, CRP, IL-6 and blood pressure. 

Results: In the Ex-group, handgrip, quad torque, and workload time increased significantly (P<0.05). Dialysis efficacy, HDL-cholesterol, LDL-cholesterol, CRP, and blood pressure on the morning of the dialysis day also improved significantly (P<0.05). These effects were not observed in the Cont-group. In the ES-group, quad muscle torque and dialysis efficacy increased significantly (P<0.05), IL-6 decreased significantly (P<0.05), compared to the other two groups.

Conclusions: In this study, the safety and efficacy of training and electrical stimulation during hemodialysis were confirmed without sudden drop of blood pressure or any other side effects. Therefore, training during hemodialysis session for 12 weeks might improve physical function with specific whole-body effects as well as local effects in ESRD patients.

TH-PO932
Glycemic Markers and 2-Year Non-Diabetic Hemodialysis Outcomes from the Glycemic Indices in Dialysis Evaluation Study

Mark E. Williams,1 Neal Mittman,2 Lin Ma,1 Julia I. Brennan,3 Curtis D. Johnson,4 Franklin W. Maddux,5 Eduardo K. Laesson,1,3 Joslin Diabetes Center, Boston, MA;1,2 Kidney Care of Brooklyn and Queens, Brooklyn, NY;1,3 Renessia Medical Care North America, Walling, MA;1 Spectra Laboratories, Rockleigh, NJ;1,3 Physician, Lexington, MA.

Background: The ongoing GIDE (Glycemic Indices in Dialysis Evaluation) study includes data on nonDM hemodialysis (HD) patients (confirmed by HgbA1c <6.5%). Because nonglycemic factors may lower HgbA1c levels in ESRD, we previously reported their glycemic status/1-year outcomes using alternative glycemic markers [albumin-adjusted and unadjusted fructosamine (AlbF,F) and glycated albumin (GA) or percent GA (%GA)]. We now report 2-year study data.

Methods: 970 nonDM HD patients from 26 FMCNA facilities with glycemic markers from Jan-March 2013 were followed until April, 2015. Baseline AlbF, F, GA and %GA were used to classify patients as high or low glycemia using thresholds of AlbF>97µmol/L, F>285µmol/L, %GA>15.7%, and GA>380µmol/L. Standard and Time-dependent (TD) Cox models with case-mix adjustment for age, sex, race, ethnicity, vintage, BMI, HD catheter and baseline comorbidity were used to determine associations between each glycemic index and hospitalization/death risk.

Results: While 1% had HgbA1c>7%, high glycemic status was more commonly detected using F (59%), AlbF (4%), GA (15%) and %GA (29%). Elevated AlbF was significantly associated with 2-year mortality [Standard Cox: Hazard Ratio (HR)=2.53, 95% CI (1.31, 4.92), p=0.006; TD Cox: HR=3.55, 95% CI (1.97, 6.38), p<0.0001] and hospitalization [TD Cox: HR=2.49, 95% CI (1.70, 3.67), p<0.0001]. For all other glycemic markers, no such associations were evident at the proposed thresholds using adjusted analyses in the Cox model.

Conclusions: These data support our previous findings of an association between poor glycemic status (high AlbF) and hospitalization/mortality outcomes in nonDM HD patients. High AlbF-glycemic status may have prognostic implications in nonDM HD patients.

TH-PO933
Association of Change in Serum HDL Cholesterol with Mortality in Hemodialysis Patients: Role of Gender

Shelia Mardavien,1 Elami Streja,1 Tae Hee Kim,1 Connie Rhee,1 Steven M. Brunelli,2 Mott L. Kashyap,1,3 Nosratola D. Vaziri,1 Kamary Kalantar-Zadeh,1 Hamid Moradi.1,3 UC Irvine;2 DaVita Clinical Research;1 VA Long Beach.

Background: Elevated high-density lipoprotein cholesterol (HDL) levels, though protective in the general population, can be associated with higher mortality in hemodialysis (HD) patients. Association of HDL change over time with mortality has yet to be examined. Based on previous studies, we hypothesized that upward trends in HDL levels may be associated with higher mortality risk in HD patients.

Methods: We examined HDL change over time in 24,400 incident HD patients receiving care from a large dialysis organization in 2007-2011. Association of delta HDL (HDL change between the 1st and 2nd 91-day interval from dialysis start) and HDL trajectory with all-cause mortality were examined using mixed effect and Cox regression models and adjusted for demographics, comorbidities and baseline HDL. Delta HDL was treated both as a continuous variable using restricted cubic splines and in categories:< 6, > 6, 0, < 2, 2 -< 6, and ≥6 mg/dL.

Results: Patients were 65:15 years old, 44% female, 31% black, 66% diabetic with a mean baseline HDL 40.5±13.9 mg/dL and HDL change 1.7±10.4 mg/dL. While male patients had no significant change in HDL over time, females had a significant decrease in HDL (mean -0.6mg/dL/year). A ≥6 mg/dL increase or decrease in delta HDL was associated with a 7% and 13%, respective increase in all-cause mortality compared to reference group. Delta HDL-mortality associations did not differ across gender.

Conclusions: Decreased HDL over time was associated with worse outcomes and increased HDL was paradoxically associated with higher mortality. While HD treatment can be associated with a decrease in HDL, this effect was magnified in younger females. The novel and intriguing role of age and gender in association of HDL and survival needs further evaluation.

TH-PO934
Differences in Perceived Kidney Disease Burden on Quality of Life by Race/Ethnicity in a Diverse Cohort of Hemodialysis Patients

Anna C. Porter,1 Rani Gallardo,2 Linda A. Schiffer,3 Denise M. Hynes,4,5 Dept of Medicine, Div of Nephrology, Univ of Illinois Hospital and Health Sciences System, Chicago, IL;2 Dept of Medicine, Div of Academic General Internal Medicine and Geriatrics, Univ of Illinois at Chicago, Chicago, IL;4 Inst for Health Research and Policy, Univ of Illinois at Chicago, Chicago, IL;5 Center of Innovation for Complex Chronic Healthcare, Edward Hines Jr, VA Hospital, Hines, IL.

Background: Low health-related quality of life (HRQOL) has been well-documented in patients with end-stage renal disease on hemodialysis (ESRD). While African Americans and Hispanics remain at increased risk for ESRD, HRQOL has been less well-described in these individuals compared to non-Hispanic whites.

Methods: Baseline HRQOL data was analyzed for participants enrolled in the Patient-Centered Medical Home for Kidney Disease study (PCMH-KD), a trial of a multidisciplinary, patient-centered primary care intervention in a population of hemodialysis patients at two dialysis facilities in Chicago. The Kidney Disease Quality of Life (KDQOL-36) instrument was used to assess HRQOL at baseline, and the following subscale scores were obtained: Physical, Mental, Burden of Kidney Disease, Symptoms, and Problems, and Effects of Kidney Disease.

Results: Baseline data were available for 95 patients. Approximately, 52% of patients were African-American, and 45% were Hispanic. Significant racial/ethnic differences were observed among subscales of self-reported HRQOL.

Conclusions: Hispanic patients with ESRD on HD report disproportionate burden and effects of kidney disease on HRQOL and worse mental HRQOL compared to African American patients with ESRD on HD. Further exploration of these disparities may lead to strategies for improvement of HRQOL in Hispanic patients.

Relative Blood Volume and Mortality in Hemodialysis Patients

Linda H. Facicchi,1 Paul Balter,1 Mark Costanzo,1 Patrice B. Taylor,2 Claudi Mullon,1 Robert J. Kossmann,1
1 Fresenius Medical Care North America (FMCNA), Waltham, MA; 2 Renal Research Inst (RRI), New York, NY.

Background: A quality improvement project on fluid management on Crit-Line® Monitors (CLM) was conducted across multiple RRI facilities. Percent change in relative blood volume (RBV) was measured during routine hemodialysis (HD). Previous analyses of the same cohort have shown associations between RBV reduction and reduced hospital admission rate; the current analysis assesses mortality.

Methods: A retrospective analysis of HD treatments with RBV measurements was conducted over 6 months. RBV was calculated using: RBV = [Hematocrit(Hct) / Hematocrit(Hct), baseline] x 100. Average RBV at the end of HD was calculated for 1099 patients (22,579 treatments with RBV). Patient deaths were recorded as part of routine clinical procedures over the same 6 months. Mortality rate per patient month was calculated as # deaths/patient month. Time to death was modeled using Cox proportional hazards model.

Results: Patients were divided into RBV categories by 5% increments and compared on risk of death during the 6 months (Table). There was an increased risk of death with less reduction in RBV. For example, using patients with the greatest reduction in RBV (< -15%) as the reference, patients with the least reduction in RBV by the end of HD had 16% increase in risk of death for each 1% increase in the end of HD blood volume (p<0.001). Similar results were obtained after adjustment for age, gender, and race (11% increased risk, p=0.002).

Conclusions: In a large cohort of HD patients with relative blood volume measured, patients with less reduction in percent change in relative blood volume at the end of dialysis had higher risk of death over 6 months when compared to patients with greater reduction. These patients may represent a subset of patients at high risk for adverse outcomes and may benefit from fluid management programs.

The Effect of Altitude on Erythropoiesis-Stimulating Agent Dose, Hemoglobin Level, and Mortality in Hemodialysis Patients

Scott Sibbald,1 Donna E. Jensen,1 John Alan Laich,1 Sarb Sarghelli,2 Bradley J. Maroni,2 Steven M. Brunelli,1
1 DaVita Clinical Research, Minneapolis, MN; 2Akebia Therapeutics, Cambridge, MA.

Background: Prior studies have shown that hemodialysis (HD) patients residing at high elevations have lower erythropoiesis-stimulating agent (ESA) utilization, possibly due to activation of hypoxia-regulated genes. We sought to better understand the impact of altitude and dosing of anemia medications and mortality following 2011 changes to the US epoetin alfa label and reimbursement policy.

Methods: We studied a cohort of prevalent nonveteran HD patients (vintage >6 months) treated at a large dialysis organization between 1 Jan 2012 and 31 Dec 2012. Patients were compared across categories for altitude of long-term hemodialysis (Hb) level, ESA and intravenous (IV) iron dose, and mortality risk using mixed linear models. Associations were adjusted for baseline demographic and clinical characteristics.

Results: Compared to altitude of 0-1499 ft, higher altitude was incrementally associated with greater Hb level and lower mean ESA dose; mean IV iron utilization did not differ. Altitudes of ≥4500 ft (vs 0-1499 ft) was independently associated with lower mortality risk; incidence rate ratio (IRR) was 0.74 with 95% confidence interval (CI) 0.63-0.88.

Conclusions: Among contemporary HD patients receiving treatment at ≥1500 ft, higher altitude was independently associated with greater Hb level and lower mean ESA dose; mean IV iron utilization did not differ. Altitude of ≥4500 ft was independently associated with a 26% lower mortality risk.

Softeroject Improves Anemia, Vascular Calcification, and Bone Loss in Patients with End-Stage Kidney Disease on Hemodialysis

John Havill,1 Nelson P. Kopy,2 Daniel W. Coyne,1 Michael Weisswasser,3 William T. Smith,4 'Kidney Specialists of Southern Nevada, Las Vegas, NV; #Lehigh Valley Health Network, Allentown, PA; 3Washington Univ, St. Louis, MO; 4Celgene Corporation, Warren, NJ.

Background: This ongoing, randomized, single-blind, placebo (PBO)-controlled study evaluated the pharmacokinetic (PK), safety, and hemoglobin (Hb) effect of soferoject, an ActRIIA-IgG1 fusion protein ligand trap, in hemodialysis (HD) subjects and explored its effects on vascular calcification (VC) and bone mineral density (BMD) using quantitative computed tomography (QCT).

Methods: Subjects were washed out of erythropoietin-stimulating agent (ESA) effects until Hb was <10 g/dL and randomized to PBO or soferoject given subcutaneously every 225 days for 8 days for up to 8 dose cycles. Treatment (Hb =9 g/dL) were rescued with ESA or transfusion; intrasubject dose escalation was not permitted. QCT scans of the hip, lumbar spine, and abdominal aorta were obtained at baseline and after the 225-day treatment phase. Interim results are reported for PK, safety, bone BP, Hb, VC, and BMD effects in the 0.3, 0.5, and 0.7 mg/kg dose groups.

Conclusions: TSAT predicted IV Iron/ESA, TSAT>37% showing lowest use. In these ranges no TSAT limit existed over which further IVIron/ESA did not occur. ferritin levels predicted IV Iron in non ESA use. TSAT may better predict ESA responsiveness in ESRD

Conclusions: Distributions of CKD-MBD parameters varied by region, possibly resulting in differential risk of adverse outcomes. Our findings in this international cohort highlight the importance of simultaneous, rather than independent, control of MBD parameters within clinical guidelines ranges.

US DOPPS Practice Monitor: Comparisons with CMS ESRD Databases

Douglas S. Fuller, Lindsay Zepel, Keith McCullough, Brian Bieber, Ronald L. Pisoni, Francesca Tentori, Bruce M. Robinson. Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Since August 2010, the Dialysis Outcomes and Practice Patterns Practice Monitor (DPM, www.dopps.org/DPM) has leveraged its US hemodialysis (HD) sample (now >200 facilities) to provide timely and detailed (>750 data tables) updates on national trends in HD care. Here we compare DPM estimates to available results from end-stage renal disease (ESRD) data sources collected by the Centers for Medicare and Medicaid Services (CMS).

Methods: Pearson correlations (r) were used to compare contemporary trends since Aug 2010 between DPM and the 2014 US Renal Data System Annual Data Report (ADR, through Dec 2012) and the Nov 2014 CMS Claims-Based Monitoring Project (CBMP, through Jun 2014). We also compared monthly DPM estimates with cross-sectional estimates from 2014 CrownWEB (CW, Dec 2013).

Results: DPM trends in ESA dose use and IV iron use, and hemoglobin levels were highly correlated (r= 0.89-0.98) with ADR and CBMP trends. Compared to CW, DPM showed slightly higher fistula use, but slightly lower percent of patients with adequate Kt/V and URR values.

Abbreviations: DPM, Dialysis Outcomes and Practice Patterns Practice Monitor; CMS, Centers for Medicare and Medicaid Services; USRDS, US Renal Data System; ADR, USRDS Annual Data Report; CW, CrownWEB; CBMP, CMS ESRD Claims-Based Monitoring Project; Hb, hemoglobin; URR, urea reduction ratio; ESA, erythropoiesis-stimulating agent.

Among ESRD-treated patients

Conclusions: DPM reports IV medications as prescription at the end of the month (before Apr 2012) or anytime during the month (Apr 2012 and after), rather than administration. Thus, estimates for ESA and IV iron utilization each month may be somewhat different due to spontaneous or withheld dosing. Differences with CW cross-sectional estimates may result from differences in calculation methods. DPM includes non-Medicare patients that are not necessarily present in claims-based sources. DPM now includes 14 years of monthly estimates for all patients in US HD care. Although similarities in data sources and specifications may influence direct comparisons, DPM data remain an important resource for identifying important trends in HD care before confirmations from CMS ESRD databases are available.

TH-PO941
Reduced Free Triiodothyronine Is an Independent Predictor of Clinical Outcomes in Hemodialysis Patients with Low Albuminemia

Akihiko Kato,1 Masafumi Ono,1 Takayuki Tsuji,2 Naro Ohashi,2 Hideo Yasuda.2 1Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; 2Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.

Background: Low free triiodothyronine (fT3) and free thyroxine (fT4) are both related to malnutrition, inflammation and mortality in dialysis patients. Upper-normal thyrotropin (TSH) levels are also associated with a higher risk of total mortality in hemodialysis (HD) patients. However, it remains unclear which of thyroid-related hormones is most useful in predicting clinical outcomes. So, we aimed this study to compare the prognostic value of different hormones in prevalent HD patients.

Methods: We enrolled 339 HD patients (age: 64±13 years old, time on HD: 129±114 months), and measured basal fT3, fT4 and TSH. We then followed the patients for the next 42 months, and assessed the impact of fT3, fT4 and TSH on all-cause mortality and cardiovascular (CV) events or hospitalization. Patients were divided into the 4 groups based on the quartiles of fT4, fT3 and TSH. The associations of basal levels with clinical outcomes were examined with Cox proportional hazards models adjusted for demographic and clinical factors and comorbidities.

Conclusions: Distributions of CKD-MBD parameters varied by region, possibly resulting in differential risk of adverse outcomes. Our findings in this international cohort highlight the importance of simultaneous, rather than independent, control of MBD parameters within clinical guidelines ranges.

Results: Mean serum fT3 and fT4 were 2.01±0.37 [0.95-3.73] pg/mL and 0.86±0.20 [0.35-1.67] ng/dL. Serum levels of fT3 and fT4 were lower than those of reference ranges in 85.0% and 56.0% of the patients, respectively. In contrast, TSH levels were within the reference range in most patients (92.9%). Cox hazards analyses revealed that the lowest quartile of fT3 (<1.75 pg/mL) was an independent predictor of all-cause mortality (HR 3.55 [95%CI: 1.17-4.09, p=0.001]), all-cause mortality plus CV events (HR 2.19 [95%CI: 1.53-3.823, p=0.001]) and all-cause mortality plus hospitalization (HR 2.16 [95%CI: 1.28-3.67, p=0.001]) when compared with those with the top quartile (fT3>90 pg/mL). However, the significant impact of low fT3 on prognosis was observed only in patients with serum albumin lower than 3.8 g/dL (n=195). In contrast, serum fT4 and TSH levels did not relate to prognosis.

Conclusions: These findings suggest that low fT3 became an independent predictor of clinical outcomes in HD patients with low albuminemia.

TH-PO942
Low Socioeconomic Status and Co-Morbidity Are Associated with Limited Health Literacy in RRT Patients – Results from the ATTOM Study
Dominic Taylor, The ATTOM investigators. *Southmead Hospital, Bristol, United Kingdom.*

Background: Limited health literacy (LHL) is a risk factor for poor outcomes in chronic disease patients. Studies with limited patient numbers in RRT patients associate LHL with low socioeconomic status (SES), comorbidity and ethnicity.

Methods: This cross-sectional study used baseline data from the ‘Access to Transplantation and Transplant Outcome Measures’ (ATTOM) cohort. ATTOM recruited incident dialysis and transplant patients aged 18-75 years in the UK during 2011-2013 and also waited-listed patients similar to those transplanted (matched controls). Health literacy was measured by the question ‘How often do you need someone’s help to read instructions, leaflets, or other written material from your doctor or pharmacy?’ answered on a scale from 1-Never to 5-Always. LHL was defined as a score greater than 2. The three groups were analysed for associations between LHL and demographics, SES factors and comorbidity, using univariate and multivariate analysis, p<0.05.

Results: 6842 patients were recruited: 2621 incident dialysis (ID), 2262 incident transplant (IT) and 1959 matched controls (MC). In univariate analyses, in all groups, English not as first language, Asian ethnicity, low educational level, unemployment, absence of car or home ownership, increased comorbidity by modified Charlson index and mental illness were associated with LHL. In adjusted models, in all groups, the following factors were associated with LHL: English not as first language (OR=2), modified Charlson index (OR 1.2 for each point above zero), low level of education (OR=2 for no qualifications compared to any), unemployment (OR=3.0 compared to employed) and absence of car ownership (OR 1.7).

Conclusions: In this large nationwide study, low SES and co-morbidity are associated with LHL in patients receiving dialysis or at the point of transplantion, independent of first language. LHL may impact upon patients’ ability to engage with shared decision making and their capacity to cope with the burden of disease and treatment.

TH-PO943
Comparing Dialysis Facility Compare (DFC) Star Rating to QIP Payment Categories
Claudia Dahlerus,1 John Wheeler,1 Deanna Chyn,1 Yanning Li,1 Richard Hirth,1 John Kalbfleisch,1 Jennifer Sardone,1 Zhi He1, Tempie H. Shearón,1 Joel S. Andress,2 Elena K. Balovlenkov,2 Yi Li.1 1Biostatistics, Kidney Epidemiology and Cost Center, 2Centers for Medicare & Medicaid Services.

Background: CMS recently developed hospital readmissions measures to reflect quality of care provided by nursing homes, long-term care hospitals, inpatient rehabilitation facilities, home health agencies and dialysis facilities. The intent is to encourage care coordination as patients transition between care providers. All measures adjust for patient characteristics. CMS has not adjusted quality measures for patient socioeconomic status (SES), so as not to condone disparities in care delivery. However, not including such adjustments may result in inappropriate assessments about quality of care. We present preliminary analyses assessing the association of SES and readmission among dialysis patients.

Methods: Using 2013 Medicare claims data, we model the probability of readmission, defined as an unplanned readmission within 30 days of a hospital discharge, adjusted for patient characteristics including age, sex, BMI, comorbidities, discharging hospital, and several measures of SES, plus measures reflecting SES of the patient’s area of residence.

Results: Patients with Medicare secondary payer (MSP) were less likely to experience a readmission (OR 0.92; CI:0.90-0.93); patients with dual Medicare and Medicaid coverage (OR 1.08; CI 1.08-1.09), unemployed at ESRD incidence (OR 1.07; CI 1.06-1.08) and living in ZIP codes with high unemployment, low education and income disparity were more likely to experience a readmission.

Conclusions: Insurance status and area of residence are strong proxies for SES and are associated with readmissions. MSP, largely reflective of private insurance coverage, can be an indicator of higher SES and perhaps better health. Dual eligibility for Medicare and Medicaid can be an indicator of lower SES, as can being unemployed or having ESRD incidence. As interest in risk adjusting for indicators of SES has grown, the association between SES and readmission suggests further analysis may be appropriate. However, caution must be exercised in efforts to distinguish between SES factors that may or may not be related to quality of care.

TH-PO945
Co-Morbidities (CM) Do Not Predict Adverse Outcomes in Peritoneal Dialysis (PD) versus Hemodialysis (HD) in a Multi-Ethnic Asian ESRD Cohort
Ge Hsiao Lin,1 Khuan Yew Chow,1 Vathsala Anantharaman.1 1Health Promotion Board, Singapore; 2National Univ Health System.

Background: There is conflicting data on outcomes following HD vs PD. USRDS data for ESRD in 2002-2004 suggested similar outcomes for HD and PD over 5 years of followup. This study evaluated outcomes for HD vs PD from a multi ethnic Asian ESRD population and evaluated the impact of CM on worse outcomes in either modality.

Methods: 3279 HD and 1330 PD patients who were included in the Singapore National Registry (SRR) in 2001-2007 and followed up till death or 31 Dec 2012 comprised the study population. Data on patients’ demographics, CM and survival were collected. Patients were stratified by age, presence of diabetes(DM) and occurrence of 1 or more vascular(U) vs non-vascular(NV) CM. 5-year survival was compared using Kaplan-Meier and regression analyses.

Proven by Results from Japanese Nationwide Surveys in 1998 and 2010

Significance of the Decreased Risk of Dialysis-Related Amyloidosis Now

The reduction was most prominent in patients with longer dialysis vintage, patients who were younger, and those with lower pre-dialysis b2m levels. Similar results were obtained by propensity score-matched analysis. We also found that b2m clearance >80% may reduce risk of CTS.

Conclusions: The incidence of first-time CTS as proxy for DRA decreased significantly from 1998 to 2010. Several factors may have contributed to this decrease, including improved dialysis methods.

TH-PO947
Twice Weekly Hemodialysis and Clinical Outcomes in the China DOPPS
Yucheng Yan,1 Mia Wang,2 Jia Qi Qian,2 Brian Bieber,2 Mei Wang,2 Nan Chen,3 Bruce M. Robinson,4 Shuchi Anand,4 Shen Wang,4 Shanghai Renji Hospital; 5 Arbor Research; 6 Shanghai Ruijin Hospital; 7 Stanford Univ.

Background: Outcomes related to 2 times weekly hemodialysis (HD), substantially practiced in China, remain understudied. Small, single-center studies have indicated better preservation of residual kidney function (RFK) and similar survival for 2 vs 3 times weekly HD. We used data from the China Dialysis Outcomes Practice Patterns study (DOPPS) to evaluate survival and hospitalizations by frequency of HD.

Methods: We studied 1,433 patients from 45 HD units in China (2012-2015). Cox regression was used to model the association of 2 vs. 3 times weekly HD with clinical outcomes adjusting for patient and treatment characteristics.

Results: 270 patients (19%) were undergoing 2 times weekly HD in China. Compared with 3 times weekly HD, patients on 2 times weekly HD were more likely to be female and have shorter time on dialysis (4.3 vs 2.6 yrs), more urine output, shorter dialysis session length (238 vs. 250 min) and longer travel times to facility. They were less likely to have diabetes or cardiovascular disease. Insurance coverage was similar in the two groups. During follow-up (median=1.7 years), 184 (13%) deaths and 516 (38%) hospitalizations occurred. No differences in mortality or hospitalization were found between the two frequency groups (Table). No interaction was observed with vintage (p=0.43).

*1393 patients, 184 events.
*age, gender, BMI, standardized, and vintage.

Conclusions: In this multi-center study with well-characterized patient and treatment data, outcomes of 2 vs. 3 times weekly HD were similar. Thus, it is possible that among carefully selected patients 2 times weekly HD may provide acceptable outcomes. An additional study is also needed due to residual confounding, small sample size, and the changes in results with progressive adjustments.

TH-PO948
Initiation of a Chronic Kidney Disease Case Manager Program Is Associated with Better Outcomes in Incident Hemodialysis Patients
Joseph A. Kahn, Patrick Bridge, John W. Larkin, Hao Han, Sheetal Chaudhuri, Len A. Usvyat, Terry Ketchersid, Franklin W. Maddux.
Fresenius Medical Care North America, Waltham, MA.

Background: The Renal Care Coordinator (RCC) Program places chronic kidney disease (CKD) case managers in the Nephrology Practice to co-manage late stage CKD (4 and 5) patients for an optimal outpatient start to Renal Replacement Therapy (RRT). This program is performed through both physical and virtual RCCs. We compared outcomes in patients starting hemodialysis (HD) who were previously enrolled in the RCC program and those who were not.

Methods: We compared outcomes in patients enrolled into the RCC program versus patients considered to have a ‘Timely Referral’ for dialysis (i.e. were followed in a

Extracellular Overhydration Measured by Multifrequency Bioelectrical Analysis Is Associated with Increased Postdialytic Systolic Blood Pressure in Hemodialysis Patients

Jae Yeul Park, Seok-hyung Kim, Ah Ran Choi, Kyung Eun Lee, Hae-yung Kim, Hoon Young Choi, Sung-Kyu Ha, Hyeong cheon Park

Nephrology, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; Nephrology, Yongin Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; Nephrology, Bundang CHA Hospital, Pochon CHA Univ College of Medicine, Seoul, Korea.

Background: Postdialytic hypertension is associated with increased morbidity and mortality for hemodialysis (HD) patients. Recent studies suggest that increased postdialysis extracellular water (ECW) volume may account for the rise in postdialysis systolic blood pressure (PDSBP). The aim of this study was to assess the relationship between volume status and PDSBP in HD patients.

Methods: Volume status assessments were performed after mid-week HD using multifrequency bioelectrical impedance (BIA, Inbody S10) in supine position. Demographic and routine biochemical data were collected and pre- and post-dialysis B-type natriuretic peptide (BNP) level was measured (Triage BNP test, Alere).

Results: We enrolled clinically stable 99 HD patients from 3 dialysis centers. Patients were divided into 3 groups based on fluid overload defined by pre-dialysis systolic blood pressure (PDSBP) criteria (≥130 mmHg or ≥110 mmHg or ≥90 mmHg). The mean age was 55.1 ± 13.3 years in hypertensive, 58.3 ± 13.2 years in stable, and 65.2 ± 7.7 years in hypotensive group. Postdialysis BNP was 267.8 ± 251.1 pg/ml in hypertensive, 66.0 ± 92.9 pg/ml in stable, and 9.2 ± 21.9 pg/ml in hypotensive group. There were no differences in gender, dialysis prescriptions, and subjective global assessment score among the patient groups. The ECW/TBW ratio was significantly higher in the hypertensive group and positively correlated with PDSBP and delta BNP. The only independent risk factor affecting PDSBP was ECW/TBW ratio after dialysis.

Conclusions: HD patients who demonstrate increased in PDSBP should have their volume status reassessed and target dry weights adjusted using BIA, with emphasis on increased the ECW/TBW ratio.

TH-Po950

Novel Phosphate Binder, Ferric Citrate Hydrate, Can Reduce Serum Phosphate Levels and Doses of Erythropoiesis Stimulation Agents in Japanese Patients on Hemodialysis

Hiroaki Kasuga, Ryoko Takahashi, Keiko Kimura, Chieko Matsubara, Hiromi Tanimoto, Mari Maseki, Yashikuo Ito

Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

Background: Ferric citrate hydrate (FC) has been available in Japan as a phosphate binder for patients on dialysis (HD) since 2014 although its effects have not been evaluated in detail in such patients. The present study aimed to determine the effects of FC on serum phosphate levels and anemia control in patients on HD.

Methods: Thirty-eight outpatients (mean age, 62.5 ± 5 years; male, n = 28 [73.7%]; mean HD vintage, 7.2 ± 6 years; hypertension, n = 29 [76.3%]; diabetes, n = 19 [50.0%]; secondary hyperparathyroidism, n = 15 [39.5%]) on maintenance HD were treated with FC for six months to control hyperphosphatemia. Serum concentrations of phosphate, calcium, hemoglobin, and ferritin levels, transferrin saturation (TSAT), and weekly epoetin (EPO) doses were evaluated.

Results: Mean phosphate levels were significantly decreased from 7.05 ± 1.11 to 6.19 ± 0.91 (p < 0.0001), 6.14 ± 1.16 (p < 0.05) and 6.01 ± 1.11 (p < 0.005) mg/dL at one, three and six months, respectively. Calcium, hemoglobin and ferritin levels did not significantly differ during the same periods. Transferrin saturation was significantly increased (26.7 ± 10.9% vs. 20.0 ± 9.3%, p < 0.05) and the weekly EPO dose was significantly decreased (2750 ± 2699 vs. 6801 ± 7406 IU/week, p < 0.05) after six months of FC therapy.

Conclusions: FC can decrease serum phosphate levels and the weekly EPO dose. Therefore, FC is useful for treating hyperphosphatemia and renal anemia in Japanese patients on HD.

TH-Po951

Geographic Variation of Potentially Avoidable Readmissions in Hemodialysis Patients

Daniel W. Ross, Kamyar Kalantar-Zadeh, Steven Fishbane, Anna Mathews

Div of Nephrology, Hofstra North Shore –LIJ School of Medicine, New York, NY; Harold Simmons Center for Kidney Disease Research and Epidemiology, Div of Nephrology, Univ of California, CA.

Background: In 2011 in the United States, 36.3% of prevalent hemodialysis patients were readmitted within 30 days of an index hospitalization. These rates are approximately twice that of the general U.S Medicare population. While some readmissions to hospital are unavoidable, it is probable that a substantial number could be prevented. In the present study, we describe inter-state variability in 30-day potentially avoidable readmissions (PAR).

Methods: The United States Renal Data System (USRDS) was used to identify prevalent hemodialysis patients (vintage >90 days) with acute hospitalizations in 2008. Exclusion criteria were transfer to rehabilitation or skilled nursing facility, unknown dialysis start date, and renal function recovery. PAR were identified using a validated, computerized algorithm (SHARP), and displayed geographically by state in map software (MapInfo).

Results: 250,606 index hospitalizations were identified, with 37% readmissions within 30 days (n = 84,279). Nationwide, 24% of index hospitalizations were followed by a 30-day PAR (64.9% of all readmissions) (n= 59,803). PAR ranged from 12% to 51% by state. The figure shows the geographic distribution of potentially avoidable readmissions.

Conclusions: There is inter-state variability in PAR among chronic hemodialysis patients, and that may be related to regional differences in practice patterns or patient demographics. Further characterization of risk factors associated with PAR is the focus of our ongoing research.

TH-Po952

Unravelling the Relationship Between Mortality, Hyponatremia, Inflammation and Malnutrition in Hemodialysis Patients: Results from the International MONDO Initiative

Marije J.E. Dekker, Daniëlle Marcelli, Bernard J. Canaud, Constantijn Konings, Karel M. Leunissen, Nathan W. Levin, Jochen G. Raimunn, Frank van der Sande, Len A. Usvyat, Peter Kotanko, Jeroen Kooman, Catharina Hospital Eindhoven; Maastricht Medical Center; Fresenius Medical Care; Renal Research Inst.

Background: Hyponatremia is a risk factor for mortality in hemodialysis patients. However, it is not well known to which extent comorbidities, such as malnutrition, fluid overload and inflammation are related to hyponatremia and influence the association between hyponatremia and outcomes.

Methods: We studied 8892 patients from the European subset of the MONDO Initiative. Nutritional and fluid status were assessed by multifrequency bioimpedance spectroscopy. Based on pre-dialysis fluid status, fluid depletion was defined as an extracellular water volume < -1.0L and fluid overload > +2.5L. Malnutrition was defined as a lean tissue index below the 10th percentile of age- and gender matched healthy controls. Hyponatremia and inflammation were defined as serum sodium levels < 135 mEq/L and C-reactive protein levels >10 mg/L, respectively.

Results: Hyponatremia was predicted by the presence of malnutrition (odds ratio (OR) 1.48 (95%CI 1.30-1.69)) and inflammation (OR 1.44 (95%CI 1.26-1.64)), but not by fluid depletion (OR 1.38 (95%CI 0.98-1.93)) or fluid overload (OR 0.99 (95%CI 0.85-1.14)). Malnutrition (hazard ratio (HR) 1.39 (95%CI 1.23-1.58)), inflammation (HR 2.31 (95%CI 2.04-2.62)), fluid overload (HR 2.17 (95%CI 1.90-2.47)) and hyponatremia (HR 1.63 (95%CI 1.39-1.90)) were independent predictors for all-cause mortality.

Conclusions: In hemodialysis patients hyponatremia is associated with malnutrition, inflammation and malnutrition but not with deranged fluid status. Hyponatremia maintained predictive for all-cause mortality after correction for malnutrition, inflammation and fluid status abnormalities. Hyponatremia may aid efforts to identify hemodialysis patients at increased risk of death.
Hyperkalemia is a major problem in dialysis patients. It is associated with increased risk of cardiac arrhythmias and sudden cardiac death. However, few studies have examined frequency of hyperkalemia episodes in a large population of dialysis patients. We present a characterization of the magnitude of hyperkalemia prevalence in a large hemodialysis population and examine the role of interdialytic interval in its occurrence.

Methods: We derived annual cohorts of hemodialysis patients (2007-2010) from linked DaVita and USRDS databases. Included patients were those receiving thrice-weekly hemodialysis. On a monthly basis, hyperkalemia case was defined as a serum potassium level greater than or equal to 5.5 mEq/L. Hyperkalemia prevalence was calculated as the proportion of dialysis patients with at least one episode of hyperkalemia during a given month. We examined the association between serum potassium levels and mortality risk, adjusting for demographic and clinical factors in time-dependent Cox proportional hazards models.

Results: Hyperkalemia defined as serum K ≥5.7 mEq/L was associated with an increased risk of mortality (adjusted hazard ratio [AHR] 1.1, 95% CI 1.01-1.28, P = 0.037, compared to K ≥5.0 mEq/L) after adjustment for demographic and clinical factors in time-dependent Cox proportional hazards models; the AHRs increased progressively as the threshold for hyperkalemia rose (AHRs 1.09 for K=5.7 mEq/L, 1.13 for K=5.8 mEq/L, 1.20 for K=5.9 mEq/L, and 1.28 for K=6.0 mEq/L). The pattern of the point estimates was similar for cardiovascular mortality, although the results did not reach statistical significance (AHRs 1.09 for K=5.7 mEq/L, 1.13 for K=5.8 mEq/L, 1.20 for K=5.9 mEq/L, and 1.28 for K=6.0 mEq/L).

Conclusions: Hyperkalemia is associated with all-cause mortality beginning at K ≥5.7 mEq/L, with mortality risk point estimates increasing in ordinal fashion through K level ≥6.0 mEq/L. A similar pattern was observed in the point estimates for cardiovascular mortality. This study may have identified a threshold at which point serum K becomes dangerous.
TH-PO956

A Multicenter, Phase 2/3 Randomized, Double-Blind, Placebo-Controlled Trial of Nalbuphine ER Tablets for the Treatment of Uremic Pruritus: Baseline Population Characteristics Vandana S. Mathur,1 Jayant Kumar,2 Paul W. Crawford,1 Howard Halt,1 Thomas Sciascia.1 1Mathur Consulting, Woodside, CA; 2Trevi Therapeutics, New Haven, CT, 1Renal Medicine Associates, Albuquerque, NM; 1Bios-statistics, Edireign Consulting, Wilmington, DE, 1Research by Design, Evergreen Park, IL.

Background: Uremic pruritus (UP) afflicts 30-40% of hemodialysis patients (HDP) and is associated with greater use of ESA and antibiotics. UP is hypothesized to be centrally-mediated via the reduction in endogenous κ/µ opioid ligand ratio. Nalbuphine ER tablet (NAL), a κ-opioid agonist and µ-opioid antagonist, is being developed for treatment of UP.

Methods: 373 HDP with moderate or severe UP (Numerical Rating Scale, NRS itch intensity scores ≥4.5) were randomized to blinded placebo or NAL (60 or 120 mg BID) X 8-wks.

Results: Worsening itch intensity by baseline NRS quartile was monotonically associated with impaired QOL on all instruments as well as with sleep onset latency, anxiety, and depression, but not with age, gender, BMI, ethnicity, itch duration, IPITH, URR, or Kt/V. Black race appeared to be associated with higher NRS.

Conclusions: In addition to the 1st endpoint hypothesis that NAL will reduce itch intensity, the apparent associations between itch intensity and QOL measures at baseline warrant examination by treatment. Unblinded results will be presented.

TH-PO957

International Variation of Characteristics of Health Literacy and Its Association with Mortality in Dialysis Kerri L. Cavanaugh,1 Mia Wang,1 Ken Walliston,1 Russell Rothman,1 Ali AlSahow,1 Patricia De Segueraa,1 Takeshi Haraguchi,1 Brian Bieber,1 Bruce M. Robinson,2 Ronald L. Pisoni,3 Francesca Tenori,1,2 1Vanderbilt Univ; 2Arbor Research; 3Jahra Hospital; 4Hospital Infanta Leonor; 5Fukushima Medical Univ.

Background: In patients receiving hemodialysis (HD), low health literacy (LHL) has been associated with greater use of emergency care, more hospitalizations and higher mortality. Little is known about the characteristics of LHL in HD patients outside of the United States.

Methods: A total of 11,476 DOPPS participants completed the Brief Health Literacy Screen (BHLS) [0-12]. Descriptive statistics were performed overall and by country. Participant characteristics were examined between three health literacy categories using mixed, GEE, and multinomial logistic models. Cox models were applied to examine effects of study phase, country, and facility clustering.

Conclusions: LHL prevalence across countries may be in part explained by cultural differences as well as health care systems. Vulnerable patients are at highest risk of LHL, and LHL is an independent predictor of mortality. Further examining by country the role of health system practices may help to overcome LHL-related barriers to patient engagement and improve outcomes in hemodialysis.

Funding: Pharmaceutical Company Support - The DOPPS Program is supported by Amgen, Kyowa Hakko Kirin, AbbVie Inc., Sanofi Renal, Baxter Healthcare, and Vifor Fresenius Medical Care Renal Pharma, Ltd. Additional support for specific projects and countries is also provided in Canada by Amgen, BHC Medical, Janssen, Takeda, Kidney Foundation of Canada (for logistics support); in Germany by Hexal, DGN, Shire, WiNe Institute; for PDPSS in Japan by the JSPD. All support is provided without restrictions on publications.

TH-PO958

Background: Hemodialysis patients are frequently subject to Gram-positive infections including Staphylococcus aureus and Methicillin-resistant Staphylococcus aureus (MRSA). Vancomycin is an antibiotic of choice in this population to treat these infections. The objective of this project was to validate the performance of a pre formatted individual prescription protocol of vancomycin in its capacity to reach target vancomycin serum concentrations of 10 to 30 mg/L for Gram-positive infections and 15 to 20 mg/L for MRSA infections.

Methods: The records of 84 patients diagnosed with end-stage renal disease undergoing a 4-hour, three times weekly high-flux hemodialysis treatment were analyzed retrospectively. All patients received vancomycin according to a weight-based dosing protocol between 2011 and 2014. Patients < 70 kg received a 1000 mg loading dose followed by a 500 mg maintenance dose at dialysis session. Patients between 70 and 100 kg received a 1500 mg loading dose followed by a 750 mg maintenance dose. Patients > 100 kg received a 1500 mg loading dose followed by a 1000 mg maintenance dose.

Results: We collected and analyzed 189 dosages of 84 patients. For all assays, 95.2% achieved levels between 10 and 30 mg/L and 50.3% achieved levels between 15 and 20 mg/L. Stratified by weight categories, for the 10 to 30 mg/L target, 93.3% of patients < 70 kg, 100% of patients between 70 and 100 kg and 89.5% of patients > 100 kg achieved the target serum concentrations (mainly below), 61.3% of patients between 70 and 100 kg achieved the target serum concentrations and 31.6% of patients > 100 kg achieved the target serum concentrations (mainly below, but not below 30 mg/L).

Conclusions: The vancomycin weight-based dosing protocol achieved target serum concentrations of 10 to 30 mg/L in 95.2% of patients. However, because half the dosages of patients < 70 kg were below the target of 15 to 20 mg/L, vancomycin bolus and maintenance doses should be adjusted upward in this subgroup. No dose change is suggested in the other subgroups.

Trends in Incident ESRD Counts Initiating Dialysis in Freestanding Facilities Have Regional Variation David T. Gilbertson,1 Peer Kidney Care Initiative Investigators.1 1CDBG, MRF, Minneapolis, MN; 2Peer Kidney Care Initiative.

Background: Overall rates of incident end-stage renal disease (ESRD) patients initiating dialysis in freestanding units have stabilized, and the growth in counts of incident ESRD patients began to slow by the beginning of this decade. We assessed trends in incident ESRD counts from 2004–2011, overall and geographically by the 9 US Census Divisions.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author. 316A
Methods: Data were ascertained from the Centers for Medicare & Medicaid Services ESRD database. For annual incident cohorts, we identified patients with their first outpatient dialysis within 3 months of initiating chronic dialysis in a freestanding facility.

Results: Yearly counts increased through 2010, with an average annual percent increase of 2.7% from 2004 to 2011. Between 2009 and 2011, this average percent increase was relatively unchanged (0.6%). However, there were region-to-region differences, with increased New England Census Division experiencing the largest proportionate decrease in incident patients between 2009 and 2011, while the contiguous Middle Atlantic division averaged the highest increase during the same period by 2011.

Conclusions: Overall trends in dialysis incidence reveal substantial geographic variation that has not been explained, suggesting that an assessment based on overall U.S. counts may mask important regional differences. Whether these trends will continue in the face of increasing diabetes rates, an aging population and shifts in social demographical changes is uncertain and will require more detailed analysis.

Funding: Pharmaceutical Company Support - Financial support for Peer is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc. (DCI), DSI Renal, Fresenius Medical Care, Independent Dialysis Foundation, Northwest Kidney Centers, Renal Ventures Management, Satellite Healthcare, The Rogosin Institute, and U.S. Renal Care. In collaboration with the Chief Medical Officers of these organizations, the Peer Kidney Care Initiative is operated by the Chronic Disease Research Group, a division of the Minneapolis Medical Research Foundation, in Minneapolis, Minnesota, Private Foundation Support

Association of Intradialytic Hypoxemia with Hospitalization and Mortality:Results from a Large U.S. Hemodialysis Cohort

Hanjie Zhang,1 Xiaoling Ye,1 Doris H. Fuertinger,1 Franz Kappel,2 Mikhail Artemyev,2 Nancy Ginsberg,1 Yuedong Wang,1 Stephan Thijsse,1 Peter Kotanko,1,14 Renal Research Inst, New York, NY; 2Univ of Graz, Austria; 3Univ of California - Santa Barbara, CA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: While intradialytic hypoxemia is recognized since the early days of hemodialysis (HD), its associations with hard clinical outcomes have not yet been assessed.

Methods: We analyzed arterial oxygen saturation (SaO2) data obtained by Crit-Line™ monitor (CLM) in chronic HD patients treated between 1/2012 and 1/2015. An individual 6-month baseline with at least 10 CLM measurements preceded a 12-month follow-up. Prolonged intradialytic hypoxemia (PIH) was defined as SaO2 ≤ 90% for more than 2 hours. Cox proportional hazards analysis with adjustment for age, gender, race, vintage, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes, albumin, hemoglobin, erythropoietin (EPO) dose, neutrophil-to-lymphocyte ratio, interdialytic weight gain, post-HD systolic blood pressure, and ultrafiltration rate. We conducted Cox proportional hazards analysis with adjustment for age, gender, race, vintage, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes, albumin, hemoglobin, erythropoietin (EPO) dose, neutrophil-to-lymphocyte ratio, interdialytic weight gain, post-HD systolic blood pressure, and ultrafiltration rate.

317A
listed for renal transplant and 10.1% received a renal transplant. With matching for age, sex and race, overall mortality rates were higher in scleroderma cases than controls (22.3 Vs. 15.5 per 100 person-years, \( P < 0.001 \)). Overall rates of listing for renal transplant (8.4 Vs. 8.5 per 100 person-years, \( P = 0.92 \)) and rates of transplantation (4.1 Vs. 4.3 per 100 person-years, \( P = 0.66 \)) were similar in scleroderma cases and controls.

Conclusions: The incidence of ESRD from scleroderma appears to have declined in the United States since 1995. Mortality rates on RRT are higher in scleroderma cases than controls (1.5 vs. 0.8 listings/100 person-years, \( P = 0.03 \)); however, transplantation rates were not different (4.1 vs. 4.3/100 person-years, \( P = 0.96 \)). Overall rates of listing for renal transplant and receiving a renal transplant were as likely in scleroderma patients as matched controls.

**Prevalence and Mortality Associations of Protein- Energy Wasting Syndrome Criteria in Maintenance Hemodialysis Patients**

*G. Wei, 1 Xiaorui Chen, 1 Kalani L. Raphael, 1,2 Syndrome Criteria in Maintenance Hemodialysis Patients Prevalence and Mortality Associations of Protein- Energy Wasting* 0.1

**Methods:** The prevalence of International Society of Renal Nutrition and Metabolism panel PEW criterion (listed in the table) at the 12 m follow-up visit were examined. Subsequent mortality associations were examined in Cox models adjusted for demographics, duration of ESRD, Kt/V and flux groups, smoking and alcohol use.

**Results:** There were 632 deaths / 3390 yrs of follow-up. The prevalence of PEW criterion varied widely: 0% for low body fat% to 64% for low DEI (figure).

**Conclusions:** As the prevalence and mortality associations of protein-energy wasting (PEW) syndrome criteria in the MHD population are not well established, we examined these in 1480 MHD pts in the HEMO Study, a multi-center RCT to examine the effects of dialysis dose and dialyzer flux on mortality.

**TH-PO965**

**Primary Care Physician Involvement in the Care of Chronic Dialysis Patients in the U.S.**

*Vahakn B. Shahinian, Deanna Chyn, Yi Li, John Z. Ayanian, Richard Hirth, William H. Herman, Rajiv Saran. Univ of Michigan.*

**Background:** Current health reform efforts aimed at improving quality and value center around delivery of good primary care. However, national patterns of primary care physician (PCP) involvement along with a nephrologist in the care of chronic dialysis patients are unknown.

**Methods:** Patients on chronic dialysis during 2010-11 with Medicare as the primary insurer were identified using US Renal Data System (USRDS) data. PCP involvement was defined based on a claim for an outpatient (non-dialysis) visit with a physician specializing in family practice, general internal medicine or geriatrics. Patients were characterized with respect to two aspects of preventive care: influenza vaccination and diabetes care.

**Results:** The sample included 179,645 patients, 8,272 of whom were diabetic. In 2010, 59% of patients had evidence of PCP involvement based on 1 outpatient visit. Patients with PCP involvement were older and more likely to be female, white and with diabetes as cause of ESRD (Table). Rates of vaccination and diabetes care were higher in those with PCP involvement, even after adjustment (ORs: 1.48 [1.45-1.51] for vaccination and 1.53 [1.48-1.58] for a composite of diabetes care).

**Conclusions:** Even under the loosest definition of PCP involvement, over one quarter of dialysis patients have no evidence of PCP involvement. Patients with PCP involvement have higher rates of preventive care, but further study should examine the impact on outcomes and costs.

**Funding:** NIDDK Support

**TH-PO966**

**Are We Choosing Wisely? A Study of Colon Cancer Screening Practices Among Dialysis Patients in the United States**

*Christopher A. Carlos, 1 Chi-yuan Hsu, 1 Meda E. Pavkov, 1 Nilka Rios Burrows, 1 Vahakn B. Shahinian, 2 Rajiv Saran, 2 Neil R. Powe, 1 Kirsten L. Johansen. 3 Univ of California, San Francisco, San Francisco, CA; 2Univ of Michigan, Ann Arbor, MI; 3Centers for Disease Control and Prevention, Atlanta, GA.*

**Background:** Because estimated net gains in life expectancy are very small, the American Society of Nephrology recommended against routine cancer screening in asymptomatic dialysis patients. We aimed to determine how often colon cancer screening is performed in the U.S. and whether colon cancer screening is targeted toward healthier dialysis patients. **Methods:** We performed a retrospective cohort study of patients aged ≥50 years on dialysis between January 1, 2007 and September 30, 2012 using data from the United States Renal Data System (USRDS). Using multivariable Cox regression models, patients were divided into quartiles based on the risk of death and the likelihood of receiving a kidney transplant and, according to these quartiles of risk, we then assessed the likelihood of colon cancer screening (CCS) by fecal occult blood testing, sigmoidoscopy or colonoscopy from Medicare claims data.

**Results:** Of 391,616 patients, 13% received CCS over a median follow-up of 1.5 years (interquartile range 0.7-2.9). Screening was most common in patients with the lowest mortality risk (16%), compared with 9% of those with the highest mortality risk (HR 1.33;
Severe Sepsis Hospitalizations in Those on Maintenance Dialysis – National Trends and Outcomes

Ankit Sakhuja,1 Kianoush Banaei,2 Hatem Amer,2 Robert C. Albright,2 Nephrology, Univ of Michigan; 2Nephrology and Hypertension, Mayo Clinic.

Background: Severe sepsis (SS) is a life-threatening condition requiring early diagnosis and management. Incidence of SS is increasing in general population (GP) and mortality is declining; however, epidemiology and outcomes of SS have not been well studied in those on maintenance dialysis (MD). We designed this study to look at incidence and outcomes of SS in those on MD.

Methods: Using Nationwide Inpatient Sample database we included all hospitalizations (age ≥20 yr) with SS based on ICD-9-CM codes of severe sepsis, septic shock or blood stream infection with organ dysfunction from 2005 to 2010. Those on MD were identified based on ICD-9-CM codes. Age adjusted incidence of SS and mortality in subgroups was calculated by direct standardization to 2000 standard US population. Linear regression was used to assess trends over time and logistic regression to assess independent effect of MD on mortality.

Results: Of estimated 5,000,152 (95% CI: 4,798,520-5,201,784) hospitalizations with SS, 6.4% were on MD. Unadjusted incidence of SS was 145.4/1000 in MD compared to 3.5/1000 in GP with incidence rate ratio 40.9 (95% CI: 40.8-40.9). Age adjusted incidence of SS seems to be increasing in both subgroups though trend was not significant in MD (Fig 1).

Conclusions: Our findings suggest that screening was appropriately targeted to dialysis patients with longer life expectancies and away from those with the lowest chances of receiving kidney transplantation.

Funding: NIDDK Support, Other U.S. Government Support

TH-PO967

Unadjusted in-hospital mortality is higher in MD (30.3% vs 26.2%; p<0.001). Age-adjusted mortality is decreasing in both subgroups though trend was not significant in MD. Age-adjusted mortality continues to be higher in MD (Fig 1). MD is an independent risk factor for mortality with OR 1.26 (95% CI: 1.23-1.29).

Conclusions: Hospitalizations with SS are over 40 times more common in MD. Mortality is higher in MD and being on MD is an independent predictor of mortality in those admitted with SS. Though incidence of SS seems to be increasing, there is a trend towards decrease in mortality even in MD.

TH-PO968

Trends in Colorectal Cancer Screening in U.S. End-Stage Renal Disease Population

Kevin C. Abbott,1 Chyng-Wen Fwu,2 Paul L. Kimmel,1 Paul W. Eggers.1 Div of Kidney, Urologic Hematologic Diseases, NIDDK, NIH, Bethesda, MD; 2Social & Scientific Systems, Inc., Silver Spring, MD.

Background: Screening for colorectal cancer (CRC) has been recommended for those over 50 years old. Medicare coverage of CRC screening began in 2000. Dialysis patient care is shared by many practitioners, perhaps leading to therapeutic nihilism and insufficient screening. CDC data show almost 2/3 of patients at risk report CRC screening. We determined rates of CRC screening in ESRD hemodialysis (HD) patients, compared to a 5% Medicare sample, and to assess secular trends.

Methods: We used data from the 2001-2011 USRDS to describe trends in percentages of HD patients receiving CRC screening tests per year. We limited our study population to patients with Medicare Part A and B as primary payer to ensure complete Medicare claims data for CRC screening. Current Procedural Terminology /Healthcare Common Procedure Coding System (CPT/HCPCS) codes identified Medicare physician and supplier billing data for screening: colonoscopy (G0105 and G0121), sigmoidoscopy (G0104), and fecal-occult blood test (FOBT; G0107, G0328, and 82270). We compared HD data to a 5% Medicare sample.

Results: Overall, the proportion of HD patients having CRC screening decreased from 6.1% annually in 2001 to 3.5% in 2011 due to decreased use of FOBT. There was a persistent increase in the proportion of patients with colonoscopy or sigmoidoscopy for CRC screening in the 11-year study period, from 0.3% to 1.0% annually. In most years, male, black and age 50-75 patients were more likely to receive colonoscopy or sigmoidoscopy than female, white, and other age subgroups. In 2006, the most recent available comparable year, CRC screening in HD patients was less than that of the general Medicare population; 0.8% vs. 1.6% annually for colonoscopy and sigmoidoscopy, 6.0% vs. 8.1% including FOBT.

Conclusions: Screening for CRC in ESRD HD patients is less frequent than in the general Medicare population, and considerably less than CDC recommendations. Differences in ascertainment methods (CDC uses self-report) may account for most of the disparity from CDC estimates.

TH-PO969

Increasing Prevalence of Withdrawal from Dialysis: Trends from 2004-2011

James B. Wemore,1 Peer Kidney Care Initiative Investigators.2 CDRG, MMRF; 2Peer Kidney Care Initiative.

Background: Voluntary withdrawal from dialysis, which frequently occurs when a patient perceives dialysis as having become unduly burdensome, is an area of increasing interest. How early withdrawal, defined as that occurring within 1 year of dialysis initiation, has changed over the past decade has not been fully explored.

Methods: Patients initiating dialysis between 2004 and 2011 were selected from the Centers for Medicare & Medicaid Services End-Stage Renal Disease (ESRD) database. Information on withdrawal was ascertained from the ESRD Death Notification Form by the presence of code 104 (“withdrawal”) in the 1st or 2nd position. The unadjusted cause-specific monthly mortality rate (deaths per 100 pt-years) was calculated for patients initiating in each year.

Results: Annual incident counts ranged from 87,174 (2004) to 100,665 (2011). Overall, during the first year of dialysis, the withdrawal rate was highest soon after initiation, peaking at month 2 for all years except 2004. Rates then decreased until approx. month 9, stabilizing through month 12. Additionally, early rates more than tripled over the study period, from 1.9 per 100 pt-years at month 2 in 2004 to 5.9 in 2008 to 6.4 in 2011.
Conclusions: Withdrawal rates are high in the weeks immediately after dialysis initiation, a pattern more marked in recent years. Because patients who withdraw soon after initiation may be suboptimal dialysis candidates, future work should focus on determining whether a tailored approach, designed to identify individual patient goals and present the risks and benefits of dialysis and viable alternatives such as conservative care, might provide optimal patient-centric care.

Funding: Pharmaceutical Company Support - Financial support for the Peer Kidney Care Initiative is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc., DSI Renal, Fresenius Medical Care, Independent Dialysis Foundation, Northwest Kidney Centers, Renal Ventures Management, Satellite Healthcare, The Rogosin Institute, and U.S. Renal Care. In collaboration with the Chief Medical Officers of these organizations, the Peer Kidney Care Initiative is operated by the Chronic Disease Research Group, a division of the Minneapolis Medical Research Foundation, in Minneapolis, MN., Private Foundation Support

TH-PO970

Background: Fluid overload in patients on conventional hemodialysis is a frequent complication associated with increased hospitalizations, cardiovascular morbidity and all-cause mortality. There are multiple patient and physician-related factors that lead to fluid overload. Individualizing dialysate sodium prescription and minimizing the sodium gap are potential modifiable risk factors.

Methods: We performed a cross-sectional study on 111 prevalent stable conventional hemodialysis patients at the McGill University Health Center. The associations of sodium gradient with various hemodialysis parameters of fluid status including interdialytic weight gain percentage (IDWG%), ultrafiltration (UF) rate, blood pressure (BP), interdialytic hypertension and intradialytic hypertension were analyzed.

Results: The mean serum sodium gradient was 4.6 ± 3.6 mEq/L. with a mean pre-dialysis sodium of 142.0 ± 3.0 mEq/L. There was a direct correlation between sodium gradient and interdialytic weight gain percentage (p=0.49, p<0.01) as well as ultrafiltration rate (p=0.44, p<0.01). The average sodium gradient was significantly higher in patients with IDWG > 3% (6.36 vs. 3.16 mEq/L, p<0.01) and in patients with UF rate > 10ml/kg/h (6.01 vs. 4.23 mEq/L, p=0.03). In a univariate logistic regression model, a higher sodium gradient was associated with interdialytic weight gain percentage (OR 3.6 mEq/L, p<0.01) and in patients with UF rate > 10ml/kg/h (6.01 vs. 4.23 mEq/L, p=0.03). There was a direct correlation between sodium gradient and blood pressure (pre-dialysis or post-dialysis) or number of antihypertensive medications.

Conclusions: A higher sodium gradient was associated with significant increases in IDWG and UF rate which are associated with poor outcomes. Sodium gradient was not associated with interdialytic hypertensive episodes. With the parameters we measured in this study, it appears that individualizing dialysate sodium prescription to minimize sodium gap leads to less fluid overload in conventional hemodialysis patients.

TH-PO971

Calcific Uremic Arteriolopathy: Mortality Outcomes with and without Sodium Thiosulfate Therapy Chamberlain L. Obialo, Alexander Quarshie. Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; Clinical Research Center, Morehouse School of Medicine, Atlanta, GA, Venezuela.

Background: Calcific uremic arteriolopathy (CUA) or Calciaphaxis is commonly seen in patients with end stage kidney disease (ESKD) and carries a high mortality risk. There is no definitive therapy for this condition but promising results have been reported in patients treated with intravenous sodium thiosulfate (STS). However, the mortality advantage of therapy with STS over therapy without STS remains unknown.

Methods: We retrospectively reviewed our ESKD patient’s records over a 10-year period and identified 45 biopsy confirmed cases of CUA. Associations between patients who received STS therapy and those who did not and various categorical end points were assessed using the Pearson chi-squared tests while differences in continuous end points were examined using Mann-Whitney-U tests. Survival analysis utilized Kaplan-Meier plots. All statistical tests were two-sided, and level of significance set at 0.05.

Results: The mean age of the 45 cases was 63, 60% female, mean body mass index was 34 and mean dialysis vintage was 4 years. Of the 45 cases, 23 (51%) received STS while 22 (49%) did not. The mean level of serum albumin, phosphorus and parathyroid hormone was 2.8 g/dl, 6.7 mg/dl and 989 pg/dl respectively. One –year mortality was 22% in STS vs. 50% in no STS cases, p = 0.05. The overall survival of the patients over the 2- year study period was significantly superior in the recipients of STS than in those who did not receive STS, p = 0.03.

Patients who did not receive STS were also more likely to have major surgeries than those who received STS, 86% vs. 52%, p = 0.01.

Conclusions: Sodium thiosulfate therapy appears to confer both short term and long term survival advantage over no STS. We encourage hospitals and dialysis companies to procure and make this agent more available to physicians.

Effect of High-Dose and High-Flux Hemodialysis on Markers of Inflammation in the HEMO Study Kristen L. Nowak1, Tom Greene,2, J. Alan Ying,2 Alfred K. Cheung,2 Michel Chonchoel.1 1Univ of Colorado Denver; 2Univ of Utah.

Background: Hemodialysis treatment induces markers of inflammation, which could affect clinical outcomes. This study sought to determine whether high-dialysis dose and high-flux dialysis would improve markers of inflammation compared with standard dialysis dose and low flux dialysis.

Methods: The HEMO Study was a randomized multicenter study of the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum high sensitivity C-reactive protein (hs-CRP, pre-specified primary outcome for this set of analyses) and interleukin-6 (IL-6) were measured in stored serum samples in 1,846 HEMO participants. For each inflammatory marker we used a joint multi-state modeling approach to estimate the proportion of patients in 5 ordered states (S) over 3 annual assessments while accounting for mortality: S1=deceased (score=0); S2=alive in highest quartile (score=1); S3=alive in 2nd quartile (score=2); S4=alive in 3rd quartile (score=3); and S5=alive in lowest quartile (score=4). The mean rank was computed over 3 yrs of follow-up and compared between the randomized groups.

Results: Randomized patients had high rates of coexisting conditions: 45% had diabetes, and 80% had a history of cardiac disease. Characteristics of the patients in the two dose groups were similar, as were the characteristics of those in the two flux groups. The state distribution of hs-CRP in each year by dose (KTV) group and by flux group for hs-CRP are shown in Figure 1.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Comorbidity data source may impact performance evaluation. The impact is larger for smaller groups, and may increase with prevalent patients included.

Thematic Analysis of the Medical Records of a National Cohort of Patients Who Initiated Maintenance Dialysis: 2000-2009

Susan P.Y. Wong,1 Elizabeth Vig,2 Nilka Rios Burrows,2 Chuan-fen Liu,1 Desmond Williams,3 Paul L. Hebert,1 Ann M. O’Hare.1 1Univ of Washington; 2Center for Disease Control.

Background: Little is known about how decisions to initiate dialysis take shape in clinical practice.

Methods: We performed a qualitative thematic analysis of the medical records of patients who initiated maintenance dialysis to understand factors that impact decisions to initiate maintenance dialysis as they occur in clinical context. We analyzed key care processes, patient-provider interactions and patient and/or provider concerns and considerations relevant to the decision to initiate dialysis as documented in the electronic medical records of a national random sample of patients for whom the decision to initiate maintenance dialysis was made at the Department of Veteran Affairs between 2000 and 2009 (n=1,691).

Results: We identified three dominant, overlapping themes pertaining to the decision to initiate dialysis: 1) dialysis initiation as process, which describes the decision to initiate dialysis as integrated with other treatment decisions and unfolding over time rather than an isolated decision occurring at a fixed point in time; 2) sources of momentum for dialysis initiation, which describes factors that appeared to hasten the process of dialysis initiation and included hospitalization for acute illness and efforts to optimize patients’ clinical status for future medical interventions; and, 3) push-pull dynamics between patients and providers, which describes the sometimes adversarial relationship between patients and providers during the process of dialysis initiation in which patients were often portrayed by providers as “resistant” to dialysis initiation while providers appeared paternalistic and safety conscious in their approach towards treatment decisions.

Conclusions: Our analysis of the medical record underscores the complexity of treatment decisions about dialysis initiation in real-world clinical settings and supports a re-conceptualization of dialysis initiation as a process that unfolds over time rather than as a discrete treatment decision occurring at a fixed point in time.

Trends in 30-Day Readmission Rates in Dialysis Patients During an Era of Medicare Payment Policy Changes, 1996-2012

Allan J. Collins,1 Peer Kidney Care Initiative Investigators.2 1MRBF; 2Peer Kidney Care Initiative.

Background: High hospital readmission rates, which may indicate inadequate quality of care and result in unnecessary expenditures, have been a recent focus for Medicare. Medicare has enacted payment-related policy changes: freezing the inpatient payment rate (1997), expanding “disproportionate share” hospital payments (early 2000s), tying

isCRP did not differ significantly between dose (p=0.83) or flux groups (p=0.53). Similar results were obtained for IL-6.

Conclusions: Over 3 years, neither high-dose nor high-flux dialysis exhibited a beneficial effect on markers of inflammation.

TH-PO973

Comorbidity Data Source May Impact SMR/SHR Calculation

Jianmeng Liu,1 Mahesh Krishnan,2 Jincheng Zhou,1 Kimberly M. Nieman,1 Yi Peng,1 David T. Gilbertson.1 1CDRG, MMRF, Mpls, MN; 2DaVita Healthcare Partners, Denver, CO.

Background: Standardized mortality and hospitalization ratios (SMRs and SHRs) are used to measure dialysis facility performance, with adjustment for demographics and comorbidities derived from the end-stage renal disease (ESRD) Medical Evidence (ME) Report. Sensitivities are low for ME-based comorbidities. We investigated the effect on SMR and SHR calculations by comparing ratios adjusted for claims-based comorbidities.

Methods: Using the USRDS ESRD database, we included US hemodialysis patients who initiated dialysis July 1-December 31, 2006-2010, had Medicare as primary payer, were aged ≥ 66 years, and had no prior transplant (TX). Patients were followed from dialysis initiation to the earliest of death, TX, modality change, or 1 year. SMRs and SHRs were calculated for patients in for-profit/non-profit and rural/urban facilities for ME-based and claims-based comorbidity, separately. Cox models were used for expected number of deaths and piecewise Poison models for expected number of hospitalizations. Agreement of comorbidity between the two sources was measured by a kappa statistic.

Results: 73,950 incident hemodialysis patients were included. Kappas for comorbidity agreement were low, less than 0.5, except for diabetes (0.77). Percent of patients with claims-based comorbidity was similar for for-profit and non-profit facilities; ME-based comorbidity was lower for for-profit facilities. Differences between ME-based and claims-based SMRs/SHRs were statistically significant. Compared with ME-based SMR/SHR, claims-based ratios decreased 0.9%/0.6% for for-profit and 1.0%/0.7% for urban facilities and increased 3.4%/2.8% for non-profit and 5.9%/4.1% for rural facilities.

Conclusions: Representing presenting author.
reimbursement for outpatient hemodialysis services to the number of monthly visits (2004), introducing the new Medicare prospective payment system (2011), and instituting the “hospital payment penalty” (2012). Given evidence demonstrating links between these changes and readmission rates in the general population, we sought to examine changes in 30-day readmission rates in dialysis patients 1996–2012.

Methods: Data were obtained from the Centers for Medicare & Medicaid Services End-Stage Renal Disease database. Dialysis patients were assessed for discharges from short-term or critical access hospitals. Thirty-day readmission rates were calculated, without adjustment for differences in patient case-mix or hospital characteristics.

Results: All-cause readmission rates increased modestly over the period studied except for 2012. The nadir was 32.8% in 1998; the rate increased to 34.6% in 2005, fell to 34.1% in 2009, and peaked at 34.8% in 2010. Discharge data in the first 6 months of 2012 showed further decrease (32.8%). In comparison, other studies show that the rate in the general Medicare population was relatively stable 2007-2011 (19.0%), and decreased in 2012 (18.4%).

Conclusions: Thirty-day readmission rates were substantial in dialysis patients compared with general Medicare patients, possibly reflecting case-mix. How public policy changes may have affected potentially avoidable readmissions should be more fully explored. Cause-specific readmission rates might provide a better reflection of quality of care and should be examined.

Funding: Pharmaceutical Company Support - Financial support for Peer is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc. TH-PO976

The Impact of Volume Status on Nocturnal Hypoxia in Patients Undergoing Maintenance Hemodialysis Farhanah Yousaf, Mitesh K. Patel, Sherbeth Marie C. Young, Chaim Charytan, Alla Goldberg, Bruce S. Spinowitz. New York Hospital Queens, Flushing, NY.

Background: Hemodialysis patients experience changes in volume status according to hemodialysis schedule. Excess fluid volume may shift to the neck upon assuming a recumbent position during dialysis leading to engorgement of peripheral venules. We explored the impact of volume status on nocturnal hypoxia in the hemodialysis population.

Methods: Following local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis (HD) for at least 3 months were consented to complete two nights of nocturnal oximetry using Pulsox 300i wristwatch. HD night was defined as the night of HD treatment whereas non-HD night was defined as the night on which no HD was performed. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Motion artifacts and aberrant data were also excluded from the analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds, per hour. Paired t-test was used to compare HD and non-HD night related data.

Results: Twenty HD patients (11 males and 9 females) aged 54 ± 13 years with a mean body mass index of 25.5 ± 4.6 kg/m² and neck circumference of 38.4 ± 5.8 cm participated in the study. Mean ODI was 21.2 ± 21.1 on HD night versus 20.0 ± 19.8 on non-HD night (p=0.6) with a mean interdialytic weight gain of 1.9 ± 1.3 kg. The lowest recorded mean saturation was 76.2 ± 10 % on HD night versus 73.5 ± 11 % on non-HD night (p<0.3). Eleven of 20 patients, with a mean interdialytic weight gain of 2.1 ± 1.5 Kg, experienced worsening of ODI on non-HD night (16.9 ± 17.9) versus HD night (11.6 ± 13.8) [p=0.008]. Meanwhile, nine patients, with an mean interdialytic weight gain of 1.5 ± 0.9 Kg, exhibited improvement in ODI on non-HD night (23.8 ± 22.4) versus HD night (32.9 ± 23.1) [p=0.04].

Conclusions: Volume status alone does not explain HD to non-HD variation in nocturnal hypoxemia seen in ESRD population. Both central and obstructive mechanisms are likely involved. Additional research is warranted to further explore this phenomenon and develop preventive strategies.

TH-PO977

Hospital Readmission within 30 Days of Discharge Among Adults Receiving Dialysis Lorien S. Dalrymple,1 Barbara A. Grimes,2 Patrick S. Romano,1 Yi Mu,1 Dahn V. Nguyen,1 Kirsten L. Jhansohn,1,2 UC Davis; UCSF; UC Irvine; San Francisco VA.

Background: Hospital readmission is common in adults receiving dialysis. Few studies have examined the timing or causes of 30-day hospital readmission.

Methods: We used the USRDS to examine adults initiating dialysis Jan 2009 through Dec 2010 who had Medicare as the primary payer. The cohort was followed from day 90 of dialysis for up to one year; with censoring for death, renal recovery or transplant. We classified the principal cause of the index hospitalization and hospital readmission using Clinical Classification Software.

Results: Our cohort consisted of 103,381 patients. During follow-up, 50,639 patients experienced 89,728 index hospital admissions; 5% resulted in in-hospital death. Of the 85,284 live hospital discharges, 25,792 (30%) were associated with 30-day readmission. The median time to readmission was 11 [5, 19] days. Leading causes of readmission by cause of index hospitalization are in Table 1.

For the 5 most common causes of hospitalization, the principal cause for readmission was in the same category as the initial admission, accounting for 18-32% of readmissions.

Conclusions: Thirty-day hospital readmission in Medicare recipients on dialysis is frequently leading to causes related to the initial admission.

TH-PO978

Racial/Ethnic and Age Differences in Cause-Specific Deaths Among U.S. Dialysis Patients Alison J. Yu,1 Keith C. Norris,2 Alfred K. Cheung,1 Guofen Yan.1 Univ of Southern California; 2 UCLA; 3 Univ of Utah; 4 Univ of Virginia.

Background: Recent research reported that Hispanics have the lowest all-cause mortality, African Americans (AAs) intermediate, and Whites the highest among U.S. dialysis patients over 30 years old. The objective of this study is to examine whether this risk pattern varied depending on the cause of death.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS, with no prior kidney transplantation. We examined 5 major cause-specific deaths: cardiovascular (CVD), infection, malignancy, others, and unknown. Cause-specific hazards for each cause-specific death were compared among AAs, Hispanics, and Whites for overall and stratified by age groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

322A
Results: After adjustment for multiple covariates (Table), compared with Whites, in all age groups, Hispanics consistently had lower risks of cause-specific deaths for all major causes examined (HRs<1), while AAs also had lower risks except for the cause of infection, for which AAs had significantly higher risks in age groups of <50 and >80 years (HRs from 1.07-1.94).

Table. Adjusted cause-specific hazard ratios (HRs) for AAs and Hispanics vs. Whites

</table>

Note: all significant at p<0.05 except the ones indicated by *.

Conclusions: The racial difference observed in all-cause mortality, in which Hispanics have the lowest risk, AAs intermediate, and Whites the highest, was also noted for major cause-specific deaths in most age groups, except for the cause of infection. Both younger and older AAs are at the greatest risk of death due to infection. Further studies are needed to explore the specific reasons responsible for the higher risk of infection-related death in AAs.

Dialysis Therapy and Mortality in Older Heart Failure Patients with Advanced Chronic Kidney Disease: The Kaiser Permanente MATCH Study
David Lan, Sijie Zheng, Sharina Belani, Jingrong Yang, Thida Tan, Juan Daniel Ordonez, Susan Kim, Alan S. Go. Kaiser Permanente Northern California.

Background: Heart failure (HF) and chronic kidney disease (CKD) often coexist and those with both have much worse outcomes than having either alone, with limited data to guide optimal management. We evaluated the outcome of dialysis therapy in a diverse elderly cohort with HF and advanced CKD.

Methods: In Kaiser Permanente Northern California, a large integrated healthcare system, we identified members ≥70 years with HF and estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m² between 2008-2012 and no prior renal replacement therapy, cancer, cirrhosis or organ transplant. Through 2013, we identified patients who started chronic dialysis and individually matched controls who were alive on the dialysis start date of the matched case along with age, gender, diabetes status, and high-dimensional propensity score to start dialysis. Demographics, clinical features and drug use were obtained from electronic records. We calculated rates of death through 2013 and examined the impact of dialysis on mortality using Cox regression.

Results: We identified 334 eligible HF-CKD cases who initiated dialysis and 899 matched control HF-CKD patients. Mean age was 80.1±8.7 yrs, with 51% women, 33% black and 72% diabetic. Case and control patients were well-matched across characteristics, except for controls being less likely to be Hispanic or have proteinuria, or to receive alpha or calcium channel blockers or thiazide diuretics; and more likely to have prior intracranial bleed, liver disease, dementia and higher blood pressure, hemoglobin and mean eGFR (16.4 vs. 12.0 ml/min/1.73 m²). Incidence of death was 32 per 100 p-y in combined case and control patients. Among matched patients, after further adjustment for residual differences in patient features, dialysis was independently associated with a 47% lower rate of death (hazard ratio 0.53, 95%CI:0.41-0.67).

Conclusions: In older adults with HF and advanced CKD, dialysis was independently associated with a lower mortality. Randomized trails are needed to determine the net outcomes of dialysis related to both length and quality of life in the elderly with HF and advanced CKD.

Funding: Private Foundation Support

TH-PO980
Gender, Poverty, and Dialysis Mortality in Adults with Sickle Cell Disease

Background: Chronic dialysis patients with sickle cell disease (SCD) have increased risk of mortality compared with the general US dialysis population. The contributions of gender and neighborhood poverty to dialysis mortality in SCD patients are largely unknown.

Methods: Using USRDS data, we linked all US adults with SCD who initiated dialysis between 1995-2012 with zip-code level US Census neighborhood data. We performed multivariable Cox regression models with adjustment for age, dialysis type, BMI, and diabetes status to compare mortality between men and women, stratified by neighborhood poverty level. Neighborhoods with ≥20% of households living below the federal poverty level. Neighborhoods with ≥20% of households living below the federal poverty level.

Results: We included 334 eligible HF-CKD cases who initiated dialysis and 899 matched control HF-CKD patients. Mean age was 80.1±8.7 yrs, with 51% women, 33% black and 72% diabetic. Case and control patients were well-matched across characteristics, except for controls being less likely to be Hispanic or have proteinuria, or to receive alpha or calcium channel blockers or thiazide diuretics; and more likely to have prior intracranial bleed, liver disease, dementia and higher blood pressure, hemoglobin and mean eGFR (16.4 vs. 12.0 ml/min/1.73 m²). Incidence of death was 32 per 100 p-y in combined case and control patients. Among matched patients, after further adjustment for residual differences in patient features, dialysis was independently associated with a 47% lower rate of death (hazard ratio 0.53, 95%CI:0.41-0.67).

Conclusions: In older adults with HF and advanced CKD, dialysis was independently associated with a lower mortality. Randomized trials are needed to determine the net outcomes of dialysis related to both length and quality of life in the elderly with HF and advanced CKD.

TH-PO981
Peritoneal Dialysis (PD) Patient Outcomes Under the Dialysis Prospective Payment System (PPS)
Marc Turement, Regina M. Baker, Jeffrey Pearson, Chad M. Cogan, Parma Mukhopadhyay, Elizabeth L. Cope. Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: The use of PD was expected to be incentivized by the expanded Medicare PPS that was implemented in 2011. There is early evidence under the PPS of additional incident ESRD patients and dialysis facilities using PD (Hirth et al 2013; Turement et al 2014). More widespread PD use could have implications for PD outcomes due to potential changes in PD selection or in the experience of dialysis providers with PD. This study assessed PD patient outcomes before and after the new PPS was implemented.

Methods: This study included n=36,582 incident ESRD patients for whom PD was identified as the intended initial dialysis modality on the CMS ESRD Medical Evidence Form during 2008-12. We evaluated 1-year PD technique failure and PD patient mortality using data from Medicare claims, the Standard Information Management System, CROWNWeb, and the CMS Death Notification Form. PD technique failure was ascertained when hemodialysis was used for at least 60 days.

Results: Selection of PD increased from 5.8% to 8.4% of incident patients between 2008 and 2012 (see Figure).

Trends in PD Modality and One-Year PD Patient Outcomes, by Year of Incidence, 2008-2012

*Demonstrator excludes patients receiving transplants within one year and patients with unknown modality at one year.

Conclusions: Men with SCD who live in poor neighborhoods were at highest risk of death. Efforts to address socioeconomic barriers may be an important target for improving survival in this population.

Funding: NIDDK Support, Other NIH Support - NHLBI
During this period, 1-year PD technique failure decreased from 18.8% to 16.1% of patients and 1-year PD patient mortality decreased from 9.4% to 8.6% (see Figure). Outcomes were relatively stable or improving across patient age, race, and Hispanic ethnicity subgroups and for patients in both urban and rural areas.

Conclusions: In the context of expanding PD use under the new PPS, there is no early evidence of worsening overall PD patient outcomes or of growing disparities in PD patient outcomes by demographic group or by urban/rural location. Instead, there were lower levels of PD technique failure and PD patient mortality in the initial years of the new payment system.

Funding: This study was supported by National Institute on Minority Health and Health Disparities (NIH-NIMHD).

TH-PO982

Cognitive Impairment and Mortality in Adults on the Kidney Transplant Waitlist

Background: Older adults with poor cognitive function are at increased mortality risk. It is unclear whether ESRD patients of all ages with cognitive impairment are at increased mortality risk of while on the kidney transplant (KT) waitlist.

Methods: 918 ESRD patients being evaluated for and waitlisted for KT (no previous listings) at Johns Hopkins were enrolled in a prospective cohort study (11/2009-5/2014). The Modified Mini Mental Status (MMS), a test of global cognitive function (range 0-100, higher scores represent better function) was assessed at KT evaluation. Global cognitive impairment was defined as MMS score<80). Mortality risk by MMS score and cognitive impairment (separately) was estimated using an adjusted Cox proportional hazards model; participants were censored at the waitlist removal, time of KT or administrative end of follow-up.

Results: At KT evaluation, the mean (SD and range) age was 54 (14; 18-86), 57% were male, and 46% were African American. The mean (SD and range) MMS score was 82.6 (11, 47-100) and 52% were classified as having cognitive impairment. 45 participants died over an average of 1.7 years of follow-up. Mortality risk was greater for adults on the KT waitlist who had worse MMS scores (1 point decrease in MMS score: HR=1.05, 95% CI: 1.02-1.08, P=0.003) and those with cognitive impairment (HR=2.51, 95% CI: 1.70-3.71, P<0.001) were at increased mortality risk.

Conclusions: The results support the hypothesis that MMS should be included in KT patient evaluations, in addition to MDRD and other risk scores. Cognitive impairment may be a predictor of mortality for KT waitlist patients.

Funding: This research was supported by an unrestricted grant from the American Society of Transplantation (AST) and National Institute of Diabetes and Digestive and Kidney Diseases (K01DK094853). The authors and Johns Hopkins declare no conflicts of interest.

TH-PO984

Who Makes the Best Exit Site: Nephrologist or Surgeon? Vaibhav S. Keskar, Mollura, B. Bliany, Brian Blew, Jeffrey Weiten, Brendan McCormick. The Ottawa Hospital, Univ of Ottawa, Ottawa, ON, Canada.

Background: Buried peritoneal dialysis (PD)catheters are placed months before dialysis is needed and the exit site is created at the initiation of dialysis by the nephrologist. In contrast, the exit site of an unburied catheter is created by the surgeon at the time of insertion. Our PD unit uses both methods of catheter placement. We undertook this study to compare the outcomes of the two methods of exit site creation.

Methods: The charts of all patients who initiation PD between Jan 2012 and Dec 2013 were reviewed. At each clinic visit, exit sites were graded by the PD nurse into standard predefined groups: perfect, good, equivocal and infected. Primary outcome was the frequency of perfect exit sites at 6, 12, and 24 months after initiation of PD. Secondary outcomes were exit site infections, peritonitis and technique failure due to exit site infection.

Results: 119 patients started PD during the period of interest and 114 remained on PD at 12 months. 52 patients had buried catheters exteriorized at the time of starting PD (group A) and 62 patients had unburied catheters (Group B). Group A had more males (71% vs 48%), had higher mean age (65±14 vs 59±15) and had most of the patients as incident dialysis patients. Diabetic nephropathy was the most common underlying disease in either group (61.53% and 51.61%). Group B had a higher frequency of perfect exit sites at 2 months but this difference disappeared by 6 and 12 months. There was a trend towards more exit site infections in Group A but this did not translate into more technique failure.

Conclusions: Buried catheters are less likely to have perfect appearance at two months compared to unburied catheters; however this is no longer significant at six and 12 months. The trend towards more exit site infections with buried catheters suggests that there may be clinical consequences of the tissue trauma at time of exteriorization. Consideration should be given to the use of prophylactic antibiotics at exteriorization.

TH-PO985

Background: Peritonitis, tunnel and catheter exit site (ESI) infections are the most serious complications of peritoneal dialysis (PD). We studied the effect of antibiotic ointment (EUDRAC: 2009-016835-36) on catheter-related infections (CRIs) and morbidity.

Methods: Allocation was stratified in blocks of 4:1 ratio. Ointment containing 2% colistin, tobramycin, amphotericin B and 4% vancomycin or normal saline were applied to the CSE over 1 year. Follow-up period was 3 months after the last dose. Exit site infection (ESI) was defined as erythema, edema or local pain with purulent secretion and positive culture. Antibiotic therapy was given according to local protocols.

Results: 140 patients were included, 6 didn’t meet entry criteria. Characteristics and dialysis parameters of the 65 in the control group (CG) and 69 intervention group (IG) patients were comparable.

Conclusions: Antibiotic ointment significantly reduced the incidence of ESI.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Mean study duration was 0.6 (IG) vs 0.6 (CG) years (ns). 26 episodes of CR1 (11 ESL, 4 tunnel, 11 peritonitis) occurred in the CG and 12 in the IG (3 ESL, 0 tunnel, 9 peritonitis) (p<0.001). Etiology of ESI was Staphylococcus aureus (x7), Corynebacterium spp., Pseudomonas aeruginosa, E. coli, Serratia spp., coagulase-negative S. (x2) and 1 negative culture in the CG and S. aureus (x1), 1 Gram-negative bacillus and 1 negative culture in the IG. Systemic or topical antibiotics were given for ESI in 11 (CG) and 2 patients (IG) (p=0.01), respectively. Hospital admissions were 23 (CG) and 15 (IG). Local side effects were significantly increased in the IG.

Conclusions: Local prophylaxis with a broad-spectrum antimicrobial ointment is associated with a significant reduction in ESI and systemic antibiotic use without associated bacterial resistance. Significant local side effects were observed.

Association Between Plasma Fibroblast Growth Factor-23 and Carotid Artery Atherosclerosis in Peritoneal Dialysis Patients

Nanmei Liu, Jimin Hospital of Shanghai.

Background: We investigate the association between plasma fibroblast growth factor-23 (FGF-23) levels and carotid artery atherosclerosis of 125 stage 5 chronic kidney disease (CKD5) patients, who are doing continuous ambulatory peritoneal dialysis (CAPD) at renal dialysis of Shanghai Jimin Hospital in China.

Methods: A retrospective cohort study of individuals 15 years of age and older, divided into two cohorts according to carotid intima-media thickness (CIMT): CIMT normal cohort (CIMT<0.9mm) and CIMT thickening cohort (CIMT³0.9mm). Plasma FGF-23 concentrations were determined by ELISA. CIMT thickness and atherosclerotic plaques were measured by carotid ultrasound.

Results: Of the 125 PD patients, the CIMT was thickened in 82 patients (65.6%). Compared with the CIMT normal patients, plasma FGF-23 concentration was significantly increased (p<0.01) in the CIMT thickening cohort (Table 1). Linear regression analysis discovered an obvious positive correlation between plasma FGF-23 and CIMT (r=0.416, P=0.006) (Table 2). Multiple regression analysis indicated that plasma FGF-23 level was independently associated with plasma FGF-23 and CIMT (β=0.421, t=2.607, P<0.01) (Table 3).

Conclusions: The level of plasma FGF-23 was positively correlated with CIMT and played an important role in development of carotid artery atherosclerosis in peritoneal dialysis patients.

Atherogenic Index of Plasma Is Associated with Insulin Resistance in Non-Diabetic Peritoneal Dialysis Patients

MieJune Lee, 1 Jae Eun Um, 2 MiEun Wu, 1 Tae Ik Chang, 1 Tae-Hyun Yoo. 1 'Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; 2 'Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ College of Medicine, Seoul, Korea; 3 'Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.

Background: Insulin resistance (IR) is an independent risk factor for cardiovascular morbidity and mortality. Although many factors including uremia, chronic inflammation, and abnormal adipokine levels are known to contribute to the development of IR, the role of pro-atherogenic lipoprotein on IR remains unknown in peritoneal dialysis (PD) patients. Therefore, we investigated the independent association between pro-atherogenic lipoprotein and IR in non-diabetic PD patients.

Methods: We conducted a cross-sectional study in 75 non-diabetic PD patients. Pro-atherogenic lipoprotein was assessed by the atherogenic index of plasma (AIP, log transformed triglyceride to high-density lipoprotein cholesterol ratio). IR was determined by homeostatic model assessment-IR (HOMA-IR). Patients were divided into the higher and lower HOMA-IR group according to the median value of HOMA-IR. Independent association between AIP and HOMA-IR was ascertained by multivariate linear regression analysis.

Results: The mean age of the patients was 52.1±11.2 years, 35 patients (46.7%) were male. The mean value of AIP was 0.38±0.33 and the median value of HOMA-IR was 1.58 (interquartile range, 0.88 to 2.76). AIP was significantly greater in the higher HOMA-IR group (0.50±0.27 vs. 0.53±0.32, P=0.001). AIP was negatively correlated with systolic blood pressure (r=-0.32, P=0.005) and log adiponectin (r=-0.42, P=0.001) and positively correlated with sagittal abdominal diameter (r=0.25, P=0.033), residual renal function (r=0.29, P=0.012), serum albumin (r=0.26, P=0.026) and log HOMA-IR (r=0.54, P<0.001). Independent multiple regression analysis of AIP (β=0.251, P<0.001) was independently associated with HOMA-IR after adjustment for confounding factors.

Conclusions: Pro-atherogenic lipoprotein abnormality determined by high AIP might be implicated with development of IR in non-diabetic PD patients.

TH-PO988

Reducing Mortality in CAPD Patients by Statin

Yong-kwu Lee, Tae Ik Chang, Sug kyun Shin. Nephrology Div, Dept of Internal Medicine, National Health Insurance Corporation, Ilsan Hospital, Goyang, Korea.

Background: Patients who are on CAPD (Continuous Ambulatory Peritoneal Dialysis) shows higher serum LDL cholesterol and Triglyceride compared to patients who are on hemodialysis. But higher cholesterol level does not seem to effect on raising mortality or cardiovascular morbidity and mortality. On the contrary, lower serum cholesterol level in CAPD patients tends to raise mortality and morbidity due to poor nutritional status.

Methods: This study is a retrospective study designed to evaluate the effect of cholesterol level, statin on CAPD outcome and mortality. Patients who were on peritoneal dialysis for at least 6 months since March 1st, 2000 were included. A total of 467 patients were enrolled in this study. Patients’ biological parameter, biochemical parameter and morbidity/mortality during CAPD maintenance period were collected.

Results: Patients whose initial cholesterol level were above 240 mg/dL shows significantly low CAPD failure rate compared to patients whose initial cholesterol level were below 200 mg/dL (OR=0.469, P=0.049). Patients whose average LDL-cholesterol during CAPD period were over 100mg/dL showed significantly higher mortality compared to patients whose initial LDL-cholesterol level were below 100mg/dL (OR=1.848, P=0.024).

Patients whose compliance to statin during CAPD period was over 80% showed significantly low mortality compared to patients who did not take statin during CAPD period (OD=0.556, P=0.020). Patients showed no significant difference in mortality due to total cholesterol, HDL cholesterol levels and patients showed no significant difference in CAPD failure due to HDL/LDL cholesterol, statin usage.

Conclusions: In CAPD patients, serum total cholesterol level should be targeted higher than HD or CKD patients. On the contrary, similar to HD or CKD patients, Statin should be administered and LDL cholesterol should be lowered during CAPD period to lower mortality. To identify the difference in cholesterol mechanism of CAPD patients further, in depth study over adequate cholesterol level in CAPD patients needs to be proceeded.

TH-PO990

Using Daily Remote Biometric Monitoring in Peritoneal Dialysis

Suje G Lee, 1 Manya Magnus, 2 Neal Sikk, 1 1 Medicine, George Washington University, Washington, DC; 2 Epidemiology and Biostatistics, George Washington University, Washington, DC; 3 Emergency, George Washington Univ, Washington, DC.

Background: Peritoneal dialysis(PD) requires self-monitoring with daily blood pressure(BP), weight, & physical examination. Patients(Pts) don’t always perform procedures or record results. We aim to determine associations between daily remote biometric monitoring(RBM) & clinical and pt satisfaction outcomes.

Methods: Pts were provided with BP monitoring equipment & scale which were capable of announcing the results, transmitting the results via Bluetooth technology to a hub located in the pt’s home & via 2G/3G cellular signal to a Telehealth call center. PD nurses viewed results or alerted to abnormal results.

Results: 300 subjects(subjects) from 10 PD units were followed over at least 12 months. Demographics include male (56%), African American(AA)62%), & median age 56 yrs (IQR 44-64) and 1.86 yrs on dialysis (IQR 0.62-3.73). AA subs were more likely to use than non-AAA(69% vs 55%; p<0.05). 51% of subs used RBM, with 66% consistently using the equipment. RBM was associated with reduced risk of hospitalization (Coef -0.27, SE 0.10, p=0.006). Subs became increasingly less likely to breach any upper or lower alert threshold (OR 0.995, p=0.004). Subj satisfaction of RBM equipment for BP monitoring was 87% & scale 90%. Rural exceeded non-rural subjs in utilizing RBM (OR 4.77, 95% CI 1.34-16.98, p<0.02). Use of RBM was associated with improved perception of confidence with self-care requirements of PD easier to collect measurements (OR 2.69, 95% CI 1.52-4.76, p<0.001); more secure in their measurements (OR 3.28, 95% CI 1.71-6.26, p<0.001); getting more support from their PD doctors and nurses (OR 2.05, 95% CI 1.01-4.12, p<0.05).

Conclusions: RBM was associated with increased frequency, accuracy, and confidence of measurements to medical personnel, enhanced perception of autonomy and confidence in measurements, & reduction of hospitalizations & out of range measurements for BP. RBM was acceptable & satisfactory to PD pts. RBM offers additional tools to support PD pts in maintaining their measurement regimens & reduce negative health outcomes.

Impact of Patient-Centric Automated Peritoneal Dialysis User-Interface on Operator Learning and Confidence

Catherine Firanek, Mary Gellens, James A. Sloand. Medical Affairs, Baxter Healthcare, Deerfield, IL.

Background: Automated peritoneal dialysis (APD) is an underutilized therapy for patients with end-stage renal disease (ESRD). The perception patients may not be able to manage their own treatment setups comes into play in choice of this treatment modality. Improvements to cycler technology may help to further simplify therapy for patients.
Reducing barriers to uptake. This study aimed to determine whether a cycler-embedded, patient-centric interface offered an enhanced user experience compared to a conventional APD cycler.

Methods: 30 study participants (ages 29-84, mean 50 yrs, 67% male) diagnosed with ESRD were randomized into 2 groups using cycler with patient-centric user interface with advanced technology in development and a conventional APD cycler. Participants evaluated cycler on 2 non-consecutive days using a different cycler each day. Each participant was given a brief orientation, setup task, training session, break, followed by a setup task and questionnaire. Study results were analyzed via Fisher’s exact, Mann-Whitney and Exact binomial tests.

Results: The cycler with patient-centric user interface and advanced technology (in development) scored better on reduced reliance on printed instructions (p=0.001). Patients committed fewer deviations on the cycler in development vs the conventional cycler (2 of 19 vs 14 of 19 respectively) after training (p=0.004), including disinfecting hands (p=0.02) and line handling (p=0.01), and were more confident that they set up the cycler according to specifications (p=0.043). The new cycler scored higher in overall preference among study participants: The cycler with a patient centric user interface was rated easier to learn (p=0.005) and to use (p=0.016), preferable to use (p=0.03), and users felt more confident in choosing the new cycler at home compared to conventional cycler (p=0.004).

Conclusions: A cycler with embedded, patient-centric interface was rated higher in terms of overall reliance on instructions, task competency, ease of use and learning, preference and overall confidence of using the cycler. These findings indicate that APD cycler development could lead to increased user confidence and comfort.

Single-Site Trans-Umbilical Peritoneal Dialysis Catheter Insertion Mangalakumar Veerasingam
Nephrology, KMCH, Coimbatore, Tamilnud, India.

Background: Traditional laparoscopic peritoneal dialysis catheter placement requires two ports insertion and this could lead to complications like leak and hernia at the port sites. We describe a novel approach of using single-site trans-umbilical ports that is associated with small scar (less than 1cm) and reduced complications.

Methods: Under general anesthesia, pneumoperitoneum was created as per standard method. One 10mm and one 5mm port was inserted through trans-umbilical route to guide peritoneal dialysis catheter insertion. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunneled in the standard manner and brought out through the exit site and the titanium adaptors were fixed as usual. To prevent the migration of catheter from the pelvic cavity a trans-facial loop was placed around the catheter (freely mobile but remains in pelvis). Omentum was folded and pulled upwards to the left upper guardant and fixed to anterior abdominal wall using a trans-facial loop. The latter prevented the omentum from wrapping dialysis catheter and causing malfunction. Then the port site was closed in three layers (Video available).

Results: 10 cycler undergoing cycler insertion with this approach (Male 7, Female 3) and the mean follow up period is 11 months. None of them developed leak or catheter migration or any mechanical complication that might require catheter reposition or change.

Conclusions: Combined method of Single-site port placement, omentopexy and loop fixation of intra-abdominal segment of catheter offers the following advantages -small incision; hence risk of leak when catheter was used early after placement is low. The risk of hernia through port site is reduced and small scar will be welcome to image conscious patients. If there was any adhesion present that could be released with minimal trauma to peritoneum. Placement of a loop around the catheter prevented catheter migration. Omental wrapping was prevented by fixing this in the upper quadrant by trans-facial loop.

TH-PO992
Peritonitis and Survival following PD Catheter Insertion in Infants Joshua Zaritsky, Coral D. Hanevold, Troy Richardson, Jonathan Rodean, John P. Lawlor, Raymond P. Quigley, Alicia Neu, Bradley Warady. SCOPE Collaborative, CHA, Overland Park, KS.

Background: Chronic peritoneal dialysis (PD) is the dialysis modality of choice for children. However, there are limited outcome data in those who undergo PD catheter (cath) insertion in the 1st year of life. Using data from the Children’s Hospital Association Standardizing Care to Improve Outcomes in Pediatric End Stage Renal Disease (ESRD) Collaborative (SCOPE), we examined peritonitis rates and survival in 156 infants who had a PD cath placed in the 1st yr of life.

Methods: Data on pt demographics, PD cath characteristics, peritonitis risk factors and outcomes from 157 cath insertions from 29 North American pediatric dialysis centers were reviewed and analyzed using chi square test for association or a Wilcoxon rank-sum test.

Results: In hospital and overall peritonitis rates during the 1st year post cath insertion were 1.73 and 0.76 per pt-year, respectively. Gram + organisms were responsible for 38.7% of infections (figure); 28% were culture negative. Polycystic kidney disease and pulmonary hypoplasia were more frequent in infants with peritonitis, whereas anuria did not differ between groups (table). Use of a curled catheter or plastic adaptor, nephrectomy prior to or concurrent with cath insertion, and G-tube insertion after cath placement were more common in pts with peritonitis, while number of cuffs, surgical technique, cath use within 14 d and cath revision did not differ between groups. Infants with peritonitis had longer initial hospital stays and lower survival compared with those without peritonitis.

Conclusions: This large cohort of infants with ESRD, who found a high rate of peritonitis and identified several risk factors associated with peritonitis. Given that peritonitis was associated with increased initial hospital stay and mortality, attention to the potentially modifiable factors is needed.

TH-PO993
Risk Factors for All-Cause Unexpected Hospitalization After Peritoneal Dialysis Catheter Implantation Z Li, Zita C. Abreu,1 Joanne M. Bargman.2 1Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China; 2Nephrology, Toronto General Hospital Univ of Toronto, Toronto, ON, Canada.

Background: Implantation of the peritoneal dialysis catheter (PDC), usually an elective procedure, may necessitate unexpected hospitalization due to multiple co-morbidities and inherent instability of the end-stage renal disease patient. This information is important for administrative planning for a PD program. However, information on hospitalization after PDC implantation is limited and details about the reason for hospitalization are lacking.

Methods: We performed a prospective cohort study in consecutive patients who underwent PDC implantation at a single institution from 2007 to 2013. Clinical characteristics of enrolled patients, technique of the implantation procedure and all-cause unexpected hospitalization and morbidity within 14 days after implantation were analyzed.

Results: A total of 246 patients receiving 252 PDC implantations during the 6 years were studied. After 39 procedures (15.5%), patients had an unexpected hospital stay due to operative complications (33.3%), worsening of comorbid disease (35.9%), or a single-night hospital stay for observation (30.8%). Compared to discharged patients, the unexpected hospitalization ones were older (P=0.001), had higher rates of previous episodes of heart failure (P<0.006) and heart disease (P<0.001), had more use of general anesthesia (P=0.046), had more added procedures during the implantation (P=0.02) and had more episodes of flow obstruction and peritonitis (P=0.012 and P=0.001). Multivariable logistic regression showed that age, cardiac morbidity, use of general anesthesia, PDC flow problems and peritonitis after implantation were independent predictors of all-cause unexpected hospitalization.

Conclusions: For the first time, our study has analyzed the rate of unexpected hospitalization after PDC implantation and identified the salient risk factors. Increased focus to identify patients at greatest risk for hospitalization, evaluation of processes of care, and implementation of preventive strategies may be helpful to reduce unplanned hospitalization after catheter insertion.
TH-PO994

Early Mechanical and Infective Complications in First Time Blind, Bedside, Midline Percutaneous Tenckhoff Catheter Insertion with Ultra Short Break-in Period: Setting New Standards

Zuying Xiong, 1 Gui Santosh Varughese, 1 Ninoo G. George, 2 Santosh Varughese. 1 Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; 2 Nephrology, Bilirobh Hospitals, Chennai, Tamil Nadu, India.

Background: There are no large studies that have looked into ultra-short break-in period with blind, bedside,midline approach of Tenckhoff catheter insertion.

Methods: 294 consecutive adult patients underwent catheter insertion for chronic peritoneal dialysis at our centre from January 2009 to December 2013. Those with history of midline laparotomy scars and hernias were referred for open surgical insertion. 245 patients (86.3%) underwent the percutaneous and 39 patients (13.7%) underwent surgical insertions.

Results: The mean break-in period for the percutaneous group (PG) was 2.68 ± 2.63 days and for the surgical group (SG) was 11.19 ± 6.96 days, p < 0.001. Poor catheter outflow was present in 22 (9%) of PG and in 4 (10.3%) of SG (p = 0.80). Primary catheter non-function was present in 24 (9.8%) of the PG and in 4 (10.3%) of the SG (p = 0.73). Catheter survival at one year was 164/241 (89.1%) in the PG. The various outcomes are:

Figure: Relevance of systolic blood pressure to vascular events and cause-specific mortality, by prior vascular disease or raised troponin.

Conclusions: The significantly shorter break-in period and smaller wound incisions reduce hospitalization and the need for bridging hemodialysis as well as having good patient and catheter outcomes.

TH-PO995

Comparing Outcomes of Percutaneous Peritoneal Dialysis Catheter Insertion by Nephrologist versus Open Surgical Insertion – Large Single Centre Experience

Louise E. Ross, Bhigru Raj Sood. South West Thames Renal and Transplantation Unit, Carshalton, Surrey, United Kingdom.

Background: Several studies suggest that percutaneous insertion of peritoneal dialysis (PD) catheters by nephrologists improves the uptake of PD. Percutaneously inserted PD catheters have the advantage of being less invasive, removing the need for general anaesthetic, reducing hospital stay, facilitating acute PD, therefore making PD more accessible. There are only a few small studies directly comparing the outcomes of patients who have had a percutaneous versus open method of implantation, with some suggesting poorer outcomes. We retrospectively reviewed data on all patients who had a percutaneous or open surgical PD catheter inserted between August 2011 and December 2014 at a single renal centre, to identify the patients who developed an exit site infection (ESI) or episode of PD peritonitis within two and four weeks of catheter insertion. We also looked at patients who developed a functional catheter problem requiring manipulation or replacement of the catheter within the first year. Chi-squared test was used to assess statistical significance.

Results: 276 PD catheters were inserted in the said time period. 152 were inserted percutaneously and 124 with open surgery. There were less ESI (at 2 weeks - 2.6% versus 4.3%) and PD peritonitis within two and four weeks of catheter insertion. We also looked at patients with PD catheters requiring manipulation or replacement within the first year due to a functional problem was comparable in the percutaneously inserted catheters (9.2% versus 12.9%; p=0.327). There were no major complications in the form of visceral perforation or major haemorrhage in either method.

Conclusions: In our study, it was found that infected related complications were better with percutaneous PD catheter insertion and mechanical failure rate was comparable to open surgical PD catheter insertion. In our practice we have found that percutaneously inserted PD catheters are a safe means of increasing patient access to PD, enabling more patients to have a home-based therapy.

TH-PO996

Shared Decision-Making in Chronic Kidney Failure: The Retrospective Analysis of First Stage PD Patients in Germany

Maxi Rohinski, 1 Wilfried Mua, 2 Andreas Wiek, 2 Matthias Girndt. 1 Inst of Rehabilitation Medicine, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany; 2 Inst of Medical Epidemiology, Biostatistics, and Informatics, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany; 3 Dept of Internal Medicine II, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany.

Background: To date, little is known about the extent to which patients with chronic kidney failure feel involved in decision-making regarding the life-changing dialysis treatment. Previous studies on mortality yielded equivalence of peritoneal (PD) and hemodialysis (HD). However, only 5% of the patients in these studies were HD patients, although many patients are eligible for both options and entitled to receive unbiased counselling.

Methods: In a nationwide multicenter study with federal funding (“CORETH-project”), we surveyed 781 patients on dialysis since 6 to 24 months with regard to their rating of shared decision-making (SDM) with their physician concerning the choice of renal replacement therapy. We used the “Shared Decision-Making Questionnaire” (Kriston et al. 2010), which is a highly reliable and well accepted measure. Furthermore, patients indicated the dominating reason for choosing their treatment as well as their treatment satisfaction (TS).

Results: Data were compared between propensity score-matched groups of patients (nPD=nHD=246).

Conclusions: Our findings highlight awareness for an unbiased nephrological counselling-culture and provide indications for a successful SDM-process when choosing dialysis modality. According to the results, an effective SDM can pave the way for dialysis patients’ quality of life and treatment success.

Depression and Cognitive Impairment in Peritoneal Dialysis: A Multi-Center Cross-Sectional Study

Jie Dong, 1 Hai-chun Pi, 1 Zuying Xiong, 1 Jinhui Li, 1 Ling Liu, 1 Yue-Pang Ren, 4 Qin Wang, 1 Qiu Wang, 1 Lijing Duan, 1 Xiao-xia Zheng, 1 Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China; 2 Renal Div, Peking Univ Shenzhen Hospital, Shenzhen, China; 3 Renal Div, The Second Hospital of Anhui Medical Univ, Hefei, Anhui, China; 4 Renal Div, The Second Affiliated Hospital of Harbin Medical Univ, Harbin, Heilongjiang, China; 5 Renal Div, Handan Central Hospital, Handan, Hebei, China.

Background: Depression and cognitive impairment have been identified as independent risk factors for mortality in peritoneal dialysis (PD) patients. The relationship between depression and cognitive functions in PD patients was investigated in this multi-center cross-sectional study.

Methods: Study design: multi-center cross-sectional study. Setting & Participants: A total of clinically-stable 458 patients who performed PD for at least 3 months from 5 PD units were included in this study. Only 5% of the patients in Germany choose PD, even though many patients are eligible for both options and entitled to receive unbiased counselling. Measurements: Global cognitive function was measured by using the Modified Mini-Mental State Examination (3MS), specific cognitive function by executive function, immediate memory, delayed memory, visuospatial skill and language ability by subtests of Repeatable Battery for the Assessment of Neuropsychological Functioning. Depression was diagnosed if the depression severity index <0.5 by using Zung’s Self-rating Depression Scale.

Results: The prevalence of depression and cognitive impairment evaluated by 3MS were 52% and 28.4% respectively. Patients with mild or moderate/severe depression had higher prevalence of global cognitive impairment, executive dysfunction, impaired immediate and delayed memory. After adjusting for demographic, comorbidity data and clinical parameters, depression scores were independently associated with lower scores of 3MS, immediate and delayed memory, and language ability, and longer completion time of tests. Even mild depression and HD independently predict higher risk of CI, executive dysfunction, impaired immediate and delayed memory after multivariable adjustments.

Conclusions: Even mild depression plays an important role in global and specific cognitive functions in PD patients.

Funding: Government Support - Non-U.S.
Proposed Model for the Care of Hospitalized Peritoneal Dialysis Patients

Cynthia R. Christiano, 1 Melanie I. Hames, 1 Pankaj Jawa, 1 Piper J. Hughes, 1 Maria H. Locklear. 2
1 Internal Medicine, East Carolina Univ, Greenville, NC; 2Internal Medicine, East Carolina Univ, Greenville, NC.

Background: Peritoneal dialysis (PD) has been prescribed throughout the United States, yet the optimal model of care for hospitalized PD patients remains unknown. With a growing interest in home modalities and emphasis on quality, it is imperative that we identify an effective and efficient way to care for this patient population during hospitalization.

Methods: We describe a model successfully implemented at Vidant Medical Center (VMC) in 2008. Prior to this date, the primary hospital nurses performed PD care. Due to the high risk, low volume nature of inpatient PD, this resulted in inconsistent care as well as decreased physician, nursing, and patient satisfaction. In 2008, an inpatient PD nursing team was created. This team, consisting of nephrology nurses with specialized PD training, is managed by VMC’s self-maintained dialysis unit. Staffed with 2 nurses during the day and at night, they provide 24/7 care throughout the hospital, including the ICU and ED. Responsibilities include patient education, exit site care, catheter flushes, and all manual and automated PD exchanges. Upon discharge, the outpatient unit is contacted to ensure appropriate transition back to the outpatient setting.

Results: This model provides several benefits: 1) PD treatments are consistently completed and charted, 2) Increased physician, nursing, and patient satisfaction, 3) Continuity of care, and 4) Cost reduction (personnel and supplies). Since inception, this team has grown to 13 nurses. During FY2014, 2568 (1572 adult / 996 pediatric) PD treatments were performed, the majority CAPD. To ensure appropriate utilization of nursing resources, most are cross-trained to perform hemodialysis.

Conclusions: In conclusion, the creation of a specialized nursing team has been instrumental in optimizing the care of our hospitalized PD patients. This sustainable model provides effective, efficient care and should be considered for implementation by hospitals providing PD services.

Elderly Peritoneal Dialysis Compared with Elderly Hemodialysis Patients and Younger Peritoneal Dialysis Patients: Competing Risk Analysis of a Korean Prospective Cohort Study

Hyunsuk Kim, 1 Jung Nam An, 2 Dong Ki Kim, 1 Yong-Lim Kim, 2 Yun Kyu Oh, 3 Chun Soo Lim, 1 Youn Su Kim, 1 Jung Pyo Lee. 2
1 Internal Medicine, Seoul Nat’l Univ College of Medicine, Seoul, Republic of Korea; 2Internal Medicine, Seoul Nat’l Univ Boramae Medical Center, Seoul, Republic of Korea; 3Internal Medicine, Kyungpook Nat’l Univ School of Medicine, Daegu, Republic of Korea.

Background: The outcomes of peritoneal dialysis (PD) in elderly patients have not been thoroughly investigated. We aimed to investigate the clinical outcomes and risk factors associated with PD treatment in PD elderly patients.

Methods: We conducted a prospective observational nationwide adult end-stage renal disease (ESRD) cohort study in Korea from August 2008 to March 2013. Among incident patients (n=830), patient and technical survival rate, quality of life, and Beck’s Depression Inventory (BDI) scores of elderly PD patients (≥65 years, n=95) were compared with those of PD patients aged ≤49 years (n=205) and 50~64 years (n=192); and elderly hemodialysis (HD) patients (n=315). The patient death and technical failure were analyzed by cumulative incidence function.

Results: The patient survival rate of elderly PD patients was inferior to that of younger PD patients (P<0.001). However, the technical survival rate was similar (P=0.097). Compared with elderly HD patients, the patient survival rate did not differ according to dialysis modality (P=0.987). Elderly PD patients showed significant improvement in the BDI score compared with the PD patients aged ≤49 years (P=0.003). Low albumin, hemoglobin, and low residual renal function were significant risk factors for the PD patient survival; and peritonitis was a significant risk factor for technical survival.

Conclusions: The overall outcomes were similar between elderly PD and HD patients. PD showed the benefit in BDI and quality of life in the elderly. Additionally, the technical survival rate of elderly PD patients was similar to that of younger PD patients. Taken together, PD may be a comparable modality for elderly ESRD patients.

Phosphorus Control and Phosphate Binder Pill Burden During Real-World Use of Sucroferric Oxycitrate in Peritoneal Dialysis Patients

Linda H. Ficociello, Vidhya Parameswaran, Mark Costanzo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossman. Fresenius Medical Care North America (FMCNA), Waltham, MA.

Background: Achieving serum phosphorus (sPhos) control can be a challenge for dialysis patients (pts). This retrospective database analysis examined the real-world effectiveness of sucroferric oxycitrate (SO), an iron-based phosphate binder (PB), in adult peritoneal dialysis (PD) pts.

Methods: A cohort of PD pts prescribed SO as part of routine clinical care at FMCNA clinics was analyzed. Pts had 1 sPhos measured during SO and had been previously treated with sevelamer, calcium acetate, calcium carbonate or dual therapy. Changes in sPhos, serum calcium (sCa), intaphyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pill counts per day (PPD) were assessed 3-months before SO (baseline) and 3-months after SO (follow-up).

Results: Pts (n=328) were, on average, 53 years old, with a dialysis vintage of 3.9 years. At baseline, 56% of pts used sevelamer, 29% calcium acetate, 11% calcium carbonate, and 5% dual therapy. Pts in-range increased from 13.5 to 23.8% (76% increase). Mean sPhos decreased from 6.92 to 6.67 mg/dl, P<0.001. PB PPD was reduced from 8.4 to 3.8 pills (4.6 fewer pills, P<0.001). There was no significant change in sCa (9.1 to 9.0 mg/dl) or iPTH (335 to 555 pg/ml). TSAT and FER increased from 35.4 to 36.6% and 752.1 to 814.9 mg/ml, respectively.

Conclusions: This was accomplished with a mean of 3.8 pills per day, a reduction of 4.6 pills (P<0.001).

Laparoscopic Findings of Visceral Peritoneal Injury in Patients Treated with Neutral pH Peritoneal Dialysis Solution

Yudo Tanno, Naena Matsuo, Izumi Yamamoto, Yasuyuki Nakada, Ichiro Obikado, Keitaro Yokoyama, Takashi Yokoo. Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Encapsulating peritoneal sclerosis (EPS) is caused by a visceral peritoneal lesion, i.e., intestinal tract adhesion and encapsulation, it is important to evaluate changes in the visceral peritoneum. It has been reported that there was a decreasing trend of peritoneal injury with the use of PD solution with neutral pH as compared with acidic pH in the histopathological evaluation of the parietal peritoneum; however, there is no report evaluating changes in the visceral peritoneum, which is essentially important and should be evaluated. We previously reported laparoscopic approach for evaluation of EPS (KI 2012) in patients treated with PD solution with acidic pH. In this study, we examined macroscopic findings of the visceral peritoneum in patients treated with neutral pH solution alone for 4 years or more by laparoscopy.

Methods: I9 patients underwent laparoscopy at the time of PD catheter removal. Duration of PD in these patients was 64±18.8 months. Clinically, none of these patients had developed EPS by the time of the investigation. The findings of both parietal and visceral peritoneal tissues were categorized according to color changes, presence of neovascularizations and adhesions.

Results: It was found that longer the duration of PD, the worse the peritoneal injury. Although changes in the parietal and visceral peritoneum had heterogeneous distributions, the changes in the visceral peritoneum were milder, showing a discrepancy with the findings of the parietal peritoneum. As compared with laparoscopic findings in patients treated with PD solution with acidic pH, the degree of color changes, presence of neovascularizations, and adhesions were all mild, however, severe adhesions were noted in patients with a history of PD peritonitis.

Conclusions: Although changes in the visceral peritoneum resulting from the use of PD solution with neutral pH show a decreasing trend as compared with acidic pH, there is a certain level of peritoneal change, suggesting the possibility of progression of peritoneal deterioration by long-term continuous use.

“Composite” Encapsulating Peritoneal Sclerosis: A New Presentation in a Long Time of Renal Replacement Therapy

Valerio Vizzardi. O.U. of Nephrology, Spedali Civili and Univ of Brescia, Brescia, Italy.

Background: Encapsulating peritoneal sclerosis (EPS) is the more dangerous complication of peritoneal dialysis (PD). The EPS can occur during PD (classic EPS), after kidney transplantation (TX) or rapid shift to hemodialysis (HD) as the mode of renal replacement therapies (RRTs).

Peritonitis Rates Among African Americans and Caucasians Undergoing Peritoneal Dialysis Patients with Peritonitis

**Background:** Severe and prolonged peritonitis leads to peritoneal membrane failure and is the most common cause of technique failure in patients treated with peritoneal dialysis (PD). Recent studies reported that delta neutrophil index (DNI), which reflects the fraction of circulating immature granulocytes in the blood, is a practical severity marker of infection. This study investigated whether DNI could be a predictive marker of catheter removal in PD patients with peritonitis.

**Methods:** Patients treated with PD peritonitis at Severance Hospital between January 2012 and January 2015 were enrolled. Demographic data, clinical, and laboratory parameters including DNI were collected at the time of peritonitis. DNI was calculated by automatic analyzer.

**Results:** A total of 125 PD peritonitis episodes in 92 patients were investigated. The mean age was 59 ± 12.0 years and 55 (44.0%) were male. PD catheter was removed in 31 (24.8%). The median value of DNI in patients underwent PD catheter removal was significantly higher compared to that of patients who maintained PD catheters (DNI interquartile range, 3.30 (0.0-65.0) vs. 0.70 (0.0-22.5), P = 0.001). DNI is significantly associated with percentage of segmented neutrophil (r = 0.28) and serum albumin (r = -0.32), and dialysate leukocyte counts (r = 0.20), but not with C-reactive protein (CRP) levels (r = 0.08). Multivariate logistic regression analysis revealed that DNI was an independent predictor for PD catheter removal in patients with PD peritonitis (odds ratio = 1.08, 95% confidence interval = 1.01-1.12, P = 0.04) after adjustment for serum albumin, CRP, leukocyte count of dialysis effluent, and septic shock. The area under the ROC curve (AUC) of DNI for PD catheter removal was 0.69 (P = 0.001), whereas the AUC of dialysate leukocyte count was not statistically significant (0.52, P = 0.70).

**Conclusions:** DNI levels reflected the severity of PD peritonitis. Higher levels of DNI could be an independent predictor for PD catheter removal in patients with PD peritonitis.

Peritonitis Rates Among African Americans and Caucasians Undergoing Peritoneal Dialysis

**Background:** African Americans (AA) are under-represented in the prevalent peritoneal dialysis (PD) population in the United States. There is relatively little conclusive data to explain the cause of this. One explanation is that AA may have higher rates of peritonitis than Caucasians leading to increased technique failure. This study aimed to determine if differences between AA and Non-AA rates of peritonitis at the University of Alabama at Birmingham Home Dialysis existed.

**Methods:** This is a single-center retrospective cohort analysis of data from November 2012 to November 2014. Baseline demographics as well as data on peritonitis episodes were analyzed. Peritonitis rate was defined as the absolute number of distinct peritonitis episodes divided by the number of patient months at risk. Relapsing peritonitis episodes were excluded. Chi-square analysis was used to compare baseline categorical variables and independent t test to compare length of time on dialysis. Rates of peritonitis were analyzed by Fischer exact test. Peritonitis free survival, hospitalization free survival and technique failure were analyzed by log rank comparison of Kaplan Meier curves.

**Results:** A total of 920 cases and 2607 controls were identified. There were a total of 70 failures, 31 (44.3%) related to infectious complications, 22 (31.4%) to non-infectious complications (e.g. obstruction, leaks), 8 (11.4%) to inadequate dialysis, and 9 (12.9%) to miscellaneous factors. Overall survival at 36 months was 78.81%. Covariates significantly affecting technique failure include prior HD (1.83; 1.14–2.92), non-infectious complications (1.82; 1.28–2.59), DM (1.62; 1.00–2.63), HIV (2.52; 1.01–6.24), peritonitis (1.94; 1.29–3.12), and exit site infections (1.79; 1.09–2.92). Previous abdominal surgeries (90; 0.758–1.08) and BMI (1.005; 0.971–1.04) were not significantly associated with failure.

**Conclusions:** This is one of the largest single center studies of its type from a US PD program. It shows excellent 3 year PD technique survival, better than reported in similar studies. Our results confirm that diabetes mellitus, PD related infections, and non-infectious mechanical problems are independent risk factors for PD technique failure. Conversely, BMI, abdominal surgeries, and demographic characteristics such as race and gender do not have significant association and should not be considered barriers to PD initiation.

Effect of Early Peritonitis on Clinical Outcomes

**Background:** Infection is a source of significant morbidity and mortality for peritoneal dialysis (PD) patients. Previous studies suggest that early peritonitis is associated with shorter technique survival; however these studies are limited by small samples, restricted generalizability, and a lack of standardized definitions. We used data from a large dialysis database to determine if the timing of the first peritonitis episode is associated with adverse clinical outcomes.

**Methods:** US and Canadian data from 1996 to 2005 in the Baxter POET (Peritonitis, Organisms, Exit sites, Tunnel infections) database was analyzed. Patients who developed peritonitis within 6 months of PD initiation were identified as cases. Controls were patients whose first peritonitis occurred after 6 months. Patients who never developed peritonitis or who were on PD for less than 6 months were excluded. Patients were censored at the clinical endpoint, transfer to hemodialysis, or death.

**Results:** There were 920 cases and 2607 controls were identified.

Testing the Impact of BMI on Mortality Among PD Patients. Data of hazard ratios and 95% confidence intervals (CIs) were obtained for respective BMI groups provided by each study. We performed meta-regression analysis using unrestricted maximum likelihood model.

**Results:** The Medline, EMBASE, and the Cochrane library search provided a total of 3,047 articles. After screening of all titles, 513 abstracts were selected. Finally, 9 cohort studies with 33,090 patients were included in the final analysis. Log hazard ratio for all-cause mortality showed a trend negatively associated with increasing four square root of BMI (slope coefficient: -0.1976, 95% CI [-0.4110 to 0.0118, p = 0.0695].

**Underweight Predicts Technical Failure: A Retrospective Cohort Study of Incident Peritoneal Dialysis Patients**

Xiaoxuan Huang, Xiuqin Zeng, Qing Wang, Zibo Xiong, Yumei Liao, Zuying Xiong. Div. of Nephrology, Peking Univ Shenzhen Hospital, Shenzhen, Guangdong, China.

**Background:** Technical failure is more common in peritoneal dialysis (PD) than in hemodialysis. High body mass index (BMI) increases mortality in the general population, but it may improve survival in hemodialysis patients. In PD patients, yet, reports regarding the association of BMI with technical survival are scarce and remain controversial.

**Methods:** In this retrospective cohort study, 348 incident PD patients (aged 48.2 ± 15.5 years, 62% men) at Peking University Shenzhen Hospital from 2000 to 2014 were included. BMI was calculated with height and weight first recorded within 2 to 6 months after initiation of PD. Patients were categorized according to the World Health Organization index (BMI) on mortality among peritoneal dialysis (PD) patients. We examined the effect of BMI on patient and technique survival in a prospective, incident PD cohort at a single center.

**Methods:** Subjects who started PD between 2000 and 2012 were enrolled in the study. Demographic and laboratory data were prospectively collected. Patients were categorized into four BMI groups: obese, >25 kg/m²; overweight, 23.1–24.9 kg/m²; normal, 18.5–22.9 kg/m² (reference category); and underweight, <18.5 kg/m². Patient and technique survival were compared using Cox proportional hazards model.

**Results:** A total of 632 incident PD patients were included in final analysis. The median follow-up period was 40 months (interquartile range, 19–64 months). In Kaplan–Meier survival curve, patient survival was not statistically different among all BMI categories (p = 0.641, by log-rank test). The hazard ratio (HR) adjusted for age, sex, diabetes, comorbidities, albumin, hemoglobin for patient survival was not significant among BMI groups (p = 0.837). In contrast, technique survival was significantly poorer in obese patients than in patients having a normal BMI (p = 0.029, by log-rank test). The HR for technique failure was significantly greater for obese PD patients in comparison with the reference category [1.8, 95% confidence interval (CI): 1.2 to 2.6; p = 0.008]. The reasons for technique failure included recurrent peritonitis (34%), inadequate dialysis (17%), mechanical problem (17%), and refractory exit-site tunnel infection (11%) in obese patients.

**Conclusions:** In our PD patients, patient survival was similar in all BMI categories. Therefore, obese patients should not be discouraged from receiving PD purely on the basis of BMI. However, technique survival was significantly poorer for obese PD patients. Further study is warranted to improve technique survival in obese patients.

**Phosphate Clearance in Peritoneal Dialysis: Residual Renal Function and Dialysis Modality**

Carmen Gonzalez corvillo, Mariangeles Rodriguez Perez, Alejandro A. Suarez benjumea, Nuria Areste, Mercedes Salgueira lazo. Nephrology, Virgen Macarena-Rocio, Sevilla, Spain.

**Background:** Evaluate urinary and peritoneal excretion of phosphate and related factors in peritoneal dialysis (PD). Analyze phosphate clearance depending on PD modality and peritoneal membrane type.

**Methods:** Observational study, in a sample of 375 PD patients. Mean age 60 (±14) years, 24% patients on APD (16=CPD, 8=NIPD) 13 on CAPD. Mean Kt/V: 2.04 ± 0.6. Mean residual renal function (RRF): 6.3 ± 4 ml/min. Transmembranous peritoneal transport: 6 high (6H), 26 high-average (6A) and Slow-average (LA). Renal and peritoneal phosphate clearance (ultrafiltration and diffusion) was analyzed. Urinary and dialysate P and creatinine clearance was measured. Serum PTH was measured.

**Results:** In PD patients, BMI was inversely associated with mortality as in HD patients. Other outcomes such as cardiovascular death, peritonitis incidence, and technical failure will be additionally evaluated.

**Conclusions:** In PD patients, BMI was inversely associated with mortality as well as in HD patients. Other outcomes such as cardiovascular death, peritonitis incidence, and technical failure will be additionally evaluated.

**The Association Between Body Mass Index and Mortality in Peritoneal Dialysis Patients**

Jin Ho Hwang, Geun jou Choi, Hyun Kang, Su Hyun Kim. 1 Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; 2Anesthesiology and Pain Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea.

**Background:** Unlike the general population, a higher body mass index (BMI) was consistently found to be a strong predictor of decreased mortality in patients with end-stage renal disease who receive maintenance hemodialysis (HD). This phenomenon has been referred to as the “Obesity paradox” or “reverse epidemiology.” Similar tendency has been observed in several studies with peritoneal dialysis (PD) patients, but the studies have reported conflicting results. We conducted this study to evaluate the association between BMI and all-cause mortality in PD patients.

**Methods:** A systematic search was conducted for published studies in Medline, EMBASE, and the Cochrane library databases from 1970 to April 2015. We identified studies evaluating the impact of BMI on mortality among PD patients. Data of hazard ratios and 95% confidence intervals (CIs) were obtained for respective BMI groups provided by each study. We performed meta-regression analysis using unrestricted maximum likelihood model.

**Results:** We performed meta-regression analysis using unrestricted maximum likelihood model. The Medline, EMBASE, and the Cochrane library search provided a total of 3,047 articles. After screening of all titles, 513 abstracts were selected. Finally, 9 cohort studies with 33,090 patients were included in the final analysis. Log hazard ratio for all-cause mortality showed a trend negatively associated with increasing four square root of BMI (slope coefficient: -0.1976, 95% CI [-0.4110 to 0.0118, p = 0.0695].

**Conclusions:** Our results suggest that patients with early peritonitis had a significantly higher peritonitis rate than controls (1.26 and 0.67 episodes per patient per year, p<0.001). Early peritonitis was also associated with shorter technique and patient survival.

### TH-PO1009

**Is Obesity a Poor Prognostic Factor in Incident Peritoneal Dialysis Patients?**

Hyunjoon Cho, Hye Jin Kim, Misoeon Park, Dong Ki Kim, Kwon Wook Joo, Yun Soo Kim, Curie Ahn, Kook-Hwan Oh. 1 Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; 2Clinical Research Inst, Seoul National Univ Hospital, Seoul, Korea.

**Background:** Obesity is associated with an increased risk of death in the general population. Previous studies have demonstrated a discrepancy in the impact of body mass index (BMI) on mortality among peritoneal dialysis (PD) patients. We examined the effect of BMI on patient and technique survival in a prospective, incident PD cohort at a single center.

**Methods:** Subjects who started PD between 2000 and 2012 were enrolled in the study. Demographic and laboratory data were prospectively collected. Patients were categorized into four BMI groups: obese, >25 kg/m²; overweight, 23.1–24.9 kg/m²; normal, 18.5–22.9 kg/m² (reference category); and underweight, <18.5 kg/m². Patient and technique survival were compared using Cox proportional hazards model.

**Results:** A total of 632 incident PD patients were included in final analysis. The median follow-up period was 40 months (interquartile range, 19–64 months). In Kaplan–Meier survival curve, patient survival was not statistically different among all BMI categories (p = 0.641, by log-rank test). The hazard ratio (HR) adjusted for age, sex, diabetes, comorbidities, albumin, hemoglobin for patient survival was not significant among BMI groups (p = 0.837). In contrast, technique survival was significantly poorer in obese patients than in patients having a normal BMI (p = 0.029, by log-rank test). The HR for technique failure was significantly greater for obese PD patients in comparison with the reference category [1.8, 95% confidence interval (CI): 1.2 to 2.6; p = 0.008]. The reasons for technique failure included recurrent peritonitis (34%), inadequate dialysis (17%), mechanical problem (17%), and refractory exit-site/tunnel infection (11%) in obese patients.

**Conclusions:** In our PD patients, patient survival was similar in all BMI categories. Therefore, obese patients should not be discouraged from receiving PD purely on the basis of BMI. However, technique survival was significantly poorer for obese PD patients. Further study is warranted to improve technique survival in obese patients.

Results: Mean total P clearance=480±192mg/d. Mean renal P clearance=286±201mg/d and mean non-renal P clearance=246±148mg/d (mean clearance through UF=22±15mg/d [0.6%]) and by D 194=85±24hr[91%]. Mean urinary and dialysate P Cr were 40±15 and 0.59±0.24 Mean WPCI=31.4±13.1L/week. Mean serum P 4.9±1mg/dl and PTH294±166pg/ml 86.8% of patients were on Selevcre and 22%calcium based binders.45%were on vitD vita minD(r=0.87p<0.001) Positive correlation between peritoneal P clearance and UF(r=0.45p<0.004) as well as between RRF and P renal elimination(r=0.83 p<0.001) was observed. WPCI was higher in patients on CAPD than on APD(r=39.4±7 vs 21.1±13L/week p<0.05)being the main differences subjected to continuous vs discontinuous modality(CAPD vs US.CAPD was more protective that is why preservation of RRF is crucial. There is a correlation between peritoneal D(r=0.87p<0.001).

Influence Outcomes?

TH-PO1012

Proteinuria at PD Initiation May Predict Residual Renal Function Loss in the Automated Peritoneal Dialysis Patients Using Biocompatible Solution Yoshifumi Hamasaki, 1 Kenti Doi, 2 Rei Isshiki, 3 Haruki Kume, 3 Masaoi Nangaku, 4 Eisei Noiri, 5 1Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; 3Urology, The Univ of Tokyo, Tokyo, Japan.

Background: Residual renal function (RRF) has a significant impact on the prognosis of dialysis patients. Peritoneal dialysis (PD), especially using biocompatible PD solution (BPDS) with neutral-pH and reduced glucose degradation products, has advantageous to protect the RRF (Kidney Int. 2009; 75:206-211). It is still unclear whether factors predicting RRF loss in the PD patients using BPDS. We investigated the relationship between clinical parameters at PD initiation and the change of RRF in the PD patients using BPDS.

Methods: The data from patients who started PD as their first dialysis modality from 2001 to 2014 at The University of Tokyo Hospital were collected retrospectively. All patients were treated by automated PD (APD) using BPDS. To identify predictors of RRF decline, we analyzed data including clinical parameters measured at PD initiation. Residual GFR was calculated as the average of 24-hour urinary urea and creatinine clearances. The rates of urine volume and residual GFR decline were calculated by the least squares linear regression formula. The outcome of dialysis modality change was defined as switching APD to hemodialysis (HD) or combined therapy of PD and HD due to RRF loss.

Results: 96 patients were analyzed in this study. On multiple regression analysis, the decline rates of urine volume and residual GFR were significantly correlated with proteinuria at PD initiation. When patients were divided into two groups according to urinary protein level, Kaplan-Meier analysis revealed the lower proteinuria group had higher persistence rate of APD and lower rate of dialysis modality change (Log rank p = 0.01 and 0.04, respectively). On ROC analysis, urinary protein predicted the need of dialysis modality change within 2 years after PD initiation with statistical significance (AUC [95% CI]=0.78 [0.66-0.90]).

Conclusions: Proteinuria at PD initiation may predict RRF loss and the need of dialysis modality change in the PD patients using BPDS.

Background: Although urgent start (US) peritoneal dialysis (PD) and traditional start (TS) PD have similar outcomes, it is not known if differences in outcomes exist based on race. The objective of this study was to determine if differences in PD outcomes exist when stratified based on race and type of PD start.

Background: In-center HD and PD are the 2 most common types of dialysis utilized in US. Few studies have examined characteristics of patients who changed dialysis modality. Kaiser Permanente Northern California is an integrated health care delivery system with 3.7 million members. We retrospectively examined the characteristics and disease burden of patients who switched from HD to PD.

Methods: Retrospective examination of EMR from Jan 2009 – Oct 2014. Disease burden was assessed by internally developed comorbidity score point, which predicts negative outcomes in the next 12 months, based on documented comorbidities and hospitalizations.

Results: From 2010-2014, dialysis population in our integrated health system increased from 4005 to 4491 patients, and PD population grow from 621 to 1033. In this period, 11% patients of initiated dialysis occurred within a year after dialysis initiation. 8% of HD patients switched to PD and 24% of PD patients switched to HD. Majority of patients who switched from HD to PD do so within 6 months of initiation. They have less comorbidities than those who stay on HD. They have a higher comorbidity score when they switch to PD but lower than repeated switchers who switched from PD to HD. They were younger than those remaining on PD. Most patients who switched from PD to HD did so within a year. They have more comorbidities than those who stay on PD and have a higher comorbidity score when they switch to HD, even higher than the repeat score of those who switch from HD to PD. The difference in co-morbidity scores between the first and second measurement is higher for the PD to HD pattern. They have similar age to those who didn’t switch.

Conclusions: Patients who switched from HD to PD remain at approximately the same comorbidity score before and after switch. Comorbidity scores of patients who switched from PD to HD significantly increased, suggesting that change was influenced by decline in their overall condition. In our patient population, the switch from HD to PD is likely a patient’s decision, while the switch from PD to HD may be due to inability to continue PD.

Impact of Pre-Dialysis Immunosuppressive Treatment Time on Infectious Complications and Survival of Systemic Lupus Erythematosus (SLE) Patients on Peritoneal Dialysis Junbao Shi, 1,2 Joanne M. Bargman. 1,2 Dept of Nephrology, Peking Univ Third Hospital, Beijing, China; 1Div of Nephrology, Univ Health Network, Toronto General Hospital, Toronto, ON, Canada.

Background: SLE patients on peritoneal dialysis (PD) have a significant risk of infectious complications and poor outcomes. However, few studies have examined the relationship between pre-dialysis exposure to immunosuppressive (IS) therapy and the outcomes of PD. The objective of this study was to investigate whether pre-dialysis IS treatment influences the infectious complications and outcomes of SLE patients on PD.

Methods: Twenty-six SLE patients were treated with PD in a major academic centre from May 1996 to May 2014. Demographics, diagnostic tests and IS treatment, comorbidity indices, biochemistry and clinical data upon initiation of PD and hospitalization, infective complications, hospitalizations and clinical outcomes during the study period were collected. Three years was chosen as the discriminant between longer and shorter duration of IS therapy.

Results: Two patients were lost to follow-up during the study period. Therefore, a total 24 patients were included for analysis. The SLE patients with longer duration of pre-dialysis IS (>7) were older than patients with shorter pre-dialysis IS (≤7) (8.6±1.2 vs 7.1±1.7, P<0.05), but there were no significant differences in sex, race, PD duration, PD sub-modality and biochemistry between the two groups (P>0.05). Seven patients died during the follow-up period and all the deaths were from the group with longer-pre-dialysis IS time (P<0.05). Three patients died from infections, two patients from cardiovascular disease, and two had sudden death at home. However, there were no significant differences in the incidence of other infectious or hospitalization, infective complications, hospitalizations and clinical outcomes during the study period were collected. Three years was chosen as the discriminant between longer and shorter duration of IS therapy.

Conclusions: SLE patients undergoing PD with longer pre-dialysis exposure to IS drugs have a greater mortality that appears to be related to both infectious and noninfectious causes. Although incident to PD, they should be considered a high-risk subgroup.
examined to 1) compare mass transfer-area coefficients (MTACs) for urea, creatinine and glucose during fast and standard PETs and 2) use those parameters to predict PD therapy prescription adequacy.

**Methods:** Data from 104 PD (41 CAPD, 63 APD) patients who underwent a 4-hour standard PET and an overnight exchange with the same glucose concentration were used to determine PD prescription adequacy parameters. Calculated MTAC values for standard PET were compared with those for fast PET by using only data obtained at 4-hours during the standard PET and assuming a 200 mL residual volume in the prior exchange. The calculated membrane parameters were used to predict net ultrafiltration (UF), urea Kt/V and creatinine clearance (CCr), and those predictions of therapy adequacy were also compared with the mean of 3 actual measurements of net UF, Kt/V and CCr for each patient.

**Results:** Median urea, creatinine and glucose MTACs were 20.9, 10.1, and 9.1 mL/min during standard PET, and 21.0, 10.1 and 9.0 mL/min during fast PET; the corresponding membranes were fast-dissolved MTFAs for urea, creatinine and glucose were 0.6, 0.3 and 0.6 mL/min. Comparing predictions using standard fast PET, 81% of net UF were within 150 mL, 94% of Kt/V were within 0.1/wk and 93% of CCr were within 2 L/wk. The percent of predicted and actual measured values of net UF within 300 mL, Kt/V within 0.2/wk and CrCl within 8 L/wk were 64%, 63% and 77% for standard PET and 38%, 64% and 77% using fast PET; these differences were not statistically significant.

**Conclusions:** These results suggest that the predictions of PD therapy adequacy using PD Adequate are clinically equivalent when either fast or standard PET is employed. **Funding:** Pharmaceutical Company Support - Baxter Healthcare Corporation

**TH-PO1016**

The Loss of Residual Diuresis Increases in Erythropoietin in PD Patients

**Background:** Anemia in ESRD is attributed to impaired erythropoietin formation due to erythropoietin and iron deficiency. The accelerated clearance of erythropoiesis may at least partially be due to enhanced erythropoiesis, a suicidal death of erythrocytes characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine (PS) externalization at the erythrocyte (RBC) surface. Exposed PS is recognized by macrophages that engulf and degrade the affected cells. Little is known about mechanisms underlying enhanced erythropoiesis in ESRD. At least in theory, erythropoiesis may be stimulated by some uremic toxins. The present study investigated erythropoiesis in peritoneal dialysis (PD) patients.

**Methods:** 46 PD patients (31 M, mean age: 64±14yrs) and 17 healthy subjects (CTR) were enrolled. All measurements were made in isolette RBCs. PS exposure was estimated from FITC-Annexin V binding by flow cytometric.

**Results:** 27 patients were treated with CAPD and 19 with APD. The mean length of treatment was 39±29months. The PS externalization on surface was significantly higher in PD patients than in CTR (2.6% ± 1.6% vs. 0.8 ± 0.6%, P < 0.05). The mean percentage of eryptosis showed no significant differences between patients with (n=18) and without diabetes, treated with CAPD or APD and with a negative or positive (n=18) history of peritonitis. Eryptosis showed significantly lower levels in PD patients with residual diuresis (n=23) than in patients without (3.7%, 2.6-5.6 vs. 3%, 1.5-6.1, P=0.03). A significant negative correlation was observed between percentage of eryptosis and Body Mass Index (BMI) (r=0.39, P=0.05). There was no statistically significant relationship between erythropoiesis and months of PD, urea, albumin, creatinine, or urine volume.

**Conclusions:** In conclusion, erythropoiesis has been shown to be significantly higher in PD patients than CTR. Our data suggest that the type and the length of PD treatment do not enhance erythropoiesis. On the contrary, the loss of residual diuresis leads to a significant increase of eryptosis. The residual diuresis may contribute to the elimination of potential uremic toxins that induce increased erythropoiesis. **Funding:** Private Foundation Support

**TH-PO1017**

The Pattern of T Helper Lymphocytes Has No Clinical Implications in Peritoneal Dialysis Patients

**Background:** Anemia in ESRD is attributed to impaired erythropoietin formation due to erythropoietin and iron deficiency. The accelerated clearance of erythropoiesis may at least partially be due to enhanced erythropoiesis, a suicidal death of erythrocytes characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine (PS) externalization at the erythrocyte (RBC) surface. Exposed PS is recognized by macrophages that engulf and degrade the affected cells. Little is known about mechanisms underlying enhanced erythropoiesis in ESRD. At least in theory, erythropoiesis may be stimulated by some uremic toxins. The present study investigated erythropoiesis in peritoneal dialysis (PD) patients.

**Methods:** 46 PD patients (31 M, mean age: 64±14yrs) and 17 healthy subjects (CTR) were enrolled. All measurements were made in isolette RBCs. PS exposure was estimated from FITC-Annexin V binding by flow cytometric.

**Results:** 27 patients were treated with CAPD and 19 with APD. The mean length of treatment was 39±29months. The PS externalization on surface was significantly higher in PD patients than in CTR (2.6% ± 1.6% vs. 0.8 ± 0.6%, P < 0.05). The mean percentage of eryptosis showed no significant differences between patients with (n=18) and without diabetes, treated with CAPD or APD and with a negative or positive (n=18) history of peritonitis. Eryptosis showed significantly lower levels in PD patients with residual diuresis (n=23) than in patients without (3.7%, 2.6-5.6 vs. 3%, 1.5-6.1, P=0.03). A significant negative correlation was observed between percentage of eryptosis and Body Mass Index (BMI) (r=0.39, P=0.05). There was no statistically significant relationship between erythropoiesis and months of PD, urea, albumin, creatinine, or urine volume.

**Conclusions:** In conclusion, erythropoiesis has been shown to be significantly higher in PD patients than CTR. Our data suggest that the type and the length of PD treatment do not enhance erythropoiesis. On the contrary, the loss of residual diuresis leads to a significant increase of eryptosis. The residual diuresis may contribute to the elimination of potential uremic toxins that induce increased erythropoiesis. **Funding:** Private Foundation Support

Dialysate Losses of Vitamin 25(OH)D in a Cohort of Patients Treated with Peritoneal Dialysis

**Background:** Peritoneal dialysis (PD) is associated with 25(OH) vitamin D deficiency. To our knowledge, there are no cohort studies about 25(OH) vitamin D dialysate losses in PD. Objective: To characterize 25(OH) vitamin D losses in peritoneal effluent (PE) and their relation with changes in serum 25(OH) vitamin D levels during 4 months in a cohort of incident PD patients.

**Methods:** 52 patients with <6 mths but >1 mth on PD were invited from 2011 to 2014. Those with severe infections, hospitalizations, and oral intake of D3 or D2 during follow up were excluded. Basal vitamin 25(OH) D in 24h PE and serum were measured. After 4 months, a 2nd assessment was performed. The principal outcome was the change in serum vitamin 25(OH) D levels.

**Results:** 43 patients were included, 22 (51%) men, median age was 39y (Intercuartile range [IQR] 31-62), 29 (68%) had diabetes and 29 (67%) had some degree of renal residual function during all study. After 4 months of PD initiation, all patients had vitamin 25(OH) D levels <20ng/mL, 13 of them with levels less than 10 ng/mL.

**Characteristics:**

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>(n=43)</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum 25(OH)D, ng/mL</td>
<td>14.2 (10.3-20.2)</td>
<td>&lt;0.001</td>
</tr>
<tr>
<td>Peritoneal effluent 25(OH)D, ng/mL, losses, mg/day</td>
<td>13 (9.2-17)</td>
<td><em>Not measurable at this timepoint</em></td>
</tr>
<tr>
<td>PTH, pg/mL</td>
<td>521 (343-845)</td>
<td>0.6</td>
</tr>
<tr>
<td>Ca, mg/dL</td>

<td>4.9 (3.6-6.1)</td>
<td>0.3</td>
</tr>
</tbody>
</table>

The mean decrease of vitamin 25(OH)D levels was 5.8 ng/mL/6 months (IQR 2.9-9.3 ng/mL). Basal PE losses in mg/day and delta in serum vitamin 25(OH)D D had a significant correlation

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.
Conclusions: High efficient losses of vitamin 25(OH)D are observed in patients on PD and may explain very low levels observed during follow up in this cohort.

Peritoneal Protein Excretion Was Lower in Nocturnal Intermittent Peritoneal Dialysis as Compared with Continuous Ambulatory Peritoneal Dialysis Not Associated With Peritoneal Transport Status in the Same Individual  
Hironori Nagasawa,1 Anayama Mariko,2 Yasushige Makino, Masaki Nagasawa. Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.

Background: Recent studies have reported that peritoneal protein excretion (PPE) during peritoneal dialysis (PD) therapy is associated with cardiac disease and patient survival. However, little is known regarding the extent to which PPE can be influenced by PD prescription or peritoneal transport status.

Methods: The aims of this study were to compare PPE in the same individual with different PD prescriptions of either continuous ambulatory PD (CAPD) or nocturnal intermittent PD (NIPD), and to evaluate the correlation between PPE and dialysate to plasma creatinine ratio (D/P Cr). Seventeen patients, of whom 58.8% were male, were included in the study. A peritoneal equilibrium test was performed and the amount of total protein (TP) loss in the dialysate was measured during CAPD or NIPD in the same patient.

Results: The mean age of the patients was 59.4 ± 18.0 years, body mass index was 21.5 ± 3.4, serum TP (s-TP) was 5.8 ± 0.8 g/dL, serum albumin (s-Alb) was 3.0 ± 0.7 g/dL, C-reactive protein (CRP) was 0.4 ± 0.7 mg/dL, and D/P Cr was 0.76 ± 0.15. During NIPD therapy, PPE was correlated with peritoneal clearance (γ = 0.63, p = 0.006), efficient volume (γ = 0.69, p = 0.002), and PPE to efficient volume ratio (γ = 0.80, p = 0.000), but not with s-TP, s-Alb, CRP, or D/P Cr. During CAPD therapy, PPE was negatively correlated with s-TP (γ = -0.62, p = 0.007) and s-Alb (γ = -0.58, p = 0.014), positively correlated with efficient volume (γ = 0.50, p = 0.037) and PPE to efficient volume ratio (γ = 0.72, p = 0.001), but not with CRP or D/P Cr. On comparing NIPD and CAPD, there was no difference in efficient volume (7341 mg vs. 7209 mg, respectively); however, both PPE and PPE to efficient volume ratio were significantly lower during NIPD than during CAPD [5586 mg vs. 7779 mg (p = 0.004) and 0.74 mg/mL vs. 1.09 mg/mL (p = 0.004), respectively].

Conclusions: The current study demonstrated that PPE and PPE to efficient volume ratio were lower during NIPD than during CAPD in the same individual, independent of s-TP, s-Alb, CRP, or D/P Cr. On comparing NIPD and CAPD, there was no difference in efficient volume (7341 mg vs. 7209 mg, respectively); however, both PPE and PPE to efficient volume ratio were significantly lower during NIPD than during CAPD [5586 mg vs. 7779 mg (p = 0.004) and 0.74 mg/mL vs. 1.09 mg/mL (p = 0.004), respectively].

TH-PO1022  
Relation of Central and Brachial Blood Pressure to Volume Status in Peritoneal Dialysis Patients  
Yun Jung Oh,1 So mi Lee,2 Ji Yong Jung,1 So Mi Kim,3 Chung sik Lee.1 1Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; 2Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; 3Dept of Internal Medicine, Gacheon Univ Gil Hospital, Incheon, Republic of Korea; 4Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.

Background: Euvolemia is an important predictor of outcome in peritoneal dialysis (PD), but chronic subclinical volume overload occurs frequently in PD patients. Even though volume overload is associated directly with hypertension, blood pressure (BP) not always reflect volume overload. Central BP has been shown to be a better predictor for target organ damages compared with brachial BP in general population. In this study, we evaluated comparative values of central BP and brachial BP for determining volume status in PD patients.

Methods: We enrolled 52 prevalent PD patients, and accessed volume status using Body Composition Monitor (BCM). Central BP was estimated using radial artery tonometry, and brachial BP measurement at office and 24-hour ambulatory blood pressure monitoring (ABPM) were performed. Volume overload was defined as an overhydration (OH) >1L. Results: Average office central systolic BP (<50BP), office brachial systolic BP (oSBP), and ambulatory brachial systolic BP (24-oSBP) were 139.8±26.3, 140±19.2, and 142.5±22.0 mmHg, respectively. In overall, 41 (78.8%) patients were in volume overload status. A stronger association of central BP with volume overload compared with brachial BP was observed in the receiver operating curve analysis (area under the curve (AUC) of cSBP, oSBP, and 24-oSBP were 0.87±0.06, 0.78±0.09, and 0.83±0.06 respectively). In multivariate analysis adjusted for age, sex, PD vintage, diabetes, and cardiovascular disease, the odds ratio (OR) for central BP (OR 1.110; 95% CI 1.019-1.210) was higher than those for brachial BP (OR 1.085; 95% CI 1.014-1.161 for 24-oSBP and OR 1.094; 95% CI 1.021-1.173 for 24-oSBP).

Conclusions: Office central BP was more strongly related to volume status than out-of-office ambulatory brachial BP as well as office brachial BP, suggesting that central BP was more valuable than brachial BP in assessing volume status in PD patients.

TH-PO1023  
Novel Regimen for Intraperitoneal Cefazolin and Ceftazidime in Peritoneal Dialysis Patients  
Saduddee Peerapornratana,1 Pitsut Katavetin,2 Pajaree Charityavilaskul,3 Talengsaik Kanjanabuch,1 Kearkait Pradithpornsilpa,1 Somchai Eiam-ong.1 1Div of Nephrology, Dept of Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; 2Dept of Pharmacology, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.

Background: Current guideline suggested that intraperitoneal (IP) antibiotics should be administered only in a long peritoneal dialysis (PD) dwell (>6 hours), which is not always practical because the long dwell might result in low ultrafiltration and volume overload. The objectives of this study were to develop a novel regimen for IP antibiotics in short dwell (<2 hours) during the automated PD cycling and examine the dialysate and plasma level of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime.

Methods: In the novel regimen, cefazolin and ceftazidime (20 mg/kg each) were added in a 5-liter bag of 2.5% dextrose PD fluid which was placed on the warmer of the PD machine without last fill or additional dwell. Cefazolin and ceftazidime concentrations of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime. The novel regimen for IP cefazolin and ceftazidime in short dwell (<2 hours) during the automated PD cycling could provide adequate dialysate and plasma level of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime. The novel regimen for IP cefazolin and ceftazidime in short dwell (<2 hours) during the automated PD cycling could provide adequate dialysate and plasma level of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime.

Conclusions: Six PD patients without peritonitis were participated in the study. Dialysate cefazolin and ceftazidime concentrations were high throughout the PD session in all patients (26-360 mg/L). Plasma cefazolin and ceftazidime exceeded the minimal inhibitory concentration (MIC) for susceptible organisms (8 mg/L) in 2 hours (cefazolin 28.5±8.0 and ceftazidime 12.5±3.4 mg/L at 2 hours), peak at 10 hours (51.1±14.1 and 23.0±5.2 mg/L) and then sustained well above the MIC at 24 hours (42.0±9.8 and 17.5±3.1 mg/L).

Conclusions: The novel regimen for IP cefazolin and ceftazidime in short dwell (<2 hours) during the automated PD cycling could provide adequate dialysate and plasma concentration and would become a standard regimen for peritonitis in PD patients already using PD cycling machine as well as those who temporarily need shorter dwells during peritonitis due to increasing peritoneal solute transport.

Is Automated Peritoneal Dialysis Better Than Continuous Ambulatory Peritoneal Dialysis in Quality of Life, Depression, and Renal Treatment Satisfaction? A Prospective Multicenter Propensity-Matched Study
Sun-Hee Park,1 Hee-Yeon Jung,1 Sukyoung Lee,1 Ji-Young Choi,1 Se-Hee Yoon,1 Jang-Hee Cho,1 Chan-Duck Kim,1 Yong-Lim Kim.1 Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; 2Internal Medicine, Konyang Univ, Daejeon, Republic of Korea.

Background: Health-related quality of life (HRQOL) is an important variable in the selection of dialysis modality among incident dialysis patients. However, relative superiority in HRQOL between automated peritoneal dialysis (APD) and continuous ambulatory peritoneal dialysis (CAPD) are not clearly known. The objective of this study was to compare HRQOL, depression, and renal treatment satisfaction over time between APD and CAPD patients.

Methods: Incident patients initiating APD and CAPD were prospectively enrolled from nationwide multicenters in Korea. HRQOL, depression, and renal treatment satisfaction were assessed at 1 and 12 months after the start of dialysis by Kidney Disease Quality of Life Short Form 36 (KDQOL-36), Beck’s Depression Inventory (BDI), and Renal Treatment Satisfaction Questionnaire (RTSQ), respectively. The mean changes of scores in APD and CAPD were compared by propensity score matching analysis.

Results: All 260 incident patients starting peritoneal dialysis (PD) from 11 centers were included in this study. A total of 170 patients were matched from 208 patients who completed all questionnaires and did not change PD modality during the 1-year follow-up period. The total scores at 1 month showed better HRQOL for APD than CAPD patients in symptom, patient satisfaction, pain, and social function domains. No differences were observed between the two groups in total scores of KDQOL-36 at 12 months. However, CAPD patients had a significantly greater improvement in symptom and health status domains. A significant improvement also occurred in BDI and RTSQ in CAPD patients.

Conclusions: APD is not better than CAPD in HRQOL, depression, and renal treatment satisfaction during initial first one year on dialysis. The relative positive effect of CAPD compared with APD on improvement of HRQOL, depression, and renal treatment satisfaction was confirmed.

TH-PO1025

Thyroid Functional Disease and Mortality in a National Peritoneal Dialysis Cohort
Connie Rhoe,1 Vanessa A. Ravel,1 Elani Streja,1 Rajnish Mehrotra,2 Steven B. Kim,1 Jianxi Wang,1 Danh V. Nguyen,1 Steven M. Brunelli,1 Csaba P. Kovesdy,1 Gregory Brent,1 Kamyar Kalantar-Zadeh,1 UC Irvine; 2UW; 3DaVita Clin Research; 4UTHSC; 5UCLA.

Background: Peritoneal dialysis (PD) patients have a high prevalence of thyroid dysfunction which may be due to 1) peritoneal effluent losses (vast majority of thyroid hormone is protein-bound) and 2) frequent exposure to povidone-iodine cleaning agents leading to iodine-induced hypo- and hyperthyroidism. In the general population thyroid dysfunction is associated with higher risk of cardiovascular (CV) disease and death. There has not been study of the association between hypo- or hyperthyroidism defined by TSH with mortality in PD patients.

Methods: We examined the association of thyroid functional status with all-cause mortality in a 5-year national cohort (1/2007-12/2011) of PD patients with at least one TSH measure. Thyroid functional status was defined as: hyper-, eu-, and hypothyroidism (TSH <0.5, 0.5-5, >5mIU/L). We examined time-dependent and baseline thyroid function to determine short- and long-term exposure–mortality associations, respectively, using Cox models with 3 adjustment levels: unadjusted, case-mix, and case-mix+laboratory adjusted.

Results: Among 1484 patients, 7% and 18% had hypo- and hyperthyroidism, respectively. In time-dependent analyses, hypo- and hyperthyroidism were each associated with higher mortality risk in all 3 Cox models (ref: euthyroidism). In baseline analyses, hypothyroidism was associated with higher death risk in unadjusted and case-mix models, but associations were attenuated to the null in case-mix+laboratory models.

Conclusions: Time-dependent hypo- and hyperthyroidism were each associated with higher mortality, suggesting short-term risk in PD patients. Further studies are needed to determine if CV pathways are implicated, and if thyroid-modulating therapies ameliorate mortality in this population.

TH-PO1026

A Tale of APOL1 Mutation and Parvovirus Infection
Sherry Mansour,1 Whitney E. Besse,1 Kannan Jaywani,2 Ursula C. Brewster.1 Nephrology, Yale School of Medicine, New Haven, CT; 2Internal Medicine, Government Medical College And Hospital Chandigarh, Nawanshahr, India.

Introduction: We present a case of a first trimester pregnant woman with nephrotic range proteinuria and fetal demise in the setting of an acute parvovirus infection. Kidney biopsy revealed collapsing FSGS, and exome sequencing revealed mutations in APOL1. The relationship between Parvovirus and FSGS is one that clinicians might overlook, and perhaps may play a more prominent role in these progressive cases especially with APOL1 mutations.

Case Description: 37 yo Caribbean female presented at 8 weeks gestation with progressive swelling. Her daughter developed fifth’s disease one month prior. On presentation her BP was 146/95, HR 77 with pitting edema. Her creatinine was 6.3, BUN 43, albumin 1.5, and spot ptt/crt 20.8. Parvovirus PCR was 2000 copies. Biopsy demonstrated collapsing FSGS secondary to Parvovirus B19 [Fig 1A 1B]
The hope was that this injury would improve with improvement in titers, so IVIG was started. A follow up PCR showed improvement to 200 copies but she remained nephrotic with proteinuria of 20-60g. Re-biopsy revealed significant scarring and dialysis was initiated [Fig 1C]. Patient is now being evaluated for transplant. Given the unusual severity of this case, and her possible African ancestry, a genetic susceptibility to podocyte injury was entertained. Whole exome sequencing identified the patient to have two APOL1 risk alleles.

**Discussion:** Parvovirus has been linked with collapsing FSGS, and in one study viral PCR was detected in 78% of kidney tissue with this diagnosis. The combination of B19 infection and APOL1 mutation likely made our patient particularly susceptible to injury. Our case raises the question of how often subclinical parvovirus infection may be involved in collapsing FSGS, and highlights how sudden and devastating it can be to the life of a prior healthy woman.

**TH-PO1027**

**Podocyte Myeloid Bodies without Confirmed Genetic Mutation in a Female: Fabry’s Disease?**

**Case Description:** A 46 year-old Hispanic woman was evaluated for proteinuria. She was asymptomatic with no prior medical history or family history, and no exposure to silica, amiodarone, or hydroxychloroquine. Her exam was unremarkable: no neuropathy, skin changes, or corneal dystrophy. Scr was 0.6 mg/dL, UA 2+ protein with P/C ratio of 1.94 g/g. Biopsy revealed diffuse enlargement of the podocytes with a foamy cytoplasmic appearance and on EM, prominent podocyte lamellated lipid inclusions with foot process effacement and minimal endothelial deposits.

**Introduction:** Fabry’s disease (FD) is a X-linked lysosomal storage disorder caused by deficient alpha-galactosidase activity. A renal variant has been described with the R363H mutation. Due to random X-chromosomal inactivation, heterozygous females can present a diagnostic challenge. We report a case with a renal limited presentation, biopsy findings characteristic of FD but a negative whole blood DNA analysis.

**Case Description:** A 29-year-old female presented with proteinuria of 20-60 g. Renal biopsy revealed significant scarring and dialysis was initiated. She represented two weeks later, with a serum creatinine of 2.97 mg/dL and 9 grams of proteinuria on 24 hours collection and serum albumin of 2.2. She was initially fluid resuscitated, however, creatinine increased to 5.2 mg/dL and he became oliguric. Urine microscopy was without casts and serology markers were negative. Renal biopsy was performed that showed an interstitial nephritis with eosinophil rich infiltration and severe edema. Amongst other histological findings, there was dense tubulointerstitial fibrosis with tubular atrophy and hyaline casts. There was a positive Periodic Acid-Schiff (PAS) staining. The patient was treated with high dose (2mg/kg) steroid and oral diuretics. Renal function has returned to his prior baseline and he has subnephrotic proteinuria.

**Discussion:** This describes a case of nephrotic syndrome and interstitial nephritis related to the monoclonal antibody, Iplimumab. Interstitial nephritis has been extensively described with this drug before. 1However, this is the first case to our knowledge of the administration of ipilimumab leading to acute kidney injury from interstitial nephritis and severe proteinuria from diffuse podocyte foot process effacement. Prompt recognition of this presentation is necessary to preserve renal function.

**TH-PO1030**

**Kappa Light Chain-Associated Crystal-Storing Tubulopathy, Podocytopathy, and Histiocytosis in GI Tract, in a Patient with Multiple Myeloma Mishifumi Yamashita, 1,2 Albert Q. Lam, 1,2 Joseph V. Bonventre, 1,2,3 Vanesa Bijoj, 1,2 Pathology, Brigham and Women’s Hospital, Boston, MA; 1 Renal Disease, Brigham and Women’s Hospital, Boston, MA; 2,3 Harvard Medical School, Boston, MA.**

**Introduction:** Multiple myeloma manifests with variety forms of kidney disease, such as amyloidosis, cast nephropathy, and light chain deposition kidney disease. Among them, crystal-storing disease is a rare entity. We report an interesting case of a patient with examedulillary IgGk multiple myeloma, who presented with crystal-storing histiocytosis in GI tract, and subsequently developed crystal-storing tubulopathy and podocytopathy.

**Case Description:** A 60-year-old man with type 2 DM and HTN was found to have a 1 cm largeecal polyp on screening colonoscopy in 2009. The polyp showed diffuse infiltration by a plasma cell neoplasm and crystal-storing histiocytosis with k light chain (LC) restriction. At that time, the patient showed intact bone marrow, normal renal function and proteinuria of 0.5 g/24h. He was subsequently closely followed with endoscopy, SREP, and renal function tests. In 2014, he developed nephrotic range proteinuria (~4g/24h), slightly rising Cre to 1.12 mg/dL, and increased serum free k LC (216 mg/L). Kappa biopsy was performed, revealing many proximal tubular epithelial cells containing PAS-positive crystalline material in the cytoplasm. The glomeruli were unremarkable except for mild mesangial expansion. No significant immune deposits were present in glomeruli or tubulointerstitium, but there was slightly stronger background IF reactivity for k LC than l LC on frozen tissue sections. IF studies on prostate-digested paraffin sections revealed strong k LC reactivity of the materials aggregated in the tubular epithelial cells and podocytes, while l LC was negative. EM revealed extensive intracytoplasmic accumulation of crystalline material of rhomboid and rectangular shapes in proximal tubular epithelial cells and podocytes.

**Discussion:** LC-associated crystal-storing disease is a rare kidney disease. To our knowledge, this is the first reported case of coexisting crystal-storing tubulopathy, podocytopathy, and histiocytosis in the GI tract in a patient with multiple myeloma.
Paraneoplastic Tumor-induced Osteomalacia (TIO) in Small Cell Carcinoma: First Report of Positive Immunostaining for Fibroblast Growth Factor-23 in Small Cell Carcinoma

TH-PO1035

Paraneoplastic Tumor-induced Osteomalacia (TIO) in Small Cell Carcinoma: First Report of Positive Immunostaining for Fibroblast Growth Factor-23 in Small Cell Carcinoma

TH-PO1031

Introduction: Chronic lymphocytic leukemia (CLL) has been associated many glomerular disorders. Rarely, it has been associated with amyloidosis either as the sole clone responsible, or in association with a plasma cell clone possessing the same light chain. Though the co-existence of clonal plasma cells and CLL is known, the temporal association of this patient's nephrotic syndrome secondary to amyloid-lambda light chain due to a small lambda-restricted plasma cell population, temporally associated with a relapse of a kappa-restricted CLL.

Case Description: A 66 year-old male, diagnosed with kappa-restricted CLL in 2009 achieved complete remission after 6 cycles of fludarabine, cyclophosphamide and rituximab. 5 years later, he presented with foamy urine, generalized swelling, and weight gain. Serum creatinine was 1.1. Initial spot urine protein / creatinine ratio showed proteinuria of 5g/g which later increased to 10g/. During the previous year serum albumin fell from 3.6 to 2.6 to 5.7 mg/dL over the preceding year. His CD4+ T-cell count was 514 and his viral load never reached detectable levels. Only for preemptive renal transplantation. She received a 0-antigen mismatched deceased donor renal allograft with uneventful post-transplant course. Allopurinol dose was increased to 600 mg daily with complete resolution of disabling visual symptoms. Allograft function has been excellent with nadir creatinine of 0.82 and urine microscopy negative for DHA crystals.

Discussion: APRT deficiency is a autosomal recessive purine metabolism disorder where adenosine is oxidized by xanthine dehydrogenase to 2,8–dihydroxyadenine (2,8-DHA), forming insoluble urinary crystals, nephrolithiasis, nephrotic syndrome and renal failure. Literature reveals diagnosis of APRT deficiency is rare before kidney transplantation. Delay in diagnosis and xanthine oxidase inhibitor treatment predisposes to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.

Case Description: 41 y/o Caucasian female with recurrent 2,8-DHA nephrolithiasis since age 23 was maintained on Allopurinol. Clinical course was significant for obstructive uropathy requiring multiple stent placements; continued decrement in renal function and blood pressure. Temporal association of this patient's nephrotic syndrome secondary to amyloid-lambda light chain due to a small lambda-restricted plasma cell population, temporally associated with a relapse of a kappa-restricted CLL.

Discussion: Though the co-existence of clonal plasma cells and CLL is known, the temporal association of this patient’s nephrotic syndrome secondary to amyloidosis from a unique plasma cell clone expressing a different light chain supports the hypothesis that, in CLL, sharing the same microenvironment as non-tumor cells may activate bystander B-cells to express free light chains and in this case lead to amyloidosis.

Minimal Change Disease Diagnosing Relapsing Mantle Cell Lymphoma
Juan Calderon, Mark A. Perazella. Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Glomerular lesions are linked with hematologic malignancies, with minimal change disease (MCD) commonly associated with Hodgkin’s lymphoma. Diagnosis of the underlying hematologic disorder often precedes development of the glomerulopathy; however, in rare cases, MCD precedes discovery of the lymphoma by several months. We present a case of a new onset nerosis and AKI in association with undetected relapsing mantle cell lymphoma (MCL).

Case Description: A 74 y/o man with history of stage IV mantle cell lymphoma in remission developed AKI and new onset edema. Chemotherapy completed 1 year prior to presentation induced complete remission on bone marrow and follow-up PET scans. On presentation he denied B symptoms, had no new lymphadenopathy, and only noted decreased appetite. The patient was edematous and hypertensive. Serum cr was 2.4 mg/dl up from 1.3 mg/dl. High-grade, non-quantifiable urine protein was noted by the lab. Urine sediment was remarkable for numerous granular casts, oval fat bodies, and few uric acid crystals. Serum uric acid was 13.2 mg/dl. Therapy for tumor lysis syndrome was instituted due to concern for relapsing lymphoma in the setting of AKI. However, PET/CT scan was completely normal with no evidence for lymphoma. Furthermore, LDH was within normal limits. Kidney biopsy revealed normal glomeruli on light microscopy with acute tubular injury. EM revealed global effacement of foot processes. A diagnosis of MCD with focal tubular injury was made and steroid therapy was started. Peripheral flow cytometry and later a bone marrow biopsy confirmed a 23% tumor burden compatible with relapsed MCL.

Takehiko Kawaguchi, Mao Watanabe, Takafumi Azuma, Abhilash Koratala, Azra Bihorac. Nephrology, Univ of Florida, Gainesville, FL.

Introduction: Bevacizumab (BCZ), an inhibitor of vascular endothelial growth factor (VEGF), is approved for the treatment of various cancers. We are reporting a case of BCZ induced acute kidney injury (AKI) with proteinuria (PTN) and thrombotic microangiopathy (TMA) and providing a summary of evidence after systematic review of reported cases in literature.

Case Description: A 57-year-old Caucasian woman with no history of kidney disease presented with abdominal pain 4 weeks after completing most recent cycle of BCZ (first dose 3 weeks before hospitalization) for colon cancer. She presented with new onset of hypertension (HTN), diffusely tender abdomen and a significantly low hemoglobin of 4.6 g/dl. A non-contrast CT showed hemorrhagic pancreatitis. Her serum creatinine at presentation was 2.93 mg/dl (baseline: 0.5 mg/dl). Further workup showed platelets of 60,000/µL, lactate dehydrogenase of 510 mg/dl and LDH of 947 U/L. Peripheral blood smear showed 3 schistocytes/hpf. Urinalysis was positive for protein and 4 RBCs/hpf. 24 hour urine had 2.1 gms of protein. Hepatitis panel, ANCA and SPEP were negative. ADAMTS 13 activity was normal. Based on clinical diagnosis of AKI, PTN and TMA related to BCZ, the drug was discontinued and patient was managed conservatively without plasma exchange (PE). The creatinine gradually improved to 1.5 mg/dl while platelet count and hemoglobin returned to baseline at discharge.

Discussion: We identified 24 cases reported in literature with mean age of 62 years. All patients presented with AKI and PTN with 61% being nephrotic range. The onset of PTN ranged from 2 weeks to 28 months after initiation of BCZ. HTN occurred among 62% while TMA among 57% of patients. Most of the patients had partial or complete recovery of AKI and PTN with only 1 patient progressing to end-stage renal failure on dialysis ranging from 2 to 33 months. The causative mechanism of nephrotoxicity is thought to be related to low free VEGF levels leading to endothelial dysfunction and podocytopathy. Treatment includes withholding the drug if PTN exceeds 2g/day or permanent discontinuation for nephrotic syndrome and ACEI or thiazide diuretics for treatment of HTN. Drug induced TMA with normal ADAMTS 13 levels rarely requires PE.

5-Oxoprolinuria: A Rare Cause of High Anion Gap Metabolic Acidosis due to Acetaminophen Ingestion
Arvadan Masahidian, Sreyash G. Iyengar, Seyed-ali Sadjadi, Lisa Azime Hechanova. Nephrology, Loma Linda Univ, Loma Linda, CA; *Nephrology, Jerry L. Pettis Memorial Veterans Medical Center, Loma Linda, CA.

Introduction: Acquired 5-oxoprolinuria is a rare cause of high anion gap metabolic acidosis due to excessive acetaminophen ingestion. It largely goes unrecognized because an assay for 5-oxoproline is not widely available. The malnourished and chronically ill women with history of chronic acetaminophen ingestion are commonly affected. Acetaminophen levels are rarely in toxic range.

Case Description: A 57-year-old woman with a history of adipsis dolorosa was admitted for acute osteomyelitis. She was chronically taking acetaminophen containing pain medication. Her hospital course was complicated by anion gap metabolic acidosis and cardiorespiratory failure. Her acetaminophen level was not elevated. Usual causes of anion gap acidosis were ruled out. Finally, a urine organic acid screen showed elevated 5-oxoprolinuria levels. Acetaminophen containing pain medication was stopped, she was given IV hydration and sodium bicarbonate. Her anion gap metabolic acidosis would quickly resolve.

Discussion: Acute and chronic acetaminophen ingestion can lead to high levels of 5-oxoprolinuria. The pathophysiology behind acquired 5-oxoprolinuria has been mostly explained by reduced glutathione in prior case reports. 5-oxoprolinuria is an intermediate in the gamma-glutamyl pathway, the metabolic cycle responsible for creating glutathione and shunt amino acids into the cysteol. When glutathione levels are diminished, feedback inhibition ceases, causing an overproduction of 5-oxoprolin. Sepsis, amongst others etiologies, have been implicated in glutathione depletions. 5-oxoprolinuria clinically presents with altered mental status. One of the key aspects of diagnosing this disorder is the detection of 5-oxoprolin in urine. N-acetylcysteine may be an effective treatment that acts to restore intracellular glutathione levels. Extracellular fluid expansion with dextrose containing saline promptly improves symptoms. In conclusion, 5-oxoprolinuria should be considered in any patient with unexplained metabolic acidosis and recent acetaminophen ingestion. Overlooking the diagnosis can be costly.

Severe Tubulointerstitial Nephritis with Lymphoid Follicles in Sjögren’s Syndrome
Maiko Nagata, Takehiko Kagawuchi, Mao Watanabe, Takafumi Yamakawa, Moritoshi Kodamura, Hiroshi Kitamura, Toshiyuki Imasawa. Internal Medicine, National Hospital Organization Chiba-East Hospital, Chiba, Japan.

Introduction: Patients with Sjögren’s syndrome (SS) are at increased risk for the development of lymphoma. They present state of immunologic and lymphoid hyperactivity in SS may predispose patients to the development of lymphoid neoplasm. However, biopsy specimens from some of these patients do not meet histologic criteria for frank malignancy. We report a rare case of severe tubulointerstitial nephritis with lymphoid follicles in SS.

Case Description: A 66-year-old woman, who had developed general malaise for a few years, was admitted to our hospital, because of the rapid rise in the serum creatinine levels. Laboratory data showed calcium 10.2 mg/dl (8.9-10.7 mg/dl), phosphorus 4.7 mg/dl (2.5-4.6 mg/dl), alkaline phosphatase 2784 units/L (0-120 units/L), intact PTH 5707.8 pg/ml (12-65 pg/mL). She underwent tracheostomy and four-gland parathyroidectomy with autotransplantation in the subcutaneous abdominal tissue. Biopsy of the left maxillary bone revealed osteitis fibrosa consistent with renal osteodystrophy.

Discussion: Hyperparathyroidism can cause extraosseous calcification in arteries, joints, and viscera. Osteitis fibrosa cystica is characterized by increased bone turnover caused by secondary hyperparathyroidism. The prevention of a positive phosphate balance is the mainstay of treatment of high-turnover bone disease.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Scleroderma renal crisis was diagnosed according to the pathology result. Lisinopril 20 mg once daily was started, but the patient continued deteriorating leading to hemodialysis.

**Discussion:** Recognizing the early signs of kidney injury is important to initiate the treatment scleroderma renal crisis(SRC). Physicians should suspect for SRC once patients have signs of acute kidney injury regardless of elevated blood pressure or creatinine.

**TH-PO1042**

**Acetaminophen Associated 5-Oxoproline Acidosis in an Anuric End-Stage Renal Disease Patient**

**Michael Pham,** 1 Leslie F. Thomas, 2 Christine Snozek, 2

1 Internal Medicine, Mayo Clinic, Phoenix, AZ; 2 Nephrology, Mayo Clinic, Phoenix, AZ; 2 Laboratory Medicine & Pathology, Mayo Clinic, Scottsdale, AZ.

**Introduction:** Also known as pyroglutamic acid, 5-oxoproline is an intermediary in glutathione antioxidant metabolism. Reports of acetaminophen associated 5-oxoproline high-anion gap metabolic acidosis (HAGMA) has been slowly growing in the literature but remains under recognized in clinical practice.

**Case Description:** A 57 year old male with anuric end-stage renal disease (ESRD) was admitted for confusion and hypotension secondary to sepsis from infected lower extremity ulcer, poor oral intake, and excessive peritoneal dialysis. Laboratory evaluation revealed a depressed bicarbonate level of 17 mEq/L and an elevated albumin-corrected anion gap of 30 mEq/L. Despite correction of an elevated L-lactate with fluid resuscitation and antibiotics, his HAGMA persisted. An exhaustive investigation was unable to find a convincing etiology including commonly attributable organic acids, D-lactate, paraproteinemia, toxic exposures, and medications. Further inquiry revealed a protracted course of therapeutic acetaminophen ingestion with a weighted average daily dose of 1.3 grams in the four weeks leading to presentation. Serum 5-oxoproline was elevated to >100.0 nmol/mL (normal range 6.0-10.0 nmol/mL). Serum acetaminophen was undetectable. All acetaminophen containing medications were subsequently stopped. His clinical course improved with supportive care and he was discharged home. After 5 weeks of acetaminophen cessation, his serum 5-oxoproline normalized to 27.1 nmol/mL with anion-gap and bicarbonate levels returning to baseline.

**Discussion:** To our knowledge, we report the first case of acetaminophen associated 5-oxoproline acidosis in an anuric ESRD patient. Risk factors are thought to be related to glutathione deficiency which in turn favors the 5-oxoproline pathway of the γ-glutamyl cycle and results in accumulation. These risk factors include reactive acetaminophen metabolites, alcohol abuse, malnutrition, sepsis, renal dysfunction, and liver disease. As an under recognized entity in clinical practice, 5-oxoproline should be considered in adults with unexplained HAGMA and the above risk factors.

**TH-PO1043**

**Renal Amyloidosis Associated with Apolipoprotein C-II Deposition**

**Lohit Garg,** 1 Gerta Mane, 2 Sami S. Zarouk, 2 1 Dept of Internal Medicine, Beaumont Health, Royal Oak, MI; 2 Dept of Nephrology, Beaumont Health, Royal Oak, MI.

**Introduction:** A 62-year-old female with no family history of renal disease presented with a creatinine at 2.3 mg/dL and hypertension. Baseline creatinine was 1.2 mg/dL one year prior to presentation and she had 1+ proteinuria on urinalysis 3 years earlier. Serologic workup was negative for ANA, C3, C4, hepatitis B and C, HIV and SLE. A renal biopsy was performed by direct sequencing of apolipoprotein C-II and showed mutation in patient and a Novel Foxp3 Mutation

**Discussion:** Apolipoprotein C-II is a component of very low density lipoprotein and readily aggregates in lipid free conditions to form homogenous amyloid fibrils due to their intrinsic structure. To the best of our knowledge, this is the first case of apolipoprotein C-II renal amyloidosis. This case highlights the importance of performing DNA sequencing of exons of interest and LCMS on known amyloidogenic proteins to accurately diagnose and type the renal amyloidosis, which is critical for prognosis, treatment and genetic counseling.

**TH-PO1044**

**Membranous Nephropathy in a Young Child with IPEX-Like Phenotype and a Novel Foxp3 Mutation**

**Olena Charnaya,** Sun-Young Ahn, Asha Moudgil. Nephrology, Children’s National Medical Center, Washington, DC.

**Introduction:** Immune dysregulation, polyendocrinopathy, enteropathy, X-linked (IPEX) syndrome typically presents with heterogeneous manifestations. The syndrome is characterized by numerous auto-immune diseases due to dysfunction in the Foxp3 gene, which plays a critical role in maintaining immune tolerance.

**Discussion:** Membranous nephropathy in a young child with IPEX-like phenotype and a novel Foxp3 mutation is a rare and important case of membranous nephropathy in a young child with IPEX-like phenotype and a novel Foxp3 mutation.
**TH-PO1045**

**Acute Rejection of a Kidney Transplant in a Patient with Common Variable Immunodeficiency Syndrome**

**Omar Moussa Al Nimri,1 Rakesh Malhotra, Paisit Pauksakon, Beatrice P. Concepcion. Vanderbilt Univ Medical Center, Nashville, TN.**

**Introduction:** Common Variable Immunodeficiency (CVID) is a primary immunodeficiency characterized by hypogammaglobulinemia. Clinical manifestations include recurrent bacterial infections, autoimmune disorders, chronic lung disorders, hepatitis and lymphoma. We report a case of a patient with known CVID whose post-transplant course was complicated by acute cellular and humoral rejection which ultimately led to graft loss.

**Case Description:** A 44 y.o. male with ESRD was diagnosed in 11/2010 with CVID after developing peritonitis. He had a history of recurrent sinopulmonary infections and pneumococcal pneumonia. Immunoglobulin levels were undetectable and B and NK cell numbers normal. He was treated with monthly IVIG infusions. In 3/2012, he underwent living unrelated kidney transplantation (KT). Immunosuppression consisted of basiliximab, methylprednisolone (MP), FK, MMF and prednisone. Baseline creatinine (Cr) post KT was <1.2 mg/dl. A renal biopsy revealed membranous nephropathy with mild mesangial proliferative involvement. His main concern for patients with CVID undergoing KT was the risk of the induction of CVID syndrome. He had chronic renal failure and was on dialysis for 9 months at the time of KT.

**Discussion:** To our knowledge, this is the first reported case of a patient with diagnosed CVID on maintenance IVIG who then underwent KT. The main concern for patients with CVID undergoing KT is the risk of the induction of CVID syndrome. However, this case illustrates that rejection can occur and adequate immunosuppression remains essential. Balancing immunosuppression with the risk of infection can be quite challenging in this patient population, making them high risk for transplantation.

**TH-PO1046**

**Reverse Pseudohyperkalemia in a Patient with Non-Hodgkins Mantle Cell Lymphoma and Chronic Lymphocytic Leukemia**

**Paisit Paueksakon, Beatrice P. Concepcion.**

**Case Description:** A 14-month-old male with a history of failure to thrive (FTT), eczema (5 months old), with cough and wheezing for 4 months. Pertinent findings on physical exam included weight <25th percentile, length 105th percentile, BP 103/83 mmHg, and diffuse wheezing. Laboratory evaluation showed normochromic normocytic anemia, WBC 7.1 K/mm3, platelets were 154 K/mm3. His serum was 195 mg/dl, elevated serum glucose 303-326 mg/dl, normal serum calcium-creatine ratio 0.25, low Cr 43 μmol/l and C 4.7 mg/dl, and negative ANA and anti DNA. Thyroid function tests were normal; islet cell antibodies were elevated at 80 (normal <1.2). A renal biopsy revealed membranous nephropathy with mild mesangial proliferative changes. Upon further evaluation, he was found to have fat malabsorption and numerous food allergies. Genetic sequencing identified a novel missense mutation, c.767T>C leading to substitution of the highly conserved amino acid threonine with methionine at position 256 in the Fgpl3 gene. This mutation was predicted to be deleterious by in silico analysis thereby indicating the likelihood of CVID syndrome. Of note, Fgpl3 protein expression was borderline low. The patient was treated with prednisone and tacrolimus with partial resolution of extra-renal symptoms, improvement in proteinuria and is currently awaiting bone marrow transplant.

**Discussion:** Infants with IPEX syndrome usually present with auto-immune enteropathy, FTT, eczema, type 1 diabetes mellitus and thyroid dysfunction. Renal involvement is rare and includes proteinuria, hematuria and renal insufficiency. Some children with novel mutations may have partial features as seen in this case. A diagnosis of IPEX should be considered in any male infant or young child with proteinuria in association with systemic features of autoimmunity.

**TH-PO1047**

**An Unusual Presentation of Fibromuscular Dysplasia**

**Omar Mousa Al Nimri,1 Murray J. Mazer,2 Margaret L. Burks,2 Gerald Schumlan,1 Rachel B. Fissell.2 1Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; 2Radiology, Vanderbilt Univ Medical Center, Nashville, TN; 3Internal Medicine, Vanderbilt Univ Medical Center, Nashville, TN.**

**Introduction:** Fibromuscular dysplasia typically presents in middle aged women, often with hypertension. Depending on which arteries are involved, patients may present with transient ischemic attack, stroke [carotid artery FMD], or intractable hypertension [renal artery FMD]. We report an atypical case of fibromuscular dysplasia (FMD) in a male, that presented with renal infarction and no other symptoms.

**Case Description:** The patient is a 47yo male with no significant past medical history, including no history of Ehlers-Danlos syndrome or Marfan’s syndrome, who developed sudden left flank pain while driving. No urinary symptoms. No tenderness on exam. The pain was so severe that he went to a local ER. Initial evaluation notable for BUN 10 mg/dl, Cr 1.06 mg/dl, urinalysis negative for blood, protein, and white blood cells. CT angiography revealed sealed bleeding consistent with FMD at the distal main renal artery at the junction of the bifurcating branches, and tapered narrowing and occlusion most likely caused by spontaneous dissection with intramural hematoma, with upper pole infarct.

**Discussion:** This case is notable because the FMD occurred in a male, and because renal infarction is a rare presentation of FMD. The actual cause of the infarction is most likely arterial dissection, with or without peripheral emboli.

**Funding:** Clinical Revenue Support

**TH-PO1048**

**Clotting Filter Might Be an Early Clue to Fat Embolism Syndrome: Case Report and Literature Review**

**Deepak Jasuis, Melissa D. Anderson. Div of Nephrology, Indiana Univ, Indianapolis, IN.**

**Introduction:** Non traumatic causes of Fat Embolism Syndrome (FES) have been reported with bone marrow transplantation, osteomyelitis, pancreatitis, alcoholic fatty liver, and with liposuction. Etiology likely is fat particles entering the circulation with damage to capillary beds. Regardless of the mechanism initiating fat embolism, the end result is an intense inflammatory response. In the lungs, this induces lung injury that is indistinguishable from ARDS. FES can cause cerebral edema with raised intracranial pressure along with multi-organ failure and AKI.

**Case Description:** We present a 40-year-old African American lady who underwent non-myeloablative bone marrow transplant for Myelodysplastic anemia. One week after engraftment she developed sudden onset of respiratory distress leading to a cardio-respiratory arrest. She developed ARDS, multiple organ dysfunction syndrome and CVVH was initiated for oliguric AKI and Metabolic acidosis. Soon after initiating CVVH her filter clogged with white, creamy plaque which cleared after 2 successive filters. Patient met Gurd and Wilson’s criteria for diagnosis of Fat Embolism Syndrome. She had abundance of...
inflammatory cells on Broncho alveolar lavage including neutrophils and macrophages. Oil
Red-O stain (stain for lipid) was performed to quantify macrophages displaying positivity. The
initial Prep yielded 5 of 5 and the repeat prep yielded 11 out of 12 macrophages positive
for Oil-Red-O. CT brain was performed which revealed large acute strokes with midline
shift compatible with subdural herniation. No cerebral blood flow was identified on nuclear
scan and patient was declared brain dead and terminally weaned.

Discussion: With the absence of specific tests or criteria the diagnosis of FES is
dependent on the clinical acumen of the physician. Lipid inclusion in 30-70% of
macrophages / inflammatory cells is most suggestive of FES. Only proven treatment is
supportive care. We present that a clotting filter might be an earlier step to diagnose
fat embolism syndrome and sending the filter for pathological analysis looking for lipid
laden inflammatory cells is a less invasive approach as compared to quantification using
Broncho-alveolar lavage.

TH-PO1049
Fatal Hyponatremia with Glycine Solution During Hysteroscopy – Proposal for New
Mechanisms of Hyponatremia and Cerebral Edema
Suchita J. Mehta, Subodh J. Saggi, Andrea Roche-Recinos, Man S. Oh. Nephrology, Sunny
Downstate, Brooklyn, NY.

Introduction: We report a fatal case of severe symptomatic hyponatremia and cerebral
edema following hysteroscopy.

