Titi Chen, Angela Makris. Dept of Nephrology, Liverpool Hospital, Liverpool, New South Wales, Australia.

Background: We evaluated the prognostic value of high-sensitivity cardiac troponin T (hs-TNT) in predicting myocardial infarction (MI) and death in dialysis patients after 4 years.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

529A
Methods: A retrospective review of a cohort of 354 hemodialysis (HD, 254) and peritoneal dialysis (PD, 109) patients was followed up to 4 years after baseline hs-cTNT. All-cause mortality, cardiac mortality and new MI were assessed.

Results: The median hs-cTNT was 60 ng/L (interquartile range IQR 38-105 ng/L) with no observed difference between HD and PD patients (P=0.18). Patients dying (n=148) had a higher baseline hs-cTNT (median 90 vs 50 ng/L, P<0.001). Similar trends were observed for both HD and PD subgroups. Patients with cardiac mortality (n=25) had a higher baseline hs-cTNT compared with non-cardiac mortality (121 vs 75.5 ng/L, P=0.013). These trends were only observed in the HD subgroup. Patients with a new MI (n=65) had no difference in their baseline hs-cTNT (66 vs 59 ng/L, P=0.064) compared to controls. The group was divided into quartiles based on hs-cTNT. Incremental increase in mortality (P<0.001), cardiac mortality (P=0.001) and MI (P=0.033) were observed with increasing hs-cTNT quartiles. Similar trends were observed for both HD and PD subgroups except MI in the PD subgroup. For every increase of 25 ng/L in hs-cTNT, the unadjusted hazard ratio (HR) was 1.094 for cardiac mortality (P=0.043, 95%CI 1.001-1.192), 1.123 for MI (P=0.000, 95%CI 1.053-1.198). The adjusted HR for MI was 1.107 (P=0.018, 95%CI 1.101-1.205). Kaplan-Meier curves demonstrated increasing hs-cTNT quartiles was associated with an increase in the incidence of cardiac mortality (P=0.014) and MI (P=0.013) but not overall mortality. 178 patients had hs-cTNT repeated at 4 years. There was a significant increase in hs-cTNT from a baseline of 60 ng/L (IQR, 38-105 ng/L) to a 4-year concentration of 64 ng/L (IQR, 42-104 ng/L) (P=0.000). This was true for both patients with (P=0.008) or without (P=0.001) new MI. Similar trends were observed for both HD and PD subgroup analysis.

Conclusions: hs-cTNT has a useful role in predicting all-cause mortality, cardiac mortality and MI in stable dialysis population. There was an increase in hs-cTNT level over a 4-year period.

FR-PO731
Temporal Trends in Myocardial Infarction Incidence and 30-Day Mortality in U.S. Dialysis Patients Charles A. Herzog,1 Keri L. Monda,2 Anne C. Beaubrun,2 Wolfgang C. Winkelmayer,3 Til Stürmer,3 Allan J. Collins,1 Akhtar Ashfaq,4 Kenneth J. Rothman,5 David T. Gilbertson.1

Background: Acute myocardial infarction (MI) is a catastrophic event in dialysis pts. Few data exist on current MI hospitalization rates. We assessed trends in type of MI (ST elevation MI [STEMI], non-ST-elevation MI [NSTEMI], and unclassifiable MI [other]), and death rates by type of MI in 2005-2011.

Methods: Using Medicare claims data, we created yearly cohorts of dialysis pts point prevalent on January 1 of each year 2005-2011. We assessed STEMI, NSTEMI, and other MI hospitalization rates, and calculated annualized 30-day death rates following MI.

Results: In 2005 there were 10,275 NSTEMI, 1,892 STEMI, and 1,918 other MI vs 2011, 16,235 NSTEMI, 2,169 STEMI, and 1,634 other MI. Demographics: mean age 67; 5% < 45, and 6% > 84 yrs; 47% female; 48% white, 32% black; 55% ESRD from DM. While overall MI rate increased slightly from 2005-2011 (80.1/1,000 PY in 2005 vs 91.2 in 2011), STEMI and other MI decreased by 44% and 29% respectively, while NSTEMI increased by 31%. Short term mortality was relatively unchanged for NSTEMI (295 deaths/1000 PY), increased slightly for STEMI (495/1000 PY in 2005 to 565/1000 PY in 2011), and was highest following other MI (881/1000 PY in 2005 and 915/1000 PY in 2011).

Conclusions: In the recent treatment era there has been little change in either rates of overall MI hospitalization or 30-day mortality. The increase in NSTEMI rates may be due to greater utilization of more sensitive cardiac biomarkers (cardiac troponins) for MI diagnosis. MI remains a catastrophic event for dialysis pts. Aggressive interventions to reduce the burden of ischemic heart disease and to improve its prognosis in dialysis pts are warranted.

FR-PO732
Risk of Acute Coronary Events and Coronary Interventions for Overweight and Obese Patients versus Normal Weight Patients Undergoing Dialysis – A National Study Austin G. Stock,1,2 Mohamed Elsayed,1,2 Muhammad Umar Sharif,1,2 John P. Ferguson.2

Background: Although elevated body mass index (BMI) is associated with increased risk of cardiovascular events in the general population, it is suggested that the converse may hold true for patients on dialysis.