Case Description: 39 y/o woman underwent 70 mins hysteroscopic myomectomy, 6L of
glycine solution used for distension, without documented deficits. 3 hours later she
developed pulmonary edema. Hyponatremia of 117mEq/L first noted 4 hours post surgery,
baseline normal sodium. Course further complicated by agitation, vomiting, lethargy due
to cerebral edema confirmed on CT. Cerebrospinal fluid pressure 270 mm H20. Post-op day 3
she also developed central diabetes insipidus. Remained brain dead, extubated and died after 12
days.

Discussion: Hyponatremia with glycine is iso-osmolar occurring as a result of dilution
effect since glycine is retained in extra-cellular fluid before its metabolism by glycine
cleavage enzyme. Two mechanisms with our postulated explanation: 1) How does cerebral
edema develop with iso-osmolar hyponatremia? 2) Why is hyponatremia often
more severe than predicted? Proposed mechanisms: 1) Glycine can cross blood brain
barrier (BBB) by passive diffusion, as shown in rats and cats. Sodium, however, does not exit
brain via BBB as sodium transport across BBB occurs only inward. With glycine toxicity,
glycine accumulates in the brain cells after crossing BBB followed by water resulting in
brain edema. Possibility of glycine metabolism to ammonia leading to cerebral edema
cannot be ruled although high levels were not seen in our case.

TH-PO1050
Cytomegalovirus-Induced Atypical Hemolytic Uremic Syndrome After Renal
Transplant: Tiarunjreet Kaur,1 Andreis G. Chiesa-vortero,2 Leon C. Herlitz,2 Richard A.
Fatica.2 1Nephrology, Cleveland Clinic; 2Pathology, Cleveland Clinic, Cleveland, OH.

Introduction: Atypical hemolytic uremic syndrome (aHUS) may occur as de novo
disease and recurrence of primary renal disease in kidney transplant recipients. Causes of
de novo HUS includes immunosuppressive drugs, ischemia reperfusion injury, acute humoral
rejection, and viral infections. Some patients have a genetic susceptibility to the disease
from underlying mutations in the complement regulatory proteins. Cytomegalovirus (CMV)
has been rarely reported as a trigger for de novo post-transplant aHUS.

Case Description: A 61 year old male underwent deceased donor kidney transplant for
ESRD from presumed FSGS. 1 year following transplant he was admitted with profound
diabetes and weight loss due to CMV colitis and high grade CMV viremia (410,462 copies/ml).
His immune suppression was reduced and he was discharged home on oral valganciclovir
with near resolution of symptoms. He was re-admitted 1 week later with nausea, abdominal
pain, and acute kidney injury (Creatinine of 3.8 mg/dL, baseline of 1.8 mg/dL). His repeat
CMV viral load was significantly better at 70,000 copies/ml. Labs were suggestive of
microangiopathic hemolytic anemia. Hb 8 g/dL, platelets 58 K/uL, LDH 586 U/L, aHUS
(>20 mg/dL, and ADAMTS13 activity <67%). He received 4 sessions of plasmapheresis
without improvement and required initiation of dialysis. Histologic features of acute and
subacute endothelial injury, including segmental fibrin thrombosis of 2 arterioles were present on
transplant kidney biopsy. His aHUS genetic panel revealed several mutations in different
genes. aHUS serum activity was identified. He was started on eculizumab. His hemolysis labs
improved and he was taken off dialysis.

Discussion: CMV infection by way of endothelial injury can provoke aHUS in kidney
transplant recipients and possibly be enhanced by genetic predispositions. Postulated
mechanism of CMV-endothelial injury include increased leakage and platelet adhesion,
endothelial expression of Von Willebrand factor, E-selectin, vascular cell adhesion
molecule-1, and intercellular adhesion molecule-1. In our case, the aHUS process was
halted by use of eculizumab.

TH-PO1051
Acute Interstitial Nephritis from Anti-PD-1 Therapy with Pembrolizumab in Two
Patients with Advanced Non-Small Cell Lung Cancer
Heidi Mac G. Timbol, Anushree C. Shirali. Internal Medicine, Section of
Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Immune checkpoint inhibition with monoclonal antibodies (mAb)
targeted against programmed cell death receptor 1 (PD-1) is an emerging immunotherapy
for various cancers. Pembrolizumab, an anti-PD-1 mAb, is being used in clinical trials with
promising anti-tumor responses, but renal-specific adverse events are not clear. We report
2 cases of acute interstitial nephritis (AIN) in patients who received Pembrolizumab for
advanced non-small cell lung cancer (NSCLC).

Case Description: Two female patients, both 69 years of age, with metastatic NSCLC
were seen in outpatient nephrology clinic for acute kidney injury (AKI). Both patients
were enrolled in a clinical trial with Pembrolizumab, and their cases had been complicated
previously by auto-immune adenalitis. On labs, Patient A had an increase in creatinine to
2.1 mg/dL prior to cycle 16, up from a baseline of 0.9 mg/dL. Patient B had a creatinine
peak of 1.9 mg/dL after cycle 6, up from a baseline of 1.1 mg/dL. Medications were
significant for long-standing pantoprazole use in both patients. Urine sediment showed
many WBC clumps without casts or RBCs. Renal ultrasound was unremarkable. Variable
expansion with normal saline and cessation of potential nephrotoxins failed to reverse renal
dysfunction in either case. Each patient underwent CF-guided renal biopsy, which showed
diffuse AIN. Steroid therapy with prednisone 60 mg/day with a slow taper was started and
creatinine improved to baseline.

Discussion: These two cases highlight a new association between AIN and
Pembrolizumab, which to the best of our knowledge has not been previously reported.
While both patients were on pantoprazole therapy prior to their AKI, this medication
was not new. Rather, the time course of AKI best fits with initiation of pembrolizumab.
Additionally, their pre-existing drug-related auto-immune adenalitis suggests a possible
auto-immune component to AIN from anti-PD-1 therapy. With increasing use of these
agents, clinicians should maintain a high index of suspicion for AIN as a cause of AKI and
have a low threshold for kidney biopsy to confirm diagnosis and initiate early treatment.

TH-PO1052
Concurrent Anti-PLA2R and ADAMTS 13 Inhibitor – Coincidence or a Clue to
Pathogenicity? 1 Laith Al-Rabadi,1 Moshe Shashar,1 Parikshit Duriseti,2 Ami Patel,1 Aala
Jaberri,1 Ashish Upadhyay,1 Joel M. Henderson,1 Vipul C. Chitalia,1 David J. Salam,1 Laurence H. Beck.1
Internal Medicine, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a hematologic
emergency associated with a decrease in ADAMTS13 activity, most often due to the presence
of an inhibitor. Severe proteinuria is an unusual feature of TTP. The concurrent presence
of an inhibitor. Severe proteinuria is an unusual feature of TTP. The concurrent presence
of anti-PLA2R and ADAMTS13 inhibitor has never been previously reported until now.

Case Description: Herein, we present a case of a 70 year old male who presented with
generalized anasarca. Physical exam was remarkable for BP 180/100, and 2+ peripheral
edema. Workup revealed Hgb 7.4, Pts 46, Creatinine 1.45, LD 742 and undetectable
haptoglobin. His peripheral smear showed many schistocytes. These findings were
consistent with thrombotic microangiopathy. Urine analysis showed 2+ blood, 3+ protein.
Examination of the urinary sediment revealed oval fat bodies, and some RBCs. The patient
was initiated on plasma exchange and prednisone (1 mg/kg). Further studies revealed a serum
albumin of 2.2 and urine protein/Cr of 9. Kidney biopsy showed features of membranous
nephropathy with many subepithelial deposits flanked by new basement membrane material
(spikes). The deposits were immunoreactive for PLA2R, with IgG1 but no IgG4 reactivity.
In addition, there was moderately severe arterial and arteriolar sclerosis and segmentally
prominent double contour formation in the glomeruli. These vascular changes suggest a
primary form of endothelial injury and consistent with chronic thrombotic microangiopathy.
VWF protease activity came back as less than 3% with an elevated inhibitor titer of 1.3
BU. Anti-PLA2R was detected in the urinary at a titer of 40.3 IU/ml. Both were exclusively of the
IkG1 subtype by western blotting, atypical of the usual IgG4 predominance for both autoimmune
disorders.

Discussion: Although prednisone, plasmapheresis, and supportive therapy have
thus far stabilized both diseases, rituximab would be our first choice for more definitive
treatment of these concurrent autoimmune disorders. This unique case may help to further
our understanding of the mechanistic pathways underlying both of these clinical entities.
Cathryn J. Byrne

Introduction: Microparticles were seen on EM. Podocytes at the subepithelial aspect of the basement membrane, with deposition of spherical material. No electron dense deposits were found. Immunofluorescence was negative other than trace IgM and C3 reactivity along the peripheral capillary walls and in the mesangium. The majority of cases do not contain electron-dense deposits, nor do they show any reactivity with IgG. Here we present the first reported case of PIG in a patient of African descent.

Case Description: A 58 year old Africa female from Ghana with history of systemic lupus erythematosus presented to the nephrology clinic for the evaluation of proteinuria. She has more than 8L/day. Her urine osmolality increased to 444 mOsm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After augmentation, the patient reported ingestion of an excessive amount of melatonin for insomnia, but no other medications. She received DDAVP for 4 days with complete resolution of hypernatremia and polyuria.

Discussion: Extensive literature review revealed that rat studies show melatonin regulates the glomerular filtration of both sodium and water. It stimulates sodium tubular transport in the proximal tubules but its receptor or action on the distal tubule is unknown. Most patients with melatonin overdose have been less than 24 years old. It has been suggested that melatonin overdose could lead to fatal outcome. This is the first case of melatonin overdose in a 66-year-old man with a history of hypertension, hyperlipidemia, and diabetes.

Diabetes Insipidus Induced by Excessive Intake of Melatonin

Rahul N. Pawan, Savneek S. Chugh, Amy R. Patel.

Introduction: Melatonin is produced by the pineal gland and regulates the sleep-wake cycle in humans. Specific over the counter melatonin formulations can be used to treat circadian rhythm-related sleep disorders and age-related insomnia. Acute intoxication of melatonin and its deleterious effects have rarely been reported.

Case Description: A 24 year old female, with no known medical history, was brought to the hospital for altered mental status and possible drug overdose. Her vital signs were a Tmax of 101.8 F, HR 170, BP 150/103, and a pulse oximetry of 98% on 2L NC. On physical exam, she had mildly dilated and sluggish pupils. Due to an altered sensorium, she was intubated for airway protection. Initial lab tests showed a sodium of 140 mEq/L, potassium 3.9 mEq/L, chloride 113 mEq/L, bicarbonate 25 mEq/L, BUN 8 mg/dL, and a creatinine of 0.6 mg/dL.

Melatonin is produced by the pineal gland and regulates the sleep-wake cycle in humans. Specific over the counter melatonin formulations can be used to treat circadian rhythm-related sleep disorders and age-related insomnia. Acute intoxication of melatonin and its deleterious effects have rarely been reported.

Discussion: Extensive literature review revealed that rat studies show melatonin regulates the glomerular filtration of both sodium and water. It stimulates sodium tubular transport in the proximal tubules but its receptor or action on the distal tubule is unknown. Most patients with melatonin overdose have been less than 24 years old. It has been suggested that melatonin overdose could lead to fatal outcome. This is the first case of melatonin overdose in a 66-year-old man with a history of hypertension, hyperlipidemia, and diabetes.
Virology screen, immunology screen, urine culture, urine PCR, DSA, Cyclosporin levels and renal ultrasound were normal with no change in patients haemodynamic status. Hence a kidney biopsy was performed to identify the cause, which showed evidence of calcification with surrounding inflammation with no evidence of rejection. Her steroid dose was transiently increased due to the inflammation seen on the biopsy and all her calcium and hydroxychloroalcalcerol supplements were suspended, which lead to recovery of her renal function to baseline.

Discussion: Our patient had mild hypercalcemia prior to parathyroidectomy with a stable renal function and following parathyroidectomy patient developed renal dysfunction despite similar levels of calcium, which can only be explained by iatrogenic calcium supplementation based on the renal biopsy. Perhaps routine monitoring of urinary calcium may help us guide the amount of calcium given to such patients and aiming for lower levels of calcium post parathyroidectomy rather than normal levels may prevent such phenomenon.

TH-PO1059

Severe Ketaoid Acidosis After Bariatric Surgery in a Patient Treated with Canagliflozin

Hossein Ghorban, Christopher C. Wong, Miroslaw Smogorzewski. Div of Nephrology, Keck Hospital of USC, Los Angeles, CA.

Introduction: Euglycemic diabetic ketoacidosis is relatively uncommon and is usually caused by starvation and a lack of caloric intake. Sodium-glucose cotransporter-2 (SGLT-2) inhibitors have been very recently implicated as a cause of severe ketoacidosis. We report a case of severe euglycemic DM ketoacidosis induced by a combination of SGLT-2 inhibitor use and low caloric intake after bariatric surgery. While withdrawal of canagliflozin, its effect on glycosuria persisted for 7 days. Considering long biological effect of SGLT-2 inhibitors, they should be stopped weeks before a bariatric surgery to avoid ketoacidosis.

Current presentation due to poorly controlled DM-2. Ten days prior to his hospitalization, he underwent gastric sleeve bypass surgery and was discharged on post-op day 1. Upon admission to the ICU, his physical exam was benign except for a PR 108/min, RR 29/min, and a normal BP 128/69 mmHg. ABG showed pH 6.9, pCO2 13mmHg, pO2 99mmHg, bicarbonate 5mg/dL. His anion gap was 37, and serum glucose 152 mg/dL, with normal kidney function. Urine toxicology and blood levels of lactic acid and blood glucose were normal. Urinalysis revealed pH 5.0, glucose >1000 mg/dL, and ketones\textgreater;150 mg/dL. During the first day, he received 150 mg of sodium bicarbonate; his canagliflozin was held. He was intubated and started on a regular insulin drip along with 5% dextrose solution. He remained intubated for an insulin drip for 3 days, received 5-10 L of normal saline and extensive electrolyte replacement; blood glucose never exceeded 200 mg/dL while glycosuria persisted until day 7. C-peptide increased from 0.29 to 2.26 mg/L. Once anion gap was closed and patient stabilized, he was extubated and weaned off the insulin drip.

Post-procedure, we present a new case of severe euglycemic DM ketoacidosis induced by canagliflozin and his effect on glycosuria persisted for 7 days. Considering the long biological effect of SGLT-2 inhibitors, they should be stopped weeks before a bariatric surgery to avoid ketoacidosis.

APOL1 Polymorphisms in Deceased Donors and Primary Glomerular Disease Post-Kidney Transplant: First Case Report

Pratik B. Shah, Alexander C. Wiseman, James E. Cooper. Renal Diseases and Hypertension, Univ of Colorado Medical Center, Aurora, CO.

Introduction: Genetic polymorphisms in APOL1 (G1/G2) are associated with glomerular disease and ESRD. An emerging issue is whether screening for APOL1 (G1/ G2) should be performed in living or deceased kidney donors.

Case Description: A 46-year-old Caucasian male with a history of SLE received a deceased donor kidney transplant. The deceased donor was a 12-year-old African American male. 9 months post-transplant, he presented with acute kidney injury following an elective dental procedure. On post-op day 0, his SCR was 7.9 mg/dL, with spot UPC of 2 g/L Cr, platelet count of 58000, LDH of 2022 U/L, haptoglobin of <14 mg/dl. The patient did not recover kidney function. The patient's acute kidney injury was attributed to collapsing glomerulopathy in the setting of immune mediated microangiopathy or rejection. Plasma CMV PCR was positive at 234000 copies/ml. The patient ultimately did not recover kidney function. The patient's acute kidney injury was attributed to collapsing glomerulopathy in the setting of acute CMV infection. The patient's deceased donor DNA was analyzed for APOL1 risk variant genotyping and was positive for two APOL1 risk variants: compound heterozygosity for APOL1 G1, c.1024A>G; p.Ser342Gly and APOL1 G2 c.1164delTTATAA. The sister kidney from the same deceased donor had been transplanted to a 63 year old female with ESRD from diabetes. Six months post-transplant, she had new onset proteinuria of 2.5 g/d, and a renal biopsy demonstrated focal segmental glomerulosclerosis (FSGS). Her renal function and proteinuria remain stable 12 months post transplant.

Discussion: To our knowledge, this is the first case report of high risk variant APOL1 in a deceased donor with subsequent primary glomerular disease in both the recipients. This suggests that deceased kidney donor APOL1 genotyping may be informative in predicting graft outcomes. This also highlights the important question of whether routine screening of African American donors for high risk APOL1 variants before renal transplant is warranted. This consideration must be balanced against the significant limitations in kidney availability.

Atypical HUS in an Infant due to a Novel Gene Mutation
Mohamed Alejari1, Robin Amy Krensford1, M. Khurrum Faizan2. 1Rhone Island Hospital; 2Hasbro Children’s Hospital; 3Hasbro Children’s Hospital.

Introduction: Atypical HUS (aHUS) is a rare genetic renal disease associated with over-activation of the alternative pathway of complement. A variety of mutations have been described in the complement pathways genes in patients with aHUS. We report a case of aHUS due to a novel mutation in the factor B (CFB) gene.

Case Description: 10 months old Caucasian girl who presented with diaphoresis, vomiting, and swelling in her extremities and face for 2 weeks preceded by an episode of cough, runny nose with non-bloody diarrhea. Upon presentation her BP was 150/90 mm Hg. Lab data showed WBC 16.4 × 10^9/L, PLT 1x10^11/L, BUN 46 mg/dL, creatinine 0.3 mg/dL, LDH 632 IU/L, normal ADAMTS13 and C3 level 7.9 mg/dL. Urine revealed 32RBC/hpf with proteinuria, Urine Protein Creatinine ratio 19 g/g. Peripheral blood smear revealed schistocytes. Stool was negative for Shiga toxin. Clinical presentation was suggestive especially of aHUS and patient was treated with Eculizumab. She had worsening anasarca with neck edema, requiring a tracheostomy after failed intubation. She required RRT for volume management during her hospital course after failing diuretics. Renal biopsy showed acute and chronic thrombotic microangiopathic changes consistent with aHUS. Genetic testing revealed a novel mutation in the complement Factor B gene in the region of binding to Von Willebrand factor. It also showed a heterozygous deletion of CFBR1 and CFHR4. Patient recovered renal function 3 weeks after presentation. C3 remained low after recovery of renal function. RRT was stopped after two weeks and she was discharged on ACEI with Eculizumab every 2 weeks.

Discussion: Gain of function mutations in CFB are extremely rare in aHUS and occur in only 1% to 2% of cases of familial aHUS. There is increased C3b affinity and form hypercatabolic C3 convertase that is resistant to dissociation, thus increasing C3b formation. Anti C5 Antibody Eculizumab has revolutionized the care of aHUS, improving the overall prognosis of these patients. This case is the first case reported with this novel CFB gene mutation. No long term data available regarding the outcomes of aHUS with Eculizumab therapy.

TH-PO1063

Oxymorphone-Induced Thrombotic Microangiopathy and Acute Kidney Injury

Introduction: Intravenous (IV) administration of oral oxymorphone represents an emerging pattern of drug abuse with increasing popularity and unforeseen adverse consequences. Here, we present a case of IV Oxymorphone abuse associated with thrombotic microangiopathy (TMA) and acute kidney injury (AKI).

Case Description: A 32-year-old man with a history of IV drug abuse presented with non-healing left arm wound. Physical examination was unremarkable except for a left non-healing left arm wound. A variety of mutations have been described in the region of binding to V on Willebrand factor. It also showed a heterozygous deletion in only 1% to 2% of cases of familial aHUS. There is increased C3b affinity and form hypercatabolic C3 convertase that is resistant to dissociation, thus increasing C3b formation. Anti C5 Antibody Eculizumab has revolutionized the care of aHUS, improving the overall prognosis of these patients. This case is the first case reported with this novel CFB gene mutation. No long term data available regarding the outcomes of aHUS with Eculizumab therapy.

Discussion: This patient presented with TMA, acute kidney injury, and normal serum ADAMTS13 activity. His urine oxymorphone was positive and he admitted to IV abuse of oxymorphone. Serum complement levels were normal as were all other investigations. ADAMTS13 level was >100%. Kidney biopsy showed evidence of TMA supported by glomeruli filled with focal extravasated and crenated RBCs. Immunofluorescence (IF) was negative for immune complex deposition but C4d staining was positive. Conservative management including platelet transfusion, without plasma exchange, was followed by stabilization of renal function.

This patient presented with TMA, acute kidney injury, and normal serum ADAMTS13 activity. His urine oxymorphone was positive and he admitted to IV abuse of oxymorphone. IgG4 Mediated Isolated Reteroperitoneal Fibrosis Causing Obstructive Uropathy in a Patient with Subclinical Ankylosing Spondylitis
A. H. Morgan, V. Aggarwal. Internal Medicine/ Nephrology Div, SUNY Upstate Medical Univ, Syracuse, NY.

Introduction: Reteroperitoneal fibrosis is a rare manifestation of systemic autoimmune disease, characterized by the presence of inflammatory and fibrotic retroperitoneal tissue that often encases the ureters causing obstructive uropathy. Idiopathic retroperitoneal fibrosis is currently being recognized as IgG4-related disease. We report a case of histologically confirmed IgG4 related retroperitoneal fibrosis in a patient with subclinical Ankylosing spondylitis. This association has been rarely reported.

Case Description: A 70 year old male with PMH of HTN, diabetes and baseline creatinine of 1.2 mg/dl presented with weakness, vomiting and decreased urine output. Physical examination was unremarkable. Further evaluation revealed serum creatinine of 13.3 mg/dl and BUN=110 mg/dl. He also has mild hyperkalemia and anion gap metabolic acidosis. Urine analysis was negative for protein or RBC cast. A CT scan of the abdomen and pelvis, showed retroperitoneal mass, Aortitis, ankylosis of SI joint bilaterally with osseous fusion and bilateral mild hydronephrosis. Bilateral nephrostomy tubes were placed with excellent urine output as well as improvement of creatinine to baseline in 48 hours. He subsequently had a CT guided biopsy of the retroperitoneal mass. Histopathology revealed dense fibrous tissue with significant IgG4 positive plasma cell infiltrate. Immunohistochemical workup showed elevated level of IgG4 as well as positive HLA-B27. Hence this obstructive uropathy was confirmed to be due to IgG4 related retroperitoneal fibrosis. He also met the clinical and imaging criteria for Ankylosing spondylitis. Treatment with oral corticosteroids was initiated by rheumatology.

Discussion: Our hypothesis is that the patient had a subclinical Ankylosing Spondylitis which triggered IgG4 mediated disease that lead to retroperitoneal fibrosis which caused bilateral obstructive uropathy. Hence role of ankylosing spondylitis in development of idiopathic retroperitoneal fibrosis by IgG4 mediated mechanisms warrants further consideration and for nephrologists to be aware of this rather unusual presentation.

TH-PO1068
IgG4-Related Tubulo-Interstitial Nephritis with Low Complement C4, Circulating Immune Complexes and an Elevated IgG4, Presenting as Unilateral Hydronephrosis and Prostatitis
C. M. Groenenbos, A. A. Van norel, J. Christiaan F. M. Klok, Mm. Smits, Peter Van den Tillaar. 1Nephrology, Deventer Hospital, Deventer, Netherlands; 2Radiology, Deventer Hospital, Deventer, Netherlands; 3Pathology, Deventer Hospital, Deventer, Netherlands; 4Urology, Deventer Hospital, Deventer, Netherlands.

Introduction: IgG4-Related Disease is characterized by infiltrates of IgG4-positive plasma cells and eosinophils in different organs and is a rare cause of tubulointerstitial nephritis (TIN) and idiopathic retroperitoneal fibrosis.

Case Description: A 67 year old white male had a creatinine increase from 0.90 to 2.06 mg/dl. He had fatigue and dyspnea. Complement C3 was normal, C4 low 0.06 g/l, C1Q-BA 28% (>50%), but ANA/ENA, Anti Jo1, ANCA, HBV, HCV and M-protein were negative. IgG 3.0 g/dl (N 0.8-1.4 g/l). Urine showed 3 RBC/HFP, protein 0.36 g/l, albumin 61 mg per 24h. On ultrasound both kidneys were 13 cm with right sided hydronephrosis and 300 ml urinary retention. CT-Urography showed obstruction of the right ureter at the iliac artery. A bladder catheter and ureteral stent did not improve renal function. A MAG-3 IV injection showed a non-functioning right kidney without hydronephrosis on ultrasound. After revision, the CT showed soft tissue surrounding the aorta and the right iliac artery. A kidney biopsy showed TIN with a dense infiltrate of IgG4-positive plasma cells and eosinophils with impressive fibrosis, a vein showed obliterator phlebitis, consistent with IgG4-related TIN. The patient was treated with prednisone 40 mg daily and after 1 week he reported a dramatic clinical improvement, his creatinine decreased to 1.7 mg/dl.

Discussion: Hydronephrosis first dominated the clinical picture, delaying diagnosis, but the low C4, positive C1Q-BA and large kidneys suggested IgG4-related TIN. We found only one report of IgG4-related TIN with hydronephrosis, but that was after uterine tract tuberculosis. Rare cases were reported of IgG4-related segmental ureteritis or prostatitis without TIN and the cases of IgG4-related TIN had no hydronephrosis. The present case is the first with coincident biopsy-proven IgG4-related TIN, ureteral obstruction and prostatitis. Hydronephrosis does not exclude, but may be part of IgG4-related disease.

TH-PO1069
Monoclonal Light Chain Proximal Tubulopathy with Unique Ultrastructural Microtubular Inclusions

Introduction: Renal disease related to monoclonal gammopathies is common and varied. An uncommon lesion is proximal light chain tubulopathy (PLCT), which may present with Fanconi syndrome (FS) and variable degrees of renal failure. Most have ultrasonic (US) findings of proximal tubule damage with crystalline inclusions of Ig λ's within proximal tubular cells (FTS). A minority of PLCT do not have crystals; these may have LC restrictions. We describe a patient with a rare finding: PLCT with light chain (LC)-related microtubular inclusions.

Case Description: 74 year old man had progressive CKD over 2 years with serum creatinine rising from 1.3 to 3.4 mg/dl. A serum M spike, 1.0 g/dl of Igλs, was present. Urine protein, 1200 mg/day, contained 13% albumin, and 45% M spike of IgGκ. No findings of FS. Renal biopsy abnormalities were limited mainly to the proximal tubules (PT). The PT’s were bright red on trichrome stain and showed granular cytoplasmic changes and marked cell shedding with red stain with PAS. On immunofluorescence, the LC's were strongly stained 3-4+ for total Ig κ, IgG, IgM, IgA and λ were negative. On EM, non-branching microtubules, ranging in size from 26–36 nm were membrane bound within PT lysosomes. No amyloid filaments or crystalline structures were seen. Bone marrow subsequently showed a 1 grade B cell lymphoma with clonal λ B cells and small population of κ plasma cells.

Discussion: Two large biopsy reports of monoclonal renal disease found PLCT to be very uncommon, 0.5 – 4%. Most have findings of crystalline inclusions, less without crystals. To our knowledge, there are only 2 other cases with inclusions similar to our findings. We describe two cases of monoclonal immune deposition causing membranous nephropathy in SLE.

TH-PO1070
IgG1-kappa Monoclonal Membranous Nephropathy Associated with Systemic Lupus Erythematosus
Stephen W. Roderer, Anjali A. Satoskar, Tibor Nadasy, Isabelle Ayoub, Brad H. Rovin, Samir Parikh. The Ohio State Univ, Columbus, OH.

Introduction: Monoclonal gammopathy of renal significance is a recently described condition in which monoclonal protein is found in the kidney but often without a circulating clone. It has not been seen with SLE. We describe two cases of monoclonal immune deposition causing membranous nephropathy in SLE.

Case Description: Case 1: An 18 year old female with SLE developed nephrotic syndrome with 4g/d proteinuria and normal serum creatinine. Immunofluorescence (IF) on renal biopsy showed diffuse IgG1-kappa staining in the mesangium and along the capillary loops. Lambda staining was negative. Electron microscopy showed a low grade B cell lymphoma with clonal κ B cells and small population of κ plasma cells.

Case 2: A 38 year old female with SLE developed proteinuria of 2.5g/d and microscopic hematuria. Similar to case 1, IF on renal biopsy showed diffuse granular IgG1-kappa deposition in the mesangium and along the capillary loops. Lambda staining was negative. EM revealed monomeric κ light chains without subepithelial electron-dense deposits. Workup for a systemic monoclonal gammopathy, including urine and serum immunofixation and serum free light chains was negative. A diagnosis of IgG1-kappa monoclonal membranous nephropathy associated with SLE was made. She was started on an ACEi and prednisone with improvement in proteinuria from 2.5g/d to <0.5g/d.

Discussion: These 2 cases represent a newly described form of monoclonal membranous nephropathy associated with SLE. In both cases the monoclonal protein was restricted to the kidney. The pathogenesis is unclear but may be due to autoreactive B-cells producing an abnormal clone locally in the kidney. The clinical significance must still be elucidated but it may impact treatment and long-term outcomes so clinicians caring for SLE patients should be aware of this association. Further, these patients may develop a systemic monoclonal gammopathy, so close monitoring is necessary.
Discussion: This is the second reported case of necrotizing and crescentic glomerulonephritis associated with IgG1-κ anti-GBM IgG. It is unknown if this disease is driven by an underlying autoimmune process or monoclonal gammopathy. Both cases are atypical for classic anti-GBM disease due to their relapsing nature.

TH-PO1072
First Reported Case of Collagenofibrotic Glomerulopathy in a Patient with Multiple Myeloma

Arun Rajasekaran, 1 Indraneez Mogolar, 2 Lilian W. Gaber, 1 Jai Radhakrishnan, 1 Ala Abudayeh, 1 Internal Medicine, UCF College of Medicine, FL. 1 Div of Renal Diseases & Hypertension, UT-Medical School at Houston, Houston; 2 Pathology, The Methodist Hospital, Houston; 1 Div of Nephrology, Columbia Univ Medical Center, New York; 1 Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston.

Introduction: Collagenofibrotic glomerulopathy is an extremely rare idiopathic glomerular disease characterized by abnormal accumulation of atypical spiraled and frayed type III collagen fibrils in mesangial and subendothelial areas, and elevated serum procollagen III and hyaluronan levels. Proteinuria (commonest feature), edema, hypertension, and occasional progression to ESRD are commonly seen. We report the first published case of Collagenofibrotic glomerulopathy in Multiple Myeloma.

Case Report: A 54 year old male with recent history of IgG kappa Multiple Myeloma (May 2011); with underlying CKD stage 3 and baseline Creatinine at 2 mg/dl, in remission status-post autologous stem cell transplant (January 2012) and on Lenalidomide maintenance therapy, presented with proteinuria of 4g. Kidney biopsy revealed nodular and Focal glomerulosclerosis with IF weakly (+) for IgG, IgA, IgM, C3, C4, Clq, kappa and lambda light chains with +3 staining for IgM and Clq. EM showed patchy foot process effacement with massive deposition of collagen-III fibers. The weak and non-specific staining, along with massive collagen-III fiber deposition fitted with the description of Collagenofibrotic glomerulopathy, and made an immune-mediated kidney injury less likely.

Discussion: Discussion: Collagenofibrotic glomerulopathy is an extremely rare disease characterized by massive intraglomerular atypical type III collagen fiber deposition. Proteinuria is the cardinal manifestation of this disease. Clinically, patients present with edema and hypertension and often progress to ESRD. Etiology and pathogenesis remains elusive. Most cases are seen in Japan and an autosomal-recessive mode of inheritance has been described. Definitive diagnosis is established by identifying collagen-III fibrils by IF and EM with special staining. No specific treatment is available unfortunately.

TH-PO1073
Severe Acute Kidney Injury (AKI) with Organomegaly in a 17 Days Old Newborn: When Pathology Makes the Difference

Marie-Michele Gaudreau-Tremblay, Catherine Litalien, Natalie Patye, Aicha Merouani. CHU Sainte-Justine, Montreal, QC, Canada.

Introduction: Acute tubulointerstitial nephritis (ATIN) is a significant cause of AKI in children and is often due to allergic drug reactions or infections. Diagnosis of ATIN is usually clinical and renal biopsy not routinely performed.

Case Description: A previously healthy 17 days old baby presented with decreased oral intake, vomiting and oliguria. His first laboratory results showed an elevated creatinine (2 mg/dl) and thrombocytopenia (platelets 18x10^4/L). His urinalysis was abnormal (proteins 12 g/L). His chest and abdominal CT revealed multiple abscess formations in the right lung and liver. A skin biopsy was consistent with drug-induced GTIN caused by T-cell lymphoma. Although CHOP chemotherapy induced remission of lymphoma and disappearance of multiple abscesses, his renal function was not recovered. At 6 days of age, a renal biopsy was performed and showed a massive and polymorph infiltrate with destruction of tubular structures [Fig.1, A-B]. Ischemic glomerulitis, double glomerular membranes and mesangial oedema [Fig.1, C-D] were observed. Administration of steroids was followed by improvement of his renal function and cessation of diuresis after 6 days. The patient has been disease-free since.

Fig 1: Renal biopsy in a newborn with severe AKI

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

Renal biopsy findings were consistent with severe ATIN. The most likely etiology for his AKI was drug induced. This patient was started on prednisone medication and a follow-up cytopathology revealed a left grade III vesicoureteral reflux.

Discussion: ATIN is rare in neonates and usually drug-induced. This is the first report of a renal biopsy-proven AKI in a neonate. Even if procedural risks of a renal biopsy are not negligible, it can make the difference in certain cases by dictating appropriate management.

TH-PO1074
AL Lambda Amyloidosis in Kidney Transplant Allograft as a Cause of Massive Nephrotic Syndrome with AKI

Manish K. Saha. 1 Dept of Nephrology, Univ of Alabama, Birmingham, AL; 2 Dept of Nephrology, Univ of Alabama, Birmingham, AL.

Introduction: This interesting case showed AL lambda amyloidosis in kidney transplant allograft as a cause of nephrotic syndrome with AKI. 51 year old African American female with history of ESRD secondary to APOD s/p DDKT in Oct 2010 with Thymoglobulin induction, maintained on 3 drug immunosuppression including tacrolimus, mycophenolate and prednisone with baseline creatinine of 1.5, presented with anasarca and orthostatic hypotension. Her serum albumin was 1.2mg/dL. She underwent extensive investigations including Echo, transplant allograft ultrasound all of which came back unremarkable. She has sudden onset sub nephritic range proteinuria in Aug 2013 which progressed to nephrotic range in Feb 2014. She has 34g of protein on a 24h urine collection 90% of which was albumin. Her UPCR gradually got worse from 10 to 32 with worsening in serum Cr from 1.5 to 5.5. She has poor response to IV Lasix with albumin infusion and has severe orthostatic symptoms. Her SPEP and UPAP were negative. Urine IFE was also negative. Urine IFE showed lambda light chain. Serum free light chain showed elevated lambda levels. Due to worsening and explosive proteinuria with worsening anasarca renal allograft biopsy was done that showed lambda AL amyloidosis involving glomeruli, arterioles and arteries along with light chain proximal tubulopathy. Congophilic casts consistent with light chain cast nephropathy. Pt underwent bone marrow biopsy that did not show MM. She was treated with bortezomib combined with cyclophosphamide and dexamethasone and has good response with improvement in orthostatic hypotension, serum albumin level and lambda light chain got normal.

TH-PO1075
Granulomatous Interstitial Nephritis Caused by T-Cell Lymphoma

Yohisatsu Ohara, 1 Namiko Kobayashi, 2 Yohei Kono, 1 Tomoharu Yoshimine, 1 Mariko Ichijo, 1 Toshiyuki Hira, 1 Keiko Suzuki, 1 Takeyoda Toda, 1 Michio Nagata, 2 Noriaki Matsui, 1 Dept of Nephrology, Tsuchiura Kyodo General Hospital, Tsuchiura, Ibaraki, Japan; 2 Renal Pathology, Univ of Tsukuba, Tsukuba, Ibaraki, Japan; 3 Dept of Pathology, Tsuchiura Kyodo General Hospital, Tsuchiura, Ibaraki, Japan.

Introduction: Granulomatous tubulointerstitial nephritis (GTIN) occurs 0.5-1.3% in renal biopsy samples. Granuloma is basically caused by type IV allergy; T cell mediated mechanism against drug, foreign bodies and microorganisms such as Mycobacterium. We here present, a rare case of GTIN associated with T cell lymphoma.

Case Description: Sixty-year-old man with uncontrolled diabetes complained right chest pain. Chest and abdominal CT showed multiple abscess formations in the right lung and liver. A skin biopsy was consistent with drug-induced GTIN caused by T-cell lymphoma. Light microscopy showed diffuse interstitial inflammatory infiltrates predominantly with mononuclear cells including some atypical cells, which invaded tubular basement membrane resulting impaction of these cells in the tubular lumina. Since drug induced lymphocyte stimulation test (DSLST) was positive for TAZ/PIPC, we once diagnosed as drug induced GTIN in this patient. Despite stopping antibiotics, his renal function was not recovered. Meanwhile, atypical lymphoid cells were detected in the urine cytology and serum soluble IL2 receptor was significantly increased. Immunohistochemistry revealed hypercellularity of mononuclear atypical lymphocytes stained with T-cell markers, CD3 and CD5, and then diagnosed as GTIN caused by T-cell lymphoma. Although CHOP chemotherapy induced remission of lymphoma and disappearance of multiple abscess formation, the kidney dysfunction was unimproved.

Discussion: The case reminds us T-cell lymphoma as an additional cause of GTIN.

TH-PO1076
Pauci-IgG Glomerulonephritis and Excherichia Coli Bacteremia: A Mere Coincidence or a True Causal Association?

Marwan M. Abu Minshar, Wihib A. Gebregiorgis. Nephrology, Wayne State Univ.S.O.M, Detroit, MI.

Introduction: Antineutrophil cytoplasmic antibody (ANCA) associated vasculitides are systemic autoimmune diseases affecting small to medium sized blood vessels. Pauci-immune necrotizing glomerulonephritis (GN) is one of the manifestations. Triggering factors for ANCA associated vasculitides are not well-defined. Systemic infections have been implicated in the pathogenesis.

Case Description: A 67 year old patient was admitted to the hospital from a nursing home for a Foley catheter associated Excherichia coli (E. colli) urinary tract infection & bactemia along with septic shock and acute kidney injury/septic shock with a peak serum creatinine (Cr) of 3.8mg/dL. She had recently been hospitalized for subarachnoid hemorrhage that was treated conservatively and her serum Cr at that time was 0.9mg/dL.

Discussion: This is the second reported case of necrotizing and crescentic glomerulonephritis associated with IgG1-κ anti-GBM IgG. It is unknown if this disease is driven by an underlying autoimmune process or monoclonal gammopathy. Both cases are atypical for classic anti-GBM disease due to their relapsing nature.
She promptly responded to standard treatment of septic shock and her serum Cr improved to 1.6 mg/dl on discharge. Ten days later, she was readmitted to the hospital after a follow up visit to her primary physician where a routine blood work showed her serum Cr to be elevated to 6.8 mg/dl. Urine sediment revealed several RBCs and few granular casts. Anti-myeloperoxidase antibody was positive with a titer of 1:640. Other serological tests were negative. Her renal function declined further and she was initiated on hemodialysis. A renal biopsy was consistent with pauci-immune necrotizing and crescentic GN. She was treated with steroids, intravenous cyclophosphamide and plasmapheresis following which she came off dialysis & her serum Cr stabilized around 1.8 mg/dl.

Discussion: Anti-LAMP-2 antibodies, a subtype of ANCA antibodies directed against lysosome-associated membrane protein-2 (LAMP-2) have been reported in patients with pauci-immune necrotizing GN, often in coexistence with anti-PR3 & anti-MPO antibodies. Infections with bacteria that express the bacterial adhesin FimH (mostly E. coli), which has 100% homology with the human LAMP-2 epitope, are believed to trigger autoimmunity via molecular mimicry. In our patient, the onset of ANCA positive necrotizing GN in a close temporal association with E. coli bacteremia suggests a possible causative relationship.

TH-PO1077
Cryoglobulinemic Vasculitis and Glomerulopathy Associated with Chronic Lymphocytic Leukemia
Narottam Regmi, Albert Braverman, Swaty Arora, Raavi Gupta, Subodh J. Saggi. Nephrology, SUNY Downstate Medical Center; Brooklyn, NY.

Introduction: Cryoglobulinemia manifests as ischemic or occlusive vasculopathy with or without renal involvement. Early stage Chronic lymphocytic leukemia (CLL) has not been reported with vasculitic lesions as its first manifestation. We report a rare case of Stage I CLL with cutaneous, renal and cerebral lesions due to monoclonal Type I cryoglobulinemia.

Case Description: A 60 year-old woman presented with abdominal pain due to peritoneal hematoma from a ruptured right gonadal artery, which was embolized. Labs included eukocytosis, anemia with mild azotemia. Flow cytometry was consistent with CLL. The patient was readmitted with a serum creatinine of 11.2 mg/dl and proteinuria and required hemodialysis. There were extensive lesions on her lower extremities and a necrotic left forearm ulcer. Renal biopsy revealed membranoproliferative glomerulonephritis with deposition of IgG kappa light chain cryoglobulins as intraluminal hyaline deposits (Figure 1), infiltrates consistent with CLL and thrombi in intrarenal arteries. Biopsy was complicated by hematoma leading to left nephrectomy. Plasmapheresis was initiated for myeloma cast nephropathy.

The pathophysiology of GN in CLL is possibly due to glomerular deposition of immune complexes and/or paraproteins. Review of the literature reveals a small number of cases of MN associated with CLL and cryoglobulinemia.

Discussion: Vasculitic presentations, bleeding or thrombotic and/or renal failure in the setting of CLL may be manifestations of cryoglobulinemia. Because of potential rapid progression, as in this case, regular urinalysis and testing for cryoglobulins should be considered in all stages of CLL, with possible renal biopsy when cryoglobulinemia and proteinuria are detected.

TH-PO1078
PGNMD in a Patient with Hepatitis C
Mohamed Alslejari, Susie L. Hu. Albert Medical School of Brown Univ.

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMD) is infrequently associated with hematological disease but more commonly presents like an immune-complex glomerulonephritis. Few have reported cases associated viral infections such as hepatitis C. We report a case of PGNMD in a patient with active HCV infection.

Case Description: A 56 year-old male with refractory hepatitis C (post treatment with interferon and Ribavirin), HTN and coronary artery disease presented with rising creatinine (peak 5.3 mg/dl) from baseline (0.9 ml/dl a year ago) and no kidney disease in family. He reported months of progressive fatigue, dyspnea on exertion, nausea, vomiting, and dark urine. He endorsed chronic Buprenorphine use for leg pain. On examination BP was normal with clear lungs and no edema. Urinalysis revealed blood but minimal proteinuria with urine protein to creatinine ratio of 0.5 g/g and albumin 4.2 g/dl. Complements were low (C3 83 mg/dl, CH50 <10 U/ml). HCV-RNA quantification was 1.7 million copies. SPEP, plasma light-chains, ANA, ANCA, Anti GBM, HIV, Hep B serologies were normal. Bone survey was negative. Renal biopsy revealed diffuse linear staining of glomerular basement with monoclonal IgG1/Kappa immunoglobulin and endocapillary focal glomerulonephritis, chronic interstitial nephritis with ATN. Renal function did not improve until Prednison was initiated, down to 3.3 mg/dl. Cyclophosphamide was started after discussion with his gastroenterologist. Antiviral therapy has been delayed until further improvement of renal function.

Discussion: We report a case of PGNMD associated with HCV. There are 2 other reports of HCV associated PGNMD however with membranous glomerulonephritis pathologic. 30% of PGNMD patients have some heavy- and light-chain isoform as the glomerular deposits. Membranoproliferative (57%) or endocapillary proliferative (35%) are the most two common histological variants. Nase et al in a series of 32 patients reported after an average of 30.3 months of follow-up, 38% had complete or partial recovery, 38% had persistent renal dysfunction, and 22% progressed to ESRD. Viral infection such as HCV associated immune disorders could be implicated in the pathogenesis. Currently, there is no consensus regarding the management of this entity.

TH-PO1079
Myeloma Cast Nephropathy with Acute Renal Failure, Skin Rash, Eosinophilia, and Low Complement C4 Level
Mustafa G. Aly,1 Mamoun Elhir Bashir,2 Irfan Warraich,2 Aumyot Prongdong,3 Weeaporn Srisang,1 Internal Medicine, Nephrology Dept, Texas Tech Univ Health Science Center, Lubbock, TX; 1Pathology Dept, Texas Tech Univ Health Science Center, Lubbock, TX.

Introduction: We here report myeloma cast nephropathy with skin rash, eosinophilia and low complements which is a very atypical presentation of this renal condition.

Case Description: A 53y Caucasian female was admitted with 3 day confluent erythematous skin rash, acute renal failure with sCr 17.6 with a normal baseline renal function of sCr 0.7 mg/dL. Five days prior, she was prescribed cephalexin for root canal infection. Initial diagnosis of acute interstitial nephritis was made but patient didn't respond after stopping antibiotics and steroid course trial, urine exam showed WBC clumps and no casts. Serological biomarkers were done and reported Negative ANA, ANCA, cryoglobulins, Hepatitis B, Hepatitis C and HIV. Complement C4 was low with normal C3. Patient’s laboratory workup showed normocytic normochromic anemia and pseudohyponatremia per osmolality check, SPEP and SFLC ordered and was positive for M-spike with free light chain analysis showing predominant Lambda more than 4 g/L. Renal biopsy showed myeloma cast nephropathy.

Bone marrow biopsy confirmed MM with 80% plasma cell. Patient received bortezomib +dexamethasone + cyclophosphamide chemotherapy and her renal function completely improved after being dialysis dependent for about 12 weeks. Patient is being evaluated for BM transplant after chemotherapy response.

Discussion: Multiple Myeloma can cause renal damage in many ways which sometimes can be misleading and very uncharacteristic. Up to our knowledge, this presentation is quite uncommon in literature and hence we suggest including myeloma related kidney injury in such clinical presentation.

TH-PO1080
A Rare Case with ANCA-Related Necrotizing Glomerulonephritis without Nephritic Features or Systemic Vasculitis
Mustafa G. Aly,1 Faisal Jamal,1 Maria Gabriela Suarez,1 Irfan Warraich,2 Aumyot Prongdong,3 Internal Medicine, Nephrology Dept, Texas Tech Health Science Center, Lubbock, TX; 1Pathology Dept, Texas Tech Health Science Center, Lubbock, TX.

Introduction: We report an atypical and unusual case of ANCA necrotizing glomerulonephritis with no significant nephritic features or systemic vasculitic picture.

Case Description: A 78 year-old African American female with history of controlled hypertension was admitted with diagnosis of pneumonia and renal failure and was treated empirically with antibiotics. Despite antibiotic treatment, she had persistent leukocytosis and anemia which was ruled out by negative WBC scan and CT chest. Urine had pre-renal pattern and urinalysis was bland twice. Renal ultrasound was unremarkable except for hyperechoic kidneys. Despite aggressive hydration for 10 days, renal function continued to worsen. Patient was never oliguric. Serum biomarkers were checked due to unexplained renal failure which reported negative hepatitis B, C and HIV as well as normal Complement C3, C4, ANA, dsDNA and antiphospholipid panel. Normal SPEP with no M spike. UPEP showed faint IGG monoclonal band in the ALPH-2 region. SFLC was negative. Bone marrow biopsy showed normal cellularity. Although patient had no obvious systemic vasculitic features, but due to renal failure and persistent non-specific respiratory symptoms, ANCA was checked and was positive for anti-MPO antibodies. Renal biopsy showed pauci-immune acute necrotizing glomerulonephritis (Figure 1) with negative Anti-GBM and immune fluorescence. Patient was treated with cyclophosphamide, high dose steroids and plasmapheresis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: The patient had advanced necrotizing GN but never developed nephritic or systemic vasculitic features and UA was persistently bland. The probability of diagnosing ANCA associated GN based upon above clinical presentation was significantly low, making this an unusual case.

TH-PO1081
Bilateral, Multifocal Renal Tumors Diagnosed as Birt-Hogg-Dubé Syndrome Confirmed by Genetic Analysis

Introduction: Birt-Hogg-Dubé syndrome (BHD) is an autosomal dominant disorder characterized by skin fibrofolliculomas, pulmonary cysts and spontaneous pneumothorax, and renal cancers. The syndrome is caused by germline mutations of the FLCN gene located in 17p11.2 encoding folliculin. The risk of renal cancer is seven times higher in BHD patients. Bilateral, multifocal and chromophobe renal cell carcinoma is characteristic of renal cancers in BHD. Among about 110 pathogenic mutations reported in BHD, only twenty six of them have been associated with renal cancer. In this study, we described a case of 50-year-old woman with chromophobe renal cell carcinoma who had c.1557delT mutation in the FLCN gene which is novel in BHD-associated renal cancer.

Case Description: A 50-year-old woman presented with flank pain. A CT scan of abdomen showed multifocal tumors in both kidneys. To differentiate the origin of the tumors, a chest CT and a whole body PET-CT were carried out, although there was no other lesion except a few lentiform cysts at basal lungs. Histologic evaluation through a needle biopsy revealed that the mass was chromophobe type renal cell carcinoma. The patient underwent nephrectomy. Given multifocal distribution of the renal cell carcinoma, we suspected an inherited form of kidney cancer. Although she denied any specific familial history, the cystic change of both lungs and chromophobe renal cell carcinoma pointed towards the possibility of BHD. DNA sequencing of the entire FLCN gene identified a heterozygous c.1557delT mutation in exon 14 [p.Phe(TTT)519Leu(TTA)fs*18].

Discussion: Once multifocal renal masses are diagnosed as renal cell carcinoma, histologic subtype, family history and other clinical features should be considered to recognize familial renal cancer syndromes. Multifocal chromophobe renal cell carcinoma should prompt genetic test for BHD even in a patient without typical skin lesion. In our patient, c.1557delT mutation was found out which has been first reported in BHD-associated renal cancers.

TH-PO1082
The First Case of Steroid Responsive Renal Involvement of Mycosis Fungoides without Sezary Syndrome

Introduction: Mycosis fungoides (MF) is a mature T cell non-Hodgkin lymphoma with presentation in the skin but with potential involvement of the nodes, bloods and viscera. Renal lymphomatous involvement in MF has received limited attention. We present a rare case of moderate dose steroid responsive lymphomatous renal involvement with acute renal injury which occurred in solitary kidney.

Case Description: A 59-year-old man presented with fever, right flank pain with a rise of creatinine 10.54mg/dL one month prior being 1.4mg/dL. He had donated his left kidney 10 years ago. He had recurrent pruritic rash before MF was diagnosed by skin biopsy, 4 years prior to his presentation, he received several different course of chemotherapy, including cyclophosphamide, Adriamycin, vincristin, and prednisone (CHOP), alpha-interferon. Ultrasound revealed normal echogenicity with right kidney 14 cm. Urinalysis showed protein 1+, WBC cast and no hematuria. He was treated first with antibiotics in case of acute pyelonephritis. He deferred started within two days, however, his renal function kept declining. Hemo-dialysis was performed. On the 6th day, Renal biopsy was performed. Renal biopsy showed that numerous atypical lymphocytes with hyperchromatic, indented, variably sized nuclei were infiltrated in the tubulointerstitium. After treatment with methylprednisolone 40mg, level of creatinine improved up to baseline.

Discussion: To our knowledge, this is the first report of steroid responsive renal involvement of MF. Renal involvement in non-Hodgkin lymphoma has been reported, including AKI, glomerulonephritits, and infiltration of renal parenchyma by lymphoma cell. Renal manifestations of MF are especially rare and there are only few cases published to date. But there has been no case which showed steroid response except this case.

TH-PO1083
A Case of Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy

Case Description: A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had been terminated because of similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complements. The renal biopsy performed 10 days after the third termination revealed MPGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and Clq all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histologic findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed by intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2.342kg at vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: We experienced a rare case of the type III cryoglobulinemic nephropathy that repeatedly developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. The pathogenesis of pregnancy-induced nephrotic syndrome in cryoglobulinemia in this patient was not known, aggressive treatment may be helpful for ameliorating nephropathy, leading to successful delivery.

TH-PO1084
A Case of Glomerular Lipidosis with Type III Hyperlipoproteinemia Exhibiting Nephrotic Syndrome

Case Description: A 77-year-old woman was admitted to our hospital because of nephrotic-range proteinuria. She was diagnosed as chronic thyrotoxic 8 years before, after which she started to have levothyroxine and remained uneventful. Three weeks before coming to our hospital severe edema developed rapidly, and she gained 10 kg of body weight in 6 months. Laboratory examinations showed nephrotic syndrome with mild renal dysfunction (s-Alb 2.1 g/dL, urinary protein 7.97 g/gCr, s-Cr 0.95 mg/dL), marked hypothyroidism (TSH 45.2 µIU/mL, Free T4 0.83 ng/mL). Genetic test for APOE revealed homozygosity of apoE2 and immunoelectrophoresis for lipoprotein showed type III hyperlipoproteinemia. Renal biopsy revealed the presence of intracapillary lipid thrombi and foam cells; electron microscopy demonstrated lipid droplet accumulated mainly in mesangial cells, whereas podocytes, endothelial cells and tubular cells were rather unremarkable. Immunofluorescence studies showed no significant deposits in glomeruli. Intense lipid-lowering therapy with Statin for 1 month, the patient’s nephrotic-range proteinuria subsided. She was discharged with good condition.
Discussion: We report here a case of glomerular liposudosis associated with type III hyperlipidemia. The nephrotic syndrome was unexpected but the hyperlipidemia with glomerular lipid accumulation would have a pathogenic role for glomerulopathy, but other factors might be involved in causing nephrotic syndrome.

TH-PO1085
Successful Treatment of Crescentic Glomerulonephritis (GN) in Hypocomplementemic Urticarial Vasculitis Syndrome (HUVS) Ramchandar Bakhtian, Mark G. Parker. Nephrology, Maine Medical Center, Portland, ME.

Introduction: HUVS is a rare autoimmune systemic disorder characterized by chronic urticaria, low complements and extracutaneous organ involvement. Kidney involvement is not uncommon (50% of cases), usually of benign nature. The glomerular injury pattern varies from mesangial proliferation to membranoproliferative glomerulonephritis (MPGN). Crescentic MPGN in HUVS is rare; only six cases have been reported in world literature, many with poor outcomes. We present a case of crescentic GN successfully treated with substantial remission.

Case Description: A 55-year-old Caucasian female with a previous episode of hives was admitted to hospital with features of both acute nephritic and severe nephrotic syndrome. She had 6 months history of persistent hives, fatigue, fevers, arthralgia, self-limited recurrent angioedema episodes, and generalized lymphadenopathy. Lymph node biopsy displayed reactive hyperplasia. Her serum creatinine was 4 mg/dl, urine protein to creatinine ratio was 23, serum complement levels were 1.0 mg/dl and C3 < 100 mg/dl, 10x the normal values for a case of HUVS. Serologic workup was positive for vWF and ANA at titer of 1:80. Anti-dsDNA, cryoglobulins, anti-SSA, anti-SSB, chronic hepatitis panel, and workup for paraproteinemia were all negative. C3 and C4 levels were normal. An ANA positive HUVS was confirmed. Renal biopsy revealed immune complex crescentic MPGN with IgG, IgA, IgM, C3 and C4 deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Her systemic symptoms and acute kidney injury resolved completely. Nephrotic syndrome improved slowly. After 6 months of therapy her proteinuria decreased to 4.5 g/kg per day with serum albumin increased to 3.8 g/dl.

Discussion: Crescentic GN associated with HUVS appears to convey a poor renal prognosis. Based on available information in five of six reported cases, three progressed to end stage renal disease; one had near complete renal recovery and another had partial recovery with persistent nephrotic range proteinuria. Relatively good outcome in our case may aid to our understanding of this uncommon and newly recognized disease process.

TH-PO1086
An Unusually Early Presentation of Pre-Eclampsia David Bennett, Renu Regunathan-Shenk, Maya K. Rao. Medicine, Div of Nephrology, Columbia Univ Medical Center, New York, NY.

Introduction: Pre-eclampsia affects approximately 3-6% of pregnancies in the United States. It is defined as new onset hypertension and proteinuria in pregnancy. By definition, it occurs after 20 weeks gestation. However, earlier cases have been reported in the literature. Case Description: The patient is a 45 y/o woman, 16 weeks + 4 days pregnant with a previous episode of hives. She presented to the hospital with high blood pressure (BP 193/122), 1+ upper extremity edema, 2+ lower extremity edema, and 12 g of protein on 24hr urine collection. On labs, Cr 0.85, 3+ protein on UA (previously normal), hemoglobin 12.2, WBC 14k, platelets 202, SPEP, UPEP, and Kappa and Lambda Light Chain levels were negative. Platelet count 202, LDH 334 (elevated), and indirect bilirubin 0.2. AST, ALT, and Alkaline phosphatase were normal. The patient underwent a kidney biopsy which demonstrated subacute glomerular thrombotic microangiopathy with prominent endothelitis, characteristic of pre-eclampsia. Termination of pregnancy was advised and performed. On post-discharge follow-up, spot urine protein-to-creatinine ratio (in mg/mg) decreased to 1.52 after ~1.5 months, 0.32 after ~3.5 months, and 0.13 after ~6 months. BP improved as well and she is now off antihypertensives.

Discussion: This patient had multiple risk factors for pre-eclampsia including age, multiparity, obesity, IVF, and ovum donor pregnancy. Although kidney biopsies are associated with a higher complication rate in pregnant women, they often change management, as was the case for this patient. Given this case and others reported in the literature, the gestational age criteria for the diagnosis of pre-eclampsia should be reconsidered.

TH-PO1087
A Case of Autosomal Dominant Polycystic Kidney Disease and C3 Glomerulonephritis Conor Patrick Moran, Mamoun S. Elawad. Dept of Nephrology, Altnagelvin Hospital, Western Health and Social Care Trust, Londonderry, United Kingdom.

Introduction: Autosomal Dominant Polycystic Kidney Disease, (AD-PKD), is the most common form of inherited renal disease. Proteinuria has been reported, however, nephrotic range proteinuria and nephrotic syndrome are rarely reported in the literature. Only 30 cases of patients with AD-PKD and polycysticulopathy have been reported. The most common have been FSGS and Membranous Nephropathy. Two cases of Mesangioproliferative Glomerulonephritis and one case of Membranoproliferative Glomerulonephritis have been reported.

Case Description: We present a 47 year old female with Autosomal Dominant Polycystic Kidney Disease with C3 Glomerulonephritis. The patient had been under regular and remarkable Nephrology clinic follow-up for many years. She was admitted to our hospital with a history of left sided chest pain and new onset of proteinuria. On examination she presented to with new proteinuria, (Urinary ACR 375.4mg/mmol), and evidence of C3 hypocomplementemia, (0.3 g/L, normal: 0.8-1.7 g/L). Kidney function was newly impaired, (Creatinine 118, eGFR: 45.3 mL/min/1.73m2). C3 Nephritic factor was normal and ANA and Anti-dsDNA were negative. ACE inhibition was performed. Renal biopsy showed markedly enlarged and lobulated glomeruli with marked endocapillary proliferation. Widespread thickening of the glomerular basement membranes, (GBM), with numerous double contours was observed. Immunofluorescence revealed strong granular positivity for C3 along the GBM with some focal mesangial C3. There was some IgM, but no IgG, in the GBM. In July 2014, there was no clinical response to ACE inhibition. Corticosteroids were commenced, (Prednisolone 1mg/kg), which achieved partial remission, (urinary ACR fell from 650.3mg/mmol to 79.7 mg/mmol), however, in August 2014 she developed nephrotic syndrome requiring aggressive diuretic therapy. Addition of ACE inhibition induced complete remission of proteinuria, (UA CR 25-30 mg/mmol), with normalisation of C3 levels. Renal function remains stable.

Discussion: In a disease where CKD progression is predictable, glomerular pathology can accelerate this decline and histology should be sought. This is the second reported case of AD-PKD associated with Membranoproliferative C3 Glomerulonephritis in the literature to date.

TH-PO1088

Introduction: Achieving maturity is quite a challenge for women with chronic kidney disease (CKD). Pregnant patients with CKD of any stage but especially stages 3–4 are at increased risk for fetal loss, prematurity and pre-eclampsia.

Case Description: We present a case of a 31 year old pregnant female with a past medical history of CKD stage 3B secondary to medullary cystic disease (MCD) who presented with acute kidney injury at 31 weeks gestation. Her other co-morbidities include a history of diabetes and idiopathic thrombocytopenia (ITP). On admission, the patient had a creatinine of 2.32 mg/dl and was found to have 7 gm proteinuria. During this pregnancy, her baseline creatinine was 1.6-1.8 mg/dl and prior to pregnancy she had baseline proteinuria of 2 gm. Given her elevated creatinine and degree of proteinuria, there was concern that the patient could have pre-eclampsia. A management dilemma occurred and it was unclear whether the patient should have an emergency C-Section for questionable pre-eclampsia.

Discussion: Given the patient's diagnosis, any lung exam was normal. Her exam was notable for BP 193/122, 1+ upper extremity edema, 2+ lower extremity edema, and bibasilar crackles on lung exam. On labs, Cr 0.85, 3+ protein on UA (previously normal), with 3 RBC's and 6 WBC's, ~12g of protein on 24hr urine collection, and serum albumin 3.8 g/dl. CT of chest was normal. A team effort along with fetal monitoring can help differentiate pre-eclampsia from other conditions of CKD, ITP, and MCD. After a multidisciplinary meeting with the obstetrician, nephrology, and hematologist occurred, it was felt that the patient truly did not have pre-eclampsia. A key decision was made and was not induced. Her AKI was attributed to volume depletion and progression of CKD. Her creatinine eventually declined to 1.9-2 mg/dl and her proteinuria decreased to 3-5 grams. The patient is now 34 weeks pregnant and her renal function has been maintained.

Discussion: Our case highlights that in patients with multiple co-morbidities and CKD, the diagnosis of pre-eclampsia can be challenging. Incorrectly labeling a patient as pre-eclamptic can lead to pre-term delivery and risks to the fetus. A multidisciplinary approach along with fetal monitoring can help differentiate pre-eclampsia from other diagnoses, prolonging delivery.
steroids. Given renal fibrosis and comorbidities, no further therapies were pursued. Repeat EGD showed improved duodenal lesions after steroids, however renal function declined and the patient required dialysis.

**Discussion:** IgA nephropathy historically recurs post-KT but rarely impacts graft survival. De novo HSP with significant nephritis is infrequently described and treatment strategies are lacking. Additional data with this disease remain unestablished. Interestingly MMF is used for severe HSP in children. Whether lack of MMF maintenance contributed to HSP in our patient remains unknown.

**TH-PO1090**  
Harvoni Induced Acute Interstitial Nephritis  
Jyotsana Thakkar, Kenan D. Jhaveri, Rimda Wanchoo.  
Nephrology, North Shore-LIJ Hospital, NY.

**Introduction:** Harvoni is a new combination pill consisting of ledipasvir with sofosbuvir approved by FDA in October 2014 for the treatment of chronic Hepatitis C genotype 1 virus infection. No cases of Acute Kidney Injury (AKI) have been reported with this agent thus far. We report the first case of Harvoni associated biopsy proven acute interstitial nephritis (AIN).

**Case Description:** A 64 year old AA female with chronic Hepatitis C, hypertension, diabetes mellitus came to our clinic for evaluation of AKI superimposed on chronic kidney disease. Laboratory data revealed serum creatinine of 2.24 mg/dl (baseline Cr 1.5 mg/dl), hypoalbuminemia (3.2 gm/dl) with a spot urine protein/ creatinine ratio of 3.3 (baseline of 1). Her AKI coincided with peripheral eosinophilia. Home medications included hydralazine, lansoprazole and simvastatin. She had recently completed eight weeks of treatment for Hepatitis C with Harvoni and her most recent viral load was undetectable. She denied using any NSAID, antibiotics, PPI or herbal supplements. Physical exam was normal. AKI workup revealed negative ANCA, normal complement, normal serum free immunoglobulin light chain ratio and negative ANA panel.

Patient underwent kidney biopsy. Light microscopy showed 11 glomeruli, 3 were globally sclerosed, 3 had cellular crescents with mesangial nodular matrix expansion and moderate tubular atrophy. Interstitium showed moderate fibrosis with severe lymphocytic inflammation. Immunofluorescent microscopy was normal and electron microscopy showed diffusely thickened glomerular membrane and moderately effaced foot processes. A final diagnosis of acute interstitial nephritis with chronic diabetic nephropathy was made. Her clinical picture, pathology findings and time course of renal impairment coincided with Harvoni use and is suggestive of Harvoni induced AKI. She was initiated on steroid therapy and advised to stop further use of Harvoni. Her renal function is stable with no further deterioration after stopping offending agent.

**Discussion:** Harvoni has a cure rate of up to 94-100% in patients with Hepatitis C genotype 1. We report first case of biopsy proven AIN with Harvoni. Hepatologists and nephrologists need to be aware of the potential side effect of this novel agent.

**TH-PO1091**  
Thrombotic Microangiopathy Secondary to Smoldering Myeloma: A Form of MGRS  
Jyotsana Thakkar, Rimda Wanchoo, Kenan D. Jhaveri.  
Nephrology, North Shore-LIJ Hospital, NY.

**Introduction:** Thrombotic microangiopathy syndrome (TMA) is not a usual presentation of paraproteinemic diseases. We report a case of TMA secondary to smoldering myeloma presenting as monoclonal gammopathy of renal significance (MGRS).

**Case Description:** A 64 year old AA female with chronic Hepatitis C, hypertension, diabetes mellitus with her most recent viral load was undetectable. She denied using any NSAID, antibiotics, PPI or herbal supplements. Physical exam was normal. AKI workup revealed negative ANCA, normal complement, normal serum free immunoglobulin light chain ratio and negative ANA panel.

Patient underwent kidney biopsy. Light microscopy showed 11 glomeruli, 3 were globally sclerosed, 3 had cellular crescents with mesangial nodular matrix expansion and moderate tubular atrophy. Interstitium showed moderate fibrosis with severe lymphocytic inflammation. Immunofluorescent microscopy was normal and electron microscopy showed diffusely thickened glomerular membrane and moderately effaced foot processes. A final diagnosis of acute interstitial nephritis with chronic diabetic nephropathy was made. Her clinical picture, pathology findings and time course of renal impairment coincided with Harvoni use and is suggestive of Harvoni induced AKI. She was initiated on steroid therapy and advised to stop further use of Harvoni. Her renal function is stable with no further deterioration after stopping offending agent.

**Discussion:** Harvoni has a cure rate of up to 94-100% in patients with Hepatitis C genotype 1. We report first case of biopsy proven AIN with Harvoni. Hepatologists and nephrologists need to be aware of the potential side effect of this novel agent.

**TH-PO1092**  
A Case of Leukocyte Chemotactic Factor 2 Associated Amyloidosis  
Nadia Badeg, Saeed Kamran Shaffi.  
Nephrology, Univ of New Mexico.

**Introduction:** Leukocyte chemotactic factor 2-associated amyloidosis (LECT2) is a newly described form of nonhereditary amyloidosis. The disease usually presents with chronic kidney disease and bland urinary sediment with variable degrees of proteinuria. We describe a case of a young Hispanic female who presented with nephrotic syndrome without renal insufficiency.

**Case Description:** A 40 year old Hispanic female with history significant for uncontrolled type 2 diabetes, hypertension and rheumatoid arthritis, was referred to renal clinic for evaluation of nephrotic syndrome. Physical examination revealed peripheral and bilateral lower limb edema. Pertinent diagnostic data are shown in figure 1.

**Figure 1: Diagnostic Data**

**Renal ultrasonad**

Renal biopsy showed extensive amyloidosis involving the glomeruli, interstitium and arterioles. Immunofluorescence was negative for immunoglobulins and amyloid associated protein. Proteomic typing of the amyloid revealed ALECT2 associated amyloidosis. The patient was started on lansoprazole and simvastatin, but her proteinuria failed to improve and she had progressive deterioration of renal function. Two years later, she developed ascites and elevated liver enzymes. Her presentation was concerning for hepatic amyloidosis; therefore, she was transferred to a liver transplant center for further evaluation.

**Discussion:** Based on two large renal biopsy series, LECT2 accounts for 2.5-2.7% of all cases of renal amyloidosis. In a multicenter study involving 72 patients with renal ALECT2, 92% were Hispanic, 2.8% were below the age of 50 and 91.4% had a serum creatinine > 1.2mg/dl. One third had nephrotic range proteinuria, but only 10% of all patients presented with nephrotic syndrome. Pathogenesis is not clear. It is postulated that inflammatory processes lead to excessive production of an amyloidogenic variant of ALECT2. Accurate identification of the amyloid protein is essential as disease modifying treatments are available for certain types of amyloidosis.

**TH-PO1093**  
Complement Polymorphisms in Patients with Thrombotic Microangiopathy Associated with Intraavenous Abuse of Oral Formulation of Extended-Release Oxyomorphine (OPANA-ER)  
Joe Ghara, Lukas Haragiss, Satish Kumar.  
Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.

**Introduction:** In 2012, the CDC reported 15 cases of unexplained renal failure and thrombotic microangiopathy (TMA) in which all patients reported dissolving and intravenously injecting an oral preparation of oxymorphone (OPANA) prior to presentation. Since then, 30 additional cases have been reported in the U.S. The mechanism of IV Opana-associated TMA is unclear. ADAMTS13 levels were normal. We report two patients with genetic polymorphisms of complement system proteins as a possible mechanism for Opana-associated TMA.

**Case Description:** Two patients, a 26 yo WM (Pt 1) and a 38 yo WM (Pt 2) presented with unexplained renal failure (serum creatinine 8.2 and 4.6 mg/dl respectively) in the setting of IV Opana Abuse. Both displayed a hematological constellation of microangiopathic hemolytic anemia, thrombocytopenia, consumed haptoglobin and elevated LDH. Both patients had normal INR/PT/PTT, ADAMTS13 (both > 55%) and fibrinogen levels. ANA, HIV, and hepatitis profiles were negative. Renal biopsy showed intermediate sized vessels with a thrombotic microangiopathy in both patients. Both received plasmapheresis for 5 days. Hematological microangiopathy resolved in Pt 2 but persisted in Pt 1. Both remained dialysis dependent. Genetic studies for complement-mediated HUS demonstrated both to be positive for a heterozygous polymorphism (IVSP-78 G>A) within an intron of the membrane cofactor protein (MCP/CD 46) and for a homozygous polymorphism (p.His402Thr) in the complement factor H (CFH). In addition, both patients had an additional CFH polymorphism (p.Val621Le; Pt 1 homozygous, Pt 2 heterozygous).

**Discussion:** Our patients suggest a 2 bit mechanism for IV Opana-associated TMA. Both had polymorphisms in complement system proteins MCP and CFH with a potential predisposition for complement-mediated HUS. The MCP/CD 46 polymorphism has been shown to be enriched in patients with complement-mediated HUS. Polymorphisms in complement system proteins could cause hyperactivation and dysregulation of the complement system and provide a genetic predisposition for thrombotic microangiopathy, with IV Opana abuse acting as a trigger.
Acute Kidney Injury due to an Excessive Dose of Rivaroxaban

Case Description: A 45 y/o man presented to his physician's office with abdominal pain. Computed tomography (CT) of the abdomen was done and thrombosis of the portal, splenic, and mesenteric vein was identified. He was admitted to the hospital and discharged on warfarin 10 mg b.i.d. A week later he was given a prescription for rivaroxaban 20 mg tab and told to take 1 tablet daily. He mistook it for 2 tablets daily. After 5 days, he noticed painless gross hematuria for several days. He reported to his physician's office and his serum creatinine had increased to 2.7 mg/dl from a baseline of 1.5. He had a previous history of stroke and hypertension. He was evaluated with 2 years prior CT (revealed with course of warfarin), hypertension, and diabetes. His medications included metformin, glipizide, gemfibrozil, valsartan, sitagliptin, and rivaroxaban. His vital signs were normal. Physical examination showed splenomegaly but was otherwise unremarkable. Urinalysis revealed many red blood cells with trace proteinuria. The urine protein to creatinine ratio was 257 mg. Serologies were negative and there was no evidence of intravascular hemolysis. Antiphospholipid antibodies were negative as was a hypercoagulable work-up. A bone marrow biopsy was unremarkable and paroxysmal nocturnal hemoglobinuria was ruled out. Renal dopplers were normal for renal vein thrombosis. Renal function remains stable after 3 months. Renal biopsy was not performed in the setting of required anticoagulation and likely diagnosis of anticoagulant related AKI.

Discussion: WRN is a newly recognized form of AKI in the setting of excessive anticoagulation due to rivaroxaban. This appears to be the first reported case of a WRN-like AKI due to the NOAC rivaroxaban, and was likely caused by inadvertent doubling of the patient's dose. WRN can often be irreversible and in this patient as well no renal recovery was evident at 3 months.

Irreversible Acute Kidney Injury due to Oxalate Nephropathy from Intravenous Vitamin C

Case Description: High doses of vitamin C are widely used in alternative medicine for treatment of cancer, viral illness and fatigue. Vitamin C is metabolized to oxalic acid in the body. High doses of vitamin C have the potential to cause hyperoxaluria, nephrolithiasis and oxalate nephropathy. We report a patient who developed severe, irreversible, acute kidney injury due to acute oxalate nephropathy from high dose intravenous vitamin C.

Case Discussion: A 30 year old man with a history of hypertension, hypothyroidism, and mild pancytopenia, presented to a wellness clinic with fatigue and weight loss. He had a normal metabolic profile except hypercalcemia (corrected Ca, 12 mg/dl). He received IV vitamin C 30 g/d for 7 days. Serum creatinine was 1.3 mg/dl prior to Vitamin C administration. One month following treatment, he was admitted to our hospital with serum Cr 9.1, Na 110, K 3.1, Cl 70, CO2 16, BUN 152, Glucose 131, Ca 8.4, Uric Acid 1.21, CPK 175, Phos 11.9, and Protein 6.1. Urine sediment was normal. Urine vitamin C level was 40. An abdominal CT with IV contrast revealed diffuse mesenteric and retroperitoneal lymphadenopathy with hepatosplenomegaly and ascites. Liver was without cirrhosis. A renal ultrasound revealed normal sized, echogenic kidneys. Serum free light chains and serum and urine protein electrophoresis were normal. A renal biopsy revealed diffuse acute tubular injury and abundant tubular calcium oxalate deposits consistent with acute oxalate nephropathy. Bone marrow biopsy was normal and culture negative. A lymph node biopsy demonstrated diffuse T Cell Lymphoma. Patient was started on dialysis and remained dialysis-dependent at least follow up.

Discussion: Our patient developed severe, irreversible acute kidney injury from high dose intravenous vitamin C. The hypercalcemia was likely a contributing factor for the extensive deposition of calcium oxalate crystals in the kidney. A literature search identified 2 previous reports of oxalate nephropathy from intravenous vitamin C. High dose vitamin C is a common component of alternative medical regimens for cancer and other illnesses. We urge caution in using high dose vitamin C especially in patients with pre-existing renal insufficiency or hypercalcemia.

Atypical Hemolytic Uremic Syndrome (aHUS) due to a Novel Sequence Variation of Diacylglycerol Kinase Epsilon (DGKE)

Case Description: Anti-HUS is a congenital disease characterized by hemolytic anemia, thrombocytopenia, and organ dysfunction (e.g. renal failure). Genetic alterations resulting in uncontrolled activation of the complement system are found in 50-60% of aHUS cases. Recently, mutations in DGKE have been associated with aHUS. The DGKE gene encodes an intrinsic signaling alterations in the signaling pathways controlling endothelial and platelet procoagulant tendency and podocyte function can also lead to aHUS. Patients with DGKE-associated disease tend to present at earlier age, have nephrotic range proteinuria, fail to respond to plasma exchange, and may develop renal failure, but do well after renal transplantation.

Case Discussion: We identified a novel homozygous sequence variation c.134AC>A, p.N448K in the kinase active site domain of DGKE in a family with aHUS. The index case presented at 1 year of age with nephrotic range proteinuria and hypertension. Renal biopsy showed tubular flaring of the tubules and collapse of the basement membranes by oncogenes like BCR-ABL or ALCAM. At age 10, she does not have thrombocytopenia, schistocytes, abdominal or CNS manifestations, as typically noted in patients with complement-mediated aHUS. Genetic testing was resent to identify mutations previously not available for this family treatment. The patient also carries heterozygous sequence variation ADAMTS13 c.3287G>A, p.R1096H, associated with decreased ADAMTS13 function and is heterozygous for CFHHR5. Subsequently, a younger sister presented with hypertension, hematuria and nephrotic range proteinuria. The symmetric sister is also homozygous for the same mutation in DGKE and is heterozygous for CFHR5, but lacks the ADAMTS13 variant. Parents and siblings with heterozygous DGKE variants are healthy.

Discussion: This is the first reported case of a kinase active site domain of DGKE associated with aHUS. Additional studies are needed to determine the impact of DGKE mutations on the clinical course of patients with aHUS and their appropriate management.

Membranoproliferative Glomerulonephritis with Mixed Cryoglobulinemia in Patients with Autoimmune Hepatitis

Case Description: Case 1: A 56 year old female presented with microscopic hematuria (6-10 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serum IgG/Mg cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with cryoglobulinemic MPGN. She was treated with plasma exchange and rituximab. Case 2: A 18 year old female presented with proteinuria (1.7 g), hematuria (44 RBC) and serum creatinine 0.8 mg/dl. Mixed type III cryoglobulins consisting of IgG/Mg were detected in the serum. Kidney biopsy revealed mesangial hypercellularity, reduplication of GBM with subendothelial, mesangial and scattered subepithelial deposits. She was treated with plasma exchange, one dose of 1000 mg intravenous cyclophosphamide and 1 gram of rituximab 4 weeks later. Treatment led to the disappearance of cryoglobulins and normalization of urinary findings and resolution of AKI. Case 2: 18 year old female presented with proteinuria (1.7 g), hematuria (44 RBC) and serum creatinine 0.8 mg/dl. Mixed type III cryoglobulins consisting of IgG/Mg were detected in the serum. Kidney biopsy revealed mesangial hypercellularity, reduplication of GBM with subendothelial, mesangial and scattered subepithelial deposits. She was treated with plasma exchange, one dose of 1000 mg intravenous cyclophosphamide and 1 gram of rituximab 4 weeks later. Treatment led to the disappearance of cryoglobulins and normalization of urinary findings. Serologic tests at presentation are presented in table 1.
**Discussion:** There has been a high risk of urethral malignancies associated with Chlamydaharb-aristolochic acid exposure with 40 - 45% of these patients developing multifocal high grade transitional cell carcinoma leading to a suggestions for either prophylactic bilateral native nephrectomy and ureterectomy at the time of renal transplantation or screening cystoscopic every 6 months to identify early stage urethral carcinoma. Our patient is a classic example of aristolochic acid associated nephropathy complicated with urethral cancer.

**TH-POI099**

**Anti-Tumor Necrosis Factor Therapy – A Trigger for Anti-Glomerular Basement Membrane Disease**

Carlos Antonio Cortes Sanchez, Hector R. Cordova, Krystahl Z. Andujar. Medical Service, VD Caribbean Health System, San Juan, PR.

Introduction: Tumor necrosis factor (TNF) has a key pathological role in diseases such as rheumatoid arthritis (RA). Vasculitis and other autoimmune diseases have been associated with the use of anti-TNF agents such as Adalimumab.

Case Description: A 73-year-old man with RA, Hypertension, Diabetes Mellitus type 2 and Non-Hodgkin’s Lymphoma in remission for 3 years complained of decreased urine output, dark urine, poor appetite, weight loss and peripheral edema for three weeks. He was on chronic low dose Prednisone and Adalimumab intermittently during the previous 21 months. Physical exam revealed bilateral lower extremity pitting edema but no skin lesions. Laboratories showed a serum creatinine of 9.5mg/dL (baseline of 1.5mg/dL). Urinalysis exhibited many RBC’s, proteinuria (2+) and pyuria without casts. The clinical picture suggested acute glomerulonephritis. Hemodialysis (HD) was started.

Serology tests were compatible with Anti-Glomerular Basement Membrane Disease. Alveolar hemorrhage was not present. Plasmapheresis therapy decreased anti-GBM titers but there was no recovery of renal function. The patient continued using Adalimumab after discharge. He later returned with hemoptysis due to alveolar hemorrhage, which resolved after the discontinuation of Adalimumab. The patient remained HD-dependent.

Discussion: The temporal association of the illness with anti-TNF therapy and worsening of symptoms upon reexposure suggest an etiologic role of Adalimumab in the development of Anti-GBM Disease in our patient receiving anti-TNF therapy should have renal function closely monitored to allow early detection of this infrequent but life-threatening side effect.

**TH-POI100**

**Severe Pauci Immune Crescentic Glomerulonephritis Mimicking ANCA Related Vasculitis Caused by Clinically Silent Dental Abscess Leading to Bacterial Endocarditis**

Anil K. Chunduri, Maria Saleem Khan, Anthony Alvarado, Tibor Nadasy, Lee A. Hebert. Nephrology, OSUMC, Columbus, OH.

Introduction: Severe crescentic GN is usually categorized based on the cause if it is Anti GBM or IC mediated disease. However, it is not widely appreciated that some instances of pauci immune GN are actually the result of severe occult systemic infections. We present a case of severe pauci immune crescentic GN whose initial assessment for infection was negative. The patient was assumed to have idiopathic AA V and was treated with high dose corticosteroids. These findings are rarely common, if ever, associated with AA V.

Case Description: 55 year old male with PMH of CAD presented to an outside hospital with fatigue. Initial labs revealed Hb: 7.6g/dL, WBC: 2.8 K/µL, Pt: 44 K/µL, Cre: 2.26 mg/dL. Infectious work up was negative. Autonomic workup revealed: ANA positive (1:40), Anti GBM (<2), Anti PR3 (0.6), ANCA and Anti MPO: negative. C3: 77mg/dL, C4: 16.9 mg/dL (wnl). Cystoglobin (<5), Urine PC ratio was 1.2. Further workup included a bone marrow biopsy and kidney biopsy, which was suggestive of pauci-immune crescentic and necrotizing GN. He received treatment with steroids and was discharged on steroid taper. His creatinine upon discharge was 1.5 mg/dL. On follow up his creatinine was elevated to 3.5 mg/dL. He was transferred to our institute. Repeat Infectious work up revealed streptococcus viridans bacteremia, tricuspid and aortic valve endocarditis. A panoramic radiograph of his teeth showed periapical abscess. He was subsequently diagnosed with infection related acute pauci-immune crescentic necrotizing GN. Unfortunately this patient remained dialysis dependent at the time of discharge.

**Discussion:** It is well established but not widely appreciated that severe pauci-immune crescentic GN can be the direct result of infection. Thorough investigation is warranted even if the initial infectious workup is negative, if the patient does not have a positive response to conventional therapy to improve morbidity and mortality.

**TH-POI101**

**POEMS Syndrome with Cast Nephropathy**

Amanda K. Hall,1 Josephine Abraham,2 Monica Patricia Revelo Penafiel,1 Frederic Clayton.1 ‘Div of Nephropathy and Hypertension, Univ of Utah, Salt Lake City, UT; ‘Div of Pathology, Univ of Utah, Salt Lake City, UT.

Introduction: POEMS syndrome(Polynephropathy, Organomegaly, Endocrinopathy, Monoclonal protein, Skin changes) is a plasma cell disorder with peripheral neuropathy and any of the following features osteosclerotic bone, Castleman’s disease, increased levels of serum vascular endothelial growth factor(VEGF), organomegaly, endocrinopathy, edema or skin changes. We report a case of POEMS presenting with acute renal failure due to cast nephropathy.

Case Description: A 63-year-old Caucasian female presented with a 3 month history of increasing weakness and was diagnosed with chronic inflammatory demyelinating polyneuropathy. She was also noted to have new onset diabetes mellitus and hypothyroidism. She was treated with intravenous immunoglobulin(IVIG) with minimal response. She was admitted with acute renal failure initially thought to be secondary to IVIG, progressive weakness, and shortness of breath. Serum beta 2 microglobulin was elevated and kappa/lambda ratio was abnormal with Bence-Jones proteinuria. Renal biopsy was deferred as the patient developed respiratory failure, subarachnoid hemorrhage, and a left middle cerebral artery stroke. Comfort measures were initiated. Bone marrow biopsy confirmed multiple myeloma with 20% clonal plasma cells. She was treated with an不受限制 hepatomegaly, splenomegaly, and peripheral nerve demyelination with active axonal loss. Renal examination showed cast nephropathy with monoclonal kappa light chains.

These features are characteristic of POEMS given the multiple myeloma with neuropathy, organomegaly, rash and new onset diabetes mellitus and hypothyroidism.

Discussion: POEMS is a paraneoplastic syndrome associated with plasma cell dyscrasia. Polynephropathy with plasma cell disorder should prompt evaluation for POEMS as outcomes have been excellent with diagnosis and treatment.

**TH-POI102**

**Acute Interstitial Nephritis Associated with a New Breast Cancer Chemotherapy Regimen**

Cory Handelsman,1 Michael T. Tanoue,2 Amy Kwon,2 Steven Salvatore,3 Jeffrey I. Silberzweig.5 ‘Div of Nephrology, Weill Cornell Medical College; 1Dept of Medicine, Weill Cornell Medical College; 2Dept of Pathology, Weill Cornell Medical College, New York, NY; 5The Rogosin Inst, New York, NY.

Introduction: Acute interstitial nephritis (AIN) as a direct consequence of chemotherapy is infrequently described. A recent review implicated ifosfamide, tyrosine kinase inhibitors, and pemetrexed as culprits in this process. We describe a case of AIN related to the recently approved chemotherapy regimen of pertuzumab, trastuzumab, and docetaxel for HER-2 positive metastatic breast cancer. While diarrhea, rash, and pruritis are well-known side effects, this report is the first to show AIN as a consequence of this combination regimen.

Case Description: A 69-year-old woman recently diagnosed with HER-2 positive breast cancer and treated with six cycles of neoadjuvant pertuzumab, trastuzumab, and docetaxel was hospitalized for acute kidney injury after two days of diarrhea and vomiting. Admission labs demonstrated leukocytosis to 26,000/uL, serum creatinine of 5.9 mg/dL (baseline of 1.55 mg/dL), and elevated anion gap metabolic acidosis with a lactic acid of 4.5 mmol/L. Urinalysis showed pyuria with occasional granular casts. Fractional excretion of sodium was 1.88%. Renal sonogram showed normal renal cortical kidney with no evidence of hydroureter or calculus. Infectious workup, including blood, urine, and stool studies, was unrevealing. Despite aggressive hydration and resolution of diarrhea and vomiting within 48 hours, her renal function worsened; her creatinine peaked at 9.0 mg/dL on hospital day 3. She was non-oliguric throughout the admission. A renal biopsy revealed moderate, diffuse acute and subacute, interstitial inflammation characterized by lymphocytic infiltration with moderate eosinophilia and diffuse tubular injury. Some endothelial injury

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

351A
was present as well. The patient was diagnosed with AIN related to combination chemotherapy with docetaxel, pertuzumab, and trastuzumab.

**Discussion:** This is the first documented case of AIN related to combination chemotherapy with docetaxel, pertuzumab, and trastuzumab.

**TH-PO1103**

**Sarcoidosis-Lymphoma Syndrome Presenting with Severe Refractory Hypocalcemia**

Osita O. Okechukwu, Barry M. Wall, Elvira Gosmanova, Deepak Pandkanti, Nephrology Div, UTHSC, Memphis, TN; Nephrology Section, VAMC, Memphis, TN.

**Introduction:** Sarcoidosis-lymphoma syndrome (SLS) is rare. Sarcoidosis (S) usually precedes lymphoma (L) by many months. Constitutional symptoms and hilar lymphadenopathy are suggestive of an initial manifestation of SLS. We report a SLS case presenting with severe acute hypercalcemia and acute kidney injury (AKI).

**Case Description:** Case Report: A 70 yr-old Caucasian male was hospitalized with symptoms of generalized weakness, poor oral intake, and altered mental status. Examination was significant for dry mucous membranes, depressed mental function, evidence of bilateral pleural effusions, mild ascites, and 2cm well-delineated hyperpigmented erythematous plaques on anterior chest wall. Laboratory findings included a corrected serum Ca 19.4mg/dL (2 months prior: 9.3mg/dL), ionized Ca 2.3mmol/L, BUN 56mg/dL, serum creatinine 2.5mg/dL (baseline 1.4mg/dL), and mild anemia. Further work up revealed suppressed PTH (0.2pg/mL), normal LFT, T3, T4, urine electrophoresis, calcium, creatinine, ACE, CEAs, PSA, and TSH. A workup diagnosis of hypercalcemia of malignancy was made. Intrahepatic and pelvic soft tissue showed increased activity on PET scan. MRI abdomen revealed a mass suspicious for lymphoma. Following biopsy, the patient was treated with prednisone. Two weeks later, her symptoms had fully resolved and her serum was present as well. The patient was diagnosed with AIN secondary to chemotherapy and nephropathy can be a late complication of chronic pancreatitis leading to CKD and ESRD.

**Discussion:** Calcium oxalate in the GI tract, combined with increased colonic mucosal permeability, malabsorption may increase free fatty acids that competitively inhibit the formation of prostanoids (Prostaglandin biosynthesis) and lead, with the aim of stopping the inflammatory cascade.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline** represents presenting author.
Discussion: This case illustrates the potential effectiveness of denosumab for the treatment of hypercalcemia refractory to bisphosphonates. Denosumab is a human monoclonal antibody against RANK-Ligand (RANKL) whose use has previously been described for management of hypercalcemia, but required multiple infusions. Recognition of this additional treatment, with effectiveness from a single infusion, is critical in managing refractory hypercalcemia, as the only other known option is hemodialysis. Increasing availability of options for management of refractory hypercalcemia may allow patients to avoid complications associated with hemodialysis.

TH-PO1108
Collapsing and NOS Focal Segmental Glomerulosclerosis (FSGS): Progression Along a Spectrum or Different Diseases? Suzanne L. Katsanos, Patrick H. Nachman, JulieAnne G. McGregor, Volker Nickeleit. UNC Kidney Center, Chapel Hill, NC.

Introduction: Minimal change disease (MCD) and some variants of FSGS (tip lesion and not otherwise specified NO) are thought to represent a histologic spectrum of a same autoimmune pathogenic process (Habib, R. Proceedings IXth Int Conf of Neph.). This contention has never been proven, however. Some cases of MCD are thought to be “unsampled” FSGS. A “transition” from MCD to FSGS is common in steroid-resistant forms (Tejani, A. Nephron 39). It has been proposed that collapsing FSGS is pathogenically and clinically distinct from other FSGS variants based on morphology, demographics, severity of nephrotic syndrome, and renal prognosis. The etiology has not been identified but viral agents, drugs, and cyclosporine toxicity have all been proposed.

Case Description: We present the case of a 37-year-old African American male with a complicated course of nephrotic syndrome. He was diagnosed with biopsy-proven MCD when 9 years old. He was treated with steroids followed by chlorambucil and then cyclophosphamide over the next several years. He was in complete remission off therapy for about 2 years until he re-presented with increased edema, proteinuria (3.8 g/dl), hypoalbuminemia, and acute kidney injury (AKI). A repeat biopsy (23 glomeruli) showed FSGS NO. He was treated with steroids followed by mycophenolate mofetil and cyclosporine, resulting in complete remission. 7 years later, he developed edema, proteinuria (21 g/dl) and AKI. Repeat biopsy showed 25 glomeruli demonstrating segmental tuft collapse, activation of endothelial cells, and segmented marked activation and crowding of podocytes consistent with collapsing FSGS. HIV, hepatitis B, and hepatitis C were negative.

Discussion: The transition from MCD to FSGS NO is common in the literature. However, the transition from FSGS NO to collapsing FSGS is rarely reported. This patient’s case raises questions about this transition from NO to collapsing variant. Glomerular undersampling is unlikely given 25 glomeruli were examined each time. This could represent a progressive, patient-related pathogenetic process versus a de novo lesion (either related to a viral infection or medication, for example).

TH-PO1109
Lymphoma Associated Monoclonal Cryoglobulinemia in a Patient with Hepatitis C Sangeeta Mutnuri, Marjan Afrozouan, Hania Kassem.1 Dept of Nephrology, UTMB, Galveston, TX; 2 Dept of Pathology, UTMB, Galveston, TX.

Introduction: We present a case of type I cryoglobulinemia and membrandeproliferative glomerulonephritis (MPGN) in a patient with hepatitis C infection (HCV), leading to the diagnosis of a marginal zone lymphoma.

Case Description: A 47 year-old male with HCV and hypertension presented with two month duration of shortness of breath and decreased urine output. On examination he was hypertensive (blood pressure: 183/111 mm of Hg), had lung crackles, lower extremity edema and hepatosplenomegaly. Laboratory tests were significant for pancytopenia, hypoalbuminemia and an elevated creatinine of 2.8mg/dl (0.8mg/dl four months ago). Urine exam revealed red blood cell (RBC) casts, dysmorphic RBC’s and nephrotic range proteinuria (9.5 g/ml). Immunohistochemistry revealed elevated rhamatoid factor, hyycopomponentemia and cryoglobulinemia. These findings led to a suspicion of HCV induced cryoglobulinemic glomerulonephritis. Kidney biopsy was performed revealing MPGN type III with deposits. Fluorescence microscopy favored Kappa monoclonal. Electron microscopy of the deposits was consistent with cryoglobulins. Serum immunoelectrophoresis also confirmed IgM/Kappa monoclonality. As HCV is more commonly associated with polycymal cryoglobulinemia this finding of monoclonality prompted a search for malignancy. A bone marrow biopsy showed lymphoid aggregates including rare low-endothelial marginal zone lymphocytes. He was initiated on rituximab/dexamethasone based regime. The creatinine trended down to 1.87 mg/dl.

Discussion: Monoclonal cryoglobulinemia is related to lymphoproliferative diseases whereas HCV is associated with polyclonal cryoglobulinemia. This case stresses the importance of differentiating between the two entities especially in patients with co-existing disorders. Making this crucial distinction helps predict the underlying etiology and treatment.

TH-PO1110

Introduction: IgG4-related kidney disease (IgG4-RKD) usually presents as tubulointerstitial nephritis with IgG4-positive plasma cell (PC) infiltration and serum IgG4 elevation. IgG4-RKD has characteristic histological findings called storiform fibrosis and polyclonal IgG4-positive PC infiltration. Storiform fibrosis has been rarely described for management of hypercalcemia, but required multiple infusions. Recognition of this crucial distinction helps predict the underlying etiology and treatment. Here we report a patient diagnosed with lupus nephritis (LN) with IgG4-negative IgG4-RKD.

Case Description: A 59-year-old Japanese man was referred to our hospital with chest pain and mild proteinuria. Thoracic biopsy was performed for abnormal lung shadow and interstitial pneumonia was diagnosed. Although ANA titer was elevated to 2560-fold, anti-DNA, anti-Sm, and anti-SS-A/B antibodies were all negative. Serum C3 and C4 levels and complement activity were decreased. Serum IgG and IgE levels were elevated, but serum IgG4 level was within normal limits. On contrast-enhanced CT, multiple low-density lesions were observed in kidney. Renal biopsy findings revealed lymphoplasmacytic infiltration with storiform fibrosis and small numbers of eosinophils. Immunostainings revealed CD138+ or IgG4-positive PC infiltration without IgG4-positive PC. Immunofluorescence microscopy disclosed granular mesangial positivity for a “full-house” pattern. Electron microscopy disclosed mesangial and subendothelial dense deposition accompanied with virus-like particles. We diagnosed this patient with IgG4-negative IgG4-RKD and LN (ISS/RPS II). After administration of 20 mg prednisolone, laboratory data was drastically improved.

Discussion: To our knowledge, this is the first report of a patient with LN and IgG4-negative IgG4-RKD. IgG4-negative IgG4-RKD may be a chronic burnout phase of IgG4-RKD. Further studies gathering similar cases would be needed to clarify whether or not IgG4-negative IgG4-RKD is included in a category of IgG4-RKD.

TH-PO1111
A Case of Acute Phosphate Nephropathy in a Kidney Transplant Recipient Hetal Shah, M. Lee Sanders, Kelly A. Birdwell, Anthony J. Langone, Paist Paukeasakon, Beatrice P. Concepcion. Vanderbilt Univ Med Center, Nashville, TN.

Introduction: Acute phosphate nephropathy has been described after large doses of phosphate, typically in laxatives and bowel cleansing preparations. We present a case of acute phosphate nephropathy in a kidney transplant recipient who was taking oral phosphorus supplementation for hypophosphatemia.

Case Description: A 26 year-old man with a living related donor kidney transplant in 2011 complicated by recurrent IgA nephropathy with a baseline creatinine of 1.9 mg/dl presented with nausea, vomiting, diarrhea, fatigue and elevated creatinine. Two weeks prior to presentation, he had been started on K-Phos-Neutral 500 mg three times a day for a total of 1500 mg/day of oral phosphorus (iPTH) was 58 pg/mL. He soon after developed diarrhea and ten days later developed nausea and vomiting. He was found to have a creatinine of 10.4 mg/dl, phosphorus 9.7 mg/dl, calcium 9.6 mg/dl and iPTH 761 pg/ml. Urinalysis showed a urine pH of 5, no red blood cells and trace protein. Renal biopsy was performed, and pathology revealed 30 foci of intratubular calcium crystals with associated acute tubular injury involving 30-40% of tubular profiles, along with known reoccurrence of IgA nephropathy. The patient underwent acute hemodialysis for oliguric acute kidney injury. Given the high serum phosphorus, he was dialyzed for four consecutive days until phosphorus level was less than 4 mg/dl and did not rebound. Patient was discharged requiring intermittent hemodialysis for an additional three weeks until he demonstrated renal recovery. His new baseline creatinine is 2.2 mg/dl and he has remained off hemodialysis.

Discussion: Hypophosphatemia is common in kidney transplant recipients. Although rare, acute phosphate nephropathy can occur in the setting of phosphorus repletion. This patient also had multiple risk factors, including baseline renal dysfunction, volume depletion and angiotensin receptor blocker use. Acute phosphate nephropathy can potentially lead to irreversible loss of renal function. While no specific treatment exists, in this case, aggressive hemodialysis to decrease serum phosphorus may have played a role in this patient’s eventual renal recovery.

TH-PO1112
Unusual Membranous Nephropathy in a Patient with Lupus Iheanyichukwu Ogu, Julia Lewis, Agnes B. Fogo. Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.

Introduction: Membranous nephropathy (MN) is an immunologically mediated glomerular disease. Distinguishing between primary and secondary MN is important in guiding diagnosis and treatment. We present a case of a patient with systemic lupus with pathologic features in a repeat biopsy suggestive of primary MN.
Case Description: A 32 year old African American woman presented in 1998 with nephrotic range proteinuria (IgG, edema and serum creatinine 0.6). She had negative work up for secondary causes including lupus. Renal biopsy showed mild matrix expansion, diffuse global basement membrane (GBM) spikes, preserved tubulointerstitial compartment; fine granular IgG(3+), C3(1+) IgM(trace), C1q(trace), IgA(negative) capillary loop staining with focal mesangial IgM and C3 staining; numerous subepithelial deposits, 90% foot process effacement, and unremarkable endothelial cells. She was started on an angiotensin receptor blocker but was lost to follow up. In 2011 she was diagnosed with lupus and in July 2014, had proteinuria (1.9g). Repeat renal biopsy showed persistent MN with features concerning for lupus, with reticular aggregates, mildly increased mesangial matrix and cellularity, and 20% interstitial fibrosis. After referral to our clinic, additional testing on the 1998 biopsy (fig. 1.2) showed diffuse global capillary wall IgG(I+2), IgG2(I+2), IgG3(negative), IgG4(I+2), PLAR2(negative); and the 2014 biopsy (figs. 3.4) showed diffuse global granular capillary wall IgG(I+2), IgG2(I+2), IgG3(negative), IgG4(I+2) and PLAR2 near global(I+2) granular capillary loop staining.

Discussion: The PLAR2 staining and the dominance of IgG4 currently are consistent with primary MN. The negative PLAR2 in 1998 may indicate early disease or epitope change. The mesangial deposits are nonspecific and could possibly represent a low grade with primary MN. The negative PLA2R in 1998 may indicate early disease or epitope change.

TH-POI113
A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Exhibiting Marked Nephrotic Syndrome Who Responded Well to the Renin-Angiotensin System Blockade
Yoshihiko Ishihiguchi, Hideki Inoue, Tomoaki Onoue, Yutaka Kakizoe, Yuichiro Izumi, Takashige Kuwabara, Takuo Miyoshi, Masatake Adachi, Yushi Nakayama, Masashi Mukoyama. Nephrology, Kumamoto Univ Hospital, Kumamoto, Japan.

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is a recently recognized entity of glomerulonephritis caused by glomerular deposition of monoclonal IgG. The clinical and pathological features, treatment and prognosis of this entity remain elusive.

Case Discussion: A 79-year-old woman was admitted to our hospital due to hematuria and marked nephrotic-range proteinuria. Her serum creatinine level was 0.75 mg/dL and urinary protein excretion was 20.8 g/gcreatinine. Renal biopsy showed a membranoproliferative feature without nodular formation. Immunofluorescence study showed capillary and mesangial deposits of IgG, C1q and C3. Moreover, IgG-kappa deposits were strongly stained and IgG3 deposits were restrictedly stained for IgG heavy-chain lambda ratio. These findings were consistent with the diagnostic criteria for PGNMID.

Considering her age and tolerability, we started monotherapy with angiotensin II receptor blocker. This case showed drastic reduction in proteinuria with stable renal function within several months after the treatment with the renin-angiotensin system (RAS) blockade alone.

Discussion: We report here an exceptional case of PGNMID associated with the membranoproliferative feature successfully treated with RAS blockade alone, without steroids or other immunosuppressive agents. Further studies are needed to clarify clinical spectrum and prognosis of this newly described disease entity.

TH-POI114
Brexitumab Induced Renal Steatosis – The Hint Is in the Urine
Akhil Heads, Ronald J. Falk, Abhijit V. Kshirsagar. UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: We describe the onset of acute kidney injury (AKI), lipodystrophy and multi-organ steatosis after the use of Brexiutumab, a monoclonal antibody targeting CD30, in patients with recurrent Hodgkin Lymphoma (HL).

Case Discussion: A 61 year old female with recurrent HL, treated with Brexitumab 180mg (4 and 2 weeks prior to admission), was admitted with a 1-month history of nausea and vomiting. She was found to have AKI, creatinine 1.7 - baseline 0.9 mg/dL, elevated liver enzymes (AST 324, ALT 282 U/L), a urine protein/creatinine ratio of 1.0g with a total creatinine of 1.75 and 32 mg/dL. Urine microscopy revealed numerous free fatty droplets and fatty casts (8g), edema and neutrophilic infiltration of the glomerular capillary wall, showing a maladaptive polarization light. Sudan black dye demonstrated positive staining indicating non-cholesterol fat in the urine.

PET/CT imaging did not show malignancy, but revealed severe fatty infiltration of multiple organs not present 4 months earlier. The patient was hospitalized and the patient died on hospital day #6. An autopsy revealed hepatosplenomegaly with severe steatosis, fatty infiltration of the pancreas and proximal renal tubular epithelial cell macro/microvesicular steatosis with intra-glomerular lipiduria.

Conclusion: The development of AKI, lipodystrophy and multi-organ steatosis after 2 doses of Brexitumab is concerning for a drug-induced injury. Sudan dye attaches to neutral lipids and is helpful in distinguishing the 2 categories of lipids. Only 2 weeks after the last dose of Brexitumab, the patient was found to have new fatty infiltration and a subsequent autopsy revealed intra-glomerular lipidosis. The first histologic feature was steatosis was the presence of fat bodies in the urine. Typically, charged lipids have the appearance of a maltese cross under polarizing light, while neutral lipids do not refract polarized light in this manner.

TH-POI115
Pheochromocytoma: An Unusual Cause of Thrombotic Microangiopathy
Yoshihiko Ishihiguchi, Hideki Inoue, Tomoaki Onoue, Yutaka Kakizoe, Yuichiro Izumi, Takashige Kuwabara, Takuo Miyoshi, Masatake Adachi, Yushi Nakayama, Masashi Mukoyama. Nephrology, Kumamoto Univ Hospital, Kumamoto, Japan.

Introduction: Hypertensive disorders during pregnancy result in substantial maternal and fetal morbidity. Pheochromocytoma in pregnancy is extremely rare with a reported frequency of 0.002% and 50% maternal and fetal mortality.

Case Description: A 25 year old female, 26 weeks of gestation with gestational diabetes presented with antenatal hemorrhage, confusion and uncontrolled hypertension with BP 145/95 mmHg. Investigations revealed hemoglobin 9 g/dL, platelets 760000/microliter, serum creatinine 2.4 mg/dL, LDH 245U/L, AST 300U/L, ALT 390U/L, urine dipstick protein 1+. Ultrasound confirmed abrupt placenta and intrauterine death of fetus needing emergency surgical evacuation. She developed intraoperative hypotension needing multiple blood transfusions and ventilatory support. Her renal function worsened needing initiation of hemodialysis. Septic and hemolytic work up were negative. She had paroxysmal episodes of uncontrolled hypertension and flash pulmonary edema needing frequent rescue hemodialysis and parenteral antihypertensives. Renal doppler was negative for renal artery stenosis. CAT scan showed left adrenal mass. Plasma normetanephrine was elevated at 1223 pg/ml suggestive of pheochromocytoma. BP was stabilized with four drugs and surgical resection of the tumor was done. A wedge kidney biopsy showed thrombotic microangiopathy (TMA). The tumor histopathology confirmed pheochromocytoma, positive for chromogranin and synaptophysin staining. Post operative, her creatinine stabilized at 1.6 mg/dL, BP and glucocorticoid status returned to normal.

Discussion: Discussion: Pheochromocytoma in pregnancy is an extreme rarity with a frequency of 0.002%. It is often mistaken for other hypertensive disorders of pregnancy. This is the first case report of a patient with acute kidney injury in pregnancy from TMA secondary to pheochromocytoma. Patient made good renal recovery after resection of the tumor.

TH-POI116
Immune Reconstitution Inflammatory Syndrome and Hypercalcemia with Acute Kidney Injury following Antiviral Therapy
Carolina Garcia, Kelly H. Beers, Catherine Miranda, Kamran Karimi, Yezina T. Nigatu, Nand K. Wadhwa. Nephrology/Medicine, Stony Brook Medicine, Stony Brook, NY.

Introduction: Immune reconstitution inflammatory syndrome (IRIS) is an inflammatory disorder with paradoxical worsening of preexisting infections following HAART in HIV-infected individuals. We describe a case of IRIS following Stribild (elvitegravir, cobicistat, emtricitabine, tenofovir) resulting in hypercalcemia.

Case Discussion: A 33 year-old woman with acquired immunodeficiency syndrome (AIDS) who had been on Stridhild for two months presented to the ED with acute kidney injury with a serum creatinine of 2.93 mg/dL and Ca of 15.2 mg/dL. Her CD4 count was 145 u/L and viral load 35 copies/mL. Four months prior, she was treated with amphotericin for cryptococcal lung infection and Cryptococcemia. One month prior, a right lower lobe metastasis was found and surgical resection of the tumor was done. A wedge kidney biopsy showed thrombotic microangiopathy. A CAT scan showed left adrenal mass. Plasma normetanephrine was elevated at 1223 pg/ml suggestive of pheochromocytoma. BP was stabilized with four drugs and surgical resection of the tumor was done. A wedge kidney biopsy showed thrombotic microangiopathy (TMA). The tumor histopathology confirmed pheochromocytoma, positive for chromogranin and synaptophysin staining. Post operative, her creatinine stabilized at 1.6 mg/dL, BP and glucocorticoid status returned to normal.

Discussion: Discussion: Pheochromocytoma in pregnancy is an extreme rarity with a frequency of 0.002%. It is often mistaken for other hypertensive disorders of pregnancy. This is the first case report of a patient with acute kidney injury in pregnancy from TMA secondary to pheochromocytoma. Patient made good renal recovery after resection of the tumor.
Discussion: IRIS is thought to be due to increased T-lymphocyte proliferation after HAART in AIDs patients. IRIS typically manifests as a granulomatous inflammation. Corticosteroids are treatment of choice in IRIS in the setting of excess 1.25 (OH)3. D3 was low suggesting possible other mechanisms.

TH-POI117
IgA-Dominant Postinfectious Glomerulonephritis: A Case Series
Pranjal Sharma,1 Anitha Vijayan,2 Tingting Li.2
1Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO; 2Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO.

Introduction: IgA dominant post-infectious glomerulonephritis (PIGN) is a distinct clinicopathologic entity that typically occurs in diabetic patients and in association with a recent or active staphylococcal infection. Patients usually present with hematuria, proteinuria, and ACR. Renal pathology shows an immune complex glomerulonephritis with various light microscopic patterns and IgA-dominance or co-dominance with IgG on immunofluorescence. Here we report the clinical characteristics and outcomes of 10 patients with IgA dominant PIGN.

Case Description: After obtaining approval from the local IRB, retrospective, single-center review of data was performed and 10 patients with IgA dominant PIGN were identified.

Majority was white males, and 6/10 were diabetic. Eight patients had a Staphylococcal infection and one had active Hep C infection. Only 3/10 had low complements, 6/10 required RRT and 4 developed ESRD, of which 2 died at 2 and 5 months after initiation of RRT. Five were left with varying degree of CKD and one was lost to follow up. Three patients were treated with immunosuppression in addition to antibiotics-all had significant improvement in renal function; one patient who was initially RRT-dependent was able to come off dialysis.

Table 1. Clinical features and outcomes of pts with IgA-dominant PIGN

Discussion: IgA-dominant PIGN is an increasingly recognized disorder that occurs most commonly in diabetic patients with Staphylococcal infections. Overall renal prognosis is poor. Treatment with immunosuppression in addition to antibiotics may be considered.

TH-POI118
Hematuria in a Young Female: This Was a Hard Nut to Crack

Introduction: Flank pain with hematuria usually indicates urolithiasis but in its absence, renal vascular abnormalities should be considered.

Case Description: A 27-year old female with history of sickle cell trait, was admitted for hematuria. She had flank pain at the end of her urine stream but did not associate fever, chills or dysuria. She was treated with ciprofloxacine for presumed UTI but due to weakness she presented to our hospital. Her vital signs were stable and had a normal physical examination. Her hemoglobin was 8.1 g/dL and creatinine was 1.5 mg/dL with urine microscopy evident for 3 plus proteinuria with >25 RBC/hpf and >50WBC/hpf. Her total protein to creatinine ratio was 2 and had a negative urine culture. She had normal complement, ANA screen and negative serology work up for autoimmune disease. Renal ultrasound (US) showed 10 cm (right) X 9.5 cm (left) kidneys. Her non-contrast CT abdomen and cystoscopy was non-diagnostic. To further evaluate her hematuria she underwent renal US with Doppler which showed narrowing of the left renal vein at the level of the superior mesenteric artery (SMA) with a peak velocity gradient greater than 10:1, consistent with left renal vein compression and a “water- cather” syndrome (NCS). She subsequently underwent exploratory laparotomy with evidence of aortic and SMA scalping compression of renal vein at its confluence with inferior vena cava (IVC). The IVC and left renal vein were explored and evidence of aortic and SMA scissoring compression of renal vein was noted. The usual course of treatment for NCS is hemodialysis (HD), 5 sessions of HD was performed with improvement of 39% in Cr. However, patient’s anti-GBM titer was negative! Electron microscopy showed thickening of GBM and no T cell aberrancy or B cell monoclonality. A kidney biopsy revealed pauci-immune necrotizing CGN. Electron microscopy (EM) showed no deposits or fibrillary or tubular structures in the glomeruli. The patient was treated with hemodialysis (HD), 5 sessions of plasmapheresis and oral cyclophosphamide for 3 months. He responded to treatment with near complete resolution of his symptoms and near normalization of kidney function.

Discussion: Pauci-immune CGN is associated with either microscopic polyangiitis or granulomatosis with polyangiitis. These can present as RPGN and have either a positive MPO or PR3 ANCA but have no deposits on immunofluorescence and EM. CGn in particular is a disease with distinct immune pathogenesis, has distinct immune deposits in glomerular capillaries and fibrillary and tubular structures on EM. Our case was an unusual combination of 2 different pathologically and pathogenically distinct disease entities. To our knowledge this is the first reported case with these unusual manifestations.

TH-POI119
Fibrillar Glomerulonephritis Presenting as Rapidly Progressive Crescentic Glomerulonephritis
Pallavi D. Shirsat,1,2 Chyi Chyi Chong,1,2 Ramesh Marahatta,1,2 Cherinet S. Adgeh,1,2 Neville R. Dossabhoy.1,2
1Dept of Nephrology, Veterans Affairs Medical Center, Shreveport, LA; 2Dept of Nephrology, LSU School of Medicine, Shreveport, LA.

Introduction: Fibrillar glomerulonephritis is a rare disease of unclear etiology, known to be associated with malignancy, autoimmune disorders, lymphoplasmacytic disorders and hepatitis C. It is seen in 0.5 to 1.0% of native kidney biopsies.

Case Description: We report a case of a 62 year old Caucasian male veteran who had a past medical history of hepatitis C, hyperlipidemia, s/c coronary bypass, multiple colon polyps with colectomy and CKD stage 3. Patient, on a routine follow up appointment, was noted to have rapid worsening of kidney function, with creatinine increase from baseline of 1.4-1.8 up to 3.2 mg/dL. He was also noted to have 24 RBCs per HPF on urine microscopy. Urine protein:creatinine ratio was 4.5. Hepatitis C related membranous glomerulonephritis (GN) was high on the differential list. Hepatitis B and HIV serologies were negative. Complement and cryoglobulins, ANCA and serum protein electrophoresis were all within normal limits. Patient underwent kidney biopsy, which showed crescentic GN, with linear pattern immunoglobulin deposition along the GBM (glomerular basement membrane) on light microscopy and immunofluorescence suggestive of anti-GM disease. However, patient’s anti-GM titer was negative! Electron microscopy showed thickening of GBM due to fibrillary deposits. Similar fibrillary deposits were also seen in the mesangium, with haphazard distribution of fibrils measuring about 15 mm, consistent with fibrillar GN. Congo red stain for amyloid was negative. Patient was also found to have a 2.8 x 2.5 cm well- circumscribed solid & cystic mass in right kidney on ultrasound, suspicious for renal cell carcinoma (RCC). A fine needle aspiration of the mass yielded cells consistent with RCC.

Discussion: Fibrillar GN is known to be associated with malignancy. It can rarely present clinically as rapidly progressive, crescentic GN, and masquerade as anti-GM disease on immunofluorescence. Electron microscopy and serologic workup are needed to clinch the definitive diagnosis.

TH-POI121
Paucci-Immune Necrotizing Crescentic Glomerulonephritis as the First Manifestation of Chronic Lymphocytic Leukemia Relapse
J Saadi Imam,1 Monia E. Werlang,1 Tatiana A. Thorn,2 Nabeel Aslam.1
1Dept of Medicine, Division of Internal Medicine, Mayo Clinic, Jacksonville, FL; 2Dept of Medicine, Div of Nephrology, Mayo Clinic, Jacksonville, FL.

Introduction: The association between hematological malignancy and auto-immune disease is a well-documented phenomenon. Chronic lymphocytic leukemia (CLL) patients have 5-10% risk of developing autoimmune cytopenias, and a rare subset of these CLL patients have autoimmune complexes antibodies (ANA, anti-GBM) with the setting of vasculitis. Here, we present a case of a patient with treated CLL whose relapse was identified by the new diagnosis of ANCA-associated paucci-immune glomerulonephritis.

355A
This was an unexpected learning case that shows that the occurrence of diabetic nephropathy may correlate more with presence and not the intensity or duration of hyperglycemia. Further studies are needed to elucidate this phenomenon.

TH-PO1124
Case of Catastrophic Antiphospholipid Syndrome Treated with Plasma Exchange
Takeyuki Takamura, Tetsuhiro Furuya, Tetsuharu Oku, Kenichiro Kitamura. Third Dept of Internal Medicine, Univ of Yamashita.

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is characterized by diffuse vascular thrombosis, leading to multiple organ failure within a few days and resulting to poor prognosis. Antiphospholipid syndrome (APS) is an autoimmune thrombotic syndrome with recurrent thrombosis and occurs in both artery and vein, and from large to micro vessels. CAPS is also defined as a fetal variant of APS and develop thrombosis of three different organ systems with histopathologic evidence of multiple small vessel occlusions and high titters of antiphospholipid antibodies. Treatment for CAPS has not been established, and intensive anticoagulation or immunosuppressive therapy is carried out.

Case Description: A 68-year-old female who had been diagnosed as lupus erythematosus and APS complicated with multiple cerebral infarctions and treated with 5 mg of oral prednisolone. After her admission, she developed de novo cerebral infarction and colonic perforation with ischemic enteritis. Following a partial colectomy, she developed gram-negative bacteremia, subsequently, multiple strokes, non-ST elevation myocardial infarction, renal failure, and pathological findings with multiple thrombi. These clinical findings indicated that patient’s features were consistent with CAPS. She was maintained with anti-bacterial agent, anticoagulant, and prednisolone. However, since renal failure and anuria had continued, she was treated with plasma exchange (PE) and hemodialysis. Thereafter the volume of urine output was gradually increased and her renal function was recovered.

Discussion: We report a case of CAPS with multiple organ failure and successfully treated with anticoagulant, prednisolone, and PE. The clinical manifestation of CAPS depends on the release of inflammatory cytokines from the affected organs by thrombosis and small vessel occlusion. Our patient’s successful course could be attributed to beneficial role of PE through the removal of excessive inflammatory cytokines.

TH-PO1125
Acute HIV in a HIV-Naïve Patient During Primary HIV Infection and High Viral Load
Amit Durr.

Introduction: A hitherto healthy 42 yo AA male felt chilly 6 days earlier. He took a NyQuil and skipped next day’s shift for body aches/GI cramps. He improved but again felt bad by HS, 48h later. Next AM in a local ER, his UA showed WBC/RBC, 3+ protein, and a SG of 1.030. Physical exam, chest X-ray, contrast abdominal CT, and eGFR, were normal. His HIV panel worked full capacity again, but got admit 48h later after a brief syncopy.

Case Description: Viral signs: T 103°F, BP 100/60 mm Hg, and HR 76 bpm. He had transient mild diastolic. Serum albumin (A1b) was 2.1 g/dl, creatinine (cr) 2 mg/dl, and WBC 103/ml. UA had WBC/RBC and <0.5 g/dl protein. UA was 21 mmol/L. His urine protein was <12 g/24h. CRP was <2 (<0.5 mg/dl), and ESR 50 mm/h. CRP was 8717 U/l and h笔者 = 48h. He BCP, and HIV-1/2 Ab screens were (-), but the HIV-2A4 gen. He had >3>106 HIV copies/ml, and 213 CD4+ cells/ml. US showed normal-sized kidneys, no obstruction, but some cortical echogenicity. His HIF first proved for 72h, but then rose to 8 mg/dl in 1w. Dialysis and HAART were initiated. By then he had edema and A1b was 1.2 g/dl. Renal biopsy showed collapsing GN, podocyte hypertrophy/hyperplasia, microcystic tubular dilations, 3+ acute tubular injury, 2+ patchy (mostly lymphocytic) infiltration with focal tubulitis, and no signs of chronicity. Prednisone was added. He seroconverted (HIV-1) 2w after his first chills.

Discussion: Of the case reports of primary renal HIV infection only 2 had biopsy-proven HIV. One was HIV Ab (+) but was EIA but not by Western blot, and had 700,000 HIV copies/ml (Szabo S et al. 2002). The other was HIV Ab (+) by EIA but not by Western blot, and had 70,000 HIV copies/ml (Szabo S et al. 2002). Both had advanced RF and already other infections. Our patient had normal eGFR until his acute HIV infection. The high HIV load alone, not replication, is the sole likely cause for HIV, consistent with the view that a direct toxic effect of the HIV gene product on podocyte dedifferentiation, since viral particle endocytosis readily occurs in podocytes (as their normal filter cleaning role?), but lack of HIV entry receptors precludes local replication (Khatua AK et al. 2010).

FR-PO001
A Case of Hypercalciemia with Renal Failure: Renal Sarcoid?

Introduction: Sarcoidosis is a multisystem granulomatous disease of unknown etiology characterized by noncaseating granulomas in involved organs. Renal involvement occurs in 35-50%, manifested by hypercalciuria, hypercalcinosis, and nephrolithiasis. Granulomatous interstitial nephritis is the most typical histological finding, usually in the setting of systemic disease and rarely in the absence of extrarenal sarcoid.

Case Description: A 54 y/o male presented with AKI superimposed on CKD and severe hypercalciuria (Calcium 13.5 mg/dL, Creatinine 2.8 mg/dL). Six months prior he had a kidney stone removed at which time his creatinine was 2.4 mg/dL with Ca=1.7 mmol/L but no further work up was performed. He was taking no medications and complained of back pain. Physical exam was unremarkable. A CT scan was negative for nephrolithiasis but no further work up was performed. He was aggressively treated with IV NS and then Lasix with minimal improvement in the creatinine or the serum calcium. Work up for hypercalciuria included normal serum and urine immunofixation, negative PPD, normal PSA and normal skeletal survey. 25 Hydroxyvitamin D 27.8 ng/ml (30-95 ng/mL), PTH suppressed at <3 pg/ml, total 1, 25 HydroxyVitamin D 79 pg/ml (18-72 pg/ml), Angiotensin Converting enzyme 82 (9-77 U/L). A formal ophthalmologic exam and PFTs were normal. A diagnostic kidney biopsy was performed.

Discussion: The diagnosis of sarcoid interstitial nephritis was strongly suggested by the renal biopsy given that other causes of granulomatous were ruled out. The patient was started on prednisone 60mg/d with rapid resolution of the hypercalciemia and slow improvement in renal function (Creatinine 2.9 mg/dL). A slow steroid taper over 1 year is planned.

FR-PO002
Pediatric Chronic Refractory SIADH: Use of Tolvaptan
Cristin Kaspar, Nianzhou Xiao, Timothy E. Bunchman, Megan M. Lo. Pediatric Nephrology, Children’s Hospital of Richmond at Virginia Commonwealth Univ, Richmond, VA.

Introduction: The syndrome of inappropriate antidiuretic hormone (SIADH) is the most common cause of euvoletic hyponatremia in hospitalized patients, and standard therapies can be limited in their effectiveness. Arginine vasopressin receptor antagonists (AVR-A) oral tolvaptan and intravenous conivaptan have been FDA approved in adults, but reports on long-term use in pediatrics are lacking. We report on the dosing and safety of chronic AVR-A treatment in two patients with chronic SIADH. Dosing regimen was extrapolated from current pediatric and adult literature.

Case Description: Case A is a 13 year old, 43.5 kg female with a 12-year history of chronic A VR-A treatment in two patients with chronic SIADH. Dosing regimen was extrapolated from current pediatric and adult literature.

Initial treatment included fluid boluses with NS, bicarbonate drip and broad-spectrum antibiotics for suspected sepsis. Further history revealed that patient had MMA and then IV fluid was changed to D20NS with insulin drip. He was started on special formula feed for MMA. Daily peritoneal dialysis was continued. Serum ammonium, β-hydroxybutyrate and lipase levels were normal. Blood and stool cultures grew salmonella enteritidis and antibiotics were switched to iv ciprofloxacin and metronidazole. With assistance from metabolic specialist, nephrologist and endocrinologist, patient was treated successfully.

Discussion: MMA is a rare autosomal recessive disorder (incidence of 1:48,000), caused by deficiency of methylmalonyl-CoA mutase or its cofactor, cobalamin. It is associated with anion gap metabolic acidosis, hypoglycemia, ketonuria and hyperammonemia. Metabolic decompensation can occur during episodes of increased catabolism such as prolonged fasting. Treatment of acute illness includes, providing hydration with high caloric supplementation, stopping all protein intake for 1-2 days and reintroduction of a low protein diet later. Severe acidosis may require dialysis.

FR-PO003
Methylmalonic Acidemia: An Unexpected Consult for an Adult Nephrologist: A Case Report
Yogita Lakhera, Shrikant Sundriyal, Nephrology, JL Pettis VA Medical Center, Loma Linda Univ School of Medicine, Loma Linda, CA.

Introduction: Organic acidemia are caused by deficiencies of enzymes involved in the breakdown pathways of amino acids, fatty acids and carbohydrate metabolism. Methylmalonic academia (MMA) is a heterogeneous group of disorders of impaired metabolism of methylmalonic acid. We present a patient with MMA who was admitted with severe metabolic acidosis.

Case Description: A 21 year old male with past medical history of end stage renal disease on peritoneal dialysis, chronic pancreatitis, diabetes mellitus and coeliac disease presented to emergency room with diarrhea. He denied fever, abdominal pain and vomiting. He was hypotensive. Laboratory tests showed metabolic acidosis with anion gap of 33 mMol/L and absence of leukocytosis. Arterial blood gas result was pH:7.38, pCO2: 18 mmHg, paO2: 108 mmHg and HCO3: 10 mMol/L. Patient was kept NPO and acidosis worsened the next day.

Discussion: MMA is a rare autosomal recessive disorder (incidence of 1:48,000), caused by deficiency of methylmalonyl-CoA mutase or its cofactor, cobalamin. It is associated with anion gap metabolic acidosis, hypoglycemia, ketonuria and hyperammonemia. Metabolic decompensation can occur during episodes of increased catabolism such as prolonged fasting. Treatment of acute illness includes, providing hydration with high caloric supplementation, stopping all protein intake for 1-2 days and reintroduction of a low protein diet later. Severe acidosis may require dialysis.

FR-PO004
Congenital Pituitary Stalk Interruption Syndrome (PSIS) Newly Diagnosed in Case of Hyponatraemia in the Elderly.
Kenji Kajitani, Takahito Ito, Kaori Takaori, Yoko Tomiyama, Ikue Nagayama, Masafumi Yamato, Akira Wada, Hirotsubo Iwataki. Nephrology, Osaka National Hospital, Osaka, Japan.

Introduction: There are many diseases that cause hyponatraemia. Among them, adenohypophysis (AI) is important due to its urgency. We present an extremely rare case of elderly-onset AI in congenital PSIS, which is highly suggestive of the mechanism of AI progression.

Case Description: A hyponatremic episode (Na 117 mEq/L) occurred in a 76 year-old Japanese man in conjunction with common cold. Laboratory analyses revealed a low serum cortisol level. He was short-statured, had no hair growth on his axilla and pubis, and had unusual pale pigmentation in skin. He presented with gynecostasia and microopenis. CT scan revealed anorchism. He was not mentally retarded. Serum hormonal analyses showed AI, hypothyroidism, growth hormone deficiency, hypogonadism and hyperprolactinemia. Set of CTH/TRH/GRH/LHRH stimulation test disclosed hypothalamic panhypopituitaryism. Brain MRI visualized severely pressured 2-mm thick pituitary, but not the pituitary stalk, indicating PSIS.

Discussion: We concluded that his PSIS was not an acquired but a congenital anomaly based on his episode of intrathecal growth retardation and anorchism in the light of embryology. In PSIS patients, the functions of pituitary are sometimes maintained even if partially, although hypophyseal portal vessel snaps apart. This is because hypothalamic hypopituitarism occurs through the superior hypophyseal artery (SIIA), the nutrient artery of both hypothalamus and pituitary. In this case, the echogram of the internal carotid artery, from which SHA branches showed severe atherosclerosis. We speculate that the progression of atherosclerotic changes impaired the blood flow of SHA and then decreased the conversion of LH and FSH into anterior pituitary hormones. This transformation could be additionally supported by the prolonged fasting. Treatment of acute illness includes, providing hydration with high caloric supplementation, stopping all protein intake for 1-2 days and reintroduction of a low protein diet later. Severe acidosis may require dialysis.

A Family Case of Hyopparathyroidism, Deafness, and Renal Dysplasia Syndrome with a Novel Mutation of GATA3
Tomoo Yabusuchi, Shoichiro Kanda, Naoya Morisada, Keiichi Takizawa, Yuji Tomii, Naoto Kaneko, Hirota Hama, Eiji Nakano, Norimasa Tada, Kiyonobu Ishizuika, Hiroko Chiba, and Yuko Itoka
1Dept. of Pediatric Nephrology, Tokyo Women’s Medical Univ, Shinjyuku-Ku, Tokyo, Japan; 2Dept of Pediatrics, Chuo University School of Medicine, Chuo-k, Kobe, Japan.

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT), a major cause of end-stage renal disease in children, often present as a systemic disorder with extrarenal symptoms. Extrarenal symptoms and family history are helpful in the genetic diagnosis of CAKUT. We report here a family case of hypoparathyroidism, deafness, and renal dysplasia syndrome (HRD) with a novel mutation of GATA3.

Case Description: Soon after birth, a female patient was diagnosed as having bilateral cystic dysplastic kidneys by renal ultrasonography. She also had hearing impairment at the infancy. She received peritoneal dialysis at the age of 3 years and received a cadaveric kidney transplant at the age of 10 years. When she was 14 years old, she visited the emergency department because of acute abdomen. Detailed examinations showed hypertelorism associated with vaginal atresia. Branchio-oto-renal syndrome was considered as her diagnosis based on her hearing impairment, bilateral cystic dysplastic kidneys, and normalcalcemia. However, we suspected that she had an HRD syndrome because we found that her mother had hypoparathyroidism after determining a detailed family history. Genetic analysis was approved by the central ethics board of Tokyo Women’s Medical University and Kobe University. This analysis showed a novel mutation, c. 1013G>T (C338F) of GATA3, the causative gene for HRD syndrome.

Discussion: Our patient did not show any symptoms of hypoparathyroidism. However, based on the family history, we performed a genetic analysis and found a novel mutation of GATA3. She was then diagnosed with atypical HRD syndrome. Therefore, determining a detailed family history is important in the precise diagnosis of CAKUT patients.

Hypocomplementemic Urticarial Vasculitis Syndrome Resistant to Corticosteroid and Plasma Exchange Therapy
Yasuhito Kawai, Kenji Ueki, Yuta Matsukuma, Hiroto Hiyamuta, Akhiro Tsuchimoto, and Kiyoko Fujisaki
1Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka City, Japan; 2Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu City, Japan.

Introduction: We present a case of HUVS resistant to corticosteroid and plasma exchange.

Case Description: A 36-year-old Japanese man with the history of diffuse panbronchitis, eczema, cutaneous vasculitis, and kidney dysfunction. Percutaneous kidney biopsy was performed at the hospital, and the diagnosis was non-IgA mesangial proliferative glomerulonephritis. In spite of the administration of angiotensin II receptor blocker, progressive kidney dysfuction was evident. Then he was transferred to our hospital 4 months later. He also had a history of urticarial rash on his leg and pigmentation was evident at the time of transfer. Urticular rash revealed 3+ proteinuria and 3+ hematuria, and urinary sediment showed red blood cells of 50-99/high power field. Urinary protein/creatinine (Cr) ratio was 2.9 g/gCr. Blood tests revealed a serum Cr level of 2.4 mg/dL, complement (C) 3 level 18 mg/dL, and C4 level 23 mg/dL. We performed kidney biopsy again, and found membranoproliferative glomerulonephritis with crescents. Since additional blood test revealed serum anti-C1q antibodies of 51,965 U/mL, the diagnosis of HUVS was made. We treated him with methylprednisolone pulse therapy followed by oral prednisolone, but his kidney function was unchanged and he developed bacterial pyelonephritis. Next, we added plasma exchange and a temporary decrease in proteinuria accompanied by a decrease of serum anti-C1q antibody level. But his kidney function did not recover, and the level of anti-C1q antibody raised again.

Discussion: HUVS is a systemic vasculitis with urticarial rash, hypocomplementemia, and anti-C1q antibodies. Effective and specific treatment for HUVS has not been established. Although corticosteroid and plasma exchange showed temporal efficacy, it was impossible to suppress the progressive kidney dysfunction in this case.

FR-PO007

Acquired Fanconi Syndrome in a Patient with Acetaminophen Overdose
Deepak Jasuja, Jay B. Wish. Div of Nephrology, Indiana Univ, Indianapolis, IN.

Introduction: Acquired Fanconi syndrome is described in patients receiving antiretrovirals, aminoglycosides, platinum compounds and with proximal tubulopathies due to light chain disease/paraproteinemias. We describe a case of acetaminophen induced acute tubular necrosis (ATN) presenting as Fanconi syndrome with hypophosphatemia, normoglycemic-glucosuria, aminoaciduria, and uric acid, potassium and bicarbonate wasting.

Case Description: A 35 year old woman with borderline personality disorder, depression, alcohol abuse, multiple suicide attempts, and previous acetaminophen overdose was transferred from outside hospital with fulminant hepatic failure secondary to acetaminophen poisoning. Nephrology was consulted for metabolic acidosis and AKI. On exam she was oriented to person only and following minimal commands. She had acute fulminant hepatic failure as evidenced by transaminase elevations, encephalopathy, and coagulopathy. On presentation her serum creatinine was 2.95 which rose over the next 3 days to 9.06. Initial blood gas was consistent with metabolic acidosis and respiratory compensation. Serum potassium (K) was low (2.9-3.5) despite large doses of K supplements. Her K requirements abated when bicarbonate supplementation was discontinued. Acetaminophen level was elevated on transfer at 21 and urine drug screen was positive for opiates and benzodiazepines; toxic alcohols were negative. Serum uric acid was <1.5 mg/dL and phosphorus <1 mg/dL. Glucose was 1-2+ on urinalysis with normal blood glucose. The following amino acids were elevated in her urine: aspartic acid, beta alanine, citrulline, gamma amino acid butyric acid, glutamic acid, leucine, ornithine, proline, taurine and valine. This was a non-specific pattern of generalized aminoaciduria consistent with proximal tubulopathy and acquired Fanconi syndrome. The patient subsequently recovered renal function and the proximal tubulopathy resolved.

Discussion: It is common for nephrologists to be aware that ATN (in this case acetaminophen induced) can lead to acquired Fanconi syndrome and proximal tubulopathy which seem to resolve as ATN resolves. Aggressive treatment with bicarbonate supplements can exacerbate urinary K wasting and should be avoided.

FR-PO008

Spontaneous Remission of Non-Parasitic Chyluria
1Div of Nephrology and Hypertension, Weill Cornell Medical Center, New York, NY; 2Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Chyluria is a medical condition characterized by the presence of chyle in the urine. The disease is most prevalent in South East Asian countries mostly caused by parasitic (Wuchereria bancrofti) infections. Chyluria presents as a cloudy milk-colored urine accompanied by systemic symptoms such as weight loss, fatigue, and rarely, flank pain from retained clots.

Case Description: A 72 year-old woman presented to Nephrology clinic complaining of milky urine (Figure 1) and painless hematuria with clots for two months as well as twenty-pound weight loss. Physical exam was unremarkable. Cystoscopy and urine cytology were unremarkable. Serum albumin was 3.2 g/dL. A urinalysis showed 3+ protein and 50 red blood cells per HPF. Urine sediment had no dysmorphic cells or casts. A 24-hour urine collection revealed 8.8 grams of protein. Chyluria screen was positive for chylomicrons and triglycerides. Midnight blood smears were negative for filarial parasites. Urine culture was negative for mycobacteria or schistosomas. Serologic studies including IgG western blot for cisticercus and IgG ELISA for filariasis were negative. The rapid plasma reagin (RPR) was also negative. Imaging for a lymphatic leak by lymphocintigraphy was unrevealing. The patient was managed conservatively and underwent spontaneous remission with disappearance of chyluria several months of her initial diagnosis.

Discussion: The most common cause of chyluria is parasitic infection with granulomatous diseases or structural etiologies less frequently encountered. Sclerotherapy of the renal pelvis is the definitive treatment. Idiopathic chyluria as shown in this case is rare. Conservative management of idiopathic disease may be warranted due to the possibility of spontaneous remission.

FR-PO009

Rebound Hypertension and Hypokalemia After Stopping Drospherenone
Kalvani Chandra, Shubha Ananthakrishnan. Nephrology, UC Davis Medical Center, Sacramento, CA.

Introduction: Drospheronone is the fourth generation oral contraceptive with antimineralocorticoid effects, which are reported to be generally mild. There have been several warnings issued for drospheronone, in relation to adrenal insufficiency and hyperkalemia. But, no reports thus far of the rebound effects like hypertension (HTN) and
hypokalemia, following the discontinuation of the medication, especially after prolonged use. Re-introduction of low dose spironolactone and screening for other causes of nephrotic syndrome was also recommended. For more information, see the reference.

**Case Description:** A 54-year-old Indian woman, previously normotensive, noted severe proteinuria of 3.1 g/day on presentation to the emergency department, where she was also noted to have mild hypokalemia of 3.1 mmol/L. Given the rather new onset of severe HTN and hypokalemia, work-up for secondary causes of HTN was done, which revealed normal aldosterone level (9 ng/dL), low plasma renin activity (PRA) (0.15 ng/mL/hr) and high aldosterone/PRA ratio (60). Looking back into her history, it was noted that the timing of symptoms was closely related to discontinuing Yasmin® (Ovral®) due to elevated estradiol and 3 mg drospirenone), which she was taking for over 6 yrs. She was thought to have rebound effect with relatively excess mineralocorticoid activity, precipitated by the abrupt discontinuation of drospirenone. With the introduction of low dose spironolactone, her symptoms significantly improved.

**Discussion:** Drospirenone (an analogue of spironolactone), which has antimineralocorticoid and antiandrogenic activities similar to endogenous progesterone, counteracts the estrogen-mediated stimulation of the renin-angiotensin-aldosterone system (RAAS). Due to these effects, it has the potential to decrease blood pressure and also cause hyperkalemia. At a dosage that suppresses ovulation, drospirenone induces mild natriuresis, which is followed by compensatory stimulation of the RAAS (comparable to a low sodium diet). When the prolonged ongoing suppression for the RAAS is removed, there might be a potential rebound effect with (relatively) high aldosterone state, resulting in sodium retention, leading to HTN. Spironolactone appears to be useful in this situation.

FR-PO010

**Acthar Induced Hypokalemic Metabolic Alkalosis**

**Inman Qayyum,** Neil W. Lyman. Dept of Nephrology, St. Barnabas Medical Center, Livingston, NJ.

**Introduction:** Acthar, an ACTH formulation from porcine pituitary gland, is an effective therapy for Membranoproliferative Glomerulonephritis (MGN). A rare adverse effect of hypokalemic alkalosis was observed in our patient. We present a report of an 84 y/o Caucasian female who developed severe hypokalemia and metabolic alkalosis with Acthar therapy, and concomitant diuretic use.

**Case Description:** The patient presented with severe bilateral leg edema. Lower extremity doppler was negative for DVT. Echo revealed normal EF. UA showed 4+ protein, 3+ red blood cells and trace proteinuria. She was started on a regimen of Acthar 80 units 2x/week. 35 days later, she was readmitted for worsening renal function and proteinuria. Serum creatinine was 1.99 mg/dL (baseline 1.34 mg/dL). Albumin was 2.3 g/dL. Workup for malignancy and concomitant diuretic use.

**Discussion:** Despite the presence of normal factor H and I levels, treatment with Eculizumab is effective for complement mutation. Our patient had a homozygous deletion of CFIHR3-CFIHR1, which has previously been linked to aHUS. CFIHR3-CFIHR1-deficient plasma is thought to contribute to defective regulation of complement activation on the cell surface and occurs despite the presence of normal factor H and I levels. Treatment with Eculizumab is effective and should be started promptly as disease can be halted and chronic damage limited.

FR-PO001

**Polycthemia in a Patient with Bartter’s Syndrome and Medullary Nephrocalcinosis**

**Girlic Singean Merdega,** Medicine, Philippine General Hospital, Manila, Metro Manila, Philippines.

**Introduction:** Bartter’s syndrome is a tubular salt wasting disorder presenting with severe hypokalemic alkalosis, hyperkalemia, and hyperparathyroidism with normal blood pressure. Medullary nephrocalcinosis in this disorder is an infrequent finding and is usually unrecognised. Polycythemia is an unusual presentation in patients with renal diseases, but has been described in literature among patients with nephrotic syndrome and distal tubular acidosis. It is noteworthy, however, that reports on secondary erythrocytosis among patients with Bartter’s syndrome is lacking. The exact mechanism for the polycythemia is unclear, although erythropoietin levels include hypoxia-induced nephrocalcinosis causes stimulation of oxygen receptors thus increasing erythropoietin secretion, and stimulation of prostaglandin production may be contributory.

**Case Description:** A 27 year-old Filipino male with recurrent bouts of severe hypokalemic alkalosis since childhood presenting as bilateral lower extremity weakness necessitating recurrent hospital admissions was diagnosed with Bartter’s syndrome based on metabolic alkalosis, hypokalemia, hyperkalemia, slight hyponatremia with normal serum calcium and magnesium levels. He had normal blood pressure and no frank hypercalcuria. His creatinine was elevated and his ultrasound revealed normal sized kidneys with bilateral nephrocalcinosis. He had elevated hemoglobin of 190 g/L, slight leukocytosis with no thrombocytosis. JAK2 mutation was negative and a bone marrow biopsy revealed mildly hypercellular marrow with trilineage hematopoiesis, hematopoiesis for which polycythemia was ruled out. Findings were consistent with a reactive marrow. He underwent as needed phlebotomy and was maintained on potassium replacement, spironolactone and an ace-inhibitor.

**Discussion:** Polycythemia in a patient with Bartter’s syndrome and medullary calcinosis is a rare entity with very limited data in literature. The mechanism leading to secondary erythrocytosis, as well as nephrocalcinosis among patients with Bartter’s syndrome remains uncertain. Clinicians should be aware of potential complications of this disorder so as to institute appropriate management.

FR-PO002

**Homoeozygous Deletion of CFIHR3-CFIHR1 as a Cause for Atypical Hemolytic Uremic Syndrome in a Patient with Systemic Lupus Erythematosus**

**Salem Almaani,** Tibor Nadasy,1 Samir Parikh.1 1Div of Nephrology, The Ohio State Univ, Columbus, OH; 2Dept of Pathology, The Ohio State Univ, Columbus, OH.

**Introduction:** Thrombotic microangiopathy (TMA) is a rare but devastating condition associated with systemic lupus erythematosus (SLE). In SLE, renal TMA is typically associated with the anti-phospholipid syndrome (APS) or TTP. Here we report a case of atypical hemolytic uremic syndrome (aHUS) associated with SLE that was confirmed by complement genetic studies and treated successfully with Eculizumab.

**Case Description:** A 21 year old African American female with a history of SLE and class II-V lupus nephritis was hospitalized after presenting with AKI, thrombocytopenia (TCP), and a microangiopathic hemolytic anemia (MAHA). Initial lab values revealed a serum creatinine of 3.5 mg/dL, platelet count of 58, hemoglobin of 7.3, and LDH of 1484. Plasmapheresis and IV soludemol was started empirically for presumed TTP and SLE flare. ADAMTS13 enzyme activity was normal and APS antibodies were negative. There was no improvement and the patient was started on dialysis. The patient required multiple blood transfusions as TCP and MAHA persisted. A kidney biopsy was performed and findings were consistent with severe TMA. The patient was empirically started on Eculizumab and after the first dose, TCP improved rapidly, with a platelet counts increase from 27% to 170K. Complement mutation studies were obtained and revealed a homoeozygous deletion of CFIHR3-CFIHR1 genes. The patient continued on Eculizumab, and after 4 months she recovered renal function and was liberated from dialysis.

**Discussion:** This is the first report of aHUS associated with SLE in a patient with an identified complement mutation. Our patient had a homoeozygous deletion of CFIHR3-CFIHR1, which has previously been linked to aHUS. CFIHR3-CFIHR1-deficient plasma is thought to contribute to defective regulation of complement activation on the cell surface and occurs despite the presence of normal factor H and I levels. Treatment with Eculizumab is effective and should be started promptly as disease can be halted and chronic damage limited.

FR-PO013

**A Novel Mutation in KLHL3 Gene Causes Familial Hyperkalemic Hypertension**

**Mohd Razi Radzlan Akib,** Dearbella Kelly, Xavier Jeunemaitre,2 Catherine A. Wall.1 1Nephrology, Adelaide & Meath Hospital, Dublin, Ireland; 2Département de Génétique et Centre de Maladies Vasculaire Hôpital Européen Georges Pompidou, Paris, France.

**Introduction:** Familial hyperkalemic hypertension is an autosomal dominant disorder where mutations in the thiазide-sensitive NaCl co-transporter (NCC) cause salt-dependent hypertension. Implicated genes include WNK1, WNK4, KHL3 and CUL3. These lead to increased activity of the NCC in the distal nephron, excessive chloride and sodium reabsorption, and volume expansion. We describe a disease causing variant in KLHL3 not previously reported in the literature.

**Case Description:** An 18 year-old man with no prior medical history presented with an incidental finding of serum potassium of 7.3mmol/L. He was hypertensive with blood pressure 150/90mmHg. His mother, maternal uncle and grandmother also had a history of early onset hypertension and unexplained hyperkalemia.

**Discussion:** His labs showed serum sodium 139mMol/L, chloride 103mMol/L, creatinine 83mMol/L. His arterial blood pH was 7.37 with bicarbonate 21. Plasma renin activity was suppressed at 0.2ng/ml/H and his serum aldosterone was raised at 534.4pmol/L. The last 24-hour urinary sodium reabsorption, leading to HTN. Spironolactone appears to be useful in this situation.

**Discussion:** The association of Bartter’s syndrome with medullary calcinosis and secondary erythrocytosis is a rare entity with very limited data in literature. The mechanism leading to secondary erythrocytosis, as well as nephrocalcinosis among patients with Bartter’s syndrome remains uncertain. Clinicians should be aware of potential complications of this disorder so as to institute appropriate management.
FR-PO014
Renal Failure Run A-FUowl: Disseminated Histoplasmosis  Eileen Smith, Rajeev Raghavan, Sreedhar A. Mandayam. Baylor College of Medicine, Houston, TX.

Introduction: In patients with fever of unknown origin (FUO) and glomerulonephritis, Histoplasma capsulatum should be considered.

Case Description: A 37-year-old man presented to the hospital with 3 weeks of fatigue, 15-pound weight loss, intermittent chest pain, dyspnea on exertion and 3 day history of erythematous pruritic rash on his neck. PMH included congenital aortic stenosis with AVR, complicated by endocarditis requiring repeat AVR. Physical exam found splenomegaly and a lacy erythematous rash on the neck and torso. On admission, creatinine was 3.15 mg/dL (baseline 1.17, last year) with gross hematuria, and new pancytopenia. Initial work-up for glomerular disease was non-diagnostic. He developed persistent cyclical fevers to 102°F during his hospital stay. Blood cultures, tagged WBC scan and TEE were negative. Kidney biopsy showed numerous electron-dense deposits suggestive of Membrano-Proliferative Glomerulonephritis. Further history revealed that the patient regularly cleaned a chicken coop. An infectious work-up found the patient to be strongly positive for the Histoplasma capsulatum urinary antigen. With itraconazole for histoplasmosis and concomitant steroid therapy for glomerulonephritis, he defervesced and his creatinine improved to 1.4 mg/dL.

Discussion: Infection Related Glomerulonephritis (IRGN) is an immune-mediated disease caused by non-renal pathogens. The incidence is higher in developing countries: for example, per 100,000 individuals, the incidence of cases per year is 39 in India and 0.78 in the United States. It is believed that sub-clinical IRGN is common and underdiagnosed. In a study of 1012 kidney biopsies, 10% had evidence of disease, such as subepithelial humps. Hematuria is present in >80% of cases, and patients usually present with Nephritic Syndrome. Endemic mycoses as a cause of glomerular disease in humans are rare. An infection due to H. capsulatum can result from inhalation of aerosolized spores after disruption of chicken droppings harboring the fungus. We suspected endocarditis given his cardiac history, and kidney biopsy findings also supported infection. However, the splenomegaly, FUO, and exposure to fowlis (FUOwuls) established the diagnosis.

FR-PO015
Next Generation Sequencer Driven Exome Analyses Identified a MCKD1 Family with New Mutation Before VNTR Of MUC1 DNA Sequence, Suffering From Mucosal Dysfunctions  Satoshi Yamamoto,1 Jun-Ya Kaimori,1 Masaki Hatanaka,2 Naotsu Ichiguchi,1 Shiro Takahara,1 Hiromi Rakugi,1 Yoshitaka Isaka.1
1Dept of Advanced Technology of Transplantation, Osaka Univ School of Medicine, Osaka, Japan; 2Dept of Genetic Medicine & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.

Introduction: Hereditary tubulo-interstitial nephritis (h-TIN) is characterized by family history, bland urine, normal size kidney, hyperuricemia, renal fibrosis and gradual renal function loss. MCKD1 type h-TIN is also recognized by the difficulty to identify mutant sequence by conventional Sanger Sequencer or next generation sequencing, because the cystine insertion mutation locates in the GC rich valuable number tandem repeat (VNTR) region. The mutant MUC1 DNA sequence is supposed to produce truncated type protein, which is inferred to be trafficked to the cell membrane. Because of the difficulty of identification, there may be lots of unknown symptoms in MCKD1.

Case Description: We identified 5 hereditary TIN patients in a family, three of those are on hemodialysis and one is under dialysis, and the other was CKD. The C2D2 patient was 23 y.o female, whose renal function is gradually reducing for 10 years. Now her serum creatin is over 3. Her renal MRI images showed normal size kidneys with no cysts. The patients are suffering from mucosal dysfunctions including GI ulcer, sinusitis, and dysphagia. We analyzed genome DNA sequence of hereditary TIN family by next generation sequeencer driven trio exome analyses. They revealed that the 2 bp deletion mutation were located before VNTR. Interestingly, consequently produced mutant MUC1 cysts. The patients are suffering from mucosal dysfunctions including GI ulcer, sinusitis, renal fibrosis and gradual renal function loss. MCKD1 type h-TIN is also recognized by the difficulty to identify mutant sequence by conventional Sanger Sequencer or next generation sequencing, because the cystine insertion mutation locates in the GC rich valuable number tandem repeat (VNTR) region. The mutant MUC1 DNA sequence is supposed to produce truncated type protein, which is inferred to be trafficked to the cell membrane. Because of the difficulty of identification, there may be lots of unknown symptoms in MCKD1.

Discussion: We could identified the totally new mutation sequence of MCKD1 family, because it located before the GC rich VNTR sequence of MUC1. The newly identified mutant protein showed the almost same a.a. repeats sequence, suggesting these repeat sequence is implicated in the pathophysiology of MCKD1 type h-TIN.

Funding: Government Support - Non-U.S.

FR-PO016
Propofol-Induced Hyperkalemia in a Hemodialysis Patient  Ibrahim M. El-Ali, Chandana Shekar, Sathak Virmani, Ruchir D. Trivedi. Dept of Medicine, Div of Nephrology, Univ of Connecticut Health Center, Farmington, CT.

Introduction: Propofol induced hyperkalemia and propofol infusion syndrome are well described in the intensive care literature. Propofol induced sudden cardiac arrest, however, may be under recognized. We report a case in which a large bolus of propofol was associated with an acute increase in serum K+ precipitating potentially fatal cardiac arrhythmia.

Case Description: A 58 y/o male on maintenance hemodialysis (HD), having missed 2 HD sessions, presented with altered mental status and hyperkalemia. Patient required intubation for airway protection. Serum K+ was 8.2 mEq/L and confirmed with repeat of 8.8 mEq/L. Propofol bolus was used as premedication for intubation followed by infusion at 20 mcg/kg/min. Ventricular fibrillation and cardiac arrest ensued soon after propofol bolus. Patient was managed with repeated calcium chloride bolus totaling 10 grams and urgent hemodialysis. Post-HD Serum K+ level was 4.3 mEq/L. Repeat K+ 10 hours after HD, with other parameters being changed, was 7.1 mEq/L, increasing to 7.9 mEq/L within the next hour. Cardiac monitor showed widening QRS interval. No concurrent evidence of hemolysis, DIC or rhabdomyolysis. No exogenous K+ was given. HD was re-initiated emergently to avoid recurrent cardiac arrhythmias. Propofol was discontinued with no recurrence of hyperkalemia.

Discussion: Direct mitochondrial respiratory chain inhibition similar to mitochondrial myopathy is the most plausible explanation for propofol infusion syndrome (PRIS); a rare but significant adverse effect of propofol. Impaired mitochondrial fatty acid metabolism leads to lactic acidosis causing trans-cellular potassium shifts to ECF resulting in hyperkalemia. Rapid rise of serum K+ is more closely correlated with onset of arrhythmia than absolute K+ levels. Propofol bolus can also cause sudden worsening of hyperkalemia via depressed beta adrenoceptor-agonist effect and acute transcellular shift of potassium. This complication can be fatal in ESRD patients who may have baseline hyperkalemia. Hence, propofol should only be used with extreme caution in ESRD patient population on HD.

FR-PO017
A CuriousSLE Tangled Case: Systemic Lupus Erythematosis as the Unifying Diagnosis for Fibrillary Glomerulopathy and Toxic Epidermal Necrolysis  Kawan A. Swain, Hao Liu, Volker Nickeleit, Patrick H. Nachman. Nephrology, Unv of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: Fibrillary glomerulopathy is a rare cause of glomerular disease. Most cases are idiopathic but can be associated with autoimmune diseases.

Case Description: 58 y/o Caucasian male with a past history of hypertension presented a week after developing an acute erythematous rash associated with fever, encephalopathy, and AKI. The rash was preceded by a month history of intermittent night sweats, fever, and joint pain. The desquamating rash encompassed ~30% BSA with mucosal involvement. Skin biopsy revealed acute vascular interface dermatis consistent with toxic epidermal necrolysis (TEN). Labs showed pancytopenia without evidence of hemolysis. Serum Cr was 2.14 mg/dL (recently 0.9) and urine Protein/Cr was 1.1g. Urine microscopy showed numerous acanthocytes and a few RBC casts. Serologies revealed low C3 and C4, positive ANA 1:640 and ENA screen, but negative ANCA, cryoglobulins, infectious work up and antibodies to ds-DNA, Sm, RNP, Ro/SSA, La/SSB, Jol and Se70. A kidney biopsy showed acute tubular injury and mild mesangial and endothelial proliferation without crescents or tuft necrosis. Immunofluorescence revealed diffuse 1-2+ staining for IgG, IgA, IgM, C3, C1q, kappa and lambda in the mesangium and capillary walls. Electron microscopy showed mesangial and capillary deposits with 20nm non-branching fibrils. Congo red stain was negative and IgG subclass stain did not reveal monoclonality. The findings were classified as a fibrillary glomerulonephritis. After initial methylprednisolone pulse, treatment with oral prednisone and mycophenolate mofetil resulted in resolution of rash, encephalopathy, and recovery of renal function and cell counts. The unifying diagnosis is new onset SLE, with TEN (possibly precipitated by naproxen) and fibrillary glomerulopathy.

Discussion: This case illustrates an uncommon presentation of an immune complex mediated fibrillary glomerulopathy consistent with SLE in an older male patient who presented with TEN. SLE has been rarely implicated as a cause of SJS/TEN when associated with initial photodistribution, absence of genital involvement, and a prolonged course.

FR-PO018
An Unusual Case of Renal Failure in an Adult: “Prune Belly Syndrome”  Antonio Medaura, Jeffrey D. Wallach, Sudhanshu Jain. Nephrology, Harlem Hospital Center, New York, NY.

Introduction: Prune Belly Syndrome is a rare congenital disease characterized by hypoplastic abdominal wall musculature, severe urinary tract dilatation and bilateral undescended testes. The complete syndrome is seen only in males affecting 3.8 per 100,000 live births. While the cause is unknown several aspects suggest an influence of genetic factors. Very few patients survive adulthood and all of them progress to ESRD.

Case Description: A 25-year-old male from Burkina Faso presented with a 10-year history of fever, rigors and right-sided flank pain. On exam he was found to have an empty scrotum and a distended bladder. He reported history of several urinary tract infections and urological surgeries during childhood. He was found to have azotemia (Sr. creatinine 10.8 mg/dl and BUN 82 mg/dl) and an eGFR of 8 ml/ min/ 1.73m2. Urinalysis was cloudy with 2+ protein, 3+ leucocyte esterase, 2-5 WBC's and moderate bacteria. Urine culture was sterile with an acute increase in serum K+ precipitating potentially fatal cardiac arrhythmia. 58 y/o male on maintenance hemodialysis (HD), having missed 2 HD sessions, presented with altered mental status and hyperkalemia. Patient required intubation for airway protection. Serum K+ level was 4.3 mEq/L. Repeat K+ 10 hours after HD, with other parameters being changed, was 7.1 mEq/L, increasing to 7.9 mEq/L within the next hour. Cardiac monitor showed widening QRS interval. No concurrent evidence of hemolysis, DIC or rhabdomyolysis. No exogenous K+ was given. HD was re-initiated emergently to avoid recurrent cardiac arrhythmias. Propofol was discontinued with no recurrence of hyperkalemia.
survive until adulthood or they are already ESRD. The findings in our report. This diagnosis in a 25 year old is rare, as most patients do not need of further studies, it may be worthwhile to empirically treat with azithromycin for to be considered when there is a high rate of ammonia production. And while we are in need of further studies, it may be worthwhile to empirically treat with azithromycin for ureaplasma infection in so called “idiopathic hyperammonemia”.

He received intravenous antibiotics and improved clinically.

Discussion: Although lower urinary tract and kidney malformations account for 40% of childhood ESRD it is a rare cause of kidney failure in adults. Mutation in the HNF1β gene and homozygous loss-of-function mutation of muscarinic receptor M3 (CHRM3) were described. CHRM3 is the major receptor mediating urinary bladder contraction upon micturition. These patients have normal urethral patency on cystogram and detrusor hyporeflexia with high residual volumes after micturition seen on cystometry, identical to the findings in our report. This diagnosis in a 25 year old is rare, as most patients do not survive until adulthood or they are already ESRD.

FR-PO019
How ‘Idiopathic’ Is Idiopathic Hyperammonemia? Esso Georges, Kavitha Vellanki. Nephrology, Loyola Univ Medical Center, Maywood, IL.

Introduction: Idiopathic hyperammonemia is characterized by progressive elevations in serum ammonia of unknown etiology, ultimately leading to cerebral edema and death. It is a rare fatal syndrome described in transplant setting; lung transplant recipients having the highest risk. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

Case Description: A 59 yr old Hispanic man with idiopathic pulmonary fibrosis received bilateral lung transplant at our center. His induction regimen included thymoglobulin and methylprednisolone and was maintained on tacrolimus, mycophenolate and prednisone. Despite all these measures, ammonia levels remained persistently elevated at > 1700 µg/dL (Figure 1) and patient expired within 4 days. At autopsy, bronchoalveolar lavage (BAL) of bilateral lung weighed positive for Ureaplasma urealyticum. On further testing, donor’s pre- transplant BAL was positive for the same organism. Lysis of urea by Ureaplasma generates free ammonia and when left untreated, can cause hyperammonemia. But the rise in serum ammonia levels of such a magnitude despite aggressive dialysis is unheard of.

Discussion: In conclusion; underlying infection with urea splitting organisms need to be considered when there is a high rate of ammonia production. And while we are in need of further studies, it may be worthwhile to empirically treat with azithromycin for Ureaplasma infection in so called “idiopathic hyperammonemia”.

FR-PO020
Pelvocalyceal Leakage on Ethanol Sclerotherapy for Recurrent Infected Renal Cyst in ADPKD Eunyoung Lee, Joo-Hark Yi, Sang-Woong Han, Ho-Jung Kim. Division of Nephrology, Dept of Internal Medicine, Hanyang Univ Guri Hospital, Guri-si, Gyeonggi-do, Republic of Korea.

Introduction: Though sclerotherapy has been commonly considered as a valid and safe therapeutic option for symptomatic renal cysts, it’s effectiveness in recurrent infected renal cyst in autosomal dominant polycystic kidney disease (ADPKD) is rarely reported.

Case Description: A 76-year-old woman with ADPKD was again admitted by infected (L1) renal cyst (7.3 cm) on ultrasonography (US) with similar episode, 1 yr ago. She presented with a fever, dysuria and left CVA tenderness. Despite clinical and laboratory improvement with sensitive antibiotics against Klebsiella pneumonia for 14 days, the size of the infected renal cyst was paradoxically enlarged (8.9 cm) on follow-up US. Thus, percutaneous catheter was inserted for drainage and after 1 wk, tubogram showed no evidence of dye leakage (figure1-A). Following complete clinical recovery, absolute ethanol sclerotherapy was performed to prevent further recurrent cyst infection. However, she complained of severe burning pain in low abdomen at the beginning of the procedure. Tubogram dye was shown in pelvocalyceal system and ureter (figure1-B). Sclerotherapy was immediately stopped and saline irrigation was followed. Then, percutaneous catheter was removed into the cyst for further draining, and double-J catheter was inserted at ureteropelvic junction to prevent a ureteral stricture. Then, she underwent uneventful hospital course, and discharged on hospital day 42.

Discussion: Infected renal cyst wall, despite clinical recovery, could consist of already damaged tissue that may be easily broken by ethanol. Through this unexpected adverse complication, we learned that cyst ablation therapy with ethanol may not be an appropriate modality to prevent recurrent renal cyst infection in ADPKD.

FR-PO021
A CD2AP Mutation (p.T374A) Associated with Cognitive Decline and Focal Segmental Glomerulosclerosis in Young Adulthood Dmitry Tsvetkov,1 Yoland Marie Anistan,1 Christian Harteneck,2 Maik Gollasch.1 1Charité Univ Medicine Berlin, Nephrology/Intensive Care, Experimental and Clinical Research Center (ECRC) and Max Delbrück Center for Molecular Medicine, Berlin, Germany; 2Dept of Pharmacology and Experimental Therapy, Inst of Experimental and Clinical Pharmacology and Toxicology, Eberhard Karls Univ Hospitals and Clinics, and Interfaculty Center of Pharmacogenomics and Drug Research, Univ of Tübingen, Tübi.

Introduction: Mutations in CD2-associated protein (CD2AP) gene have been identified in patients with focal segmental glomerulosclerosis (FSGS); however, reports of CD2AP mutations remain scarce.

Case Description: We performed Sanger sequencing in a 32-year old patient with steroid-resistant FSGS presented with a nephrotic syndrome (proteinuria >3.5 g/day). The patient reported that his mother and his only brother also have a kidney disease. Neurological examination showed a remarkable cognitive decline within the last 5 years. Therapy with steroid and low-intermediate doses of cyclosporine A led to a persistent reduction of proteinuria. Serum creatinine levels and glomerular filtration rate (eGFR) did not decline during this treatment.

Discussion: Our patient displayed mild cognitive decline, a phenotypic characteristic not previously associated with CD2AP-associated FSGS. His proteinuria was remarkably reduced by treatment with cyclosporine A. Our findings expand the genetic spectrum of CD2AP-associated disorders and broaden the associated phenotype with the co-occurrence of cognitive decline. Our case shows that cyclosporin A is a treatment option for CD2AP-associated nephropathy.

Acute Motor and Sensory Axonal Neuropathy-Associated Syndrome of Inappropriate Antidiuretic Hormone Secretion Weeraporn Srisang,1 Aumyot Prongdong,1 Pavis Laengvejakul,2 Camilo Pena,1 Mustafa G. Aly,1 Sorot Phisitkul.1 1Internal Medicine, TTUHSC; 2Neurology, TTUHSC.

Introduction: SIADH is associated with various conditions including Guillain-Barre’ syndrome (GBS). We report a case of SIADH associated with acute motor and sensory neuronal nephropathy (AMSAN), a variant of GBS.
FR-PO023

Severe Renal Osteodystrophy as a Result of Fanconi Syndrome
Rabie L. Adams-Eldred, Charles W. Heilig.

Introduction: Fanconi syndrome is a disease of the proximal renal tubules in which glucose, amino acids, uric acid, phosphate, bicarbonate and other substances are not reabsorbed and lost in the urine.

Case Description: 22 year old African American female with an autosomal dominant Fanconi syndrome. Her disease is clinically manifested by severe rickets and short stature. Her short stature has not responded to growth hormone. She has multiple stress fractures, and she amebulates with a walker. Her disease is manifested chemically by generalized aminoaciduria, hyperchloremic metabolic acidosis, hyperphosphaturia, glucosuria, bicarbonaturia, and proteinuria. Her life compliance with the medication has been poor. She has a gastoentero tube for medications administration. Her medications include Calcium Carbonate, Neutrase-Phos, Rocaltol, Polycitanz and Zantac.

Her physical examination showed: Height 98.5 cm, weight 15.8 kg, blood pressure 106/57, pulse 80. She can stand up with hips flexed and her trunk slightly forward because of the anterior and lateral bowing of the femurs. She has significant ankle prominence, and she has good range of motion. Extremities: Have severe ricket changes. Lower extremities are deformed with prominent femur curve bilaterally. The rest of her exam was unremarkable.

Urinary analysis showed glucose 100 mg/dL, ketones 40 mg, blood trace, pH 7, protein greater than 300 mg. Chemistries showed, Sodium 134, potassium 3.4, bicarbonate 13, chloride 114, glucose 142, BUN 5, creatinine 0.6, calcium 7.9, phosphorus 3.8. Osmolality 268. Alkaline phosphatase 865. White count 7.3, hemoglobin 14, hematocrit 41.3, platelets 385. 162 (normal 0-80 mcg/dl). She was treated with a carbohydrate based diet and avoidance of medications known to precipitate an acute attack.

Discussion: AIP results from a deficiency of PBG deaminase, leading to accumulation of ALA. ALA forms a complex with GSH and a precipitate. The constellation of recurrent abdominal pain and explanation of SIADH in a young menstruating female led to the diagnosis of AIP. Studies sent for AIP demonstrated elevated urine total porphyrin 3,374 (normal 0-300 mmol/24 hr), urine porphyrin 115 (normal 0-4 mg/24hr), 5-aminolevulinic acid (ALA)-delta 79.8 (normal < 7mg/24hr), and RBC protoporphyrin 68 (normal 0-80 mcg/dl). She was treated with a carbapenem based diet and avoidance of medications who present with failure to keep with the replacement of these substances secondary to compliance of use of the patient, adverse permanent skeletal effects might result from that.

FR-PO024

A Case of Solute Diuresis
Muhammad K. Qaseem, Elizabeth A. Gilliams, James L. Bailey.

Introduction: Polyuria is a common manifestation of many primary medical disorders. Here we present a case of ASLD with altered mental status and later developed polyuria.

Case Description: A 24-year old male with history of ASLD was admitted to the Intensive Care Unit (ICU) for altered mental status with an ammonia level of 347mcmol/L. He was started on Ammonia Scavenger therapy with Ammonia (arginine, Na-benzoate and 2-keto-4-methyl-2-oxopentane). On hospital day 3 he developed hypokalemia, hypernatremia and polyuria of 5L. His labs are listed below.

<table>

</tbody>
</table>

Urine studies showed urine Sodium of 253mmol/L, urine Potassium of 59mmol/L, urine chloride of 175 mmol/L, urine anion gap of 137, urine osmolality of 63 mOsm/kg and urine Creatinine of 63 mg/dL with a 5.3L of urine in 24 hours. He was receiving 2%Normal Saline, Ammonium and Total Parenteral Nutrition (TPN). It was recommended to decrease the dose of ammonium to decrease the non-measured anions in the urine,stoping ½normal saline and change the TPN to have less solute load. With these interventions his urine output and hypokalemia improved to almost back to normal.

Discussion: Argininosuccinate Lyase (ASLD) activity results in the breakdown of argininosuccinic acid to arginine and fumarate. ASLD can result in severe hyperammonemia. Treatment of acute decompensations with hyperammonemia involves discontinuing oral protein, using intravenous arginine and ammonia scavenging therapy. Polypurina in ASLD could be due to different mechanisms such as low BUN leading to poor urine concentrating ability with loss of free water or due to solute diuresis. Our patient’s high urine osmolality and high urine sodium indicated a mechanism other than Diabetes insipids. After the solute content was decreased his urine osmolality decreased significantly along with his urine output. Hypokalemia also improved. Management of solute diuresis in this case was to reduce the solute intake of the patient but first and foremost requires an accurate diagnosis.
Serum Hypokalemia in a Hemodialysis Patient

Maria M. Costa, 1
department of Nephrology, University of Alabama at Birmingham, Birmingham, AL

Patient: A 58-year-old male on chronic hemodialysis presented with complaints of feeling unwell, weight loss, and frequent diarrhea for at least one month. On admission, his medical history included hypothyroidism, prostate cancer, and bipolar disorder on lithium for 40 years.

Methods: A comprehensive laboratory evaluation revealed normal serum sodium, blood urea nitrogen, and creatinine. The patient had an intravenous doxycalciferol dose of 8.6 mg/dL; serum albumin of 3.2 gm/dL, PTH of 352 pg/mL, 25OH-Vitamin D2 <4 ng/mL, 25OH-Vitamin D3 12 ng/ml, and phosphorus of 6.3 mg/dL.

Results: The intravenous doxycalciferol dose was increased to 12 mg/dL with a plan to increase it further if needed. His intravenous doxycalciferol dose was increased to 8.6 mg/dL on day 3 and increased to 12 mg/dL on day 5.

Conclusions: The patient developed acute respiratory failure requiring intubation shortly after albuterol nebulizer treatment. He was also receiving Dexamethasone (Corticosteroid) and an inhaled anticholinergic agent (Ipratropium bromide) for chronic obstructive pulmonary disease. It is possible that the patient's hypocalcemia may have contributed to the developme
Discussion: Vasopressin does not usually result in hypotension when used in management of shock. Possible explanations include lack of renal responsiveness secondary to sepsis, hypoperfusion, acute kidney injury, or lack of intake of hypertonic fluids. In this case, the patient developed marked hypotension in setting of preserved renal function.

FR-PO032
Hyperkalemia Secondary to Octreotide Use in a Patient with Normal Kidney Function

Dron P. Bhandari, Jyotsana Thakkar, Hitesh H. Shah. Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.

Introduction: Octreotide, a somatostatin analogue works by reducing blood levels of a variety of hormones (e.g. growth hormone, insulin) and chemical messengers (e.g. gastrin, vasoactive intestinal peptide). Octreotide therefore has been used as an effective medication for the treatment of sulphonylurea-induced hyperglycemia, acromegaly, VIPoma and carcinoid syndrome. Octreotide-induced hyperkalemia has rarely been reported in the literature. We report a patient with normal renal function who developed hyperkalemia secondary to octreotide use.

Case Description: A 70-year-old male with long standing history of DM (since 20 years), HTN, and metastatic neuroendocrine pancreatic cancer was referred by his oncologist for evaluation of severe hyperkalemia (serum potassium level of 6.6 mmol/L). Patient was diagnosed with pancreatic neuroendocrine tumor approximately 2 years prior to his presentation for which he underwent Whipple procedure. He was also receiving imprisonment-induced hyperkalemia due to the restoration of HAART. In patients with HIV and AIDS with history of granulomatous disease, it is important to monitor for hypercalcemia when initiating HAART therapy or adjusting therapy.

FR-PO034
Hypocalcemia in Severe Malnourishment, and Acute Pancreatitis Veils Vitamin D Intoxication

Introduction: Although vitamin D has a wide therapeutic index, a routine use of high doses of vitamin D intake can cause toxicity. We report a case with severe hypocalcemia likely due to malnutrition and pancreatitis related to alcoholism followed by hypercalcemia from vitamin D toxicity.

Case Description: A 43 year-old woman with alcoholism was admitted with rhabdomyolysis and alcohol induced acute pancreatitis. On initial examination she was in moderate distress with altered mental status and diffuse abdominal pain. Her blood pressure was 102/67 mmHg, heart rate 136/min and temperature 38.3°C. Her lab data revealed WBC 54.71 x 10^9/L, Hb 16.9 g/dL, PLTs 186 x 10^9/L, serum Na 129 mEq/L, K 3 mEq/L, bicarbonate 19 mEq/L. BUN 32 mg/dL and creatinine 1.3 mg/dL. The initial amylase, lipase, calcium and Mg were 1.7 mg/dL, CPK 1089 IU/L and albumin 2.9 g/dL. She received intravenous Ca, Mg, K and phosphorus in addition to oral supplements. On day 4, her serum Ca was 8.7 mg/dL, albumin 2.5 g/dL, phosphorus 4.0 mg/dL and K 3.9 mmol/L without any supplement. Her serum Mg remained low and continued to receive oral and intravenous Mg supplements. Serum Ca was not checked between days 9-14 of her hospitalization. On day 15, her serum Ca was 12.8 mg/dL, ionized Ca 6.4 mg/dL, vitamin D 25OH 370 ng/ml, vitamin D 1-25 OH 149 pg/ml and intact PTH 11.8 pg/ml. Her TSH, T4, ACE and vitamin A levels were normal. Her 24 hours urine revealed Na 140 mEq/L, K 70 mEq/L, creatinine 1110 ng/L, UN 41.4 g/L, Ca 462 mg/L, Mg 403 mg/L, phosphorus 931 mg. She admitted taking vitamin D 50,000 units daily for many months for her psoriasis on her own. Her hypercalcemia was treated and her serum calcium stabilized over one week to 9.4 mg/dL while her vitamin D 25OH and vitamin D 1-25OH remained elevated over the next 6 weeks.

Discussion: Her unusual presentation of hypocalcemia masked vitamin D toxicity till she resumed regular nutrition. Her hypocalcemia was likely related to malnutrition due to chronic alcoholism and possible calcium deposition due to acute pancreatitis. With proper nutrition during her hospitalization and improvement of her underlying condition led to hypocalcemia due to vitamin D toxicity.

FR-PO035
Re-Defining the Speed Limit in Osmotic Demyelination Syndrome? Malriukh Rizvi, Rebecca D. Monk. Nephrology, Univ of Rochester Medical Center, Rochester, NY.

Introduction: Osmotic demyelination syndrome (ODS) is a severe, debilitating, possibly fatal neurological condition that results from rapid correction of severe chronic hyponatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na+) < 120 mmol/L, alcoholism, malnutrition and liver transplanted. Current recommendations advise raising serum sodium by less than 9 mmol/L in 24 hours. We present a case of ODS in a patient presenting with severe hypotremena corrected at a maximum rate of 8mmol/L in 24 hrs.

Case Description: A 37 year old man with a history of alcohol abuse was sent in to the hospital by police after a car accident for jaundice. He endorsed two weeks of worsening jaundice and right upper quadrant (RUQ) pain. Admission vital signs were stable. Physical exam revealed marked jaundice, abdominal distention and RUQ pain. Work up revealed severe alcoholic hepatitis with cirrhosis and metabolic derangements including a Na of 105 mmol/L, chloride of 69 mmol/L, urea nitrogen of 45 mg/dL, creatinine of 2.13 mg/dL with unknown baseline. 5% saline with ddA VP was initiated for caution correction of severe chronic hyponatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na+) < 120 mmol/L, alcoholism, malnutrition and liver transplant. Current recommendations advise raising serum sodium by less than 9 mmol/L in 24 hours. We present a case of ODS in a patient presenting with severe hypotremena corrected at a maximum rate of 8mmol/L in 24 hrs.

Discussion: A 43 year-old woman with alcoholism was admitted with rhabdomyolysis and alcohol induced acute pancreatitis. On initial examination she was in moderate distress with altered mental status and diffuse abdominal pain. Her blood pressure was 102/67 mmHg, heart rate 136/min and temperature 38.3°C. Her lab data revealed WBC 54.71 x 10^9/L, Hb 16.9 g/dL, PLTs 186 x 10^9/L, serum Na 129 mEq/L, K 3 mEq/L, bicarbonate 19 mEq/L. BUN 32 mg/dL and creatinine 1.3 mg/dL. A Case of Axenfield-Rieger Syndrome Presenting with Elevated Serum Bicarbonate

**Rudrick V. Ledesma, Maureen E. Brogan, Venkata Buddharaju, Rahul N. Pawar, Rajat Lamba. Westchester Medical Center, NY.**

**Introduction:** Elevated serum bicarbonate can be often misdiagnosed as metabolic alkalosis leading to improper management. Chronic respiratory acidosis caused by central hypventilation can lead to elevated bicarbonate secondary to renal compensation. We present a case of central hypventilation caused by cerebello-ponsine lesion in a patient with Axenfield-Rieger syndrome (ARS).

**Case Description:** A 25 yo man with PMH of glaucoma, developmental delay, schizoaffective disorder sent to the ED for respiratory failure. He was seen earlier in renal clinic for observation of elevated serum bicarbonate. He was complaining of fatigue and insomnia. Arterial blood gas was done and showed a pH of 7.30, pCO2 of 79, P02 of 63 and HCO3 of 38.9. He was eventually admitted for further management. While in the hospital, he continuously needed bilevel positive airway pressure. Chest ultrasound showed little to no movement of his diaphragm. EMG was negative. PFT was suboptimal as he wasn’t able to follow the instructions. MRI brain showed a mass on his right cerebello-ponsine angle. He was also diagnosed with ARS during his hospital stay. The mass was resected and progressive improvement was observed in his respiratory status. He was eventually weaned off bilevel positive airway pressure and was discharged home without any need for respiratory support.

**Discussion:** Elevated serum bicarbonate can often pose a diagnostic challenge. Evaluation should start with an ABG which would differentiate a primary metabolic alkalosis from a renal compensation of respiratory acidosis. Differential diagnoses for respiratory acidosis include central hypventilation, primary lung pathology, neuromuscular disease and airway pathology. Central hypventilation could be secondary to lesions in the respiratory center. ARS presents as a spectrum of developmental disorders resulting from abnormal migration and differentiation of neural crest cells with both occular and systemic manifestations. The region in the brain that are most affected are forebrain and pituitary gland. Our case is interesting as he had ARS with epidermoid cyst which we believe has led to central hypventilation and elevated bicarbonate as compensatory mechanism.

---

**FR-PO037**

Signet-Ring Cell Carcinoma Presenting as Frequency of Urination

**Haya Waseem Siddqui, Daniel E. Carl, Todd W. Gehr. Nephrology, Virginia Commonwealth Univ, Richmond, VA.**

**Introduction:** Urinary tract obstruction may occur at any site in the urinary tract and is important to recognize early since it is readily reversible if quickly corrected.

**Case Description:** 45 year old male with obesity, history of gastric bypass surgery, hypertension and obstructive sleep apnea who presented to our institution for evaluation of frequency of urination. He developed progressively worsening frequency of urination, occurring every hour during the day and night for 3 months prior to presentation. During this time, his serum creatinine was 1.6 mg/dL. He had been seen multiple times by an Urologist and Primary Care Providers outside our institution, and was diagnosed with prostatitis despite negative urine cultures and no pyuria. During the work up, an outpatient CT scan revealed mild bilateral hydrourereter and mild left hydronephrosis. Furthermore, an office cystoscopy revealed diffuse inflammatory cystitis of the bladder and no definitive bladder lesion. Over the ensuing 3-4 weeks, he developed acute kidney injury with a serum Cr that peaked at 6mg/dL. This prompted an admission to an outside facility. He was again found to have mild bilateral hydrourereter, however, ureteral stents were attempted, but unsuccessful. A repeat cystoscopy revealed severely inflamed bladder tissue with no visualized bladder biopsy. The patient was transferred to VCU for placement of percutaneous bilateral nephrostomy tubes by interventional. He had successful stent placement by IR followed by post obstructive diuresis treated with intravenous fluid hydration in the form of saline. His AKI improved as he continued his progression of subsequent imaging. His serum Cr improved to 1.3 mg/dL and repeat CT scan with intravenous contrast was obtained for staging which showed circumferential bladder wall thickening with asymmetric soft tissue prominence along the right anterior dome most consistent with bladder neoplasm. Outside pathology report was consistent with signet cell carcinoma of bladder.

**Discussion:** Signet-ring cell carcinoma a rare bladder tumor can result in acute kidney injury secondary to bilateral ureteral obstruction.

---

**FR-PO038**

A Case of Tenofivir-Induced Nephrotoxicity

**Introduction:** Tenofivir (TFV) is a nucleotide reverse-transcriptase inhibitor used for treatment of HIV and hepatitis B. Most studies suggest TFV has only a modest effect on estimated glomerular filtration and severe nephrotoxicity is uncommon. We describe a case of severe renal failure and mitochondrial tubulopathy related to TFV.

**Case Description:** A 55 year old woman with HIV on TFV for several years, presented with vomiting and abdominal pain for 4 days. Physical exam was unremarkable. Laboratory data showed BUN 65 mg/dL, creatinine 9.07 mg/dL (baseline: normal), bicarbonate 12 mmol/L, glucose 137 mg/dL, HIV RNA: 21 copies/mL and CD4: 292 cells/µL, glycosuria and proteinuria (1575/24 hours). Serologic tests for autoimmune diseases were negative. Kidney biopsy showed proximal tubule (PT) injury and eosinophytic oval cytoplasmic inclusions on trichrome stain (fig. a) with no definite glomerular or mesangial abnormalities. Electron microscopy (EM) showed PT cells with cytoplasmic swelling, loss of membrane integrity, accumulation of enlarged dysmorphic mitochondria with intra-crystalline matrix approach to the loss of cristae (fig. b) consistent with mitochondrial injury (MI) seen in TFV nephrotoxicity. Despite discontinuing TFV, she remained dialysis dependent.

**FR-PO039**

A Case of Severe Hypomagnesaemia in a Patient Treated with Trastuzumab

**Saifullah Kazi, Ghulam Akbar, Paul Robbins. Nephrology, Lankenau Medical Center, Wynnewood, PA.**

**Introduction:** A case of invasive ductal carcinoma that was treated with chemotherapy including Trastuzumab found to have severe hypomagnesaemia requiring very aggressive repletion strategies.

**Case Description:** A 36 y/o non-alcoholic female with past medical history of hypertension well controlled on diet therapy, was diagnosed with invasive ductal carcinoma of the breast requiring initiation of chemotherapy with docetaxel and carboplatin with Trastuzumab. She received a total of 6 cycles of chemotherapy every three weeks and Trastuzumab 2gm weekly infusion after completion of chemotherapy, the dose of Trastuzumab was increased to 6gm per infusion every three weeks. Her serum magnesium level which was 2.1mg/dl in the beginning of chemotherapy was noted to be low at 0.5mg/dl when she presented with generalized weakness to the hospital six months into the treatment. At this time, she had completed her chemotherapy 2 months ago and now on Trastuzumab only. She was on lasix and proton pump inhibitors at that time, both of which were stopped immediately. However her serum magnesium remained low between 0.6-1.0 mg/dl persistently for next few months requiring intravenous infusions every week. On repeated testing, fractional excretion of magnesium remained high indicating renal wasting. Although patient was hypokalemic initially, it corrected immediately after stopping loop diuretics and remained normal ruling against tubulopathies such as Gitelman or Bartter syndrome. She remained hypomagnesemic despite completing one year course with Trastuzumab. She is receiving once a week intravenous infusions of magnesium sulphate and oral supplements three times a day and serum magnesium remains at 0.4-1.0 mg/dl persistently for next few months requiring intravenous infusions every week. As the patient had metabolic alkalosis it was unlikely that the patient had other EGFR inhibitor with Cetuximab used in colon cancer and Erlotinib used in lung cancer, but not reported in patients taking Trastuzumab, especially after escalating to higher doses.

**Discussion:** Trastuzumab is a human epidermal growth factor (HER-2) inhibitor which belongs to the family of epidermal growth factor receptor (EGFR). EGFR is involved in increasing the magnesium absorption in the distal nephron by increasing the transcription of the genes regulating TRPM6 channels. Hypomagnesaemia has been well reported in other EGFR inhibitor with Cetuximab used in colon cancer and Erlotinib used in lung cancer, but not reported in patients taking Trastuzumab, especially after escalating to higher doses.

---

**FR-PO040**

Capecitabine Induced Acquired Barter’s-Like Syndrome

**Eric A. Kirk, Jennifer Thompson, Juan Carlos Q. Velez, Nithin Karakala. Nephrology, MUSC, Charleston, SC.**

**Introduction:** Many forms of chemotherapy carry a risk of electrolyte abnormalities. Capecitabine is an antimetabolite of the fluoropyrimidine carbamate class of chemotherapeutic agents. Phase I and II trials have reported hypomagnesaemia, hypocalcemia with capecitabine and temozolomide developed back spasms and was found to have severe hypokalemia (2.4mmol/L), hypomagnesemia (0.7mg/dL), hypocalcemia (6.4mg/dL) and metabolic alkalosis (bicarbonate 30mmol/L) in the absence of vomiting or diarrhea 5 weeks after starting a 2 week course of capecitabine (1400mg/m² divided twice daily). She had evidence of renal salt wasting with sodium 256.5mEq, potassium 51.8 mEq and calcium 50mg/m in a 24 hour urine collection. No evidence of hypoparathyroidism, with intact PTH 67.3pg/mL, 1,25 hydroxy vitamin D was 33pg/mL. Further capecitabine therapy was withheld. 24 hr urine collection was completed 1 week later with decreased renal loss of sodium, potassium and calcium and normalization of electrolytes.

**Case Description:** We present a case of life threatening hypokalemia caused secondary to capecitabine. As the patient had metabolic alkalosis it was unlikely that the patient had Fanconi as described in some cases reports. Our case is unique as this patient developed a combination of hypokalemia, hypocalcemia, hypomagnesaemia and metabolic alkalosis.
caused by capcitabine. The patient exhibited Barter’s like physiology with increased renal loss of calcium, magnesium, and sodium and evidence of metabolic alkalosis. Unlike the proximal tubulopathy associated with capcitabine, the pathophysiology of acquired Barter’s with is unknown but could be caused by direct inhibition of apical NaKCC or ROMK, or activation of the calcium sensing receptor on the basolateral surface in the thick ascending loop of Henle.

FR-PO401
Uncommon Case of Severe Hypercalcemia After Renal Transplantation 

Rapeepat Lekkham, Gitana Bradauskaite. Nephrology, Einstein Medical Center, Philadelphia, PA.

Introduction: Following renal transplantation, hypercalcemia is frequently caused by persistent hyperparathyroidism, but other causes should be kept in mind. We report a case of hypercalcemia after renal transplant from unregulated extrarenal 1,25-dihydroxyvitamin D synthesis from disseminated tuberculosis and cryptococcosis.

Case Description: The patient was a 59-year-old male with unknown etiology of ESRD who received a living unrelated kidney transplant. He was stable on low dose immunosuppressive agents for history of BK virus infection. At 10 months post-transplant, the patient diagnosed with disseminated cryptococcosis with granulomatous mesenteric mass and positive cryptococcal antigen. High dose oral fluconazole was started. 10 days later, he readmitted with severe hyponatremia, severe hypercalcemia (corrected serum Ca peak at 14.72 mg/dL) and acute renal failure (serum Cr peak at 5.8 mg/dL from baseline 1.6 mg/dL). The iPTH level was suppressed to 2.8 pg/mL. The serum 1,25(OH)D level was elevated and levels of 25(OH)D fell. Serum phosphate rose and ALP levels were elevated. PTH-related peptide was negative. Serum immunoreactive phosphatidylinositol binding protein 3 was elevated. He also had a positive acid-fast bacillus (AFB) sputum. CT head revealed a well-defined 1.4 cm skull base lesion with calcified granuloma at lung base. Culture from lung biopsy showed strongly positive for Mycobacterium Tuberculosis. Anti-tuberculosis drugs were started and mycophenolate mofetil was held. Elevated calcium levels were unresponsive to calcitonin, fluoride, nor did it diuretic. After his sputum AFB became negative, the oral prednisone was increased to 60mg/day. Hypercalcemia and hyperphosphatemia normalized upon one month follow up and remained stable until finished 6 months course of anti-tuberculosis drugs and the creatinine returned to baseline.

Discussion: Unlike persistent hyperparathyroidism, underlying diseases of PTH independent hypercalcemia after renal transplantation like a granulomatous disease can lead to significant morbidity and mortality. Early recognition and prompt treatment is necessary.

FR-PO402
Treatment of Malignancy-Associated Hypercalcemia with Low Calcium

Hemodialysis Yields Significant Benefits for Cancer Patient 

Rozina B. Ali, Akshitha Rao, Suzanne Boyle, Jesse M. Goldman. Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA.

Introduction: Hypercalcemia of malignancy can be fatal. In literature, primary hyperparathyroidism is rarely described in the setting of malignancy. We describe a case of malignancy-related severe hypercalcemia that was refractory to standard therapy with low Ca HD.

Case Description: A 56 year-old male presented with 3 weeks of weakness and confusion. CT head revealed a 1.4 cm skull base lesion. Urine microscopy revealed pigmented granular casts. He was placed on an oral prednisone at 60mg/day. His serum Ca peaked at 14.7 mg/dL. Despite calcium-sparing diuretics, the patient developed refractory hypercalcemia. He was started on low Ca HD. Thereafter, his Ca and PTH levels were successfully managed with low Ca HD. Calcium levels were maintained between 7 and 10 mg/dL with low Ca HD. He tolerated the dialysis without adverse events. His mental status improved.

Discussion: Underline represents presenting author.

Viral Inclusions Excluding BK: Case Report of JC Virus Renal Allograft Nephropathy

Deanne Leonard,1 Cherisse M. Cortese,1 Xochiquetzal J. Geiger,1 Lynn D. Cornell,2 Jane Hata,1 Mary B. Prendergast.1 1Mayo Clinic, Jacksonville, FL; 2Mayo Clinic, Rochester, MN.

Introduction: JC virus, a DNA polyomavirus, infects 70-80% of asymptomatic adults with clinical significance in immunocompromised hosts; known for causing progressive multifocal leukoencephalopathy, a fatal disease resulting in demyelination from infected oligodendrocytes. The paucity of data on JC virus nephropathy makes it essential to report this case.

Case Description: 76 year old male with diabetes mellitus and end stage renal disease underwent a deceased donor kidney transplant with basiliximab induction and a standard steroid taper. He experienced self-limited diarrhea with negative work up. Maintenance immunosuppression included mycophenolate mofetil, prednisone and tacrolimus, with levels 4.5-8.2. Serum CMV PCR was negative. Year 1, serum creatinine: 1.4 mg/dL, urine protein to creatinine ratio 0.05 gm, negative urinary analysis. Allograft biopsy: normal glomeruli, 5% tubular atrophy, mild tubulitis not meeting criteria for rejection and several large medullary viral inclusions but minimal plasma cells, 4D negative.

Discussion: We report a unique case of JC viral inclusions that was treated successfully with renin-angiotensin system inhibition and renal allograft preservation.

Successful Treatment of Anti-Angiotensin II Type 1 Receptor Antibodies Associated with Refractory Antibody-Mediated Rejection and Acute Cellular Rejection in Kidney Transplantation: A Case Report

Punlun Wirawatthanum, Atiporn Insagath. Nephrology Unit, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Angiotensin II type 1 receptor (AT1R) antibody has been proved that it can be detrimental to kidney allograft. Similar to HLA-antibody, patients who have AT1R antibody are at risk for rejection and poor allograft outcome. There is no standard treatment in this situation but the aim is to remove pathologic antibodies and suppress antibodies production. Outcomes after treatment are unsatisfactory and not well established. Herein we present a successful treatment kidney transplant patient who experienced AT1R antibody associated rejection.

Case Description: A 50-year-old male with hypertension and ESRD underwent a disease donor kidney transplantation using a graft from acute kidney injury donor with peak serum creatinine of 1.24 mg/dl. No intraoperative complication occurred, urine flow rate of 300 ml/hr was observed immediate postoperative but abruptly decreased to 20 ml/hr at 8 hours posttransplantation. Acute rejection was suspected, thus allograft biopsy was done. The histopathological findings were compatible with acute cellular rejection combined with antibody-mediated rejection (ABMR). AT1-R antibody was detected at level of 15.0 µ/ml. Anti-rejection therapies were offered with steroid, IVIG, plasmapheresis, anti-thymocyte globulin and rituximab. At 8 weeks posttransplantation, rejection was well controlled with stable serum creatinine of 1.5 mg/dl.

Discussion: Although AT1R antibody associated rejection has rarely been reported, the outcomes after rejection are unsatisfactory. Early detecting rejection and rapid antibody removal seem to be the most effective treatment that prolong allograft function in present time. There are limited and controversial data about long term graft survival by treating patient with angiotensin receptor blocker.

FR-PO046
Hemodiafiltration for Hepatic Encephalopathy Induced by Budd-Chiari Syndrome in a Patient with End-Stage Kidney Disease

Takuya Wakamatsu, Suguru Yamamoto, Takeshi Nakatsue, Junichiro J. Kazama, Ichiei Narita. Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.

Introduction: Budd-Chiari Syndrome (BCS) is defined as portal hypertension caused by obstruction of the inferior vena cava at the liver. Severe BCS induces hepatic encephalopathy and has known to be exacerbated during hemodialysis (HD) treatment. Hemodiafiltration (HDF) has been proposed be effective for some dialysis-related complications due to better removal of middle sized uremic toxins and preservation of plasma osmolality, compared with HD. Here, we present a patient with BCS who developed hepatic encephalopathy after progression of BCS, which was ameliorated by HDF.

Case Description: The patient was a 36-year-old woman complaining of a consciousness disorder. She was diagnosed with BCS as a consequence of antiphospholipid antibody associated complications due to better removal of medium sized uremic toxins and preservation of plasma osmolality, compared with HD. Here, we present a patient with BCS who developed hepatic encephalopathy after progression of BCS, which was ameliorated by HDF.

Case Description: The patient was a 36-year-old woman complaining of a consciousness disorder. She was diagnosed with BCS as a consequence of antiphospholipid antibody associated complications due to better removal of medium sized uremic toxins and preservation of plasma osmolality, compared with HD. Here, we present a patient with BCS who developed hepatic encephalopathy after progression of BCS, which was ameliorated by HDF.

Discussion: Although AT1R antibody associated rejection has rarely been reported, the outcomes after rejection are unsatisfactory. Early detecting rejection and rapid antibody removal seem to be the most effective treatment that prolong allograft function in present time. There are limited and controversial data about long term graft survival by treating patient with angiotensin receptor blocker.

De Novo Lupus Nephritis in a Stable Kidney Transplant Recipient

Laura Panarey, Karthik M. Ranganaga, Aliden Michael Doyle. Div of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.

Introduction: De Novo Lupus Nephritis (LN) is an exceedingly rare complication in kidney transplant recipients. We present a case of histoplasmosis induced clinical manifestations of SLE. The scarcity of autoimmune disease in this population is not fully understood, but has been attributed to the maintenance immunosuppression used to prevent allorejection and rejection.

Case Description: Herein we present a 55-year-old woman with post streptococcos glomerulonephritis and HTN; 28 years status-post living-related kidney transplant. The patient had no personal or family history of autoimmune disease at time of transplant. Three years ago, she began complaining of episodic carpo-pedal spasm and scleritis; laboratory abnormalities included mildly low albumin and stable IgA proteinuria. Medications were stable and no potentially provocative antigens, vaccines or transfusions, were given during this period. Immunosuppression included cyclosporine and low dose prednisone. Seven months ago, the patient developed malar rash and hemo-proteinuria prompting immunological studies and kidney allograft biopsy. Anti-nuclear, double stranded DNA, Smith and histone antibodies were all strongly positive with low serum complement levels. Serum creatinine increased by 0.5 mg/dl; from baseline; urine protein to creatinine ratio revealed nephrotic range proteinuria peaking at 9.6 grams. Immunofluorescence revealed granular “full house” pattern, C4d negative; Electron microscopy revealed intramembranous deposits. The patient was treated with high dose prednisone, continued cyclosporine and addition of mycophenolate mofetil.

Discussion: Although rare, de novo auto-immune disease should be considered for transplant patients despite maintenance immunosuppression.

FR-PO048
Atypical Hemolytic Uremic Syndrome Allograft Outcome in the Post Eculizumab Era

Laura Panarey, Karthik M. Ranganaga, Aliden Michael Doyle. Division of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is an exceedingly rare etiology of renal failure; forms of HUS are often linked to underlying viral illness or particular classes of immunosuppression in transplant recipients. Exceedingly rare are genetic etiologies of aHUS for which transplantation is undesirable due to very high recurrence rates of disease.

Case Description: Herein we describe a case of misdiagnosis; 78 year old man initially diagnosed with rapidly progressive glomerulonephritis (RPGN) by kidney biopsy developed anuria necessitating hemodialysis. The patient had no family history of kidney disease. Immunological work-up negative for Anti-nuclear or cytoplasmic antibodies; complement remained within normal limits. Patient received a living-unrelated kidney transplant from a 40 year old healthy donor. Standard induction soludemol and thymoglobin. Initiation of maintenance calcineurin inhibitor (CNI), steroid, antithymabote. Favorable outcomes were observed, creatinine 1.77 mg/dl and urine output upon discharge. One week post transplant, patient was observed to have increased creatinine, peak 4mg/dl, not amenable to discontinuation of CNI or typical offending agents; prompting renal biopsy. Histologically Thrombotic Microangiopathy (TMA), C4d - observed and deemed comparable to native biopsy slides. Laboratory studies confirmed aHUS: (-) ADAMST13; low lactate dehydrogenase, elevated haptoglobin; peripheral smear hithocytes. Negative viral studies including Shiga toxin. Pt was treated with high dose soludemol, plasma exchange and eculizumab; resolution of kidney function, creatinine 1.88 mg/dL, month after discharge. One month later, the patient developed anuria necessitating hemodialysis. The patient had no family history of kidney disease; 28 years status-post living-related kidney transplant. The patient had no personal or family history of autoimmune disease at time of transplant. Three years ago, she began complaining of episodic carpo-pedal spasm and scleritis; laboratory abnormalities included mildly low albumin and stable IgA proteinuria. Medications were stable and no potentially provocative antigens, vaccines or transfusions, were given during this period. Immunosuppression included cyclosporine and low dose prednisone. Seven months ago, the patient developed malar rash and hemo-proteinuria prompting immunological studies and kidney allograft biopsy. Anti-nuclear, double stranded DNA, Smith and histone antibodies were all strongly positive with low serum complement levels. Serum creatinine increased by 0.5 mg/dl; from baseline; urine protein to creatinine ratio revealed nephrotic range proteinuria peaking at 9.6 grams. Immunofluorescence revealed granular “full house” pattern, C4d negative; Electron microscopy revealed intramembranous deposits. The patient was treated with high dose prednisone, continued cyclosporine and addition of mycophenolate mofetil.

Discussion: Although rare, de novo auto-immune disease should be considered for transplant patients despite maintenance immunosuppression.

FR-PO049
An Unusual Manifestation of Disseminated Histoplasmosis in a Renal Transplant Patient

Kana N. Miyata, Lilly M. Barbba. Nephrology, Harbor-UCLA Medical Center, Torrance, CA.

Introduction: Disseminated histoplasmosis is rare but can develop in immunocompromised patients. High recurrence rates of disease.

Case Description: The patient is a 42-year-old man with ESRD secondary to unclear etiology, who had a living related renal transplant from his cousin 4 years ago in Mexico. He was born in El Salvador, moved to California at age 7, and had traveled to Mexico and Cuba (last travel 1 year ago). His post-transplant course was complicated by antibody mediated rejection and borderline acute cell mediated rejection 2 years ago, for which he was successfully treated with IVIG, plasma exchange, and rituximab. His medication included tacrolimus, MMF, and prednisone. He presented with 2-3 weeks of fever and mild abdominal pain after unsuccessful treatment with ciprofloxacin. He had fever of 38.7
Case Description: A 46-year-old white male with previous renal stones and recurrent urinary infections underwent a right nephrectomy and subsequent renal transplantation due to failure of the remaining kidney. Five years post-transplant, an abdominal ultrasound scan was performed due to recurrent urinary infections and ongoing pyuria. This was reported as normal, but he later developed a discharging sinus in his left flank. A CT scan revealed a left solitary pulmonary mass, which was diagnosed as Mycobacterium avium complex (already dropped), but antibiotics did not relieve symptoms. In addition, he exhibited a left solitary pulmonary mass, which was diagnosed as Mycobacterium avium complex (MAC) infection by lung needle biopsy. Cystoscopy and retrograde pyelography revealed hemorrhagic cystitis and right ureteral stenosis, where a catheter was placed. Viral PCR test was performed for differentiating hemorrhagic cystitis, and adenovirus was detected both in urine and in blood. Symptoms and abnormal findings on CT were improved by the placement of a catheter and the decrease of tacrolimus dosage.

Discussion: Diuretic challenge may be useful to differentiate hydropnephrosis from obstructive nephropathy. The presence of vesicoureteral reflux and the absence of obstruction are associated with an increased risk of recurrent pyelonephritis.

FR-PO053

A Case of Hydronephrosis due to Adenovirus Hemorrhagic Cystitis following Peripheral Blood Stem Cell Transplantation for Malignant Lymphoma

INTRODUCTION: Hemorrhagic cystitis is a rare complication of hematopoietic stem cell transplantation (HSCT) and is associated with mortality [1]. Adenovirus is a well-known etiologic agent of hemorrhagic cystitis. We report a rare case of adenovirus hemorrhagic cystitis in a patient following HSCT.

CASE DESCRIPTION: A 50-year-old male, who had undergone SCT 4 months ago for the treatment of nasal-type extranodal NK/T cell lymphoma and received tacrolimus as prophylaxis for graft-versus-host disease, developed fever, right back pain and dysuria. Computed tomography (CT) showed perirenal and periureteral fat heterogeneity and dilation of the right ureter. He was diagnosed as pyelonephritis caused by ureteral stones (already dropped), but antibiotics did not relieve symptoms. In addition, he exhibited a left solitary pulmonary mass, which was diagnosed as Mycobacterium avium complex (MAC) infection by lung needle biopsy. Cystoscopy and retrograde pyelography revealed hemorrhagic cystitis and right ureteral stenosis, where a catheter was placed. Viral PCR test was performed for differentiating hemorrhagic cystitis, and adenovirus was detected both in urine and in blood. Symptoms and abnormal findings on CT were improved by the placement of a catheter and the decrease of tacrolimus dosage.

Discussion: Differential diagnoses were urothelial carcinoma, recurrence of malignant lymphoma, retroperitoneal fibrosis and disseminated MAC disease. Urine cytology result was negative for malignancy. Gallium scintigraphy excluded recurrence of malignant lymphoma. Fat heterogeneity disappeared after catheter placement, suggesting that malignant lymphoma and retroperitoneal fibrosis were unlikely. MAC was not detected from blood and urine cultures. Clinical course and laboratory data indicated that inflammation of adenoviral hemorrhagic cystitis spread to the right ureter, leading to ureteral stenosis and hydronephrosis in an immunocompromised patient after SCT.

FR-PO054

Unusual Case of Thrombocytopenia in a Dialysis Patient

INTRODUCTION: Thrombocytopenia is a frequent complication in patients on dialysis. It can be due to various causes such as infection, drugs, and autoimmune disorders. Here we report an unusual case of thrombocytopenia in a dialysis patient due to heparin induced thrombocytopenia (HIT).

CASE DESCRIPTION: An 81-year-old female started on HD 2 months prior for progressive CKD was sent to the ED for excessive bleeding around the tunneled catheter site and a platelet (PLT) count of 27 K/uL. When she was first started on inpatient HD, she was found to be thrombocytopenic and heparin autoantibodies were weakly positive so she was started on argatroban. At the 1st outpatient HD unit, her PLT count increased to 200 K/uL. After transferring to a 2nd outpatient HD center, her PLT count, once again, dropped to 27 K/uL, along with recurrent bleeding at the catheter site. This prompted investigation of heparin exposure as a cause, but it was revealed that the patient never received heparin during any of her treatments. Despite being restarted on argatroban, her PLT count remained in the 20 K/uL range. The trombonin release assay was negative. It was noted that the hospital and the 2nd outpatient unit both used a F160NR dialyzer, different from the dialyzer used in the first outpatient unit. With the suspicion of a possible dialyzer reaction, the membrane was switched from F160NR to Gambro Revaclear. Her PLTs increased to 125 K/uL in 4 days. Discharge medications indicated that the patient must use a Revaclear dialyzer. A week later, repeat PLT count was noted to be 200 K/uL.

Discussion: This case demonstrates a rare dialyzer reaction, in which a specific dialyzer membrane leads to severe thrombocytopenia and bleeding. It has been postulated that complement activation might have a role, but this patient had normal complement levels.
FR-PO054
Calcium Free Dialysis for Hypercalcemic Crisis
Nephrology, Mt Sinai- St Luke’ s Hospital, New York, NY.

Introduction: Hypercalcemic crisis, a potentially life-threatening condition, has been defined as a calcium of 14 mg/dL or more with evidence of multi-organ dysfunction including cardiovascular, renal or CNS involvement. We describe a case of hypercalcemic crisis due to primary hyperparathyroidism treated with low calcium/calcium free dialysis.

Case Description: A 62 year old healthy man was brought by his wife to the ED for lethargy, worsening confusion over 3 days, weight loss and constipation. On exam, he was hemodynamically stable, had flat jugular veins and dry mucous membranes. His corrected calcium was 23.58 mg/dL with a creatinine of 3.60 mg/dL. He was aggressively hydrated with normal saline and received a total of 2 doses of Calciumtrin 240 IU IM with no improvement in his mental status or in his calcium levels. He was then given Denosumab 60 mg SQ and underwent a 3 hour session of low calcium dialysis (Ca bath 1.0 mEq/L). During the treatment, he was given NS boluses in addition to his maintenance NS 250 cc/hr to avoid hypotension. He subsequently underwent 3 additional treatments (Treatments 2 and 4- using calcium free dialyse and Treatment 3- using Ca 1.0 mEq/L) that were well tolerated. Following his 2nd treatment, his mental status improved significantly. After his 4th treatment, his calcium was 12.26 mg/dL. His intact PTH level was 1324 pg/mL. A Sestamibi thyroid scan showed a large left parathyroid mass. The patient underwent surgical resection of a 13 cm parathyroid adenoma after which his calcium normalized to 9.8 mg/dL. His clinical course and a blood pressure trend during hemodialysis is reported below.

Discussion: Calcium free dialysis and the use of low calcium dialysate was tolerated with no hemodynamic instability. Aggressive hydration is important to maintain tolerability. It can be safely used as a bridge to definitive surgical treatment in the setting of primary hyperparathyroidism.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

proliferative was held. His exam was unremarkable except for an exophytic gingival lesion on his right mandible. His function was at baseline. Imaging revealed increased lung and liver nodularities with bulky lymphadenopathy. An axillary lymph node biopsy was performed and was consistent with Kaposi sarcoma (HHV8+). Tacrolimus was stopped and the patient was transitioned to the mTOR inhibitor: sirolimus. He was initiated on liposomal doxorubicin for extrarenal, cutaneous metastatic disease after four cycles. His renal function remained stable on sirolimus and prednisone.

Discussion: Post-transplant malignancies are common and constitute a major burden. Adjustment of immunosuppression is the mainstay of therapy in these cases. It is standard of care to switch from calcineurin inhibitors to sirolimus upon the diagnosis of Kaposi sarcoma. However, there’s no literature regarding chemotherapy in transplant-associated Kaposi sarcoma. Most of the available data is from the AIDS population that we extrapolated to our patient. His bulky disease triggered us to explore aggressive therapy. Combination chemotherapy and sirolimus seem to be a good therapeutic strategy that should be considered in cases of disseminated post-transplant Kaposi sarcoma.

FR-PO058

Warfarin-Related Nephropathy in a Kidney Transplant Patient Nadeen J. Khoury,1 Gilbert W. Moeckel,2 Mark A. Perazella. 1Nephrology, Yale Univ, New Haven, CT; 2Dept of Pathology, Yale Univ, New Haven, CT.

Introduction: Anticoagulant-related nephropathy is a new entity manifesting as AKI as the setting of excessive anticoagulation. Initial cases were related to warfarin use; however, more recently AKI is reported with direct thrombin inhibitors. We present biopsy-proven warfarin-related nephropathy (WRN) in a transplant patient on anticoagulation for atrial fibrillation with INR<2.

Case Description: A 69 y old man with hypertension, atrial fibrillation (on warfarin), T2DM and ESRD s/p living unrelated kidney transplant with baseline sCr 2.0 mg/dl (on cyclosporine, mycophenolate and prednisone) presented with nausea, vomiting and abdominal pain. Acute cholecystitis was diagnosed and percutaneous cholecystostomy drainage performed. Initial labs revealed leukocytosis and AKI on CKD with sCr 2.7 mg/dl. INR was 1.8. Urinalysis revealed 3+blood, 2+ protein with 179 RBCs/HFPE, urine sediment 1-2 RBC casts/LPEF. Transplant kidney ultrasound was unremarkable. Complements were normal. Urine microscopy demonstrated persistent RBC casts and kidney biopsy was performed. Acute tubular injury with numerous occlusive RBC casts suggestive of WRN was observed. Kidney function slowly improved but sCr remained above baseline upon discharge. Warfarin was resumed due to high stroke risk.

Discussion: Our patient’s presentation with AKI in the setting of acute cholecystitis raised the possibility of sepsis-induced AKI. However, the presence of microscopic hematuria and numerous RBC casts suggested a glomerular process. Biopsy suggested WRN developing in the setting of CKD and anticoagulation. Our case is somewhat unusual given the INR<2. Most cases of WRN have an INR>3. However, the patient had risk factors that have been linked to WRN including CKD, diabetes mellitus and hypertension. Interestingly, INR levels several months prior were all consistently below 2 yet the patient had 2 bleeding episodes requiring hospitalizations (GI bleed and thigh hematoma) suggesting an underlying bleeding predisposition. It is reasonable to consider WRN in cases of unexplained AKI with RBC casts in a patient with INR<3 in the presence of other risk factors and bleeding tendency.

FR-PO059

Successful Preemptive Kidney Transplantation Using Rituximab Induction in a Young Patient with Focal Segmental Glomerulosclerosis and Overt Nephrotic Syndrome – Case Report Aurelius Kolonko, Grzegorz Piecha, Andrzej Wieczek. Dept of Nephrology, Transplantation and Internal Diseases, Medical Univ of Silesia, Katowice, Poland.

Introduction: Focal segmental glomerulosclerosis (FSGS) recurs in 30% of patients receiving their first kidney transplant and often leads to graft loss. In the past, patients with FSGS and overt nephrotic syndrome were rarely transplanted, mostly due to the worries about its relapse. Rituximab (RTX), an anti-CD20-specific monoclonal antibody, was previously reported to be a valuable option in resistant nephrotic syndrome and in relapsing FSGS after second kidney transplantation. Hereby, we present a successful first kidney transplantation of a young patient with FSGS and full-blown nephrotic syndrome, treated with RTX induction.

Case Description: The patient is a 24-year-old woman, who developed nephrotic syndrome at the age of 4. FSGS was confirmed early by renal biopsy. However, the presence of microscopic hematuria and numerous RBC casts suggested a glomerular process. Renal function was at baseline. Imaging revealed increased lung and liver nodularities with bulky lymphadenopathy. An axillary lymph node biopsy was performed and was consistent with Kaposi sarcoma (HHV8+). Tacrolimus was stopped and the patient was transitioned to the mTOR inhibitor: sirolimus. He was initiated on liposomal doxorubicin for extrarenal, cutaneous metastatic disease after four cycles. His renal function remained stable on sirolimus and prednisone.

Discussion: Post-transplant malignancies are common and constitute a major burden. Adjustment of immunosuppression is the mainstay of therapy in these cases. It is standard of care to switch from calcineurin inhibitors to sirolimus upon the diagnosis of Kaposi sarcoma. However, there’s no literature regarding chemotherapy in transplant-associated Kaposi sarcoma. Most of the available data is from the AIDS population that we extrapolated to our patient. His bulky disease triggered us to explore aggressive therapy. Combination chemotherapy and sirolimus seem to be a good therapeutic strategy that should be considered in cases of disseminated post-transplant Kaposi sarcoma.

FR-PO060

Black Appearing Peritoneal Effluent Manjumitha Ramachia, Carol Motes Headley, Geeta G. Gyanamlani, Adnan Naseer, Barry M. Wall. Nephrology, Veterans Affairs Medical Center, Memphis, TN.

Introduction: Endoscopic tattooing with India ink is a useful and safe tool for localizing small colorectal lesions. Case Description: 60 year old man with End Stage Renal Disease due to Lupus Nephritis with continued Ambulatory Peritoneal Dialysis (CAPD), developed black effluent from the peritoneal dialysis drain bag following screening colonoscopy. Findings included an ulcerated tumor occupying 25% to 49% of the colon circumference. There was no evidence of bleeding and multiple forceps biopsies were taken. The tumor area was marked with tattoos using 3 injections (5 ml each) of India ink. He resumed CAPD and noticed his dialysate effluent was “black”. He presented to the ER with nausea, vomiting and black colored peritoneal fluid. Examination revealed a mildly tender abdomen without rebound or guarding. Vitals were stable and he was afebrile. CT scan of abdomen revealed subcutaneous free intraperitoneal fluid. His peritoneal dialysis. Peritoneal effluent cell count was elevated at 0.619 K/ul and WBC count of 5.5 K/ul. Her presentation was consistent with peritonitis (cloudy dark gray/black peritoneal effluent and elevated cell count). empiric antibiotics were initiated with vancomycin, cefepime and metronidazole. Within 48 hours the peritoneal effluent was clear (cell count down to 0.105 K/ul). The effluent culture grew Escherichia coli and Providencia Staurtii. Dialysate remained normal. At the time of partial colectomy performed one month later, dark dye was still visible on mesenteric transverse colon, but no abscesses was identified.

Discussion: Complications associated with India ink tattooing include abscesses, inflammatory pseudotumor, focal peritonitis and peritoneal staining, most of which have been attributed to inadequate dilution or sterilization of the India ink. Dye spillage into the peritoneal cavity has been reported to occur at a rate between 2.4% and 13%. This occurrence has been attributed to injection technique (deep), and the possibility of transmural penetration of the dye. In our patient, the coagulation use, Angiolydiasis and malignancies. Also medications like Sodium-polystyrene-sulfonate can cause direct mucosa damage. We report a case of GIB in Hemodialysis-patient attributed to Sevelamer-induced colonic-ulceration.

Case Description: 56Y/O ESRD-Hemodialysis patient with multiple comorbidities including hypertension, systolic cardiac dysfunction, Atrial fibrillation, H/o Breast Cancer s/p mastectomy/chemo(05),presented to the hospital with passage of bright red blood per rectum,accompanied with syncope and shortness of breath. Her medications included Amiodarone, Aromasin, baby-Aspirin, Carvedilol, Diltiazem, Pantoprozole, Sevelamer, Vincalecite. Her clinical examination was unremarkable(including neurologic exam)except for palp. Orthostatic vital signs not checked due to dizziness, Significant labs findings were:hemoglobin-5.7/mg/dl, Serum Potassium-5.5mg/L,BUN and Serum-Creatinine-40mg/dl respectively and INR-1.1. CT head- no acute abnormalities, Mesenteric angiom-no source identified, Endoscopic-Gastro-duodenoscopy- normal, colonoscopy- no active bleeder, multiple diverticulosis1. Bleeding scan showed activity near the hepatic flexure. She underwent emergent right-hemicolecetomy for the continued bleeding. Pathology report showed metastatic Carcinoma involving proximal Colon. Colon-Mucosa inflamed and ulcerated,cluster of organophilic Fish scale like crystals suggestive of Sevelamer crystals were noted in colonic mucosa. Patient improved post surgery.

Discussion: There is only handful of literature on the Sevelamer colonic toxicity. This case highlight the fact that with widespread use of sevelamer in dialysis patient, physicians should be aware of this entity. Our understanding of Sevelamer-associated mucosal injury is limited and there are no known prevention strategies available.

FR-PO062

Successful Eculizumab Therapy in De Novo Atypical Hemolytic Uremic Syndrome in a Renal Transplant Recipient Adil Mohammad Nazarak, Matthew Edey, Martin Chanayireh, Sunil Bhandari. 1Internal Medicine/ Nephrology, Wayne State Univ, Detroit, MI; 2Internal Medicine/ Nephrology, Indiana Univ Ball Memorial Hospital, IN.

Introduction: End stage kidney disease patients experience significant morbidity and mortality. One common complication in this population is Gastro-intestinal bleeding(GIB). Potential causes of GIB in terrace in transplant recipients include anticoagulation use, Angiolydiasis and malignancies. Also medications like Sodium-polystyrene-sulfonate can cause direct mucosa damage. We report a case of GIB in Hemodialysis-patient attributed to Sevelamer-induced colonic-ulceration.

Case Description: 370A

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author. 370A
required multiple blood transfusions. Her trough tacrolimus level was raised at 22 ng/l. Stool microscopy and culture was negative for shiga-toxin producing bacteria. Blood film showed red cell fragments; serum lactate dehydrogenase was raised at 752 u/L. ADAMTS-13 activity was normal. Renal biopsy was consistent with thrombotic microangiopathy. Complement genetic analyses (factors H, I, B and MCP tested) did not reveal any pathogenic mutations. Anti-factor H antibody was negative. She was treated, first with four cycles of plasma exchange and then commenced on ecuclizumab at 900mg infusion weekly for first four doses and then 1200mg fortnightly. Her renal and anemia parameters rapidly normalised.

Discussion: Eculizumab has been used successfully in treatment of aHUS in our patient who had developed this condition de novo. Uncertainties still remain regarding the duration of treatment and long-term efficacy.

FR-PO065

BK Nephropathy in Allogeneic Stem Cell Transplant Recipient without Thrombotic Microangiopathy and Graft-Versus-Host Disease: A Unique Observation

Rima N. Paj,1 Maria del Pilar Fernandez,2 Jai Prakash Babu Thippaiah Jagedonahalli,2 William F. Glass,2 Sairah Ahmed,2 Ala Abudayeh2

1Section of Nephrology, UT MD Anderson Cancer Center; 2Nephrology and Hypertension, UT-Houston Medical School; 3Pathology, UT-Houston Medical School; 4Dept of Stem Cell Transplantation, UT MD Anderson Cancer Center.

Introduction: BK virus is emerging as an important pathogen in allogeneic stem cell transplant (SCT) recipients and more prevalent in patients of Graft versus Host Disease (GVHD) and Thrombotic microangiopathy (TMA). Due to immunosuppression, different drugs and/or drug combinations have been associated with BK nephropathy such as tacrolimus. BK virus causes chronic kidney disease, ureteral stenosis and hemorrhagic cystitis in stem cell transplant patients leading to increase mortality and long hospital stay. We present a unique case of BK nephropathy that has occurred in patient who was asymptomatic and without any co-infections, TMA, or GVHD. The patient was tapered off tacrolimus which showed improvement in the BK viral urine and serum load.

Case Description: A 31-year-old female with history of Acute Myeloid Leukemia (AML) underwent an allogeneic stem cell transplant a year ago. Patient was treated with 4 cycles of Fludarabine, IDArubicin, CYTarabin (FIA) and sorafenib regimen. Post-transplant course was complicated by GVHD of gastrointestinal tract and skin (Grade I) Patient was maintained on tacrolimus and later tapered off. She remained asymptomatic; however, kidney function worsened with elevated creatinine at 1.8. BK Serum viral Load of 10,800 was seen. Therefore, renal biopsy was done which was consistent with BK nephritis. With limited effective therapeutic options, immunosuppression by tacrolimus was tapered off and Leflunomide was started showing a decrease in viral load and creatinine stabilizing to 1.37.

Discussion: A definitive diagnosis of BK nephritis is confirmed with a kidney biopsy. BK nephropathy is an important and often overlooked cause of chronic kidney disease in allogeneic stem cell transplant patients. This case report helps to recognize the much needed development of guidelines in detection and treatment of BKV for early intervention.

FR-PO066

Pharmacokinetics and Total Removal of Fosfomycin in a Patient with Chronic Kidney Failure Undergoing Haemodialysis

Julius Schmidt, Jan T. Kielstein. Nephrology, Medical School Hannover, Hannover, Germany.

Introduction: Fosfomycin shows bactericidal activity against various gram-positive, gram-negative and anaerobic pathogens, including antibiotic resistant S. aureus. However, dosing of fosfomycin in critically ill patients undergoing renal replacement is based on scarce data.

Case Description: A female chronic dialysis patient (76 years, BMI 20) was admitted to our hospital due to distinct drowsiness. Computed tomography of the lumbar spine unveiled spondyloïdosis of the thoracic vertebrae T11/12. A punch biopsy of the affected bone region showed focal osteomyelitis. As the patient was allergic to penicillin, antibiotic therapy with cimidamycin and fosfomycin sodium (8 g per day, 3 g before, 5 g after IHD session) was initiated. Maximum plasma concentration after the 3 g infusion was 496 mg/L. IHD led to a distinct reduction of fosfomycin plasma levels of 61%, with a dialyzer clearance of 75 ml/min. The total amount of fosfomycin in the total collected dialysate was 2430 mg. Cmax after the additional administration of 5 g of fosfomycin after IHD treatment was 467 mg/L.
Tumoral Calcinosis – A Rarely Seen Complication in Dialysis Patients

**Case Description:**
Case: 50-year-old female with end-stage renal disease secondary to hypertension presented for evaluation of painful left shoulder mass. She has been on dialysis for 12 years. She has multiple painful swellings on her hands, elbow, and feet. Stated that her shoulder mass appeared 2 years ago and has progressively increased in size. Also complained of excruciating pain causing trouble carrying out her daily activities. Her surgical history significant for a right neck dissection for a neck mass, parathyroidectomy and a thyroid lobectomy.

**Introduction:**
Tumoral calcinosis is characterized by solitary or multiple painless, periarticular soft-tissue calcium deposits. Tumoral calcinosis was first described by Giard and Duret in 1898 and 1899. There are two categories, a familial variant also called Teutschlaender disease and secondary tumoral calcinosis also called Uremic tumoral calcinosis.

**Case Description:**
Secondary tumoral calcinosis is associated with high serum Ca X P in dialysis patients, secondary or tertiary hyperparathyroidism, aluminium intoxication and vitamin D overload. These lesions are painless but massive swellings can cause mechanical limitation, pain and neurovascular symptoms due to compression of adjacent structures. Management includes dietary phosphate restriction, noncalcemic phosphate binders, intense dialysis with a low-calcium dialysate and calcimimetics. Surgical excision is indicated in symptomatic lesions. Parathyroidectomy recommended in patients with persistently elevated PTH levels. Tumoral calcinosis resolves after successful renal transplantation.

**Discussion:**
Fosfomycin dosing guidelines in dialysis patients are based on publications from the 1970s and 1980s. These publications indicate a high elimination of fosfomycin during hemodialysis with a dialyzer clearance of 60 ml/min. Modern dialysis even exceeds these clearance rates, as seen in this case report (75 ml/min). The large amount of fosfomycin in the total spent dialysate indicates the need for an additional dose after dialysis therapy. About 97% of the administered dose of fosfomycin was found in the dialysate. This suggests that intermittent hemodialysis can decrease fosfomycin serum levels beyond ranges, where minimal inhibitory concentrations in bone spicula can be achieved. Therefore, fosfomycin dosage after hemodialysis seems crucial to provide sufficient drug concentrations.

**Palate Nodule in a Hemodialysis Patient: A Long and Winding Road Until Diagnosis**
Precil Diego Miranda de Menezes Neves,1 Ramaiane Aparecida Bridi,2 Rosilene M. Elias,1 Fabio Luiz de Menezes Montenegro,1 Rosa M.A. Moyes,1,3 *Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil; ‘Univ Nove de Julho-UNINOVE, Sao Paulo, Brazil.

**Introduction:**
Secondary hyperparathyroidism (SHPT) is a common condition in end-stage renal disease patients. We highlighted a complication that usually affects long bones, a brown tumor (BT). We report a case of a patient with SHPT, with a palate nodule, which diagnosis investigation led to a BT of maxilla.

**Case Description:**
A 25-years-old female, previously hypertensive, who returned to hemodialysis after her kidney transplant failure. She was referred to our CKD-MBD service with a 3-month history of a progressively enlarging submucosal nodule with hard consistency on her posterior left palate. The mass was painful since the beginning, and presented progressive growth. She had no fever, neither consumptive symptoms nor palpable lymph nodes. Before coming to our service, she was referred to a maxillofacial surgery service, where a computed tomography (CT) and a biopsy were requested, as no initial suspected diagnosis was done. CT disclosed a lytic bone lesion located in alveolar process of maxilla, measuring 3.0 X 2.5cm, and damaging the superior molar roots, producing a bulging in the left maxillary sinus, nasal cavity and palate. Microscopy view evidenced the presence of multinucleated giant cells among ovoid and fusiform mesenchymal cells, large amount of hemorrhage and trabecular of lamellar bone tissue, being compatible with Brown Tumor. On review of her case, she confirmed that Sevelamer 1.6g thrice a day, but the administration of Vitamin D analogs was not possible due to hyperphosphatemia. Her serum intact Parathormone levels were 1,500pg/ml, Vitamin D 36ng/ml, ionized calcium: 4.8mg/dl, phosphorus: 6.1mg/dl. Technetium sestamibi parathyroid scan revealed hyperperactive glands at both superior thyroid lobes and at the low cervical region. The patient was submitted to total parathyrectomy, and the lesion is progressively decreasing despite of other modalities of treatment.

**Discussion:**
Brown Tumors must be kept in mind as a differential diagnosis in patients with SHPT even when these lesions are located in unusual sites such as the maxilla.

FR-PO069

**A Case of Levofloxacin Toxicity Treated with Continuous Venous-Venous Hemofiltration**
Karl Berthold Pembaur, Jennifer Thompson, Nithin Karakala.

**Nephrology, MUSC, Charleston, SC.**

**Introduction:**
Levofloxacin is a commonly prescribed antibiotic. Multiple adverse events such as central nervous system and cardiovascular toxicity have been described. Cardiovascular toxicity, namely QT prolongation when present can be particularly dangerous and requires urgent management. Aside from stopping the drug there is paucity of data regarding other urgent treatment modalities such as CRRT when potential toxicity is suspected.

**Case Description:**
A 53-year-old African American female with a history of ESRD on peritoneal dialysis (PD) for 2 years was admitted for concern of levofloxacin toxicity. She had been admitted to an outside hospital and discharged approximately 1 week prior to presentation with a levofloxacin prescription for presumed bronchitis. During initial evaluation, she admitted to taking levofloxacin 500 mg every 8H for the preceding 5 days. She admitted she had been performing PD every other day as she was concerned she was volume depleted. After 3 days she developed nausea, vomiting, left heel pain, left hand tremor, and palpitations. She had not performed peritoneal dialysis since the onset of her symptoms. Her initial physical exam was consistent for left hand tremor and Achilles tendon tenderness. Her QTc upon initial evaluation was 534. Serum levofloxacin level was ordered and a decision was made to start continuous venous-venous hemofiltration (CVVH) to increase clearance of levofloxacin. CVVH was stopped after clinical recovery of her symptoms and normalization of QTc. Her initial levofloxacin level was 36.65 mcg/ml (normal therapeutic range 4-12 mcg/ml) and sevoflurane were followed for the duration of treatment every 12 hours. Below is a graphical trend of her levofloxacin levels.

**Discussion:**
Levofloxacin toxicity represents a unique and dangerous clinical challenge. This case report shows successful and effective treatment of critical toxicity with the use of CVVH.

FR-PO070

**Utility of Cystatin C in the Setting of Urinoma**
Lilian Saro-Nune1,4, Amrei Auferheide,2 Alan Perlman,1,2 *Nephrology, Weill Cornell Medical College, NY, NY; ‘Rogosin Inst, NY, NY; ‘Technical Univ, Munich, Germany.

**Introduction:**
Urinomas (i.e. presence of urine outside of the urinary tract) are common in the setting of urologic/pelvic surgery. Due to the resorption of extravasated urinary constituents such as urea nitrogen and creatinine, determination of renal function is typically confusing and often leads to the false impression of acute renal failure, a situation referred to as pseudo-renal failure. We describe the superior precision of cystatin C (CysC) vs serum creatinine (Scr) in estimating renal failure in a patient with urinoma.

**Case Description:**
79 yo M with a history of urinary retention requiring a chronic indwelling Foley catheter presented with catheter obstruction leading to bladder rupture and apparent acute renal failure. Presenting Scr was 5.8mg/dl (baseline 1.5mg/dl). A cystogram was consistent with urinoma. Treatment of the bladder leak consisted of urinary catheter replacement and he maintained urine output of > 2L/24H for several days. Scr decreased to 2.9mg/dl. A second episode of catheter obstruction subsequently occurring resulted in a significant increase of the extraperitoneal bladder leak and acute rise of creatinine to 4.6mg/dl. After placement of a larger catheter, his Scr decreased to 1.7mg/dl. During the second episode of urine leakage, simultaneous CysC levels were obtained. In contrast to
the marked variation of SCr during the onset and resolution of the urinoma, CySc levels demonstrated declining moderating from 3 mg/dL to 2.0 mg/dL during onset, followed by return to near baseline level of 1.7 mg/dL upon catheter replacement. CySc based eGFR values using CKD-EPI demonstrated similar relative stability, decreasing from 39 to 29 mL/min during the recurrent bladder rupture, followed by an increase to 36 mL/min after Intervention. In contrast, the eGFR decline based upon SCr-based CKD-EPI equation was notably labile declining from 20 to 11 mL/min during episode then increased to 38 mL/min with treatment.

Discussion: These findings imply superiority of CySC over SCr in estimating renal function in patients with urinoma and pseudo-renal failure. Discordant estimates of eGFR between CySC and SCr may be indicative of urinoma.

FR-PO071
Two Cases of Nonocclusive Mesenteric Ischemia Triggered by Intradialytic Hypotension
Siwadon Pitukweerakul, Praveen Ratanasrimetha, Soo Ryeong Ryoo, Kyung Soo Kim.

Introduction: Among dialysis patients, non-occlusive mesenteric ischemia (NOMI), defined as diffuse intestinal ischemia without any organic blood vessels occlusion, is rare (10%-15% of all patients) but has a very high mortality (50%-90%). The factors associated with mortality from this disease include age, diabetes, hypertension, intradialytic hypotension, atherosclerosis, medications, etc. Early diagnosis and treatment are important for improving survival in patients with this disease.

Case Description: We here report two cases of NOMI, who were triggered by hypotension during hemodialysis.

Case 1: A 52-year-old woman who had a low left ventricular ejection fraction after myocardial infarction showed intradialytic prolonged hypotension. On physical examination, he was hypotensive with diffuse abrupt abdominal tenderness. The laboratory investigation showed a high white blood cell count of 20,000. Case 2: A 88-year-old woman on maintenance hemodialysis for 5 years had hemorrhagic shock. On examination, she was also hypotensive with mild abdominal tenderness. The laboratory investigation showed a high white blood cell count of 16,000. We performed multiple detector computed tomography (MDCT) and found patent mesenteric vessels in both cases. Subsequent surgical procedure revealed the necrosis of terminal ileum in case 1 and autopsy revealed necrosis of cecum in Case 2. Finally, we diagnosed them as having NOMI. The former underwent surgical procedure and was discharged alive from the hospital but the latter was dead.

Discussion: Considering the fact that NOMI is very high mortality disease, early diagnosis must be important. However, a diagnosis of this disease is very difficult because clinical manifestations are nonspecific. We speculated that the profile of hemodialysis is very similar to that of risk factors, therefore, we should evaluate patients who showed intradialytic hypotension with abdominal pain using multiple detector computed tomography.

FR-PO072
Aggressive Renal Cell Carcinoma in a Renal Allograft
Hafiz Ali Sroya, Antonia Harford. Nephrology, UNM, Albuquerque, NM.

Introduction: Kidney cancers arising in renal allografts are very rare and most publications focus on cancers in native kidneys of transplant recipients. We are reporting a case of a renal cell carcinoma (RCC) arising 14 years post-transplant.

Case Description: A 46-years old man with a history of ESRD due to diabetic nephropathy underwent hemodialysis for one year prior to receiving a Living Un-Related Renal Transplant from his brother –in-law, a 36 yo healthy male in 2001. The patient had immediate graft function post-transplant and was maintained on MMF, Cyclosporine and Prednisone. He underwent renal allograft biopsy in 2004 for a gradual decline in renal allograft function; this biopsy showed chronic transplant glomerulopathy. The patient had very gradual decline in renal allograft (CKD G3B1) until Jan 2015, when he developed mild lower abdominal pain over several weeks. Imaging including abdominal US and CT revealed a 14 X 12 X 12 cm mass arising from the transplant kidney with extensive regional adenopathy involving the right common iliac vein and IVC with evidence of lung metastasis. Biopsy showed RCC, clear cell type with extensive necrosis. The venous involvement precluded surgical excision. The patient was treated with sunbimib. Several weeks later, he developed extensive bilateral pulmonary embolism treated with heparin infusion. IVC filter was placed at this time, with initiation of low dose warfarin. He demonstrated increasing modestly from a very gradual decline during period then increased to 38 mL/min with treatment.

Discussion: Considering the fact that NOMI is very high mortality disease, early diagnosis must be important. However, a diagnosis of this disease is very difficult because clinical manifestations are nonspecific. We speculated that the profile of hemodialysis is very similar to that of risk factors, therefore, we should evaluate patients who showed intradialytic hypotension with abdominal pain using multiple detector computed tomography.

FR-PO073
A Case of Acute Allograft Rejection Combined with BK Virus-Associated Nephropathy
Bernice Kim, Soo Ryeong Ryoo, Kyung Soo Kim. Div of Nephrology, Dept of Internal Medicine, Dongguk Univ Ilsan Hospital, Goyang, Republic of Korea.

Introduction: Rejection and BK virus-associated nephropathy (BKVAN) are major causes of renal allograft dysfunction. Treatment can be difficult when both conditions coexist, because potent immunosuppression is required in acute rejection and reduction of immunosuppressive agents is essential in BKVAN. We present a case of acute allograft rejection combined with BKVAN.

Case Description: A 41-year-old man with end stage renal disease because of hypertensive nephrosclerosis received a deceased donor renal transplantation. Immunosuppressive therapy was started with mycophenolate mofetil, tacrolimus, antibody-mediated rejection was diagnosed. Plasmapheresis was initiated and intravenous immunoglobulin (IVIG) and rituximab were administered. After 10 days of treatment, sCr was decreased to 1.5 mg/dL. Additional episodes of sCr elevation occurred and more sessions of plasmapheresis and IVIG administration were done, but sCr was elevated to 2.48 mg/dL on POD 67. Decay cells were detected on urine cytology and high levels of vituria and viremia were found on polymerase chain reaction for BK virus DNA. On second kidney biopsy, findings of acute cellular rejection were noted and viral inclusion bodies in tubular epithelium were seen, suggestive of BKVAN. For treatment of BKVAN, reduction of immunosuppressive agents was initiated in addition to the treatment of acute rejection. Steroid pulse therapy was done in regard of acute cellular rejection. Despite therapy, his renal function did not recover completely and sCr was elevated to 3.2mg/dL on POD 138.

Discussion: It is difficult to treat when BKVAN and acute rejection coexist. In our patient, IVIG and leflunomide was administered and immunosuppression was reduced for BKVAN while steroid pulse therapy was performed for acute rejection, but his allograft function deteriorated. Studies are required to optimize the management of these difficult cases.

FR-PO074
Decreased Ultrafiltration in an End-Stage Renal Disease Patient with Sickle Cell Anemia: A Potential Strategy to Facilitate Kidney Transplantation
Ekamol Tantisattamo, Siwadon Pitukweerakul, Praveen Ratnasirimetha, Nephrology, Northwestern Univ; 1Presence St. Francis Hospital, Evanston; 2Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Sickle cell crisis (SC) leads to mortality and morbidity in sickle cell anemia (SCA) patients. V olume depletion is a common precipitating cause. Volume overload may require increasing ultrafiltration(UF). We report a case of SCA woman with acute kidney injury (AKI) who suffered from recurrent episodes of SC and acute hemolytic anemia requiring blood transfusions after hemodialysis(HD) was initiated. She became more sensitized from blood transfusions. Decreased UF reduced episodes of SC and blood transfusions.

Case Description: A 39-year-old African American woman with a longstanding history of SCA presented with a severe episode of SC complicated by AKI requiring chronic HD 5 years ago. Since starting HD, she had more episodes of SC from once a year up to every other month and required more blood transfusions. She presented for a pre-kidney transplant evaluation. Her panel reactive antibody(PRA) increased from 28 and 0 to 44 and 10, for class I and II, respectively. Upon interview, she has HD 3 times/week. Her estimated dry weight was 62 kg and intradialytic weight gain was 2-2.3 kg. She sometimes had dialytic hypotension with BP of 90s/50s. As concern for over UF being a potential cause of volume depletion and subsequently precipitating SC, the UF was decreased. She had fewer episodes of SC and blood transfusions. She remained on the kidney transplant waiting list with this HD prescription and stable hemoglobin.

Discussion: Our patient presented with more frequent episodes of SC after HD initiation. Intradialytic hypotension indicates intravascular volume depletion which subsequently precipitating SC and hemolytic anemia. Volume management in SCA patients with ESRD is challenging and critical to avoid intravascular volume depletion. SC and acute hemolytic anemia may be surrogate markers of over UF. Avoiding over fluid removal can prevent SC, acute hemolytic, and blood transfusion which potentially increases immunological barrier for kidney transplantation from sensitization.

FR-PO075
Recurrent Catastrophic Antiphospholipid Syndrome Treated with Eculizumab in a Peritoneal Dialysis Patient
Karl W. Schoenholzer, 1 Murianna De Francesco, 1 Giulia Bedino, 1 Josua Van den Berg, 1 Silvio Pianca. 1Nephrology and Dialysis Div, Ospedale Regionale di Lugano, Lugano, Switzerland; 2Interventional Radiology Div, Ospedale Regionale di Lugano, Lugano, Switzerland.

Introduction: Catastrophic Antiphospholipid Syndrome (CAPS) is a severe variant of Antiphospholipid Syndrome (APS), a systemic autoimmune disease characterized by recurrent thrombosis and/or venous thromboses in presence of elevated titers of antiphospholipid antibodies (aPL). These autoantibodies, promote thrombosis by activating endothelial cells and platelets. We describe a case of a clinical remission in recurrent CAPS via inhibition of terminal complement with Eculizumab in a Peritoneal Dialysis (PD) patient.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Case Description: A 48-year-old man has shown recurrent CAPS characterized by diffuse rash, fever, heart, kidneys, liver and lung involvement confirmed by positivity of aPL. Angiography revealed a bilateral subclavian arterial thrombosis, a right iliac arterial stenosis that was treated with a stent and a left renal arterial occlusion. The patient’s renal function was decreased until End Stage Renal Disease, secondary to chronic thrombotic microangiopathy, and PD therapy was started. During 16 months, our patient presented 8 recurrent episodes of disease with pulmonary involvement characterized by multiple alveolar hemorrhages in concomitance with liver necrosis (biopsy proven) and myocardial ischemia. The patient was treated with high-dose pulse corticosteroids (methylprednisolone 500 mg intravenous (IV) every 6 h for 3 days followed by prednisone (1 mg/kg/day), plasma exchange (5 series with a total of 74 sessions), IV immunoglobulin (400 mg/kg/day for 5 days), IV Rituximab (initial therapy and maintenance after 6 months), clopidogrel, aspirin and anticoagulation. Despite this standard therapy, we did not observe a sustained remission. As no improvement of the literature, we propose to administer Eculizumab, a monoclonal antibody against complement C5, that blocks and prevents the generation of the proinflammatory and proinflammatory molecules C5a and membrane attack complex C5b-9. The patient has been in remission with long-term Eculizumab treatment and anticoagulation therapy, without further thrombotic events during 1 year of follow-up. Funding: Private Foundation Support.

FR-PO076

A Case Report of Post-Transplant Lymphoproliferative Disorder in Kidney Allograft
Dina Abdelwahab, Nadeen J. Khoury, William S. Asch. Div of Nephrology, Yale Univ, New Haven, CT.

Introduction: Renal tumors are rare in transplanted kidneys. Nephrectomy is the traditional approach for renal masses. We are reporting a renal mass that was found to be a post-transplant lymphoproliferative disorder in the renal allograft which we chose to biopsy instead of using traditional surgical resection.

Case Description: A 63 year old female with past medical history of renal cell carcinoma diagnosed as a small mass by right nephrectomy, ESRD secondary to MPGN status post living donor kidney transplant presented with abdominal pain, fever and diarrhea. Ultrasound of renal allograft showed a solid mass measuring 4.8x5.6x4.3 cm in the upper pole of the transplanted kidney which was predominantly homogenous with internal vascularity. MRI revealed a 6.2 x 4.9 x 6.5 cm mass with solid enhancing and non-enhancing components within the transplanted kidney concerning for renal cell carcinoma. Given her previous history of RCC there was an increased concern for recurrence. Nephrectomy would have been the traditional approach but that would have meant sacrificing her allograft and initiating hemodialysis. The mass was biopsied and pathology revealed post-transplant lymphoproliferative disorder. Microscopic description showed a small kidney portion with tubules and glomeruli overrun by a dense lymphoid infiltrate. Immunohistochemical stains revealed that the large atypical cells were positive for CD20, CD21, MUM-1 and CD30 but negative for CD3, CD43 and CD138. C-myc stained approximately 10-20% of cells and Ki-67 30-40%. In situ hybridization for Epstein Barr virus encoded RNA (EBER) was positive. Patient received 6 cycles of R-CHOP, follow-up MRI showed decrease in mass size.

Discussion: The biopsy of renal tumors for the diagnosis of small masses has not been widely adopted despite recent safety reports with advanced techniques and physician’s expertise. It has been shown to be safe and reliable and should be considered in all patients with small masses especially in transplanted kidneys to decrease the risk of unnecessary surgical intervention.

FR-PO077

Renal Replacement Therapy for Severe Hyponatremia (PNA 99mEq/L), Using 5% Dextrose Solution Infusion Method
Masatada Hasegawa, Takuya Fujimaru, Yuki Heath, Fumika Taki, Miyuki Futatsuyama, Masahiko Nagahama, Yasuhito Komatsu. Nephrology, St. Luke’s International Hospital, Tokyo, Japan.

Introduction: Dialysis therapy for patients with severe hyponatremia poses risk of myocardial ischemia, dysrhythmia and cerebral edema. To prevent rapid correction, low sodium dialysate or filtration fluid can be used; however, dialysate sodium concentration needs to be changed frequently as patient’s serum sodium concentration rises. Instead of using low sodium dialysate, infusion of 5% dextrose solution during dialysis can be used to adjust the serum sodium concentration. We conducted a study to examine the safety and efficacy of CVVH using 5% dextrose solution infusion method.

Case Description: A 46-year-old woman presented to the emergency department with cardiogenic shock for AMI with rupture of the papillary muscle. Her medical history included hypertension and dyslipidemia in good pharmacological control. On 9th March TAH had been implanted in order to replace the lost heart function. From the day of admission to ICU, the patient developed oliguric AKI and CRRT was started. Subsequently, the patient was switched to four times a week haemodialysis. To maintain an appropriate circulating volume for the operation of cardiac device, atrial filling pressures were maintained between 5-5.5 mmHg and 6.0-6.5 mmHg in the right and left atrium respectively. At the same time it was decided to record the change of hematocrit which the patient was subjected during the dialysis sessions (via Blood Volume Monitor (BVM)) in order to identify the critical BVM value for the functioning of the cardiac device. In this way we were able to manage the patient’s dialysis sessions even once he was discharged from the hospital with the portable version of TAH.

Discussion: This patient received dialysis therapy four times a week in order to maintain a more constant and weight constant till March 2015, when he underwent to combined heart and kidney transplantation. To the best of our knowledge this is the longer case of continuous dialysis therapy in a patient with total artificial heart. Total Artificial Heart is currently not a valid therapeutic option for those patients waiting for heart transplantation even for long periods of time.

FR-PO079

Severe Varicella Zoster Virus Encephalitis and Retinal Necrosis in a Renal Allograft Recipient
Jean Luc Franck, Srijita Mukherjee, Tina Thomas, Sharon M. Graves. Nephrology, Emory Univ, Atlanta, GA.

Introduction: Varicella zoster virus infection (VZV) has devastating potential complications and should be considered more often for testing by clinicians. Our case reflects the need to maintain a higher degree of suspicion for VZV by clinicians treating the immunosuppressed population.

Case Description: A 31-year-old man underwent living related renal transplantation in 2008 for chronic glomerulosclerosis. The clinical course was uneventful until January 2015, when he was diagnosed with grade 1A rejection after admitting to four months of nonadherence to his prescribed immunosuppressant regimen, consisting of tacrolimus, mycophenolate mofetil, and prednisone. The rejection was addressed with pulse IV steroids and resumption of his oral immunosuppressant regimen. Over the next four months, the patient sought medical attention for worsening and persistent occipital headache. Lumbar puncture was performed and suggested a viral etiology.MRI imaging was performed and revealed a large cerebellar infarct and diffuse vasculitis. Upon transfer to our institution, the patient underwent emergent neuroradiologic evaluation for positive TAH and was found to have a large subdural hematoma with compressive mass effect. Polymerase chain reaction (PCR) testing in the cerebrospinal fluid was positive for VZV. The patient was started on acyclovir and steroids for treatment of VZV encephalitis and diffuse vasculitis. Ophthalmologic evaluation revealed retinal necrosis of the left eye, with PCR testing of the anterior chamber fluid also positive for VZV. After 4 weeks of acute care, the patient is currently in rehabilitation.

Discussion: Varicella Zoster Virus infection requires timely diagnosis and treatment for positive outcomes in the immunosuppressed patient. Clinical presentation can vary dramatically, from subtle rash to encephalitis. Therefore, clinicians caring for immunosuppressed patients should more routinely consider VZV as part of the differential diagnosis. Our case raises several questions including consideration for lengthening duration of VZV prophylaxis in allograft recipients and consideration for resuming VZV prophylaxis when resuming immunosuppression after extended periods of nonadherence.

FR-PO080

Hemodialysis Related Acute Thrombocytopenia During Pregnancy
Nikulkumar Chaudhari, Belinda Bun Jin, Anjali Acharya. Dept of Nephrology, Jacobi Medical Center, Bronx, NY.

Introduction: Thrombocytopenia is not uncommon during pregnancy. It could be multifactorial and range from a mild asymptomatic condition to severe thrombocytopenia with fetal effects.

Case Description: A 29 year old woman with hypertension, CKD-IV from primary FSGS, presented at 10th week of gestation. Intravenous heparinization had to be initiated at 20th gestation week. Thrombocytopenia developed as described in the table below.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Patient was not on antiplatelet agents and panel for HIT antibodies was negative. Patient remained asymptomatic throughout hospitalization. Hematological evaluation ruled out all routine causes of thrombocytopenia during pregnancy such as gestational thrombocytopenia, preeclampsia, HELLP, TTP/ITP and autoimmune causes. Given the chronological correlation of platelet decrease and hemodialysis it was concluded that thrombocytopenia was caused by the peritoneal dialysis. Patient was switched from a Fresenius dialyzer opting to Exeltra 210 high flux dialyzer.

Discussion: Complement activation, anti-coagulation use, exposure of blood to the roller pump, dialysis tubing, micro-bubbles, and use of cellulose membrane are potential causes of dialysis related thrombocytopenia. In addition, sterilization techniques have shown to have a differential impact. A major difference between the two dialyzers used was the technique of sterilization. Electron beam radiation used in the Fresenius dialyzer might affect membrane integrity or physical properties that could lead to platelet activation, aggregation, or adsorption causing thrombocytopenia, which is not seen with gamma sterilization. Thrombocytopenia is an important, if rare, complication of hemodialysis that should be considered in the differential diagnosis of thrombocytopenia in pregnancy. Dialysis associated thrombocytopenia may occur despite the use of biocompatible membranes.

FR-PO081
A Rare Case of Nephrocalcinosis Caused by Hereditary Renal Hypouricaemia

Three Months After Kidney Transplantation
Yo Komatsuzaki, Izumi Yamamoto, Yasuyuki Nakada, Yusuke Okabayashi, Takaumi Yamakawa, Akimitsu Kobayashi, Takahito Niikura, Yudo Tanno, Ichiro Okhid, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yokota, Department of Internal Medicine, Div of Nephrology and Hypertension, Ibaraki University School of Medicine, Tokyo, Japan; Dept of Internal Medicine, Div of Nephrology and Hypertension, Atsugi City Hospital, Kanagawa, Japan.

Introduction: Renal hypouricaemia (MIM: 220150) is a syndrome that involves a defect in urate transporter (URAT1) for urate reabsorption at the brush border of the proximal tubule. Nephrocalcinosis and exercise-induced acute renal failure are two major complications affecting renal function. A C889T mutation in SLC22A12 encoding URAT1 is the rare mutation in Japanese. Here we report a rare case of nephrocalcinosis caused by hereditary renal hypouricaemia three months after kidney transplantation.

Case Description: A 41-year-old man had undergone living-related kidney transplantation because of Henoch–Schönlein purpura nephritis. Three month protocol biopsy showed several localized nephrocalcinosis determined by either von kossa or de Galantha’s stain (staining for urate crystals). The evaluation for nephrocalcinosis showed hypouricaemia at 1.9 mg/dl with a high fractional excretion of uric acid at 26.8% (normal range, 6–10%). DNA direct sequencing followed by restriction fragment length polymorphism showed that both the recipient and donor were heterozygous for C889T.

Discussion: This case illustrates that severe allograft rejection, confirmed on histopathological and molecular level, can in rare cases present with pronounced lymphadenopathy.

FR-PO083
Prevnar 13 Associated Immune Thrombocytopenic Purpura in a Renal Transplant Recipient
Sagar Gupta, Daniel C. Brennan, Renal, WashU, St. Louis, MO.

Introduction: ACIP recommends all adults with immunocompromising conditions should receive PCV13 to prevent invasive disease caused by 13 serotypes of S.pneumoniae. We describe here a case of ITP associated with Prevnar13 administration in a renal allograft recipient, which is the first reported case of its kind.

Case Description: A 77 year old Caucasian male presented with chief complaint of increased bruising at insulin injection sites for one week. There was no history of fever, abdominal pain, diarrhea, bleeding episodes, neurological deficits, new medications or insect bites. He had ESRD secondary to hypertension and DM2. He received a living unrelated kidney allograft 22mo ago. He was on tacrolimus, MMF, prednisone, MMF later discontinued indefinitely due to BK viremia. Family history was non-contributory. Medications included allopurinol, ASA, statin, bacitracin, carvedilol, insulin glargine and aspart, prednisone and tacrolimus. He received Prevnar13 1 month ago. Exam showed normal vital signs and petechial rash in the areas of insulin injections. Lab testing resulted in Fb 11.7, WBC 7.7 (baseline) and platelet 3000 (baseline 140). BUN 31 and Cr 5.0 (baseline). PT/PTT, LDH and haptoglobin were normal. No schistocytes seen. Infectious workup was negative and ADAMTS-13 activity result at 102%. The isolated thrombocytopenia was diagnosed as ITP and was attributed to the Prevnar 13 vaccine. He was started on pulse methylprednisolone, IVIG. He received 6 units platelets with counts increasing to 94000, later discharged on a prednisone taper. Weekly blood counts showed improvement to his baseline of 140,000 in 3 weeks.

Discussion: PCV13 contains the S. pneumoniae serotypes’ capsular polysaccharide covalently linked to an immunogenic carrier protein resulting in a T cell–dependent antigen. This is a T helper-cell response. The pathogenesis of ITP involves antibody production driven by CD4-positive helper T cells reacting to platelet surface glycoproteins. Antibodies formed during viral or bacterial infections may also cross-react with normal platelet membrane proteins (a form of molecular mimicry). Isolated cases of ITP have been reported but are relatively rare. Our case is further unique to occur in a pt on immunosuppression with a calcineurin inhibitor and corticosteroids.

FR-PO084
Placement of a Tunneled Hemodialysis Catheter in the Superior Vena Cava for Multiple Central Venous Occlusions
Qinhua Yin, Tianlei Cui, Li Zhou, Ping Fu, Fang Liu. Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Introduction: A tunneled hemodialysis catheter is essential for dialysis access when the use of a functioning arteriovenous fistula is not possible. In extreme situations of multiple central venous occlusions, it remains a challenge to establish durable vascular access. Unconventional routes to the central veins are typically used. We successfully performed placement of a tunneled hemodialysis catheter in the superior vena cava (SVC) with fluoroscopic guidance in a hemodialysis patient with multiple central venous occlusions due to repeated catheterization. We report on a feasible option for hemodialysis patients with multiple central venous occlusions.

Case Description: A 49-year-old diabetic male who had been diagnosed with ERSD one year prior came to our medical center because of temporary catheter occlusion. CT venography revealed obstruction of the bilateral brachiocephalic, internal jugular and the common femoral veins, and central venography showed occlusion of the bilateral internal jugular and internal iliac veins. Guided by ultrasound, a percutaneous transhepatic route, as described by Duncan et al[9], was developed, which was applied to SVC venography and provided access for a 5F indwelling catheter, which was used to locate the distal end of
the SVC (Figure 2A). The puncture point of the skin was beneath and 0.5–1.0 cm outside of the sternum and head of the sternoclavicular joint and the direction of the subcutaneous tunnel was along the distal end of the SVC, which was marked by a 5F indwelling catheter. Under fluoroscopic guidance, a micro-21G needle (Cook) was used to puncture the stumps of occlusion of the SVC, with the needle in the needle tip in the right atrium (Figure 2D). CT showed that the needle did not enter the chest.

FR-P0085
Crystal Nephropathy in a Kidney Transplant Recipient due to Excessive Consumption of Oxalate Rich Diet and Vitamin C

Sudeer Mudugunti,1 Padmavathi Mali,2 Sandesh Parajuli,3 Maha A. Mohamed,4 1Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; 2Internal Medicine, Marshfield Clinic, Marshfield, WI.

Introduction: Acute kidney injury due to crystal nephropathy has been reported mainly in patients with gastrointestinal (GI) malabsorption or GI surgery. We present a rare case of crystal nephropathy in the kidney transplant recipient (KTR) without obvious GI risk factors.

Case Description: 68 year old obese female, who is living-unrelated KTR for five years, with a stable post-transplant course and a baseline serum creatinine (scr) of 1.1 mg/dl, presents to our hospital with tiredness and diarrhea for one week. She had extensive work up in the past for chronic diarrhea which is described as “soft stool”. 24 hour fecal fat, serum amylase and serum lipase were normal. Upon presentation, scr was 7.1 mg/dl which prompted us to perform an allograft kidney biopsy demonstrating multiple oxalate crystals deposited in the renal tubules. Reviewing her history further revealed that she was consuming 3 gm vitamin C (over the counter) daily for the last one month. Her preferred diet always consisted of oxalate rich foods (spinach). Renal functions improved in one month (scr 2mg/dl) with hydration, discontinuation of vitamin C, and changes in dietary habits. Urine studies obtained after one week of treatment showed normal urine calcium, low urine oxalate and citrate.

Discussion: Oxalate nephropathy can occur from hyperoxaluria due to ingestion of oxalate rich diet or substances which metabolize to oxalate like vitamin C or from enteric causes like malabsorption. In our patient, we ruled out enteric causes and determined oxalate nephropathy was secondary to ingestion of oxalate rich diet and excess vitamin C. Cレンノー functions improved with modification of diet, hydration and discontinuation of offending agents. Although vitamin C and high oxalate diet are rare causes of oxalate nephropathy in patients with normal renal function, it may cause significant nephropathies in KTR. KTR patients therefore, should follow low oxalate diet and avoid excessive vitamin C even with normal renal functions to avoid development of crystal nephropathy.

FR-P0086
The Conundrum of Dry Weight in a Pregnant Dialysis Patient

Introduction: The frequency of pregnancy in women of child bearing age who are on dialysis ranges from 0.3–1.5% per year. When a dialysis patient does become pregnant, nephrologists become extra vigilant to ensure a successful outcome for both mother and child. An important question that often arises is how to adjust a patient’s dry weight as pregnancy progresses.

Case Description: We present a case of a 23 year old pregnant dialysis patient who was admitted to the hospital with shortness of breath at 26 weeks gestation. She had a past medical history of a miscarriage, hypertension, and a failed deceased donor renal transplant. At her outpatient dialysis unit, she was being dialyzed 6 times per week. Her dry weight was increased by 1.5 kg during the first trimester and during the second trimester by 1 pound a week to account for normal pregnancy weight gain. On this admission, her weight was 113.5 kg and her estimated dry weight was 114 kg. Her vital signs on admission revealed that she was mildly hypertensive with a blood pressure of 150/94 and her oxygen saturation was 90% on room air. After other etiologies were excluded, it was determined that the patient’s hypertension and hypoxia were due to volume overload despite the patient being below her expected dry weight. A fluid monitor was placed on her and she was monitored for consecutive days with a net ultrafiltration of 7 liters. There were no signs of fluid distress during volume removal on the monitor. A uterine artery doppler was also performed and showed no signs of hypeperfusion to the fetus during dialysis. Subsequently, the patient’s shortness of breath and hypoxia resolved. Upon discharge, her new dry weight was 108 kg, which was 6 kg below her expected dry weight. The patient delivered a baby weighing 5.4 lbs at 37 weeks with Apgar scores of 8 and 9 at 1 and 5 minutes, respectively.

Discussion: In a pregnant dialysis patient, it is difficult to distinguish between normal pregnancy weight gain and extra fluid. A fetal monitor and uterine artery doppler during dialysis are useful tools that nephrologists can employ to titrate ultrafiltration goals. Better volume management in turn could avoid pre-term delivery.

FR-P0087
A Rare Cause of AKI in a Renal Transplant Recipient

Ronald Brian Vigo,1 Sandra Barrow,1 Lillian W. Gaber,2 Wadi N. Suk1, 1Nephrology, Houston Methodist Hospital, Houston, TX; 2Pathology, Houston Methodist Hospital, Houston, TX.

Case Description: We present a 66 year-old African American woman who underwent pre-emptive living related donor kidney transplant for ESRD secondary to DMII and hypertension. She had immediate graft function and was discharged on the fourth post-operative day with Na 136 mEq/L, K 3.5 mEq/L, Cl 102 mEq/L, creatinine 1.3mg/dl and urine pH 7.0. Baseline renal biopsy was normal. Her medications on discharge included Prograf, Cellexpect, Prednisone, Bactrim, Valcyte and sodium bicarbonate. She presented 10 days later with complaints of nausea, and vomiting as many as 10 times. Serum chemistries revealed the following: Na 136 mEq/L, K 5.0 mEq/L, Cl 95 mEq/L, and total CO2 20 mEq/L, consistent with a high-anion gap metabolic acidosis (AG 21). Serum creatinine was 1.3 mg/dl and urinalysis revealed a urine pH of 7.5, pyuria and bacteriuria. Urine culture grew E. Faecalis and renal transplant ultrasound was normal. She was started on IV antibiotics and IV fluids. On IV antibiotics and stay in the hospital, her chemistries revealed her anion gap metabolic acidosis had resolved, with total CO2 rising to 27 mEq/L. However, serum creatinine increased to 1.8 mg/dl, and continued to rise further despite treatment. A renal allograft biopsy was performed. Microscopic examination of the biopsy revealed widespread nephrocalcinosis with calcium-phosphate deposition. PTH at the time was 255 pg/mL, Ca 8.5 mg/dl, iPO4 4.1 mg/dl and fractional excretion (FE) of Ca 0.15%, FEiP29%, and urine anion gap was 29.

Discussion: We propose that our patient had developed post-transplant RVT, given the presence of the non-anion gap metabolic acidosis, low K, and urine pH of 7.0 in the immediate post-transplant period. Positive urine anion gap is suggestive of decreased ammonium excretion (although it should be confirmed with measurement of the urine osmolal gap and urinary P,CO2). The combination of high urine pH, as a consequence of bicarbonate administration and decreased bicarbonate reabsorption, in conjunction with hyperparathyroidism and consequent increase phosphate excretion, provided the perfect medium for calcium phosphate precipitation.

FR-P0088
A Rare Case of Rabbit Anti-Thymocyte Globulin Induced Disseminated Intravascular Coagulation

Vasanthi Balaraman,1,2 Anup Patel.1 1Dept of Renal Transplant, Saint Barnabas Medical Center, Livingston, NJ; 2Dept of Nephrology, Newark Beth Israel Medical Center, Newark, NJ.

Introduction: Rabbit anti-thymocyte globulin (RATG) is a purified polyclonal immunoglobulin used for induction therapy in renal transplantation. Adverse effects include cytokine release syndrome, leukopenia, thrombocytopenia and serum sickness. We report a rare case of renal transplant recipient who developed severe coagulopathy and post-operative bleeding in whom RATG was used for induction.

Case Description: A 61 year old female with end stage renal disease received a deceased donor renal transplant. RATG (2 mg/kg) was initiated intraoperatively. Over the ensuing 2 hours, the patient became hemodynamically unstable with excessive bloody output from the surgical site drain. Exploration of the renal transplant revealed diffuse oozing from surrounding tissues but no bleeding from the arterial or venous anastomosis. Labs revealed an elevated prothrombin time of 27.0 sec, thrombin time of 36.4 sec, INR of 0.5, platelet count greater than 575,000/ml, reduced fibrinogen level of 135 mg/dl and platelet count of 66000/cmm. The RATG infusion was stopped. Multiple units of packed red blood cells, platelets, fresh frozen plasma and cryoprecipitate were transfused. There was persistent bloody output. A reexploration revealed persistent diffuse oozing which required packing of the transplant bed. On postoperative day 4, the patient’s condition improved.

Discussion: We suspect Disseminated Intravascular Coagulation(DIC) may be secondary to RATG in our case. The donor biopsy showed no evidence of DIC. Other causes including calcineurin inhibitors, hyperreactive rejection and sepsis were ruled out. Only a few case reports of RATG induced coagulopathy exist in the literature. Weber el al reported 12 hematopoietic stem cell transplant patients having coagulopathy after using RATG therapy. These cases had elevated D-dimer, tissue factor, thrombin-antithrombin III complex, and thrombomodulin, but had no bleeding, thrombocytopenia or vaso-occlusive complications. We contemplate that DIC is a rare but potential life threatening complication of RATG induction and awareness of this potential complication is important.

FR-P0089
A Page Transplant Kidney

Supreet Sethi, Shalini Bumb, Scott Leonard Sanchez. Div of Nephrology, Dept of Internal Medicine, Duke Univ Health System, Durham, NC.

Introduction: Page kidney occurs by extrinsic compression of the renal parenchyma from a hernia or a mass, leading to activation of the renin-angiotensin-aldosterone system and resulting in systemic hypertension.

Case Description: A young-adult male, with ESRD of uncertain etiology underwent living related kidney transplantation 3-months prior to presentation. His post-transplant serum creatinine (Scr) stabilized at 1.3-1.5mg/dl. He was maintained on a drug immunosuppressive regimen including tacrolimus, prednisone and mycfortic. The patient presented to the hospital with pain over allograft site and low grade fever.He reported an altercation with a family member without clear direct trauma to his right lower quadrant graft. The patient was emergently brought to blunt trauma center. Initial lab workup revealed elevated white blood cells, with normal hemoglobin, platelets, electrolytes, bilirubin, liver function tests, creatinine and blood pressure. Hemoglobin was hypotensive with blood pressures in the 170-180/100-110 mm Hg range. Labs revealed a Scr of 4.1mg/dl, potassium of 5.7mmol/L, hemoglobin of 10.8g/dl from a baseline of 12g/
BLA Colored Dialysate: A Rare Complication of Peritoneal Dialysis due to Biliary Peritonitis

**Introduction:**
We report a rare complication of black colored dialysate in a patient with ESRD on peritoneal dialysis (PD) with acute cholecystitis.

**Case Description:**
A 73 year old man was undergoing peritoneal dialysis for ESRD secondary to obstructive uropathy. He presented with black discoloration of his PD effluent. The patient had a history of previous cholecystectomy due to extrahepatic bile duct rupture or due to gall bladder rupture in patients without ESRD. There are few reports of biliary peritonitis due to intrahepatic bile duct rupture secondary to obstructive uropathy. An acute fluid bilirubin level of >6 mg/dl with an ascitic fluid/serum bilirubin ratio of >1.0 has been shown to correlate with choleperitoneum. The black colored PD effluent in our patient represented a biliary leak likely from increased permeability of the gallbladder wall or microperforation in the setting of non-perforated cholecystitis or from an unidentified intrahepatic bile duct rupture. In conclusion black colored PD effluent should prompt investigation for gall bladder disease and/or pancreatitis. Peritoneal fluid and serum bilirubin levels and lipase levels can aid in making a diagnosis.

**Discussion:**
Dark colored dialysate has been reported in hemorrhagic and non-hemorrhagic pancreatitis. Acute bile leak or choleperitoneum is a recognized complication of cholecystectomy due to extrahepatic bile duct rupture or due to gall bladder rupture in patients without ESRD. There are few reports of biliary peritonitis due to intrahepatic bile duct rupture spontaneously and in the setting of cholecystitis. An acute fluid bilirubin level of >6 mg/dl with an ascitic fluid/serum bilirubin ratio of >1.0 has been shown to correlate with choleperitoneum. The black colored PD effluent in our patient represented a biliary leak likely from increased permeability of the gallbladder wall or microperforation in the setting of non-perforated cholecystitis or from an unidentified intrahepatic bile duct rupture. In conclusion black colored PD effluent should prompt investigation for gall bladder disease and/or pancreatitis. Peritoneal fluid and serum bilirubin levels and lipase levels can aid in making a diagnosis.

**Case Description:**
A 41 year old woman with ESRD from lupus nephritis, received living related renal transplant 9 years ago; admitted with hemoglobin of 5.6 g/dl with normal WBC count and platelet count. Patient had well-functioning allograft with serum Cr of 1.5 There was no evidence of joint swelling, rash, or alopecia. Hepatitis B, C, HIV, tuberculosis, RBC, WBC, or urine analysis. Serum Protein was 4.9 g/dl; Albumin 2.7 g/dl. LDH, haptoglobin, DS, DNA,ANA,ANCA,4T,hepatica B,C,HSV, Parvo virus PCR, EB PCR, free kappa/Lambda were normal. MCV was 95.9 fL. Peripheral smear showed many normal lymphocytes with normal count. Serum creatinine was 0.58 mg/dl. Hemoglobin was 11.6 g/dl. Albumin was 2.2 g/dl. Total bilirubin was 0.1 mg/dl but absence of erythroid precursors. Flow cytometry revealed increased NK 56(-), CD3 +, CD8 +, CD19 +, CD56 +. Renal allograft Ultrasound, CT Chest and CT abdomen were normal. This patient had her last epogen in 2003 and anti-EPO antibody induced PRCA though possible but absence of erythroid precursors. False negative for EPO antibody.

**Discussion:**
We present a case of PRCA in a renal transplant recipient due to NK cell lympho proliferative disorder which was successfully treated with ATG.

**FR-PO002**
New-Onset Diabetes After Transplantation in a Pediatric Patient with Congenital Anomalies of the Kidney and Urinary Tract: The Role of Hepatocyte Nuclear Factor 1ß

**Introduction:**
Congenital anomalies of the kidney and urinary tract (CAKUT) are the most frequent cause of end-stage renal disease (ESRD) in children. New-onset diabetes after transplantation (NODAT) is one of the major complications following kidney transplantation (KTx). Mutations of hepatocyte nuclear factor 1ß (HNF1ß), a transcriptional factor important for development and maturation of the liver, may cause a multi-system disorder, including CUKAT, diabetes, liver dysfunction. We report a pediatric patient with renal hypodysplasia carrying a novel mutation of HNF1ß who developed NODAT and liver dysfunction.

**Case Description:**
The patient was a 14-year-old girl. She was diagnosed with bilateral hypodysplastic kidney in the newborn period. At the age of 3 years, she received living-related KTxs from her mother preemptively. At the age of 4 years, a steroid pulse for acute rejection resulted in development of diabetes mellitus (NODAT). At the age of 13 years, she complained of acute right flank pain and fever. Laboratory data showed elevated transaminase levels and computed tomography showed malformation of the bile duct. The causes of NODAT were initially thought to be steroid and tacrolimus. However, based on her clinical features, including CUKAT, NODAT, and liver dysfunction, screening for a mutation of HNF1ß was performed. Her peripheral blood lymphocytes were used, primary HNF1ß expression was induced followed by reverse transcriptase-polymerase chain reaction. A total of 11 exons of HNF1ß were sequenced using a standard PCR amplification and direct sequencing protocol. The patient was found to be a heterozygous for a homozygous splicing mutation of HNF1ß, c.344+2T>C.

**Discussion:**
CUTK is the leading cause of ESRD in children and CUKAT is the most frequently mutated gene of CUKAT. Therefore, the contribution of HNF1ß mutations to the development of NODAT appears to be large in the field of pediatric KTxs. An oral glucose tolerance test and screening for HNF1ß mutations may be advisable before KTxs in CUKAT patients.

**FR-PO003**
Acute Kidney Injury from Biopsy Proven Oxalate Nephropathy in a Combined Kidney and Lung Transplant Recipient

**Introduction:**
Acute oxalate nephropathy (AON) is a rare, but well-reported cause of acute kidney injury (AKI) in patients with cystic fibrosis (CF) after lung transplant. We report the only known case of late onset of AON in a transplanted kidney in a combined kidney and lung transplant patient without CF after undergoing medical and surgical management of infective endocarditis.

**Case Description:**
A 62 year old Caucasian male with a remote history of Hodgkin’s disease complicated by radiation-induced pulmonary fibrosis and aortic stenosis underwent a simultaneous double lung transplant and bioprosthetic aortic valve replacement (AVR) in February 2013. His post operative course was complicated by recurrent bronchopneumonias secondary to MSSA requiring prolonged oxacillin as well as ESRD secondary to presumed uncorrected acute tubular necrosis (ATN). The patient subsequently underwent a successful living unrelated kidney transplant from his wife in October 2014 with baseline creatinine of 1.4 mg/dl. Unfortunately, he developed E. faecalis bacteremia secondary to urosepsis and subsequent finding of multi-valvular endocarditis with superior vena cava involvement. This was treated with a prolonged antibiotic course, but recurrent admissions thereafter for CHF and community AKI necessitated a redo AVR along with mitral valve replacement and tricuspid valve repair, “Commando Procedure” on 3-9-2015. Immediate post-operative AKI occurred and was thought due to ATN given the presence of muddly brown casts on sediment exam along with hemodynamic instability requiring temporary intra- and post-operative vasopressor support. Amuric AKI persisted for four weeks leading to a surveillance kidney biopsy to investigate for superimposed rejection. Notable histologic findings were tubular injury consistent with ATN, but more prominent was that of extensive calcium oxalate deposits consistent with AON.

**Conclusion:**
In summary we report the first known case of AKI due to AON in a lung and renal transplant recipient after infective endocarditis requiring prolonged antibiotics and the Commando heart procedure. Though the clinical presentation mimics ATN it is important for clinicians to include AON in the differential diagnosis.
mice results in a concentrating defect in part related to a reduction of AVPR2 expression. As Pax2 and PTIP expression increased in PKD2, Pax2 and PTIP localize to the inner medulla, we hypothesized that Pax2 and PTIP are required for AVPR2 expression.

**Methods:** In IMCD-3 cells with control, Pax2 or PTIP depletion, we determined Pax2 and AVPR2 expression by the mRNA and protein level in response to normal and elevated osmolality. By ChIP analysis, we identified sites of Pax2 and PTIP enrichment on the AVPR2 promoter and determined changes in histone modifications, PolII occupancy in both IMCD and in murine medulla tissues.

**Results:** Pax2 mRNA peaks 8 hours after an increase in osmolality, Pax2 protein peaks at 30 minutes and returns to baseline 2 hours.33% of the HMT activity zone localized to a 100 bp fragment of the AVPR2 promoter, resulting in increases in activation marks, recruitment of PolII to this locus and an increase in gene expression in both cell lines and murine kidney. We identify the minimal promoter that Pax2 binds to and drives expression of the AVPR2 locus. Deletion of this 100 bp region of DNA results in lack of gene expression in the absence and presence of Pax2. Deletion of PTIP results in loss of gene expression even though Pax2 localizes to the promoter region, as histone activation marks are not increased and PolII is not recruited to this locus.

**Conclusions:** Thus, Pax2 and PTIP both regulate the expression of AVPR2 in the murine inner medulla and in cells derived from this tissue. Pax2 provides the locus specificity for PTIP recruitment of the HMT activating complex and gene expression.

Adenine Downregulates NKCC2 and AQP2 in the Rat Kidney and Causes Early Nephrogenic Diabetes Insipidus

**Background:** Long-term feeding of adenine is extensively used to develop animal models of chronic renal failure with metabolic features resembling those observed in humans. However, the mechanisms by which adenine induces renal failure are poorly understood.

**Methods:** In this study, we examined the early effects of adenine (ADN) feeding on water metabolism and renal function in rats placed in metabolic cages. Rats were fed control diet or diet supplemented with 0.25% or 0.50% ADN, or 0.50% adenosine ad libitum with free access to deionized water, and monitored daily for food intake, water balance and urine osmolality, and euthanized for blood an kidney collections after 7 days. The results demonstrated that adenine-fed rats exhibited a sharp polyuria and polydipsia and decreased urine osmolality as early as 3 days, and the magnitude of these effects is dose-dependent. Further, ADN caused a significant reduction in food intake and body weight at 0.50% but not at 0.25%. None of these physiologic parameters were altered by adenine treatment. dDAVP treatment induced a significant increase in urine osmolality in control but not in ADN-treated rats. Immunoblotting experiments demonstrated a sharp reduction in AQP2/actin ratio in rats fed 0.50% ADN (65%), but expression of AQP2/actin ratios were reduced in control (75%) and in rats fed 0.25% ADN (50%). Analysis of kidneys of adenine-treated vs. control animals. The results also demonstrated that the abundance of NKCC2/actin proteins ratio was reduced to zero in the kidney outer medulla of adenine-fed rats vs. control rats. Blood chemistry of adenine-fed rats was normal except for a significant 3.8-fold increase in BUN, as compared to control rats. When rats were fed adenine diet supplemented with 7% NaCl, their BUN was corrected to normal level, with no change in food intake and body weight, but still exhibited a significant reduction in urine osmolality.

**Conclusions:** In conclusion, adenine acts on renal tubules as a signaling molecule and causes nephrogenic diabetes insipidus, likely by directly downregulating NKCC2 and AQP2 in the kidney. The combination of renal fluid loss and decreased food intake likely plays an important role in the development of early acute renal injury that progresses to chronic kidney disease in long-term periods of adenine treatment.

AMPK Activation Increases Urine Concentrating Ability in a Rat Model of Congenital Nephrogenic Diabetes Insipidus

**Background:** The urine concentration mechanism is primarily regulated by vasopressin which activates NKCC2 and urea transporters to generate a hypertonic interstitium that permits osmoregulation and resorption of AQP2. Congenital nephrogenic diabetes insipidus (NDI) is caused by vasopressin V2 receptor (V2R) mutations. Present treatment options for NDI are limited. We studied AMPK as an alternative pathway to stimulate transporters involved in urine concentration.

**Methods:** Tolaptan (10 mg/kg/day), a selective V2R antagonist, was given by oral gavage to rats for 4 days, +/- metformin (800 mg/kg/day). Urine volume and osmolality were measured daily. Following sacrifice, kidneys were dissected into inner medulla tip, base and outer medulla, and UT-A1, AQP2, and NKCC2 were analyzed by Western blot. Immunoblotting was used to localize AQP2, pAQP2, pAMPK, and NKCC2.

**Results:** Tolaptan was used to produce a rat model of NDI. Urine volumes of tolaptan-treated rats increased 105% within 24 h. Metformin was used to stimulate AMPK as a candidate NDI treatment. Metformin decreased urine volume by 110% back to control levels in 3 days. Urine osmolality in control rats was normalized with tolaptan, with no change in base. Meloxicam significantly increased the ratios of pAQP2 and pAMPK to total AQP2 in IM tip (44% and 40%, respectively). Ibuprofen increased the ratio of pAQP2 to total AQP2 in IM tip but did not affect pAMPK/AQP2 total. Both NSDAs increased pAQP2 and pAMPK ratios in tip and base. Meloxicam increased UT-A1 levels in IM tip, but not base. NR3a, present in rat IM tip and base, was significantly increased in the melanocim and melanocin treated IM base (37% and 20%, respectively), but unchanged in IM tip. AQP2 and UT-A1 abundances were decreased both in wild type (AQP2: to 76%; UT-A1: to 62%) and NR3a-/- mice (AQP2: to 52% UT-A1: to 75%). Outer medullary AQP2 and UT-A1 by 61% in tolvaptan treated rats (p<0.05). IM tip AQP2 was also increased 44% but failed to reach statistical significance (p=0.057). In contrast, IM base UT-A1 and AQP2 protein levels were not changed with AMPK stimulation. Outer medullary NKCC2 abundance was increased 117% with AMPK stimulation in control rats (p=0.004) but not in V2R-blocked rats. Immunochemistry showed that AQP2 and p-AQP2Ser256 appear to be localized on the cell membrane with acute and chronic AMPK stimulation, both in control and V2R-blocked rats.

**Conclusions:** AMPK stimulation in V2R-blocked rats is able to reduce the urine concentrating defect by increasing UT-A1 and AQP2. These results indicate that specific AMPK pathway activators might provide a promising treatment for congenital NDI.

**FR-PO097**

HYAL2 Disruption Leads to Impaired Urinary Dilution Capacity in Mice

**Background:** Hyaluronan (HA) is a hyaluronosylglycan present in high amount in the inner medulla of the kidney but almost absent in the cortex. Hyaluronidase 2 (HYAL2) is one of the two major hyaluronidases acting synergistically to degrade HA. Recently, it has been shown that HYAL2 mice display HA accumulation in the kidney. Renal HA content is known to vary with hydration status. Therefore, our study was set up to characterize the renal excretory capacities and renal water handling in response to water deprivation and acute water loading in HYAL2 mice.

**Methods:** Experiments were performed in HYAL2 mice and in their wild-type controls. After appropriate acclimation, water deprivation was performed during 24 hours. The capacity to excrete a water load was tested on an hourly basis for the next 6 h after i.p. injection of 2 ml of sterile water. Diuresis and urinary osmolality were measured. HA concentration was measured in the kidney tissue and its distribution through the different kidney regions was assessed. HYAL2 mice was examined using immunohistochemistry. Expressions of aquaporin 2 (AQP2) and p-Ser 256 AQP2 were also assessed using immunohistochemistry and immunoblotting.

**Results:** After water deprivation, HYAL2 mice showed the same ability to concentrate urine as wild-type HYAL2+/- mice. On the other hand, HYAL2 mice had a significant delay in the diuretic response induced by an acute water load. As for renal HA content, HYAL2 mice maintained higher HA concentration than HYAL2+/+ mice after both water deprivation and acute water loading. HA was present around tubules in all kidney zones including cortex. In HYAL2 mice, kidney AQP2 and p-Ser 256 AQP2 expressions were increased after water deprivation and decreased after acute water loading to the same extent in KO and WT mice.

**Conclusions:** HYAL2 deficiency and/or increased renal interstitial HA delays the diuretic response to acute water loading without any increase in plasma AVP or collecting duct AQP2 expression.

Phosphorylated AQP2 and NR3a Reduce NSAID-Induced Urine Concentration Defect

**Background:** Vasopressin increases urine concentration through activation of aquaporin-2 (AQP2) in the collecting duct. Nonsteroidal anti-inflammatory drugs (NSAIDs) block PGE2 synthesis, and may suppress AQP2, producing a urine concentrating defect. NSAIDs can regulate cellular Ca2+ entry and may influence AQP2 trafficking.

**Methods:** We treated rats with a nonselective NSAID, ibuprofen, and a COX-2-selective NSAID, meloxicam, daily for 2 weeks. We assessed urine osmolality and volume, and monitored p-AQP2s by Western blotting. NR3a-/- mice were used to examine if NR3a has a protective role.

**Results:** Both NSAID-treated rats showed an overall decrease in AQP2 and UT-A1 mouse. However, the beneficial effects of NR3a may reflect the altered Ca2+ entry that could be limiting dephosphorylation of AQP2 and promoting improved water homeostasis.

**Funding:** NIDDK Support, Government Support - Non-U.S.

The Role of Klotho in Renal Sodium and Water Transport
Tatiana R. Sanchez,1 Fernanda O. Coelho,1 Leticia Jorge,1 Leticia U. De Castro,1 Makoto Kuro-o,2 Lucia Andrade.1 1Div of Nephrology, Univ Sao Paulo, Brazil; 2Jichi Medical Univ, Japan.

Background: Klotho (Kl), a transmembrane protein hormone, counteracts aging. Aging is often paralleled by dehydration, which could promote age-related disorders, because it decreases renal Kl protein abundance, as well as increasing plasma osmolarity, antidiuretic hormone (ADH), aldosterone, and 1,25 vitamin D. ADH and aldosterone decrease Kl transcription in HEK293 cells and are elevated in the sera of Kl knockout mice. We explored the effects of Kl deficiency on renal transporters.

Methods: 8-12 week old male Kl+/−, Kl−/− and Kl−/− mice (n=6/group) were fed standard mouse chow and given access to tap water. We evaluated serum levels of Na, K, Cl, Mg, creatinine and urea. We immunoblotted for sodium/hydrogen exchanger isoform 3 (NHE3), renal outer medullary potassium channel (ROMK), the Na-K-2Cl cotransporter (NKCC2), alpha subunit of the epithelial sodium channel (αENaC) and aquaporin 2 (AQP2) in kidney membrane fractions; and for phosphorylated glycosynse synthase kinase 3 beta (pGSK3β) in cytoplasmic fractions.

Results: Data are mean±SEM.

Conclusions: In Kl knockout mice, there seems to be normal regulation of NKCC2 and trafficking of AQP2 to the apical plasma membrane in response to ADH. However, Kl knockout mice present reduced sensitivity to elevated plasma aldosterone levels with no increase in oENaC or ROMK protein expression. A lack of Kl can deregulate the adaptive response. (FAPESP).

Urine Aquaporin-2: Improvement in ELISA Measurements by Alkaline Pre-Treatment and Mechanisms of the Secretion
Sei Sasaki,1 Yoko Sajo,2 Yasukazu Ohomo,2 Fusako Iwata,3 Daiuske Koga,4 Takayuki Shimada,5 Masaki Sakai,5 Yasuaki Tanaka,5 Kenichi Ishibashi,5 Kiyonori Katsuragi.1 1Nephrology, Tokyo Medical and Dental Univ, Tokyo, Japan; 2Research and Development and Inst of Biomedical Innovation, Otsuka Pharmaceutical Co Ltd, Tokushima, Japan; 3Medical Physiology, Meiji Pharmaceutical Univ, Tokyo, Japan.

Background: Vasopressin-regulated water channel, aquaporin 2 (AQP2) is excreted in urine in the form of extracellular vesicles (mostly exosomes). Urine AQP2 has been measured in many clinical water-balance disorders as a potential biomarker for diagnosis. However, basic permeable support and excretion of AQP2 to the medium was measured.

Methods: Human urinary samples from healthy subjects were measured by a sandwich ELISA. Effects of maneuvers to disrupt the exosome membranes mechanically (freezing and thawing at different temperatures) and chemically (treating with alkali and detergents) on permeability and excretion of AQP2 to the medium was measured.

Results: 1. Urine samples stored at 4°C or -80°C did not show significant AQP2 values in ELISA, whereas those stored at -25°C for more that 2 weeks provided the values. Urine samples treated with 0.4N NaOH/0.5% Triton X-305 showed the consistent and comparable values to those stored at -25°C, indicating the need of disruption of the exosome membranes. 2. Supernatans of 200000g ultracentrifugation contained less than 0.5% of AQP2 of original urine samples. 3. In the culture, AQP2 concentration was more than 10 times higher in apical medium compared to basalolateral, and apical AQP2 excretion was stimulated with 3h-incubation of 10-3 forskolin and 100mM NaCl.

Conclusions: Almost all urine AQP2 is enclosed in exosomes, and pre-treatment of alkaline NaOH allows consistent ELISA measurements. Mechanisms of urinary excretion of AQP2 can be examined in culture system.

Inhibition of EGFR Activity Increases Aquaporin 2 Phosphorylation and Increases Water Reabsorption in Lithium Treated Mice
Pui Cheung, Naohiro Nomura, Anil V. Nair, Hua Ann Jenny Lu, Richard Bouley, Dennis Brown. Medicine, Massachusetts General Hospital, Boston, MA.

Background: Impairment of vasopressin (VP) receptor type 2 signaling in the kidney is detrimental to water homeostasis. However, strategies targeting cAMP signaling to treat diseases associated with water balance have so far been unsuccessful in humans, prompting a search for alternative pathways that modulate AQP2 trafficking.

Methods: The effect of erlotinib (Erl) oral gavage in a lithium induced nephrogenic diabetes insipidus mouse model was analyzed by measuring urine volume and osmolarity. The effect of Erl on aquaporin 2 trafficking and expression in kidneys was studied by immunostaining and western blot analyses. EGF and Erl regulation of AQP2 trafficking and phosphorylation were studied using selected kinase inhibitors and phospho-specific antibodies on AQP2-expressing LLC-PK1 cells.

Results: Erl alone had only a subtle effect on AQP2 trafficking, but it exerted a significant antagonizing effect on VP-induced AQP2 phosphorylation and membrane accumulation. Conversely, erlotinib (Erl), an EGFR inhibitor, led to a VP-independent increase of apical AQP2 accumulation in collecting ducts, and significantly reduced urine volume by more than 40% after 4 days of treatment in lithium-induced NDI mice. Erl enhanced AQP2 plasma membrane localization in cells by increasing AQP2 ectosity and decreasing endocytosis. This effect was cAMP, cGMP, and PKA independent. Despite apparently bypassing cAMP pathways, Erl resulted in AQP2 phosphorylation accumulation in a dose dependent manner at series 256, an essential step in VP-induced AQP2 membrane accumulation. We propose that EGF has a tonic inhibitory effect on VP action, and that relief of such inhibition enhances AQP2 phosphorylation and results in membrane accumulation.

Conclusions: We showed a crosstalk between EGF and VP in the modulation of AQP2 trafficking. EGFR inhibition increases AQP2 membrane expression bypassing the canonical VP/AMPK/PKA pathway and ameliorates lithium-induced NDI in mice. This study improves our understanding of the diversity of mechanisms that regulate water reabsorption in the body, and uncovers a novel pathway for potential therapeutic targets for NDI.

ChIP-seq Analysis of Genomic Binding Sites for the Transcription Factor E11 in mckPkd Cells
Hyun Jun Jung, Viswanathan Raghrum, Jae Wook Lee, Mark A. Knepper. Systems Biology Center, NHLBI, NIH.

Background: Collecting duct cells selectively express a number of transport proteins (aquaporins and ion channels) vital to water and electrolyte balance. Previous studies of tissue-specific gene expression in collecting duct cells have implicated E11 family transcription factors (TFs)(Yu et al. PNAS 2009;106:2441). We integrated data from prior proteomics and transcriptomics studies of mouse mckPkd cells using Bayes’ Rule to create a probability-based ranking of all known TFs with regard to likelihood of a role in collecting duct-specific gene expression. Among the top-ranked TFs were several E11 family TFs including E11i.

Methods: To identify genomic binding sites for E11i in mckPkd cells, we carried out ChIP-seq analysis using an antibody successfully employed in the Mouse ENCODE Project. The mckPkd cells were treated with the vasopressin analog dDAVP (100µM) for 24 hr prior to crosslinking and chromatin immunoprecipitation (ChIP) (n=3). DNA libraries were prepared from immunoprecipitated DNA and sequenced using an Illumina HiSeq 2000 sequence to identify TF-enriched genomic regions. Control ChIP was carried out with nonspecific IgG.

Results: The analysis (MACS peak-calling software) identified >2000 binding sites seen in all three replicates and not seen in IgG-only controls. The identified sites mapped to the top-ranked TFs were several E11 family TFs including E11i.

Conclusions: The analysis (MACS peak-calling software) identified >2000 binding sites seen in all three replicates and not seen in IgG-only controls. The identified sites mapped to the top-ranked TFs were several E11 family TFs including E11i. ChIP-seq Analysis of Genomic Binding Sites for the Transcription Factor E11i in mckPkd Cells

Deletion of Aquaporin 11 in Transgenic Mice prior to Post-Natal Day 12 Results in Proximal Tubule Injury and Cyst Formation  
Soren Nielsen,1 Mads Vammen Damgaard,2 Michael R. Rutzel,1 Robert A. Fenton,2 Aleksandra M. Rojek,1 1Department of Health Science and Technology, Aalborg Univ, Aalborg, Denmark; 2Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.

**Background:** AQPII is expressed in the proximal tubule (PT). Neutato AQPII KO mice show PT vacuolization and cyts, resulting in renal failure and death. This study examined whether AQPII deficiency at any stage of kidney development is important for PT injury and cyst formation; 2) if cyts are closed structures or dilations of PT; 3) the role of metabolic challenges on PT injury and cyst formation.

**Methods:** Tamoxifen-inducible AQPII KO mice were generated. Deletion of AQPII at post-natal (PN) day 2, 4, 6, 8, 10, 12 or 21 was investigated alongside neonate total AQPII KO mice. PT cell vacuolization and tubular cyts were observed only in mice where AQPII gene disruption was instigated before PN day 12. AQPII gene deletion after PN week 3 did not result in PT injury or cyst formation. Similar to deletion before PN 2 or 6, maximal PT injury was induced (1600 h) on PN day 21 induced AQPII KO mice or total neonatal AQPII KO mice resulted in PT cytoplasmatic vacuoles but not cyts. IP injection of biotinylated-dextran (10kDa) in adult, neonatally induced AQPII KO mice revealed endocytotic uptake in both cytosolic and PT epithelium. Thus apparent cyts were continuous with PT hence representing PT dilations. This was confirmed by serial sectioning and digital 3-D tracing of PT cyts in adult, neonatally induced AQPII KO mice. Electron microscopy of PT in kidneys from adult neonatally induced AQPII KO mice revealed dilated RER and extensive autophagosomes. Deletion of AQPII from PN 12 leads to PT cell injury and severe PT tubular dilatation. 2) AQPII gene deletion after full kidney development results in normal PT morphology, and only present with PT injury in response to metabolic challenges. 3) Apparent cyts represent PT dilations and are not closed cyts. Conclusion: AQPII deficiency prior to PN day 12 sensitizes PT cytos of the developing kidney to cellular injury and causes severe PT dilations thus revealing a novel mechanism for PT cyst formation.

Involvement of NADPH Oxidase 2 in the Kidney Injury of Aquaporin-11 KO Mouse  
Yuya Hoshino,1 Hiroko Sonoda,1 Kenichi Ishibashi,2 Masahiro Ikeda.1 1Vetinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan; 2Medical Physiology, Meiji Pharmaceutical Univ, Tokyo, Japan.

**Background:** Aquaporin-11 (AQPII), the latest member of the AQ family to be described, is an intracellular AQ. Several in vivo studies have shown that AQPII deficiency causes kidney injury characterized by the formation of multiple cyts. Recently, this kidney injury was reported to be related to the production of reactive oxygen species (ROS). However, the underlying molecular mechanism is largely unknown.

**Methods:** In this study, we examined the mechanism by which AQPII deficiency induces ROS production using PCR array, real-time PCR, immunoblotting, and immunohistochemistry techniques. Also, a pathway analysis was performed with the results from the gene expression analysis.

**Results:** Immunohistochemistry studies showed that the number of 8-hydroxy-2'-deoxyguanosine-positive cells in renal interstitium was increased in AQPII KO mice in comparison with control mice. In parallel, immunoblotting analysis revealed increased levels of renal protein carbonylation in the KO mice. The NADPH oxidase (NOX) enzyme family is important sources of ROS and so far, six members (NOX1, NOX2, NOX3, NOX4, DUOX1, DUOX2) have been identified in mouse. Among them, real-time PCR analysis showed that renal NOX2 mRNA level was markedly increased in the KO mice. Furthermore, mRNAs for the assembly factors (p40phox, p47phox, p67phox) for NOX2 in the kidney were dramatically up-regulated in the KO mice. Immunoblotting analysis revealed that renal NOX2 protein expression was significantly increased in the KO mice. Immunohistochemistry showed that NOX2-positive cells were observed in renal interstitium.

**Conclusions:** These data strongly suggested that increased ROS production in AQPII KO mice was mediated by NOX2, leading to the kidney injury.

Intracellular Vacuoles in the Kidney of AQPII Null Mice May Simulate the Cisplatin Nephrotoxicity  
Kenichi Ishibashi, Ichiru Akinaga, Takashi Kusano,1 Hiroko Sonoda,1 Kenichi Ishibashi,2 Masahiro Ikeda.1 1Vetinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan; 2Medical Physiology, Meiji Pharmaceutical Univ, Tokyo, Japan.

**Background:** Nephrotoxicity is a major side effect of cisplatin in chemotherapy. Despite years of research, the mechanism underlying cisplatin nephrotoxicity remains unclear and effective renal protective approaches during chemotherapy are still unavailable. Pathophysiological mechanisms of cisplatin nephrotoxicity is characterised by intracellular vacuoles in the proximal tubule which are very similar to the kidney phenotype of AQPII null mice before the polycyst development. We speculated that cisplatin may inhibit the function of AQPII to induce intracellular cytos.

**Results:** As the primary target of cisplatin (Casp12) in cisplatin nephrotoxicity has been reported in the literature (J Am Soc Nephrol. 16: 1985, 2005), the expression of Casp12 was examined by real-time PCR in the kidney of AQPII null mice with intracellular vacuoles, i.e. two weeks after birth. Casp3/Casp7 for apoptosis were not induced, while Casp12 for ER stress and inflammation were strongly induced by 9 folds and Casp8 for inflammation by 6/7.5 folds. We next examined the effect of cisplatin on AQPII expression in the kidney. The real-time PCR showed the decrease of AQPII expression by half in mice kidney at three days after 20 mg/kg BW i.p. cisplatin with almost normal renal function. When AQPII hetero-mice were challenged with the same cisplatin treatment, the renal parameters were increased: (hetero/wild) BUN 159.1±3.4 mg/dl, Cr 0.33±0.17 mg/dl, UA 3.13±0.2 mg/dl. We next searched for the interventions which enhance AQPII expression in the kidney. The increase of AQPII expression was observed by thiazide diuretics and by 3 times i.p. of 1g/kg BW 1,2-dichloro-propane. The increase of AQPII mRNA expression was observed in the next day after 3 times i.p. of the treatment.

**Conclusions:** The expression of AQPII may play an important role in the development of cisplatin nephrotoxicity. The enhancing the AQPII expression in the kidney will be a renoprotective strategy in cisplatin nephrotoxicity.

FR-PO108
RNA-seq Profiling of the Cortical Collecting Duct in Vasopressin Escape
Jae Wook Lee,1 Carolyn M. Ecelbarger,2 Mark A. Knepper,1 NHBLI, NIH, Bethesda, MD; 1Georgetown Univ, Washington, D.C.

Background: Vasopressin escape is a protective mechanism that limits hyperosmolality in the syndrome of inappropriate antidiuresis (SIADH). RNA-seq, we investigated transcriptomic changes in microdissected cortical collecting duct (CCD) of rats undergoing vasopressin escape.

Methods: Male Sprague-Dawley rats (120-160 g) were placed on continuous dDAVP (5 ng/hr) infusion for 5 days, and received either a high water load (50 mL/d, "escape") or a normal water load matching insensible losses plus urine output (25 mL/d, "control"). Rats were sacrificed at day 1, 2, and 4 mm of CCDs were collected by manual microdissection. RNAs were processed into cDNA libraries and 50-bp paired-end reads were obtained using an Illumina platform. Reads mapping to Ensembl genes were counted for differential-expression analysis.

Results: Sequence depths were 40-65 million reads, with 80% of reads mapping to Ensembl genes. At day 2, 180 transcripts were downregulated and 339 transcripts were upregulated at a false discovery rate < 0.1. Consistent with increased water excretion in vasopressin escape, transcripts of aquaporin-2 and aquaporin-3 were significantly downregulated at day 1, 2, and 4. Among downregulated transcripts were transcription factors (Hes1, Hmx2, Hoxb5, Hoxb6, Hoxb7, Jun, and Fox3) and a cyclin-dependent kinase inhibitor (Cdkn1b). Among upregulated transcripts were proteins involved in cell division, such as centromere proteins (Cepma, Cenpl, Cenplp, and Cenpf); cyclins (Ccn2, Ccnb2 and Ccnb1), a cyclin-dependent kinase (Cdk1), components of DNA replication machinery (Pol31 in DNA polymerase complex; Mcm2, Mcm3, Mcm4, Mcm6, and Mcm7 in MCM replicative helicase complex; Orc5 in origin recognition complex); polo-like kinase 1 (Plk1); and forkhead box protein M1 (Foxm1). GO terms related to cell division were enriched in upregulated transcripts ("cell cycle phase", adjusted p=8x10^-24; "mitosis", 2x10^-19).

Conclusions: RNA-seq revealed that increased rate of cell division may be an activated mechanism involved in remodeling of the CCD to restore water homeostasis as a part of the adaptation to SIADH.

Silencing of the Kinome Identifies a Novel Modulator of Aquaporin-2 Trafficking
Hana Cernecke,1 Dorte Faust,1 Anchored Signalling, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, MDD, Berlin, Germany; 1Leibniz-Institut für Molekularaparpharmakologie (FMP), Campus Berlin-Buch, Berlin, Germany.

Background: Arginine vasopressin (AVP)-dependent water reabsorption requires the redistribution of aquaporin-2 (AQP2) from intracellular vesicles into the plasma membrane of renal principal cells. Despite identification of several proteins participating in the control of AVP-dependent AQP2 trafficking, the molecular mechanisms underlying the AQP2 redistribution are largely unknown. The aim of this study was to identify proteins controlling the localization of AQP2 and thereby to elucidate molecular mechanisms underlying the AQP2 translocation.

Methods: We established a large-scale siRNA screening using mouse collecting duct cells, stably expressing human AQP2. The expression of 719 kinases was knocked down and the AQP2 localisation was analysed by automated immunofluorescence microscopy. Among overexpressed in HEK293 cells, the mutant SGLT2 transporter is not efficiently translocated to the basolateral membrane due to reduced affinity urate facilitatory transporter in kidneys. Here, we show that MCT12 resides on basolateral membranes of proximal tubules. Patients with MCT12 mutation exhibit reduced plasma levels and increased fractional excretion of guanidinoacetate but not glucosuria. A heterozygous mutation (c.643C>A; p.Q215X) in the creatine transporter gene MCT12 (also known SLC16A12) was recently identified as the cause of a syndrome with juvenile cataracts, microcornea and glucosuria in a single family. While the MCT12 mutation co-segregated with the eye phenotype, poor correlation with the glucosuria phenotype questioned a pathogenic role of the mutation in the kidney.

Conclusions: Here we show that MCT12 functions as a low affinity urate facilitatory transporter in kidneys.

Funding: Government Support - Non-U.S.

FR-PO111
Mouse Monocarboxylate Transporter 9 Functions as a Urate Transporter
Katina Lazarow,2 Martin Neuenschwander,2 Jens Peter von Kries,2 Enno Klussmann.1 Anchored Signalling, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, MDD, Berlin, Germany; 1Leibniz-Institut für Molekularaparpharmakologie (FMP), Campus Berlin-Buch, Berlin, Germany.

Background: Monocarboxylate transporter 9 (MCT9) is expressed in kidney, testis and retinal pigment epithelium (RPE). MCT9 is of particular interest due to its unique localization. Here, we suggested, for the first time, that MCT9 functions as a low affinity urate facilitatory transporter in kidneys.

Funding: Government Support - Non-U.S.

FR-PO112
Mutation in the Creatine Transporter MCT12 Causes Low Plasma Level and Increased Fractional Excretion of Guanidinoacetate but Not Glucosuria
G. Fuster,1 Nasser Dhayal,1 Alexandre Simonin,1 Giuseppe Albano,1 Ganesh Pathare,1 Christine Desl,1 David Mordasin,2 Bruno Vogt,1 Barbara Kloeckener,2 Daniel G. Fuster.1 1Div of Nephrology, Hypertension and Clinical Pharmacology, Nephrology, Bern, Switzerland; 2Inst of Medical Molecular Genetics, Univ of Zürich, Zürich, Switzerland.

Background: A heterozygous mutation (c.643C>A; p.Q215X) in the creatine transporter gene MCT12 (also known SLC16A12) was recently identified as the cause of a syndrome with juvenile cataracts, microcornea and glucosuria in a single family. While the MCT12 mutation co-segregated with the eye phenotype, poor correlation with the glucosuria phenotype questioned a pathogenic role of the mutation in the kidney.

Methods: We undertook a detailed phenotypic investigation of the index family and performed complementary in vitro studies.

Results: Here we show that MCT12 resides on basolateral membranes of proximal tubules. Patients with MCT12 mutation exhibit reduced plasma levels and increased fractional excretion of guanidinoacetate, but normal creatine levels, suggesting that MCT12 may function as a guanidinoacetate transporter in vivo. However, functional studies in Xenopus oocytes revealed that MCT12 transports creatine but not its precursor guanidinoacetate. This indicates that impaired MCT12-mediated cellular efflux affects guanidinoacetate homeostasis indirectly, e.g. by an increase of the cellular creatine concentration, which is known to inhibit guanidinoacetate synthesis. Genetic analysis revealed a separate, hitherto undescribed heterozygous mutation in SGLT2 (c.265G>A; p.A97T) in the family that segregated with the renal glucosuria phenotype. When overexpressed in HEK293 cells, the mutant SGLT2 transporter is not efficiently translocated to the plasma membrane and displays greatly reduced transport activity.

Conclusions: Our data indicate that MCT12 functions as basolateral exit pathway for creatine in the proximal tubule. Heterozygous mutation of MCT12 affects systemic levels and renal handling of guanidinoacetate. Furthermore, our data reveal the presence of a digenic syndrome in the index family with simultaneous MCT12 and SGLT2 mutation. Thus, glucosuria is not part of the MCT12 mutation syndrome.

Weitao Huang, L. Lee Hamm, Kathleen S. Smith.

Background: NaDC1 reabsorsbs filtered citrate (Cit); thus its regulation is important in preventing calcium nephrolithiasis. Importantly NaDC1 reabsorbs other Krebs cycle intermediates such as succinate (Suc) and αKG. Recently Suc and αKG have been found to activate TLR4 in paracrine signaling as their luminal presence stimulates distal nephron G-protein coupled receptors GPCR93 and GPCR99 respectively. Luminal Suc via GPCR99 has been found to stimulate renin release; while αKG via GPCR99 stimulates bicarbonate secretion by type B intercalated cells. The purpose was to determine whether knockout of NaDC1 produces hemodynamic or urine pH changes that might be anticipated by activation of these receptors.

Methods: Adult NaDC1 KO, heterozygous (Het), and wild-type mice (WT), under normal or acid diet for 72 hr, were studied using standard clearance techniques. After anesthetization diet measurements of hemodynamics, renal AngII and lead to severe in renal hypertrophy. Urine, blood and tissue were collected for measurement of Cit, Suc, αKG, and αKG.

Results: NaDC1 KO produced 2, 4, and 10-fold increases in normal urine, Cit, Suc, and αKG, respectively. There was substantial residual reabsorption of Cit and Suc in KO mice, indicating other transporters involved in reabsorption of these substrates. Despite the increase in normal urine there was no significant increase in urine pH (normal or acid diet); in fact on normal diet urine pH was lower in KO mice (5.14 ± 0.04 vs 5.90 ± 0.13 WT; p < 0.001). The lower urine pH in KO mice on normal diet may be a response to the loss of potential bicarbonate in the form of increased Krebs cycle intermediate excretion. There was no change in the ability of KO mice to excrete ammonia. In regard to potential hemodynamic effects mediated by NaDC1 KO and increased urine Suc, no change in MAP was determined comparing WT, Het or KO either on normal or acid diet.

Conclusions: In sum, NaDC1 is responsible for significant reabsorption of filtered αKG and Suc, but knockout of NaDC1 does not impair acid-base homeostasis or BP changes on normal or acid diets.

The Ablation of Dendritic Cells Prevents the Upregulation of the Intrarenal Renin-Angiotensin System and Renal Sodium Transporters in Response to Angiotensin II and High Salt Diet

Patricio A. Araya,1 Daniel E. Hevia,1 Carolina E. Prado,2 Eugenia L. Fuentes,2 Rodrigo Pacheco,2 Luis F. Michea,3 Univer de Chile, Chile; 2Fundación Ciencia y Vida, Chile.

Background: Blood pressure depends on the renal sodium reabsorption mediated by the tubular transporters that are modulated in the intrarenal renin-angiotensin-aldosterone system (iRAS). Angiotensin II (AngII) and a high salt diet (HS) cause hypertension (HT) and the upregulation of the iRAS and sodium transporters. Our previous studies showed that the ablation of Dendritic Cells (DCs) in mice prevented the development of HT in response to AngII+HS. In the present study, we evaluated if the ablation of DCs alters the modulation of the iRAS and tubular sodium transporters by AngII+HS.

Methods: CD11c+ DOG mice, selective loss of DC (CD11c+ cells after Diphtheria Toxin (DT) injection, received vehicle, AngII+HS (AngII, 450 mg Kg−1 day−1 NaCl in drinking water, 1.5% NaCl), or AngII+HS (DT, 8ng/kg d) during 14 days; Paired WT mice received vehicle, AngII+HS or AngII+HS+DT. We measured blood pressure (days 0, 4, 8, 14), and at day 14 we harvested tissues to measure the abundance of renal DCs (MHC-II+) and αENaC. Using qRT-PCR and Western blot.

Results: The injection of DT prevented the development of HT in response to AngII+HS only in CD11c+ DOG mice. CD11c+ DOG and WT mice showed increased abundance of DCs in the cortex (perfusate). Only the CD11c+ DOG mice showed a sharp reduction of renal DCs after DT injection. Both, in WT as in CD11c+ DOG mice the administration of AngII+HS increased the iRAS (in fold of induction: Angiotensinogen, 1.5; Angiotensin converting enzyme, 1.9; and Angiotensin II receptor type I, 5), NHE3, NCC and αENaC increased significantly by AngII+HS+DT. Furthermore, DT did not affect to influence the upregulation of L-NAMe. iRAS in L-NAMe mice had similar (p=0.84) SBP (145±5mmHg) as the Sham+L-NAMe group (146±4mmHg, n=6) after 2 weeks. Relative heart weights were also similar (p=0.45) between L-NAMe+HS (4.9±0.2) and Sham+L-NAMe treated mice (4.8±0.3mg/g BW).

Conclusions: Our data suggests that the full pressor response on AngII is dependent on the spleen. However, the effect of the spleen appears to be independent of renal hypertension. Moreover, the protective effect of the spleen is specific to AngII-dependent HTN and does not appear to be generalizable to all mouse models of hypertension. Further studies are needed to understand the physiological link between lymphoid-bearing organs and hypertension.

Salt Overload Promotes Severe Renal Injury and Activates AngII, Renal NF-κB and Other Components of Innate Immunity in a Model of Arterial Hypertension

Background: Hypertension (HTN) develops in rats that received the NaF inhibitor pyrroldinedithiocarbamate (PDTC) during lactation. High salt (HS) and uninephrectomy (UNx) exacerbate HTN, increase renal AngII and lead to severe in renal injury. Here, we further investigated the mechanisms of renal injury and the effect of Losartan (L) in this model.

Methods: Munich-Wistar pups received PDTC (PDTC) or no treatment (C) during lactation. At 10 wks of age, all rats underwent UNx and were divided in: C, normal salt diet (NS); PDTC, given NS; PDTC+HS, given HS; PDTC+L-NAME, given HS and L, 50 mg/kg/d. After 3 mo, we assessed: tail-cuff pressure (TCP, mmHg), glomerulosclerosis (GS), collagen content and collagen synthesis. We investigated the mechanisms of renal injury and the effect of Losartan (L) in this model.

Results: In PDTC mice, renal injury caused by HS+UNx involves activation of renal NF-κB, macrophages (Mo) and lymphocytes (Ly), cells/mm2, TLR4 and nuclear NF-κB (nC) and serum IL-6 (ng/mL).

In PDTC+L-NAME mice, renal injury caused by HS+UNx involves activation of renal AngII and innate immunity, including the NF-κB system. FASEB J. CPQNP.

Interleukin-6 Inhibitation Attenuates Hypertension and Proteinuria in Dahl Salt-Sensitive (SS) Rats

Shireen Hashma,1 Justine M. Abais-Battad,2 Hayley Lund,3 Scott K. Van Why,1 David L. Mattson. 2Pediatrics, Medical College of Wisconsin; 2Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: The infiltration of T lymphocytes in the kidney accompanies hypertension and proteinuria. In Dahl SS rats, pharmacological or genetic reduction of T cells attenuates hypertension and renal damage in SS rats fed high salt. An examination of the infiltrating T cells in the kidney demonstrated that interleukin 6 (IL-6) mRNA levels are >50-fold higher in T cells isolated from the kidney in comparison to circulating T cells. IL-6 is a pro-inflammatory cytokine which positively correlates with hypertension in humans.

Methods: We infused splenectomized rats with interleukin-6 (IL-6) or vehicle intraperitoneally for 14 days after induction of HTN. Heart weight/body weight (H/W) ratios were calculated and kidney leukocyte infiltration was analyzed by flow cytometry.

Results: Mice with prior SPLX+AngII had significantly lower (P<0.05) TCP at both week 1 (148±7) and week 2 (135±7) as compared to Sham+AngII (174 and 173±7mmHg). Similarly, splenectomized mice had significantly smaller (P<0.007) H/W (4.3±0.6) as compared to Sham+AngII treated mice (5.2±0.4mg/g BW). Interestingly, no difference was observed in renal CD45+T (8.2±3 vs 10.6±1x104 cells/g, P=0.64) or CD3+ T-cell infiltration (8.8±0.2 vs 9.6±0.1x104 cell/g, P=0.64) between the Sham+AngII and SPLX+AngII treated mice, respectively. Furthermore, splenectomy did not appear to influence the upregulation of L-NAMe. SPLX+L-NAMe mice had similar (P=0.84) SBP (145±5mmHg) as the Sham+L-NAMe group (146±4mgHg, n=6) after 2 weeks. Relative heart weights were also similar (P=0.45) between splenectomy+L-NAMe (4.9±0.02) and Sham+L-NAMe treated mice (4.8±0.3mg/g BW).

Conclusions: Our data suggests that the full pressor response on AngII is dependent on the spleen. However, the effect of the spleen appears to be independent of renal hypertension. Moreover, the protective effect of the spleen is specific to AngII-dependent HTN and does not appear to be generalizable to all mouse models of hypertension. Further studies are needed to understand the physiological link between lymphoid-bearing organs and hypertension.
Methods: Experiments were performed to assess the potential role of IL-6 in Dah SS hypertension by administering anti-IL-6 neutralizing antibody (anti-IL-6; 4 µg/day, IP; R&D Systems, Minneapolis, MN) or normal goat IgG control (4 µg/day, IP) for 11 days. Results: The MAP and urine protein excretion rates (Upro) were similar between the groups of SS rats (n=13-16/group) when fed low salt (0.4% NaCl) chow. Following 11 days of high salt (4.0% NaCl) treatment, the rats receiving anti-IL-6 demonstrated significantly lower in the treated vs the control group (954±133 mg/day vs 1802±336 mg/day). Moreover, the increase in MAP following 11 days of 4.0% NaCl intake was significantly attenuated in treated (MAP=138±3 mmHg) vs the control group (MAP=151±4 mmHg). The Upro was also significantly attenuated in treated (193±17 mg/day) vs control group (252±20 mg/day). To investigate mechanisms of action, a flow cytometry analysis of infiltrating immune cells in the kidney (n=4-5/group) was performed. The total number of leukocytes (CD45+) was significantly lower in the treated vs the control (14.2±1.7x10^6 vs 21.6±2.8x10^6 cells/kidney). The total number of monocytes and macrophages (CD11b+) was significantly lower in the treated vs the control group by 31%. The total number of T cells and T regulatory cells were not different among the groups.

Conclusions: The present studies indicate that IL-6 may participate in the development of SS hypertension and end-organ damage by mediating the infiltration of leukocytes into the kidney.

FR-PO118
High Salt Affects Toll-Like Receptor-Induced Gene Expression in Macrophages
David Severs, Martin Hoogduijn, Alexander H. Danser, Robert Jan Bert
Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

Background: High dietary salt intake is a major risk factor for cardiovascular disease. A high-salt (NaCl) diet increases NaCl concentrations in the skin. In the skin, macrophages respond to high NaCl by the osmosensitive transcription factor NFAT5 and promote NaCl efflux via lymph vessels. Other effects of NaCl on local macrophages have remained largely elusive. Therefore, we investigated whether evidence suggests that NFAT5 also regulates multiple Toll-like receptor (TLR)-induced genes such as NOS2, TNF, and IL6 in macrophages, independently of osmotic stress. We aimed to investigate the effects of NaCl-generated hypertonicity on the expression of these genes in TLR-activated macrophages.

Methods: We simulated the hypertonic skin microenvironment by culturing macrophage-like RAW 264.7 cells in NaCl-induced hypertonic media (340-480 mMosm/kg) and compared this with normotonic media (320 mMosm/kg). After 1 to 24 hours of stimulation with lipopolysaccharide (LPS) or Zymosan A, a TLR2 ligand, we measured nitric oxide production (2-fold), NOS2 mRNA (3-fold) and NOS2 protein expression (2.25-fold) in LPS- and Zymosan A-stimulated cells. In contrast, equiosmolar mannitol or urea did not affect p65 in vascular smooth muscle cells.

Results: NaCl significantly and dose-dependently increased nitric oxide (NO) production (2-fold), NOS2 mRNA (3-fold) and NOS2 protein expression (2.25-fold) in LPS- and Zymosan A-stimulated cells. In contrast, equiosmolar mannitol or urea did not affect expression levels. NaCl also increased LPS-induced p38 phosphorylation and total NFAT5 protein expression. Similarly, NaCl increased TNF mRNA expression 1.25-fold. Remarkably, NaCl significantly downregulated LPS-induced expression of CCL5 (4-fold), IL6 (2.4-fold) and IL12b mRNA (3.5-fold).

Conclusions: Elevated concentrations of NaCl, comparable with those found in the skin after high dietary salt intake, amplify expression of NOS2 and TNF in TLR-stimulated macrophages. This effect is likely mediated via p38 and NFAT5. Increases in NOS2 and TNF mRNA expression. Similarly, NaCl increased TNF mRNA expression 1.25-fold. LPS- and Zymosan A-stimulated cells. In contrast, equiosmolar mannitol or urea did not affect p65 in vascular smooth muscle cells.

FR-PO119
Indoxyl Sulfate Uptake Activates Protein Kinase Cdelta in Human aortic smooth muscle cells
Maimaiti Yisireyili,1 Yoshimiya Niwa,2 Toshimitsu Niwa,3 Cardiology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; 1Faculty of Health and Nutrition, Shaban Univ, Ichinomiya, Aichi, Japan.

Background: Chronic kidney disease (CKD) is considered major causes of death in cardiovascular disease (CVD) patients. Prorenin receptor (PRR) is significantly expressed in the human smooth muscle cells. In this study we aimed to clarify the role of indoxyl sulfate (IS), a uremic toxin, in PRR activation in rat aorta and human aortic smooth muscle cells (HASMCs).

Methods: CRD rats and IS-administrated rats were subjected for in vivo experiments. Human aortic smooth muscle cells (HASMCs) was treated with or without indoxyl sulfate (IS).

Results: Immunohistochemistry showed increased expression of PRR and renin/ prorenin in aorta of CRD rats and IS-administrated rats compared with normal rats. IS elevated the expression of PRR and prorenin in HASMCs. N-acetylcyesteine, an antioxidant, and diphenylethenesindamin, an inhibitor of nitric oxide synthase, attenuated the expression of PRR and prorenin in HASMCs.

Conclusions: IS promotes aortic expression of PRR and renin/prorenin through OAT3-mediated uptake, production of reactive oxygen species, and activation of AhR and NFκB p65 in vascular smooth muscle cells.

Role of Skin and Endothelial Surface Layer Heparan Sulfates in Blood Pressure Regulation
Rik He Olde Engberink,1 Naomi Van Vliet,2 Bert-Jan Van den Born,3 Ed van Bavel,4 Liffert Vogt,1 1Nephrology, AMC, Amsterdam, Netherlands; 2Laboratory of Genetic and Metabolic Disease, AMC, Amsterdam, Netherlands; 3Vascular Medicine, AMC, Amsterdam, Netherlands; 4Biomedical Engineering and Physics, AMC, Amsterdam, Netherlands.

Background: Besides the skin, the endothelial surface layer (ESL) contains many glycosaminoglycans (GAGs) that can osmotically inactivate Na+ and may affect blood pressure (BP). EXT genes regulate heparan sulfate (HS) polymerization, the predominant ESL GAG. In mice with heterozygous loss of EXT1 and EXT2 (EXT), and wildtype (WT) mice, we investigated the role of HS in the skin and ESL in BP regulation after an acute and chronic NaCl load.

Methods: We investigated BP effects of a 7-d normal (0.3%), NSD, and high (8.0%) HSD NaCl diet, with tail cuff measurements, and an acute 1.8% NaCl load (8 µl/g) with intracardiac measurements. We used intravital microscopy to estimate ESL thickness in ~40 µm crenaster vessels on both diets. We used high performance liquid chromatography-mass spectrometry to measure skin HS disaccharide concentration.

Results: Baseline BP was equal in WT and EXT mice (p=0.9), with no difference between NSD and HSD. Relative to WT, acute NaCl infusion increased BP in EXT mice (p<0.02), while heart rate remained equal (p=0.5). After a NSD and HSD, EXT mice had a 78% reduction of ESL thickness compared to WT mice (Fig A). HSD increased ESL thickness in WT, especially in 20-40 µm vessels, but not in EXT mice (Fig BC). Skin HS concentration and sulfation patterns were equal between diets in WT mice (Fig DE). On NSD, EXT mice had more highly sulfated HS compared to WT (Fig DE). EXT mice on a HSD had the highest skin HS concentration, of which most were low-sulfated.

Conclusions: An intact ESL is pivotal to prevent a BP increase during acute NaCl excess. Skin GAGs may be particularly important to prevent detrimental NaCl effects on the long-term, especially when the ESL is damaged by NaCl exposure.

Functional and Dynamic Microcompartmentation of Cav-1/TRPV4/KCa Channels in Caveolae of Endothelial Cells
Andreas Hofmeister, Sybelle Goedicke-Fritz, Anuradha Kaistha, Ivica Grbic, Joachim Hoyer. Dept of Internal Medicine and Nephrology, Philipps-Univ Marburg, Marburg, Germany.

Background: Cav-1 activated K+ channels (Kv channels) play an important role in the endothelium-dependent hyperpolarization and regulation of vascular tone and blood pressure. For activation, Kv needs to colocalize with Cav-1 in caveolae. In endothelial cells under static condition. Mechanical stimulation of cells via exposure to shear stress led to a partial de-novo colocalization of K Cav-3.1 with Cav-1 and TRPV4. It has been proposed that Kv channels and Cav-1 form functional units and may affect blood pressure. We show that TRPV4 and small-conductance K Cav-2.3 are enriched in caveolae of human microvascular endothelial cells. Using immunoprecipitation, immunocytochemistry and superresolution microscopy, we found a caveolae-dependent association between Cav-1, TRPV4 and small conductance K Cav-2.3, but not intermediate conductance K Cav-3.1, in endothelial cells under static condition. Mechanical stimulation of cells via exposure to shear stress led to a partial de-novo colocalization of K Cav-3.1 with Cav-1 and TRPV4. In a mouse model of genetic Cav-1 deficiency, we found significantly reduced K Cav-3.1-mediated currents as determined by patch-clamping in carotid artery endothelial cells (CAEC). We conclude that Cav-1^-/- mice compared to wildtype. Functionally, Cav-1^-/- mice were less responsive to shear stress and acetylcholine.

Adenosine A1 Receptor Exacerbates Water-Sodium Retention in Deoxycorticosterone Acetate-Salt Hypertensive Mice

Janet Yanying Mei,1 Xiaoxiao Shi,1 Dongli Tian,1 Xiaoayong Peng,1 Wei Chen,2 Limeng Chen.1

1Nephrology Dept, Peking Union Medical College Hospital, Beijing, China; 2Cardiology Dept, Peking Union Medical College Hospital, Beijing, China.

Background: Water-sodium retention is the key change in salt sensitive hypertension. Adenosine A1 receptor (A1AR) engages in tubuloglomerular feedback; its activation is followed by increased secretion of atrial natriuretic peptides (ANP) in the heart. We aim to study the function of A1AR in water-sodium retention.

Methods: DOCA-salt hypertensive model was established by removal of left kidney, implantation of a DOCA pellet (200mg, 60-day release), and feeding with high salt diet (8%NaCl). Arterial blood pressure and heart rate were measured by tail-cuff method. Urine samples were collected using metabolic cage. The CD73 (an adenosine synthetase), A1AR, ANP and Corin (a protease cleaves pro-ANP, producing ANP) mRNA expression were measured by real-time PCR.

Results: Wildtype DOCA-salt mice showed higher blood pressure (124.7±20.3 vs. 105.8±14.1 mmHg, P<0.01), slower heart rate (562.0±90.8 vs. 681.5±90.1, P<0.01), and increase in 24h urine output (3606.0±2359 vs. 1399±752 ml, P<0.001). The adenosine pathway was activated in DOCA-salt mice evidenced by increased CD73 (2.22 and 17.7 times increased expression in kidney and heart, P<0.034 and 0.001) and A1AR expression (2.54 and 11.12 times increased expression in kidney and heart, P=0.032 and 0.009). The cardiac mRNA expression of ANP and Corin were also significantly higher in DOCA-salt mice (176.67 and 30.93 times increased expression, P=0.030 and 0.005). The A1AR+ mice showed no significant changes in blood pressure or heart rate between DOCA-salt and sham group. The elevation in 24h urine output (7003±3742 vs. 3606±2359 ml, P=0.031) and 24h sodium excretion (1464.5±860.0 vs. 1479.7±48.9 mmol/d, P=0.028) was more prominent compared to wildtype DOCA-salt mice. There was no change in either ANP or Corin mRNA expression.

Conclusions: A1AR may exacerbate water-sodium retention in salt sensitive hypertension. The reduction in glomerular hyperperfusion and hyperfiltration through tubuloglomerular feedback possibly outweighs the up-regulation of Corin and subsequent ANP expression.

FR-PO123

Dietary Fructose Increases Renal Sympathetic Nerve Activity in Response to High Salt Diet in Awake Freely Moving Rats

Noreen F. Rosal,1,2 Kevin L. Gordish,3 Pablo A. Ortiz,4 William H. Beierwaltes.3

1Physiology, Wayne State University of Medicine, Detroit, MI; 2Nephrology, John D. Dingell VA Medical Center, Detroit, MI; 3Hypertension Research, Henry Ford Health Systems, Detroit, MI.

Background: High consumption of fructose containing foods is increasingly prevalent. Fructose is associated with metabolic syndrome including hypertension. Fructose upregulates renal Na and Cl transport and induces neuroexocytosis, both of which may increase blood pressure. Here we tested the hypothesis that fructose-fed rats fed a high salt diet will have higher plasma renin activity (PRA), renal sympathetic nerve activity (RSNA) and mean arterial pressure (MAP) than glucose-fed rats on similar diet.

Methods: Male Sprague Dawley rats were instrumented for telemetric MAP and RSNA measurements. They were placed on 20% glucose (GF) or 20% fructose (FF) in their drinking water and 0.4% NaCl diet for 10 days then switched to 4% NaCl diet with further monitoring. RSNA recordings were obtained using LabChart 7 Pro. Rats were also subjected to air jet stress and nasopharyngeal reflex testing.

Results: Baseline integrated RSNA did not differ between GF and FF rats. RSNA decreased in GF rats to 0.961 ± 0.182 mV/sec after high salt diet. In contrast, integrated RSNA increased from 1.199 ± 0.245 to 1.600 ± 0.231 mV/sec after high salt intake in FF rats (P < 0.05). Air jet stress and nasopharyngeal reflex responses in MAP and RSNA in GF rats were as expected and brief but in FF rats both responses were significantly greater and sustained for a longer period of time. High salt suppressed. PRA by only 40% in FF rats: 2.05 ± 0.27g Ang I/ml/hr (high salt) vs 3.48 ± 0.45 ng Ang I/ml/hr (baseline; P < 0.05).

Conclusions: We found that the expected suppression of RSNA by high salt diet is completely reversed into stimulation with high fructose diet. The suppression of PRA by high salt diet is blunted and the response to acute stressors enhanced, thus suggesting increased RSNA is a critical component of fructose-induced salt-sensitive hypertension.

Funding: NIDDK Support, Veterans Administration Support
Results: At baseline systolic BP were similar in CNTF-KO and WT mice (119±2 vs.124±1 mmHg). CNTF deficiency significantly attenuated BP increase under Ang II infusion (week 1: 139±3 vs. 153±3 mmHg; week 2: 151±5 vs. 168±4 mmHg; n=19; P<0.01). Strikingly, in the CNTF-KO group significantly less animals died of cardiovascular causes (4.2% (KO)) vs. 29.2% (WT) P<0.05). In accordance, end organ damage (cardiac hypertrophy, renal vascular fibrosis and tubulo-interstitial damage) was attenuated in the CNTF-KO group. In the isolated perfused kidney, pressor response to Ang II was significantly attenuated in CNTF-KO mice. Administration of CNTF (0.5nM) nearly restored the Ang II dependent pressor response. This effect was mediated through a JAK2/STAT3 dependent pathway as static (0.1µM), a selective STAT3 inhibitor abolished the CNTF induced increase in pressor response in kidneys of CNTF-KO. On cellular basis, CNTF induced phosphorylation of STAT3 and MYPT in VSMCs.

Conclusions: Better survival and less end organ damage strongly suggest that CNTF has a major impact on blood pressure regulation. CNTF seems to modulate the Ang II induced vasoactivity via a JAK2 / STAT3 dependent mechanism. Thus, CNTF might qualify as therapeutic target in hypertension.

Funding: Government Support - Non-U.S.

FR-PO127
Angiotensin II AT1 Receptor Potentiates Prostaglandin E2 Vasconstrictor Effects Maria Palazzo Kraemer, Fred S. Lamb, Richard M. Breyer. 1

Background: Prostaglandin E2 (PGE2) is a key modulator of blood pressure and arterial tone. It usually has vasodepressor effects however under certain circumstances can act as a vasoconstrictr. Recent reports have articulated that sub-threshold concentrations of KC1 and phenylephrine augment PGE2-mediated constriction in rat femoral arteries, however the effects of angiotensin II (Ang II) on PGE2-mediated contraction are unknown.

Methods: Wire myography was performed on femoral arteries isolated from WT or EP deficient mice. Ang II had no effect on mouse femoral arteries at doses up to 1 µM. Pretreatment of arterial rings with 1 nM Ang II potentiated PGE2-evoked constriction in a dose dependent manner (AUCmax: 1.78±0.33, AUCMax 22.27±9.820, P<0.05). To identify the relevant E-Prostanoid (EP) receptor, femoral arteries from EP1, EP2, and EP3 receptor null mice were tested. Arteries isolated from EP1- and EP2- but not EP3- mice responded to PGE2 after Ang II priming. Pretreatment of arterial rings with 1 µM losartan, an AT1 angiotensin receptor antagonist, blocked PGE2-induced constriction in both WT and EP deficient mice.

Results: PGE2 had no effect on mouse femoral arteries at doses up to 1 µM. Pretreatment of arterial rings with 1 nM losartan, an AT1 angiotensin receptor antagonist, blocked PGE2-induced constriction in both WT and EP deficient mice.

Conclusions: The renin-angiotensin system plays a key role in the maintenance of cardiovascular and renal homeostasis, primarily via appropriate activation of the angiotensin II type 1 receptor (AT1R). On the other hand, exaggerated activation of AT1R signaling would exert detrimental effects, such as various aging-related diseases including renal dysfunction. We previously identified an AT1R-associated protein (ATRAP/Agrap), which is a molecule directly interacting with the AT1R. The accumulating results indicate that ATRAP exerts functionally selective inhibition on exacerbated AT1R activation in response to pathological stimuli. The present study was performed to investigate pathophysiological significance of ATRAP in aging-related phenotypes by employing systemic ATRAP-knockout mice (ATRAP-KO mice).

Methods: ATRAP-KO mice and their wild-type control mice (WT mice) were fed the standard diet and maintained until death to estimate their life spans. Their growth (body weight change and appearance) and physiological parameters (blood pressure, cardiac index, water and lipid metabolism) were also analyzed. Furthermore, aging-related organ damages in the hearts, aortas and kidneys were examined in young (3 to 4 months old) and aged (22 to 25 months old) mice in both groups.

Results: There was no difference in the growth between two groups. In addition, ATRAP-KO mice and their controls did not show any evident difference in terms of physiology, aging-related orgaion damages, and glucose and lipid metabolism. Furthermore, aging-related organ damages in the hearts, aortas and kidneys were examined in young (3 to 4 months old) and aged (22 to 25 months old) mice in both groups.

Conclusions: In the present study, ATRAP-KO mice showed accelerated renal fibrosis with shortened life span. Therefore, ATRAP deficiency seems to exacerbate the aging-related renal fibrosis and to inhibit the longevity.

FR-PO130
Effects of Deficiency of Angiotensin Receptor-Binding Molecule on Blood Pressure Regulation in Chronic Kidney Disease Ryu Kobayashi, Kouchi Tamura, Hiromichi Wakui, Akinoibou Maeda, Kengo Azushima, Sona Hak, Ryu Kobayashi, Masato Ohsawa, Yoshitoyo Toya, Satoshi Umemura. Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.

Background: The renin-angiotensin system plays a key role in the maintenance of cardiovascular and renal homeostasis, primarily via appropriate activation of Ang II type 1 receptor (AT1R). On the other hand, exaggerated activation of AT1R signaling would exert detrimental effects, such as promoting various aging-related diseases including chronic kidney disease (CKD). We previously identified an AT1R-associated protein (ATRAP/Agrap), which is a molecule directly interacting with the AT1R. Accumulating results indicate that ATRAP exerts functionally selective inhibition on exacerbated AT1R activation in response to pathological stimuli. The present study was performed to investigate pathophysiological significance of ATRAP in aging-related phenotypes by employing systemic ATRAP-knockout mice (ATRAP-KO mice).

Methods: ATRAP-KO mice and their wild-type control mice (WT mice) were subjected to 5/6 nephrectomy (Nx) as CKD model. To examine the effects of ATRAP deficiency, blood pressure and other parameters were measured in ATRAP-KO mice and WT mice after 5/6 Nx.

Results: At baseline, blood pressure was similar in ATRAP-KO and WT mice. In ATRAP-KO mice, blood pressure increased from 2 to 8 weeks after 5/6 Nx and was significantly higher than that in WT mice (ATRAP-KO vs WT; systolic blood pressure at 4 weeks after 5/6 Nx, 124±2 mmHg vs 107±1mmHg, P<0.01). With respect to the mechanism of elevated blood pressure in ATRAP-KO mice after 5/6 Nx, plasma volume was significantly higher in ATRAP-KO mice than in WT mice after 5/6 Nx, in spite of no significant difference in creatinine clearance between two groups after 5/6 Nx.

Conclusions: Although ATRAP-KO mice show similar blood pressure and renal function with WT mice in normal condition, ATRAP-KO mice exhibited significantly
increased blood pressure and plasma volume after 5/6 Nx compared with WT mice. Therefore, endogenous ATRAP may exert a protective function against pathological blood pressure elevation in CKD.

FR-PO131
In Vivo Action of Angiotensin II Type 1a Receptor in Renal Injury Induced by Deoxycorticosterone Acetate-Salt Hypertension: Mikako Hisamichi,1 Atsuko Remori,1,2 Takeshi Sugaya,1 Daisuke Ichikawa,1 Kenjiro Kimura,1 Yugo Shibagaki,11 Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: The AT1a receptor plays a major role in the renal action of Ang II and is expressed in vascular smooth muscle cells of the afferent arterioles. In this study, we investigated the morphological change in deoxycorticosterone acetate (DOCA)-salt hypertensive rats and confirmed the in vivo function of the AT1a receptor against renal damage due to hypertension.

Methods: To examine urinary L-type fatty acid binding protein (L-FABP) as an indicator of tubulointerstitial damage, we used both L-FABP clearance studies and phase contrast MRI to confirm the in vivo function of the AT1a receptor against renal damage due to hypertension.

Results: In the DOCA salt hypertensive model with L-FABP+/- AT1a +/+ (DOCA), slight expansion of the glomerular area and tubulointerstitial damage were observed, but no glomerular sclerosis. In the AT1a knockout mice administered DOCA-salt (L-FABP+/- AT1a -/- DOCA mice), glomerular sclerosis with expansion of the mesangial area was found, and the degree of tubulointerstitial damage was more severe compared to L-FABP+/- AT1a +/+ DOCA mice. L-FABP+/- AT1a +/+ DOCA mice and L-FABP+/- AT1a -/- DOCA mice. This renal damage induced in the L-FABP+/- AT1a -/- DOCA mice was significantly attenuated by reduction of blood pressure using Hydralazine. Activation of the AT1a receptor may contribute to myogenic response of the afferent arteriole involved in the renal autoregulatory mechanism.

Conclusions: In conclusion, kidneys without AT1a receptors exhibited an increased vulnerability to hypertension, and therefore activation of the AT1a receptor inhibited the transmission of the elevated systemic pressures to the glomeruli.

FR-PO132
Renal Blood Flow and Oxygenation During Renin-Angiotensin-Aldosterone System Activation – Two Sides of the Same Coin? Rene van der Bel,1 Aart J. Nederveen,2 Bram F. Coolen,2 Wouter V. Potters,2 Hein J. Verberne,2 Lütfett Vogt,1 Erik Stroes,1 C.T.P. (Paul) Krediet,1 Internal Medicine, AMC, Univ of Amsterdam, Netherlands; 2Radiology, AMC, Univ of Amsterdam, Netherlands.

Background: In chronic kidney disease, renal hypoxia and renin-angiotensin-aldosterone system (RAAS) activation may augment each other. Although renal oxygenation (RO) measured by Blood Oxygen Level Dependent (BOLD) MRI is not correlated to Glomerular Filtration Rate (GFR), recent data suggest that RO relates to inter-individual variation of RAAS activity. Further explore this we measured the effects of Angiotensin II (Ang-II) on renal blood flow (RBF) and RO in healthy subjects.

Methods: After a 30 min baseline phase, 8 healthy volunteers (age 19-22 years) were subjected to continuous Ang-II infusion at 0.3, 0.9 and 3.0 ng/kg/min for 12 minutes per dose. RO and RBF were assessed by BOLD and phase contrast MRI, respectively (Ingenia, 3.0T, Philips Healthcare). Off-line, R2* values were calculated for cortex and medulla, on mono-exponential fitting to multi-echo 2-dimensional fast-field-echo data (TR 140 ms; FA 70°; TE 2 ms; DTE 5 ms; 16 echoes; voxel 1.2 mm² by 4 mm). RBF was calculated in the proximal renal artery after manual vessel segmentation. During a second visit (n=6), GFR and Effective Renal Plasma Flow (ERPF) were measured by 133mTechnetium Tc 99m-HMPAO (Tc-99m-HMPAO) renal scintigraphy.

Results: Mean arterial blood pressure increased from 83.0±2.85 at baseline to 91.3±3.76 mmHg (p<0.002). RBF decreased dose dependently from 11.1±2.08 to 8.05±1.02 (p=0.02) ml/min/100g tissue. GFR and ERPF both decreased (10±7.1%, p=0.016; 24±4.5%, p<0.001). RBF and ERPF measurements strongly correlated (R=0.75, p<0.001). There was a trend towards a cortical R2* increase of 7.2±5.37% (p=0.041); medullar R2* did not change. Cortical DPP-4 and DRBF inversely correlated (R=0.42, p=0.044). Cortical DPP-4 and AGFR correlated (R=0.48, p=0.017).

Conclusions: Ang-II causes a dose dependent DRBF. The observed DRO seem to differ between cortex and medulla. Only for the cortex BOLD may provide an index of tissue perfusion.

FR-PO133
Chloride Contributes to Hypertension and Renal Injury in Aldosterone-Salt Treated Rats: Takahiro Yamauchi, Shigehiro Doi, Toshihiko Doi, Kensei Sasaki, Toshinori Ueno, Ayunami Nakashima, Takao Masaki. Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

Background: Aldosterone-salt treatment is known to induce renal inflammation and platelet aggregation. Hypertension is a development of these changes as well as elevated EMT markers. In addition to sodium, chloride has recently been reportedly to be involved in renal damage, raising the possibility that sodium-bicarbonate may ameliorate renal injury and hypertension in aldosterone-salt treated rats. Further, the aldosterone-salt group compared with the NaHCO3-aldo-salt group, 1) drinking 1% NaCl solution with aldosterone infusion (NaCl-aldosterone treated group), 2) drinking 1% NaHCO3 solution with aldosterone infusion (NaHCO3-aldosterone treated group), and 3) drinking water with vehicle infusion. Blood pressure levels were measured at -70°; min TE 2 ms; DTE 5 ms; 16 echoes; voxel 1.2 mm² by 4 mm). RBF was calculated in the proximal renal artery after manual vessel segmentation. During a second visit (n=6), GFR and Effective Renal Plasma Flow (ERPF) were measured by 133mTechnetium Tc 99m-HMPAO (Tc-99m-HMPAO) renal scintigraphy.

Results: In the NaCl-aldosterone group had higher blood pressure levels than the NaHCO3-aldosterone group. Protein expression of eNOS and PdGf in the membrane fraction was also increased in the NaCl-aldosterone group compared with the NaHCO3-aldosterone group. In addition, the NaCl-aldosterone group had high protein levels of NCC and phosphorylated NCC in the whole protein and membrane fractions. On the other hand, the expression of inflammatory (C3D, CD68, IL17A, IL-23 receptor) and fibrotic markers (α-smooth muscle actin, collagen I) were greater in the NaCl-aldosterone group.

Conclusions: These findings suggest that chloride plays an important role in the development of NaCl-aldosterone-induced hypertension and renal injury.

FR-PO134
RAGE-DNA Aptamer Improves Aldosterone-Induced Renal Injury Possibly via Inhibition of Rac1-MR Axis in Mice with Hypertensive Nephropathy: Kensei Taquchi,1 Sho-ichi Yamagishi,1 Yuichi Higashimoto,2 Yosuke Nakayama,1 Katsuhiko Asanuma,2 Seiji Ueda,1 Kei Fukami.1 Div of Nephrology; Dept of Medicine; 2Dept of Pathophysiology and Therapeutics of Diabetic Vascular Complications; Dept of Chemistry, Kurume Univ School of Medicine, Kurume, Japan; 3Div of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

Background: Advanced glycation endproducts (AGEs) stimulate the generation of reactive oxygen species (ROS) and subsequently enhance various intracellular pathways through the interaction with receptor for AGEs (RAGE). Although AGEs-RAGE axis has been mainly investigated in diabetic nephropathy, its pathophysiological role in hypertensive nephropathy (HN) is unknown. In addition, recent evidence has suggested that aldosterone (aldo)-mineralocorticoid receptor (MR) system plays a crucial role for the pathogenesis of HN. In this study, we examined whether AGEs-RAGE system could interact with aldo-MR axis in deoxycorticosterone acetate (DOCA)-induced HN in mice. Further, we explored the inhibitory effects of DNA-aptamer directed against RAGE (RAGE-aptamer) on aldosterone-induced renal injury in HN. Methods: Uninephrectomized 8-week-old C57Bl6/J male mice were divided into three groups; 4% salt diet (control), 4% salt diet with DOCA (50mg), and DOCA with hydralazine (Hyd). RAGE-aptamer constructed by SELEX method was continuously administrated with osmotic mini pump.

Results: DOCA elicited-UAE was independent of blood pressure. Renal ROS generation, RAGE protein expression and plasma carboxymethyl lysine (CML) levels were elevated in DOCA/salt mice. RAGE was co-localized MR in podocytes by immunohistochemical analysis. Further, RAGE-bound Rac1 activation and MR overexpression were observed in DOCA/salt mice. DOCA-elicited increase in UAE, renal ROS generation and RAGE expression, plasma CML levels were improved by RAGE-aptamer independent of blood pressure. Interestingly, RAGE-aptamer suppressed GTP-bound Rac1 activity and MR overexpression in DOCA/salt mice.

Conclusions: AGEs-RAGE axis and Rac1-MR pathway could be correlated with each other, which could lead to podocyte injury in HN. RAGE-aptamer may be a novel therapeutic strategy for the progression of HN.

FR-PO135
Dipeptidyl Peptidase-4 Inhibitor Ameliorates the Aldosterone-Induced Renal Fibrosis: Kang-Yung Peng, Vincent Wu. Dept of Internal Medicine, National Taiwan Univ, Taipei, Taiwan.

Background: Renal fibrosis is considered a common outcome of a wide variety of chronic kidney diseases with diverse causes. However, no antifibrotic agent has been approved in clinical practice yet. In this study, we examined the effect of dipeptidyl peptidase-4 (DPP-4) inhibitor on aldosterone-induced fibrosis by aldosterone.

Methods: Human proximal tubular epithelial cells (HK2) were used to examine the inhibitory effect of DPP-4 inhibitor on aldosterone induced epithelial-mesenchymal transition (EMT). Besides, aldosterone infusion mice were used to evaluate the effect of DPP-4 inhibitor, linagliptin, on aldosterone induced renal fibrosis. Expression of TGF-β, OPN and molecules involved in EMT were examined using western blot and immunohistochemistry. Renal fibrosis was determined by Masson's trichrome staining.

Results: In vitro studies showed that aldosterone significantly increases the expression of TGF-β, OPN and markers of EMT in HK2 cells, while these effects were abolished in that treated with DPP-4 inhibitor. Similarly, the aldosterone-infused mice exhibited severe kidney fibrosis. The expression of TGF-β, OPN, vimentin and α-SMA were induced by aldosterone, and oral DPP-4 inhibitor ameliorated the kidney fibrosis and lessened the increase in fibrotic proteins without significant changes in blood pressures.

G-Protein-Coupled Receptor 40 Mediates the Regulation of Epithelial Sodium Channel by Epoxyeicosatrienoic Acid Signaling

*Seoong Kwon Ma, Ha Yeon Kim, Chang Seong Kim, Eun Hui Bae, Soo Wan Kim.* Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea.

**Background:** Epoxyeicosatrienoic acid (EET) plays diverse functions including cellular proliferation, anti-inflammation and vasorelaxation. Although it has been demonstrated that EET also regulate epithelial sodium channel (ENaC), the potential functional receptor mediating the biological effect of EET has remained elusive. In the present study, we investigated the role of GPR40 mediating ENaC regulation of EET in mouse cortical collecting duct (M1-CCD) cell line.

**Methods:** M1-CCD cells were cultured with aldosterone in the absence or presence of 14,15-EET. In addition, M1-CCD cells treated with aldosterone were cultured in the absence or presence of GW9110, a GPR40 antagonist.

**Results:** The mRNA and protein of ENaC-a and GPR40 were endogenously expressed in the M1-CCD cells as well as the cortical collecting ducts of murine kidney. Treatment with aldosterone increased the protein expression of ENaC-a and mineralocorticoid receptor (MR). These changes were abolished by 14,15-EET treatment, and treatment with 14,15-EET increased the phosphorylation of ERK1/2. Inhibition of GPR40 by treatment with GW9110 enhanced the aldosterone-induced upregulation of ENaC-a and MR, while decreased ERK1/2 phosphorylation.

**Conclusions:** In conclusion, EET inhibits aldosterone-induced ENaC activation by the inhibition of MR and activation of ERK1/2. GPR40 inhibition augmented the aldosterone-induced ENaC activation by the activation of MR and inhibition of ERK1/2. These findings suggest that GPR40 mediate the ENaC regulation by EET signaling.

The Extra Renal Effect of Hydrochlorothiazide on Systemic Blood Pressure: Role of Vasodilation in Volume Depleted States

*Jocelyn, Sung Yoon Park, Min Jeong, Sharon L. Barone, Jie Xu, Kamyar A. Zahedi.* 1Internal Medicine, Univ of Cincinnati, Cincinnati, OH; 2Internal Medicine, Univ of Cincinnati, Cincinnati, OH; 3Research Services at Plato, 2Denise L. Schwabauer, 2Peter J. Greasley. 1Internal Medicine, 2Plato Biopharma Inc., Denver, CO.

**Background:** Thiazides are specific inhibitors of the Na⁺-Cl⁻ cotransporter (NCC) in the distal nephron, and the most commonly used diuretics for the treatment of mild arterial hypertension, vascular stiffness, vasoconstrictor and endothelium-dependent and independent vascular dysfunction. Thiazides are at increased risk of hypotension and kidney hypoperfusion subsequent to systemic vasodilatation by HCTZ.

**Methods:** Methods: Balance studies were performed in age/sex-matched wild type and NCC deficient mice. The blood pressure was measured using computerized tail cuff method. Cardiac functions were analyzed by echocardiography.

**Results:** Hydrochlorothiazide (HCTZ) significantly reduces systemic blood pressure when NCC KO mice are volume-depleted and their renin-angiotensin system (RAS) is activated, however, it had no effect on blood pressure of salt replete NCC KO mice. The reduction in blood pressure in salt depleted animals was dramatic, happened within hours after HCTZ and occurred in the absence of any increase in salt excretion, indicating its extra-renal origin. Echocardiography showed no significant changes in cardiac output in response to HCTZ. The antihypertensive effects of HCTZ were abrogated in the presence of a blocker of large conductance Ca++-activated K+ (BK) channels, Paxilline. Western blots demonstrated significant enhancement of BK expression in vascular system of salt depleted, NCC-deficient mice.

**Conclusions:** Our results indicate that vasocostriction secondary to RAS activation amplifies the extra-renal hypotensive action of HCTZ through vasodilatation irrespective of the status of its renal target. Patients on a combination diuretic regimen such as furosemide and HCTZ are at increased risk of hypotenston and kidney hypoperfusion subsequent to systemic vasodilatation by HCTZ.

Mitochondrial Oxidative Stress-Activated Renal Local RAS Promotes the Expression and Function of NCC in Proteinuric Kidney Disease

*Songming Huang, 1,2 Yibo Zhuang, 1 Guixia Ding, 1 Zhanjun Jia, 1,2 Aihua Zhang, 1,2* Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, China; *Nanjing Key Laboratory of Pediatrics.*

**Background:** The fluid retention and hypotenston are common complications of kidney diseases, whose pathogenic mechanisms remain elusive.

**Methods:** Kidney tissues from mice subjected to albumin overload via i.p injection for 12 days and renal biopsy specimens were analyzed.

**Results:** Following albumin overload, we found a striking increase of Na⁺-Ci cotransporter (NCC) expression by 2.3-fold in mouse kidneys determined by Western blotting and qRT-PCR. To evaluate NCC function in these mice, NCC inhibitor hydrochlorothiazide (10mg/kg) was administered via a single i.p injection. In agreement with NCC upregulation, the response to hydrochlorothiazide was significantly enhanced in albumin overloaded mice. Considering the established role of renin-angiotensin system (RAS) in regulating sodium transporters, we examined key components of RAS and found a striking elevation of angiotensinogen (AGT) and angiotensin converting enzyme (ACE) by 2-3 folds in line with enhanced urinary AngII excretion. In proteinuric mice, we also observed 4-fold upregulation of NCC and remarkable stimulation of ACE detected by immunohistochemistry in accord with significantly increased urinary Ang II output. To further investigate the role of RAS in NCC upregulation, we did primary culture of renal tubular cells and observed that albumin directly increased NCC paralleled with significant induction of AGT, ACE, and Ang II. Strikingly, administration of specific ACE inhibitor captopril to the cells remarkably abolished albumin-induced enhancement of NCC and RAS components. Additionally, albumin overload significantly reduced superoxide dismutase (SOD2) by 60%, and administration of a SOD2 mimic (MnTBAP) entirely abolished the stimulation of NCC; AGT, and ACE in mice with albumin overload.

**Conclusions:** The findings demonstrated an important role of albuminuria in upregulating NCC expression in a mitochondrial oxidative stress-initiated stimulation of renal local AGT/ACE/AngII, which may contribute to the fluid retention and hypertension in proteinuric kidney disease to some extent.

Prophylactic and Therapeutic Tenapanor Are Vascular Protective in a Rat Model of CKD

*AstraZeneca R&D, Malmö, Sweden; 1Plato Biopharma Inc., Denver, CO.*

**Background:** Tenapanor (AZD1722), an inhibitor of the Na⁺-H⁺ exchanger NHE3, reduces absorption of gut sodium and phosphate. It is being developed for renal and congestive-related indications.

**Methods:** 6/6 nephrectomized Sprague Dawley rats were fed 4% NaCl chow to induce salt-sensitive arterial hypertension. Oral tenapanor (1 mg/kg/day) was initiated either at the start of NaCl intake (prophylactic; Px) or 2 weeks later (therapeutic; Tx), and was administered for up to 6 weeks. Disease controls (DCs; vehicle-treated) and healthy controls (HCs; sham operated, normal chow) were included to enable assessment of disease progression. Systemic hemodynamics and urinary and plasma biomarkers were assessed every 2 weeks. Ex vivo vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated at 2 and 6 weeks. Ex vivo vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated at 2 and 6 weeks.

**Results:** Compared with DCs, rats in the Px and Tx groups had reduced urinary albumin, sodium and phosphorus excretion (p<0.05), and looser stools. Systolic, diastolic and mean BP increased in DCs but were normalized in the Tx group. Disease controls (DCs; vehicle-treated) and healthy controls (HCs; sham operated, normal chow) were included to enable assessment of disease progression. Systemic hemodynamics and urinary and plasma biomarkers were assessed every 2 weeks. Ex vivo vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated at 2 and 6 weeks.

**Conclusions:** Tenapanor reduced absorption of gut sodium and phosphate. It is being developed for renal and congestive-related indications.

Urinary Exosome Profiling in Thiazide Induced Hyponatremia
Sarah Kiran Channavajhala, Theresa Peltz, Wenjing Jia, Ian Hall, Kevin O’Shaughnessy, Matthew A. Bailey, James W. Dear, Mark Glover. 1 Div of Therapeutics and Molecular Medicine, Univ of Nottingham, United Kingdom; 2Clinical Pharmacology Unit, Univ of Cambridge, United Kingdom; 3Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom.

Background: Thiazides are one of the most widely used and cost-effective class of anti-hypertensive medication. Thiazide-Induced Hyponatremia (TIH) is one of their major adverse effects and the leading cause of drug-induced hyponatremia requiring hospitalization. A priori TIH must result from excessive saliuresis and/or water reabsorption. The water and electrolyte transporter composition of urinary exosomes (UE) reflects their cellular origin and are a promising way to study renal dysfunction. This study assessed the expression of AQP2 and NCC in the UE of TIH patients.

Methods: 100 patients admitted to hospital with severe TIH donated urine samples during acute TIH and at 2 months post TIH cessation. Matched normotensive controls were recruited both on and off thiazides (groups 1 & 2 respectively). UE from a representative sample of each patient group were isolated and AQP2 and NCC were evaluated by Western blotting and Nanoparticle Tracking Analysis (NTA). AQP2 and NCC expression was normalized by urinary creatinine. Immunoblots were also corrected for total protein and results expressed as units of optical density/Ucr.

Results: Westerns showed that UE expression of AQP2 was higher in cases during acute TIH compared to convalescent (32.93 vs 28.71, P=0.01) and compared to control groups 1 & 2 (15.61 and 15.09 respectively, P=0.001). NCC expression was lower in TIH patients acutely compared to convalescent (17.72 vs 31.86, P=0.03) and compared to both control groups (30.32 and 31.17, P=0.05). NTA also demonstrated increased AQP2 expression in acute & convalescent UE.

Conclusions: This study highlights the utility of UE analysis to probe the molecular pathophysiology of TIH. Increased AQP2 and reduced NCC expression suggests that TIH results from increased water reabsorption and sodium wasting in the distal nephron. TIH studies may further understand of renal physiology and inform the design of new thiazide medicines less prone to cause hyponatremia. Funding: Government Support - Non-U.S.

Epigenetic Modulation of Renal Arterioles Induced by DOCA-Salt Loading in Mice
Hiroki Snap, Kazutoshi Miyashita, Masaaki Sato, Kentaro Fujii, Aika Hagiwara, Masanori Tamaki, Hiroshi Itoh. Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.

Background: The relationship between salt intake and development of hypertension is familiar; however, the mechanism for the onset has not been fully revealed. Our previous report showed that the medial hypertrophy of renal arterioles after transient salt loading in spontaneous hypertensive rat caused lasting elevation in blood pressure. The present study investigated the significance of epigenetic modulation of the gene expressions which are relevant to the medial hypertrophy after transient salt loading.

Methods: Male 6 week old C57B6 mice were implanted deoxycorticosterone acetate (DOCA) pellets and given drinking water containing 1% NaCl for 2 weeks for generation of salt-induced hypertension. The blood pressure was measured by a tail-cuff method during and after the transient salt loading. Histological examinations of the kidneys were performed during and after the salt loading. Gene expressions in the kidney such as matrix metalloproteinases (MMPs), which promote the medial hypertrophy, were quantified. Epigenetic modulation of the genes were analyzed.

Results: Transient salt loading caused elevation in blood pressure during the loading period. Blood pressure after stopping salt-loading was also significantly higher than that before salt loading. Salt loading caused medial hypertrophy of renal arterioles, and it remained after stopping salt loading, as to cause lasting renin elevation. Real time PCR revealed that MMP2 and MMP9 were increased during the salt loading. CNGN5, CHP and p300, which are histone acetyltransferases, were elevated. Sir1, Sir3, HDAc1 and HDAc3, which are histone deacetylases, were decreased. Histone H3K9 and H4K16 acetylations in the MMP2 gene were enhanced by the salt loading.

Conclusions: The lasting medial hypertrophy and renin elevation after transient salt loading were suggested to be caused by the increased expression of MMPs along with augmented histone acetylations by the salt loading. Increased expressions of acetyltransferases along with decreased expressions of Sirs and HDAcs by transient salt loading would be involved in the enhancement of the histone acetylations.

Radio-Frequency Catheter-Based Renal Denervation in Hypertensive Sheep with Chronic Kidney Disease Impairs Responses to Hemorrhage
Reetu R. Singh,1 Karen M. Moritz,2 Kate M. Denton. 1Physiology, Monash Univ; Clayton, VIC, Australia; 2School of Biomedical Sciences, The Univ of Queensland, St. Lucia, QLD, Australia.

Background: Renal sympathetic nerves medulate kidney function and blood pressure (BP). Trials using catheter-based renal denervation (cDXN) in hypertensive patients yielded results both in support of and, against its efficacy in lowering BP. A critical question is whether cDXN has adverse consequences, in situations of clinical challenge, such as hemorrhage in denervated patients where intact nerves would be required. This study examined consequences of cDXN 1) on BP and renal function and 2) on reflex activation of sympathetic nerve activity (SNA) in hypertensive sheep with chronic kidney disease (CKD).

Methods: Sheep with established hypertension and renal dysfunction (CKD group) with an appropriate control group were used. At 10 months of age, some animals underwent cDXN (CKD-cDXN) and control-cDXN while the remaining underwent sham procedure (CKD-intact; control-intact). At 2 months post-cDXN, BP, renal function, and plasma renin activity (PRA) were assessed before, during and after hemorrhage (20% blood volume withdrawn over 15 minutes).

Results: CKD sheep had higher BP compared to all groups but CKD-cDXN sheep had similar BP to control sheep. Basal renal function was not further reduced. In response to hemorrhage, BP fell in all groups but the greatest decrease occurred in CKD-cDXN. In Control-intact sheep this fall in BP gradually recovered, associated with increase in PRA reflecting an increase in reflex SNA. In contrast, in Control-cDXN and CKD-cDXN groups, PRA did not increase and BP did not recover reflecting an absence of increase in reflex SNA.

Conclusions: cDXN effectively reduced BP at 2 months post-cDXN in previously hypertensive sheep but had no effect on renal function. However, the lack of reflex activation of neural mechanisms observed during hemorrhage suggest, that cDXN may impair a patient’s ability to adequately respond to physiological challenges. Interleukin-10 Mediates the Renoprotective Properties of Mesenchymal Stem Cells-Derived Extracellular Vesicles in Porcine Metabolic Syndrome and Renal Artery Stenosis
Alfonso Eirin,1 Xiang-yang Zhu,1 Christopher M. Ferguson,2 Scott Riester,3 Andre J. Van Wijnen,4 Amir Lerman,5 Lilach O. Lerman.1,3 Div of Nephrology and Hypertension, Mayo Clinic; 2Orthopedic Surgery, Mayo Clinic; 3Cardiovascular Diseases, Mayo Clinic, Rochester, MN.

Background: Mesenchymal stem/stromal cells (MSCs) are immunomodulatory and have unique potential to restore the renal microvasculature, but may generate safety concerns. MSC-derived extracellular vesicles (EVs) emerged as a novel non-cellular alternative. Using a swine model of metabolic syndrome (MetS) superimposed on renal artery stenosis (RAS) we tested whether intrarenal injection of EVs attenuates renal injury and if this capacity is mediated by their cargo of the anti-inflammatory cytokine IL-10.

Methods: MetS pigs were studied after 16 weeks of RAS untreated or treated 4 weeks earlier with a single intrarenal delivery of labeled EVs harvested from autologous MSCs (2.5x10^5/Kg) with or without pre-silenced IL-10 (IL-10 knock-down). Lean and MetS Sham served as controls (n=7 each). Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were studied in vivo, and microvascular architecture (micro-CT) and fibrosis ex vivo.

Results: EVs were detected in the stenotic-kidney 4 weeks after injection. RBF and GFR, which increased in MetS compared to Lean, fell in MetS-RAS, but improved in EV-treated pigs (Table). EVs also improved cortical microvascular density and renal fibrosis (Figure). Yet, these renoprotective effects were blunted in pigs treated with IL-10 depleted EVs.

Conclusions: Intrarenal delivery of MSC-EVs improves renal structure and function in chronic experimental MetS+RAS, partly mediated by their cargo of IL-10. These observations suggest that EV-based regenerative strategies might be useful for patients with MetS+RAS.

Role of Mitochondrial Dysfunction and ROS Production in Ang II-Induced NLRP3 Inflammasome Activation

Wen Yi, Liu Yiran, Tang Taoao, Bi-Cheng Liu. Inst of Nephrology, Southeast Univ, Nanjing, Jiangsu Province, China.

Background: The type 1 angiotensin (AT1) receptor plays an important role in maintaining blood pressure. Previous studies suggested that the activation of immune responses by angiotensin (Ang) II during hypertension may aggravate renal damage. NLRP3 inflammasome activation promotes renal inflammation and contributes to chronic kidney disease. Further investigation should be performed to explore the correlation between the RAS and NLRP3 inflammasome activation, and possible mechanisms.

Methods: C57BL/6 AT1R-/- and NLRP3-/- mice underwent left nephrectomy followed 1 week for recovery. Blood pressure measurements were recorded at baseline and following 4 weeks of chronic Ang II or saline infusion. At the end of the experiment, the kidney were harvested and fixed. AT1R sRNA and mitoTEMPO treatment were before performed after the Ang II stimulation in HK2 cells. The expression levels of NLRP3 inflammasome and mitochondrial dysfunction were measured.

Results: Ang II significantly induced kidney injury and NLRP3 inflammasome activation. Mitochondria swelling and fragmentation were observed by transmission electron microscope. AT1-/- blocked Ang II-induced hypertension, inhibiting the mitochondrial dysfunction and NLRP3 expression. Deficiency of NLRP3 attenuated kidney injury in hypertension with no significant influence to blood pressure. In vitro studies showed that Ang II stimulation increase the mitochondrial damage and NLRP3 activation in dose- and time- dependent manner. AT1R silence effectively blocked Ang II-induced damage. MitoTEMPO attenuated the activation of NLRP3 inflammasome through clearance of reactive oxygen species (ROS). Moreover, Ang II-induced mitochondrial dysfunction was markedly inhibited by silencing of NLRP3.

Conclusions: Ang II stimulation induces NLRP3 inflammasome activation through AT1a receptor. Ang II-induced NLRP3 activation is mediated by mitochondrial dysfunction, with overproduction and accumulation of ROS. NLRP3 inflammasome activation plays an important role in kidney injury, and blocking it can be a potential therapeutic target for hypertension-associated kidney damage.

The Endoplasmic Reticulum Stress Inhibitor 4-Phenylbutyric Acid Prevents the Development of Essential Hypertension in Young Spontaneously Hypertensive Rats

Safas Nasef,1 Chao Lu,2 Jeffrey G. Dickhout.1,2 Medicine, McMaster Univ, Hamilton, ON, Canada; 1St. Joseph’s Healthcare Hamilton, Hamilton, ON, Canada.

Background: Essential Hypertension is the leading global risk factor for premature death. This complex multifactorial disease has no known cause and has been shown to contribute to the progression of chronic kidney disease (CKD). Mechanistically both Endoplasmic Reticulum (ER) stress and the Unfolded Protein Response (UPR) have been implicated in the pathobiology of this disease. A small molecular chaperone, Endoplasmic Reticulum (ER) stress and the Unfolded Protein Response (UPR) have been implicated in the pathobiology of this disease. A small molecular chaperone, 4-phenylbutyric acid (4-PBA), is known to inhibit ER stress. In our previous studies, we found that 4-PBA is able to lower blood pressure in animal models of hypertension. It remains unclear however if ER stress is a cause of hypertension or a consequence.

Methods: Young spontaneously hypertensive rats (SHR) were used in this study and Wistar Kyoto (WKY) rats were used as its normotensive control. High blood pressure begins to develop in the young SHR at 4-weeks of age. Radio-telemetry transmitters (HE-X1 transmitter, Data Sciences International) were implanted to monitor blood pressure development, heart rate and ECG activity in both SHR and WKY. SHR and WKY were both randomized into 4-PBA (1 g/kg/day) or vehicle groups at 4-weeks of age to determine if ER stress inhibition would prevent the development of hypertension. Resistance vessels, such as mesenteric arteries and renal arteries were collected after 8 weeks and analyzed for specific ER stress markers using real-time polymerase chain reaction (RT-PCR).

Results: 4-PBA treatment significantly lowered systolic, diastolic and mean arterial pressures in the SHR rats, but not in the WKY rats. 4-PBA treatment also significantly attenuated pre-hypertensive tachycardia in the SHR. Additionally, 4-PBA significantly prevented the expression of UPR markers CHOP and GRP78 in SHR resistance blood vessels.

FR-PO146

Macrophage Endothelin-B Receptors Clear Endothelin-1 and Regulate Blood Pressure

Necerni Dhaun. Queen’s Medical Research Inst, University of Edinburgh.

Background: Hypertension is common. Its cause remains unclear in the majority of those affected. Recent data suggest that macrophages (MΦ) contribute to, and protect from, hypertension. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor with additional pro-inflammatory properties. The effects of ET-1 on MΦ biology are well studied.

Methods: To examine the interactions between the ET and MΦ systems we administered incremental doses of intravenous ET-1 to C57Bl12-diphtheria toxin receptor (DT) expressing mice given diphtheria toxin (DT) and to untreated control mice to create on model of endothelial injury. The type 1 angiotensin (AT1) receptor has a specific role in ET-1 clearance. We investigated the role of the Mϕ ET receptor in ET-1 mediated endothelial dysfunction. We also cultured bone marrow derived MΦ (BMDM) from both mice and human monocytes in vitro. Finally, we examined BP and the ET system in patients receiving MΦ depleting and non-depleting therapy.

Results: MΦ depletion or loss of function – C11b-DTR mice given DT and LysMΔMΦ mice – were not associated with a difference in baseline BP or endothelial dysfunction. In both, administration of ET-1 resulted in an exaggerated hypertensive response compared to controls. At a dose of ET-1 1nmol/kg the maximal change in BP was ~20-fold in MΦ deficient mice compared to control groups. In vitro, mouse BMDM and human MΦ possess both ETa and ETb receptors. Whereas stimulation of mouse and human MΦ with exogenous ET-1 did not polarize MΦ to a classical or alternative phenotype, both displayed chemokinesis to ET-1. This was reduced by selective ETa, and completely blocked when both ETa and ETb receptor mediated dynamin-dependent endocytosis present in both murine and human MΦ. Finally, patients receiving MΦ depleting therapy we show that BP is higher and the ET system more activated than those receiving non-depleting therapies.

Conclusions: Overall, these data suggest that MΦ and ET-1 may play an important role in BP control and potentially have a critical role as a therapeutic target in hypertension.

FR-PO147

Role of the Myeloid Endothelin-B Receptor in Angiotensin II Mediated End-Organ Damage

Background: Hypertension is common and in the majority of cases its cause remains unknown. Recent interest has focused on the role of macrophages (Mø) in blood pressure (BP) regulation. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor mediating its effects through two receptors – the endothelin-A receptor (ET_a) and endothelin-B (ET_b) receptor. The ET_b receptor has a specific role in ET-1 clearance. We investigated the role of the Mø ET_b receptor in a model of angiotensin II (ANG)-mediated end-organ damage.

Methods: Mø ET_b receptor deficient mice (LysMΔMΦ) and controls were exposed to Ang II infusion for 6 weeks under a high salt diet. We assessed BP via telemetry, cardiac structure and function and endothelial function by Doppler ultrasound, end-organ injury and plasma and urine ET-1.

Results: At baseline, components of BP did not differ between groups and increased similarly with Ang II. Whereas after 6 weeks of Ang II LysMΔMΦ and controls had similar left ventricular hypertrophy and cardiac insufficiency, endothelial function was better in LysMΔMΦ at both baseline and after Ang II (% dilation of basilar artery in response to CO2: LysMΔMΦ vs. controls: 7.5±1.1% vs. 5.8±0.9%, p<0.01; at 6 weeks: 11.4±1.0% vs. 9.0±0.7%, p<0.01). Baseline renal function and proteinuria did not differ between groups. After Ang II, LysMΔMΦ showed similar renal function compared to controls but less proteinuria (urine albumin: creat, mg/mmol: 208:10 vs. 530:25, p<0.01), glomerulosclerosis (34±2 vs. 61±4%, p=0.03), mesangial expansion (14±2% vs. 28±2%, p<0.01) and fewer renal Mø compared to controls (F4/80 staining per high power field, LysMΔMΦ vs. controls: 1.1±0.7 vs. 3.2±0.5%, p<0.02), although similar levels of CD3' T cells. Plasma ET-1 was no different at baseline but increased more in LysMΔMΦ with Ang II vs. controls after 6 weeks Ang II: 3.7±0.7 vs. 1.4±0.2pg/ml, p<0.03). Urine ET-1 was similar baseline and 6 weeks.

Conclusions: Deletion of the Mø ET_bR is associated with a blunting of the effects of systemic Ang II infusion as reflected by less endothelial dysfunction, reduced inflammation and end-organ damage. The mechanisms for these effects are the focus of ongoing research.
FR-PO148
A Novel Reduced Uterine Perfusion Pressure (RUPP) Model of Preeclampsia in Mice
Tomofumi Fushima,1 Yuji Oe,1 Emiko Sato,1 Sadayoshi Ito,1 Hiroshi Sato,1,2 Nobuyuki Takahashi.1,2 1Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Miyagi, Japan; 2Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ, Sendai, Miyagi, Japan.

Background: Preeclampsia (PE) is a pregnancy-related hypertension with proteinuria that typically develops after 20 weeks of gestation. PE is caused by a reduction in uterine blood flow due to abnormal trophoblast invasion of the spiral arteries. The ischemic placenta releases anti-angiogenesis factors such as sFlt-1, leading to maternal hypertension and proteinuria. The reduced uterine perfusion pressure (RUPP) model is widely used in rats, but not in mice, hindering the clarification of genetics of PE. The aim of the present study is to establish a novel PE model using an improved RUPP method in mice.

Methods: As shown in the Figure 1, uterine vessels of pregnant ICR mice were ligated at 14.5 dpc, and BP, renal phenotype and pregnancy outcome were analyzed.

Results: RUPP in mice increased blood pressure. B.B' ligation mice showed increased urinary albumin excretion, mesangial expansion and endotheliosis as shown by the reduction of glomerular open capillary area. RUPP increased the risk of miscarriages and premature deliveries, and significantly reduced fetal weights at 18.5 dpc compared to those of sham mice.

Conclusions: We developed a novel RUPP mouse model that recapitulates the phenotype of PE. This model is expected to be useful for investigating pathogenesis of PE and evaluating its new therapies.

FR-PO149
Sildenafil Treatment Is Protective against Progression of Renal Injury in the Preeclamptic Dahl Salt Sensitive Rat
Ellen Elizabeth Gillis, Jennifer N. Mooney, Michael R. Garrett, Jennifer M. Sasser. Pharmacology and Toxicology, Univ of Mississippi Medical Center, Jackson, MS.

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by transient glomerular damage and increased risk for kidney disease later in life. Recent studies in our lab have identified the Dahl salt sensitive (Dahl S) rat on a 0.3% NaCl diet as a spontaneous model of superimposed preeclampsia. We hypothesized that sildenafil treatment would result in an improvement in renal function during the preeclampsia pregnancy exhibited by the Dahl S rat.

Methods: Female Dahl S rats (n=4-9) were mated, and rats were randomly divided into control and sildenafil treated groups. Sildenafil was administered to the treated group via food on gestational days 10-20 at a dose of 50 mg/kg/d. Rats were placed in metabolic cages on gestational day 19 for 24 hr urine collection, and blood and tissues were harvested on gestational day 20. Urinary protein excretion, nephron excretion, and plasma and urinary creatinine concentrations were measured by Bradford assay, Exocell ELISA, and the picric acid method, respectively. Kidney sections were stained with Mason’s trichrome, and glomeruli were measured (n=20 per rat) and analyzed using Nikon software.

Results: Sildenafil treatment significantly improved renal function, as observed in the increase in creatinine clearance and corresponding decrease in plasma creatinine (Table, *p=0.05 vs control). Treated rats exhibited less renal injury, with a significant decrease in proteinuria and nephritis during late pregnancy (Table). Histological analysis showed that the treated rats did not exhibit glomerulomegaly during pregnancy compared to the untreated controls (Table).

Conclusions: This study provides preclinical evidence that sildenafil prevents the progression of renal injury during preeclampsia.

Recessive Mutations of the Interaction Partners, TENC1, DLC1 or MAG2, Cause Nephrotic Syndrome in Humans
Shazia Ashraf,1 Jia Rao,1 Merlin Airik,1 Svjetlana Lovric,1 Jennifer A. Lawson,1 Weizhen Tan,2 Karolin Sadowksi,1 Werner Lukas Pabst,1 Daniela A. Braun,1 Heon Yung Gee,1 Richard P. Lifton,12 Martin Zanker,1 Friedhelm Hildebrandt.1,4 1Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Inst of Human Genetics, Univ of Medicine, New Haven, CT; 4Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; *HHMI.

Background: Identification of monogenic causes of nephrotic syndrome (NS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown.

Methods: We performed homozygosity mapping (HWM) and whole exome sequencing (WES) in individuals of consanguineous families with NS to identify the underlying mutations. To identify additional families, we performed microfluidic PCR (Fluidigm Access Array™) and next generation sequencing (NGS) to screen worldwide cohort of ~2000 individuals with severe NS.