Methods: We tested this hypothesis in a national cohort of 1,072,737 incident Medicare-eligible US patients, who began dialysis between 5/1995 and 12/2008. Hospitalizations attributed to first myocardial infarction (MI) [ICD 9 codes; 410] and major coronary interventions (coronary angioplasty, stent, and coronary bypass surgery) following first MI were obtained from the US Renal Data System. Multivariable Cox regression compared hazard ratios [HR] of MI and subsequent coronary interventions among BMI categories.

Results: The adjusted HR of MI was highest for overweight patients and lowest for morbidly obese patients, decreasing significantly with increasing BMI category. Overweight patients were significantly more likely to receive a coronary intervention post-MI compared to normal weight individuals but this benefit did not extend to morbidly obese or underweight patients.

Conclusions: In contrast to the general population, higher BMI is associated with lower risk of major coronary events in US dialysis patients suggesting a protective effect. Furthermore, access to coronary interventions following a major coronary event is not equal across BMI categories.

FR-PO733
Propensity-Based Comparison of Haemodialysis and Peritoneal Dialysis with Risk of Haemorrhagic and Ischaemic Stroke Among New Dialysis Patients Austin G. Stock,1,2 Mohamed Elsayed,1,2 Muhammad Umar Sharif,1,2 John P. Ferguson.2

Background: The risk of stroke is between 6-10 fold higher in dialysis patients compared to the general population. It is hypothesised that the choice of dialysis modality at initiation may influence the risk of stroke.

Methods: We tested this hypothesis in a national cohort of 1,097,747 US patients (n=86,168 on PD) who were Medicare eligible and began dialysis between 5/1995 to 12/2010 and followed until 9/2011. Hospitalizations attributed to first Haemorrhagic Stroke (H-CVA) and Ischaemic stroke (I-CVA) were obtained from the US Renal Data System files and merged with data from the medical evidence, treatment history and mortality files. Multivariable Cox regression compared the hazards ratio [HR] of H-CVA and I-CVA for PD versus HD with a propensity-matched intent-to-treat (ITT) approach and as-treated analysis. Patients were censored at transplantation, death, recovery of kidney function, or end of study (Sept 2011). Approval was received from University Hospitals Ethics Committee.

Results: The adjusted PD/HD HRs for first hospitalized H-CVA using the intent-to-treat model was 0.89 (0.83,0.95) and this decreased from 0.73 (0.61,0.87) in the period 1995-1998 to 0.64 (0.51,0.80) in the period 2007-2010. In contrast, overall HRs for I-CVA were 1.15 (1.12-1.18) and this decreased from 1.20 (1.13-1.27) in the period 1995-1998 to 1.06 (0.97-1.15) in the period 2007-2010. The as-treated model suggested more favourable outcomes for H-CVA with overall HR of 0.61 (0.57,0.67) and for I-CVA with a HR 0.96 (0.90-1.02) in 2007-2010 period. Patients who switched from PD to HD or HD to PD had significantly higher HR of H-CVA, while patients who switched from PD to HD had higher HR of I-CVA.

Conclusions: PD and HD contribute differentially to the overall risk of I-CVA and H-CVA among new dialysis patients. While PD is similar to HD with regard to hazards of I-CVA, it appears to protect against the hazard of H-CVA. These associations should be taken into consideration when choosing treatment options for new dialysis patients.

Predictors of Sudden Cardiac Death in Hemodialysis Patients with and without Previous Arrhythmia – Results from a Multinational Cohort

Viviane Calice-Silva, 1 Stephan Thijsse, 2 Xiaoliang Ye, 2 Aileen Grassmann, 3 Daniele Marcelli, 2 Bernard J. Canuda, 2 Peter Kotanko, 1 Roberto Pecotis-Filho, 1
1Pontifícia Unv Católica do Paraná, Brazil; 2Renal Research Inst; 3Fresenius Medical Care, Germany.

Background: Cardiac dysfunction, rapid electrolyte shifts and high ultrafiltration rates during hemodialysis (HD) are associated with increased vulnerability to arrhythmogenic events. Patients with previous arrhythmia (ARR) are at a higher risk of sudden cardiac death (SCD – Herzog et al, 2011). Our aim was to analyze predictors of SCD in HD patients with and without previous ARR.

Methods: Incident HD patients from the Monitoring Dialysis Outcomes (MONDO) cohort who received in-center treatment between 1/2006-12/2011 and survived at least 90 days on HD were included and followed until 12/2012. Causes of death were classified as SCD according ICD-10/ICD-9. Patients with comorbidity or prior hospitalization due to ARR and/or ARR predisposition were identified. Cox proportional hazards models were constructed to explore associations between baseline parameters and SCD.

Results: We studied 19,129 patients (16 countries), 7,538 patients with complete data were included in the models, 613 died of SCD. Mean age 62.7±15.5 years, 58.1% male, 48.4% diabetics. Age, ischemic heart disease, albumin, serum sodium, interdialytic weight gain in % of post-HD weight and pre-HD-systolic blood pressure were identified as predictors of death in both subgroups. Distinct predictors are shown below. The complete table is not provided in the document.

Table 1: Predictors of SCD in patients with (N=158) and without ARR history and/or predisposition (N=455).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>SCD with ARR</th>
<th>Hazard Ratio(±SE) P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum bicarbonate [mmol/L]</td>
<td>0.07 (0.04)</td>
<td>0.04</td>
</tr>
<tr>
<td>Leukocytes [1000/mm 3 ]</td>
<td>0.02 (0.005)</td>
<td>&lt;0.0001</td>
</tr>
<tr>
<td>Hemoglobin [g/dl]</td>
<td>0.11 (0.04)</td>
<td>0.005</td>
</tr>
<tr>
<td>Dialysate sodium [mmol/L]</td>
<td>0.095 (0.03)</td>
<td>0.0008</td>
</tr>
<tr>
<td>Catechol as vascular access</td>
<td>0.41 (0.1)</td>
<td>&lt;0.0001</td>
</tr>
</tbody>
</table>

Conclusions: Despite the small sample size, some predictors of SCD seem to differ depending on the presence or absence of arrhythmia history or predisposition. These findings may assist the identification of patients at high risk for SCD. Further studies have to be done to corroborate these results.

FR-P0735

The Risks of Acute Health Events After Incident Atrial Fibrillation in Older Hemodialysis Patients

Medha Arya, 1 Benjamin A. Goldstein, 2 Mark A. Hlatky, 3 Nisha Bansal, 4 Alan S. Go, 5 Wolfgang C. Winkelmayr, 1 Baylor College of Medicine, Houston, TX; 2Duke Univ, Durham, NC; 3Stanford Univ, Palo Alto, CA; 4Univ of Washington, Seattle, WA; 5Kaiser Permanente Northern California, Oakland, CA.

Background: Limited data exist about whether incident atrial fibrillation/flutter (AF) impacts the risks of major acute health events in patients with ESRD undergoing hemodialysis (HD).

Methods: From the US Renal Data System, we studied older (≥67 years) adults with ≥2 years of uninterrupted Medicare A&F coverage before starting HD (2006-11) and no known AF prior to ESRD. Incident AF was ascertained from ICD-9 diagnosis codes (427.3x) in inpatient claims. We used extended Cox regression to adjust for sociodemographic characteristics and key comorbidities to estimate hazard ratios (HR [95% confidence intervals]) for death, ischemic stroke, myocardial infarction (MI), and hip fracture (as a negative control outcome). AF was treated as a time-varying covariate, with time since first AF diagnosis further categorized as ≤30, 31-90, and >90 days. Patients were censored at time of kidney transplant or end of data (12/31/2011).

Results: We identified 85,377 eligible HD patients; 16.7% developed incident AF and 58.2% died during follow-up. Incident AF was associated with higher adjusted mortality: 8-fold higher during the first 30 days (HR=8.2 [7.9-8.6]), 4-fold higher between 31-90 days (HR=4.2 [4.0-4.4]), and 2-fold higher beyond 90 days after AF diagnosis (HR=2.2 [2.1-2.2]). Incident AF also increased the adjusted rate of ischemic stroke 1.5-2.5-fold during the first 30 days (HR=2.1 [1.6-2.7]), 31-90 days (HR=2.5 [2.0-3.0]), and beyond 90 days (HR=1.5 [1.3-1.7]). Quantitatively similar findings were obtained for MI. However, the adjusted rate of hip fracture was only marginally increased following AF diagnosis (~30 days: 1.0 [0.7-1.6], 31-90 days: 1.4 [1.0-1.8], >90 days: 1.2 [1.1-1.4]). All associations were attenuated when requiring incident AF to be indicated as principal discharge diagnosis.

Conclusions: While AF was independently associated with higher risks of ischemic stroke, MI, and hip fracture in older ESRD patients on HD, it was more strongly associated with excess all-cause mortality.

The CRASH-ILR Study: Half a Million Hours of Continuous ECG Monitoring in a Hemodialysis Population

Robert Lewis, 1 Darren Green, 2 Philip A. Kalra, 3 Donah Zachariah, 2 Paul Kalra, 1 Paul R. Roberts, 4 Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; Salford Royal NHS Trust, Salford, United Kingdom; 3Royal Bournemouth Hospital, Bournemouth, United Kingdom; 4Southampton Univ Hospitals Trust, Southampton, United Kingdom.

Background: Sudden cardiac death (SCD) may cause ≥5% of all hemodialysis (HD) patient deaths. Multiple potential mechanisms may contribute to the risk of life-threatening arrhythmias in this population. The CardioRenal Arrhythmia Study in Hemodialysis has continuously monitored patients using an Implantable Loop Recorder (ILR) for more than 350,000 hours.

Methods: A total of 158 patients (60% male) aged 67±12 years on established HD for 39±44 months with various etiologies of CKD (diabetes 37%, hypertension 23%) were included. A total of 568±8 events were ascertained from the CRASH-ILR database (Medtronic, MN, USA). Patients were monitored for a minimum of 2 years after enrollment. Mortality was due to SCD in 50% of patients.

Results: Patients were monitored for a minimum of 2 years after enrollment. Mortality was due to SCD in half of the study population. Mortality was high, but this was due to SCD as an expected end-of-life event in 5 out of 6 patients.

Funding: Pharmaceutical Company Support - Medtronic, MN, USA

FR-P0737

Revisiting Ultrafiltration Rate (UFR), Treatment Time (TT) and Mortality in Thrice Weekly Hemodialysis

Jennifer L. Bragg-Gresham, Brett W. Plattner, Debabrata Ray, Yi Li, Rajiv Saran. KECC, Univ of Michigan, Ann Arbor; MI.