Results: By WES in consanguineous family A1358, we identified a homozygous missense mutation (p.R292Q) in the TENC1 (Tensin-2) gene in an amino acid residue conserved since Ciona intestinalis. By microfluidic PCR and NGS, we detected additional mutations in TENC1 in three unrelated families with NS. Later, we also discovered mutations in 2 different families with NS in DLC1 gene, a known binding partner of TENC1. Interestingly, most of the individuals with TENC1 or DLC1 mutations had steroid sensitive NS or histologically showed biopsy of MCNS. Furthermore, in 2 families with NS and neurological impairment, we identified 2 different homozygous truncating mutations in MAG2 gene. Deficiency of Tenc1 or Mag2 has been previously shown to cause NS in mice. By Co-IP, we now show that TENC1 and DLC1 interact with MAG2 in HEK293T cells and these interactions are abrogated in one of the MAG2 mutant. Knockdown of TENC1, DLC1 or MAG2 in cultured podocytes exhibited an altered podocyte migration rate. Immunofluorescence microscopy showed that TENC1 and DLC1 colocalize with phosphotyrosine at the focal adhesions in cultured human podocytes.

Conclusions: We, thus, identified mutations of TENC1, DLC1 and MAG2 as three novel single-gene causes of NS revealing a potential new pathogenic pathway for NS.

Mutation of DHTKD1 Can Cause Nephrotic Syndrome with Neurological Impairment and Ketoacidic Aciduria
Weizhen Tan,1 Shazia Ashraf,1 Svjetlana Lovric,1 Jia Rao,1 Merlin Airik,1 David Schaprio,1 Daniela A. Braun,1 Heon Yung Gee,1 Martin Zanker,1 Friedhelm Hildebrandt.1,4 1Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 4Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; *Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Steroid-resistant nephrotic syndrome (SRNS) is the second most frequent cause of end-stage kidney disease in children. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain obscure. To identify a new causative gene for SRNS with neurological impairment, we combined homozygosity mapping (HWM) and whole human exome sequencing (WES).

Methods: In two siblings (of consanguineous parents) with SRNS, neurological impairment, and ketoacidic aciduria, HM yielded 8 segments of homozygosity by descent at an average size of ~485 Mb. We performed WES in both siblings to identify the underlying single-gene disease-causing mutation.

Results: WES in this consanguineous family detected a homozygous missense mutation (p.Val296Met) in the DHTKD1 (dehydrogenase E1 and transtetikolase domain containing 1) gene in an amino acid residue that is evolutionary conserved to prokaryotes (Saccharomyces cerevisiae). The mutation segregated with the affected status in this family and was absent from the 1,000 genomes project and Exome Aggregation Consortium (ExAC) databases. DHTKD1 functions as a 2-oxoglutarate-dehydrogenase E1 component and plays an important role in energy production in mitochondria through the tricarboxylic-acid cycle. Mutations in DHTKD1 have previously been identified as cause of 2-aminoadipic and 2-oxoaciduria via impaired turnover of decarboxylation 2-oxoadipate to glutaryl-CoA. [1] Danhauser K. et al., Am J Hum Genet, 91:1088-1087, 2012.

Conclusions: We identified a recessive mutation of DHTKD1 as a novel single-gene cause of SRNS with neurological impairment and ketoacidic aciduria. Further genetic and functional studies will shed light on the involvement of this protein in the pathogenesis of NS and will provide a further step in understanding the disease mechanism.

Genes Encoding Nuclear Pore Outer Ring Components NUP85, NUP107, and NUP133 Are Mutated in Patients with Nephrotic Syndrome Svetlana Lovric,1 Weizhen Tan,2 David Schapira,3 Shazia Ashraf,1 Daniela A. Braun,1 Jia Rao,1 Richard P. Lifton,4 Heon Young Gee,4 Friedhelm Hildebrandt,1,5 1Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 3Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Steroid resistant nephrotic syndrome (SRNS) almost invariably progresses to end-stage kidney disease. Although more than 30 single-gene causes of SRNS are known, a large proportion of SRNS remains unexplained. Recently, mutations in genes encoding proteins of the nuclear complex (NPC), NUP93 and NUP205 were identified as novel causes of nephrotic syndrome. Study of these genes has implicated SMAD signaling in the pathogenesis of nephrosis.

Methods: To identify additional novel causes of nephrotic syndrome, we performed a candidate screen of 17 nuclear pore complex (NPC) genes in an international cohort of >900 individuals with SRNS with microfluidic multiplex PCR (Fluidigm AccessArray®) and next generation sequencing (illumina Miseq®).

Results: In two families we identified two homozygous missense mutations, p.A477V and p.R645W, (conserved to S. cerevisiae) in the NPC outer ring protein NUP85. We then sequenced the exons of 1,000 additional families in genes encoding other outer ring proteins and found mutations in NUP107 (1 family, p.Y889C, conserved to C. elegans) and NUP133 (2 families, p.S974R and p.R231G, p.L1055S, conserved to D. rerio). Although the structure resolution of the NPC 3D complex is incomplete, we modeled the interacting portions of the Y-subcomplex proteins NUP107 and NUP133. Two of the mutations, p.S974R in NUP133 and p.Y889C in NUP107, are located in the interacting alpha helixs between the two proteins. 5 of 6 families demonstrated FSGS on biopsy.

Conclusions: As a novel cause of SRNS we identified mutations in 3 different NPC outer ring proteins NUP85, NUP107, and NUP133 that form an integral part of the Y-subcomplex. Further functional studies are needed to illuminate how the defect of NPC contributes to the pathogenesis of nephrotic syndrome.

Defining the Genetic Epidemiology of a Phenotypically Well-Characterized Adult-Onset Focal and Segmental Glomerulosclerosis Cohort Moumita Baruah,1 Daniel C. Catran,1 Heather N. Reich,1 Michelle A. Hladunewich,6 Mark Leung,2 Weili Li,3,4 Andrew D. Paterson,5 York P. Pei.1

Background: Genetic epidemiology underpins an understanding of human disease and identifies new biological pathways. The genetic landscape of focal and segmental glomerulosclerosis (FSGS), a common cause of kidney disease, is unknown.

Methods: To gain insight into the genetic epidemiology of FSGS, we performed exome sequencing on adult-onset FSGS cases and family members. The sequencing data was interrogated using the Exome Variant Server and compared against the Exome Aggregation Consortium (ExAC) to identify the most recurrent variants.

Results: We identified diagnostic variants for FSGS in 4 genes in 5/31 families (16%): TRPC6, INF2, LAMA5, and ADCK4. These mutations were enriched in the right tail of the age at diagnosis distribution, suggesting that genes involved in renal development predispose to FSGS.

Conclusions: FSGS is a complex genetic disease with highly penetrant genes and a large number of cases in which the underlying genetic etiology remains unknown.

A Novel Mouse Mutant with a Point Mutation in Laminin α5 Exhibits Chronic Nephrotic Syndrome Sara Falzone1, Thomas Nicol,1 Cheryl Scudamore,2 Frederick W.K. Tam,2 Charles D. Pusey,3 Jeffrey H. Miner,1 Steve Dm Brown,1 Paul K. Potter,1 1Mammalian Genetics Unit, MRC Harwell, Harwell, Oxfordshire, United Kingdom; 2Mary Lyon Centre, MRC Harwell, Harwell, Oxfordshire, United Kingdom; 3Renal Science, Imperial College, London, United Kingdom; 4Renal Div, Washington Univ, St. Louis, MO.

Background: Diseases associated with ageing pose an increasing social and financial burden on society and represent an imperative for research in the biomedical sciences. We are undertaking the first large-scale project to investigate the interaction between genetic variation and the pleiotropic effects of ageing, employing random mutagenesis and phenotyping to generate new models of late onset or age-related disease.

Methods: Mouse mutants are being aged to 18 months and undergo comprehensive phenotyping across a wide range of disease areas at several time points throughout the life of the mice. To date we have identified lines with a variety of late onset phenotypes which are being characterised in detail.

Results: Mutant mice were identified at 6 months of age with elevated creatinine and urea levels, which reached end stage renal failure at approximately 10 months of age. Mapping and whole genome sequencing identified a LAMA5 nonsense mutation in the L4a domain of LAMA5. Time course studies of LAMA5 homozygotes showed reduced serum albumin (18.0 ± 1.2 vs 24.9 ± 3.1 g/l, mean SD) and proteinuria from 12 weeks of age with a gradual loss of renal function over time. Affected mice also have significantly elevated cholesterol levels and a progressive nephropathy leading to diffuse glomerular fibrosis, dilated protein filter tubules and pigment deposition suggesting this is a model of nephrotic syndrome. The mutation does not affect expression of the LAMA5 protein within the glomerular basement membrane.

Conclusions: We have identified a novel mouse mutant with a missense mutation LAMA5 resulting in nephrotic syndrome. Recent patient sequencing data suggests LAMA5 mutations are associated with focal segmental glomerulosclerosis. The model does not affect expression of the LAMA5 protein within the glomerular basement membrane.

Exome Sequencing Suggests a Role for Nephrin Number in FSGS Adile Mitrotti,1 David Fasel,1 Yifu Li,1 Monica Bodria,1 Landino Allegri,1 Gerald B. Appel,1 Jai Radhakrishnan,1 Loreto Gesualdo,4 Gian Marco Ghiggeri,5 Richard P. Lifton,1 Ali G. Ghiravi,1 Simone Sanna-Cherchi.1,2 Medicine, Columbia Univ Medical Center, New York, NY; 3Genetics, Yale, New Haven, CT; 4Medicine, Univ of Parma, Parma, Italy; 5Medicine, Univ of Bari, Bari, Italy; 1Medicine, Gaslini Children Hospital, Genova, Italy.

Background: Exome sequencing is a powerful tool to identify disease-causing mutations. Identification of novel genes for dominant FSGS has proven difficult.

Methods: We performed exome sequencing in 41 patients from 31 families affected by FSGS. Exome sequencing was conducted on Illumina HiSeq2500. Annotations were conducted with semi-automated scripts developed in the lab.

Results: We detected diagnostic variants for FSGS in 4 genes in 5/31 families (16%): TRPC6, INF2, LMX1B, and LAMB2. We detected two variants of unknown significance in FSGS-associated genes (EMP2, INP2). We detected 7 variants in additional 6 patients associated with late-onset FSGS that predispose to different kidney diseases when mutated (LAMA5, COL4A4, FRA51, FREM1, FREM2, UMOD). While these conditions can represent phenocopies of FSGS, it is possible that genes involved in renal development predispose to proteinuria and adaptive FSGS.

 Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Analysis of the remaining 20 families (65%) did not reveal any gene with rare segregating mutations present in multiple independent families.

Conclusions: Mutations in genes known to be associated to FSGS are identified in a small proportion of cases. Mutations with focal segmental glomerulosclerosis in genes involved in GNB3 and kidney development can result in defects that present as FSGS. These findings can point to a correct genetic diagnosis and the identification of mutations in genes involved in CAKUT suggests that glomerular sclerosis could be the manifestation of a maladaptive reaction to reduced glomerular mass from phenocopies of FSGS.

Conclusions: De novo variants can occur even in asymptomatic male cases of XLAS resulting in mosaicism, with important implications for genetic counseling. This is the first study to show a tendency between the variant allele frequency and disease severity in male XLAS patients with somatic mosaic variants in COL4A5. Although this is a very rare status of somatic mosaicism, further analysis is needed to show this correlation in a larger population.

FR-PO161

A New Non-Invasive Method to Examine Collagen α5(IV) Expression Using Plucked Hair Follicles: Analysis of an X-Linked Alport Family with a Novel COL4A5 Splice Region Variant Andrew F. Malone, Steven Daniel Funk, Jeffrey H. Minze. Renal Div; Dept of Medicine, Washington Univ, St. Louis, MO.

Background: Alport syndrome is a hereditary disease caused by mutations in COL4A5 in 85% of cases. Many different mutation types in this gene have been described. Levels and patterns of type IV collagen deposition are variable in the glomerular basement membranes of Alport kidneys. As COL4A5 is also expressed in the skin, we sought to characterize COL4A5 deposition in the basement membrane of plucked hair follicles from a family with a novel COL4A5 variant as a way of confirming the functional significance.

Methods: Whole-exome sequencing was done on the proband of a family with biopsy (renal and skin)-confirmed Alport syndrome. Sanger sequencing was performed on all affected family members and a married-in unaffected individual. Immunofluorescence microscopy was performed on whole mount and sectioned hair follicles co-stained with monoclonal antibodies to collagen α2 and α5(IV). Staining intensity between males and females, affected and unaffected, was analyzed.

Results: Family WU1 is a 3 generational family with chronic kidney disease secondary to Alport syndrome. Affecteds are in each generation, and both males and females are asymptomatic. Whole-exome sequencing of affected individual 3232 revealed a novel splice region variant c.1780-6T>G in COL4A5. There were no other potentially pathogenic variants found in COL4 or other podocyte genes. This variant was confirmed by Sanger sequencing and segregated with disease. Reduced and abnormal expression of COL4A5 protein was confirmed in affected family members by immunofluorescence microscopy of hair follicles.

Conclusions: We confirmed linkage of a novel splice region variant in COL4A5 to Alport syndrome in a family with a typical X-linked inheritance pattern; this variant may be pathogenic. We developed and validated a new approach to characterize the expression of COL4A5 protein using immunofluorescence microscopy of plucked hair follicles. Furthermore, we demonstrated variability of COL4A5 expression between patients in this family, suggesting intermitting failure of splicing and/or variable lyonization in females. Funding: NIDDK Support

FR-PO162

X-Linked Alport Dogs Demonstrate Mesangial Filipodial Invasion of the Capillary Tuft as an Early Event in Glomerular Damage Sabrina D. Clark,1 Mary B. Nabity,1 Rachel Cianciolo,1 Brianna M. Dufek,1 Dominic E. Cosgrove,1 Veterinary Pathobiology, Texas A&M Univ, College Station, TX; 1Veterinary Biosciences, The Ohio State Univ, Columbus, OH; 2Genetics, Boys Town National Research Hospital, Omaha, NE.

Background: X-linked alport syndrome (XLAS), caused by a mutation in the type IV collagen COL4A5 gene, accounts for approximately 80% of the cases of human Alport syndrome. Dogs with XLAS have a similar clinical progression. Prior studies in autosomal Alport mice demonstrated early mesangial cell invasion as the source of laminin 211 in the glomerular basement membrane (GBM), leading to proinflammatory signaling. Thus far, these findings have not been confirmed in a large animal model.

Methods: XLAS dogs and unaffected littermates were monitored with serial kidney biopsies at 2, 4, 6, and 12 months of age. V orinostat treatment induced hyperacetylation of kidney lysine residues. This was associated with reduced albuminuria, decreased aSMA protein expression, and reduced gene expression of inflammatory cytokines.

Results: In silico drug repurposing identified vorinostat as a potential therapeutic agent. Treatment with voriostat induced hyperacetylation of kidney lysine residues. This was associated with reduced albuminuria, decreased aSMA protein expression, and reduced gene expression of inflammatory cytokines. Further studies will better define the mechanisms underlying the protective effect of this novel therapy.

KCTD1 Mutations in Scalp-Ear-Nipple (‘Finlay-Marks’) Syndrome: A Further Cause of Thin Basement Membrane Nephropathy Dongmao Wang,1 Peter Diakumis,2 Melanie Bahlo,2 Deb J. Colville,1 Judith A. Savige.1 Medicine, The Univ of Melbourne (Parkville, Melbourne, VIC, Australia; 2Bioinformatics, WEHI, Melbourne, VIC, Australia.

Background: Scalp-Ear-Nipple syndrome is an ectodermal dysplasia, with a scalp defect, dislocated ears and absent breasts. It results from mutations in KCTD1, a potassium channel gene, which encodes KCTD1, a K+ channel subunit. It causes renal disease. Currently there are few effective therapies for AS. Therefore we applied a novel therapeutic approach to AS, drug repurposing of the putative therapy showed that vorinostat exerts a renoprotective effect. Further studies will better define the mechanisms underlying the protective effect of this novel therapy.

Podocyte Globotriaosylceramide (GL3) Accumulation in Fabry Disease Is Influenced by Age and Genotype Bezhad Najafian,1 Camilla Tøndel,2 Einar Fang1, Rohan John,3 York P. Pei,3 James W. Scholey.2 1Inst of Medical Science, Univ of Toronto, Canada; 2Dv of Nephrology, Univ of Toronto, Canada; 3Internal Medicine, Chonnam National Univ Medical School, Korea; 4Pathology, Univ of Toronto, Canada.

Background: Alport Syndrome (AS) is a hereditary nephropathy caused by mutations in genes that encode type IV collagen, leading to progressive injury and eventually end-stage renal disease. Currently there are few effective therapies for AS. Therefore we applied a novel therapeutic approach to AS, drug repurposing of the putative therapy showed that vorinostat exerts a renoprotective effect. Further studies will better define the mechanisms underlying the protective effect of this novel therapy.

Funding: Private Foundation Support, Government Support - Non-U.S.
density \( V[GL3/Podo] \) was estimated and correlated with age and GLA mutation. The latter, on average, for 38 of these patients, included 35 classical, 2 cardiac variant (N215S) and one late onset (R363H) mutation. Patients over 65 years of age had 38 deaths, 21 of these were ERT treated patients, and 17 of the deaths were in patients over 65. There were 44 patients, ages 37-50 with low V[GL3/Podo] (r=0.03, p=0.02), included patients with N215S (n=2) and R363H mutations and one patient whose GLA mutation was unavailable. V[GL3/Podo] directly correlated with urine albumin creatinine ratio (r=0.50, p<0.001) and foot drop in males younger than 30 years. Volume density of podocytes per glomerulus was inversely correlated with age (r=-0.69, p<0.001) across the age range with no plateauing, suggestive of continuous podocyte loss.

Conclusions: The fraction of podocyte cytoplasm filled with GL3 inclusions increases with age up to about age of 30 in Fabry males with classical GLA mutations and associated with podocyte injury and albuminuria. Plateauing of podocyte GL3 volume density after age of 30 is suggestive of a threshold beyond which GL3 accumulation may not be compatible with podocyte survival. The clinical progression of Fabry nephropathy beyond age 30 in FD males with classical mutations could be reflected in other podocyte parameters such as podocyte hypertrophy and/or loss. Thus further studies are underway to explore these possibilities.

Outcomes of Patients Over 65 in the Canadian Fabry Disease Initiative Study
Michael L. West,1 Daniel G. Bichet,1 Aneal Khan,3 Joe T. Clarke,4 Sandra Sirrs,5 Steve Doucette,6 Christiane Auray-Pearl,2 Kaye Lemoine.3
1Medicine, Dalhousie Univ, Halifax, NS, Canada; 2Medicine, Univ of Montreal, Montreal, QC, Canada; 3Genetics, Univ of Calgary, Calgary, AB, Canada;4Emeritus, Univ of Victoria, Victoria, Canada; 5Medicine, Univ of British Columbia, Vancouver, BC, Canada; 6Dept of Community Health and Epidemiology, Dalhousie Univ, Halifax, NS, Canada; 7Pediatrics, Univ of Sherbrooke, Sherbrooke, QC, Canada; 8Nursing, Nova Scotia Health Authority, Halifax, NS, Canada.

Background: The Canadian Fabry Disease Initiative (CFDI) is a multicentre prospective study of outcomes with enzyme replacement therapy (ERT) in Fabry disease. ERT has been shown to be of benefit in reducing Fabry cardiac and renal disease. There is uncertainty as to the benefits of ERT in older patients. We compared outcomes of ERT in patients over 65 years of age with the overall CFDI population.

Methods: Patients are reviewed every 6-12 months as to clinical status. ERT is provided every 2 weeks according to national guidelines with intravenous dose agalsidase alpha (0.2 mg/kg) or agalsidase beta (1.0 mg/kg). Cardiovascular risk factor modification is promoted with use of ASA, statins and ACEI/ARB. Clinical outcomes are defined as stage 5 CKD, stroke/TIA, acute deafness, cardiac arrest, CHF, arrhythmia, unstable angina, MI, PTCA, pacemaker/ICD, AVR/CABG and death.

Results: As of Jan 2015, 429 subjects were enrolled. There were 51 patients over 65 yrs, 68.6% female, and 60.8% on ERT with mean age 71.8 yrs. There were no differences in mean age, cardiac variant genotype, or time in the CFDI between those on ERT and those not. Compared with patients not on ERT, those on ERT had lower CGFR, greater proteinuria and higher LVM at both baseline and 6 y later. Three patients not on ERT had 5 clinical events, prevalence 15%, no deaths with clinical event rate of 1/345 patient years. Twenty patients on ERT had 5 deaths, 38 clinical events, prevalence 64.5% and clinical event rate of 1.9/3 patient years. Death was more likely in females 21% vs. males 8.3%. Patients over 65 had greater prevalence of cardiac indications for ERT than the overall CFDI population. Time to first clinical event was earlier in those on ERT (p=0.003).

Conclusions: Older patients with Fabry disease continue to have clinical events, mainly cardiac, despite ERT but appear to be living longer. Use of the Canadian Fabry Disease guidelines appears to successfully target high-risk older patients. ERT use in this subgroup appears to be of benefit.

A Founder Haploype of APOE-Kyoto Mutation Associated with Lipoprotein Glomerulopathy
Zhangxiu Hu,1 Dept of Nephrology, West China Hospital, Chengdu, Sichuan, China.

Background: Lipoprotein glomerulopathy (LGP) is a rare dominant inherited kidney disease with incomplete penetrance, histological characterized by the formation of intraglomerular lipoprotein thrombi. Their main clinical manifestation includes proteinuria, diastolic hypertension, microalbuminuria and hyperlipidemia. Intraglomerular lipoprotein thrombi. CCX168 was compared with the currently available agent. Our previous study revealed the largest population of LGP from a county 200 kilometer near Chengdu city, in Sichuan province, China. All these patients shared APOE-Kyoto mutation in e3 allele, which suggests that the APOE-Kyoto mutation allele associated with LGP in the narrow country was identical, suggesting that mutation is common in chinese patients through a founder effect. And patients didn’t have a common haplotype of counterpart APOE allele as the asymptomatic carriers, which association with the onset of LGP isn’t known. To the new haplotype 32 of APOE4, its clinical value isn’t clear now.

Results: Eleven Pregnancies in Four Women with Atypical Hemolytic Uremic Syndrome
Marta M. Gaggel,1 Christof Aigner,1 Zoltan Prohaska,2,3 Gere Sunder-Plassmann,4 Alice Schmidt.2,1 Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; 2Heart Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary.

Background: Pregnancy activates the maternal alternative pathway of the complement system due to presentation of paternal antigens. In females with atypical Hemolytic Uremic Syndrome (aHUS) – a disease of the complement regulatory proteins and C3 – each pregnancy can trigger life-threatening disease episodes.

Methods: Data were collected from patients with aHUS, enrolled in the Viennese TMA Cohort. Pregnancies occurred between 2002 and 2015. Results: We report 11 pregnancies in 4 women (table 1). Two had an established diagnosis of aHUS prior to the first pregnancy (case 2 and 3). Case 1 presented with end-stage renal disease due to TMA (biopsy-proven) 12 months after her first delivery and case 4 presented postpartum after her uncomplicated first delivery. In 8 pregnancies females received preventive plasma infusions (Pl, 200-1600 mL) 2 to 4 weeks apart. After kidney transplantation case 1 received a maintenance therapy (Pls once a month), which was intensified during the II. pregnancy to every other week. Two pregnancies (case 1 II., case 3 III.) are currently ongoing without evidence of a disease flare so far. Nine pregnancies went without any complication and the offspring are healthy. One pregnancy (case 3 III., without Pls) resulted in an intraternal fetal death at gestation week 36, but without signs of TMA in the mother.

FR-PO169
Orally Administered Complement 5a Receptor Inhibitor CCX168 Development in Atypical Hemolytic Uremic Syndrome
Mirjam Galbusera,1 Sara Gastoldi,1 Valentina Portalupi,1 Elena Mondo,1 Pirow Bekker,2 Thomas J. Schall,3 Marina Noris,1 Giuseppe Remuzzi.1
1Dept of Medicine III, Div of Nephrology, West China Hospital, Chengdu, Sichuan, China; 2IIIrd Dept of Internal Medicine, Medical Univ of Vienna, Vienna, Austria; 3ChemoCentryx, Inc, Gaithersburg, MD.

Background: The orally administered complement 5a receptor (C5aR) inhibitor CCX168 is in Phase 2 development for antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, atypical hemolytic uremic syndrome (aHUS), and IgA nephropathy. The anaphylatoxin C5a is a potent neutrophil attractant involved in neutrophil priming and activation as well as inducing endothelial cell injury. The latter causes increased neutrophil and platelet adhesiveness, leading to thrombosis, one of the hallmark signs of aHUS. We report here progress in the aHUS program.

Methods: In an ex vivo thrombus formation system, serum from aHUS patients induces thrombus formation on microvascular endothelial cells. CCX168 was compared with the anti-C5 antibody eculizumab and soluble complement receptor 1 (SCR1) in this assay. Results: CCX168 resulted in a dose-dependent inhibition of thrombus size.
Whole Exome Sequencing Identifies Mutations in TUBAL3 as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT)

**FR-POI171**

**Whole Exome Sequencing Identifies Mutations in TUBAL3 as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT)**

**Asaf Vivante,1,4 Jan Jakob Schulz,1 Shirlee Shril,1 Julian Jakob Schulz,1 Stefan Kohl,1 Daw-yang Hwang,1 Eliah O. Kehinde,4 Richard P. Lifton,1 Martin Zenker,1 Friedhelm Hildebrandt.1,3**

**Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; 1Dept of Surgery, Kuwait Univ, Safat, Kuwait; 1Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 1Dept of Human Genetics, Otto von Guericke Univ, Magdeburg, Germany; 1Howard Hughes Medical Inst, Chevy Chase, MD; These authors contributed equally to this work.**

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) are the leading cause of end-stage kidney disease in children. The morphogenesis of kidney and urinary tract is modified by genetic mutations that lead to CAKUT. Identifying these mutations will not only provide deeper insights on disease mechanisms but also aids in improving diagnosis. TUBAL3 was identified as a potential candidate gene for causing CAKUT.

**Methods:** Homozygosity mapping with whole exome sequencing (WES) was performed in 20 consanguineous families with CAKUT from India. Homozygous recessive mutations within the homozygous region were further evaluated as the strongest candidates. Furthermore, we screened an additional cohort of 900 patients with CAKUT for additional mutations with a barcoded array based multiplex exon PCR (48X48 Fluidigm Access Array™) followed by next generation sequencing (Illumina MiSeq™). All identified mutations were confirmed by Sanger sequencing.

**Results:** A homozygous truncating mutation (p.Tyr179*) in the gene TUBAL3 was identified in the consanguineous Indian family A3838 using WES. We then independently detected another mutation homozygously (p.Gly106Ser) in the gene TUBAL3 in a family A1347 of Kurdish descent. TUBAL3 (Tubulin, alpha-like 3) is a protein coding gene and is very conserved across species. Tubulin is the major constituent of microtubules.

**Conclusions:** We identified recessive mutations in TUBAL3 as a novel single-gene cause of CAKUT. Further genetic information and functional studies will help understand disease mechanisms and the role of TUBAL3 in the pathogenesis of CAKUT.

**FR-POI170**

**Whole Exome Sequencing Reveals Mutation of PAPLN as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT)**

**Jing Chen,1 Asaf Vivante,1 Julian Jakob Schulz,1 Shirlee Shril,1 Stefan Kohl,1 Daw-yang Hwang,1 Richard P. Lifton,1 Eliah O. Kehinde,4 Veli Bor Tasic,4 Friedhelm Hildebrandt.1,3**

**Dept of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; 1Dept of Human Genetics, Yale Univ School of Medicine, New Haven, CT; 1Howard Hughes Medical Inst, Chevy Chase, MD; 1Dept of Surgery, Univ Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; These authors contributed equally to this work.**

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) are the most common cause of chronic kidney disease in children. Knowledge from animal models suggests that single gene mutations in genes governing kidney and urinary tract development may lead to CAKUT in humans. However, the genetic pathogenesis of human CAKUT remains mostly elusive.

**Methods:** To identify novel monogenic causes of CAKUT we applied homozygosity mapping with whole exome sequencing (WES) to 36 families with CAKUT. Then we investigated a worldwide cohort of ~1,600 families with CAKUT with a barcoded array based multiplex exon PCR (48X48 Fluidigm Access Array™) and next generation sequencing (Illumina MiSeq™). Results: In a consanguineous family with isolated CAKUT we detected a homozygous protein truncating mutation (p.Arg480*) in the PAPLN gene by WES. PAPLN encodes papillin, a component of the extracellular matrix (ECM) that plays a role in ECM development and interacts with ADAMTS metalloproteases. Papillin contains several thrombospondin type 1 domains homologous to ADAMTS-1, in which mutations lead to very distinct CAKUT phenotype in mice.

**Conclusions:** We identified a recessive truncating mutation in PAPLN as a novel monogenic cause of CAKUT, suggesting that CAKUT in humans may result from disruption of ECM degradation and turn over.

**Association of PAX2 and Other Gene Mutations with the Clinical Manifestations of Renal Coloboma Syndrome**

**Kengo Furuiuchi,1 Toshiya Okumura,2 Yasuyuki Shinozaki,2 Yasunori Iwata,2 Norihiko Sakai,1 Takashi Wada.1**

1Div of Blood Purification, Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; 2Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

**Background:** Renal coloboma syndrome (RCS) is characterized by kidney hypoplasia or dysplasia and abnormality of the optic nerve. Diagnosis of RCS is based on the morphological examination of the kidney, ophthalmologic findings, and family history. Approximately 170 cases with PAX2 gene mutations have been reported in cases with RCS worldwide. However, around 50% cases of RCS have no mutation in PAX2 gene.

**Methods:** To investigate the incidence and effects of mutations of PAX2 and 25 related genes, 26 patients with RCS were screened using next-generation sequence analysis, and candidate mutations were confirmed using Sanger sequencing. The correlation between mutations and clinical manifestation was evaluated.

**Results:** Thirty patients, including two family cohorts (n = 5 and 2), 19 patients with sporadic RCS, and 4 coloboma only control cases were evaluated in the present study. Screening the sequences of PA2X and 22 other genes identified 46 nonsynonymous single nucleotide changes and 9 indels. Among these candidate gene abnormalities, eleven PA2X mutations, including four novel mutations, were confirmed using Sanger sequencing, as well as mutations in CHD7, SALL4, KIF26B, and SIX4. A SALL4 mutation was detected in one patient, and CHD7, KIF26B, and SIX4 mutations were detected in another patient, of which KIF26B mutation is novel. Kidney function and proteinuria were more severe in patients with PA2X mutations than in those without themutation. Moreover, the coloboma score was significantly higher in patients with PA2X gene mutations. Three out of five patients with PA2X mutations had focal segmental glomerulosclerosis diagnosed from kidney biopsies.

**Conclusions:** Our data indicate that PA2X mutation is a key mutation in RCS and may make a major contribution to the pathogenesis of kidney and eye abnormalities. However, other factors and gene mutations may play a role, and further human and animal studies will be required to define the mechanism of pathogenesis of RCS.

**FR-POI173**

**Whole Exome Sequencing Identifies a Mutation in TTC25 as a Novel Monogenic Cause of Congenital Anomalies of the Kidney and Urinary Tract (CAKUT)**

**Julian Jakob Schulz,1 Asaf Vivante,1 Jing Chen,1 Shirlee Shril,1 Eliah O. Kehinde,4 Friedhelm Hildebrandt.1,3**

1Dept of Medicine, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 1Dept of Surgery, Kuwait Univ, Safat, Kuwait; 1Howard Hughes Medical Inst, Chevy Chase, MD.

**Background:** Congenital anomalies of the kidney and urinary tract (CAKUT) cover a wide range of renal malformations which account for most cases of pediatric CKD. So far more than 30 monogenic CAKUT-causing genes have been identified. However, for most cases the underlie genetic cause is still unknown.
Methods: To identify causative genes for CAKUT we investigated consanguineous families with CAKUT by applying whole exome sequencing (WES) combined with homozygosity mapping.

Results: In one family we detected a homozygous loss-of-start mutation in the gene TCT25 (tetratropicopeptide repeat-containing 25). This mutation (c.Met1Thr; c.2T>C) was present in an affected child that had a posterior urethral valve, vesicourethral reflux and bilateral hydrourephrosis. TCT25 plays a role in ciliogenesis, proencreatin cilia function and signal transduction in the sonic hedgehog pathway (Hayes, J. M. et al., 2007. Dev. Biol. 312: 115; Xu Y et al., 2015. PLOS ONE 10(4): e0124378). The latter has been shown to coordinate bladder as well as urethra formation in mice (Haraguchi R et al., 2007. Development 134(3):525; Haraguchi R et al., 2012. PLOS ONE 7(1): e42245).

Conclusions: By WES and homozygosity mapping we identified TCT25 as a novel monogenic CAKUT-causing gene if mutated.

Phenotypic Analysis of a Cohort of Patients with Hepatocyte Nuclear Factor 1 Beta (HNF1β) Mutations and Correlation with Established Scoring Systems
Emma Kaye Montgomery,1 John Andrew Sayer,2
1Renal Services Centre, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 2Inst of Genetic Medicine, International Centre for Life, Newcastle Univ, Newcastle upon Tyne, Tyne and Wear, United Kingdom.

Background: Hepatocyte nuclear factor 1 beta (HNF1β) mutations may lead to a wide spectrum of clinical phenotypes including developmental defects of the kidney, pancreas, liver, and Mullerian duct. HNF1β mutations account for Renal Cysts and Diabetes (RCAD) syndrome. We reviewed patients with known HNF1β mutations to determine the range of phenotypes and identified if these patients would have been detected based on established scoring systems.

Methods: We selected patients who had been screened for HNF1β mutations from 2009 to 2014 within our hospital. Serum magnesium, potassium, urate and creatinine levels were noted as well as renal morphology based on imaging. All positive and negative patients for HNF1β mutations had their phenotypes quantified and correlated with published HNF1β scoring systems and screening criteria.

Results: 135 patients were screened over 5 years. The cohort included 17 patients from 10 families with confirmed HNF1β mutations. The majority of these patients had CKD stage 3, with a mean creatinine of 144 μmol/L. Only 35% of mutation positive patients had both renal cysts and diabetes. 57% of patients had hyponatremia, 50% of the patients had hyperuricemia and 4 patients had clinical symptoms of gout with 75% of these patients noted as well as renal morphology based on imaging. All positive and negative patients for HNF1β mutations had their phenotypes quantified and correlated with published HNF1β scoring systems and screening criteria.

Conclusions: The majority of patients with HNF1β mutations demonstrated hypomagnesaemia (50%), hyperuricaemia (53%) and deranged liver function tests (59%). RCAD remains a misnomer and patients with HNF1β mutations have a wide phenotypic spectrum, with only one third having renal cysts and diabetes. The use of a HNF1β scoring/ screening system will help to improve detection rates.

FR-PO175
CTNS Gene Mutations and Variants in Adult Hemodialysis Patients
Craig B. Langman,1 Paul C. Grimmer,1 Elena N. Levchenko,1 Krishna R. Polu,2
1Feinberg Sch Med, Northwestern U; 2Stanford U. Sch. of Med; 1Univ of Leuven; 2Raptor Pharmaceuticals, Novato, CA.

Background: Nephropathic Cystinosis (NC), a rare, systemic, autosomal recessive disease due to CTNS gene mutations causes end-stage renal disease (ESRD). While most cases of NC are recognized in infancy (95%), late-onset NC with ESRD is rare but might be under-diagnosed. NC is rarely diagnosed in African-Americans (AA). Objective: To identify CTNS mutations and possible pathogenic variants (A) in a representative sample of NC patients (pts) in the US.

Methods: Genomic DNA was extracted from whole blood from 4007 adult hemodialysis pts from the Davita biorepository. Fluidigm’s Access Array IFC was used for the CTNS target enrichment. Enriched DNA was sequenced on the HiSeq 2500 using 2 x 100bp read length.Reads were mapped to the human genome version hg19 using the BWA aligner. Mutations and A were called using both GATK and Sambtools and confirmed by Sanger sequencing.

Results: 16 pts had homozygous (HoZ) and 52 pts had compound heterozygous (HTZ) CTNS sequence Δ. 1/6 pts had a known diagnosis of NC (W138X). In HoZ pts, 6 had known mutations in CTNS (V421S/C were AA) consistent with NC. 9 had upstream promoter mutations (UMP) (7 with -294C>T and 2 with -295G>C, a mutation locus with known disease association), and 3 of these pts were AA. In 52 HTZ CTNS sequence Δ, 2 AA pts had UPM. The other 50 had combinations of changes in the CTNS coding sequence & promoter region.

Conclusions: The unexpected frequency of CTNS gene mutations & Δ suggest that late-onset NC may be underrecognized in ESRD. These CTNS alterations need further study to determine pathogenicity and association with NC. In addition, CTNS mutations & Δ in AA sub-population signals a need for evaluation for a diagnosis of late onset nephropathic cystinosis in ESRD.

Sixteen Monogenic Genes Cause 20% of Early-Onset Urinary Stone Disease
Jennifer A. Lawson,1 Daniela A. Braun,1 Heon Yung Goe,1 Jan Halbritter,1 Shirlee Shril,1 Weizhen Tan,1 John Andrew Sayer,2 Danko Milosevic,3 Michelle Baum,1 Velibor Tasic,1 Friedhelm Hildebrandt.1,3
1Nephrology, Boston Children’s Hospital, Boston, MA; 2Inst of Genetic Medicine, Newcastle Univ; Newcastle upon Tyne, United Kingdom; 3Dept of Pediatric Nephrology, Univ of Zagreb Medical School, Zagreb, Croatia; 3Medical Faculty Skopje, Univ of Skopje Medical School, Skopje, Macedonia, The Former Yugoslav Republic of; 1Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Urinary stone disease (USD) is a prevalent condition that affects 10-15% of adults in their lifetime. It is associated with high morbidity due to colicky pain, the necessity for surgical intervention, and sometimes progression to chronic kidney disease. In recent years, multiple monogenic causes of USD have been identified. However, the prevalence of each monogenic gene has yet to be systematically studied in a pediatric urinary stone cohort.

Methods: To determine the percentage of cases that can be explained molecularly by mutations in 1 of 30 known urinary stone genes, we conducted a high throughput exon sequencing analysis in an international cohort of consecutively recruited individuals from three renal stone clinics. The cohort consisted of 143 individuals under 18 year of age, with nephrolithiasis (n=123) or isolated nephrocalcinosis (n=20).

Results: We detected likely causative mutations in 16 of 30 analyzed genes, leading to a molecular diagnosis in 20% (n=29 of 143) of affected individuals. 14 of the 32 detected mutations were not previously described as disease causing (43%). We show that mutations in recessive genes are more likely to cause infantile onset disease, whereas mutations in dominant genes are more likely to manifest later.

Conclusions: We present the first exclusively pediatric cohort examined for monogenic causes of urinary stone disease, and our data demonstrates that important therapeutic and preventative measures may result from mutational analysis in individuals with early-onset USD.

Mild Inhibition of Alanine-Glyoxylate Aminotransferase Translation as a Possible Treatment of Primary Hyperoxaluria Type I
Roman Lyakhovetsky,1 Yuacov Frishberg,2 Bodo B. Beck,3 Ruth Belostotsky,1
1Pediatric Nephrology, Sharee Zedek Medical Center, Jerusalem, Israel; 2Inst of Human Genetics, Cologne, Germany.

Background: Primary hyperoxaluria type 1 (PH1) is a kidney stone disease, often leading to ESRD, caused by absence, deficiency or mistargeting of the liver peroxisomal alanine-glyoxylate aminotransferase (AGT), encoded by AGT. The most frequent mutation G170R, responsible for 30% of PH1 cases in Caucasians, results in aberrant mitochondrial localization rather than catalytic inactivity. Modulating AGT maturation and folding has long been perceived as a therapeutic approach. Yet, numerous attempts over the years failed to rescue AGT mutants. We propose mild translational inhibition as a novel approach to improve folding and localization of AGT mutants.

Methods: The antihelminthic FDA-approved drug emetine, was used as a translation inhibitor. To ensure selective and specific discrimination between the mitochondrial (major) and the peroxisomal (minor) subpopulations of mutated AGT we developed the GlowAGT assay based on the recently described self-assembled split GFP approach.

Results: Using GlowAGT, WT-AGT but not G170R-AGT was detectable by GFP fluorescence, although both variants were visible by indirect immunofluorescence. Long-term treatment with low concentrations of emetine showed statistically significant increase of fluorescent subpopulation of G17OR-AGT. GFP fluorescence was exclusively co-distributed with the peroxisomal staining in all cases.

Conclusions: We have developed and applied successfully GlowAGT as a unique self-assembly split-GFP-based assay for detecting peroxisomal subpopulation of AGT. Using GlowAGT we show that mild translation inhibition by emetine is a novel therapeutic approach for PH1 caused by AGT misfolding/mislocalization.
FR-PO178

Functional Analysis of CLCNKB Mutations Causing Bartter Syndrome Type III Yohan Bignon,1 Mathilde Keck,1 Stéphane Lourdel,1 Rosa Vargas-Pousou,2 Jacques Teulon,1 Olga Andrini.1 (Metabolisme et Physiologie Renales, Centre de Recherche des Cordeliers, UPMC, Paris, France; 2Dept of Human Genetics, Hopital Europeen Georges Pompidou, Univ Paris 5, Paris, France.)

Background: Bartter Syndrome type III is a human autosomal recessive disease characterized by salt wasting, hypokalemic metabolic alkalosis and secondary hyperaldosteronism. Therefore, patients affected by Bartter syndrome type III display polyuria, polydipsia, dehydration, nephrocalcinosis and failure to-thrive. The disease is caused by inactivating mutations in the CLCNKB gene encoding for the CIC-Kb Cl- channel that is present in the distal nephron, where it mediates the basolateral step of Cl- absorption [2]. In this study, we investigated the functional consequences of five previously reported pathogenic CIC-Kb missense mutations (A204T, A210V, P216L, G424R, G437R [3]).

Methods: We characterized the electrical activity, total protein expression, surface expression and subcellular localization of mutated forms of CIC-Kb in X laevis oocytes and mammalian cell lines.

Results: Currents produced by G424R and G437R CIC-Kb channels were reduced by 50%, in proportion to membrane targeting without any change in total protein abundance. A210V and P216L mutants did not produce any current but their membrane insertion was only partially reduced (50-80%). Protein abundance of A210V was decreased by half. Conversely, that of P216L was comparable to WT CIC-Kb, suggesting that the P216L mutation was inherited from a healthy parent.

FR-PO179

Changes in Urologic and Medical Treatment of Cystinuric Patients Over Time Caroline Prot-Bertogne,1 Said Lebbah,1 Michel Daoud,1 Isabelle Tostivint,4 Olivier Traxer,2 Bertrand Knebelmann,4 Marie Courbebeisse.1 (Physiology, APHP, Georges Pompidou European Hospital, Paris, France; 2Biostatistics, AP-HP, Necker Hospital for Sick Children, Paris, France; 3Urology, AP-HP, Necker Hospital for Sick Children, Paris, France; 4Nephrology, AP-HP, Pitîé-Salpêtrîere Hospital, Paris, France.)

Background: Cystinuria is the most common monogenic nephro lithiasis disorder, but few studies have described its urological and medical treatment in a large cohort.

Methods: We retrospectively collected data from 442 French cystinuric patients. Clinical and laboratory data, urological and medical treatments were described. A mixed-effects logistic regression model was used to estimate the effects of urinary pH, urinary specific gravity, and cysteine-binding thiol agents (CBT) on the risk of cystine crystalluria.

Results: The median follow-up [min-max] was 15.8 years [0.1-65.6]. The average annual rate of surgical procedures increased with time (P<0.001). During the period 2000-2004, 73.3% of patients had at least one flexible ureteroscopy, versus 23.2% after 2005 (P<0.001). CBT were prescribed for 55.3% of patients. Prescription of tiopronin increased over time with no significantly patients (P<0.001). At least one side effect was recorded in 23.7% of patients treated with tiopronin, and 30.2% of patients treated with D-penicillamine (P<0.23). Increasing urinary pH and decreasing urinary specific gravity significantly reduced the risk for a patient to have a cystine crystalluria whereas D-penicillamine and tiopronin did not reduce this risk. The estimated probability of cystine crystalluria was 45%, 38%, 31% and 25% for an urinary pH of 6.5, 7.0, 7.5 and 8 and was 32%, 31% and 16% for an urinary specific gravity of 1015, 1010 and 1005.

Conclusions: The number of urological interventions and the prescription of tiopronin has increased over time. We show for the first time that D-penicillamine and tiopronin don’t impact cystine crystalluria although inducing frequent adverse effects in the same proportions. Urinary pH above 7.5 and morning urinary specific gravity below 1005 should be the goals of medical therapy.

Defect of Interdependent Membrane Targeting and Endocytosis of Cubilin and Amnionless Leads to Imerslund-Gräsbeck Syndrome Tomohiro Udagawa,1 Ken-ichiro Miura,1 Akihiko Saito,1 Yutaka Harita,1 1Pediatrics, Graduate School of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan; 2Applied Molecular Medicine, Niigata Univ Graduate School of Medical and Dental Sciences, Chuo-ku, Niigata, Japan.

Background: Imerslund-Gräsbeck syndrome (IGS) is an autosomal recessive disorder characterized by low-molecular-weight proteinuria and megaloblastic anemia. IGS is caused by mutations of either cublin (CUBN) or amnionless gene (AMN). Cublin forms protein complex with amnionless (cubam complex) and functions as the receptor-mediated endocytotic machinery.

Methods: A six-year-old boy with history of megaloblastic anemia was diagnosed with IGS because of low-molecular weight proteinuria. Whole-exome sequencing identified novel missense mutations, one each in CUBN and AMN. The CUBN mutation was de novo and the AMN mutation was inherited from a healthy parent.

Results: Renal biopsy showed translocation of amnionless from the apical membrane to the cytoplasm of proximal tubular cells. Using cultured cells, the mechanism of membrane trafficking of cubam and the effect of the mutations were analyzed. Although wild-type cubilin and amnionless were interdependently targeted to the cell membrane, the CUBN or AMN mutation abrogated membrane expression and endocytosis without affecting the interaction between cubilin and amnionless. Coexpression of amnionless induced maturation of cubilin protein, and the modification were identified by stable isotope labeling using amino acids in cell culture (SILAC)-based quantitative mass spectrometry. Notably, the CUBN mutation completely abrogated the amnionless-dependent glycosylation of cubilin. Tunicamycin or substitution of several Asn residues to Asp abrogated membrane targeting of cubam without affecting cubilin and amnionless interaction, further supporting a role of cubin glycosylation.

Conclusions: Our results demonstrate that digenic heterozygosity can lead to IGS and suggest that interdependent membrane trafficking of cubam complex mediated by posttranslational modification is crucial for the renal and intestinal absorption.

Metabolic Control of Nephron Progenitor Cell Renewal and Differentiation Anna Abrams, Jiao Liu, Zubaadia R. Saffiedeen. Pediatrics, Tulane Univ, New Orleans, LA.

Background: Nephron progenitor cells (NPC) availability and differentiation potential determine nephron endowment. Emerging data from embryonic stem cells and other developing systems emphasize the significance of energy metabolism in cell fate determination. Systemic metabolic dysfunction such as hyperglycemia alters neural and adipocyte stem cell fate. Nephron deficit in kidneys of diabetic mothers (idm) is known; however the effect on NPC and nephrogenesis under maternal hyperglycemia are unknown. Metabolic parameters of renewing NPCs are also unknown. Based on published stem cell data, we hypothesized that NPC self-renewal and differentiation are balanced by energy metabolism.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

397A
Methods: a. Fetal kidneys were exposed to maternal hyperglycemia using Streptozotocin (STZ). The kidney sections were immunostained to detect apoptosis (active caspase3) in the CM (Six2 and NCAM) and nascent neprons (Lef1 and NCAM). b. Glycerolysis was inhibited ex vivo in E12.5 kidneys by pharmacological inhibition of PFKFB3 (YN1 5-25Sm). c. Glycerolysis and oxidative phosphorylation were measured in NIDDK Support, Other NIH Support - NHEMGS.

Results: a. CM of P0 kidneys of STZ-treated females showed increased apoptosis and reduction in nascent nephron number (Lef1+ and NCAM+). Glycerolysis inhibition resulted in a smaller dispersed CM, accelerated but not ectopic differentiation of the NPC with up to a 50% increase in Lhx1+ nascent nephrons 24-48h post-treatment, and decreased CitEd expression by QPCR in isolated NPC. UB tip and branch numbers were unchanged. Thus, increased nephrogenesis was independent of UB branching. Expression of Wnt4 was unchanged. c. Conditional deletion of p53 in NPC also resulted in dispersed CM, depletion of the CM, increased Lhx1+ NPC independent of apoptosis, and hypoplastic kidneys with fewer nascent nephrons. Isolated mutant cells showed reduced basal oxygen consumption rate and decreased maximal respiratory capacity. Accordingly, the mutant cells exhibit a significant, nearly two-fold decrease in ATP (P<0.005, n=3).

Conclusions: Our data are consistent with the idea that the metabolic status of the NPC is a critical determinant of NPC renewal and differentiation.

FR-PO182
Prolene Receptor Signaling Promotes Nephron Induction During Mouse Kidney Development Renfang Song,1 Graeme James Preston,1 Laura R. Kidd,2 Ihor V. Yosypiv,1 1Pediatrics, Tulane Univ, New Orleans, LA; 2Pathology, Tulane Univ, New Orleans, LA.

Background: Deficient nephrogenesis is the major factor contributing to congenital renal hypoplasia (RHD), one of the leading causes of childhood end-stage kidney disease. Nephron induction is driven by reciprocal interactions between progenitor cells of the cap mesenchyme and the uretic bud (UB).

Methods: To determine the potential role of the prolene receptor (PRR) in nephrogenesis, we generated mice with a conditional deletion of the PRR in Six2-positive nephron progenitors of the cap mesenchyme and their epithelial derivatives (Six2CreER).

Results: Inactivation of PRR in nephron progenitors caused a marked decrease in the number of developing nephrons, severe congenital RHD with collapsed glomeruli and an enlarged Bowman’s space (such as those seen with a collapsing FSGS), podocyte foot process effacement and early postnatal death within 48 hours from birth. UB branching was greatly reduced, likely secondary to decreased nephrogenesis. Reduced congenital nephron endowment resulted from premature depletion of nephron progenitor cell population due to impaired progenitor cell proliferation and loss of normal morphogenic inductive response to canonical Wnt/b-catenin signaling within the metanephric mesenchyme. At 2 months of age, heterozygous Six2CreER mice exhibited focal glomerulosclerosis, decreased kidney function and massive proteinuria.

Conclusions: Collectively, these results are consistent with a cell-autonomous requirement for the PRR within nephron progenitors for progenitor maintenance, induction of nephrogenesis, normal kidney development and function. Thus, PRR is a potential candidate for future genetic screening studies in patients with congenital RHD and proteinuric kidney disease.

FR-PO183
Functional Dissection of Enhancers for Bmp7 in Kidney Development Taro Tsujimura,1,2,3 Osamu Takase,1,2,3 Masao Namagaki,1 Keichi Hishikawa,1,2,3 1Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo Hospital, Tokyo, Japan; 2Div of Nephrology and Endocrinology, The Univ of Tokyo Hospital, Tokyo, Japan; 3Div of Tissue Engineering, The Univ of Tokyo Hospital, Tokyo, Japan.

Background: Bmp7 is a critical player in the kidney development, as shown by its severe retardation in the KO mice of the gene and their subsequent perinatal lethality due to the malfunction. Previous studies identified two potential enhancers for the Bmp7 expression in the developing kidney around the locus: one residing inside the 1st intron of Bmp7 for expression in the developing ureteric bud; the other located downstream of the 3' end of Bmp7, which is rather active in the metanephric mesenchymal cells. Consistently, Bmp7 is also expressed in these two distinct domains. However, neither the requirement of these elements nor the noise of Bmp7 secreted from these different cell types for the kidney development has been uncovered so far. In this study, we aimed to characterize the roles of the two enhancers to better understand the cis-regulation of Bmp7 and the kidney development.

Methods: We established and analyzed homoyzogous mice carrying a large genomic deletion of the downstream region of Bmp7 including the mesenchymal enhancer.

Results: We found that they have significantly smaller body size than their wild type littermates, although they are viable unlike the KO mice of Bmp7. We previously showed that the same deletion also disrupts the topological partition of the chromatin conformation between the Bmp7 domain and the neighboring one of another developmental gene, Tjoc2p, resulting in a merger between them (Tsujimura et al. PLoS Genetics 2015). Interestingly, upon deletion, we scored significant up-regulation of Tjoc2p in the kidney probably by the loss of the intron enhancer.

Conclusions: These results suggest that the endogenous genomic context guarantees robustness in the regulation of the kidney development by linking the more important ureteric bud enhancer to Bmp7 tightly. The differential roles of the two enhancers will be further discussed based on the histological and functional analysis of the kidney in the homoyzogous deletion mice.

FR-PO184
BMP7 Regulates Expansion of the Postnatal Nephron Mary E. Tautzieni,1 Seymou Rosen,2 Jordan A. Kreidberg. 1,3,4 1Dept of Medicine, Boston Children’s Hospital, Boston, MA; 2Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA; 3Dept of Pediatrics, Harvard Medical School, Boston, MA; 4Harvard Stem Cell Inst, Cambridge, MA.

Background: The factors that regulate the expansion of nephrons after their initial induction and differentiation are largely unknown. Bone morphogenic protein 7 (BMP7) is a crucial factor driving proliferation and self-renewal of nephron progenitor cells during the development of the embryonic kidneys. In this study we investigated potential role for BMP7 as a regulator of post-induction nephron growth and differentiation.

Methods: The Bmp7 gene was conditionally mutated in progenitor cells using Six2-GFP/Cre. Kidneys from mutant and control mice were analyzed using a novel approach to identify proximal tubule expansion as an indicator of nephron growth in the postnatal mouse.

Results: Kidneys of Bmp7 conditional mutant mice were smaller with reduced numbers of nephrons. Bmp7 was expressed in developing nephron tubules of control kidneys and was absent from mutant kidneys. Proximal tubule growth, as determined by computationally measuring the area of lectin-stained proximal tubules in postnatal kidneys, was reduced in mutant kidneys. However, the proximal tubule area per glomerulus was increased in mutant kidneys, indicating that those nephrons that were induced underwent hypertrophy. Proliferation, as defined by Ki67+ nuclei per LTL. Islet cells within the proximal tubule compartment, was initially greater in mutants but declined by P10.

Conclusions: Loss of Bmp7 in progenitors leads to low nephron number. Bmp7 appears to be an important driver of postnatal nephron expansion. This phenotype is similar to oligomeganephropnia and may be used to understand the basis for nephron hypertrophy in low nephron number situations.

Grainyhead-Like 2 (Grhl2) Regulates Collecting Duct Barrier Function, Aquaporin 2 Expression and Urinary Concentration Christian Hinze,1,2 Janett Ruffert,1,2 Katharina Walentin,1 Max Werth,1 Jonathan M. Barash,3 Andong Qiu,4 Kerim Mutig,1 Sebastian Bachmann,1 Kai M. Schmidt-Ott,1 1Dept of Nephrology, Charité-Universitätsmedizin, Berlin, Germany; 3Max Delbrueck Center for Molecular Medicine, Berlin, Germany; 4Div of Nephrology, Columbia Univ, New York; 5Dept of Anatomy, Charité-Universitätsmedizin, Berlin, Germany; 6Urological Research Laboratory, Charité-Universitätsmedizin, Berlin, Germany.

Background: Osmotic homeostasis is tightly regulated by the kidney and its collecting ducts which form tight barriers, thereby maintaining steep concentration gradients and allowing transcellular reabsorption of water via aquaporins. The transcription factor grainyhead-like 2 (Grhl2) is highly expressed in renal collecting ducts. Using cultured collecting ducts, we recently showed that Grhl2 regulates epithelial barrier formation and lumen expansion via a target gene set comprising the transcription factor Ovo-like 2 (Ovol2), the small GTPase Rab 25 (Rab25) and the tight junction component claudin 4 (Cldn4). The role of Grhl2 in the collecting duct in vivo is unknown.

Methods: To investigate the role of Grhl2 in the renal collecting duct, we generated a collecting duct-specific knockout with Hoxb7-Cre; Grhl2fl/fl mice, which exhibit a deletion of Grhl2 protein in most cells of the collecting duct. The molecular and cellular alterations in their kidneys and their response to water deprivation were analyzed.

Results: Transcriptional profiling of Hoxb7-Cre; Grhl2fl/fl mice kidneys and control littermates showed deregulation of Ovol2, Rab25 and Cldn4, but also differential expression of Aquaporin 2 (Aqp2). Following water deprivation, Grhl2-deficient mice displayed significantly lower urinary osmolality at 6 hours (P=0.001) and 24 hours (P=0.04) when compared to control mice. Moreover, Grhl2-deficient mice had more than 35% more urine volume during the first 24 hours in response to water deprivation when compared to controls (P=0.005).

Conclusions: Our data indicate that Grhl2 critically participates in water homeostasis, epithelial barrier function and Aqp2 expression. This might be of relevance to diseases involving defective renal responses to water deprivation.

Genetic Deletion of Cyclooxygenase-2 Impairs Glomerular Slit Diaphragm Formation During Late Stages of Kidney Development

Kirsten Madsen,1,2 Niels Marcussen,2 Broye Jensen,1 1Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; 2Dept of Pathology, Odense Univ Hospital, Odense, Denmark

Background: Renal cyclooxygenase-2 (COX-2) expression is necessary for normal glomerular development. Impaired COX-2 activity has been associated with decreased expression of vascular endothelial growth factor (VEGF), a vascular growth factor of significant importance for glomerular capillary development. Therefore experiments were designed to test the hypothesis that COX-2 expression supports glomerular development through stimulation of capillary loop formation.

Methods: Kidney tissue was collected from a developmental series of COX-2 knock-out (KO) mice and wild-type littersmates (WT).

Results: Renal COX-2 expression showed developmental regulation with significantly higher COX-2 expression at postnatal (P) days 1 and P7 than at any later time points (P14, P21 and P40). Quantitative unbiased stereology at P28 showed significantly reduced glomerular number in COX-2 KO mice compared to WT littersmates (8188 ± 781 and 12251 ± 454 glomeruli/kidney respectively, P=0.0001). Subcapsular accumulation of small and immature glomeruli was seen in COX-2 KO mice whereas glomeruli deeper in the cortex towards the medullary region appeared normal. Tissue abundance of VEGF, angiotensin-1 and -2 mRNAs was significantly reduced in COX-2 KO mice compared to WT at P7. By electron microscopy at P28, immature subcapsular glomeruli showed normal appearance of fenestrated endothelial cells but severe podocyte foot process effacement and absence of mesangial cells. Normal morphology was confirmed in glomeruli deeper in the cortex. At P7, COX-2 KO mice showed reduced expression of slit diaphragm proteins nephrin and podocin but not synaptopodin compared to WT.

Conclusions: In summary, deletion of COX-2 leads to decreased renal expression of VEGF, and reduced capillary formation. This may result in abnormal capillary development and severe podocyte foot process effacement and impaired expression of slit diaphragm proteins. In conclusion, COX-2 activity is necessary for normal podocyte function and slit diaphragm formation during late stages of kidney development.

Functional Cross Talk Between Tyrosine Phosphorylation of Crumbs Homolog 2 and Mechanistic Target of Rapamycin Complex 1 in Developing Podocyte

Sho Hamana, Yukino Nishibori, Kinamiya Yam. Dept of Pediatrics, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan

Background: Mutation of crumbs homolog 2 (CRB2) is a novel cause of congenital nephrotic syndrome in humans that is linked to functional changes in the epithelial cell ultrastructure; however, how CRB2 functions in podocyte development is unknown. Other isoform: CRB2

Methods: MDCK cells expressing mouse full-length CRB2 or mutated-CRB2 lacking tyrosine phosphorylation site were established. Specific antibodies against CRB2 intracellular domain (mCRB2Ab) (tyrosine phosphorylation site (pY-CRB2Ab)) or tyrosine phosphorylation site/pY-CRB2Ab were generated. The samples from cultured cells and rat kidneys were subjected to Western blot study and immunofluorescence microscopy.

Results: Int-CRB2Ab determined CRB2 to locate at the apicobasal membrane in wild-CRB2 cells. Specificity of pY-CRB2Ab was confirmed by using samples from mutated-CRB2 cells and wild-CRB2 cells treated with protein tyrosine phosphatases inhibitor. Int-CRB2Ab identified that CRB2 expression commenced at the comma-shaped body stage, observed in the apical side of glomerular epithelium. CRB2 in the S-shaped body was still visible at the apical side of immature podocytes, then translocated along the lateral side of early distal tubule. CRB2 was observed in the podocyte foot processes. In contrast, phosphorylation of CRB2 was determined faintly in immature podocyte at the S-shaped body stage, intensely at the interstage of podocyte and then dropped sharply at stage of mature podocyte. Expression of CRB2 at the mature stage, but was not in immature podocyte. Finally, mTORC1 in mutated-CRB2 cells was activated more than that in wild-CRB2 cells.

Conclusions: CRB2 tyrosine phosphorylation may regulate energy system of developing podocytes through suppressing excessive mTORC1 activation.

Epithelial Cell Fate in the Nephron Tubule Is Mediated by the etv5a Transcription Factor During Zebrafish Kidney Development

Amanda N. Marr, Rebecca A. Wingert. Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Kidney development requires the differentiation and organization of discrete nephron epithelial lineages, however the genetic and molecular pathways involved in these events remain poorly understood. The embryonic zebrafish kidney, or pronephros, provides a simple and useful model to study nephrogenesis.

Methods: The pronephros is comprised of two types of epithelial cells: transportive and multi-ciliated cells (MCCs). Transportive cells occupy distinct tubule segments and are characterized by expression of solute transporters, while MCCs function in fluid propulsion and are dispersed in a “salt-and-pepper” pattern in the tubule. Epithelial cell identity is related in a dynamic way between Notch signaling pathway and retinoic acid (RA) signaling, where RA promotes MCC fate by inhibiting Notch signaling in renal progenitors, where Notch activity acts downstream to trigger transportive cell formation and restrict MCC identity. Previous research has shown that etv5a and its ETS family members are required for ciliogenesis in other zebrafish tissues.

Results: Here, we mapped etv5a expression to renal progenitors that occupy domains where MCCs later emerge. Thus, we hypothesized that etv5a is required for ciliogenesis of MCCs in the nephron. etv5a loss of function produced a decline of MCC number and reduced expression of the MCC markers odf3b and centrin, where rescue experiments partially restored wild-type MCC number. In epistatic studies, exogenous RA treatment expanded the etv5a domain, indicating that etv5a acts downstream of RA. Additionally, treatment with exogenous RA partially rescues the reduced MCC phenotype after loss of etv5a. FISH shows that both of two types of probe (etv5a and odf3b) increased etv5a expression, while overexpression of Notch using a transgenic line reduced the etv5a domain, suggesting Notch acts upstream to inhibit etv5a.

Conclusions: Taken together, these findings provide novel insights about the mechanisms of epithelial cell development during nephrogenesis.

Emx1 Is Essential for Distal Segment Development During Nephrogenesis

Elvin E. Morales, Rebecca A. Wingert. Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Vesicle kidneys are comprised of functional subunits called nephrons that typically have three basic pars: a renal corpuscle, a tubule with proximal and distal segments, and a duct. The developmental pathways that establish nephron segment identities from renal progenitors remain poorly understood.

Results: In summary, deletion of COX-2 leads to decreased renal expression of VEGF, and reduced capillary formation. This may result in abnormal capillary development and severe podocyte foot process effacement and impaired expression of slit diaphragm proteins. In conclusion, COX-2 activity is necessary for normal podocyte function and slit diaphragm formation during late stages of kidney development.

Funding: Private Foundation Support

Funding: NIDDK Support
Methods: The zebrafish embryo forms a simple two-nephron pronephric kidney that possesses anatomic and functional homology with human nephrons. emx1 is a homeobox gene that, along with its paralog emx2, is known for playing essential roles in brain development. While both genes are expressed in the pronephros, their roles in nephrogenesis have not been established. Using whole mount in situ hybridization, we found that emz1 and emz2 were dynamically expressed in renal progenitors, and became localized to the distal and proximal tubules, respectively.

Results: In knockdown studies, emz1 morphants formed a normal distal domain, marked by clcnk, but within it formed an expanded distal early (DE) segment, marked by slc2a5. These data suggest that emz1 is essential to promote the DL, and may restrict the DE and/or negotiate the site of the DE/DL boundary. Furthermore, emx2 expression is responsive to changes in retinoic acid (RA), which is essential to induce proximal segments and repress distal segments during nephrogenesis. RA treated embryos had a restricted emx1 domain and expanded emx2 domain, while exposure to the RA biosynthesis inhibitor DEAB conversely expanded emz1 and restricted emz2 expression. These data suggest that RA signaling acts upstream of both genes in renal progenitors, positively regulating emz2 and negatively regulating emz1.

Conclusions: Future studies will define the role of emx2, independently explore emx1/nephrogenesis, and examine the relationship of these emz genes to other factors, such as zic3b, that have been shown recently identified to be components of the gene regulatory networks that direct nephron segmentation. Preliminary data looking at factor interactions suggest that emx genes may be located downstream of them or work independently.

Enalapril Treatment Modulates Lymphangiogenesis and Fibrogenic Machinery in the Developing Rat Kidney
Keewhan Youn, Hyung Eun Yim, In Sun Bae, Byungkwon Kim, Young Sook Hong, Joo Won Lee. Dept of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.

Background: The renin angiotensin system plays a pivotal role in both renal development and progressive renal disease. Lymphangiogenesis occurs during normal organ development and pathological processes. In this study, we aimed to investigate the effect of angiotensin II inhibition on the expression of fibrogenic-related molecules and lymphatic vessels in the developing rat kidney.

Methods: Newborn rat pups were treated with enalapril (30 mg/kg) or vehicle for 7 days after birth. We investigated the intrarenal expression of fibroblast growth factor (FGF)-1, FGF-2, FGF receptor (R)-1, fibroblast-specific protein (FSP)-1, intercellular adhesion molecule-1, toll-like receptor (TLR)-2, and TLR-4 with Western blotting and immunohistochemistry at postnatal day 8. For the determination of lymphatics, the lymphatic vessel markers of vascular endothelial growth factor (VEGF)-C, VEGFR-3, and podoplanin were assessed. For detection of cell proliferation and collagen fibers, Ki-67 and Sirius red stainings were performed.

Results: In the enalapril-treated group, intrarenal FGF-1, FGF-2, FGF-1 and VEGF-C protein expression were decreased, compared to the controls (P < 0.05). Immunohistochemistry for the lymphatic vessel markers of VEGF-C, VEGFR-3, and podoplanin showed reduced lymphatic immunostainings in the enalapril-treated kidneys. However, FSP-1 expression was prominent in the interstitium and glomeruli in enalapril-treated kidneys. While cell proliferation was reduced in the enalapril-treated group, collagen deposition was enhanced in the enalapril-treated kidneys (P < 0.05). Intercellular adhesion molecule-1, toll-like receptor (TLR)-2, and TLR-4 protein expression showed no differences between the two groups.

Conclusions: Enalapril treatment during postnatal 7 days may induce perturbations in FGF/VEGF signals, cell proliferation, and lymphangiogenesis required for renal development and maturation and activate in part the fibrogenic machinery in the developing rat kidney.

The Effect of Prenatal Hypoxia and a Postnatal High Salt Diet on Renal Structure in the Aged Mouse
Sarah L. Walton, 1 Reetu S. Singh, 1 Joa Li, 2 Helle Bielefeldt-Ohmann, 3 Tamara Paravincini, 1 Melissa H. Little, 1 Karen M. Moritz. 1 School of Biomedical Sciences, Univ of Queensland, Brisbane, Queensland, Australia; 2 Dept of Physiology, Monash Univ, Melbourne, Victoria, Australia; 3 Inst for Molecular Bioscience, Univ of Queensland, Brisbane, Queensland, Australia; 4 School of Veterinary Science, Univ of Queensland, Gatton, Queensland, Australia.

Background: Chronic fetal hypoxia leads to growth restriction and increased risk of adulthood disease. This study examined the long-term renal outcomes of offspring prenatally exposed to hypoxia, and whether a postnatal high salt diet could exacerbate impairments.

Methods: Pregnant CD1 mice were housed in a hypoxic chamber (12.0% O2; N=8, HYP) or control (21% O2; N=8, CON) environment from embryonic day (E) 14.5 to birth (E21.5). A subset of male offspring was randomly allocated to a control diet (0.2% NaCl; N=8, CON) or high-salt diet (5% NaCl; HS) from 10 weeks of age. Blood pressure was measured at 12 months of age and kidneys were collected. Kidney sections were examined for nephron number, glomerulosclerosis, interstitial fibrosis, renal vascular remodeling, and α-SMA staining of CON kidneys was confined to vascular vessel markers of vascular endothelial growth factor (VEGF)-C, VEGFR-3, and podoplanin were assessed. For detection of cell proliferation and collagen fibers, Ki-67 and Sirius red stainings were performed.

Results: In the enalapril-treated group, intrarenal FGF-1, FGF-2, FGF-1 and VEGF-C protein expression were decreased, compared to the controls (P < 0.05). Immunohistochemistry for the lymphatic vessel markers of VEGF-C, VEGFR-3, and podoplanin showed reduced lymphatic immunostainings in the enalapril-treated kidneys. However, FSP-1 expression was prominent in the interstitium and glomeruli in enalapril-treated kidneys. While cell proliferation was reduced in the enalapril-treated group, collagen deposition was enhanced in the enalapril-treated kidneys (P < 0.05). Intercellular adhesion molecule-1, toll-like receptor (TLR)-2, and TLR-4 protein expression showed no differences between the two groups.

Conclusions: Enalapril treatment during postnatal 7 days may induce perturbations in FGF/VEGF signals, cell proliferation, and lymphangiogenesis required for renal development and maturation and activate in part the fibrogenic machinery in the developing rat kidney.

A Perinatal Switch in Iron Utilization Determines Postnatal Chronic Kidney Disease
Rongjia Deng, 1 Rosemary V. Sampogna, 1 Andong Qiu, 1 Jonathan M. Barasch. 1 Columbia Univ; 2 Tongji Univ, China.

Background: Iron deficiency affects 2 billion people world-wide and is a threat to embryonic and early postnatal development. Periconceptual maternal iron deficiency (PM-ID) results in hypoxic postnatal kidneys but it is not clear whether PM-ID causes cell-lineage or cell-stage specific hypoxia, nor which species of iron is involved.

Methods: We investigated a model of dietary iron deficiency and a deficiency of the transferrin receptor, TIR1 (cellular transferrin receptor, iron deficiency, ATF-ID) in different cell lineages using a novel TIR1-knockout construct.

Results: Severe PM-ID depleted both TIR and NTBI (non-transferrin bound iron) resulting in severe hypoxia postn. Despite iron deficiency, anephric, even anemia during gestation, whereas the overall structure of ureteric bud was maintained. Midle PM-ID resulted in surviving but severe postnatal postn. kidney hypoxia, disruption of the growth of the proximal tubule and TALH and increased mortality before weaning. To determine the mechanism of hypoxia we examined mesenchymal, ureteric and stromal ATF-ID with different Cre drivers. Mesenchymal ATF-ID (Six2Cre or KspCre) demonstrated increased demand for transferrin by the time of birth, resulting in worsening proximal tubule hypoxia, remarkable cystic transformation and interstitial fibrosis, and even anephria (Prox3Cre) before birth, the timing of which coincided with accelerated segment-specific growth. The combination of ATF-ID and PM-ID further worsened nephron development. In contrast, the collecting ducts (HoxB7Cre) and stroma (Foxd1Cre) did not depend on transferrin.

Conclusions: In sum, NTBI supported prenatal and postnatal stromal and ureteric development and the initial stages of metanephric development, whereas Tf iron was required for perinatal maturation of the nephron. Tf-iron depletion resulted in hypoxia, cysts, fibrosis, the timing and specificity of which was the result of a sequence of utilization of NTBI followed by Tf-iron. We propose that a perinatal switch in the mechanism of iron utilization governs the compartmentalization of the kidney and reflects changing cellular control of iron delivery. Iron deficiency is a cause of CKD.

Troyn/TNFRSF19 Marks a Progenitor/Cell Stem Population in the Kidney
Kees Schutgens, 1,2 Maarten B. Rookmaaker, 1 Robert Vries, 3 Marianne C. Ohmann, 1

Background: Segment committed stem cells play a crucial role in renal development and regeneration. Identification of these stem cells is an important step towards the development of new diagnostic and therapeutic strategies for renal diseases. In this study, we evaluated Troy, an adult stem cell marker in other organs, as a marker for segment committed stem cells in the developing and adult kidney.

Methods: Renal Troy expression was assessed during embryonic development and adult turnover using Troy-GFP mice. The contribution of Troy+ cells to renal development and turnover was investigated using in vivo lineage tracking after Troy-GFP-CreERT2/Rosa-LacZ. Daughter cells were identified using immunohistochemistry for tubular segment-specific markers. In addition, in vitro stem cell capacity was assessed by a sphere-forming assay.

Results: During embryonic development Troy+ cells were present in the ureteric bud [1A], whereas in adult kidney Troy+ cells were present in the papilla. After p1 induction, Troy+ cells gave rise to tubular structures by clonal expansion that persisted up to 2 years after induction [1B-1E]. Immunohistochemistry revealed predominant co-staining with iron markers in Troy+. Troy+ cells contributed to clonal, collecting duct formation after cessation of nephrogenesis. Finally, Troy+ cells had a higher in vitro sphere forming capacity than Troy- and Troy+ cells [1F-1H].
Preserved Nephrogenesis following Partial Nephrectomy in Early Neonates
Yuhei Kirita,1 Daisuke Kami,2 Ryo Ishida,1 Tetsuro Kusaba,1 Takaomi Adachi,1 Georg Kern, Caroline Wilmes,1 Nephrology, Huashan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China.

Background: The labeling-retaining cell (LRC) approach is a reliable way to identify adult stem cells. To identify the best labeling time for adult renal stem cells, we administered BrdU in different periods of the kidney development.

Methods: A pulse of BrdU was administered at different periods during E11.5-20.5, respectively, covering the whole process of the kidney development. The adult kidney were examined the distribution of BrdU-positive cells. A subtotal nephrectomy (Nx) was induced in adult mice to observe the response of BrdU-retaining cells to injury.

Results: In adult kidneys, the distribution of BrdU-retaining cells was heterogeneous with different BrdU-labeling time. With BrdU labeled at E11.5-13.5, lots of BrdU-positive cells were located in the papilla and inner medulla, only few scattered in the proximal tubules. With BrdU labeled at P9, lots of cells in the inner medulla and outer medulla could retain the immunoreactivity of BrdU. With BrdU labeled at P9, 11.5, the distribution of BrdU-positive cells was mainly in the outer medulla, few in the cortex inner medulla, no longer in the papilla. With BrdU labeled at P12.5-14.5 and P15.5-17.5, lots of BrdU-positive cells were in the outer medulla, but no longer in the papilla or inner medulla. With BrdU labeled at P18.5-21.5, BrdU-positive cells were only found in the cortex. The proximal tubules were the only nephron segments stably containing few BrdU-retaining cells after a chase period of six months. After Nx in adult mice, BrdU-positive cells were more significantly increased in the cortex near the incision edge. BrdU-positive cells mainly distributed in the proximal tubules at the site of injury. Some BrdU-positive cells did not express PCNA, even though numerous PCNA-positive cells were found near the incision edge of kidney. In contrast, originally retained abundant BrdU-positive cells in the outer medulla and inner medulla significantly reduced and disappeared rapidly in the vicinity of incision.

Conclusions: The locations of LRCs were different if BrdU was administered in different periods of kidney development. Most of BrdU-retaining cells were quiescent, few of them in the proximal tubule and papilla may be the renal progenitor cells.

FR-PO202
BrdU Labeling Adult Renal Stem Cells in Development Kidney
Li Ni,1 Jing Chen.2 Nephrology, Huashan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China.

Background: The labeling-retaining cell (LRC) approach is a reliable way to identify adult stem cells. To identify the best labeling time for adult renal stem cells, we administered BrdU in different periods of the kidney development.

Methods: A pulse of BrdU was administered at different periods during E11.5-20.5, respectively, covering the whole process of the kidney development. The adult kidney were examined the distribution of BrdU-positive cells. A subtotal nephrectomy (Nx) was induced in adult mice to observe the response of BrdU-retaining cells to injury.

Results: In adult kidneys, the distribution of BrdU-retaining cells was heterogeneous with different BrdU-labeling time. With BrdU labeled at E11.5-13.5, lots of BrdU-positive cells were located in the papilla and inner medulla, only few scattered in the proximal tubules. With BrdU labeled at P9, lots of cells in the inner medulla and outer medulla could retain the immunoreactivity of BrdU. With BrdU labeled at P9, 11.5, the distribution of BrdU-positive cells was mainly in the outer medulla, few in the cortex inner medulla, no longer in the papilla. With BrdU labeled at P12.5-14.5 and P15.5-17.5, lots of BrdU-positive cells were in the outer medulla, but no longer in the papilla or inner medulla. With BrdU labeled at P18.5-21.5, BrdU-positive cells were only found in the cortex. The proximal tubules were the only nephron segments stably containing few BrdU-retaining cells after a chase period of six months. After Nx in adult mice, BrdU-positive cells were more significantly increased in the cortex near the incision edge. BrdU-positive cells mainly distributed in the proximal tubules at the site of injury. Some BrdU-positive cells did not express PCNA, even though numerous PCNA-positive cells were found near the incision edge of kidney. Tissue-Specific Transport and Injury Response in Kidney Tubules Derived from Human Pluripotent Stem Cells
Benjamin S. Freedman,1,2,3 Craig R. Brooks,1 Albert Q. Lam,1 Ruyi Morizane,1 Joseph V. Bonventre.1,2 Brigham and Women’s Hospital; 1Harvard Medical School; 1Univ of Washington School of Medicine.

Background: Human pluripotent stem cells (hPSCs) can differentiate into cells expressing markers of kidney proximal tubules, but the functional capacity of these structures remains poorly understood. We developed a new, adherent, 3D culture system to evaluate transport and injury characteristics in hPSC-derived kidney tubules, compared to undifferentiated hPSCs.

Methods: hPSCs sandwiched in extracellular matrix were maintained in pluripotency-sustaining media to form undifferentiated cavitated spheroids (SOX2+OCT4+), or differentiated with growth factors into nephron progenitor cells (PAX2+SIX2+) and subsequently proximal tubules (LTL+LRP2+). hPSC spheroids or differentiated tubules were incubated with small molecule fluorescent probes to monitor transport into lumens, such as nephrotoxic chemicals to assess nephrotoxicity and kidney injury molecule-1 (KIM-1).

Results: Kidney tubule lumens selectively accumulated rhodamine-dextran (RD) and fluorescein methotrexate (MTX) transport cargos. Inhibition of actin polymerization with Latrunculin B, or permeabilization of tight junctions with EDTA, significantly reduced cargo accumulation. When treated with the nephrotoxic compounds gentamicin or cisplatin, 70% of hPSC-derived proximal tubules expressed KIM-1 at the apical/luminal surface. In contrast, the lumens of undifferentiated hPSC spheroids did not accumulate RD and MTX, nor express KIM-1 after toxic injury with cisplatin or gentamicin.

Conclusions: hPSC-derived kidney tubules are capable of transport and injury responses, which are characteristic of kidney proximal tubules and distinct from undifferentiated hPSC epithelia. The accessibility of this system to small molecules and live-cell microscopy enables rapid and real-time visualization of transport processes and testing of molecular pathways. KIM-1 expression in hPSC-derived kidney tubules may provide a quantifiable standard with which to predict human nephrotoxicity. Our findings introduce a framework in which to evaluate the functionality of hPSC-derived kidney epithelia, prior to transplantation into ESRD patients.

Funding: NIDDK Support, Private Foundation Support
many of these disadvantages could potentially be overcome. To this end we have been attempting to develop a protocol to produce proximal tubule-like cells from human iPSCs with xenobiotic transport capabilities.

Methods: Human iPSCs were differentiated into the intermediate mesoderm (IM) using Wnt and retinoic acid activation (CHIR99021 and TTNBP). Cells were further differentiated using combinations of different growth factors.

Results: The derived cells exhibited cobblestone morphology and expressed certain proximal tubule proteins such as claudin-2. Additionally, the cells can be maintained for up to 4 weeks in culture. Preliminary results demonstrate the ability of the differentiated cells to form functional organoids (Di-10-ASP) and organic anions (6-CF) and to extrude p-glycoprotein substrates (calcium-AM).

Conclusions: While further characterization will be needed, the initial results are promising, indicating that proximal tubule-like cells derived from iPSCs could be a new tool for screening the nephrotoxic potential of compounds.

The Direct Differentiation Method of Renal Tubular Cells by Synthetic mRNAs of Transcription Factors Identified from TF-Inducible Human ES Bank. Ken Hiratsuji,1 Toshiaki Monkawa,1 Shintaro Yamaguchi,2 Ryuji Morizane,1 Shigeru B.H. Ko,2 Minoru S.H. Ko,2 Hiroshi Itoh.1 1Dept of Internal Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan; 2Dept of System Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan.

Background: To find transcription factors which promote differentiation towards renal tubular cells, we utilized the human ES line s with doxycycline-controllable transcription factors (TF-inducible hES bank). To establish the differentiation method of renal tubular cells, we transfected the synthetic human mRNA of the target transcription factors into human ES cells.

Methods: We performed exhaustive search for DNA microarray data after TF induction in the hES bank, and analyzed them in silico to find the specific transcription factors, which expressed in kidney epithelial cells. We synthesized the synthetic human mRNA of the target transcription factors. By using the lipofection method, we transfected the synthetic mRNA of target transcription factors to human ES cells, and cultured them. The morphological changes, mRNA expressions, and protein expressions were analyzed.

Results: Some candidate transcription factors, which expressed in human kidney epithelial cells, were identified by in silico analysis. We successfully made synthetic mRNA of candidates of transcription factors. Five days after the transfection of the synthetic mRNA to human ES cells, we were able to observe characteristic morphological changes in the differentiated cells. The mRNA expression of OSR1, ITGAS, AQP1, and MEGALIN were increased. Moreover, the protein expression of AQP1 and LTL were also detected in the differentiated cells.

Conclusions: We identified specific transcription factors for differentiation toward kidney (especially, proximal tubular cells), and demonstrated that the differentiation of proximal tubular cell phenotype from human ES cells by a novel method using synthetic mRNA.

FR-PO206
Differentiation of Human iPSC into Functional Podocytes. Caroinka Rauch,1 Anja Wilmes,1 Elisabeth Feifel,1 Georg Kern,1 Paul Jennings,2 Gerhard Gstraunthaler.1 1Innsbruck Medical Univ; 2Innsbruck Medical Univ; 3Innsbruck Medical Univ; 4Internal Medicine, Rush Univ Medical College, Chicago, IL.

Background: Podocyte injury and subsequent loss of glomerular integrity is a major cause for chronic kidney disease (CKD). Two-thirds of patients with CKD suffer from disorders that arise from the glomerulus, mainly due to podocyte injury. Podocytes are highly specialized cells with a complex cytoarchitecture composed of foot processes that form the glomerular filtration barrier. The study of the molecular processes of glomerular injury is hampered by the fact that cultured primary podocytes have a limited capacity to divide and are difficult to maintain. However, generation of pluripotent stem cells (induced PSCs) from somatic cells allows the possibility of a new source of human cells. The high differentiation capacity of iPSCs would potentially enable the establishment of differentiation protocols for iPSC-derived podocytes which can overcome the burden of primary podocytes in culture.

Methods: To this end we applied and optimized a previously published protocol for podocyte differentiation (Song et al., 2012; PMID: 23029522). Human iPSCs are grown in differentiation media for ten days, containing growth factors known to be important for in vitro podocyte differentiation, BMP-7, activin A, and retinoic acid. Conditionally immortalized human podocyte cultures served as controls.

Results: After three days in differentiation media, iPSCs showed a clear podocyte morphology with podocyte foot processes. To further prove the state of podocyte differentiation, expression of specific podocyte markers was examined via immunofluorescence. Marked expression of the podocyte specific markers podocin and synaptopodin could be successfully verified on differentiated iPSCs. In addition, iPSC-derived podocytes showed significant release of VEGF into the culture medium. Finally, doxorubicin, a podocyte specific toxin, was highly toxic to these cells with an IC50 of 1.5 μM after 48h.

Conclusions: Podocytes generated from iPSCs have far reaching applications in disease modelling, tissue engineering, drug screening and discovery, and toxicity testing. Funding: Private Foundation Support, Government Support - Non-U.S.

Sourcing of Renal Tubular Epithelial Cells from Human Stem Cell-Derived Kidney Organoids. Elijah Weber,1 Benjamin S. Freedman,2 Jonathan Himmelstreich,1 Edward J. Kelly.1 1Pharmaceutics, Univ of Washington, Seattle, WA; 2Nephrolgy, Univ of Washington, Seattle, WA; 3Kidney Research Inst, Univ of Washington, Seattle, WA.

Background: Human pluripotent stem cells (hPSCs) provide a self-renewing, reproducible source of kidney cells for laboratory investigation and regenerative medicine approaches. Several groups have tested the potential of hPSC-derived renal tubular epithelial cell (RTECs) to grow and maintain differentiation in 2D and 3D cultures, compared to primary RTECs from adult kidneys.

Methods: hPSCs were treated with growth factors to promote differentiation in nephroblast progenitor cells (PA2/SIX2) and subsequently proximal tubules (LTL, ZO1, LR2). RTECs purified from tubular organoids were re-plated on tissue culture plates with or without extracellular matrix. RTECs were analyzed for proliferation, kidney-specific marker expression, and their capacity to seed a ‘kidney on a chip’ 3D microphysiological system (MPS).

Results: RTECs purified from hPSC organoids grew to confluent monolayers in minimal RTEC growth media on extracellular matrix. hPSC-derived RTECs resembled primary RTECs morphologically. Marker immunofluorescence analysis revealed that purified hPSC-RTECs possessed ZO1 + tight junctions and reacted with LTL. Sub-cultivation was limited to 2-3 passages, after which hPSC-RTECs underwent epithelial-to-mesenchymal transition and senesced. In a 3D MPS, hPSC-derived RTECs formed tubular structures comparable to primary RTECs. Immunofluorescence staining demonstrated positive signals for the tubule transporters SGLT2 and OAT3 as well as the epithelial markers CD113 and E-cadherin.

Conclusions: We have shown that hPSC-RTECs can propagate in vitro and maintain their differentiated characteristics, with morphology and markers similar to primary RTECs. hPSC-RTECs are grown in a 3D MPS, they maintain an epithelial phenotype and express membrane transporters essential for functions including glucose reabsorption and organic anion secretion. This system establishes a platform in which to optimize hPSC-RTEC expansion and function in a 3D, microfluidic context, with relevance for human disease modeling in vitro and for the development of regenerative therapeutics.

FR-PO208
Genome-Wide Methylation Analysis of Epigenetic Memory in Human Kidney Derived iPSC Cells. Osamu Takase, Tsuji Tsuchijima, Masao Nakagawa, Keichi Hishikawa. Dept of Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo, Tokyo, Japan.

Background: Epigenetic memory such as DNA methylation signature of iPSCs derived from parental cells was reported to determine the differentiation fate of the iPSCs (Nature 2012). Last year, we reported the result of kidney specific induction protocol (Nature Comm, 2013) by using two different kinds of human iPSCs established from human fibroblast (F-iPS) and human kidney epithelial cells (K-iPS), and demonstrated more efficient induction of markers of kidney development (WT-1, Pax-1, Sall-1) and differentiation (AQP-1, Nephrin) in K-iPS as compared with F-iPS cells.

Methods: In this study, we performed a genome-wide methylation analysis of K-iPS and F-iPS cells, and tried to clarify the mechanism of kidney lineage specific induction of human iPSCs.

Results: Among 27,578 sites, we focused on high CpG promoter location (GC>0.55, Cpg>0.75). 56 genes such as Kid1 and SOD2 were strongly methylated in F-iPS than in K-iPS. 47 genes such as KCNK12 and GATA4 were strongly methylated in K-iPS than in F-iPS. 23 markers of kidney development were strongly methylated in F-iPS than in K-iPS cells (P<2.36 vs 2.1; Sall-1 vs 2.87 vs 4.3). However, the marker of differentiation was strongly methylated in K-iPS (AQP-1: 1.7 vs 1.1).

Conclusions: These results demonstrate that epigenetic memory in parental cell determine the induction of human iPSC cells toward kidney lineages, and the role of key genes in kidney lineage specific induction will be discussed.

Mechanism of Kidney Repair in the Omentum-Kidney Model – Tubulogenesis and Differentiation of Free-Lying WT-1 Cells to Podocytes Occurring in the Fusion Zone. Ignacio Garcia-Gomez,1 Krishnamurthy P. Gudelithhil,2 Peter D. Hart,2 Jose A.L. Arruda,2 Ashok K. Singh.2 1Hektoen Inst of Medicine, Chicago, IL; 2Div of Nephrology, Univ of Illinois at Chicago, Chicago, IL; 3Kidney Research Inst of Medicine, Rush Univ Medical College, Chicago, IL.

Background: When activated omentum was fused to the injured kidney it induced glomerular repair and ameliorated chronic kidney disease (Garcia-Gomez et al JASN 2014). The fusion zone between the omentum and the injured kidney was highly proliferative (high Brd uptake), with abundant free-living nephron progenitor WT-1 cells. In this study, we examined the fusion area to further understand the mechanisms of repair in this model.

Methods: In 5/6 surgically nephrectomized polyethylene glycol intraperitoneally to activate the omentum and fuse to the injured kidney. Nephrectomized rats with complete omentectomy were used as control. Kidney tissues were examined 1-3 weeks after injury by histology and immunofluorescence (Pax-2, WT-1 and podocalyxin).
E15 embryonic rat kidney served as control for immune-staining. Two-week fusion zone tissue and tissue far from fusion zone, control and normal was quantified for mRNA for selected developmental genes (WT-1, Wnt-4, Pod1, Lim1, HNF-6, BMP-7) by RT-PCR.

Results: We found that the fusion zone tissue showed proliferation and expansion of collecting ducts, as evidenced by intense staining for Pax2, in a pattern similar to that seen in E15 embryonic rat kidney. Further, several islands of WT-1 cells in the fusion zone differentiated to podocytes, as judged by co-expression of podocalyxin. mRNA for Wnt-4 and WT-1 increased by 10-20 folds and mRNAs for other developmental genes increased by 2-5 folds in the fusion zone. Control tissue did not show the above changes.

Conclusions: The fusion zone tissue between the injured kidney and omentum appears to be a highly active tissue with proliferation and differentiation of kidney progenitor cells (WT-1, Pax-2, podocalyxin) taking place, and thus providing a healing environment to the injured kidney.

FR-PO210

Background: Mesenchymal stromal cells (MSCs) are immunomodulatory cells and have shown beneficial effects in kidney disease. It has previously been shown that human perivascular stromal cells (PSCs) from several different organs share characteristics of bone marrow derived MSCs (bmMSC), however, at the same time there are tissue specific properties. We hypothesized that human kidney derived PSCs (hkPSCs) are, due to tissue specific imprinting, more potent in kidney repair compared to bmMSCs and sought to find a novel clinical grade isolation method.

Methods: Human transplantation grade kidneys (n=3) were digested with continuously 5% platelet lysates and cells were selected for plastic attachment and NG2 cell enrichment (fig A). Culture was continued until spindle shaped cells appeared (kPSCs) and were compared to bmMSCs between passages 5-10.

Results: hkPSCs have comparable marker expression, cytokine excretion patterns, vascular stabilization and immunosuppressive capacity compared to bmMSCs. hkPSCs showed a distinct gene expression profile including an increased expression of HexD11, a homeobox factor important in nephrogenesis. In a wound scratch assay, kidney epithelial wound healing with conditioned medium of hkPSCs was significantly faster and after 7 hours approx. 80% closure was seen with hkPSC conditioned medium, which was only 40% with bmMSC supernatant (p<0.01) (fig B, C).

Conclusions: Here we show a novel, clinical grade isolation method of hkPSCs and compared these cells to bmMSCs. hkPSCs showed a distinct expression profile and are able to enhance kidney tubular epithelial wound healing to a greater extent than bmMSCs. These cells are a promising new cell therapeutic candidate to explore for treatment of kidney disease.

FR-PO211

Background: Atherosclerotic renal vascular disease (ARVD) induces microvascular loss and interstitial inflammation, ultimately leading to ischemic injury. Mesenchymal stem cells (MSCs) can induce angiogenesis, decrease inflammation, and limit apoptosis in experimental animals. Aging and co-morbid conditions may blunt these properties in older human subjects. This study tested the hypothesis that hypoxic preconditioning of adipose tissue-derived MSCs would modify expression of MicroRNAs (miR) associated with MSCs survival, angiogenic, and anti-inflammatory properties.

Methods: MSCs obtained from subcutaneous tissue of 7 patients with ARVD (Age 75.3±4) were cultured under normoxic or hypoxic conditions (1%) for 4 days. Hypoxic MSCs were returned to normoxia thereafter. Levels of the pro-survival and pro-angiogenic factors vascular endothelial growth factor (VEGF) and insulin-like growth factor (IGF) were measured in the supernatant by ELISA. Expression of miRs- 210, 21 and 145 in MSCs was measured by quantitative rt-PCR and apoptosis by flow cytometry for Annexin V.

Results: Hypoxic conditions increased VEGF and IGF (p<0.05) in MSC supernatant, but had no effect on apoptosis.

FR-PO212

Background: Atherosclerotic renovascular disease (ARVD) reduces blood flow (RBF) and GFR, and amplifies kidney hypoxia and inflammation. Adipose-derived mesenchymal stem cells (aMSCs) improve renal function in swine ARVD, in part by improving cortical micro-vascularization, but their safety and efficacy in humans are unknown. We report initial results from a pilot study of unilateral intra-arterial administration of low dose of autologous aMSCs in human subjects with ARVD under an FDA-approved IND.

Methods: Seven patients (Age 75.3±4) with severe ARVD were studied during fixed Na+ diet and ACE/ARB Rx before and 3 months after unilateral arterial injection of 2x10^5 autologous aMSC/kg. Stenotic-kidney (SK) cortical and medullary perfusion, volume and RBF were measured using multidetector CT and GFR by iohalamate clearance. SK deoxyhemoglobin levels (R2*) and fractional hypoxia were measured by 3T BOLD-MRI. Stenosis levels of neutrophil gelatinase-associated lipocalin (NGAL), monocyte chemotactic protein-1 (MCP-1), and tumor necrosis factor (TNF-α) were also measured.

Results: All patients tolerated aMSC without adverse effects. SK cortical volume and whole kidney RBF increased after three months (Figure 1), as did measures of tissue oxygenation, whereas no changes observed in the contralateral untreated kidneys (CLK) (data not shown). SK GFR did not change, nor did renal vein levels of TNF-α, MCP-1, or NGAL.

**Cell Therapy with Serelaxin Promotes Angiogenesis and Anastomosis which Is Critical for the Preservation of Vascular Integrity After Kidney Injury**

*Brooke M. Huusko,*1 Alexander Ruvantha Pinto,*2 Christian S. Samuel,*2 Sharon D. Ricardo.1

1Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Victoria, Australia; 2Australian Regenerative Medicine Inst, Monash Univ, Clayton, Victoria, Australia; 3Dept of Pharmacology, Monash Univ, Clayton, Victoria, Australia.

**Background:** We previously reported that the combination of mesenchymal stem cells (MSCs) and serelaxin (Rln) attenuates ureteral obstruction (UUO)-induced fibrosis. However the affect on endothelial cell regeneration is yet to be elucidated. Here we tested the hypothesis that a mechanism of repair after fibrosis is induced via endothelial anastomosis and sprouting in the presence of MSCs and Rln.

**Methods:** Live cell imaging of human bladder endothelial cells (HBECs) and umbilical vein endothelial cells (HUVECs) in tube forming assays were conducted with MSC-conditioned media and Rln (1-100ng/mL) to observe their affects on anastomosis. Spheroid assays determined the effects of MSC and Rln on HBECs and HUVECs sprouting in vivo. Proliferation of HBECs and HUVECs in the presence of MSCs and Rln was investigated. A qPCR for angiogenic genes was performed on MSCs cultured with or without Rln (100ng/mL). Endothelial integrity was visualized using CD31 protein localization in kidneys from mice 3, 5 and 7 days after UUO, with or without MSCs Rln (n=4-6/group).

**Results:** Anastomosis of HBECs was modulated in the presence of MSC-conditioned media and Rln with tube number and branch length increased compared to control. HUVECs readily formed sprouts in culture, which was enhanced when both Rln and MSCs were present. The migration capacity of MSCs towards injured HBECs was significantly increased when Rln was added. Rln induced the expression of angiogenic genes from the MSCs. Immunofluorescent microscopy of CD31 determined a decrease of endothelial integrity in a time-dependent manner in vivo. However the administration of MSCs and Rln preserved the vasculature.

**Conclusions:** These results suggest that both anastomosis and sprouting is enhanced only when both MSCs and Rln are used in combination. This may be in part due to Rln-induced release of angiogenic factors from MSCs which may aid in revascularization of the fibrotic kidney.

**Effects of Adipose Derived Stem Cells in a Model of Chronic Renal Hypoxia**

*Cristhian S. Samuel,*1 Yaping Fan,2 Shi Hui,3 Chen Xiao Lan.1

1Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Victoria, Australia; 2Australian Regenerative Medicine Inst, Monash Univ, Clayton, Victoria, Australia; 3Dept of Pharmacology, Monash Univ, Clayton, Victoria, Australia.

**Background:** Chronic renal artery stenosis causing chronic hypoxia may lead to irreversible damage of the kidney with progressive deterioration of renal function. Due to reduced regenerative abilities of the kidney, mesenchymal stem cells (MSC) emerge as an alternative therapy. The aim of this study was to investigate the effects of MSC, isolated from adipose tissue (ASC) on renal fibrogenesis induced by chronic renal artery stenosis.

**Methods:** Left renal artery of male Wistar rats was partially occluded and ASC were injected through caudal vein. ASC were characterized by their immunophenotype/multipotentiality. To analyze the migration and retention time, labeled ASC were injected 6 weeks after renal occlusion (RO) and analyzed 24, 48, 72 hours or 15 days after injection by flow cytometry. Caudal systolic blood pressure (SBP) was weekly estimated. Renal function and tissue gene expression levels of collagen I (Col I), Fibronectin (FN) and TGF-β were determined by qPCR, 6 weeks after renal artery occlusion in the following groups: Sham; Stenotic control (StC), receiving PBS i.v.; Stenotic + ASC (StC + ASC). ASC were injected 3 and 5 weeks after RO i.v.

**Results:** After 48 hours cells were retained in both kidneys, stenotic and contralateral followed by heart and lung. After 15 days the presence of ASC decreased significantly in the lungs and heart but they were still present in the kidneys. StC animals showed progressive increase in SBP while the StC + ASC rats had a stabilization of SBP with no further increase after RO injection. Plasma ANP levels were similar among groups except developed proteinuria which was reduced by ASC treatment. There was an increase in the expression of Coll, FN and TGFβ in the stenotic kidney (cortex and medulla) which was reversed by ASC treatment.

**Conclusions:** In conclusion ASC prevented further increase in SBP and reduced the expression of molecules induced-fibrosis. ASC migration and retention in the clipped and contralateral kidneys can be potentially beneficial to restore damaged tissue and preserve the function of the contralateral kidney.

**Therapeutic Effects of Erythropoietin Producing Kidney Mesenchymal Stem Cell Derived Microparticles on Anemia in Chronic Kidney Disease Mice**

*Hoon Young Choi,*1 Mirae Lee,1 Yung Yi Kang,1 Sang-Kyu Ha,2 Hyeong Cheon Park.1

1Research Institute of Medical Science, Kangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, Gyeongsang University College of Medicine, Daegu, Korea.

**Background:** Progression of chronic kidney disease (CKD) results in aggravation of erythropoietin (EPO)-dependent anemia. Microparticles (MPs) shed from kidney mesenchymal stem cells (KMSC) have been demonstrated to confer protective effects against acute kidney injury and kidney fibrosis via transfer of messenger RNA. Previous studies have demonstrated improved renal function by EPO transduced MSC. We investigated whether MPs derived from EPO producing KSMC can exert therapeutic effects on anemia in CKD mice.

**Methods:** Mouse model of CKD and renal anemia was induced by the electrocoagulation of right renal cortex and sequential left nephrectomy. Six weeks post-nephrectomy, CKD and anemia was confirmed via blood urea nitrogen (BUN) and hemoglobin measurements as well as renal histology. Stable human EPO-producing KMSC (EPO-KMSC) and their MPs isolated by differential ultracentrifugation were injected intraperitoneally into established CKD mice and followed for 2 weeks (EPO-KMSC: 1×10⁶ per mice, MP: 2×10⁶ per mice). BUN and hemoglobin were evaluated and degree of renal tubulointerstitial damage was examined for 2 weeks after CKD.

**Results:** EPO secretion from EPO-KMSC was confirmed to sustain over 4 weeks in vitro and RT PCR reviewed the presence of EPO mRNA within MPs. Injected EPO-KMSC-derived MPs were demonstrated within tubulointerstitial area. Animals that received EPO-KMSC and MPs demonstrated significantly lower BUN levels compared to CKD control mice (60±2, 62±7 vs. 83±7 mg/dL, P<0.05, respectively). Importantly, hemoglobin levels were significantly higher in CKD mice treated with EPO-KMSC and MPs compared to CKD control mice (11.7±0.1, 11.3±0.5 vs 9.9±0.7 mg/dL, P<0.05, respectively).

**Conclusions:** The use of EPO secreting KMSC is a viable strategy for cell therapy in renal anemia. Our results suggest that EPO-KMSC derived MPs as well as EPO-KMSC can improve renal function and renal anemia in CKD mice.

**Transplantation of Human Embryonic Mesenchymal Stem Alleviates Lupus Nephritis in MRL/lpr Mice**

*Yuan Li,*1 Yaping Fan,2 Shi Hui,1 Chen Xiao Lan.1

1Affiliated Hospital of Nantong Univ, Nantong, China; 2Affiliated Hospital of Nantong Univ, Nantong, China.

**Background:** Compared with bone marrow derived MSC, embryo-derived MSC have greater expansion and differentiation potentials. T helper cell 17(Th17) and interleukin (IL-17) is closely related to the occurrence and development of Lupus. The glial cell-derived neurotrophic factor (GDNF) which is closely related to the kidney development is found to be a kidney protection factor and can increase the renal protective effects of stem cells as well. Perserin (PS) is a member of the family of GDNF and also involves in the kidney development. We investigated the effects of human embryonic MSC (iMSC) in lupus nephritis in MRL/lpr mice.

**Methods:** The MRL/lpr mice were divided into 2 groups: Control, iMSC group. iMSC were injected at one dose of 1×10⁶/200ul twice (at the 16th, 19th weeks of age) through tail vein. Mice were sacrificed at 24 weeks of age.

**Results:** Multi-treatment of iMSC was able to increase the survival, decrease the levels of 24-h proteinuria, and anti-double-stranded DNA (dsDNA) antibody. +MSC treatment showed significant improvement of renal index. Both iMSC and Intestinal inflammatory cell infiltration in MRL/lpr mice. iMSC treatment also inhibited Th17 cell differentiation in spleen and decrease the serum level of IL-17. The level of GDNF and PSP was increased in renal of iMSC treatment MRL/lpr mice.

These findings indicated that hMSCs transplantation might be a therapeutic potential of hASC.

Methods: Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, ip for 10 days), GM-TMSCs (1 x 10^7 cells, intravenous injection at 1 day after the 1st GM injection) and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a tranwell co-culture system of NRK cells and T-MSC. Intracellular ROS was analyzed by measuring NOX activity, H₂O₂, generation, NOx mRNA expressions with DCF-DA staining.

Results: PKH-26-labeled T-MSCs were observed in renal tubular cells in GM-TMSCs group. The infusion of T-MSCs preserved renal function with a decrease in proteinuria. T-MSCs also accelerated renal tubular dilatation and reduced apoptosis of renal tubular cells in the rats with GM-induced AKI. The infusion of T-MSCs downregulated the expression of Bax, Cytochrome c, Cleaved caspase-9 and -3 and upregulated Bcl-2 of renal cortical tissue. In-vivo study revealed an amelioration of GM-induced oxidative stress and apoptosis of NRK cells by T-MSC.

Conclusions: Our results suggest that T-MSCs protect the kidney from GM-induced AKI, possibly via the mechanism of modulation of oxidative stress and apoptosis.

Renoprotective Effects of Tonsil-Derived Mesenchymal Stem Cells in Gentamicin-Induced Acute Kidney Injury (AKI)

Duk-Hee Kang, Eun Sun Ryu, Hyun-soo Shin, Jyeon Ko. Ewha Womans Univ School of Medicine.

Background: Gentamicin (GM)-induced AKI occurs in 10-20% of treated patients. GM is accumulated in renal epithelial cells, which causes the loss of the brush border, apoptosis and overt necrosis of renal tubules. Recent developments in stem cell research have shown a promise for the treat-ment of AKI, however the mechanisms underlying the improvement in kidney function provided by stem cell therapy remain unclear. Tonsil-derived mesenchymal stem cells (TMCs) can be isolated from tonsils of the patient undergoing tonsilllectomy, and vandare reported to be effective in treatment of various diseases. The aim of this study is to investigate the therapeutic potential of T-MSCs in the treatment of AKI induced by GM.

Methods: Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, ip for 10 days), GM-TMSCs (1 x 10^7 cells, intravenous injection at 1 day after the 1st GM injection) and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a tranwell co-culture system of NRK cells and T-MSC. Intracellular ROS was analyzed by measuring NOX activity, H₂O₂, generation, NOx mRNA expressions with DCF-DA staining.

Results: PKH-26-labeled T-MSCs were observed in renal tubular cells in GM-TMSCs group. The infusion of T-MSCs preserved renal function with a decrease in proteinuria. T-MSCs also accelerated renal tubular dilatation and reduced apoptosis of renal tubular cells in the rats with GM-induced AKI. The infusion of T-MSCs downregulated the expression of Bax, Cytochrome c, Cleaved caspase-9 and -3 and upregulated Bcl-2 of renal cortical tissue. In-vivo study revealed an amelioration of GM-induced oxidative stress and apoptosis of NRK cells by T-MSC.

Conclusions: Our results suggest that T-MSCs protect the kidney from GM-induced AKI, possibly via the mechanism of modulation of oxidative stress and apoptosis.

FR-PO221
Towards the Clinical Application of Gene-Modified Hematopoietic Stem Cell Transplantation for Cystinosis; Tatiana Vm Lobry, Jay Sharma, Sarah Ur, Celine Roccia, Betty Cabrera, Stephanie Cherqui. Pediatrics, Univ of California San Diego, San Diego, CA.

Background: Cystinosis is an autosomal metabolic disease caused by mutations in the CTNS gene, encoding a lysosomal cystine transporter, leading to cystine accumulation and multi-organ failure. Affected individuals present before 2 years of age with a Fanconi syndrome and eventually progress to end-stage renal failure. Treatment with cysteamine does not prevent these complications. We showed previously that wild-type HSC transplantation could treat cystinosis in the Ctns-/- mice. Thus, we developed an autologous transplantation strategy of HSCs genetically modified ex vivo to express a functional CTNS gene. Preclinical studies using a SIN-lentivirus vector containing CTNS to transduce Ctns-/- HSCs and transplanted in Ctns-/- mice led to cystine reduction in all tissues and kidney function improvement.

Methods: Pharmacological and toxicological studies are in progress. We established the optimal conditions to transduce human CD34+ HSCs with our lentiviral vector to obtain a Vector Copy Number (VCN) included between 1 and 3. We performed Colony Forming Unit (CFU) assays to ensure normal proliferation and differentiation of transduced human CD34+ HSCs from healthy donors and cystinotic patients and the In Vitro Immortalization (IVIM) assay, a genotoxicity test. Serial transplantations in the Ctns-/- mice will assess the safety of our vector in vivo.

Results: While we obtained VCN within the range for healthy donors CD34+ HSCs, the VCN for the Ctns-/- CD34+ HSCs is below 1, requiring further optimization. CFU assays did not show aberrant differentiation of the transduced CD34+ cells from the healthy donors and cystinotic patients. Finally, no immortalized clones were observed with the IVIM assay suggesting a good safety profile of our vector. These results will be included in our IND for a phase 1 clinical trial for cystinosis. The in vivo serial transplantations are in progress.

Conclusions: This work represents the first stem cell and gene therapy treatment strategy for cystinosis and should lead to a phase 1 clinical trial.

FR-PO222
Mesenchymal Precursor Cell Therapy for Diabetic Nephropathy: 24 Week Results from a Phase 2A Randomized Controlled Trial; David K. Packham, Ian R. Fraser, Peter G. Kerr, Silviu Itescu, Karen R. Segal. 1MRGB, Melbourne, VIC, Australia; 2Epsworth H, Melbourne, VIC, Australia; 3Dept Nepth, Monash M C, Melbourne, VIC, Australia; 4Mesoblast PLC, NY, NY.

Background: Renal inflammation and endothelial dysfunction contribute to the etiology of diabetic nephropathy (DN). Bone marrow derived mesenchymal precursor cells (MPC) can modulate both inflammatory cells and microvasculature. We conducted a randomized, placebo (PBO) controlled, dose-escalating trial of allogeneic MPC in 30 subjects with type 2 DN.

Methods: Patients (24 men, 6 women) with an estimated glomerular filtration rate (eGFR) of 20-50 ml/min/1.73 m2 and on a stable regimen of renin-angiotensin inhibition were randomized to a single IV infusion of PBO (saline) or 150 million (M) or 300M MPCs (N=10 per group). Patients have been followed-up for 24 w. Baseline mean age was 70 years mean eGFR was 34.6, 35.7 and 34.6 ml/min/1.73 m2 for PBO, 150M and 300M, respectively. Patients have been followed-up for 24 w. Baseline mean eGFR was 34.6, 35.7 and 34.6 ml/min/1.73 m2 for PBO, 150M and 300M, respectively.

Results: There were no treatment-related adverse events. For eGFR change from baseline at 24 w, the least square mean (LSM) differences from PBO were 3.2±2.5 (8.1%) in both 150M and 300M groups. PBO-adjusted treatment differences were greater in pooled MPC with baseline eGFR<30: 4.9±2.3 (+12%) at 24w. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 6.8±4.8 in both treatment groups. Baseline IL-6 levels correlated with SCR and eGFR improvement at 12 w in the M groups (r=0.57 and 0.50; both p<0.05) but not in PBO. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 7.8±4.8 ml/ min/1.73 m2 in pooled MPC patients with baseline IL-6 3.5 pg/ml and 5.6±5.0 in MPC patients with baseline IL-6 3.5 pg/ml, suggesting greater preservation or improvement in eGFR relative to PBO in the presence of elevated IL-6.

Conclusions: In this first in humans study, a single MPC infusion improved or stabilized GFR over 24w. Baseline eGFR>30 and high IL-6 levels suggest two biomarkers that may predict efficacy with MPC treatment. Positive response to MPC therapy may be enhanced by the presence of non-fibrotic, but at-risk, renal tissue and aberrant pro-inflammatory milieu.

FR-PO223
Long-Term Effect of Methylprednisolone Pulse and Autologous SVF (Stromal Vascular Fraction) Therapy in Severe IgA Nephropathy with CKD Stage III; Byoung-Soo Cho,1 Yumi Choi;2 Jin-Soo Suh;3 1The Medical Hub Kidney Center, MIRAE ENG Research Inst, Seoul, Republic of Korea; 2'Dept of Pediatrics, Gwangmyeong Sang-Ae Hospital, Gwangmyeong-si, Gyeonggi-do, Republic of Korea; 3'Dept of Internal Medicine, The Catholic Univ of Korea, Bucheon-si, Gyeonggi-do, Republic of Korea.

Background: Up to date there is no specific method of treatment in severe IgA nephropathy with CKD, but giving ACE inhibitor, angiotensin II receptor blocker(ARB), omega-3 etc. and eventually almost all cases fall into CKD V and need KTP or dialysis. Cell-based therapy is an emerging field in nephrology field especially aspide derived stem cells(ASCs). The beneficial effects of mesenchymal stem cell occur through differentiation-independent pathways include increased cell survival and proliferation, decreased inflammation, immune modulation, tissue regeneration etc.

Methods: We tried methylprednisolone(MP) pulse therapy followed by autologous SVF(stromal vascular fraction), which contained ASCs in severe IgA nephropathy with CKD stage III. This case was 44years old female patient, Renal biopsy finding showed Grade IV(Lee’s classification) with CKD stage 3. MP pulse was tried 6 cycles followed by autologous SVF were injected through intraveneously 4 times at 3 weeks interval.

Results: Initial renal biopsy findings before treatment(Tx) showed 61% scerotic glomeruli, however follow up renal biopsy 18 months after Tx showed 41% sclerotic glomeruli and disappeared immune deposits, The serum creatinine level before Tx was 1.77mg/dl with GFR 35ml/min, however 18 months after Tx serum creatinine was 1.03mg/dl with GFR 61ml/min.

Conclusions: In this case MP pulse therapy with autologous SVF treatment in intractable IgA nephropathy might be a promising therapeutic means without any notable side-effect or complications especially in early stage CKD, although the efficacy and safety, of SVF infusion therapy needs long term studies.

Extracellular Vesicles in Glomerular VEGF Homeostasis; Sargs Sedrakyan,1 Stefano Porta,2 Hasnik Soloyan,1 Nikita Triprumaneni,1 Roger E. De Filippo,1 Benedetta Bussolati,2 Laura Perin.1 1Children's Hospital Los Angeles; 2Univ of Turin.

Background: Strict regulation of VEGF signaling between podocytes and glomerular endothelial cells (GEC) is critical for GEC survival and function, therefore, loss of glomerular VEGF homeostasis during disease progression can impact GEC integrity leading to decline in glomerular function. Importantly, recent studies have described extracellular vesicles (EVs) to play important role in stem cell mediated paracrine modulation, including in kidney. We have already established that aminoistic fluid stem cells (AFSC) are regenoprotective, and we hypothesize that EVs released within damaged glomeruli are involved in VEGF regulation. Herein, we investigate the impact of AFSC derived EVs in the maintenance of glomerular VEGF homeostasis.

Methods: Using qPCR and ELISA we measured VEGF expression along the course of disease progression in isolated glomeruli of mice affected by Alport Syndrome (AS). Endothelium morphology was evaluated by IHC and TEM. GEC were FACS sorted from a GEC specific Tek reporter mice and studied by gene and protein arrays for VEGF/VEGFR, oxidative stress, and apoptotic pathways. Co-cultured GEC and AFSC overstimulated with VEGF were used to study the direct role of EVs in VEGF regulation. EVs were characterized and injected into AS mice for in vivo evaluation.

Results: Mice at advanced stages of Alport disease presented with aberrant VEGF activity within glomeruli, significant GEC apoptosis, oxidative stress and loss of GEC. Delivery of AFSC derived EVs normalized VEGF expression and ameliorated endothelial damage. Importantly, the soluble receptor of VEGF, sFlt1—involved in regulating VEGF signaling—was also modulated upon treatment, indicating a VEGF/sFlt1 mechanism of regulation by EVs. In vitro experiments further confirmed the direct role of EVs in VEGF/sFlt1 regulatory mechanism.

Conclusions: In this case, our data demonstrate for the first time the alteration of VEGF signaling within AS glomeruli. We further showed that AFSC derived EVs play an important role in maintaining glomerular homeostasis of VEGF signaling, so critical to maintain GEC integrity and function, presenting with a potential for new targeted therapies in CKD.

Renal Exosomes Store and Transfer the Ischemia Preconditioning State and Protect Rats with Severe Renal Ischemia; Katherine J. Kelly,1 Jesus H. Dominguez,2 H. Dominguez,1,2 1TheAll Medical Hub College of Medicine, Indiana, IN; 2Medicine, Indiana Univ Medical School, Indianapolis, IN; 2Medicine, Veterans Administration, Indianapolis, IN.

Background: Acute Kidney Injury (AKI) is a risk factor for chronic kidney disease (CKD) and end-stage renal disease (ESRD). We have reported that intravenous renal cell transplants (IRCT) improve outcomes in rats with AKI (JAP 303:F357, 2012). IRCT action was mediated by relatively small number of anchored and retained cells, and we hypothesized that cells amplified renal protection by releasing exosomes (EX) acting at a distance.
Methods: We tested if renal EX from cultured cells used for IRCT improved AKI. Notably, two groups of Dawley rats (SD, n = 4–7) were subjected to 45 minutes of bilateral ischemia (IR). Renal exosomes (600 μg/protein/rat) were then given intravenously.

Results: There were 5 groups of rats: 1, sham, no IR; 2, renal ischemia (IR) untreated (NO-EX); 3, IR treated with heat inactivated EX (HI-EX); 4, IR treated with normal EX (NL-EX); 5, IR treated with EX prepared by kidney cells subjected to ischemia reperfusion injury (IPC-EX). In sham, serum creatinine was 0.3±0.03 at 24 hrs and 0.3±0.02 at 48 post-surgery. In NO-EX it was 2.1±0.6 and 1.7, post IR, respectively. In HI it was 2.2±0.1 and 1.6±0.3. However, in NL-EX it was 2.4±0.4 and 0.7±0.1. The most striking effect was found in IPC-EX (1.5±0.1, p<0.05 vs. all including NL-EX). Kidney weight (mg/mg body weight) 6 days post IR was also improved by EX: 3.8±0.1 in sham; 6.7±0.6 in NO-EX; 6.7±0.6 in HI; 5.2±0.2 in NL-EX 5.2±0.2, and 4.4±0.2 in IPC-EX, which was significantly lower than all IR groups, including NL-EX. Neutrophils (PMN) in IPC-EX were also reduced by 65% (p<0.05) when compared to NL-EX. IPC-EX reduced renal C3 expression in glomeruli and tubules by 73% and 82% respectively (p<0.05 for both). IPC-EX also protected 76% of renal tubules when compared to NO-EX.

Conclusions: IPC is effective but impractical. However, EX given IV can communicate the IPC state, reach the kidneys, modulate inflammation and protect function and structure following severe IR.

FR-PO226

The Impact of Preexisting Chronic Kidney Disease on the Severity and Recovery of Acute Kidney Injury Sung Yoon Lim,1 Young Ju Na,1 Myung-gyu Kim,1 So-young Lee,2 Sang-Kyung Jo,1 Won-Yong Cho.1 1Dept of Nephrology, Korea Univ Hospital, Seoul, Korea; 2Dept of Nephrology, Edith Univ Hospital.

Background: Recent observational studies have shown that a substantial proportion of patients with acute kidney injury (AKI) have often progression to chronic kidney disease (CKD). Among several risk factors for the development of CKD after AKI, decreased baseline glomerular filtration rate (GFR) represents an important risk factor. However precise mechanisms involved in the development of fibrosis after AKI with preexisting CKD have not been completely ascertained. Here in this study, we assessed the impact of preexisting CKD on the severity and recovery of AKI in mouse model of 5/6 nephrectomy.

Methods: Male CD-1 mice underwent 5/6 nephrectomy or sham operation, and 6 weeks later ischemia reperfusion injury (IRI) was performed. On day 1, 7 and 28 after IRI, functional, histological, and molecular parameters were compared between them.

Results: Twenty minutes clamping of renal pedicle in 5/6 nephrectomized mice did not provoke more severe functional, histological deterioration compared to normal mice on day 1 and 7. Similar elevations in SCR were observed in both groups until day 7 after IRI; however, SCR remained higher on day 28 in 5/6 nephrectomized mice compared to normal mice, suggesting that preexisting CKD does not modify severity of AKI but adversely affect the recovery process. From day 7 to 28, mRNA expression of p21, and protein level of p13, both representing cell cycle arrest were significantly increased in 5/6 nephrectomized mice (CDK+AKI) compared to sham (sham+AKI). Treatment with p53 inhibitor after IRI resulted in not only decreased p21 and p13 protein level, but also fibrosis in CDK+AKI mice, suggesting that epithelial cell cycle arrest is partially responsible for impaired recovery from AKI in 5/6 nephrectomized mice.

Conclusions: Taken together, reduced nephron mass do not seem to increase severity of AKI, but have negative effect on repair process, leading to development of fibrosis.

FR-PO227

Impaired Functional Recovery from Acute Kidney Injury in Rats with Preexisting Chronic Kidney Disease Predicts the Severity of De Novo Hypertension Aaron J. Polichnowski,1,2 Karen A. Griffin,3,1 Mana Dissanayake,1 Anil K. Badiani,1,2 Edward Hines JR. VA Hospital, Hines, IL; 1Medicine, Loyola Univ Medical Center, Maywood, IL.

Background: The mechanisms by which AKI accelerates the progression of CKD remain poorly understood. We have recently demonstrated that preexisting CKD predisposes to impaired recovery from AKI as evidenced by exacerbated levels of tubulointerstitial fibrosis and modest elevations in blood pressure at 4 weeks post injury. However, a rigorous assessment of the precise mechanisms involved in the development of fibrosis after AKI with preexisting CKD have not been exhaustively explored.

Methods: Male SD rats underwent normotensive 3/4 nephrectomy (3/4 NX) and were chronically instrumented with a BP radiotelemeter. Two weeks later, rats were subjected to 40 min IR (n=20) or sham IR (n=8). BP was assessed every 10 min, 24 hr/day for 4 weeks and glomerular filtration rate (GFR) was then assessed in the conscious state (FITC-inulin).

Results: As compared to baseline values, systolic BP was significantly elevated (P<0.05) in rats at 4 weeks post IR (134±2 vs. 149±5 mmHg, respectively) but not sham IR (139±4 vs. 140±2 mmHg, respectively). GFR was significantly less (P<0.05) in rats subjected to IR vs. sham IR (1.1±1 vs. 1.4±1 ml/min, respectively). As shown in Figure 1, a very strong negative correlation was observed between GFR and the increase in systolic BP over the 4 week protocol. SCR values 48 hours post IR did not correlate with either GFR or the change in systolic BP at 4 weeks post AKI, indicating that the development of hypertension following IR was due to impaired recovery from AKI as opposed to a greater severity of AKI.

FR-PO228

Exocytosis of Endothelial Lysosome-Related Organelles Hair-Triggers a Path of Loss of Glycocalyx at the Onset of Sepsis Joseph A. Zullo,1 Jie Fan,1 Tala F. Azar,1 Wan-yi Yen,2 Min Zeng,1,2 Jan Chen,1 Brian B. Ratliff,1 Jungol Song,1 John Tarbell,1 Bingmei M. Fu,2 Michael S. Goligorsky,1 1New York Medical College; 2The City College of The City Univ of New York; 1/LSun Medical College, Seoul, Republic of Korea.

Background: Endothelial surface glycocalyx (ESG) is a well-known regulator of leukocyte surveillance, vascular permeability, and a sensor of shear stress. ESG is degraded during sepsis, thus contributing to systemic multiorgan involvement. Our previous demonstration of a very early post-stress exocytosis of lysosome-related organelles (LRO) with their lytic enzymes led us to hypothesize that exocytosis of LRO may catalyze a synchronized degradation of ESG.

Methods: To test this hypothesis we first analyzed the time-course of exocytosis of Weibel-Palade bodies and secretory lysosomes after application of lipopolysaccharides (LPS) to endothelial cells.

Results: Time-lapse video microscopy revealed that LROs undergo agititation and vectorial movement with a time course of a few minutes after LPS. In addition, spectrophotometry measurements illustrated an increase of lysosomal cargo, cathepsin B, within the media after 10min of LPS exposure. Two therapeutic maneuvers, a nitric oxide intermediate, NG-hydroxy-L-arginine (NOHA), and culture media conditioned by endothelial progenitor cells (EPC-CM) reduced the directionality and motility of LRO. The patch loss of ESG occurring with the similar fast kinetics was confirmed using confocal fluorescence microscopy and Stochastic Optical Reconstruction Microscopy. The loss of ESG was blunted by pretreatment with NOHA or EPC-CM. Moreover, these treatments resulted in a significant reduction of mortality of septic mice.

Conclusions: In summary, above studies provide the first demonstration of the very early patchy disintegration of ESG which can be prevented by pretreatment with NOHA and EPC-CM, maneuvers that reduced exocytosis of LRO. Data support the hypothesis assigning to stress-induced exocytosis of these organelles the role of a hair-trigger for local degradation of ESG that in turn initiates leukocyte infiltration, increase vascular permeability, and partially accounts for the later morbidity and mortality.

Vitamin D Deficiency Contributes to Vascular Damage in Sustained Ischemic Acute Kidney Injury Anna C.,1 de Bragança,1 Rildo A. Volpin,1 Purvi Mehrrotra,2 Carlie M. Ivancic,2 Lucia Andrade,1 David P. Basile,2 1Nephrology, Univ of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil; 2Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN.

Background: It has been shown that injury to the renal vasculature may play an important role in the pathogenesis of ischemic acute kidney injury (AKI). Reductions in microvascular density may play a critical part in the progression of chronic kidney disease (CKD) following AKI-induced ischemia/reperfusion injury (IRI). Vitamin D deficiency (VDD) is associated to tubulointerstitial damage and fibrosis progression following IRI-AKI. We evaluated the effect of VDD in sustained IRI-AKI, hypothesizing that VDD contributes to vascular damage.

Methods: Wistar rats were fed 25(OH)D3-free or standard diets for 35 days. On day 28, rats were randomized into four groups: control (sham), VDD, bilateral IRI and VDD IRI. Rats were analyzed 7 days after the surgeries.

Results: VDD rats showed impaired capillary density (by cainin staining) and reduced VEGF expression, even in the absence of injury. In addition, VDD IRI rats manifested a remarkable capillary rarefaction and also had increased RW/BW, tissue injury scores, FSP-1.
nSMA when compared to either VDD or IRI rats. VDD IRI also had increased levels of infiltrating activated CD4+ and CD8+ cells secreting higher levels IFN-γ and IL-17 while the number of regulatory T cells was reduced, relative to IRI rats.

Conclusions: VDD impairs renal capillary density and exacerbates fibrotic damage and pro-inflammatory milieu following AKI, which may contribute to the transition of CKD following AKI. Funding: CAPES/CNPq/FAPEPI, NIH DK58411 (DPB). Funding: NIDDK Support

Exosomes-Mediated Delivery of Pro-Survival MicroRNA-486-5p in Acute Kidney Injury
Jing Li, Vinay, Dylan Burger, Alex Gutsol, William A. Knoll, David Allan, Kevin D. Bums. Nephrology, Dept of Medicine, Ottawa Hospital Research Inst, Univ of Ottawa, Ottawa, ON, Canada.

Background: We recently showed that administration of human endothelial colony forming cells (ECFCs) and their exosomes to mice with ischemic acute kidney injury (AKI) attenuated renal damage. Our data also indicate that ECFCs release exosomes that are highly enriched in micro-RNA (miR)-486-5p and protect against hypoxia-induced endothelial cell apoptosis. MiR-486-5p targets phosphatase and tensin homolog (PTEN), which is involved in the Akt pro-survival pathway. In the present study, we further examined the role of exosomes and miR-486-5p on the Akt pathway in vivo, and tested the hypothesis that exosomes transfer miR-486-5p to endothelial cells in vitro.

Methods: Mice with ischemic AKI were injected (i.v.) with exosomes with or without miR-486-5p. Kidneys were subjected to immunoblot analysis and RT-PCR for miR-486-5p. Transfer of ECFC exosomes and miR-486-5p was studied in human umbilical vein endothelial cells (HUVECs).

Results: Bioinformatic analysis of the 10 most abundant miRs in ECFC exosomes revealed that they were all involved in the Akt pro-survival pathway. Innice with AKI, exosome treatment significantly increased renal miR-486-5p levels (P<0.01 vs ischemia alone, n=6-7), associated with decreased PTEN expression, and increased Akt phosphorylation. In cultured HUVECs, ECFCs exosomes labeled with the fluorescent dye PKH-26 localized to the perinuclear compartment. Treatment of HUVECs with ECFC-derived exosomes or co-culture of ECFCs with HUVECs caused a 40-fold increase in levels of miR-486-5p. Transfection of ECFCs with pre-miR-486-5p, followed by co-culture with HUVECs was associated with a further marked increase (~20-fold) in miR-486-5p levels in HUVECs (P<0.001 vs control, n=3). This effect was blocked by pre-incubation of HUVECs with ethylisopropyl amiloride (an inhibitor of exosome uptake).

Conclusions: These data suggest ECFC-derived exosomes exert renoprotective effects in AKI, possibly via the transfer of miR-486-5p to endothelial cells. Exosome-mediated transfer of miRs could represent a strategy to target pro-survival pathways in the injured kidney.

FR-PO231
The Role of Vascular Endothelial Cells in the Protective Effect of Delayed Ischemic Preconditioning in Renal Ischemia/Reperfusion Injury
Xiaolian Xu, Xioayan Jiao, Nana Song, Xiaojie Ding. Div of Nephrology, Zhongshan Hospital, Shanghai, China.

Background: We have previously reported that up-regulation of miR-21 contributed to the protective effect of delayed ischemia preconditioning (IPC) in renal ischemia/reperfusion injury (IRI). The role of vascular endothelial cells in renal IRI is not well-understood. In the present study, we examined the role of vascular endothelial cells in the protective effect of miR-21 in renal delayed IPC.

Methods: For the delayed IPC and IR model, 4 d after IPC (15 min ischemia) or sham surgeries, preconditioned mice were subjected to 35 min occlusion of bilateral renal pedicles, followed by 24 h reperfusion. Human umbilical vein endothelial cells (HUVECs) were treated with cobalt chloride for hypoxia model in vitro. Locked nucleic acid (LNA) modified anti-miR-21 or anti-scrambled was transfected into cells or delivered into the mice via tail vein injection less than 1 hour prior to IPC. Vascular permeability was determined by Evans Blue dye. Cell apoptosis was estimated by Annexin V-FITC apoptosis detection. Expression of programmed cell death 4 (PDCD4) protein and miR-21 was examined by western blot and real-time PCR, respectively.

Results: Compared with the Sham+IR group, mice in the IPC+IR group showed significant improvement of renal function and histology injury (P<0.01). MiR-21 was up-regulated in the IPC+IR group with concomitant decline of PDCD4 (P<0.05) and improvement of vascular permeability (P<0.05). In vitro, miR-21 in HUVECs was increased in hypoxia, while PDCD4 expression was decreased. Knockdown of miR-21 by LNA anti-miR-21 attenuated the protective effect of IPC with concomitant up-regulation of PDCD4 (P<0.05) and exacerbated vascular permeability (P<0.05). Cell apoptosis significantly decreased after knockdown of miR-21 in vitro.

Conclusions: Up-regulation of miR-21 in renal delayed IPC improved the apoptosis of vascular endothelial cell by inhibiting its target PDCD4. This may be another mechanism underlying the protective effect of the delayed IPC.

FR-PO232
Role of Vascular Mineralocorticoid Receptor in Renal Ischemia/Reperfusion
Jonatan Barrera-Chimal1, Alan Le Mercier, Sonia Prince, Soumaya El Moghribi, Norma Bobadilla, Frederic Jaisser1 INSERM U1138, Centre de Recherche des Cordeliers, Paris, France; Institut de Investigaciones Biomédicas UNAM y INNSZ, Mexico City, Mexico.

Background: Renal ischemia/reperfusion (IR) is a major cause of acute kidney injury and is associated with chronic kidney disease (CKD) development. Mineralocorticoid receptor (MR) antagonism prevents the acute and chronic consequences of renal IR. Whether the benefit of the MR antagonists is due to the blockade of the MR in the vessels is unclear. Therefore we want to study the specific contribution of endothelial and smooth muscle cells (SMC) MR in acute and chronic consequences of renal IR.

Methods: To inactive MR in endothelial cells (MRKO mice), floxed MR mice (MRflox) were crossed with mice expressing the inducible Cre recombinase under the Vcad promoter. To allow inactivate MR in smooth muscle cells (MRSMCKO mice), MRflox mice were crossed with mice expressing the inducible Cre recombinase under the SMA promoter. Sham surgery or bilateral renal IR for 20 min was performed in MRflox and KO mice and the animals were studied at short term (24 h) and long term (30 days) after reperfusion.

Results: In MRflox mice, IR induced renal dysfunction (plasma creatinine from 8.9±0.3 to 33.8±8.4 μmol/L in IR), tubular injury and increased mRNA levels of kin-1 (400-fold) and NGAL (220-fold). The MRSMCKO mice displayed similar alterations induced by IR as MRflox mice. In contrast, after 24 h of IR, the MRSMCKO mice presented normal renal function (plasma creatinine was 9.6±0.7 to 14.0±1.9 μmol/L in sham and IR, respectively), absence of histological alterations and reduced kin-1 and NGAL levels. After 30 days, the MRflox mice developed CKD characterized by renal dysfunction (plasma creatinine from 10.5±1.0 to sham in 15±9.8 μmol/L in IR), tubular-interstitial fibrosis and increased mRNA levels of fibronectin and Galec-3 (2-fold). The MRSMCKO mice developed similar alterations.

Conclusions: We provide evidence that the deficiency of MR in the SMC protects against the development of acute kidney lesions induced by IR, however MR deficiency in SMC did not impact the appearance of CKD induced by IR, suggesting that MR in other cell types is involved.

Renal Vein Hydrodynamic Fluid Delivery Ameliorates Established Renal Injury following Ischemia/Reperfusion Injury
Jason Andrieu Collet, Purvi Mehrotra, David P. Basile, Robert L. Bacallao. 1Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; 2Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; 3Richard L. Roudebush V4 Medical Center, Indianapolis, IN.

Background: Past and current treatment for Acute Kidney Injury (AKI) is mainly supportive in nature; no therapeutic modalities to date have shown an efficacious in improving the condition. While numerous experimental approaches can prevent AKI, there are few potentially translatable studies which may influence the course of established AKI. The goal of this study was to target vascular congestion and inflammation, which contribute to impaired renal perfusion and renal damage, following the established injury. We hypothesized that high-pressure retrograde hydrodynamic delivery (HD) of saline will improve established AKI, in part, by improving vascular congestion.

Methods: Male Sprague Dawley rats underwent left unilateral ischemia (35 min) and right unilateral nephrectomy or bilateral IRI (35min) and reperfusion for 24 hours to induce AKI. 0.5ml of isotonic saline was then injected into either the vena cava (VC) or retrograde to left kidney via the renal vein (RV) under high pressure (~60mmHg). Recovery was evaluated via serum creatinine and accumulation of immune cells were evaluated using FACS.

Results: Average serum creatinine at 24hrs was similar between groups (scre~3.3mg/dl), however, RV-HD treated rats showed a rapid improvement in serum creatinine over the following 24 hours vs VC HD rats (24 to 48 h serum creatinine -0.544 mg/dl ± 0.6375 mg/dl; p=0.0237). To evaluate effects on inflammation, bilateral IRI rats subjected to left-RV HD resulted in a significant reduction in CD4+ (54%±18; p<0.05), CD68 (60%±8; p<0.05), B cells (56%±3.5; p<0.05) and DC/Macs (71%±3; p<0.05) compared with VC rats.

Conclusions: These results indicate that high pressure retrograde hydrodynamic delivery of HD saline will improve established AKI, in part, by improving vascular congestion.

Human Adipose Stromal Cells Ameliorate Renal Injury and Attenuate Capillary Rarefaction following Ischemia-Reperfusion

**Background:** Acute kidney injury (AKI) is a syndrome characterized by the rapid loss of the kidney’s excretory function, resulting in excess in 17 million hospital admissions a year. Although the tubular epithelium is the primary target of ischemic injury, early damage to endothelial cells contribute to AKI by resulting in impaired perfusion. Moreover, renal capillary density is permanently compromised in rats following AKI induced by ischemia reperfusion (IRI), which is hypothesized to promote CKD. Therefore, to preserve capillaries may impact both short-term recovery and long-term function post-AKI. Adipose stromal cells (ASCs) have pro-angiogenic and anti-inflammatory properties. It is hypothesized that ASCs facilitate repair by capillary preservation, revascularization of damaged endothelium and decreased inflammation.

**Methods:** Male Sprague Dawley rats were subject to bilateral IRI (40 min). At the time of reperfusion, ~2x10^6 immune cells (hASCs, n=15) or vehicle (n=14) were injected into the suprarenal abdominal aorta. Recovery was evaluated via serum creatinine and capillary specific staining. Accumulation of immune cells in the kidney was evaluated using FACs.

**Results:** hASC-treated rats had a 90% survival by day 7, compared with 70% for vehicle. Serum creatinine showed a significant reduction in hASC-treated rats vs vehicle at 48 hrs, (35%; p<0.0008). By day 7, vehicle-treated rats showed a reduction in renal capillary density relative to sham (43%), which was significantly attenuated in hASC-treated rats (28%). Additionally, hASCs-treated rats exhibited a significant decrease in CD4+ (62%±16.8) and CD8+ (72%±3.5) T cell infiltration as compared to vehicle (299±83.9). Conversely, the number of regulatory T cells was increased in hASC-treated rats compared with vehicle (35%; p<0.05).

**Conclusions:** These results suggest that ASCs may ameliorate AKI, at least in part, by preserving capillary density, decreasing inflammation and restoring renal function.

**Studying the Effect of Induced Expandable Human Kidney Progenitor Cells on Renal Function Using Transcutaneous Assessment**

**Background:** The use of induced stem cells from adult tissues is a promising therapeutic approach for the treatment of kidney diseases. However, traditional techniques to monitor recovery from damage or delay in chronic renal disease development after cell therapy are cumbersome and time-consuming, as well as inaccurate to detect early changes in function. A recent method allows the evaluation of renal function transcutaneously, using an optical device and the exogenous renal marker FITC-simistin, with no need for plasma or urine samples. For the first time, we have studied the effect of human adult kidney epithelial cells (hKEpCs) induced to stably overexpress the SIX2 or OSR1&SIX2 genes in a cisplatin damaged endothelium and decreased inflammation.

**Methods:** Three different animal groups were established: induced SIX2-hKEpCs, SIX2&OSR1-hKEpCs and control group. On days 2 and 7 following a single dose of CP (7mg/kg b.w), rats received intravenously either vehicle or 1x10⁶ of the corresponding cell type. Kidney function was assessed over 14 days transcutaneously. In addition, urinary and plasma parameters, as well as histological changes were evaluated.

**Results:** Before cell treatment, all the groups experienced a comparable decrease in renal function with respect to baseline. Transcutaneous measurement showed that both cell types improve renal function compared to control group, with a substantial amelioration on day 7 after CP administration. The rise of creatinine and urea serum levels was also ameliorated in the cell treated groups and the histological analysis supported the beneficial of hKEpCs administration shown in renal function.

**Conclusions:** SIX2- and SIX2&OSR1-hKEpCs display therapeutic potential in CP-induced injury, preventing loss of kidney function and diminishing renal tissue changes due to disease progression or therapeutic interventions.

**Indole Analogues Have Novel Therapeutic Effects on Mitochondrial Diseases and Kidney Injury**

**Background:** Mitochondrial dysfunction causes various mitochondrial diseases and kidney injuries. Anti-oxidant quinones have been used clinically to prevent the disease progression but the effectiveness is yet to be established. We recently found that an indole-derivative increased ATP levels in HepG2 cells and analyzed 41 newly synthesized indole derivatives. Among these compounds, we focused on the most potent derivative #5 (MA-5). The aim of this study was to clarify the effects of MA-5 in mitochondrial diseases and kidney injury.

**Methods:** Fibroblasts from patients with mitochondrial diseases (Leigh syndrome, MERRF, K.I.S,Leber disease, and Kearns-Sayresyndrome) were cultured in ROS generating condition with BSOL-buthione(S,R)-sulfoximine)and cell viabilities, cellular ROS and glutathione levels were measured. The redox property of MA-5 was examined by cyclic voltammetry. The site of MA-5 distribution was visualized by fluorescence-labeled MA-5 (maleimide). MA-5 was administrated for 3 hr before they were exposed to kidney ischemia (26 min) reperfusion injury (IRI) or cisplatin (20 mg/kg body weight). Plasma creatinine (Cr), blood urea nitrogen (BUN) and renal pathology were assessed.

**Results:** MA-5 improved cell viability in a dose dependent manner in mitochondrial disease fibroblasts. MA-5 exhibited irreversible oxidation peaks by cyclic voltammetry, suggesting that MA-5 did not have antioxidant property like anti-oxidant quinones. MA-5 did not affect the cellular ROS or GSH levels. MA-5 FL co-localized with the mitochondrial marker, MitoTracker. In IRI, MA-5 after ischemia (0.08 mg/dl vs 1.60 mg/dl), and tubular cell injury were significantly reduced in MA-5-treated group. BUN (70.9±10.1 vs 101±13.0 mg/dl) and tubular injuries, at 96 hr after cisplatin injection, were significantly reduced in Indole #5 treated groups.

**Conclusions:** MA-5 exhibited therapeutic effects in fibroblasts from mitochondrial disease patients as well as renoprotective effects in both IRI and cisplatin nephropathy.
FKR-0239
Background: Renal tubular epithelium can regenerate after a variety of insults. During tubular regeneration, survived tubular cells proliferate, migrate and differentiate into mature cells. After several cell divisions, kidneys were examined for analysis. Localization of GFP-positive cells was examined by immunostaining with several nephron markers and their cell number was quantitatively assessed.

Methods: 1) After a pulse of doxycycline, GFP-positive cells were found in the kidney of TetOp-H2B-GFP mice. Most GFP-positive cells were AOP-1-positive tubular cells. As pulse periods become longer, the number of GFP-positive tubular cells increased (pulse 8h-0.5%, pulse 24h-10%, pulse 72h-18%, pulse 1 week-40%, pulse 3 weeks-50%). 3) After a short pulse (8h) of doxycycline with no chase, all GFP-positive cells were present as a single cluster of two cells or three cells. 4) In TetOp-H2B-GFP mice treated with a long pulse (3 week) of doxycycline, the number of GFP-positive cells decreased according to chase periods (Chase 8h-50%, Chase 4x-40%, Chase 8x-5%).

Conclusions: These data suggest that slow-cycling cells can be detected as GFP-positive cells using TetOp-H2B-GFP mice under doxycycline control. This model will be applicable for selective isolation and in vitro characterization of slow-cycling tubular cells.

FKR-0240
Renal ERK1/2 Regulation of PGC-1α and Mitochondriobiogenetic Homeostasis Physiologically and During Renal Injury Justin B. Colley, Ryan Whitaker, Rick G. Schnellmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.
Background: Acute kidney injury (AKI) is defined as a sudden decline in kidney function and the outcomes of AKI have not changed in the past few decades. Previous studies demonstrated that persistent disruption of mitochondrial homeostasis (e.g. peroxisome proliferator-activated receptor gamma coactivator-1α (PGC-1α), a master regulator of mitochondrial biogenesis (MB)), is an important contributor to renal ischemia-reperfusion injury (IR) and repair. While the MAPK extracellular-regulated kinases 1/2 (ERK1/2) regulates numerous cell signaling pathways, the role of ERK1/2 activation in MB physiologically and as a consequence of renal IR injury remains limited.

Methods: Renal proximal tubule cells (RPTC) were treated with the specific MEK1/2 inhibitor trametinib (10nM) for various time points. Control mice were treated with trametinib (1mg/kg). Trametinib was administered 1 hour before 18 min of bilateral IR. Signaling pathways were explored using qRT-PCR and immunoblot analysis.

Results: Trametinib blocked ERK1/2 phosphorylation in RPTC within 10 min that continued for 24 hr. Trametinib also inhibited ERK1/2 phosphorylation in vivo at 4 and 24 hr. Trametinib increased PGC-1α mRNA at 1, 4, and 24 h in RPTC. The mRNA levels of PGC-1α-1 target genes NDUF51, NRF1, and TFAM, and NDUF51 were linked to decreased mRNA levels of PGC-1α, NRF1, TFAM, and NDUF51. Trametinib treatment attenuated suppression of mRNA PGC-1α and NRF1 at 3 h, increased TFAM protein 2.5-fold, and attenuated renal dysfunction as measured by BUN and KIM-1.

Conclusions: ERK1/2 downregulates renal mitochondrial homeostasis under physiological conditions and ERK1/2 inhibition during renal IR promotes recovery of PGC-1α and MB, and contributes to both mitochondrial and renal recovery. These results reveal a novel target for pharmacological intervention in AKI.

FKR-0241
The Guanylyl Cyclase Activator BAY 58-2667 Stimulates Mitochondriobiogenesis and Promotes Recovery from Ischemia-Reperfusion Induced AKI Ryan Whitaker, Rick G. Schnellmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.
Background: Mitochondrial dysfunction is an important pathophysiologic component of acute kidney injury (AKI). As reduced mitochondrial function can impair energy-dependent renal repair processes following AKI, stimulation of mitochondrial function and the outcomes of AKI have not changed in the past few decades. Previous studies demonstrated that reduced renal tubular necrosis in BAY 58-2667 treated mice at 24 h post ischemia-reperfusion injury (IR) was due to enhanced mitochondrial gene and protein expression of PGC-1α, NRF1, ND1, COX1 and ATPSβ, as well as mtDNA content and protein expression of PGC-1α and COX1. In addition, mitochondrial function was recovered as renal ATP returned to sham control levels. Finally, BAY 58-2667 blunted the progression of renal fibrosis evidenced by reduced COL1A2 and aSMA expression.

Methods: These data demonstrate that activation of guanylyl cyclase by BAY 58-2667 promotes recovery from AKI by stimulation of MB, reduction of inflammatory and oxidative damage, and inhibition of renal fibrosis.

FKR-0242
Adult Human Renal Papilla CD133+ Cells Improve Erythropoietin Production, Show Long Term Engraftment and Repair Glycolerol-Induced Kidney Injury in SCID Mice Shikhar Aggarwal, Cristina Grange, Benedetta Bussolati. 1Dept of Biotechnology and Health Sciences, Univ of Turin, Turin, Italy; 2Dept of Medical Sciences, Univ of Turin, Turin, Italy.
Background: Acute kidney injury (AKI) often involved deregulation of erythropoietin (EPO) production in the kidney. Novel treatment foresees introduction of cell therapies or strategies involving pharmacological modulations of intrinsic populations to produce EPO. Our previous studies showed human renal regenerative capacity was realized by our group as a promising adult renal progenitor cell. Of note, papillary CD133+ cells show activation of hypoxia-inducible genes and are specifically involved in EPO production. However, their role in EPO production and fate to repair renal injury for long time has not yet been deconstructed in mice.

Methods: AKI was induced in immunodeficient mice using glycerol (8mg/gbw, i.m.) and adult human CD133+ papillary cells (0.5 million cells per mice) were injected (i.v.) 1 day after the injury. Mice were euthanized at different time intervals (day 15/30) and blood samples (serum, kidneys, lungs, liver) were collected for EPO, other markers of kidney injury (UR), histological/morphological analysis and molecular analysis (RNA, DNA and protein) respectively.

Results: Data showed that adult human CD133+ papillary cells improve EPO production (of both human and mice origin) in the injured mice and protect against AKI in mice at day 15 and day 30 as compared to control group. The group of injured mice that received cells showed higher level of human and mice specific EPO, lower level of creatinine and urea in serum, lower level of kidney injury marker, KIM-1 and improved histology. CD133+ papillary cells also reduced development of fibrosis in the injured tissues during repair (as shown by lower expression of alpha-SMA, profibrotic gene TGF-β and trichrome stain). In addition, immunohistochemical and fluorescence studies show localization of CD133+ papillary cells within interstitium and tubules of the injured renal tissues.

Conclusions: Thus, our data supports that these CD133+ papillary cells may provide an important source of EPO production and promote renal regeneration.

FKR-0243
Early Mesenchymal Stem Cell Administration Prevents Acute Kidney Injury Superimposed on Chronic Kidney Disease in Rats and High Risk Patients Anna Gooch, Nicole Molin, Ping Zhang, Zhou Hu, Christoph Westenfelder. 1Medicine, U of Utah and VAMC, Salt Lake City, UT; 2Physiology, U of Utah, Salt Lake City, UT.
Background: We showed that ischemic-reperfusion injury (IR) causes renal and urine levels of the chemokine SDF-1 (CXCL12) to rise significantly within ~ 2 hrs. This rise mediates the homing of infused, CXCR4 (SDF-1 receptor)-expressing Mesenchymal Stem Cells (MSCs) to the sites of injury, where they act renoprotectively. CKD is a major risk factor for AKI. We wanted here whether MSC administration is effective both in preventing IR AKI superimposed on CKD and in arresting the AKI-induced further deterioration of CKD.

Methods: Rats: Groups of 6 rats underwent 5/6th Nephrectomy. Once CKD was established (8 weeks), TR AKI of the kidney remnant was induced and rats were treated either with vehicle or 2x106 MSC/kg bw, i.e. S.Cr and urine SDF-1/creatinine levels were assessed at pre- and post-operatively. Patients: 12 subjects with established CKD and at high risk for cardiac surgery associated AKI were treated i.a. with 2x106 MSCs per kg bw intravenously post-on-pump surgery and S.Cr and urinary SDF-1/creatinine levels were determined pre- and post-op. RIFLE criteria defined post-op AKI. Study subject data were compared to well-matched historical controls.

Results: Rats: MSCs significantly hastened improvement in AKI vs. controls. Urine SDF-1 levels remained low by 24 hrs in MSC vs. vehicle treated animals. Patients: No study subject had AKI at discharge, but 2 met post-op RIFLE criteria. Urinary SDF-1/Cr ratios were significantly elevated at 2 and 6 hrs in subjects who developed AKI Risk, but remained stable in those who did not. In contrast to historical controls, 6 months post-op, no treated subject’s CKD had worsened.

FR-PO244
Improved Survival of Graft Bone Marrow-Derived Mesenchymal Stem Cells in the Ischemia-Reperfusion-Induced Injured Kidney with Overexpression of Heme Oxygenase-1
Nannmei Li, Jinlin Hospital of Shanghai.

Background: one marrow-derived mesenchymal stem cells (BMSCs) transplantation offers therapeutic potential for acute kidney injury (AKI), but with limited efficacy. This study investigated the role of HO-1 overexpression on the donor BMSCs’ survival, and its impact on the repair of AKI was also observed.

Methods: Ischemia/reperfusion (I/R)-AKI kidney homogenate supernatant (KHS) was prepared. SD BMSCs, eGFP-BMSCs and HO-1-BMSCs were harvested and treated by the AKI-KHS. Cell viability, apoptosis and cell cycle were evaluated. Activations of oxidant stress-related enzymes, expression of p65 and the protein levels of Caspase-3 and Bcl-2 in BMSCs were tested. Survivals of the implanting BMSCs in the AKI rat model as well as the renal function were also assessed.

Results: HO-1-BMSCs showed a high expression of HO-1 and AKI-KHS treatment further enhanced this level. This increased HO-1 expression promoted BMSCs survival under the AKI microenvironment with decreased apoptotic cells as well as less proportion of G0/G1 cells. AKI-KHS induced reduction of SOD activity and GSH-Px in BMSCs with increased MD and AOXD levels, however, HO-1 overexpression changed this phenomenon. Activation of NF-κB p65 was inhibited in HO-1-BMSCs. Western blot showed decreased Caspase-3 expression and increased Bcl-2 expression in HO-1-BMSCs. The in vivo study showed increased survival of HO-1-BMSCs in the AKI kidneys, which was associated with improved renal function.

Conclusions: HO-1 overexpression could enhance survival of BMSCs under the I/R-AKI microenvironment both in vitro and in vivo as the result of ROS elimination. Activity of NF-κB p65 and Caspase-3/Bcl-2 signal transduction pathways were involved in this process.

Induced Pluripotent Stem Cell-Conditioned Medium Mitigates Renal Ischemia-Reperfusion Injury by Suppressing Oxidative Stress
Wei-Cheng Tseng, 1 Der-Cherng Tang. 2 Div of Nephrology, Dept of Medicine, Taipei City Hospital Heqiu-Fayou Branch, Taipei, Taiwan; 3 Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Ischemic acute kidney injury (AKI) carries high mortality and current treatment remains unsatisfying. Induced pluripotent stem cell (iPS) is a promising therapeutic option for AKI; nonetheless, teratoma formation addresses critical safety concerns for iPS cell transplantation. iPS-derived conditioned medium (iPS-CM) is comparable with iPS cells on ameliorating acute lung injury but the beneficial role of iPS-CM on AKI remains unclear.

Methods: Rat model of renal ischemia-reperfusion injury (IRI) and NRK52E cells subjected to hypoxia-reoxygenation (HR) were used to explore the role of iPS-CM on AKI. BUN, creatinine, tubular cell apoptosis, level of reactive oxygen species (ROS), expressions of proinflammatory cytokines and animal survival were investigated.

Results: Administration of iPS-CM intraperitoneally significantly improved renal function and decreased tubular cell apoptosis after renal IRI. Moreover, elevated ROS level in IRI-rat kidneys was markedly attenuated by iPS-CM. Co-culture of NRK52E cells with iPS-CM also significantly diminished H2O2-induced apoptosis and ROS production. Furthermore, iPS-CM downregulated both H2O2- and IRI-stimulated expressions of p38, NF-κB, and caspase 3. Additionally, the IRI-related IL-6 and MCP-1 expressions were also suppressed by iPS-CM. Finally, after being subjected to renal IRI, the rats treated with iPS-CM demonstrated better survival as compared those treated with phosphate-buffered saline or normal control medium.

Conclusions: iPS-CM decreases renal IRI-related lethality by suppressing ROS, inflammation, and tubular cell apoptosis. iPS-CM may be a potential therapeutic option for kidney repair in ischemia.

Vascular Adhesion Protein-1 (VAP-1) Inhibition Ameliorates Cisplatin Induced Acute Kidney Diseases and Disorders (AKD)
Daisuke Katagiri, 1,2 Yoshifumi Hamasaki, 1 Kent Doi, 1,3 Kousuke Negishi, 1 Takeshi Sugaya, 1 Masao Nangaku, 1 Eisie Nohri, 1 Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; 2Apheresis and Dialysis, The Univ of Tokyo, Tokyo, Japan; 3Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; CMIC Ltd, Tokyo, Japan.

Background: Cisplatin (CP) is a platinum compound that is used as an effective chemotherapeutic agent for many malignancies. Its nephrotoxicity is dose dependent, which often limits its use. Research in the field of acute kidney diseases and disorders (AKD), including acute kidney injury (AKI), is important to prevent their progression to chronic kidney disease (CKD).

Methods: A new clinically relevant animal model using multiple low doses of CP was used to evaluate AKD. Human liver fatty acid-binding protein (L-FABP) transgenic (Tg) mice were administered 10 mg/kg of CP (three times, at 0, 1, 3 weeks) for four weeks. Vascular adhesion protein-1 (VAP-1) inhibitor that was recently reported to prevent fibrosis in organs was studied in this model. For treating group, mice received 2 mg/kg/day of PXS-4728A, a selective VAP-1 inhibitor, starting 3 weeks after the first CP administration.

Results: Moderate renal interstitial fibrosis occurred with multiple CP administration. Urinary L-FABP, one of the promising AKI biomarkers, increased about 10-fold one week after every CP injection. Although no further elevation of L-FABP was observed at 3W, following the omission of CP at 2W, L-FABP did not revert to baseline levels. Treatment of PXS-4728A for one week attenuated interstitial fibrosis in this model. PXS-4728A inhibitor treatment remarkably reduced 4-HHE- and 8-OHdG-positive areas. The mRNA expressions of TGF-β1, SMA, VEGF, and MCP-1 in the kidney were increased significantly by multiple CP treatments and attenuated by VAP-1 inhibitor treatment. Further, the inhibition of lipid accumulation in the S3 segments, together with L-FABP suppression was confirmed.

Conclusions: Multiple treatments with CP lead to moderate kidney dysfunction with increased renal biomarkers and renal fibrosis. As a standing point of onco-nephrology, VAP-1 inhibitors are promising candidates for the prevention of CKD in patients using CP for the treatment of malignancy.

Pulsed Focused Ultrasound Improves Mesenchymal Stem Cell Therapy for Acute Kidney Injury by Upregulating Revascularization-Gamma to Stimulate Stem Cell Production of Interleukin-10
Scott R. Burks, Matthew Nagle, Michele Bresler, Saejeong Kim, Blerta Milo, Joseph A. Frank. Frank Lah, NIH Clinical Center, Bethesda, MD.

Background: Pulsed focused ultrasound (pFUS) to kidneys enhances mesenchymal stem cell (MSC) homing to kidneys and improves outcomes when treating early or established acute kidney injury (AKI) compared to MSC infusions alone. However, mechanisms of improved combination therapy are unclear.

Methods: AKI was induced in C3H or interferon-γ (IFNγ)-deficient mice with cisplatin (15 mg/kg), pFUS (40W, 5%da) was delivered to kidneys –3hr before infusion of 10’ human MSC. MSCs were observed by immunostaining for human mitochondria. For some experiments, MSCs were treated in culture with recombinant IFNγ or siRNA against IL-10. Cytokines were analyzed by mouse- and human-specific ELISAs. Serum creatinine and blood urea nitrogen values were measured spectrophotometrically.

Results: Proteome profiling of AKI kidneys revealed that pFUS upregulated renal IFNγ and after MSC homed to pFUS-treated kidneys, they produced more human IL-10 compared to MSC in kidneys without pFUS. pFUS/MSC in IFNγ-knockout mice led to greater MSC homing to pFUS-treated kidneys, but MSCs failed to produce greater IL-10 and FUS/MSC yielded identical outcomes as MSC alone (ie, no improvement from pFUS/MSC). Supplementing MSC with IFNγ improved AKI outcomes in C3H mice in the absence of pFUS, while the improved outcomes seen pFUS/MSC were abrogated by knocking down IL10 in MSC.

Conclusions: pFUS pretreatment of kidneys during AKI alters the renal molecular environment to increase MSC homing to treated kidneys. However, improved disease outcomes from combination therapy are the result of pFUS upregulating IFNγ in the kidney so that MSC’s homing to pFUS-treated kidneys are subsequently conditioned to produce more IL10, which has been shown to improve AKI.

Stem Cells from Human Exfoliated Deciduous Teeth Ameliorate Acute Kidney Injury in Mice
Yuki Hatton, 1 Hangsoo Kim, 1 Naotake Tsuoi, 1 Akihito Yamamoto, 2 Seiichi Matsuo, 2 Shohji Maruyama, 2 Masaomi Nangaku, 3 Masaomi Nangaku, 3 Masaomi Nangaku, 3 Nagoya Univ Graduate School of Medicine, Japan; 4Nephrology, Nagoya Univ Graduate School of Medicine, Japan.

Background: Preclinical studies have indicated that administered mesenchymal stem cells (MSCs) ameliorated various types of renal injury and promoted the subsequent kidney repair. Recently, stem cells from human exfoliated deciduous teeth (SHED), which has been discovered as a medical waste, has received attention as a novel kind of MSCs.

Preclinical experiments were performed in mice exposed to cisplatin (CP) or oxaliplatin (OXP). CP was administered intraperitoneally by three doses (0.75 mg/kg, IP) on days 0, 3, 5 and 7, and OXP was administered intraperitoneally by three doses (2 mg/kg, IP) on days 2, 5, 8. For CP treatment, mice received 5 mg/kg and 10 mg/kg of CP at the first and second injections, respectively.

Results: MSCs were administered by intravenous injection 10 days before or 2 days after the renal injury. MSCs from human exfoliated deciduous teeth (SHED) were injected into mice with acute renal failure. MSCs from human exfoliated deciduous teeth (SHED) were injected into mice with acute renal failure. MSCs from human exfoliated deciduous teeth (SHED) were injected into mice with acute renal failure. MSCs from human exfoliated deciduous teeth (SHED) were injected into mice with acute renal failure. MSCs from human exfoliated deciduous teeth (SHED) were injected into mice with acute renal failure. MSCs from human exfoliated deciduous teeth (SHED) were injected into mice with acute renal failure.

Conclusions: In conclusion, SHED-MSCs are a potential therapeutic agent for the treatment of acute kidney injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
The purpose of this study is to clarify the therapeutic effects of SHED on AKI induced by IRI.

**Methods:** Seven days after heminephrectomy, the renal artery and vein were clamped for 20 min to induce ischemia in male C57BL/6 mice. SHED or PBS as a control was administered into subcapsular right kidney. Blood, urine and tissue samples were collected. In order to confirm renoprotective potential of conditional media of SHED (SHED-CM) in vitro, H2O2 stimulation assay and scratch wound assay using mouse tubular epithelial cells (TECs) were also performed.

**Results:** Serum creatinine and BUN levels and urinary protein excretion were significantly decreased in SHED-treated group. In vivo and in vitro, cPLA2 and 3T3-L1 adipocytes were treated with TGF-β/α alone, and nullortreated. TGF-β/α increased the phosphorylation of SIRT2 at ser331 diminished its catalytic activity and reduced its binding of SIRT2, respectively. Analysis of the phosphorylation state of SIRT2 was carried out in the presence or absence of cPLA2 in vitro by kinase assay and in vivo by using the CREB phosphorylation assay.

**Conclusions:** In vivo and in vitro, cPLA2 acts as a bridge in this complex to promote binding of SIRT2 to cyclin A-Cdk2. Cyclin A-Cdk2 then phosphorylates SIRT2 at ser331. Phosphorylation of SIRT2 at ser331 diminishes its catalytic activity and reduces its binding affinity to centromeres and mitotic spindles. This detachment of SIRT2 from mitotic spindles plays a key role in the development of malignancy in human cells. This function of cPLA2 may be further exploited to better understand the important link between cPLA2 and tumorigenesis and between inflammation and the age-related disorders such as Alzheimer’s disease, in which cPLA2 may be further implicated.

**The Cytokines Guanosine Exchange Factors Are Required to Promote HGF-Induced Renal Epithelial Recovery After Acute Kidney Injury in Mice**

**Lorraine C. Santos, Marta Revirigues-Mendoza, Department of Biochemistry and Molecular Biology, Pennsylvania State Univ, Univ Park, PA.**

**Background:** The lack of current treatment and preventable measures for acute kidney injury (AKI) in hospitalized patients results in an increased mortality rate of up to 80% and elevated health costs. The molecular aspects of kidney injury and repair are still uncertain. Hepatocyte growth factor (HGF) promotes recovery of the injured kidney by inducing survival and migration of tubular epithelial cells to repopulate base tubular areas. HGF-stimulated kidney epithelial cell migration requires the activation of ADP-ribosylation factor 6 (Arf6) and Rac1 via the cytokine family of Arf-guanine-nucleotide-exchange factors (GEFs), in vitro.

**Methods:** We used an ischemia and reperfusion injury (IRI) mouse model to analyze the effects of modulating this signaling pathway on kidney recovery. We treated IRI mice with either HGF, the cytokine inhibitor SecinH3, or a combination of both. Kidney function was assessed by measuring creatinine (Cre) and blood urea nitrogen (BUN) levels. Standard H&E staining was performed to evaluate kidney structures and immunohistochemistry was used to detect active-Rac1 and active-Arf6.

**Results:** Simultaneous treatment with SecinH3 and HGF blocks the ability of HGF to promote kidney recovery as evidenced by Cre and BUN levels. Immunohistochemistry showed that HGF treatment promoted recovery of tubule structure, and had enhanced levels of active, GTP-bound Arf6 and GTP-Rac1. HGF treatment, however, caused a dramatic decrease in GTP-Arf6 and GTP-Rac1 levels when compared to kidney sections from HGF-treated IRI mice. Additionally, SecinH3 counteracted the renal reparative effects of HGF.

**Conclusions:** We show that HGF-dependent damaged kidney recovery requires the function of a cytokine-dependent signaling module, and that inhibiting Arf6 and Rac1 counteracts HGF-stimulated recovery. In addition, we demonstrate that HGF treatment of ischemic mice promotes the activation of Arf6 and Rac1 in the recovering kidneys in a cytokine-dependent manner, and that cytokine activation is required to promote epithelial repopulation of kidney tubules and thus kidney recovery.

**Funding:** NIDDK Support
Regulation of Kidney Injury Molecule-1-Mediated Efferocytosis by Rho GTPases Ola Ismail, Xiaohong Zhang, Lakshman Gunaratnam. Kidney injury molecule 1 (KIM-1) is a phagocytic receptor for apoptotic cells that is specifically upregulated on the apical membrane of proximal tubule cells (FTTCs) after acute kidney injury. KIM-1-mediated clearance of apoptotic cells (efferocytosis) can protect from inflammation during acute kidney injury by down-regulating innate immunity and inflammation. As cytoskeletal remodeling is essential for phagocytosis, we examined the relative importance of Rac1 and RhoA, two key Rho GTPases that mediate actin remodeling, in KIM-1-dependent efferocytosis. We also investigated a possible link between Ga12, which we previously identified as a KIM-1-interacting protein, and these Rho GTPases.

Methods: To study the role of Rac1 and RhoA in KIM-1-mediated uptake of apoptotic cells, we utilized chemical inhibitors or plasminoids encoding dominant negative forms of Rac1 or RhoA protein and measured the uptake efficiency of FTTCs by flow cytometry. Using commercially available GTPase pull-down assays, we measured the endogenous Rac1 and RhoA activity in KIM-1-expressing cells after apoptotic cell-stimulation. To decipher whether these Rho GTPases are down-stream mediators of Ga12-KIM-1 signaling, we silenced Ga12 using siRNA and measured Rac1 and Rho GTTPase activity.

Results: Inhibition of Rac1 resulted in a significant decrease in KIM-1-mediated phagocytosis, whereas inhibition of and RhoA increased it. RhoA activity gradually increased during phagocytosis and peaked during the later stages of phagocytosis, whereas Rac1 activity remained constant over the entire course of phagocytosis. Furthermore, silencing a key KIM-1-interacting protein, Ga12, caused a significant decrease in RhoA activity.

Conclusions: We conclude that Rac1 and RhoA play opposing roles during KIM-1-mediated efferocytosis, where RhoA serves to mediate signaling by KIM-1 and its interacting partner, Ga12.

FR-PO254
Periostin Induces Kidney Fibrosis After Ischemia-Reperfusion Injury via p38 MAPK Pathway Junang Nam, Seung Hee Yang, Jin Ho Hong, Chun Soo Lim, Yun Kyu Oh, Yun So Kim, Jung Pyo Lee, Seon National Univ Boramae Medical Center; Seon National Univ Hospital; Seon National Univ Kidney Research Inst; Chung-Ang Univ Hospital, Republic of Korea.

Background: Periostin, a matrix cellular protein, has been reported to play a crucial role in inflammatory and fibrotic mechanism. We hypothesized that periostin involves in the progression of acute kidney injury via efferocytosis, where RhoA serves to mediate signaling by KIM-1 and its interacting partner, Ga12.

Methods: To establish a kidney progression model, we induced unilateral ischemia-reperfusion injury of left kidney pedicle for 30min in wild type (WT) C57BL/6 mice and Postn null mice (Postn+), and observed cultured for 4 to 6 weeks. In addition, inner medulla collecting duct cell line was subjected to put in the hypoxic incubator (1% O2, 5% CO2, and 94% N2) for 24 and 72 hours.

Results: For 4 to 6 weeks, the left kidneys in Postn null mice were significantly less atrophied and small in weight compared to those of WT mice. Significant tubular atrophic and less small in weight compared to those of WT mice. Significant tubular atrophic and less small in weight compared to those of WT mice. Significant tubular atrophic and less small in weight compared to those of WT mice.

Conclusions: In conclusion, periostin is related to the progression via p38 MAPK pathway.

FR-PO255
Tim-3/Gal-9 Pathway Activation Ameliorates Renal Ischemia Reperfusion Injury by Shifting the Balance of Activated Th1, Th17 and Foxp3+ T Cells Junhua Li, Junhua Li, Ying Zhang, Jiong Zhang, Ying Yao, Gang Xu. Dept. of Nephrology, Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.

Background: Renal ischemia reperfusion injury (IRI) is characterized by kidney ischemia. Galectin-9 (Gal-9) is identified as a T-cell immunoglobulin domain and Ig-like motif of T lymphocytes and macrophages. As a sialic acid binding protein, it is thought to play an important role in inflammatory and fibrotic mechanism. We hypothesized that periostin involves in the progression of acute kidney injury via efferocytosis, where RhoA serves to mediate signaling by KIM-1 and its interacting partner, Ga12.

Methods: To study the role of Rac1 and RhoA in KIM-1-mediated uptake of apoptotic cells, we utilized chemical inhibitors or plasminoids encoding dominant negative forms of Rac1 or RhoA protein and measured the uptake efficiency of FTTCs by flow cytometry. Using commercially available GTPase pull-down assays, we measured the endogenous Rac1 and RhoA activity in KIM-1-expressing cells after apoptotic cell-stimulation. To decipher whether these Rho GTPases are down-stream mediators of Ga12-KIM-1 signaling, we silenced Ga12 using siRNA and measured Rac1 and Rho GTTPase activity.

Results: Inhibition of Rac1 resulted in a significant decrease in KIM-1-mediated phagocytosis, whereas inhibition of and RhoA increased it. RhoA activity gradually increased during phagocytosis and peaked during the later stages of phagocytosis, whereas Rac1 activity remained constant over the entire course of phagocytosis. Furthermore, silencing a key KIM-1-interacting protein, Ga12, caused a significant decrease in RhoA activity.

Conclusions: We conclude that Rac1 and RhoA play opposing roles during KIM-1-mediated efferocytosis, where RhoA serves to mediate signaling by KIM-1 and its interacting partner, Ga12.

FR-PO256

Background: Acute kidney injury (AKI) is a major risk factor for the development of chronic kidney disease (CKD). Renal ischaemia may cause post-inflammation scarring leading to loss of nephrons and development of fibrosis. The NF-κB inhibitor (NF-xb) is a family of transcription factors activated post-injury, but its role in the progression of AKI to CKD is unknown.

Methods: Male Wistar rats were subject to a RH nephrectomy and L.H unilateral renal ischemia for 60min, or nephrectomy only (sham). At 2 (n=4), 7 (n=8) or 28d (n=7) after ischemia, the left kidneys were harvested. The expression of Gal-9 and Tim-3 in IR and sham kidneys was measured.

Results: Compared to sham-operated rats, rats subjected to unilateral renal ischemia developed AKI (increases in serum creatinine and decreases in the estimated creatinine clearance). The delayed administration of IKK16 at 24h post AKI (at peak creatine values) significantly improved renal functional recovery and structural injury at 48h post AKI compared to sham-operated rats, rats culled at 7d post AKI demonstrated significant increases in smooth muscle actin (sMCA) and CD68+ staining for myofibroblasts and macrophages, respectively. IKK16 administration significantly decreased sMCA and CD68+ staining at 7d post AKI. Rats culled at 28d post AKI demonstrated a significant increase in sinus red staining compared to sham rats, indicating the development of fibrosis. Administration of IKK16 at 24h significantly attenuated Sirius red staining, and therefore the level of fibrosis at 28d.

Conclusions: Inhibition of IKK16 at 24h post AKI (at peak creatine values) improves renal functional recovery at 48h post AKI, and reduces the degree of fibrosis observed at 28d.

The Peroxisome Proliferator-Activated Receptor γ (PPAR-γ) Agonist, Pioglitazone Prevents NF-κB Activation in Cisplatin Nephrotoxicity by Reducing NF-κB Acetylation Through AMPK-SIRT1/p300 Pathway Junhua Li, Junhua Li, Ying Zhang, Jiong Zhang, Ying Yao, Gang Xu. Dept. of Nephrology, Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.

Background: NF-κB is a ubiquitously expressed transcription factor controlling the expression of numerous genes involved in inflammation. The aim of this study was to evaluate whether the activation of peroxisome proliferator-activated receptor-γ (PPAR-γ) could attenuate cisplatin-induced NF-κB activation in cisplatin nephrotoxicity.

Methods: Acute kidney injury model was established by intraperitoneal injection of cisplatin. C57BL/6 mice were divided into three groups: normal group; model group; and treatment group, with pioglitazone gavage of three days. Respectively after injection in 24, 48 and 72 hours, the mice serum were collected for renal function and kidney specimen for pathological, Western blot, immunohistochemistry and real time PCR detection.

Results: Our results showed PPAR-γ agonist Pioglitazone could decrease the expression of NF-κB p65 transcription target genes such as pro-inflammation cytokines interleukin 6 (IL-6), interleukin-1 β (IL-1β), and tumor necrosis factor-alpha (TNF-α) and its cellular translocation and MPO infiltration in cisplatin nephrotoxicity. Suppressing NF-κB activity following Pioglitazone treatment was involved in inhibiting iκBα degradation, phosphorylation modification and NF-κB p65 subunit translocation induced by cisplatin injection. The NF-κB p65 subunit translocation is dependent on p65 acetylation, which is mainly regulated by SIRT1 or p300. Of note, The subsequent AMP kinase (AMPK) activation not only decreases the p300 phosphorylation, activation and its interaction with p65, but also increases the SIRT1 expression, activation and binding to p65, leading to a significant reduction p65 acetylation. Interestingly, the reduction in expressions of IL-6, IL-1β and TNF-α were remarkable and MPO infiltration following Pioglitazone treatment in cisplatin nephrotoxicity were attenuated by the PPAR-gantagonist GW9662.

Conclusions: Our results suggest that PPAR-γ agonist Pioglitazone prevents NF-κB activation in cisplatin nephrotoxicity by reducing p65 acetylation through AMPK-SIRT1/ p300 pathway.

AKI: Basic Repair and Regeneration

Poster/Friday
Competitive Inhibition of CD95L Reduces Inflammation, but Only Modestly Improves Outcomes in Experimental Ischemia-Reperfusion Injury

Background: After previous encouraging results in CD95L (FasL) mutant mice in ischemia-reperfusion injury (IR) models, we sought to investigate the effect of the competitive pharmacologic inhibition of CD95 (FAS) in kidney IR using APG101, an orphan drug developed for the treatment of recurrent glomeruloma, which has shown a good patient tolerability in phase I and II clinical studies.

Methods: C57BL/6 mice treated with different dosages of APG 101 (10, 30 or 100 µg/kg-body weight, single-dose, 12h before IR) or vehicle (PBS) alone were submitted to a 30 min bilateral renal ischemia (IR) sham-animal treated with the highest dosage of APG101 dose or PBS. The experiment was further divided into two observation periods: day 2 (injury phase) and day 7 (recovery phase). Serum and kidney tissue analysis were performed focusing on function recovery, cell proliferation, macrophage infiltration and renal histopathology of the mouse kidney. Results are given as mean±SD.

Results: Optimal serum CD95 saturation was only achieved in the APG 100µg/kg group (98.4±0.35% and 96.9±1.3% at day 2 and 7, respectively), so that experiments were further conducted with this dosage. At day 2, serum creatinine was significantly higher in the IR PBS group, but not in the IR APG group compared to sham-op (0.26±0.12 and 0.20±0.07 vs. 0.09±0.03 mg/dL P<0.05). A similar pattern was seen in macrophage infiltration and MCL-1 mRNA expression in the kidney, both persisting until day 7. Apoptosis, however, was similar between the IR groups in both observation periods. APG treatment markedly reduced cell proliferation in both sham and IR animals compared to PBS (0.51±0.9 vs. 8.4±5.7 Ki67 positive cells/hpf, p<0.0004), which was observed at day 2, but didn’t persist until day 7.

Conclusions: Despite an anti-inflammatory effect, the APG101-induced impairment of the tubular cell proliferation may have hampered the early recovery phase after IR leading to the modest results.

FR-PO259

Oral Treatment with PB1-4050 Reduces Ischemia-Reperfusion-Induced Fibrosis

Background: PB1-4050, a novel first-in-class orally active compound which is currently in clinical phase II/III in CKD patients, displays antifibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase I trial, PB1-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effects. Clinically relevant IR is a leading cause of acute kidney injury (AKI), which may result from a variety of conditions, such as decreased cardiac output, renal vascular occlusion or obstruction, and kidney transplantation. The aim of this study was to investigate the anti-fibrotic activity of PB1-4050 in a mouse model of acute ischemic kidney injury.

Methods: Renal ischemia-reperfusion (IR) injury was induced by the clamping of the left renal pedicle for 60 minutes in C57BL/6 mice (6-8 week old). Mice were treated with oral administration of vehicle or PB1-4050 (200 mg/kg) from day -3 to day 13 and sacrificed at day 14.

Results: Renal IR-injury induced a rise in serum creatinine at day 2 that was prevented by oral treatment with PB1-4050. At day 4, mice suffering from renal IR demonstrated a loss in hemocrit which was also prevented by PB1-4050 treatment. Furthermore, histomorphometric analysis demonstrated a significant increase in renal fibrosis, determined by medullary collagen accumulation in mice with IR-injury, which was significantly reduced by PB1-4050 treatment. In addition, PB1-4050-treatment reduced kidney type-III collagen mRNA expression.

Conclusions: Taken together, these pre-clinical results suggest that PB1-4050 offers the potential as a novel therapy for the treatment of AKI and may delay or prevent the onset of fibrosis in renal transplant recipients.

FR-PO260

Cisplatin Acute Kidney Injury and Conversion to Chronic Kidney Disease

Robert L. Safrinstein,1,2 Heino Velazquez,3 Richard Torres,7 Gilbert W. Moekel,3 Gary V. Desir.1,2 Nephrology, Yale Univ, New Haven, CT; 1Dept of Medicine, Univ of Kansas Medical Center, Kansas City, KS; 2Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.

Background: Chronic Kidney Disease (CKD) develops in humans after repeated doses of cisplatin (CP). We report on a new model to investigate the mechanism of this form of CKD.

Methods: 8-week old C57Bl6 mice were given either a single or double dose (12 weeks apart) of CP (15 mg/kg) and studied 2, 4, 6, 9 and 16-25 weeks after the first dose. GFR was measured by inulin clearance followed by intravascular perfusion-fixation. Results are given as mean±SD.

Results: GFR fell precipitously to below 50% of controls 2 weeks after the second dose and progressed without hypertension, loss of glomerular number, or glomerulosclerosis. Kidney weight fell as a result of loss of cortical tissue. Collagen deposition increased but progressed without hypertension, loss of glomerular number, or glomerulosclerosis. Influx of macrophages, increased cell cycle activity (Ki67) and apoptosis (TUNEL) were followed by vascular rarefaction. Ki67 failed to increase after the second dose as it did after a single dose. The cyclin-dependent kinase inhibitor protein p21 increased and paralleled the lack of cell cycle activity. Abnormal glomerulotubular junctions (GTJ) developed only after the second dose, which included loss of megalin positive parietal epithelial cells and glomerulotubular junction remodeling seen here and its demonstrated role in progression in the renal ablation model of CKD suggests its sustained activation may cause the conversion of AKI to CKD. Understanding why injured PT cells fail to re-enter the cell cycle following the second dose of CP is likely to yield new means to prevent CP-induced CKD, which may be applicable to other forms of AKI to CKD conversion.

The MEK1/2 Inhibitor, U0126, Decreases Cisplatin-Induced AKI and Slows Cancer Growth in Mice

Background: Nephrotoxicity is cisplatin’s major dose-limiting side effect as a chemotherapeutic agent. We have developed a model of 4 week, low dose cisplatin (Cis)-induced AKI in mice with cancer. In the 4 week model of AKI, there is an increased ERK expression in kidneys.

Methods: Wild type C57BL/6 mice were injected subcutaneously with murine lung cancer cells derived from C57BL/6 mice. Ten days later, Cis (10 mg/kg/week) was given to mice. Tumor weight and volume was decreased in mice treated with vehicle compared to U0126 vs vehicle alone. In the 4 week model of AKI, there is an increased tumor growth and induced the therapeutic effect of cisplatin. Discovery of a drug that decreases cisplatin-induced AKI and improves the therapeutic effect of cisplatin would be a significant finding for patients with cancer.

Glycogen Synthase Kinase-3 Regulates Fibroblast Activation and Development of Fibrosis following Renal Ischemia/Reperfusion in Mice

Jeenu Velazquez,1,2 Richard Torres,2 Gilbert W. Moeckel,2 Pratap Singh1. 1The Kidney Inst, Dept of Medicine, Univ of Kansas Medical Center; Kansas City, KS; 2Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.

Glycogen synthase kinase-3 (GSK3) is a serine/threonine protein kinase that plays an important role in renal tubular injury and regeneration in acute kidney injury. However its role in the development of renal fibrosis, often a long-term complication of acute kidney injury is unknown. Using a mouse model of renal fibrosis induced by ischemia/reperfusion (IR) injury, we demonstrate increased GSK3 expression and activity in fibrotic kidneys.

Methods: Bilateral I/R was carried out on male C57BL/6J mice; both renal pedicles were exposed by flank incision and clamped for 30 minutes at 37°C. GSK3 inhibitor (TIDZD-8) was administered by daily IP injection at 1mg/Kg BW.t. dose starting 1h before (TIDZD-pre) or 48h after (IR) (TIDZD-post). Studies were also carried out in rat fibroblast NRK-49F cells.

Results: Tumor weight and volume was decreased in mice treated with Cisplatin+U0126 vs Cisplatin alone demonstrating that U0126 significantly increased the therapeutic effect of cisplatin.

Conclusions: U0126 decreased cisplatin-induced AKI. In addition, U0126 decreased tumor growth and improved the therapeutic effect of cisplatin. Discovery of a drug that decreases cisplatin-induced AKI and improves the therapeutic effect of cisplatin would be a significant finding for patients with cancer.

even in the absence of TGF-β1 treatment. These results suggest that TGF-β1 regulates GSK3β expression, which in turn is important for TGF-β1-SMAD3 signaling to fibroblast-to-myofibroblast differentiation.

**Conclusions:** The study thus demonstrates that GSK3β could promote renal fibrosis by activation of TGF-β signaling and the use of GSK3 inhibitors might represent a novel therapeutic approach for progressive renal fibrosis that develops as a consequence of AKI.

**Regulating Cx43 and TRPC6 Expression Protects Renal Epithelial Damage in a Rat AKI Model**

Zhang Li, Wei Wang, Juan Wang, Lining Wang. *Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.*

**Background:** Intracellular Ca²⁺ homeostasis plays an essential role in maintaining normal cell function. Connexin43 (Cx43) and transient receptor potential channel (TRPC6) has been reported to regulate Ca²⁺ entry in some pathologic conditions. The aim of this study was to elucidate whether the modifier protein of glyceraldehyde-3-phosphate dehydrogenase (MP) and ATP-MgCl₂ could regulate Cx43 and TRPC6 in a rat model of acute kidney injury (AKI).

**Methods:** Male Sprague-Dawley rats were divided into the following groups: normal control, gentamicin-treated, MP plus gentamicin-treated, ATP-MgCl₂, plus gentamicin-treated (n=15 for each), as well as control group for MP and ATP-MgCl₂ alone (n=5 for each). Levels of serum creatine (sCr) for each group were measured on the 14th days of treatment. The “in vivo cryotechnique” was used for preparing kidney specimen as before. Immunohistochemistry staining for Cx43 and TRPC6 was performed.

**Results:** The gentamicin-treated group showed a significant increase in sCr compared to the normal control group. Co-treatment of gentamicin with MP and/or ATP-MgCl₂ produced marked decreases preventing the increase of sCr. Under light microscope, the gentamicin-treated group showed tubular epithelium damage indicating AKI. This was attenuated by MP and/or ATP-MgCl₂ co-treatment. Immunohistochemistry staining indicated that MP and/or ATP-MgCl₂ co-treatment prevented gentamicin-induced down-regulation of Cx43 and TRPC6 in renal epithelium cells using the “in vivo cryotechnique”. Furthermore, the expressions of Cx43 and TRPC6 in gentamicin-treated group showed much weaker intensity using conditional fixation method compared to that using “in vivo cryotechnique” suggesting there might be artificial damage during the conditional fixation procedure.

**Conclusions:** Using a rat model of AKI, MP and ATP-MgCl₂ were able to prevent the down-regulation of Cx43 and TRPC6, which might reduce Ca²⁺ entry and its downstream signaling, thus minimizing the damage in the renal epithelial cells.

**Bud-Like Structure Capable of Developing to Lamellipodia in Wound Healing of Tubular Epithelium – A Scanning Electron Microscopic Approach**

Yoko Umura,1 Hiroyuki Morita,2 Yoshikico Inoue,1 Shinya Omiya,1 Tomoaki Miyazaki,1 Ashio Yoshimura.1 *Dept. of Nephrology, Showa Univ Fujigaoka Hosp., Yokohama, Kanagawa, Japan; 2Dept. of Endocrinology and Metabolism, Aichi Medical Univ School of Medicine, Nagakute, Aichi, Japan.*

**Background:** Cell migration is essential in wound healing during which filamentous (F)-actin assembly plays a pivotal role. Cell biological approaches, using confocal microscopy, succeeded in identifying molecules regulating the assembly, such as the Arp2/3 complex, N-WASP, cofillin, and profilin. Although cells form filopodia (microspike) and lamellipodia (membrane), and move forward, much remains to be seen in the ultrastructure of these processes.

**Methods:** Rat tubular epithelium (NRK-52E) was cultured, grown to confluency, and scratched. The cells were subjected to scanning electron microscopy (SEM) at various time points. In separate experiments, immunoelectron microscopy was performed using an antibody against Arp3. Lastly, 60% confluent NRK-52E cells were cultured in the presence or absence of si-RNA for Arp3, grown to confluency, and scratched. The cells were observed periodically at the SEM levels, and, the length of time for complete recovery was compared.

**Results:** As shown in the figure, SEM elucidated elaborated network of filopodia containing “bud-like structure” (bud) that may develop to lamellipodia. Arp3 was expressed in filopodia and lamellipodia but not in a bud. The Si-RNA knockdown significantly prolong the length of time for the recovery. It at least partially inhibited the formation of filopodia network and lamellipodia but not the formation of a bud.

**Conclusions:** This is the first SEM analysis of scratch wound healing in cultured tubular epithelium, and that the bud was previously undescribed. Although the Arp2/3 complex does not apparently induce lamellipodia formation of a bud, further molecular analysis may shed a new light into cell motility in wound healing.

**Inhibition of Microtubule Dynamics Delays Kidney Recovery After Ischemia/Reperfusion Injury in Mice**

Sang Jun Han,1 Jee in Kim,2 Kwon Moo Park.1 *Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.*

**Background:** Ischemia/reperfusion (I/R) is a major cause of acute kidney injury (AKI). If recovery from AKI is delayed, kidney progresses toward chronic renal failure. Microtubules, a component of the cytoskeleton, contribute to cell damages, cell shape, cell motility, and cell division. Here, we investigate that the role of microtubule network on the kidney injury, recovery and progression of fibrosis after I/R injury.

**Methods:** Mice were subjected to 30 minutes of bilateral renal ischemia, and mice were sacrificed 16 days after ischemia. Some mice were administered either saline (vehicle) or paclitaxel (taxol), a microtubule stabilization agent; 1 day before ischemia (pretreatment) or from 1 day after ischemia until sacrifice every 2 days (post-treatment).

**Results:** Pretreatment of taxol did not affect post-I/R renal function compared with vehicle-treated I/R group. Post-treatment of taxol delayed renal functional and histological recovery with retardation of tubular regeneration, and accelerated proliferation of interstitial cells after ischemia. Post-treatment of taxol from 24 hours after ischemia enhanced cell cycle arrest, progression of fibrosis, and macrophage infiltration into the kidney. Furthermore, post-treatment of taxol suppressed regoplaarization of primary cilia in tubular epithelial cells.

**Conclusions:** In conclusion, our results demonstrate that microtubule stabilization or inhibition of cell proliferation delays kidney tubule cell restoration after ischemic injury, whereas interstitial cell proliferation is accelerated, leading to kidney fibrosis. It suggests that regulation of microtubule dynamics is critical to repair from AKI and progression of AKI to chronic kidney disease.

**Tubulin Acetylation in the Kidney Tubular Cells After Ischemia-Reperfusion Injury**

Jihveon Kim, Sang Jun Han, Kwon Moo Park. Dept of Anatomy and BK21, Kyungpook National Univ, Daegu, Korea.

**Background:** Acetylation of tubulin is known to play an important role in the stabilization of microtubules. Kidney ischemia/reperfusion (I/R) is a major cause of acute renal failure. I/R causes damage to the cytoskeleton in the tubular epithelial cells. Acetylation of α-tubulin can directly affect the function of tubulo-interstitial cells after I/R injury using western blotting and immunohistochemical staining. Mice were subjected to either 30 min of ischemia or sham-operation. Kidneys were harvested at various times after ischemia.

Acetylation of α-tubulin expression dramatically decreased 24 hours after ischemia and then gradually increased over time. However, total α-tubulin expression was not significantly changed after I/R. In normal kidney, immune-reactivities of kidney epithelial cell to acetylated α-tubulin antibody were different in tubules; the orders were the collecting duct, distal tubules and the proximal tubule. Twenty-four hours after ischemia, acetylated α-tubulin expression increased in the proximal tubule and the distal tubule with strong expression in the nuclei of the tubular cells. In the glomerulus, acetylated α-tubulin was also observed and the expression was very strong in the podocyte and Bowman’s capsule. Twenty-four hours after ischemia, acetylated α-tubulin expression in the proximal tubule was lower than that of normal cells. Nine days after ischemia, acetylated α-tubulin expression in the podocyte and interstitial cell increased. Expression of α-tubulin acetytransferase-1 (αTAT1), an enzyme involved in acetylation of α-tubulin, continuously decreased after ischemia. Histone deacetylase 6 (HDAC6), an enzyme involved in deacetylation of tubulin, also decreased after ischemia.

**Conclusions:** Ischemia/reperfusion reduced tubulin acetylation in renal tubular cells, suggesting that I/R-induced decrease of tubulin acetylation is associated with reduction of stability of microtubule in cells.

**Hypertension Aggravates Acute Kidney Injury (AKI) and Accelerates Progression to Chronic Kidney Disease (CKD)**

Robert Grote, 1 Anja Thorenz, 1 Falka Gueler, 1 Katja Hupeer, 2 Song Hong, 1 Hermann G. Haller, Jan H. Braesen. 4

**Background:** Acute kidney injury (AKI) results from ischemia/reperfusion (I/R) and toxic injury in the kidney. AKI is often associated with cardiovascular complications. The aim of this study was to investigate the link between hypertension and AKI in a mouse model of AKI. The results showed that hypertension significantly aggravated AKI and accelerated the progression to chronic kidney disease.

**Methods:** Male Sprague-Dawley rats were divided into four groups: control, hypertensive, AKI, and hypertensive AKI. The hypertensive group received bilateral renal artery stenosis (BRS) for 12 weeks, while the AKI group was treated with furosemide for 24 hours. The hypertensive AKI group received both BRS and furosemide. Renal function was assessed by measuring urinary creatinine and blood pressure was measured by tail cuff method.

**Results:** The hypertensive AKI group had significantly higher blood pressure and lower renal function compared to the other groups. The histological analysis showed more severe tubular and interstitial injury in the hypertensive AKI group compared to the other groups.

**Conclusions:** Hypertension significantly aggravates AKI and accelerates the progression to chronic kidney disease. These findings highlight the importance of managing hypertension in patients with AKI to prevent the development of chronic kidney disease.

**Pericyte MyD88 Controls Inflammatory and Fibrotic Responses to Kidney Injury**

Irina Alexandra Lea, 1 Ivan G. Gomez, 1 Bryce Gordon Johnson, 1 William A. Altermeier, 1 Jeremy Stuart Duffield. 1

**Background:** Pericytes, a type of smooth muscle cell, play a crucial role in regulating blood vessel tone and microenvironment. However, the role of pericytes in kidney injury is not fully understood. The aim of this study was to investigate the role of pericytes in kidney injury.

**Methods:** Male C57BL/6 mice were subjected to unilateral ischemia reperfusion (UIR) injury. Pericyte-specific MyD88 knockout mice and wild-type littermates were compared.

**Results:** Pericyte-specific MyD88 knockout mice had significantly worse renal function and tubulointerstitial injury compared to wild-type littermates.

**Conclusions:** Pericyte MyD88 plays a critical role in regulating inflammatory and fibrotic responses to kidney injury.

**Funding:** Government Support - Non-U.S.
Background: Ischemia reperfusion injury (IRI) of the kidney leads to acute kidney injury (AKI) and frequently precipitates the development of tubulointerstitial fibrosis. Bone morphogenic protein (BMP) signaling has been implicated in the pathogenesis and progression of the disease, but its tubular-specific role is unclear.

Methods: We induced IRI in mice by clamping the left renal pedicle for 25 minutes. The severity of IRI was determined by histology scoring, elevated mRNA expression of renal injury markers NGAL and KIM-1 and increased urinary NGAL (uNGAL) excretion 24h post-ischemia. Activation of canonical BMP signaling was detected by nuclear pSmad1/5/8 immunostaining and Western blotting. To achieve a doxycycline-dependent Cre-mediated inactivation of BMP receptor 1a (Bmpr1a) in renal tubules, we generated Pax5rtTA.LC1.Bmpr1a Δ/Δ mice (Bmpr1a Δ/Δ mice).

Results: Canonical BMP activity, as revealed by pSmad1/5/8, was widely detected in healthy wild-type (wt) mouse kidney tubules. IRI caused a sustained injury in wt kidneys as shown by elevated NGAL and KIM-1 expression and increased uNGAL excretion. In parallel, we observed a transient decrease of pSmad1/5/8 with minimal activity at 48 hours and a subsequent re-activation at 7 days post-ischemia. Bmpr1a Δ/Δ mice displayed normal renal tissue morphology and renal functions at baseline. Following IRI, Bmpr1a Δ/Δ mice exhibited improved initial injury similar to controls, but at 7 days post-ischemia, the expression of collagen IV and TGF-β1 were significantly up-regulated in Bmpr1a Δ/Δ kidneys compared to controls. Unlike controls, Bmpr1a Δ/Δ mice failed to reactive tubular pSmad1/5/8 activity at 7 days after injury. 21 days following IRI, Bmpr1a Δ/Δ kidneys displayed an increased percentage of tubulointerstitial fibrosis compared to controls.

Conclusions: Tubular Bmpr1a-dependent Smad1/5/8 signaling is transiently decreased after renal IRI and its reactivation limits the progression of tubulointerstitial fibrosis.

FR-P0273
PNUTS (Phosphatase 1 Nuclear-Targeting Subunit) is Down-Regulated in Acute Kidney Injury and by Aging, and Regulates Cell Cycle, Fibrosis, DNA Damage of Renal Tubular Cells

Background: PNUTS (phosphatase 1 nuclear-targeting subunit, also known as PPP1R10) has recently reported to be regulated in cardiac aging and play roles in DNA damage. Aging and fibrosis play crucial roles in AKI to CKD transition, however the precise mechanism is not known. Because the biological role of PNUTS in aged kidney, fibrosis, and cell cycle in AKI is poorly understood, we studied the regulation and the functional roles of PNUTS in AKI and aging.

Methods: We used an in vivo mice aristolochic acid (AA)-induced AKI model and cultured renal tubular cells (NRK-52E cells). To assess aging effects, we evaluated PNUTS expression, renal function, and renal fibrosis in AA-induced AKI model in different aged mice (20-, 50- and 90-week-old). To elucidate the function of PNUTS, cell cycle regulation (by FACs), DNA damage (by gammaH2AX expression), and fibrosis (by CTGF expression) were examined in NRK-52E cells transfected with siRNA for PNUTS or PNUTS expression vector.

Results: In mice with AA-induced AKI, protein and mRNA expression of PNUTS were reduced compared with control mice. Moreover, PNUTS expression were decreased in accordance to aging. Reduction of renal function and renal fibrosis were more apparent in aged AKI mice. Immunohistochemical examination revealed the reduced expression of PNUTS in the proximal tubular cells in AA-induced AKI. PNUTS mRNA and protein expression showed a dose-dependent reduction by H2O2 in NRK-52E cells. Overexpression of PNUTS reduced H2O2-induced caspase3 activity and apoptotic (TUNEL positive) cell number. Transfection of siPNUTS significantly increased G2/M phase cell cycles, CTGF expression, and DNA damage.

Conclusions: These results indicate that PNUTS expression was reduced in AA-induced AKI and in aged mice. Expression of PNUTS was partially regulated by oxidative stress. PNUTS regulates cell cycle, CTGF expression, DNA damage, and apoptosis in NRK-52E cells. These results suggest that regulation of PNUTS may play a key role in the pathophysiology of AKI and age-related renal damage.

FR-P0274
Class Ia HDAC Inhibitors Restore BMP-7 Expression and Inhibit the Pathogenesis of Renal Fibrosis following Chronic Renal Injury

Background: BMP-7 is a potent anti-fibrotic cytokine that is also required for the repair of renal injuries. However, chronic renal injury leads to the loss of BMP-7 and fibrotic response. We investigate molecular mechanisms that lead to the loss of BMP-7 expression and examine potential therapeutic strategies for stimulating the innate reparative mechanisms of the kidney.

Methods: BMP-7 expression was studied in vitro in normal and diseased kidney (IMCD cells and in vivo in rats, dogs, and in patients of unilateral ureteral obstruction, UUO). The therapeutic effects of broad spectrum histone deacetylase (HDAC) inhibition with Trichostatin A (TSA) and Class Ia HDAC inhibition with MS-275 were evaluated by assessing renal pathology.

Results: MS-275 results in an 83.1% decrease in BMP-7 mRNA expression that is paralleled by a 63.0% decrease in the acetylation of histone proteins in the proximal Bmp7 promoter, a process that results in gene repression. These changes are HDAC-dependent and blocked by treatment with TSA. An in vitro pharmacological screen in IMCD cells revealed that MS-275 stimulates BMP-7 expression, while inhibitors of other HDAC isoforms have no effects. These results were confirmed by using siRNA-mediated genetic ablation to demonstrate specificity and chromatin immunoprecipitation to show binding of the Class Ia HDAC proteins HDAC1 and HDAC2 to the Bmp7 promoter. MS-275 also stimulates TGF-β-dependent pro-fibrotic genes of BMP-7 in vitro by suppressing the expression of the TGF-β-dependent pro-fibrotic genes COL1α1 and asdBα by 68.2% and 97.6%, respectively.

Conclusions: These findings demonstrate that HDAC1 and HDAC2 are responsible for the loss of BMP-7 expression and its renal protective functions in the injured kidney. Furthermore, our study suggests that Class I HDAC inhibitors have a tremendous therapeutic potential for stimulating kidney repair and inhibiting disease progression following chronic renal injury.

FR-P0275
Gli2 in Perivascular MSC Is Required for Kidney Fibrosis and Can Be Targeted Pharmacologically

Background: We recently demonstrated that perivascular mesenchymal stem cell (MSC)-like cells are defined by expression of Gli2 and are critical myofibroblast precursors. We now investigate the role of Gli transcriptional activators in myofibroblast progenitors during kidney fibrosis and value as therapeutic targets.

Methods: We utilized mouse genetics, drug binding, RNAi and retroviral overexpression to dissect the roles of Gli1 vs. Gli2 in myofibroblast activation and fibrosis. We pharmacologically targeted Gli proteins with Darniparsin, an arsenville, and GANT61, a small molecule Gli inhibitor. We evaluated them in two separate mouse CKD models. We measured hedgehog pathway activity and expression of Gli in human kidney fibrosis specimen.

Results: In vitro knockdown of Gli1 had no appreciable effect whereas knockdown of Gli2 induced a G0/G1 cell cycle arrest of murine fibroblasts. Conversely, Gli2 overexpression rescued this cell-cycle effect and drove proliferation. In vivo, knockout of Gli1 showed no effect on fibrosis severity after UUO whereas either conditional knockout of Gli2 or overexpression of the Gli3 repressor in Gli1+ mice pericytes ameliorated fibrosis and induced a G1/G0 cell cycle arrest specifically in myofibroblasts, consistent with our in vitro results. We show that darniparsin directly binds to Gli2, lowers Gli2 protein levels and induces a G0/G1 cell cycle arrest. This effect of darniparsin absolutely requires Gli2, and Gli2 overexpression rescued the cell cycle defect. When administered in a therapeutic dosing strategy after UUO or IRI, darniparsin potently reduced Gli1 and Gli2 expression, fibroblast-specific protein 1-like 1 (Fsp1-like 1) expression, Gli1-dependent TGF-β-dependent pro-fibrotic genes (SMA, TGF-β, CTGF, COL1α1), structurally unrelated to darniparsin, showed the exact same effects. In human kidneys with fibrosis there is strong upregulation of Gli1 and Gli2 mRNA, suggesting this pathway is conserved in humans.

Conclusions: Gli2 is a critical driver of myofibroblast proliferation and a novel therapeutic target in kidney fibrosis.

Funding: NIDDK Support

FR-P0276
Klotho Influences the Fate of Fibrosis in Cardio-Renal Protection

Background: Soluble Klotho is an endogenous hormone produced predominantly by extracellular domain shedding of membrane Klotho in the kidney. Although Klotho is not thought to provide cardio-renal protection through its regulation of ion transport and growth factor signaling, specific cellular localization and function of Klotho in the normal and diseased kidney are not clearly defined.

Methods: We evaluated Klotho expression and localization in human and mouse kidney via immunohistofluorescence (ISH), immunohistochemistry (IHC) or RNAseq. Cardio-renal protective effects of soluble human Klotho administration were studied in mouse unilateral ureteral obstruction (UUO; 5 day) and isoproterenol-induced cardiac hypertrophy (ISO, 5 mg/g/l x 10 days) models.

Results: In normal adult human kidney (fresh nephrectomy and autopsy, n=9), Klotho was highly expressed in distal tubules (DT) and in both cortical and outer medulla collecting ducts (CD). Proximal tubule and podocyte expression was low but detectable. Following UUO, renal Klotho mRNA was decreased 61% and protein content was reduced greatly in the remaining renal vs sham kidney. Klotho treatment (10 μg/kg, QD, IP) attenuated UUO-induced tubulointerstitial fibrosis (picrosirius red stain, n=10) by 67% (*p<.05) and...
biomarker mRNA (40.4%±6.2%; 25.1±5.5%; 16.0±3.7%) vs Vehicle control. In the ISO model, IRX-injected mice showed significantly increased cardiac hypertrophy (HW/BW; n=6): 5.4±1.0 (p≤0.01) in Klotho- vs 5.8±0.8 in Vehicle control.

Conclusions: Klotho is highly expressed in normal human and mouse distal nephron. Klotho mRNA and protein are reduced in preclinical models of cardiac and renal disease. Development of a combinatorial Klotho antagonist severity of pathology and biomarker expression in the UUO model of renal fibrosis and ISO-induced cardiac hypertrophy. Klotho pharmacotherapy has the potential to prevent CKD progression as well as the progression of extra-renal Klotho-dependent diseases.

**FR-P0277**

**Kidney Interstitial Cell Derived Tenascin C Plays an Important Role in Promoting Injury-Repairing of the Kidney by Stimulating Cell Proliferation**

Min Zhang, Qionghong Xie, Xiaoyi Mao, Da Shang, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Shanghai, China.*

**Background:** Tenascin-C (TNC) is a glycoprotein expressed in extracellular matrix during development and injury repairing. This study explored the role of TNC in acute kidney injury (AKI).

**Methods:** A TNC promoter driven inducible CreERT2 knock-in mouse with EGFP reporter (IRE6-EGFP) as generated (TNC-CreERT2;EGFP). AKI was induced by 40 minutes of ischemia followed by reperfusion in unilateral nephrectomized mice (UN+UiR). Cell lineage tracing was conducted in TNC-CreERT2;R26-tdTomato mice to examine the origin of TNC expressing cells. The effect of TNC on cell proliferation was examined using a cell count kit in cultured HK2 cells. TNC expression was also examined in human biopsies with IRB approval.

**Results:** In normal kidney, TNC was restricted in renal papilla in both mice and human. Following IR, TNC was markedly induced in renal cortex, particularly in injured areas. TNC reporter showed that induced TNC expression is localized in interstitial cells, but not tubular epithelial cells. TNC induction was also shown in human biopsies with IRB approval.

**Conclusions:** TNC is induced in renal interstitial cells after IR-induced AKI, protecting the kidney from injury. The protective effect of TNC on AKI may be associated with promoting renal recovery by stimulating epithelial cell proliferation.

**Funding:** Government Support - Non-U.S.

**FR-P0278**

**TAZ and YAP Are Mechanoregulators of TGF-β Smad Signaling and Renal Fibrogenesis**

**Background:** Fibrosis is a final common injury pathway responsible for the progression of most forms of CKD, for which no specific treatments exist. Driven largely by TGF-β signalling, fibroblast-myofibroblast transition is crucial for fibrogenesis. While it is known that fibroblast activation is mechanosensitive, with soft matrix akin to a healthy kidney, fibrogenesis of most forms of CKD, for which no specific treatments exist. Driven largely by TGF-β signalling, fibroblast-myofibroblast transition is crucial for fibrogenesis. Here, our aim was to examine how stiffness regulates TGF-β signalling via TAZ/YAP, and to test if TAZ/ YAP inhibition can attenuate renal fibrosis.

**Methods:** The effects of matrix stiffness on TAZ/YAP localization and TGF-β-Smad signalling were examined in rat renal fibroblasts (NRK49Fs) cultured on soft (2 kPa) and stiff (100 kPa) gels. To test the effect of TAZ/YAP inhibition, NRK49F cells and mice were treated with verteporfin (VP), a drug used as a masacural degeneration treatment with retinal disease in animal models.

**Results:** In NRK49F cells, stiff matrix resulted in nuclear TAZ/YAP localization and enhanced TGF-β signalling. On growth on soft matrix, contrast, reduced TAZ/ YAP nuclear localization, and impaired TGF-β-induced Smad2/3 nuclear accumulation and transcriptional activity. Verteporfin treatment of TAZ/YAP-overexpressing cells resulted in a dramatic loss of TAZ/YAP localization, leading to a significant inhibition of TGF-β-Smad signaling. VP-induced TAZ/YAP loss also enhanced prostatesmal Smad2/3 degradation following TGF-β stimulation. *In vivo*, VP similarly reduced renal TAZ/YAP and Smad2/3 levels in UUO mice, leading to diminished myofibroblast accumulation and interstitial collagen deposition.

**Conclusions:** Our data suggest that fibrogenesis is regulated by a novel mechanism through stiffness that, through control of the mechanosensory proteins TAZ and YAP, regulates TGF-β-Smad signaling. Furthermore, we speculate verteporfin as a potential anti-fibrotic treatment that interferes with this pro-fibroblast-mechanochemical synergy.

**Targeted Deletion of Numb from Proximal Tubules Attenuates Interstitial Fibrosis by Mitigating G2/M Arrest**

Fengxin Zhu, Jing Nie. *Div of Nephrology, Nanfang Hospital, Guangzhou, Guangdong, China.*

**Background:** Progressive tubulointerstitial fibrosis (TIF) is the final common pathway leading to end stage renal disease. Tubular epithelial cells (TECs) have a crucial role in the pathogenesis of TIF. Numb is a multifunctional protein involved in diverse cellular processes. However, little is known about the physiologic and pathologic role of Numb in kidney.

**Methods:** We examined the expression and distribution of Numb in normal adult mouse kidney as well as in mouse model of renal fibrosis induced by unilateral ureteral obstruction (UUO). Here we report for Numb’s role in renal fibrosis, we generated a conditional knockout mouse model in which Numb is selectively ablated from proximal tubules (PEPCK-Numb-KO). To confirm the role of Numb in regulating cell cycle, Numb was overexpressed in NRC2 cells by infecting with a Numb adenovirus (Ad-Numb) and endogenous Numb was knocked down by siRNA in HK-2 cells before aristolochic acid (AA) treatment. To examine the role of p53 in Numb-induced G2/M arrest, Ad-Numb infected HK-2 cells were incubated with pifithrin-α, a p53 inhibitor.

**Results:** Numb is expressed in renal tubules and glomeruli. The expression of Numb in renal tubules was significantly increased after UUO. After UUO, PEPCK-Numb-KO mice exhibited significantly attenuated TIF. Ectopic expression of Numb increased the fraction of cells in G2/M stage and upregulated the expression of TGF-β1 and CTGF in NRC2 cells. Knocking down endogenous Numb attenuated AA-induced G2/M arrest and profibrotic cytokines production. Furthermore, G2/M arrest and expression of profibrotic cytokines were significantly reduced in PEPCK-Numb-KO mice after UUO. Inhibiting p53 activity dramatically mitigated Numb-induced G2/M arrest and profibrotic cytokines production.

**Conclusions:** In summary, our studies demonstrate that Numb has a profound effect on promoting G2/M arrest of TECs through stabilizing p53 protein. Depletion of Numb markedly attenuates G2/M arrest of proximal tubules which in turn reduces TIF. Collectively, these data indicate that targeting Numb might be a novel therapeutic approach for the treatment of fibrotic kidney diseases.

**Identification of a New Aldosterone Synthase Inhibitor with Anti-Fibrotic Activity in Animal Models**

**Background:** The renin-angiotensin-aldosterone system (RAAS) plays a critical role in renal physiology. Inhibitors of ACE and ARBs are currently the mainstay in the treatment and management of the chronic kidney disease (CKD). Despite initial success in reducing aldosterone, concentrations return to pretreatment levels in 30-40% of patients. This “aldosterone escape” significantly limits the therapeutic effectiveness. Through mineralocorticoid receptor dependent and independent processes, aldosterone is thought to directly accelerate renal damage by sustaining inflammation and fibrosis. An attractive approach to deal with aldosterone escape is to inhibit aldosterone synthase (AS), the enzyme responsible for aldosterone production (encoded by the CYP11B2 gene).

**Methods:** We have identified a promising series of potent and selective small molecule inhibitors of AS. Lead compound ANG3586 has 7 nM potency against AS and excellent selectivity against other P450 enzymes. It is orally bioavailable in rodents and appears to be well tolerated. ANG3586 was tested in the rat remnant kidney model (25 mg/kg, po, bid) and the mouse unilateral ureteral obstruction (UUO) model (25 mg/kg, po, bid, ten days). In vivo, rats treated with vehicle or ANG3586. The elevated blood pressure in 5/6 nephrectomized animals was reduced to normal by compound treatment. ANG3586 also markedly reduced kidney collagen content and improved renal histology. Renal function, as determined by urine BUN and creatinine levels, urine albumin to creatinine ratio and urine NGAL, was found to be markedly improved. In the mouse UUO model, ANG3586 reduced the increase in kidney weight, kidney collagen and alpha-smooth muscle actin staining. Since UO does not result in distinctly increased blood pressure, the anti-fibrotic activity appears independent of blood pressure lowering activity of ANG3586.

**Conclusions:** Taken together, ANG3586 shows promise as a potential novel anti- fibrotic agent.

**Tubulointerstitial Fibrosis Increases Peritubular Capillary Permeability and Induces Subsequent Hypoxia**

Jun Zou, Jae Won Yang, Haiyun Yang, Agnes B. Fogo. *Dept of Pathology, Microbiology, and Immunology, Vanderbilt Univ, Nashville, TN; Div of Nephrology, Xinhua Hospital, Shanghai, China.*

**Background:** We previously showed that folic acid-induced tubulointerstitial injury significantly increased peritubular capillary permeability. In this study, we investigated whether the administration of folic acid induces the expression of peritubular capillaries and oxygen supply changes contribute to this cross-talk of tubular to glomerular injury.

**Methods:** We identified L-carcinofaiceae, which have carcinoeaease collagen in the collagen I promoter, were mated with Neph25 mice, which express human CD25 receptor on podocytes, and develop glomerulocarcinoma when immunotoxic in mice. Treated were fed with folic acid (FA, 240mg/kg BW, i.p.). At day 42,
mice were sacrificed to assess interstitial fibrosis, peritubular capillary number (CD31 positive), and collagen I were increased in FA compared to VEH (picrosirius red area, FA 14.5 ±1.6 vs. VEH 31.6±5.1×10⁴, p < 0.05). Interstitial pathological changes were assessed in tissue sections stained with Collagen I and Masson's trichrome. The expression of Col1A1 and Collagen I were examined by Western blot and qPCR. Renal expression fibrotic factors, including renal fibrosis. Excess deposition of extracellular matrix (ECM) components including collagen is the eponymous lesion of renal fibrosis. Results: Wild-type C57BL/6 mice, at the age of 6-9 weeks, were fed with either standard rodent chow or HM diet. After 2 weeks on the diet, mice were sacrificed. Kidney sections were stained with antibodies against CD31 or Collagen I and Masson's trichrome. The expression of Col1A1 and Collagen I were examined by Western blot and qPCR. Renal pathological changes were assessed in tissue sections stained with Collagen I and Masson's staining. OCC-2 cells were transduced with pCol-GL3 reporter plasmid, pRL null together with siG9a or Flag-tagged G9a to examine the promoter activity of COL1A1. The level on G9a and H3K9me2 on the promoter of COL1A1 was assessed by CHIP assay. Conclusions: We demonstrated that elevated concentration of Hcy induced the expression of collagen type I in cultured HK-2 cells as well as in kidney tissue of Hcy mice. Meanwhile, Hcy inhibited the expression of histone methyltransferase G9a. Mechanistically, silencing endogenous G9a by siRNA enhanced the promoter activity of COL1A1 in HK-2 cells. Conversely, overexpression G9a inhibited the promoter activity of COL1A1. CHIP assay demonstrated that G9a binds to the promoter-less restrictive silencer element (NRESE) on the promoter of COL1A1. The level on G9a and H3K9me2 on the promoter of COL1A1, led to upregulation of COL1A1. These results show that homocysteine induces collagen I expression by downregulating histone methyltransferase G9a and provide a novel mechanism on explaining how Hcy promotes ECM production. The Podocyte Adhesive Exhibits Matrix Ligand Specificity with Implications for Glomerular Disease

J. M. Randles,1 Roy Zent,1 Martin J. Humphries,1 Rachel Lennon.2 1Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester; Manchester, United Kingdom; 2Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester; Manchester, United Kingdom; Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.

Background: Adhesion at both the podocyte slit diaphragm and podocyte-extracellular matrix (ECM) interface is essential glomerular filtration barrier integrity. These structures converge onto many of the same signalling pathways, including those controlling the actin cytoskeleton. Podocytes adhere to laminin-521 in the glomerular basement membrane via integrin α3β1 and evidence suggests that attachment to collagen IV is upregulated in disease states. Whether changes in ECM ligand alter podocyte adhesion signalling remains unclear.

Methods: We analysed podocyte morphology following engagement of either laminin-521 or type IV collagen (α1α1α2) and isolated basolateral adhesion complexes for MS was generated. These cell phenotypes were enhanced with overexpression of the key slit diaphragm protein nephrin. The composition of isolated adhesion complexes was determined by ECM ligand and nephrin expression status. MS and protein interaction network mapping highlighted PKCs as a key signalling node in laminin adhesion complexes. Analysis of nephrin-nephrin complexes highlighted significant overlap with ECM adhesion signalling, suggesting crosstalk mechanisms.

Conclusions: In human podocytes we discovered that both ECM ligand and overexpression of nephrin influences morphology, adhesion complex composition and intracellular signalling. Enhanced understanding about the pathways that control podocyte adhesive responses may ultimately inform therapeutic strategies to correct or repair glomerular barrier function. Low-Density Lipoprotein Receptor-Related Protein 5 Drives Tubulointerstitial Fibrosis via Regulation of TGF-β Signaling

Xueming He, Rui Cheng, Jian-xing Ma. Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: Low-density lipoprotein receptor-related protein 5 (LRP5), a co-receptor of the canonical Wnt/b-catadin pathway, was recently reported to drive idopathic pulmonary fibrosis through activating β-catenin. In this study, we examined the potential role of LRP5 in the regulation of TGF-β signaling in tubulointerstitial fibrosis.

Methods: LRP5-deficient (Lrp5−−) mice and age-matched wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO). Renal expression fibrotic factors, including α-SMA, CTGF, collagens and fibronectin, was quantified by picro-sirus red staining, western blot analysis and immunostaining. Primary tubular epithelial cells (PTECs) were cultured from Lrp5−− mice and WT mice. Co-Immuno precipitation was performed in a human proximal tubular epithelial cell line (HKC-8) over-expressing LRP5 and TGF-β receptors. Results: Lrp5−− mice with UUO showed ameliorated collagen I fibrosis and alleviated TGF-β signaling compared with WT mice with UUO. However, activation of the Wnt-β-catenin signaling was not different between Lrp5−− mice and WT mice, indicating that attenuated tubulointerstitial fibrosis in Lrp5−− mice was not due to mitigated activation of the fibrotic Wnt-β-catenin pathway. Instead, LRP5+/+ kidneys displayed alleviated TGF-β signaling in comparison to that in WT/WW kidneys. Overexpression of LRP5 in HKC-8 resulted in enhanced TGF-β signaling including enhanced TGF-β driven transcriptional activity and elevated expression of fibrosis markers regulated by TGF-β signaling. Knock-down of LRP5 in HKC-8 cells diminished the activation of the TGF-β signaling pathway. Meanwhile, LRP5−−/− PTECs were subjected to UNO. In addition, immunoprecipitation assay demonstrated physical association between LRP5 and TGF-β receptor 1, suggesting that LRP5 might act as a co-receptor of the TGF-β signaling pathway in the regulation of tubulointerstitial fibrogenic process. Conclusions: LRP5 promotes tubulointerstitial fibrosis via regulation of the TGF-β signaling. This activity is independent of its role in the Wnt/β-catenin pathway. Loss of Endothelial Nitric Oxide Oxides Sma3 Linker Phosphorylation and Precedes Insulin Resistance in High-Fat Diet Induced Obesity

Yu bo Yang Sun, Xinli Qu, Jinhua Li. Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia.

Background: Deficiency of endothelial nitric oxide synthase (NOS3/enOS) confers susceptibility to diet-induced obesity and it’s complications. enOS-derived nitric oxide (NO) acts as a potent vasodilator, enhances insulin sensitivity and also inhibits inflammation. TGF-β/Smad signaling plays an important role in regulating glucose and energy homeostasis. Sma3 deficient mice are protected from diet-induced obesity and obesity-related kidney injury. This study investigated whether the loss of endothelial-derived NO promotes Sma3 activation, which precedes insulin resistance in high-fat diet (HFD) induced obesity.

Methods: C57BL6/J wild type, eNOS deficient (eNOS−/−) with C57BL6/J background mice were given HFD or normal diet (ND) treatment for 1, 3, 7 days and 4, 8 or 16 weeks. Results: Within 7 days of HFD treatment in WT mice, Western blotting showed a marked decrease in total eNOS level but it’s complications. NO derived NO promotes Smad3 activation, which precedes insulin resistance in high-fat diet (HFD) induced obesity.

Conclusions: Lrp5−−/− mice was not due to mitigated activation of the fibrotic Wnt-β-catenin pathway. Instead, LRP5+/+ kidneys displayed alleviated TGF-β signaling in comparison to that in WT/WW kidneys. Overexpression of LRP5 in HKC-8 resulted in enhanced TGF-β signaling including enhanced TGF-β driven transcriptional activity and elevated expression of fibrosis markers regulated by TGF-β signaling. Knock-down of LRP5 in HKC-8 cells diminished the activation of the TGF-β signaling pathway. Meanwhile, LRP5−−/− PTECs were subjected to UNO. In addition, immunoprecipitation assay demonstrated physical association between LRP5 and TGF-β receptor 1, suggesting that LRP5 might act as a co-receptor of the TGF-β signaling pathway in the regulation of tubulointerstitial fibrogenic process. Conclusions: LRP5 promotes tubulointerstitial fibrosis via regulation of the TGF-β signaling. This activity is independent of its role in the Wnt-β-catenin pathway. HIF1α and HIF2α Both Mediate Glomerulosclerosis but Differentially Regulate the COL1A2 Promoter  

**Promoter** Bethany Baumann, Tomoko Hayashida, Xiaoyan Liang, H. William Schnaper. Northwestern Univ, Chicago, IL.

**Background:** TGFβ increases HIF1α and HIF2α levels in normoxia and both HIFs contribute to TGFβ induction of type I collagen in vitro, suggesting a potential role for HIFs in renal disease regardless of oxygen tension. Here, we studied the role of HIFs in mouse glomerulosclerosis (GS).

**Methods:** HIF1α-/- or +/+; bactin-Cre;ERT2, NEP52 mice express human Tac on podocytes. LM2B, a toxin/anti-Tac chimera, binds to Tac, ablatting podocytes to cause GS. Systemic Cre recombination was induced by tamoxifen at 4 weeks of age and LM2B injected after 9 weeks. Mice were sacrificed 4 weeks later HIF2α-/- or +/+ mice were generated on a 129 background and bred with PDKGFRβ-Cre mice to delete HIF2α from pericytes and mesangial cells. GS was induced by Adriamycin injection at 8 weeks of age. Mice were sacrificed 2 weeks later. Disease progression was analyzed by histology, scoring 50-100 glomerular/animal on a fibrosis scale of 0-4, and by qPCR for COL1A2 mRNA with laser-captured glomeruli. In vitro studies investigating a mechanism by which HIFs regulate COL1A2 promoter were also performed.

**Results:** HIF1α: Histologically, control mice scored 0.46 (+/- 0.12), diseased WT mice 3.13 (+/- 0.19), and diseased HIF1αKO mice 1.42 (+/- 0.28). Glomerular COL1A2 mRNA with LM2B injection was increased 3.4x over the healthy controls in WT, but only 1.9x with HIF1α KO. In vitro, TGFβ induced COL1A2 promoter activity by 2.4x, which was abrogated when a hypoxia response element (HRE) 335 bp 5′ to the transcription start site was mutated. By DNA precipitation assay, HIF1α binding to a -335 COL1A2 HRE probe was detected after TGFβ treatment. Interestingly, Smad3 also bound the -335 COL1A2 HRE probe in both TGFβ-treated cell lysate and whole kidney lysate from WT HIF1α NEP52 mice with GS. HIF2α; PDKGFRβ-Cre mice showed less GS than HIF2α-/- mice by histology. In vitro, HIF2α enhanced COL1A2 promoter activity independently of the -335 HRE. Instead, HIF2α increased the transcriptional activity of Smad3.

**Conclusions:** Both HIF1α and -2a contribute to the development of GS in mice. Out in vitro studies strongly suggest that HIF1α and -2a each enhance TGFβ-mediated fibrogenesis, but through distinct mechanisms.

MiR302a-3p Modulates Renal Epithelial-Mesenchymal Transition in DKD by Targeting ZEB1  

**Authors** Xiaoyan Liang, H. William Schnaper. Dept of Nephrology, Xiangya Hospital, Central South Univ, Kidney Inst, Changsha, Hunan, China.

**Background:** Recent study found that miRNAs are involved in diabetic kidney disease (DKD). The objective of this study is to determine the role of miR302a-3p in the process of renal epithelial-mesenchymal transition (EMT) in DKD.

**Methods:** The levels of miR302a-3p in the plasma of DKD patients were detected by realtime PCR and the relationship of miR302a-3p and UAE or eGFR were analyzed. Secondly, miR302a-3p expression was determined in HK-2 cells treated with high glucose for different time. And then miR302a-3p mimics and inhibitor were transfectated to HK-2 cells following exposure to high glucose and low glucose respectively. The expressions of ZO-1, vimentin and ZEB-1 were determined by realtime PCR and western blot.

**Results:** The expression of circulating miR302a-3p was significantly increased in the diabetes mellitus group (DM, n=22) compared with control (healthy persons, n=30) and then decreased in the early stage of diabetic nephropathy group (DNG, n=20). Furthermore, its expression in clinical diabetic nephropathy group (DNC, n=18) was decreased significantly compared with DM group. Circulating miR302a-3p expression had negative relevance with UAE and eGFR (p<0.0001). In contrast, plasma levels of Pro-C6, a biomarker of collagen Type III and VI turnover were strongly correlated with eGFR (p<0.0001). In advanced disease stages compared to early and mild stages. Plasma levels of Pro-C6, a marker for collagen type III degradation, were strongly correlated with eGFR (r=0.62, P=0.0001), with lower levels in advanced disease stages compared to early and mild stages. Plasma levels of Pro-C6, a marker for collagen type VI degradation, significantly increased with disease progression and strongly correlated with eGFR (p<0.0001). In contrast, plasma C3M and urinary Pro-C6 levels showed no correlation with renal function.

**Conclusions:** We identified two biomarkers of tissue turnover associated with ECM remodeling and subsequent fibrosis in the transplanted kidney leading to loss of renal function. As such they have great potential as early diagnostic markers for kidney allograft failure.

**Kruppel-Like Factor 15 Works as an Early Anti-Fibrotic Transcriptional Regulator in Angiotensin II-Induced Renal Fibrosis via Down-Regulation of Connective Tissue Growth Factor**  

**Authors** Xiaonan Cui, Xiangchen Gu, Xiang Gao, Changlin Mei, 1 Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China; 2Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China; 3Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China.

**Background:** Angiotensin II (Ang II) has been regarded as an important profibrogenic cytokine in renal fibrosis. One of the main targets of Ang II in renal fibrosis is CTGF. Krüppel-like factor 15 (KLF15) is recognized as an important negative transcription factor in renal fibrosis. This study is aimed to detect the possible role and mechanism of KLF15 in renal fibrosis induced by Ang II.

**Methods:** Firstly, mice were randomized into control group, Ang II group, Ang II+losartan group, the renal fibrosis levels and KLF15 were measured by Real-Time PCR and IMF methods respectively at 4 weeks or 6 weeks. Then NRK-49F were stimulated with Ang II and (or) infected with Ad-GFP-KLF15, and the expressions of KLF15, COL1A2, and extracellular matrix were detected by Real-Time PCR and Western Blot. CoIP and ChIP assay were also performed to investigate the relationship among coactivator P/CAF, transcription regulator KLF15, and CTGF promoter.

**Results:** The mRNA model of Ang II-induced renal fibrosis demonstrated a significant decrease in renal KLF15 expression at 4 weeks and progressive renal fibrosis at 6 weeks. Losartan effectively prevented the decrease in KLF15 expressions induced by Angiotensin II. Stimulated with Ang II, NRK-49F exhibited significant decreases in KLF15, accompanied by increased increase in CTGF and extracellular matrix. Losartan prevented the decrease in Ang II induced KLF15. Furthermore, overexpression of KLF15 inhibited Ang II induced CTGF in NRK-49F. CoIP and ChIP demonstrated KLF15 could directly bind to P/CAF, and repressed its recruitment to CTGF promoter.

**Conclusions:** These results unveiled that Ang II could downregulate KLF15 via AT1 receptor. Transcription regulator KLF15 is likely to inhibit Ang II induced CTGF by repressing coactivator P/CAF’s recruitment to CTGF promoter.

Biomarkers of Collagen Type III and VI Turnover Can Identify Renal Allograft Failure in Kidney Transplant Recipients  

**Authors** Federica Genovese,1 Signe Holm Nielsen,1,2 Daniel Guldager Kring Rasmussen,1,2 Morten Asser Karsdal,1,3 Stephen J.L. Bakker,1 Peter Olinga,1 Elisabeth G.D. Stribos,1 Henricus A.M. Matthews.1,2 Fibrosis Biology and Biomarkers, Nordic Bioscient, Herlev, Denmark; 3Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China; 4Southern Denmark Univ, Odense, Denmark; 5Univ of Groningen, Groningen, Netherlands.

**Background:** Chronic allograft loss poses a major problem in improving long-term survival in renal transplant recipients (RTR). Intestinal fibrosis and tubular atrophy are already present in 40% of kidney allografts 3-6 months after transplantation. Extracellular matrix (ECM) turnover levels, reflecting the onset of fibrosis, can be early and superior markers to detect early fibrosis in RTR. We evaluated a non-invasive tool measuring the plasma and urinary biomarker profile related to ECM turnover.

**Methods:** 78 patients attending the University Medical Center Groningen during one week for a routine check-up after kidney transplantation were enrolled in the study. Plasma and/or 24-hour urine samples were collected from 75 and 42 RTR, respectively. Afterwards, markers of collagen remodeling were determined by competitive ELISAs.

**Results:** There was no correlation between age or time after transplant and glomerular filtration rate (eGFR) in this population. Urinary levels of C3M, a marker for collagen type III degradation, were strongly correlated with eGFR (r=0.62, P=0.0001), with lower levels in advanced disease stages compared to early and mild stages. Plasma levels of Pro-C6, a marker for collagen type VI fibrosis, significantly increased with disease progression and strongly correlated with eGFR (r=0.62, P=0.0001). In contrast, plasma C3M and urinary Pro-C6 levels showed no correlation with renal function.

**Conclusions:** We identified two biomarkers of tissue turnover associated with ECM remodeling and subsequent fibrosis in the transplanted kidney leading to loss of renal function. As such they have great potential as early diagnostic markers for kidney allograft failure.

Hyaluronidase-2 Dependent Regulation of CD44 Variant Expression in Anti-fibrotic versus Pro-Fibrotic Cells  

**Authors** Soma Meran, Adam Midgley, Robert Steadman, Aled O. Philips. Nephrology, Cardiff Univ, Cardiff, United Kingdom.

**Background:** Hyaluronan (HA) is a GAG with increased expression in progressive renal disease, and its expression correlates with poor renal outcomes. The HA receptor (CD44) is a transmembrane protein that plays a role in the adhesion of cells and the regulation of extracellular matrix expression, thus playing an important role in the maintenance of tissue homeostasis. We have previously identified CD44v7 as a key mediator in the reversal of myofibroblast phenotype, but its mechanism is unknown. Here we investigate whether HA2 plays a regulatory role in alternative splicing of CD44v7/8 variant isoforms.

---

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: Fibroblasts & renal epithelial cells were incubated with TGFβ1 to induce myofibroblast differentiation, and compared to cells incubated with a TGFβ1 & BMP2 to induce myofibroblast reversal. QPCR, confocal microscopy, ChIP, siRNA & plasmid overexpression were used to assess Hyal2 effects.

Results: Hyal2 was upregulated by both profibrotic (TGFβ1) & anti-fibrotic (BMP7) cellular treatments. However in profibrotic cells, Hyal2 was cytoplasmic, whereas in anti-fibrotic cells Hyal2 translocated to the nucleus. In profibrotic cells Hyal2 did not associate with CD44. In contrast in anti-fibrotic cells Hyal2 associated with CD44s at the nucleus, whilst CD44s/7-8 located to the cell surface. In anti-fibrotic cells Hyal2 nuclear translocation was increased CD44s/7-8 mRNA & protein expression. CD44s/7-8 was subsequently necessary for HA internalization and consequent reversal of myofibroblast phenotype. ChIP demonstrated association between Hyal2 and introns flanking the CD44s-7-8 exon nucleotide sequence similar to a2G splice facilitator. Moreover, Hyal2 inhibits endocytosed BMP7 directed activation of splice regulators SL2E & SRSF5.

Conclusions: Hyal displays nonenzymatic activity & translocates to the nucleus regulating expression of CD44s-7-8 splice variant, which is crucial for reversing myofibroblast phenotype. Hence Hyal is a novel splice regulator and a critical regulator in reversal of myofibroblast phenotype & fibrosis prevention.

FR-PO291 FGF Signaling Contributors to Podocyte Injury in Murine HIV-Associated Nephrupathy Koji Okamoto, Eisei Norii, Jeffrey B. Kopp. 1 Kidney Section, NIDDK, NIH, Bethesda, MD. 1 Dept of Nephrology, Endocrinology, Hemodialysis & Apheresis, Univ Hospital, The Univ of Tokyo, Tokyo, Japan.

Background: We reported that fibroblast growth factor receptor (FGFR), its ligand fibroblast growth factor 2 (FGF2), and their amplifying co-factor glypicans 5 (GPC5) play important roles in idiopathic nephritic syndrome and diabetic nephropathy (Okamoto, Nature Genetics, 2011). We have investigated the role of the FGF2 signal pathway in HIV-associated nephropathy (HIVAN).

Methods: FGF2 ligands and FGF expression were studied in a mouse podocyte cell line and HIVAN transgenic mice, both of which express the HIV accessory protein Vpr in the presence of doxycycline. To study FGF2 trapping in glomeruli, biotinylated FGF2 was administered intravenously and detected with fluorescent streptavidin. Vpr mice and control mice received FGF2 (5 mg/animal/weekly for 4 weeks) or FGF antagonist (PD173074,50 mg/animal/bi-weekly for 4 weeks).

Results: In cultured mouse podocytes FGF3 mRNA was increased 11-fold after Vpr induction. In Vpr mice compared with control mice, renal cortex FGF2 content was increased 3-fold, as assessed by ELISA. Intra-glomerular protein expression of FGF3 and GPC5 were increased detected by immunofluorescent staining. These results suggest that Vpr mouse glomeruli might have increased FGF2 binding capacity and so we tested the binding capacity of FGF2 in vivo. One hour after intravenous administration of biotinylated FGF2, more bioactive signal remained in glomeruli of Vpr mice compared with control mice (60% increase). Urine albumin/creatinine ratios (g/g) were significantly increased in FGF2-treated Vpr mice compared to untreated Vpr mice on day 14 (0.50±0.19 vs 2.3±0.6), day 21 (1.7±0.16 vs 18.7±5.1) and day 28 (1.87±0.44 vs 21.8±9.9). Further, the FGF antagonist diminished albuminuria in Vpr mice at day 21 (0.47±0.16 vs 1.7±0.16 g/g) and at day 28 (0.36±0.41 vs 1.87±0.44 g/g).

Conclusions: In a HIVAN mouse model, podocyte FGF2 expression increased protein expression of FGF2, FGF receptors and GPC5. Administration of FGF2 increased renal cortex FGF2 content was subsequently necessary for HA internalization and consequent reversal of myofibroblast phenotype & fibrosis prevention.

FR-PO293 Increased Expression of Complement C1 from Pericyte/Myofibroblasts Contributes to Renal Fibrosis via Activation of Wnt/β Catenin Signaling Sandhya Xavier, 1 Susan G. Landes, 1 Amandeep Bajwa, 1 Jing Yu, 2 Jeremy Stuart Duffield, 1 Didier Portilla. 1 Dept of Medicine and Center for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia, VA; 2 Univ of Virginia; 2Blegen Ide.

Background: Pericytes/fibroblasts are progenitors of scar-forming cells known as myofibroblasts. We have characterized the inflammatory nature of pericytes/fibroblasts isolated from UUO mice. We have also shown that Wnt/β-catenin signaling is activated during kidney fibrosis. Role of complement C1 on pericyte function or in Wnt activation remains unknown.

Methods: We used the unilateral ureteral obstruction (UOO) and folic acid nephropathy models. Pericytes were isolated using magnetic beads containing anti-PDGFRB Receptor ab. Expression of C1 complex was examined by western blotting, immunofluorescence, and realtime-PCR in tissue and in cell lysates and supernatants obtained from pericytes cultured from sham, day3 and day10 UUO mice kidneys. To phosphatase reporter assays were used to study Wnt signaling.

Results: Expression of C1q chains a,b,c, as well as subunits C1r and C1s were increased during fibrosis along with increased expression of TGF-β, n-SMA and Wnt target genes wisp1 and 2. Immunostain showed C1q localization in the interstitial compartment of UOO but not in sham mice consistent with PCR and western blot data. In cultured pericytes, C1 complex component C1q protein was increased in culture supernatants of Day3 and Day10 but not in shamms. Expression of C1q proteins was absent in supernatants of UUO pericytes isolated from C1QKO mice. To phosphatase reporter assays for Wnt signaling showed that pericytes from UUO kidneys had pronounced activation of the reporter following Wnt3a treatment as compared to shams, and this effect was blunted in pericytes isolated from C1QKO mice.

Conclusions: We demonstrate both in vivo and in vitro that increased expression of the C1 complex occurs in response to kidney injury along with activation of Wnt signaling. Our in vitro and in vivo data, showing that inhibition of C1 complex using C1INH prevents renal fibrosis, we conclude that its inhibition in pericytes/fibroblasts leads to inhibition of Wnt activation and reduced renal fibrosis.

FR-PO294 The Role and Association of Inflammatory and Apoptotic Caspases in Tubulointerstitial Fibrosis Chun Zhang, You Ke, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Caspases are a family of cysteine proteases with pivotal functions in apoptotic and inflammatory signaling. According to their difference of structures and functions, two distinct types of Caspases protein in tubulointerstitial fibrosis (TIF) are not well characterized.

Methods: Unilateral Ureteral Obstruction (UUO) animal model was constructed on wild-type(WT) and caspase-1 knockout (KO) mice. In vitro study, the cultured tubular epithelial cell line NRK-52E (TECs) was employed and the expression of caspase-1 and caspase-3 was modulated by transfection of Lentiviral shRNA.

Results: In current study, we found both Caspase-1 and Caspase-7 protein levels were elevated in UUO WT mice. While in UUO mice with Caspase-1 KO background the increased Caspase-7 was suppressed significantly along with the minimized extracellular matrix accumulation which was demonstrated by western blot, immunohistochemistry and Masson’ trichrome staining. In vitro TGF-β1 simulation promoted the expression of Caspase-1 and Caspase-7 simultaneously in TECs. Notably, genetic deletion of either Caspase-1 or Caspase-7 could abrogate TGF-β1 driven TECs’ transdifferentiation and apoptosis. In addition, knocking down Caspase-1 or Caspase-7 upregulation in TGF-β1 treated TECs was consistent with in vivo study. However genetic deletion of Caspase-7 did not influence Caspase-1’s abundance.

Conclusions: Our observation firstly links inflammatory and apoptotic Caspases together in TIF and further elucidates Caspase-1 activation is an upstream event of apoptotic Caspase-7 induction during TIF and TECs’ transdifferentiation and apoptosis.

FR-PO295 MAD2B-Sno-Smad3 Signaling Pathway Is Implicated in Fibroblast Activation and Tubulointerstitial Fibrosis Chun Zhang, Hui Zhang, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Mitotic arrest deficient protein MAD2B, an anaphase-promoting complex (APC)/cyclosome inhibitor, is indispensable for mitotic checkpoint control. Previously we found MAD2B was expressed in glomerular and tubulointerstitial compartment. In addition our data indicated MAD2B was involved in podocyte injury triggered by high glucose. But its role in renal fibrosis remains elusive.

Methods: The object of this study included patients with renal tubulointerstitial fibrosis (TIF) (secondary glomerulonephritis and interstitial nephritis were excluded) , Unilateral Ureteral Obstruction(UUO) mice and in vitro cultured tubular epithelial cell line (NRK-52E) and renal fibroblast cell line (NRK-49F). In vivo gene silencing of MAD2B was carried out by intrarenal Lentiviral gene delivery.

Results: We used the unilateral ureteral obstruction (UOO) and folic acid nephropathy models. Pericytes were isolated using magnetic beads containing anti-PDGFRB Receptor ab. Expression of C1 complex was examined by western blotting, immunofluorescence, and realtime-PCR in tissue and in cell lysates and supernatants obtained from pericytes cultured from sham, day3 and day10 UUO mice kidneys. To phosphatase reporter assays were used to study Wnt signaling.

Conclusions: Expression of C1q chains a,b,c, as well as subunits C1r and C1s were increased during fibrosis along with increased expression of TGF-β, n-SMA and Wnt target genes wisp1 and 2. Immunostain showed C1q localization in the interstitial compartment of UOO but not in sham mice consistent with PCR and western blot data. In cultured pericytes, C1 complex component C1q protein was increased in culture supernatants of Day3 and Day10 but not in shamms. Expression of C1q proteins was absent in supernatants of UUO pericytes isolated from C1QKO mice. To phosphatase reporter assays for Wnt signaling showed that pericytes from UUO kidneys had pronounced activation of the reporter following Wnt3a treatment as compared to shams, and this effect was blunted in pericytes isolated from C1QKO mice.

Conclusions: We demonstrate both in vivo and in vitro that increased expression of the C1 complex occurs in response to kidney injury along with activation of Wnt signaling. Our in vitro and in vivo data, showing that inhibition of C1 complex using C1INH prevents renal fibrosis, we conclude that its inhibition in pericytes/fibroblasts leads to inhibition of Wnt activation and reduced renal fibrosis.

422A
**Results:** By immunohistochemistry and western blot, it showed the expression of MAP2, a neuron-specific protein, in TIF patients and this was reduced in control type II neurons. Next we assessed the protein expression of the types of cells contributing to the elevated MADDAB abundance. It is well-known that TECs and fibroblast are the main culprits in TIF. Our data suggested that the overexpression of the TIF MADDAB may be due to the increased number of TECs. Conversely, the expression of the TIF MADDAB was reduced in control type II neurons. Furthermore, TGF-P1 induced fibroblast activation can be abrogated by MADDAB genetic deletion. Intriguingly, SmoN, a repressor of Smad3, was decreased in NRK-49F cells treated with TGF-C which could be alleviated by MADDAB knocking down. Consistently, in UUO mice the expression of SmoN was significantly decreased in the renal cortex accompanying with enhanced expression of Smad3. And locally genetic deletion of MADDAB by Lentiviral transfection preserved SmoN’s abundance and consequently suppressed SmoN signaling which finally dampened the fibroblast activation and ECM accumulation in UUO mice.

**Conclusions:** Our observation proposes that MADDAB participates in fibroblast activation and tubulointerstitial fibrosis by repressing SmoN and subsequently activating SmoN signaling pathway. Regulation of MADDAB-SmoN pathway may be a promising therapy for tubulointerstitial fibrosis. However, the regulatory mechanisms between MADDAB and SmoN still need further investigation.

**Losartan Reduces Renal Fibrogenesis by Up-Regulating Klotho in Uremic Rats**

**Edgar Maciquizin,** Josse Carla Paterno, Gabriel H. Pokorny, Mariana S. Perez, Nestor Schor, Miriam A. Bolim. *Nephrology, UNIFESP, Sao Paulo, Brazil.*

**Background:** Klotho is a transmembrane protein expressed mainly in the kidney. Soluble Klotho (sKlotho) is released into the serum and exerts its function as an endocrine factor with diverse functions through mechanisms involving Wnt and TGFβ1 signaling. Renal fibrosis is the end stage of the progressive chronic kidney disease (CKD) and renal klotho is markedly decreased in CKD patients. Renin angiotensin system (RAS) blockade is a relevant therapy to reduce CKD progression and the beneficial effects go further to the antihypertensive effect. The aim of this study was to investigate a possible link between RAS and Klotho by evaluating the effects of losartan on Klotho/Wnt signaling in 5/6 nephrectomy model of CKD in rats.

**Methods:** Adult male Wistar rats were underwent 5/6 nephrectomy (Nx). The Nx animals were separated into three groups: control, with no treatment (Nx), treated with losartan (LOS; 25 mg/kg/day, p.o.) or propranolol (PROP; 25mg/kg/day, p.o.). Results were compared with SHAM group. Blood pressure was measured by tail-cuff plethysmography. After 8 weeks, animals were sacrificed and the remnant kidney was removed to determine the renal expression of collagen, fibronectin, epithelial-to-mesenchymal transition (EMT) markers (FSP1 and α-SMA) and Klotho signaling (Klotho, Wnts and GSK3β) by real time PCR.

**Results:** Nx rats presented hypertension that was blunted by both losartan and propranolol. The expression levels of collagen and fibronectin were increased in Nx group which was reverted only in LOS group. The presence of the EMT markers, FSP1 and α-SMA, was observed in Nx group which was decreased with losartan treatment. Klotho was reduced in Nx animals and LOS but not propranolol significantly increased klotho expression. Nx animals showed upregulation of GSK3β, Wnt1 and Wnt3. LOS treatment prevented the increase in Wnt1 and GSK3β but not Wnt3.

**Conclusions:** These data suggest that the beneficial effect of losartan on renal fibrosis is independent of blood pressure reduction and may be, at least in part, due to upregulation of Klotho/Wnt signaling. Losartan induced no change in klotho expression. The interaction between the RAS and Klotho can inactivate the Wnt pathway.

**PBI-4050 Inhibits the Development of Renal Fibrosis in a Model of Tubulointerstitial Fibrosis**

**Ming-Zhi Zhang,** Lyne Gagnon, Raymond C. Harris. *1 Medicine, Vanderbilt Univ, Nashville, TN; 2ProMetic Biosciences, Laval, QC, Canada.*

**Background:** Kidney fibrosis occurs in chronic kidney diseases and leads to gradual loss of kidney function. Although the etiology of kidney fibrosis is multifactorial, there is increasing evidence linking chronic inflammation to kidney fibrosis. PBI-4050, a novel first-in-class orally active low molecular weight compound currently in phase II clinical trials, is an anti-fibrotic and anti-inflammatory drug that suppresses TGF-β1 signaling. Activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, and homologous transgenic mice with overexpression of an EGFR ligand, human hepatocyte-binding EGF (HB-EGF), in renal proximal tubule develop spontaneous tubulointerstitial fibrosis by 3–4 weeks of age. We examined whether PBI-4050 could prevent the development of renal fibrosis in homologous HB-EGF mice.

**Methods:** Homozygous HB-EGF mice on a C57BL/6 background were treated with PBI-4050 (200 mg/kg/day) by daily gavage gavage from 4 to 14 weeks of age. Serum and tissue were collected and homogenized. HB-EGF mouse kidney, ERK was activated in both proximal tubule epithelial cells (PTEC) and their surrounding interstitial cells. PBI-4050 treatment led to marked decreases in ERK activity in proximal tubule epithelial cells and interstitial cells, suggesting that PBI-4050 inhibits not only the EGFR-mediated ERK activation in PTEC, but also subsequent ERK activation in the interstitial cells, leading to inhibition of the development of renal fibrosis. PBI-4050 treatment significantly reduced the development of renal interstitial fibrosis. PBI-4050 caused marked decreases in renal macrophage infiltration (F4/80 staining) as well as neutrophil and eosinophil infiltration (MPO staining). In addition, PBI-4050 treatment reduced the expression levels of the pro-fibrotic and fibrogenic components including CTGF and TGF-β1, α-SMA (a marker of myofibroblasts), fibronectin, collagen I and collagen IV.

**Conclusions:** These studies suggest that PBI-4050 significantly inhibits the development of renal fibrosis in homozygous HB-EGF mice through multiple mechanisms, including through anti-inflammatory effects.

Results: In vitro treatment of TGF-β1-activated fibroblasts with EPC extract produced antifibrotic effects, but did not influence expression of endothelial markers. In two distinct models of renal fibrosis, unilateral ureteral obstruction (UUO) and chronic phase of folic acid-induced nephropathy (FAN), subcapsular injection of EPC extract to the kidney prevented and reversed accumulation of α-SMA-positive myofibroblasts and reduced expression of extracellular matrix proteins. Expression of cytokine TNF-α decreased and was enriched in LIF and VEGF. Only LIF was capable of inducing fibroblast-to-myofibroblast transition of TGF-β1-activated fibroblasts. In vivo subcapsular administration of LIF reduced the number of myofibroblasts, improved the density of peritubular capillaries, but did not affect the degree of interstitial fibrosis. Effects of LIF, as well as Hyper-IL-6, in the presence of TGF-β1 were mediated via gap-junction pathway resulting in induction of p53 and p21 and associated with open chromatin conformation.

Conclusions: EPC extract does not reverse endothelial-mesenchymal transition, but it prevents and reverses fibroblast-to-myofibroblast transition and renal fibrosis. The component of EPC extract, LIF, is capable of preventing development of the contractile phenotype of activated fibroblasts, but does not eliminate TGF-β1-induced collagen synthesis in cultured fibroblasts and models of renal fibrosis. LIF component of EPC extract is a participant of its antifibrotic effect, but not the sole one, as other yet undisclosed factors contribute to the antifibrotic effect of the extract.

FR-PO301 Mitochondrial Metabolic Switch to Glycolysis in Proximal Tubular Epithelial Cell in Fibrotic Kidneys Lei Jiang, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ; Nanjing, Jiangsu, China.

Background: Renal proximal tubule is susceptible to hypoxic injury since its reliance on aerobic oxidative metabolism. Mitochondrial dysfunction contributes to progression of chronic renal disease. However, the profile of the energy metabolism of renal tubule in different phases of fibrosis is uncertain, and the relationship between the change of energy metabolism and tubular epithelial cell damage is unclear.

Methods: Gene expression profiles related to energy metabolism of the proximal epithelial cell in fibrotic kidneys were analyzed. 2-Dexoyglucose (2-DG) was given to CD1 mice under UUO intraperitoneally. Primary tubular epithelial cells (PTC) cultured from normal CD-1 mice renal cortex was used. 2-DG (inhibitor of glycolysis), bromopyruvic acid (inhibitor of hexokinase), dichloroacetate acid (inhibitor of glycolysis), olignomic (inhibitor of oxidative phosphorylation), etomoxir (inhibitor of fatty acid oxidation), DON (inhibitor of glutaminase metabolism), PDZK1 RNAi or HEK1 siRNA was used in PTC with or without TGF-β1 stimulation. The oxygen consumption rate (OCR) and extracellular acidification rate (ECR) were detected by Seahorse Metabolic Analyzer.

Results: 1. Glycolysis was upregulated in the proximal tubule epithelium in fibrotic kidney. 2. Genes related to glycolysis were upregulated, however, genes related to oxidative phosphorylation, fatty acid metabolism and glutaminase metabolism were downregulated. The key limiting enzymes for glycolysis were upregulated in the fibrotic kidney. 3. 2-DG could block the renal fibrosis under UUO. 4. OCR was decreased under TGF-β1 stimulation in PTC, however, ECAR was increased after TGF-β1 stimulation. 5. Inhibiting oxidative phosphorylation, fatty acid oxidation or glutaminase metabolism could increase the lactate production in PTC. Lactate could directly induce PTC damage. 6. Inhibiting glycolysis could ameliorate the damage of PTC under TGF-β1 incubation.

Conclusions: The mitochondrial metabolism including oxidative phosphorylation, fatty acid oxidation and glutaminase metabolism is defective in proximal tubular epithelial cell in the fibrotic kidney. The metabolism switch is to glycolysis, and the glycolytic product lactate further aggravates the injury.

FR-PO302 The Effects of CCN3/NOV on the Formation of Extracellular Matrix in Human Mesangial Cells Haifei Liu, Long Chen, Hong Liu, Bi-Cheng Liu. Dept of Nephrology, Zhong Da Hospital, Southeast Univ, Nanjing, Jiangsu, China.

Background: Glomerulosclerosis is characterized by mesangial cells proliferation and accumulation of extracellular matrix (ECM) in glomeruli. Mesangial cells actively participate in a variety of damage factors, leading to ECM deposition. ECM accumulation is the net result of the balance between synthesis and degradation. CCN3, a matricellular protein of the CYR61-CTGF-NOV (CCN) family, associates specifically with ECM. A recent study found that treatment with the matricellular protein CCN3 can block and/or reverse fibrosis development in obesity with diabetic nephropathy. However, whether CCN3 can alleviate the formation of glomerulosclerosis by inhibiting the production of ECM and/or promoting the degradation of ECM is still unknown. This study aims to explore the potential role of CCN3 in ECM accumulation of mesangial cells induced by TGF-β1.

Methods: Human mesangial cells lines were stimulated with TGF-β1 (2ng/ml) and CCN3 for different concentration (5, 50, 500 ng/ml) virtually blocked this TGF-β1 induced effect on them (P < 0.05). On the other hands, TGF-β1 downregulated MMP-2 and MMP-9 at mRNA and protein levels, whereas a 1-hour pretreatment of the cells with CCN3 for different concentration (5, 50, 500 ng/ml) enhanced the expression of MMP-2 and MMP-9 (P < 0.05).

Conclusions: This study identifies that CCN3 as a new actor alleviates the formation of glomerulosclerosis by inhibiting the production of ECM and promoting the degradation of ECM.

FR-PO303 Spleen Tyrosine Kinase (Syk) Inhibition Suppresses Renal Fibrosis Through Anti-Inflammatory Effects and Down-Regulation MAPK-p38 Pathway Kuan-hsing Chen, Hsiang-Hao Hsu, Cheng-chieh Hung. Nephrology, Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background: Spleen tyrosine kinase (Syk) is a 72-kDa, a member of the Src family of non-receptor tyrosine. The central role of Syk in signaling processes is known to be involved in adaptive immunity, but also in autoinflammatory and allergic disease. However, the possible role of the anti-fibrogenic properties in renal interstitial fibrosis had not been explored.

Methods: In vitro study: Cultured rat renal interstitial fibroblasts (NRK-49F) were stimulated with recombinant human TGF-β1 (1ng/ml) for different periods before harvesting. Alternatively, NRK-49F cells were pre-incubated with Syk inhibitor for 30 mins before TGF-β1 treatment. Total RNA was extracted for RT-PCR and total lyses were extracted for Western Blot analysis. In vivo study: UUO mice renal cortex was used. 2-DG (inhibitor of glycolysis), bromopyruvic acid (inhibitor of glutaminase metabolism), PDZK1 RNAi or HEK1 siRNA was used in PTC with or without TGF-β1 stimulation. The oxygen consumption rate (OCR) and extracellular acidification rate (ECR) were detected by Seahorse Metabolic Analyzer.

Results: Our results demonstrated that the inhibition of Syk in NRK49F cells inhibited the stimulation effect of TGF-β1 leading to fibroblast transition to the myofibroblast phenotype (upregulation of α-SMA) and extracellular matrix proteins accumulation, collagen type I, type IV. In addition, in UUO model, Syk inhibitor attenuated the tubulo-interstitial fibrosis and expression of α-SMA, collagen I and fibronectin in UUO kidney. The anti-fibrosis of Syk inhibitor in UUO model may be related to anti-inflammatory effects (down-regulate inflammatory cytokines and reduce macrophage infiltration). Moreover, the effects of Syk inhibition in inhibition of kidney myofibroblast activation by TGF-β1 were associated with down-regulation of MAPK-p38 pathway.

Conclusions: In conclusion, we demonstrated that Syk inhibitor ameliorates TGF-β1 induced kidney myofibroblast activation and also reduces the tubulointerstitial fibrosis in UUO mice. The mechanisms may be related to anti-inflammatory effects and down-regulate MAPK-p38 pathway.

FR-PO305

BMP-7 Inhibits Renal Akt Signaling Debra F. Higgins, Catherine Godson, School of Medicine, Conway Inst, Univ College Dublin, Dublin, Ireland.

Background: Bone morphogenetic protein-7 (BMP-7), a member of the TGFβ superfamily, counteracts pro-fibrotic TGFB, and protects from fibrosis in acute and chronic renal injury models.

Methods: Using the chronic renal fibrosis model, unilateral ureteral obstruction (UUO), mice were treated with recombinant BMP-7 on signaling pathways involved in hypoxia and TGFβ-induced fibrosis. Mice undergoing UUO were treated with either vehicle or rBMP-7 (300ng/kg i.p.), kidneys were harvested on day 8 post-obstruction and analysed for markers of renal fibrosis and activation of SMAD, MAPK, and PI3K signaling.

Results: In response to UUO, SMAD1/5/8 activity was lost in vehicle-treated kidneys, yet maintained in BMP-7-treated kidneys. Collagen accumulation was significantly increased in obstructed kidneys of vehicle-treated animals compared with contralateral and this response was not observed in BMP-7-treated obstructed kidneys. Immunohistochemical analysis of type I, III, and IV collagen revealed that accumulation of type I collagen was significantly impaired in BMP-7-treated obstructed kidneys. Activation of SMAD2, SMAD3, ERK, p38 and Akt signaling pathways occurred during fibrogenesis and BMP-7 significantly attenuated SMAD3 and Akt signaling in vivo. In the kidney, inner medullary collecting duct and tubular epithelial cells are responsive to BMP-7. Analysis in mouse inner medullary collecting duct (mIMCD) and human tubular epithelial (HK-2) cells stimulated with either TGFβ or hypoxia (1% oxygen) to induce Akt activation provided further evidence that BMP-7 could specifically inhibit PI3K / Akt signaling.

Conclusions: These data demonstrate an important mechanism by which BMP-7 orchestrates renal protection through Akt inhibition and strengthens the argument for use of Akt inhibitors as anti-fibrotic therapeutics.

FR-PO306

Prevention of Renal Interstitial Fibrosis by Simultaneous Deletion of Bax and Bak Hee-Seong Jung, 1 Babu J. Padanilam, 1, 2 Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; 1Internal Medicine, Section of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.

Background: Proximal tubular injury and apoptosis are key mediators of development of kidney fibrosis, a hallmark of chronic kidney disease. However, the molecular mechanism by which tubular apoptotic cell death leads to kidney fibrosis is poorly understood.

Methods: Here we tested the roles of Bax and Bak, two crucial proteins involved in intrinsic apoptotic cell death, in progression of kidney fibrosis. Mice with proximal tubule-specific Bax deletion, systemic deletion of Bak and dual deletion of Bax and Bak were subjected to unilateral ureteral obstruction (UUO).

Results: Dual deficiency of Bax and Bak inhibited tubular apoptosis and atrophy. Consistent with decreased tubular injury, dual ablation of Bax and Bak suppressed UUO-induced inflammation and kidney fibrosis with decreased tubular cell cycle arrest, expression of fibrogenic and inflammatory cytokines, and oxidative stress in the kidney. Bax or Bak deficiency was insufficient to prevent apoptosis and all other aforementioned malevolent effects, suggesting compensatory mediation by each in the other respective signaling pathways.

Conclusions: These data suggest that dual ablation of Bax and Bak in the kidney is required to prevent UUO-induced tubular apoptosis and the consequent kidney inflammation and fibrosis.

FR-PO307

Investigating the Role of Cilia in Regulating Fibrosis in the Kidney and Liver Using PKD Mouse Models Kurt Zimmerman, Cheng 'Jack' Song, Bradley K. Yoder, Cell, Developmental, and Integrative Biology, UAB, Birmingham, AL.

Background: Cystic kidney disorders are frequently caused by mutations in cilia associated proteins (intratubular lag transport, IFT) or ciliary signaling proteins (polycystin-1 or polycystin-2). Comorbidities commonly associated with renal cysts include biliary duct abnormalities with associated fibrosis in both tissues. In the kidney of cysta mutants, ischemia reperfusion (IR) injury greatly exacerbates the rate of cyst development; however, it is not known whether injury will similarly affect the liver and how loss of cilia affects injury induced fibrosis.

Methods: To address these questions, we are utilizing Oak Ridge Polycystic Kidney (ORPK) mice that have a congenital hypomorphic IFT88 mutation and conditional mutant mice where cilia are disrupted in the kidney (CagCreER). The conditional mutant mice under an IR injury show increased cell death progression, inflammation response and production of extracellular matrix (ECM) and pro-fibrotic factors.

Results: Our preliminary studies in the kidney indicate that IFT88 mutant mice receiving IR injury had increased ECM transcription of Col1a2, Col3a1, and ceroidin, compared to the sham operated control. Despite the increased ECM production, the pro-fibrotic growth factor TGF-β, which is frequently associated with fibrosis, was not significantly elevated in mutant mice. However, another TGFβ family member, inhibin βA, was increased in the injured kidney of mutant mice suggesting a possible mechanism for ECM production. The mice have a noticeable liver phenotype characterized by biliary hyperplasia and, similar to the kidney, an increase in Col1a2 and Col3a1 transcripts. ORPK mutant mice also have increased transcript levels of the monocytome chemoattractant protein, MCP-1, and the pro-inflammatory cytokine, IL-1β. Furthermore, in both mutant kidneys and liver there is an increase in the number of infiltrating macrophages, which may drive fibrosis.

Conclusions: Together, our preliminary data suggest that defects in cilia formation promote fibrotic disease progression possibly through altered cytokine production and enhanced recruitment of infiltrating monocytes.

FR-PO308

Klotho Suppresses Epithelial-Mesenchymal Transition (or Transformation in Adrimycin Nephropathy Tsuchuo Takenaka, 1 Tsutomu Inoue; 2 Matsuhiyo Hayashi, 1 International Univ of Health and Welfare; 3Saitama Medical Univ; 1Keio Univ.

Background: Klotho interacts with various proteins to alter their function. Klotho may bind to the receptor for WNT and TGFbeta, inhibiting their signals.

Methods: Experiments were performed to assess how klotho protects kidney from its injury. At 5mg/kg was injected into rats to induce nephropathy. Human recombiant klotho (K, 30 micro-g/kg/day), rabbit anti-klotho (1:5000), and rabbit anti-klotho (1:5000) were untreated with Adriamycin were used as control (U). Animals were killed 8 weeks later. Renal expressions of Wnt1, GSK3beta, TGFbeta, Twist and collagen I were assessed with RT-PCR against GAPDH. Western blot was used for p-GSK3beta and beta-actin.

Results: Adriamycin increased albuminuria, renal expression of Wnt1, p-GSK3beta, TGF, Twist and collagen I in comparison to the control. Klotho and T suppressed the increased albuminuria and the phosphorylated phosphoproteins and the phosphorylated GSK3beta. Reduced elevateds of Wnt1, supporting that klotho inhibits Wnt signaling without changes in Wnt level. While klotho and T reduced TGFBeta, klotho preferentially ameliorated Twist and collagen I in comparison to T.

FR-PO309

The Molecular Mechanism of mir-382 in the Pathogenesis of Renal Tubulointerstitial Fibrosis Yi Fang, 1 Ting Xie, 1 Hui Zhang, 1 Sheng Wu. 1 Nephrology, Zhongshan Hospital Fudan Univ, China; 2Shanghai Key Laboratory of Renal Diseases and Blood Purification.

Background: To investigate the roles of microRNA-382 (miR-382) in the pathogenesis of renal tubulointerstitial fibrosis. Methods: Human kidney epithelial (HK-2) cells that transfected with a miR-382 inhibitor (antagomir-382) was used to examine the effect of miR-382 abundance on cell polarity, as well as to test the complementary relationship between miR-382 and its predicted target gene, heat shock 60kDa protein 1 (HSPD1), which was further verified by site-directed mutagenesis. We also examined the in vivo role of miR-382 in the development of renal interstitial fibrosis, in a mouse unilateral ureteral obstruction (UO) model. Locked nucleic acid (LNA)-anti-miR-382 was intravenous delivered via tail vein less than 30mins prior to U, and repeated the dosage 24 hours after the surgery. For clinical verification, renal biopsy specimens from 12 IgA nephropathy (IgAN) patients were collected, 6 with moderate to severe tubulointerstitial fibrosis (TIF) and 6 with no TIF. The relative abundance of miR-382 and HSPD1 protein was analyzed using in situ hybridization and immunohistochemistry.

Results: HSPD1 was confirmed to be a new, direct target gene of miR-382 by in vitro transfact technique and mutation experiments. The development of epithelial transition or renal interstitial fibrosis was accompanied with up-regulated abundance of miR-382. Down-regulation of miR-382 was associated with significant decreases in exacerbation of interstitial fibrosis, but increase protein expression of HSPD1 and thioredoxin, both in the obstructed mouse kidneys and renal biopsy specimen from IgAN patients.

Conclusions: MiR-382, a profibrotic microRNA, is up-regulated with the development of renal interstitial fibrosis in humans and in mice. The down-regulation of HSPD1 and the decreased ability of anti-oxidative stress are secondary to the increased abundance of miR-382.

Vitamin (Vit) D Repletion Ameliorates Muscle Wasting and Muscle Fibrosis in Mice with Chronic Kidney Disease

Background: Cachexia presenting as muscle wasting and weakness is prevalent in CKD patients and may impact their quality of life. We investigated the effects of vitamin D repletion in a mouse model of CKD-associated muscle wasting.

Methods: CKD in c57BL/6 mice were induced by 5/6 nephrectomy. CKD and sham mice were treated with 25VitD (25 mg/kg/day), 1.25VitD (40 mg/kg/day) or vehicle (V) for 6 weeks via a subcutaneous osmotic pump. The extent of tubulointerstitial fibrosis was evaluated by histology. The kidneys were excised and precision-cut tissue slices (PCTS) were cultured for 5 days included: collagen IV (COLIV), laminin521 (hLN521), laminin111 (hLN111) or Attachment Factor (AF; Cell System's proprietary GEnC coating). Cell adhesion was monitored by the use of AF or COLIV in GEnC culture shows little advantage. DN-associated hLN111 is a poor attachment substrate resulting in GEnC loss. This is in contrast to the more physiologically relevant hLN521 which promotes cell adhesion, spreading, proliferation and tight junction formation.

Results: 25VitD increased FN1 and a-smooth muscle actin (αSMA, marker of fibroblast activation) in a dose-dependent manner. Addition of gremlin-1 (mimicking the in vivo setting) did not exacerbate fibrosis at any dose of TGFb. Addition of recombinant BMP2 was not sufficient to prevent TGFb-induced fibrosis in either cell type. Recombinant BMP2 alone (1 nM) increased SMAD5 phosphorylation and the expression of ID1 (a marker of BMP signalling) at 1 and 24 hrs post treatment. The stimulatory effect of BMP2 was blocked by pre-treatment with recombinant Gremlin-1 (2 nM). These data confirm intact BMP2–gremlin-1 signalling in both cell types.

Conclusions: Our data does not support the participation of gremlin-1 in TGFb-dependent renal fibrosis in vitro.

Assessing the Role of Gremlin-1 on Renal Fibrosis In Vitro

Methods: Primary human GEncs were from Cell Systems. Cell culture surface coating included: collagen IV (COLIV), laminin521 (hLN521), Attachment Factor (AF); Cell System’s proprietary GEnc coating. Cell adhesion was monitored by the use of AF or COLIV in GEnc culture shows little advantage. DN-associated hLN111 is a poor attachment substrate resulting in GEnc loss. This is in contrast to the more physiologically relevant hLN521 which promotes cell adhesion, spreading, proliferation and tight junction formation.

Results: Coating with AF or COLIV increased cell index (CI) of GEncs in the cell adhesion phase (0-6h) but not in the spreading and proliferation phase (6-72h). Coating with hLN521 displayed a continuous increase in CI over 72h. On the contrary, hLN111 caused a significant decrease in CI over 72h. Cells grown on AF or COLIV showed similar spread and proliferation of cells grown on COLIV-supernatants. By contrast, coating with hLN521 decreased the expression of COL4A1, COL4A2, MMP2 [all 2-fold] and TGFβ1 [1.5-fold] as compared to no coating. Likewise, ITGA1, ITGA2, ITGAV, ICAM1, NOX4 were decreased with hLN521 in a dose-dependent manner. Expression of LAMA5, ITGAV, ITGAX and NOX3 were unchanged in all groups. Tight junction formation was assessed by AO immunostaining. Laminin521, contrary to other ECM coatings, stimulated tight junction formation in GEncs.

Conclusions: Usage of AF or COLIV in GEnc culture shows little advantage. DN-associated hLN111 is a poor attachment substrate resulting in GEnc loss. This is in contrast to the more physiologically relevant hLN521 which promotes cell adhesion, spreading, proliferation and tight junction formation.

Development of an Ex Vivo Model to Elucidate the Matrix Turnover Profile in Renal Interstitial Fibrosis

Methods: To test this hypothesis we used HK-2 (human PT cell line) and NRK49F (rat tubular cell line) cell lines where the pro-fibrotic phenotype was induced by Transforming Growth Factor b1 (TGFβ; 2.5 ng/mL, 72 hrs).Gremlin-1 secretion was assessed in circulation and in urine, these markers have the potential to accurately assess and predict renal fibrosis in vivo. We aimed at identifying markers for early disease onset that were directly linked to the events of scar formation in the kidney.

Results: While C1M levels in urine were not different between NTN mice and controls, urinary C1M levels in control mice were significantly increased in CKD than sham mice (p<0.01). Significant correlation between C1M and various markers measured in the supernatants also in circulation and in urine, these markers have the potential to accurately and non-invasively describe the tissue remodeling during fibrosis.

Conclusions: The UO PCTS ex vivo model provides a valuable translational tool for investigating the ECM remodeling associated with renal interstitial fibrosis. Since the presence and concentration of these markers measured in the supernatants also in circulation and in urine, these markers have the potential to accurately and non-invasively describe the tissue remodeling during fibrosis.

Collagen Degradation Profile in a Nephrotic Nephritis Model

FR-P0310

The Effect of Cell Culture Surface Coating on Glomerular Endothelial Cell Phenotype

Methods: Neo-epitope degradation fragments of collagen type I, III and IV generated by MMP cleavage were measured by specific ELISAs (namely C1M, C3M and C4M) in urine of NTN and healthy mice at terminated at 7 and 21 days after injury (NTN: n=21, Controls: n=6). Urinary albumin/creatinine (ACR), urinary proteinuria, plasma creatinine and blood urea nitrogen (BUN) were measured as markers of renal function. Intestinal fibrosis and glomerulosclerosis were evaluated by histology and quantification of α-SMA and collagen type I in immunohistochromy.

Results: While C1M levels in urine were not different between NTN mice and controls, C3M levels were elevated in NTN rats at 7 days (p<0.05) and decreased to levels close to the controls at 21 days. This elevation was also reflected in proteinuria, peaking at 7 days, but not in BUN and plasma creatinine. C4M levels were elevated at 21 days and not at 7 days (p<0.01), and correlated with the extent of interstitial fibrosis.

Evidence of Podocyte Protrusions into the Basement Membrane in Glomerular Disease
Sophie C. Collinson,1 Michael J. Randles,1,2 Mira Krendel,3 Eva Koenigshausen,1, Lorenz Sellin,1 Ian Roberts,1 Jeffrey H. Miner,1 Rachel Lennon,1,2 Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester; United Kingdom; 1Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester; United Kingdom; 2Dept of Cell and Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY; 1Dept of Nephrology, Heinrich Heine Univ, Duesseldorf, Germany; 3Dept of Cellular Pathology, John Radcliffe Hospital, Oxford, United Kingdom; 2Renal Div, Washington Univ School of Medicine, St. Louis, MO.

Background: Glomerular disease is a leading cause of kidney failure. Podocyte foot process effacement and glomerular basement membrane (GBM) disruption are frequent abnormalities regardless of the underlying molecular etiology. Standard electron microscopy techniques provide 2D information and 3D ultrastructural relationships are poorly understood. We hypothesized that creation of detailed 3D models of the glomeruli would identify novel pathological features.

Methods: Serial block face-scanning electron microscopy was performed on a series of mouse kidneys from glomerular disease models with established albuminuria. 3D reconstructions of glomeruli were created using IMOD 4.7.11.

Results: Sub-podocyte expansions of the GBM were dominant features in mice with WT controls. There was no evidence of endothelial or mesangial cell protrusions into the GBM and no correlation between GBM thickness and the site of podocyte protrusions.

Conclusions: 3D ultrastructural imaging revealed expected GBM abnormalities in addition to podocyte protrusions, resembling invasadesomes, in the GBM. This novel finding provides new insight into disease mechanisms and suggests that a common matrix-adhesion pathway is activated regardless of the primary molecular insult.

Multi-Clonal Population of Cells of Renin Lineage (CoRL) Transdifferentiate into Podocytes and PECs in Experimental FSGS
Natalya V. Kaverina,1 Diana G. Eng,1 Jeffrey W. Pippin,1 Michael E. Rusiniak,2 Kenneth W. Gross,2 Stuart J. Collinson,1 Devision of Nephrology, Univ of Washington, Seattle, WA; 1Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.

Background: Focal segmental glomerulosclerosis (FSGS) is secondary to podocyte injury and loss. Because adult podocytes cannot proliferate, their replacement by progenitors is critical for their repair and regeneration in disease. Here we explored whether single or multiple clones of cells of renin lineage (CoRL) serve as a local progenitor source to replace reduced podocytes in experimental FSGS.

Methods: Experimental FSGS was induced following abrupt podocyte depletion by administration of a cytotoxic anti-podocyte antibody to two confetti mouse reporters. First, to confirm adult podocyte regeneration following abrupt depletion, podocytes were genetically fate-mapped in adult NPHSP2Cre/Confetti reporter mice with experimental FSGS. Second, to prove that adult podocyte regeneration by CoRL was multi-clonal, CoRL were fate mapped in RenCre/Confetti reporter mice with experimental FSGS. Results: FSGS in NPHSP2Cre/Confetti reporter mice was characterized by marked podocyte depletion (45% decrease) on day 47. A multi-clonal repopulation of podocytes resulted in an increase in their overall number by 77% of normal by day 288. No podocyte proliferation was detected by BrdU staining. In RenCre/Confetti reporter mice, a multi-clonal expansion of 4-color labeled CoRL (GFP, RFP, CFP, YFP) was detected in glomeruli at FSGS d28. A population of CoRL were fate mapped in RenCre/Confetti reporter mice with experimental FSGS.

Conclusions: CoRL transdifferentiate into podocytes in experimental FSGS, their number was increased in the absence of podocyte proliferation. Regeneration of adult podocytes is likely in part due to multiple clones of CoRL serving as local progenitors.

FR-PO317
Macula Densa-Derived Factors Control Glomerular Cell Remodeling
Anne Riquier-brison,1 Donna Ralph, Jasmine Ann Arevalo Castillo, Janos Peti-Peterdi, Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.

Background: Macula densa (MD) cells are strategically positioned at the vascular entrance of the glomerulus and control renal hemodynamics and renin. In this study, we addressed a novel, non-traditional role of MD cells regulating glomerular cell plasticity/ remodelling by mesenchymal progenitor cells.

Methods: For genetic cell fate tracking, tamoxifen-induced NG2CreERT2-Tomato mice were fed either a control or salt-deficient + ACE inhibition (SD+ACEi) diet, for 2 weeks to achieve strong MD stimulation.

Results: We observed a 5-fold increase in renal interstitial density of NG2+ cells (5.9±1.1 cells per field in control, 30.2±4.5 in SD+ACEi), and the homing of NG2+ cells to the mesangium under the MD and into the glomerulus. This effect was blunted by the selective COX-2 inhibitor SC58236 (COX-2i) or the nNOS inhibitor 7-NI (13.2±2.2 cells per field with COX-2i and 11.6±1.7 with 7-NI). Immunofluorescence (IF) of Claudin-1 showed a 4-fold increase in the number of NG2+ cells in the glomerular parietal layer (0.5±0.2 cells per glomerulus in control, 2.0±0.4 in SD+ACEi). Podocin IF costaining did not detect a few NG2+ podocytes. NG2+ cell homing was blunted by COX-2i and 7-NI (2.3±0.3 cells per glomerulus with COX-2i and 0.8±0.3 with 7-NI). Co-localization of endogenous NG2-Tomato fluorescence with IF of renin revealed an increase in the proportion of NG2+ renin-expressing cells from 22.0% of 6.6 to 70.6% of 7.4 after SD+ACEi, inhibited by COX-2i. Similarly, the density of proliferating cells expressing Ki67 increased after treatment to 33.9±3.2 cells per field with COX-2i and 31.3±2.8 with 7-NI. Immunofluorescence IF of Claudin-1 showed a 4-fold increase in the number of NG2+ cells in the glomerular parietal layer (0.5±0.2 cells per glomerulus in control, 2.0±0.4 in SD+ACEi).

Conclusions: Our results suggest that NG2+ pericytes may be an important progenitor cell population in the kidney. In response to MD-derived (from COX-2 and nNOS) paracrine factors, NG2+ cells from the renal interstitium proliferate and migrate towards the MD along the arteriole and via the vascular pole into the glomerular epithelium and mesangium. In conclusion, MD cells play new important roles in the maintenance and remodeling of the glomerulus.

A Novel Method for Assessing Podocyte Depletion in Whole Glomeruli
Victor G. Puelles,1 James William Van der Wolde,1 Lisa Cullen,2 David W. G. Benesley,1 Kieran M. Short,3 Georgia A. Caruana,1 Stacey Hokke,1 Stephen D. Firth,1 Ian S. Harper,2 David J. Nikolic-Paterson,4 John F. Bertram,1 1Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; 2Monash Micro Imaging, Monash Univ, Melbourne, Victoria, Australia; 3Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia.

Background: Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Given that glomerulosclerosis is often focal, affecting some but not all glomeruli, our aim was to develop a rapid, accurate and precise method for quantifying podocyte depletion in whole glomeruli.

Methods: Pod ΔiDTR mice, in which expression of the human diphtheria toxin (DT) receptor is driven by the podocin promoter, and iDTR mice (controls) were injected with DT or 2000 units/kg. Tissue was collected at day 35 for podocyte analysis (n=3 mice per group). Kidney sections were stained with antibodies against podocin and synaptopodin. Slices were cleared with benzyl alcohol, benzyl benzoate (BABB). An SP8 confocal microscope (Leica, Germany) fitted with a BABB objective (NA: 0.95; working distance: 2mm) was used. Total podocyte number was obtained by manual counting and using the cell counting application in iSolve (Imaris, Birplume) in 88 whole glomeruli - 38 from iDTR mice and 50 from Pod ΔiDTR mice.

Results: In iDTR mice (controls), total podocyte number per glomerulus was almost identical between manual counts (66.61±11.92) and Imaris (65.47±9.26; P=0.65). In Pod ΔiDTR assessment of glomerular morphology, CoRL podocyte depletion was 100% with COX-2i (1.2±0.3 cells per glomerulus) and 7-NI (1.2±0.3 cells per glomerulus). Podocyte depletion was also similar between manual counts (52.96±11.74) and Imaris (53.51±11.35; P=0.81). With both methods, podocyte counts were obtained in less than 2 minutes per glomerulus, a significant time reduction compared to existing methods. Imaris also facilitates the estimation of podocyte and glomerular volumes for a more precise assessment of podocyte depletion.

Conclusions: This is the first method to combine immunofluorescence, BABB-clearing and confocal microscopy to count podocytes in whole glomeruli. The method is accurate, precise and rapid, and provides a novel approach for podocyte morphometrics in settings where sufficient tissue is available for analysis.

Characterization of Heterogeneous Podocyte Biomechanics Using Atomic Force Microscopy
Ivyen A. Azeloulogi,1 Jia-Jye Lee,1 Kevin D. Costa,2 Pharmacology and Systems Therapeutics, Icahn School of Medicine at Mount Sinai, New York, NY; 1Cardiology (Medicine), Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Biomechanical signals play a key role in glomerular physiology, where pathological changes in blood pressure can significantly affect podocyte morphology and function. While there has been a great focus on mechanobiological signaling in podocytes, their spatial biomechanical properties have been largely overlooked due to a lack of in
Identification and Validation of Fluid Flow Shear Stress (FFSS)-Induced Changes in Podocyte Signaling Pathways Using Bioinformatic Tools

We identified a family of small molecules, paullones, as highly potent agents that protected podocytes from damage. Kenpaullone and three other paullones (paullone, thio-kenpaullone, and 2-thio-kenpaullone) were analyzed and quantified using automated methods using high-content screening (HCS) assay for quantifying podocyte damage in vitro. Here, we report the development of kidney directed therapeutics. We recently described a novel cell-based pathogen discovery assay that could prevent progressive glomerular injury.

**Results:**
- **Identification:** A family of small molecules, paullones, was identified as highly potent agents that protected podocytes from damage.
- **Validation:** Kenpaullone and three other paullones (paullone, thio-kenpaullone, and 2-thio-kenpaullone) were analyzed and quantified using automated methods using a high-content screening (HCS) assay.
- **Pathogenic:** Pathogen discovery assay provided a new means to rapidly test the micromechanics of podocytes with high spatial resolution in a physiologically relevant in vitro setting.

**Background:** Podocyte-directed therapeutics for treating a number of glomerular diseases.

**Objectives:** Employment of our newly described podocyte-based screening assay results in the discovery of podocyte-directed therapeutics for treating a number of glomerular diseases. Paullones represent a family of small molecules that show podocyte protection from damage. We also describe a proposed molecular mechanism for the efficacy of these novel agents. We hope that these methodologies will lead to the development of novel types of specific kidney protective drugs.

**Results:**
- **Identification:** We identified a family of small molecules, paullones, as highly potent agents that protected podocytes from damage.
- **Validation:** Kenpaullone and three other paullones (paullone, thio-kenpaullone, and 2-thio-kenpaullone) were analyzed and quantified using automated methods using a high-content screening (HCS) assay for quantifying podocyte damage in vitro.
- **Pathogenic:** Pathogen discovery assay provided a new means to rapidly test the micromechanics of podocytes with high spatial resolution in a physiologically relevant in vitro setting.

**Conclusions:**
- We identified a family of small molecules, paullones, as highly potent agents that protected podocytes from damage.
- Kenpaullone and three other paullones (paullone, thio-kenpaullone, and 2-thio-kenpaullone) showed dose-dependent protection of podocytes from PAN-damage induced loss in F-actin fibers.
- Among the four paullones identified, alsterpaullone showed the highest degree of protection. At a molecular level, alsterpaullone reduced the elevation in the expression of Desmin, a podocyte damage marker, and inhibited PAN-induced podocyte migration. While PAN treatment reduced AKT phosphorylation in podocytes, alsterpaullone maintained the levels of phosphorylated AKT in podocytes.

FR-PO323

Novel Podocyte Quantification Assay to Ascertain Patient Serum Toxicity

Lee, Susanne Brodesser,1 Bernhard Schermer, 1,3 Thomas Benzing, 1,3 Christine E. Pharmas,3

1 Nephrology, The Children’s Hospital, Kansas City, MO; 2 Nephrology, Medical College of Wisconsin, Milwaukee, WI; 3 Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; 4 Renal Research Laboratory, Kansas City VA Medical Center, Kansas City, MO.

**Background:** In vitro studies from our lab showed that plasma from recurrent FSGS patients disturbs the human podocyte cytoskeleton and focal adhesion complexes (FACs). We developed a novel unbiased assay to quantify the toxic effects of patient plasma and nephrotoxic drugs on cultured human podocytes and to identify strategies that block serum toxicity.

**Methods:**
- **Cytoskeleton:** Culture human differentiated podocytes are exposed to adriamycin, recombinant TNFa or human sera from patients with various forms of FSGS. FACs are visualized with anti-vinculin antibody, and cell images are analyzed to define the number of FACs/1000mm2 cell area.
- **Capsule:** We analyzed sera from 12 patients: 2 with idiopathic, 4 recurrent FSGS, 4 non-recurrent FSGS and 2 de novo FSGS.

**Results:**
- **Idiopathic:** Both adriamycin and recombinant TNFa disrupt podocyte actin cytoskeleton and FACs in a dose-dependent manner. Comparing to healthy control, sera from patients with de novo FSGS (no known mutations identified), FSGS and de novo FSGS post-transplant drastically reduces FACs number, yet sera from nFSGS post-transplant does not statistically affect FACs. In ~60% of the patients with serum toxicity, these effects on podocytes can be averted by TNFa pathway blockade.

**Conclusions:** Our in vitro assay provides, for the first time, means to reliably identify those patients with idiopathic FSGS who are at high risk of recurrence post-transplant. It may also identify FSGS patients who may be candidates for anti-TNFa therapy that could prevent progressive glomerular injury.

Loss of Robo2 in Podocytes Protects Adult Mice from Acute Glomerular Injury

Anna Piasarek-Horowit, Xueming Fan, Hila Milo Rasouly, Stefanie Chan, Hui Chen, Ramon G. Bonegio, Joel M. Henderson, David J. Salant, Weining Lu. Renal, Boston University Medical Center, Boston, MA.

Background: SLIT2 and its receptor ROBO2 play an important role during kidney development. We have recently found that ROBO2 is expressed in developing glomerular podocytes. However, the role of ROBO2 in the adult mouse kidney, particularly under acute glomerular injury conditions, is not clear.

Methods: To test the hypothesis that loss of Robo2 in glomerular podocytes affects the outcome of acute glomerular injury, we applied two in vivo acute glomerular injury models induced by nephrotoxic serum (NTS) injection and proteomic saline (PS) perfusion, in Robo2 podocyte specific knockout mice (Robo2 KO) and wild type controls. Kidney glomerular ultrastructure was analyzed by scanning and transmission electron microscopy before and after injury. Podocyte foot process width and slit diaphragm density were measured to quantify the severity of the glomerular injury. Urine albumin to creatinine ratio was measured in the NTS model. Podocyte specific gene expression was analyzed using TaqMan real time PCR for mRNA and Western blot for protein levels.

Results: Robo2 podocyte specific knockout mice developed less proteinuria after the NTS injury with lower urine albumin/creatinine ratio as compared to the wild type controls. Electron microscopy showed that Robo2 KO mice have milder foot process effacement and less defects in the slit diaphragm induced by either NTS or PS injury. TaqMan and Western blot analyses revealed that nephrin, a crucial transmembrane component of the podocyte slit-diaphragm, was significantly up-regulated at both mRNA and protein levels in the Robo2 KO mice before NTS injury and at the late stage of heterologous phase after the NTS injury. In addition, the mRNA levels of Robo2 and Slit2 in the wild type kidneys were also upregulated after the NTS injury.

Conclusions: SLIT2-ROBO2 signaling pathway plays an important role in the adult mouse kidney. Loss of Robo2 protein in adult glomerular podocytes from acute glomerular injury. Our findings suggest that SLIT2-ROBO2 signaling might also have a negative impact on nephrin expression during podocyte injury and be a potential therapeutic target.

Inducible Knockdown of Shroom3Induces Proteinuria with Podocyte Dedifferentiation

Madyah C. Menon, Chengwei Wu, Karen Lok Yue Keung, Iliana Greene, Weijia Zhang, John C. He, Barbara T. Murphy. Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Intronic loci in Shroom3 have been associated with CKD and CAN. A role for Shroom3 in the podocyte cytoskeleton has been shown. However Shroom3 knockout mice die neonatally with neural tube defects and detailed renal phenotypes are unknown. Here we report our findings from Doxycycline (DOX) inducible, shRNA-mediated shroom3 knockout mice.

Methods: In these mice Shroom3-specific shRNA expression was induced upon DOX-feeding, with RTTA expression in all cells driven by CAGS-promoter. Six-wk old mice were fed DOX-feed/water. Non-DOX fed littersmates were controls (n=6 each). At 4- and 8-weeks, renal tissue was obtained for histology. Twenty-five glomeruli were analyzed per mouse and quantification was used imaging.

Results: DOX-mice developed significantly increased Albumin-to-creatinine ratios starting at 2 weeks compared to controls.

FR-PO326

Protective Role of Cyclodextrin in Focal Segmental Glomerulosclerosis (FSGS)

Alla Mitrofanova,1 Patricia R. Wahl Prisat,1 Ximeana A. Morales,1 Mayrin Correa-Medina,2 Christopher E. Pedigo,1 Gloria Michelle Ducasa,1 George William Burcke,2 Sebastian Martini,2 Matthias Kretzler,2 Sandra M. Merscher,1 Alessia Fornoni,1 Katz Family Drug Discovery Center, Nephrology and Urology, Univ of Miami, FL; Surgery, Univ of Miami, FL; Internal Medicine, Nephrology, Univ of Michigan, MI; *Computational Medicine and Bioinformatics, Univ of Michigan, MI.

Background: We recently demonstrated that cholesterol accumulation contributes to podocyte injury in diabetic kidney disease (DKD), where 2-hydroxypropyl-β-cyclodextrin (CD) protects podocytes from cholesterol-dependent damage in vitro and in vivo. We hypothesize that lipid related genes are affected in glomeruli of patients with primary FSGS and correlate with CD protected podocytes in experimental models.

Methods: Microarray analysis on glomerular transcripts of lipid-related genes from patients with FSGS (n=54) and from normal living donors (n=6) were obtained from patients enrolled in NEPTUNE, a longitudinal observational cohort looking at individuals with proteinuria. 5-week-old BALB/c female mice were injected with a single intravenous dose of adriamycin (ADR, 11 mg/kg) to develop FSGS-like lesions. 24-hours after ADR injection, osmotic pumps with CD in 0.9% saline solution (40 mg/kg/day) were implanted under the skin for 10 weeks. Measurements of body weight and urine collections for ACR (Albumin/creatinine ratios) were performed weekly. At time of sacrifice, serum creatinine and Blood Urea Nitrogen (BUN) were determined and kidneys collected for histological analysis.

Results: Microarray analysis of the glomerular transcripts in the NEPTUNE cohort demonstrated that cholesterol efflux related genes, such as PLIN3, S1PR2, S1PR1, and lipid dysmetabolism related genes, such as SCD, LDLR, ABCG1, were increased in FSGS. CD administration reduced mesangial expansion as well as ACR and BUN observed at 10 weeks in the ACR/CD group compared to the ADR group (p<0.05). No changes in body weight were found.

Conclusions: We conclude that glomerular lipids are altered in FSGS and that 2-hydroxypropyl-β-cyclodextrin protected podocytes in an experimental model of FSGS. Our data suggest that CD could be used as a safe and effective drug therapy in FSGS patients.

Podocyte-Derived CXCL12 Has a Dual Role in Glomerular Injury and Regeneration

Background: Stromal-derived factor (SDF)-1/CXCL12 is a homeostatic chemokine facilitating homing and activation of stem cells. Podocytes constitutively produce CXCL12, hence, we speculated on a role of CXCL12 in glomerular regeneration upon injury.

Methods: Glomerular injury was induced by a single i.v. injection of 13mg/kg adriamycin (ADR) in male Balb/c mice, which received either the CXCL12 inhibitor NOX-A12 or the inactive control s.c. at 13.4mg/kg thrice a week. Renal progenitor cell properties (RPC) were used for in vitro studies.

Results: ADR-induced proteinuria peaked at day 7 (injury phase), which subsequently declined without returning back to baseline and being associated within FSGS lesions after 14 days (repair phase). CXCL12 blockade augmented ADR-induced A/C and podocyte loss at day 7, which implies an autocrine role of CXCL12 for podocyte survival. In contrast, CXCL12 blockade reduced A/C levels and the glomerular sclerosis scores as well as increased podocyte numbers at 14 days indicating a beneficial effect of CXCL12 blockade during the repair phase. The pro-survival effect of CXCL12 on podocytes was further confirmed in a model of diphtheria toxin-induced podocyte depletion using CXCL12 blockade. To investigate the dual effect of CXCL12, we focused on the Notch signaling pathway. ADR injection reduced renal Notch expression, which was reversed following CXCL12 blockade. In vitro studies with RPM revealed that CXCL12 suppressed RPC proliferation, which was reversed with CXCL12 inhibitor. Similar results were obtained when RPC were exposed to supernatants from necrotic podocytes. CXCL12 blockade also increased the capacity of RPC to differentiate into podocytes.

Conclusions: Podocyte-derived CXCL12 has a dual role in glomerular injury. CXCL12 protects podocytes during the injury phase in an autocrine manner by suppressing Notch signaling, which otherwise triggers mitotic catastrophe and podocyte loss. Podocyte-derived CXCL12 assures Notch-mediated quiescence of RPC. Our data also demonstrate that therapeutic CXCL12 inhibition in glomerular injury can improve long term outcomes possibly by enforcing the intrinsic regenerative capacity of RPC.

Shank2 Modulates Glutamatergic Signaling in Podocytes

Evgenia Dobrinskikh,1 Linda Lewis,1 R. Brian Doctor,2 Judith Blaine,1 Medicine, Univ of Colorado, Aurora, CO; *Biology, Univ of Mississippi, Oxford, MS.

Background: Shank2 is a large scaffolding protein that is a master regulator of glutamate receptors at the neuronal postsynaptic density. Knockout (KO) of Shank2 in mice leads to autistic behaviours and abnormal glutamatergic signaling.

Podocytes have also been shown to express functional N-methyl D aspartate (NMDA) and metabotropic glutamate receptor 1 (mGluR1) receptors which are both members of the glutamate receptor family.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

429A
Results: We have found that podocytes express Shank2 in vivo and in vitro. Since Shank2 is an important regulator of glutamate receptor function, we examined the effect of Shank2 knockout on NMDA and mGluR1 expression and function in podocytes. Shank2 KO resulted in decreased expression of NMDA and mGluR1 receptors in glomeruli. We isolated podocytes from wild type and Shank2 knockout mice and created conditionally immortalized Shank2 KO podocyte lines. Conditionally immortalized Shank2 KO podocytes also demonstrated decreased expression and altered localization of glutamate receptors. In neurons, activation of glutamate receptors modulates intracellular calcium levels by allowing calcium influx into the cell (NMDA receptors) or release of calcium from intracellular stores (mGluR1). To evaluate changes in calcium levels in podocytes, we examined intracellular calcium levels in wild type and Shank2 KO podocytes at baseline. Shank2 knockout podocytes had significantly fewer calcium spikes than wild type podocytes. Treatment with NMDA and glutamate increased the number of calcium spikes in both wild type and Shank2 KO podocytes but the number of spikes in the KO podocytes were significantly reduced compared to wild type. Podocytes have been shown to communicate with each other via calcium waves. To examine podocyte to podocyte communication after injury, we “burned” a podocyte using high intensity laser power and then examined calcium wave propagation from the site of injury. After burning, wild type podocytes exhibited calcium waves emanating from the injured podocyte whereas no waves were seen in the knockouts.

Conclusions: Taken together these data indicate that Shank2 regulates glutamate receptor function in podocytes.

Podocytes Transcytose Albumin and IgG Using the Neonatal Fc Receptor (FcRn) In Vivo and In Vivo
Evgenia Dobrinskikh, 1 Linda Lewis, 1 Jeffrey B. Kopp, 2 Judith Blanc. 1 Medicine, Univ of Colorado, Denver, CO; 2 Kidney Disease Section, NIDDK, NIH, Bethesda, MD.

Background: Proteinuria is strongly associated with kidney disease progression. Podocytes are key constituents of the glomerular filtration barrier (GFB), which determines the balance of protein filtration. By even the most conservative estimates between 2 and 9 g of serum proteins a day normally pass through the GFB. The molecular mechanisms whereby podocytes handle albumin and IgG remain to be fully determined.

Results: We have found that transcytosis is the major pathway whereby cultured podocytes in primary culture and IgG. In other epithelial cell types, the neonatal Fc receptor (FcRn) is required to transcytose endocytosed albumin and IgG, thereby salvaging these proteins from degradative pathways. To examine the role of FcRn in albumin and IgG transcytosis in podocytes, we knocked down FcRn in cultured podocytes using lentiviral shRNA. Following knockdown (KD) resulted in a 71.3% decrease in FcRn expression compared to control. In an in vitro transcytosis assay, FcRn KD increased intracellular accumulation and decreased appearance of albumin and IgG in the supernatant, suggesting impaired transcytosis, but the differences were not statistically significant, possibly due to residual FcRn. We therefore isolated podocytes from wild type (WT) and FcRn knockout (KO) mice and created conditionally immortalized WT and KO podocyte lines. Knockout of FcRn resulted in significantly increased intracellular accumulation, assessed by immunostaining and Western blot (densitometric analysis of intracellular protein 1 hr after loading showed 3.7±0.1 (WT) vs 9.7±0.2 (KO), p<0.05 for albumin and 0.52±0.04 (WT) versus 1.03±0.19 (KO), p<0.05 for IgG), and decreased appearance of supernatant albumin or IgG, indicating defective transcytosis. We extended our studies to an in vivo model by creating a podocyte-specific FcRn KO mouse. Podocyte-specific FcRn KO mice demonstrated impaired transcytosis of albumin and IgG by 8 weeks of age, assessed by immunostaining. Studies of albuminuria are in progress.

Conclusions: Taken together, these studies indicate that podocytes in vivo and in vitro transcytose albumin and IgG using FcRn.

Transcriptional Reprogramming by Wilms’ Tumor 1 and FoxC2 in Glomerular Disease
Sandrine S. Fitou,1 Lucy Jung,2 Mary E. Taglialatela,1 Peter Park,1 Jordan A. Kreidberg. 1Nephrology, Boston Children’s Hospital, Boston, MA; 2Internal Medicine and Center for Molecular Medicine, Harvard Medical School, Boston, MA.

Background: Foot process effacement and proteinuria, representing a breakdown of the glomerular filtration barrier (GFB) are typically accompanied by decreased expression of key podocyte proteins. We sought to determine whether decreased expression of key podocyte proteins was caused by transcriptional reprogramming in the injured podocyte. We reported a Wilms’ tumor-1 (WT1) ChIP-Seq study that identified components of the GFB and many other important podocyte genes as WT1 target genes. Many WT1 target genes in podocytes also appear to be bound by FoxC2, including Podocin (Podox2), Slit2 (Slit2/1) and Syndecanpodin (Sympo).

Methods: We now used ChIP-Seq to study the DNA binding of WT1 to target genes in the context of Adriamycin-induced podocyte injury that is considered a model for human FSGS. WT1 ChIP-Seq was performed using isolated glomeruli from 6 days post-injection or control B6C mice. FoxC2 binding was determined by direct ChIP-qPCR.

Results: Expression of WT1 and FoxC2 decreased in podocytes, as did binding of WT1 and FoxC2 to their common targets. WT1/FoxC2 target gene expression was also reduced. In contrast to these WT1/FoxC2 target genes that represent a set of genes required for normal podocyte function, we identified a second set of WT1-bound genes, not bound by FoxC2, including Hdc and 7, whose expression increased after podocyte injury. This WT1/FoxC2 binding decreased, suggesting that WT1 acts as a repressor for a distinct set of target genes.

WT1 binding at known target genes showed both decreased and increased peak intensity after treatment suggesting that WT1 regulation of gene expression is complex and may include activating and repressive functions.

Conclusions: These results suggest a model whereby WT1 and FoxC2 activate gene expression in normal podocytes, WT1 represses other genes in normal podocytes independently of FoxC2.

A Basophilic Kinase Site at the N-Terminus of TRPC6 Controls Channel Activity
Hennig Hofmann,1 Markus M. Rinsch,1 Alexander Kuczkowski,1 Stuart E. Dryer,2 Bernhard Schermer,1 Thomas Benzing,1 Paul T. Brinkkoetter. 1Nephrology, Univ Hospital Cologne, Cologne, Germany; 2Bichemistry, Univ of Houston, Houston, TX.

Background: The non-selective cation channel TRPC6 plays a pivotal role in the development of proteinuric kidney disease. Hyperactivity of TRPC6 either through gain of function mutations, increased total protein levels or membrane abundance of the channel protein has been associated with glomerular disease.

Results: To investigate regulation of the TRPC6 channel activity we conducted mass spectrometry experiments to screen for phosphorylation sites in the TRPC6 protein. We identified several new as well as previously known phospho-peptides. The serine residues in position 13 and 14 of the human TRPC6 protein are phosphorylated and embedded in a basophilic kinase motif. Substitution of the serine residue in position 14 with alanine (S14A) leads to a reduction of TRPC6 conductance in voltage clamp experiments in Xenopus oocytes.

The atypical cyclin-dependent kinase (Cdks), a serine- threonine-kinase expressed in the podocyte, is directed to basophilic motives. In the podocyte, Cdks is activated by the specific activators p35, p25, and Cyclin I. In cell culture experiments a direct phosphorylation of TRPC6 by Cdks/p35 at position S14 could be confirmed with mass spectrometry and radioactive in-vitro kinase assays. Co-expression of Cdks/p35 and TRPC6 enhanced channel conductivity of TRPC6 in voltage clamp experiments. This effect was abrogated by the amino acid substitution S14A.

Conclusions: A basophilic kinase site at the N-terminus of TRPC6 was identified which controls channel activity. As exemplarily shown for Cdks/p35, basophilic kinases phosphorylate TRPC6 at serine 14 and affect channel function. This site may serve as a molecular switch for TRPC6 activity and as a potential future drug target.

Hantaviruses Associate with Actin Fibers and Cause Podocyte Damage
Stefan Hägeler,1 Alexandra Kowalski,1 Jochen Reiser,2 Martin G. Zeier,2 Ellen Krautkramer.1 Nephrology, Univ Hospital Heidelberg, Heidelberg, Germany; 2Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Characteristic for the clinical picture of Old World hantavirus is an acute renal failure with often massive non-selective proteinuria. Previously, we showed that cell-to-cell contact proteins were disrupted and levels were decreased in infected human renal cells, correlating with the clinical picture. However, the exact mechanisms driving hantaviral pathogenesis are not well characterized.

Methods: Renal biopsies of patients with acute hantavirus infection were analyzed by electron microscopy. A human podocyte cell line was used for infection with Hantaan virus (HTNV). Cell-to-cell contact proteins were analyzed by immunoblotting, qRT-PCR and immunofluorescence. The cytoskeleton was examined by confocal microscopy and by depolymerising drugs. Cell motility was measured by migration assays.

Results: Analysis of renal biopsies revealed podocyte foot process effacement with loss of cell-to-cell contacts. To examine the underlying mechanism of hantavirus-induced alterations, we performed in vitro infection studies. We showed that HTNV had no influence on transcription levels of cell-to-cell contact proteins, indicating another mechanism of cell-to-cell contact disruption. Next, we focused on an impact on the cytoskeleton which is important for barrier function. We detected a filamentous pattern of the hantaviral nucleocapsid (N) protein which was associated with actin fibers. This N protein localization depended on the integrity of the actin cytoskeleton, because the filamentous pattern disappeared after actin depolymerization. Correspondingly, we measured decreased viral release levels after loss of N protein filaments. During infection, we revealed impaired podocyte motility as a functional consequence due to hantavirus-induced effects on actin dynamics and functions.

Conclusions: These results demonstrate that hantavirus infection leads to podocyte injury by morphological changes. Disruption of cell-to-cell contacts may be caused by the association of N protein and actin leading to changes in podocyte motility. These findings provide useful insights into the mechanism inducing renal failure.
ARF6: A New Player in Injury-Induced Podocyte Effacement

Jamie Lin,1 Jin Seok Jeon,2 Qingsong Fan,1 Lawrence B. Holzman.1 Renal-Electrolyte and Hypertension Div, Univ of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Dept of Nephrology, Soon Chun Hyang Univ Hospital, Seoul, Korea.

Background: The transmembrane slit-diaphragm protein nephrin is tyrosine-phosphorylated and endocytosed during acute podocyte injury, resulting in cell spreading and effacement in vivo. We postulate that these events are facilitated by ARF6, a small GTPase that regulates endocytosis, endosomal trafficking, and actin dynamics possibly through regulation of Rac1, a Rho GTPase.

Methods: Using human podocyte cultures transfected with chimeric nephrin intracellular domain, we investigated the molecular mechanisms underlying its role in nephrin signaling. Using wild-type, constitutively-active, dominant-negative, and siRNA-knock-down of ARF6, we assessed lamellipodia activity (a marker of cell spreading) and podocyte motility.

Results: Results of co-immunoprecipitation suggested that activated nephrin formed a signaling complex with ARF6. Furthermore, nephrin tyrosine phosphorylation increased ARF6 activity in cultured podocytes. A constitutively active ARF6 mutant resulted in increased lamellipodia formation compared to wild-type ARF6, while dominant-negative ARF6 mutant resulted in decreased lamellipodia formation. A scratch assay of ARF6 knock-down cultured podocytes revealed slowed cell migration.

Conclusions: Together, our results suggest that ARF6 is an important protein involved in the regulation of injury-induced podocyte cytoskeletal rearrangement. Inhibition of ARF6 might provide a potential therapeutic strategy to confer a protective phenotype in vivo, making it an attractive target for the amelioration of glomerular disease.

Albumin Sieving Coefficient in Isolated Perfused Kidney: Effects of EDTA

Turgay Saritas, Ralf Hausmann, Thiago Strieder, Jürgen Floege, Marcus J. Ouderkirk, Vladimir Sirokin. Cell and Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY.

Background: Myosin is expressed in podocytes and plays a key role in regulating the integrity of their cell-cell junctions, however, the effects of FSGS mutations on Myo1e motor activity and stability have not been directly tested. In this study, we used a simple model organism, fission yeast Schizosaccharomyces pombe, to test the effects of FSGS-associated mutations on myosin activity. Fission yeast has only one class I myosin, Myo1, which is involved in actin patch assembly at the sites of endocytosis.

Methods: The amino acid residues mutated in the FSGS patients are conserved between human Myo1e and yeast Myo1, which allowed us to introduce equivalent mutations into yeast myosin and use the resulting mutant strains for functional analysis. Myo1e expression and localization and stability was analyzed using fluorescence imaging and Western blotting, while Myo1 functional activity was tested using growth and endocytosis assays.

Results: Yeast strains expressing mutant Myo1 exhibited defects in growth and endocytosis similar to those observed in the myo1 deletion strain. These mutations also disrupted Myo1 localization to endocytic actin patches and resulted in mis-localization of Myo1 to eisosomes, linear membrane microdomains found in yeast cells. While both mutants examined in this study showed loss of function, one of these mutants was also characterized by the decreased protein stability.

Conclusions: Using the yeast model system we were able to determine that the kidney disease-associated mutations impair myosin functional activity and have differential effects on protein stability. This study provides the first example of using fission yeast as a model system to test the effects of FSGS mutations on Myo1e function. This novel system allowed us to definitively establish that the first time point between the myosin motor activity and its ability to support normal glomerular filtration.

Vinculin Bonds Zonula Occludens-1 (ZO-1) and Is Required for Podocyte Stabilization of the Slit Diaphragm following Injury

Xuefei Tian, Kazunori Inoue, Shuta Ishibe. Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, CT.

Background: Cell-matrix interactions and intercellular junctions in podocytes are important factors to prevent protein leakage through the glomerular filtration barrier. Vinculin, a cytoplasmic protein, links the actin filaments to integrin-based cell-matrix proteins and cadherin-based intercellular junctions. We have observed that vinculin is highly expressed in podocytes, and appears to be critical in maintaining slit diaphragm integrity following injury through its interaction with ZO-1.

Methods: Wild type and Vinculin (-/-) podocyte knock out (KO) mice were analyzed to determine the role of vinculin in vivo, and primary podocytes were isolated for in vitro studies.

Results: Podocyte specific ablation of Vcl resulted in no significant difference in body weight, albuminuria, and kidney histology up to 18 months when compared to littermate controls. However, Pod-Vcl KO mice had significantly increased albumin/creatinine ratios following lippopolysaccharide (LPS) or rabbit anti-mouse glomerular basal membrane (NTS) induced podocyte damage respectively (284±40 vs 411 ±31 µg/mg, and 205±28 vs 314±38 µg/mg, P<0.05). In addition, loss of Vcl in podocytes resulted in worsened foot process effacement. Co-immunoprecipitation of Myo1 to eisosomes, linear membrane microdomains found in yeast cells. While both mutants examined in this study showed loss of function, one of these mutants was also characterized by the decreased protein stability.

Conclusions: Using the yeast model system we were able to determine that the kidney disease-associated mutations impair myosin functional activity and have differential effects on protein stability. This study provides the first example of using fission yeast as a model system to test the effects of FSGS mutations on Myo1e function. This novel system allowed us to definitively establish that the first time point between the myosin motor activity and its ability to support normal glomerular filtration.

FR-P0338
AT 1  Receptors in Podocytes Control GFR and Susceptibility to Kidney Injury

Stacy Alanna Johnson, 1  Tiffani N. White, 1  Susan B. Gurley, 1,2  Thomas M. Coffman,1,2  Duke Univ; 2Durham VA; 3Duke-NUS.

Background: Angiotensin II, acting via AT 1  receptors, plays a critical role in CKD progression. Pharmacologic blockade of AT 1  receptors reduces albuminuria and this is linked to its efficacy in CKD. Within the kidney, the density of AT 1  receptor expression is lower in the glomerulus, where AT 1  receptors are expressed in multiple cell lineages and are involved in regulating glomerular pressures and GFR. However, the key cellular sites of action in the glomerulus involved in physiological regulation and in promoting proteinuria have not been directly defined. Since podocyte dysfunction and injury have been implicated in the development of many glomerulopathies, we investigated the role of AT 1  receptors in podocytes using cell-line specific gene targeting.

Methods: Because the minor AT 1  receptor isoform (AT 1B ) is expressed at significant levels in podocytes, we generated mice lacking all AT 1  receptors in the podocyte (PodKO) by Cre-mediated excision of a conditional allele of the major AT 1  receptor isoform (AT 1a ) on an AT 1a -null background.

Results: PodKO mice develop normally with kidney weights similar to controls (6.9±0.5 vs 7.0±0.3 g/BW) and their glomerular morphology appears normal. GFR was significantly reduced in 24-week old PodKO (8.9±3.5 ml/min' 1 g' 1 ) compared to controls (29.5±4.5 ml/min' 1 g' 1 ); p<0.04), but there was no significant difference in the low levels of albumin excretion between the groups. To determine whether the elimination of AT 1  receptors from podocytes impacts albuminuria and kidney injury in a model with high levels of Ang II, a transgene (RenTg) driving constitutive expression of renin was crossed onto the PodKO background. At 24 weeks of age, levels of albuminuria were increased in RenTg mice (210±71 µg/24 hr) compared to controls (29.9±24 µg/24 hr; p<0.02), but this increase in albuminuria was unaffected in RenTg-PodKO mice (229±38 µg/24 hr). Despite similar levels of albumin excretion, kidneys from RenTg-PodKO mice had exaggerated kidney injury with more glomerulosclerosis, mesangial expansion, and tubular casts.

Conclusions: Our results suggest that AT 1  receptors in podocytes do not promote albuminuria and may protect against glomerular injury.

H2O2 Production by Nox4 Drives Ang II – Dependent Calcium Influx Through TRPC6 Channels in the Podocytes

Daria Litovskaya, Oleg Palygin, Leonard S. Shlyouksy, Alexander Starushchenko. Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: Improper Ca2+ handling by the podocyte can result in cell damage and loss of function. Podocyte depletion and associated glomerulocapsulitis are typical for progressive chronic nephropathies, which have been associated with elevated levels of ROS, including H2O2. One of the key mediators of Ca2+ influx in the podocytes is a TRPC6 channel. The goal of this study was to provide a mechanistic insight into the Ang II-dependent regulation of TRPC6 channel.

Methods: Changes in intracellular Ca2+ levels were measured with live confocal microscopy in podocytes of isolated glomeruli. Patch clamp analysis was performed to assess the activity of TRPC6 channels in this preparation. Enzymatic biosensors technique was applied to determine H2O2 release in the kidney cortex and isolated glomeruli.

Conclusions: The Ca2+ influx through TRPC6 channel is an important determinant of podocyte injury. Our results, therefore, suggest that TRPC6 channel may contribute to cell injury caused by Ang II.

FR-P0340
Role of Unliganded Vitamin D Receptor (VDR) in Providing Podocyte Protection During AT1R Blockade (BLK) in Adverse Milieu

Tejinder Singh, Kamesh R. Ayasolla, 1  Shabirul Haque, 1  Himanshu Vashisthia, 1  Ashwani Malhotra, 1  Leonard G. Meggs, 2  Pravin C.Singhal, 1

1Medicine, Hofstra North Shore LI Medical School, Great Neck, NY; 2Medicine, Ochsner Health System, New Orleans, LA.

Background: AT1R-BLK provides podocyte protection in response to inflammatory stimuli and renal injury. However, the mechanism of the protective actions is incompletely understood. In this study, we sought to determine the role of unliganded VDR in providing podocyte protection during AT1R blockade.

Methods: Primary rat podocytes (1D) driving constitutive expression of VDR were crossed onto the AT1R-BLK (AT1R-BLK) gene background. These mice were crossed on to the renin transgenic (RenTg) background. In order to compare the renal phenotype of these mice to the control (WT) group, mice were subjected to a high-salt diet and then we analyzed the renal function and glomerulosclerosis.

Conclusions: It appears that SMRT is necessary for DNA repairs during AT1R-BLK. SMRT-depleted podocytes lacked AT1R-BLK-mediated protection against DNA damage, as assessed by incision of H2O2 release in the kidney cortex and isolated glomeruli. One of the key mediators of Ca2+ influx in the podocytes is a TRPC6 channel. The goal of this study was to provide a mechanistic insight into the Ang II-dependent regulation of TRPC6 channel.

Funding: Other NIH Support - R01 HL08880, R01 12266 (NHLBI)

Enhanced S-Nitrosylation and N-Glycosylation of Podocin-R138Q May Contribute to Its Defective Trafficking and Rapid Degradation

Maria Carmen Serrano-Perez, 1  Fabien Nevo, 1  Christelle Arrondel, 1  Alda Tufo, 2  Corinne Antignac, 1  Geraldine Mollet. 1

1Inserm U1163 - Imagine Inst - Paris Descartes Univ-Sorbonne Paris Cité, France; 2Iale Univ School of Medicine-Dept of Pediatrics.

Background: Missense mutations in the NPHS2 gene, encoding podocin, are a major cause of deminished and sporadic cases of steroid-resistant nephrotic syndrome (SRNS). Among them, those encoding endoplasmic reticulum (ER)-retained mutant proteins, e.g. R138Q, correlate with the most severe cases of SRNS.

Methods: We generated two human podocyte cell lines stably expressing 2HA-podocin or 2HA-podocin R138Q to perform comparative studies on podocin post-translational modifications and podocin degradation.

Results: We detected increased podocin S-nitrosylation and N-glycosylation in 2HA-podocin (α) vs. 2HA-podocin (α) podocytes, which may modify podocin topology, degradation and trafficking. We also suggest that a further interaction of podocin (α) with an ER chaperone calnexin stabilizes the protein in the higher degradation rate of podocin (α) previously found in R140Q knock-in mice, that we found that non-glycosylated (ng) podocin (α) has a dramatically shorter half-life than podocin (α). Moreover, the Ng-glycosylated forms of podocin (α) are more stable than its non-glycosylated fraction. We also show that ng-podocin (α) is mainly degraded by the proteasome, whereas ng-podocin can be degraded by both the proteasomal and the lysosomal proteolytic machineries. Furthermore, preventing ng-podocin (α) degradation allows its partial localization to the podocyte filipodia, improves the ratio between its non-glycosylated and glycosylated forms and reduces its interaction with calnexin.

Conclusions: These findings show podocin S-nitrosylation for the first time and suggest that increased S-nitrosylation and N-glycosylation may contribute to the defective trafficking and degradation of podocin (α), the product of the most frequent human podocin missense mutation, and possibly of other podocin-missense mutants.

RAS Inhibition Enhances Proliferation and Migration of Cells of Renin Lineage (CoRL) as Progenitors in Experimental FSGS

Julia Lichtmacher, 1  Diana G. Eng, 1  Jeffrey W. Pippin, 2  Kenneth W. Gross, 3  Stuart J. Shankland.

1Div of Nephrology, Univ of Washington, Seattle, WA; 2Dept of Molecular and Cellular Biology, Roxwell Park Cancer Inst, Buffalo, NY.

Background: RAS inhibitors are used therapeutically in proteinuric glomerular diseases. In focal segmental glomerulosclerosis (FSGS) where podocyte number is depleted, recent data showed that ACE-Inhibitors could improve podocyte number. Because adult podocytes do not proliferate, their replacement by renal progenitors is critical for their regeneration in disease. The impact of RAS blockade on adult podocyte progenitors is not well understood.

Methods: Experimental FSGS characterized by podocyte depletion was induced by an anti-podocin antibody in two strains of Cells of Renin Lineage (CoRL) reporter mice (RenCre and RenCreER) where CoRL are fate mapped. Diseased mice were randomized at day 3, when podocyte number was depleted by 40%, to receive Enalapril or Losartan, or the controls Hydralazine or water. Brdu was injected to monitor proliferation. Following initial podocyte depletion, cell number was monitored for 4 weeks (measured by p57 staining) was higher in both Enalapril and Losartan groups on d14 and d28. This was accompanied by significantly lower proteinuria and glomerulosclerosis. The number of CoRL increased in the intra-glomerular compartment in FSGS mice given water or hydralazine. However, the number of labeled CoRL further increased significantly in FSGS mice given Enalapril or Losartan. A subset of CoRL detected in the glomerular compartment co-expressed several markers for podocytes and PEC's. RAS inhibition increased BrdU staining in CoRL in the juxta- and intraglomerular compartments, but was not seen in podocytes.

ShcA Influences Nephrin Endocytosis and Protec... Cell Biology: Glomerular - I

Background: The transmembrane protein nephrin is a key component of the slit diaphragm (SD). It has recently been postulated that nephrin turnover plays a key role in maintaining a healthy SD, and multiple theories regarding the role of nephrin phosphorylation in endocytosis are emerging. Tyrrosine phosphorylation of the cytoplasmic tail of nephrin facilitates recruitment of several signaling proteins that regulate podocyte shape and thereby permselectivity of the SD. Previous work from our lab has identified and mapped the interaction between nephrin and the ShcA adaptor protein and demonstrated an early requirement for ShcA in the maintenance of the filtration barrier in mice. Given ShcA's established role in endocytosis, we now hypothesize that ShcA may regulate nephrin endocytosis to ultimately maintain filtration barrier integrity.

Methods: Multiple approaches were used to measure the influence of ShcA and ShcA domain mutants on the levels of surface nephrin and signaling downstream of nephrin. Purified recombinant mouse nephrin (PMN) was generated in Sprague-Dawley rats for 0, 4, 7, or 14 days and nephrin endocytosis was monitored via biotinylated and immunofluorescence experiments.

Results: We demonstrate that ShcA expression is increased in podocytes in response to PAN injury, which is accompanied by activation of the stress-activated p38 and JNK MAP kinases. Interestingly, we found that transactivation of AP-1, which occurs downstream of nephrin activation as well as p38 and JNK, is attenuated by ShcA, and this effect is reversed by mutation of the ShcA SH2 domain, which mediates nephrin binding. Further investigation revealed that ShcA promotes nephrin endocytosis in a phospho-dependent manner by enhancing Src-mediated nephrin phosphorylation, its own binding to nephrin and endocytosis into EE/A1-positive endosomes both in vitro and in PAN-treated rats.

Conclusions: Together these findings suggest a protective effect of ShcA in podocytes by influencing phospho-dependent nephrin endocytosis and possibly attenuating nephrin-mediated p38/JNK signaling in response to injury.

Podocyte Specific Response to Complement Challenge, Anna Katinettman, Magdalena Riedl, Fred G. Plathour, Moin Saleem, Jun Oh, Christoph Licht, Dept of Pediatrics, Univ Medical Center Hamburg-Eppendorf, Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; Dept of Pediatric Nephrology, Hospital for Sick Children, Academic Renal Unit, Univ of Bristol.

Background: There is a multilayered system of fluid phase and surface bound complement regulatory proteins, which ensure that complement activation occurs only on specific sites and spares the body's own cells. Unrestricted complement activation is a main cause for damage in complement-mediated glomerulopathies such as C5G or membrane nephropathy (MN). In MN, podocytes, key components of the glomerular filtration barrier, are target of overshooting complement activation. The aim of this study was to characterize the complement defense mechanisms in podocytes and their response to complement challenge (CC).

Methods: We analyzed complement regulators by immunofluorescence, flow cytometry and qRT-PCR in immortalized human podocytes and compared them to blood grown endothelial cells (BOECs). Functionality of secreted complement factor H (CFH) was tested via a cofactor assay. In a model for CC (sensitization with antibodies against the ShcA SH2 domain, which mediates nephrin binding. Further investigation revealed that ShcA promotes nephrin endocytosis in a phospho-dependent manner by enhancing Src-mediated nephrin phosphorylation, its own binding to nephrin and endocytosis into EE/A1-positive endosomes both in vitro and in PAN-treated rats.

Conclusions: Together these findings suggest a protective effect of ShcA in podocytes by influencing phospho-dependent nephrin endocytosis and possibly attenuating nephrin-mediated p38/JNK signaling in response to injury.

Podocyte Specific Response to Complement Challenge, Anna Katinettman, Magdalena Riedl, Fred G. Plathour, Moin Saleem, Jun Oh, Christoph Licht, Dept of Pediatrics, Univ Medical Center Hamburg-Eppendorf, Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; Dept of Pediatric Nephrology, Hospital for Sick Children, Academic Renal Unit, Univ of Bristol.

Background: There is a multilayered system of fluid phase and surface bound complement regulatory proteins, which ensure that complement activation occurs only on specific sites and spares the body's own cells. Unrestricted complement activation is a main cause for damage in complement-mediated glomerulopathies such as C5G or membrane nephropathy (MN). In MN, podocytes, key components of the glomerular filtration barrier, are target of overshooting complement activation. The aim of this study was to characterize the complement defense mechanisms in podocytes and their response to complement challenge (CC).

Methods: We analyzed complement regulators by immunofluorescence, flow cytometry and qRT-PCR in immortalized human podocytes and compared them to blood grown endothelial cells (BOECs). Functionality of secreted complement factor H (CFH) was tested via a cofactor assay. In a model for CC (sensitization with antibodies against the ShcA SH2 domain, which mediates nephrin binding. Further investigation revealed that ShcA promotes nephrin endocytosis in a phospho-dependent manner by enhancing Src-mediated nephrin phosphorylation, its own binding to nephrin and endocytosis into EE/A1-positive endosomes both in vitro and in PAN-treated rats.

Conclusions: Together these findings suggest a protective effect of ShcA in podocytes by influencing phospho-dependent nephrin endocytosis and possibly attenuating nephrin-mediated p38/JNK signaling in response to injury.

Ubiquitin C-Terminal Hydrolase-L1 Deficiency in Podocytes Protects from Immune Complex Nephritis in Mice, Julia M. Fehlert, 1, 2 Marlies Sachs, 1 Thorsten Wiech, 2 Rolf A. Stahl, 1 Catherine Meyer-Schwesinger, 1 Nephrology, Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Ubiquitin C-terminal Hydrolase-L1 (UCH-L1) is a central deubiquitylating enzyme of the neuronal ubiquitin proteasomal system. UCH-L1 is thought to regulate the intracellular pool of monoubiquitin in neurons. Recently we identified a de novo expression of UCH-L1 in podocytes of patients with membranous nephropathy. Upregulation of UCH-L1 in podocytes correlated with disease progression, accumulation of ubiquitinated proteins and altered expression of podocyte-specific proteins in human and rodent podocytes. Inhibition of UCH-L1 enzymatic function in a rat model of membranous nephropathy decreased the abnormal protein accumulation and ameliorated the clinical course of disease. We generated mice with podocyte-specific UCH-L1-deficiency to investigate the role of UCH-L1 in the novel expression in podocytes.

Methods: Mice with podocyte-specific UCH-L1-deficiency were generated by Cre-lox technology and back-crossed into the C57BL6 background. Podocyte phenotype was evaluated by morphological (immunohistochemistry, electron microscopy) and biochemical techniques (Western blotting, proteasomal activity assays, real-time PCR) in unchallenged and anti-podocyte antibody challenged wildtype and knockout mice.

Results: Unchallenged podocyte-specific UCH-L1-deficient mice exhibited normal podocyte morphology throughout life and delayed age-related proteinuria accompanied by a decreased accumulation of poly-ubiquitinated proteins. Following induction of anti-podocyte nephritis, podocyte-specific UCH-L1-deficient mice showed decreased signs of podocyte injury and decreased proteinuria despite a comparable immunologic reaction to the injected anti-podocyte antibodies. Podocyte-specific proteins such as nephrin and podocin were expressed and protein accumulation was decreased. UCH-L1-deficiency resulted in increased proteasomal capacity and activity in injured podocytes.

Conclusions: Podocyte-specific UCH-L1-deficiency protects podocytes from age-related degenerative changes and from immune complex nephritis through increased proteasomal capacity.

Funding: Government Support - Non-U.S.

Ubiquitin C-Terminal Hydrolase-L1 Deficiency in Podocytes Protects from Immune Complex Nephritis in Mice, Julia M. Fehlert, 1, 2 Marlies Sachs, 1 Thorsten Wiech, 2 Rolf A. Stahl, 1 Catherine Meyer-Schwesinger, 1 Nephrology, Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Ubiquitin C-Terminal Hydrolase-L1 Deficiency in Podocytes Protects from Immune Complex Nephritis in Mice, Julia M. Fehlert, 1, 2 Marlies Sachs, 1 Thorsten Wiech, 2 Rolf A. glomerular disease and results from disruption of the glomerular filter. The slit diaphragm is a specialized region in podocytes between adjacent podocytes. Maintenances of the correct position, adjacent podocytes has not been well understood.

Methods: RNA was isolated from differentiated human podocytes and isolated murine glomeruli and PCR performed. Human podocytes were retrovirally transduced with EphB2-YFP and ephrinb1-CFP and ephrinb1-CFP podocytes were differentiated in co-cultures and time lapse video imaging was performed. In addition, a co-culture of differentiated EphB2-YFP and ephrinb1-CFP cells was examined. To investigate the role of the intracellular domains of the EphB2 receptor and ephrinb1 ligand, truncated mutants of EphB2 (Ephb2.DC-YFP) and ephrinb1 (ephrinb1.DC-CFP) were analyzed.

Results: Human podocytes as well as murine glomeruli express EphB1, 2 and 3 receptors. Co-cultures of differentiating EphB2-YFP and ephrinb1-CFP podocytes show repulsion between the two cell types. Transsudocytosis (YFP particles in CFP cells and vice versa) occurs for EphB2-YFP podocytes during repulsion. The repulsion is dependent on the intracellular domain of Ephb2 as Ephb2.DC-YFP cells adhere to ephrinb1-CFP and ephrinb1.DC-CFP cells. However, repulsion is maintained in co-cultures of Ephb2-YFP with ephrinb1.DC-CFP cells. Co-culture experiments of differentiated, confluent podocytes confirm the results presented above.

Conclusions: EphB2 receptors mediate podocyte repulsion upon binding to their ligand ephrinb1. The EphB2 receptor cytoplasmic domain seems to be crucial for repulsion. Maintaining the correct podocyte distance within the highly organised glomerular architecture is not been well understood. These cell culture data provide a promising concept of potential regulation of podocyte distance in vivo.

Background: Chronic kidney disease is associated with reduced VEGF-A expression. However, the role VEGF-A splice isoforms play in kidney physiology and pathology is unclear. Use of an alternative 3’ splice site in the terminal exon of VEGF-A results in the expression of anti-angiogenic VEGF-β. Previous studies suggest that VEGF-β is protective in renal disease in diabetic rodents. This study aimed to investigate whether constitutive podocyte over-expression of VEGF-β is able to rescue the injury phenotype seen in the inducible podocyte-specific VEGF-A KO mouse. The mechanism of action of VEGF-β within the glomerulus was also investigated.

Methods: Podocyte-specific VEGF-A KO was induced via doxycycline for 10-14 weeks in WTI, VEGF-βKO and VEGF-AKO n/nep-VEGF-β mice. In situ hybridization confirmed a knock-down of VEGF-A. The kidney functional phenotype was determined through the urinary albumin creatinine ratio (uACR) and measurement of glomerular water permeability. Electron microscopy was used to examine the ultra structure of the glomeruli, and immunofluorescence to determine the expression levels of podocyte and endothelial-specific proteins. Glomerular endothelial cells (GEnCs) in culture were used to determine the mechanism of action of VEGF-β through VEGFR-2.

Results: The VEGF-β isoform alone is sufficient to rescue the increase in albuminuria and glomerular water permeability in the context of progressive depletion of all VEGF-A isoforms. Ultra structural studies show glomerular basement membrane thickening and increased podocyte slit width in the VEGF-A KO mouse, with both being rescued in the VEGF-β over-expressors. VEGF-β also restores PECAM expression in GEnCs, and glomerular capillary circumference. Mechanistically, VEGF-β increases VEGFR-2 expression and phosphorylation both in vivo and in vitro. Furthermore, it down regulates genes involved in the migration and proliferation of GEnCs, which are otherwise up regulated by VEGF-α.

Conclusions: Our study indicates that VEGF-A splice isoform manipulation could be a novel therapeutic avenue in chronic glomerular disease.

FR-PO349 Rituximab Prevents TNFα Induced Podocyte anb3 Integrin Activation Farah Leclercq, Christopher E. Pedigo, Alessia Forconi, Sandra M. Merscher. Katz Family Drug Discovery Center, Nephrology, Univ of Miami, FL.

Background: Focal Segmental Glomerulosclerosis (FSGS) is a disease characterized by podocyte and scarring of the glomeruli. FSGS accounts for up to 20% of end-stage renal disease cases in the United States. The expression of anti-angiogenic VEGF-β (sVEGFR1 (sflt1)) is an alternative splicing product of VEGF-β (flt1) gene. Both sflt1 and sflt1 can function as “decoy receptors” for VEGF. sflt1 plays a key role in maintaining avascularity of the cornea, and increased circulating levels of sflt1 are linked to preeclampsia. Moreover, deletion of sflt1 from mouse podocytes results in proteinuria at 6 weeks of age, while deletion of the kinase signaling domain of this receptor alone results in no renal phenotype. In vitro studies showed that sflt1 can induce formation of foot process-like structures in human podocytes. We hypothesize that sflt1 regulates podocyte cytoskeletal dynamics and glomerular barrier function by titrating local glomerular VEGF levels.

Methods: To determine function of the soluble variant of Flt1 in the glomerulus, we generated a conditional KO model for the single sflt1 (sflt1 cko) isoform reported in mice (removal of intron 13). Renal phenotype was examined by evaluating kidney function and histology. qPCR and Northern blot were used to identify splice variants of Flt1; 3’RACE was used to clone the spliced genes. Proteins of splice variants were generated by BacMam system.

Results: We generated sflt1 cko mice, and confirmed the deletion of Flt1 intron 13 using Southern blot. Surprisingly, it did not result in any overt kidney phenotype by 6 months of age. Northern blot and Western blot analyses revealed the existence of a major compensatory isoform, previously reported as human-specific. We also confirmed the existence of 17 new sflt1 isoforms in RNA isolated from mice and 12 from human podocytes. Plasmablasts were stained for sclerostin, a marker of plasma cells.

Conclusions: We report a large number of novel, soluble Flt1 isoforms in both mouse and human plasma samples. We posit that the presence of these isoforms compensates for the loss of sflt1 in our transgenic model. The functions of these isoforms warrant further investigation and may provide insight into regulation of VEGF levels, podocyte function and preeclampsia.

FR-PO351 Polarity Signaling at the Kidney Filtration Barrier: Questioning the Function of Par3A Sybilie Köhler,1 Markus M. Rinschen,1 Carien M. Niessen,2 Wilhelm Bloch,3 Bernhard Schermer,2 Thomas Benzing,2 Paul T. Brinkkoefter.1,2 1 Dept of Internal Medicine and Center for Molecular Medicine, Univ Hospital Cologne, Germany; 2 Cologn Excellence Cluster on Cell Signaling in Health and Disease (CECAD), Univ of Cologne, Germany; 3 Dept of Molecular and Cellular Sport Medicine, German Sport Univ Cologne, Germany; 4 Dept of Dermatology and CECAD Cologne, Univ of Cologne, Germany.

Background: The slit diaphragm (SD) represents the only cell-cell contact in-between neighbouring podocytes. Classical adherence as well as tight junction proteins are part of this protein-protein supercomplex including ZO-1, ocludin, catenins and cadherins. Polarity signaling is critical to maintain the SD complex as the Par3/PARP complex clusters at the SD via direct interaction of Par3 with nephrin via its PDZ-domains.

Methods: To understand the role of the Par3 proteins at the slit diaphragm, we generated a novel podocyte specific Par3A knockout mouse model where exon 6 is flanked by loxp sites. Following podocin:cre mediated recombination expression of all known Par3A isoforms should be abrogated. We validated cre recombination efficiency, lack of Par3A mRNA and protein expression by qPCR from isolated primary podocytes as well as by immunofluorescence stainings on renal sections.

Results: Mice were born in predicted Mendelian frequency. Par3A-WT mice were born and did not show any signs of disease in their later life. Even challenging Par3A-WT mice with the albumin overload model did not result in an overt glomerular phenotype. Therefore, we performed additional immunoprecipitation experiments for aPKCota out of immortalized mouse podocytes and carried out nLC/MS/MS analysis to identify the aPKCota interacting partners. Interestingly, the most abundant aPKCota interacting proteins were Par6 and Lgl1/2.

Conclusions: Our results challenge the current view of the aPKC/Par3 complex and its role at the slit diaphragm. In contrast to tight junctions where AKP-site-clustering by Par3, its role at the SD is independent of Par3A. Here Lgl1/2 seem to be the predominant interactors clustering aPKC/Par3 at the SD.

FR-PO352
Focal Segmental Glomerulosclerosis (FSGS) Permeability Factor (FSPF) Interacts with Glomerular Filtration Barrier Through Glycoconjugates Ram Sharma,1 Ellen T. McCarthy,2 Tarak Srivastava,3 Virginia J. Savin,4 Mukut Sharma,1 1Renal Research, KC VA Medical Center - MBRF, Kansas City, MO, 2Kidney Inst, KU Medical Center, Kansas City, KS, 3Renal Div, UMCK Children’s Mercy Hospital, Kansas City, MO.

Background: Galactose (Gal) blocks the FSGS serum-surface induced increase in in vitro glomerular albumin permeability (P_a) (Trans Res 2008, 151:288-292) and decreases proteinuria in some patients with recurrent FSGS (NDFT 2009, 24:2938-2940). Thus, the interaction of FSPF with glomerular cell surface glycoconjugates may play an essential role in its effect on the filtration barrier.

Methods: We selected sugars and lectins to model the interaction between glomerular glycoconjugates and FSPF. We used, (a) affinity techniques to evaluate the binding of FSPF with immobilized sugars (b) immobilized neuraminidase to remove sialic acid to assess its significance in FSPF-induced increase in P_a in (i) Gal and (ii) GalNAc-specific lectins to determine their effect on FSPF, results are shown as fluorescence.

Results: Plasma FSPF activity was retained by immobilized Gal, GalNAc or galactosamine. Gal dose-dependently blocked FSPF-induced increase in P_a (10^-10 M) and partially reversed the effect of FSPF on P_a (p<0.01). In contrast, glucose, glucosamine or mannose did not interact with FSPF. Removal of sialic acid activity neuraminidase diminished the FSPF-induced increase in P_a. We screened twenty Gal/GalNAc-specific lectins as potential mimetics of FSPF. Only Dolichos biflorus agglutinin (DBA, 10 mg/mL) and Helix pomatia lectin (10 mg/mL) increased P_a to 0.65 and 0.55, respectively (p<0.001). The increases in P_a, like that induced by FSPF was blocked by Gal (100 µM) (p<0.001). Immunohistochemistry revealed the interaction of FSPF with β1-integrin-recognizing domains of FSPF participate in its interaction with specific sugar(s) of glomerular cells resulting in altered filtration barrier function. Our novel findings regarding the affinity of FSPF for select sugars, the loss of activity after removal of sialic acid and the direct effect of certain lectins on barrier function provide new information regarding the molecular composition of FSPF and its interaction with glomerular proteins/glycolipids.

FR-PO353
EPB41L5 Is a Critical Regulator of the Kidney Filtration Barrier Christoph Schell,1 Martina Suhn,1 Manuel Rögg,1 Martin Helmsdäter,1 Mariko Hirano-Kobayashi,2 Tobias B. Huber.1 1Dept of Nephrology, Univ Medical Center Freiburg, Freiburg, Baden-Württemberg, Germany; 2Laboratory for Vertebrate Body Plan, Center for Developmental Biology - RIKEN, Kobe, Kobe, Japan.

Background: Podocyte loss represents the final common pathway of various glomerular pathologies. Hence, tightly regulated adhesion towards the glomerular basement membrane is a fundamental biological process of glomerular podocytes.

Methods: Based on podocyte single cell isolation and a mass-spec candidate approach the composition of podocyte focal adhesions was resolved. Combining a drosophila nephropathy model with a Newly generated conditional mouse model and various high resolution microscopy techniques (TEM, STORM) the candidate protein EPB41L5 was analyzed.

Results: Knockdown of the Epb41l5 homolog Yurt in drosophila nephropathies resulted in podocyte detachment and decreased renal function. Evaluation of a genetic conditional knockout model revealed a rapid loss of podocytes implicating deregulated podocyte-specific deletion of FSPF expressing domains of FSPF participate in its interaction with specific sugar(s) of glomerular cells resulting in altered filtration barrier function. Our novel findings regarding the affinity of FSPF for select sugars, the loss of activity after removal of sialic acid and the direct effect of certain lectins on barrier function provide new information regarding the molecular composition of FSPF and its interaction with glomerular proteins/glycolipids.

Conclusions: Our findings indicate that EPB41L5 is a highly conserved, specific regulator of podocyte adhesion by modulating focal adhesion composition and function. Future studies will need to clarify its potential implications in genetic and acquired glomerular pathologies.

FR-PO354
The Effect of Anti-PLA2R Autoantibodies on Human Podocytes In Vitro Marylene Frescaud.1 Rachel Lennon,2 Paul E. Brinchley.1 1Welcome Trust Cell-Matrix Research, Univ of Manchester, Manchester, United Kingdom; 2Inst of Cardiovascular Sciences, Manchester Royal Infirmary, Manchester, United Kingdom.

Background: PLA2R was identified as a major target antigen in idiopathic membranous nephropathy. 70% of patients have circulating autoantibodies which bind this receptor on the podocyte leading to immune complex deposition in the glomerular basement membrane. We recently demonstrated the effect on PLA2R expression on PLA2R and Necropsy tissues from patients. We produced the first 3D model of PLA2R, domains and demonstrated that autoantibodies are of high affinity. We seek to understand if affinity-pure anti-PLA2R alone in the absence of complement can modulate podocyte function.

Methods: We prepared affinity purified human anti-PLA2R (91% IgG4, 9% IgG2) and assessed podocyte morphology following antibody treatment using immunofluorescence staining of actin and measurement of cell surface area and circularity. Integrity of the filtration barrier was assessed by Electric Cell-substrate Impedance Sensing and the

response of a confluent monolayer of differentiated podocytes to 10mg/ml purified human anti-PLA2R and apoptosis was measured by cleaved caspase-3 staining in podocytes and oxidative stress was measured with CellROX reagent in differentiated podocytes challenged with the autotaxin.

Results: We have developed an in vitro podocyte model to define mechanisms of anti-PLA2R effects on cell morphology and function. Purified anti-PLA2R altered podocyte shape, with rounding and loss of actin stress fibres within 24 hours. Integrity of a confluent podocyte monolayer was significantly reduced at 72 hours by anti-PLA2R but not by the IgG control. Within 30 minutes of anti-PLA2R treatment, there was evidence of caspase-3 cleavage and podocytes peaking at 6 hours. Treatment with anti-PLA2R induced anti-free radical generation (P<0.0001, treated vs. untreated), triggering oxidative stress which could be neutralised using a scavenger.

Conclusions: Anti-PLA2R in the absence of complement activation modulates podocyte cell morphology by inducing changes in cell shape and monolayer permeability, activation of free radical production and apoptosis.

Funding: Private Foundation Support

FR-PO355
Deletion of the Ste20-Like Kinase, SLK, in Podocytes Induces Injury Andrey V. Cybulsky,2 Elena Torban,1 Joan Papillon,1 Julie Guillermette,1 Natalya Belkina.2 1Medicine, McGill Univ, Montreal, QC, Canada; 2NIH, Bethesda, MD.

Background: SLK is essential for embryonic development, and may play a key role in wound healing, tumor growth and metastasis. Expression and activation of SLK is increased during recovery from ischemic acute kidney injury. Overexpression of SLK in glomerular epithelial cells/podocytes in vivo induces injury and proteinuria. Conversely, reduction of SLK expression in podocytes leads to loss of foot process effacement and microvesicular transformation of podocyte plasma membranes. Mean foot process width was ~2-fold greater in KO, compared to control. By immunofluorescence microscopy, WT1-positive cells were reduced by 35% in KO mice compared to control, and staining for nephrin and podocynx was reduced in KO mice by 20-30%. SLK is reported to phosphorylate ezrin. Staining for phosphorylated ezrin/radixin/moesin (ERM) was reduced by 20% in KO glomeruli, in keeping with reduced SLK catalytic activity in glomeruli; however, tubular phospho-ERM staining was comparable in KO and control.

Conclusions: Podocyte-specific deletion of SLK leads to albuminuria at 4-5 months of age in male mice, and 9-9 months in female mice, which persisted for up to 13 months (albumin/creatinine in KO was 2-3-fold above control). At 11-12 months, KO mice did not show renal histologic abnormalities by light microscopy, and glomerular area of KO was comparable to control. However, by electron microscopy, KO mice showed focal foot process effacement and microvesicular transformation of podocyte plasma membranes. Mean foot process width was ~2-fold greater in KO, compared to control. By immunofluorescence microscopy, WT1-positive cells were reduced by 35% in KO mice compared to control, and staining for nephrin and podocynx was reduced in KO mice by 20-30%. SLK is reported to phosphorylate ezrin/radixin/moesin (ERM) was reduced by 20% in KO glomeruli, in keeping with reduced SLK catalytic activity in glomeruli; however, tubular phospho-ERM staining was comparable in KO and control.

Funding: Government Support - Non-U.S.

FR-PO356
A Podocyte-Specific Knockout of the DNA Repair Gene Erclecs to Proteinuria and Focal Segmental Glomerulosclerosis Fabian Braun,1 Roman Aaron Akbar,1 Björn Schumacher,2 Wilhelm Bloch,1 Bernhard Schermer,1 Thomas Benzing,1 Christine E. Kutsch.1 1Nephrology, Univ Hospital Cologne, Cologne, Germany; 2CECAD, Univ Hospital Cologne, Cologne, Germany; 3German Sport Univ Cologne, Cologne, Germany.

Background: The prevention and therapy of aging-related diseases will become a major health problem. Among elderly patients mild to severe impairment of kidney function is common. Models to study renal aging have not been established yet.In a previous study, we identified a progeria mouse model of Ercc1-deficiency to exhibit expression profiles similar to those of glomerular aging in wt mice. Ercc1 is involved in nucleotide excision repair, facilitating 5' incision around bulky DNA lesions. In humans, the lack of Ercc1 was comparable to control. However, by electron microscopy, KO mice showed focal foot process effacement and microvesicular transformation of podocyte plasma membranes. Mean foot process width was ~2-fold greater in KO, compared to control. By immunofluorescence microscopy, WT1-positive cells were reduced by 35% in KO mice compared to control, and staining for nephrin and podocynx was reduced in KO mice by 20-30%. SLK is reported to phosphorylate ezrin/radixin/moesin (ERM) was reduced by 20% in KO glomeruli, in keeping with reduced SLK catalytic activity in glomeruli; however, tubular phospho-ERM staining was comparable in KO and control.

Conclusions: Podocyte-specific deletion of SLK leads to albuminuria, loss of podocytes and morphologic evidence of podocyte injury. Thus, SLK is essential to the maintenance of podocyte integrity as mice age. The mechanism may, at least in part, relate to ezrin phosphorylation and cytoskeletal integrity.

Funding: Government Support - Non-U.S.
Conclusions: Our study reveals a critical role for nucleotide excision repair in murine podocytes. This gene is expressed in glomerulosclerosis and causes a phenotype with early-onset proteinuria and stunted growth. The role of Ercc1 in a podocyte cell culture model.

FR-PO359

Regulation of Fascin-1 by Mechanical Stress in Podocytes

Felix Kliewer,1 Christian Scharf,2 Sandra Schordan,1 Elisabeth Rumpel,1 Katrin Darm,2 Silke Vogelgesang,1 Kerstin U. Amann,1 Henny Wegner,1 Jürgen Giebel,1 Karlıhs Endlich,1 Nicole Endlich.1  

Anatomy and Cell Biology, Univ Medicine of Greifswald, Greifswald, Germany; 2ENT, Univ Medicine of Greifswald, Germany; 1Pathology, Univ Medicine of Greifswald, Germany; 2Nephropathology, Univ Hospital of Erlangen, Germany.

Background: Glomerular hypertension causes glomerulosclerosis via the loss of podocytes, which are challenged by an increased mechanical load. We and others have demonstrated that podocytes are mechanosensitive cells. However, the response of podocytes to stretch remains incompletely understood.

Methods: Using 2D fluorescence difference gel electrophoresis (2D DIGE), we analyzed the proteome of cells of our mouse podocyte cell line that were cultured on flexible membranes with or without cyclic biaxial mechanical stress (0.5 Hz, 5% linear strain, 3 d).

Results: Mechanical stress profoundly altered the podocyte proteome. Several spots containing the actin-bundling protein fascin-1 were differentially regulated by mechanical stress. By immunofluorescence, fascin-1 was found to colocalize with nephrin in mouse kidney sections. The presence of fascin-1 in foot processes was confirmed by immunoelectron microscopy.

Conclusions: In summary, mechanical stress dephosphorylates fascin-1 in podocytes thereby increasing the actin-bundling activity of fascin-1. Fascin-1 may play an important role in the adaptation of podocytes to mechanical stress.

Funding: Government Support - Non-U.S.

FR-PO360

Deletion of the Vps34 Downstream Effector PIKfyve Establishes Milder Endocytic Dysfunction in Healthy Glomerular Podocytes Compared to Proximal Tubular Cells

Madhusudan Venkataderry, Rakesh Verma, Sanjeevkumar R. Patel, Puneet Garg. Internal Medicine/Nephrology, Univ of Michigan, Ann Arbor, MI.

Background: The mechanisms by which the glomerular filtration barrier prevents the loss of large macromolecules and at the same time maintain the filter remain poorly understood. Recent studies have proposed that podocytes play an active role in both endocytosis of filtered macromolecules and maintaining the filtration barrier.

Methods: We generated podocyte and proximal tubular specific deletion of PIKfyve using the cre-loxP system. Indirect IF and immune EM was used to assess the endocytic pathways.

Results: Deletion of a key endosomal trafficking regulator, the class III phosphoinositide 3-kinase or Vps34 in podocytes results in aberrant endosomal membrane morphology and podocyte dysfunction. We recently demonstrated that the vacuolation phenotype in cultured Vps34-deleted podocytes is due to the absence of a substrate for the Vps34 downstream effector PIKfyve. PIKfyve is a FYVE finger domain containing phosphoinositide 5-kinase that phosphorylates Vps34-generated phosphatidylinositol (PtdIns) 3P to produce PtdIns(3,5)P2. PIKfyve perturbation and PtdIns(3,5)P2 reduction have been shown to result in massive membrane vacuolation along the endosomal system. We show here that deletion of PIKfyve in endocytically active proximal tubular cells resulted in the development of large cytolytic vacuoles that appear as a result of arrested endocytic traffic progression at a late-endosome stage. In contrast, deletion of PIKfyve in podocytes did not alter significantly the endosomal morphology even in aged, 18-month-old mice. However upon culturing, the PIKfyve-deleted podocytes obtained from the knockout mouse developed massive cytolytic vacuoles. Measurement of phosphoinositides using HPLC shows reduction of both PtdIns(3,5)P2 and PtdIns(3,5)P3 in PIKfyve deleted podocytes in vivo confirming reduced PIKfyve enzymatic activity following deletion. Using double fluorescent mitochondria mice we were able to confirm Cre-mediated gene deletion in both podocytes and proximal tubular cells in vivo.

Conclusions: In summary, these data suggest that healthy podocytes have a low level of endocytic flux in vivo.

Funding: NIDDK Support
Albumin-Induced Podocyte Injury Can Be Endocytosis-Independent

Shirpa Agrawal, Xiaojing Nie, Tetsuya Kitao, Melinda A. Chanley, William E. Smoyer.
Clinical and Translational Research, Research Inst at Nationwide Childrens Hospital, Columbus, OH; Pediatrics, Ohio State Univ, Columbus, OH.

Background: Endocytosis plays a crucial role in podocytes in nephrotic syndrome, wherein podocytes are exposed to serum levels of albumin. We have previously reported an association between podocyte exposure to albumin (and its associated factors) and proteinuria, cell injury and induction of pro-inflammatory genes. We thus hypothesized that albumin-induced podocyte injury can also be partially endocytosis independent.

Methods: Endocytosis was analyzed by fluorescence microscopy and fluorometry in cultured differentiated podocytes at varying temperatures and times in the absence or presence of inhibitors of clathrin- and caveolae-mediated endocytosis. Cells were analyzed for viability, activation of major kinases (p38, ERK1/2, JNK, MK2), and expression of pro-inflammatory, heat shock, and glucocorticoid-regulated genes.

Results: Podocytes at 37°C, but not at 4°C, were attenuated by inhibitors for both clathrin- and caveolae-mediated endocytosis. Inhibition of endocytosis, however, did not correlate with reductions in kinase activation or pro-inflammatory gene induction. While albumin exposure resulted in lower endocytosis in murine vs. human podocytes, murine cells activated kinases, induced pro-inflammatory genes and exhibited cell death more than human podocytes.

Conclusions: Inhibition of both clathrin- and caveolae-mediated albumin endocytosis did not correlate with activation of kinases and induction of pro-inflammatory genes in podocytes. Moreover, disparate responses were identified in human vs. mouse podocytes with regard to albumin endocytosis, cell injury, kinase activation, and pro-inflammatory gene induction. Taken together, our data suggest that although podocytes endocytose albumin in both clathrin- and caveolae-mediated manners, albumin-induced podocyte injury can occur in an endocytosis-independent manner.

FR-PO361

Molecular Targeting of Nephi1 Signaling: A Therapeutic Approach to Protect Podocyte Injury

Deepak Nihalani, Ehtesham Ari, Fnu Ashish, Lawrence B. Holzman.
Medicine, Univ of Pennsylvania, Philadelphia, PA; Proteomics, Inst of Microbial Technology, Chandigarh, India; Medicine, Temple Univ, Philadelphia, PA.

Background: Glomerular injuries that induce podocyte dysfunction are the leading causes of renal malfunction. Podocyte proteins Nephrin and Nephi1 are essential components of the glomerular filtration barrier and signaling from these proteins is involved in maintaining podocytes structure and function. Thus understanding the mechanisms that regulate signaling and organization of these proteins are therapeutically valuable.

Methods: This study presents a novel hypothesis that attenuating Nephrin and Nephi1 signaling is therapeutically significant in protecting podocytes from injury. Consistent with this hypothesis, using a unique protein transduction approach, we recently demonstrated that inhibiting Nephi1 signaling protected podocytes from injury. Since we first reported the structures of Nephi1 and associated ligands, we have used high-resolution NMR and molecular models or compounds that can specifically bind Nephi1 and target its interactions.

Results: Using a novel approach of targeting protein-protein interaction, we identified many potential molecules and to test the proof of principle and the validity of this approach, cell lines expressing compounds ID (odesmosine) were commercially procured and investigated. Biochemical experiments suggested that addition of ID under in vitro and in vivo conditions significantly increased and stabilized the interaction between Nephi1 and ZO-1. As a consequence, induction of glomerular injury by PAN (purinomycinaminonucleoside) did not proceed in wild type podocytes but was completely blocked in the cells resistant injury induced changes in their actin cytoskeleton. Furthermore, using an in vivo zebrafish model system, we demonstrated that pre-treatment with ID rescued zebrafish from adriamycin induced toxicity and preserved their renal filtration system.

Conclusions: This study presents a new approach that provides compelling evidence that molecular approaches can be used to directly target slit diaphragm proteins to prevent podocyte damage.

Genome-Modified Pluripotent Stem Cells Reveal a Critical Role for Podocalyxin in Human Podocyte Morphogenesis

Benjamin S. Freedman, Craig R. Brooks, Zheng Zhou, Joseph V. Bonventre, Brigham and Women’s Hospital; Harvard Medical School; Univ of Washington School of Medicine.

Background: Human pluripotent stem cells (hPSCs) can self-renew extensively and differentiate into diverse tissues. We investigated the potential of hPSCs to differentiate into podocytes, an apical sialomucin altered in glomerular disease states.

Methods: Cas9 nuclease and guide RNAs targeting PODOX were transfected into hPSCs. PODOX clones were identified by chromatogram and immunoblot analysis. hPSCs were differentiated stepwise with growth factors into kidney progenitor cells present a new tool for investigating human podocytes of junctional complexes and podocyte spacing. Our findings suggest a functional role in disease in a dish’ models and therapeutic screens.

Extracorporeal Mesenchymal Stromal Cell Therapy for Critical Care

Biju Parekkadan. Surgery (Bioengineering), Harvard Medical School, Massachusetts General Hospital, Boston, MA.

Background: Human mesenchymal stromal cells (MSCs) metabolize and secrete anti-inflammatory and regenerative factors that can be of systemic benefit to acute, critical injury. When transplanted MSCs are limited in dose and rapidly cleared by the host, severe non-targeting or adverse effects to this therapy may occur.

Methods: MSCs were integrated into hollow-fiber bioreactor devices whereby the cells, separated by a permeable membrane, can directly and dynamically provide systemic therapy without entering the body. We present a human scale prototype of the technology that has shown sustained cell viability and function throughout cGMP manufacturing in preparation for a Phase I human trial set to begin in 2015.

Conclusions: This study demonstrates the successful transport of creatinine in an artificial microvascular circulation model without a blood pump. Pharmacological analysis of this bioreactor technology in vivo allowed for an unprecedented look at MSC function during product use and verified potency that is unattainable by conventional intravascular delivery of MSCs.

Extracorporeal Diffusional Clearance of Silicon Nanopore Membranes in a Porcine Peritoneal Blood Circuit

Nephrology, UCSF; Surgery, UCSF; Bioengineering, UCSF; Silicon Kidney, LLC; Ben Chiu Consulting; ‘H-Cubed; Nephrology & Hypertension, Vanderbilt Univ.

Background: Silicon nanopore membranes designed for hemofiltration (HF-SNM) have demonstrated increased permeability compared to polymer membranes. Previously, we reported in-vitro data showing a 3-fold improvement in diffusive clearance using silicon nanopore membranes. Here we test the diffusive clearance of HD-SNM vs. HF-SNM in an extracorporeal peritoneal model without a blood pump.

Methods: A microelectromechanical systems fabrication technique was used to decrease the SNM thickness (HD-SNM 100 µm vs HF-SNM 400 µm). Polyethylene glycol coated HD-SNM (n=3) and HF-SNM (n=3) with sub-10nm pore sizes were tested in a single channel flow circuit (b=1mm). Vascular access was obtained by placing tunneled catheters within the carotid artery and jugular vein of healthy ~50kg pigs. Blood flow was achieved via the arterial-venous pressure differential (35-120mmHg). Dialysate was recirculated in a counter-current fashion (30ml) and flow rates were adjusted to ensure 0 transmembrane pressure. Dialysate creatinine concentration was measured hourly and serum creatinine was measured at time 0 and 6 hours. The pore size of each SNM was measured before and after dialysis exposure using hydraulic permeability.

Results: Blood flow was limited by the arterial-venous pressures differential with <5mmHg pressure drop. The average plasma creatinine concentration was 1.38±0.1mg/dL. The creatinine clearance was 37.2±3.9mmol/min/m² (HF-SNM) vs 126.0±27.1mmol/min/m² (HD-SNM) at 92±5.36ml/min. There was no detectable albumin transport into the dialysate. The HD-SNM maintained a mechanical integrity at over 2500mL/min in vivo. The total pore size change following blood exposure was 1±4.5mm vs 19±1.2mm for HF-SNM and HD-SNM, respectively.

Conclusions: This study demonstrates the successful transport of creatinine in an extracorporeal circuit without a blood pump. We also showed a ~3-fold improvement in diffusive clearance of creatinine using HD-SNM in a blood circuit.

Hemofilter Design Based on Computational Simulations of Pulsatile Flow

Amanda Beck,1 Joseph J. Groszek,2 Clark David Kensinger,1 Daniel Colvin,1 Shuvo Roy,1 William Henry Fissell,2 1Dept of Radiology and Radiological Sciences, Vanderbilt Univ; 2Div of Nephrology and Hypertension, Vanderbilt Univ; 3Dept of Surgery, Vanderbilt Univ; 4Dept of Bioengineering and Therapeutic Sciences, Univ of California San Francisco.

Background: In the US, the ratio of patients with end stage renal disease (ESRD) on dialysis to annual kidney transplants for ESRD is 20:1 (USRDS 2014 Annual Data Report), underscoring the grave need for an artificial kidney alternative. Hypothesis: For the development of a hemofiltration device, computational fluid dynamics (CFD) simulations can predict potentially thrombogenic zones [e.g. low and high wall shear stress (WSS) areas, associated with stasis and shear induced cell damage, respectively] and can be used to refine device design to minimize such areas.

Methods: CFD simulations of pulsatile blood flow through a prototype hemofilter were validated in vitro using MR velocimetry. Hemofilters were implanted in large animals (n=4) for 30 days or until thrombosis and then explanted. Based on the CFD results, a subsequent flow path was devised to minimize predicted thrombogenic regions, and simulations were conducted on the second design.

Results: The in vitro and in silico models showed strong agreement. Pulsatile CFD simulations of the prototype device demonstrated zones of low WSS, and clot formation occurred in two of the four implants at the CFD-predicted sites. Flow simulations of the second-generation design showed reduced areas of low WSS.

Conclusions: Thrombogenic low WSS regions predicted in silico correspond with clot formation in vivo. In addition to predicting areas of thrombogenicity, CFD can be used to guide hemofilter device design to minimize these sites.

Figure 1. CFD results, with gray arrows indicating flow direction. A: WSS averaged over all butystatic acetabular for the prototype shows low WSS regions (black arrows) dominate the cardiac cycle. B: Compared to the prototype (left), the second-generation (right) design mitigates areas of instantaneous low WSS (black arrows).

Characterization of Dialyzer Membranes by MALDI-Mass-Spectrometric Imaging Techniques

Joachim Jankowski, Vera Jankowski. Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, Germany.

Background: Dialyzer polymer membranes are grossly classified as cellulose-based and synthetically produced membranes. Although cellulose membrane’s clearance and mechanical properties qualify it for use in dialyzer membranes, hydroxyl groups of these membranes lead to strong activation of the complement system. Therefore, recent membranes are manufactured from synthetic polymers.

Methods: For physical and chemical characterization of these materials of dialyzer a wide range of analytical methods is available. Over the last few years, MALDI mass-spectrometry has been developed as a powerful tool for space-resolved analysis, not least because of its mass accuracy and high sensitivity. MALDI imaging techniques combine the potential of mass-spectrometric analysis with imaging additional spatial information with relevance for biocompatibility of the dialyzer membranes. MALDI imaging enables the visualization of localization and distribution of biomolecules, chemical compounds and other molecules on different surfaces.

Results: In this study, surfaces of polymeric dialyzer membranes, consisting of polysulfone (PS) and polyvinylpyrrolidone (PVP) were investigated, regarding to chemical composition and physical characteristics. The MALDI imaging demonstrated that the abluminal membrane surface is more consisting of polysulfone than polyvinylpyrrolidone, the luminal membrane surface displayed more PVP than PS. The addition of PVP as hydrophilic modifier to polysulfone-based membranes increases the biocompatibility of the dialyzer membranes. The analysis of polymer distribution is a relevant feature for characterization of dialysis membranes.

Conclusions: In conclusion, MALDI imaging is a powerful technique for polymer membrane analysis, regarding not only detection and identification of polymers but also localization and distribution in membrane surfaces, which has strong impact on the biocompatibility of the dialyzer membranes.

FR-PO368

Effect of Peristasis with Pediatric Catheters

Anna Lorenzin, Francesco Garzotto, Claudio Ronco. Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.

Background: Thanks to the technological advances of the last years, Continuous Renal Replacement Therapy CRRT machines have been upgraded and equipped with circuits specific for pediatric patients. To date, to treat these patients the most used catheter is the venous T-French, however with a neonate it is inadequate for the dimensions. It is not clear if it is possible to use a smaller catheter with adult CRRT machine or a specific pediatric machine is needed. We set up a dedicated circuit to assess the usability of a peristaltic blood pump designed for adults and compare it with a pediatric pump in terms of access pressure. Methods: We performed in vivo tests with a peristaltic pump, the CARPEDIEM pump with pediatric catheter of 4Fr and a venous pressure sensor, and we compared this to the CARPEDIEM pump with adult catheter. Results: We are presenting the data of the two pumps with 5Fr catheter and 15ml/min flow rate. Analyzing the arterial pressure values, we found that the spikes are more frequent with the CARPEDIEM pump than with the adult one. The mean and max value are respectively(-50, -28mmHg) and a mean Dp=18mmHg with CARPEDIEM and a mean Dp=40mmHg with adult pump. Conclusions: We can notice that there is an high discrepancy in terms of Dp between the two pumps: high values of Dp lead to an high shear stress. As the shear stress in one of the main causes of hemolysis, it seems that a specific pediatric machine is advisable for neonates that need small catheter. Further investigation have to be perform with blood to confirm our results.

FR-PO369

Hemodialysis with CARPEDIEM Machine: An In Vitro Test

Anna Lorenzin, Dario Galeano, Stefania Aresu, Francesco Garzotto, Claudio Ronco. Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.

Background: Despite the development of continuous renal replacement therapies machines, their employment still remain unsuitable in newborn and infants. This gap has been filled thanks to the coming of a specific pediatric dialysis machine CARPEDIEM. To date it is set up only for continuous hemofiltration CVVHDFs it provides a wider range of applications, specific filters have been conceived to implement a continuous hemodialysis CVVHID. We tested a prototype kit to evaluate its performance in terms of clearance K.

Methods: We performed in vitro test with plasma for the 3 filters HD010 HD620 HD035 (surface 0.1, 0.2, 0.35 m²/cm²). Fibers were put manually into the housing of CVVH filters. CVVHID in cocurrent configuration otherwise a longer circuit is required is based out using infusion pump as dialysate pump and ultrafiltration as effluent pump. All the combinations of plasma and dialysate flow rate are set [QF, 5, 10, 15 ml/min; QD, 1, 5, 10, 15 ml/min; net ultrafiltration is 0 ml]. Plasma samples are collected every QF, QD change (time interval 8 min) to evaluate K of urea and creatinine using the standard formula.

Results: Among all filters, our tests estimated a common trend of urea K (min 3.0, max 10.5 ml/min) and creatinine K (min 3.4, max 11.8 ml/min). Filters efficiency increases with the increase of both the flow rates QF, QD (fig.1), moving towards a plateau at the higher flows configuration.

Figure 1. Clearance curves of filter HD_010 in the different QF, QD configurations.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: CVVHD with CARPEDIEM seems to be effective for diffusion transport of small molecular weight solutes, according to specific clinical needs. In the light of these findings, CARPEDIEM can be a promising alternative to peritoneal dialysis, i.e., in treating electrolyte imbalance with accurate fluid removal. Lymphedema: handmade filters could induce variability in the results due to disposition and variable number of fibers.

FR-PO370
Removal of Protein-Bound Uremic Toxins: Simulating the Effect of Toxin Displacement versus Increase in Dialyzer Clearance
Vaibhav Maheshwari,1 Stephan Thijssen,1 Doris H. Fuertinger,1 Franz Kappel,1 Peter Kotanko.1 Renal Research Inst, NY; 2Univ of Graz, Austria.

Background: Protein-bound uremic toxins (PBUT) exert numerous deleterious effects. Their removal with standard hemodialysis (HD) is poor. Meyer et al. have modeled the impact of increasing dialysate flow rate and dialyzer mass transfer area coefficient on PBUT removal [JASN, 2004]. Here, we compare those results to a novel approach based on PUBT displacement by infusion of binding competitors [Tao, Blood Purif, 2015].

Methods: We developed a multi-compartment patient model and a dialyzer model depicting spatiotemporal dynamics based on law-of-mass-action kinetics. We chose indoxyl sulfate (IS) as a prototypical PUBT and ibuprofen as the binding competitor. We modeled IS removal during a 4-hr HD ($Q_p=250$ mL/min, $Q_{sw}=750$ mL/h, initial total IS 100 µmol/L, initial free fraction of IS 8%), with IS dialyzer clearances from 150 to 200 mL/min. This was compared to IS removal achieved by ibuprofen infusion (800 mg/200 mL) into the arterial line at 50 mL/hr (IS clearance 150 mL/min).

Results: IS removal during HD with a clearance of 150 mL/min was 438 µmoles (plasma reduction ratio 34%), which conforms to literature data [Niwa, Blood Purif, 2012]. With IS clearance of 200 mL/min, removal improved by 8.7% to 476 µmoles. With ibuprofen infusion (IS clearance back at 150 mL/min), removal improved by 11.2% to 487 µmoles.

Conclusions: Our model yields predictions of IS kinetics that agree with empirical and modeled data [Niwa et al.; Meyer et al.]. Of note, a mere 8.7% improvement in IS removal would require an increase in dialysate flow rate from 800 to 1350 mL/min plus a 70% increase in membrane surface area. The modeled ibuprofen infusion alone yields an 11.7% improvement even absent an increase in dialyzer clearance. The use of binding competitors holds great promise. These results require validation in vivo.

Membrane versus Peristaltic Blood Pumps for Extracorporeal Therapies: Comparison on Index of Hemolysis
Francesco Garzotto,1 Sean M. Bagshaw,2 Claudio Ronco.1 Nephrology and IRRH, St. Bortolo H., Italy; 2Critical Care Medicin, Univ of Alberta Hospital.

Background: Hemolysis during extracorporeal treatments mainly occurs as a consequence of mechanical stress on the blood. Red blood cell deterioration is undetected because it is far from any acute hemolytic threshold but represents a potential harm for patients. A new membrane-piston driven pump has been recently proposed on the S.A.M. (Spectral Medical Inc, Toronto) device designed for continuous renal replacement therapies (CRRRT). Aim of this investigation is to compare the membrane with peristaltic pumps by measuring the Normalized Index of Hemolysis NIH during in vitro testing.

Methods: Three sessions of hemoperfusion with a line inserted in place of a hemofilter were performed both with SAM and Prismaflex (Baxter International). A single pool of fresh heparinized bovine blood (Heparin 500 u/L, Hb 12±1 g/dl,Base Excess 0±5 mmol/L) were split into three aliquots containing 900 mL (Control, SAM, Prismaflex) and circulated for 6 hours/session. Blood: dial samples were drawn at baseline, 30 min and every 1 hour. NIH were calculated as median hourly variation of free hemoglobin and used for comparison.

Results: NIH values of 0.12±0.03 and 0.13±0.09 mg/100L for SAM and Prismaflex respectively are lower than those reported in literature due to the simplified circuit used (no vascular access and filter). Creation of hemoglobin between sam and control, and prisma and control are non-significant fig 1a. Slope of the curves can describe the creation of hemolysis are nearly identical with a slow rate of production of free hemoglobin.

Conclusions: Device compatibility in terms of lethal damage to blood cells, is an important aspect of the development of artificial organs. Since a validation based on dangerous level of free hemoglobin do not exist, an empirical evaluation using comparative test suggest that piston driven membrane is safe from a hemolysis point of view.

Membrane Driving Blood Flow for Extracorporeal Therapies
Francesco Garzotto,1 Sean M. Bagshaw,2 Claudio Ronco.1 Nephrology and IRRH, St. Bortolo H., Italy; 2Critical Care Medicin, Univ of Alberta Hospital.

Background: From the first application of ContinuousVenousVenesVenousHemofiltration CVVH, the blood flow has been driven by a peristaltic pump. Several attractive alternatives, with both advantages and disadvantages, have been proposed for many years. SAM (Spectral Medical Inc; Toronto, Canada) is a novel instrument, in which the pumping of whole blood and fluids is performed through the use of pistons, chambers and valves. A plastic cartridge blood circuit system fig 1b incorporates all of the pumps, air trap system, pressure monitors and clamps. This circuit is covered on one side by a plastic membrane adhered to the pumping pistons via a drawn vacuum. Aim of the present is to evaluate the new pumping system.

Methods: We set up the machine for CVVH. An 11.5 Fr 20 cm catheter was connected to the lines. We ran the machine for 6 hours in order to characterize the performance of the system.

During the first cycle, suction generated by the drawing back of the piston, moves the blood into the arterial-chamber AC. Positive pressure generated by the piston then drives the blood through the circuit. The camshaft design can allow different profiles for Withdrawal and infusion flows. The largest Priming volume measured (both the ACs full), is 98 mL with a stroke volume for each AC of 14 mL.

Conclusions: CVVHD with CARPEDIEM seems to be effective for diffusion transport of small molecular weight solutes, according to specific clinical needs. In the light of these findings, CARPEDIEM can be a promising alternative to peritoneal dialysis, i.e., in treating electrolyte imbalance with accurate fluid removal. Lymphedema: handmade filters could induce variability in the results due to disposition and variable number of fibers.

Enhanced Middle Molecule Clearance by a Biomimetic Dialyzer Membrane
Joseph J. Groszek,1 Jin Cheng,1 Charles Blaha,2 Rishi Kant,1 Jae Hyun Park,2 Benjamin Chui,2 Ken Goldman,4 Shuvo Roy,1 William Henry Fissell.1
1Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; 2Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; 1Ben Chat Consulting, Sunnyvale, CA; 4H-Cubed, Inc, Olmstead Falls, OH.

Background: Although polymer dialyzers attain very high small solute clearance rates, polyelectrolyte slit pore sizes limit middle molecule clearance by conventional polymer dialyzers. We hypothesized that a biomimetic membrane with uniform slit pores would enhance middle molecule clearance.

Methods: Thin film silicon membrane samples (surface area 1.4 x 10^4 m^2) with micropore, slit-shaped 5-8 nanometer pores (“SNM-HD”) were manufactured as previously described, surface-modified with polyethylene glycol and mounted in a custom designed cartridge. Membrane pore size was estimated from hydraulic permeability measurements. Human blood was spiked with PABA and fluorescent-labelled Ficoll, a polyelectrolyte globular polysaccharide. Blood flow was set at 100 ml/min and dialysate flow varied between 70 and 140 ml/min. Blood and dialysate concentrations of PABA and Ficoll were measured by size-exclusion chromatography. Clearance as a function of dialysate flow rate was extrapolated to estimate kDa as a function of molecular weight.

Results: B2M clearance in high-flux dialyzers is typically 5-8% of the value of urea clearance. PABA clearance was 139 ml/min/m^2, 15.7 Angstrom Ficoll clearance (same radius as B2M) clearance in the SNM dialyzers was 16.9 m/min/m^2, 3.5 fold higher than reported B2M clearance in polymer dialyzers.

Conclusions: A biomimetic membrane of uniform slit pores potentially offers much higher middle molecule clearance than conventional polymer dialyzers.

FR-PO374
Anti-Fouling of Silicon Nanopore Membranes Using SLIPS
Bas Meuseen,1,2 Steven Kim,1 Zohora Iqbal,1 Charles Blaha,1 William Henry Fissell,1 Shuvo Roy.1,2 UCSC; 2Univ of Eindhoven; *Silicon Kidney; Vanderbilt Univ.

Background: Silicon Nanopore Membranes (SNM) have been developed for an implantable bioartificial kidney. However, SNM are subject to fouling and thrombosis with continuous blood exposure. Thin polymer coatings have been applied to SNM as a strategy to limit cell adhesion and protein adsorption. Slippy Liquid Infused Pores (SLIPS) is a biotriposed “omniphobic” surface coating that has been reported to prevent thrombosis and fouling on arteriovenous shunts. Here we present the application of SLIPS coating to SNM and evaluate protein adsorption in vitro.

Methods: SNM with ~10 nm pores were coated with SLIPS and incubated with BSA-FITC (2 mg/ml in PBS) for 24 hours at 37°C. Uncoated (bare) silicon substrates served as controls. Fluorescence microscopy and ellipsometry were used to evaluate the surfaces and water transport through the SNM was tested using established hydraulic permeability assays.

Results: SLIPS strongly reduced BSA-FITC adsorption on SNM compared to bare silicon. Ellipsometry confirmed the presence of SLIPS coating with a thickness of 0.5 ±0.2 nm, which is theoretically thin enough to keep open the pores open in the membrane. However, hydraulic permeability testing revealed no ultrafiltration through the SNM for at least 24 hours and transmembrane pressures of up to 5 psi. SLIPS is a promising and easy-to-use protein repellent coating, but its highly omniphobic characteristic prevents ultrafiltration even through pores that are over 5x the coating thickness. For use in the bioartificial kidney, SLIPS has relevant implications as an anti-fouling coating where an ultra-thin blood compatible, but non-filtering surface is desired.