Background: UFR and TT are two potentially modifiable practices for improving outcomes in HD. UFR > 13 ml/kg/hr has been associated with higher mortality. We re-examined this association, focusing on the effect of higher UFR at TT ≥ 4 hours, as longer TT has been claimed to be ‘protective’, even though TT > 4 hours is logistically difficult to implement in the prevailing US practice setting.

Methods: Using recently available national data from CROWNWeb (CW), we analyzed 233,759 adults on thrice-weekly, in-center HD. Baseline CW data was extracted from June 2012. Patients were followed through December 31, 2013. Cox regression was used to examine the association between UFR (calculated as the intradialytic weight loss / TT and expressed in ml/kg post HD-weight/hr) and mortality, adjusting for demographics, co-morbidities, dialysis vintage, interdialytic weight gain (IDWG) and dialysis dose (Kt/V), stratified by TT. Average follow-up was approx 1 year.

Results: Individuals receiving TT ≥ 240 were younger, more likely to be black and male, and had larger BMI. In both strata of TT (< 240 and ≥ 240) those patients with UFR > 13 tended to be younger, non-black race, have a lower BMI, longer HD vintage, higher Kt/V, and higher IDWG than patients with UFR < 13. Congestive heart failure was more prevalent in patients with UFR ≤ 13 regardless of TT. In both strata of TT, patients with a UFR >13 had higher hazard of mortality, with a larger risk found in those with TT ≥ 240.

Conclusions: A higher UFR (>13) was associated with higher mortality irrespective of TT category. The association was surprisingly strong among those receiving longer TT. In the US, longer TT is prescribed in order to achieve small solute targets (confounding-by-indication) and not necessarily to lower the UFR, as high UFR is a consequence of high IDWG and the average shorter TT.

Funding: NIDDK Support.

Sudden Death and Dialysate Potassium in Hemodialysis: Results from the Dialysis Outcomes and Practices Patterns Study (DOPPS)

Angelo Karabas,1 Jarcy Zee,1 Steven M. Brunelli,2 Len A. Usuyat,3 Daniel E. Weiner,1 Franklin W. Maddux,2 Allen R. Nissenson,4 David C. Mendelsohn,5 Michel Y. Jadoul,6 Friedrich K. Port,1 Bruce M. Robinson,3 Francesca Tentori,1 Arbour Research Collaborative for Health, Ann Arbor, MI; 2DaVita Clinical Research, Minneapolis, MN; 3FMCNA, Waltham, MA; 4Tufts Medical Center, Boston, MA; 5DaVita Healthcare Partners, Inc., El Segundo, CA; 6Humber River Regional Hospital, Toronto, Canada; 7Université Catholique de Louvain, Belgium.

Background: Sudden death (SD) is common in hemodialysis (HD) patients. We investigated trends in dialysate (DK) and pre-dialysis serum (SK) potassium across the Dialysis Outcomes and Practices Patterns Study (DOPPS) phases 1-5 (1996-2015) and evaluated whether the risk of SD is higher with lower DK.

Methods: 67,263 patients in 21 countries were studied. Instrumental variable methods were used to model the effect of DK on SK. Adjusted Cox regression was used to test the associations of baseline DK and SK with all-cause death, and an arrhythmia composite (AC) of SD or arrhythmia-related hospitalization.

Results: In the US, DK and SK (mEq/L) have been stable over time (70% DK=2, 25% DK=3; mean±StdDev SK=4.7±0.7). In Europe, DK has increased (currently 15% DK=1, 1.5, 45% DK=2, 33% DK=3) while mean SK has decreased from 5.2 to 4.9. SK was only 0.08 mEq/L higher per 1 mEq/L higher DK. SK ≥ 6 (ref 4.9-5.4) was associated with death (HR=1.12, 95% CI: 1.05-1.19) and AC (HR=1.17, 1.04-1.33). Compared to DK=2, DK=3 was not associated with death or AC, overall or at any level of SK (Fig).

Conclusions: In this large international cohort, SK was associated with elevated risk of SD, but risk of SD was similar for DK=2 or DK=3 across SK levels. Because DK had minimal influence on pre-dialysis SK, efforts to limit dietary K intake may be a more effective strategy to lessen the risks associated with high SK.

FR-PO739
Acute Health Events and the Risk of Incident Atrial Fibrillation in Older Patients Undergoing Maintenance Hemodialysis

Medha Airy,1 Benjamin A. Goldstein,2 Mark A. Hlatky,3 Alan S. Go,4 Nisha Bansal,5 Wolfgang C. Winkelmayr,1 Baylor College of Medicine, Houston, TX; 2Duke Univ, Durham, NC; 3Stanford Univ, Palo Alto, CA; 4Kaiser Permanente Northern California, Oakland, CA; 5Univ of Washington, Seattle, WA.

Background: Acute health events might increase the risk of developing atrial fibrillation (AF). We examined the incidence of new onset AF relative to several acute events in patients with end-stage renal disease (ESRD) initiating hemodialysis (HD).

Methods: From the USRDS, we studied older (67+ years) patients with 2 years of Medicare A&B coverage prior to initiating HD (2006-11) who had no documented diagnosis of AF, or claims indicating ischemic stroke, myocardial infarction (MI), or hip fracture prior to ESRD. We used time-varying Cox regression to estimate adjusted hazard ratios for incident AF relative to the acute events of interest, adjusted for socio-demographics and baseline comorbidities. The incidence of AF after either an acute MI, or hip fracture was modeled in time-varying fashion, during the periods of <30, 30-90, and >90 days after the acute event. Patients were censored at kidney transplantation or end of database (12/31/2011).

Results: 85,377 older HD patients met the inclusion criteria. The risk of AF was approximately doubled in the 90 days after an ischemic stroke, and remained elevated thereafter (Table). The risk of AF after an acute MI followed a similar pattern, with highest risk in the 30 days after the MI. The risk of AF after hip fracture followed a slightly different pattern, peaking between 30 and 90 days after the event, with no significant late hazard after 90 days. These associations were essentially unchanged when requiring that the acute health event be reported as principal diagnosis.

Conclusions: The risk of incident AF among patients on HD is increased after a stroke, MI, or hip fracture. Risks were highest in the first 90 days after the event, and remained elevated >90 days after an ischemic stroke or MI, but not after a hip fracture.

FR-PO740
Arrhythmias as a Potential Cause of Dizziness and Syncope in Patients with End-Stage Renal Disease

Katti Kaartinen,1 Jani Alhovonen,2 Seppo Ojansen,3 Joonas Markku Rautavaara,3 Ollli Anttonen,3 Tuomas Kerola,3 Kati Vaaraniemi,1 Marja H. Miettinen,4 Juhani Koistinen,4 Atte Atikosuo,4 Tuomo Nieminen.5 1Dept of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; 2Dept of Nephrology, Fälähti–Häme Central Hospital, Lahti, Finland; 3Dept of Nephrology, Central Hospital of Central Finland, Jyväskylä, Finland; 4Dept of Cardiology, Vaasa Central Hospital, Vaasa, Finland; 5Dept of Internal Medicine, Univ of Helsinki, Helsinki, Finland.

Background: It is unknown how often arrhythmias underlie dizziness and syncope in end-stage renal disease. We launched a study to implant subcutaneous loop recorders for their estimation.

Methods: Data is shown for 40 patients (62.4±8.2 years [mean±SD]), range 39 to 78 y, 26 M with stage 4 or 5 renal failure and F of >2 months. Main kidney diseases were diabetic (18), polycystic disease (8) and chronic glomerulonephritis (6). One patient was pre-dialytic, five had peritoneal dialysis, and rest were on hemodialysis. Median time since the start of dialysis was 1.6 years. Seven patients (18%) had either chronic or paroxysmal atrial fibrillation (AF) prior to the implantation of the recorder, being in line with published data.

Results: During the F of 14±7 months, recorder revealed bradycardia in six (15%) patients with an R-R arrest of >5.0 sec with a max. of 9.0 sec; two patients with symptoms thus far received a pacemaker. AF occurred in 21 (53%) patients. The median time to detect new AF was 235 days. Four patients (10%) had non-sustained ventricular tachycardia unknown before the recorder data.

Conclusions: Arrhythmias are more typical than estimated in patients with severe kidney disease. Particularly, symptomatic bradycardia is relatively common and can be easily treated with a pacemaker. AF is three times more common than known before. These findings may change diagnostics and treatment of dizziness in these patients.

FR-PO741
Blood Pressure and Risk of Cardiovascular Events Among Hemodialysis Patients: The CRIC Study

Nisha Bansal,1 Charles E. McCulloch,2 Feng Lin,2 Cassianne Robinson-Cohen,3 Mahboob Rahman,4 John W. Kusek,4 Amanda Hyre Anderson,1 Raymond R. Townsend,1 Jackson T. Wright,2 Alan S. Go,3 Arnold B. Alper,7 Radhakrishna Reddy Kallem,1 Chi-yuan Hsu,1 1UW; 2UCSF; 3UH; 4NIDDK; 5UPenn; 6Case Western; 7KFNC; 8Tulane.

Background: Among hemodialysis (HD) patients, previous studies have reported a U-shaped association between systolic blood pressure (SBP) and risk of mortality. However, the shape of the association between SBP and risk of cardiovascular events (CVD) is not well characterized.

Methods: We studied participants on HD in the Chronic Renal Insufficiency Study (CRIC). SBP was measured at the dialysis unit (“dialysis-unit SBP”, N=803) and at the CRIC study visit (“out-of-dialysis-unit SBP”, N=326). We studied the association of SBP
with time to adjudicated CVD (defined as heart failure, myocardial infarction, peripheral vascular disease and stroke), adjusting for demographics, diabetes, smoking, BMI, prior CVD, k/τ, serum albumin and hemoglobin.

**Results:** Mean age was 60 (±11) years, 42% were women and 64% were Black. There were a total of 121 CVD events over a median time of 1.15 years. The association between dialysis-unit-SBP was U-shaped, with the greatest risk of CVD at the highest and lowest quartiles of dialysis-unit-SBP.

Conversely, the association between out-of-dialysis-unit-SBP was linear, with the highest quartile having greater than 2-fold risk of CVD than the lowest quartile.

**Conclusions:** Among HD patients, the association of SBP measured in the dialysis unit with CVD is U-shaped, while the association of SBP measured outside the dialysis unit with CVD is linear, similar to what has been reported for mortality ( Bansal et al., Hypertension 2015). Targeting SBP measured outside the dialysis unit may improve CVD outcomes in HD patients.