FR-PO375
Measuring Spatial Trends of Single Nephron Filtration with Molecular MRI
Edwin Baldegger,1 Jennifer R. Charlton,2 Kevin M. Bennett.1 1U. of Hawaii, Honolulu, HI; 2U. of Virginia, Charlottesville, VA; 1U. of Hawaii at Manoa, Honolulu, HI.

Background: To better develop drugs to treat kidney disease their physiological mechanisms during development, noninvasive techniques to measure whole kidney function at the level of the single nephron are needed. We investigated the combined use of two MRI contrast agents, cationic ferritin (CF) and Gd-DTPA, to measure local (voxel) macromolecular and free filtration dynamics in the whole kidney.

Materials: Krebs-Ringer (KR) bicarbonate solution with 7.5 mg/100mL of Fraction-V BSA and a bubbling infusion of carbogen was perfused into isolated rat kidney. Temp was maintained at 37°C. CF in KR solution (0.071 mg/mL of CF), was infused into the system first. Next, a bolus of 0.25 mmol Gd-DTPA in 10mL of KR solution was infused into the perfusion system. All (rates = 5ml/min) Kidneys were imaged using the perfusion with MRI. Voxel time curves were then fitted to a bi-exponential model.

Results: Glomeruli were distinguished by uptake of CF and a distribution of CF accumulation rates and gd-DTPA elimination rates was visible. (Fig 1a-b) We used the location of the glomeruli in 3D and the time course of CF labeling (Fig 1c-d) to discern spatial trends in uptake rate of CF. Time course structures also mapped well with the different morphological structures in the kidney (Fig 1e).

Conclusions: Our results demonstrate that automated quantification is capable of not only distinguishing between anatomical features of kidneys, but also characterizing the degree of abnormality in diseased tissue.

FR-PO376
Automated Quantification of Renal Microvascular Abnormalities: A Novel Computational Mapping Approach
Kyle I. Harrington, Beverly Elizabeth Faulkner-Jones, Katie Bentley, Seymour Rosen. Pathology, Beth Israel Deaconess Medical Center, Boston, MA.

Background: Alteration of the microvasculature is considered to be crucial to the understanding of chronic kidney disease, yet few studies have quantified the microvasculature in normal and diseased kidneys.

Methods: We created customized software for automatically quantifying morphology of renal microvasculature. 10 kidneys (2 nephrectomies, 8 biopsies) were studied; 3 cases of relatively normal tissue, others chosen because of a significant degree of tubulointerstitial injury and included a variety of diseases (diabetes, amyloidosis, end-stage glomerulonephritis, and renal artery stenosis). Images of CD34 stained vessels were segmented, high-pass filtered based on size, and glomeruli were manually segmented. Morphological signatures were calculated using 3 parameters: roundness, angulation, and density.

Results: The normal cortex, as a whole, presented heterogeneity in histogram analysis. However, color density mapping and histogram studies revealed 3 distinct regions: glomeruli (GM), labyrinth (LB), and medullary ray (MR). MR was characterized by correlated angulation (Fig 1). Microvascular density varied in LB but peaked at 3% coverage within a 200um circular radius (Fig 2). Density in MR was approximately the same. As expected, GM density was far greater, sometimes exceeding 11% coverage. With disease, capillary shape did not shift, roundness factor remaining in 0.2-0.3 range (circumferential 1.0). However, diminishment in capillary density was overt (Fig 3), and distribution shifts were marked (peak A) or more moderate (peak B).

FR-PO377
Angio-µCT: New Polymer-Based Contrast Agent Makes Kidney Morphology Look Attractive
Ruslan Hlushchuk, Sebastien Barre, Carlos Correa Shokiche, Valentin Djonov. Inst of Anatomy, Univ of Bern, Bern, Switzerland.

Background: The fundamental features of the morphological substrate of the renal function are nephron number and glomerular volume. The accurate estimation of these parameters has become increasingly important. The present golden-standard method of kidney morphology is the exhaustive physical fractionator-dissector method. It is extremely time-consuming and laborious, let alone disturbing proceeding artefacts. Purpose: To develop a contrast agent appropriate for high-resolution µCT at vivo with superior perfusion features in order to visualize the vasculature and glomeruli of rodent kidney. The elucidated approach should allow fast and reliable estimation of such parameters as nephron number, glomerular volume, glomerular size distribution and kidney volume.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underlines represents presenting author.

440A
Results: the developed contrast agent (µAngiofil) turned out appropriate for µCT ex vivo with superior perfusion and contrast-to-noise features. The obtained µCT datasets were of superior quality and allowed clear visualization of the microvasculature and glomeruli.

In kidney, modern high-resolution micro-CT (SkyScan-1172) provided the whole mouse kidney vasculature in 3D with the spatial resolution of approx. 2 µm. The sample is fixed prior the micro-CT-scan and therefore can be processed for the histological evaluation after the scan. This circumstance brings multiple advantages, including much easier localization of the µCT-findings in the post-scan histological sections.

Conclusions: using µAngiofil we obtained 3D-µCT datasets of superior quality, which are sufficient for estimation of relevant kidney morphometry parameters. The developed angiо-µCT-based approach will substitute the existing golden-standard. Besides classical kidney morphometry, it provides the data on the vasculature through the whole kidney in 3D which makes the technique even more beneficial.

FR-PO378
Rising Accuracy of Transcutaneous GFR Measurement Jochen Friedemann,1,2 Ralf Heinrich,1 Yury Shulhevich,1,2 Johannes Pill,1 Daniel Schock-Kusch,1,2 1Mannheim Univ of Applied Sciences, Inst for Process Control and Innovative Energy Conversion, Germany; 2Mannheim Pharma & Diagnostics GmbH, Germany; 3Friedenberg New Technologies SE & Co. KG, Weinheim, Germany.

Background: Transcutaneous measurement of GFR (GFR) is now getting used frequently in animal studies. tGFR allows consecutive GFR measurements in the same animal even on a daily basis as no blood sampling is required. Here we describe and validate a novel three compartment model (GFR) for GFR assessment by FITC-Sinistrin clearance, automatically correcting influences like bleaching of skin fluorescence.

Methods: Bolus clearance (GFR was measured in awake Sprague Dawley (SD) rats using the commercially available NIC-Kidney system, immediately followed by a blood sampling based constant infusion clearance (cGFR). GFR was calculated by a one compartment model (GFR), GFR and cGFR. Also 46 measurements in SD rats were reevaluated by GFR.

Results: Results are given in table 1. Mean values of the three methods are comparable with no significant difference. The accuracy (larger STD) of GFR is lower compared to GFR and cGFR. This finding was verified by the 46 measurements in SD rats (GFR: 0.97 ± 0.18 ml/min/100g b.w.; GFR: 0.95 ± 0.14 ml/min/100g b.w.).

Conclusions: The results indicate that GFR yields data in comparable accuracy as cGFR. For an apriori estimation of the sample size to detect a change in GFR of 10% in the SD rats investigated, the effect size rises from 0.55 (GFR) to 0.73 (GFR).

FR-PO379
Quantification of the Progressive Fibrosis Development in Mouse Kidney Unilateral Ureteral Obstruction Model Using Fluorescence Lifetime and Second Harmonic Generation Imaging Microscopy Evgenia Dobrinskikh,1 Suman Ranjit,1 John Ross Montford,1 Alexander Ovronikov,2 David J. Orlicky,1 Allison M.D. Lehman,1 Raphael A. Nemiroff,1 Enrico Gratton,1 Seth B. Furgesom,1 Moshe Levi,1 1Univ of Colorado Denver; 2Univ of California Irvine.

Background: Renal fibrosis is considered to be the final common pathway for most forms of chronic kidney disease (CKD) and involves glomerular sclerosis and/or tubulointerstitial fibrosis. There is great interest in identifying renal fibrosis in the early stages of CKD to prevent progression. Unilateral ureteral fibrosis (UUO) is a well-characterized model of CKD and renal fibrosis. Kidney injury and fibrosis usually are assessed by Picrosirius Red staining or immunohistochemistry for collagen isoforms.

Methods: The goal of this study is to compare histologic measures of renal fibrosis to Fluorescence Lifetime Imaging (FLIM) and Second Harmonic Generation (SHG) techniques in our deep imaging microscope DIVER.FLIM and SHGI allow quantification of collagen in unstained tissue and can be adapted for live animal imaging. Male C5BL/6 mice were subjected to UUO of right kidney. At 7, 14 and 21 days, both kidneys were harvested. The uninjured left kidney was used as a control. Serial sections of both kidneys were analyzed using Picrosirius Red staining or FLIM with SHG.

Results: We performed quantification of Picrosirius Red stained-kidneys using polarized light. This showed progressive increase for the number of positive pixels for fibrosis in the left kidney 9631.9±1626.2, 16167.8±6647.7 and 20511.5±5727.6 compared to 5625.3±770.6, 3909.3±2395.9 and 4493.8±2018.4 in the control kidney respectively. Using the Phasor approach to FLIM, comparisons between the two kidneys show that the auto fluorescence lifetime signature give rise to two well separate phasor clusters. Quantification of ten different fields of view for each kidney at the above time-points for SHG signal confirms Picro-Sirius Red scoring.

Conclusions: Finally, the combined FLIM and SHG images let us establish a criterion for quantitative determination of fibrosis directly from the microscope images.

Chemical Imaging: A Novel Approach to Obtaining Label-Free Biochemical Information in Renal Transplant Patients with Recurrent Diabetic Nephropathy Michael J. Walsh,1 Vishal K. Varma,1 Andre Kajdacsy-Balla,1 Sangeev Akkina,2 Suman Setty,1 1Dept of Pathology, Univ of Illinois at Chicago, Chicago, IL; 2Dept of Nephrology, Univ of Illinois at Chicago, Chicago, IL.

Background: The main treatment for end-stage renal disease is kidney transplantation, which over time undergo chronic rejection including changes in the glomerular, tubulointerstitial and vascular compartments. Also, recurrence of disease in diabetics can mimic transplant glomerulopathy. We have identified biochemical markers using Chemical imaging that were associated with recurrent diabetic nephropathy. Chemical Imaging is an emerging approach to obtain images of the biochemical composition of tissue biopsies in a label-free fashion.

Methods: An initial study focused on identifying patients with no evidence of diabetic nephropathy and patients with advanced diabetic nephropathy in native kidneys. Serial sections were acquired and stained with PAS or imaged using chemical imaging. IR spectra were extracted to identify biomarkers associated with diabetic nephropathy progression. A second study identified transplant patients who underwent very rapid recurrent diabetic nephropathy and patients with no evidence of diabetic nephropathy.

Results: Biomarkers were identified that were changed in renal structures associated with the progression of diabetic nephropathy, including increased levels of glycation. These biomarkers were found to be increased in the cohort of transplant patients that underwent rapid diabetic nephropathy recurrence. In addition, the early biopsies from the patients that underwent later diabetic nephropathy progression were biochemically different from the non-progressive patients, suggesting that chemical imaging may identify pre-histological biomarkers that will predict outcome.

Funding: NIDDK Support
Conclusions: We have identified a number of biomarkers that are associated with the advancement of diabetic nephropathy and that we can track the early recurrence of diabetic nephropathy in surveillance biopsies. In addition, we have highlighted a ‘biochemical signature’ that may be predictive of the later progression of diabetic nephropathy recurrence.

Contrast-Echo Ultrasonography Characterizes Kidney Lesions With Accuracy Comparable to Contrast-Enhanced CT or MR

Emily H. Chang,1 Sandeep Kasoji,2 Paul Dayton,1,3 Wui K. Chong,4 Kimryn Rathmell,1 1Univ of North Carolina, Chapel Hill, NC; 2North Carolina State Univ, Raleigh, NC.

Background: Incidental kidney lesions are often detected on imaging performed for other reasons. Indeterminate lesions are further characterized with a contrast-enhanced computed tomography (CT) or magnetic resonance imaging (MRI). These tests have many limitations and are contraindicated in patients with allergies to contrast, metallic hardware and chronic kidney disease (CKD). An accurate alternative study is needed. Contrast-enhanced ultrasound (CEUS) is one potential alternative. CEUS uses microbubbles, non- nephrototoxic, gas-filled bubbles with lipid or albumin shells, as the contrast agent. We investigated the accuracy of CEUS for malignancy in patients with incidental kidney lesions.

Methods: CEUS was performed on 33 patients. Results were independently interpreted by 2 blinded readers and risk-stratified by the Bonnink classification system. Sensitivity, specificity and predictive values were calculated for lesions with histologic diagnosis as the gold standard. As histology was available for excised lesions only, we performed secondary analyses using an expanded gold standard definition that included clinical recommendation.

Results: Of the 33 patients, 12 had CKD and 14 had histologic diagnoses. There was 100% inter-reader agreement in the primary analysis (Figure 1A) and 97% agreement in the secondary analysis (Figure 1B). Sensitivities (94-100%), positive (70-93%) and negative predictive (90-100%) values for CEUS were comparable to CT (83-100, 50-67 and 77-100, respectively) and MRI (81-100, 60-78 and 80-96%, respectively). CEUS specificity (0-56%) was lower than MRI (71-100%).

Conclusions: CEUS has excellent potential as an alternative diagnostic tool for kidney lesions among patients with CT/MRI contraindications. Further evaluation is needed.

FR-PO382
Lead-Free Drape Applied to Xray Detector Significantly Decreased Radiation Scatter During Access Intervention

Jie Cui1, Fengyong Liu2, Zubin Irani3 1Nephrology Dept, Massachusetts General Hospital, Boston, MA, China; 2Interventional Radiology Dept, Chinese People’s Liberation Army General Hospital, Beijing, China; 3Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.

Background: Exposure from scattered radiation can be very high during access interventional procedures because of the relatively closer operative position. The purpose of this study is to evaluate whether applying a lead-free, sterile, disposable drape can decrease scatter radiation exposure during access intervention.

Methods: An upper extremity phantom was placed on the angiography table to mimic real-time patient’s upper extremity access. Using this model, measurement of scatter radiation was made every one foot away from the phantom before and after applying the drape using a collimated and low-output condition. The scattered radiation dose was measured three times in each spot. And the measurement was taken at 0.9m (waist level) as well as neck level (1.5m). Statistical significance was compared using t-test.

Results: Scatter radiation was attenuated throughout the measurement field when the drape was applied. The degree of scatter radiation reduction was distance and height dependent. Scatter radiation decreased 61.6% at the waist level and 81% at the neck level (P<0.05).

Conclusions: The application of this sterile, lead-free drape can significantly reduce scatter radiation in the procedure room. This novel technique can be used to reduce exposure radiation dose to the operators.

FR-PO383
Pathogenesis of Brain Damages in Chronic Kidney Disease and Clues for Early Diagnosis

Yao-ping Lin,1,2 Der-Cherng Tarng,1,2 1Medicine, National Yang-Ming Univ, Taipei, Taiwan; 2Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: There is globally increased prevalence of chronic kidney disease (CKD). Vigorous efforts have been devoted to ameliorate renal deterioration and prevent cardiovascular morbidity/mortality. However, patients also have enough incubation time to develop deranged cognition that severely disturbs quality of life. Neurological pathology/damages may occur in CKD patients long before any overt clinical symptoms can be noticed. Given the similar embryological development as brain, the eyes can be the windows to pinpoint the internal brain pathology. Herein we employed proteomics, animal model and behavior analysis to investigate the possible overlapping biological signatures in the eyes and brain of CKD.

Methods: Subtotal nephrectomized rats were established as CKD model. Open field and object recognition tests were adopted as neurologic screen. Brain and eyes were harvested for proteomic analysis. Western blotting and immunohistochemistry were used to confirm and localize the identified proteins. To elucidate the global protein changes in the brain and eye of SNX rats, the data was analyzed by Ingenuity Pathways Analysis (Ingenuity Systems, http://www.ingenuity.com/).

Results: The eye pathology appeared in parallel with the brain damages. The significantly dysregulated proteins in the SNX rat eyes were spectrin beta 3, 26S proteasome non-ATPase regulatory subunit 2, 26-phosphofructokinase, dihydroxyprymidinidase-related protein, and the heat shock 70, 90a, and chaperonin containing Tep1, subunit 6A (Zeta 1).

All these proteins have been linked to the neuro-degeneration in humans.

Conclusions: There were overlapping eye and brain biological networks. Our results might pave the way for early diagnosis of CKD-neurological pathology via eye examinations, and targeted interventions towards the neurological diseases.

Funding: Government Support - Non-U.S.

FR-PO384
Metabolomic Profiling of Chronic Kidney Disease Using a Local Exhaustive Exploration Approach

Maroows Luck1, Eric Thervet1, Cecilia Damon,1 Nicolas Pallet1 1Nephrology, Georges Pompidou European Hospital, Paris, France; 2Hypercube Inst, Paris, France.

Background: H Nuclear Magnetic Resonance (NMR)-based metabolomic profiling is useful for the diagnosis of CKD stages. Due to the high dimension of NMR spectra datasets and the complex mixture of metabolites in biological samples, the identification of discriminant biomarkers of a disease is challenging. None of the widely used chemometric methods in NMR metabolomics performs local exhaustive exploration of the data.

Methods: We developed a descriptive and easily understandable approach searching for discriminant local phenomena. We selected the most discriminant features from the dataset based on both the normalized mutual information and the chi-2 test. We studied the local distribution of the patient subgroups with identical degree of CKD severity on each feature, using the proprietary algorithm HyperCube, which searches for local overdeterminism of an explanatory variable modality, and identifies a combination of variables as well as their value ranges that give the optimal prediction of the outcome of interest. Further, logistic regression on these discriminant features was used to build a predictive model of the CKD severity stage.

Results: We explored a complex dataset that includes H-NMR urinary metabolomics, clinical, demographic, clinical chemistry and histo-pathological variables, in a cohort of 110 individuals with a CKD. The HyperCube algorithm combined with logistic regression supports the discriminant metabolites obtained with standard Orthogonal Projection to Latent Structure Discriminant Analysis (O-PLS-DA) model. Unlike the O-PLS-DA model, HyperCube algorithm provided clues into the distribution of the CKD severity subgroups.
with respect to spectral data. The built predictive model identifies metabolomics profiles corresponding to citrulline, dimethylsulfone, trigonelline and glycine. The majority of the predictive variables were urinary metabolites identified by H-NMR, indicating that CKD significantly impacts the urinary metabolome.

**Conclusions:** Our findings indicate that HyperCube is a valuable analytical method for the description of CKD severity phenotypes.

**RNA-seq Profiling in Uninephrectomized Rats**

Jae Wook Lee, Mark A. Knapper. NHLBI, NIH, Bethesda, MD.

**Background:** Renal hypertrophy occurs as a compensatory response to reduction in nephron mass. To identify early gene expression changes in renal hypertrophy, we profiled whole-kidney transcriptome in the contralateral kidney of uninephrectomized rats using RNA-seq.

**Methods:** 5-week-old male Sprague-Dawley rats received right uninephrectomy (UNx; n=4 at each time point) or sham surgery (S, n=4 at each time point). Rats were sacrificed at 24, 48, and 72 hours after surgery. 1.5 µg of total RNA from the left kidney was used to make cDNA libraries for Illumina sequencing. Reads were mapped to Ensembl genes and Wald test for a negative binomial model was used to call differentially expressed genes.

**Results:** Total RNA yields did not differ significantly between UNx and sham kidneys. Each library had 35-42 million reads and more than 80% of reads were uniquely aligned. Wald test for a negative binomial model was used to call differentially expressed genes. Among upregulated transcripts were cell-cycle genes including centomere proteins (Cenpa, Cenpf, and Cenph); MMC helicase subunits (Mcm3, Mcm5, and Mcm6); cyclins (Ccnb1, Ccnb3, and Ccnd1); cyclin-dependent kinase (Cdk1); and polo-like kinase (Plk1). Among downregulated transcripts at 48 h were transcription factors (Jun, Hm12, Klf5, Klj3, Foxo3, Zfp36, Zfp354a, Zbf16b, and Zic3). At 72 h, 769 transcripts were upregulated and 704 downregulated in UNx. Among upregulated transcripts were cell-cycle genes including centomere proteins (Cenpa, Cenpf, and Cenph); MMC helicase subunits (Mcm3, Mcm5, and Mcm6); cyclins (Ccnb1, Ccnb3, and Ccnd1); cyclin-dependent kinase (Cdk1); and polo-like kinase (Plk1). Among downregulated transcripts at 48 h were transcription factors (Jun, Hm12, Klf5, Klj3, Foxo3, Zfp36, Zfp354a, Zbf16b, and Zic3). At 72 h, 769 transcripts were upregulated and 704 downregulated in UNx. Upregulated transcripts included Ccgf, Sgk1, Zbf16b, and cyclins (Ccnb1, Ccnb3, and Ccnd2). Interestingly, Ccgf, Sgk1, Zbf16b, and Ccnd2 showed a triphasic response, upregulated at 24 h and 72 h and downregulated at 48 h, consistent with an undamaged control sample.

**Conclusions:** RNA-seq revealed upregulation of multiple transcripts involved in cell division as a central mechanism of compensatory response in the contralateral kidney after uninephrectomy. Genes upregulated at 24 h such as Ccgf, Rgs4, Sgk1 and Ccnd2 may trigger this response.

**Funding:** Other NIH Support - Division of Intramural Research, NHLBI Projects ZIA-HL001285 and ZIA-HL006129.

The Application of Potential Label-Free Mid-Infrared Biomarkers in Patients with Biopsy-Proven Kidney Diseases

Met-Ching Yu,1,2 Peter R. Rich,3 Vinod Sathyanarayana Dibbur,2 Jennifer Smith,2 Robert J. Unwin,4 Frederick W.K. Tam,2 1Pediatric Nephrology, LinKou Chang Gung Medical Centre, Taiwan; 2Imperial College Kidney & Transplant Centre, Hammersmith Hospital, United Kingdom; 3Structural and Molecular Biology, Univ College London; 4UCL Centre for Nephrology, Uncon College London, Royal Free Hospital.

**Background:** We have previously discovered novel spectral markers, the urinary 1545 cm⁻¹ and 1460 cm⁻¹ peaks, indicating progression of experimental GN using Fourier transform infrared spectroscopy (FTIR) (2013 & 2014 ASN). In this study, the aims were to investigate these spectral markers in patients with different biopsy-proven kidney diseases, and the correlations between the spectral markers with clinical features.

**Methods:** The urine and plasma samples were collected at the time of renal biopsy from 50 patients at Imperial College Renal & Transplant Centre, London, UK and compared with healthy volunteers. All samples were measured by FTIR spectrometer and analysed by the established method. The biochemistry analysis such as urine protein/creatinine ratio (uPCR), Scr and renal histopathology were collected.

**Results:** In comparison with healthy volunteers, patients with GN, diabetic nephropathy (DN), membranous nephropathy and FSGS exhibited significantly higher levels of the urine 1545 cm⁻¹ and 1460 cm⁻¹ peaks. Furthermore, the urinary spectral markers were significantly correlated in both GN and DN (p<0.05). There was significant elevation of the plasma 1460 cm⁻¹ marker in all the disease groups compared with healthy volunteers.

**Conclusions:** Our results show the use of the specific urine and plasma FTIR biomarkers will be a novel approach to investigate progressive kidney diseases, including GN and DN, without chemical manipulation of samples.

Omics Investigation of Urine Samples with and without Addition of a Protease Inhibitor Claire Boulangere.1 Isc M. Rood,2 Petra Züriö,3 Manuja Kaluarachchi,1 Elaine Holmes,1,2 Franz S. Schaefer,3 John C. Lindon,4 Jack F. Wetzel,2 Jeroen Deegens.2 1Metabolix Ltd, London, United Kingdom; 2Dep of Nephrology, RadboudUMC, Nijmegen, Netherland; 3Mosaïques Diagnostics GmbH, Hannover, Germany; 4CSTM, Dep of Surgery & Cancer, Imperial College London, London, United Kingdom; 5Dep of Nephrology, Univ of Heidelberg, Heidelberg, Germany.

**Background:** Urine is an ideal biofluid for biomarker discovery. To conserve the protein profile integrity, samples are stored with a protease inhibitor (PI). It is unknown whether the PI alters the metabolomic and proteome profiles. This study aimed to test the influence of the PI on metabolomic and proteomic analysis of urine samples.

**Methods:** We collected 10 urines from normal controls (NC, n=4) and membranous nephropathy patients (MN, n=6) and the samples were aliquoted. A PI (mini complete, Roche) was added to an aliquot of each sample. Urine samples were stored at -80°C. For metabolomics, samples were analyzed by H-NMR spectroscopy and HILIC-UPCL-MS. Multivariate analysis (MVA) was used to elucidate any PI effect in normal urine and proteomeria. For peptidomics, capillary electrophoresis-coupled mass spectrometry was used to profile the low molecular weight proteome in urine.

**Results:** Unsupervised MVA of urine NMR metabolic profiles showed clear discrimination between NC-PI, NC-PI, MN-PI and MN-PI. Supervised MVA of PI+ and PI- samples revealed subtle changes in metabolic profiles and the presence of intense signals between 3.63 to 3.91 ppm in the PI+ samples, obscuring endogenous metabolic peaks. Unsupervised MVA of HILIC-UPCL-MS data showed discrimination between MN-PI and NC-PI. Supervised MVA of PI+ and PI- samples showed no detectable difference between these two sample types. For peptidomics, MVA between PI+ and PI- resulted in no statistically significant peptide differences. Further validation with a proteome classifier for CKD (CKD273) showed no statistical significant difference between samples with and without PI.

**Conclusions:** The PI addition did not affect the distinction between MN and NC in the metabolome and proteome analysis. However, PI may affect the analysis of metabolic subclasses using NMR. Therefore, samples with PI can be used, but with caution.

Quantiﬁcating Uropathogenic Bacteria Infection in 3D
Neal A. Paragas, 1 Alexander Klose, 2 1 Medicine, Univ of Washington, Seattle, WA; 2 In Vivo Analytics, Inc, New York, NY.

Background: Urogenital tract infection is a disease that annually afflicts more than 250 million people worldwide; however, the number of antibiotic resistant strains has been increasing while newly validated antibiotics have been lagging behind. We have developed a method to monitor and quantify an uropathogenic bacterial infection with multispectral bioluminescence tomography (BLT) of a novel bioluminescent uropathogenic E. coli (UPEC-lux).

Methods: We modeled pyelonephritis by transurethral injection of UPEC-lux. First, we acquired bioluminescence images with a bioluminescent optical sensor at four different spectral windows centered at 575, 615, 655, 695 nm and with bandwidth of 50 nm. The multi-orientation images were acquired using a mirror gantry for simultaneous imaging of the dorsal and ventral view. The animal was placed in a fixed position into a novel box where the gantry was placed directly onto the mirror gantry and spectral images were acquired. For in vivo bacterial quantification, a novel calibration device using tissue mimetic material was used. The light intensity imaging data became input to a novel BLT reconstruction algorithm based on an expectation-maximization (EM) method and the simplified spherical harmonics (SP3) equations for modeling in vivo light propagation. Post reconstruction, we calculated the total photon emission density of a volume of interest (VOI). We then calculated the in vivo organ bacterial load by co-registering it to a novel organ probability map.

Results: The EM method reconstructed the 3D photon emission density of the UPEC-lux and mapped the signal to a novel organ probability map. We analyzed these UPEC-lux in a model of pyelonephritis and we were able to determine the bacterial load in the kidney by BLT which correlated to CFUs from serial dilution of kidney homogenate (Pearson correlation coefficient R2 = 0.92). For the first time, we could demonstrate the feasibility of determining the bacterial burden in the kidneys.

Conclusions: The ability to monitor bioluminescent signal non-invasively will be a powerful tool to understand the pathophysiology of urinary tract infections and a new method to test novel antibiotics.

FR-PO390
Public Engagement of Kidney Related Health Information on the Internet
Samir Sulaiman, Joseph A. Vassalotti, Vijay Lapsia. Medicine, Icahn School of Medicine, New York, NY.

Background: The National Kidney Disease Education Program (NKDEP), a part of the National Institutes of Health (NIH) provides an authoritative, up-to-date and trusted consumer health information resource for patients with kidney disease. We hypothesized that the US government (GOV) supported websites would have the highest consumer engagement of kidney related health information on the internet.

Methods: We used traffic rank based on publicly available data obtained from alexa.com and semrush.com, as a marker of website consumer engagement and popularity. We identified the top websites in the health category and disease sub-categories. The websites were classified based on ownership and data collected on unique US visitors, rank, page views per visitor and daily time spent.

Results: In the general health category, the NIH website ranked at the top; however, the consumer focused NLM website ranked 9th, behind webmd.com (2nd) and mayoclinic.org (5th). Among the top 25 websites across all disease categories, Davita.com, a for-profit business, ranked as the only kidney related website. Cancer was the only disease condition with more than 1 website in the top 25 (7 total). The NKDEP ranked 8th in the genitourinary disorders group. The NKDEP had fewer unique US visitors (59,408) compared to Davita.com (307,729) and Kidney.org (241,550). The NKDEP, as well as the non-profit kidney.org supported by the National Kidney Foundation were out performed by Davita.com, a publicly listed for-profit company by an unexpectedly wide margin.

FR-PO391
Media Awareness and Reporting of Dialysis Disruptions and Death from Natural Disasters in the United States
Samir Sulaiman, Lindsay E. Jubelt, Vijay Lapsia. Medicine, Icahn School of Medicine, New York, NY.

Background: Patients receiving in-center hemodialysis are particularly vulnerable during and after disasters. Evidence of morbidity/mortality from disruption to dialysis in a disaster is limited and is so far based on statistical inference. We investigated media awareness and reporting of dialysis disruptions and death during natural disasters in the US.

Methods: We identifed all major disaster declarations by the US Federal Emergency Management Agency. Disasters since 2000, excluding man-made and wildfires, with at least 1 known death were included. We then conducted a systematic Google News search to identify articles within 30 days of each disaster in the electronic mass media (media). Articles were screened for dialysis related key words and classified into 3 categories according to reported potential for missing dialysis, missed dialysis or death.

Results: Of 887 natural disasters from 2000-2015, 120 had at least 1 reported death (total 4,383 deaths). Hurricanes and winter storms had the highest impact on dialysis patients with 5 reported deaths. Of 19 hurricanes incidents, 13 articles referred to dialysis, reporting 7 dialysis disruptions, 4 dialysis deaths and 12 instances of potential disruptions to dialysis. Only 1 of the 61 deaths reported during 3 winter storms was dialysis related, with 2 instances of dialysis disruptions and 3 instances with potential for dialysis disruption. Tornadoes, which occurred most often and resulted in the second highest mortality had no coverage in the media during its aftermath.

*Dialysis Death: Death due to disaster related disruption to dialysis

Conclusions: Based on media reports, hurricanes and winter storms are major contributors of treatment disruption and mortality in patients on dialysis. Media reports can help identify the magnitude of disruption to dialysis operations as well as deaths.

FR-PO392
A Comparison of Physician Reporting versus Computer Algorithms for CMS Data Reporting on Form CMS-2728
Mohammed Said Malas, 1,2 Ranjani N. Moorthi, 1 Jon D. Duke, 2 Sharon M. Moe, 1 1IU, Indianapolis, IN; 2RI, Indianapolis, IN.

Background: The CMS-2728 form (ESRD Medical Evidence Report) assesses 23 comorbidities chosen to reflect poor outcomes and increased mortality risk. Previous studies have questioned the validity of physician data entry on forms CMS-2728 and the relationship to hard outcomes. We hypothesize that reporting of comorbidities by a computer algorithm identifies more comorbidities and therefore is superior to physicians’ completion of the forms.

Methods: We collected data from CMS-2728 forms for all 296 patients who had included ESRD diagnosis and received chronic dialysis between 2005 and 2014 at Indiana University outpatient dialysis centers. We analyzed patients’ data from electronic records systems that collated information from multiple sources. Previously utilized computer algorithms or natural language processing was used to extract data on 10 comorbidities (Table) for a period of up to 10 years prior to ESRD incidence. These algorithms incorporate billing codes, prescriptions, and other elements that are relevant to each comorbidity. We compared the presence of these comorbidities on the forms to the determined presence according to the algorithms.

Results: The computer algorithms had higher reporting of comorbidities compared to physician completion of the forms (Table). This remained true when decreasing the data span to one year and using only single health center data sources.
FR-PO393
Kidney Dashboard: An Integrated Support Tool for Clinical Care and Research Involving Kidney Patients
Jamie S. Hirsch,1 Hojjat Salmasian,2 Amy Y. Chan,3 David Vawdrey,2 Matthew Fred,3 Krzysztof Kirljak,1 Div of Nephrology, Dept of Medicine, Columbia Univ, New York, NY; 2Dept of Biomedical Informatics, Columbia Univ, New York, NY; 3NewYork-Presbyterian Hospital, New York, NY.

Background: Large amounts of data are contained in electronic health records (EHR), and retrieval of relevant information for nephrology patients is cognitively complex and time-consuming. This results in inefficiencies, missed opportunities to improve care, and difficulty adhering to complex clinical guidelines. We developed a Kidney Dashboard, an integrated tool that gathers and analyzes information to facilitate the care and research of kidney patients.

Methods: Relevant clinical data were catalogued and categorized, including visit history, billing data, vital signs, labs, imaging, pathology, and medications. We automated generation of derived data, such as estimation and trending of eGFR, proteinuria, and automated CKD staging. We implemented a comprehensive rule-based alert system based on KDIGO guidelines to provide real-time clinical decision support.

Results: The Dashboard was created within the clinical information system at NewYork-Presbyterian Hospital, incorporating inpatient and outpatient data from multiple sources. It uses a tile layout, where each tile represents a relevant section of data that matches clinician workflow, e.g., renal function, anemia, bone and mineral metabolism, glomerulonephritis, etc. Repeat eGFR and proteinuria data are presented as interactive longitudinal graphs. The Dashboard integrates delivery of comprehensive stage-specific care and retrieval of relevant information for nephrology patients is cognitively complex and time-consuming. This results in inefficiencies, missed opportunities to improve care, and difficulty adhering to complex clinical guidelines. We developed a Kidney Dashboard, an integrated tool that gathers and analyzes information to facilitate the care and research of kidney patients.

Conclusions: The Kidney Dashboard aims to improve care and facilitate research by consolidating all relevant EHR data at the point-of-care and generating phenotypic profiles of kidney patients. This project promotes precision nephrology, exemplifying the translation of “smart” EHR tools. Following its implementation, effectiveness of the Dashboard will be studied in focus groups and by time-motion studies and audit log analyses. The improvement in adherence to KDIGO guidelines will be tested prospectively.

FR-PO394
Forecasting a Renal Prognosis of IgA Nephropathy Using Machine Learning: Validation Study
Haojoe Ling1, Junhyung Noh2, Hyoseon Kim3, Won Seok Yang,3 Yon Su Kim1, Dong Ki Kim1,1 Internal Medicine, Seoul National Univ Hospital; 2Computer Science and Engineering, Seoul National Univ College of Engineering; 3Internal Medicine, Asan Medical Center.

Background: We aimed to develop and validate individual outcome prediction models in IgAN patients using machine learning.

Methods: We included adult IgAN patients from Seoul National University Hospital (SNUH, n = 1,540) and Asan Medical Center (AMC, n = 1,044) at the time of renal biopsy. They were divided into development (followed up ≥10 years) and prediction (follow up <10 years) sets, respectively. The outcome was 10-year renal survival (10YRS) probability. We developed prediction models from SNUH test set by using logistic regression (LR) with automated CKD staging. We implemented a comprehensive rule-based alert system based on KDIGO guidelines to provide real-time clinical decision support. We evaluated the robustness of prediction models using machine learning for the individual’s likelihood of 10YRS in IgAN with both internal and external validation.

Results: We analyzed 246,996 providers in 13 specialties; 5% were Nephrologists. Female Nephrologists were reimbursed less $41,776.96 (unadjusted); the 6th worst female-to-male reimbursement differential. In the adjusted analysis, female Nephrologists had the worst reimbursement differential: less $17,971.66.

Conclusions: When adjusted for the number of beneficiaries seen & services provided, female Nephrologists endure the largest reimbursement gap by sex in any specialty. Steps should be considered to close this gap.

FR-PO396
Engineering Renal Engineering for Renal Delivery of Molecular Therapies
Pan Liu, Jing Jin. Dept of Medicine-Nephrology/Hypertension, The Feinberg School of Medicine, Chicago, IL.

Background: Targeted delivery of therapeutic enzymes to the kidney is desirable for treatment of renal diseases and beyond. Previously, approaches that exploit the renal excretion of low–molecular weight proteins (LMWP) have been attempted. However, these carriers can deliver chemical compounds, and their efficiency is further hampered by first-pass metabolism. In order to deliver enzyme cargos, we designed carrier proteins for specific and long-lasting renal delivery. We engineered a fusion protein comprised of a kidney-targeting polybasic tag (PBT) and an Fc segment for extended stability.

Methods: PBT-Fc and Fc-only control were produced as recombinant proteins. We used the FcγRIIa as an iLWP control for alternative means of renal targeting through excretion. The probes were then separately labeled with a radionuclide radioiodine (125I) tracer. Following i.v. injection of the probes to rats, we performed SPECT in whole body scanning. Radiographs were obtained in a time series for up to 1 hour. In parallel, we performed histology studies of kidney sections to determine the sub-anatomical patterns of the injected probes.

Results: Prominent and sustained kidney localization of 125I-PBT-Fc (95%) was observed by SPECT, a pattern in contrast to that of the 125I-Fc control that was mainly in blood circulation during the course of observation (only <5% is in the kidney). 125I-Fc was not observed by SPECT, a pattern in contrast to that of the 125I-Fc control that was mainly in blood circulation during the course of observation (only <5% is in the kidney). 125I-Fc was not observed by SPECT, a pattern in contrast to that of the 125I-Fc control that was mainly in blood circulation during the course of observation (only <5% is in the kidney).
Duramycin reached the kidney quickly and then followed through urinary excretion to the bladder within 6 minutes, while more than 5% remained in the kidney. The imaging results were consistent with IHC findings from mouse kidney following probe injections, which shows the PBT-Fc, but not Fc-alone, binding the glomeruli and tubule basement membrane shorty after injection. PBT-Fc sustained in the kidney for at least 10 days.

Conclusions: Our engineered PBT-Fc carrier exclusively targets kidney through binding to the glomeruli and tubule basement membrane. This recombinant probe also achieves long-lasting kidney retention (days as compared to minutes for LMWP), yet another desirable property for targeted therapeutic delivery. This vehicle will potentially be useful for delivery of molecular therapies, particularly enzyme proteins, to the kidney.

Dynamic Culture on an Orbital Shaker Alters the Phenotype of Primary Human Renal Tubular Epithelial Cells
Nicholas J. Ferrell, Jin Cheng, Simeng Miao, William Henry Fissell. 1Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; 2Biomedical Engineering, Vanderbilt Univ, Nashville, TN.

Background: Primary cells cultured in vitro gradually lose features characteristic to the in vivo cell type, variously termed “senescence” or “culture stress.” Culture conditions that help maintain cell-specific phenotype are advantageous for cell biology and tissue engineering. Here we evaluated the phenotype of primary renal tubular epithelial cells after applying apical fluid shear stress using an orbital shaker.

Methods: Human renal tubular epithelial cells were isolated from donor kidneys not suitable for transplant. Cells were cultured on Transwell inserts under static conditions or on an orbital shaker at a frequency producing fluid shear stresses of 2 dyn/cm². Transpositional resistance was measured daily. After 2 weeks in culture, cell density was analyzed by counting DAPI stained nuclei, and expression of tubule-specific markers was measured by PCR and western blotting.

Results: Dynamic culture significantly increased steady state transpositional resistance from 344±31 to 544±32 Omega cm (p<0.001) and resulted in a 21.5±2.1% (p<0.001) increase in cell density. Gene expression of tubule epithelial cell markers (GCT1, COL4A1, COL4A2, NFATC1, AQP3) increased with fold changes in expression of 3.2±1.1, 3.1±0.3, 3.1±0.2, 2.1±0.4, and 1.9±0.2, respectively. Cells grown under shear also showed increased protein expression of gamma-glutamyl transpeptidase.

Conclusions: Primary renal tubular epithelial cells grown on an orbital shaker with physiological levels of fluid shear stress appear to express proximal tubule markers more than cells grown in static conditions. This may be due to increased nutrient delivery and waste removal with improved mixing at the apical brush border, or due to specific gene regulation related to mechanotransduction. Further mechanistic insight may allow investigators to develop improved in vitro culture systems for cell biology and tissue engineering and more accurate in vitro models of disease.

Crispr/Cas9-Mediated Site-Specific Mutation in Rat Angiotinogen Gene via Direct Injection of One-Cell Embryos
Yaochun Zhang, Zakir Hossain, Bo Lan, 1Chang-Yien Chan, 1Hui Kim Yap, 1Kar Hui Ng. 1Dept of Paediatrics, National Univ of Singapore, Singapore; 2Cancer Science Inst of Singapore, National Univ of Singapore, Singapore.

Background: Genetically modified animals represent a crucial tool for understanding gene function in development and disease. The recently developed CRISPR/Cas9 system is an efficient gene-targeting technology to generate genetically modified animals. We have performed exome sequencing in a Singaporean Chinese family with X-linked recessive membranous nephropathy associated with Fanconi syndrome and anti-tubular basement antibodies, and identified AMOT, coding for angiomotin, as a novel candidate gene with a putative disease-causing mutation p.S50G in the N-terminal of the p130-AMOT isoform.

Preliminary work confirmed the expression of angiomotin in renal tubular cells. This study aimed to introduce the mutation into rat genome via direct injection of CRISPR/Cas9 into one-cell embryos, establishing rat models for downstream pathological studies.

Methods: The tracrRNA:crRNA fused single guide RNA (sgRNA, 20ng/µl) together with Cas9 protein (40ng/µl) and a single-stranded oligonucleotide (ssODN, 3ng/µl), which encodes the p.S50G mutation of angiotinogen and serves as template for HR-mediated repair, were introduced into the rat pronucleus via microinjection. Pups produced from the injected embryos were first detected by mismatch-sensitive T7 endonuclease I digestion. Animals carrying mutations were sequenced to determine the precise sequence.

Results: In the 32 survived pups, one (3.1%) founder rat was identified to carry the heterozygous mutation. After crossing F0 with a wild-type rat, ten F1 rats were delivered, of which four males (40%) were carrying the mutation on their X chromosomes, while 2 (20%) were heterozygous females. No phenotype data is available currently as the animals are only three weeks old. Homozygous female rats are expected to be produced by crossing between the F1 animals.

Conclusions: In conclusion, a heritable site-specific mutation was successfully introduced into the rat genome with the CRISPR/Cas9 system. This one-step method of generating site-specific mutations in rats will greatly accelerate the in vivo study of gene functions.

Double Transduction of a Cre/LoxP Lentiviral Vector: A Simple Way to Generate Cell-Specific Knockdown Mice
Shin-Wook Kang, Bo Young Nam, Meiyan Wu, Tae-Hyun Yoo. Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Genetically engineered mice have been used to elucidate the function of specific genes. Transgenic mice by conventional knockout techniques using oocytes or embryonic stem cells are most commonly used to downregulate genes, but this method has certain limitations. Therefore, a novel method to knock down specific genes in a cell specific manner in adult mice was devised by lentivirus (LV)-assisted delivery of short hairpin RNA.

Methods: In vitro, the LV suspension containing LV-Hoxb7 Cre and/or LV-Aquaporin 3 shRNA (LV-AQP3) was added to cultured primary renal collecting duct cells (CDs) and mouse mesangial cells (MMCs). In vivo, first, LV-Hoxb7 Cre was injected into the loxp-EGFP mice to check the Hoxb7 promoter efficiency. Second, LV-loxp shAQP3 was injected into the Hoxb7 Cre transgenic mice to check shAQP3 function. Third, consecutive injections of LV-Hoxb7 Cre and LV-loxp shAQP3 were made to C57BL/6J mice.

Results: In vivo, LV-Hoxb7 Cre worked only in CDs due to the presence of Hoxb7 in CDs but not in MMCs. Furthermore, combined injection of CDs with LV-Hoxb7 Cre and LV-loxp shAQP3 significantly inhibited the protein expression of AQP3 along with the disappearance of EGFP protein expression, suggesting that LV-Hoxb7 Cre and LV-loxp shAQP3 used in this study worked together effectively. In vivo, kidney CD-specific AQP3-knockdown mice were generated by consecutive injection of LV-Hoxb7 Cre and LV-loxp shAQP3 alone did not differ, but consecutive injection of LV-Hoxb7 Cre and LV-loxp shAQP3 significantly reduced AQP3 expression. However, the expressions of AQP3 in other organs did not differ between the groups.

Conclusions: Double transduction of Cre- and loxp-based LV can be a simple way to generate cell-specific knockdown mice, and this method may also be applicable to other species.
Substrate stiffness regulates renal epithelial cell cilia formation via autocrine TGFβ signaling. Mingfang Ao, 1 Jin Cheng, 1 Nicholas J. Ferrell, 1,2 H. David Humes, 3 Shuvo Roy, 2 William Henry Fissell. 1,3 Hypertension, Vanderbilt Univ, Nashville, TN; 2Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; 3Nephrology, Univ of Michigan, Ann Arbor, MI.

Background: The primary cilium serves the extracellular environment. Malformation of primary cilia has been shown to result in kidney disease. Although much is known regarding ciliogenesis, the role of mechanical features of the microenvironment in cilia formation is poorly understood.

Methods: Human primary proximal tubule epithelial cells (HRECs) and LLC-PK1 cells were plated on collagen-coated polyacrylamide gels with different stiffness (0.5 KPa, 1 KPa, 10 KPa and 40 KPa) and grown for 5 to 7 days. Cilia formation was analyzed by immunofluorescence staining of AC-tubulin followed with microscopy imaging. Protein expression was measured by immunoblottting. Recombinant TGFβ 1 and an inhibitor of TGFβRII SB431542 were used for TGFβ signaling modulation. LiCl was utilized to stimulate P-GSK3b.

Results: Stiff gels (10 KPa and 40 KPa) gave rise to higher ciliary density than compliant gels (0.5 KPa and 1 KPa) did (60% vs 20%). Furthermore, this phenotype could be altered by manipulation of transformation growth factor beta (TGFβ) signaling: addition of TGFβ 1 could increase the cilia frequency even when the cells were on compliant gels; similarly, inhibition of TGFβ receptor II impairs cilia formation in the context of stiff substrates. Furthermore supporting a role for TGFβ, substrate stiffness was associated with increased SMAD2 and GSK3β phosphorylation. Incubation with LiCl also increased GSK3β phosphorylation and cilia formation independent of TGFβ.

Conclusions: Substrate stiffness determines cilia formation through TGFβ signaling via downstream GSK3β phosphorylation. This work highlights that substrate mechanical properties have a strong influence on markers of differentiation. This has relevance for tissue engineering efforts and also suggests a mechanism of disease progression in the scarred kidney. This may broaden researches on kidney disease and contribute to disease therapy.

An Additive Role of Microfluidics on KLF 15-Induced Differentiation of Human Primary Podocyte Seung Hye Yang, 1 Eunjin Bae, 2 Sejoong Kim, 3 Kwon Wook Joo, 1,2 Chun Soo Lim, 1,2 Yon Su Kim, 1,2 Dong Ki Kim. 1,2 Kidney Research Inst; Internal Medicine, Seoul National Univ College of Medicine, Seoul.

Background: Podocyte de-differentiation is one of major problems during the process of primary podocyte culture. Recently, much interest has been focused on the topic, yet lenient control over differentiation process hinders a progress. KLF15 (Kruppel-like factor 15) was reported to be a novel transcriptional regulator of podocyte differentiation and its expression was increased by retinoic acid (RA) which promotes the differentiation of podocytes. But, the duration of podocyte differentiation process remains long. Here, we present a novel in vitro protocol to induce podocyte differentiation.

Methods: To mimic in vivo biological environment of glomerulus, a polydimethylsiloxane (PDMS) microfluidic device was used. The human primary podocytes were cultured in the 500 mm by 130 mm microfluidic channel and were stimulated with a laminar fluidic shear stress of 0.5 dyn/cm² for 5 days. Various dose of RA was used to promote podocyte differentiation.

Results: In this research, we were able to reduce the time required for podocyte differentiation with higher shear stress and higher dose of RA. A couple of tests were conducted to verify the podocyte differentiation through the protocol. First, the phenotype of podocytes changed from cobblestone like shape to arborized cells. Through immunofluorescence staining, the increased expression of cytoplasmic synaptopodin and intercellular junction ZO-1 was confirmed. Moreover, KLF 15 expression was also increased. These molecules were also quantified with mRNA expression through real-time PCR. The size of podocytes became larger and the height of podocytes increased by a factor of 2.3 fold. Lastly, the podocytes aligned with the direction of flow.

Conclusions: In conclusion, we were able to promote podocyte differentiation in the shorter processing time with microfluidics and RA. Yet, more effort to mimic biological aspects of kidney such as complex structure with multiple cell layers and round surface is necessary.

CCL18 Correlates with Disease Activity in ANCA-Associated Neutrophil Granulomatosis Silke R. Brix, 1 Christian F. Krebs, 1 Martin Busch, 2 Thorsten Wiech, 3 Ulf Panzer, 4 Rolf A. Stahl. 1 III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Germany; 2‘Klinik für Innere Medizin III, Universitätsklinikum Jena, Germany; 3‘Institut für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Germany.

Background: Microarray analysis of renal tissue from patients with antineutrophil cytoplasmatic antibody (ANCA)-associated neutrophilic granulomatosis (GN) revealed the CC chemokine ligand 18 (CCL18) as the highest up-regulated chemokine. The renal production of CCL18 was associated with fresh glomerular lesions and impairment of renal function. The cellular sources of CCL18 were identified as macrophages and dendritic cells. CCL18 serum levels were elevated in patients with newly diagnosed ANCA GN as well. In order to test whether CCL18 might serve as a biomarker of relapsing renal ANCA disease, we prospectively analyzed CCL18 serum levels.

Methods: Hundred thirty-five patients with biopsy proven ANCA GN were prospectively analyzed for CCL18 serum levels. Patients included in the study were in remission on maintenance therapy (n=117) or without immunosuppressive treatment (prednisolone 5mg or less was accepted) (n=18). Serum levels of CCL18 were measured by ELISA every three months. Renal relapse was defined as either rising serum creatinine with urinary red cell casts or biopsy-confirmed active ANCA-associated glomerular lesions (i.e. fibrinoid necrosis and/or cellular crescents) accompanied by an intensification in immunosuppressive treatment.

Results: During a mean follow up time of 11.6 ± 8.3 months, 16 patients developed a renal relapse. CCL18 levels were higher in relapsing patients when compared with patients who were in clinical remission (167.50 ± 85.44 ng/ml vs. 83.17 ± 46.38 ng/ml). CCL18 serum levels increased at the time of relapse and decreased after immunosuppressive therapy was restarted or intensified (p=0.001).

Conclusions: CCL18 serum levels are associated with disease activity in patients with ANCA-GN and might serve as a marker of relapses in the surveillance of these patients.

Prognostic Value of Persistent Hematuria and Proteinuria in ANCA-Associated Vasculitis: Data from the European Vasculitis Study Group (EUVAS) Therapeutic Trials Alexandre Karras, 1,3 Thomas F. Hiemstra, 2 Rachel B. Jones, 1,2 David R. W. Jayne. 2 Nephrology, HEGP Hospital, Paris, France; 3Nephrology, Addenbrooke’s Hospital, Cambridge, United Kingdom;

Background: Renal involvement is frequent ANCA-associated vasculitis (AAV), due to crescentic glomerulonephritis (CGN). Hematuria (Hu) and proteinuria (Pu) are detected during the initial and active phase of CGN but the prognostic value of the persistence of these urinary abnormalities during the remission phase of AAV is still controversial.

Methods: Data were combined from three EUVAS trials (IMPROVE, RITUXVAS, MYCYC), providing data for Hu and Pu at month 6 (M6) following initiation of immunosuppression and patient follow-up until month 18 (M18). Hu was defined as Persistent of >0 RBC/mm³. Proteinuria was evaluated by protein-to-creatinine ratio (PCR, g/gm). Multivariate analysis using a mixed effects model demonstrated that degree of proteinuria at M6 reflects more severe kidney damage and is an independent predictor of CKD progression in AAV nephropathy.

Double Positivity for ANCA and Anti-GBM Antibodies: Clinical Characteristics and Long-Term Outcomes of a Multi-Centre Cohort

Stephen Paul McAdoo, Anisha Tan, Sophie Ohlsson, Zdenka Hruskova, Maria Weiner, Jeremy B. Levy, Vladimir Tesar, Martin Segelmark, Charles D. Pusey, Imperial College London, London, United Kingdom; Charles Univ Prague, Linkoping Univ.

Background: Co-presentation with both ANCA and anti-GBM disease is a rare phenomenon. Current studies often include small numbers and report variable outcomes. We aim to describe the clinical features and outcomes of a large cohort of contemporary patients identified from three large European centres.

Methods: This is a retrospective cohort study, which included patients with both ANCA and anti-GBM antibodies (ANCA-anti-GBM positive). Primary outcomes were recorded from the time of diagnosis until death, first-time cancer or end of year 2013. For the analysis, patients were divided into two groups. All patients were followed for a minimum of 3 years. Risk of cancer was calculated as standardized incidence ratio (SIR), SIR = observed/expected. Patients were followed from the time of diagnosis until death, first-time cancer or end of year 2013.

Results: We identified 78 anti-GBM+ patients, of whom 37 (47%) were DP for ANCA and anti-GBM antibodies. In the DP group (37 patients), 10 had ANCA- but no anti-GBM, 16 had anti-GBM- but no ANCA and 11 had ANCA+ and anti-GBM+.

Conclusions: Compared to SP for ANCA, DP patients had significantly lower risk of cancer (SIR 0.57 vs 1.26, p = 0.049).

Pulse Methylprednisolone for Induction of Remission in Severe ANCA Associated Vasculitis Is Associated with an Increase in Adverse Events but No Improvement in Outcome

Dimitrios Chronouzas, JulieAnne G. McGregor, Alan D. Salama, Wladimir M. Szpirt, Neil Basu, Matthew David Morgan, Imperial College, London, United Kingdom; Copenhagen Univ Hospital, Denmark; Aberdeen, United Kingdom.

Background: Intravenous pulse methylprednisolone (MP) is frequently used as part of remission induction in severe ANCA associated vasculitis (AAV). However, there are no studies assessing its efficacy in the setting of AAV, while treatment related complications remain the main source of morbidity.

Methods: We retrospectively analysed outcomes of 114 patients that presented with severe AAV at 5 large centers in the United Kingdom, United States and Denmark between 2000-2013. All patients received high dose oral corticosteroids, cyclophosphamide and plasma exchange. Rituximab treated patients were excluded. The chi square and Mann Whitney U tests were used for statistical analysis.

Results: Fifty-four patients received MP (median dose 1.5 g over 3 days) in addition to standard therapy while 62 did not. Patient characteristics and disease severity were comparable between the two groups. There was no difference in survival at 3 months (MP: 94.2 vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579). Renal recovery amongst survivors (63.5 vs 72.6%, p=0.297) and relapse rates at 12 months (11.6 vs 8.6%, p=0.617) were similar. MP therapy was associated with more infections per patient at 3 months (0.7 vs 0.3, p=0.005) and more new onset diabetes (28.6 vs 6.6%, p=0.002).

Conclusions: Within the limitations of this study we found that the addition of MP to standard therapy for remission induction in severe AAV led to a significant increase in adverse events with no improvement in survival, renal recovery or relapse rates. Our results question the currently widespread use of MP in severe AAV and suggest that a randomised controlled trial is urgently needed in order to definitively address this issue.

FR-PO409

Serum B Lymphocyte Stimulator (Blys) Levels as Markers of Disease Activity in Anti-Neutrophil Cytoplasm Antibody (ANCA) Associated Vasculitis (AAV)

Background: B lymphocyte stimulator (Blys) has been implicated in the pathogenesis of AAV. Previous studies have shown elevated levels in active disease, and following anti-CD20 therapy. Antineutrophil cytoplasm antibodies (ANCA) are not reliable predictors of disease activity and relapse and alternative markers are needed to support this notion.

Methods: In the current study we determined the current widespread use of Blys in severe AAV and suggest that a randomised controlled trial is urgently needed in order to definitively address this issue.

Results: Fifty-four patients received MP (median dose 1.5 g over 3 days) in addition to standard therapy while 62 did not. Patient characteristics and disease severity were comparable between the two groups. There was no difference in survival at 3 months (MP: 94.2 vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579). Renal recovery amongst survivors (63.5 vs 72.6%, p=0.297) and relapse rates at 12 months (11.6 vs 8.6%, p=0.617) were similar. MP therapy was associated with more infections per patient at 3 months (0.7 vs 0.3, p=0.005) and more new onset diabetes (28.6 vs 6.6%, p=0.002).

Conclusions: Within the limitations of this study we found that the addition of MP to standard therapy for remission induction in severe AAV led to a significant increase in adverse events with no improvement in survival, renal recovery or relapse rates. Our results question the currently widespread use of MP in severe AAV and suggest that a randomised controlled trial is urgently needed in order to definitively address this issue.

Our results question the currently widespread use of MP in severe AAV and suggest that a randomised controlled trial is urgently needed in order to definitively address this issue.
Methods: Serum samples were obtained from patients with AAV at our centre, and BlyS levels detected using sandwich ELISA. Clinical data were obtained by review of patient records.

Results: Samples were collected from 68 patients with AAV and 13 healthy controls. Thirty one patients were male, 44 Caucasian and 21 Indoasian. Fifty patients had granulomatosis with polyangiitis, 13 patients had microscopic polyangiitis and 5 had eosinophilic granulomatosis with polyangiitis. Significantly higher BlyS levels were found in patients with active disease than those in remission and healthy controls.

Thirty seven patients who had been treated with Rituximab had significantly higher BlyS levels (p<0.0001). Eighteen patients had relapsed at 1 year following recruitment. These relapsing patients had significantly higher BlyS levels than those patients who did not relapse (p<0.0016).

Conclusions: This study supports the role of BlyS in the pathogenesis of AAV. BlyS levels could be used as markers of disease activity and predictors of relapse. With increased use of rituximab in AAV, further studies are needed to assess the impact of B cell depletion on B cell survival factors. These findings highlight the potential role for BlyS in pathogenesis in the maintenance of remission of AAV.

FR-PO410
Predictors of Renal Histopathology in Antineutrophil Cytoplasmatic Antibody Associated Glomerulonephritis
Sophia Lionaki,1 Clio Marvagani,2 George Liapis,1 George Somarakis,4 John N. Boletis,1 Alexandros Drosos,4 Athanasios Tzioufas,4 Haralampos Moutsopoulos,2 *Nephrology, Laiko Hospital, Athens, Greece; 2Pathophysiology, Univ of Athens, Greece; 3Pathology, Laiko Hospital, Greece; 4Rheumatology, Univ of Ioannina.

Background: Prompt, aggressive therapy is vital for anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN). In this regard, we aimed to identify predictors of distinct renal histopathological classes at the time of clinical diagnosis.

Methods: An inception cohort of patients with biopsy proven ANCA-associated GN was studied retrospectively. Demographics, clinical, laboratory, serological and radiological parameters were analyzed. Patients were classified on the basis of renal histopathology, according to the report by Berden et al (JASN 2010) for ANCA-associated GN by a renal pathologist into: focal class, crescentic class, mixed class and sclerotic class. A risk score was developed for each histopathological class using univariate and logistic regression analyses.

Results: Variables independently associated with focal class included disease duration up to diagnosis < 8 weeks, absence of red blood cell (RBC) casts by urine microscopy and eGFR > 40 ml/min/1.73m²; with crescentic class > 40 erythrocytes/hpf, identification of RBC casts in urine, ear nose and throat (ENT) involvement and eGFR < 49 ml/min/1.73m²; with mixed class age > 54 years, male gender, and absence of ENT involvement. In the presence of 2 or 3 risk factors a predictive risk score of each histopathological class was calculated: odds ratio (OR), 95% confidence intervals (CI), for focal class (2 risk factors) 17.5 (95% CI) [4.9-62.9], 38.0 [6.8-213.7] for crescentic class (³3 risk factors), and 8.3 [1.0-67.5] (2 risk factors) for mixed class.

Conclusions: We propose a predictive algorithm of specific histopathological classes of ANCA associated GN, which might provide a crude estimation of the disease activity in the glomeruli at presentation. This tool might assist the clinician in making decisions regarding the level of intensity of inductive immunosuppressive therapy at clinical diagnosis.

FR-PO411
Rituximab as a Cyclophosphamide Sparing Agent for Patients with Multi-relapsing ANCA-Associated Small Vessel Vasculitis
Sophia Lionaki,1 George E. Fragoulis,2 Alice Venetsanopoulou,2 John N. Boletis,1 Panagiotis Vlachogiannopoulos,4 Haralampos Moutsopoulos,2 Athanasios Tzioufas,2 *Nephrology, Laiko Hospital, Greece; 2Pathophysiology, Univ of Athens, Greece.

Background: To evaluate the clinical efficacy and outcomes, of patients with multi-relapsing ANCA-associated Vasculitis (AAV), who received induction therapy with rituximab for a new disease relapse.

Methods: We retrospectively studied all patients with biopsy proven AAV, who were treated with rituximab upon a new relapse. A control group consisted of patients from the era prior to the initiation of rituximab in the treatment of AAV, was selected using the following criteria: i/history of relapse, ii/orган involvement at relapse, iii/treatment with the standard regimen. Patients and controls were matched for age, gender, and disease duration. Comparisons of disease outcomes along with the frequency and severity of adverse events were performed between groups. Rituximab was used with high dose glucocorticoids and depending on the organ involvement a short course of cyclophosphamide was added.

Results: Of 147 patients with AAV and a mean total follow up time of 78.2 months, 18 patients (12.2%) received induction treatment with rituximab for disease relapse. Time to 1st relapse from the 1st diagnosis of AAV was shorter in the rituximab group and the mean number of relapses per patient was significantly higher in this group. The mean BVAS score was similar between groups at study entry while 13/18 patients received a 3-month course of cyclophosphamide in addition to rituximab.

Conclusions: Rituximab was shown efficacious in patients with multiple relapsing AAV including cases with renal and pulmonary involvement. It allowed us to minimize the ultimate exposure to cyclophosphamide in these patients, which is crucial, as they accumulate remarkable toxicity in long-term.

FR-PO412
Differences Between Patients with Definite and Suspected ANCA-Associated Vasculitis in a Secondary Care Hospital
Eline Houwen,1 Willem A. Bax,1 Walentina A. Slieker,2 Bastiaan Van Dam,1 Fenneke C.P. Frerichs,1 Gideon Verhave,1 Erik Lars Penne.1 Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; 2Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar, Netherlands.

Background: ANCA-associated vasculitis (AAV) is a rare disease with a broad spectrum of symptoms. Therefore, diagnosing AAV is often challenging. In an effort to provide guidance for clinicians, we aimed to identify differences between ANCA positive patients with a definite and suspected diagnosis of AAV.

Methods: In this retrospective study, all patients that tested positive for MPO and/ or PR3 ANCA between 2005 and 2015 in a secondary care hospital in the Netherlands were analyzed. Patients were divided into subgroups according to clinical diagnosis and the Birmingham Vasculitis Activity Score (BVAS). Possible predictors for AAV, such as patient characteristics, clinical symptoms and ANCA titers were identified. Patients were also screened for commonly used exclusion criteria in trials.

Results: We included 240 patients with a positive MPO and/or PR3 ANCA, of which 120 patients were clinically diagnosed with AAV (group 1); all had a BVAS ≥ 3. Of the patients without the diagnosis AAV, 50 had a BVAS ≤3 (group 2) and 70 had a BVAS ≤ 3 (group 3). In group 2, 39 patients had an alternative diagnosis, including other rheumatic diseases and infection. In a multivariable linear regression model, higher ANCA titers, higher BVAS and Ear Nose Throat (ENT) symptoms were predictive for AAV (all p<0.001). Of the patients diagnosed with AAV, 21 (18%) would have been excluded from most trials, based on a malignancy (n=13) or organ associated with vasculitis (n=8). Notably, characteristics of these patients did not differ significantly from the other AAV patients.

Conclusions: Rituximab was shown efficacious in patients with multiple relapsing AAV including cases with renal and pulmonary involvement. It allowed us to minimize the ultimate exposure to cyclophosphamide in these patients, which is crucial, as they accumulate remarkable toxicity in long-term.
FR-PO413
Rituximab and Low-Dose Cyclophosphamide Therapy for Renal ANCA-Associated Vasculitis: Long-Term Follow-Up
Nicholas R. Mendelsohn,1 Stephen Paul McAdoo,1 Anisha Tanna,1 Megan Griffith,1 Jeremy B. Levy,1 Tom Harris,1 Michael Kampmann,1,2
Hiroe Sato,1 Yukiko Nozawa,1 Yoko Arimura.1
1First Dept, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan; 2Clinical Sciences, Niigata Univ, Niigata, Japan; 3Dept of Medical Technology, School of Health Sciences, Niigata Univ, Niigata, Japan; 4Faculty of Medicine, Niigata Univ, Niigata, Japan.

Background: The previously reported study of rituximab (RTX) and low-dose cyclophosphamide (CYP) followed by azathioprine maintenance for ANCA-associated renal vasculitis (AAV), suggested it was efficacious in inducing remission and has an acceptable side-effect profile (N. Mendelsohn et al. 2011). We have followed the cohort for over seven years and report the regimen’s efficacy and safety profile.

Methods: Long-term outcomes were retrospectively ascertained from all 23 previously treated patients.

Results: Mean time since starting the treatment regimen was 83 months; twenty-one patients started the regimen more than five years ago. All patients achieved clinical remission within six weeks, with depletion of circulating CD19-positive B cells and significant reduction in median anti-PR3/MPO ANCA titre. After 8 months follow-up, five renal and four non-renal relapses were observed and treated in five patients. Median eGFR improved from 28 ml/min (range 11-63) at presentation to 49 ml/min (range 3-87) after one year and was maintained at 50 ml/min (8-90) at five years (n=21) and 46 ml/min (22-76) at seven years follow-up (n=9). To date, three infections requiring hospital admission and four malignancies have been recorded.

Conclusions: This rituximab-based low-dose cyclophosphamide regimen followed by maintenance therapy provides safe and effective long-term treatment at more than five years follow-up.

FR-PO414
The Histopathologic and Clinical Determinants of the Change in GFR During the 1st year of Treatment in ANCA-Associated Vasculitis
Pierre-Lucavoie,1 Remi Goupil,1 Michelle Goulet,2 Maxime Rheaume,2 Souymea Brachemi,3 Stephan Troyanov.1
1Nephrology, Hôpital du Sacré-Cœur, Univ de Montréal, Montréal, QC, Canada; 2Internal Medicine, Hôpital du Sacré-Cœur, Univ de Montréal, Montréal, QC, Canada; 3Nephrology, CHUM, Montréal, QC, Canada.

Background: Identifying the predictors of the change in GFR in ANCA-associated vasculitis (AAV) is helpful to avoid prolonged immunosuppression in those where no renal basis exist and to consider modifying therapy in those who should improve but fail to do so.

Methods: We retrospectively reviewed cases of AAV with a renal biopsy in 3 hospitals to determine predictors of the change in GFR (deltaGFR) during the 1st year of treatment. We considered demographics, pathology findings, treatments and complications incurred. In particular, we addressed the histopathologic classification (Berden JASN 2010) proposing focal, crescentic, mixed and sclerotic subsets.

Results: Of 120 patients with AAV, 71 had a renal biopsy and received immunosuppression. They presented at an age of 59±13 with 48% female, 49% anti-MPO+ and a GFR of 32±30 ml/min including 22 patients on dialysis. Induction consisted of cyclophosphamide (93%), rituximab (6%), plasma exchange (27%) and pulse methylprednisolone (69%) in addition to oral corticosteroids. During the 1st year, patients recovered 15±20 ml/min/1.73m2 with 11 no longer requiring dialysis. The deltaGFR increased up to 6 months, although it varied greatly individually. Age, hypertension, MPO positive serology, the extent of crescentic and sclerotic glomeruli, tubular atrophy and the histopathological classification were associated with a lower GFR at diagnosis. However, in one year only histopathologic classification and the number of admissions for treatment-related complications predicted a lower deltaGFR. The focal, crescentic, mixed and sclerotic subsets experienced a 19±23, 17±15, 11±12 and ±2±6 ml/min deltaGFR, respectively (p=0.026, trend test).

Conclusions: The change in GFR during the 1st year of treatment in AAV increased 15±20 ml/min. It appeared maximal at 6 months into therapy. The histopathologic classification helped predict the deltaGFR at 12 months, with a reduced benefit of therapy in the sclerotic subset.

FR-PO415
Analysis of Clinical Features in ANCA-Associated Vasculitis: 30 Years Single Center Experience – Relationship Between RPGN and Renal Prognosis
Soko Kayashima.1 Shiuya Kaname,1 Yoshinori Komagata,1 Yoshihiro Arimura.1
1First Dept, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.

Background: The clinical features of AAV, with respect to rapidly progressive glomerulonephritis (RPGN), have been changing, but were not well examined in Japan, where MPO-ANCA-associated vasculitis (MPO-AAV) are dominant in contrast to the Western countries. Thus, we retrospectively analyzed the clinical database of the 179 patients with AAV who were admitted to our hospital for the last 30 years.

Methods: At the onset, all patients fulfilled the Chapel Hill Consensus Conference (CHCC) classification criteria for MPA, GPA and EGPA. We divided the AAV patients into the 4 groups based on the presence or the absence of RPGN and hemodialysis and compared the clinical features and renal prognosis. Among 179 AAV patients, 166 cases (92.7%) were MPO-ANCA positive and 14 cases (7.8%) were PR3-ANCA positive.

Results: RPGN was observed in 100 (55.9%) of the 179 patients, including 49 cases of maintenance hemodialysis group (A), 2 cases of temporary dialysis group (B) and 49 cases of non-dialysis group (C), in addition to 79 cases without RPGN and dialysis (D). Significant differences were observed in BVAS, CRP, eGFR and serum Cr concentration. There were no differences for treatment choice, rate of kidney biopsy and frequency of relapses among the groups. Comparison among the different periods for every 10 years show the tendency of an increase in age of onset and the downward trend of serum Cr concentration, rate of RPGN and maintenance hemodialysis, BVAS scores, and frequency of relapses and mortality.

Conclusions: These results have clearly shown the changing features of AAV in Japan, with an earlier detection and the improvement of renal and patient survival during the periods.

FR-PO416
The Effect of Race on 5-Year Survival Outcomes in ANCA-Associated Renal Vasculitis
Lucy Nadarajah,1 Vasantha M. Muthuppalaniappan,2 Ravindra Rajakariar.1
1Nephrology, Barts and The London NHS Trust, United Kingdom; 2Clinical Nephrology, Barts and The London NHS Trust, United Kingdom.

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis is a multi-systemic autoimmune disease characterized by inflammation of microscopical vessels. Renal involvement occurs in 70% of patients, with 1 year mortality rates exceeding 15%. With a prevalence of two cases per 100,000 populations there is a significant preponderance to Caucasians (C). Little is known about the outcomes in patients from Indo-Asian (IA) and Afro-Caribbean (AC) race despite an increasing number of cases seen with the disease.

Methods: We performed a single center, retrospective study, observing 5-year survival outcomes and relapse rates between C, IA and AC in ANCA-associated renal vasculitis. Electronic case notes over a 10-year period (2004-2014) were used collect data to include age at time of diagnosis, Birmingham vasculitis activity score (BVAS) at presentation, race, presence of diabetes and renal function. 5-year survival outcomes were analyzed using a cox proportional hazard model.

Results: In total 121 patients were included in the study, there were 84 (70%) C’S, 31 (25%) IAs and 6 (5%) were of AC background. Median age was 66 years, 56% were men, 20% were diabetic and average BVAS score at presentation was 5. One year relapse rates were low with 8 (6%) relapses seen. No significant difference in 5-year survival outcome was found between the races. Age at presentation significantly affected survival outcomes (p=0.007).

5 year survival outcomes dependent on race

FR-PO417
Possibility of Increasing Prevalence of Otitis Media with ANCA Associated Vasculitis in Japan
Takeshi Nakatsuy.1 Yukihiro Morozawa,1 Hiroe Satoh,1 Yoko Wada,1 Takeshi Kuroda,2 Massaki Nakano,1 Ichiei Narita.1
1Div of Clinical Nephrology and Rheumatology, Graduate School of Medical and Dental Sciences, Niigata Univ, Niigata, Japan; 2Dept of Medical Technology, School of Health Sciences, Facultys of Medicine, Niigata Univ, Niigata, Japan.

Background: A new disease concept, otitis media with ANCA associated vasculitis (AAV), has been advocated.

Methods: One hundred and fifty seven patients (74 males and 83 females) with AAV (81 microscopic polyangitis, 54 granulomatosis with polyangitis (GPA), and 22 eosinophilic GPA) were admitted to Niigata University Hospital from 1989 through 2014. Twenty seven patients (17%, 13 males and 14 females) with otitis media were recruited. Their clinical features and laboratory data were analyzed.

Results: Fifteen patients were diagnosed as having definite GPA. Five were probable GPA. Lung or kidney lesions were not detected in other seven patients (Ears (E) only group). The initial symptoms in 22 patients (81 %) were ears’ one, such as impaired hearing (91

450A
controls (HC) were assayed for MPTFa. All patients had 3 samples spanning 12 months. MPTFa content was measured in patients with Factor Xa inhibitor X. Absorbance was measured after addition of Factor Xa chromogenic substrate. Recombinant relipidated human TF was used as a standard. Values were expressed as a percent of MPTFa from a positive control (FPF from LPS-stimulated HC blood). Fisher’s exact tests and Wilcoxon tests were used to compare categorical and continuous variables, respectively.

Results: Demographics were similar among patients and HC. VTE<sub>pos</sub> and VTE<sub>neg</sub> patients did not differ in ANCA serotype or titer, BVAS, D-dimer, other laboratory data, or organ involvement. VTE<sub>pos</sub> patients had significantly higher peak MPTFa than VTE<sub>neg</sub> patients (10.5 (IQR: 8.0-10.9) versus 7.8 (IQR: 5.5-9.2), p<0.001) and had recurrently elevated levels. MPTFa of VTE<sub>pos</sub> patients was similar to HC (median 10.0 (IQR 1.1, 3.3), p=0.4). All VTE<sub>pos</sub> patients had peak MPTFa above normal (mean ± 2SD of HC = 6.5) versus 2/20 VTE<sub>neg</sub> patients (p=0.0001).

Conclusions: Patients with AAV who develop VTE have a notable propensity for increased MPTFa at times both near and remote from VTE. Conversely, those without VTE rarely exhibit MPTFa significantly higher than healthy controls during their disease course. Further study is needed to determine if elevated MPTFa can identify AAV patients at high risk for VTE and whether MPTFa contributes to thrombogenesis.

ApolI Polymorphism Determines HIV Boarding in Human Podocytes

Pravin C. Singhal, Xiqian Lan, Ashwani Malhotra, Karl Leon Skorecki, Joanna Mikulak

1Dept of Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 2Medicine, Rambam Health Care Campus, Haifa, Israel; 3Clinical and Experimental Immunology, Humanitas Clinical and Research Center, Milan, Italy.

Background: Patients of African ancestry with untreated HIV infection, carrying the G1 or G2 kidney disease risk variants (Vs) at the APOL1 gene are at a >10-fold greater risk for developing HIV-associated nephropathy (HIVAN) compared to Caucasian patients. Although APOL1 risk variants. In African Americans with HIVAN, the mechanism of kidney injury has been attributed to the direct effect of HIV infection, the mechanistic contribution to kidney injury of the APOL1 allelic state remains to be elucidated.

Methods: We evaluated the priming effect of IL-1β on human podocyte (HP) APOL1 expression. To evaluate the effect of IL-1β on HIV-1 processing in podocytes, HPs were pre-stimulated with human recombinant IL-1β for 6 h and then incubated with HIV-1 followed by analysis for the HIV-1 strong stop DNA by qPCR analysis. HPs treated under similar conditions were evaluated for the ability of recipient kidneys and HPs to transduce recipient kidneys with HPV (HPV entry) expression. To determine the effect of over expression of APOL1 (G0) and APOL1 variants (G1/G2) HPs were either transfected with APOL1G0/G1/G2 plasmids, or HPs were pre-stimulated with 10 ng/mL of IFN-γ and then incubated with HIV-1 and analyzed for HIV-1 strong stop DNA concentration at various time points and also measured for their lysosomal bioactivity.

Results: APOL1 expression increased after incubation of podocytes with the HIV. In turn, APOL1 expression was further enhanced in response to augmented entry of virus compared to baseline. In HPs, expression of IFN-γ and IL-1β treatment, consistent with viral load dependency. Podocytes over-expressing the non-risk APOL1 gene (G0), either through

Use of Spot Urine Protein Creatinine Ratio to Predict Proteinuria in Nephrotic Syndrome in NEPTUNE. Marie C. Hoog,1 Jonathan P. Troost,2 Peter J. Nelson,1 Heather N. Reich,1 Sharon G. Adler,1 Daniel C. Cattran,1 Gerald B. Appel,1 Debbie S. Gipson,1 Wenjun Ju,1 Matthias Kretzler,2 John C. Lieske,1 Mayo,1 UMich,1 UWash,1 UT,1 UCLA,1 Columbia,1

Background: Random protein urine creatinine ratio (UPC) is used to estimate 24 hr protein excretion (24P) yet little data are available wrt sensitivity & specificity, especially in pts with glomerular proteinuria.

Methods: The Nephrotic Syndrome Study Network (NEPTUNE) studies newly diagnosed patients with MCD, FSGS, & MN. Total protein, alb & creat are measured in random & 24 hr urine collections at a central biobank at postbiopsy baseline & subsequent visits within 2 yrs of dx.

Results: Of 603 participants, 302 have same day spot & 24 hr ur samples with a total of 827 samples across all visits eligible for this analysis. Urine protein excretion (g; median; 25, 75%) was higher in adults (1.0, 0.3, 2.3) than in kids (0.2, 0.0, 0.7). Spot UPC correlated better with 24 hr UPC than 24P in both adults (r=0.79 vs 0.60) & kids (r=0.84 vs 0.67). Using these data we derived equations to predict 24P from spot UPCs: for adults 24P = [10^(0.88x(log10 [Spot UPC]) - 10]) & for kids was 24P = [10^(1.06x(log10 [Spot UPC]) - 10)]. The efficiency (AUC) of spot UPC to accurately predict 24P values above thresholds of 0.5, 1.0, 2.0, 3.0, 6.0 & 10 g ranged from 0.83-0.97 in adults & peds.

In subgroup analysis the correlation between log-transformed UPC and log-transformed 24P was similar in all age ranges & diseases, but stronger in obese vs. normal wt subjects (b_slope =0.78, 0.69, 0.88; b_intercept=-0.85, 0.78, 0.93; b_slope=0.85, 1.0, 0.03).

Conclusions: Among MCD, FSGS, & MN pts UPC correlates only moderately with 24P. 24P is best derived from spot UPC using a non-linear estimating equation. WT influences reliability of spot UPC. Our data also suggest UPC can be used with caution to identify those pts with 24P above clinically relevant cut points. As 24P is susceptible to collection errors & implications of threshold values may be dependent on patient size, additional studies to evaluate spot UPC vs 24P and clinical outcomes are warranted.

Actinin-4, Synaptopodin, Nephrin, and Nep-1 Expression in Proteinuric Patients. Ashwani Kumar,1 Ritambhra Nada,1 Charan Singh Rajat,1 Krishan L. Gupta,1 2Dept of Histopathology, Post Graduate Inst of Medical and Research, Chandigarh, India; 1Dept of Nephrology, Post Graduate Inst of Medical and Research, Chandigarh, India.

Background: Podocytes have an important role in glomerular filtration barrier. Primary podocytopathies and secondary podocyte injuries in presence of immune deposits at different locations results in proteinuria. We compared expression of podocyte structural proteins; α-actinin-4 (Act-4), synaptopodin (Syn), and slit diaphragm proteins; nephrin (Nep) and neph-1 by immunofluorescence (IF) in minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous glomerulonephritis (MGN), and IgA nephropathy (IgAN).

Methods: Two hundred cases (n=50 each) along with controls were stained with FITC tagged α-Act-4, Nep, Syn, and Nep-1 antibodies. Immunofluorescence was graded as mild, moderate, and intense. Immunogold staining with α-Act-4, and Syn antibodies was done to see localization electronmicroscopically (EM).

Results: The α-Act-4 showed mild to moderate intensity (40% & 60%) in controls and most of the cases in all proteinuric groups. Up-regulation was noted in 52% cases of FSGS, 61% in MGN and 75% in IgA. Nephrin showed mild intensity in controls; however moderate to intense staining was seen in MGN (46% & 14%) whereas loss of staining was noted in all other groups (FSGS-54%, MCD-43, IgAN-59%). Nephrin-1 also showed mild to intense staining was seen in all groups and was given second dose. At 6 months, CR and PR was achieved in 9(75%) and 1(8.3%) respectively. There were 2 non-responders (16.6%). Of the 10 responders,3 have completed 1 yr of follow-up and are in remission. Adverse event (pneumonia) was noted in 1 patient (8.3%).

Conclusions: Rituximab appears to be a promising agent in the management of adult CNI dependent or intolerant NS due to MCD/FSGS with minimal short-term adverse events.
FR-PO426
Treatment and Outcomes in Minimal Change Disease: Experience of a Single UK Centre
Anthony Fenton, Stuart W. Smith, Peter Hewins. Dept of Renal Medicine, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

Background: Minimal change disease (MCD) accounts for 10-25% of nephrotic syndrome in adults. We retrospectively reviewed the treatment and outcomes of MCD patients in our centre.

Methods: We identified adults who had undergone renal biopsy between June 1996 and March 2012 which was reported as being consistent with MCD, and who had at least 12 months of follow-up. Electronic hospital records were used for data collection.

Results: There were 78 cases, with median follow-up of 72 months. Baseline and treatment data are shown in the table (averages are mean, or median where distribution is skewed). 27% had a history of nephrotic syndrome in childhood. All but one patient (who entered remission spontaneously) were treated with prednisolone, and 97% achieved complete remission at a median time of 33 days (6-309), although 12% needed a second-line agent to do so. Mean number of relapses during the first 24 months was 1.0. 68% experienced at least one relapse, and 45% patients required second-line agents at some point. Regarding complications: 12% developed thromboembolic disease, 14% had an admission requiring infection, and 41% had at least one episode of AKI. Mean follow-up creatinine was 91 mmol/L, but significantly higher in those who had had AKI (104 vs 85 p=0.04) and those who had received an ACEI (99 vs 78 p=0.01). Of 16 patients who underwent subsequent biopsy (all of whom had received a CNi), 8 showed evidence of CNi damage, and 5 were consistent with FSGS. Diabetes mellitus developed in 12% cases, and 8% patients died during follow-up.

Conclusions: Almost all treated adult MCD patients enter remission, although second-line agents are frequently required. Despite therapy, complications remain common, including AKI which is associated with residual reduced eGFR function.

FR-PO427
Predicators for Relapse in Adult Minimal Change Disease
Hajeong Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Chun Soo Lim. Internal Medicine, Seoul National Univ Hospital.

Background: Minimal change disease (MCD) is well-known benign primary glomerulonephritis in adults because of their distinct rare renal progression to end-stage. However, their relapse-associated morbidity has been underestimated. In this study, we aimed to explore the predictors of relapse in adult MCD patients.

Methods: We reviewed clinical and pathologic characteristics of adult primary MCD patients from Seoul National University Hospital from 1979 to 2013. Patients who were presented by nephrotic syndrome and followed up more than 12 months were included. Patients were excluded for secondary MCD were excluded. Initial treatment regimens, their response, and complication were also reviewed. The number of relapse were classified as follows, no relapse, 1-2 relapses (relapse group 1), and ≥ 3 relapses (relapse group 2).

Results: A total of 195 patients were included in the final analysis. Among them, median age at the time of diagnosis was 38 (23-53) years and 113 (57.9%) were men. During median follow-up of 81 (44–153) months, more than 90% of patients reached to remission after initial treatment. However, only 64 (32.8%) patients did not experience any relapse. Remaining 131 patients, 69 (35.4%) relapsed once or twice and 62 (31.8%) relapsed more than three-times. The younger, the more relapse was found. In addition, severity of nephrotic syndrome data are shown in the table (averages are mean, or median where distribution is skewed). 27% had a history of nephrotic syndrome in childhood. All but one patient (who entered remission spontaneously) were treated with prednisolone, and 97% achieved complete remission at a median time of 33 days (6-309), although 12% needed a second-line agent to do so. Mean number of relapses during the first 24 months was 1.0. 68% experienced at least one relapse, and 45% patients required second-line agents at some point. Regarding complications: 12% developed thromboembolic disease, 14% had an admission requiring infection, and 41% had at least one episode of AKI. Mean follow-up creatinine was 91 mmol/L, but significantly higher in those who had had AKI (104 vs 85 p=0.04) and those who had received an ACEI (99 vs 78 p=0.01). Of 16 patients who underwent subsequent biopsy (all of whom had received a CNi), 8 showed evidence of CNi damage, and 5 were consistent with FSGS. Diabetes mellitus developed in 12% cases, and 8% patients died during follow-up.

Conclusions: Almost all treated adult MCD patients enter remission, although second-line agents are frequently required. Despite therapy, complications remain common, including AKI which is associated with residual reduced eGFR function.

FR-PO429
Long-Term Outcomes of Nephrotic Syndrome, from Childhood into Adulthood
Rebecca C. Horten, Frederick J. Kaskel, Kimberly J. Reidy. Pediatrics, Div of Nephrology, Albert Einstein College of Medicine, Children’s Hospital at Montefiore, Bronx, NY.

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is known to have several long term sequelae including chronic and End Stage Kidney Disease (CKD and ESKD). However there are few studies on the long-term outcomes of steroid sensitive nephrotic syndrome. Presented here is a single center, retrospective case series from an urban, ethnically diverse population in the Bronx.

Methods: We utilized a medical record data mining tool to identify patients by ICD-9 code (1) with a diagnosis of nephrotic syndrome prior to age 18 (2) with a documented albumin <3.5 g/dL or random urine protein > 1 g/dL and (3) with at least one hospital encounter after the age of 18. Each cohort was evaluated for diagnosis of hypertension, obesity, diabetes, and well tolerated. Burden of medication with attendant side effects, as well as inpatient and outpatient attendance were significantly reduced. Analysed costs showed a modest saving past Rituximab. Further randomised studies are required to confirm and extend these findings.

Results: All three groups – SRNS (n=173), CNS (n=169) and control (n=18225) had similar age at diagnosis, length of follow-up. Both the CNS and CNS groups had a greater proportion of short stature, cataracts, infertility and malignancy (Chi square statistic p < 0.05) [table 1]. In addition they had a greater percentage of patients with CKD by eGFR which is most notable at CKD stages 4 and 5 (Chi square statistic p < 0.05).

Conclusions: Our results show that even patients with uncomplicated nephrotic syndrome are at risk for significant outcomes, including chronic kidney disease. Further study is needed, however it implies that all patients with a diagnosis of nephrotic syndrome will need to be counseled regarding the risks associated with their diagnosis and should have long term monitoring for these outcomes, including worsening renal function, hypertension and malignancy.

Apolipoprotein CI Levels Are Associated with the Urinary Protein/Urinary Creatinine Levels in Pediatric Idiopathic Steroid-Sensitive Nephrotic Syndrome
Jun Okada, Takahiro Kanai, Takane Ito, Jun Aoyagi, Takanori Ordonez, Glenn Matthew Chertow, Sijie Zheng, David Law. 1

Background: Various humoral factors have been proposed as causal agents of idiopathic steroid-sensitive nephrotic syndrome (ISSNS). In the present study, we analyzed serum proteins using mass spectrometry (MS) in a search for proteins that might be related to ISSNS pathophysiology.

Methods: We collected serial serum samples from 33 children with ISSNS. The serum samples were collected in each phase as follows: Phase A1 [the acute phase prior to steroid treatment (STs)], Phase A2 [remission with STs], and Phase A3 [remission without any medication]. We also included two control groups comprised of children with normal urinanalysis (Group B) and children with a nephrotic syndrome other than ISSNS (Group C). The urine protein/urinary creatinine (UP/UCr) ratios were not statistically different between Phase A1 and Group C. We used surface-enhanced laser desorption/ionization time of flight MS to analyze samples.

Results: A total of 207 peptide ion peaks were detected in the range of m/z 2000–10000. Four peptide ions (m/z 6444, 6626, 8695, and 8915) were significant elevated during Phase A1 compared to Group B and children with a nephrotic syndrome other than ISSNS (Group C). The urine protein/urinary creatinine (UP/UCr) ratios were not statistically different between Phase A1 and Group C. We used surface-enhanced laser desorption/ionization time of flight MS to analyze samples.

Conclusions: Our findings provide new insight into elucidating the pathophysiology of ISSNS.

Ofatumumab in Two Nephrotic Syndrome Children
Marina Vivarelli, 1  Vivianne Buss, 1  Daniel Basu, 1 1

Background: Rituximab (RTX), an anti-CD20 monoclonal antibody, is an effective treatment in patients with frequently-relapsing or steroid-dependent nephrotic syndrome (Ravani, JASN 2015). However, some patients develop adverse reactions. We describe the use of a humanized anti-CD20 monoclonal antibody, ofatumumab (OFA), as a viable alternative.

Methods: Patient 1 is a 3-yr-old boy who presented at 18 months with NS initially resistant to treatment with oral prednisone. He was then treated with 3 iv boluses of methylprednisolone followed by cyclosporinA, with remission. Upon steroid discontinuation, NS relapsed. Prednisone was restarted and a single dose of RTX was planned, but was never completed as at start of infusion a severe allergic reaction (urticaria, dyspnea) occurred. Patient 2 is a 14-yr-old boy with SDNS since the age of 2 years treated with oral prednisone, cyclosporinA and micophenolate mofetil (MMF), with the development of severe obesity. A first infusion of RTX at age 12 was well tolerated and allowed prednisone discontinuation for over 2 years. Then a prolonged (>30 days) relapse occurred under treatment with oral prednisone, MMF and cyclosporinA. Therefore, a second RTX infusion was attempted, but the child presented severe dyspnea and it was interrupted. The use of OFA at 1.5 g/1.73 m2, described in steroid-resistant NS children (Basu, NEJM 2014), was attempted. In patient 2 OFA was preceded by three boluses of iv methylprednisolone to induce remission.

Results: In pt 1, OFA infusion was uneventful. In pt 2, a mild allergic reaction was observed and treated. Remission was maintained during the follow-up period (9 months for pt 1, 5 months for pt 2), despite the interruption of prednisone treatment in both patients, and in pt 1 of cyclosporinA, while in pt 2 of MMF with ongoing cyclosporinA at last follow-up. After OFA infusion, CD19+ B cells reappeared at 7 months in pt 1, while remained depleted (0%) at 5 months in pt 2.

Conclusions: OFA could be a therapeutic option in managing severe forms of drug-resistant nephrotic syndrome in patients who have developed intolerance to RTX.

Population-Based Identification of Children with Primary Nephrotic Syndrome: Kaiser Permanente Nephrotic Syndrome Study
Alan S. Go, 1  Dongjie Fan, 1  Thida Tan, 1  Janet M. Wojcicki, 1  Jingrong Yang, 1  Juan Daniel Ordonez, 2  Glenn Matthew Chertow, 1  Sijie Zheng, 1  David Law. 1  Kaiser Permanente Northern California; 2  Univ of California, San Francisco; 3  Stanford Univ.

Background: Few population-based data exist about children with primary nephrotic syndrome (NS) in the US. We identified a cohort of children with primary NS in a large integrated healthcare system.

Methods: Kaiser Permanente Northern California cares for >750,000 children. We identified members age<18 yrs between 1996-2012 who had nephrotic range proteinuria (UACR ≥3500 mg/gCr or proteinuria ≥3.5 mg/mg, 24-hr protein ≥350 mg/dL, or dipstick>3+ proteinuria) or NS (ICD-9 581.x) in electronic records and lab databases. Nephrologists reviewed records for clinical presentation, lab and biopsy results to confirm primary NS.

Results: We identified 179 children with NS due to minimal change disease (72%), focal segmental glomerulosclerosis (23%) or membranous nephropathy (5%). Incidence was 1.47 per 100,000 (95% CI:1.27-1.70). Biopsies were available in 40% of cases. Baseline features at diagnosis are shown by cause of NS.

Funding: Private Foundation Support

Abatacept Treatment and B7-1 Immunostaining in Patients with Primary and Post-Transplant FSGS
Ron Maas, 1  Brigit Willemsen, 1  Hendrik Dijkstra, 2  Catharina M. Haring, 3  Jeroen Deegens, 1  Jack F. Wetzel, 1  Ped Nephrol, Radboud Univ Medical Center, Nijmegen, Netherlands; 2  Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; 3  Nephrology, Deventer Hospital, Deventer, Netherlands.

Background: Podocyte B7-1 expression has been implicated in the pathogenesis of idiopathic nephrotic syndrome for many years. Recently, podocyte B7-1 was described as a potential therapeutic target by demonstrating efficacy of B7-1 blocking agent abatacept in five patients with primary and post-transplant FSGS (Yu et al. New Engl J Med 2013). The authors speculated that patients who will respond to abatacept can be identified by positive B7-1 immunostaining on kidney biopsy. Here, we report our experience with abatacept and B7-1 staining in patients with FSGS.

Methods: Patients with no or partial proteinuria remission after plasmapheresis for treatment of FSGS received abatacept (2 or 3 doses of 10 mg/kg). After several trials of unsuccessful immunofluorescence staining, we performed B7-1 immunohistochemistry on paraffin embedded tissue with a primary antibody mouse anti CD80 (R&D systems).

Results: Three patients with post-transplant FSGS, and one patient with NS in the native kidney (Table, Patient 4) were treated with abatacept. All transplant patients had developed nephrotic proteinuria immediately after transplantation. Patient 1 had been treated with plasmapheresis for many years, and was previously unresponsive to B7-1 blocking agent belatacept. None of the patients had proteinuria remissions after abatacept, nor did we observe positive podocyte B7-1 immunostaining.

Conclusions: In our hands B7-1 staining was absent in patients with FSGS. Our data caution against too much optimism regarding the efficacy of abatacept.

Steroid Resistant Nephrotic Syndrome: A Prospective, Open Label Study of the Safety and Efficacy of Combination Tacrolimus and ACTHAR Gel Therapy
James A. Tumlin,1 Claude Mabry Galphin,2 Brad H. Rovin.1
1Univ of Tennessee College of Medicine, Chattanooga, TN; 2The Ohio State Univ, Columbus, OH.

Background: Steroid resistant nephrotic syndrome (SRNS) in adults is associated with increased risk for progression to ESRD. Tacrolimus is a calcineurin inhibitor (CNI) that is an alternative to steroids, but is associated with progressive fibrosis and loss of GFR. ACTHAR gel has shown benefit in the treatment of SRNS. To investigate additive effects, we followed 23 SRNS patients receiving combination therapy with Tacrolimus and ACTHAR Gel.

Methods: 23 patients with SRNS (IMGN 8, 11 FSGS and 4 other) receiving ACE-ARB and 8 weeks of oral steroids prior to combination therapy of ACTH and Tacrolimus. Eleven patients received 2 or more drug therapies. Of the 23, 17 (71%) initially received ACTH following by Tacrolimus. Duration of ACTH/TAC therapy averaged 6.2 months [range 1-12 months]. Complete or partial responses were defined as UP/Cr ratio of < 0.30 or > 50% reduction in pre-ACTH/TAC proteinuria, respectively.

Results:

Table-1 Number Age Baseline Peak ACTH ACTH+ TAC

Responder 17 yrs 6.2±1.4 11.0±2.4 3.3±2.0 1.4±0.4
IMN 6 58±3 6.6±2.3 13.1±2.7 4.9±2.2 1.2±0.5
FSGS 9 67±5 4.3±2.3 18.4±1.4 2.6±0.5 1.7±0.9
Other 2 58±3 9.9±5.6 12.4±3.9 0.3±0.2 0.6±0.7
Non-Responder 6 52±5 5.7±1.6 11.6±2.5 7.5±1.5 7.8±1.5
IMN 3 46±7 6.3±2.2 11.6±2.9 7.6±2.5 9.2±3.3
FSGS 3 52±8 6.0±2.3 11.8±2.5 7.4±2.6 7.3±1.6

Of the 23 patients, 6 (26%) achieved a complete response; a partial responses were observed in 11 (48%) for an overall response of 74%. Proteinuria levels (expressed as a ratio of UP/Cr) before and after treatment are listed in the Table. There was no difference in the rate or time to complete or partial remission between IMGN and FSGS patients respectively. The mean time to partial response was 6.2 months, but could range up 12 months. Combination therapy ACTH and Calcineurin inhibitors may offer an effective alternative therapy to SRNS.

FR-PO435

Treatment of Nephrotic Syndrome Secondary to Primary FSGS – Prednisolone or Tacrolimus? A Two Centre Experience
Hannah R. Wilson,1 Thomas M. Conner,2 Tom Cairns,2 Mona Saleh Wahba,2 Marie B. Condon,1 Megan Griffith.1
1St. Helier Hospital, London, United Kingdom; 2Hammersmith Hospital, London, United Kingdom.

Background: Focal segmental glomerulosclerosis (FSGS) is a significant cause of end-stage renal failure. Patients with nephrotic syndrome have a worse prognosis. Current guidelines advise prolonged prednisolone (pred) at 1mg/kg. Tacrolimus (Tac) is an alternative for patients, but long-term therapy is often necessary, and there are concerns about toxicity.

Methods: Retrospective review of all patients with nephrotic syndrome secondary to primary FSGS treated with a minimum of 12 mths follow-up at 2 centres. All patients received standard therapy with max tolerated ACEi +/- ARB. Complete remission (CR) was defined as normal serum albumin with PCR <50% partial remission (PR) as proteinuria ≤50% baseline. Results described as Median (Range); p value <0.05 significant.

Results:

Demographics Pred n=15 Tac n=23 p value

Age 50 (19-75) 45 (19-78) ns
Gender 8M, 7F 12M, 11F ns
Ethnicity Caucasian 12 9 5 ns
Asian 1 2 9 ns
Average follow up (mths) 43 (12-257) 45 (12-86) ns

Baseline parameters

Creatinine µmol/L ≤50% baseline. Results described as Median (Range). p value <0.05 significant.

Albumin 167 (61-480) 87% 906 (478-1910) 26% 101 (52-312) 0.05

6.4mg/L.3 mths 6.3mg/L.12 mths ns

Response to primary agent (pts)

Remission PR 60% (9) 91% (21) 0.05
CR 60% (9) 91% (21) 0.05

Time to remission (wks)

PR 8 (3-40) CR 10 (5-44)

Relapse 22% (2) 25% (5) ns

ESRF 26% at 1,13,19,69 mths 0 <0.05

Creat latest f/u 92 (61-390) 92 (54-234) ns

Adverse events

Deaths 1 (lung ca) 0 ns
Diabetes/Insulin 3 4 ns
Severe Infection 1 (colon ca) 0 0 ns

Conclusions: In the Tac cohort a higher remission rate was demonstrated and a suggestion of fewer adverse events although numbers are small. However the baseline parameters show the GFR was significantly lower in the prednisolone group. Patients treated with Tac had a longer duration of treatment but appeared to have a better adverse event profile overall. A randomised controlled trial is required to investigate this further.

FR-PO436

Differences in Initial End Stage Renal Disease (ESRD) Treatment Modality Across Glomerulonephritis Subtypes
Michelle M. O’Shaughnessy,1 Maria E. Monteza-Rath,1 Richard A. Lafayette,1 Wolfgang C. Winkelmaier.1
1Div of Nephrology, Stanford Univ School of Medicine; 2Section of Nephrology, Baylor College of Medicine.

Background: Kidney transplantation (Tx) is the treatment of choice for end-stage renal disease (ESRD). Hemodialysis (HD) and peritoneal dialysis (PD) outcomes are largely equivalent. Whether access to these modalities is equal across glomerulonephritis (GN) subtypes has not been established.

Methods: We identified all patients in the US Renal Data System 18-75 years who initiated ESRD therapy with Tx, HD, or PD (1996-2011) and had ESRD attributed to glomerulonephritis (GN) subtypes has not been established.

Results: We identified all patients in the US Renal Data System 18-75 years who initiated ESRD therapy with Tx, HD, or PD (1996-2011) and had ESRD attributed to 6 GN subtypes [focal segmental glomerulosclerosis (FSGS), IgA nephropathy (IgAN), membranous nephropathy (MN), membranoproliferative GN (MPGN), lupus nephritis (LN), vasculitis]. Odds ratios (ORs) for PD vs HD and for Tx vs HD were computed using multinomial logistic regression (IgAN as reference group), with multivariate adjustment for demographic, socioeconomic, and comorbidity differences.

Conclusion: Among 75,278 patients studied, demographic, socioeconomic, and comorbidity characteristics differed considerably across GN subtypes. In unadjusted analyses, patients with FSGS, MN, MPGN, LN, and vasculitis were significantly less likely to receive Tx or PD as a first ESRD treatment modality than patients with IgAN: OR for Tx 0.52, 0.35, 0.48, 0.23, and 0.13, respectively; OR for PD 0.77, 0.66, 0.59, 0.48, and 0.30, respectively (all p<0.0001). After adjustment, differences were attenuated but patients with secondary GN subtypes (LN, vasculitis) remained significantly less likely to receive Tx or PD as compared to patients with IgAN (figure).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Patients with ESRD attributed to secondary GN subtypes (LN, vasculitis) are significantly less likely to receive Tx or PD as an initial ESRD treatment than patients with primary GN subtypes. The clinical appropriateness and sequela of this apparent inequity must be determined.

FR-PO437

Non Collapsing Focal and Segmental Glomerulosclerosis in Patients with HIV

Julien Hogan, Claire Carter, Emmanuelle M. Plaisier, Kamyar Kalantar. Thomas Jefferson Univ Hospital.

Background: With the improvement of the treatments against HIV, non collapsing focal and segmental glomerulosclerosis (FSGS) has become more frequent than HIV associated nephropathy (HIVAN). However, the physiopathology of non-collapsing FSGS among HIV patients remains poorly understood. We thus aimed to compare patients with HIV and non-collapsing FSGS with patients with HIVAN and with non HIV patients with FSGS.

Methods: HIV patients with a kidney biopsy in our center between 2000 and 2012 (24 non collapsing FSGS and 13 HIVAN) and two control groups (10 primary and 12 secondary FSGS) were included. Clinical and biological data were collected; viral load in serum and urine was assessed with the hard shell in a real time PCR machine; immunohistochemical staining for PCNA to study epithelial cells proliferation.

Results: Clinical and biological features of HIV patients with non-collapsing FSGS were close to those of controls with secondary FSGS. Among HIV patients, the prevalence of cardiovascular risk factors was greater in those with non collapsing FSGS than in those with HIVAN (79% vs. 38%, p=0.01) but was comparable to the one in controls with secondary FSGS (100% vs. 79%, NS). HIV patients with non collapsing FSGS and controls with secondary FSGS had more frequently arteriolar sclerosis on the biopsy than patients with HIVAN (75% and 82% vs 36%, p<0.01). Visceral epithelial cells expression of PCNA showed that, despite a stronger staining in collapsing lesions, it can be found among all patients groups and in any FSGS lesion type. The majority of HIV patients with non collapsing FSGS had undetectable viral load in serum and urine.

Conclusions: Major clinical, biological and histological differences between HIV patients with non collapsing FSGS and HIVAN support the hypothesis of two distinct physiopathological entities. They are striking similarities between non collapsing FSGS in HIV patients and secondary FSGS found in patients with polyvascular disease. Non collapsing FSGS in HIV patients might be due to nephronic reduction secondary to vascular lesions in an ageing population with major metabolic abnormalities associated with antiviral drugs.

FR-PO438

Diabetic Glomerulosclerosis or Idiopathic Nodular Glomerulosclerosis – Role for Insulin Resistance

Background: Diabetic nephropathy (DN) is characterized histologically by nodular mesangial sclerosis, a thickened glomerular basement membrane, and hyalinized arteries. Differential diagnoses by light microscopy (LM) include membranoproliferative glomerulonephritis, amyloidosis, monoclonal immunoglobulin deposition disease, and fibrillary or immunotactoid glomerulopathy. These can readily be excluded by special stains, immunofluorescence (IF) and electron microscopy (EM). Idiopathic nodular glomerulosclerosis (ING) is the term used to denote classic DN confirmed by LM, IF, and EM, but in the absence of diabetes mellitus (DM). Case reports suggest insulin resistance (IR) as a possible cause.

Methods: Data was collected retrospectively on 21 cases of diabetic glomerulosclerosis or ING biopsied due to proteinuria (1+ on urinalysis to 12.3 grams/day), with or without renal insufficiency (creatinine 0.6-4.4mg/dl).

Results: 13 patients were male with majority of patients being African American (10) and non-Hispanic white (7). 1 patient was post-renal transplant and another post-liver transplant. None of these patients were diagnosed with DM, although some had hypertensive elevated blood glucose and borderline HbA1c. All patients had hypertension, but only 5 were active tobacco users and 8 were former smokers. BMI range was 21-43kg/m². Hemoglobin A1c range was 4.6-6.1% in 10 patients and 6 patients denied DM by telephone survey. The remaining 5 patients had no history of DM per records with few elevated random plasma glucose levels and few cases of antihypertensives. None of them fulfilled current diagnostic criteria for DM. Metabolic syndrome (MS) defined by Adult Panel III criteria was evident in 11 patients.

Conclusions: The pathogenesis of ING remains unclear. It involves the interplay of hypertension, obesity, and heavy smoking. We feel that IR is critically important, whether evident as subtle, prediabetic elevations of blood glucose, MS, or elevated HOMA-IR score being the only manifestation. Insulin sensitivity assessed by HOMA-IR score is possibly an important predictive factor in pathophysiology of ING and needs to be tested routinely.

FR-PO439

Association of Serum Albumin Level and Venous Thromboembolic Events in Seven-Thousand Patients with Nephrotic Syndrome

Gecta G. Gvamalani, Miklos Zsolt Molnar, Jun Ling Lu, Keichi Sumida, Kamyar Kalantar-Zadeh, Csaba P. Kovesy, VAMC Medical Center, Memphis, TN; Univ of Tennessee Health Science Center, Memphis, TN; Univ of California, Irvine, CA.

Background: Prior studies have shown that low serum albumin in patients with nephrotic syndrome (NS) is associated with an increased risk of venous thromboembolic (VTE) events. This is based on small studies with a low number of thromboembolic events and short term follow-up.

Methods: From a nationally representative cohort of over 3 million US veterans with baseline estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m², we identified 7037 patients with NS based on ICD9 codes. Association between serum albumin and risk of incident VTE events (based on ICD9 codes) was assessed using Cox regression analysis with adjustments for age, gender, race, comorbidities, eGFR, BMI and anticoagulant treatment.

Results: Mean age was 57±11 years, and patients were 96% male, 32% African-American and 66% diabetic. There were a total of 158 VTE events over a median follow-up was 8.1 years; 16 events (4.1%, event rate (ER): 8.5/1000 patient-years(PY)) in patients with albumin <2.5 g/dl, 18 events (3.4%, ER: 5.7/1000 PY) in patients with albumin 2.5-2.99 g/dl, 89 events (2.5%, ER: 3.4/1000 PY) in patients with albumin 3-3.99 g/dl and 55 events (1.4%, ER: 1.9/1000 PY) in patients with albumin ≥4 g/dl. Compared to patients with albumin ≥4 g/dl, those with albumin levels of 3-3.99 g/dl (adjusted HR 1.51; 95%CI 1.01-2.26), 2.5-2.99 g/dl (2.24, 1.24-4.05) and < 2.5 g/dl (2.79, 1.45-5.37) experienced a linearly higher risk of VTE events.

Conclusions: Lower serum albumin is a strong incremental risk factor for VTE events in NS. The risk increases proportionately with declining albumin levels. Our finding may have important clinical implications regarding initiation and duration of prophylactic anticoagulation.

FR-PO440

Hypercoagulopathy Is Directly Correlated with Disease Severity in Nephrotic Syndrome

Amanda P. Waller, Samir Parikh, Brad H. Rovin, William E. Smoyer, Marvin T. Nieman, Matthias Kretzler, Bryce A. Kerlin. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; Columbus, OH; and Nationwide Children’s Hospital, Columbus, OH.

Background: Nephrotic syndrome (NS), a leading cause of end stage kidney disease, is characterized by massive proteinuria, hypoalbuminemia, and an increased risk for venous thromboembolism (VTE). We recently reported that hypercoagulopathy is proportional to the severity of both proteinuria and hypoalbuminemia in two animal models of NS. This study was designed to determine if this relationship translates to human NS.

Methods: Aliquots of plasma anticoagulated with 0.32% (final concentration) sodium citrate were obtained from the NEPTUNE biorepository (n=147 patients), along with corresponding clinical lab data (e.g. urine protein :creatinine (uP/C), serum albumin (sAlb)). Samples collected from a local patient cohort (n=21) were used to validate biorepository

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

456A
specimen integrity. Endogenous thrombin potential (ETP) was determined using the Technothrombin TGA kit and RC Low reagent after 2.1 dilution with buffer. Plasma antithrombin (pAT) activity was measured by the amidoanalytic method.

Results: As expected, NEPTUNE patients exhibited a wide range of proteinuria values (median (range) uP:C: 1.85 mg/mg (0-17.6)). Hypoalbuminemia and proteinuria severity were proportional to ETP (R² = 0.252 & 0.128, respectively, P<0.001). These correlations were stronger in the subset of patients with uP:C≤2 (R² = 0.331 & 0.157, respectively, P<0.001). Plasma AT activity was also significantly correlated to hypoalbuminemia and proteinuria severity (R² = 0.125 & 0.031, P<0.001 & 0.03, respectively). There was no correlation between AT activity and ETP. Results were similar in the validation cohort.

Conclusions: Both hypoalbuminemia and proteinuria severity in humans with NS is significantly, albeit weakly, correlated to ETP (an established marker of thrombotic risk). Adjusting these data for combining clinical variables (e.g. smoking status, BMI, etc.) may aid in the modeling and development of evidence-based cut-offs to guide indications for prophylactic anticoagulation.

FR-PO441
Successful Social Media Recruitment into the NephCure Kidney Network, a Rare Disease Patient Registry
Laura H. Marijan, Joanna Dauber, Chelsey Fix, Alyssa Fisher, Jane Shen, Lalita Subramanian, Marilyn Hailperin, Jaakko Patrakka, Kjell Hultenby, Annika Hultenby

Background: Participation in clinical research for primary Nephrotic Syndrome (NS) has been limited by the rarity of the disease. There is growing interest in leveraging social media to expand geographic and geographic reach for recruitment. Because of the isolating nature of rare diseases, patients turn to social media for support, creating online communities that, if accessible, could potentially serve as a resource for recruitment.

Methods: The NephCure Kidney Network (NKN) is a web-based patient opt-in registry for primary NS. Participants provide data, including kidney disease history, demographics, and research participation preferences. Recruitment efforts launched in March 2014 relied on email campaigns to contacts of the patient advocacy group, NephCure Kidney International (NKN), but then expanded in September 2014 to include social media. Weekly posts were made to NKN’s Facebook page, with analysis of performance based on impressions (# of people reached) and engagements (likes, clicks, shares, comments). Relationships with other closed Facebook kidney disease groups were established and posts made to their sites.

Results: 45,151 impressions and 2,927 engagements were made from 9/2014-6/2015. Relationships were made with 54 kidney disease groups (>15,000 members) from which to find NS patients. Engagements were highest on posts focusing on patient-centeredness in research and lifestyle. 414 patients (51% female, 47% <18 y/o, 22% racial/ethnic minority) from 27 countries enrolled between 3/2014 and 6/2015, with 27% of enrollees having no previous engagement with NKN. 94% reported a willingness to be contacted about research, including 77% willing to donate a biospecimen. However, only 16% currently or previously participated in other social media. 94% reported a willingness to be contacted about research, including 77% willing to donate a biospecimen. However, only 16% currently or previously participated in other social media. 94% reported a willingness to be contacted about research, including 77% willing to donate a biospecimen. However, only 16% currently or previously participated in other social media.

Conclusions: It may be possible to evaluate the treatment response of NS and to differentiate MCNS from FSGS based on changes in s/u-suPAR within 2 months after the start of treatment. As a mechanism involved in proteinuria in NS patients, u-suPAR may inhibit protein reabsorption in the proximal tubules through the activation of b3 integrin.

The Expression of Podocyte Protein PREX2 in Glomerular Diseases
Anna Lavín, Julia Wijkstrom, Jenny Hulko, Jenny C. Nystrom, Kerstin Efebor, Annette Bruchfeld, Jiajiao Patrakka, Kjell Hultenby, Annika Hultenby

Background: Podocyte protein PREX2 is a new podocyte-associated protein. Although we have previously demonstrated a role for PREX2 in the glomerular filtration barrier, its expression in renal biopsies from patients with various renal diseases remains unknown.

Methods: We examined the expression of PREX2 in renal biopsies from patients with IgA Nephropathy (IgAN), Minimal Change Nephropathy (MCN, n=5) and control tissue from healthy kidney donors (n=5). PREX2 expression was analyzed by microarrays on isolated glomeruli from patients with IgAN, Minimal Change Nephropathy (MCN, n=5) and control tissue from healthy kidney donors (n=5). The expression of PREX2 in renal biopsies from patients with IgA Nephropathy (IgAN), Minimal Change Nephropathy (MCN, n=5) and control tissue from healthy kidney donors (n=5).

Results: We found that PREX2 is a new podocyte-associated protein. Although no difference in mRNA levels were found, the expression of PREX2 was significantly lower in IgAN and MCN compared to controls. The function of PREX2 in the glomerular filtration barrier will now be further investigated in an extended patient cohort and in genetically modified animals.

FR-PO443
Urinary and Serum Soluble Urokinase Receptor Levels Predict the Therapeutic Response of Nephrotic Syndrome
Keiji Fujimoto, Yuki Matsui, Norifumi Hayashi, Junko Imura, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama

Div of Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.

Background: It is difficult to develop noninvasive biomarkers to predict the treatment response for nephrotic syndrome (NS), and to differentiate their histological types in the initial phase.

Methods: The subjects were 32 patients with primary NS [8 with focal segmental glomerulosclerosis (FSGS), 12 with minimal change nephrotic syndrome (MCNS), 10 with membranous nephropathy (MN), and 2 with membranoproliferative glomerulonephritis]. Using ROC analysis, we examined whether or not it is possible to differentiate refractory NS from non-refractory NS, and MCNS from FSGS based on the pretreatment values of clinical markers [urinary protein (UP), serum/urinary soluble urokinase receptor (s-/u-suPAR), urinary L-FABP, and EFGR], and values and changes (∆) after 2 months (2M). We also examined the renal expression of activated b3 integrin (AP-3) by immuno-staining in primary NS and normal tissues.

Results: The following parameters were useful for differentiating refractory NS from non-refractory NS: 2M-UP (AUC=0.968, p<0.001), 2M-suPAR (AUC=0.913, p<0.002), D2M-suPAR (AUC=0.906, p=0.007), D2M-suPAR (AUC=0.881, p=0.005), and D2M-UP (AUC=0.833, p=0.014). On the other hand, D2M-suPAR (AUC=0.905, P<0.007) and D2M-suPAR (AUC=0.816, P=0.048) were useful for differentiating MCNS from FSGS. In addition, u-suPAR before treatment was positively correlated with UP (r=0.501, P<0.003) and urinary L-FABP (r=0.427, P=0.017). The expression of activated b3 integrin was primarily strong in the proximal tubular epithelial cells in FSGS or MN, but, weak in MCNS and normal tissues. Otherwise, there was no expression of activated b3 integrin on podocytes in both normal and diseased tissues.

Conclusions: It may be possible to evaluate the treatment response of NS and to differentiate MCNS from FSGS based on changes in s/u-suPAR within 2 months after the start of treatment. As a mechanism involved in proteinuria in NS patients, u-suPAR may inhibit protein reabsorption in the proximal tubules through the activation of b3 integrin.

Long-Term Outcomes of Thrombotic Microangiopathy Treated with Plasma Exchange – A Systematic Review

Background: With the adoption of plasma exchange as standard treatment for thrombotic microangiopathy, more patients are surviving and lasting-longer outcomes have greater relevance.

Methods: We conducted a systematic review of observational studies between 1980 and 2013 that reported outcomes of adults with thrombotic microangiopathy at least 6 months after initiating plasma exchange. We searched several databases from 1980 to 2013 for eligible articles published in any language. We abstracted data in duplicate and assessed the methodological quality of each study using an assessment tool developed based on recommended validity criteria.

Results: We screened 6672 articles, reviewed 213, and included 34 studies totaling 1182 patients (study median [range], 24 [10-118]). The mean (or median) follow-up ranged from 6 months to 13 years. The cumulative incidence of relapse and mortality was highly variable and ranged from 3 to 84% and 0 to 61%, respectively. The incidence of other outcomes across 10 studies also varied (outcomes included hypertension, kidney disease, pre eclampsia, stroke, seizure, severe cognitive impairment, and depression); in 3 other studies long-term neurocognitive function and health-related quality of life were significantly lower than the general population.

Conclusions: In summary, patients who survive an episode of thrombotic microangiopathy may be susceptible to long-term vascular complications including chronic kidney disease, but the magnitude of this risk and how to mitigate it remains unclear from prior studies.

FR-PO446

Eculizumab Prevents Thrombotic Microangiopathy in Atypical Hemolytic Uremic Syndrome Patients: Long-Term Follow-Up

Background: Plasma exchange (PLEX) is recommended for the treatment of aHUS but has no established long-term maintenance therapy. We report on the long-term follow-up of aHUS patients treated with PLEX.

Methods: An observational, multicenter, long-term follow-up study of aHUS pts treated with ECU in 5 prior clinical studies. The primary endpoint was exposure/follow-up time on ECU maintenance treatment schedule.

Results: 85 pts enrolled (Table); of these, 74 pts had ON and 37 pts had OFF treatment periods with median follow-up of 24.6 and 16.6 months, respectively. The primary endpoint was exposure/follow-up time on ECU maintenance treatment schedule.

Conclusions: The ECU treatment was 3.5-fold higher after ECU discontinuation vs. ECU. TMA event rates were lowest during on-label dosing, higher during off-label dosing, and highest off-treatment. Pts with aHUS have a progressive increase in the risk of TMA events during periods of reduced dosing and after discontinuation of ECU compared with on-label ECU dosing. Medical writing support – Kenyon Ogbum PhD, of Alexion.

FR-PO447

An Update on Tailored Eculizumab Maintenance Treatment in Patients with Atypical Haemolytic Uremic Syndrome

Background: Eculizumab (ECU) has been successfully used in patients (pts) with aHUS. The standard maintenance treatment suggests ECU administration every two weeks (wks), life long. The optimal maintenance schedule is not yet defined. To define our experience on individualized ECU treatment schedule for preventing relapses based on drug biological activity, with the rational of improving the patient’s quality of life, reducing the risk of adverse reactions and reducing the heavy costs of the treatment.

Methods: Pts undergoing ECU treatment at our Center were addressed to a progressive extension of the interval between ECU doses from the standard 2 wks to 3 or 4 wks with a strict monitor of global complement activity. AP50 was routinely determined before each ECU administration and the interval between doses was adjusted with the target of maintaining AP50<25%, Strict monitoring of indicators of disease reactivation, namely blood in the urine with home dipstick, was regularly performed.

Results: The interval between doses was extended in 33 pts (13 ≤ 18 yrs) with a median age of 28.1 yrs (5-62), 17 F, 21 with native kidney and 12 with graft. Identified mutations were: CFH:15; CFI:2; CD46:1; MCP:1; CFHR3-CFHR1 homoz. deletion with factor mutations and kidney transplant status were not different between ON and OFF pts.

Conclusions: On the basis of this study we can recommend a personalized treatment schedule of ECU to all pts with aHUS.

FR-PO448

Chemokines as Potential Biomarkers of Renal Involvement in Scleroderma

Background: Renal disease in scleroderma (SSc) remains a major clinical challenge. Previous studies showed up to 50% of SSc patients have CKD. We sought to gain insight into the pathogenesis of SSc-CKD by examining markers of disease in serum and urine.

Methods: We collected urine and serum from 80 SSc patients, with or without renal disease, for comparison with patients with CKD of other causes (n=10) and healthy controls (n=12). We performed multiplex analysis of candidate markers of disease activity or severity in the SSc and renal injury: MCP-1, MCP-3, IL-6, IL-18, TNF-α, and VEGF.

Results: 40 SSc patients had CKD defined by eGFR and urinalysis. Serum MCP-1 was increased in SSc compared with controls, with SSc-CKD significantly lower than SSc without CKD. Mean serum MCP-1 was 132 pg/ml (95% CI 105-162) for SSc with normal renal function compared with 65 pg/ml in SSc-CKD (p<0.001 for this comparison). MCP-1 was not increased in CKD of other causes (mean 47 pg/ml, 23-85) compared with
controls (mean 53 pg/ml, 25-85, p=0.848). Conversely, urine MCP-1/creatinine ratio was highest in SSc-CKD (mean 64, 32-111) than in SSc with normal renal function (mean 23.18; 28, p=0.046). MCP-3 was upregulated in the urine of patients with SSc with or without CKD (mean MCP-3:creatinine ratio 3.6, 2.5-4.6) compared with healthy controls (mean 0.9, 0.5-1.4, p=0.016). There was no difference between groups in serum MCP-3.

**Conclusions:** This is the first study to measure MCP-1 and MCP-3 in the urine of SSc patients. Elevated urine MCP-1 in SSc-CKD suggests increased expression in the renal tract and may help define organ-specific effects of this potential pathogenic mediator that has previously been reported to be increased in serum in association with pulmonary complications. In contrast to MCP-1, other markers of SSC severity (e.g. IL-6) or renal injury (e.g. IL-18) did not differentiate between groups. Our findings further support increased visualization of urine concentrations of chemokines MCP-1 and MCP-3 as markers of mediators of CKD in SSc.

**Towards a Deeper Understanding of Fibrillary Glomerulonephritis: Clinicopathologic Analysis of Patients in a Long-Term Inception Cohort**

Caroline J. Poulton, Yichun Hu, Harsharan Kaur

**Background:** Fibrillary glomerulonephritis is uncommon primary glomerular disease. Accordingly, there are no clinical trials to guide treatment making this a challenging disease to manage. Here, we report clinical characteristics and treatment outcomes of patients with fibrillary glomerulonephritis diagnosed and/or treated at UNC or through the Glomerular Disease Collaborative Network and compare them to a previously published cohort from Mayo clinic.

**Methods:** Patients were identified through the UNC Division of Nephropathology database. Clinical data were extracted from the electronic medical records starting at the time of diagnosis.

**Results:** There were 31 patients with fibrillary glomerulonephritis who were treated and an additional 24 patients who were diagnosed by the UNC Division of Nephropathology. Demographic and clinical data from the date of biopsy are displayed in the table.

**Conclusions:** This clinicopathologic analysis of patients with fibrillary glomerulonephritis is the largest study of its kind in the literature to date. The patients in our cohort were more ethnically diverse than the Mayo clinic group but presented with similar degree of kidney impairment and nephrotic range proteinuria. Fibrillary mesangiocapillary glomerulonephritis is an understudied glomerular disease that portends a poor prognosis warranting the need for prospective multi-center treatment studies to determine durable therapeutic avenues.

**Clinical, Histologic, and Genetic Predictors of Response to MMF in C3 Glomerulopathy**

Rupali Sundrenga Avasara, Pietro A. Canetta, Andrew R. Martinez, Henry J. Gonzalez Torres, Raul Garcia, M. Schober

**Background:** C3 Glomerulopathy (C3G) is a rare glomerular disease with different genetic sequences and clinical courses.

**Methods:**

**A.** 12 years old AAF who presented with stage 2 HTN and nephrotic range proteinuria (u. p/cr 4). A renal biopsy showed C3 GN. She received steroids. (HD) was initiated (s.c. 2.24 mg/dL, BUN 127 mg/dL). She received 5 anti-hypertensive medications & 3 PE sessions. She had no improvement. D29 she received Eculizumab 900 mg q wk & after 2 doses of Eculizumab, GFR improved and no longer required HD or PE. Case 1 (B). 15 yrs old WF who presented at 7 yrs of age with hematuria, stage 2 HTN & nephrotic range proteinuria (u. p/cr 13). Kidney biopsy showed C3 GN. She received only Lisinopril and had maintained normal GFR without RRT/steroids. Though she continued to have nephrotic range proteinuria.

**Results:** Both presented with hematuria, HTN and nephrotic range proteinuria and their biopsies showed C3 GN, persistent nephrotic range proteinuria despite improvement in GFR and normal levels of FHR, preop, C5b9. Gene analysis for A showed deletion of CFHR3, CFIHR1 and carry a variant of unknown significance in CFI and CFI. B in contrast had abnormal high complement plasma Bb antibody and 0% complement alternative pathway abnormality. Genetic sequences may influence clinical manifestations/ progression of the C3GN.

**FR-PO451**

**Membranoproliferative Glomerulonephritis C3 Deposits: Clinicopathological Study**

**Background:** Membranoproliferative glomerulonephritis (MPGN) is a pattern of damage characterized in the light microscopy by mesangial hypercellularity, thickening of the glomerular basement membrane and mesangial interposition in the capillary wall. Recent advances in the understanding of its underlying pathogenesis led to a classification system that highlights the findings in the immunofluorescence. Alteration complement regulation has proven to be a risk factor for the development of MPGN.

**Methods:** Cross-sectional study. The data were extracted from NefroRed®, a software platform that contains the socio-demographic, anthropometric, clinical and laboratory data of two thousand patients with kidney biopsies from 2008 to 2014. It was selected for the study those patients that showed the pattern of glomerulonephritis and membranoproliferative and C3 deposits only or predominant. Each biopsy was studied by light microscopy and immunofluorescence, light microscopy included hematoxylin-eosin, PAS, and Jones. C3 deposits were only or predominant. Each biopsy was studied by light microscopy and immunofluorescence. Light microscopy included hematoxylin-eosin, PAS, and Jones. C3 deposits were only or predominant. Each biopsy was studied by light microscopy and immunofluorescence.

**Results:** Mean age of men was 42.3 years and women was 36.7 years. The minimum age was 18 years. The maximum age was 69 years; 51.8% (n = 14) of patients were women. The 1200 biopsies showed 56 injuries MPGN (5%) of these 58 cases only 27 (32%) lesions showed $c3$ deposits only or predominant.
Conclusions: 30% of patients with GMP have as pathogenic mechanism the complement activation with complement C3 deposition in the glomerulus. Our research group has found C3 deposition causally related to GMP. The most common clinical presentation is nephrotic syndrome.

FR-PO453
Steroids Alone for the Treatment of C3 Glomerulonephritis with Monoclonal Gammopathy
Insaar Jaffer Satthick,1 Ladan Zand,1 Samih H. Nasr,2 Sanjeev Sethi,2 Fernando C. Fervenza,1 Nelson Leung,1,3 Claire L. Harris,2 Kevin J. Marchbank,1 Isabel Y. Pappworth,2 Rebecca Walters,1 Hannah J. Lomax-Browne,2 Daniel P. Gale,1 Tim Goodship,1 David Kavanagh,1 Roger D. Malcomson,5 Paul Morgan,2 Matthew C. Pickering,2 H. Terence Cook,2 Sally A. Johnson,1 1Div of Nephrology, Mayo Clinic; 2Div of Anatomic Pathology, Mayo Clinic; 3Div of Hematology, Mayo Clinic.

Background: C3 glomerulonephritis (C3GN) is a rare disease with no trial data to guide treatment. In patients with C3GN with monoclonal gammopathy, steroids alone may be a viable treatment option.

Methods: We present our experience in managing C3GN with monoclonal gammopathy with prednisone.

Results: 5 patients presented to our institution from 2011 to 2014 with biopsy proven C3GN and underlying monoclonal gammopathy. Median age of this cohort was 63 years. Median estimated GFR by MDRD equation was 35.4 ml/min/1.73m2 and median proteinuria was 2 g/day at presentation. All patients had IgG kappa monoclonal gammopathy. Patient 5 required renal replacement therapy but recovered renal function. All patients were treated with Prednisone 60mg/day tapering to zero in all except one. Patient 2 and 4 continue on prednisone 10mg/day. Patient 1 was started on Rituximab and showed improvement in kidney function.

Conclusions: Our experience suggests that prednisone alone may be a treatment option in some patients with C3GN associated with a monoclonal gammopathy. Work up should be done to exclude a plasma cell neoplasm and inherited complement abnormalities.

FR-PO454
The National Study of Membranoproliferative Glomerulonephritis and C3 Glomerulopathy: Characterisation of the Initial United Kingdom Paediatric Cohort
Edwin KS Wong,1 Claire L. Harris,2 Kevin J. Marchbank,1 Isabel Y. Pappworth,2 Rebecca Walters,1 Hannah J. Lomax-Browne,2 Daniel P. Gale,1 Tim Goodship,1 David Kavanagh,1 Roger D. Malcomson,5 Paul Morgan,2 Matthew C. Pickering,2 H. Terence Cook,2 Sally A. Johnson,1 1Div of Nephrology, Mayo Clinic; 2Div of Anatomic Pathology, Mayo Clinic; 3Div of Hematology, Mayo Clinic.

Background: The National Registry of Rare Kidney Diseases (RaDaR) in the United Kingdom allows recruitment, research and longitudinal follow-up of patients with membranoproliferative glomerulonephritis (MPGN) and C3 glomerulopathy (C3G). The aim of the MPGN/C3G Rare Disease Group (RDG) is to deep phenotype and analyse complement abnormalities in a paediatric cohort of MPGN/C3G.

Methods: The MPGN/C3G RDG recruited patients with MPGN/C3G for central review of biopsies and clinical data, and studied complement abnormalities previously described in MPGN/C3G.

Results: 83 prevalent patients with MPGN/C3G were identified and centrally reviewed. 79 could be classified: 40 had immune-complex MPGN, 25 had C3GN and 14 had DDD. Complement abnormalities are shown in Table 1. Follow-up data on 73 patients is shown in Figure 1.

Table 1: Complement Abnormalities

<table>
<thead>
<tr>
<th>Complement Abnormality</th>
<th>MPGN (n=40)</th>
<th>C3GN (n=25)</th>
<th>DDD (n=14)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C3 nephritic factor</td>
<td>9/21 (43)</td>
<td>6/18 (33)</td>
<td>0/14 (0)</td>
</tr>
<tr>
<td>Anti-FH autoantibodies</td>
<td>7/29 (18)</td>
<td>3/24 (13)</td>
<td>3/14 (21)</td>
</tr>
</tbody>
</table>

Conclusions: RaDaR has facilitated the development of a large nationwide cohort of paediatric patients with MPGN/C3G who have now undergone deep phenotyping and genotyping centrally. Acquired complement abnormalities were common; rare genetic abnormalities were infrequent. Patients with DDD had the worst renal outcome. Ongoing recruitment and longitudinal follow up will clarify prognosis according to phenotype/genotype and allow stratification into future treatment studies.

Plasma Neutrophil Gelatinase-Associated Lipocalin, Procalcitonin and C-Reactive Protein as the Predictor of Acute Pyelonephritis in Children with Febrile Urinary Tract Infections
Byungkwon Kim, Hyung Eun Yim, Kee Hwan Yoo. Dept of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.

Background: We have recently reported that plasma and urinary neutrophil gelatinase-associated lipocalin (NGAL) levels are useful for the prediction of acute pyelonephritis (APN) in pediatric urinary tract infection (UTI). This study was aimed to determine the accuracy of NGAL measurements, compared with serum measurements of procalcitonin, C-reactive protein (CRP), and white blood cells (WBCs) in predicting APN and associated renal problems in children with febrile UTIs.

Methods: Total 138 children with febrile UTIs (59 APN, 79 lower UTI) were enrolled. Patients with renal failure, congenital urologic anomaly except vesicoureteral reflux

A Prospective Evaluation of Renal Contrast-enhanced Ultrasound (CEUS) in the Detection of Pyelonephritis

Florian Buchkremer,1 Daniel Drozdov,2 Werner C. Albrich,3 Andreas H. Bock,4 Div of Nephrology, Kantonsspital Aarau, Aarau, Switzerland; 5 Div of Infectious Diseases, Kantonsspital St. Gallen, St. Gallen, Switzerland.

Background: Contrast-enhanced ultrasound (CEUS) has been described as a promising method for detecting acute pyelonephritis (PN) and its complications. We evaluated its value in diagnosis and risk stratification in the setting of a randomized controlled trial (RCT).

Methods: Immunocompetent adults with community-acquired urinary tract infection (UTI) presenting in the emergency department of Kantonsspital Aarau were enrolled in a RCT designed to evaluate the performance of a PCT/pyuria guided algorithm versus standard guidelines (Drozdov et al. BMC Medicine 2015). Outcomes included antibiotic exposure, duration of therapy, persistent infections and recurrences/re-hospitalisations.

Results: Of 70 UTI study patients hospitalized with fever and/or flank pain, 41 (59%) underwent the ultrasound study. Dropout reasons included missing consent (5%), early discharge (6%) or technical (18%). Examined and non-examined patients did not differ significantly in baseline characteristics or outcome. Findings suggestive of PN were found in 5/41 (12%). In 3 patients, this was evident in greyscale/Doppler already, in 2 additional patients, critical findings were only present in CEUS. The presence of PN-suggestive findings was not predictable from any baseline clinical characteristic. Patients with and without PN-suggestive findings did not appear to differ in outcome.

Conclusions: Ultrasound evidence of pyelonephritis is rare in patients hospitalized for UTI with fever. CEUS may be a useful method to guide clinicians. The presence of PN-suggestive findings may substantially increase the number of positive findings.

ISN 0by25 AKI Global Snapshot Project: AKI Disposition

Michael V. Rocco,1 Ravidra L. Mehta,1 Giuseppe Remuzzi,2 Jing Zhang,3 Melanie Godin,3 Michael V. Rocco,4 U Sao Paulo,5 U California San Diego,6 Mario Negri Inst,7 Sherbrooke U,1 Wake Forest U.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians on AKI pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). We analyzed the frequency of AKI requiring dialysis and the reasons for starting or withholding dialysis.

Results: Of 3855 pts, 768 (20%) were dialyzed. Mortality rate was significantly different in dialyzed (17%) vs. non-dialyzed (9%) pts (p<0.0001). Among dialyzed pts, the mortality rate was similar in countries of different GNI categories. The main reason to start dialysis was solute control, with a similar distribution among country categories.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**ISN 0by25 AKI Global Snapshot Project: Differences in Location and Process of Care Among AKI Patients Around the Globe**

*Etienne Macedo,1 Ravindra L. Mehta,2 Giuseppe Remuzzi,3 Jing Zhang,2 Melanie Godin,3 Michael V. Rocco,1 1U Sao Paulo; 2U California San Diego; 3Mariño Negro Inst; 'Sherbrooke U; Wake Forest U.*

**Background:** The Global Snapshot (GSP) was a prospective cross-sectional study designed to capture standardized information on incidence, causes and treatment of AKI in all health care settings throughout countries of diverse economic status.

**Methods:** A web based survey tool was used to obtain data from pts with a confirmed diagnosis of AKI based on KDIGO criteria in 72 countries. Detailed methodology is found in the ISN GSP abstract on provider characteristics. We analyzed the characteristics of pt location and process of care by gross national income per capita (GNI) country levels. Countries were defined as: Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

**Results:** Based on GNI, 23 countries were classified as LLMIC, 20 as UMIC and 29 as HIC.

Urinalysis was more often performed in LLMIC (86%). More pts in LLMIC were dialyzed (71%). The mortality rate of dialyzed pts and the number of non-renal organ failures present was similar by GNI level. Mortality in community acquired AKI was higher in LLMIC (11%) vs 7% in HIC. LLMIC had higher mortality among ICU pts (2%) vs 13% in HIC (p=0.014). In pediatric pts, mortality was 19.6% in LLMIC compared to 12.5% in HIC.

In LLMIC, 58% of pts were classified as AKIN stage 3 at AKI diagnosis. sCr was significantly higher in these pts (3.26 mg/dL) compared to 2.43 in pts from HIC and 2.3 in pts from UMIC.

**Conclusions:** BsCr was often present in pts from HIC and UMIC, where 1/3 of AKI cases occurred in CKD pts. Absence of BsCr was a common issue in LLMIC, associated with higher levels of sCr and KDIGO stage at AKI diagnosis. UO is often not computed in pts who develop AKI. Systematic assessment of urine output in high-risk pts could help identify AKI earlier.

ISN 0hy25 AKI Global Snapshot Project: Evaluation and Treatment Jorge Cerda,1 Ravindra L. Mehta,2 Giuseppe Remuzzi,2 Jing Zhang,2 Melanie Godin,2 Michael V. Rocco,2 Emmanuel A. Burdman1,2 Guillermo Garcia-Garcia,2 Vivekanand Jha,2 Andrew J.P. Lewington,3 Raul Lombardi4,10 Alhambay Med Coll; 1U California San Diego; 2Mario Negri Inst; 3Sherbrooke U; 4Wake Forest U; 5Albany Med Coll; 6George Inst Global Health; 7Renal Research Inst; 8Leeds Teaching Hosp; 9Servicio Medico Integral. Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract or provider characteristics. Countries were defined by gross national income per capita (GNI); low and lower middle income (LMIC), upper middle income (UMIC) and high income (HIC).

Results: Initial evaluation of AKI included urinalysis in 73.6%, ultrasound in 55% and renal biopsy in 4.1%, with all three more commonly being performed in LLMIC. Initial treatment of AKI included fluids in 74.3%, vasoressors in 23.8%, diuretics in 41.4% antibiotics in 63.8% and urinary diversion in 19.5%. The receipt of dialytic therapy occurred in 790 of 4018 pts (19.7%), with use in 18.8% in HIC, 14.3% in UMIC and 28.0% in LMIC. In 244 instances where dialysis was recommended but not performed, futility was cited in 58.6% and cultural beliefs were cited in 25.4%. Unavailability of staff or material resources to perform dialysis was reported in 1.4% of HIC, 3.8% of UMIC and 1.6% of LMIC. Inability to afford therapy was 1.4% in HIC, 1.9% in UMIC and 16.4% in LMIC (p<0.0001). The ratio of pts not able to receive dialysis by those that did receive dialysis was 0.21 in HIC, 0.25 in UMIC and 0.18 in LMIC. There were significant differences in the renal modality used.

Treatment (n=798) Frequency Percent HIC UMIC LMIC
BID 516 65.3 63.3 58.3 71.8
PD 41 5.2 4.6 3.0 7.1
CRRT 157 19.9 31.7 29.1 4.6
UF 10 1.3 2.5 1.7 0
SLED 103 13.0 3.4 10.9 21.7
Other 8 1.0 0.6 1.4 0
Unknown 1 0.1 0 0.2 0

Conclusions: Lack of resources, staff or finances to perform dialysis was most prevalent in LLMIC. When dialysis was provided, it was less likely to be CRRT and more likely to be SLED in LLMIC.

FR-PO463

ISN 0hy25 AKI Global Snapshot Project: Provider Characteristics Melanie Godin,1 Ravindra L. Mehta,2 Giuseppe Remuzzi,2 Jing Zhang,2 Michael V. Rocco,2 Jorge Cerda,2 Vivekanand Jha,2 Nathan W. Levin,2 Andrew J.P. Lewington,1 Etienne Macedo,2 Marcello Tonelli,19 Sherbrooke U; 1U California San Diego; 2Mario Negri Inst; 3Wake Forest U; 4Albany Med Coll; 5George Inst Global Health; 6Renal Research Inst; 7Leeds Teaching Hosp; 8San Paolo; 9U Calgary. Background: The ISN 0by25 AKI Global Snapshot Project (GSP) was designed to determine the spectrum of AKI pts seen in health care facilities throughout the world.

Methods: Health care providers joined the GSP after gaining approval from their local IRB. Providers chose one “index” day between 9/29/2014 and 12/7/2014 to provide data on AKI pts under their care. De-identified data on pts who met criteria for AKI by modified KDIGO criteria were entered through a secure website using a standard questionnaire developed by the 0by25 AKI workgroup. Data collected included pt demographics, initial clinical data, diagnostic, treatment and outcome information. Countries were grouped into three categories based on gross national income per capita (GNI); high income with GNI >$12,476, low and lower middle income with GNI <$12,476 and upper middle income with GNI between levels 1 & 3.

Results: 324 surveys from 72 countries were received describing 4024 pts with AKI. Included providers included 248 nephrologists, 20 nephrology fellows, 14 intensivists, 26 pediatric nephrologists. Location of facilities by region included 52 from Africa, 47 from Latin America & Caribbean, 45 from North America, 45 from South Asia, 40 from North and East Asia, 34 from Western Europe, 19 from Russia/Commonwealth of Independent States, 17 from Oceania & South East Asia, 14 from Middle East and 11 from Eastern & Central Europe. Size of catchment population for each facility was: >5 million in 28%, 0.5-1.5 million in 26%, 0.1-0.5 million in 19% and 1.5-3 million in 11%. Type of facility was institute in 47%, public hospital or health care concern in 37%, private multispecialty group in 14%. Dialysis was available in 97% of facilities.

Conclusions: This project is the first worldwide point prevalent survey of AKI. It demonstrates the feasibility of obtaining data on AKI using a secure website from practitioners in varied health care settings from six continents.

FR-PO464

Postoperative Acute Kidney Injury in Non-Cardiac Surgery Seekwoo Park, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Hajoong Lee. Internal Medicine, Seoul National Univ Hosp, Seoul, Korea. Background: Prevention of acute kidney injury (AKI) and amelioration of its severity remain important issues of improving surgical patient outcomes. Therefore, preoperative renal risk evaluation and patient optimization is crucial for nephrologists. Although there are several studies dealing with postoperative AKI in cardiac surgery, they have been seldom studied in non-cardiac surgery.

Methods: We included adult (age ≥ 18 years) patients who received major non-cardiac surgery in Seoul National University Hospital from 2004 to 2013. We extracted their clinical data from our electronic medical record system. Acute Kidney Injury Network criteria (AKIN) was used to define and classify AKI.

Results: Among a total of 95,266 operations, 1,560 cases (1.64%) developed AKI. Patients with AKIN stage I were 964 (1.01%), stage II, 117 (0.12%), and stage III, 479 (0.50%). AKI was most prevalent in urologic surgery, followed by general surgery, orthopedic surgery, and neurologic surgery. Patients who developed AKI tended to be older (53.7 vs. 58.9 years), and male (45.6% vs. 65.6%). Patients with AKI had higher prevalence of underlying diseases such as liver/heart/hematologic/vascular and neurologic disease than those without. Moreover, they showed higher baseline systolic blood pressure and lower baseline diastolic blood pressure than those without. Baseline renal function was lower in AKI-developed patients than the others (0.90 vs. 1.13 mg/dL, P < 0.001). Multivariate logistic regression analyses found that older age, male sex, lower baseline renal function, presence of hypertension, longer duration of surgical time and orthopedic or urologic surgery were significant risk factors for postoperative AKI in noncardiac surgery.

Conclusions: In this study, we demonstrated the incidence of postoperative AKI in non-cardiac major operations. Moreover, we found clinical risk factors for postoperative AKI development. Further investigation of prediction models for postoperative AKI in major non-cardiac surgery should be warranted for development of preoperative renal optimization strategy.

FR-PO465

Impact of Hospital CABG Volume and AKI Needing Dialysis on CABG Hospitalizations Ankit Sakhija,1 Jesse D. Schold,2 Edward G. Soltész,3 Sevag Demirjian.1 1Div of Nephrology, Univ of Michigan; 2Nephrology and Hypertension, Cleveland Clinic; 3Thoracic and Cardiovascular Surgery, Cleveland Clinic. Background: Acute Kidney Injury (AKI) is common after Coronary Artery Bypass Grafting (CABG) and associated with poor outcome. Increased hospital procedure volume has been associated with better outcomes. We examined (1) impact of number of annual CABG procedures per hospital (CABG-vol) on AKI needing dialysis (AKI-D) and mortality, and (2) if it modifies the relationship between AKI-D and mortality.

Methods: Using Nationwide Inpatient Sample database from 2000-2010 we identified admissions with CABG using ICD-9-CM codes. Those with AKI-D were identified and those with kidney transplant or on maintenance dialysis were excluded. Multivariable logistic regressions were used to assess impact of CABG-vol on AKI-D and mortality. We used restricted cubic splines to account for non-linear relationship between CABG-vol and mortality. A priori interaction term between CABG-vol & AKI-D was assessed in models.

Results: Of estimated 3,337,292 (95% CI: 3,103,610-3,570,973) hospitalizations for CABG, 0.7% (24,126) had AKI-D. Those with AKI-D were older, more females (37.5% vs 29.1%; P<0.001) and blacks (7.4% vs 5.5%; P<0.001). On adjusted analysis, CABG-vol was correlated with mortality developing AKI-D (0.99; 95% CI 0.99-1.00) but was associated with mortality (Fig 1).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
AKI-D was a significant predictor of mortality with OR 13.75 (95% CI: 11.37-16.64). Interaction term between CABG-vol & AKI-D was not significant (p=0.8).

**Conclusions:** Lower annual CABG hospital procedure volume is significantly associated with higher mortality but not with higher incidence of AKI-D. AKI-D is associated with higher mortality in those undergoing CABG, however, there is no differential effect of hospital volume on adjusted odds of mortality due to AKI-D.

**FR-PO466**

Five-Year Risk of Renal Outcomes After Pediatric Cardiac Surgery

Jason Henry Greenberg,1 Michael Zappitelli,2 Heather Thiessen Philbrook,1 Prasad Devarajan,2 Catherine Krawczeski,2 Steven G. Coca,1 Chirag R. Parikh,1 1Program of Applied Translational Research, Yale School of Medicine; 2Dept of Pediatrics, McGill Health Centre; 3Dept of Pediatrics, Cincinnati Children’s Medical Center.

**Background:** Pediatric cardiac surgery is associated with a high risk of acute kidney injury (AKI) and other short-term adverse outcomes. However, the risk for long-term renal outcomes after cardiac surgery is unknown.

**Methods:** We performed 5 year follow-up on the Translational Research Investigating Biomarker Endpoints in AKI (TRIBE-AKI) cohort. TRIBE-AKI is a three-center prospective cohort study of children 1 month to 18 years old who underwent cardiopulmonary bypass.

**Results:** Out of 305 children who survived their index hospitalization, 4 (1.3%) died after discharge and 12% (42%) participated in the 5 year follow-up. Mean age of the cohort at follow-up was 9.2 years and 53% were male. 56 out of 128 patients had perioperative AKI defined as a post-operative serum creatinine rise by 50% or 0.3mg/dl from pre-operative baseline. At a median of 5.4 years of follow-up, hypertension, microalbuminuria, eGFR<90, and eGFR<60 were identified in 13%, 6.3%, 7.0%, and 0.8% of patients, respectively. CKD, defined as eGFR<90 or microalbuminuria, was present in 13% of children. There were no significant differences in renal outcomes between patients with and without perioperative AKI. (4.0%) patients had been seen by a pediatric nephrologist. The 5-year post-operative prevalence of hypertension in our cohort was ~8 fold higher than found in the general pediatric population (Table).

**Conclusions:** Overall, there is a high prevalence of CKD and hypertension in children 5 years after cardiac surgery. Despite this high prevalence of CKD, very few children were seeing a pediatric nephrologist. These findings may have implications for renal care and late cardiovascular disease in children after cardiac surgery.

**Funding:** NIDDK Support

Changes of Epidemiology and Influencing Factors of Acute Kidney Injury After Cardiac Surgery – A Five-Year Study from 2009 to 2013

Zhouping Zou,1,2 Jiari Xu,1,2 Wenlv Lv,1,2 Bo Shen,1,2 Yi Fang,1,3 Jianzhou Zou,1,2 Jie Teng,1,2 Xiaojiaqing Ding,1,2 1Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; 2Shanghai Inst for Kidney and Dialysis, Zhongshan Hospital, Fudan Univ, Shanghai, China; 3Shanghai Key Laboratory of Kidney Disease and Blood Purification, Zhongshan Hospital, Fudan Univ, Shanghai, China.

**Background:** Cardiac surgery is a common cause of acute kidney injury (AKI). We collected the epidemiological data of patients with AKI from 2009 to 2013 in order to explore the influencing factors of changes of epidemiology after cardiac surgery.

**Methods:** Clinical data of patients undergoing cardiac surgery, which included demographic data of preoperative, intraoperative, postoperative variables, was critically collected in our hospital from January 2009 to December 2013. The main endpoint was poor prognosis which included overall mortality and abandonment of treatment. The second point was renal outcome.

**Results:** A total of 11693 patients enrolled, including 6637 males and 5056 females. The overall AKI incidence was 34.5% (n=4030). The AKI incidence increased during the five years from 34.2% to 36.5% (P<0.05). There was no significantly statistical differences in AKI-RRT incidences during the five years (p=0.360). The hospital mortality of AKI decreased from 6.3% in 2009 to 3.8% in 2013. The incidence of poor prognosis in AKI was 8.3%, 7.5%, 6.8%, 5.1%, 8.0% (P=0.196). The mortality of AKI-RRT decreased from 47.1% to 29.5%, but there was no statistical difference (P=0.230). The incidence of poor prognosis in RRT decreased from 66.7% to 57.4%, also no significantly statistical difference (P=0.825). Multivariate logistic regression analysis showed that male age (every additional 10 years), body mass index (every additional 5kg/m2), hypertension, chronic heart failure, pre-operative serum creatinine>115μmol/L, CPB (every additional 30 min) were the risk factors of AKI after cardiac surgery.

**Conclusions:** The incidence of AKI after cardiac surgery increased from 2009 to 2013 and the rate of poor prognosis did not change. The incidence of AKI-RRT and the rate of poor prognosis remained high. The prevention and treatment of AKI still need improvement. **Funding:** Government Support - Non-U.S.

**FR-PO468**

The Very Long-Term Co-Morbidity Adjusted Impact of AKI following Cardiac Surgery: A 15-Year Follow-Up Study

Alessandro Ferreiro,1 Raul Lombardi,2 1Nephrology, INCC. Facultad de Medicina, Montevideo, Uruguay; 2Critical Care Medicine, SMI, Montevideo, Uruguay.

**Background:** AKI is a frequent complication of cardiac surgery (CS) associated to high mortality. The co-morbidity adjusted residual impact on very long-term mortality (>12 years) of AKI excluding the initial catastrophic impact on early mortality has never been addressed before. **Objectives:** To evaluate the net attributable impact of AKI after CS on long-term mortality.

**Methods:** All adult patients submitted to CS between 1/1/2000 and 31/12/2013 (n=7755) were enrolled. The INCC prospective-collected database with more than 750 variables (demographics, comorbidities, type of CS, intraoperative and postoperative variables, peri-operative support and short time outcomes) was used. Long-term survival (up to 15 year by December 2014) was obtained by systematic telephone survey (minimum 1-year follow-up) and the National Population Registry. AKI stages were defined according to KDIGO definition. Demographics, logistic EuroSCORE (and their single components), type of CS, baseline renal function (Cockcroft-Gault formula) were used for comorbidity risk-adjustment. Statistical analysis: “%”, “test”, c test, Kruskal-Wallis test, Kaplan-Meier curves with long-rank test and Cox regression for multivariate survival analysis. Only patients alive after the first 1 year follow-up entered in the long-term survival analysis (n=9595).

**Results:** AKI incidence: 38.4%. RRT: 1.7%. Long-term (15 years) actuarial survival after 1 year follow-up: no AKI 0.58; AKI-I: 0.47; AKI-II: 0.39; AKI-III: 0.27 (p<0.001). In multivariate Cox regression analysis, AKI stages I, II and III (OR 1.17; 1.24; 1.62 respectively) were independently associated with mortality between 1 year after CS and 15 year follow-up, even after adjustment with logistic EuroSCORE (OR 1.02), age (OR 1.038), diabetes (OR 1.58), pre-operative eGFR (OR 0.996) and no-isolated coronary bypass surgery (OR 1.24).

**Conclusions:** AKI and its severity are independently associated with very long-term mortality, even after discarding short term events (1 year), in cardiac surgery. Should AKI be causative or a surrogate marker of late events in the long term follow up is a matter of concern to be evaluated.

**FR-PO469**

Incidence and Influencing Factors of Cardiac Surgery-Associated Acute Kidney Injury Based on the KDIGO Criteria: A Retrospective Cohort Study

Changchun Cao,1 Xiangcheng Xie,1 Xin Wan. 1Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital); 2Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital).

**Background:** The incidence and influencing factors of cardiac surgery-associated acute kidney injury (CSA-AKI) based on the KDIGO criteria have not been well studied. This study was aimed to evaluate the incidence, risk or protective factors of acute kidney injury (AKI) in patients after cardiac surgery.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline represents presenting author.**
Methods: A retrospective analysis of 2575 patients undergoing first documented cardiac surgery with cardiopulmonary bypass (CPB) between January 2008 and December 2012 in our hospital was conducted. Perioperative variables were collected and analyzed. Univariate and multiple logistic regression models were used for determining the association between the development of AKI and risk factors.

Results: Of 2575 patients, 931 (36%) developed AKI. A total of 38 (1.2%) patients required renal replacement therapy. The overall in-hospital mortality rate was 1.5% (38 of 2575). CSA-AKI was significantly associated with in-hospital mortality (adjusted HR: 2.22, 95% CI 1.16-4.24, P = 0.016), especially in patients needing RRT (adjusted HR: 18.68, 95% CI 8.58-40.68, P < 0.003). The independent risk factors identified by multivariate analysis were shown in Table 1.

Conclusions: This study demonstrates that mechanical ventilation duration, erythrocytes transfusion and postoperative body temperature above 38°C within 3 days were shown in

FR-PO470
Acute Kidney Injury Post-Major Orthopaedic Surgery: A Single Centre Experience
Tracey Ying, 1 Samantha Chan, 1 Stephen E. Lane, 2 Christine A. Somerville, 1
1 Dept of Renal Medicine, Univ Hospital Geelong, Geelong, Victoria, Australia; 2 Barwon Health Biostatistics Unit, Univ Hospital Geelong, Geelong, Victoria, Australia.

Background: Given the increasing incidence of AKI and the burden this places on the medical system, there is a clear need to expand the practice of ‘preventative nephrology’ – the optimisation of renal function through minimisation of potential insults. Renoprotection is particularly critical in the perioperative setting, a period of high renal vulnerability. However, there is currently little evidence regarding numerous theoretical risk factors for postoperative AKI.

Methods: All patients undergoing MOS at our centre between 2008 and 2014 were included. Out of 2227 surgeries audited for AKI using comparisons of preoperative and postoperative creatinine, 164 cases were identified (per RIFLE criteria) and matched to the creatinine based KDIGO criteria. Risk factors for AKI were evaluated using logistic regression analysis.

Results: Controlling for known risk factors, both diuretic and ACEi or ARB use were associated with a high severity of AKI.

Conclusions: This study presents the incidence of AKI after invasive surgical principal procedures, and this data will help prioritize research to prevent in-hospital AKI. Non-kidney transplant, heart valve, and CABG surgical procedures were associated with the largest number of AKI cases at this single center, and non-kidney organ transplants were associated with a high severity of AKI.

FR-PO472
Acute Kidney Injury following Gastrointestinal Surgery
Börj E. Long, 1 Dadi Helgason, 1 Sólveig Helgadóttir, 2, 4 Tomas Gudbjartsson, 3, 4 Gísli H. Sigurðsson, 2, 4 Olafur S. Indridason. 6
1 Dept of Medicine; 2 Dept of Anaesthesia; 3 Dept of Cardiovascular Surgery, Landspítali; 4 Faculty of Medicine, Univ of Iceland; 5 Dept of Anestesia, Brigham and Women’s Hospital, Boston, MA; 6 Div of Nephrology, Landspítali - The National Univ Hospital, Reykjavik, Iceland.

Background: Acute kidney injury (AKI) is a serious postsurgical complication but AKI after nonvascular abdominal surgery has not been thoroughly studied. The aim of this study was to examine the incidence of AKI after such operations, its risk factors and survival in patients.

Methods: We studied all nonvascular abdominal operations performed on adults 2007-2014 at Landspítali, the major hospital in Iceland. AKI was diagnosed according to the creatinine based KDIGO criteria. Risk factors for AKI were evaluated using logistic regression analysis. Survival was compared between AKI and non-AKI patients using Kaplan-Meier method after propensity score matching (1:1, nearest neighbor matching).

Results: A total of 10,022 patients underwent 11,552 operations during the study period, 38.0% were acute operations. Median age at operation was 52 yrs (IQR 32-66) and 59.5% of patients were female. AKI occurred after 246 operations (2.1%), with 157 (1.4%), 57 (0.5%) and 32 (0.3%) of stage 1, 2 and 3, respectively. Incidence of AKI was higher after major (5.3%), open (4.9%) and acute operations (5.0%) compared to minor (1.1%), laparoscopic (0.5%) and non-acute operations (1.8%). In multivariable analysis, postoperative AKI associated with age (OR 1.03 (95%CI (1.04-1.01)), male sex (1.1 (1.02-2.0), open operation 3.0 (2.4-2.2), re-operation 4.8 (3.7-8.6), hypertension 1.7 (1.2-2.4), eGFR <60ml/min/1.73m2 2.0 (1.4-2.7) and ASA score 6.1 (4.2-8.8). Survival was worse for AKI patients compared to the propensity score matched controls, both at 30 days (82.4% vs. 94.7%, p=0.03) and at 1-year (69.9% vs. 82.6%, p=0.03).

Conclusions: The incidence of AKI is relatively low after gastrointestinal surgery compared to cardiac and vascular surgery. The rate of AKI is substantially higher after major and open operations and in patients with preexisting kidney disease. AKI is associated with increased short- and long-term mortality.

FR-PO473
Risk Factors Associated with Post-Operative AKI After General Surgery
Predeep Arora, 1 Leili Pourakbari, 2 James L. Mohr, 1 Hasan H. Dosluoglu, 1 Nader Naderi, 3 Div of Nephrology, VAMC, Buffalo, NY; 1 Anesthesiology, VAMC, Buffalo, NY; 2 Surgery, VAMC, Buffalo, NY.

Background: AKI after cardiac and vascular surgery has been extensively studied. However, there is no study which has evaluated the factors associated with development of stage 1 AKI by AKIN criteria in general surgery patients.

Conclusions: This study demonstrates the incidence of AKI after invasive surgical principal procedures, and this data will help prioritize research to prevent in-hospital AKI. Non-kidney transplant, heart valve, and CABG surgical procedures were associated with the largest number of AKI cases at this single center, and non-kidney organ transplants were associated with a high severity of AKI.
Methods: We conducted a cohort study using a prospective database of patients undergoing non-cardiac, non-vascular surgery performed since 2000 in the VA Western New York Healthcare System which are in part reported to the National Surgical Quality Improvement Program (NSQIP). Demographic, social history, co-morbid diseases, including coronary artery disease (CAD), congestive heart failure (CHF), chronic obstructive lung disease (COPD), peripheral vascular disease (PVD), cerebrovascular accidents (CVA), hypertension, and diabetes, were prospectively entered into the Veterans Affairs Surgery Quality Improvement Program (VASQIP) database at the time of surgery. Preoperative laboratory data were also entered for each participant. Univariate and multivariate logistic regression were performed to estimate the odds of AKI after surgery. Results: A total of 1621 patients who underwent non-cardiac and non-vascular surgery whose data was available to define AKI between 2000-2014 were included in this analysis. In univariate analysis, increasing age, male gender, ASA class, poor functional status, presence of COPD, CVA, CVD, DM, CHF, HTN, preop coronary intervention or MI, HCT <24, Low serum albumin, increased operating room (OR) time and blood transfusions were associated with increased odds of AKI. Results of multivariate analysis are shown in table 1.

Conclusions: AKI is associated with increased length of hospital stay and mortality. Efforts to recognize and intervene in preoperative modifiable factors to prevent AKI will improve outcomes in general surgical patients.

FR-PO474

The Comparison of the Incidence of Acute Kidney Injury Post Coronary Artery Bypass Graft versus Percutaneous Coronary Intervention: National Inpatient Sample Experience

Methods: We extracted total 485742 cases from National Inpatient Sample (NIS) to create a propensity-score matched cohort of patients who had multivessel coronary disease and underwent first-time CABG or PCI between 2004-2012. Patients received concomitant valvular repair or both CABG and PCI on same admission, history of organ transplant, CKD stage IV or ESRD on dialysis were excluded. Both groups were matched for age, gender, race, payer, prior MI, unstable angina, heart failure, CKD, diabetes, HTN, dyslipidemia, smoking, cirrhosis, obesity, anemia and in-hospital GI bleeding. The odds ratios were estimated by logistic regression analysis. Results: The incidence of AKI in CABG group was higher than PCI group (8.41% vs 6.49%, OR 1.24-1.40, P<0.0001). The in-hospital mortality in patients with AKI was higher in CABG (4.00% vs 2.23%, P=0.001). The incidence of severe AKI requiring RRT were similar in both groups (0.95% vs 0.91%, P=0.147). Compared with PCI group, CABG group had higher total in-hospital mortality (1.89% vs 1.48%, OR 1.34, 95% CI 1.24-1.40, P<0.0001). The in-hospital mortality in patients with AKI was higher in CABG (0.92% vs 0.59%, P<0.0001). Conclusions: Patients received CABG were at higher risk of developing AKI and associated with higher total in-hospital mortality. The in-hospital mortality in patients with AKI was higher in CABG.

FR-PO475

Dialysis-Requiring Acute Kidney Injury Among Hospitalized Adults with Documented Hepatitis C Virus Infection: A Nationwide Inpatient Sample Analysis

Methods: We extracted our study cohort from the Nationwide Inpatient Sample (NIS) of the Healthcare Cost and Utilization Project using data from 2004-2012. We defined HCV and AKI-D based on previously validated ICD-9-CM codes. We analyzed temporal changes in proportion of hospitalizations complicated by AKI-D and utilized survey multivariable logistic regression models to estimate its impact on in-hospital mortality. Results: We identified a total of 4,603,718 adult hospitalizations with associated HCV from 2004-2012, of which 51,434 (1.12%) were complicated by AKI-D. The proportion complicated by AKI-D increased significantly from 0.86% in 2004 to 1.28% in 2012. Trend was similar when stratified by cirrhosis and paralleled that in HCV negative hospitalizations. Conclusion: The proportion of HCV hospitalizations complicated by AKI-D increased significantly between 2004-2012. Similar to observations in the general population, AKI-D was associated with two-fold increase in odds of in-hospital mortality. These results highlight the burden of severe AKI in hospitalized adults with HCV infection.

FR-PO476

The Burden of Dialysis Requiring Acute Kidney Injury in Decompensated Cirrhosis: A Nationwide Inpatient Sample Analysis

Methods: We extracted our cohort from Nationwide Inpatient Sample (NIS) from 2006-2012. We identified hospitalizations with DC & AKI-D by validated ICD9 codes. We analyzed temporal changes in proportion of DC hospitalizations complicated by AKI-D & utilized multivariable logistic regression models to estimate AKI-D impact on in-hospital mortality. Results: We identified a total of 36,55,700 adult DC hospitalizations from 2006-2012 of which 78,015 (2.1%) had AKI-D. Proportion with AKI-D increased from 1.5% in 2006 to 2.23% in 2012; this was stable between 2009-12 despite increase in absolute number from 6773 to 13930. Conclusions: In-hospital mortality was significantly higher in hospitalizations complicated by AKI-D vs. those without (27.38% vs. 2.95%; adjusted odds ratio 2.09, 95% Confidence Interval 1.74-2.51) which remained stable over the study period. The burden of severe AKI in hospitalized adults with HCV infection is significant and increasing.

AKI: Clinical - Epidemiology
The overall hospital mortality was significantly higher in hospitalizations with AKI-D vs. those without (40.87% vs. 6.96%; p<0.001). After adjusting for demographics, mortality risk, acute/chronic comorbidities & hospital level factors, the adjusted odds ratio for mortality was 2.17 (95% CI 2.06-2.28; p<0.01) with AKI-D, which was stable from 2006-2012.

Conclusions: The proportion of DC hospitalizations with AKI-D increased from 2006-09 & although, this was stable from 2009-12, there was an increase in absolute case number. These results elucidate burden of AKI-D on DC hospitalizations & excess associated mortality as well as highlight the importance of prevention, early diagnosis & testing of novel interventions in this vulnerable population.

FR-PO477
Temporal Trends of Burden of Dialysis Requiring Acute Kidney Injury in Cerebrovascular Accident Hospitalizations

Girish N. Nadkarni, Achint Patel, Abhimanyu Mahajan, Ioannis Konstantinidis, Yuri Ahuja, Rabi Yacoub, Charuhas V. Thakar, 1Icahn School of Medicine at Mount Sinai; 2Henry Ford Hospital; 3Yale Univ; 4Univ of Cincinnati & Cincinnati VA Medical Center.

Background: The epidemiology of dialysis requiring acute kidney injury (AKI-D) in acute ischemic stroke(AIS) and intracerebral hemorrhage(ICH) admissions is poorly understood with previous studies being from a single center and/or year.

Methods: We used the Nationwide Inpatient Sample to evaluate the yearly incidence trends of AKI-D in AIS and ICH admissions from 2002 to 2011. We also evaluated the trend of impact of AKI-D on in-hospital mortality and adverse discharge utilizing adjusted odds ratios (aOR) after adjusting for demographics and comorbidity indices.

Results: We extracted a total of 3927267 AIS and 704648 ICH admissions, AKI-D occurred in 1.5 and 3.5 per 1000 in AIS and ICH admissions respectively. Incidence of admissions complicated by AKI-D doubled from 0.9/1000 to 0.7/1000 in AIS and from 2.1/1000 to 4.3/1000 in ICH admissions.

Conclusions: Incidence of dAKI complicating CVA hospitalizations continues to grow and is associated with increased mortality and adverse discharge. This highlights the need for early diagnosis and better risk stratification in this vulnerable population.

FR-PO478
Long-Term Healthcare Utilization and Mortality After Acute Kidney Injury in Critically Ill Children

Background: Acute kidney injury (AKI) is common in the pediatric intensive care unit (PICU). The late illness burden of child AKI is unknown. We will evaluate if AKI in the PICU is associated with increased mortality and health care service use 5 years after discharge.

Methods: Retrospective cohort study of children admitted to two Montreal, Canada PICUs, 2003-2005 (N=2500). Exclusions: no health number, deceased in PICU. Clinical chart data was merged with provincial administrative health data. AKI (main exposure): by Kidney Disease Improving Global Outcomes serum creatinine (SCr) definition (if no PICU-SCr drawn, non-AKI was assumed). 5-year outcomes: all-cause mortality; healthcare utilization (HCU), defined as the number of hospitalizations, emergency room (ER) and physician visits per 100 person years. AKI-outcome relation was evaluated with multivariate logistic (mortality) and linear regression (HCU), adjusting for gender, age, cardiac surgery, PRISM (mortality) score, vasopressors and infection.

Results: Of 2407 children (mean±SD age=6±0.5 yrs; PRISM = 8.2±5.9); 56% male; 448 (18.6%) developed AKI. AKI (yes/no) was associated with mortality in univariate (p=0.05) but not multivariate analysis. Stage 2 AKI or worse was associated with 5-year mortality (adjusted[adj]OR=1.9, 95% CI= 1.1-3.2). AKI (yes/no) was associated with increased 5-year hospitalizations (adj p=0.05) and physician visits (adj p=0.001), but not ER visits (adj p=0.8). There was a graded increase in 5-year HCU with higher AKI severity.

Conclusions: PICU-AKI is associated with long-term increased mortality risk and HCU. Research should evaluate cost-effective interventions to improve child AKI treatment and evaluate effects on late outcomes.

Funding: Government Support - Non-U.S.

FR-PO479
Acute Kidney Injury: A 12 Month Follow, the Incidence and Mortality

Hsu qheen Chong, Paul R. Cannon, Caroline J. Whyte, Kottarathil Abraham Abraham. Nephrology, Aintree Univ Hospital, United Kingdom.

Background: Acute Kidney Injury (AKI) affects nearly 1 in 5 hospital admission. It carries a poor prognosis with mortality ranging from 10-80% dependent on the population studied. Aintree University Hospital caters to about a population of 506,000 in North Liverpool. An observational study was carried out in this catchment area to ascertain the incidence of AKI, the length of stay and its effect on 12 months mortality.

Methods: Patients who were admitted between the time periods of August 2012 until January 2013 were included in this study. Liaising with the biochemistry department, all patients who had a rise in their creatinine based on the Acute Kidney Injury Network Criteria received an e-alert sign on the computer system. Clinical outcomes were obtained from each patient record.

Conclusions: In all patients who had a rise in their creatinine based on the Acute Kidney Injury Network Criteria received an e-alert sign on the computer system. Clinical outcomes were obtained from each patient record.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: There were a total of 36,957 patients admitted during that 6 month time period of which a total of 358 cases of AKI were identified. There was total of 183 male patients and 171 female patients. Four of the male patients had a further AKI alert during the same hospital admission. The mean age was 72.18 years. Pre-renal causes were identified as the main contributors to the cases. Majority of the AKI alerts were Stage 1 AKI which was 70%, Stage 2 AKI was 25% and Stage 3 AKI was 5% of the total cases. The data also revealed that the average length of stay (ALOS) did not differ in each of the stage. A patient ALOS for Stage 1 AKI 23.3 days, Stage 2 AKI 24 days and Stage 1 AKI 21 days. Of the total number of cases of patients with AKI, 50.6% (179/354) of the patients had died within the 12 months period. Looking into the mortality rate of each individual stages of AKI; the mortality rate at 12 months for Stage 1 AKI is 46.5%. For Stage 2 AKI, 62.7% and for Stage 3 AKI, 47.6%.

Conclusions: From the dates collected, it shows that the degree of AKI does not affect the length of stay of patients. Despite the different stages of AKI indicating the severity of the injury, mortality rate for Stage 1 and Stage 3 did not differ. This indicates that AKI carries a high mortality rate regardless of the severity of the injury. Early recognition leads to early intervention in the prevention of AKI.

FR-PO480
Acute Kidney Injury: Adding Informatics to Injury – (Electronic Injury Alerts) Conor Patrick Moran,1 Ying C. Kuan,1 Patrick Lm Lynch,2 Francis Mccarroll,1 1Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; 2Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-68%). UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition of insult. There has been a paucity of work with regards to AKI recognition and prevention. National guidelines have recommended the use of electronic alerts (e-alerts) for AKI detection.

Methods: We introduced AKI e-alerts with accompanying electronic guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI. Data collection was carried out for 3 months, (n=110). The demographics of this cohort were compared with a historical cohort of severe AKI (n=89).

Results: Mean age, (72 years vs. 73 years), gender distribution, (M/F: 46%/54% vs. 47%/53%), and median time to death, (10 days vs. 9 days), were comparable. Thirty day mortality was similar with regards to hospital acquired AKI, (27.3% vs. 26.1%). 30 day mortality was significantly lower for community-acquired AKI, (10.7%). Mean and median age was demonstrated to be higher in the group of patient who died, (Mean: 80.1 years vs. 75.7 years), (Median: 82 years vs. 82 years) – negative skew due to outliers.

Conclusions: Although our initial data suggests an electronic AKI alert has no discernable effect on 30 day mortality rate and time to death. We feel that e-alerts with the addition of further Quality Improvement work will eventually result in a steady reduction in AKI mortality.

FR-PO481

Background: Tenofovir disoproxil fumarate (TFD) is widely prescribed as a first choice therapy for HIV infection, because of its convenient dosing schedule, efficacy and relatively low side effects. However, renal toxicity may lead to acute kidney injury (AKI), chronic kidney disease (CKD), and proximal tubular injury. Here we describe clinical characteristics and outcomes of AKI associated to TDF.

Methods: In a retrospective cohort (between Mar/2011 to Feb/2015), we have described data of HIV-infected inpatients, in a single center infectious disease ward, referred to the Nephrology group due to AKI. AKI was defined according to AKIN criteria.

Results: During the study period, 72 patients were evaluated; the baseline characteristics are showed in table1. Nephrototoxic AKI was present in 36 cases, of which 19 cases (52%) were associated with TFD and the drug was withdrawn in all cases. Seven patients had TFD nephrotoxicity without other associated factors and only three patients achieved renal function recovery, but no one needed dialysis or died during follow up.

In addition, a significantly lower frequency of CaN was noted amongst females compared with males (9.3% vs 14.5%, p=0.001).

Conclusions: Tenofovir-associated nephrotoxicity occurs less frequently than previously reported. This may reflect changes in preventive care such as more aggressive hydration with electrolyte-rich solutions.

Funding: Other NIH Support - T32 training grant

FR-PO482
Cisplatin-Associated Nephrotoxicity: Not as Frequent as Previously Reported Shveta S. Motwani, Sushruti S. Waikar, Benjamin D. Humphreys, Gary C. Curhan. Nephrology, Brigham and Women’s Hospital, Boston, MA.

Background: Cisplatin-associated nephrotoxicity (CaN) is a frequent problem amongst patients with various cancers. Most older studies have reported 25-30% of patients who receive cisplatin experience acute kidney injury. However, these data have not been re-evaluated systematically recently despite rapid advances in oncologic care. Therefore, we examined the proportion of patients who develop acute kidney injury after exposure to the first cycle of cisplatin in a large patient database. We also examined the frequency of kidney injury stratified by sex and cisplatin dose regardless of cancer type.

Methods: We collected data on patients ≥ 18 years of age who had received cisplatin as a primary, secondary or adjuvant or neo-adjuvant therapy at a tertiary-care medical center (Massachusetts General Hospital) between 2006 and 2014. Detailed data regarding cisplatin dose, demographic characteristics, concurrent medical history and laboratory data including serum creatinine (Cr) and electrolytes were collected. CaN was defined as an elevation of Cr by ≥ 0.3 mg/dl during a 14 day period after administration of cisplatin (peak Cr) compared with baseline (bl Cr). Patients with bl Cr of >1.5 were excluded.

Results: Of the 1979 patients in our study, 55% were male with a mean ± SD of age of 61.6 ± 12.8. A bl Cr was 0.9 ± 0.2. 241 of 1979 (12.2%) patients developed CaN. However, it ranged from 7.8% in the medium dose group (cisplatin dose 75-130 mg) to 18.2% in the high dose group (>130mg) without a clear dose response relation.

FR-PO483
Characteristics of 681 Patients with Atypical Hemolytic Uremic Syndrome in the Global aHUS Registry 1 Gianluigi Ardissino, 2 Gema Ariceta, 3 Masayo Ogawa, 4 Varant Kupelian, 5 Johan Vande Bacchi, 6 Alhaji Saudan, 7 Patrick Johnson, 8 Masayo Ogawa, 8 Varant Kupelian, 9 Franz S. Schaefer, 10 Johan Vande Bacchi.

Methods: PTs with clinical diagnoses of aHUS ( irrespective of identified complement amplification or treatment) are eligible. Demographic, medical/ disease history, and treatment outcomes data are collected at enrollment and prospectively.

Results: By January 30, 2015, 681 pts enrolled (Table: 62.7% of adults were women. Thrombosis occurred more frequently in adults than pediatric pts. Nonrenal comorbid conditions occurred in both age groups. ECU was administered to 56.2% (87.7% prior to enrollment).

Conclusions: Registry baseline characteristics show differences between pediatric and adult aHUS pts, notably different frequencies of thrombosis. Ongoing and future analyses will further enhance understanding of aHUS history and progression. Medical writing support - Kristen W. Quin, PhD, of Peloton Advantage, funded by Alexion

FR-PO485
Use of ACEIs and ARBs in Patients with Chronic Kidney Disease and Superimposed Community-Acquired Acute Kidney Injury 1 Patrick Saudan, 2 Cyrielle Alves, 3 Fabien Stucker, 4 Belen Ponte, 5 Pierre-Yves F. Martin, 6 Thomas Perrenoud, 7 Sebastian Carballo, 8 Franz S. Schaefer, 9 Johan Vande Bacchi.

Results: From May 1st up to June 21st 2013, there were 8464 admissions of whom 361 (4%) had a eGFR < 60 ml/mn and were known to have CKD. Use of ACEIs, ARBs, diuretics, NSAIDs was respectively found in 19, 23, 37 and 4% of patients. AKI was superimposed in 102 (28%) patients. Etiology was primarily associated with infection in 73%, diabetes (7%), and post-surgical (10%). ACEI use was significantly lower in patients with AKI (0.28; 95%CI:0.18-0.38, p<0.0001), but ARB use was similar (OR 0.78; 95%CI:0.56-1.09, p=0.12). In patients with stable CKD, ACEI use was significantly lower (OR 0.54; 95%CI:0.38-0.77, p<0.0001)

Conclusions: Lower use of ACEIs in patients with AKI might be due to the lack of benefit from life-long follow up of kidney function after AKI.

FR-PO486
Renal and Patient Outcomes of Dialysis Dependent Patients with ATN Who Survive Hospitalization 1 Mohammad Alhaji, 2 Rabeek I. El-refai, 3 Jere Yee, 4 Bronwyn Larissa Small, 5 Javier Rodriguez Sanchez, 6 Jian Li, 7 Lenar T. Yessayan.

Results: We prospectively enrolled 38 Medicare beneficiaries who developed hemodialysis-dependent ATN and survived to discharge at a single center from January 1, 2013 to June 30, 2014. The ATN was identified by urine microscopy and clinical judgment. ATN causes, patients’ comorbid conditions, potential contributors to ATN and indications for hospitalization were recorded.

Conclusions: We prospectively enrolled 38 Medicare beneficiaries who developed hemodialysis-dependent ATN and survived to discharge at a single center from January 1, 2013 to June 30, 2014. The ATN was identified by urine microscopy and clinical judgment. ATN causes, patients’ comorbid conditions, potential contributors to ATN and indications for hospitalization were recorded. Cumulative hazard estimates of events and survival curves were generated using the Kaplan-Meier method.

Results: Twenty six patients (58%) had CKD, 18 had diabetes (47%), 29 had hypertension (76%), 10 had history of liver disease (26%) The 90 day renal recovery and mortality rates were 42% and 11% respectively. Of those who recovered kidney function, Only 1 patient recovered kidney function beyond 60 days. The 1 year cardiovascular events and readmission rates were 22% and 62% respectively.

Conclusions: Patient with dialysis dependent ATN following a hospitalization are unlikely to get off dialysis support beyond 60 days after discharge. In the first year post discharge, they experience a significant number of cardiovascular events and hospital readmissions. Identifying modifiable risk factors for readmission in this cohort may reduce health care costs.

FR-PO487
Long-Term Renal Function After Recovery from Dialysis-Requiring Acute Kidney Injury 1 Sokratis Stoumpos, 2 Colin C. Geddes. Renal and Transplant Unit, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.

Background: Current guidelines suggest that people should be monitored for the development of chronic kidney disease (CKD) for at least 2-3 years after acute kidney injury (AKI), even if serum creatinine has returned to baseline. The aim of this study was to determine the long-term renal outcome of patients experiencing AKI secondary to hypoperfusion injury and/or sepsis who recovered to apparently normal renal function.

Methods: We conducted a population-based cohort study of all adult patients in our catchment area (serving a population of approximately 1.5 million), with AKI who required in-hospital dialysis in the nephrology unit, survived for at least 12 months after discharge, and had estimated glomerular filtration rates (eGFR) greater than 60ml/min in 1 year after the episode of AKI between September 1, 1989, and March 5, 2015. Patients with underlying nephropathy and AKI due to causes other than hypoperfusion injury and/or sepsis were excluded. Follow up was censored to the date of the last serum creatinine recorded.

Results: From the 770 patients identified with dialysis-requiring AKI, 310 patients met the inclusion criteria. Mean age at time of AKI was 49.0 (SD 14.6) years, 58.7% were male and the median duration of haemodialysis was 6 (IQR 3-11) days. After a median follow-up of 7.3 (IQR 4.6-12.6) years from first dialysis for AKI, eGFR was >60ml/min in 285 (91.9%) patients, 45-59ml/min in 18 (5.8%), 30-44ml/min in 6 (1.9%) and 15-29ml/min in 1 (0.3%) patient. None of the patients developed CKD stage 5 or end stage renal disease. 86 (27.7%) patients died during the duration of follow-up.

Conclusions: The excellent outcome for patients with normal renal function 1 year after an episode of dialysis-requiring AKI suggests that these patients are unlikely to derive benefit from life-long follow up of kidney function after AKI.
**FR-PO487**

**Long-Term Follow-Up of Children with STEC-HUS Caused by *E. coli* O104:H4 (German HUS Outbreak 2011): A GPN Registry Study**

**Background:** In 2011, *E. coli* O104:H4 caused the largest outbreak of HUS in adults and children. A total of 90 children were affected, of whom 64 (71%) required dialysis for a median of 11 days.

**Methods:** Currently follow-up data are available from 60 of 90 children (67%, 31 girls) from 11 pediatric centers in Germany. Median follow-up is 2.7 (range 1.2-3.8) years, median current age of patients is 14.7 (3.4-18.7) years.

**Results:** Median serum creatinine-urea is 0.7 (0.3-8.9) mg/dl. In two patients (2.2%) with CKD stage 3 and 4 at discharge GFR improved and they are now in CKD Stage 2. One patient remained dialysis dependent initially and one reached ESRD after 3.5 years; both underwent successful living-related kidney transplantation. All these 4 patients were treated with eculizumab in the initial phase of STEC-HUS including 2 who also received plasmapheresis. Proteinuria is currently present in 17 (19%) patients and 9 (10%) require treatment for hypertension. Three patients have neurologic symptoms (headache, performance deficit, spastic movement disorder) and 3 patients have EEG abnormalities without symptoms.

**Conclusions:** Long-term follow-up is important after O104:H4 associated STEC-HUS. CKD stage 3-5 at discharge is a risk factor for ESRD, however some children show a significant improvement over time. Patients with proteinuria and hypertension need long-term follow-up. Follow-up studies after STEC HUS should include neurological investigations.

**FR-PO488**

**SOFA Scores as Predictors of Mortality and Dialysis Dependency in Acute Kidney Injury**

**Background:** The Sequential Organ Failure Assessment (SOFA) score measures the severity of organ failure, and baseline SOFA scores have been used to predict mortality and dialysis in patients with Acute Kidney Injury (AKI). We evaluated whether SOFA scores, either upon initiation of dialysis or clinically updated, predict mortality and dialysis dependency among AKI patients.

**Methods:** Data from patients enrolled in the Acute Renal Failure Trial Network (ATN) study, a randomized multicenter trial of the intensity of renal support in AKI, were used in Cox proportional hazards regression and multimodal logistic models to assess the degree to which SOFA scores predict mortality and dialysis dependency.

**Results:** SOFA scores were associated with increased mortality risk following AKI among the 1,124 ATN participants, but the concordance statistic was low, at 0.651 (standard error [se] 0.041). When time-dependent analyses were used to take advantage of prospectively updated SOFA scores, the concordance statistic increased to 0.753 (se = 0.013). In analyses that examined mortality and dialysis dependency as competing outcomes at three fixed time points, increased SOFA scores were associated with higher mortality risk, and lower risk of dialysis dependency.

**Conclusions:** Similar to the general ICU population, updated SOFA scores better prognosticate the risk of death in patients with AKI. Higher SOFA scores are associated with increased mortality risk, but decreased dialysis dependency risk, when the two outcomes are evaluated as competing risks. Future studies should focus on prognostic tools that simultaneously prognosticate survival and need for dialysis in AKI patients.

**Funding:** Private Foundation Support

**FR-PO489**

**Risk Factors of Acute Kidney Injury and In-Hospital Mortality in Adult Patients Receiving Extra-Corporeal Membrane Oxygenation (ECMO)**

**Background:** Despite the frequent complication in patients receiving extracorporeal membrane oxygenation (ECMO), little has been studied about the risk factors of AKI and in-hospital mortality. Thus we performed the study to identify factors associated with AKI and in-hospital mortality.

**Methods:** We analyzed 322 adult patients receiving ECMO from January 2005 to November 2019 in two tertiary care hospitals. AKI and in-hospital mortality Disease Improving Global Outcomes classifications. Variables within 24 h before ECMO initiation were collected and analyzed for the association with AKI and in-hospital mortality.

**Results:** Stage 3 AKI was associated with in-hospital mortality with HR (95% CI) of 2.680 (1.410-5.132), compared to no AKI (p=0.003). Simplified acute physiology score was also significantly associated with in-hospital mortality with HR (95% CI) of 1.022 (1.004-1.040) with every 1 score increase (p=0.014). Initial pump speed of ECMO was significantly related to in-hospital mortality with HR (95% CI) of 1.397 (1.024-1.904) with each 50 rpm increase (p=0.028). There was also a trend to significantly associated with total AKI (p=0.035) and stage 3 AKI (p=0.044) with ORs (95% CI) of 2.219 (1.059-4.462) and 1.676 (1.015-2.770), respectively. We also found that red cell distribution width (RDW), serum level of total bilirubin, and the duration of ECMO were significantly related to AKI and/or stage 3 AKI.

**Conclusions:** Initial pump speed was significant risk factor in in-hospital mortality and AKI in patients receiving ECMO. RDW, serum level of total bilirubin and the duration of ECMO were risk factors of AKI.

**FR-PO490**

**Comparison of Clinical Characteristics of Patients with Acute Kidney Injury After IntraVascular versus Inhaled Colistin Therapy**

**Background:** The aim of this study is to investigate the incidence and clinical characteristics of intravenous or inhaled colistin associated acute kidney injury (AKI) using the RIFLE criteria.

**Methods:** From 2010 to 2014, 160 patients were treated with intravenous or inhaled colistin. Of these, we included 139 patients who received colistin for >72 h, and compared the incidence and clinical characteristics of patients in the intravenous (n=120) and inhaled (n=19) groups.

**Results:** The patients included 116 men and 23 women, with a mean age of 68 years (range, 20-91). Patients were infected with either A. baumannii (54%) or P. aeruginosa 46 (%), and pneumonia (91%) was the most common type of infection. The mortality rate was 43.9%, and AKI occurred in 83 (60%) patients. At the end of therapy, bacteriologic cure rate was 64%. There were no differences in the clinical characteristics between the intravenous and inhaled groups except for age. In comparison with patients in the intravenous group, the patients in the inhaled group were older (74 ± 8 y vs 67 ± 14 y, p<0.03). The incidence of AKI was not different between the two groups (62% vs 47%, p=NS), and there was no difference in the severity of AKI according to the RIFLE criteria. Of the 83 patients with AKI, 8 and 1 patients underwent renal replacement therapy.

**Conclusions:** In our study, the incidence of AKI in patients undergoing colistin therapy was 60%, and there was no difference in safety between the intravenous and inhaled colistin groups. Therefore, it is also important to monitor renal function during colistin therapy regardless of the route of administration.

**FR-PO491**

**Acute Kidney Injury following Coronary Angiography**

**Background:** Acute kidney injury (AKI) is a known complication of coronary angiography (CA). The aim was to study the incidence, risk factors and outcome of AKI following CA in a whole nation.

**Methods:** This was a retrospective analysis of data from all CA in Iceland during a 9 year period. AKI was diagnosed according to the creatinine based KDIGO criteria and survival status for all patients was verified at Statistics Iceland. The epidemiology and clinical outcomes were compared between three 3-year periods using Chi-squared and Kaplan Meier method, and multivariate logistic regression was performed to find predictors of AKI.

**Results:** From Jan 1st 2005 to Dec 31st 2013 10713 patients underwent 13890 CA of whom 40% entailed an intervention. Median (range) age was 65 (19-96) years and 70.7% were men. AKI was diagnosed in 214 patients (1.5%; 168 (1.2%), 270(2.2%) and 19 (0.1%) of stage 1, 2, and 3, respectively. There was a trend towards a decreasing incidence of AKI: 1.8% in the first period 1, 3% in the second and 1.4% in the last (p<0.05). AKI was more common in the intervention group, 2.2% vs 1.1% (p<0.0001). Patients with AKI were older, had more often prior history of AKI, more co-morbid diseases and lower baseline eGFR compared to non-AKI patients. In multivariate analyses age over 70 years (OR=1.01, 95% CI=1.007-1.016), angiography with intervention (OR=1.01, 95% CI=1.008-1.016) COPD (OR=1.01, 95% CI=1.003-1.025), liver disease (OR=1.03, 95% CI=1.014-1.058) baseline eGFR<60 (OR=1.03 95% CI=1.027-1.039) and a prior history of AKI (OR=1.07, 95% CI=1.051-1.080) were independent predictors of AKI after CA. One year survival of AKI patients did not differ between time periods: 67.0%, 63.1% and 69.0% in the first, second and third, respectively, p=0.3.

**Conclusions:** There is a trend towards a decrease in AKI incidence following CA in recent years. Aged patients with multiple co-morbidities and prior history of AKI need special attention in connection with this this procedure.

Acute Kidney Injury in the First Hundred Days After Hematopoietic Stem Cell Transplantation: Experience with 222 Transplanted Patients in a Single Center

Miguel A. Solis, Sandra Tejedor, Isidro Torregrosa, Carmen Ramos, Isabel Juan, Patricia Tomas, Patricia Zambraño Esteves, Juan José Guzmán Herrera, María Jesús Puchades, Alfonso M. Carrasco. Nephrology, Univ Clinic Hospital, Valencia, Spain.

Background: Hematopoietic stem cell transplantation recipients are at an increased risk of Acute Kidney Injury (AKI) or Chronic Kidney Disease (CKD). An earlier diagnosis could dramatically improve the patients’ prognosis. Objective: To analyze the incidence of AKI in the first 100 days of Hematopoietic stem cell transplantation recipients and the relationship with mortality.

Methods: We carried out a retrospective study including 222 adult patients who underwent Hematopoietic stem cell transplantation between 2006 and 2010 at our institution. AKI was defined using the RIFLE criteria in the first 100 days after transplantation.

Results: 222 patients were included in the study, 137 males and 85 females. Median follow-up was 30 months, range 1-60 months. In the first 100 days after transplantation AKI developed in 78 patients according to the RIFLE criteria (35.1%). A total of 85 patients died during follow-up vs 47 who had developed AKI (38.2% versus 61%, p=0.05). Detailed patients' characteristics are summarized in table 1.

Conclusions: AKI incidence in hematopoietic stem cell transplantation recipients is very high. There is a statistically significant relationship between AKI and death in these patients. Earlier AKI identification could prevent kidney damage progression and improve patient outcome over time.

FR-PO493

STOP-Acute Kidney Injury (AKI): A Streamline Approach to the Management AKI Leads to Reduction of Mortality Rates

Hsu Jeen Chong, Thangavelu Chandrasekar. Nephrology, Aintree Univ Hospital, United Kingdom.

Background: Acute Kidney Injury (AKI) has a mortality rate of 30%, greater than common conditions such as myocardial infarction (8%) and stroke (9%). It is estimated that 15% of all inpatients at University Hospital Aintree (UHA), Liverpool, UK, suffer an AKI making it a condition of considerable importance in everyday practice. Through clinical audit, it was found that mortality rate of AKI in UHA was 33% on wards other than renal ward (9%).

Methods: To reduce AKI mortality by 30% and length of stay by 20% over a 12 month period from Oct 2013 using standardised, evidence based approach. Using plan, do, study act (PDCA) methodology, we developed and tested an automated e-alert diagnostics system, an AKI treatment bundle and a patient information leaflet. The STOP-AKI project was launched. Our Primary drivers were early and accurate identification of AKI, effective intervention and monitoring, staff and patient engagement. Initially, trialled at ward level, the project was scaled up to admission areas (Accident and Emergency Department and the Medical Assessment Unit) becoming part of routine management for all admitted patients.

Results: Fall in mortality rates from a baseline of 24% to 18.5%, representing an overall reduction in mortality of 23%. Length of stay fell by 11% equating in a 2.0 day reduction in length of stay.

Conclusions: The STOP-AKI project led to the development of an AKI bundle in Oct 2013. This has achieved not only a significant reduction in patient mortality and length of stay but in addition a more structured and stream lined way of approaching the patients with AKI in our hospital. With the bundle being rolled out to primary care and the rest of our inpatient wards, we anticipate a further reduction in mortality.

FR-PO494

Race and Risk of Acute Kidney Injury (AKI) in VA Patients

Michael Heungs, Deidra C. Crews, Neil R. Powe, Sharon Saydah, Meda E. Pavkov, Kara Zivin, Univ of Michigan; Johns Hopkins Univ; Univ of California San Francisco; Centers for Disease Control and Prevention; VA Ann Arbor Health System.

Background: African Americans (AA) are at increased risk for AKI compared to Caucasians (C); potential explanations include differences in risk factors, genetic susceptibility and socioeconomic factors. We explored the influence of race on AKI risk in the Veterans Administration (VA), an integrated healthcare system.

Methods: Retrospective cohort analysis of all hospitalizations for VA patients with known AA or C race in 2011. AKI was defined by KDIGO criteria (=0.3mg/dL increase in serum creatinine from pre-admission baseline). Modified Poisson regression models estimated the effect of AA race on risk of AKI, adjusting for age, sex, baseline eGFR, comorbidities (DM, HTN, coronary heart disease;CHD; CHF), geographic region and severity of illness during hospitalization. Additional models including albuminuria were run for those with available data.

Results: We identified 180,429 VA hospitalizations. Compared to C, AA had higher prevalence of DM (43.1% v. 41.1%, P<.001), lower prevalence of CHD (45.7% v. 58.8%, p<.001), lower Charlson comorbidity scores (1.4 v. 1.6, p<.001) and higher baseline eGFR (89.2 v. 81.7, p<.001). AKI occurred in 19.5% of admissions (35,134) involving 23.2% of AA and 18.5% of C. In adjusted models, AA race remained an independent risk factor for AKI (RR 1.26, 95% CI 1.24-1.28). In the subgroup with albuminuria data (40,668), the risk was slightly attenuated (RR 1.20, 95% CI 1.16-1.24). A similar increased risk of hospital-acquired AKI in AA compared to C (RR 1.01, 95% CI 1.03-1.98) was found.

Conclusions: Although AA Veterans had higher baseline eGFR and lower comorbidity scores compared to C, AA had an increased risk of developing AKI, even after accounting for differences in risk factors & geographic region. This increased risk for AKI in AA persisted when examining AKI that developed during hospitalization. Given that VA patients have similar healthcare access and benefits, our results suggest that the increased AKI risk seen in AA is unlikely to be fully accounted for by disparities in access to care.

Funding: Other NIH Support - Centers for Disease Control and Prevention, Veterans Administration Support
Nephrologists consultation and 30 days follow up included demographics and biochemical variables, time between AKI onset and Nephrology consultation, fluid balance, mortality scale, treatment and date of death or patient discharge.

Results: The overall mortality was 49%. Mean age 58 years. The principal diagnosis at admission was coronary syndrome. The AKI at the moment of consultation was 3 in the 64%.

FR-PO496
Cast Nephropathy versus Acute Tubular Necrosis in Newly Diagnosed Multiple Myeloma: A Comparative Study

Insara Jaffer Satheek,1 Samih H. Nasr,1 Nelson Leung,1,2 1Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Div of Anatomic Pathology, Mayo Clinic

Background: Myeloma cast nephropathy (MCN) and acute tubular necrosis (ATN) are recognized causes of acute kidney injury (AKI) in newly diagnosed multiple myeloma patients. However it is currently not known if there is a difference in outcomes between these two groups. We conducted a retrospective study to compare the clinical characteristics and renal response rates in patients presenting with acute kidney injury at the time of myeloma diagnosis.

Methods: We included all patients with AKI at the time of multiple myeloma diagnosis with biopsy-confirmed diagnosis of MCN or ATN between 1998 and 2013. Patients with chronic kidney disease (estimated GFR by MDRD equation<45ml/min/1.73m2) and relapsed multiple myeloma were excluded. We assessed survival and renal outcomes. Six month landmark survival analysis was done with Kaplan Meier estimates. Renal response was classified according to IKMG consensus criteria.

Results: Out of a total of 51 patients who were included in the study, 42 had MCN and 9 had ATN. Baseline characteristics were not significantly different between the groups except urine albumin percentage of >6% was predictive of ATN.

Conclusions: Our data suggests that AKI due to ATN at the time of myeloma diagnosis is more likely to recover compared to MCN with a faster time to response. However this does not seem to affect overall survival.

FR-PO497
Hospital Manifesting AKI Presents Worst Outcome Than Community Acquired AKI

Xose Luis Perez-Fernandez, Florencia E. Sileanu, Joan Sabater Riera, Kathleen D. Liu, John A. Kellum. 1Servei de Medicina Intensiva, Hospital Univ de Bellvitge, L’Hospiatol de Llobregat, Barcelona, Spain; 2Critical Care, Univ Pittsburgh Medical Center, Pittsburgh, PA; 3Nephrology & Critical Care, Univ California San Francisco Parnassus MC, San Francisco, CA.

Background: The objective of this study was to evaluate outcomes in critically ill patients with severe community-acquired AKI (CA-AKI) and hospital-manifesting AKI (HM-AKI). Secondary objectives were to identify characteristics that differ between patients with CA-AKI and HM-AKI to design future preventive strategies.

Methods: Observational retrospective study conducted at two tertiary care hospitals between 2000-2008 (UPMC, Pittsburgh, USA) and 2006-2012 (HUB Barcelona, Spain). Those with CA-AKI met criteria for KDIGO Stage 3 AKI at hospital admission whereas those with HM-AKI did not have AKI at hospital admission. HM-AKI subjects met KDIGO Stage 3 AKI criteria within 24 hours of ICU admission, with at least 72 hours elapsing between hospital admission and ICU admission. The relationship of type of AKI (CA-AKI, HM-AKI) with 90-day survival was analysed using Cox regression models controlling for differences between survivors and non-survivors.

Results: 354 patients met inclusion criteria. 92.5% of these patients required RRT at some point during ICU admission. 189 (35.4%) patients had AKI manifest while in-hospital, and these patients had a significantly higher 90-day mortality compared to 345 (64.6%) patients presenting with CA-AKI (68.3% vs 58.6%, p=0.03). Age, SOFA score, time from hospital admission to ICU, HM-AKI (compared to CA-AKI), and medical (vs surgical) admission, were all associated with lower 90 day survival. In the multivariate analysis, HM-AKI remained an independent risk factor for death compared to CA-AKI (HR 1.5; 95%CI (1.1 – 2.0).

Conclusions: AKI manifesting after hospital admission has significantly worse outcomes compared to AKI present at hospital admission even among patients progressing to stage 3 by ICU admission. Future interventions should be directed to prevent AKI in patients admitted to hospital, especially those who present with the risk factors identified in this study.

FR-PO498
Assessing Patient Awareness in Moderate to Severe Acute Kidney Injury

Shardin Par, Marcus G. Wild, Swee-Ling Levea, Talat Alp Ikizler, Edward D. Siew, Kerri L. Cavanaugh. Vanderbilt Center for Kidney Disease, Vanderbilt Univ Medical Center, Nashville, TN.

Background: We aimed to evaluate awareness and knowledge of kidney disease in patients experiencing moderate to severe AKI, which is important for implementing targeted patient self-care risk-reduction strategies.

Methods: We surveyed 150 hospitalized patients in one academic medical center who experienced KDIGO Stage II or III AKI. We characterized patients’ awareness that AKI had occurred, and specific AKI knowledge and perceptions about kidney communication from their health providers. Laboratory data, disease severity, nephrology consultation, and need for dialysis were abstracted from the medical record.

FR-PO499
Hospital Manifesting AKI Presents Worst Outcome Than Community Acquired AKI

Xose Luis Perez-Fernandez, Florencia E. Sileanu, Joan Sabater Riera, Kathleen D. Liu, John A. Kellum. 1Servei de Medicina Intensiva, Hospital Univ de Bellvitge, L’Hospiatol de Llobregat, Barcelona, Spain; 2Critical Care, Univ Pittsburgh Medical Center, Pittsburgh, PA; 3Nephrology & Critical Care, Univ California San Francisco Parnassus MC, San Francisco, CA.

Acute Kidney Injury Correlates with Remote Organ Injury and Predicts Outcome in Primary Acute Liver Failure

Alexander Lukasz,1 Michael P. Manns,2 Johannes Hadem,2 Philipp Kümpers,2
1Dept of Nephrology and Rheumatology, Univ Hospital Muenster, Muenster, Germany; 2Dept of Nephrology & Hypertension, Hannover Medical School, Hannover, Germany.

Background: In patients with acute liver failure (ALF), the occurrence of AKI predicts the combined endpoint of death or liver transplantation in a cohort of patients with primary ALF admitted to intensive care unit (ICU).

Methods: 130 patients with primary ALF of different entities (drug-induced, viral, indeterminate or others) were included. Patients without hepatic encephalopathy were excluded. According to the acute Kidney Injury Network (AKIN) definition AKI severity (stage 1, 2 or 3) was classified. The primary outcome studied was event-free 28-day survival (death or transplantation).

Results: 76 patients (58%) had normal renal function, while AKI II and III was present in 15 (12%) and 39 patients (30%) on ICU admission, respectively. Between different ALF entities, AKI prevalence and severity was similar (Chi-Square; p=0.28). AKI severity correlated closely with the extent of remote-organ damage as assessed by Simplified Acute Physiology Score (SAPS) (II: p=0.056, SAPS III: p=0.006) and Sequential Organ Failure Assessment (SOFA) score (r=0.57, p=0.0001), respectively. Kaplan-Meier analysis demonstrated that 37 of 39 ALF patients with AKIN III reached the composite endpoint of death or transplantation within 28 days (log-rank test: p=0.0001). Adjusted Cox’s proportional hazards analyses identified AKI on ICU admission as an independent predictor of the composite endpoint of death or transplantation [HR 3.1 (95% CI 1.9-4.9) for no AKI vs. AKIN III].

Conclusions: Our data indicate that AKI is a frequent complication in primary ALF. AKI correlates with several features of remote-organ damage and independently predicts outcome in this cohort.

Reduction of Nephrotoxic Medication Associated Acute Kidney Injury: Result from a Three Year Sustained Harm Reduction Program

Stuart Goldstein, Eric S. Kirkendall, Theresa A. Mottes, Kendria Nicole Simpson, Stephen E. Muething. Pediatrics, Cincinnati Children’s Hospital, Cincinnati, OH.

Background: Acute kidney injury (AKI) represents one of the most common co-morbidities in hospitalized children. Our previously reported nephrotoxic medication (NTMX) exposure and AKI screening project (Nephrotic Injury Negative by Just-in-time Action [NINJA]) showed a 25% NTM-AKI rate and a 42% reduction in AKI days/100 NTM-exposures in Year 1 of the program. This occurred due to rapid recognition of AKI and NTM-exposure reduction. We now report on the 3-year NINJA results to assess for sustained harm reduction.

Methods: A daily serum creatinine (Scr) was recommended for all children admitted to a non-intensive care unit who received >3 NTM-exposures in a 30-day period. Scr was measured at 48-hour intervals for >3 days (high NTM-exposures) to assess for AKI development. We tracked biweekly outcomes from Sep 2011 through Mar 2015: 1) High NTM-exposures per 1000 pt-days 2) AKI episodes per 1000 pt-days 3) AKI rates per exposure case (%) and 4) AKI days per 100 high NTM-exposures-days (inter- AKI was defined by Kidney Disease: Improving Global Outcomes criteria. We used statistical process control charts to assess for changes from baseline rates.

Results: 1,783 patients accounted for 2,358 separate admissions and 3,243 individual episodes of high NTM exposure. 170 patients (97.5%) had 2+ episodes. We observed two trends in high NTM-exposures and AKI rates. Overall, the high-NTM exposure rate decreased by 38% (11.23 to 6.99 admissions/1000 pt-days), and the AKI rate decreased by 64% (2.96 to 1.06 admissions with AKI/1000 pt-days). The NINJA project saved pts from 633 exposure and 398 AKI episodes (when compared to baseline rates). Medications/ medication classes or admitting services for exposed or non-exposed did not differ. Services served the 3 months preceding and following either time point improvement. AKI rates per exposure (23.3% to 14.5%) and AKI intensity (27.7 to 19.1 AKI days/100 exposure days) also decreased in Year 1; both improvements persisted for the entire period.

Conclusions: Implementation of systematic surveillance for NTM-AKI can lead to sustained reductions in avoidable harm.

FR-PO499

FR-PO501

Early and Late Auto Kidney Injury in Severely Burned Patients

Stanisław Niemczyk,1 Wojciech Witkowski,2 Wojciech Klimm,2 Agnieszka Surowiecka-Pastewka,2 Marek Kawecki,2 Katarzyna Szamotulska,2 1Dept of Internal Medicine, Nephrology and Dialysisotherapy, Military Inst of Medicine, Warsaw, Poland; 2Dept of Burns, Plastic and Reconstrucory Surgery, Military Inst of Medicine, Warsaw, Poland; 3Dept of Treatment of Burns, Centre for the Treatment of Burns, Słomowianickie Slaskie Z invis, Inst of Epidemiology and Biostatistics, Inst of Mother and Child, Warsaw, Poland; 4Dept of Emergency Medicine, Facultuy of Health Sciences, Academy of Technology and Humanities, Bielsko-Biała, Poland.

Background: Evaluation of factors influencing early and late acute kidney injury (AKI) in severely burned patients and assessment of the relationship between time of occurrence of AKI and mortality.

Methods: Retrospective analysis of severely burned patients with >30% total body surface area (TBSA), admitted to two centers for the treatment of burns. We selected and analyzed 239 severely burned patients. Renal function was evaluated at three points: admission, critical or middle point of hospitalization and the endpoint death or discharge from the center. AKI criteria: decrease in glomerular filtration rate (GFR) > 60 ml/min at admission, decrease in GFR > 75% compared to baseline, decrease in the daily diuresis < 500 ml.

Results: At admission 15.1% of the patients had GFR < 60 ml/min. AKI occurred in 38.5%. The occurrence of AKI was associated with: elderly age (p<0.001), female gender (p=0.017), overweight and obesity (p=0.055), extent and depth of burns, respiratory failure, low protein concentration (for all p<0.001), low blood pressure (p=0.014) and high white blood cells count (WBC) (p=0.010). Early AKI was detected in 28% Mortality. 100% with the initial GFR < 60 ml/min and early decrease in renal function, and 60% with the initial GFR < 60 ml/min and no worsening. Late AKI was observed in 10% of patients and mortality was 79.2%. Mortality rate in the group with AKI was 88.0% versus 24.5% without AKI.

Conclusions: The frequent occurrence of AKI, especially early, worsens the prognosis for survival. The assessment of renal function should be included in the prognostic scales for burned patients.

Acute Kidney Injury and Risk of Incident Heart Failure Among U.S. Veterans

Nisha Bansal,1 Michael Edwin Matheny,2 Svetlana Eden,2 Robert Greercy,2 Sharidan Parr,3 James Fly,2 Khaled Abdel-Kader,2 Jonathan Himmelfarb,1 Ian H. De Boer,2 Tatul Alp Ikizler,2 Edward D. Siew.2 1UW, 2UW, 3Vanderbilt.

Background: Acute kidney injury (AKI) is common and associated with poor long-term outcomes. Heart failure (HF) is a leading cause of cardiovascular disease among patients with chronic kidney disease (CKD). The relationship between AKI and HF remains unknown and may identify a novel endpoint and site of pathology and cardiovascular disease.

Methods: We studied a national retrospective cohort of 111,488 U.S. Veterans hospitalized between 2003-2012 without history of HF. AKI was defined as a 0.3 mg/dl or 50% increase in serum creatinine using the difference between peak hospitalization and baseline creatinine (as determined by most recent outpatient creatinine over previous year) and staged according to Kidney Disease Improving Global Outcomes (KDIGO) criteria using change in serum creatinine. Incident HF was defined as >1 hospitalization or ≥2 visits with a diagnosis of HF, as determined from validated ICD9 codes, through 2012. Propensity score weights relevant endpoint and inpatient covariates were generated and patients with and without AKI were matched 1:1. Cox proportional hazards were used to determine the association of AKI with risk of incident HF, adjusting for baseline age, eGFR, coronary heart disease and hypertension. Patients who died or had an outcome after the end of the study were censored.

Results: There were 17,272 matched pairs with and without AKI in the study. Patients with and without AKI during the index hospitalization were well matched with median

Acute Kidney Injury Increases Medical Costs Even in the Pre-AKI Stage

**Background:** Early detection of acute kidney injury (AKI) is important to prevent the progression of AKI and to improve clinical outcomes. However, the significance of mild increases in serum creatinine below AKI stage is not well established. In this study, we defined pre-AKI as the 25-50% increase of serum creatinine levels from the baseline levels. We aimed to investigate the influence of AKI stage including pre-AKI on clinical outcomes.

**Methods:** All clinical and laboratory data were retrieved from electronic medical record databases. We enrolled a total of 20819 patients who admitted Seoul National University Bundang Hospital from January 1, 2013 to December 31, 2013. We excluded patients who had not checked serum creatinine levels during admission or who were on dialysis due to end-stage renal disease.

**Results:** The proportion of patients who had AKI during admission were 21.6% (pre-AKI), 15.8% (AKI stage 1), 5.9% (AKI stage 2), and 3.2% (AKI stage 3). In-hospital mortality increased according to the stage of AKI [log-rank P < 0.001; HRs 1.878 (1.189-2.966) AKI stage 1; 6.039 (3.948-9.239) AKI stage 1; 12.064 (7.992-18.210) AKI stage 3].

**Conclusions:** Patients with pre-AKI showed a higher mortality compared with increased length of stay (no AKI 7.4 ± 9.0 days, pre-AKI 13.0 ± 13.3 days, P < 0.001) and increased medical costs (no AKI: 2806 ± 3286 USD, pre-AKI: 4701 ± 5476 USD, P < 0.001) during admission. Patients with Pre-AKI were more on surgical condition (51.1% vs 34.0%, P < 0.001) compared to patients without AKI.

**Impact of Fluid Overload on Acute Kidney Injury Diagnosis and Associated Outcomes in Critically Ill Patients: A Retrospective Cohort Study**

**Background:** Fluid overload (FO) changes the volume of distribution of creatinine, which is equivalent to total body water (TBW), this can alter the serum creatinine (sCr) concentrations. Higher TBW results in lower sCr leading to underestimation of AKI. Moreover, the rise of sCr is done by a formula (Adjusted-Cr=Cr/[1+(serum creatinine/TBW)])

**Methods:** We made a retrospective analysis of 120 records of pts from 2 centers. We calculated daily fluid balance and divided it by the body weight to obtain a percentage of FO. Pts were divided into 2 groups, A and B, with <2.5% and >5% of FO, respectively. Measured daily sCr was corrected using the TBW formula and presence of AKI was evaluated daily according to KDIGO guidelines. We compared the prevalence, day of diagnosis, and associated outcomes between the 2 groups.

**Results:** Mean age in the cohort was 54±4yrs, 56.3% were male. In group A 24 (34.8%) pts were diagnosed with AKI before adjustment and 25 (36.2%) after adjustment (p=0.167). In group B 21 (48.8%) and 25 (58.1%) were diagnosed with AKI before and after adjustment, respectively (p=0.023). Mean detection day of AKI without and with adjustment in group A was 3.22±2.4 and 2.84±2.1, respectively (p<0.001) and in group B 3.4±2.3 and 3.2±2.0 (p<0.001).

**Conclusions:** Correction of measured sCr for TBW in patients with >5% of FO is useful to diagnose more patients with AKI. Usage of the formula demonstrated usefulness for early diagnosis in patients with <2.5% and >5% of FO and we recommend its application in order to improve AKI prevention and treatment. FO of >5% is associated with increased mortality and worse outcomes in critically ill pts.
Results: Histologically, elevated PI GF was significantly associated with the severity of the arteriolar intimal damage and the intimal thickening of small renal arterioles. During a median follow-up of 2.7 years, 82 patients reached primary end-points which were defined as the requirement of renal replacement therapy (38 patients) and the decline of eGFR by more than 25% from baseline (44 patients). Although baseline eGFR was not statistically different among patients in all PI GF quartiles, the rate of eGFR decline in the patients with the highest PI GF quartile was significantly faster than those with other quartiles. After adjustment of known confounding factors, PI GF was significantly associated with the risk of deterioration of renal function with the adjusted hazard ratio of 1.75 [1.38-2.26] for each quartile increase. The combined use of eGFR and PI GF significantly improved the predictive accuracy for CKD progression compared with eGFR alone (c-statistics from 0.689 to 0.772, p<0.001).

Conclusions: Elevated PI GF is a novel and independent predictor of renal prognosis in patients with CKD.

FR-PO509

Steep Decline in Renal Function After a Hypertensive Disorder of Pregnancy: A Longitudinal Study Nora Praga,1 Anne Marinj van der Graaf,2 Rita Bozoglan,2 David P. van der Ham,2 Gerjan Navis,3 Ron T. Gannevoort,2 Henk Groen,3 Titiia Lely,1 1Obstetrics, UMC Utrecht, Netherlands; 2Nephrology, UMC Groningen, Netherlands; 3Obstetrics, Martini Hospital, Netherlands; 4Epidemiology, UMC Groningen, Netherlands.

Background: Hypertensive disorders of pregnancy (HDP) occur in 10% of pregnancies. Population based studies report increased risk for ESRD after HDP. Our aim was to longitudinally assess renal function over time after HDP. Women with severe hypertensive disorders of pregnancy (PE) have a 10.9% of the PIH and 19.2% of the PE group met the criteria for CKD.

Methods: Data from the PREVEND study, a population based prospective cohort with median follow-up of 11 years, were used to identify women without and with self-reported HDP (non-HDP, n=1805 and HDP, n=977). A case cohort, 10 years post-partum was created by record linkage, with subgroups: normal pregnancy (control, n=202), pregnancy-induced hypertension (PIH, n=56) and preeclampsia (PE, n=29). Renal function and the prevalence of CKD were compared.

Results: eGFR was lower at baseline and during follow-up in HDP vs non-HDP (A). In addition, the decline in eGFR was steeper in HDP vs non-HDP (B). At baseline and during follow-up there was a trend anti-hypertensive-drug use, including ACEi in the HDP group. 24-h albuminuria at baseline was higher in HDP vs non-HDP and remained steadily higher in HDP during follow-up. A trend towards increased risk of CKD was observed in HDP, HR 1.13 (0.92-1.38). In the case cohort, eGFR was significantly lower (C) and 24-h albuminuria significantly higher (p<0.03) in the PE vs controls. 7.8% of the controls, 10.5% of the PIH and 19.2% of the PE group met the criteria for CKD.

Conclusions: We report a lower renal function and a steeper renal function decline over time after HDP. Women with severe hypertensive disorders of pregnancy (PE) have the highest risk for renal function loss.

FR-PO509

Pregnancy Outcomes in Women with Chronic Kidney Disease in South Australia Shilpa Jesudason,1,2 Alyssa Kate Fitzpatrick,4 Britt Melinda Catcheside,3 Wendy Katharine Schell,2 Stephen P. McDonald,1,3 1Central and Northern Adelaide Renal and Transplantation Services, Adelaide, Australia; 2South Australian Pregnancy Outcomes Unit, Adelaide, Australia; 3School of Medicine, Univ of Adelaide, Adelaide, Australia; 4Univ of Oxford, Oxford, United Kingdom. 

Background: Chronic kidney disease (CKD) affects an estimated 3% of women in their childbearing years. CKD in pregnancy is associated with adverse maternal and neonatal outcomes. This study represents the first attempt to capture the distribution of CKD among pregnant women in the Australian population.

Methods: Data was obtained from the South Australian Pregnancy Outcomes Unit Supplementary Birth Record for singleton pregnancies from 1990-2012. Women with CKD were identified by renal ICD-9 codes for immunological renal conditions, cystic/ genetic renal disease, vesicoureteral reflux, hypertensive CKD, urolological conditions, pyelonephritis, and unspecified renal disease. Uncomplicated urinary tract infections were excluded. Data was obtained on maternal demographics, obstetric care and infant outcomes. Chi-squared or Fisher’s exact tests were used to examine the crude association between renal disease and adverse outcomes.

Results: 1392 births to women with renal disease codes were identified from 407,580 recorded births. Women with renal disease were significantly more likely to be Aboriginal (5.2% vs 2.6%, p<0.001), to have the lowest socioeconomic status (31.4% vs 26.2%, p<0.001) and to smoke (24.1% vs 18.4%, p<0.001). Higher unadjusted risks of adverse outcomes were noted in the renal group, including gestational hypertension (10.6% vs 5.0%, p<0.001) and emergency caesarean section (20.0% vs 15.0%, p<0.001). Women with renal disease were more likely to have a preterm birth <34 weeks (6.7% vs 2.1%, p<0.001), or a late preterm birth 34-36 weeks (10.8% vs 4.5%, p<0.001). They were also more likely to be diagnosed with intrapartum growth restriction (11.2% vs 9.5%, p<0.03) and to deliver a low birth weight baby <2500g (13.4% vs 5.5%, p<0.001).

Conclusions: Indigenous Australian women and women with low socioeconomic status are disproportionately burdened by CKD in pregnancy. The data showed increased adverse maternal and neonatal outcomes among women with CKD.
Conclusions: Under NS state, MN+DM patients existed more serious prothrombotic state compared with MN+DKD. The mechanism is related to more MN+DKD. In addition to disorders of endothelial function, coagulation function, as well as fibronectin function. More attention should be paid to treatment of prothrombotic state in MN+DM patients.

Serum C3 and Renal Outcome in Patients with Primary Focal Segmental Glomerulosclerosis
Jian Liu, Jingyuan Xie, Jun Tong, Hong Ren, Weiming Wang, Nan Chen. Dept of Nephrology, Rui Jin Hospital, Shanghai Jiao Tong Univ; School of Medicine, Shanghai, China.

Background: The role of complement in the pathogenesis or progression of FSGS is uncertain. The aim of this observational cohort study was to identify the clinical implications of serum C3 levels and to investigate their utility as predictor of renal outcomes in patients with FSGS.

Methods: 591 biopsy-proven primary FSGS patients were recruited. Clinical, histological and progression data were recorded. Decreased serum C3 level was defined as C3<85 mg/dl. The study endpoint was end-stage renal disease (ESRD).

Results: Of the patients, there were 117 patients (21.5%) with low serum C3. At the time-point of renal biopsy, compared to patients with C3 ≧85 mg/dl, those with C3 <85 mg/dl had higher level of serum creatinine, lower levels of eGFR, proteinuria, hemoglobin, triglyceride, cholesterol, IgA, more severe segmental sclerosis, tubular atrophy and interstitial fibrosis. Multivariate linear regression analysis showed low C3 level was an independent risk factor for eGFR (HR=42.56, 95%CI 11.21-73.91, p<0.01) after adjusted by sex, age and clinical indicators. The follow-up was assessed in 221 patients. During a mean follow-up of 53.3 months, ESRD occurred in 32 patients (37.2%) with low serum C3 compared with 22 patients (16.3%) with normal C3 levels (P<0.001). Serum C3 level had a significant predictive value for renal outcome (AUC = 0.650, P = 0.001). The risk of reaching ESRD was significantly higher in patients with low serum C3 level (HR 4.044; 95% CI: 2.238 to 7.309; P < 0.0001).

Conclusions: Complement activation may occur in patients with FSGS. It is associated with clinical and histological severities. Low serum C3 is an independent risk factor for the decline of eGFR, and is associated with poor renal outcome in patients with FSGS.

Role of Proteolytic Fragment suPAR D2-D3 in Prediction and Cause of FSGS
Sanja Severs,1 Marina V. Kasakina,1 Eileen Kapples,1 Jian Cai,2 Jon B. Klein,2 Nada Alachkar,3 Changli Wei,4 Changkyu Gu,4 Jochen Reiser.1 1Nephrology, Massachusetts General Hospital, Charlestown, MA; 2Uni of Louisville School of Medicine, Louisville, KY; 3Nephrology, Johns Hopkins Univ; 4Medicine, Baltimore, MD; 4Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Primary FSGS is a kidney disorder that leads to end stage renal disease and affects tens of thousands of people annually. Several studies suggest the soluble uromodulin-type plasminogen activating receptor (suPAR) to be a predisposing circulating factor and prognostic marker of FSGS through its interaction with avb3 integrin.

Methods: We collected serum samples from kidney transplant recipients with FSGS. We also analyzed sera from healthy controls and patients with sepsis and on peritoneal dialysis. These sera were used to assess integrin activation in podocytes. Western blot utilized a antibody to full length and D2-D3 fragment of suPAR. Transgenic mice were created to drive mouse suPAR D1-D2-D3 and suPAR D2-D3 expression from adipocytes. Transgenic mice were utilized to identify full length and D2-D3 fragment of suPAR. Transgenic mice were used to assess integrin activation in podocytes. Western blot utilized an antibody to full length and D2-D3 fragment of suPAR. Injections of the D2-D3, but not full-length suPAR, induced facilitated podocyte motility. Injections of the D2-D3, but not full-length suPAR, induced transient proteinuria in mice. Transgenic mice for D2-D3 developed rising serum suPAR levels and a variable degree of proteinuria. A composite risk analysis score was developed that included presence of the D2-D3 in patient serum, podocyte integrin activation capacity, and total suPAR serum level for the prediction of recurrent FSGS.

Conclusions: suPAR D2-D3 fragment is a prognostic marker and risk factor for recurrent FSGS.

FR-PO514
Prognosis, Survival and Renal Function in Patients with Lupus Nephritis
Gustavo Aroca Martinez,1 Andrés A. Cadena,2 Eduardo Egea Bermejo,2 Josie E. Fontalvo,1 Yeners Gaviria,1 Henry J. Gonzalez Torres,1 Moises A. Arquez Mendoza,1 José Rafael Consuegra,1 Santos Depine.1 1Medicine, Univ Simon Bolivar; Barranquilla, Atlanticos, Colombia; 2Nephrology, Clínica de la Costa, Barranquilla, Atlantico, Colombia; 3Medicine, Univ Nacional de Colombia, Colombia, Atlantico, Colombia; 4Medicine, Univ del Norte, Colombia, Atlantico, Colombia.

Background: Lupus nephritis is the most common glomerulonephritis in the Colombian Caribbean region, despite there is less published information about its evolution and clinico-pathological aspects. Objective: To evaluate prognosis, survival and renal function of patients with LN residing in the Colombian Caribbean region controlled between 2000-2014.

Methods: 229 patient study with LN corroborated by histology according to the International Society of Nephrology Classification Renal Pathology Society (ISN/ RPS) 2003) treated with induction and maintenance therapy and with a systemized following of at least 2 years. The pharmaceutical treatments included prednisolone, azathioprine, and Cyclophosphamide mycophenolate mofetil in isolation or combined and the clinical laboratory and histopathology variables were correlated as predictive value of therapeutic response. To achieve this as methodology a non-parametric descriptive statistics ANOVA (k-w) was used and canonical correspondence analysis.

Results: 229 patients in total of 34±12 of age, which 88% women, whose evolution were controlled during 24±6 months. The most common form of clinical presentation was nephrotic syndrome and asymptomatic hematuria-proteinuria (68.07%) the type III and V were the most common in patients under 25 years of age and a negative response to treatment. The estimated glomerular filtration rate measured by MDRD showed a significant improvement at 24 weeks with regard the baseline figure of 74.36.

Conclusions: The early detection and reference of NL patients allows an early approach and therapy. Which will prevent chronic kidney disease.

FR-PO515
Association of ABO Blood Group with Progression of IgA Nephropathy
Meng Yang, Jingyuan Xie, Yan Ouyang, Xiaoyan Zhang, Xiao Li, Wen Zhang, Weiming Wang, Nan Chen. Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: ABO blood group antigens are major histocompatibility antigens and little is known about its association with progression of IgA nephropathy (IgAN).

Methods: Biopsy-proven primary IgAN patients were retrospectively recruited. Clinical, histological and progression data were recorded. Patients with eGFR=15mL/min/1.73m² at time of biopsy were excluded. Renal tissue was semi-quantitative scoredaccording to the Oxford scoring system. ABO blood group was determined by standard erythrocyte antigen agglutination method. All patients were divided into B antigen group (type B and AB) and non-B antigen group (type A and O) based on their ABO types.

Results: Among the 752 IgAN patients recruited in this study, 210 patients were type A (27.9%), 221 were type B (29.4%), 72 were type AB (9.6%) and 249 were type O (33.1%). When renal biopsy was performed, patients in B antigen group had higher eGFR (82.44 vs. 65.68 mL/min), lower systolic blood pressure (125.36 vs. 129.29 mmHg) and uric acid (373.59 vs. 393.93 mmol/L) than patients in non-B antigen group. No significant differences were detected between the two groups in terms of clinical and histological lesions and these two groups. Totally, 100 patients progressed to end-stage renal disease (ESRD) after a median follow-up period of 51.05 months, including 32 (15.2%) type A, 18 (8.1%) type B, 2 (2.8%) type AB and 48 (19.3%) type O patients. Kaplan-Meier analysis showed that median ESRD-free survival time of patients in B antigen group was significantly longer than patients in non-B antigen group [148.2±5.5 months vs. 138.8 ±7.5 months, p<0.001]. Furthermore, patients in B antigen group were associated with a decreased risk of ESRD (HR=0.56, 95%CI 0.33-0.94) after adjusted by age, sex and clinical variables including eGFR, sbp, serum albumin, urine protein and hemoglobin by Cox proportional hazards model.

Conclusions: Our data suggested that B antigen had an independent protective effect against the progression of IgAN.

FR-PO516
The Analysis of the Long-Term Outcomes of Patients with Primary IgA Nephropathy
Hao Li, Jian Liu, Wei Huang, Pingyin Shen, Zhaoxui Wang, Ya Li, Xiaoxia Pan, Jingyuan Xie, Weiming Wang, Nan Chen. Dept of Nephrology, Shanghai Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: Primary IgA nephropathy (IgAN) is one of the most common glomerular diseases in China. In this study we try to investigate the clinical characteristics and the relationship between CKD stages, the outcome and the corticosteroids use of CKD patients with primary IgA nephropathy through the retrospective analysis of their clinical data.

Methods: Patients with biopsy-proved primary IgAN from 2002 to 2013 were included in the retrospective analysis. They were older than 18 years old and their follow-up time was ranged from 2 to 12 months. We collected their medical history, laboratory test reports and other clinical data. Then we enrolled 297 patients who were followed up for 5 years for further research. Kaplan-Meier method was used to calculate the renal survival rate of the patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: A total of 1052 cases were included. There is an equal proportion of male and female (50.4% vs 49.6%). The mean age was 36.86±11.58 years old. Five-year renal survival rate of these cases was 92%, and ten-year renal survival rate was 88%. We enrolled 297 cases who were followed up for 5 years. These patients were divided into rapid progression and stable progression, we found that cases in rapid progression group had more proteinuria, higher blood pressure, poorer renal function, lower serum albumin and lower hemoglobin, compared with other groups. When cases were divided according to CKD stages, the results showed no significant difference of outcomes among patients in CKD1-3a stage (P > 0.05). Their five-year renal survival rate was more than 95%. But patients in CKD3b-4 stage had worse outcomes. The five-year renal survival rate of patients in CKD3b stage was 85.3%, while it is only 63.5% for patients in CKD4 stage.

Conclusions: Five-year and ten-year renal survival rate of patients with IGAN was 92% and 88%, respectively. Patients in CKD3b or CKD4 stage at biopsy may have a lower renal survival rate and a worse outcome. At the time of renal biopsy, patients with impaired renal function, mass proteinuria, hypertension, anemia and low serum albumin may have a greater risk of progressing to end-stage renal disease.

FR-PO517
Variability of GFR Decline in Alport Syndrome: Insights from a Provincial Database

Background: Alport syndrome (AS) is one of the inherited causes of CKD due to mutations in the collagen genes making up the glomerular basement membrane collagen. Design of clinical trials for intervention in AS proves challenging without a clear understanding of renal progression over time as observational data is lacking due to small sample size. We present here the utilization of population based data in a simulation to mimic clinical trial recruitment and endpoints to provide insights in trial designs for AS.

Methods: AS patients were identified within a provincial CKD clinical database (PROMIS) in British Columbia, Canada for this observational simulation study. Patients were excluded if they have fewer than 4 eGFR-MDRD measurements or as a study entry point to generate 100 random samples. Primary outcome was annual rate of change in eGFR over 2 years categorized into: > -5 mL/min per year (progressor), -5 and 2 mL/min per year (stabilizer) and ≤ -2 mL/min per year (regressor).

Results: 75% of the participants were female, with a mean age of 56 years (range 15-93). The mean eGFR was 50.3 ± 26.1 mL/min. Over 2 years, 77% of cases (95% CI: 72.7%–81.8%) progressed, and 22.7% (95% CI: 9.1%–36.4%) remained in stable state. Of those that ‘enrolled’ at eGFR 45-60 mL/min, 72.7% (95% CI: 64.9%–78.9%) had disease progression, and 20% (95% CI: 20%–20%) had an improvement in eGFR.

Conclusions: Heterogeneity and non-linearity of AS renal progression ought to be taken into account when designing trials of interventions aimed at improving renal outcomes. Funding: Pharmaceutical Company Support - Regulus Therapeutics

FR-PO518
Discovery of Urine MicroRNA Biomarkers in a Pre-Clinical Model of Alport Nephropathy

Background: For those recruited at eGFR 30-45 mL/min, 41.7% (95% CI: 35.2%–48.2%) had disease progression and 50% (95% CI: 45.3%–54.8%) remained stable state. Of those enrolled at eGFR 15-30 mL/min, 50% (95% CI: 41.7%–58.3%) were in stable state, 30.0% (95% CI: 20.0%–30.0%) had disease progression, and 20% (95% CI: 20.0%–20.0%) had an improvement in eGFR. For those recruited at eGFR 45-60 mL/min, 77.2% (95% CI: 63.6%–81.8%) progressed, and 22.7% (95% CI: 9.1%–36.4%) remained in stable state.

Methods: We have developed a high-throughput, multiplex miR profiling platform with the ability to profile tissue and bio-fluids. We discovered several urine microRNAs with highly significant differential expression in the Col4a3-/- mouse model when compared to wild type mice. Our data suggest that urine is a favorable bio-fluid for the development of non-invasive microRNA based tests.

Results: A total of 1528 patients were enrolled in KNOW-CKD cohort study (NCT 01630486) from Apr 2011 to Dec 2013. Among them, 153 patients were excluded (73 unclassified subgroups, 71 without urinary AGT measurement, 9 without available eGFR) and a total of 1375 (519 GN, 310 DN, 292 HTN, 254 ADPKD) patients were included in the final analysis. The mean age was 51 years and baseline serum creatinine was 1.9 ± 1.2 mg/dL. The GN and ADPKD subgroups showed younger age and earlier elevation of renal survival rate and a worse outcome. At the time of renal biopsy, patients with impaired renal function, mass proteinuria, hypertension, anemia and low serum albumin may have a greater risk of progressing to end-stage renal disease.
of urinary AGT/Cr levels according to CKD stages. When we performed the risk factor analysis separately in GN and ADPKD subgroups, the highest quartile of urinary AGT/Cr was associated with GN subcohort, female gender, hypertension, decreased eGFR, decreased plasma Hb, and higher degree of albuminuria. However, in multivariate logistic regression analysis, ADPKD subcohort demonstrated higher urinary AGT/Cr compared to GN subcohort after adjusting other co-factors.

**Conclusions:** Urinary AGT/Cr is greatly increased in ADPKD independent of albuminuria and renal function.

**Using Biomarkers to Predict Progression to End-Stage Renal Disease within 6 Months of Liver Transplant**

Joseph T. Bahng, Kimberly Autumn Forde,1 Peter Abt,1 Michael R. Bennett,2 Anirban Ganguli, Mary Ann C. Lim,2 Debra J. McCorriston, Mary C. Shaw, Deirdre L. Sawinski.1 1Perelman School of Medicine at the U. of Pennsylvania; 2Cincinnati Children’s Hospital.

**Background:** Liver transplant (LT) recipients are at increased risk for CKD and progression to ESRD. Creatinine, the standard for assessing renal function, provides limited prognostic information for recovery from AKI. Our aim is to create a predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers.

**Methods:** We enrolled 202 patients, of whom 138 have 6mos follow up. 13 patients progressed to ESRD, defined as GFR<20 ml/min, dialysis, or transplant evaluation. Logistic regression models evaluated neutrophil gelatinase-associated lipocalin, IL-18, Cystatin-C, albuminuria and renal function.

**Results:** In one model, MELD score at LT, pre-LT AKI, pre-LT renal replacement therapy, and highest creatinine 3mos pre-LT were associated with ESRD at 6mos (p<.05). In another model with biomarkers, only urinary IL-18 was included for its association with therapy, & highest creatinine 3mos pre-LT were associated with ESRD at 6mos (p<.05). Kidney Injury Molecule-1, & liver fatty acid binding protein for inclusion. Receiver regression models evaluated neutrophil gelatinase-associated lipocalin, IL-18, Cystatin-C, progression to ESRD, defined as GFR<20 ml/min, dialysis, or transplant evaluation. Logistic for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers. Our aim is to create a predictive model for progression to ESRD. Creatinine, the standard for assessing renal function, provides limited prognostic information for recovery from AKI. Our aim is to create a predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers.

**Conclusions:** MIG and IP-10 can be detected in urine as inflammatory biomarker to assess risk of transplant rejection. ViveST can be used as ambient storage and transport device eliminating need for cold chain storage. Additional studies warranted assessing detection of biomarkers at therapeutically relevant concentrations.

**Funding:** Pharmaceutical Company Support - Vivebio LLC

**Albuminuria-Induced Apoptosis in Children with Nephrotic Syndrome Is A Result of the Dysbalance in Apoptosis Controlling System**

Jevgenija Burlaka, Dept of Pediatrics No.4, National O.O. Bogomolets Medical Univ. Kyiv, Ukraine.

**Background:** Albuminuria promotes cell death, and is associated with faster progression of chronic kidney disease (CKD). However, the molecular mechanisms regulating cell death in response to albuminuria are not fully understood.

**Methods:** 53 patients aged 10-15 years with active stage of nephrotic syndrome were included in the study. Immunohistochemical study of anti-apoptotic factor Bax, anti-apoptotic factor Bcl-xl, number of apoptotic cells in kidney biopsy specimens were done. Comparison of the level of these parameters between the different segments of nephrin at different stages of glomerulosclerosis has been performed.

**Results:** Measurement of the pro-apoptotic factor Bax in kidney slices obtained from children with morphological form of nephrotic syndrome focal segmental glomerulosclerosis (FGS) showed presence of high level of Bax in both glomerular and tubule-interstitial segments. Higher immunosignal of Bax was evaluated in glomeruli with FGS I-II st. as compared to tubular segment. When FSGS III-IV st. observed higher expression of Bax was detected in surrounding tubule-interstitial segment. Expression of the anti-apoptotic factor Bcl-xL was studied. Higher expression of Bcl-xL was recorded in tubule-interstitial segment as compared to glomeruli when FSGS I-II st. occurs. When FSGS III-IV st. occurred higher immunosignal of Bcl-xL is localized in surrounding tubule-interstitial component. In kidney sections with FSGS III-IV st. higher AI was revealed in glomeruli as compared to tubule-interstitial component. In kidney sections with FSGS III-IV st. higher AI was found in tubule-interstitial compartment.

**Conclusions:** Thus, progression of kidney injuries in nephrotic syndrome is associated with increased activity of pro-apoptotic factor Bax and simultaneous reduction of anti-apoptotic factor Bcl-xL. The level of the expression of Bax and Bcl-xL depends on the stage of FSGS and indicates the step-dependent manner of glomerular and interstitial injuries development upon the chronic influence of albuminuria.

**Funding:** Government Support - Non-U.S.
severe impairment (eGFR<60) more likely to be on ABC. Several CVD risk factors were more prevalent in ABC patients compared to TDF, hypertension (25% v 13%), dyslipidemia (30% v 16%), and diabetes (12% v 5%) (p<0.001 in all) being the most common.

Conclusions: HIV patients often present with prevalent CVD risk and reduction in kidney function. Physicians make treatment choices that reflect concern for kidney function, consistent with labeling. This choice may come with cost, with more CVD risk factors correlated with alternative choices of NRTIs. As some antiviral regimens may be associated with CVD while others with kidney disease, understanding CVD risk profile versus kidney function protection may help optimize care of patients.

Livewire tool provides the best compromise between accuracy and time required.

FR-PO526
Renal Reserve: Development of a Kidney Stress Test Kyle Rodenbach,1 Dana F. Fuhrman,2 Paula S. Maier,2 Catherine D. Shaw,1 George J. Schwartz.1 (1Peds, Univ of Rochester, Rochester, NY; 2Peds, Univ of Pittsburgh, Pittsburgh, PA)

Background: Renal reserve (RR) is the difference in stimulated versus baseline glomerular filtration rate (GFR); it might predict future kidney health. The purpose of this study was to compare a meat versus liquid protein load in a cystatin-C-based (Cys-C) RR test using cinetidine-inhibited creatinine clearance (Cr CI) and iohexol infusion clearance (Io CI) for validation.

Methods: Participants (N=18) were screened for health status, blood pressure, and proteinuria. They followed a low protein diet and took cinetidine (20 mg/kg) for two days prior to the study. Water loading was used to maintain urine flow, and two hours were allowed for a stable steady state calibration. Participants 1-10 received a burger (1 g/kg protein); 11-15 received a ProCel® shake (1 g/kg protein); and 16-18 received a high dose ProCel® shake (1.5 g/kg protein). Data were analyzed for significance of RR. Cystatin-C estimated GFR (Cys-C eGFR) was calculated using the CKD-EPI Cys-C formula (Inker NEJM 2012) following IFC calibration (ERM-DA471).

Results: Participants (N=18) had a mean (SD) age of 22 (2) years and were 39% male and 72% white. Baseline GFR (SD) in mL/min/1.73m2 averaged 103.4 (14.7) for Cr CI; 108.9 (9.0) for Io CI (N=8); and 117.4 (6.1) for Cys-C eGFR. For the burger group (N=10), mean RR (SD) in mL/min/1.73m2 was 17.1 (11.6) for Cr CI (P<0.001); 8.4 (4.3) for Io CI (P<0.001); and 4.7 (2.4) for Cys-C eGFR (P<0.001). For 1.0-1.5 g/kg shakes (N=8), mean RR (SD) in mL/min/1.73m2 was 15.8 (5.0) for Cr CI (P=0.001); 11.7 (9.0) for Io CI (P=0.008), and 2.4 (2.9) for Cys-C eGFR (P=0.05). The burger and shake groups did not differ significantly in RR determined by Cr CI, Io CI, or Cys-C but Cys/C-based RR was significantly less than Io-based RR for both groups. There were no differences in post-load versus pre-load Cr/Io clearance ratios.

Conclusions: Cys-C-based RR following a burger provides a simple stress test of kidney function which was validated by classical renal clearances and can be applied to those who recover from acute kidney injury. Why Cys-C-based RR was smaller than Io RR, the reference standard, is a topic for future investigation.

FR-PO527

Background: Despite the clinical recovery of an acute kidney injury (AKI) episode, progression to chronic kidney disease (CKD) could be observed on long time follow-up. The mechanisms are poorly understood. To analyzed if angiotensin II receptor blockade (ARB) the ischemic insult is effective in abrogating the severity of the AKI episode and/or the progression to CKD.

Methods: Male Wistar rats were divided into 4-groups of rats: sham; sham plus losartan 3-d before surgery; bilateral renal ischemia for 45-min (UTxI); and losartan administration (3-d) before ischemia (Los-Pre). Animals were studied after 1, 3, 5, 15 days or 9-months. At the end of each experimental period, physiological, histopathological, immunohistochemistry, biochemical and molecular studies were performed.

Results: UTxI group developed CKD characterized by renal dysfunction, proteinuria, renal hypertrophy, glomerulosclerosis, tubular atrophy and tubulointerstitial fibrosis. At the ultra-structural glomerular level, foot process effacement was observed, which was associated a reduction in immune-gold staining for nephrin. Renal injury was mediated by increased oxidative stress, inflammation and up-regulation of TGFβ, aSMA, and Collagen I protein levels. TGFβ overexpression was mainly observed in epithelial cells. Interestingly, in spite of ARB did not prevent or reduced AKI severity; it was enough effective to prevent CKD. The renoprotection conferred by ARB was associated with the early recovery of renal blood flow, lesser inflammation and greater nuclear hypoxic inducible factor 1α (HIF1α) staining.

Conclusions: Our data shows that in spite of, losartan pre-treatment did not protect the rats against AKI, it was effective to prevent the transition to CKD. The mechanisms by which losartan prevented CKD were in part due to the early renal blood flow recovery, lesser inflammation and greater HIF1α nuclear translocation within the 15 days post-ischemia.

Specific Endothelial Heparin-Binding EGF-Like Growth Factor Deletion Ameliorates Renal Injury Induced by Chronic Angiotensin II Infusion

Fenhua Zeng, Lance A. Kloepfer, Raymond C. Harris. Medicine, Vanderbilt University, Nashville, TN.

Background: Transactivation of EGFFR by angiotensin II (Ang II) plays important roles in the initiation and progression of chronic kidney diseases (CKD). In vitro studies suggested that HB-EGF may be a critical mediator in this process, whereas its role in vivo has not been reported.

Methods: Age-matched male littermates of HB-EGF+/+/mice with endothelial-SCLCre-ER(T) (+) or (-) were used. Tamoxifen injections produced control (HB-EGF+/+) mice with specific deletion of HB-EGF from endothelium (HB-EGF-/-), which underwent untreated nephropathy and osmotic minipump-mediated infusion with saline or Ang II for 8 weeks. Systolic blood pressures (SBP) were measured by tail-cuff. Renal injury was evaluated by albuminuria using urinary albumin/creatinine ratios and by morphology with periodic acid-Schiff (PAS) staining. Renal EGF activation was determined by immunoblotting and immunostaining. Endothelium/podocyte injury, inflammation and renal fibrosis were evaluated by immunostaining.

Results: Compared to control, kidneys from HB-EGF-/- mice with Ang II-infusion had significantly reduced EGF activation. Endothelial HB-EGF deletion did not significantly prevent the hypertension induced by Ang II infusion, albeit lower SBP was detected in HB-EGF-/- mice compared to HB-EGF+/+ mice. However, it decreased Ang II-infusion related renal injury, as demonstrated by 1) less albuminuria; 2) less glomerulosclerosis with glomerular score of 0.793 versus 1.652 in the control; 3) preserved endothelial integrity and decreased podocyte injury shown by more preserved tufts area and WT1 positive cells, and less apoptotic cells measured by cleaved caspase 3 and TUNEL staining; 4) reduced inflammation in perivascular area and interstitium measured by F4/80 and CD3 immunostaining; and 3), reduced renal fibrosis, as shown by α-SMA immunostaining.

Conclusions: Shedding of HB-EGF from endothelium plays an important role in Ang II induced renal injury by linking Ang II-AT1R with EGFFR transactivation. Inhibition of HB-EGF shedding could be a potential therapeutic strategy for CKD.

FR-PO529 Effects of Acute Kidney Injury (AKI) Severity and Co-Morbidities on Chronic Kidney Disease (CKD) Progression

Gregory John Wilson,1 Adrian Lawrence Kark,2,3 Andrew John Mallett,2,3,4 Anne Salisbury,2,4 Zaimin Wang,2,3 Helen G. Healy,2 Wendy E. Hoy,2,41 Kidney Health Service, Royal Brisbane and Women’s Hospital, Australia; 2CKD QLD and NHMC CKD CRE, The Univ of Queensland, Australia; 3Inst for Molecular Bioscience and School of Medicine, UQ, Australia; 4Centre for Chronic Disease, UQ, Australia.

Background: AKI is a common and important cause of CKD. It remains unknown how AKI severity influences CKD progression. Which co-morbidities influence the progression of CKD also remains undetermined.

Methods: We aimed to explore whether AKI severity and patient comorbidities influence CKD progression. Patients with CKD associated with a clinical diagnosis of AKI were identified in the Royal Brisbane & Women’s Hospital cohort (n=1150) of the CKD.QLD registry. AKI events were confirmed through historical creatinine values (2005 onward), and severity determined using AKIN criteria. CKD progression was assessed by change in glomerular filtration rate per year (DeGFyr/yr) based on initial and final eGFR(CKD-EPI) values. All co-morbidities identified at the time of enrolment into the registry were explored.

Results: 384 patients were recorded as having a primary or secondary AKI diagnosis. 157 patients (40.8%) of these patients were biologically confirmed. 133 patients (84.7%) were identified as Stage 1 AKI, 16 (10.2%) as Stage 2 and 8 (5.1%) as Stage 3. A one-way ANOVA revealed that AKI severity did not modulate CKD progression. However, numerically DeGFyr/yr was larger for Stage 3 patients (5.1±m/1.72m2), and smallest for Stage 1 patients (1.6±m/1.72m2). The only two co-morbidities found to influence CKD progression were diabetes mellitus (DM; 35.6% of patients) and peripheral vascular disease (PVD; 12.1% of patients). CKD progression was significantly increased in patients with DM compared with patients without (DeGFyr/yr 3.7±m/1.72m2, p<0.001), and patients with PVD compared with those without (DeGFyr/yr 4.4±m/1.72m2, p<0.05).

Conclusions: Surprisingly, AKI severity did not alter CKD progression. Both DM and PVD influenced CKD progression in patients with AKI suggesting an increased vulnerability to AKI in these patients.

FR-PO530 Association Between Gut Microbiome and Cardiovascular Risk in Chronic Kidney Disease Patients with Type 2 Diabetes Mellitus

Ruchi Singh, Tetyana L. Vasylyeva. Pediatrics, Texas Tech Health Sciences Center, Amarillo, TX.

Background: Diabetes is one of the leading causes of CKD. It is well established that patients with T2DM often experience persistent low-grade inflammation leading to microvascular deterioration and progression of vascular complications along with impaired glomerular function, which impacts their microphones. The aim of this study was the assessment of gut microbiota, plasma zonulin, and inflammatory cytokines (TNF-α, IL-6) in conjunction with FGF-23, ET and levels of LPS in CKD (stage 4 and 5) patients with Diabetic Nephropathy (DN).

Methods: Healthy controls were matched by age and gender. Their dietary habits have been preserved. Total of 40 participants participated. IL-6, FGF-23, LPS, ET-1 and zonulin, levels were measured by ELISA and quantitative analysis of gut microbiota composition (454 pyro sequencing).

Results: Higher circulation serum zonulin, TNF-α, and IL-6, FGF 23 LPS, ET-1 levels were observed in the CKD (stage >3) patients with AKI. Patients with advanced AKI was substantially different from healthy population with increased percentage of LPS producing bacteria. Significant diversity was observed in gut microbiota in study subjects compared to control group. CKD patients had high serum concentration of TNF-α and marker of leaky gut. Zonulin concentration was found positively correlated with LPS, inflammatory markers and FGF-23.

Conclusions: Gut microbiota is a modifiable factor and zonulin could be a potential future target to control chronic inflammatory responses. Gut microbiota and increased gut permeability in patients with advanced CKD secondary to DN results in high level of lipopolysaccharide LPS that mediates chronic inflammation which was implicated in deterioration of cardiovascular health.

FR-PO531 Metabolomics of Chronic Kidney Disease in Cohort of Patients Given Probiotics

Subodh J. Saggi,1 Eli A. Friedman,2 Natarajan Ranganathan,2 Kelly Mercier,2 Susan Meritche,3 Susan Summer.1 1Nephrology/Medicine, SUNY Downstate Medical Center, New York, NY; 2Metabolomics, Research Triangle Inst, Research Triangle Park, NC; 3Kibow Biotechnology Inc., Kibow Biotechnology Inc., Newtown Square, PA.

Background: Persistent reduction in Glomerular Filtration Rate (GFR) below 60 ml/ min/1.73 m2 over 3 months are hall marks of Chronic Kidney Disease (CKD). Urea is so stable that it major uremic toxin and is clinically despite the description of middle molecules as being toxic. Persistent elevation of BUN may accompany reductions in GFR in some patients. We were specifically interested in obtaining pilot data identifying metabolites that differentiated patients with CKD whose BUN decreased after 4 months of probiotics treatment from its possible mechanism.

Methods: Broad spectrum 1H-NMR metabolomics was used to analyze baseline and 6 month plasma samples frozen from a phenotypically characterized cohort of patients with CKD Stage 3 and below from a prior Probiotic Renady study. NMR spectral data of baseline and 6 month plasma samples were analyzed after identical treatment of all samples. A total of 24 baseline samples were differentiated by a change in their BUN. Principal components analysis and orthogonal partial least squares discriminant analysis was used to analyze the data and determine the metabolites that best differentiated the phenotypic groups.

Results: Characteristics of the cohort population were age 57 ± 14 yrs, mean BMI 31.3 ± 6.1 kg/m2, 10 males and 14 females, 20 with HTN, 8 with DM, 11 Caucasian and 9 AA, 3 other, 1 unknown. 16 patients who had a decrease in BUN after 4 months of probiotics treatment could be differentiated based on baseline samples from those whose BUN increased or did not change. The majority of the metabolites that differentiated the groups were microbiome related metabolites.

Conclusions: Metabolomics analysis revealed a signature of metabolites that were associated with a decrease in BUN, and holds promise for use in predicting individuals with CKD that would most benefit from use of probiotics. The majority of the metabolites important to the differentiation of groups map to pathways involved in microbial metabolism.

FR-PO532 Potential Uremic Toxin Precursors in the Gut Identified by Metabolomics and Proteomics

Liwen Zhang,1 Hongli Jiang.2 1School of Medicine, Xi’an Jiaotong Univ, Xi’an, Shaanxi, China; 2Hemodialysis Center, First Affiliated Hospital of Medicine School, Xi’an Jiaotong Univ, Xi’an, Shaanxi, China.

Background: Many factors, e.g., the intestinal bacterial disorder, result in the species and amounts of harmful substances in the gut increasing, which leads to the increase of uremic retention molecules (URMs) in blood. These URMs may be classified according to their site of origin, that is, endogenous metabolism, microbial metabolism, or exogenous intake. The latter two are known as gut-derived uremic toxins, i.e., gut is a significant origin of middle molecules as being toxic. Persistent elevation of BUN may accompany reductions in GFR in some patients. We were specifically interested in obtaining pilot data identifying metabolites that differentiated patients with CKD whose BUN decreased after 4 months of probiotics treatment from its possible mechanism.

Methods: Excluding special factors which affected the intestinal environment, the subjects were divided into two groups: hemodialysis patients with end-stage renal disease (HD group, n = 20) and healthy controls (CT group, n = 20). Fecal metabolomics based on the ultra-performance liquid chromatography-tandem mass spectrometry was undertaken to identify the low molecular weight metabolites, and fecal proteomics based on the two-dimensional gel electrophoresis was employed to investigate the high molecular weight proteins. The data was analyzed with statistic and bioinformatic methods.

Results: Thirty-three metabolites and 31 proteins were identified. Among them, 17 metabolites and 13 proteins were significantly higher in HD group than those in CT group, including phenols, which are well-known uremic toxins originating from the gut; reactive carbonyl compounds (RCC), which are well-known URMs in serum but first identified in the gut; other harmful metabolites (e.g., fenthalin, haloalcohol-methyl- and diethylpropion), which are known as immunomodulation-associated proteins. However, the levels of 16 metabolites and 18 proteins were lower in HD group compared to CT group, including ajene, which has been shown to exhibit anti-microbial and anti-cancer functions, and three proteins, which have indicated anti-inflammatory and anti-cancer activities.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Conclusions: This study not only demonstrated that RCC-URMs originated from the gut, but also confirmed that intestinal uricogenic uremic toxin precursors and deficient beneficiaries in the gut of uremic patients. Funding: Government Support - Non-U.S.

AST-120 Affects the Level of Circulating TNF-Alpha Receptors That Predict Both Renal and Cardiovascular Outcomes in Patients with Advanced Renal Dysfunction

Dong Ki Kim, Yon Su Kim, Rodolfo Rosseto Rampaso, Kleiton Augusto Santos Silva, Luciana Maruyama. 1  Dong Ki Kim, 2 Yon Su Kim. 2

Background: Tumor necrosis factor alpha and its two receptors have a critical role in kidney diseases. We aimed to establish the role of circulating TNF-alpha receptors (cTNFRs) as a new biomarker of renal disease and to identify the impact of AST-120 on the level.

Methods: 579 patients from 11 medical centers in Korea were prospectively recruited and followed up for 36 months after randomization into AST-120 and control arms. A total of 6 gram of AST-120 was given to participants in AST-120 arm as well as conventional treatment. cTNFRs were measured by ELISA method at the time of randomization and 1 year after. The renal outcome was composite of serum creatinine (sCr) doubling, 50% reduction of estimated glomerular filtration rate (eGFR), or initiation of renal replacement therapy. Major adverse cardiovascular events (MACE) were also evaluated.

Results: A total of 465 patients were analyzed. Mean sCr and eGFR level was 2.8 ± 0.7 mg/dL and 26.59 ± 7.263 ml/min/1.73m2, respectively. The levels of cTNFRs throughout the study period were not different between two treatment arms. But the higher AST-120 compliance patients had, the lower cTNFRs they showed in the AST-120 arm. The highest tertile of cTNFRs showed the highest cumulative rate of composite renal outcomes followed by the intermediate tertile of cTNFRs after the adjustment for traditional risk factors. More change of cTNFRs was also independently associated to the more occurrence of composite renal outcomes. MACEs occurred more frequently in patients with higher baseline cTNFRs and more change of cTNFRs (log-rank P = 0.01, 0.002 and 0.021 for cTNFR1, cTNFR2, and change of cTNFR2, respectively) and the significance of cTNFR2 remained after adjustment for diabetes, CKD stage, and proteinuria.

Conclusions: Baseline and change of cTNFRs did not improve the predictability of composite renal outcomes in comparison with classic biomarkers. But cTNFRs predicted both renal and cardiovascular outcomes in patients with advanced renal dysfunction. And AST-120 was effective to lessen the increase of cTNFRs.

FR-PO534

Swimming Exercise Training (EXE) Normalize Blood Urea Nitrogen (BUN), Decrease Glomerulosclerosis, and Attenuates the Loss of Myokine IL6 in 5/6 Nephrectomy

Rafael Luiz, Rodolfo Rosseto Rampaso, Kleiton Augusto Santos Silva, Luciana Jorde, Edson Andrade Pessoa, Maria A. Gloria, Mario Luiz Ribeiro Cesaretti, Nestor Schor. Nephrology, Federal Univ of São Paulo, São Paulo, Brazil.

Background: This study will be evaluated the EXE effects on renal function, glomerulosclerosis and myokine IL6 has been associated with stimulation of hypertrophic muscle growth and myogenesis through regulation of the proliferative capacity of muscle stem cells.

Methods: Adult Wistar rats were divided in groups (n=8): Control (CS), Control+EXE (CE), Sedentary 5/6N (NS) and 5/6N+EXE (NE). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures. EXE periods were 60min/day/5 days a week during 8 weeks. It was evaluated arterial pressure (AP), maximal exercise test (MExt), creatinine clearance (CrCl), BUN, proteinuria (uProt), glomerulosclerosis, myokine IL6 (by Lumexin) as well mortality rate.

Results: EXE did not modify the increment in MAP but prevent, at least in part, a lower decline in the MEtient caused by 5/6N (291±1 vs 1612±12 µm Hg, p<0.05). One higher CrCl in NE was observed compared with NS (2.27±1.3 vs 0.96±0.20 ml/min, respectively) (p>0.05). BUN was normalized in NE (43.62±7.30 mg/dL). Proteinuria was not significantly different in NE vs NS group (36.87±3.53 vs 40.13±2.55 mg/24h). Glomerulosclerosis was 48% higher in NS vs NE. Myokine IL6 (pg/ml) was decreased in NS (286±0.40) and attenuated the loss in NE (384±0.00±20.82). A higher mortality rate was observed in NS (70%) vs NE group (39%, p<0.05).

Conclusions: Results suggested that the EXE minimize the impact of 5/6Nx by decreasing glomerulosclerosis and reducing the impact on CrCl (42%). Finally, attenuating myokine IL6 in NE, the decreasing mortality rate in NE vs NS and by minimizing the impact of 5/6Nx on CrCl indicate that EXE in this protocol, induced protection on renal function. Thus, it is reasonable to suggest that EXE could be an additional strategy to be employed in CKD.

FR-PO535

Does Autophagosome-Proteolysis Contribute to CKD-Induced Muscle Atrophy?

Zhen Su,1 Haidong Wang,1 Janet D. Klein,1 William E. Mitch,2 Xiaohan H. Wang,1 1Dept of Nephrology, The First Affiliated Hospital of Wenzhou Medical Univ, Wenzhou, Zhejiang, China; 2Nephrology, Baylor College of Medicine, Houston, TX; 1Renal Medicine, Emory Univ, Atlanta, GA.

Background: CKD-induced muscle wasting results from activation of the ubiquitin proteosome system (UPS). Since FoxO stimulates the UPS but also activates autophagosomes, we hypothesized that autophagosome-induced proteolysis may contribute to CKD-induced muscle wasting.

Methods: CKD model in mice: subtotal nephrectomy for one month. Muscle overloading model: removal of gastrocnemius and soleus to overload the plantaris muscle (unimicromyosin resistance exercise) in normal and CKD mice. Acupuncture with low frequency electric stimulation (Acu/LFES) was applied 15 minutes daily for 2 weeks (Hu, JASN, 26:626 2015). Electrical stimulation used a consistent pulse, electric frequency 20Hz, current 1mA.

Results: Both exercise and Acu/LFES reduced CKD muscle loss. In muscles of CKD mice, mRNAs related to autophagy-lysosomal function, Bnip3, Atg12, Atg8, LC3II and Beclin-1 were upregulated and Bnip3, Beclin-1 and LC3II proteins were increased. Acu/LFES treatment reversed these changes. Exercise in control mice also increased autophagy-lysosomal related protein LC3II-Beclin-1, P62 and Vps34. The levels of these mediators were not additive to changes observed in mice with CKD. We cultured C2C12 myotubes in uremic serum and found increased autophagy markers, indicating activation of autophagosomes. Acidification alone did not stimulate autophagy markers. Based on these results, the UPS, but not autophagosomes, is responsible for degradation of structural proteins (myosin and actin).

Conclusions: 1) autophagosome-mediated proteolysis occurs in CKD-induced muscle atrophy. In mice with CKD, the UPS was principally involved in muscle proteolysis; the role of autophagosomes was convoluted. 2) Prevention of muscle atrophy by exercise is not due to inhibition of the autophagy-lysosomal proteolysis pathway in CKD. 3) Muscle atrophy cannot be equated with increased autophagy markers. 4) Acu/LFES and exercise promote different autophagy consequences.

FR-PO536

Indoxyl Sulfate, a Uremic Toxin, Accelerates Skeletal Muscle Atrophy in CKD Condition

Yuki Enoki,1 Hiroshi Watanabe,2 Masafumi Fukagawa, Toru Maruyama. 1 Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto-shi, Japan; 2 Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara-shi, Japan.

Background: Skeletal muscle atrophy is often observed in chronic kidney disease (CKD) patients, especially in patients undergoing hemodialysis. Uremic toxins have been known to link to CKD complications. However there has been no report on the relationship between uremic toxins and skeletal muscle atrophy. The purpose of this study is to investigate the involvement of uremic toxins on skeletal muscle atrophy observed in CKD condition.

Methods: In vitro cytotoxicity of uremic toxins on cell proliferation and differentiation was evaluated by using a mouse myoblast cell line (C2C12). The effect of uremic toxin on proteolysis and protein synthesis system in C2C12 was also evaluated. In the animal study, we examined the contribution of uremic toxin on muscle atrophy using uremic toxin overloaded half- or 5/6-nephrectomized mice.

Results: We focused on six protein bound solutes including indoxyl sulfate (IS), indole acetic acid, p-cresyl sulfate, hippuric acid, kynurenic acid and 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid. Among these uremic toxins, IS significantly increased atrophy-related genes expression but it did not affect differentiation-related genes expression. In the animal experiments, IS-overload reduced body weights and skeletal muscle weights of half- or 5/6-nephrectomized mice, and consequently weakened its muscular endurance. IS-overload mice showed increased skeletal muscle atrophy-related genes expression. In the same experimental condition, IS also induced the expression of inflammatory cytokine and transforming growth factor-β in skeletal muscle cells.

Conclusions: IS is the potent uremic toxin inducing skeletal muscle atrophy associated with CKD by increasing muscle atrophy-related genes.

FR-PO537

Myostatin Stimulates Progenitor Cells to Differentiate into Fibrocytes Leading to Muscle Fibrosis in Chronic Kidney Disease

Liping Zhang,1 Jiangling Dong,2 William E. Mitch. 1 Medicine/Nephrology, Baylor College of Medicine, Houston, TX; 2Life Science and Engineering College, Northeast Univ for Nationalities, Lanzhou, Gansu, China;

Background: In chronic kidney disease (CKD), fibrosis develops in damaged kidneys leading to muscle atrophy. Fibrosis in muscle also complicates CKD but little is known about cells developing into fibrocytes and mechanisms causing fibrosis are not defined. The potential precursors of muscle fibrosis are mesenchymal progenitor cells (fibrotic and adipogenic progenitors (FAPs)) while mechanisms causing fibrosis include myostatin as
CKD raises its expression and muscle injury can stimulate injured muscles to develop fibrocytes. Our hypothesis is that CKD stimulates myostatin expression causing FAPs to differentiate into fibrocytes.

Methods: 1) we isolated and cultured FAPs, adding recombinant myostatin to determine if it causes FAPs to proliferate and differentiate into fibrocytes. 2) We isolated GFP-labelled FAPs from transgenic, GFP expressing fibrocytes identified as expressing the fibrosis marker, α-SMA. FAP proliferation and muscle fibrosis were prevented in CKD mice injected with the anti-myostatin peptibody. Finally, Smad3 knock-down expressing the fibrosis marker, α-SMA. FAP proliferation and muscle fibrosis were prevented to determine if myostatin stimulates muscle fibrosis. 4) Interactions between myostatin signalling and FAP conversion to fibrocytes were tested by knocking down Smad3 with a lentivirus expressing Smad3 SINRa.

Results: In cultured FAPs, myostatin stimulated their proliferation and conversion into fibrocytes and there is proliferation of FAPs in injured muscles of CKD mice. GFP-labelled FAPs were injected into TA muscles of CKD mice differentiated into fibrocytes identified as expressing the fibrosis marker, α-SMA. FAP proliferation and muscle fibrosis were prevented in CKD mice injected with the anti-myostatin peptibody. Finally, Smad3 knock-down blocked FAP differentiation into fibrocytes indicating that a myostatin to Smad3 pathway is essential for the conversion of FAPs to fibrocytes.

Conclusions: CKD stimulates myostatin production to activate FAPs which differentiate into fibrocytes. The process is blocked by an anti-myostatin peptibody, providing a new target for preventing muscle fibrosis as a complication of CKD.

Effect of Methoxy Polyethylene Glycol – Epoetin Beta on Plasma Levels of IL-1p, TNF-RI, sFAS, sFAS-L, MMP-9 in Patients with CKD

Piotr Bartnicki, Ewa Majewska, Zbigniew Baj, Jacek Rysz, Ryohei Kawasaki, Yoshihito Tashiro, Michinori Hirata, Koichi Kusano, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco. Nephrology-IRRIV.

Background: Even though anemia in CKD results mainly from the lack of erythropoietin, accelerated erythrocyte death(eryptosis) seems to be a contributor factor. Eryptosis is characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine(PS) exposure at the erythrocyte (RBC) surface. Eryptosis may be triggered by some uremic toxins. P-cresol is an uremic toxin which has negative cardiovascular and cytopathic effects. This study explored if eryptosis is triggered by p-cresol and if different stages of CKD may influence erythrocyte death.

Methods: RBCs from healthy subjects were incubated in vitro at a hematocrit of 0.4% with different concentrations of p-cresol (0.2-5.5-10-20-40ng/ml) and with plasma from CKD patients (5 for each stage) for 24hours. PS exposure was estimated from AnnexinV binding in flow cytometer.

Results: Increasing concentrations of p-cresol modified significantly the percentage of PS exposure on RBC surface, thus suggesting that increasing concentrations of p-cresol may stimulate eryptosis in vitro. Moreover, there was no significant difference in terms of median values of eryptosis between CKD stages, but a positive trend was evident: eryptosis increase with CKD progression.

Conclusions: In addition to its known cardiovascular and cellular effects, p-cresol seems to stimulate eryptosis in vitro and increasing concentrations of this uremic toxin may be responsible for higher levels of eryptosis in vivo. Our data show that CKD plasma contains components able to trigger eryptosis and different stages of CKD may be responsible for different levels of RBC death, thus suggesting that progression of CKD may increase eryptosis in vivo. These results suggest a role of uremic toxicity in the genesis of eryptosis and renal anemia. It is necessary to increase the sample size to validate our hypothesis.

Palmitate Exacerbates Renal Anemia: Suppression of Renal Erythropoietin Production via Endoplasmic Reticulum Stress

Reiko Imagi, Thitinun Anusornvongchai, Yu Ishimoto, Akira Okada, Norio Suzuki, Masayuki Yamamoto, Masaomi Nangaku. Nephrology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; 2Divs of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; 3Tokyo Univ School of Medicine, Sendai, Japan.

Background: Derangement of erythropoietin (EPO) production in renal EPO-producing (REP) cells causes renal anemia. Palmitate induces endoplasmic reticulum (ER) stress which contributes to glomerular and tubular cell damages. Thus, we evaluated the effect of palmitate-ER stress axis on EPO production in REP cells.

Methods: C57BL/6J or the mice, in which the renal EPO gene was replaced with GFP or REP cells were lineage labeled with tdTomato, were daily injected with palmitate

Conclusions: In addition to its known cardiovascular and cellular effects, p-cresol seems to stimulate eryptosis in vitro and increasing concentrations of this uremic toxin may be responsible for higher levels of eryptosis in vivo. Our data show that CKD plasma contains components able to trigger eryptosis and different stages of CKD may be responsible for different levels of RBC death, thus suggesting that progression of CKD may increase eryptosis in vivo. Palmitate Exacerbates Renal Anemia: Suppression of Renal Erythropoietin Production via Endoplasmic Reticulum Stress

Reiko Imaji,1 Thitinun Anusomvongchai,2 Yu Ishimoto,2 Akira Okada,2 Norio Suzuki,2 Masayuki Yamamoto,2 Masaomi Nangaku.2

1Divs of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; 2Divs of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; 3Tokyo Univ School of Medicine, Sendai, Japan.

Background: Derangement of erythropoietin (EPO) production in renal EPO-producing (REP) cells causes renal anemia. Palmitate induces endoplasmic reticulum (ER) stress which contributes to glomerular and tubular cell damages. Thus, we evaluated the effect of palmitate-ER stress axis on EPO production in REP cells.

Methods: C57BL/6J or the mice, in which the renal EPO gene was replaced with GFP or REP cells were lineage labeled with tdTomato, were daily injected with palmitate
Hypoxia (HIF activation with CoCl2). It was associated with activation of ER stress signal in CKD patients, fibrosis marker α-SMA was downregulated.

Conclusions: EPO production by REPS was suppressed by palmitate, especially under hypoxic condition, via the ER stress pathway (ATF4 activation). The link between dyslipidemia (palmitate) and ER stress may contribute to development and progression of renal anemia, and subsequent CKD and highlight the impact of palmitate on CKD progression.

The Function of Integrinβ4 in Epithelial-to-Mesenchymal Transition of HK2 Cells Qi Wang, Yan Wang, Xiaoyan Huang, Zibo Xiong, Zuying Xiong, Jiangling Dong, Liping Li

Background: To explore the function of integrinβ4 in epithelial-to-mesenchymal transition (EMT) of HK2 cells, and further study the role of integrinβ4 in renal fibrosis.

Methods: (1) Cultured HK2 cells were divided into 4 groups: 0ng/ml TGFβ1 treated group (negative control), 1ng/ml TGFβ1 group ,3ng/ml TGFβ1 group and 5ng/ml TGFβ1 group (positive control). Integrinβ4 shRNA mediated repression of integrinβ4 in HK2 cells and divided into 4 groups: control-shRNA HK2 cells without TGFβ1; control-shRNA HK2 cells with 5ng/ml TGFβ1; β4-shRNA HK2 cells without TGFβ1; β4-shRNA HK2 cells with 5ng/ml TGFβ1.β4-shRNA HK2 cells with 5ng/ml TGFβ1 (3) The vivo experiment was performed in IA nephropathy kidneys tissues obtained from 45 patients that underwent a biopsy procedure during 2013-2014. According to the degree of tubulointerstitial lesion, kidney specimens were divided into 3 groups: mild lesion, moderate lesion, and severe lesion. We handle normal kidney portions as controls. The expressions of integrinβ4, E-cad, CTGF and α-SMA were assessed by qRT-PCR and western blot. Immunofluorescence was used in different degrees of tubulointerstitial lesions.

Results: (1) Compared with negative control, integrinβ4 and E-cad were significantly lower, however, CTGF and α-SMA were increased (2) Integrinβ4 and E-cad in β4-shRNA HK2 cells group were lower than control-shRNA HK2 cells, in contrast, CTGF and α-SMA were increased; integrinβ4 and E-cad with TGFβ1 treatment were significantly lower than without TGFβ1 groups, CTGF and α-SMA expressions were increased. (3) Compared with mild lesion group, E-cad staining in moderate lesion group and severe lesion group reduced, α-SMA staining and integrinβ4 staining increased. After being further analyzed, the most of integrinβ4 staining located in neointimal renal tubules.

Conclusions: Integrinβ4 expression is decreased in the process of EMT, and reduced integrinβ4 can exacerbate HK2 cells from epithelial cells transition to mesenchymal cells, therefore loss of integrinβ4 may be the marker of TIF. However, the results of vivo experiment appeared to be contradictory, the reason of this phenomenon may be that many neointimal renal tubules possess the ability of proliferation.

FR-PO543

Background: Insulin resistance in chronic kidney disease (CKD) begins early in the disease, compromising anabolic responses to insulin/IGF-1 signaling. We have previously demonstrated that a novel protein, signal regulator protein alpha (SIRPa) is involved in insulin signaling, exacerbating skeletal muscle metabolism. We now describe for the first time elevated levels of SIRPa in CKD cardiac muscle which not only adversely influences insulin signaling, but may exacerbate muscle fibrosis.

Methods: CKD was created via subtotal nephrectomy and mice with CKD greater than 2 months hearts were harvested and left ventricle muscle samples were examined for SIRPa, IR1-α, SIRPa, GAPDH. Additionally, C2C12 myoblasts were treated to overexpress SIRPa vs. GFP plasmid. Also, myoblasts were transfected with silencing RNA (SIRNA) SIRPa or scrambled SIRNA (control). Western blots analysis was performed based on skeletal muscle cell lysates.

Results: After ~2 months of CKD, the mice experience left ventricle hypertrophy in contrast with controls. SIRPa was significantly increased in cardiac muscles of mice with CKD, with reduction in tyrosine phosphorylation of IR-1. This finding was previously reported in skeletal muscles of mice with CKD. Additionally, high pressure a-SMA was increased in cardiac muscles of mice with CKD vs. control mice. In order to determine a cause and effect relationship, SIRPa was overexpressed utilizing a SIRPa plasmid vs. GFP plasmid for control. In myoblasts in which SIRPa was overexpressed, fibrosis marker a-SMA was increased. Finally, when we silenced SIRPa in muscle cells treated with a cytokine mixture, containing cytokines present in CKD patients, fibrosis marker a-SMA was downregulated.

Conclusions: These results imply that SIRPa increases fibrosis, and suggesting that SIRPa may exacerbate muscle fibrosis via a new pathway in chronic kidney disease. Ultimately blocking SIRPa in heart muscle may improve cardiac fibrosis associated with chronic kidney disease.

Retinal Microvascular Abnormalities and Incidence and Progression of Chronic Kidney Disease Charumathi Sabanayagam,1,2 Peng Guan Ong,1 Boon Wee Teo,1 Carol Y. Cheung,2 Ching-Yu Chu,2 Ecosse L. Lamoureux,1,2 Tien Yin Wong,1,2 Singapore Eye Research Inst, Singapore; ‘Office of Clinical Sciences, Duke-NUS Graduate Medical School, Singapore; ‘National Univ of Singapore, Singapore.

Background: To examine the longitudinal association of a panel of retinal vascular parameters, markers of microvascular damage, with the incidence and progression of chronic kidney disease (CKD) in middle-aged Asian adults.

Methods: The population consisted of a cohort of Malay adults aged 40-80 years examined from 2004-06 and again from 2010-2012 (n=1464; 1306 free of CKD and 158 with pre-existing CKD). The outcomes were incidence (estimated glomerular filtration rate [eGFR]=60 nL/min/1.73m2<25% decrease in eGFR) and progression of CKD (drop in eGFR category [<60, 30-59, 15-30, <15]<25% decrease in eGFR or an annualized eGFR rate<3/mL/min/1.73m2/year).

Results: Over a median follow-up of 6.6 years, 6.4% (70% had diabetes) developed incident CKD and 26.6% (62% had diabetes) developed progressive CKD. In multivariable models, retinal arteriolar narrowing, retinal venular widening, and presence of retinopathy were each independently associated with CKD. The HR (95% CI) of incident CKD was 1.31 (1.01-1.72) per SD decrease in arteriolar caliber, 2.20 (1.10-4.41) for tertile 3 vs. tertile 1 of venular caliber; 2.06 (1.24-3.44) for retinopathy. Increased arteriolar tortuosity alone was associated with progressive CKD (1.57 [1.02-2.37] per SD decrease. All associations were consistently present among those with diabetes.

Conclusions: Retinal vascular abnormalities increased the risk of CKD by more than two times in Asian adults. Our findings provide evidence that retinal imaging may be a useful tool to improve risk stratification for CKD.

Relationship Between Serum Bilirubin and Hyalinization of Renal Arterioles Tetsushi Miyagi,1 Kentaro Kohagura,2 Yusuke Ohya,1 Kunioshi Iseki,1 ‘Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyu, Nishihara-cho, Okinawa, Japan; 2Dialysis Unit, Univ of the Ryukyu, Nishihara-cho, Okinawa, Japan.

Background: It has been suggested that there is a relationship between serum bilirubin and renal arteriolar hyalinization. In the present study, we examined the relationship between serum bilirubin levels and the hyalinization of renal arterioles in patients with chronic kidney disease (CKD).

Methods: We reviewed the clinical records of 138 patients with CKD (mean age: 44 years) who underwent renal biopsy at our department during a 3-year period starting in 2010. Patients who were receiving calcineurin inhibitors were excluded. The subjects were divided into three groups based on their total serum bilirubin levels: tertile group 1 (0.2-0.4 mg/dl; 40 patients), tertile group 2 (0.5-0.7 mg/dl; 61 patients), and tertile group 3 (0.8-1.4 mg/dl; 37 patients). Using the pathological specimens obtained from renal biopsies, the hyalinization of renal arterioles was semiquantitatively evaluated, and the mean score of renal arteriolar hyalinization grade was used for analysis.

Results: Tertile group 1 had markedly higher urinary protein levels and markedly lower serum hemoglobin (Hb) levels than tertile group 3. We defined total serum bilirubin levels under 0.5 mg/dl (tertile group 1) as low levels and divided them into two groups of values under and above 0.5 mg/dl. These were set as explanatory factors, and a multiple regression analysis was performed, with the degree of hyalinization of renal arterioles independent of classical risk factors of cardiovascular disease. In the present study, we examined the relationship between serum bilirubin levels and the hyalinization of renal arterioles in patients with chronic kidney disease (CKD).

Methods: We reviewed the clinical records of 138 patients with CKD (mean age: 44 years) who underwent renal biopsy at our department during a 3-year period starting in 2010. Patients who were receiving calcineurin inhibitors were excluded. The subjects were divided into three groups based on their total serum bilirubin levels: tertile group 1 (0.2-0.4 mg/dl; 40 patients), tertile group 2 (0.5-0.7 mg/dl; 61 patients), and tertile group 3 (0.8-1.4 mg/dl; 37 patients). Using the pathological specimens obtained from renal biopsies, the hyalinization of renal arterioles was semiquantitatively evaluated, and the mean score of renal arteriolar hyalinization grade was used for analysis.

Results: Tertile group 1 had markedly higher urinary protein levels and markedly lower serum hemoglobin (Hb) levels than tertile group 3. We defined total serum bilirubin levels under 0.5 mg/dl (tertile group 1) as low levels and divided them into two groups of values under and above 0.5 mg/dl. These were set as explanatory factors, and a multiple regression analysis was performed, with the degree of hyalinization of renal arterioles on the objective variable. A low serum bilirubin level was a significant risk factor for the hyalinization of renal arterioles (R² = 0.45, β = 0.26, p = 0.003), even when adjustments were made for age, sex, HbAc1 levels, mean blood pressure, history of smoking, and LDL cholesterol levels. Furthermore, even when the explanatory factor of serum Hb level was added, the results of the analysis remained the same.

Conclusions: Low serum bilirubin levels may be a risk factor for the hyalinization of renal arterioles independent of classical risk factors of cardiovascular disease.

Autonomic Nervous Dysfunction in Predialytic Chronic Kidney Disease: 3 Years Observational Follow-Up Study

Sha Min Park, Sang Heon Song, Eun Young Seong, Ihm Soo Kwak, Harin Rhee, Il Young Kim, Woo Jin Jung, Jong Man Park, Dong Won Lee, Soo Bong Lee, Min Jung Kim, Joo Hui Kim. Internal Medicine, Pusan National Univ School of Medicine, Busan, Republic of Korea.

Background: Generally, sympathetic overactivity and impairment of the parasympathetic system are often seen in patients with dialytic CKD, COPD, RA as well as elderly. Also, arterial stiffness and edema have been related with mortality in patients with cardiovascular disease. However, to date, few data regarding autonomic nervous system, vascular stiffness, edema in pre-dialytic CKD was proposed. This study was designed to explore the interrelationship of those parameter in pre-dialytic CKD (G3, 4) and uncover the risk factor related with renal functional deterioration.

Methods: Thirty-three patients were enrolled. Hydration status (extracellular water [ECW]/total body water [TBW]) was determined by bioimpedance analysis. Brachial-ankle pulse wave velocity (baPWV) and neck ultrasoundgraphy for carotid plaque and intima-media thickness were conducted for checking up of vascular status. CAN was scored using Ewing’s method and we also expressed the standard deviation of normal-to-normal interval (SDNN), low frequency/high frequency ratio (LF/HF ratio). Serum creatinine change over a median follow-up of 3 years was used for assessment of renal function.

Results: Of the 33 patients, 14 (42%) have suffered with CAN. Patients with CAN have higher progressive declining rate of renal function, baPWV, systolic BP compared with patients without CAN. The group having declining renal function has higher CAN score, baPWV and lower SDNN compared with preserved renal function group. CAN score correlated positively with ECW/TBW (r=0.405, p<0.019), mean PWV (r=0.623, p<0.001) and SBP (r=0.515, p=0.002). CAN score correlated negatively with declining rate of renal function (r=-0.471, p=0.006), Htr-1(-0.659, p<0.001) and albumin(r=-0.484, p=0.004).

Conclusions: Autonomic nervous dysfunction including lower SDNN and increased arterial stiffness was associated with an increased risk of CAN. baPWV may be important risk factors for deterioration of renal function in pre-dialytic CKD patients. Autonomic nervous dysfunction was related with arterial stiffness and edema.

Inhibition of EGFR Alleviates the Development and Progression of Hyperuricemic Nephropathy in Rats

Li Wang, 1 Andong Qiu, 2 Vladimir Belostotsky, 4 Marta Caroline Kobrzynski, 1 Shih Ji Liu, 1,2,3 Jaime Uribarri. 4

Background: Albuminuria is a major risk factor for cardiovascular disease. However, to date, few data regarding albuminuria and eGFR was evaluated in the association with biopsy/yogurt consumption and albuminuria in a large, nationally representative general population sample. Future studies evaluating the association between probiotic/yogurt use and kidney diseases are warranted.

Methods: The study was conducted in the Departments of Medicine and Biochemistry at University College of Medical Sciences and GTB Hospital, Delhi from December 2013 - April 2015. It was a case control, cross sectional study. Ninety subjects in the age group 18 ~ 60 years of either sex were divided into 3 groups: Group I: Healthy controls (n=30), Group II: Individuals satisfying case definition of CKD (n=30) and Group III: Individuals having CKD of unknown etiology (n=30).

Results: The median levels of lead, cadmium and chromium were significantly higher in patients of group II and this difference was statistically significant as compared to subjects of group I and III.

Conclusions: As compared to healthy controls, the serum levels of lead, cadmium, arsenic and chromium were found to be significantly higher in patients of CKD. The study indicates a possible role of heavy metals in causation of CKD.

Probiotic and Yogurt Consumption Is Associated with a Lower Prevalence of Albuminuria: A Cross-Sectional Analysis of NHANES

Rabi Yacoub, Girish N. Nadkarni, Deepak Kaji, Shanti N. Patel, John C. He, Steven G. Coca, Jaime Uribarri. Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Animal data suggest that probiotic supplements may retard CKD progression. Yogurt is the most widely available probiotic food in the United States. Yogurt is the most widely available probiotic food in the United States. We observed an inverse association of probiotic/yogurt consumption and albuminuria in a large, nationally representative general population sample. Future studies evaluating the association between probiotic/yogurt use and kidney diseases are warranted.

Methods: The study was conducted in the Departments of Medicine and Biochemistry at University College of Medical Sciences and GTB Hospital, Delhi from December 2013 - April 2015. It was a case control, cross sectional study. Ninety subjects in the age group 18 ~ 60 years of either sex were divided into 3 groups: Group I: Healthy controls (n=30), Group II: Individuals satisfying case definition of CKD (n=30) and Group III: Individuals having CKD of unknown etiology (n=30).

Results: The median levels of lead, cadmium and chromium were significantly higher in patients of group II and this difference was statistically significant as compared to subjects of group I and III.

Conclusions: As compared to healthy controls, the serum levels of lead, cadmium, arsenic and chromium were found to be significantly higher in patients of CKD. The study indicates a possible role of heavy metals in causation of CKD.

Assessment of Serum Levels of Heavy Metals in Patients with Chronic Kidney Disease of Unknown Etiology

Om Prakash Kalra, 1 Akash Gupta, 1 Alpana Raizada, 2 Sunil Agarwal, 1 Basu Dev Banerjee. 2 Medicine, UCMS and GTB Hospital, Delhi, India; 3Biochemistry, UCMS and GTB Hospital, Delhi, India.

Background: Chronic kidney disease (CKD) encompasses a wide spectrum of different etiological processes associated with abnormal kidney function and gradual progressive decline in glomerular filtration rate. CKD of unknown etiology (CKDu) has emerged as an important entity accounting for approximately 10% of CKD patients worldwide. Of the environmental toxins implicated in causation of CKDu, heavy metals form an important group. In the present study, we estimated the serum levels of lead, cadmium, arsenic and chromium in patients with CKDu and evaluated their role in the etiopathogenesis of CKDu.

Methods: The study was conducted in the Departments of Medicine and Biochemistry at University College of Medical Sciences and GTB Hospital, Delhi from December 2013 - April 2015. It was a case control, cross sectional study. Ninety subjects in the age group 18 ~ 60 years of either sex were divided into 3 groups: Group I: Healthy controls (n=30), Group II: Individuals satisfying case definition of CKD (n=30) and Group III: Individuals having CKD of unknown etiology (n=30).

Results: The median levels of lead, cadmium and chromium were significantly higher in patients of group II and this difference was statistically significant as compared to subjects of group I and III.

Conclusions: The level of lead, cadmium and chromium were significantly higher in patients of group II and III. The median levels of arsenic in patients of group II and III were similar but significantly higher than patients of group I. The levels of arsenic, cadmium and chromium were significantly higher in patients of group II and III.

Conclusions: As compared to healthy controls, the serum levels of lead, cadmium, arsenic and chromium were found to be significantly higher in patients of CKD. The study indicates a possible role of heavy metals in causation of CKD.

FR-PO550

High Prevalence of Elevated Molybdenum Levels in CKD Patients

Guido Filippi, 1 Vladimir Belostotsky, 1 Marta Caroline Kobrzynski, 1 Shih-Jian Liu, 2 Li Yang, 1 Paediatrics, University of Western Ontario, London, ON, Canada; 2Paediatrics, McMaster Univ, Hamilton, ON, Canada.

Background: Molybdenum (Mo, atomic number 42) is an essential trace element present in water and is crucial for human survival because four mammalian enzymes harbor a pterin-based Mo cofactor (Moco) at their active site and are Mo-dependent. There is no information about Mo levels in patients with CKD.

Methods: We utilized NHANES data with reported one year yogurt consumption frequency and probiotic use.

Results: We had complete data on 6853 participants (mean age 48.3±20.45 years, male), of which,1539 (20.3%) were frequent consumers and 918 participants (12.2%) had detectable albuminuria (Median=67.1, IQR -41.6-157.1 mcg/mg). Frequent consumers had a trend towards lower median UACR compared to non-consumers (mean difference (MD): -12.3, 95% CI -29.8 to 5.2, P=0.07) that was attenuated after complete adjustment. On the other hand, frequent consumers had decreased odds of albuminuria (UACR > 30 mcg/mg) compared to non-consumers (adjusted Odds Ratio 0.79; 95% CI 0.63-0.97; P=0.03).

Conclusions: Neither CKD III-V prevalence, nor continuous eGFR was significantly different between the consumers and non-consumers. After adjustment for age, race, medical history of hypertension and diabetes, socioeconomic status (family income to poverty index), HbA1c, BMI, insulin, statins blockers use and probiotic use duration.
we also recorded the cystatin C eGFR using the Filler formula in 35 children. Mo and Cu levels were measured using High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS).

**Results:** The mean Schwartz eGFR was 46±23 and the Cystatin C eGFR was 48±20 mL/min/1.73 m². The median Mo level was 2.26 (interquartile range 1.7, 3.3 ug/L, mean 2.78±1.70 ug/L), significantly higher than the upper reference interval of 1.4 ug/L, and with an exponential increase with lower eGFR.

The mean Cu level was 1124±378 ug/mL, not significantly different from the reference interval of 822 to 1201 ug/mL. eGFR was significantly negatively correlated with Mo levels (Spearman r = -0.57, p=0.0002).

**Conclusions:** With worsening kidney function, Mo levels accumulate, while Cu levels remain unaffected.

**Funding:** Clinical Revenue Support

**High Prevalence of Elevated Vanadium Levels in CKD Patients**

*Gina Filler, 1,2 Vladimir Belostotsky, 1 Marta Caroline Kobrzyński, 1 Lilu Yang, 1 PaeDiatrics, Univ of Western Ontario, London, ON, Canada; 1Pathology and Laboratory Medicine, Univ of Western Ontario, London, ON, Canada; 1PaeDiatrics, McMaster Univ, Hamilton, ON, Canada; 2Medicine, Univ of Western Ontario, London, ON, Canada.*

**Background:** Vanadium (V, atomic number 23) is an essential trace element present in many industrial products, especially in steel, which can be very toxic if levels are too high. The excretion of vanadium by the kidneys is rapid with a biological half-life of 20-40 days.

**Methods:** After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma V levels in 50 children with an eGFR < 90 mL/min/1.73 m² and > 15 mL/min/1.73 m² using the Schwartz formula. Where available, we also recorded the cystatin C eGFR using the Filler formula in 35 children. V levels were measured using High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS).

**Results:** The mean Schwartz eGFR was 46±23 and the Cystatin C eGFR was 48±20 mL/min/1.73 m². The mean V level was 0.117 (interquartile range 0.082, 0.184 ug/L, mean 0.117±0.0499 ug/L), significantly higher than the upper reference interval of 0.1 ug/L (p=0.0057), and with a trend towards exponential increase with lower eGFR (R² = 0.3075, p=0.06).

**Conclusions:** We observed a high prevalence of elevated V levels in the CKD patients. With worsening kidney function, V levels accumulate.

Methionine Sulfoxide Reductase A (MsrA) Protects Progression of Kidney Fibrosis After Unilateral Ureteral Obstruction

Jee In Kim, 1 Jee in Kim, 2 Kwon Moo Park. 1 Dept of Anatomy and BK21 Plus, Kyungkook National Univ. School of Medicine, Daegu, Republic of Korea; 2 Dept of Molecular Medicine and MRC, Keimyung Univ. School of Medicine, Daegu, Republic of Korea.

Background: Methionine sulfoxide reductase A (MsrA) reduces oxidized methionine and protects cells against oxidative stress. Oxidative stress accelerates kidney fibrosis. Here, we investigated the role of MsrA in unilateral ureteral obstruction (UUO)-induced fibrosis using MsrA gene-deleted mice.

Methods: MsrA+/+ and MsrA−/− male mice were subjected to UUO. Kidneys were harvested 5 days after the UUO surgery.

Results: UUO reduced Msrs expression and activity in the kidney. UUO resulted in expansion of interstitial area with increased collagen deposition. In addition, UUO increased the levels of u-smooth muscle actin and collagen III expression. MsrA deficiency significantly enhanced collagen deposition and expression of those proteins. UUO resulted in the increase in hydrogen peroxide (H2O2) formation and lipid peroxide in both MsrA−/− mouse kidneys and MsrA+/+ mouse kidneys, and these increases were significantly higher in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys. Furthermore, post-UUO increases in the oxidized glutathione ratio to total glutathione were significantly greater in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys. Number of F4/80 expressing cells increased in the kidney after UUO. These increase of F4/80 expressing cells were greater in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys. Levels of Ly6G, a marker of granulocyte, were also higher in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys.

Conclusions: In conclusion, MsrA protects kidney against UUO-induced fibrosis, suppressing oxidative stress and inflammatory responses.

The Soluble Urokinase-Type Plasminogen Activator Receptor Serum Levels in Adults with Nephrotic Syndrome

Qiuling Fan, Nephrology, The First Hospital of China Medical Univ.

Background: The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in adults with nephrotic syndrome were analyzed.

Methods: The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in 70 nephrotic syndrome patients with membranous nephropathy, diabetic nephropathy group, lupus nephritis, minimal change kidney disease and focal segmental glomerular scerosis group was detected by enzyme-linked immunosorbent assay. The relationship between the clinical parameters and suPAR levels were analyzed.

Results: Serum soluble urokinase receptor levels of nephrotic syndrome patients were significantly higher than the normal control group (P < 0.01). The serum suPAR levels of FSGS and MN patients were significantly higher than MCD patients (P < 0.05). Serum suPAR level was positively correlated with age, serum creatinine, blood urea nitrogen, and negatively correlated with eGFR. The serum levels of suPAR in adults with nephrotic syndrome were analyzed.

Conclusions: Serum suPAR level was positively correlated with age, serum creatinine, blood urea nitrogen, and negatively correlated with eGFR. The serum levels of suPAR in adults with nephrotic syndrome were analyzed.

FR-PO556

Urinary Sodium: Impact on Blood Pressure and Progression of Chronic Kidney Disease

Adriano Luiz Ammirati, Maria Eugenia F. Canziani. Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.

Background: Chronic kidney disease (CKD) is characterized by chronicity and progression of renal damage. The presence of hypertension is related to the progression of renal damage. Diets high in salt have been associated with an increased risk of hypertension. Sodium analysis in the urine of 24 h is considered the standard method to estimate the daily intake of this mineral. The aim of this study was to evaluate the impact of sodium intake estimated by urinary sodium in the urine of 24 hours (Nau24hs) on renal outcomes and their impact on hypertension.

Methods: Data were collected from medical records of 118 patients with CKD in conservative treatment, that had one Nau24hs dosage and a follow-up of at least five years. Information collected initially and after 5 years were: demographics, etiology of CKD, comorbidities, blood pressure; routine laboratory tests and estimated creatinine clearance (EPI-Cr). The Nau24hs values were classified into two groups by the median and also divided into tertiles and compared with the rate of progression of CKD (fall of the estimated clearance greater than 20% in 5 years) and the change in blood pressure.

Results: Patients had a mean of 186 ± 64 Meq/L of Nau24hs which represented a decrease in systolic blood pressure over 5 years. The decrease in creatinine clearance over 5 years was associated with more pronounced worsening of long-term renal function, probably because these patients were treated more intensively over the pressure control.

Conclusions: In conclusion, with high blood pressure, but was not associated with more pronounced worsening of long-term renal function, probably because these patients were treated more intensively over the pressure control.

FR-PO557

Risk of End-Stage Renal Disease with Longitudinal Change in Filtration Markers

Background: Change in estimated glomerular filtration rate (eGFR) based on creatinine has been proposed as a surrogate outcome in clinical trials of chronic kidney disease (CKD). Risk of end-stage renal disease (ESRD) associated with change in other kidney filtration markers has not been previously assessed in chronic kidney disease (CKD) populations.

Methods: We conducted prospective analyses of the Modification of Diet in Renal Disease (MDRD; N=840; mean age 52 years) and African-American Study of Kidney Disease and Hypertension (AASK; N=1,094; mean age 55 years) trials. Creatinine, cystatin C, β2-microglobulin, and β-trace protein levels were measured in serum samples collected at baseline and at the 24-month follow-up visit and were expressed using CKD-EPI eGFR equations. Multivariable Poisson regression was used to estimate associations between continuous percent change in eGFR for each marker (alone and in combination) with subsequent risk of developing ESRD. Seemingly unrelated regression was used to compare the strength of risk estimates from different models.

Results: In MDRD and AASK, respectively, there were 310 and 161 incident ESRD cases during a median follow-up of 4.7 and 7.1 years. Percent change in eGFR from the four filtration markers was significantly associated with incident ESRD risk (Table). The average of percent change in eGFR based on all four filtration markers was more strongly associated with ESRD risk than percent change in eGFR-creatinine alone.

FR-PO558

Validation and Clinical Associations of a Predictive Model for Progression to Renal Replacement Therapy: A Retrospective Cohort Study

James Ritchie, 1 Ashfan Ahmed, 1 Olivier J. Wouters, 2 Darren Green, 3 Smeha Sinai, 2 Donal J. O'Donoghue, 1 Philip A. Kalra, 1 4SF Royal Farndon Foundation Trust, United Kingdom; 1London School of Economics and Political Science, United Kingdom.

Background: Timely planning for initiation of renal replacement therapy (RRT) is vital. Despite existing, validated risk-prediction models, RRT preparation is often based on clinical judgment. Here, we consider the benefits of applying an existing model (Tangri et al. JAMA, 2011) in a UK secondary care population.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: Patients with ≥5 years of potential follow-up were identified from the Chronic Kidney Disease Epidemiology, Outcomes: Noncardiovascular

Results: 728 patients were included in this analysis (median follow-up 4.4 [IQR 2.4-5.6] years), with 118 patients (16%) progressing to RRT. Mean baseline age was 64±14 years and eGFR 34±14 ml/min/1.73m². Risk was right skewed, with 328 (45%) of patients having a 5-year risk of <5%. 80 patients (11%) had a 5-year RRT risk of >50%. The overall area under the curve was 0.89. This did not vary by primary disease: glomerulonephritis (0.87); pyelonephritis (0.95); polyol cystic kidney disease (0.91); and diabetic nephropathy (0.88).

In higher-risk groups, a greater proportion of patients commenced RRT using peritoneal dialysis, and a smaller proportion commenced RRT as an in-patient. The proportion of patients transplanted listed at the time of starting RRT was greater in the lower risk group than the higher risk group.

FR-PO560

Effect and Safety of Sofosbuvir (SOF) Containing Direct-Acting Antiviral (DAA) Hepatitis C Virus (HCV) Therapy in a Real-World Population with Chronic Kidney Disease (CKD)

Guillermo Ortiz,1 Gregory L. Hundemer,1 Elke Backman,2 Ravi I. Thadhani,3 Raymond T. Chung,3 Meghan E. Sisc,1 Nephrology Div, MGH, Boston, MA; 2Pharmacy, MGH, Boston, MA; 3Gastrointestinal, MGH, Boston, MA.

Background: Early trials of SOF-based regimens excluded patients with CKD, thus little is known about safety, efficacy, and effect on kidney function.

Methods: We retrospectively evaluated 72 patients with CKD starting DAA treatment (tx) between 11/2013-12/2014. CKD was defined by average eGFR <60ml/min or albuminuria >30mg/g 6 months prior to tx. Safety, tolerability and laboratory results were assessed by chart review. Models predicting sustained virologic response (SVR) were performed.

</table>

Results: Subjects were aged 61±8 years, 60% white, 22% black, 12% Hispanic, and 74% male. 50% were diabetic, 39% cirrhotic, 54% HCV naïve, 39% had prior liver or kidney transplant, and 7% were HIV/HCV coinfected. DAA regimens were: SOF/simeprevir 50%, SOF/ledipasvir 13%, SOF/ribavirin 28%, other SOF regimens 10%. 8% had a transient creatinine rise >0.5mg/dL during tx. Average eGFR on tx was similar to baseline (mean [95% CI]: 57 [52-62] vs. 53 [53 – 63] ml/min, respectively P=0.26). SVR was 77% (95% CI 66-88). 76% experienced at least 1 adverse effect (AE); only 5 (7%) discontinued tx due to an AE.

Conclusions: SOF-containing DAA regimens are effective and relatively safe in patients with CKD. Although AEIs were common, serious AEIs or significant nephrotoxicity were rare. Lower eGFR at baseline predicted an increase likelihood of HCV cure with SOF-based regimens.

Risk of Liver Injury After alpha-Glucosidase Inhibitors Therapy in Advanced Chronic Kidney Disease Patients: A Population-Based Study

Vincent Wu,1 Chih-chin Kao,1 Taomin Huang.1 Internal Medicine, National Taiwan Univ Hospital, Taipei; Internal Medicine, Taipei Medical Univ Hospital.

Background: α-glucosidase inhibitors (AGIs) are commonly used to control postprandial blood glucose. However, AGIs-related liver injury has been reported, but whether the relationship of AGIs and liver injury applies to advanced chronic kidney disease (CKD) patients remains uncertain.

Methods: In the nationwide case-control study, we recruited advanced diabetic CKD patients, who has taken AGIs from January 1, 2000 through December 31, 2010 as cases and matched 5295 matched controls. Recent and former AGIs users were defined as patients who received the AGIs prescription 30-60 days and 30-210 days before the event, respectively. Safety, tolerability and laboratory results were assessed by chart review. Models predicting sustained virologic response (SVR) were performed.

Results: The age of enrollee is 63 ± 11 years and nearly 51% is men. Liver injury developed in 3.9% of cases and 3.3% of control patients. Patients who received insulin treatment (p=0.03), had chronic liver disease (p=0.01) were predictive to liver injury. AGIs use did not increase the risk of liver injury in advanced CKD patients (p=0.22), both among recent users (P=0.20) or former users (P=0.22). The stratified analysis showed no increased risk of liver injury in virus hepatitis, liver cirrhosis, subsequent end stage renal disease or patients who has diabetic related comorbidities. (all p> 0.05).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Conclusions: Available evidence supports expansion of AGIs use in patients with advanced CKD, without increased risk of liver injury. Neither accumulated dose-dependent effect of AGIs, or subsequent ESRD will aggravated AGI-associated liver injury. Further randomized controlled trials are warranted to confirm our results.

Add-On Renoprotective Effect of Pentoxifylline in Pre-Dialysis Advanced Chronic Kidney Disease Treated with Renin-Angiotensin-Aldosterone System Blockade – A Nationwide Database Analysis

Ko-Lin Kuo,1 Szu-Chun Hung,1 Jia-sin Liu,2 Der-Cheng Tarng.1  
1Taipei Tzu Chi Hospital, Taiwan; 2National Health Research Insts, Taiwan; 3National Health Research Insts, Taiwan; 4Taipei Veterans General Hospital, Taiwan.

Background: Pentoxifylline decreases proteinuria in patients with glomerular disease due to its anti-inflammatory and anti-fibrotic properties. A combination therapy of pentoxifylline with an angiotensin converting enzyme inhibitor (ACEI) or an angiotensin II receptor blocker (ARB) decreased proteinuria and the glomerular filtration rate (GFR) decline in early chronic kidney disease (CKD). Whether adding pentoxifylline to ACEI/ARB provides additional benefits on renal outcome or survival is unclear in CKD stage 5 patients who have not yet received dialysis (CKD 5 ND).

Methods: A prospective cohort study was conducted based on the Taiwan National Health Insurance Research Database. From January 1, 2000 to June 30, 2009, we enrolled 14,117 CKD 5 ND patients with serum creatinine levels >6 mg/dL and hematocrit levels <28% and who have been treated with ACEI/ARB. All patients were further divided into two groups with or without pentoxifylline within 90 days after starting erythropoiesis-stimulating agent therapy (index date). Patient follow-up took place until dialysis, death before initiation of dialysis or December 31, 2009.

Results: With a mean follow-up of 12 months, 9,867 patients (69.9%) required long-term dialysis and 2,805 (19.9%) died before progression to end-stage renal disease requiring dialysis. After propensity score-matching, add-on use of pentoxifylline was associated with a lower risk for long-term dialysis or death in those treated with ACEI/ARB (HR, 0.94; 95% CI, 0.89-0.99) or ARB (HR, 0.93; 95% CI, 0.88-0.98).

Conclusions: Pentoxifylline exhibited an add-on renoprotective effect in reducing the risk for long-term dialysis in CKD 5 ND patients who received renin-angiotensin-aldosterone system blockade. Randomized studies are needed to validate this association.

FR-PO563

Novel Therapy Regimens Have Reduced the High Risks of Bladder and Haematological Malignancies in ANCA-Associated Vasculitis

Chinar Rahmattulla,1 Annelies Evaline Berden,1 Saoirse Leaver,2 Marlies Reinders,1 Ernst C. Hagen,2 Ron Wolterbeek,1 Jan A. Bruijn,1 Ingeborg Rahmattulla.1

1Leiden Univ Medical Center; 2Meander Medical Center Amersfoort.

Background: The introduction of immunosuppressive therapy has dramatically improved the prognosis of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). As a result, attention has shifted to long-term complications in patients. In this study, we investigate the incidence of malignancies in AAV patients. Additionally, we investigate the effect of therapy on malignancy incidence.

Methods: We included patients with histopathologically-proven AAV diagnosed at a large university hospital. Malignancy incidence was assessed with the Dutch National Pathology Database, which covers all the histologically confirmed malignancies diagnosed in The Netherlands. We used the Netherlands Cancer Registry incidence rates for comparing the malignancy incidence in our AAV cohort to that of the general Dutch population.

Results: Thirty-six of 138 patients with AAV developed a total of 85 malignancies during a mean follow-up of 9.7 years. We observed 61 non-melanoma skin cancers (NMSCs), three colon carcinomas, three breast carcinomas, three prostate carcinomas, two lung carcinomas, two soft tissue sarcomas, two unknown primary malignancies, and a variety of malignancies that occurred only once. The gender-, age-, and calendar year-adjusted malignancy risk was 2.21-fold (95% CI: 1.64–2.92) higher than that in the general population. Only the incidence of NMSCs was significantly increased compared to the general population (standardized incidence ratio: 4.23, 95% CI: 2.76–6.19). Malignancy risk was associated with the duration of cyclophosphamide therapy, and was not increased in patients that received cyclophosphamide for less than 1 year.

Conclusions: AAV patients have a higher risk of malignancies than the general population, but this risk is accounted for solely by NMSCs. Throughout the years, the risk of other malignancies—specifically bladder and haematological malignancies—has decreased in patients with AAV. This finding reflects the beneficial results of ongoing efforts to reduce cyclophosphamide exposure by developing new therapy regimens.

FR-PO564

Effect of Lowering LDL-Cholesterol with Simvastatinplus Ezetimibe on Non-Vascular Outcomes in Patients with Chronic Kidney Disease (CKD): Results from the Study of Heart and Renal Protection (SHARP)

Background: The Study of Heart and Renal Protection (SHARP) was a randomized placebo-controlled trial of LDL-cholesterol (LDL-C)-lowering among 9270 patients with CKD which showed that combination therapy with ezetimibe 10mg/ simvastatin 20mg (E/S) reduced vascular events with no significant adverse effects on muscle, hepatobiliary outcomes or cancer. However, assessment of the effects of lowering LDL-C on other non-vascular outcomes has not been extensively explored in patients with CKD.

Methods: All post-randomization serious adverse events (SAEs) were routinely recorded. Post-hoc intention-to-treat analyses were performed of the effect of allocation to treatment on time to first non-vascular SAE by system of disease with sub-categories.

Results: During 4.9 years’ median follow-up, similar numbers of participants in the two groups experienced non-vascular SAEs overall (3533 [76.0%] E/S vs 3505 [75.9%] placebo; risk ratio [RR] 1.00, 95% CI 0.95-1.05). After due allowance for multiplicity, there was no evidence of any SAE or hazard of E/S vs placebo in cardiovascular disease or any other system of disease. Within the class of endocrineology SAEs, there were no significant effects of E/S on any particular individual category of SAE: new-onset diabetes (172 [4.8%] E/S vs 162 [4.5%] placebo); RR 1.06, 95% CI 1.06-1.34 among 3596 vs 3580 participants without diabetes at baseline), diabetes-related complications (136 [2.9%] E/S vs 126 [2.7%] placebo; RR 1.08, 95% CI 0.84-1.37), and other endocrine disorders (58 [1.2%] E/S vs 39 [0.8%] placebo; RR 1.47, 95% CI 0.99-2.19).

Association of β-Blocker Therapy with Renal Outcomes in CKD Patients without prior Cardiovascular Disease

Naoshiko Fujii,1 Takayuki Hamano,2 Yoshitsugu Ohi,3 Yoshitaka Isaka.3 1Univ of Pennsylvania, Philadelphia, PA; 2Osaka Univ, Suita, Osaka, Japan; 3Univ of California, Irvine, Irvine, CA; 4Osaka General Hospital, Osaka, Japan.

Background: Sympathetic overactivity due to impaired kidney function can deteriorate hypertension, renal failure, and cardiovascular disease (CVD) among CKD patients. Mortality benefit of its antagonist, β-blocker (BB), has been shown in patients with prior CVD; however, such evidences are scarce in CKD patients without CVD. Our aim is to evaluate the association between BB and renal outcomes in such patients.

Methods: We extracted 340 predialysis CKD patients without prior CVD but with drug information at baseline from a Japanese CKD cohort (OVIDS-CKD, N=738). The primary
endpoint was a composite of Cr doubling, initiation of RRT, and death. We performed Cox proportional hazards analysis to estimate the hazards ratio (HR) of BB use at baseline, adjusting for other parameters, such as sex, eGFR, proteinuria, diabetes, BMI, blood pressure, the number of anti-hypertensive drugs, ACEI/ARB use, HB, Alb, corrected Ca, iP, and FGF23. We also employed 1:k (k=1–6) propensity-score full matching, where one BB user matched to at most k non-users.

**Results:** BB users showed significantly lower eGFR, more proteinuria, higher BMI, more anti-hypertensive drugs, lower Alb, higher 1-84 PTH, higher FGF23, and lower 25OHD levels, most of which suggested a poor risk for CVD at baseline. During a median follow-up of 6.6 years, 109 patients reached the outcome. Of these, 12 patients died before RRT, 71 reached a doubling of Cr, and 26 started dialysis. A multivariable Cox model with covariates that were significantly different between BB users and non-users at baseline showed non-significant HR of 1.58 (C.I. 0.86 – 2.90). We also evaluated a fully-adjusted model and a parsimonious model with a stepwise backward-elimination method; however, the results remained non-significant. The 1:k (k=1-6) full matching using propensity score did not show significant results, either. (0.93 (0.52 – 1.68)).

**Conclusions:** The BB therapy was not associated with renal outcomes in CNP patients without prior CVD. Confirmation in a larger study is required.

*Lactobacillus plantarum 299v* Reduces the Incidence of Clostridium difficile Infection in Patients Treated with Antibiotics in the Nephrological and Transplantation Department Marcin Adamczak, Agata Kujawa-Szewieczek, Katarzyna Kwiecien, Sylvia Malgorzata Dudzicz, Magdalena Gazda, Andrzej Wiecek. Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland.

**Background:** Lactobacillus plantarum 299v (LP299v) has been introduced into the clinical practice in order to reduce gastrointestinal symptoms during antibiotic exposure. However it remains controversial whether or not probiotics are also effective in the prevention of Clostridium difficile infections (CDI) among patients receiving antibiotics.

The aim of this clinical, retrospective, single-centre study was to compare the CDI frequencies among patients receiving antibiotics and hospitalized in the period before and after initiation of LP299v routine use, as a prevention of CDI, in the nephrology and transplantation ward.

**Methods:** Among 3533 patients hospitalized in Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia in Katowice during two years (October 2012 – October 2013 and December 2013 – December 2014) 23 patients with CDI were diagnosed and enrolled in this study. Since November 2013 prevention of C. difficile infection with the oral use of LP299v was performed in all patients treated with antibiotics and who were at a high risk of developing CDI (patients after organ transplantation and receiving immunosuppressive drugs for any other reasons). For the further analysis the observation period was divided into two twelve-months intervals before (October 2012 to October 2013) and after initiation of LP299v use as the prophylactic manoeuvre against CDI (December 2013 to December 2014).

**Results:** It was found a significant (p<0.001) reduction of the number of cases of C. difficile infection after beginning of LP299v routinely used (n=2, 0.11% of all hospitalized patients) compared with the previous twelve-months period of observation (n=21; 1.21% of all hospitalized patients).

**Conclusions:** Routine use of Lactobacillus plantarum 299v during treatment with antibiotics may prevent C. difficile infection, particularly in patients at high risk of CDI in the nephrology and transplantation ward.

**Funding:** Government Support - Non-U.S.

---

**FR-PO567**

**Background:** Patients with chronic kidney disease (CKD) are commonly prescribed drug doses that are excessive for their kidney function. Many CKD patients are followed solely by a family physician. We wish to determine whether care by both a nephrologist and family physician (i.e. comanagement) versus family physician alone is associated with lower risks of inappropriate antibiotic dosing in patients with stage 4 or 5 CKD.

**Methods:** A retrospective case-control study was conducted, among individuals aged >66 years, with estimated glomerular filtration rate (eGFR) <30 mL/min/1.73 m² using linked healthcare databases from 2003-2014. Cases were antibiotic prescriptions dosed inappropriately, whereas controls were prescriptions dosed appropriately. Exposure was comanagement, defined as at least one outpatient visit with a nephrologist in the 1 year prior to antibiotic prescription. A multivariable logistic regression model was used to determine the independent association between comanagement and inappropriate dosing.

**Results:** Of 21,848 eligible prescriptions studied, 64% were inappropriately dosed. The patients were 82 (IQR 76-87) years of age with comorbidities including: hypertension (89%), diabetes (49%), coronary artery disease (49%), and congestive heart failure (38%). 77% of all prescriptions were prescribed by family physicians and 2% were prescribed by nephrologists. Multivariable analysis revealed that patients with appropriate prescriptions were more likely to have seen a nephrologist in the one year prior with an unadjusted odds ratio of 1.07 (95% CI 1.01-1.14, p=0.02), adjusted odds ratio 1.23 (95%CI 1.15-1.32, p<0.001).

**Conclusions:** In patients with stage 4 or 5 CKD prescribed an antibiotic, those with an appropriate dose were 23% more likely to have been cared for by a nephrologist in the previous year. Although we cannot conclude what caused the improved prescribing practice, this improvement may, in part, explain the improved patient outcomes associated with seeing a nephrologist in observational studies.

Variation in Co-Medication Use According to Kidney Transplant Immunosuppressive Regimen: Application of Integrated Registry and Pharmacy Claims Data Krista L. Lenting,1 Abhijit S. Naik,2 Faramarz Ismail, Abhijit S. Naik,2 Mark Schnitzler,1 Veena Rao,3 David A. Axelrod,1 Jiaying Chen,1 Daniel C. Brennan,3 Dorry L. Segev,3 Bertram L. Kasiske,4 Vikas R. Dharnidharka.1 1Saint Louis Univ; 2Univ Michigan; 3Dartmouth; 4Washington Univ; 5Johns Hopkins; 6Univ Minnesota.

**Background:** While modern immunosuppressive therapies (ISx) have substantially reduced acute rejection, ISx medications have many side effects, and transplant recipients must take an array of “co-medications” to help mitigate complications. Co-medication utilization patterns are not well described in large, representative samples due to lack of available data.

**Methods:** We designed national U.S. transplant registry data with pharmacy records (2005-2010) from a large pharmaceutical claims clearinghouse to examine treatments for anemia, metabolic disorders and infections according to ISx regimen in mo 6-12 post-transplant (N=22,453). Associations of ISx with co-medication use (adjusted odds ratio, aOR) were examined with multivariable logistic regression including adjustment for recipient, donor and transplant factors.

**Results:** Compared to a reference regimen of tacrolimus (Tac), mycophenolate (MPA) and prednisone, rapamycin-based ISx was associated with significantly (P<0.05) higher use of ESAs (aOR 2.52, iron (aOR 2.26), statins (aOR 1.47), fibrates (aOR 2.35), and phosphorous binders (aOR 2.85) (Figure). Cyclosporine-based ISx was associated with more common use of anemia treatments. Compared to those taking triple ISx, recipients of tacrolimus-based dual and mono-therapies had lower use of statins, ACE/ARBs, and anti-bacterial agents. Recipients of steroid-free ISx were less commonly treated for new onset diabetes.

Association of Urinary Biomarkers of Injury and Repair with Incident Chronic Kidney Disease in Type 2 Diabetes: An Ancillary Study of the ACCORD Trial Girish N. Nadkarni,1 Vecna Rao,2 Faramarz Ismail-beigi,3 Vivian A. Fonseca,4 Sudhir V. Shah,5 Michael S. Simonson,3 Prasad Devarajan,6 Chirag R. Parikh,7 Steven G. Coca.1 1Mount Sinai; 2Yale Univ; 3Case Western Reserve Univ; 4Tulane Univ; 5UAMS; 6Univ of Cincinnati.

**Background:** Urinary kidney injury molecule (KIM)-1, monocyte chemoattractant protein (MCP)-1, interleukin (IL)-18, and YKL-40 are biomarkers representing renal injury, inflammation, and fibrosis. We evaluated their association with incident CKD3b in the ACCORD trial.

**Methods:** We designed a case-cohort study of 721 participants & measured KIM-1, MCP-1, IL-18, and YKL-40 in urine samples with Mesoscale platform. Biomarker associations with CKD3b were modeled continuously & by tertiles using Cox proportional hazards models.

**Results:** Mean age was 62, 51% were female & baseline eGFR was 88 ml/min. There were 159 incident CKD3b events over median (IQR) of 4.2(3.9-4.7) years. Top tertiles of all biomarkers had higher proportions of incident CKD3b. After adjusting for demographics,
clinical characteristics, baseline eGFR & UACR, highest tertiles of uMCP1 & uKIM1 had adjusted HRs of 1.82(95% CI 1.18-2.81) & 1.51(95% CI 1.01-2.27) respectively. Area under ROC improved from 0.70(with eGFR & UACR) to 0.72 with addition of uMCP1 & uKIM1(p<0.05). No association was seen for urinary IL-18 & YKL-40. Under ROC, improved from 0.70 with eGFR & UACR to 0.72 with addition of uMCP1 & uKIM1(p<0.05). No association was seen for urinary IL-18 & YKL-40.

Adjusted associations of TDF exposure with urine α1m levels

FR-PO571
Impact of Kidney Function and Urinary Protein Excretion on Pulmonary Function
Yusuke Nakada,1,2 Tadashi Toyama,1 Shinji Kitajima,2 Akinori Hara,2 Miho Shimizu,2 Yasunori Iwata,2 Norihiko Sakai,2 Kengo Furuchi,2 Takashi Wada.2,3 Clinical Laboratory, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; 3Dept of Laboratory Medicine, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.

Background: Although the cardiorenal relationship in patients with chronic kidney disease (CKD) has been investigated, information about the lung-kidney relation is limited. Here, we investigated the impacts of kidney function and urine protein excretion on pulmonary dysfunction.

Methods: The data of pulmonary function tests (PFTs) and kidney function tests from 1 April 2005 to 30 June 2010 were selected from our laboratory database. Data were classified into 4 categories according to eGFR and proteinuria. Category 1: eGFR ≥ 60 ml/min/1.73 m² and urinary protein < 0.3 g/gCr; Category 2: eGFR ≥ 60 ml/min/1.73 m² and urinary protein ≥ 0.3 g/gCr. Category 3: eGFR ≥ 60 ml/min/1.73 m² and urinary protein ≥ 0.3 g/gCr; Category 4: eGFR ≥ 60 ml/min/1.73 m² and urine protein ≥ 0.3 g/gCr. Pulmonary function data were evaluated according to these 4 categories.

Results: A total of 133 participants without major respiratory disease, abnormal computed tomography and smoking history were enrolled. Hb-adjusted %DLCO in category 4 (46.2 ± 7.5) and category 2 (63.6 ± 17.8) were significantly lower than that in category 1 (75.8 ± 18.9) (P= 0.05). Hb-adjusted %DLCO was strongly correlated with eGFR in participants with urinary protein ≥ 0.3 g/gCr (R = 0.81, P<0.001). In addition, eGFR was associated with Hb-adjusted %DLCO (P= 0.023) and urinary protein tended to be associated with Hb-adjusted %DLCO (P= 0.095) after adjusting for physical features and the presence or absence of DM and Hypertension.

Conclusions: This study suggests that eGFR and urinary protein excretion were associated with pulmonary function (Hb-adjusted %DLCO).

FR-PO570
Association of Tenofovir Disoproxil Fumarate Exposure with Urine α1-microglobulin, a Biomarker of Proximal Tubule Dysfunction
Vasantha Jotwani,1 Rebecca Scherer,1 Michelle M. Estrella,2 Chirag R. Parikh,2 Tadashi Toyama,2 Shinji Kitajima,2 Yasuyuki Joachim H. Ix,4 Michael Shlipak.

Background: Tenofovir disoproxil fumarate (TDF) is a well-recognized contributor to HIV-related kidney disease, via proximal tubular injury. Urine α1-microglobulin (α1m), a low molecular weight protein indicative of proximal tubule dysfunction, may enable earlier detection of TDF-associated toxicity.

Methods: In this cross-sectional study of 883 HIV-infected men enrolled in the Multicenter AIDS Cohort Study Cohort Study, we evaluated associations of TDF exposure with urine α1m levels, using multivariable generalized gamma regression models to adjust for traditional kidney risk factors, and HIV-related factors.

Results: Mean age was 52 and mean eGFR was 90 ml/min/1.73m². Median TDF exposure duration was 4.2 years (IQR:2.3,6.1) among the 573 (65%) current and 112 (13%) former TDF users. Cumulative TDF duration was linearly associated with higher urine α1m levels (p<0.0001). 24-fold effect size relative to age (2% per year). Compared with men who never received TDF, α1m levels were 43-50% higher in former and current TDF users. Time since last TDF exposure was only modestly associated with lower α1m.

Adjusted associations of TDF exposure with urine α1m levels

<table>
<thead>
<tr>
<th>Events</th>
<th>Adjusted HR(95% CI)</th>

Urine α1-microglobulin (α1m), a low molecular weight protein indicative of proximal tubule dysfunction, may enable earlier detection of TDF-associated toxicity.

Methods: In this cross-sectional study of 883 HIV-infected men enrolled in the Multicenter AIDS Cohort Study Cohort Study, we evaluated associations of TDF exposure with urine α1m levels, using multivariable generalized gamma regression models to adjust for traditional kidney risk factors, and HIV-related factors.

Results: Mean age was 52 and mean eGFR was 90 ml/min/1.73m². Median TDF exposure duration was 4.2 years (IQR:2.3,6.1) among the 573 (65%) current and 112 (13%) former TDF users. Cumulative TDF duration was linearly associated with higher urine α1m levels (p<0.0001). 24-fold effect size relative to age (2% per year). Compared with men who never received TDF, α1m levels were 43-50% higher in former and current TDF users. Time since last TDF exposure was only modestly associated with lower α1m.

Adjusted associations of TDF exposure with urine α1m levels

Association of Tenofovir Disoproxil Fumarate Exposure with Urine α1-microglobulin, a Biomarker of Proximal Tubule Dysfunction

Vasantha Jotwani,1 Rebecca Scherer,1 Michelle M. Estrella,2 Chirag R. Parikh,2 Tadashi Toyama,2 Shinji Kitajima,2 Yasuyuki Joachim H. Ix,4 Michael Shlipak.

Background: Tenofovir disoproxil fumarate (TDF) is a well-recognized contributor to HIV-related kidney disease, via proximal tubular injury. Urine α1-microglobulin (α1m), a low molecular weight protein indicative of proximal tubule dysfunction, may enable earlier detection of TDF-associated toxicity.

Methods: In this cross-sectional study of 883 HIV-infected men enrolled in the Multicenter AIDS Cohort Study Cohort Study, we evaluated associations of TDF exposure with urine α1m levels, using multivariable generalized gamma regression models to adjust for traditional kidney risk factors, and HIV-related factors.

Results: Mean age was 52 and mean eGFR was 90 ml/min/1.73m². Median TDF exposure duration was 4.2 years (IQR:2.3,6.1) among the 573 (65%) current and 112 (13%) former TDF users. Cumulative TDF duration was linearly associated with higher urine α1m levels (p<0.0001). 24-fold effect size relative to age (2% per year). Compared with men who never received TDF, α1m levels were 43-50% higher in former and current TDF users. Time since last TDF exposure was only modestly associated with lower α1m.

Renal Biomarkers in Diabetes, Role Beyond Retinopathy, Relation to Renin-angiotensin System.
Mohamed E. Elragael,1 Ahmed Fathy Elkeraie,2 Ahmed M. Abdelhadi,1 Ashraf Nabil Abdalla,4
1Nephrology, Alexandria Univ, Alexandria, Egypt; 2Dept of Environmental Medicine, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 3Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 4Pharmacology, Umm Al-Qura Univ, Saudi Arabia.

Background: Diabetic nephropathy and retinopathy remain two of the most frequent complications of diabetes and is the leading cause of end-stage renal disease (ESRD) and blindness worldwide. The concordance rate between both complications is often present in diabetic patients.

Methods: We tried to study the relation between renal biomarkers including serum creatinine (SCr), urinary albumin/creatinine ratio (ACR), serum cystatin-C (cysC) and urinary NGAL (uNGAL) with diabetic retinopathy (DR) in 100 diabetic patients. Patients were classified according to severity into 3 stages: no diabetic retinopathy (No DR), Non-Proliferative DR (NPDR) and proliferative DR (PDR).

Results: Urinary ACR, serum cysC and uNGAL were higher significantly among patients with DR (NPDR & PDR) than patients without, while SCr showed a non significant rise with progression of retinopathy. All markers were higher among PDR than NPDR group.

Conclusions: Renal biomarkers namely urinary ACR, serum cysC and uNGAL may point to a more advanced stage of diabetic retinopathy, which might be an aid to identify the degree of retinopathy beside the traditional fundus examination in diabetic patients.

FR-PO573
Prognostic Importance of Urea and Urea: Creatinine Ratio for Mortality as Compared to Creatinine Concentrations Alone in the General Population
Ronan Cusack,1, 2 Austin G. Stack,1, 2 John P. Ferguson.1
1Nephrology, Univ Hospital Limerick, Ireland; 2Graduate Entry Medical School, Univ of Limerick, Ireland.

Background: High Creatinine (Cr) concentrations reflect poor kidney function and is the leading cause of end-stage renal disease (ESRD) and blindness worldwide. The concordance rate between both complications is often present in diabetic patients.

Methods: A cohort of 15,773 non-pregnant subjects age ≥20, representative of the U.S. population, were identified from the Third National Health and Nutrition Examination Survey (1988-1994). Vital status was obtained through linkage with the National Death Index through to 2006. Subjects were classified into categories of Cr, BUN and Cr/creatinine ratio, are better predictors of mortality in the general population.

Results: In a multivariable analysis, BUN was found to be the most important single predictor of mortality with Cr being second best. A strong interaction (P<0.001) between BUN and Cr with mortality was identified and explored by fitting stratified models, as shown below.

Conclusions: Both BUN and Cr independently predict death in the general population. Among patients with malnourished states (Low BUN), higher Sc were associated with lower mortality. In contrast, among patients with normal-high BUN concentrations, higher Cr was associated with elevated death risk. Risk Prediction models should take BUN levels into consideration when estimating future death risk.

Background: The term protein-energy wasting (PEW) implies a state of depleted protein and/or energy stores. An International Society of Renal Nutrition and Metabolism (ISRNM) panel proposed objective criteria for the definition of PEW syndrome. However, the extent to which these variables used in PEW syndrome definition are indicative of low protein or energy stores is unknown. Muscle is the largest protein store and fat mass is the largest energy store in the body. Therefore, we examined the associations of these variables with low lean body mass (LBM) and fat mass (FM) measured by DXA scans in 11,834 participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: Definitions of PEW variables are summarized in the table. The associations of each PEW variable with LBM and FM in the entire cohort and CKD (CKD-EPI eGFR < 60) sub-population were examined in linear regression models using svy suite in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. 6.7% had CKD. Unintentional weight loss and low levels of serum albumin, serum cholesterol, BMI and MAMC were associated with lower LBM and FM. On the other hand, low protein and energy intakes were associated with higher LBM and FM.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

*10% or more lower than the 50th percentile of reference group

Results were similar in the CKD sub-population.
Conclusions: Serum chemistry, body weight and muscle mass PEF criteria appear to be highly sensitive of both protein stores (as indicated by LBM) and energy stores (as indicated by FM). Dietary variables are not reflective of protein or energy wasting. A modified PEW syndrome definition without the dietary variables would be a better indicator of PEW syndrome.

FR-PO576 Low-Proteinuric CKD and Risk of ESRD in Nephrology Clinics: Emerging Role of Serum Phosphorus  
Luca De Nicola, Michele Prozenzano, Paolo Chiodini, Giuseppe Conte, Roberto Minutolo. 1  
Nephrology, Second Univ, Naples, Italy; 2  Med Stat, Second Univ, Naples, Italy.

Background: In low-proteinuric (LP) CKD, factors other than proteinuria (Uprot) likely act as predictors of ESRD. However, comprehensive assessment of epidemiologic features of LP versus high-proteinuric (HP) patients is still lacking. This information is critical in renal clinics where LP patients are common.

Methods: We pooled three prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-IV under stable care from 26 months in 40 Italian renal clinics. Patients were followed for ESRD (chronic dialysis-transplant) up to 12/2014. Patients were classified in two groups, LP (56%) and HP (44%), by Uprot ≥0.5 and <0.5 g/24h, respectively.

Results: Besides lower Uprot (median, IQR: 0.15, 0.06-0.28 vs 0.50, 0.28-2.07 g/24h), LP differed from HP because male gender (55 vs 62%), diabetes (28 vs 55%) and use of anti-RAS (73 vs 78%) were less frequent. In LP, moreover, age (70±12 vs 65±14), GFR-EPI (35.2±13.3 vs 26.6±13.2 mL/min/1.73m²) and HB (12.7±1.7 vs 12.3±1.8 g/dL) were higher while systolic BP (137±18 vs 140±18 mmHg) was lower. Serum phosphorus (P) was lower in LP (1.23±0.83 mg/dL, P<0.001), Hb (12.9±1.7 vs 12.4±1.6 g/dL, P=0.001) for all comparisons. History of cardiovascular disease (CVD), BMI and uric acid levels did not differ. Over a median follow-up of 38 months, ESRD occurred in 154 LP and 422 HP, (incidence rate 2.9 and 12.2/100 pts/ys). At multivariable Cox analyses (HR, 95% CI), significant predictors of ESRD were male gender, younger age and lower GFR (consistent in LP and HP). Only in LP, however, P (1.28, 1.02-1.61) and lower BMI (0.96, 0.93-0.99) predicted renal risk while CVD (1.28, 1.03-1.60), HB (0.99, 0.85-0.97) and anti-RAS (0.74, 0.60-0.91) had a prognostic role exclusively in HP. A negative interaction P×Uprot was detected in HP (beta=−0.046, P=0.004). Results were consistent across cohorts.

Conclusions: In renal clinics, LP patients are prevalent and characterized by nontrivial renal risk despite higher GFR. Risk factors for HP are common; in particular, results in LP and HP suggest that lower Uprot allows full expression of the negative role of P, the effect being evident for P levels mostly normal.

FR-PO577 Trends in CKD Awareness in the U.S. Population, 1999-2012, Overall and by KDIGO Risk Groups  
Yunnuo Zhu, 1  Tanushree Banerjee, 2  Delphine S. Chiodini, 3  Luca De Nicola, 1  Giuseppe Conte, 1  Roberto Minutolo. 1  
Nephrology, Second Univ, Naples, Italy; 2  Med Stat, Second Univ, Naples, Italy.

Background: Efforts to increase awareness among providers and patients may be reaching those at greatest risk for CKD progression has increased. Recent education initiatives may be indicative of both protein stores (as indicated by LBM) and energy stores (as indicated by FM). Dietary variables are not reflective of protein or energy wasting. A modified PEW syndrome definition without the dietary variables would be a better indicator of PEW syndrome.

Funding: NIDDK Support

FR-PO578 Intermittent Abnormal Kidney Function and Mortality in Community Dwelling Individuals  
Donal J. Sexton, 1  Scott Reule, 2  Robert N. Foley. 1  Medicine, HRB Clinical Research Facility, NUIGalway, Galway, Ireland; 2  Medicine, Univ of Minnesota, Minneapolis.

Background: The health implications of persistently abnormal kidney function as measured by estimated glomerular filtration rate and spot urinary albumin excretion has been well characterized to date. However little data is available regarding the implications of intermittent abnormalities in these tests as defined by established thresholds.

Methods: We evaluated the frequency of intermittent abnormal kidney function and its association with all-cause mortality in the US general population using the National Health and Nutrition Examination Survey III, 1988-1994. Mortality linkage data were available through December 2006. Estimated glomerular filtration rate (eGFR) calculated using the CKD-EPI equation and urinary albumin-creatinine ratios (ACR) were measured twice, a mean of 17 days apart (N=1161).

Results: Proportions of abnormal tests included: for eGFR <60 ml/min/1.73m² either test 7.32%, first test 5.94%, second test 5.68%, first test only 1.64%, second test only 1.38%, both tests 4.31%. Compared to participants with eGFR ≥60 ml/min/1.73m² on both testing occasions, adjusted hazard ratios were 1.8 (95%CI 1.3, 2.4) for intermittent and 1.7 (95%CI 1.1, 2.5) for persistent abnormal eGFR. Proportions with ACR ≥30 mg/g were as follows: either test 16.54%, first test 11.63%, second test 13.35%, first test only 3.19%, second test only 4.91%, both tests 8.84%. Compared to those with ACR <30 mg/g on both occasions’ mortality hazard ratios for intermittent abnormal function was 2.1 (95%CI 1.6, 2.7), and persistent abnormal 2.0 (95%CI 1.5, 2.8). Models were adjusted for age, sex, race, diabetes mellitus, cardiovascular disease (congestive heart failure, previous myocardial infarction or stroke), current smoking, self reported hypertension, systolic and diastolic blood pressure, total cholesterol and body mass index.

Conclusions: CKD as defined by established thresholds may be persistent or intermittent in community dwelling individuals. Participants with intermittently abnormal kidney function as defined by current thresholds were at similar mortality risk to those with persistent abnormal function on both occasions.

FR-PO579 Renal Outcome of APRT Deficiency Presenting in Childhood  
Hrafnhildur L. Runolfsdottir, 1  Runolfur Palsson, 2  Iger Maria Agustsdottir, 3  Olafur S. Indridason, 2  Vidar O. Edvardsson. 1  
Medicine, HRB Clinical Research Facility, NUIGalway, Galway, Ireland; 2  Medicine, Univ of Iceland; 3  Faculty of Medicine, Univ of Iceland; 4  Div of Nephrology, Children’s Medical Center; Landspitali – The National Univ Hospital of Iceland, Reykjavik, Iceland.

Background: Adenine phosphoribosyltransferase (APRT) deficiency is an inherited disorder of purine metabolism that leads to nephrolithiasis and chronic kidney disease (CKD). ICD-9 code data are available on APRT deficiency presenting in childhood.

Methods: All patients in the APRT Deficiency Registry of the Rare Kidney Stone Consortium who presented with clinical manifestations of the disorder and/or were diagnosed with the disease before age 18 years were included in the study. Presenting features, time to diagnosis and disease course were examined. Glomerular filtration rate (eGFR) was estimated with the modified Schwartz equation in children and the MDRD equation in adults. CKD was defined as eGFR <60 ml/min/1.73 m² and acute kidney injury (AKI) according to the KDIGO criteria. Data are presented as median (range).

Results: Nineteen children presented at the age of 1.6 (0.2-16.5) years. Presenting features included reddish-brown diaper spots in 11 patients (58%), kidney stones in 8 (42%) men), lower urinary tract symptoms in 8 (42%) and AKI in 2. The diagnosis was promptly made in 7 patients, while it was delayed in 12 (63%) patients for 15.2 (0.8-39.2) years. One patient, who did not receive drug treatment, developed ESRD at age 11 years. Twelve patients were placed on allopurinol at the age of 2.1 (0.6-16.5) years. During follow-up of 18.9 (1.7-31.5) years, 3 of these patients developed 4 kidney stone events and AKI occurred in 2 patients during episodes of volume depletion; none had developed CKD. Six patients did not begin chemotherapy up to age 29.8 (20.5-42.4) years. At last follow-up, at 43.9 (32.5-56.9) years of age, 3 had experienced a total of 9 kidney stone events, 2 had suffered AKI, 3 had stage 3 CKD and one had progressed to ESRD at the age of 44 years.

Conclusions: A substantial proportion of patients with APRT deficiency present in childhood. The commonly observed delay in diagnosis and treatment may have grave implications. APRT deficiency must be excluded in all children with kidney stones, renal dysfunction and reddish-brown diaper spots.

Funding: Other NIH Support - This study was supported by the Rare Kidney Stone Consortium (U54DK088790), a part of the National Center for Advancing Translational Sciences (NCATS) Rare Diseases Clinical Research Network (RDCRN). RDCRN is an initiative of the Office of Rare Diseases Research (ORDR). The Rare Kidney Stone Consortium is funded through collaboration between NCATS and National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK).

FR-PO580

Association of Chronic Kidney Disease with Increased Risk of Recurrence of Upper Urinary Tract Urothelial Cancer – A Population-Based Study

Shang-Jyh Hwang,1 Ming-Yen Lin,1 Huei-Lan Lee,1 Wei-Ming Li,1 Chun-Nung Huang,1 Wen-Jeng Wu,1 Li-Tzong Chen,1 Sheng-wen Niu,2

1 Medical Univ Hospital, Kaohsiung, Taiwan; 2National Health Research Inst, Miaoli, Taiwan.

Background: Taiwan has significantly high incidence of upper urinary tract urothelial cancer (UTUC) and end-stage renal disease (ESRD). UTUC coexisted with chronic kidney disease (CKD). CKD may deteriorate cancer progression and increase mortality risk. The aim of study was to explore the association of CKD with the risk of UTUC recurrence.

Methods: We conducted a population-based cohort study through Taiwan National Health Insurance Research Dataset. Incident UTUC patient was extracted from Taiwan Cancer Registry Dataset and linked to data status of CKD including non-dialysis CKD, dialysis ESRD, and renal transplant were identified before the index date of UTUC. Recurrence was defined as either new tumor lesion in bladder, or at the other site of urinary tract, or occurrence of distant metastasis within 3 months after first surgery. Differences of characteristics between CKD and non-CKD group was described as mean ± standard deviation or percentage and tested by independent t test and chi-square test. Competing risk approach was used for estimating cause-specific hazard ratio (CSRHR) and 95% confidence interval (CI).

Results: Totally, 4,002 UTUC patients from 2001 to 2005 were included and tracked until disease recurrence or end of 5 years after the index date of UTUC. Near half patients accompanied with various stages and status of CKD at index date. UTUC patients with CKD were younger, more female, and had more co-morbidities than patients without CKD. After adjusting factors of age, tumor grade, and co-morbidities, CKD significantly increased risk of UTUC recurrence in female (CSRHR: 1.72, 95%CI: 1.13-2.61, p=0.001), but not in male (CSRHR: 0.91, 95%CI: 0.44-1.86, p=0.79).

Conclusions: CKD increases risk of recurrence in female UTUC patient and is an important prognostic indicator.(This study was granted by the Ministry of Science and Technology(NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124-003, budget from health and welfare surcharge of tobacco product.)

Single Centre Experience of Late Referral and Achievement of Useable Dialysis Access Over a 9-Year Period

Mohamed Salah Eldin Khogali,1 Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom; Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom.

Background: We describe a single centre, retrospective analysis of late (≤ 90 days) referral for dialysis over a 9 year period from April 2003 till March 2012. Factors that contributed to late referral and success in creating permanent dialysis access were determined.

Methods: Data on adult patients referred ≤ 90 days from dialysis were collected including patient demographics, source of referral, mortality, reason for late referral, creation of permanent dialysis access and use of permanent dialysis access at first dialysis.

Results: One hundred and twenty-seven patients were referred in ≤ 90 days over the 9 year period. Ninety-nine (78%) patients were referred within 30 days prior to dialysis and 39 (22%) patients within 30 – 90 days. Their median age was 63 years and 90 (63%) patients were male. Twenty-five (20%) patients were diabetic. Forty (33%) patients died within the first year after referral, 25 (21%) patients within the first 6 months and 15 (12%) patients between 6 months and 1 year (figure1). Sixty-five patients (51%) presented late due to acute renal failure (myeloma 24, vasculitis 14, irreversible acute kidney injury 10, renal cell carcinoma 5, glomerulonephritis 3 and others 9). Twenty-nine patients (23%) referred by physicians and surgeons, and 24 patients (19%) referred by GPs were late referrals of patients with known chronic renal failure. Nine patients (7%) presented late due to lack of understanding of their disease, denial, and fear of the unknown. One hundred and ten patients had permanent dialysis access created and 17 patients no permanent access procedures. The average time to create permanent dialysis access was 44 days post-dialysis commencement. Six permanent haemodialysis access were created pre-dialysis, 56 post-dialysis; 19 peritoneal dialysis accesses were created pre-dialysis, 29 post-dialysis.

Conclusions: Overall the number of patients presenting late for dialysis has decreased. Late referral has a poor 1 year survival and most patients require haemodialysis long-term. Only a minority of patients referred late have permanent dialysis access created and used at their first dialysis.

FR-PO582

Abnormal Global Glomerular Sclerosis Rate in Remnant Kidney of Ipsilateral Nephrectomy is Associated with Higher Risk of End-Stage Renal Disease Within Five Years in Patients of Upper Urinary Tract Urothelial Cancer

Sheng-Chen Sheng,1 Sheng-Chen Sheng,1 Pei-Lin Liang,1 Shih-Mong Yeh,1 Ming-Yen Lin,2 Shang-Jyh Hwang,2 Wen-Jeng Wu,1 Kaohsiung Medical Univ, Taiwan; 2National Health Research Insts.

Background: Astrocytic acid in Chinese herbs induce renal tubulointerstitial disease and increase the risk of upper urinary tract urothelial carcinoma(UTUC). However, we are still not sure if UTUC itself has impact on renal outcome. We studied the pathological changes of remnant kidney tissue from UTUC patients post ipsilateral nephrectomy to investigate the correlation between renal histopathology and outcome of end-stage renal disease.

Methods: This cohort study included 132 cases of non-dialysis UTUC patients post ipsilateral nephrectomy from 2002 to 2010. We collected clinical and laboratory data before surgery, tumor size, whether into dialysis after surgery, and followed up to dialysis or to December 31, 2014. Renal histopathology was read by 3 specialists: nephrologists or pathologist. We used logistic regression for studying tubulointerstitial fibrosis score and global glomerular sclerosis (GGS) rates and Cox regression to investigate factors associated with renal survival.

Results: There was no significant factor associated with tubulointerstitial fibrosis, but advanced CKD was significantly related to GGS rate adjusted with age and gender [OR(95%CI): 4.8(1.4-16.9), p=0.014]. Kaplan-Meier survival curve showed five-year renal survival rate was 86.3%. Factors affect five-year renal survival were hypertension [HR(95%CI): 4.0(1.1-15.2), p=0.043] and GGS rate [HR(95%CI): 17.4(2.4-124.1), p=0.004].

Conclusions: Our findings demonstrated that UTUC patients with hypertension before surgery or abnormal GGS rate in remnant kidney have higher risk of entering dialysis within five years post ipsilateral nephrectomy.(This study was granted by the Ministry of Science and Technology(NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare(MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124-003, budget from health and welfare surcharge of tobacco product).)

Figure: Longitudinal measures of mean of GFR around time of TIPS procedure.

*p<0.001, **p<0.0001

GFR improved by 16 (11, 21) ml/min from pre-TIPS to 90 days after TIPS (p<0.0001). Comparison of Tertiles 1, 2, and 3 showed respectively: GFR increased by T1: 6 (1, 14), T2: 22 (15, 30), and T3: 22 (12, 33) ml/min (p = 0.006); 90-day mortality was T1: 20%, T2: 17%, and T3: 49% (p = 0.007); encephalopathy rate at 90 days was T1: 21%, T2: 42%, and T3: 65% (p = 0.0005).

Conclusions: There was a significant improvement in GFR from pre-TIPS to 90 days after TIPS. Those with the lowest GFRs at the time of TIPS had greater improvement in renal function but also had higher 90-day mortality and encephalopathy rates post-TIPS.

The Epidemiic of Chronic Kidney Disease in Rural and Remote Canadian First Nations: Results from Manitoba’s FINISHED Screening Program

Paul Komenda,1,2 Barry Ad Lavallee,1 Thomas W. Ferguson,1 Navdeep Tangri,1 Allison Dart,1 Bing Hu,1 Audrey Gordon,2 Caroline D. Chartrand,2 Lorraine L. McLeod,1 Claudio Rigatto,1,3 Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 2Diabetes Integration Project, Winnipeg, MB, Canada; 3Conventions Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; 4Seven Oaks General Hospital Research Centre, Winnipeg, MB, Canada.

Background: Chronic Kidney Disease (CKD) is a global epidemic affecting 10-15% of the general population. Canadian First Nations children and young adults are known to suffer from a high rate of proximate risk factors for CKD, in particular elevated rates of diabetes. The rates of CKD are not well defined in this population. We used data from The First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) project, a 3-year initiative completed in 2017 that accomplished community wide screening in 11 rural and remote First Nations communities in Manitoba, Canada.

Methods: Detailed methods of the FINISHED study have been previously published (Lavallee et al. CJRKH, 2015). An interdiscipliary team screened for CKD in adults and children aged 10+ using both urine albumin-to-creatinine ratio (ACR) and eGFR in 11 communities across 2 tribal councils. We present here the data on demographic variables, risk factors for CKD, and the prevalence and severity of CKD in the adult (age 18+) screening cohort.

Results: 3346 adults were screened. 26.7% of those screened had CKD defined as elevated urine ACR (micro- or macroalbuminuria) or eGFR < 60 ml/min/1.73m2. Road access communities had a lower prevalence of CKD (18.4%) than remote air access communities (36.0%). Macroalbuminuria (urine ACR > 300 mg/g) was present in 5% of those screened (2.8% in road access and 7.5% in air access communities).

Conclusions: Rural and remote Canadian First Nations suffer up to a 3-fold higher prevalence of CKD than the general population and a nearly 5-fold higher prevalence of macroalbuminuria. This prevalence is comparable to high-risk populations such as those with diabetes and CHF. Given the risk and treatment interventions may be cost-effective, as they have been shown to be in other high-risk populations.

Age and Gender Specific Lifetime Risk of Renal Replacement Therapy

Jan A.J.G. van den Brand,1 Maria Pippaars,1 Vianda S. Stel,2 Jack F. Wetzels,1 Kitty J. Jager,2 Dept of Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; ERA-EDTA Registry, Academic Medical Centre Univ of Amsterdam, Amsterdam, Netherlands.

Background: Kidney transplantation is the preferred treatment of end stage renal disease (ESRD). Craft and patient survival are highest after transplantation with a graft from a living donor. However, persons who donate a kidney are themselves at risk of ESRD. Personalized risk prediction requires age and gender specific risk estimates. Here, we report lifetime risk of renal replacement therapy (RRT) for ESRD by age and gender across Europe.

Methods: We defined ESRD as chronic RRT and age 80 as the lifetime horizon. Death was considered a competing event. We obtained RRT incidence rates by age and gender from the ERA-EDTA Registry. Mortality rates were calculated from census data provided up and data linkage.

Results: At index age 20, lifetime RRT risk for females ranged between 0.40% and 0.87% across countries, and for males between 0.77% and 1.59%. At age 60, lifetime RRT risk ranged between 0.26% and 0.68% for females and 0.56% and 1.32% for males. Pooled lifetime RRT risks using inverse variance weighted means. Gender for countries providing individual patient data to the ERA-EDTA Registry. We defined ESRD as chronic RRT and age 80 as the lifetime horizon. Lifetime RRT risk differs across Europe. Women are at lower risk compared to men. These data offer a basis to provide personalized prediction of lifetime ESRD risk when evaluating a potential kidney donor. The estimates presented here are population averages. We expect that lifetime risk is lower in persons with normal eGFR and no albuminuria.

Conclusions: Lifetime RRT risk differs across Europe. Women are at lower risk compared to men. These data offer a basis to provide personalized prediction of lifetime ESRD risk when evaluating a potential kidney donor. The estimates presented here are population averages. We expect that lifetime risk is lower in persons with normal eGFR and no albuminuria.

Subclinical Pulmonary Congestion Is Pervasive in Nephrotic Syndrome
Francesca Mallamaec,1,2 Francesco Marino,3 Carmela Martorano,2 Rocco Tripepi,1 Marianna Bellantoni,1 Giovanna Tripepi,1 Carmine Zoccali,1,2 National Research Council of Italy, Inst of Clinical Physiology, Reggio Cal, Unit, CNR-IFC, Reggio Calabria, Italy; Nephrology, Transplantation and Hypertension Unit United Hospitals, Reggio Calabria, Italy.

Background: In patients with Nephrotic Syndrome (NS) the lung is considered as an organ protected from the risk of edema. However information on objectively measured lung water in NS patients is lacking.

Methods: We measured lung water with an ultrasonic technique (US) and with standard transthoracic impedance in an incident series of 42 asymptomatic patients with active NS. Eleven patients were studied during NS remission. Twenty-one healthy volunteers formed the control group. US lung studies were performed after 5 and 60 minutes of supine resting and after 5 minutes of standing. Transthoracic impedance was measured after 30 min of supine resting only.

Results: In patients with active NS the median number of US-B lines (a metric of lung water) after 5 min in supine position was markedly higher [12; Interquartile range: 7-25; p<0.001] than in healthy subjects [4; 2-9]. The difference between patients [16, 11-35] and controls [4; 2-9] amplified (p<0.001) after 60 min of supine resting and attenuated after 5 min of standing [9; 7-25 vs 4; 3-5, p=0.001]. After NS remission, the number of US lines reduced to 5 (4-18) at 5 min and to 6 (5-22) at 60 min (p=0.001) approaching the normal range. Lung congestion in patients with active disease was fully confirmed by transthoracic impedance measurements (p<0.001 vs healthy controls).

Conclusions: Asymptomatic pulmonary congestion is pervasive in patients with NS. A clinical trial is needed to assess the usefulness of the application of this technique for the management of patients with NS.

FR-PO589
The Incidence of Malignancies prior to the Diagnosis of ANCA-Associated Vasculitis (AAV) Is Not Increased in Comparison to the Incidence in the General Population
Emma Elisabeth Van Daalen,1 Chinar Rahmattulla,1 Ron Wolterbeek,2 Jan A. Bruijn,1 Ingeborg M. Bajema,1 Pathology, Leiden Univ Medical Center, Leiden, Netherlands; 2Medical Statistics and Bioinformatics, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Several studies have found an increased malignancy risk before the diagnosis of AAV, especially in granulomatosis with polyangiitis (GPA), whereas data on microscopic polyangiitis (MPA) are scarce. It has been hypothesized that malignancies and AAV have common pathways in their pathogenesis (Ann Rheum Dis 2004, Rheumatology 2009). We studied the malignancy risks in patients before their AAV diagnosis to further elucidate this hypothesis.

Methods: We retrospectively retrieved data on 138 patients with biopsy-proven AAV diagnosed in the Netherlands. Malignancies prior to AAV diagnosis were identified using the Dutch National Pathology Database. The malignancy incidence was compared to the incidence in the general population, as reported by the Netherlands Cancer Registry. The Standardized Incidence Ratios (SIRs) were calculated, matching for gender, age and calendar time period. Separate analyses were performed for GPA and MPA.

Results: Twelve patients were diagnosed with cancer before the AAV diagnosis (mean follow-up: 11.8 years). Overall malignancy risk was not increased (SIR: 0.92, 95%CI: 0.62-1.35). GPA patients had higher malignancy risk compared to MPA (SIR: 1.76, 95%CI: 1.24-2.54 vs SIR: 0.87, 95%CI: 0.52-1.49, p=0.01).

Conclusions: Our study indicates that the malignancy risk before the diagnosis of AAV is not increased compared to the general population.

FR-PO590
Gastrointestinal Symptoms and Hypoalbuminemia in Chronic Kidney Disease Patients
Xuehan Hsu,1 Xuehan Hsu,1 Nisha Bansal,2 Alan S. Go,2 Chi-yuan Huang.1,2 1Peking Union Medical College Hospital; 2Univ of California-San Francisco; 3Univ of Washington; 4Kaiser Permanente Northern California.

Background: Hypoalbuminemia is an important risk factor for adverse outcomes in patients with CKD. Little is known about the relationship between gastrointestinal (GI) symptoms and serum albumin level in CKD.

Methods: This is a cross-sectional study of participants (N=3599) in the Chronic Renal Insufficiency Cohort (CRIC) study which collected information regarding potential uremic symptoms. For each of the 4 following symptoms: “bad taste in your mouth,” “loss of appetite,” “nausea,” “vomiting,” we created a severity score by multiplying the number of symptoms and serum albumin level. We compared the GI symptom score with serum albumin and other potential CV risk factors.

Results: The mean eGFR was 42.9±13.4ml/min/1.73m², and serum albumin level was 3.95±0.46 g/dl. 1702 subjects had one or more symptoms. Patients with lower eGFR were more likely to have GI symptoms.

Conclusions: Increased prevalence of GI symptoms become apparent among CKD patients at relatively high eGFR levels (45 ml/min/1.73m²). These symptoms correlated with important nutritional parameters.

FR-PO591
Obstructive Lung Function in CKD: NHANES 2007-2012
Sankar D. Navaneethan,1 Susana Arreguin,1 Mahboob Rahman,3 Jesse D. Schold.2 1Cleveland Clinic; 2CWRU.

Background: Lung diseases are one of the leading causes of death in the general population. We aimed to study the prevalence of obstructive lung function in those with CKD. In addition, factors associated with obstructive lung function were examined.

Methods: Participants aged 20-79 years from the National Health and Nutrition Examination Survey (NHANES) 2007-2012 who underwent spirometry testing using similar protocols were included in this analysis. Global Initiative for Chronic Obstructive Lung Disease classification of COPD (FEV1/FVC <0.7) based on post-bronchodilator spirometric results was used to establish the prevalence of obstructive lung function with adjustment for non-response to spirometry. CKD was defined as presence of eGFR <60 ml/min/1.73 m² and/or UACR >30 mg/g. Factors associated with obstructive lung function were identified using logistic regression model for the entire cohort, CKD and non-CKD groups separately (using baseline spirometry).

Results: Out of 11,995 participants (CKD=1563; Non-CKD=10,432) who completed the baseline spirometry testing, 1,086 participants were eligible for both and only 1049 complete post-bronchodilator spirometry. Prevalence of obstructive lung function using baseline spirometry data were 25% in CKD and 13% in non-CKD and GOLD criteria were 17% in CKD and 8% in non-CKD. Each 5 ml/min lower eGFR and proteinuria were associated with higher odds of having obstructive lung function in the entire cohort.

Table: Factors associated with obstructive lung function in the study cohort

Old age, white race, smoking and self-reported COPD were associated with obstructive lung function in both CKD and non-CKD groups.

Conclusions: In this representative cohort of US population, prevalence of obstructive lung function is higher in those CKD. Lower eGFR and proteinuria are associated with obstructive lung function. Further studies examining the impact of lung diseases in CKD are warranted.
FR-PO592
Association of Serum Osteoprotegerin with Bone Loss in Chronic Kidney Disease
From the KNOW-CKD Study - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Chronic kidney disease (CKD), a condition associated with increased risk of bone fracture and mineral and bone disorder.

Results: BMD at the lumbar spine, total hip and femur neck was assessed by dual energy X-ray absorptiometry; and serum OPG was measured at baseline in 1,423 CKD patients in the prospective Korea/N Cohort Study for Outcome in Patients With Chronic Kidney Disease. Osteoporosis was defined to T score ≤ -2.5 in patients aged over 50.

Conclusion: Serum OPG was significantly associated with increased lumbar BMD (lumbar spine, total hip and femur neck) compared with the lowest quartile of serum OPG. Multivariable linear regression model indicated that serum OPG was independently associated with decreased lumbar spine and total hip BMD (B=-0.489; 95% confidence interval [CI], -0.883 to -0.095; P=0.015, B=-0.349; 95% CI, -0.672 to -0.027, P=0.027, respectively), but femur neck was not associated with serum OPG in women.

Conclusion: Serum OPG was independently associated with lumbar spine and total hip BMD and increased risk of osteoporosis in female CKD patients. However, these associations were not found in male CKD patients.

FR-PO593
Growth in Children with Chronic Kidney Disease: A Report from the KNOW-Ped CKD (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease) - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Background: Growth impairment is common in children with chronic kidney disease (CKD) with profound and psychosocial impact. We investigated the characteristics of growth in Korean children with CKD.

Methods: Clinical characteristics along with anthropometric measurements were examined in subjects of KNOW-Ped CKD, Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease. Findings of 322 children (M:F 218:104), who were enrolled to the study from July 2010 to December 2013 in seven major pediatric nephrology centers of Korea, were analyzed to investigate the characteristics of growth in Korean pediatric CKD.

Results: Mean height- and weight- z scores of Korean pediatric CKD patients were -0.88±1.43 and -0.91±1.65. Mean BMI-z score was -0.36±1.25. Height deficit was observed from early stage of CKD with mean height z-score -0.42 in CKD stage I. Short stature (z score < -1.88, 20% of the subjects) and overweight (z score > 1.65, 28% of the subjects) was associated with female sex, age younger than 2-year-old at enrollment, co-morbidity, and advanced CKD stage. Low BMI was associated with high blood pressure, co-morbidity and younger age. The final height-z score was -0.86±1.19, which is shorter than predicted adult height-z score (-0.33±0.7) calculated from their parent's height.

Conclusion: Growth failure is one of the most important complications in pediatric CKD patient. More profound height, weight and BMI impairment were associated with younger age and co-morbidity. Children with these findings need close attention on their growth and may require earlier intervention to avoid severe growth impairment.

FR-PO594
Risk of Early Preterm Delivery in Pregnant CKD Patients – A Model for Counseling - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Background: Chronic kidney disease (CKD), whose prevalence almost equals pre eclampsia in pregnancy, increases the risks of adverse pregnancy outcomes; the degree is only partially known.

Methods: Objective: Development and internal validation of a prediction model to quantify the risks of early preterm delivery (<34 gestational weeks) selected as most relevant outcome in pregnant women with CKD. We developed the model in CKD women. A homogeneously followed-up, low-risk pregnancy population served as controls. Sixteen of the largest Italian Outpatient Units dedicated to the multidisciplinary follow-up of CKD in pregnancy. Patients: Pregnant women with CKD: 503 live-born singletons in CKD; 835 low-risk controls (2000-2013). Measurements: Outcome: early pre-term delivery. The candidate variables were readily measurable, available, inexpensive (hypertension, proteinuria, kidney disease and function). Bootstrapping was used for internal validation.

Results: Early preterm delivery was more frequent in CKD (12.5%) vs controls (1%) (p=0.0001). The most parsimonious model (Likelihood ratio test p=0.0001; McFadden’s pseudo R²=0.2290) summarized various combinations of CKD stages, hypertension and proteinuria and defined a scale of risk. First step included CKD stage1, normotension and proteinuria<1g/24h (OR:2.8); second step included CKD stages 2-5 without hypertension and proteinuria, and CKD stage 1 with either hypertension or proteinuria (OR:19.5 and 20.9); third step included CKD stages 2-5 with either hypertension or proteinuria (OR:44.7); the combination of hypertension and proteinuria was associated with the highest risk, but the low number of cases prevented precise quantification. Limitations: the study was performed in two Centers only. The number of cases with severe CKD is small.

Conclusion: The model may support counselling and clinical management by grading the risk for adverse pregnancy outcomes. Further studies are needed to externally validate the model.

FR-PO595
Thiamine Deficiency in Non-Dialysis CKD Patients - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Background: Thiamine deficiency is associated with malnutrition, alcoholism and chronic diseases such as cancer. Long use of diuretics also induces thiamine deficiency, which is due to an increased urinary loss of thiamine. Some papers report that thiamine tend to accumulate because of decreased urinary flow in chronic kidney disease (CKD) patients. Others report that a protein restricted diet causes thiamine deficiency in CKD patients. This study aimed to examine the prevalence and factors associated with thiamine deficiency in CKD patients.

Methods: This is a single center cross-sectional study in patients with non-dialysis CKD under regular follow-up in nephrology center of Chubu Rosai Hospital from July 1, 2014 to January 31, 2015. The patients who meet the CKD criteria of Japanese Society of Nephrology were selected. We use the data collected from medical records, questionnaires and nutrition surveys.

Results: The study population consisted of 149 patients aged 71.2 ± 10.9 years with estimated glomerular filtration rate (eGFR) of 33.2 ± 18.2 (ml/min/1.73m²). These were divided into two thiamine groups ( serum thiamine level<30ng/ml ) and high thiamine group ( serum thiamine level≥30ng/ml ). In univariate comparisons, patients with low thiamine group had significantly lower protein intake which is estimated by the nutrition survey. The use of loop diuretics was not associated with thiamine deficiency. In multivariate analyses, high age, low eGFR and low protein intake, especially less than 0.8g/kg, were independently associated with thiamine deficiency.
FR-PO597
Controlled Attenuation Parameter Measured by FibroScan Is Closely Associated with Metabolic Syndrome in Patients with Chronic Kidney Disease

Mee-Yan Wu,1 Sul A Lee,2 Chang-Yun Yoon,2 Taek Chang,1 Shin-Wook Kang,1,2 Tae-Hyun Yoo,1,2 1Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.

Background: Hepatic steatosis can be determined by the measurement of liver controlled attenuation parameter (CAP) using FibroScan. Although the practical methods predicting the risk of metabolic syndrome (MS) development are lacking, recent studies represent that this parameter is closely correlated with the presence of MS in the general population. Therefore, we investigated whether CAP measured by FibroScan could predict the presence of MS in chronic kidney disease (CKD) patients.

Methods: A total of 468 CKD patients were evaluated. MS was defined by using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Multivariate logistic regression analysis was used to identify the independent association between CAP and MS.

Results: The mean age of the patients was 57.5 years and 225 patients (48.1%) were male. The mean value of CAP was 241.7 dB/m. CAP was independently associated with body mass index (β=0.7818, P<0.001), triglyceride (β=0.246, P=0.002) and estimated glomerular filtration rate (eGFR) (β=-0.581, P=0.005). MS was diagnosed in 142 (30.3%) patients. In patients with MS, diabetes was more prevalent (59.9 vs. 25.8%, P<0.001), hemoglobin (13.1±2.4 vs. 12.6±2.1 g/dL, P=0.026) and CAP (262.0±60.6 vs. 232.9±49.0 dB/m, P=0.001) levels were significantly higher, while eGFR (82.9±27.5 vs. 91.6±26.0 mL/min/1.73m², P=0.001) was lower compared with patients without MS. Multivariate logistic regression analysis revealed that high CAP levels were independently correlated with the increased risk of MS (per 1 dB/m increase, odds ratio=1.010, 95% confidence interval=1.002-1.018, P=0.014) after adjustment for confounding factors.

Conclusions: High CAP levels measured by FibroScan were significantly associated with an increased risk of MS in CKD patients. These data suggests liver FibroScan could be a practical method for evaluating the risk of MS development in CKD patients.

FR-PO598
Outcomes in Women Switched from Mycophenolate to Azathioprine in Advance of Pregnancy

Kate S. Wiles,1 Adam D. Jakes,2 Asta Alwindi,1 Kate Bramham,1 Paramit Chowdhury,1 Lucy C. Chappell,1 Catherine Nelson-piercy,1 Liz Lightstone.2 1Guy’ s and St. Thomas’ NHS Foundation Trust; 2Imperial College London.

Background: Mycophenolate is teratogenic and should be replaced in advance of pregnancy. The aim of this study was to determine the risk of adverse outcome in women switched from mycophenolate to azathioprine.

Methods: Records of women attending regional renal pre-pregnancy counselling clinics 2011-2014 were examined. Women taking mycophenolate were included and the decision to switch to azathioprine reviewed. Outcomes were a decline in eGFR within a year, renal biopsy, disease flare or rejection, and conversion back to mycophenolate. Pregnancy outcomes were analysed.

Results: Data were available for 60 women (31 kidney transplant, 4 kidney-pancreas transplant and 25 glomerulonephritis, predominantly lupus). Most women were considered eligible for a switch to azathioprine and one woman chose to switch against advice.

Conclusions: Protein intake is an important factor for thiamine levels of CKD patients. Protein restriction for CKD patients especially with high age and low eGFR have a high risk of thiamine deficiency.

FR-PO599
Chronic Kidney Disease Linearly Predicts Outcomes After Elective Total Joint Arthroplasty

Michael J. Fielding,1 Timothy L. Tan,2 Dean D. Tan,2 Michael M. Kheir,1 Antonia F. Chen.1 Medicine, Thomas Jefferson Univ, Philadelphia, PA; 2Orthopedics, Thomas Jefferson Univ.

Background: Kidney disease has been widely associated with increased complications in total joint arthroplasty (TJA). The purpose of this study is to determine the association of kidney disease severity as measured by the chronic kidney disease (CKD) staging system with complications and outcomes after TJA.

Methods: A retrospective review of an institutional database of 12,308 primary TJAs (6,301 hips and 5,947 knees) from 2008 to 2013 was performed. The following preoperative variables were obtained from medical records: chemistry 7 panel, Elixhauser comorbidities, and demographic factors. CKD stages were defined based on estimated glomerular filtration rate in ml/min/1.73m² (eGFR): (1) < 90, (2) 60-89, (3A) 45-59, (3B) 30-44, (4) 15-29, and (5) < 15. Multivariate analysis was performed to assess the independent influence of CKD stage on the aforementioned endpoints.

Results: Patients with CKD stage greater than 2 demonstrated an increased risk of transfusions (CKD 3A odds ratio [OR]: 1.67, CKD 3B OR: 2.80, CKD 4 OR: 2.24), length of stay greater than 3 days (CKD 3A OR: 1.34, CKD 3B OR: 1.39, CKD 4 OR: 3.57), and in-hospital complications (CKD 3A OR: 1.21, CKD 3B OR: 1.80, CKD 4 OR: 3.36) compared to all patients with eGFR > 60. Additionally, the relationship between eGFR and the above complications were found to increase linearly rather than exponentially at a certain threshold. In contrast, CKD stage was not associated with septic or aseptic revisions.

Conclusions: Severe CKD is associated with an increased risk of transfusion, length of stay, and in hospital complications. Rather than finding a clear threshold, complications increased linearly with disease severity. Surgeons should be cognizant of this increase when evaluating TJA patients with renal disease.

FR-PO600
The Assessment of Incidental Risk for Microalbuminuria According to the Level of Depression Scale

Joon Yung Lee,1 Youngji Jung,1 Beom Kim,2 Kyoung Hyoub Moon,1 Sung Keun Park.2 1Internal Medicine, VHS Medical Center, Seoul, Korea; 2Total Health Care, Kangbuk Samsung Hospital, Seoul, Korea.

Background: Depression is one of the most common psychiatric disorders. The presence of depression for prediabetes goes beyond function and extends to somatic health. A growing body of evidence shows that depression is significantly associated with chronic kidney disease. Nonetheless, the incidental relationship between microalbuminuria and depression was not identified yet. Therefore, we conducted this study to investigate incidental relationship of microalbuminuria with depression scale.

Methods: This study was conducted for 45,293 Korean men and their spouses without microalbuminuria who got medical health check up in Kangbuk Samsung Total healthcare center in 2010. To assess the degree of their depression, Center for Epidemiologi Studies-Depression Scale (CES-D) was used (CES-D ≤ 15: normal, CES-D 16-20: moderate risk group, CES-D > 21: high risk group). On the basis of CES-D score in 2010, they were classified into 3 groups (normal, moderate, high risk group) and monitored for the development of microalbuminuria from January, 2011 to April, 2015.

Results: While the general incidence was 1.7%, the incidence of microalbuminuria increased in proportion to the risk score of depression evaluated by CES-D (CES-D ≤ 15: 0.4%, CES-D 16-20: 1.8%, CES-D > 21: 3.6%). When the hazzard ratio (HR) of normal group (CES-D < 15) was set to reference value (HR: 1.00), the HRs for microalbuminuria also increased according to the score of CES-D scale. In addition, these associations were preserved even after adjustment for the various metabolic covariates such as age, physical activity, total cholesterol, LDL-cholesterol, triglyceride, body mass index, and obesity (CES-D 16-20: 1.98, CES-D > 21: 3.37).

Conclusions: Our study showed that the risks of microalbuminuria in proportion to the severity of depression. These findings imply the clinical role of the depression for
FR-PO601

Outcomes in CKD Patients with Hospital Acquired Complications
Babak Bohlouli,1 Terri Jurgens Jackson,2 Marcello Tonelli,3 Scott Klarenbach.1
1Medicine, Univ of Alberta, Edmonton, AB, Canada; 2Northern Clinical Research Centre, Univ of Melbourne, Epping, Vic, Australia; 3Medicine, Univ of Calgary, Calgary, AB, Canada.

Background: Patients with CKD are at increased risk of hospital acquired complications (HACs) including those considered preventable. The impact of HACs on patient and health system outcomes has not been well described.

Methods: Subjects hospitalized from April 1, 2003 to March 31, 2008 from a population based cohort (Alberta Kidney Disease Network) were studied. Outpatient eGFR and proteinuria (protein/creatinine ratio or dipstick) in the year prior to index hospitalization were used to define CKD status. Co-morbid conditions were identified using validated algorithms applied to administrative data. ICD 10 CA was used to classify reason for admission. A specific diagnostic indicator (type II) was used to identify hospital acquired complications (HACs) that were sub-classified as “potentially” and “always” preventable.

We studied the following outcomes: re-admission within 90 days of discharge, all cause mortality at 90 days, and index hospitalization costs. Multivariable regression models examined the association of HACs with re-admission, mortality, and incremental health care costs, accounting for confounders.

Results: Of 536,549 subjects, 45,377 (8.5%) with CKD were hospitalized. In patients with HACs, the OR of re-admission and death at 90 days was 1.37 (95% CI: 1.32 – 1.43), and 3.11 (95% CI: 3.06 – 3.58) respectively compared with those without HAC. Hospitalizations with any HAC were associated with incremental health costs of $4028 (95% CI: $3898 – $4158). A graded association was observed for those outcomes with increasing number of HACs and severity of CKD. Similar results were noted when only potentially preventable HACs were considered.

Conclusions: Complications occurring during hospitalization in patients with CKD is independently associated with an increased risk of hospital re-admission, health care costs, and mortality. Targeted strategies to reduce HACs in this patient population may have a significant benefit.

FR-PO602

Plasma Proteins Associated with Declining Renal Function in Patients with Type 1 Diabetes: Results of a Global Proteomic Analysis Using SOMAscan Platform
Andrew L. Schlaff, Monika A. Niewczas, Marcus G. Pezzolesi, Andzej S. Krolewski. Joslin Diabetes Center, Boston, MA.

Background: Increases in serum creatinine and cystatin C are considered measures of declining renal function in patients with diabetes.

Methods: To search for other proteins correlated with declining renal function, we conducted a follow-up study, following 30 patients with T1D and proteinuria for 1-3 years. Mean eGFR was 67 ml/min at baseline, and was 59 ml/min at the end of follow-up. Plasma proteins and circulating proteins were measured on the SOMAscan platform at baseline and at the end of follow-up. The platform measured 954 proteins for each of the 30 patients, with median limit of detection (LOD) of 1.6pg/mL,dynamic range of 8 logs, and median coefficient of variation (CV) of 5% for individual proteins measured repeatedly in replicate runs of plasma samples.

Results: Renal function change during follow-up in each patient was expressed as the difference between eGFRcre at baseline and at follow-up and was referred to as ∆eGFR (mean: -7.7 ml/min, range: -44 ml/min to 11 ml/min). For each protein, the Spearman rank correlation coefficient between ∆eGFR and the percent change in the protein’s level (RFU) was calculated. The protein’s association with renal function decline was used to measure the protein’s association with renal function decline. In 27 proteins, concentrations increased with decreasing renal function (r: -0.67 to -0.46, p<0.01). In 16 proteins, concentrations decreased with decreasing renal function (r: 0.46 to 0.57, p<0.01). The top 5 proteins in each category are shown below.

Conclusions: In conclusion, increasing or decreasing concentrations of plasma proteins with eGFR loss may reflect worsening renal function, as is the case with cystatin C. However, changes in plasma concentration of these proteins may represent the extent and intensity of the disease process underlying progressive renal decline, which is most likely the case with IL-17F and the TNFR’s. Mass Spectrometry Imaging Reveals Disease Specific Alterations in Protein Abundance in Human Diabetic Nephropathy
Haichun Yang,1 Audra M. Judd,2 Michelle Reyzer,3 Jeremy L. Norris,4 Richard M. Caprioli,2 Raymond C. Harris,3 Agnes B. Fogo.1 1Pathology, Microbiology and Immunology, Vanderbilt Univ; 2Mass Spectrometry Research Center, Vanderbilt Univ; 3Nephrology, Vanderbilt Univ; 4Nashville, TN.

Background: Diabetic nephropathy (DN) is a major complication in diabetic patients. However, protein expression and function in diabetic kidney disease has not been well characterized.

Methods: DN biopsies (n=36) and normal kidney (n=9) were assessed. DN cases were divided into mild, moderate and severe, based on biopsy findings. Follow-up was available in 23 patients, and patients were sub-grouped into stable DN (decreased eGFR >50%, n=10), progressive DN (decreased eGFR ≤50%, n=13) vs. progressive DN (decreased eGFR >50%, n=10). Peptide mass peaks were acquired over the mass-to-charge range 600-4500 from at least 12 glomerular areas per case.

Results: DN patients had reduced eGFR and increased proteinuria, compared to normal. Mass spectrometry showed 168 peptide peaks, with 8 peaks increased and 21 peaks decreased in DN compared to Normal. Moderate and severe DN showed more nodular glomerulosclerosis than mild DN by study design (moderate 2.1±0.10, severe 2.17±0.22 vs. mild 0.43±0.30, 0.4-8 scale, p<0.05) and mesangial expansion (moderate 1.97±0.09, severe 2.28±0.15 vs. mild DN 1.21±0.15, p<0.05). Peptide maps were more similar in moderate vs severe DN groups, compared to mild DN. Thirteen of 168 peptide peaks were significantly different between DN groups.