**Intradialytic Dynamics of Systolic Blood Pressure in Hemodialysis Patients Based on Survival Status**

**John W. Larkin,1 Dugan Maddux,1 Yue Jiao,1 Jeroen Kooman,1 Frank van der Sande,2 Hao Han,1 Sophia Rosen,1 Len A. Usyvat,1 Peter Kotanko,1,2 Franklin W. Maddux,3 Fresenius Medical Care North America (FMCNA), Waltham, MA; 4Maastricht Univ Medical Centre, Maastricht, Netherlands; 5Renal Research Inst, New York, NY; 6Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Low systolic blood pressure (SBP) before dialysis has been reported to be associated with worsened outcomes in hemodialysis (HD) patients (Maddux et al.,ASN 2014). However, the dynamics of intradialytic SBP and patient outcomes have not been well characterized in this population. We aimed to understand the dynamics of SBP during dialysis in patients based on their survival status.

**Methods:** We studied HD patients treated at FMCNA facilities in 2014 with recorded intradialytic SBP. The intradialytic mean intradialytic SBP was computed in 20 minute intervals during dialysis per patient per treatment; all treatments were then averaged per patient and thereafter for the entire cohort. Patient survival was recorded in 2014 (i.e. "alive" or "died").

**Results:** 31,053 and 2,835 patients (338,771 and 20,380 measurements respectively) were used for calculation of the mean SBP at each 20 minute time point in “alive” and “died” groups, respectively. The results show that the mean intradialytic SBP declines to a similar extent in both patients who died and survived, but patients that died exhibited a lower initial predialysis SBP and greater overall intradialytic variability.

**Conclusions:** These investigations of the dynamics of intradialytic SBP identify increased variability during dialysis and lower starting levels in patients who died. In both patients who were alive and died, SBP declines to a similar extent throughout dialysis. These findings suggest that lower predialysis SBP and intradialytic variability may be associated with mortality in the HD population.

Choosing the Right Analysis of Repeated Events for Clinical Trials in Dialysis

**George Tomlinson,1 Stephanie Dixon,2 Amit X. Garg,3 Charmaine E. Lok.1 1Medicine, Toronto General Hospital, Toronto, ON, Canada; 2ICES-KDT; 3London Health Sciences Centre.

**Background:** Cardiovascular (CV) events are a leading cause of morbidity and mortality in hemodialysis (HD) patients. There is a paucity of randomized clinical trials (RCT) in nephrology and fewer positive ones, perhaps due to incorrect choice of endpoints or inadequate power. We simulated RCTs with repeated CV events and competing non-CV death to determine how different analytic methods affected study power (sample size).

**Methods:** We simulated 1000 RCTs of 1100 patients, with frequency and timing of CV events (CV death, MI, stroke, PVD, CV revascularization, and leg amputations) based on real observations in an Ontario HD administrative cohort (n=9647) from 2004-2011. In simulations, patients were randomized to placebo or a treatment with a known effect and censored at 4 years or non-CV death. We analyzed this data with 1) a Cox model for time to first event, 2) a model with non-CV death as a competing risk, 3) a negative binomial (NB) model and 4) several adaptations of the Cox model for repeated events (e.g., Wei, Lin and Weisfeldt, WLW). To check for 2 potential problems (finding a difference when there was none and missing a true difference), we ran simulations in 2 scenarios: 1) with zero treatment effect, we calculated the false positive rate; 2) when the treatment delayed CV events by 33%, we calculated the true positive rate (power) based on the 1000 simulations.

**Results:** In the source (real) data, 45% of patients had >2 CV events; the overall CV event rate was 0.26/yr. When there was no effect of treatment, the NB model had a false positive rate of 11%; for all other models, it was the expected 5%. For the time to first event, competing risk and the WLW marginal Cox model, power was similar (72%) and notably higher than for the remaining Cox-type models (52%-61%).

**Conclusions:** The WLW Cox model for repeated events was as powerful as models for time to first event but has the advantage of assessing the impact on all (repeated) events a patient experiences. This highlights the importance of choosing the appropriate analytic method when designing a clinical trial in HD patients to maximize the likelihood of both a positive and a meaningful result.

Routine Predialysis Measurements of Systolic Blood Pressure Are Higher Than Predialysis Standardized Measurements of Systolic Blood Pressure

**Dana Miskulin,1 Jennifer J. Gassman,2 David W. Ploth,2 Manisha Jhamb,2 Lavinia A. Negrea,3 Mahboob Rahman,1 Ronald Schrader,2 Susan Paine,2 Philip Zagar,2 Tufts; 2UNM; 3DCI; 4Cleveland Clinic; 5MUSC; 6Univ of Pittsburgh; 7Case Western.

**Background:** Measurement of blood pressure (BP) in the dialysis unit does not follow American Heart Association recommendations. We determined the differences between systolic BP (SBP) measured in routine practice versus a standardized procedure.

**Methods:** The Blood Pressure in Dialysis Study is a pilot, multicenter, randomized clinical trial that assesses treatment of hypertensive HD patients to two BP targets. Measurement of predialysis SBP is done after 5 minutes rest, 3 readings 1 minute apart, with attention to cuff size, placement and patient positioning. We compared the 2-week averaged routine predialysis SBP (RDUSBP) taken immediately prior to enrollment with the 2-week averaged predialysis standardized SBP (SDUSBP) in the first 2 weeks of baseline. The within subject variability in SBP, (s^2) was estimated by mixed linear regression.

**Results:** We studied 186 patients. The two week averaged RDUSBP was a mean (SD) 10.3 (16.6) mm Hg higher than 2 week averaged SDUSBP (p<0.001).

**Conclusions:** RDUSBP was ± 5 mm Hg of the SDUSBP in 20% of patients, 6-15 mm Hg higher in 30%, 15-25 mm Hg higher in 17%, >25 mm Hg higher in 17% and >5 lower in 16%. Estimating s^2 for RDUSBP (15.7^2) and SDUSBP (19.6^2) were not significantly different, (p=0.99). Differences between RDUSBP and SDUSBP tended to be greatest among those with a high body mass index.

**Conclusions:** SDUSBP were, on average, 10 mm Hg lower than RDUSBP measured in the dialysis unit. Reliance on routine BP measurements may lead to over-treating hypertensive HD patients. More attention to the measurement of BP in dialysis unit is needed.

**Funding:** NIDDK Support, Pharmaceutical Company Support - Dialysis Clinic, Inc.
Comparison of Central and Peripheral Blood Pressure in Predicting Cardiovascular Surrogates in Patients with End-Stage Renal Disease

Younkyung Kee, Shin, Elaine-1,2

Patients with ESRD. These values did not provide additional information beyond pBP in predicting CV risk in (cSBP) and central pulse pressure (cPP) was 140.2 ±28.9 and 57.1±22.8 mmHg. Mean intima-media thickness, pulse wave velocity (PWV) and left ventricular mass index (LVMI).

We investigated the association between cBP and CV surrogates compared with peripheral blood pressure (pBP) in patients with ESRD.

Methods: A cohort of 92 ESRD patients from the Cardiovascular and Metabolic Disease Etiology Research Center between November 2013 and February 2015 was selected. cBP was measured by SphygmoCor noninvasively. CV surrogates were determined by carotid Etiology Research Center between November 2013 and February 2015 was selected. cBP and pSBP were independently associated with PWV ( ß=0.381, P<0.001; ß=0.353, P<0.001) and LVMI (adj ß=0.411; P<0.001; ß=0.497, P=0.001) after adjustment for confounding factors. However, there were no significant differences in the predictive value of cSBP and pSBP for estimating PWV (adjusted R², 0.494 vs. 0.431, P=0.07) and LVMI (adj R², 0.215 vs. 0.220, P=0.885). No significant difference was found for cPP and pPP for predicting PWV (adj R², 0.451 vs. 0.429, P=0.546) and LVMI (adj R², 0.220 vs. 0.265, P=0.320).

Conclusions: Although cBP values were closely associated with CV surrogates, these values did not provide additional information beyond pBP in predicting CV risk in patients with ESRD.

FR-PO746

Early Mortality in Hemodialysis Patients Anticoagulated for Atrial Fibrillation

Stanislav S. Bushik, N. Stanley Nahman, 1, Riad Elmoro, 2, Jennifer L. Waller, 3 Robert A. Sorrentino, 1, William R. Maddox, 1 Mufaddal F. Kheda, 1, B. Mark. 3

Background: Atrial fibrillation (AF) is prevalent in the Hemodialysis (HD) population and portends a high mortality rate. AF also causes embolic stroke and is treated with lifelong oral anticoagulation (OAT). We have previously shown early increased mortality in HD patients receiving OAT without significant stroke reduction (JASN, 25:690A, 2014). It is unclear why OAT increased early mortality in these patients. To address this question, we queried the USRDS for unique risk factors for mortality in this cohort.

Methods: All incident adult HD cases from the USRDS for 2005-2008 were queried for demographics, access type, risk factors before dialysis, and mortality. Data were derived from ICD9 and CPT codes, or Form 2728. Proportional hazards models were used to estimate the hazard ratio (HR) for death within 90 days.

Results: 34,522 incident HD patients with AF were identified, 6,664 (19.3%) of whom died within 90 days of the initiation of dialysis. For the entire group, demographics showed: 83.1% Caucasian, mean age 57.4 years (SD=9.0), and 41.5% female. When controlling for diabetes, cardiomyopathy TIA, pulmonary hypertension, aortic stenosis, CHF, MI, congestive heart failure, obesity, cardiac device, age and access type the HR for death in the OAT group was 1.10 (95% CI 1.04 - 1.16). The 1-, 2- and 3-month mortality rates were 6%, 15% and 22% in OAT and 5%, 12% and 19% in non-OAT, respectively. Major bleeding episodes were not significantly associated with mortality (p=0.59).

Conclusions: OAT therapy in HD patients with AF may contribute to the increased death rate observed during the first 90 days of dialysis, but not apparently due to bleeding. We speculate that OAT use may be associated with non-hemorrhagic complications that may lead to increased mortality in the HD population. Defining this level of clinical detail is beyond the scope of an administrative dataset like the USRDS. Future studies addressing non-hemorrhagic effects of OAT may provide new insights on possible causes of early mortality in these patients.

Reduced Temperature Hemodialysis Augments Dialysis Induced Improvement of Cardiac High Energy Phosphate Levels

Rajan Patel, Elaine Ruthford, Kathryn K. Stevens, Sandosh Padmanabhan, Alan G. Jardine, Patrick B. Mark. 1 Department of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom.