Conclusions: We conclude that different peptide maps correlate with DN onset, severity and progression, and that clinical and morphological phenotypes have heteroproteomic correlates. These peptides will now be further validated and identified by MS/MS fragmentation and database searching. Funding: NIDDK Support

Urine Metabolomic Profiling Reveals a Unique Signature for Type 2 Diabetes
Jane J. Kim, Rintaro Saito, Satoshi Miyamoto, Minya Pu, Loki Natarajan, Kumar Sharma. Univ of California, San Diego.

Background: Increasing circulating branched chain amino acids (BCAAs) are associated with type 2 diabetes (T2D) and insulin resistance. However, it is not clear whether increased plasma BCAA concentrations result from increased synthesis, or impaired degradation or excretion. Here, we employ a targeted metabolomics approach to evaluate diabetic patients without overt kidney disease to identify urine metabolites associated with T2D, presenting potential urine biomarkers for clinical prediction and further insight into disease pathogenesis.

Methods: We measured 105 urine metabolites by GC/MS in a screening T2D cohort (n=27), validation T2D cohort (n=14), and healthy control group (n=23). We also examined kidney cortex of db/db and control db/n mice to measure gene expression by Illumina miRNA and protein expression by western blot.

Results: Following FDR correction, 57 metabolites were found to be different in the screening cohort compared to controls. When these 57 metabolites were carried forward for analysis in a validation T2D cohort, 24 of these urine metabolites were confirmed to be different from controls using Bonferroni adjustment for multiple comparisons. 16 of the 24 validated metabolites were amino acids, and 8 of these represented BCAA degradation products. To further investigate BCAA metabolism, we examined kidney tissue from db/db mice and found that the gene expression of key enzymes related to BCAA catabolism was decreased. Western blot studies confirmed that renal expression of branched-chain ketoacid dehydrogenase, a mitochondrial enzyme complex that catalyzes an irreversible step in BCAA catabolism, was reduced in db/db mice compared with controls.

Conclusions: Prior studies have reported impaired mitochondrial BCAA metabolism in adipose, muscle and liver. However, our results show a robust pattern of increased BCAA metabolites, likely reflecting increased BCAA catabolism and/or increased metabolic flux. The reduced renal expression of BCAA enzymes supports a role for dysregulated BCAA metabolism by the kidney. The elevated BCAA metabolites may have an affect on regulating insulin resistance and the development of kidney disease with T2D.

Urinary Matrix Metalloproteinase Activities Are Associated with Renal Hyperfiltration in Adolescents With Type 2 Diabetes
Petter Bjornstad,1 Laura Raymond,2 Kathryn Snell-bergens,2 Kristin Nadeau.3 Barbara Davis Center for Diabetes; 1univ of Colorado Denver; 2Children’s Hospital Colorado.

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease. Matrix metalloproteinases (MMP) modify extracellular matrix during vascular remodeling and are known to be elevated in diabetes, and associated with DN in type 1 diabetes. We hypothesized that activities of latent MMP and neutrophil gelatinase-associated lipocalin (NGAL-L) proteins are associated with microalbuminuria and hyperfiltration in adolescents with type 2 diabetes (T2D).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
498A
Methods: 295 adolescents with T2D (14.0±1.8 years, <2 years duration, BMI ≥85%, and HbA1c ≥5%) in the Treatment Options for Type 2 Diabetes in Adolescents and Youth (TODAY) study had urine and blood evaluated at baseline and annually for 5 years. MMP2, MMP9 and NGAL activities were measured by gelatin zymography and normalized to urinary creatinine. Microalbuminuria was defined as albumin-to-creatinine ratio (ACR) >30mg/g. Estimated GFR was calculated by Schwartz (eGFR=36.5*height/creatinine) and hyperfiltration defined as >135mL/min/1.73m².

Results: Mixed models evaluated the longitudinal relationships between MMP-2, MMP9 and NGAL with eGFR, ACR, hyperfiltration and microalbuminuria respectively. MMP2, MMP9 and NGAL-MMP9 activities were natural logarithm transformed (ln) due to skewed distribution. The CKD classifier was an independent predictor of severe but not mild progression in retinopathy. It was not possible to develop a retinopathy specific marker panel with clinically relevant accuracy.

Conclusions: In conclusion, urinary MMP and NGAL activities were associated with early DN in adolescents with T2D over time.

Conclusions: In conclusion, urinary MMP and NGAL activities were associated with early DN in adolescents with T2D over time.

FR-PO609 Neutrophil Gelatinase Associated Lipocalin as an Early Biomarker of Nephropathy in Diabetic Patients and Effect of RAAS Blockade on NGAL as Marker of Tubular Damage in Diabetic Nephropathy

Background: Neutrophil gelatinase associated lipocalin (NGAL) is a neutrophil-derived protein that is rapidly released during tissue damage. NGAL is a specific marker for tubular injury and dysfunction, making it a potential biomarker for diabetic nephropathy (DN). However, its role in the early detection of DN remains unclear.

Methods: We conducted a retrospective analysis of patient data from a large clinical trial assessing the efficacy of RAAS blockade on NGAL levels in patients with type 2 diabetes mellitus (T2DM). The trial enrolled 300 patients with T2DM and followed them for 2 years. Plasma NGAL levels were measured at baseline, 6 months, and 2 years post-randomization.

Results: The mean baseline plasma NGAL level was 2.5 ng/ml. At 2 years, the mean plasma NGAL level had increased to 3.2 ng/ml, indicating progressive kidney damage. There was a significant correlation between the increase in NGAL levels and the decrease in eGFR (p=0.03). Patients treated with RAAS blockade showed a significant reduction in NGAL levels (p=0.01), indicating improved kidney function.

Conclusions: NGAL is a promising biomarker for early detection of diabetic nephropathy. RAAS blockade appears to have a beneficial effect on NGAL levels, suggesting its potential in preventing kidney damage.
Mechanism of Increased Urinary Full-Length Megalin Excretion in Type 2 Diabetes Mellitus Patients with Nephropathy

By: Maria Celeste Nicoletti, Monica Carmosino, Bladzinska-Bladzinska, Gudeta D. Fufaa, Robert G. Nelson, Paulina Dumnicka, Agnieszka Zylka, Beata Kustomierz-cabala, Marek Kazniewski, Shi Queen Jadwiga Hospital No 2, Rzeszow, Poland; Dept of Medical Diagnostics, Jagiellonian Univ Medical College, Krakow, Poland; Dept of Nephrology, Jagiellonian Univ Medical College, Krakow, Poland.

Background: Two clinical phenotypes of diabetic kidney disease (DKD) have been identified, i.e. with or without increased albuminuria. The aim of this study was to assess the usefulness of uNGAL for the preclinical diagnosis of DKD in the course of diabetes mellitus type 2 (DM2).

Methods: The study group consisted of 115 DM2 patients (63F, 58M) aged 18 and over (62±14), with normal to moderately increased albuminuria (i.e. urine albumin/creatinine ratio (UACR) <300 mg/gCr) and eGFR (CKD-EPI) ≥60ml/min/1.73m². Control group included 22 non-diabetic persons with comparable age (57±14; p=0.1) and sex (9F, 13M, p=0.5), and with similar comorbidities. Urine concentrations of NGAL, albumin and creatinine (uCr) were measured in the first morning urine sample. Urine albumin/creatinine ratio (UACR), and analogically, uNGAL/uCr were calculated.

Results: In control group, maximum uNGAL/uCr was 39.64 µg/g. In DM2 group, 24 patients (21%) had higher results, with the maximum value of 378.6 µg/g. Twenty three (20%) of DM2 patients had UACR >30 mg/g; of these, 11 had uNGAL/uCr <39.64 µg/g. Among patients with uNGAL/uCr >39.64 µg/g, 13 did not have markedly increased albuminuria (in uraemic patients those ranged from 2.35 to 16.10 mg/g). Women with DM2 had significantly higher uNGAL/uCr than men (median 28.06; IQR 9.05-65.60 versus 11.40; 3.36-18.02 µg/g; p=0.001), without significant difference in UACR (p=0.09). uNGAL/ uCr in DM2 patients correlated significantly with HbA1c (R=0.28; p=0.013), however, it did not correlate with eGFR (R=0.54; p=0.1), age (R=0.14; p=0.1), or time from DM2 diagnosis (R=0.13; p=0.1).

Conclusions: Increase in urine NGAL and uNGAL/uCr may indicate early tubular damage particularly worse diabetes control patients, especially female with DM2.

Plasma Bradykinin and Early Diabetic Nephropathy in Type 1 Diabetes Mellitus

Background: Bradykinin (BK) and its modified forms are potential biomarkers of diabetic nephropathy (DN). We examined their association with development of DN lesions in normoalbuminuric normotensive subjects with normal or increased glomerular filtration rate (GFR) and type 1 diabetes (T1D) from the Renin-Angiotensin System Study (N Engl J Med 2009;361:40-50).

Methods: Plasma concentrations of BK and modified BKs were measured at baseline and 5 years using a mass spectrometry-based multiple reaction monitoring assay in samples from 246 subjects who underwent kidney biopsies at baseline and after 5 years. Relationships of BK and modified BKs with morphometric variables were assessed using multiple linear regression after adjustment for age, sex, T1D duration, HbA1c, mean arterial pressure, albumin excretion rate (AER) and eGFR.

Results: Baseline mean age was 29.8 years, mean duration of T1D 11.3 years, median AER 5.1 mg/min, and mean GFR 128 mL/min/1.73 m². At multivariable adjustment, higher BK concentration was associated with the peripheral glomerular basement membrane surface density (p=0.001), and analogically with the thickness of the basement membrane at the podocyte-mesangial cell interface (p=0.03). Elevated plasma BK concentration measured before clinical findings of DN in people with T1D was associated with increased peripheral glomerular basement membrane surface density, suggesting that it may reflect an adaptive response to early glomerular changes in DN.

Serum Omentin and Progression of Diabetic Nephropathy. Tetsuharu Oku,
Fumihiko Furuya, Takeyuki Takamura, Kenichiro Kitamura. Third Dept of
Internal Medicine, Univ of Yamanashi, Chuo, Yamanashi, Japan.

Background: A novel adipokine, omentin, preferentially produced by visceral
adipose tissue compared with subcutaneous adipose tissue. Animal experiments indicated that
treatment with recombinant omentin enhanced insulin-stimulated glucose uptake in
subcutaneous and omental adipocytes. Furthermore, serum omentin levels are decreased in
obesity and diabetics. The purpose of this study was to elucidate whether serum omentin is
associated with progression of diabetic nephropathy in diabetic patients.

Methods: The prospective follow-up study; 114 diabetes patients were followed for
5 ± 1.1 years. Patients were divided at baseline into three groups according to their
urinary albumin-to-creatinine ratio (UACR): 68 patients with normoalbuminuria (UACR <30
mg/gCr), 31 patients with microalbuminuria (30 mg/gCr ≤ UACR < 300 mg/gCr), and 17 patients
with macroalbuminuria (UACR >300 mg/gCr). Progression of albuminuria was the main outcome.
Omentin was measured by ELISA, and the values were adjusted for age, BMI, and sex before analysis.

Results: Progression either to the next albuminuria level in 16 patients or to end-stage
renal disease (ESRD) occurred in 5 patients. No difference in adiponectin concentrations was
observed between progressors and nonprogressors in patients with normoalbuminuria. In the
patients with microalbuminuria and macroalbuminuria, progression of albuminuria was
associated with higher omentin. Progression to ESRD was also associated with estimated
glomerular filtration rate (eGFR). When these covariates were inserted in a Cox regression
analysis, eGFR and omentin were significantly associated with progression of albuminuria.
Conclusions: Serum omentin levels predict the progression from microalbuminuria to macroalbuminuria and from albuminuria to ESRD in diabetic patients.

FR-PO615
The Expressions of Vitamin D and Its Receptor in Patients with Diabetes
Associated with Proteinuria and Diabetic Nephropathy. Yang Yang, Jia Guo,
Zhiangso Liu. The Firs Affiliated Hospital of Zhengzhou Univ, Zhengzhou,
Henan, China.

Background: Vitamin D receptor (VDR) is a member of the nuclear receptor
superfamily, and there was no report about the expression of Vitamin D and its receptor
in patients with diabetes associated with proteinuria and diabetic nephropathy. So, this study
aimed to test the expression trends of VDR in blood, urine specimens and renal tissues
of diabetic nephropathy patients who were diagnosed by renal biopsy (DN3 group). 2. The expressions
of peritubular capillaries in renal tissues with DN. Increased serum omentin levels predict the progression from
microalbuminuria to macroalbuminuria and from albuminuria to ESRD in diabetic patients.

Conclusions: There was no report about the expression of Vitamin D and its receptor
in patients with diabetes associated with proteinuria and diabetic nephropathy. So, this study
aimed to test the expression trends of VDR in blood, urine specimens and renal tissues
of diabetic nephropathy patients who were diagnosed by renal biopsy (DN3 group). 2. The expressions
of peritubular capillaries in renal tissues with DN. Increased serum omentin levels predict the progression from
microalbuminuria to macroalbuminuria and from albuminuria to ESRD in diabetic patients.

Conclusions: There was no report about the expression of Vitamin D and its receptor
in patients with diabetes associated with proteinuria and diabetic nephropathy. So, this study
aimed to test the expression trends of VDR in blood, urine specimens and renal tissues
of diabetic nephropathy patients who were diagnosed by renal biopsy (DN3 group).
FR-P0619
Macrophyage Accumulation and Phenotype in Human Diabetic Nephropathy
Yang Ying, Yinfeng Guo, Zhixia Song, Min Zhou, Xiaoliang Zhang. Southeast Univ.

Background: Macrophage, especially its distinct phenotype is involved in the progression of DN. M1 is characterized with pathogenic function, while M2 displays anti-inflammatory. This study tries to examine the macrophage phenotype and its relationship to the renal function and histological changes in human DN.

Methods: We studied retrospectively 46 patients with DN who were confirmed by diagnosis of renal biopsy. Biopsies were divided into I Ha Ib III IV classes according to the pathologic classification of DN. Patients with renal trauma or renal tumor were considered as control group. Serum creatinine, proteinuria were calculated. Kidney tissues were used to assess histological changes and the presence of macrophage marker CD68, M1 marker iNOS, M2 marker CD206, Arg-1, TREM1 and TREM2.

Results: In biopsy renal tissue of human DN, Expression of CD68, M1 were significantly increased in the glomeruli (2.835±1.045/pcs VS 1.203±0.547/pcs for normals P=0.031; 2.330±1.343/pcs VS 0.896±0.548/pcs for normals P=0.046) and interstitium (0.037±0.142%area VS 0.019±0.002%area P=0.016; 0.018±0.008%area VS 0.009±0.005%area P=0.023). While M2 were mainly observed in the interstitium (0.019±0.008%area VS 0.010±0.004%area P=0.038). Interstitium M2 correlated strongly with interstitium M1 infiltration. Additionally there was a positive correlation between the glomerular CD68, M1 numbers and serum creatinine (r=0.619, p<0.001; r=0.463, p=0.017), proteinuria (r=0.641, P=0.000; r=0.508, P=0.008), mesangial matrix, interstitial collagen deposition. Likewise, the expression of interstitial CD68, M1, M2 also correlated strongly with serum creatinine (r=0.638, P=0.000; r=0.606, P=0.001; r=0.520, P=0.006), proteinuria (r=0.749, P=0.000; r=0.651, P=0.000; r=0.694, P=0.000), mesangial matrix, interstitial collagen deposition. Besides TREM1,2-positive cells were apparent in the interstitium and the expression levels significantly correlated with interstitium M1, M2 expression.

Conclusions: Macrophage infiltration and polarization participate in the development of diabetic nephropathy.

FR-P0620
Risk of Diabetes Increased According to the Level of Urinary Albumin Excretion Even Within Normal Range
Dong-Young Lee, Beom Kim, Kyounghyub Moon, Sung Keun Park, Youngou Jung. Internal Medicine, VHS Medical Center, Seoul, Republic of Korea; Total Health Care Center, Kangbuk Samsung Hospital, Sungkyunkwan Univ; School of Medicine, Seoul, Republic of Korea.

Background: Urine albumin creatinine ratio (UACR) as a reliable index of urinary albumin excretion is getting great attention on its predictive role for various diseases related with diabetes. Nevertheless, predictive value of UACR within normal range was not clarified for diabetes yet. Therefore, this study was aimed at examining the clinical association between normal range of UACR and development of diabetes.

Methods: We identified 1,274 non-diabetic Korean men within normal range of UACR in 2005, and followed them up until 2010. All subjects were classified into three categories with respect to baseline UACR, from the lowest to the highest. The incidence rates of diabetes were compared according to the tertile groups of UACR, and the independent hazard ratios (HRs) of UACR levels for diabetes was measured by Cox proportional hazards analysis.

Results: During follow-up, diabetes developed in 97 out of 1,274 subjects (7.6%). Incidence rate of diabetes increased in proportion to the levels of UACR (tertile 1; 4.9%, tertile 2; 7.3%, tertile 3; 10.6%, p<0.001).

Conclusions: Elevated UACR, even within normal range, was significantly associated with the future development of diabetes.

FR-P0621
Albuminuria Is Positively Associated with Elevated Numbers of Circulating Endothelial Pre- and Mature Cells, but Inversely Associated with Circulating Fibrocytes

Background: Diabetic nephropathy is characterized as a microvascular disease with enhanced vascular leakiness in the kidney and aberrant tissue remodelling. Abnormal number and function of endothelial cells, stem cells and activation of leucocytes is considered as contributing mechanisms to the “kidney-micro”-vascular leaky syndrome. We determined if circulating endothelial pre- and mature cells, fibrocytes or monocyte sub-populations were abnormally regulated in type 2 diabetic patients with albuminuria.

Methods: Cross-sectional study of 37 type 2 diabetic patients; 18 with normalalbuminuria (<30mg/24h) and 19 with albuminuria (³30mg/24h). 8-color flow cytometry analysis of peripheral blood was performed. ANCOVA compared expression of cell markers and absolute number of specific cell populations in patients with normalalbuminuria vs. albuminuria.

Results: Expression of VEGFR2 was significantly enhanced in patients with albuminuria (p=0.009). Also, the total number of circulating mature endothelial cells (CEC) was significantly enhanced in albuminuria (p=0.001). Circulating fibrocyte number and collagen-1 expression was inversely associated with albuminuria (r=0.39, P<0.037) and TGFbeta stabilizing and M2-associated galectin-3 expression on M1-like and M0-like monocytes was positively associated with albuminuria (r=0.029). In contrast, expression of the M1-associated marker CD11c (p=0.042) was inversely associated with albuminuria on all monocytes, particularly on M0-like macrophages (p=0.014).

Conclusions: The enhanced number of CEC together with elevated expression of VEGFR2 may indicate an aberrant function of the CEC with reduced capacity to heal the kidney microvascular disease. The imbalanced M2-polarization of monocytes and aberrant fibrocyte count may favour improper repair leading to excessive tissue fibrosis. Hence therapeutic approaches addressing migratory pattern of CEC, providing adjuvant activating signals or restoring the immune balance might provide novel individualized treatment regimes.

FR-P0622
Prognostic Value of Tubulointerstitial Lesions and Urinary N-Acetyl-b-D-Glucosaminidase in Patients with Type 2 Diabetes and Biopsy-Proven Diabetic Nephropathy
Koki Mise, Junichi Hoshino, Toshiharu Ueno, Masayuki Yamanouchi, Noriko Hayami, Tetutsu Suwabe, Kenmei Takaichi, Yoshifumi Ubara. Nephrology Center, Toranomon Hospital Kajigaya, Kavasaki, Kanagawa, Japan; Nephrology Center, Toranomon Hospital, Tokyo, Japan.

Background: Recently, it has been reported that some biomarkers of renal tubular injury are useful to predict the renal prognosis in the early stage of diabetic nephropathy (DN). However, how closely such biomarkers reflect actual tubulointerstitial damage remains unknown.

Methods: Among 210 patients with type 2 diabetes and biopsy-proven DN, 152 patients were enrolled, 89% of whom had overt proteinuria. The endpoint was defined as 50% or more decrease of the estimated glomerular filtration rate (eGFR) from baseline or commencement of dialysis due to end-stage renal disease. The Cox proportional hazard model was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) for the death-censored endpoint.

Results: A significant correlation was found between baseline urinary N-acetyl-b-D-glucosaminidase (NAG) excretion and the score for interstitial fibrosis and tubular atrophy (IFTA score) (r=0.39, P<0.001). The influence of urinary NAG on the renal prognosis was attenuated after adjustment for known promoters of progression (+1SD for log NAG, HR: 0.87 [95% CI: 0.66-1.13]). On the other hand, the IFTA score was significantly related to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 2.20 [1.50-3.21]).

Conclusions: The assessment of urinary NAG excretion did not improve the prognostic power of known indicators of progression, whereas the IFTA score did. The IFTA score may be more useful for predicting the renal prognosis than current tubulointerstitial markers, especially in patients with advanced DN.

Is There Any Benefit of Performing Renal Biopsies in Patients with Diabetic Nephropathy when No Other Diagnosis Than Diabetic Nephropathy Is Found?  
Rosa M. Montero, 1 Dimitrios Anestis Moutzouris, 1 Ranmith Perera, 2 David Goldsmith. 1 \textit{Nephrology & Transplantation, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom}; 2 \textit{Histopathology, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom.}

\textbf{Background:} The risk of renal biopsy has long been thought to outweigh the benefit of performing these on patients with diabetes mellitus (DM) leading to small numbers of renal biopsies in this population. Those biopsied have a propensity to more proteinuria or haematuria precipitating biopsy. Glomerular lesions alone have long been the hallmark of diabetic nephropathy (DN) however looking back at the biopsy can there be more to see?  

Methods: \textbf{All native renal biopsies diagnosed with DN from 2009-2014 were retrieved from archive at Guy’s & St Thomas’ NHS foundation trust. Renal biopsies were performed in patients with DM who had heavy proteinuria or haematuria on presentation. Biopsies with a DN diagnosis alone were identified and Tervaert’s new DN classification was applied. Clinical outcome data was collected from electronic patient records. Cox regression models were used to perform statistical analysis.}  

\textbf{Results:} 3000 native kidney biopsies were performed from 2009-2014. 34 DM patients had DN alone on renal biopsy, 12 T1DM and 22 T2DM. 20 male, 14 females. Ethnicity: 35% white, 35% black, 3% asian, 27% other. Age range: 24-86 years (median 55). UPCR: 13.492 mg protein/mmol creatinine (median 392) eGFR 7-74.9 (median 23). 8.8% 5 year mortality. Glomerular IV and Interstitial III lesions were significant predictors of renal survival (p=0.013 HR 27.5, p=0.066 HR 21, respectively). Renal survival ranged from 1-60 months post renal biopsy (median 3).  

\textbf{Conclusions:} Interstitial fibrotic lesions are as important as glomerular lesions in predicting renal survival. Determining the significance of the compartments in predicting outcome may be more sensitive; however few biopsies are undertaken in this population. The role of an earlier renal biopsy showing less well established features in the DN population may be more sensitive; however few biopsies are undertaken in this population. The risk of renal biopsy has long been thought to outweigh the benefit of performing these on patients with diabetes mellitus (DM) leading to small numbers of renal biopsies in this population. Those biopsied have a propensity to more proteinuria or haematuria precipitating biopsy. Glomerular lesions alone have long been the hallmark of diabetic nephropathy (DN) however looking back at the biopsy can there be more to see?  

Understanding the Relationship Between Histopathology and Renal Function in Hypertension and Diabetes  
Matthew Palmer, 1 Jordana B. Nagata, 2 Holly J. Cornish, 3 Michaela J. Obel, 4 Ana M. Ramos, 5 Emily Ansell, 6 Reuben Wilkins, 7 David G. Cooper. 1 \textit{Nephrology & Transplantation, Guy’ s & St Thomas’ NHS Foundation Trust, London, United Kingdom}; 2 \textit{Histopathology, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom}.  

\textbf{Background:} The link between obesity and renal disease is unclear. Hyperfiltration is suspected to induce arteriolar hyalinosis and glomerular hypertrophy in moderate to severe obesity. To assess morphological changes in obesity, we investigated human normotensive renal tissue from 7 mild obese cases (Ob)(BMI 27) and 7 non-obese cases (Con) and compared with 7 hypertensive case (HT) and 4 control(Con).  

\textbf{Methods:} Total 130 of serially cut paraffin sections were double immunostained with CD34 as endothelial marker, and smooth muscle actin as medial marker, followed by PAS staining. Incidence of hyalinosis in afferent and efferent arterioles, intraglomerular cleft dilatation connecting to efferent arterioles, segmental sclerosis, sclerotic glomerul(GS) and average size of glomeruli were assessed using 50-40 glomeruli per case. \textbf{Results:} The morphological data were as follows; average glomerular diameter 203±26, 181±19, 136±14, incidence of arteriolar hyalinosis 43±13, 47±29, 20±16%, incidence of that of efferent arterioles, 30±10**, 13±14, 5±4% for Ob, HT and Con, respectively (**P<0.05 vs Con, **P<0.05 vs Con and HT). Higher incidence of cleft dilatation near efferent arterioles was noticed in Ob (21±15%) than HT and Con (2±15%, 0%, respectively)(P<0.05). Obese cases revealed neither significant intimal thickening nor distortion in the interlobular arteries, no segmental sclerosis, low incidence of GS (11±7%) and minimal interstitial damage(<10%).  

\textbf{Conclusions:} Effector arterioles are targets for obesity, which suggest that specific mechanism of glomerular hyperfiltration involves obese cases, even in mild form.  

Fundings: \textit{Government Support - Non-U.S.}
Methods: A total of 396 patients with T2D and biopsy-proven DN from Nanjing DN registration system who were followed-up for at least 1 year were recruited and median 5-year follow-up. Renal outcomes were defined by progression to end-stage renal disease and doubling of serum creatinine.

Results: Of the participants, the mean baseline eGFR was 73.86±33.52 mL/min per 1.73 m². The levels of the urinary tubulointerstitial injury markers including the NAG, RBP and NAGL were significantly different among quintiles of serum phosphorus (P<0.01). The participants whose eGFR<90 mL/min per 1.73 m² had a higher rate of tubulointerstitial injury (interstitial fibrosis tubular atrophy scores of 2 and 3, P<0.005; interstitial inflammation scores of 1 and 2, P<0.035) in hyperphosphatemia (>1.45 mmol/L) group than in lower phosphorus group (<1.17 mmol/L). Participants with baseline levels of serum phosphorus in higher quintiles had a higher cumulative incidence of ESRD (log-rank, P<0.001). In the analyses adjusted by age, sex, diabetes status, BP, Fbg, BMI, proteinuria, cholesterol, and eGFR, the relationship between higher serum phosphorus and an increased risk of ESRD remained. The association between serum phosphorus and ESRD risk persisted and was stronger when the sample was restricted to those with a baseline eGFR equal to 60-90 mL/min per 1.73 m², but not when it was restricted to patients with a baseline eGFR of 30-60 mL/min per 1.73 m².

Conclusions: These findings indicated the baseline serum phosphorus is associated with tubulointerstitial injury of T2D patients. And serum phosphorus >1.45 mmol/L is an independent risk factor of ESRD in T2D, especially in the patients with eGFR>60 mL/min per 1.73 m².

The Relationship Between Diabetic Retinopathy and Diabetic Kidney Disease in a Population-Based Study in Korea (KNHANES V2-3)

Methods: Urinary/serum cyst c and NAG were estimated in total 491 age-matched patients enrolled for our cross-sectional study. Their efficacy was compared with conventional microalbuminuria, serum creatinine and eGFR in patients with varying type 2 diabetes (T2DM) duration and various stages of DN.

Results: Patients with 5-10 yrs of T2DM duration showed a significant increase in cyst of urinary NAG in patients with nonproteinuric DN (p<0.001) in all stages of T2DM duration. The ROC curve signifies diagnostic efficacy of urinary cyst c (AUC = 0.820) over urinary NAG (AUC = 0.678), in detecting T2DM patients susceptible to develop DN. Figure 1: Comparison of urinary Cystatin c and NAG in various groups.
previous congestive heart failure (n=23 799) (HR 1.26, 95% CI 1.17, 1.36). In addition, a 25-50 mmHg decrease in SBP from the last observation was associated with an increase in risk of all-cause mortality (HR 1.44, 95% CI 1.33, 1.56) compared to a change in the range -10 to 10 mmHg.

Conclusions: A systolic blood pressure < 130 mmHg and a decrease in systolic blood pressure during follow up with or without previous congestive heart failure, is associated with an increase in the risk of all-cause mortality in patients with type 2-diabetes and renal impairment. Intensity of hypertensive medication and co-morbidities are important confounders and will be further evaluated.

FR-PO632 Increased Expression of WNT5a in Renal Tubules Is Associated with Diabetic Nephropathy in Humans Malik Asad Anjum, An Xiao, Dean Troyer, Michael J. Solhaug, Anca Dobrian, Jerry L. Nadler, Liwei Huang.

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease worldwide. In recent years, convincing data has come forward suggesting that inflammatory pathways play a pivotal role in the pathogenesis and progression of DN. Identification of these inflammatory pathways and associated biomarkers may help in the early diagnosis of DN and development of novel targeted therapeutic strategies to help prevent, treat and even slow the progression of DN. Wnt5a, a secreted glycoproteins, plays an important role in normal kidney development and is also a pro-inflammatory factor which has been associated with renal fibrosis and disruption of matrix metabolism. The objective of our study was to investigate the expression of WNT5a in diabetic kidneys in humans.

Methods: 11 subjects with biopsy confirmed DN were included in our experimental group. Normal kidney tissues from non-diabetic subjects who underwent nephrectomy for renal cell carcinoma were used as controls. Exclusion criteria for the experimental group were HIV positivity, chronic/acute inflammatory diseases (including hepatitis C) and steroids-immunosuppressant medication. WNT5a expression was evaluated in paraffin embedded tissues.

Results: Immunohistochemical analysis of WNT5a expression showed positive staining on the apical side of the plasma membrane of the renal tubular epithelial cells in control kidney tissues. The intensity of the staining is increased in patients with DN compared to normal kidney control tissues. In patients with DN, WNT5a expression is localized both in the cytoplasm and on the apical side of the plasma membrane of the renal tubular cells. WNT5a is also expressed on glomerular cells, but there are no differences in Wnt5a expression between the tissues from diabetic subjects and controls.

Conclusions: Our results suggest that WNT5a expression in renal tubules might have a pathogenic role in the development of human renal tubular fibrosis. These studies are the first to demonstrate an increase in WNT5a expression in renal tubules in DN.

FR-PO633 Accuracy of Serum Creatinine and Glomerular Filtration Rate Estimation for Adjusting Metformin Prescription in European Type 2 Diabetics Olivier Moranne, Coraline Faïfin, Pierre Delanaye, Martin Flamant.

Background: There is a debate in the literature about the thresholds of serum creatinine (Scr) above which the drug is contraindicated (1.5 mg/dL in men & 1.4mg/dL in women). For KDIGO, recommendation is a dose-adjustment between 45 and 30 mL/min and a withdrawal below 30 mL/min. However, in DM2, estimation of renal function based on Scr alone or on eGFR may vary from the true renal function (mGFR). The purpose of our study was to define the performance of the GFR assessment method (Scr or eGFR) calculated with Cockcroft-Gault (CG) or CKD-EPI in terms of metformin dose adjustment in DM2 who underwent a GFR measurement.

Methods: In 243 DM2 patients, GFR was measured by urinary clearance of CrEDTA. Non indexed GFR was used. We analyzed the agreement between classification of patients based on mGFR and, first, Scr alone with a cutoff value of 1.5 mg/dL in men and 1.4 mg/dL in women, second, on eGFR with threshold values of 45 or 30 mL/min. When both methods classified the patient in the same subgroup, the data were considered concordant otherwise overprescription (underprescription) was defined for discordance according to mGFR.

Results: Age was 61 ± 12 y/o, median mGFR was 42 [30-61] mL/min. Based on mGFR, the distribution of the patients according the following GFR class: [90-45] 110(45%), [44-30] 74(30%), < 30: 59(24%). In patients with a Scr above the cutoff value, mGFR(Scr) was <30 mL/min in respectively 23/40 women and 33/106 men. With a threshold of 45 mL/min then 30 mL/min, concordance was found in 80/85% then 88/88% of the patients for the CG and CKD-EPI. With a threshold of 30 mL/min, discordance was an overestimation (or underestimation) in 22(9%) and 19(8%) or 14(6%) and 11(5%) of the patients with the CG and CKD-EPI.

Conclusions: In this population creatinine-derived equations outperformed Scr alone in correctly classifying the patients in prescription subgroups. However, even with creatinine-based equations, discordance with mGFR occurs in 12-20% of the patients. New strategies such as drug concentration monitoring may be necessary to improve appropriate prescription of metformin in DM2.

FR-PO635 Changes in Glycaemia During Haemodialysis (HD) Are Not Associated with Changes in QTc Interval in Insulin-Treated Diabetic Patients Naveen H. Siddaramahal, Ddidem Tez, Thanh Phan, Nicholas J. Linker, Mary Bilous, Sue Winship, Sally M. Marshall, RudolfW. Bilous.

Background: Changes in albuminuria may have useful prognostic value. We sought to assess the association between change in urine albumin-to-creatinine ratio (UACR) and the risk of all-cause death, cardiovascular disease (CVD), and end-stage renal disease (ESRD) in the ADVANCE trial.

Methods: We defined UACR change (baseline to 2 years) as ≥30% decrease, <30% decrease to >30% increase (minor change; reference), and >30% increase. Follow-up for outcome ascertainment commenced at the second UACR measurement. We used Cox regression to estimate the hazard ratio (HR), after adjustment for demographics, ADVANCE randomized treatment assignments, comorbidities, laboratory measurements (including baseline UACR), and drug use.

Results: From baseline to 2 years, 34% of 9195 patients experienced a UACR decrease of ≥30%, 26% experienced a minor change, and 40% experienced an increase of ≥30%. Over the next 2.9 years (median), 520 deaths, 524 CVD events, and 12 ESRD events were recorded. An increase of >30% in UACR was associated with 30% higher mortality when compared to a minor change ([Figure 1] HR 1.30, 95% CI 1.18-1.40). Increase in UACR associated with increased CVD or ESRD, although the direction of effect was similar. A >30% UACR decrease was not significantly associated with the risk of death or CVD when compared to those with minor change but was significantly associated with lower ESRD risk (HR 0.10, 95% CI 0.01-0.79).

Conclusions: In type-2 diabetes patients, ≥30% increase in albuminuria predicted higher mortality while >30% decrease was associated with decreased ESRD risk. Our results suggest change in albuminuria may be a potential prognostic marker for clinical outcomes in type-2 diabetes.
Results: QTc interval was prolonged significantly at the end of HD in all sessions (p<0.001). Change in glucose level (mean±SD -1.8±4.2 vs. -1.7±3.0) did not have a significant effect on the change in QTc interval (p=0.396), which was not different in diabetic subjects compared to non-diabetic group (p=0.390). Serum K+ , Mg++ and Ca++ levels dropped significantly (p<0.001) during all 3 HD sessions. There was no significant difference in Mg++ levels and the drop in K+ , Mg++ and Ca++. The change in Mg++ (p<0.05) and Ca++ (p<0.05) levels but not K+ (p=0.202) were more pronounced in diabetic subjects. The change in Mg++ levels in diabetic subjects was associated with QTc prolongation (p<0.05).

Conclusions: Significant QTc prolongation occurs at the end of HD in people with and without diabetes, often reaching abnormal levels and appears to be related more to changes in blood electrolytes than glycaemia. The fall in serum Mg++ levels during HD had a larger effect on QTc than K+ or Ca++ and this appears to have a more pronounced effect in diabetic subjects. The changes in QTc may increase the risk of cardiac dysrhythmia and sudden death in HD patients.

FR-PO636

Markers of Inflammation and Endothelial Dysfunction Are Associated with Cardiovascular Morbidity and Mortality in Type 2 Diabetic Patients with Microalbuminuria

Bernt Johan Ilmum von Scholten,¹ Henrik Reinhard,¹ Tine Hansen,¹ Casper Schalkwijk,² Coen Stenhouse,² Hans-Henrik Parving,² Peter Karl Jacobsen,¹ Peter Rossing,¹ Steno Diabetes Center, Denmark;² Maastricht Univ Medical Center, Netherlands;³ Rigshospitalet, Denmark.

Background: Accumulating evidence suggests that inflammation and endothelial dysfunction link type 2 diabetes (T2D) to cardiovascular disease (CVD). We evaluated the predictive value of markers of inflammation and endothelial dysfunction for combined fatal and non-fatal CVD and for all-cause mortality in patients with T2D and microalbuminuria but without known coronary artery disease (CAD).

Methods: Prospective study including 200 patients. All received intensive multifactorial treatment. Markers of inflammation (TNF-α, ICAM-3, hsCRP, SAA, IL-1β, IL-6, IL-8) and endothelial dysfunction (thrombomodulin, VCAM-1, ICAM-1, E-selectin, P-selectin) were measured at baseline. Adjusted multiregression models included sex, age, total cholesterol, smoking, HbA1c, creatinine, systolic blood pressure and urinary albumin excretion. Fully adjusted models additionally included NT-proBNP and coronary artery calcium score (CAC).

Results: Participants were 76% men, age (± SD) 59 ± 9 years, HbA1c was 7.9 ± 1.3%. Occurrence of CVD (n=40) and mortality (n=26) was traced after 6.1 years (median). In adjusted Cox analysis, higher TNF-α predicted the CVD endpoint and mortality (p<0.002). After full adjustment higher TNF-α remained predictive of both endpoints (p<0.007). Higher thrombomodulin and ICAM-3 were associated with risk of CVD and mortality in adjusted analyses (p<0.05) and predicted mortality after full adjustment (p<0.001). Higher VCAM-1 and ICAM-1 were associated with risk of mortality in adjusted (p<0.002) and fully adjusted models (p<0.005). The composite z-score of all markers of inflammation and of endothelial dysfunction predicted CVD and mortality (p<0.008).

Conclusions: In patients with T2D and microalbuminuria without known CAD, biomarkers of inflammation and endothelial dysfunction were independently associated with risk of CVD and mortality. Especially TNF-α was a robust predictor, even after adjusting for albuminuria, NT-proBNP and CAC.

FR-PO637

Predictors of Glycemic Status and Associations with Mortality in Incident Diabetic Hemodialysis Patients

Connie Rhee,¹ Steven B. Kim,¹ Rajnish Mehrotra,¹ Elani Streja,¹ Danh V. Nguyen,¹ Steven M. Brunelli,³ Gregory Brent,¹ Csaba P. Kovessy,¹ Kamyar Kalantar-Zadeh,¹ UC Irvine;² Univ Washington;³ DaVita Clinical Research; ¹UCLA; ²UTHSC.

Background: In the general population, intensive glycemic targets confer higher mortality in diabetics with cardiovascular risk. In diabetic hemodialysis (HD) patients, some but not all studies show that lower glycemic levels defined by HbA1c are associated with higher mortality. We sought to examine predictors of low glycemic status in HD patients with one or more HbA1c measures during the first 91-days of dialysis, we examined the association, respectively, were examined using case-match laboratory adjusted Cox models.

Results: Among 63,607 diabetic HD patients, 37% had low HbA1c levels. Female gender and non-Hispanic race/ethnicity; lower BMI and nPCR; and higher serum bicarbonate, creatinine, and albumin were associated with higher risk of low HbA1c. Baseline HbA1c levels <7% were associated with lower mortality. However, time-dependent HbA1c levels <5% were associated with higher mortality.

Methods: We performed a cross-sectional study of a representative sample of 1594 persons recruited from the general population of the municipality of Tromso, Norway, aged 50-62 without prevalent cardiovascular disease, diabetes or renal disease. GFR was measured by iohexol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). RHF was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height.

Results: In multivariable adjusted logistic regression models, the odds ratios (95% confidence intervals) for RHF were 1.56 (1.11-2.18) per 0.10 increase in WHR, 0.82 (0.51-1.32) per 2 kg/m2 of BMI and 1.23 (0.92-1.65) per 10 cm of WC. WHR was consistently associated with RHF across different models. Higher BMI and WC were significantly associated with RHF only when an alternative definition of RHF, not adjusted for body weight, was used. Higher BMI, WC and WHR were also independently associated with increasing GFR analyzed as a continuous variable.

Conclusions: Baseline HbA1c levels <7% were associated with lower mortality, suggesting that moderately low glycemic status has long-term benefits in diabetic HD patients. Yet time-dependent HbA1c levels <5% were associated with higher mortality, suggesting that very low glycemic status carries short-term risk. Further studies are needed to determine if pharmacotherapies targeting these glycemic ranges reduce mortality in diabetic HD patients.

FR-PO638

Waist-Hip Ratio Is Associated with Renal Hyperfiltration in the Non-Diabetic, Middle-Aged General Population

Vidar T. N. Stefansson,¹ Jorgen Schiøtz,¹ Trond G. Jensen,¹ Toralf Melsom,² Bjorn Odvar Eriksen,²³ ¹Metabolic and Renal Research Group, UiT the Arctic Univ of Norway, Tromso, Norway; ²Section of Nephrology, Univ Hospital of North Norway, Tromso, Norway; ³Dept of Organ Transplantation, Oslo Univ Hospital, Oslo, Norway.

Background: Renal hyperfiltration (RHF) is a maladaptive response to increased metabolic stress in the kidneys which may result in chronic kidney disease. Diabetes causes RHF, but whether obesity in non-diabetic persons is a cause of RHF has not been adequately studied in the general population. This study aimed to establish whether RHF assessed by measured glomerular filtration rate (GFR) is associated with obesity independently of metabolic and cardiovascular risk factors.

Methods: We performed a cross-sectional study of a representative sample of 1594 persons recruited from the general population of the municipality of Tromso, Norway, aged 50-62 without prevalent cardiovascular disease, diabetes or renal disease. GFR was measured by iohexol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). RHF was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height.

Results: In multivariable adjusted logistic regression models, the odds ratios (95% confidence intervals) for RHF were 1.56 (1.11-2.18) per 0.10 increase in WHR, 0.82 (0.51-1.32) per 2 kg/m2 of BMI and 1.23 (0.92-1.65) per 10 cm of WC. WHR was consistently associated with RHF across different models. Higher BMI and WC were significantly associated with RHF only when an alternative definition of RHF, not adjusted for body weight, was used. Higher BMI, WC and WHR were also independently associated with increasing GFR analyzed as a continuous variable.

Conclusions: Central obesity measured as WHR is associated with RHF and higher GFR independently of age, sex, body weight, metabolic indices (including fasting glucose,
insulin and HbA1C) and cardiovascular risk factors (including ambulatory blood pressure, antihypertensive medication and smoking status). WHR may be a better indicator of the renal effects of obesity than BMI or WC.

Obesity Associates with High Hemoglobin A1c but Low Alternative Indices in Both Diabetic and Nondiabetic Hemodialysis Patients

Mark E. Williams,1 Neal Mittleman,2 Lin Ma,1 Julia I. Brennan,2 Chiuin M. Jani,1 Curtis D. Johnson,3 Franklin W. Maddux,1 Eduardo K. Lacson,4,5 *Joslin Diabetes Center, Boston, MA; 2Kidney Care of Brooklyn and Queens, Brooklyn, NY; 3Prescient Medical Care North America, Waltham, MA; 4Spectra Laboratories, Rockleigh, NJ; 5Physician, Lexington, MA.

Background: The GIDE (Glycemic Indices in Dialysis Evaluation) study is evaluating several glycomic markers inhemodialysis (HD) cohorts with and without diabetes. We have reported that alternative glycomic indices may be elevated out of proportion to hemoglobin A1c (HgbA1c). Because obesity is known to affect markers of glycemia, we examined its association with these indices.

Methods: A combined cohort of 2,394 active HD patients (1,424 with diabetes, 970 without) from 26 U.S. FMCNA facilities had baseline indices [HgbA1c; albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA] measured Jan-Mar 2013 and monthly until April, 2015. Mean of body mass index (BMI) was determined for the entire cohort. Obesity—BMI ≥30 kg/m². Cox models adjusted by age, sex, race, ethnicity, vintage, HD cather, baseline comorbidity and laboratory albumin values were utilized to determine associate between obesity with death outcome.

Results: Average BMI (kg/m²; mean±SD) by risk as determined by indices (low=within target range, high=above target range) are shown in (table 1).

The Hazard Ratio (HR) for death was reduced with obesity [HR=0.76, 95% CI (0.62, 0.94), p=0.01].

Conclusions: Obesity is positively correlated with HgbA1c but negatively correlated with other glycomic indices in hemodialysis patients. Further studies are needed to elucidate underlying mechanisms and assess the relationship of these findings to superior survival outcomes in obese HD patients.

FR-PO640

BMI and Causes of Death in Chronic Kidney Disease

Sankar D. Navaneethan,1 Jesse D. Schold,2 Susana Arrigain,2 John P. Kirwan,3 Joseph V. Nally,3 Nephrology, Cleveland Clinic; 2Quantitative Health Sciences, Cleveland Clinic; 3Pathobiology, Cleveland Clinic.

Background: Chronic kidney disease (CKD) is associated with higher risk for cardiovascular related death. In CKD, a higher body mass index (BMI) is associated with a lower risk for death, but cause specific death details are unknown across the BMI range.

Methods: We included 54,506 patients with CKD (two estimated glomerular filtration rate <60 ml/min/1.73 m²); 90 days apart; January 2005 – December 2012) from our institutional electronic medical record-based CKD registry. We examined the associations between various causes of death (cardiovascular, malignancy and non-cardiovascular/ non-malignancy related deaths obtained from the State of Ohio mortality files) across the BMI range using the Cox proportional hazards model.

Results: During a median follow-up of 3.7 years (25th percentile,75th percentile: 1.8-5.8), 14,151 patients died. In the multivariable model, an inverted J-shaped association was noted between BMI and overall, cardiovascular, malignancy-related, and non-cardiovascular/ non-malignancy related deaths.

FR-PO641

Weight Reduction with Low Calorie Diet Reduces Urinary Megalin and Improves Albuminuria in Obese Men

Tetsuro Takeda,1 Akihiko Saito,2 1Nephrology, Dokkyo Medical Univ Koshigaya Hospital, Koshigaya, Saitama, Japan; 2Applied Molecular Medicine, Niigata Univ, Niigata, Japan.

Background: Megalin, an endocytic receptor in proximal tubules, is involved in the mechanisms of albuminuria in diabetic nephropathy. A urinary full-length megalin (C-megalin) assay is linked to the severity of diabetic nephropathy and IgA nephropathy. Also, albuminuria is a frequent sign of obese individuals and could be reduced by losing body weight. We investigated the relationship between level of urinary C-megalin and albuminuria on a weight reduction program in obesity.

Methods: Thirty-three obese male volunteers (age 36.6 ± 6.9 years, BMI >25 kg/m²) were enrolled but 30 subjects completed the 12-week weight reduction program. The program consisted of replacement of evening meal by a low calorie formula food (MICRO-S®) for first 4 weeks and followed by bi-weekly dietary counseling session with nutritionist. Of these, 20 subjects with metabolic syndrome were included (based on the Japanese criteria). Urinary albumin/C-megalin ratio (ACR) and urinary C-megalin were measured at baseline and after the program.

Results: The mean weight loss was 5.2 ± 2.9 kg (5.6% of the original BW). The baseline ACR ranged from 2.8 to 52.9 mg/gCre. After the program, BMI, waist circumference, BP, total cholesterol and FFA were significantly decreased. HDL-cholesterol and adiponectin were significantly increased. Overall, ACR was not changed (11.9 ± 12.4 to 8.8 ± 5.3 mg/gCre). However, in the cases with ACR >8 mg/gCre at baseline (n=11), ACR was more effectively reduced (22.9 ± 15.1 to 12.7 ± 6.4 mg/gCre) without a change in eGFR. The reduction of ACR was correlated with the reduction of urinary C-megalin. No other parameters like insulin resistance were associated with the reduction of ACR or C-megalin.

Conclusions: Losing BW with a formula food is effective in reducing urinary ACR in obese men. This improvement of ACR is related to the reduction in urinary C-megalin. Since albumin is excreted into urine by its increased glomerular leakage and/or decreased proximal tubular reabsorption via megalin and cubilin, our observations suggest that megalin metabolism in proximal tubules may determine albuminuria in obesity.

Funding: Pharmaceutical Company Support - CCF CKD registry creation was supported by an unrestricted grant from Apen to the Department of Nephrology and Hypertension at Cleveland Clinic.
FR-PO642
Obesity Management in Patients with Chronic Kidney Disease (CKD): A National Survey
Christopher Lawrence,1 Helen L. MacLaughlin,2 Ken Farrington,1 Andrew H. Frankel.1 1Lister Hospital, United Kingdom; 2Kings College London, United Kingdom.
Background: Obesity contributes to the development and progression of CKD and may be a barrier to, or increase risks of, transplantation. Evidence for how the renal multi-disciplinary team (MDT) should proceed is limited and sometimes counterintuitive i.e., association of increased weight and better survival on hemodialysis. The study assessed approaches to obese patients with CKD across the UK and describes the availability of, and extent of co-working with, bariatric services.
Methods: An online survey tool was designed and sent by the British Renal Society to UK renal clinical directors and dieticians. The survey focussed on patients with CKD stage ≥ 3, with proteinuria and co-existent Obesity stage II (BMI ≥ 35kg/m²) as these patients are most likely to progress to ESRD.
Results: 58/71 (82%) of UK units responded with respondents split between dieticians (53%) and nephrologists (47%). Most respondents (78%) thought the prevalence of obesity has increased over the last decade. There was no consensus on the BMI cut off for kidney transplantation: 30%, 16%; 35%, 71%; ≤40, 12%; none, 2%. The 3 most common actions for initial obesity management were: to provide education/motivation (81%); dietary referral (60%) and test fasting glucose and lipids (43%). The other 17% did not feel confident to bariatric services. The main perceived barriers to weight loss were: lack of patient motivation (79%); no funding (60%); lack of services (53%). 54% of renal units co-locate with bariatric services. Only 35% of renal units can refer directly to local/regional bariatric service, the remainder were uncertain of referral pathways (27%) or relied on primary care physicians to refer. Only 5 units (9%) have a joint care pathway for obese patients with CKD undergoing bariatric surgery.
Conclusions: The response to obesity in CKD falls short of National (NICE) guidelines. The increasing prevalence of obesity is a challenge to the renal MDT. Strategies to tackle this include wider recognition of the problem; identifying and sharing best practice and development of a robust evidence base to foster investment in renal dietetic and support services.

FR-PO643
Effects of Renin-Angiotensin Blockade (RASB) on the Components of Early Interstitial Expansion in Patients (pts) with Type 1 Diabetes (T1D) Zarah Khan, Michael Maurer, Maria Luiza A. Caramori. Medicine and Pediatrics, Univ of Minnesota, Minneapolis, MN.
Background: Interstitial expansion is important for GFR loss in the later stages of a variety of disease processes, including diabetic nephropathy (DN). The Renin-Angiotensin System Study (RASS; NEJM 2009;361:80) considered whether RASB with enalapril or losartan compared to placebo could slow progression of early DN lesions over 5 years (yrs) in 285 normaloalbuminuric (NA), normotensive (NT), normal GFR T1D pts. RASS found no treatment benefit of RASB on DN lesions but observed an unexpected ~50% increase in the light microscopic measures of the fractional volume of renal cortex which is interstitium ([Vv(Int/Cortex)]. However, possible effects of RASB on individual Int components, i.e., Int collagen (Col), Int cells (C), peritubular capillaries (PTC) and undefined Int space (S) were not assessed. Here we report these additional studies.
Methods: Baseline and 5-yr renal biopsies from 21 RASS pts (52% males), from a single research center, 7 from each treatment group, with a wide range of change in [Vv(Int/Cortex)], mean age of 34±10 yrs, and T1D for 11±4 yrs were selected. These pts were matched for age and sex, and selected for electron microscopic (EM) measurements of the fractional volume of renal cortex which is interstitium ([Vv(Int/Cortex)]. However, possible effects of RASB on individual Int components, i.e., Int collagen (Col), Int cells (C), peritubular capillaries (PTC) and undefined Int space (S) were not assessed. Here we report these additional studies.
Results: Baseline at 12 months p value at 24 months p value
HbA1c (%) 6.90 ± 0.87 6.15 ± 0.65 0.009 6.04 ± 0.52 0.002
SBP (mmHg) 142.3 ± 12.4 130.9 ± 14.9 0.018 125.1 ± 13.4 0.007
dGFR (ml/min/1.73m²) 21.6 ± 11.4 24.1 ± 14.6 n.s. 22.4 ± 13.0 n.s.
LVMI (g/m²) 178.6 ± 59.7 n.d. 143.7± 40.2 0.047
EF (%) 0.60 ± 0.13 n.d. 0.64 ± 0.15 0.395
No adverse events were seen.
Conclusions: These findings suggest that liraglutide therapy for type 2 diabetes patients with renal impairment was safe and effective for decreasing glucose levels and blood pressure. Moreover it preserved renal function and improving left ventricular function.

FR-PO645
Liraglutide Improves Glycemic and Blood Pressure Control and Preserves Renal Function and Left Ventricular Function in Patients with Type 2 Diabetes Mellitus with Renal Impairment Takeyuki Hiramatsu, Akiko Ozeki, Kazuki Asai, Akinori Hobe, Hideaki Ishikawa, Shinji Furuta. Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.
Background: Diabetes mellitus(DM) is a progressive multifactorial disease associated with cardiovascular complications. To prevent progression of systemic cardiovascular complications in DM patients, glycemic control is important. However using of anti-diabetic agents was restricted in patients with renal impairment. In this study, we examined the efficacy and safety of the glucagon-like peptide analogue, liraglutide to treat type 2 DM patients with renal impairment.
Methods: Twenty type 2 diabetes patients with renal insufficiency (Age; 65.4 y, DM duration;11.9 y, eGFR;21.6ml/min/1.73m²) were enrolled. Anti-diabetic agents were switched to liraglutide from others. Prior to liraglutide therapy, 9 patients used insulin, 8 used oral antidiabetic agents, and 3 were only diet therapy. During 24 months liraglutide use, we examined the change of blood pressure and renal function. Echocardiography was examined at baseline and 24 months after liraglutide initiation.
Results: Hemoglobin A1c, and systolic/diastolic blood pressure levels were gradually decreased with liraglutide use. Renal function indicated by eGFR was not changed during (table1), and the slope of the reciprocal of serum creatinine was improved after use of liraglutide(≥0.001). Moreover Liraglutide induced ameliorating left ventricular function(LVMI and EF).

FR-PO646
Do SGLT2 Inhibitors Affect GFR and Albuminuria in Diabetic Patients? A Systematic Review and Meta-Analysis Luhun Xu, Yang Li, Peng Xia, Limeng Chen. Dept of Nephrology, Peking Union Medical College Hospital.
Background: SGLT2 inhibitors are a new class of antihyperglycemic drugs that lower blood glucose levels by inhibiting renal reabsorption of glucose. SGLT2 inhibitors can have potential renoprotective capacities through modulation of tubuloglomerular feedback and alleviation of hyperfiltration. However, there are also concerns about deleterious effects on renal function caused by volume depletion.
Methods: We performed this systematic review and meta-analysis to assess the effects of SGLT2 inhibitors on estimated GFR (eGFR) and urinary albumin/creatinine ratio (ACR) in diabetic patients. We conducted a systematic search of PubMed, Embase, Cochrane Central Register of Controlled Trials and Sinomed through April 2015 to identify published randomized double-blind controlled trials of SGLT2 inhibitors reporting renal outcomes. Two reviewers worked independently to extract data and assess the quality of included studies. Random effects model were used in data synthesis.
Results: We retrieved 2279 studies, 53 of which met the predefined criteria. Among included studies, 33 studies examined short-term effect with follow up less than 26 weeks, and 20 studies examined long-term effects with follow-up longer than 48 weeks. 4 studies included subjects with CKD 2-4. SGLT2 inhibitors did not cause statistically significant changes in eGFR (mean change, -0.19 ml/min/1.73m², 95% CI, -0.86 to 0.47) or in ACR (mean change, -23.76 mg/g, 95% CI, -66.75 to 19.23).

Effects of Statins on Diabetic Kidney Disease in Patients with Type 2 Diabetes  
Ko Hanai, Tetsuya Babazono, Yasuko Uchigata. Diabetes Center, Tokyo Women’s Medical Univ School of Medicine.

Background: Renoprotective properties of statins have received much attention; however, a recent large cohort study found no beneficial effect of statins on diabetic kidney disease (DKD). Furthermore, whether there are differences among statins in their effects on the kidney remains unclear. We compared effects of statins on progression of DKD.

Methods: This was a single-center historical cohort study of Japanese adult ambulatory patients with type 2 diabetes. We studied 412 patients who were newly prescribed one of the following 4 statins: pravastatin, rosuvastatin, atorvastatin and pitavastatin, and who had estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m². As the control group, 946 patients without prescription history of statins were enrolled. Two outcomes were defined: 1) annual decline in eGFR and 2) progression to a more advanced stage of albuminuria. To adjust for the effects of confounding factors, we used the propensity score (PS) as the covariate. PS was estimated using a multinomial logistic regression model that included 18 clinical parameters. Furthermore, to take into account the varying number and spacing of eGFR measurements, and the variable follow-up period for each individual, we conducted the linear mixed-effects model regression analysis. The intercept and slope were treated as random effects.

Results: During the median follow-up period of 5.3 years (range, 2.0–8.6 years), the adjusted eGFR decline (± standard error) in the control group (1.6 ± 0.1 mL/min/1.73 m²/year) was significantly slower than that in rosuvastatin (2.4 ± 0.2, p<0.001), atorvastatin (2.6 ± 0.3, p<0.001) and pitavastatin group (2.3 ± 0.3, p=0.036), but not in pravastatin group (1.7 ± 0.2, p=0.780). Next, during the median follow-up period of 4.2 years (range, 0.1–8.5 years), a trend of ACR reduction (mean change: -2.6 ± 0.3, p<0.001) and a hematocrit level of ≤ 28% and received higher risk of reduced albuminuria. We used Cox proportional hazards models to account for the complex correlation structure of repeated measurements. In absolute terms, treating 1000 patients with tight glycemic control (HbA1c below 7% or fasting glucose levels <120 mg/dL) had a 0.87 (CI 0.34-1.47) of microalbuminuria. In absolute terms, treating 1000 patients with tight glycemic control for 1 year might prevent 7 experiencing new-onset albuminuria and 22 with worsening albuminuria.

Conclusions: Statins may have no beneficial effect on the progression of DKD. Instead, some statins are likely to be associated with faster renal function decline.

FR-PO648
Glucose Targets for Preventing Diabetic Kidney Disease and Its Progression: A Meta-Analysis  

Background: Diabetes is the leading cause of end-stage kidney disease (ESKD). Blood pressure lowering and glucose control are considered central to prevention of kidney function decline in diabetes nephropathy, however the optimal target range for blood glucose for preventing the onset and progression of kidney disease remains unclear. Here, we compared the effects of 4 statins on progression of DKD.

Methods: Using standard Cochrane methods, we did a systematic review and meta-analysis of randomized controlled trials that evaluated intensive versus standard glycemic control administered to adults and children with type 1 or type 2 diabetes with or at risk of kidney disease. Intensive glycemic control was defined by a treatment targeting an HbA1c <7.0% or fasting glucose levels <<120 mg/dL. In absolute terms, treating 1000 patients with tight glycemic control for 1 year might prevent 7 experiencing new-onset albuminuria and 22 with worsening albuminuria.

Conclusions: Intensive glycemic control among adults with diabetes had very uncertain effects on developing of ESKD and progression of kidney failure, while providing small clinical benefits on the onset and progression of microalbuminuria.

FR-PO649
Patient Benefits and Cost Savings Predicted for Mineralocorticoid-Receptor Antagonist Treatment of Early and Advanced Diabetic Kidney Disease  
Michael Blankenburg, Henri J. Folse, Christina Nowack, Bastian Hass, Bayer Pharma AG, Berlin, Germany; 2Amedeo Avogadro Univ of Eastern Piedmont; 3Univ of Otago Christchurch; 4Diaverum Medical Scientific Office; 5Amedeo Avogadro Univ of Eastern Piedmont; 6Sanofi-Aventis; 7Univ of Sydney; 8Univ of Bari.

Background: Exploratory studies suggest that mineralocorticoid-receptor antagonists (MRA) may improve outcomes in patients with diabetic kidney disease (DKD). Fosinopril (BAY 94-8862) is a selective, potent and non-steroidal MRA for the treatment of patients with DKD and is currently being studied in two clinical phase III trials, “FIDELIO” and “FIGARO.”

Methods: A Markov cohort model was used to emulate disease history, treatment effects, and outcomes for DKD patients with various disease severities (by albuminuria, measured by urinary-albumin-creatinine ratio [UACR], and chronic kidney disease [CKD] stage, measured by estimated glomerular filtration rate [eGFR]). Efficacy of finerenone is accomplished by reducing albuminuria evidenced by phase 2 trial data. The model has US

**Results:** The model predicts that finerenone is an effective treatment option for DKD patients, primarily by virtue of reduced risk of end-stage renal disease (ESRD) and renal death. A 10% absolute risk reduction (ARR) of up to 9.7% and 9.3%, respectively, for advanced DKD, i.e. macro-albuminuria and CKD3/4 and increased health-related quality of life, and that it would generate cost savings on renal replacement therapy (up to $19,100 for advanced DKD). From a clinical outcomes perspective the optimal time point to begin finerenone treatment appears to be after patients have progressed to either macro-albuminuria or CKD stage 3, as represented by both phase III trial populations.

**Conclusions:** Treatment with the MRA finerenone appears to be of significant benefit to patients and the healthcare system, particularly if initiated in advanced stages of DKD.

**Independent Association of Systolic Blood Pressure and Hemoglobin A1c Levels on Clinical Outcomes in Diabetic Patients with Normal Kidney Function**

_Presenting author:_ Aidar Gosmanov, Jun Ling Lu, Miklos Zsolt Molnar, Keichi Sumida, Praveen Kumar Potukuchi, Kamyar Kalantar

**Background:** Systolic blood pressure (SBP) goal of <140mmHg is recommended for majority of patients with diabetes mellitus (DM). It is however unknown if glycinemic control modifies the association of uncontrolled hypertension (HTN) with mortality and morbidity in DM patients.

**Methods:** We examined 894,661 US veterans with DM and baseline eGFR >60 mL/min/1.73m² (mean age 66±10.9 years, 97% males, 17% African-Americans). The association of mutually exclusive combined categories of hemoglobin A1c (A1c; <6.5, 6.5-6.9, 7.0-7.9, 8.0-8.9, 9.0-9.9, >10%) and SBP (<120, 120-139, 140-159, 160-179, >180mmHg) with the risk of all-cause mortality, incident CKD, coronary heart disease (CHD), and stroke was examined in Cox models adjusted for baseline characteristics, statin use, and co-morbidities, using patients with A1c 6.5-6.9% and SBP of 120-139 mmHg as referent.

**Results:** A total of 221,983 (25%) patients died, and 178,628 (20%), 43,374 (5%) and 4,722 (0.5%) respectively developed incident CKD, CHD and stroke, respectively, during a median follow up of 7.4 years. SBP displayed a U-shaped association with mortality in each A1c category. Conversely, SBP >120-139 mmHg was associated with a monotonous increase in the risk of CKD, CHD and stroke in all A1c categories. A1c levels were linearly associated with worse outcomes for all end points and in all SBP categories.

**Conclusions:** SBP above 120-139 mmHg and higher A1c levels were associated with higher mortality and morbidity in diabetic patients, independent of each other. Tight glycemic control modifies association of mortality and morbidity across all SBP categories in patients with normal kidney function.

**Clinical Benefit of Pre-Dilution On-Line Hemodiafiltration for Reduction of Low-Molecular-Weight Proteins and Fibroblast Growth Factor-23**

**Background:** Increased concentration of fibroblast growth factor 23 (FGF-23) is reportedly associated with increased risk of cardiovascular complication and mortality in dialysis patients. Therefore, there is a possibility that reduction of FGF-23 levels may improve prognosis of dialysis patients with elevated its levels. We compared the removal performance of low-molecular-weight proteins (LMWP) and FGF-23 between pre-dilution on-line hemodiafiltration (HDF) and hemodialysis (HD) with super high-flux dialyzer.

**Methods:** The study involved 31 patients (15:HDF, 16:HD, 4 hrs, Qd:600 mL/min). Blood flow rates were 284±20 for HDF, 281±14 mL/min for HD. Replacement fluid volume in HDF was 49.2±9.9 L/session. Removal rates (RR,%) and removal amounts (RA,mg) of urea nitrogen (UN), creatinine, β2-microglobulin (β2-M, MW:11.8kDa), α1-microglobulin (α1-M, MW:44kDa) and FGF-23 (32kDa) were examined. We followed the changes in FGF-23 levels of patients for 4 month period.

**Results:** Ra/V, RRs of UN and creatinine were significantly higher in HD than in HDF, whereas RRs and RAs of β2-M, α1-M, and FGF-23 were significantly higher in HDF. RRs of β2-M and α1-M were 80.3±3.7 and 42.0±6.1 for HDF, 73.5±4.1 and 25.0±6.8 for HD, respectively. RR and RA of FGF-23 were 66.9±6.5 for HDF, 51.1±8.3 for HD and 0.11±0.01 for HDF, 0.01±0.01 for HD, respectively.

**Conclusions:** The results confirmed that HDF was superior to HD in removing LMWP and FGF-23, which are removed mainly by convection. The convection volume can be much easily controlled in HDF than HD due to its internal filtration. The RRs of FGF-23 were 24 points higher than those of α1-M in both modes despite the small difference in MW, suggesting that distribution volume of FGF-23 was smaller than that of α1-M. No clear trend was detected in changes of FGF-23 during 4-month observation period.

**Comparison of Removal Performance of Small- to Large-Molecular-Weight Substances Between Pre-Dilution On-Line Hemodiafiltration and Hemodialysis with Super-High-Flux Dialyzer**

**Background:** In pre-dilution on-line hemodiafiltration (HDF), net dialysate flow rate is reduced, because replacement fluid accounts for 30% to 50% of total dialysate flow (Qdtotal). Therefore, removal efficiency of small-molecular-weight substances by diffusion is reduced, whereas that of low-molecular-weight proteins (LMWPs) by convection is

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
improved. In hemodialysis (HD) using super high flux dialyzer, the increased blood flow rate (Qb) increases amount of internal filtration, thereby improving the removal efficiency of LMWPs. In this study, we compared the removal efficiency of small- to large-molecular-weight substances between HDF and HD to verify the superiority of HDF. 

Methods: The study involved 62 patients (31 HD, 31 HDF). Super high flux dialyzers for HD and high-performance hemodialyzers for HDF were used. Qd was 500 for HD and QDtotal was 600 mL/min for HDF. Replacement fluid volume for HDF was 44.4 ± 10.0 L/session. Qb was 256 ± 23, 257 ± 25 mL/min and Treatment time was 4.1 ± 0.2, 4.0 ± 0.1 hours in HD and HDF, respectively. Removal rates (RR) of b2-microglobulin (b2-M; 11.8 kDa), protein bound indoxyl sulfate (IS; 144 kDa), protein bound FUR (FUR; 472 kDa), and tryptophan (TRP; 1 mmole/l in plasma) were studied by rapid equilibrium dialysis (RED) to select suitable model compounds for the HD study. The method was then tested in an in vitro HD experimental model with human whole blood spiked with PBUTs. After 10 min baseline test, the binding competitors were introduced upstream of dialyzer blood inlet. The removal of uremic toxins was estimated as the amount leaving dialysate outlet relative to the amount entering blood inlet.

Results: The infusion of IBU and FUR mixture (647 µmole/l and 126 µmole/l in blood, respectively) in the HD model increased removal of IS from 6.3 ± 0.1 to 15.2 ± 0.3 % (mean ± SEM) (2.4-fold) and IAA removal increased from 15.9 ± 0.2 to 29.8 ± 0.6% (1.9-fold). TRP (1 mmole/l in plasma) infusion increased the removal of IS and IAA to 9.4 ± 0.1% and 26.0 ± 0.3% (1.4- and 1.3-fold, respectively). Only moderate effects were observed in the change of HIPA removal.

Conclusions: The performance of HDF in removing LMWPs was superior to that of HD, and there was no significant difference in Kt/V in both modes. An increased convective removal by HDF greatly contributed to improved removal of LMWPs and appropriate control of dialysate flow rate improved the removal efficiency for small molecular substances to the level achieved by HD.

The Effect of Increasing Kt/Vurea in the HEMO Study on Levels of Non-Urea Solutes

Tariq Shafi,3 Tammy L. Sirin,2 Stephan Thijssen,2 Peter Kotanko,2 Xia Banerjee,4 Neil R. Powe,3 Thomas H. Hostetter.4

Background: In the HEMO study, outcomes were no better in patients randomized to “high dose” thrice weekly hemodialysis providing spKt/Vurea 1.73 than in those randomized to “standard” hemodialysis providing spKt/Vurea 1.32.

Methods: This study assessed whether “high-dose” treatment lowered levels of non-urea solutes. Solutes were measured by LC/MS/MS in plasma samples obtained at least 3 months after randomization in 1281 HEMO subjects.

Results: (mean±sd; CI, confidence interval).

</table>

Increasing Kt/Vurea caused statistically significant but only modest reductions in the levels of trimethylamine oxide, phenylacetylglutamine, and symmetric dimethylarginine. Mathematical modeling showed that limited reduction in the levels of these solutes was a predictable consequence of the intermittency of treatment. Their reduction ratios with standard treatment are high and the increased intensity of treatment reflected by a 30% increase in Kt/Vurea in HEMO’s high dose arm could not remove much more solute. Remarkably, increasing Kt/Vurea in HEMO caused no reduction in the levels of asymmetric dimethylarginine or p-cresol sulfate, two solutes which have been associated with cardiovascular disease in dialysis patients. Modeling showed that stability of their plasma levels could be accounted for by increased solute production accompanying the increase in Kt/Vurea and/or the presence of non-dialytic clearance.

Conclusions: Levels of non-urea solutes may fall only slightly or not at all when Kt/Vurea is increased above standard levels for thrice weekly treatment. Treatments that are more effective in reducing solute levels may be required to improve outcomes.

Improved Protein-Bound Uremic Toxins Dialytic Removal with Use of Albumin Binding Competitors: An In Vitro Human Whole Blood Study

Xia Tao,2 Stephan Thijssen,2 Peter Kotanko,2 Chih-Hu Ho,2 Michael E. Henrici,3 Eric W. Stroup,2 Garry J. Handelman.1

Background: Protein-bound uremic toxins (PBUT) are intensively studied retained solutes that accumulate in chronic kidney disease patients. Efficient removal of PBUTs by hemodialysis (HD) is difficult because of limited free fraction in blood. We propose an innovative method for improving the dialytic removal of PBUTs by increasing their free fractions with use of protein binding competitors.

Methods: The binding properties of indoxyl sulfate (IS), indole-3-acetic acid (IAA) and hippuric acid (HPA); and their binding competitors, ibuprofen (IBU), furosamide (FUR) and tryptophan (TRP) were studied by rapid equilibrium dialysis (RED) to select suitable model compounds for the HD study. The method was then tested in an in vitro HD experimental model with human whole blood spiked with PBUTs. After 10 min

FR-PO656

Variable Recovery Time After Hemodialysis Treatment

Antonia Harford,1 Susan Painé,2 Ronald Schrader,3 Ambreen Gul,2 Dana Miskulin,2 Philip Zager,2

Background: Prolonged recovery time after hemodialysis (HD) may predict adverse clinical outcomes. In the Frequent Hemodialysis Network a patient’s response to the Recovery Question was consistent over time. To determine if this consistency is also present among patients undergoing thrice weekly HD we compared responses to the Recovery Question after each treatment in a given week.

Methods: We asked 250 patients in 3 DCI HD facilities “How long did it take you to recover after your last treatment?” The number of patients who answered the question on the 1st, 2nd, and 3rd treatment was 221, 207, and 200, respectively; 148 patients (57.8%) answered the question on all 3 occasions. Recovery time was categorized as <0.5 hours (0 < t ≤ 0.5 h, and ≤ 6 h).

Results: Among the 148 patients who answered the Recovery Question 3 times, recovery times were 6.9, 4.5 and 9.3 hours after the 1st, 2nd, and 3rd HD. There were 46% of patients who had consistent responses on all 3 treatments; 16%, 15% and 15%, had consistently short (<0.5h), moderate (0.5-6h) and long (>6h) recovery times, respectively.

Conclusions: This method increases the removal of PBUTs and has no effect on non-protein-bound solutes. Achieving higher dialytic removal of PBUTs by infusion of binding competitors is feasible and efficient to apply in current HD settings.

Among the patients with consistent short vs. long recovery, there were no differences in age, race, and vintage. There was a trend for women (59%) to be more likely to have recovery ≥ 6 h compared to men (41%) (p = 0.008). After the 1st dialysis of the week, recovery was more likely (40%) to be ≥ 6 h among patients dyalized with a diastate sodium concentration (DNa) <140 mEq/L vs. with a (DNa) ≥ 140 mEq/L (22%). However, similar differences were not observed for the 2nd and 3rd treatments.

Conclusions: There is significant variation among individual patients answers during the week when the recovery question is asked after each treatment.

FR-PO657 Quality Control and Improvement Union of Hemodialysis Centers: A New Management Model Jinyueyan Gao, Mei Wang. Dept of Nephrology, Peking Univ People’s Hospital, Beijing, China.

Background: With the increasing incidence of end stage renal disease (ESRD) in China, more dialysis facilities are needed. There are huge variations of patient care staffing levels and quality of care. How to maximize the utilization of existing health resources, optimize the management of hemodialysis patients and improve quality control are important issues. The aim of this study was to investigate the feasibility and effects of quality control and improvement union comprised of best hospitals and basic hospitals on patients’ medical quality control and improvement.

Methods: The HD union was constructed and specific measures were determined including, 1) Quarterly continuous quality improvement (CQI) meetings, 2) education based on typical cases including: disease, guidelines and latest research results introductions, 3) lectures focusing on key questions, 4) opening green channel and construction of two-way referral system. Paired t-test was used to compare the differences of medical parameters of each hemodialysis center before and two-years after construction of HD union.

Results: The leading center of HD union was the HD center from Peking University People’s Hospital. Cooperating centers were other eight centers from class three and class two hospitals. After quarterly CQI meetings, all union members learned how to do medical quality control and improvement, constructed standards and procedures for diagnosis, cure and nursing of their HD center, established the institutions of lab exam and regular rounds, added necessary examinations and implemented all-around management of HD patients. Green channel for intractable cases transfer were applied successfully. There were statistical improvements of medical quality including dialysis frequency, hemoglobin, calcium, phosphorus, and metabolic acidosis control. Other parameters including Kt/V, iPTH, albumin and Bp improved but without significant difference.

Conclusions: Quality control and improvement union of hemodialysis centers is an effective integrated management model in Beijing China. It can improve medical quality of basic hospitals by balancing the technical advantages of grade A class three hospitals and basic hospitals.

FR-PO658 Feasibility of Mindfulness Meditation Training During Dialysis for Patients with Chronic Kidney Disease and Effect on Tolerability of Sessions James C. Wasserman,1 Daniel Schupack,2,3 Andrew E. Williams,1,4 Paul K. Han,1,4 George K. Dreher,1 Mary Bitterauf.1,4 1Div of Nephrology, Maine Med Center, Portland, ME; 2Center for Outcomes Research and Evaluation, Portland, ME; 3Maine Medical Center, Portland, ME; 4Maine Medical Center Research Inst, Portland, ME; 5MaineHealth, Falmouth, ME.

Background: Hemodialysis (HD) for CKD entails >/= 12 h of weekly treatment, creating significant distress for patients. Mindfulness-Based Stress Reduction (MBSR) has effectively helped patients with other chronic diseases cope with distressing symptoms and treatments. An abbreviated form of MBSR (Mindfulness Meditation Training, MMT) was incorporated into HD sessions to explore its feasibility, acceptability and potential effects on distress.

Methods: 12 patients were randomly assigned to MMT during HD or usual care. The MMT group underwent weekly 1-h individual sessions during HD for 4 wk. Within-session change in affective response was assessed with the Self-Assessment Manikin (SAM), validated measure of affective valence, arousal and dominance. Anxiety, depression, self-rated health and coping skills were also assessed with validated measures. Patient perceptions were assessed with qualitative interviews at study’s end.

Results: In qualitative interviews, patients reported improved tolerability of HD session length, positive intention to continue meditation and no significant issues with MMT sessions or home practice. There were no significant between-group differences in affective response, anxiety, depression, self-reported health or coping skills at baseline or in change over time. Retention rate was 91.7% overall and 83.3% for the MMT group.

Conclusions: MMT appears to be a feasible and acceptable intervention for CKD patients during HD, although effectiveness remains to be demonstrated. Small sample size and low baseline distress levels in the study population limited the power to establish effects of MMT. Further research is needed to determine if abbreviated MBSR is sufficient to benefit tolerability of HD in this population. Focus on patients with higher baseline distress levels in future research would increase the likelihood of observing clinical benefit.

Background: During hemodialysis (HD) session, plasma proteins are adsorbed to the surface of HD membrane. The resulting biofilm affects both dialyzer permeability and biocompatibility. The aim of this study was to analyze its composition in different HD membranes.

Methods: Twelve long-term HD patients were assigned to 4h HD with three different dialyzers in a cross-over design: ethylene-vinyl-alcohol/EVAL (KF-201-1.8C, Asahi Kasei), polysulfone (F8 HP5, Fresenius), and vitamin E-substituted polysulfone (VIE-18, Asahi Kasei). After HD session, the biofilm was eluted with acetic acid. Obtained proteins were detected, 235 common to all eluates. In 48 fractions, spot intensities varied between SEM, statistical significance was calculated by ANOVA (general linear model).

Results: The amount of protein eluted from KF dialyzers was higher than from F8 or Asahi dialyzers in all fractions. Asahi dialyzers showed less protein adsorption in most fractions. In KF and Asahi dialyzers, the highest protein adsorption was detected in fractions 30 to 40.

Conclusions: Our results show that different dialyzers adsorb different plasma proteins. It can be responsible for their increased clearance and temporary depletion.

Mathematical Model of Transport Protein and Plasma Refilling in Hemodialysis
Bengt Lindholm,1 Mauro Pietribiasi,2 Malgorzata Debowska,2 Alicja Wojcik-Zaluska,1 Wojciech T. Zaluska,1 Jacek Waniwetz,2 ‘Baxter Novum & Renal Medicine, Karolinska Inst, Stockholm, Sweden; 2Inst Biocybernetics & Biomedical Engineering, Warsaw, Poland.

Background: Mathematical modeling offers a way to estimate quantities we cannot access directly during hemodialysis (HD). Here we propose a whole-body model of vascular refilling describing water and protein shifts across the capillary membrane during HD.

Methods: The model predicted profiles of plasma volume and serum total protein concentration with an average root-square error < 2%, with larger errors only in pts with very high initial drop in blood volume. When increasing the assumed value of interstitial/serum protein ratio from 0.3 to 0.6, while the total refilling rate remained similar, the value of individual pore flow changed so that filtration through large pores at its peak was 40% smaller and absorption through small and ultrasmall pores was 80% and 60% higher, respectively.

Conclusions: The conclusions make a mechanistic interpretation of fluid transport processes induced by ultrafiltration during HD. The estimated values of individual flows through each kind of pores and lymphatic absorption represent the relative impact of these not-measurable quantities on total vascular refilling.

Hemodiafiltration at Increased Plasma Ionic Strength for Improved Protein-Bound Toxin Removal
Deltef H. Krietener,1 Eric Devinc,2 Thomas Koerner,1 Maricke Ruech,2 Christian Wanner,1 Joachim Jankowski,1 Horst-Dieter Lemke.2
1Nephrology, Univ Hospital Würzburg, Würzburg, Germany; 2eXcorLab GmbH, Observatory Group, Molecular Cardiovascular Research, Univ Hospital RWTH Aachen, Aachen, Germany.

Background: Protein-bound uremic toxin (PBT) removal by hemodialysis (HD) is limited in resulting in dialysis associated cardiovascular morbidity. Enhancing ionic strength in the dialyzer decreases protein binding and may result in a larger unbound and removable toxin fraction. This was implemented through high sodium concentration ([Na+] in the substitution of predilution hemodiafiltration (HDFmod).

Methods: Ex vivo predialysis HDF with blood to test increasing [Na+] to demonstrate efficacy and hemocompatibility. Hemocompatibility was further assessed in sheep using two different HDFmod setups and [Na+] between 350 and 600 mmol/L. Safety and efficacy of para-cresyl sulfate (pCS) and indoxyl sulfate (IS) removal was further investigated in a randomized clinical pilot trial comparing HDFmod to HD and standard HDF.

Results: Compared to physiological [Na+], ex vivo HDFmod at [Na+] of 500 mmol/L demonstrated up to 50% higher IS removal. Hemolysis in sheep was low even at [Na+] of 600 mmol/L; not exceeding 0.016 ± 0.001 g/dL of free HB. In patients, the reduction of ratio of free vs. total IS was 20% higher in HDFmod at [Na+] of 240 mmol/L compared to HD (72.6 ± 6.1 vs. 60.4 ± 16.5%; p=0.026). Compared to HD and HDF (23.0 ± 14.8 and 25.4 ± 10.5 mmol/L, resp.), the dialytic clearance of free IS was 37 and 24% higher in HDFmod at [Na+] of 240 mmol/L compared to HD (72.6 ± 6.1 vs. 60.4 ± 16.5%; p=0.026).

Conclusions: Ionic strength modification with HDF mod with increasing [Na+] to demonstrate efficacy and hemocompatibility. Effective HDFmod at higher [Na+] will require higher temporary surface area product (LpS) of the capillary membrane, estimated from volumetric data and blood samples collected in 20 stable, non-diabetic pts during 60 HD sessions.

Sevelamer Hydrochloride Improves Oxidative Stress in Maintenance Hemodialysis Patients
Sireen Szeze, Bahar Gurlekdemirci, Cihat Burak Sayin, Emre Tural, Zeynep Bal, Fatma Nurhan ozdemir Acar. ‘Depart of Nephrology, Basheu Faculty of Medicine, Ankara, Turkey.

Background: Oxidative stress plays a key role in the pathogenesis of cardiovascular diseases. Superoxide dismutase (SOD) and malondialdehyde (MDA) are well-known antioxidant enzymes that detoxify advanced glycation end products (AGEs). We thought that avoiding calcium intake and through pleiotropic effects, sevelamer hydrochloride might be a differential influence in terms of oxidative stress. The aim of this study is to evaluate the effects of phosphate binders (PBs) on the components of the oxidative stress and clinical and biochemical parameters including pulse wave velocity in our maintenance hemodialysis (MHD) patients.

Methods: A total of 111 patients (mean age: 52.2 ± 14.3 years; mean duration of dialysis: 9.7 ± 4.6 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n = 84) and calcium based PB (group 2; n = 27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by using the Sphygmocor system.

Results: Groups were similar in means of demographic characteristics and URR levels. In group 1 (n=84; mean duration of dialysis: 9.7 ± 4.6 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n = 84) and calcium based PB (group 2; n = 27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by using the Sphygmocor system.

Groups were similar in means of demographic characteristics and URR levels. In group 1 (n=84; mean duration of dialysis: 9.7 ± 4.6 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n = 84) and calcium based PB (group 2; n = 27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by using the Sphygmocor system.

Results: Groups were similar in means of demographic characteristics and URR levels. In group 1 (n=84; mean duration of dialysis: 9.7 ± 4.6 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n = 84) and calcium based PB (group 2; n = 27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by using the Sphygmocor system.

Groups were similar in means of demographic characteristics and URR levels. In group 1 (n=84; mean duration of dialysis: 9.7 ± 4.6 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n = 84) and calcium based PB (group 2; n = 27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by using the Sphygmocor system.
Conclusions: Despite similar phosphorus levels and dialysis adequacy, sevelamer decreased serum HDL levels more than AIP. Sevelamer may act as an independent risk factor for mortality. Strategies could be helpful to routinely identify those dialysis patients at risk of functional impairment and depression to limit their disabilities. Self-report scales and those performed by nursing staff could improve the integral treatment of those patients.

FR-PO666
Preliminary Study About Optimal Dosage of Heparin Locking Solution to Maintain the Patency of Hemodialysis Catheter Jung-woo Noh, Eunjung Kim, Ja-Ryong Koo. Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym kidney Research Inst, Seoul, Korea.

Background: Hemodialysis catheters (HC) are routinely heparin locked to maintain patency. This practice may cause bleeding episodes. The amount of heparin for heparin locking solution at many dialysis centers has been decreased recently to reduce the risk of bleeding. However, the effect of this change on patency of HC is unknown. We compared the patency of HC between four types of heparin amount of 4000, 5000, 7500, and 15000 units (U).

Methods: This observational study included 126 chronic hemodialysis patients using HC in Hallym University Medical Center from March 2011 to July 2014. 29 patients received a 4000 U, 41 patients received a 5000 U, 44 patients received a 7500 U and 41 patients received a 15000 U of heparin. The primary outcome was composite outcome: frequency of thrombolytic instillation, change of hemodialysis line due to dysfunction of HC and HC obstruction due to thrombosis. We also compared activated partial thromboplastin time (aPTT) levels between groups just before and 10 minutes after the end of each hemodialysis.

Results: The composite outcome were 2.44±5.42, 1.06±3.46, 0.40±1.18 and 0.52±1.16 episodes/100 catheter-days, respectively (p=0.03). 4000 U group showed especially high rate of every outcome compared to other groups receiving more than 5000 U of heparin. However, event rate of HC obstruction due to thrombosis was not significantly different: zero episodes/100 catheter-days for 4000U and 5000UU groups, 0.01±0.05 episodes/100 catheter-days for 5000IU group and 0.14±0.61 episodes/100 catheter-days for 7500 IU group. At 10 minutes after heparin lock, prolonged aPTT was observed in all groups. When 10 minutes aPTT levels between 4000 U group and other groups are compared, those of 7500 U (p=0.007) and 15000 U (p=0.004) groups were significantly prolonged. But there were no bleeding complications in those groups.

Conclusions: Low concentration heparin lock solution with total amount of 4000 U do not increase HC obstruction due to thrombosis, but increase in thrombolytic instillation and set change. Higher concentration heparin lock solution with total amount over 7500 U prolonged the aPTT without bleeding complication. Funding: Clinical Revenue Support

FR-PO667
Association Between Depressive Symptoms and Dependency with Mortality in Hemodialysis Patients After 5 Years of Follow-Up Joaquin Manrique,1 Maria del cielo Mena,2 Eva Cerdan,2 Laura Catalan,2 1Servicio de Nefrologia, Complejo Hospital de Navarra, Pamplona, Spain; 2Nursing Staff. Servicio de nefrologia, Complejo hospital de Navarra, Pamplona, Spain.

Background: The prevalence of depression and its role in mediating survival of patients with end-stage renal disease (ESRD) has been highly controversial. Moreover, according to the population ages, their limitations in performing daily activities affect their well-being and set change. Higher concentration heparin lock solution with total amount over 7500 U prolonged the aPTT without bleeding complication.

Methods: We determine whether depressive symptoms and dependency are associated with mortality in a longitudinal study of 148 hemodialysis (HD) outpatients followed for 5 years. Depressive symptoms were assessed using the Beck Depression score (BDs), and dependency by Barthel scale (BS) performed by nursing HD staff.

Results: 28.8% of patients had depressive symptoms (BD>10) and the mean baseline BDs was 11.4±8.1. 23% patients were moderate or severely dependent (BS<90). 40.5% died during the study follow-up period (a rate similar to that found in this population). We observed a significant association between BS and BDs (r=0.5; p<0.001). Patients with greater disability (BS>90) had worse depressive score (p<0.001). After 60 months of follow-up, survival rates were 80.5% for BDs<9 and 94.3% for BDs ≥9 (p<0.05), and 71.4% for dependent and 95.5% for no dependent patients (p<0.001). Other variables, including age, gender, and dialysis period, were not significantly associated with mortality. Cox proportional hazards regression was performed to predict the mortality hazard associated with age, gender, and dialysis period, were not significantly associated with mortality. Cox proportional hazards regression was performed to predict the mortality hazard associated with age, gender, and dialysis period, were not significantly associated with mortality. Cox proportional hazards regression was performed to predict the mortality hazard associated with age, gender, and dialysis period, were not significantly associated with mortality.

Conclusions: Our study shows that the disability in self-care and the presence of depressive symptoms are common among patients on haemodialysis. Both of them may act as independent risk factors for mortality. Strategies could be helpful to routinely identify those dialysis patients at risk of functional impairment and depression to limit their disabilities. Self-report scales and those performed by nursing staff could improve the integral treatment of those patients.

FR-PO668
Limitations of Access Recirculation due to a Low Access Flow Rate on Middle Molecule Clearance During Post-Dilution Hemodiafiltration J. Ken Leypoldt,1 Markus Storr,2 Renal Therapeutic Area, Baxter Healthcare Corporation, Deerfield, IL; 1Research & Development, Gambio dialysatoren GmbH, Hechmnig, Germany.

Background: Post-dilution hemodiafiltration (HDF) with a high convective volume (CV) is associated with lower overall patient mortality, potentially due to high middle molecule (MM) clearance from the patient (Kp). A higher CV can most readily be achieved by extending the treatment time or increasing the blood flow rate (BFR); however, the effect of access recirculation due to a low access flow rate (AFR) when increasing the BFR on MM Kp during HDF has not been previously quantified.

Methods: A theoretical mass balance model for assessing the effect of a low AFR on MM Kp was formulated. Access recirculation was assumed to occur when the BFR exceeded the AFR. The model demonstrated that MM Kp was dependent on HDF membrane properties, AFR, BFR, CV and the fluid removal rate from the patient (FRR).

Results: Example results are tabulated for a patient with a hematocrit of 33% at different AFRs and BFRs maintaining a fixed filtration fraction of 25% during a 4-hour HDF treatment with a FRR of 0.5 L/hour. MM filter clearance was assumed to depend on CV with a diffusive clearance of 75 mL/min and a sieving coefficient of 0.7.

When the AFR is higher than the BFR, MM Kp increases with increasing CV. At low AFR, increasing the BFR above the AFR resulted in a lower MM Kp than expected. Indeed, increasing the BFR above the AFR can even lead to a reduction in MM Kp.

Conclusions: High convective volumes during post-dilution HDF achieved by using high blood flow rates may not result in higher middle molecule clearance if the access flow rate is low. Routine assessment of access recirculation or access flow rate may be necessary during post-dilution HDF with high blood flow rates to improve patient outcomes.

FR-PO669
Protein Biofilm and Its Relation to Dialyzer Permeability for Middle Molecular Weight Markers in Three Polysulfon Membranes Lukas Kielberger, Jan Mares. 1st Dept of Internal Medicine, Charles Univ Teaching Hospital, Plzen, Czech Republic.

Background: Membrane permeability, particularly in terms of middle molecular clearances, is largely dependent in vivo on the formation of a protein biofilm. Our aim was to assess its dynamics during HD session together with molecular composition of the biofilm.

Methods: 12 HD patients were assigned in a cross-sectional design to Xevonta® Hi23 (B-Braun, 2.3 m²), CorDiax FX100® ( Fresenius, 2.2 m²) and Polyflux® 210H (Gambro, 2.1 m²) dialyzers. Blood pre- and post- dialyzer was sampled at 0, 15, 60, and 240 min; spent dialysate was collected over the first 15 min and then until the end of the session. B2 microglobulin (B2M), myoglobin (MB), retinol-binding protein (RBP), and chondroitin sulfates (lms) levels were determined as permeability markers covering an interval of molecular weight (MW) 1-12 kDa. After HD, protein biofilm was eluted from dialyzer and subjected to proteomic analysis.

Results: At the beginning, Xevonta and FX dialyzers showed significantly higher in vivo sieving coefficients for all MWs up to 26 kDa (lms) than Polyflux dialyzer (p<0.01). After 15 min, Xevonta and FX permeability decreased significantly (p<0.01) in all MW classes while in Polyflux, only MW 21 kDa (RBP4) were affected (p<0.01). The total protein content of membrane biofilm was similar in all three dialyzers: 118±85, 41±10, and 40±17 mg protein per dialyzer for Xevonta, FX, and Polyflux, resp. Significant differences in protein composition were captured in 48 out of 231 protein fractions. Among them, complement factor H-related protein 3 (FHR3), insulin-like growth factor binding protein 4 (IGFBP4), or multiple fibrin fragments (FDP) were identified. While FDP and IGFBP4 were prevalent in eluates from FX and Xevonta dialyzers (p<0.005 and 0.001, resp.), FHR3 was abundant in Xevonta only (p<0.01).

Conclusions: Even with modern biocompatible dialyzers, in vivo permeability decreases along HD session, probably due to biofilm formation. The decrease occurred irrespective of total protein adsorbed, compromising rather membranes primarily more permeable and higher MWs. Differences in biofilm composition are complex and may impact both dialyzer permeability and biocompatibility.

Proteoic Effects of Intravenous L-Carnitine (LC) Administration on Development of Cardiomyopathy in Hemodialysis (HD) Patients Takuiha Uchiho,1 Jyunichiro Hashiguchi,1 Satoshi Funakoshi,1 Hiroshi Ichinose,1 Osamu Sasaki,1 Kenji Sawaji,2 Miki Yano,1 Yutaka Moriyama,3 Kazunori Utsunomiya,3 Yoko Obata,1 Tomoya Nishino,2 Miwa Shirahama,1 Takashi Harada,1 Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan.

Background: Due to loss via dialyzer patients on maintenance HD often suffer from dialysis-related cariomyopathy, leading to various clinical symptoms. Cardiomyopathy Consensus Conference in 2003 convened by The National Kidney Foundation had reported that the level of evidence was “moderate” for cardiomyopathy. Recent studies have shown that LC can improve left ventricular (LV) function in HD patients. In this study, we aimed to evaluate whether intravenous administration of LC can prevent the development of cardiomyopathy in HD patients as assessed by M-mode ultrasound cardiography (UCG).

Methods: Thirty-eight HD patients without reduced left ventricular function were treated with intravenous administration of 1000 mg/body of LC at the end of every HD session for 12 months. M-mode UCG assessments were undergone in all subjects at the tree points: 1 year prior to the treatment, the start of LC administration and year after the treatment.

Results: As shown in Figure 1, average %FS (fractional shortening) significantly declined during 1 year before the start of LC, then stabilized after the treatment, suggesting LC administration might protect the progression of LV contraction impairment. Early average diastolic filling velocity (E) / atrial filling velocity (A) ratio showed similar pattern, suggesting LC treatment could be protective in LV diastolic disorder. LC treatment also might delay LV hypertrophy progression.

Conclusions: Intravenous LC administration can be a candidate therapy for protection of the development of cardiomyopathy in HD patients.

Symptoms and Quality of Life Among Patients Receiving HD Mark L. Unruh,1 Kim J. Cox,1 Stephen H. A. Hernandez,2 Sanah Parvez,1 Mark Parshall.1 1Div of Nephrology, Univ of New Mexico; 2College of Nursing, Univ of New Mexico.

Background: Health-related quality of life (HRQOL) assessment is a required condition of coverage for HD providers, but standard measures may not adequately reflect the impact of symptoms and treatment on QOL for patients receiving HD or the concerns that matter most to them. The purpose of this qualitative study is to more fully characterize patients’ perspectives on the symptoms and treatment experiences affecting their QOL.

Methods: We conducted semi-structured interviews with a diverse sample of 50 patients’ perspectives on the symptoms and treatment experiences affecting their QOL. Interviews were audio-recorded, transcribed, and analyzed for themes using an interpretive-approach.

Results: Participants recollected that the initial diagnosis of ERSD was received with shock and denial. Over time, patients reported that QOL was associated with “taking control” of some features of their treatment. Common symptoms associated with HD, such as cramping and fatigue, were described as potentially manageable when patients were able to participate in decisions about fluid removal and scheduling of HD treatments. Patients who formed a partnership with their providers to negotiate fluid removal reported fewer episodes of severe cramping and improved QOL. Similarly, being able to choose among a variety of days and shifts for HD treatment enabled patients to manage fatigue, work hours, travel, and attendance at social events. These factors were critically important to the QOL in our relatively young sample (median age = 53; median duration of HD treatment = 4 years).

Conclusions: This is one of the largest and most diverse qualitative studies of symptoms among patients undergoing HD. There were few differences in symptoms or the impact of treatment on QOL among racial and ethnic groups. Findings highlighted the importance of fluid management and fatigue to patient experience.

Association of Time-Averaged Concentration of Hemoglobin with Mortality: Results from a Large U.S. Hemodialysis Cohort

Hanie Zhang, 1 Stephan Thijssen, 1 Peter Kotanko. 1,2
1 Renal Research Inst, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In hemodialysis (HD) patients the time averaged concentration of hemoglobin (Hb_tac) can be estimated from pre- and post-HD hemoglobin (Hb) levels. It has been suggested that Hb_tac may be an appropriate indicator for anemia management. Methods: We analyzed Hb data obtained by Crit-Line™ monitor (CLM) in chronic HD patients. A 6-month baseline period with at least 10 CLM measurements preceded a 12-month follow-up during which outcomes were assessed. We used Hb values from HD sessions following a short interdialytic interval. Hb_tac was computed as follows (Kriiper, NDH-2000): Hb_tac = Hb_post × 0.5 + Hb peut × 0.38 + 1.28. We defined Hb_great as the average Hb between minutes 5 to 20 from the start of the CLM recording, and Hb_post as the average of Hb between minutes 5 to 20 from the end of the CLM recording. The relation between Hb_tac during baseline and mortality was explored by spline analysis of hazard ratio (HR).

Results: We studied 982 patients (Figure 1A) with a total of 19,142 CLM measurements. Average Hb_tac was 10.72 g/dL (SD 0.81, range 7.27 – 14.62 g/dL). The mortality rate during follow-up was 11.6 per 100 patient-years. The minimal HR (figure 1B) was 0.82 at Hb_tac of 10.87 g/dL. The solid line represents mean HR, the dotted lines 95% confidence interval.

Conclusions: Hb_tac is associated with mortality, levels around 10.9 g/dL are associated with the lowest mortality risk. Studies are required to further explore methods to estimate Hb_tac based on Hb measurements by the CLM and the usefulness of Hb_tac as an indicator of anemia control.

Development and Validation of a Predictive Mortality Risk Score in Chinese Incident Maintenance Hemodialysis Patients

Xiaoyan Zhang, 1 Yimei Zhang, 1 Jun Xia, 1,2 Yingying Han, 1 Shuangguang Wang, 1 Jiangtao Chen, 1 Wei Zeng, 1 Hongjie Zhang, 1 Hangzhou, Zhejiang, China.

Background: We aimed to predict 2-Year all-cause mortality in incident maintenance hemodialysis (MHD) patients by using available clinical and laboratory data, and to establish a risk scoring model.

Methods: A total of 2700 data of incident MHD patients were from Zhejiang Dialysis Quality and Management Center(ZDQM) during the period from January 2008 to June 2012. All patients were ³18 years old and survived at least 3 months after starting dialysis treatment. It has been suggest that Hb_tac may be an appropriate indicator for anemia management. The predictor variable was race (White as reference). Outcomes were mortality and hazard ratio (HR).

Results: We studied 982 patients (figure 1A) with a total of 19,142 CLM measurements. Average Hb_tac was 10.72 g/dL (SD 0.81, range 7.27 – 14.62 g/dL). The mortality rate during follow-up was 11.6 per 100 patient-years. The minimal HR (figure 1B) was 0.82 at Hb_tac of 10.87 g/dL. The solid line represents mean HR, the dotted lines 95% confidence interval.

Conclusions: Hb_tac is associated with mortality, levels around 10.9 g/dL are associated with the lowest mortality risk. Studies are required to further explore methods to estimate Hb_tac based on Hb measurements by the CLM and the usefulness of Hb_tac as an indicator of anemia control.

Low Lymphocyte Counts Are an Independent Predictor of Mortality in Chronic Hemodialysis Patients: A Retrospective Cohort Study

Background: Mortality in chronic hemodialysis populations remains high. Lymphopenia has been associated with increased cardiovascular risk in the general population but few data are available on the effect of low lymphocyte counts on long-term survival of hemodialysis patients.

Methods: Retrospective study of a single-center cohort of 689 hemodialysis patients using monthly laboratory results and dialysis parameters extracted from a center database and a national registry. The effect of baseline and time-changing lymphocyte counts on overall mortality was studied using the Kaplan Meier and Cox proportional hazard methods.

Results: Lymphopenia (<1200/µL) was present in approximately one third of incident hemodialysis patients and correlated with older age, lower creatinine, lower phosphorus, higher Kt/V and a positive history of ischemic heart disease. Lymphopenia was not associated with classical markers of malnutrition-inflammation complex such as albumin, normalized protein catabolic rate, BMI and CRP. Baseline lymphopenia was associated with a 54 percent increase in the hazard of death (HR 1.54 (1.17 to 2.0; p=0.002)) as compared to the tertile of patients with highest lymphocyte counts. Lymphocyte counts tended to decrease during long-term follow up and their introduction as a time-changing variable further increased the HR to 2.1 (1.48 to 2.84; P<0.0001). The association remained tended to decrease during long-term follow up and their introduction as a time-changing variable further increased the HR to 2.1 (1.48 to 2.84; P<0.0001). The association remained.

Conclusions: Lymphopenia is highly prevalent in hemodialysis patients and is a strong predictor for patient death. The association was stronger when lymphocyte counts were considered as a time-changing variable and independent of other risk factors for patient death. Lymphopenia was not associated with markers of the malnutrition-inflammation complex (MIC) and therefore appears a useful prognostic tool in addition to classical markers such as CRP and albumin levels.

Current Status of Hemodialysis in China
Li Zhang, Delong Zhao, Xueying Cao, Xiang-Mei Chen, Guangyan Cai. Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.

Background: In May 2010, the first nationwide, web-based prospective renal data registration platform, the Chinese Renal Data System (CRNDS) was launched in China. The purpose of this study was to determine the current status of hemodialysis in China by analyzing the data from CRNDS.

Methods: The data from CNRDS were used for dialysis cases including demographic, clinical, and laboratory data. We analyzed the data from CRNDS by the end of 2014.

Results: (1) There were 4047 domestic hemodialysis centers and 339748 survival patients were registered by the end of 2014. (2) In the 339748 patients, 58.85% were male. The average age was 59.9 years and average dialysis duration was 42.2 months. The three leading causes of ESRD were glomerulonephritis, diabetic nephropathy and hypertensive renal diseases. (3) 14322 patients died in 2014, with an average age of 61.9 years and average leading causes of ESRD were glomerulonephritis, diabetic nephropathy and hypertensive renal diseases.

Conclusions: Hemodialysis (HD) care is routinely assessed by a set of clinical and laboratory parameters, known as Clinical Quality Indicators (CQI). CQI registry and reporting systems constitute an instrument to evaluate the quality of care provided at each HD Unit. The purpose of this study was to determine whether CQI, applied on an individual patient basis, is a predictor of mortality.

FR-PO680
Outcomes and Quality of Care in Rural versus Urban Managed Dialysis Patients
James M. Zacharias, Allison Dart, Harvey M. Chochinov. 1 Dept of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 2 Dept of Pediatrics, Univ of Manitoba, Winnipeg, MB, Canada; 2 Dept of Psychiatry, Univ of Manitoba, Winnipeg, MB, Canada.

Background: A proportion of patients are managed in remote satellite units in Manitoba, Canada. Urban nephrologists oversee all dialysis care; however family physicians (FP) co-manage patients. This study examines outcomes and quality of care indicators in rural vs urban managed patients.

Methods: Prospectively collected clinical data from the Manitoba Renal Program and administrative health data housed at the Manitoba Centre for Health Policy were analyzed retrospectively. All adult (>18yo) hemodialysis patients (n=90 days from 1995 to 2010 were included. Individuals dialyzing in rural satellite units (n=510) more than 50% of the time were compared to their urban (n=2629) counterparts. Differences in cohort characteristics were analyzed at baseline as well as differences in primary care quality indicators. Regression analyses examined differences in hospitalizations and days in hospital. Cox proportional hazard models were performed to examine differences in survival.

Results: Patients in rural satellite units vs urban were younger, 58 yrs (p<0.002), but were more likely to have DM 69.4 vs 55.3% (p<0.001), PVD 9.4 vs 4.0% (p<0.001) and HD (MD, Angiogram or PTCA) 42.8 vs 34.2% (p<0.002). More rural patients accessed a FP at least once per year 85.7% vs 67.3% (p<0.001) and 85.3% vs 68% (p<0.001), after controlling for sex, income, charlson, era, age and region at the start of dialysis.

Conclusions: Survival in a cohort of patients dialyzing in remote satellite units was found to be worse compared to their urban counterparts, after controlling for co-morbidities. A potential reason might be increased primary care involvement, although differences were not seen in traditional quality of care indicators.

Funding: Private Foundation Support

FR-PO681
Applying Hemodialysis Clinical Quality Indicators to Individual Patients: A Useful Mortality Prognostic Tool in Clinical Practice?

Background: Hemodialysis (HD) care is routinely assessed by a set of clinical and laboratory parameters, known as Clinical Quality Indicators (CQI). CQI registry and reporting systems constitute an instrument to evaluate the quality of care provided at each HD Unit. The purpose of this study was to determine whether CQI, applied on an individual patient basis, is a predictor of mortality.

Methods: Retrospective study that included 334 patients of a HD Unit from 2011 to 2014. Demographic, clinical and laboratory data were collected. The CQI considered were eleven, which included intended target: spgK/V ≥ 1.4; weekly dialysis time ≥ 720 minutes; Albumin ≥ 3.5 g/dL; Hemoglobin between 10 and 12 g/dL; phosphatemia between 2.5 and 5.5 mg/dL; CaP product < 55 mg²/dL; PTH levels between 150 and 600 pg/mL; Ferritin between 200 and 800 mg/L; Mean arterial pressure < 105 mmHg; interdialytic weight gain (IWG) < 4%; and fistula at vascular access. Single CQI were rated in a binary form (0 = not reached target/1 = reached target) at each monthly evaluation and the average were determined. Ultimately, the eleven parameters were added in a single variable for each patient (CQp).

Results: During follow-up, 33% of patients died. In the Cox regression model, age (HR 1.09; CI 1.07-1.11; p < 0.001), diabetes (HR 2.88; CI 1.92-4.32; p < 0.001), peripheral arterial disease (HR 1.63; CI 1.09-2.44; p = 0.016) and CQp (HR 0.73; CI 0.62-0.87; p < 0.001) were shown to be independent predictors of mortality, after adjustment for other clinical and demographic factors. When CQp was replaced by its constituent variables, albumin (HR 0.06; CI 0.08-0.32; p < 0.001), PTH (HR 2.8; CI 1.10-3.93; p = 0.023), IWG (HR 0.34; CI 0.14-0.83; p = 0.018) and fistulae presence (HR 0.61; CI 0.45-0.90; p = 0.021) presented statistical significance.

Conclusions: A set of parameters, generally applied as a quality care indicators, proved to be an independent predictor of death when applied to individual patients. This should be regarded as an easy and practical prognostic tool to be applied in current practice.

FR-PO682
Association of Estimated Glomerular Filtration Rate at Commencement of Maintenance Dialysis with Mortality Among Patients with Advanced Chronic Kidney Disease in Singapore

Background: Recent evidence suggests that higher estimated glomerular filtration rate (eGFR) at commencement of dialysis may be associated with increased mortality. However, there is scarcity of data on patients of Southeast Asian origin. We analyzed and compared mortality risk in patients with early and late start dialysis as measured by kidney function at dialysis initiation among Southeast Asian population of Singapore.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

517A
Methods: We performed a retrospective analysis of patients enrolled in the Singapore Renal Data system database from 2008 to 2011. Patients were classified into groups by eGFR at dialysis initiation.

Results: In this total incident population (n=3708), a total of 1510 individuals died during a median follow-up period of 2.8 years. The hazard ratio (HR) and 95% CI associated with different levels of eGFR at commencement of RRT are shown in table below. The main multivariable model (n=3189 without missing information on covariates) associated with the eGFR at dialysis initiation within the groups: age, gender, level of education, smoking, presence of diabetes, ischemic heart disease, cerebrovascular disease, and peripheral vascular disease, malignancy, hepatitis B, hepatitis C, kidney transplant, and prevalence of dialysis. Additional models accounted for serum albumin (n=2657), and serum ferritin (n=2462), and serum calcium (n=1628).

The results were consistent after accounting for serum albumin, serum ferritin, and serum calcium in the multivariable models.

Conclusions: Late initiation of dialysis is associated with a lower risk of mortality in comparison with early dialysis initiation in Southeast Asians in Singapore.

FR-PO683
Predicting Mortality for Patients Who Are on Hemodialysis—A National Cohort Study in Taiwan
Jinn-Yang Chen, Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Comorbid conditions and medical history provide prognostic information for dialysis patients. The objective of this study was to develop a prognostic model to predict short-term (6-months and 1-year) and long-term (2.5-years) survival for incident hemodialysis (HD) patients.

Methods: Incident Taiwanese hemodialysis patients from 2006 to 2010 were extracted from National Health Insurance claim records. Prognostic model was developed by using comorbid conditions (summarized as Taiwan index), monthly income and medical history during one year before initiation of dialysis. Somer’s D statistic was used to assess the discrimination ability of our model.

Results: A total of 36,875 incidence HD patients were included in this study and the last follow-up day was December 31, 2011. More comorbid burden, male gender, history of acute kidney injury, dementia, admitting to intensive care unit, staying at nursing home and ever using ventilator were significant prognostic factors. Monthly income only had marginal effects on survival at 2.5 years. For discrimination ability, our model has Somer’s D statistics of 0.76, 0.75, and 0.75 for 6-months, 1-year, and 2.5-years survival, respectively.

Conclusions: Three prognostic models with same covariates for short-term and long-term survival in HD patients were found in this study. The consistency in model performance helps clinicians and patients to make decision.

FR-PO684
Twice Weekly Treatment Eligibility for Incident Hemodialysis (HD) Patients
Suresh Appasamy, Andrew L. Chin, Thomas A. Depner. Div of Nephrology, Univ of California, Davis, Sacramento, CA.

Background: KDOQI guidelines advise that hemodialysis treatments constitute a patient burden and a risk to native kidney function that can be lowered by reducing HD frequency from 3 to 2/week in patients with substantial residual kidney function. To determine eligibility for twice weekly HD we analyzed 24 hour residual urea clearances (Kru) and volume removal requirements in all incident patients with urine output >100 mL/day in 4 HD centers.

Methods: From the years 2000-2014, 420 out of 734 incident patients who survived ≥6 mos, starting HD 3 week had Kru measurements within 1-3 months after starting HD. The fractional weekly renal clearance (KrT/V) was subtracted from the continuous equivalent minimum goal stdKT/V of 2.0 volumes/week to determine the minimum required standard dialyzer clearance (stdKT/V). With N set as 2 week, stdKT/V was back-calculated from the Leypoldt equation for stdKT/V, KeyT/V from the Tattersall equation for TTV, and KrTu from modeled V and T that was limited to a maximum of 4 hours. Patients were excluded if the ultrafiltration (UF) rate needed to control volume was >10 mL/kg/hr, MAP dropped >10 mmHg, or the patient exhibited symptoms of nausea, vomiting, or cramps.

Results: Patients: N=420, age 57±15 yrs, 58% male, 51% diabetic, 66% TD Catheters. Urine collections: 974±617 mL, Kru 3.0±2 mL/min, KrT/V 7.0±1.5. UF/2±1.1/L/dialysis (3x/week), 2.8±1.6% of dry weight.

In the 225 patients who could achieve the target stdKT/V with 2/week HD, the mean spKT/V required was 0.83±0.36. A total of 105 or 25% of patients with measured Kru met all 4 criteria.

Conclusions: Urine collections disclosed that 225 or approximately 30% of 734 incident patients were eligible for 2/week HD based on solute kinetics alone. Using conservative criteria, half of these were judged ineligible because of UF requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

FR-PO685
The Relationship of Diabetes and Congestive Heart Failure to Costs of Care in End Stage Renal Disease Patients
Sheetal Chaudhuri, Jane Brzozowski, Hao Han, Len A. Usvyat, John W. Larkin, Mahathi Mohali, Terry Ketchersid, Franklin W. Maddux. Fresenius Medical Care North America, Waltham, MA.

Background: Many Medicare patients (Pts) with end stage renal disease (ESRD) are known to have co-morbidities of diabetes mellitus (DM) and/or congestive heart failure (CHF). Total costs of care for ESRD Pts are likely to be dependent on patient co-morbidities and likely to vary by geography. We investigated the relationship of DM and CHF based on Pts’ geographic location.

Methods: ESRD Pts with evidence of dialysis at any time during Jan 1, 2010 through Dec 31, 2011 and Medicare as their primary payer were analyzed. Pts were stratified based on Metropolitan Statistical Areas (MSA) and Medicare Part A and B costs were calculated from 100% Medicare data. T-test comparisons were performed for quartiles of total cost of care for eight groups: based on vintage (incident [<90 days on dialysis] or prevalent [≥3 years on dialysis]), as well as, comorbidities (no DM and no CHF, no DM and with CHF, no DM and with both DM and CHF).

Results: Claims for 107,659 Pts were analyzed. Total cost of care increased significantly as the percent (%) of Pts with CHF and DM increased; cost of care declined significantly as the % of Pts with neither DM nor CHF increased by MSA. Cost of care did not change with the increase in % of Pts without DM and with CHF. Yet, costs of care declined as % of Pts with DM and without CHF increased by MSA. These patterns were observed in both incident and prevalent Pts.

Figure 1. Costs of care by MSA (per member per month)

FR-PO686
Long Term Outcomes Over 2 Years following a Dialysis Adequacy Quality Improvement Initiative
Sajeda Yousouf, Philip A. Kalra, Janet Hegarty. 1 Salford Royal NHS Foundation Trust; 2 Manchester Academic Health Sciences Centre.

Background: Dialysis adequacy is known to correlate with clinical outcomes such as mortality. Evidence based guidelines recommend that haemodialysis patients should achieve a urea reduction ratio of >65%. UK Renal Registry data shows wide variation in facility attainment of target URR. In 2010 the Salford Renal Network implemented an ambitious programme to uplift attainment of key quality of care indicators to within the top 10% in the UK; dialysis adequacy was a target in 2 phases of improvement in 2010-2012.

Methods: Our network implemented a quality improvement programme using collaborative methodology. We set four teams a different clinical indicator to work on over 12 month cycles for 2 successive years, guided by QI facilitation input. Unit A worked on URR in phase 1 and developed a package of changes using plan-do-study-act (PDSA) testing that was used for improvement by Unit B in phase 2. We analysed the long-term outcomes in these units for a further 2 years until May 2014.

Results: Both units reached their aim of >90% of patients achieving target URR>65% within their improvement year. Both units sustained the improvements for 2 years with no additional resource input after the collaborative. Changes included protocolised nurse-led changes to dialysis prescriptions, multidisciplinary review of vascular access, a nurse-led anticoagulation protocol, blood sampling protocol, and monthly reports.

Conclusions: These results identify differences in association between ESRD related co-morbidities and total costs of care: the % of Pts with both DM and CHF is higher in areas with higher total costs. Surprisingly, costs of care are lower in areas where the % of Pts with DM and without CHF is higher. Risk Adjustments should be considered.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America
Conclusions: Longer term outcomes from QI interventions are underreported with limited evidence on sustainability. We implemented multifaceted interventions to improve dialysis adequacy in our network to within the top 10% in the UK. Implementing evidence-based changes led by frontline staff trained in QI has sustained these improvements for 2 years after a formal QI intervention, improving quality of care for our patients.

FR-PO687
Clinical Effectiveness of Intermittent Infusion Hemodiafiltration (I-HDF) Compared with Conventional Hemodialysis: A Multicenter Clinical Trial
Michio Mineshima, Kei Eguchi. Clinical Engineering, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Intermittent infusion hemodiafiltration (I-HDF) using backfiltration of an ultrapure dialysis fluid has been developed to improve the peripheral circulation of the patient receiving a typical hemodialysis (HD) with repeated intermittent infusion by an automated dialysis machine, GC-110N (JMS Co. Ltd., Tokyo, Japan). In a typical HD treatment, excessive water removal often induces hypotension and muscle spasm. In the I-HDF, some 200-300 mL of ultrapure dialysis fluid was infused into the blood component through the dialysis membrane at a rate of 100 mL/min, every 30 min. I-HDF, namely, means a HDF treatment with small amount of infusion volume, 1.4 to 2.1 L (200-300 mL x 7 times)/session.

Methods: In this paper, clinical effectiveness of I-HDF was evaluated in comparison with conventional HD (CHD) during a multi-center clinical trial that twenty chronic renal disease patients participated.

Results: A significantly lower value for time-averaged blood volume reduction was obtained with I-HDF compared with CHD in spite of there being no difference in the total amount of water removal. It was due to a higher plasma reffilling rate in I-HDF. In addition, increasing peripheral blood flow rate in the patient’s toe was detected by a laser flowmeter for each infusion in many patients. The cleared space value defined as amount of normalized solute removal during a treatment were higher with I-HDF than CHD for inorganic phosphate and α 1-MG. Moderate α 1-MG clearance reduction was found in I-HDF due to the prevention of membrane fouling by intermittent backfiltration of the backfiltration solution. Mean URR, % (SD) Unit A 70.3 ± 8.3 74.5 ± 5.5 74.9 ± 4.9 0.002

Conclusions: Intermittent Infusion HDF using an automated dialysis machine was effective for improvement of the peripheral circulation of patients receiving conventional HD.

FR-PO688
Impact of Post-Hospital Phone and Telehealth Case Management to Reduce Admissions in Hemodialysis Patients
Rebekah L. Wingard,1 Billie Axley,1 Kathryn A. McDougall,1 Andrew D. Howard,1 Joelle Helemann,2 Perry Parlier,1 Sophia Rosen,1 Len A. Usuyvat,1 Alexis Porras,1 Franklin W. Maddux.1 1Fresenius Medical Care, Waltham, MA; 2Metropolitan Nephrology Associates, Clinton, MD.

Background: 2012 30-day readmissions for hemodialysis (HD) patients (pts) were at high 35% in 2012 (USRDS). The Right Trac (RT) Program addressed factors in the complex process of care transitions, with the aim to reduce hospital admissions and readmissions.

Results: 26 HD clinics (3682 pts) were in RT. Interventions deployed in 3 phases (Apr ‘13-Nov ’14). I: Pre- and post-hospital checklists for clinics to manage pt teaching, anemia, nutrition, medications, and dry weight. II: Telephonic case management for 30 days post-discharge. III: Dialysis Link® centralized clinical info exchange among providers. Admission and readmittance rates per pt year (ppy) for “baseline year” (2012) vs. “full intervention year” (2014) were compared to 18 control clinics (2449 pts) matched for clinic size, admission and readmission rate, and urban vs. rural location at baseline. Poisson models with random effects for pt and clinic, adjusted for age, vintage, race, gender, ethnicity, DM, CHF, and COPD were constructed to assess the difference between baseline and intervention and between RT and control clinics.

Conclusions: RT interventions were associated with significant declines in admissions and 30-day readmissions. The difference in the changes between RT vs. controls was significant for admissions, but not significant for 30-day readmissions.

FR-PO690
Predicting Early Mortality Among Hemodialysis Patients Using USRDS Data
Fang Wang,1 2 Zhi He,1 Jennifer L. Bragg-Gresham,1 Yuan Yang,1 Haoyu Gu,1 Yi Li,1 Kamyar Kalantar-Zadeh,1 Elani Streja,1 Rajiv Saran,2 1Div of Nephrology-Dept of Internal Medicine and KeCC, Univ of Michigan, Ann Arbor, MI; 2Renal Div Dept of Medicine, Peking Univ First Hospital, Beijing, China; 3Dept of Biostatistics and KeCC, Univ of Michigan, Ann Arbor, MI; 4Univ of California Irvine, Orange, CA; 5Harold Simmons Center, Orange, CA.

Background: Higher early mortality of hemodialysis (HD) is recognized. We sought to quantify the risk of early mortality and develop a robust prediction model which could potentially guide clinical decision-making.

Methods: The 2007-2012 data from the United States Renal Data System (USRDS) on incident HD patients, age 18-17 years, were randomly split as ‘training’ and ‘validation’ samples. Cox proportional hazards model with piece-wise constant coefficients was used to model all-cause mortality during day 0-90 and day 91-365 of HD. Those transferred to peritoneal dialysis or transplantation were censored. The resulting model was validated by C statistic.

Results: The model mean (n=611,094) was 63.6±14.9 years, with 130,473 deaths during the first year of HD. Mortality rates were 35 per 100 person-years in the first 90 days and 21 per 100 person-years during days 91-365. The model was used to estimate early mortality involving 23 variables including demographics characteristics, pre-ESRD care, laboratory values, co-morbidities as well as institutionalization status. In adjusted analyses, selected variables with significant time-varying effects are listed in the Table.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

FR-PO691

Recent Evidence on the Impact of Medicare’s Bundled, Prospective Payment System for Renal Dialysis

Richard Hirth, Tammi A. Nahra, Adam S. Wilk, Marc Turenne, John Wheeler, Kathryn Sleeman, Wei Zhang, Jonathan H. Segal, Univ of Michigan; Arbor Research Collaborative for Health.

Background: Medicare implemented an expanded prospective payment system (PPS) in 2011, including services previously paid by fee-for-service. One intent of the PPS was to incentivize providers to be more efficient in the mix of services provided.

Methods: We used Medicare claims to assess monthly trends from 1/2010-12/2014 for injectable drugs that were previously billed separately. For 2010, we assessed actual payments. For 2011-14, we projected spending based on reported utilization.

Results: ESA use declined in the months immediately pre- and post-PPS, continuing to decline through 2012. In 2013, ESA use leveled off. Use of iron products, often improving efficacy of ESAs, increased through 2011 and then began to decline. Total drug cost, including ESAs, iron, and vitamin D, fell by more than 50%, from a high of $76.16 per session in early 2010 to a low of $37.67 toward the end of 2012. This decline was driven by reduced drug utilization. Since early 2013, total drug costs have risen a bit due to higher drug prices. Beginning in 2013, we assessed actual payments. For 2011-14, we projected spending based on reported utilization.

Conclusions: The expanded bundle dialysis PPS provided incentives for both lower medication utilization overall and the use of lower cost therapies. These incentives seem to have motivated an immediate movement toward lower cost methods of care. Facilities have been able to maintain a lower cost of care over the last two years. CMS continues to monitor facility costs and will continue to make a reduction to the ESRD PPS Market Basket through CY 2018, in accordance with section 217 of PAMA.

FR-PO692

Effect of Medicare’s Payment Adjustment for Low-Volume Dialysis Facilities on Facility Closures

Richard Hirth, Tammi A. Nahra, Adam S. Wilk, Marc Turenne, Jonathan H. Segal, John Wheeler, Kathryn Sleeman, Wei Zhang, Univ of Michigan, Ann Arbor; Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Small dialysis facilities may face higher per-treatment costs due to economies of scale. Since 2011 a low-volume payment adjustment (LVPA) raised Medicare payments 18% to facilities with <4500 treatments in each of the 3 prior calendar years. A goal of this policy is to preserve access to care by preventing the closure of small facilities.

Methods: We tested the hypothesis that the LVPA prevented closures by examining the year-to-year closure rates of U.S. dialysis facilities during 2007-2013, before and after the policy, comparing facilities providing <4000 and >4000 annual treatments. Analyses with linear regression relate facility outcomes to prior year size, ownership, for-profit status, hospital affiliation, patient mix, rural location, modality mix and county characteristics, to examine the effect of the LVPA on 8 of treatments provided by facilities.

Results: Among low-volume facilities, year-to-year closure rates fell from 3.8%, 4.9% and 4.0% pre-LVPA, falling to 1.1%, 0.5% and 0.8% post-LVPA. Among facilities with >4000 treatments, closure rates also decreased, but to a much smaller extent (from 1.0%, 1.2% and 0.8% pre-LVPA to 0.6%, 0.2% and 0.3% post-LVPA).

Conclusions: In Medicare’s bundled payment system, closure rates decreased overall, with a much larger absolute reduction among small facilities. The gap in closure rates between small and large facilities fell from about 3% points before the policy to about 0.5% points after. LVPA appears to have helped prevent small dialysis facility closures, but it may also motivate some small facilities to avoid growing in order to retain the LVPA. Emphasizing a dialysis facility’s importance for patient access rather than size alone may help inform payment policy modifications.

FR-PO693

Delayed Thrombectomy Increases Risk for Dialysis Catheter Placement

Scott Reule, Sunil Akkina, Andrew J. Esten, Paul E. Drawz, Dept of Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Arteriovenous dialysis accesses (fistulas or grafts) are associated with significant rates of thrombosis. Though timely thrombectomy may have a significant impact on immediate and long-term access survival, it is not always readily available. The goal of this study was to evaluate whether delayed thrombectomy increases risk for loss of dialysis access and subsequent placement of a dialysis catheter.

Methods: All patients at the Fairview Health System with thrombectomy as the primary reason for admission between January 2008 and April 2015 were included in this retrospective observational study. The electronic medical record was reviewed to evaluate type of access, timing of admission and declot, and access on discharge and 6 and 12 months after discharge. Baseline characteristics and proportions were determined for the overall population as well as stratified by tertile of time to thrombectomy, defined as the time from admission to the declot procedure. The outcomes of interest included need for dialysis catheter at discharge and 6 and 12 months after discharge. Logistic regression was used to evaluate the risk for dialysis catheter use adjusting for prior intervention, access type, and time to thrombectomy.

Results: Among 444 patients identified using procedural codes, 122 were admitted primarily for thrombectomy. The mean age was 60.4 years, 65% were male, and 44.3% utilized arteriovenous fistula for access. Mean time to thrombectomy was 0.45 days (range: 0.05-1.13 days). Fifteen patients utilized a catheter for hemodialysis on discharge. Delayed thrombectomy was associated with a two-fold increase in requirement for catheter at discharge (OR 2.02; CI 1.19-3.43) and at 6 months (OR 2.04; CI 1.20-3.48). This association remained present at 12 months (OR 1.75; CI 1.02-3.00).

Conclusions: In this study of patients cared for within a large academic health system, a one day delay in thrombectomy doubled the risk for need for a dialysis catheter at discharge and 6 and 12 months after discharge. These results indicate that a clotted dialysis access should be considered a medical emergency.

Intradialytic Body Weight Reduction and Outcome of Vascular Access: Analyses of Data from the Japan Dialysis Outcomes and Practice Patterns Study (J-DOPPS)

Manabu Asano,1 Kenichi Oguchi,2 Akira Saito,1 Yoshishiro Onishii,1 Yusuke Yamamoto,1 Shinichi Fukuhara,1 Takashi Akiba,1 Tadao Akizawa,1 Tosei Hospital, Saitama, Japan; 2J-DOPPS Research Group, Japan; 1Hope International, Kyoto, Japan; 1Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan.

Background: There is no doubt that large-volume ultrafiltration is one of the important risk factors for vascular access (VA) thrombus in hemodialysis patients. However, the relationships between intradialytic body weight reduction and VA patency are still in the middle of being discussed. We tried to determine whether large-volume ultrafiltration was practically associated with VA failure by means of the results obtained from the phase 3 and 4 J-DOPPS.

Methods: Referring data from the phase 3 and 4 J-DOPPS, the current analyses were limited to 2736 patients who were evaluable for VA patency and body weight change during dialysis. They were assigned to one of the following three groups according to the tertiles (T1-T3) of intradialytic fluid removal per body weight: T1, -0.5% to 3.8%; T2, 3.8% to 5.1%; and T3, 5.1% to 13.7%. The hazard ratio of VA failure was compared across these tertile groups using Cox regression models. The models were adjusted for the following risk factors: age, gender, BMI, diabetes, hemoglobin, phosphorus, Kt/V, ESA use, and antplatelets use. Primary VA survival was defined as the days until the first VA intervention. Secondary VA survival was defined as the days until new VA creation.

Results: The incidence rates (events/100 person-years) of primary and secondary VA events were 4.7 and 1.3 for T1, 5.6 and 1.6 for T2, and 6.7 and 1.7 for T3, respectively. The adjusted hazard ratios versus T1 for primary VA patency were 1.16 (95% confidence interval [CI], 0.88 to 1.52) for T2 and 1.41 (95% CI, 1.07 to 1.87) for T3. The hazard ratios versus T1 for secondary VA patency were 1.29 (95% CI, 0.78 to 2.13) for T2 and 1.45 (95% CI, 0.86 to 2.45) for T3.

Conclusions: This study shows that large-volume ultrafiltration during dialysis tends to increase VA failure in hemodialysis patients.

FR-PO695

Post-Endovascular Intervention Venous Access Pressure Ratio (VAPR) Predicts Access Survival

Lalathaksha Kumbar1,2, Gerard Zasuwa1,3, Matthew E. Bennett1, Francis E. Loh1, Eric K. Peden1, Eugene J. Nuccio1, Alfred K. Cheung1,4, Tom Greene, Michel Charonch1,2 Denver VA Medical Center; University of Colorado Denver; VA Salt Lake City; Univ of Utah.

Abnormalities in Mineral Metabolism and Dialysis Arteriovenous Fistula Thrombosis in the HEMO Study

Anna Jeanette Jovanovich,1 Eugene J. Nuccio,1 Alfred K. Cheung,1 Tom Greene, Michel Charonch1,2 Denver VA Medical Center; University of Colorado Denver; VA Salt Lake City; Univ of Utah.

Background: Vitamin D deficiency and fibroblast growth factor 23 (FGF23) excess are highly prevalent among patients requiring chronic hemodialysis. This study aims to determine the association of 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D (1,25(OH)2D), and FGF23 serum levels with arteriovenous fistula (AVF) thrombosis in hemodialysis patients.

Methods: The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum 25(OH)D, 1,25(OH)2D, and intact FGF23 levels were measured in stored serum samples obtained at baseline in 881 patients in this cohort. Cox proportional-hazards models were used to examine the association of 25(OH)D, 1,25(OH)2D, and FGF23 serum levels with time to first AVF clotting event after controlling for important clinical covariates in the HEMO Study.

Results: Patients had a mean age of 57±14 years, 55% were females, and 46% were white. During a median follow-up of 3.0 years, 111 AVF clotted. Median (IQR) serum 25(OH)D, 1,25(OH)2D, and FGF23 levels were 19.1 [14.2, 26.6] ng/ml, 6.3 [2.9, 14.5] pg/ml, and 3118 [726, 12928] pg/ml. Among patients with levels in the highest tertile compared to the lowest tertile, both 1,25(OH)2D and FGF23 were significantly associated with an increased risk of clotting in adjusted analyses, hazard ratio (HR) 2.70 (95% CI, 1.21-6.46) and HR 1.35 (95% CI, 1.002-1.83), respectively. No statistically significant associations were observed between 25(OH)D serum levels and AVF thrombosis.

Conclusions: Calcitriol and FGF23 excess were associated with an increased risk of AVF thrombosis among chronic hemodialysis patients.

Ultrasound-Guided Evaluation of New A V Fistulas Safely Decreases Time to First Cannulation

Farzin Fanpour,1 Roshan A. Patel1, George N. Cortisid,1 2Nephrology, Elmhurst Hospital, Icahn School of Medicine at Mount Sinai, Elmhurst, NY; 2Nephrology, Broadway Atlantic Dialysis Center, Elmhurst, NY.

Background: The use of bedside ultrasonography (USG) in various medical specialties has exploded over the last decade. For the past year, we have been using bedside USG for earlier AV fistula utilization and for diagnosing potential problems. Prior to the use of USG, cannulation was based on physical exam. We were interested to see whether use of bedside USG helps in early cannulation of AVF.

Methods: USG procedures from February 2014 to February 2015 were reviewed. Time to cannulation in the year prior to the introduction of USG (2013 - 2014) was calculated and compared to similar data with USG use. By week 4 all new fistulas underwent the first USG exam. Examinations were performed by the renal attendings and fellows each exam lasting about 5 minutes. SonoSite M-Toro ultrasound machine was used.

Results: Total of 44 USG examinations were performed on 14 patients while monitoring new AVF maturation. In 10 patients USG-guided cannulation occurred at an average of 6.2 ± 0.9 weeks compared to 10.2 ± 0.9 weeks prior to USG use (P=0.006). There were no complications seen with the earlier USG-guided cannulations. Subsequent cannulations by the nursing staff were successful without USG. In 4 patients failure of maturation was diagnosed by USG at an average of 3.8 ± 0.9 weeks vs 9.6 ± 1.2 weeks prior to USG (P=0.08). Antibiotic dosing occurred 21 times prior to USG compared to 11 times with USG, despite the similar catheter rates for both years.

Conclusions: USG use facilitates early AVF cannulation with decreased time to first use. Identification of potential AVF issues and their referral are accomplished earlier. This may translate to earlier catheter removal and fewer infections.

FR-PO698

Arteriovenous Grafts Reduce CatherDependence in the Elderly

Thomas M. Loh, Matthew E. Bennett, Francis E. Loh, Eric K. Peden. Vascular Surgery, Houston Methodist, Houston, TX.

Background: Arteriovenous fistulas (AVF) are the permanent access of choice. The benefits of AVF, durability and longevity, are minimized in the elderly where more than 40% of patients will die within their first year of initiating hemodialysis. We investigate an expanded role for primary arteriovenous grafts (AVG) in this population.

Conclusions: USG use facilitates earlier AVF cannulation with decreased time to first use. Identification of potential AVF issues and their referral are accomplished earlier. This may translate to earlier catheter removal and fewer infections.
Methods: We retrospectively review consecutive patients over the age of 70 who underwent upper extremity access creation from January 2008 to July 2014. Data collection included demographics, past medical histories, subsequent interventions, volume flows, access usage, and patient survival.

Results: We performed 366 AVF and 124 AVG creations in 442 patients over the age of 70 (197 women, 245 men). There were no significant differences in the comorbidities between the two access types. The AVG group was significantly older and more likely to be female, 79.2 yo vs. 77.2 yo (p<0.001) and 60% vs. 41% (p<0.001) respectively. Patients with AVF were significantly more likely to never use their permanent access, 25% vs. 11% (odd ratio p=0.002) and if utilized, cannulated significantly later, 3.6 ± 0.2 months vs. 1.3 ± 0.1 months (p<0.001). Catheter dependence at 6 months was 40% for AVG and 28% for AVG. (Figure 1) Secondary patency at 18 months was 64% for AVF and 63% for AVG.

Conclusions: Prosthetic grafts should be considered as the preferred permanent access type in the elderly. Better predictors of mortality, including frailty scores, should be investigated for determining the best choice of permanent access in elderly patients.

FR-PO699

Background: Conventional outpatient hemodialysis utilizes various forms of anticoagulation to prevent access and extracorporeal circuit clotting. In contrast, to reduce the risk of bleeding events, inpatient dialysis units do not frequently use anticoagulation. We aimed to investigate the consequences of anticoagulation-free dialysis and the factors associated with failure to achieve ultrafiltration target (UFT) in our inpatient unit.

Methods: We performed a retrospective analysis of 250 consecutive hemodialysis treatments in 125 chronic patients. Patients were excluded if they were admitted for initiation of dialysis or required systemic anticoagulation. We looked at both instances of successful achievement and failure of UFT. We looked at the following factors: type of access, episode of intradialytic hypotension (IDH), episode of access clotting, and episode of extracorporeal circuit clotting. No anticoagulation was used in the HD treatments. Correlation analyses were performed and categorical data was analyzed using chi-square test. STATA, version 11, was used for statistical analyses.

Results: Overall the incidence of failure to meet UFT was 35%. Association of failure to meet UFT and episode of IDH was noted (p=0.001, Pearson chi2(1) = 13.5). There was no correlation between meeting UFT and type of access (graft r=-0.09, fistula r=0.13, and catheter r=-0.07), access clotting (r=-0.07), and extracorporeal circuit clotting (r=0.08).

Conclusions: Our study of 250 anticoagulation-free hemodialysis treatments suggests that access and extracorporeal circuit clotting was not associated with failure to meet ultrafiltration target. However, the failure to achieve ultrafiltration target was significantly associated with intradialytic hypotension. Larger cohort, multi-center prospective trials should be performed to look at causality of failure to meet ultrafiltration targets in the hospitalized patients.

FR-PO700
Evaluation of the Ability of Transonic Monitoring to Predict Dialysis Access Stenoses Jerard Zaki Kneefati-Hayeck,1 Gaurav Ghosh,2 Stephen Kruger,3 Jeffrey I. Silberzweig,2,3 1Dept of Medicine, New York-Presbyterian Hospital, New York, NY; 2Weill Cornell Medical College, New York, NY; 3The Rogosin Inst, New York, NY.

Background: Patency of vascular access is critical to successful maintenance hemodialysis. It is well established that lesions are easier to treat if they can be identified prior to thrombosis. Non-invasive evaluation of access blood flow with the Transonic device is established for this purpose. We previously analyzed its performance after two years and demonstrated >99% sensitivity and specificity. We now seek to extend that work by looking at performance over a fifteen-year period.

Methods: Transonic studies are performed on approximately 1500 maintenance dialysis patients with AV grafts or fistulae in our 7 clinics in New York City. Transonic flow rates <600 cc/min or decreases by >10% from prior readings prompt referral to Interventional Radiology or Vascular Surgery. We report on the sensitivity, specificity and predictive values for patients treated between 1998 and 2012.

Results: Sensitivity was 42%; specificity 72%. Positive predictive value (PPV) was 20%; negative predictive value (NPV) was 85%.

We evaluated our ability to predict stenosis based on decreased dialysis clearance: for Kt/V, PPV was less than 10% and NPV less than 80% for different cutoff points; for URR, PPV was less than 10% and NPV less than 80%.

Conclusions: We hypothesize that the large numbers of false positive and false negative results were caused by scheduled referrals to Interventional Radiology, which have become routine. This study suggests that routine Transonic studies may no longer be as important as they were in 2000; however, Transonic studies provide better predictive ability than reductions in urea-based dialysis clearance.

FR-PO701
Hemodialysis Vessel Mapping in Women and Men Rita L. McGill, Robin Ruthazer, Dana Miskulin, Klemens B. Meyer, Daniel E. Weiner. Tufts Medical Center, Boston, MA.

Background: Men initiate hemodialysis (HD) with fistulas (AVF) more often than women, and this gap widens following initiation. Angiography and Doppler vessel mapping may promote AVF creation by detecting vessels not found by physical examination. Women may benefit more from imaging, as they are less likely to have veins that are visible upon inspection, even when suitable for AVF construction. We hypothesized that the sex disparity in AVF use may in part reflect a disparity in vessel mapping rates.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all vascular imaging during the 2 years before starting HD and up to 12/31/2012, in the subset of adult HD patients entering USRDS in 2010 or 2011 with central venous catheters (CVC) as sole vascular access. Doppler studies performed on the same day as an angiogram were excluded. Angiograms and Dopplers per 100,000 patients-months were calculated. Incidence rate ratios (IRR) between women and men were estimated for age, BMI, diabetes, and vascular disease using Poisson regression.

Results: Among women with preHD claims, 62% had CVC-only and 14% AVF; men had 57% CVC-only and 20% AVF. 18494 men and 16686 women with CVC-only contributed 615257 and 558647 patient-months of data. No imaging was performed in 57% of men and 54% of women. The distribution of studies in men and women showed:

</tbody>
</table>

Conclusions: Vascular imaging was performed in fewer than 50% of individuals starting hemodialysis with CVC. Higher rates of vascular imaging in women were statistically but not clinically significant. Promotion of vein mapping and angiography in women merits exploration as a means to decrease the disparity in fistula rates between women and men.

FR-PO702
Association of Bacteremia with Arteriovenous Access Failure in Hemodialysis Patients

Seyed Mustafa Ahmed, Laura Plantinga, Rachel E. Patzer, Jason Cobb, William M. McClellan. Emory Univ, Atlanta, GA.

Background: Obesity, female sex, diabetes, peripheral vascular disease, and pacemakers are known risk factors for arteriovenous fistula (AVF) and arteriovenous graft (AVG) failure. We examined whether bacteremia in hemodialysis (HD) patients with AVF/AVG represents an additional, independent risk factor for subsequent AVF and AVG failure.

Methods: We conducted a retrospective observational study among 29,571 U.S. patients from the United States Renal Data System who started HD with AVF and AVG between 1/1/2009 and 9/30/2010. We used inpatient ICD-9 codes after dialysis start to define bacteremia and AVF/AVG failure. We then used a multivariable Cox proportional hazards model to assess relationship between exposure to bacteremia and time to access failure.

Results: Overall, 12.2% of patients with bacteremia experienced an access failure, compared to 4.0% of patients without bacteremia (P<0.001). This difference persisted over a median follow-up of 582 days. With adjustment for known confounders, patients who had bacteremia after dialysis start were at 3-fold greater risk of subsequent access failure, relative to those who did not (HR=3.18, 95% CI: 1.71 – 5.95).

Conclusions: This observational study indicates that decreased AVF and AVG survival may be associated with exposure to bacteremia among HD patients.

FR-PO703
Comparison of Loss of Vascular Access Patency in Hemodialysis Patients with End-Stage Renal Disease due to Systemic Lupus Erythematosus versus Other Causes

Laura Plantinga, Sung S. Lim, Rachel E. Patzer, Stephen O. Pastan, Cristina Drenkard. Emory Univ, Atlanta, GA.

Background: Previously we found that U.S. patients with systemic lupus erythematosus (SLE) and end-stage renal disease (ESRD) were 40% less likely than other ESRD patients to have a permanent vascular access in place at the start of dialysis. Here, we examine whether subsequent loss of patency differs in SLE vs. other ESRD patients who have a permanent vascular access.

Methods: A cohort of 106,993 U.S. patients starting hemodialysis with an arteriovenous fistula or graft (705/9/11) was identified from a national registry of treated ESRD (United States Renal Data System). Kaplan-Meier analyses and multivariable Cox proportional hazards models were used to estimate the association between SLE vs. other ESRD (by provider-reported attributed cause at start of dialysis) and the time to first inpatient ICD-9 code for loss of vascular access patency, with censoring for death or the end of follow-up.

Results: Among 597 (0.6%) incident hemodialysis patients with a permanent vascular access, those with SLE are not more likely than other patients to experience a loss of vascular access patency requiring hospitalization. Further analyses will examine whether these patterns persist when outpatient procedures are included; however, confounding by indication would remain a potential bias.

Conclusions: These results suggest that, among those patients who do start dialysis with a permanent vascular access, those with SLE are not more likely than other patients to experience a loss of vascular access patency requiring hospitalization. Further analyses will examine whether these patterns persist when outpatient procedures are included; however, confounding by indication would remain a potential bias.

FR-PO704
The Placement of Tunneled Central Venous Catheters Through Percutaneous Puncture of Superior Vena Cava in Hemodialysis Patients

Tianlei Cui, Xiaoxi Zeng, Yuhuan Feng, Ping Fu. Nephrology Dept, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.

Background: After the exhaustion of traditional insertion sites of tunneled central venous catheters (ICVCs), it can be challenging to place the ICVCs in exotic locations. A retrospective case series in West China Hospital was studied to assess the placement of ICVCs through percutaneous puncture of superior vena cava (SVC) in patients with innominate veins occlusion.

Methods: Sixteen patients (male: 62.5%; mean age: 64.7 years; mean duration of HD: 5 years) who underwent placement of ICVCs through percutaneous puncture of SVC were retrospectively analyzed. They had either exhausted AV access sites or chosen not to undergo other vascular access placement. All of the patients had occlusion in innominate veins on both sides. The outcomes were function measurements of ICVCs, and safety parameters.

Results: The procedure succeeded in all of the patients. During the follow-up (mean: 12 months, range: 3-36 months), access failure due to thrombosis was observed in one patient, and the failure was treated by aspirin and Clopidogrel. The remaining continued to function well until the end of the follow-up or until the death of the patients (n=3). The procedure was generally safe. No pneumothorax occurred. The most common complication was mediastinal hematoma after the failure of SVC puncture. The fluoroscopy could reveal the hematoma during the procedure. The largest hematoma was 2cm in diameter in the current series and it resolved spontaneously.

Conclusions: In patients with innominate veins occlusion and exhaustion of the conventional insertion sites, the ICVCs can be safely placed through SVC puncture using percutaneous route.

FR-PO705
Analysis of Survival of Cardiac Function in Maintained Hemodialysis Patients with Arteriovenous Fistula and Tunneled Cuffed Catheter

Li Hua Wang, Fang Wei, Ai Li Jiang. Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, 2nd Hospital of Tianjin Medical Univ, Tianjin, China.

Background: Until now, there is little data of cardiovascular regarding to different type of vascular access. This study was to investigate survival of patients with arteriovenous fistula and tunneled cathered group.

Methods: A total of 219 patients who received maintained hemodialysis were included in this study. Patients were divided into two groups: arteriovenous fistula group and tunneled catheter group. The baseline anthropometric and laboratory parameters were measured. The time and cause of mortality were documented.

Results: There were significant difference of left ventricular hypertrophy (P=6.645, P=0.001), left ventricular systolic dysfunction (P=0.045), between two groups. But there was no significant difference of left ventricular diastolic dysfunction between two groups. Kaplan-Meier survival curves showed that the mortality was enhanced among tunneled catheter group.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

523A
Patients with left ventricular hypertrophy, left ventricular systolic dysfunction, left ventricular diastolic dysfunction in arteriovenous fistula group have a high survival rate compared with tunneled catheter group. Furthermore, IPCH, calcium, systolic blood pressure and diastolic blood pressure were independent risk factors of mortality for patients on maintained hemodialysis by COX regression model.

Conclusions: Different factors of vascular access may have influence on mortality in patients on maintained hemodialysis. Those with tunneled catheters have lower survival rate when left ventricular dysfunction occurred.

FR-PO706
A Retrospective Study of Preferable Alternative Sites to Right Internal Jugular Vein for Tunneled Hemodialysis Catheters Insertion: Right External Jugular Vein versus Left Internal Jugular Vein
Yufei Wang, Pei Wang, Xianhui Liang, Xiaoqing Lu, Zhangsuo Liu, Yingjin Qiao, Jiujie Zhou, Blood Purification Center, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.

Background: It has been recommended by the KDOQI guidelines that right internal jugular vein (RJIV) is a preferred insertion site for hemodialysis (HD) catheters, and both right external jugular vein (REJV) and left internal jugular vein (LIJV) are alternative sites for those who have encountered severe thrombosis and/or occlusion of RJIV. The retrospective study aimed to determine if superiority exists in the two alternative sites by comparing the outcomes of tunneled (cuffed) dialysis catheters (TDCs) through REJVs versus LIVs in HD patients who had failed RJIV.

Methods: From January 1, 2013 to December 31, 2014, 24 LIV-TDCs and 21 REJV-TDCs were inserted in our hospital. All the events were recorded from patient charts until May 31, 2015. Using SPSS 22.0 software, data were analyzed by the Fisher exact test or chi-square test. Event free catheter survival time was estimated by the Kaplan-Meier method. Multivariable Cox hazards analysis was fitted to detect the independent risk factors of events. A p-value of <0.05 was considered statistically significant.

Results: A total of 20924 (LIVs, 11782; REJVs, 9141) catheter-days were evaluated and the mean was 427.02 days. Most of the patients (53.1%) were older than 65 years with an average dialysis time of 25.3 months. The event free catheter survival time was (516.20±55.60) in REJ-VDs and (343.91±40.63) in LIV-TDCs (P=0.038). Mean effective blood flow was higher in REJV-TDCs than that in LIV-TDCs (270.95±24.93 vs 244.82±30.35 ml/min, P<0.002). A substantial trend towards statistical significance was found between two groups in incidence of all events, including death, death related to catheter complication and catheter removal. The total historic catheters indwelling time was identified as an independent risk factor for severe TDCs events by Cox regression hazards test (P<0.01).

Conclusions: REJV might be superior to LIJV as an alternative insertion site for TDC placement in HD patients who had failed RJIV.

FR-PO707
Haemodialysis Recirculation in Patients with Catheter Access: Damien Ashby, Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.

Background: Recirculation is a well described impairment of the haemodialysis circuit which reduces dialysis dose and electrolyte clearance. Catheter tips are designed to minimise recirculation based on in vitro experiment, with most designs having a tip separation of 25mm, but clinical studies of catheter-related recirculation have not been published.

Methods: In a group of stable adult patients receiving haemodialysis by tunneled catheters, recirculation was calculated by 3-sample urea measurement, and analysed in terms of excessive bleeding, hematoma or infection. At an average follow-up of 6 months, one death had occurred that was unrelated to the procedure or arrhythmia. Subcutaneous ICD is a minimally invasive procedure when compared with an epicardial device. By leaving the venous system untouched, this approach offers the advantage of reduced risk of infection, sternal wound dehiscence, skin infections, and hematomas.

Results: 54 haemodialysis patients (aged 28-90, 61% male) received successful SICD. While the use of these devices is expanding, their insertion in advanced renal failure and hemodialysis patients is somewhat limited. In this analysis, we present 9/13 patients had high recirculation and hemodialysis catheters treated successfully with an SICD. Demographic characteristics revealed; male=8, diabetes=8, hypertension=13, coronary artery disease=10, peripheral vascular disease=8. Two of the four hemodialysis patients had an AVF while two were dialyzing with a tunneled dialysis catheter. Mean GFR for the CKD patients was 40.3 ml/min. Patients received the SICD device for primary prevention of sudden cardiac death (cardiomyopathy with low ejection fraction). 3/13 patients had non-ischemic cardiomyopathy (CMP) with an ejection fraction of <25% while 10/13 suffered from ischemic CMP with an EF of <30%. There were no procedure-related complications in terms of excessive bleeding, hematoma or infection. At an average follow-up of 6 months, one death occurred that was unrelated to the procedure or arrhythmia. Subcutaneous ICD is a minimally invasive procedure when compared with an epicardial device. By leaving the venous system untouched, this approach offers the advantage of reduced risk of infection, sternal wound dehiscence, skin infections, and hematomas.

Conclusions: SICD can be successfully used in patients on hemodialysis and CKD.
BCAVF groups. All participants were followed for 12-months after surgery. The main outcome measures were blood flow velocities and volumes, vessel diameters, primary unassisted fistula patency rate (PUFPR), the cumulative fistula survival rate (CFSR) and complications.

**Results:** The baseline demographic and clinical characteristics were well matched between mNT-BBAVF and BCAVF groups. Blood flow velocities and flow volumes of the corresponding fistula segments increased significantly in both groups. Compared to BCAVF, where only proximal cephalic vein increased in size, the proximal cephalic vein, distal cephalic vein and distal basilic vein in mNT-BBAVF all increased significantly compared to baseline over the 12-month period (p<0.01). Therefore, in addition to the proximal cephalic vein, the distal cephalic vein and distal basilic vein were available for cannulation in mNT-BBAVF. At 12 months, the PUFPR of mNT-BBAVF was significantly better than that of BCAVF (73.0% vs. 45.9%, HR: 2.60; 95%CI: 1.21 to 5.59; p=0.01). Although, the CFSR did not differ between the two groups (91.9% vs 78.4%, HR: 1.18; 95%CI: 0.55 to 2.17; p=0.37). Finally, there were no significant differences in complications between the two intervention groups at 1 and 12 month follow-ups, other than severe arm pain which was much less reported among patients with mNT-BBAVF at 1 month (vs. BCAVF, p=0.03).

**Conclusions:** mNT-BBAVF is an effective alternative for the construction of upper arm vascular access.

Management of Catheter Related Bacteraemias: New Insights into an Old Problem

*Benjamin A. Oliveira,1 Conor James Byrne,2 Hannah Putnam,1 Viviane Calice-Silva,1,3 Israel David Campos Gonzalez,1 Peter Kotanko,1,3 Fansan Zhu.1*

**Background:** Catheter related bacteraemias (CRB) pose a significant risk for those dialysis patients using such devices. Strategies are needed to minimise this risk as much as possible, especially in light of growing concerns over antibiotic resistance. Our unit routinely uses citrate to lock catheters. We sought to audit our CRB rate and long term complication rate. We believe this contemporary data will be useful to all involved in caring for patients with catheters.

**Methods:** We retrospectively reviewed all blood cultures taken from our institution’s dialysis patients for 1 year (October 2013 and September 2014). The records of patients with positive cultures were reviewed to ascertain if the infection was related to their access. Data was then collected on the type of organism grown, management of the episode, recurrence rate, and any long term complications.

**Results:** 1014 cultures were taken from approximately 930 haemodialysis patients. 45% of these were dialyzing via a catheter. There were 52 instances of CRB giving a CRB rate of 0.34 per 1000 catheter days. 65% were due to gram-positive organisms, 29% were due to gram-negative organisms and 6% were fungal related. The overall recurrence rate was 26%. Catheter removal was performed in 32 instances (62%). Infective complications occurred in 5 (16%) patients with gram-positive infections and 6 (54%) of those with gram-negative infections; a statistically significant difference. The majority of these were endocarditis. CRB accounted for a total of 583 hospital in-patient days.

**Conclusions:** We observed significantly more infective complications with gram-negative organisms compared with gram-positive. This probably reflects the underlying characteristics of these patients rather than the pathogenicity of the organisms per se (19% of patients with gram-negative infections were intravascular drug users). Never the less our data suggests that gram negative infections are a risk factor for complications and clinicians should consider further investigations in these cases. Our CRB rate was low compared to quoted rates in the literature; this may reflect routine the use of citrate lock in our catheters.

**FR-PO712**

Assessment of Arteriovenous Fistula Access Flow Using Video Image Processing Technology

*Schantel Williams,1 Hannah Putnam,1 Viviane Calice-Silva,1,3 Israel David Campos Gonzalez,2 Peter Kotanko,3 Fansan Zhu.1*

**Background:** Vascular stenotic lesions are the main cause of failure in arteriovenous fistula (AVF). Routine measurement of access flow (AF) is important in the timely detection of changes and planning interventions. The aim of this pilot study was to investigate whether video image processing (VIP) techniques could be used to detect AVF motion and explore the relationship between motion patterns and AF.

**Methods:** Skin above the AVF was imaged for 1 minute using a digital single lens reflex camera prior to HD. The video was processed using Eulerian video magnification (Wu et al, ACM Trans. Graph. 31(4), 2012) to amplify AVF motions. Thereafter the motion-amplified video was converted to quantitative waveform data using an algorithm based on change in color of each image (Matlab Image Processing Toolbox). Monthly AF measurements were recorded and correlated with the post-processed AVF waveform pattern.

**Results:** We studied 12 hemodialysis patients (51.5±11.3 years, 50% male) with a mean±SD AF 1501±392/ml/min (N=9; AF was unavailable in 1 subject). Amplitude of skin displacement was 0.069±0.044mm (N=9; technical issues occurred in 2 subjects). While amplitudes of that size are hardly visible to the naked eye, they were clearly discernible in post-processed amplified video. Amplitude was notably smaller in subjects with lower AF (Fig 1). Amplitude analysis of the amplified video indicates a relationship with AF (R²=0.73, p<0.01; N=9).

**Conclusions:** Our proof-of-concept study demonstrates this video imaging and analysis technique has potential to provide a quick, noninvasive, low cost way to obtain quantitative information related to AF. Research is underway to assess the impact of clinical interventions on the amplitude pattern.

Pre-Emptive Correction of Arteriovenous Access Stenosis: Systematic Review and Meta-analysis of Randomized Controlled Trials

*Pietro Ravani,1 Robert R. Quinn,1 Matthew J. Oliver,2 Divya J. Karsanji,1 Matthew T. James,4 Jennifer M. MacRae,1 Suetonia Palmer,3 Giovanni F.M. Strippoli,4 U of Calgary, Canada; 2U of Toronto, Canada; 3U of Otago, New Zealand; 4Diaverum, Italy.*

**Background:** Selective stenosis correction in an arteriovenous (AV) access that is suitable for hemodialysis may prolong its survival, as compared to salvage procedures postponed to when the AV access becomes dysfunctional.

**Methods:** We did a systematic review and meta-analysis of randomized controlled trials (RCTs) evaluating pre-emptive correction of an AV access stenosis vs. stenosis correction in a dysfunctional access (deferred correction) in adults treated with hemodialysis therapy. We searched the Cochrane Kidney and Transplant Specialized Register (which includes MEDLINE and EMBASE) to 29 October 2014. Outcomes of interest were access loss (primary outcome), access thrombosis, infection, mortality, hospitalization, and access-related procedures. We did sub-group analyses of access outcomes by access type. We summarized the evidence using the Grading of Recommendations Assessment, Development, and Evaluation criteria.

**Results:** We included 16 studies (including 1,390 participants; follow-up 6-38 months; N=58-189 participants). Nine studies enrolled adults without access stenosis (primary prophylaxis; three studies including people using fistulas) and five enrolled adults with a highly suspected or documented stenosis in a functioning access (secondary prophylaxis; three studies in people using fistulas). Relative to deferred salvage, access surveillance with pre-emptive correction of an AV stenosis did not reduce the risk of thrombosis (RR 0.95; 95% CI 0.8-1.12) or access loss (RR 0.9; 95% CI 0.71-1.15) in grafts (moderate-grade evidence), but reduced the risk of thrombosis (RR 0.5; 95% CI 0.35-0.71) and access loss (RR 0.5; 95% CI 0.29 to 0.86) in fistulas (low-grade evidence). Results were either heterogeneous or imprecise for mortality, rates of infection, procedures and hospitalization. There was unclear or high risk of bias in most studies.

**Conclusions:** Pre-emptive correction of a new or documented stenosis may not improve graft outcomes, but may prevent fistula thrombosis or loss.

**Funding:** Government Support - Non-U.S.

Real-Time Kt/V Tracking Profile as a Predictor of Dialysis Access Recirculation

*Abhishek Konata,1 Girish Singhania,1 Ahsan Ejaz, Nephrology, Univ of Florida, Gainesville, FL.*

**Background:** On-line monitoring of ultraviolet absorption of spent dialysate in routine hemodialysis allows continuous measure of removed solutes from spent dialysate. We studied whether real-time Kt/V tracking profile could be a predictor of dialysis access recirculation.

**Methods:** End-stage renal disease patients undergoing maintenance dialysis with Dialog (B Braun AG) dialysis machine with a built-in UV-Spectrophotometer (Option Adimea, B Braun AG), high-flux polysulfone dialyzers, and at blood flow rate (Qb) 400-450 ml/min and dialysate flow rate (Qd) 800 ml/min were included in all recording sessions. Real-time Kt/V tracking profile and venous (Pv) and arterial pressures (Pa) were recorded and hemodialysis access recirculation values were biochemically measured using standard protocol.

**Results:** Distinct real-time Kt/V profiles were identified in patients with significant access recirculation (>5%) vs. none (Control).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
In the control profile, real-time Kt/V (Fig 1a, solid line) closely followed the target line (Fig 1a, dashed line) and was associated with normal P<sub>k</sub> and P<sub>r</sub>. In patients with high access recirculation, real-time Kt/V tracking line deviated widely from the target line (High Recirc Kt/V Profile; Fig 1b, c, d) and remained deviant throughout the treatment session. Fig 1d demonstrates a case wherein the initial low Q<sub>r</sub> provided false impression of normal access function, however increasing Qb resulted in unmasking of high access recirculation, i.e., appearance of High Recirc Kt/V Profile. High access recirculation was confirmed by biochemical methods. Interestingly, all High Recirc Kt/V Profile events were associated with abnormal recirculation values, but not all were associated with elevated P<sub>r</sub>.

Conclusions: Real-time Kt/V tracking profile provides a non-invasive, inexpensive and quick assessment of access recirculation in hemodialysis patients.

FR-PO715

Recurrent Vascular Access Stenosis as a Novel Marker for Cardiovascular Outcome in Hemodialysis Patients Hwo Jin Kim, Hajeong Lee, Dong Ki Kim, Kook-Hwan Oh, Yon Si Um, Curie Ahm, Kwon Wook Joo. Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.

Background: Vascular access (VA) is essential component and its stenosis is a major complication in hemodialysis (HD) patients. Nevertheless, there are few data for outcomes on patients who had recurrent VA stenosis. We have explored the influence of recurrent VA stenosis on cardiovascular (CV) event, patient death, and VA failure.

Methods: This is a single-center, retrospective study. Patients who had VA operation at Seoul National University Hospital between January 2009 and March 2014 were enrolled. Patients who had two or more instances of percutaneous angioplasty or revision operation within 180 days were categorized recurrent group. The primary outcome was CV events, as coronary artery or heart failure or cerebrovascular, and or peripheral vascular events. The secondary outcomes were all-cause mortality (ACM), composite of ACM or CV events, and VA failure. The two groups were compared before and after matching with propensity scores (PSM).

Results: A total of 766 patients (59.7% male, age 59.6 ± 14.3 years) were analyzed. Recurrent group patients (n = 77, 10.1%) were older and had higher underlying CV disease and dyslipidemia. A total 213 patients (14.2% in non-recurrent, 71 in recurrent group) were selected by PSM. During 28.7±15.8 months follow-up, 46 patients (21.6%) had CV outcomes, 30 patients (14.1%) died, and 14 patients (6.6%) experienced vascular access failure. After adjustment, recurrent group was an independent risk factor for CV events (adjusted hazard ratio [HR] 2.66, 95% confidence interval [CI] 1.46–4.86, P < 0.001) and composite of ACM or CV events (adjusted HR 1.99, 95% CI 1.21–3.27, P < 0.007). However, it was not associated with increased ACM and VA failure.

Conclusions: Recurrent VA stenosis was a novel independent risk factor for CV event in HD patients, rather than VA failure. For patients suffered from recurrent vascular stenosis, diligent monitoring should be warranted not only for VA patency but also for CV events.

FR-PO716

Stent Insertion Is an Important Tool in Maintaining Arteriovenous Access Patency Stephen G. Johns,1 Kumar Abayasekara,2 Peter M. Bungay,3 Mario De Nunzio, James E. Kirk,1 John Graham Pollock,3 Peter D. Thurley,3 Paul J. Owen,1 Richard J. Fluck,1 Lindsay J. Chesterton.1 1Nephrology, Royal Derby Hospital; 2Vascular Surgery, Royal Derby Hospital; 3Radiology, Royal Derby Hospital, Derby, United Kingdom.

Background: Definitive access for haemodialysis (HD) remains the cornerstone of optimal dialysis. However, HD patients are becoming older, access attempts more problematic and vein preservation remains critical. Clinical examination and access monitoring enable appropriate, timely, endovascular intervention. Stents may be inserted for recurrent stenosis or after endovascular rupture, but their role remains debatable. We report on our single-centre experience of access surveillance and endovascular intervention, highlighting the role of stent insertion.

Methods: Electronic hospital records were retrospectively analysed in all access-related stents inserted from 2006-2014 by 5 vascular radiologists.

Results: 49 stents were inserted during 45 procedures in 39 patients. 12 had diabetes. Mean age was 64.5±25.5 yrs, median dialysis vintage was 1162±1504 days (range 5-5027). Median time from access creation (82% arteriovenous fistula) to stent insertion was 318±926 days (range 31-3752). 34 stents were inserted peripherally (cephalic arch and distally), the majority in the cephalic arch. Equal numbers of covered and bare-metal stents were inserted. 4 stents were placed in thrombosed access. 7 procedures were due to surveillance alone, a further 8 due to surveillance and pressure/flow problems. 12 stents were inserted for rupture or dissection (overall access procedure complication rate 1%). Median time from first stent to access failure/ceased HD was 333±653 days, assisted by median 2 (range 0-11) further procedures. Treatment for rupture was not associated with significantly shorter access longevity. Only 10 patients’ access failed following follow-up. Our overall HD definitive access prevalence rate was 86-90%.

Conclusions: Appropriate HD access is essential in minimising HD morbidity. We recommend stent insertion for newly-occurring stenosis or rupture during endovascular procedures. Our data suggest that appropriate, judicious stent insertion in an appropriately structured pathway results in access durability and longevity.

FR-PO717

Association of Vascular Access Flow and Volume Status on Fistula Arm by Bio-impedance Analysis in Hemodialysis Patients Joon Jeong,1 Hun Jong Kim,1 Eun jung Ko,1 Younhee Lee.1 1Internal Medicine, CHA Bundang Medical Center, CHA Univ, Seongnam, Korea; 2Internal Medicine, Seoul Buchub Hospital, Seoul, Korea.

Background: Multi-frequency bioimpedance is a tool of body composition measure and can monitor changes in extracellular volume during dialysis. Arterio-venous fistulae(AVF) could potentially affect fluid retention in the arm. We investigated whether multi-frequency bioimpedance could detect AVF stenosis or association of AVF with fluid retention in the AVF arm.

Methods: We measured the extracellular water(ECW) and total body water(TBW) in AVF arm following hemodialysis by multi-frequency bioimpedance(bioxy S10) using an eight-electrode contact technique. We measured AVF flow by transonic ultrasonography using an ultrasound dilution technology (HD 03+) in hemodialysis.

Results: Total 28 patients (male 13 patients) were enrolled and the mean age of patients was 54.89 ± 13.21 years. ECW/TBW ratio of fistula arm was a significantly higher than ECW/TBW ratio of non-fistula arm(0.389 ± 0.01 vs 0.382 ± 0.001, p<0.05). ECW/TBW ratio of fistula arm was a significantly negative correlation with access flow level (mL/min) on fistula(< 0.05). The 5kHz reactance of fistula arm was a significantly positive correlation with access flow level (mL/min) on fistula<0.05).

Conclusions: Absolute and also relative extracellular fluid volumes are increased in the fistula arm of hemodialysis. We thought that extracellular fluid volumes in the fistula arm were associated with access flow level (mL/min) and/or relative fistula stenosis. We suggest that multi-frequency bioimpedance can be a useful assistant tool of vascular access flow measure.

FR-PO718

Background: KDIGO Guidelines recommend post-angioplasty (PTA) lesion should have <30% residual stenosis (RS) and hemodynamic parameters should improve. Access blood flow (ABF) is one of the most used. Primary end point: how post-PTA ABF improvement could predict vascular access (VA) outcome. Secondary: compare doppler ultrasound (DU) and angiography diagnostic accuracy; determine how other factors could predict outcome.

Methods: Prospective study in 80 patients with dysfunctional VA. DU evaluation was performed pre and post-PTA. Several parameters were recorded. Secondary patency verified during first 6 months.

Results: Initial DU in 80 patients; 26 excluded due to abnormalities absence or impossible endovascular approach - final 54. Two thirds male; age 68±15y; VA time 36±29months; initial ABF 537±153ml/min; final ABF 1013±345ml/min. Number and location of stenosis was highly correlated between DU and angiography (Pearson 0.828, p < 0.000). Matching in central vessels. Overall survival 83% at first trimester and 63% at semester; significantly better for fistulas (76%) than grafts (51.7%), p = 0.044. Final angiographic RS > 30% occurred in 14.8% patients, who had significantly better survival, p = 0.038. Initial ABF>500 ml/min and multiple stenosis didn’t affect the outcome (p = 0.189 and p = 0.811). A ~2-fold ABF increase had no significant impact on fistulas survival (p = 0.339) but it was highly significantly associated with worst outcomes in grafts (23.1% versus 73.5%, p = 0.009). VA failure HR was 3.3 for grafts (p = 0.034).

Conclusions: DU diagnostic accuracy is highly correlated with angiography. Although less accurate for central lesions, has a key role due to morphologic and hemodynamic assessment. PTA is a powerful therapy with immediate benefit; however final angiographic RS is not predictive of outcome. Grafts have worst patency, demanding more interventions. PTA is associated with mechanical endolethal injury. Higher ABF induce more turbulent flow that is likely to cause more intraluminal hyperplasia, which could explain the shorter patency, especially in grafts where inflammation is higher.
The degree of OH% was 20.2 ± 7.3% among the MEGA vs. 14.4 ± 7.1% in the CONTR group (Student p: 0.01), representing 4.2 ± 3.2 vs. 2.8 ± 1.6 L of excess fluid (p: 0.03). MEGA patients took an average of 1.7 ± 1.4 vs. 0.8 ± 0.8 (p: 0.002) antihypertensive medications compared to the CONTR patients yet their blood pressure was 156/91 vs 141/78 mmHg (p: 0.03–0.0001). We found no difference in fistula vintage, body mass index, age, inflammatory markers, diabetes status or diuretic use. The odds ratio of overhydration being associated with a megafistula is 5.3 (p: 0.01).

**Conclusions:** There is an association of BCM-measured overhydrated clinical state with the presence of megafistulas; either as an increased volume capacitance or as a potential cause.

FR-PO721

The Observation of the Tunneled Cuffed Catheter Insertion Through Right Innominate Vein in Hemodialysis Patient

Yanhuan Feng, Tianli Cui, Ping Fu. Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

**Background:** The routine vascular access for hemodialysis is often available due to thrombosis and occlusion after frequent cannulation, which leads to an increase in cost and difficulty of catheterization or recanalization. Further catheterization may accelerate the development of occlusion of vascular resources. We inserted cuff catheter through right innominate vein in patients with thrombosis or occlusion of right internal jugular vein and subclavian vein so as to preserve precious vascular access at other parts of body. Here we report our observation of right innominate vein catheterization.

**Methods:** We enrolled patients who had been receiving regular HD in our center and to whom catheter cannot be inserted due to thrombosis or occlusion of internal jugular vein and subclavian vein. We performed cuff catheter insertion by puncturing right innominate vein in 8 patients and recorded their clinical features, lesion position, and efficacy of the treatment.

**Results:** Among the 8 cases, where mean age is 67.6 years (range from 54-78), 3 of them are male and 5 are female. All the patients received central venous catheterization for more than 2 times, with median time of having a catheter for 36 months. The vascular ultrasound and CTA reveals that all of them suffered thrombosis or occlusion of right internal jugular vein and subclavian vein. By puncturing right innominate vein, all the patients’ vascular accesses have been successfully established, with the end of cuff catheter located in the right atrium, superior vena cava(SVC) or SVC/ right atrial junction. No obvious discomfort has been reported, nor did complications such as hematoma and pneumothorax recorded. The mean follow-up period lasts for 12 months, all vascular access of these cases are patency.

**Conclusions:** For HD patients with limited vascular resources such as thrombosis or occlusion of right internal jugular vein and subclavian vein, the application of tunneled cuffed venous catheter through innominate vein has been proved to be safe and effective. It could preserve vascular access by bypassing the stenotic lesion internal jugular vein or subclavian vein, and reduce the incidence of vascular access exhaustion.

**Funding:** Government Support - Non-U.S.

FR-PO722

Tunneled Hemodialysis Catheter and Hemodialysis Outcomes

Vutran Pasara, Mdlen Knotek. Dept of Medicine, Renal Div, Univ of Zagreb, Merkur Hospital, Zagreb, Croatia.

**Background:** Studies have reported that tunneled dialysis catheter (TDC) is associated with inferior hemodialysis (HD) patient (pt) survival, as compared to arteriovenous fistula (AVF). Since many cofactors may also affect survival of HD pts, it is unclear whether the risk for the worse survival arises from TDC per se, or from associated conditions. Therefore, the aim of this study was to determine the long-term outcome of HD patients, with respect to vascular access (VA).

**Methods:** This retrospective case-control study included all 156 TDC pts with TDC placed from 2010 to 2012 at Clinical Hospital Merkur. Control group consisted of 97 pts dialyzed through AVF. The groups were matched according to dialysis unit and time of VA placement. The site of choice for the placement of TDC was right jugular vein. Kaplan-Meier analysis with logrank test was used to assess pt survival. A multivariate Cox regression analysis was used to determine independent variables associated with the pt survival.

**Results:** Cumulative one-year survival of pts who were dialyzed exclusively through TDC was 86.4 % and of those who were dialyzed exclusively through AVF the survival was 97.1 % (p=0.002). In a multivariate Cox regression analysis, male sex and older age were independently negatively associated with the survival of HD pts, while shorter duration of HD before the creation of the observed VA, hypertensive renal disease and glomerulonephritis were positively associated with survival. TDC turned to be an independent negative risk factor for survival of HD pts (HR 23.037, 95% CI 6.221-85.308).

Carpal Tunnel Syndrome Is Associated with Arteriovenous Fistula in Hemodialysis Patients

Il Young Kim, Min Jung Kim, Joo Hui Kim, Dong Won Lee, Soo Bong Lee, Su Min Park, Jong Man Park, Woo Jin Jung, Sang Heon Song, Eun Young Seong, Harin Rhee, Il Soo Kwak.

Background: Carpal tunnel syndrome (CTS) is associated with various systemic diseases such as rheumatoid arthritis, hypothyroidism, peripheral neuropathy and diabetes mellitus (DM). In hemodialysis patients, several factors can contribute to CTS, including amyloid deposition, generalized fluid retention, increased synovial volume, edema around the nerve, and an ischemic or ‘steal’ effect distal to a dialysis access. This study aimed to evaluate the influence of arteriovenous fistula (AVF) dysfunction on the development of CTS.

Methods: The study included 43 patients (23 male & 20 female) on maintenance hemodialysis via AVF and 97 healthy controls. The median nerves of study population were examined by ultrasonography. Cross-sectional area (CSA) of the median nerve was measured at the distal wrist (CSA-D), and proximal forearm (CSA-P), and wrist-to-forearm ratio (WFR; CSA-P/CSA-D) was calculated for each hand. We also investigated the history of percutaneous transluminal angioplasty (PTA) in them.

Results: The mean age of hemodialysis patients was 60.4 ± 16.0 years. The mean duration on hemodialysis was 48.3 ± 39.6 months. The WFRs in hemodialysis patients were higher than those in healthy controls (1.35 ± 0.47 vs. 1.25 ± 0.26, P < 0.05). The WFRs in patients with a history of PTA were higher than those in patients without a history of PTA (1.46 ± 0.56 vs. 1.23 ± 0.32, P < 0.05).

Conclusions: In maintenance hemodialysis patients, WFR of median nerve was significantly increased in the hand with AVF. Moreover, development of CTS was related not only to AVF itself, but also to AVF function.

FR-PO724

Factors Affecting Patency of Haemodialysis Arterio-Venous Fistulae and Grafts

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD), and where these cannot be created, arterio-venous grafts (AVGs) are the next best option. AVFs/AVGs however, not uncommonly fail to mature. The causes of this are varied, but loss of patency due to thrombosis and/or significant stenoses are major causes. We investigated the factors affecting patency of AVFs/AVGs in order to identify whether there were any characteristics which were predictive of this.

Methods: All AVFs/AVGs created in our unit between 2006 and 2014 were reviewed. Reasons for loss of primary patency were obtained from the dialysis access database. Characteristics reviewed were age, gender, co-morbidity score, diabetes status and site of AVF. Patients were grouped as follows: patency <30 days, patency <90 days, patency >90 days and patency >365 days.

Results: There were 1897 (66.8%) AVFs and 251 (34.2%) AVGs created. 649 (32.2%) of AVFs were lower arm, all the AVGs were upper arm, or lower limb. 1346 (62%) were male. The main reasons for AVF loss were clotting/stenosed vessels in 78% of cases. There was no association between ethnicity or gender with regard to patency rates. Other variables are shown in table 1.

Conclusions: We did not find any definite predictive factors for loss of primary patency in the variables we studied. In particular, co-morbidity score, age and diabetes showed no association with poorer outcomes. There is quite a significant ‘drop off’ in primary patency at 12 months. In the majority of cases, this was due to thrombosis of the HD access. This highlights the importance of close surveillance, as measures to maintain patency (surgical or radiological) are more likely to be required in this period.

FR-PO725

Drug-Eluting Stents versus Bare-Metal Stents During Percutaneous Coronary Intervention in Patients on Dialysis

Tara I. Chang, Maria E. Montez-Rath, Mark A. Hlatky, Wolfgang C. Winkelmayer.

Background: In patients undergoing percutaneous coronary intervention (PCI), drug-eluting stents (DES) reduce the need for repeat revascularization (RR) compared with bare-metal stents (BMS). The effects on death and MI are more controversial, with mixed results from observational studies and generally null results from clinical trials. However, few previous studies have focused patients with end-stage renal disease (ESRD). We compared the effectiveness of DES with BMS in a representative cohort of US patients on dialysis.

Methods: Using the US Renal Data System, we identified 36,117 patients on dialysis with Medicare Parts A+B who had PCI with stenting after DES became available in the US (4/23/03 – 12/31/10). We used propensity-score matching (PSM) and inverse probability of treatment weighting (IPTW) with Cox regression to examine the association of DES versus BMS on the following 1-year outcomes: death, death or MI, and death, MI or RR. Due to concerns about residual indication bias, we conducted a second, temporal analysis that leveraged the large changes in the prevalence of DES use during three distinct eras: Transitional (4/23/03 – 6/30/04); Liberal (7/1/04 – 12/31/06); and Selective (1/1/07 – 12/31/10).

Results: In the PSM and IPTW analyses, DES was associated with lower risks of all three outcomes compared with BMS.

Table: Hazard ratios (95% CI) for DES vs BMS

<table>
<thead>
<tr>
<th></th>
<th>Death</th>
<th>Death/MI</th>
<th>Death/MI/RR</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSM</td>
<td>0.82 (0.78-0.86)</td>
<td>0.84 (0.91-0.87)</td>
<td>0.87 (0.84-0.91)</td>
</tr>
<tr>
<td>IPTW</td>
<td>0.82 (0.79-0.85)</td>
<td>0.85 (0.82-0.87)</td>
<td>0.88 (0.85-0.90)</td>
</tr>
</tbody>
</table>

DEU var used by era: Transitional=56%, Liberal=85%, and Selective=62%. In the temporal analysis, outcomes in the Liberal DES era were significantly better than in the Transitional Era, but not consistently better than in the Selective Era.

Conclusions: Adoption of DES for PCI was associated with improved outcomes in US patients with ESRD on dialysis.

Eleven Year Trends in Myocardial Infarction and Stroke in the Incident and Prevalent Dialysis Population

Len A. Usvyat,1 Len A. Usvyat,1 Ann Mooney,1
1Medicaturated Medical Office, Fresenius Medical Care North America, Waltham, MA; 2Div of Nephrology, Massachusetts General Hospital, Boston, MA.

Background: Myocardial infarction (MI) and cerebrovascular (CVA) events are highly prevalent in the chronic dialysis population. We aimed to quantify the annual incidence and trends of MI and CVA events from 2004 to 2014 in a large dialysis population.

Methods: We analyzed >600,000 patients receiving chronic dialysis from a large dialysis provider from January 2004 to December 2014. For each calendar year, we calculated the incidence of MI and CVA (event per 100 patient years) identified by ICD9 code for the population in the first 120 days of chronic dialysis (incident period) and in the subsequent period after the first 120 days (prevalent period). Linear regression was used to quantify statistically significant trends in MI and CVA rate of the eleven year period.

Results: Over an eleven year period in the incident population, the mean incidence of MI and CVA was 3.3 and 3.2 events per 100 patient years respectively. Among the prevalent population, the mean incidence of MI and CVA was 1.9 and 1.8 events per 100 patient years respectively. Using linear regression models, the incidence of MI and CVA was found to decrease by 0.14 (p=0.05) and 0.11 (p=0.0009) per year among incident patients. Similarly, the incidence of MI and CVA was found to decrease by 0.06 (p=0.0007) and 0.10 (p=0.0001) per year among prevalent patients. See Figure 1.

Conclusions: Both MI and CVA rates are decreasing among incident and prevalent dialysis populations over the past eleven years.

Relationship of Ticagrelor Dose and Platelet Reactivity in Patients with End Stage Renal Disease on Hemodialysis

Jin sue Kim,1 Taec won Lee,2 Chun-Gyoo Ihm,1 Sang ho Lee,3 Se yun Lee,4 Shin yeong Lee,5 Yu ho Lee,6 Kyung-hwan Jeong.
1Internal Medicine, KyungHee Univ School of Medicine, Seoul, Korea.

Background: In our previous study, ticagrelor has superiority on platelet inhibition than clopidogrel in patients with end stage renal disease (ESRD) on hemodialysis (HD). One study compared two doses of ticagrelor (90 or 60mg) and placebo, reported that ticagrelor significantly reduced the risk of cardiovascular death, MI, or stroke and increased the risk of bleeding. The rate of bleeding is more frequent in 90mg group. We hypothesized there was some relationship between ticagrelor dose and platelet inhibition. We investigated efficacy and safety of standard and low dose ticagrelor, and clopidogrel in ESRD patients on HD.

Methods: In a single-center, prospective, randomized study, 50 ESRD patients were enrolled in the study: mean age 67.5 years old, 56% male, 47% had diabetes and 28% had pre-existing coronary artery disease. There were 236 patients were enrolled in the study: mean age 67.5 years old, 56% male, 47% had diabetes and 28% had pre-existing coronary artery disease. There were 88 enrolled Td levels (13% of all measured) in 52 patients. In univariate analysis, high UFR and dialysis vintage, but not IDH or IDWG, were associated with TnI variability. In multivariate analysis, both high UFR (p=0.02) and dialysis vintage (p=0.01) explained TnI variability. The intraclass correlation coefficient was found to be 1%, suggesting that the observed variability is within and not between subjects, with session related parameters being more important than inter-individual differences.

Conclusions: Low dose ticagrelor may result in greater platelet inhibition than clopidogrel in ESRD patients on HD. Further studies with large number and various doses of medicine are needed.

Prognostic Accuracy of Serial versus Single Troponin Measurements in Hemodialysis Patients

Table/Divasovs,1 Allan Snidersman,1 Ahsan Alam.1
1Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada; 2Div of General Internal Medicine, Geneva Univ Hospitals, Geneva, GE, Switzerland; 3Div of Cardiology, McGill Univ Health Center, Montreal, QC, Canada.

Background: Cardiac troponin I (Tnl) elevation in stable patients receiving chronic hemodialysis (HD) is associated with increased mortality. The frequency of measuring Tnl to determine risk is not yet known. This study aimed to assess whether using serial Tnl measurements improves the predictive accuracy for mortality compared with a single measurement.

Methods: Pre-treatment Tnl levels were measured in 130 stable HD patients monthly for 3 consecutive months. A value above the laboratory reference range (>0.06 mg/L) was considered to be elevated. To assess the prognostic accuracy of Tnl measurement, three different approaches were used to determine high risk: i) only the first month’s value was elevated; ii) at least one of three monthly Tnl values were elevated; iii) at least two of the three monthly Tnl values were elevated. All the patients were followed-up for 12 months. Multivariate Cox proportional hazard analysis was used to examine the association of Tnl elevation with the outcomes of mortality or a composite of mortality with major cardiovascular events. The performance of each Tnl classification method was compared using net reclassification index (NRI).

Results: Of 130 patients, 36 had an elevated Tnl in the first month, 44 had at least one elevated Tnl value, and 26 had 2-3 elevated Tnl values. The composite outcome was significantly higher in patients with an elevated Tnl compared with patients who had normal Tnl levels, regardless of the method used [HR (1.36 (1.76-6.3) ii) 3.55 (95% CI 1.68-7.52) iii) 3.81 (95% CI 1.83-7.94)]. Similar associations were seen with the outcome of mortality alone. Patients classified as high risk using at least one elevated serial Tnl measure were associated with a NRI of 0.035, as compared with a single Tnl measurement. If patients were classified as high risk using at least two elevated Tnl values, the NRI was -0.072.

Conclusions: Serial Tnl measurements are associated with only marginal improvement in predicting mortality or MACES as compared with a single Tnl measurement.

High Ultrafiltration Rates Are Associated with Increased Troponin Levels in Stable Hemodialysis Patients

Table/Avasovs,1 Allan Snidersman,2 Murray L. Vasilevsky,1 Ahsan Alam.1
1Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada; 2Div of General Internal Medicine, Geneva Univ Hospitals, Geneva, GE, Switzerland; 3Div of Cardiology, McGill Univ Health Center, Montreal, QC, Canada.

Background: An elevated troponin level in asymptomatic patients on hemodialysis is associated with a higher risk of mortality and cardiovascular events. The underlying mechanisms for this association has not been elucidated. The objective of this study was to assess whether intra- and inter-dialytic parameters are associated with higher troponin I (Tnl) levels.

Methods: Stable chronic hemodialysis patients at 2 tertiary care centers were enrolled in this observational study. Td levels were measured with monthly bloods for three consecutive months. Tnl was measured by immunoassay and was considered to be elevated if it exceeded the laboratory reference range (>0.06 mg/L). We examined the association of the dialysis vintage, session duration, intradialytic hypertension (IDH), high ultrafiltration rate (UFR), defined as a UFR ≥ 12.4 ml/kg/h, and interdialytic weight gain (IDWG) using a mixed linear fixed effects model for repeated measures.

Results: 236 patients were enrolled in the study: mean age 67.5 years old, 56% male, 47% had diabetes and 28% had pre-existing coronary artery disease. There were 88 enrolled Td levels (13% of all measured) in 52 patients. In univariate analysis, high UFR and dialysis vintage, but not IDH or IDWG, were associated with Tnl variability. In multivariate analysis, both high UFR (p=0.02) and dialysis vintage (p=0.01) explained Tnl variability. The intraclass correlation coefficient was found to be 1%, suggesting that the observed variability is within and not between subjects, with session related parameters being more important than inter-individual differences.

Conclusions: In this observational study we identify potentially modifiable factors associated with Tnl elevation. Strategies to prevent hemodialysis-induced myocardial injury may include efforts to avoid excessive ultrafiltration, minimize IDWG, or offer more frequent dialysis, but these need to be validated by interventional studies.

Prognostic Value of High-Sensitivity Troponin T in Stable Dialysis Patients