Background: 31P magnetic resonance spectroscopy (31P-MRS) measures levels of high-energy phosphate compounds, including phosphocreatine (PCr) and adenosine triphosphate (ATP). PCr/ATP ratios which evaluates cardiac metabolic activity. PCr/βATP is significantly reduced in end stage renal disease (ESRD) patients. Reducing hemodialysate temperature by 1°C improves intradialytic hypotension and cardiac function. The effects of reduced temperature dialysis on cardiac metabolism have not been evaluated. We compared myocardial function and PCr/βATP ratios levels before and after normothermic and reduced temperature dialysis.

Methods: Twelve hemodialysis patients underwent cardiac MRI and 31P-MRS of their left ventricle (LV) within 30 minutes before (pre) and after (post) three normothermic (36.5°C) and three reduced temperature (35.0°C) maintenance dialysis sessions. Left ventricular dimensions were measured by an observer blinded to intervention. PCr/β ATP were calculated from 31P-MR spectra.

Results: Reduced temperature hemodialysis was significantly associated with increased predialysis LV ejection fraction (36.5°C:64.5%±6.5 vs 35.0°C:69.0%±6.1, p=0.03). At both temperatures, hemodialysis was significantly associated with increased mean LV ejection fraction (36.5°C:Pre 64.5%±6.7 Post 70.9%±6.8, p=0.002;35.0°C: Pre 69.0%±6.1, post 74.2%±6.3, p=0.01). PCr/βATP was significantly higher after normothermic (p=0.01) and reduced temperature hemodialysis (p=0.003). Mean increase in PCr/βATP was higher after reduced temperature compared to normothermic hemodialysis (+51.5% vs +74.1%, respectively).

Conclusions: Hemodialysis is associated with improved myocardial metabolic activity and this effect may be amplified by reducing the dialysate temperature even in patients with no intradialytic hypotension.
Conclusions: CHA2DS2-Vasc score is useful for predicting the risk of outcomes in non-dialysis subjects with AF and dialysis subjects without AF. Dialysis patients with AF already had very high scores and the risk grading by CHA2DS2-Vasc score is not useful.

Post Stroke In-Hospital Disability Deterioration and Mortality of Community-Onset Stroke in Patients with and without End-Stage Renal Disease

Tomoeko Usui, i Norio Hanafusa, i Hideo Yasunaga, i Masaomi Nagakuki, 1
1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, the Univ of Tokyo, Japan.

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during hospital stay of community-onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age ≥20 years old, admitted within 3 days after community-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Disability deterioration was defined as an increase in disability level. The odds ratio (OR) for in-hospital disability deterioration and mortality was calculated using a logistic regression model.

Results: Out of 438,569 patients, 7,633 (1.7%) had dialysis therapy. The median length of stay was 21 and 20 days for patients with and without dialysis, respectively. During the hospital stay, there were 101,924 (23.0%) disability deterioration and 46,029 (10.5%) death. The patients with dialysis had higher rate of disability deterioration (26.7%) and mortality (13.0%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antipatelet, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of dialysis for deterioration of disability was 1.57 (95%CI 1.48-1.66) and in-hospital mortality was 1.72 (95%CI 1.59-1.86).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of community-onset stroke.

FR-PO750

Proportion of Treatments with Low Systolic Blood Pressure and Short Term Mortality in Incident Hemodialysis Patients

Dusan Maddux, i John W. Larkin, i Danqing Xu, 2 Len A. Usvyat, 1 Frank van der Sande, 3 Jeroen Kooman, 3 Peter Kotanko, 4 Franklin W. Maddux 1
1Medical Office, Fresenius Medical Care North America, Waltham, MA; 2Univ of California at Santa Barbara, Santa Barbara, CA; 3Maastricht Univ Medical Centre, Maastricht, Limburg, Netherlands; 4Renal Research Inst, New York, NY.

Background: Prior studies have associated low mean predialysis systolic blood pressures (preSBP) with increased 120 day risk for mortality in incident hemodialysis (iHD) patients (Maddux et al., ASN 2014). This study aimed to investigate how the percent (%) of low mean preSBP during the prior weeks’ hemodialysis treatments affects the risk of mortality in iHD patients (Maddux et al., ASN 2014). This study aimed to investigate how the percent (%) of low mean preSBP during the prior weeks’ hemodialysis (HD) treatments affects the mortality of incident hemodialysis (iHD) patients. In the present study, we compared it among PD, HD, and ND patients.

Methods: For this study, 56,525 iHD patients at Fresenius Medical Care North America (FMCNA) clinics were investigated from 1/1/2004 to 12/31/2010. From the first date of outpatient chronic dialysis (FDD), the % of the prior weeks’ mean preSBP <110 mmHg was calculated for the first 4 months of HD. Mortality risk in the following week (7 days) was analyzed by the % of the prior week’s mean preSBP <110 mmHg at weeks 2, 4, 6, 12, and 16 from FDD.

Results: We observed that the short term risk for mortality in the following week increases in iHD patients as the % of the prior week’s mean preSBP <110 mmHg increases at weeks 2, 4, and 6 from the FDD; the risk for mortality was found to be the greatest at week 2 and was slightly reduced by week 6. Conversely, by week 12 and 16 from the FDD, the % of the prior week’s mean preSBP <110 mmHg was not found to be related with the risk of mortality in the next week.

Conclusions: This study demonstrates that increases in the % of low mean preSBP during the prior weeks’ hemodialysis (HD) treatments is associated with heightened short term risks of mortality during the first 6 weeks of iHD, but not during weeks 12 and 16 from the FDD.

The Possibility of Faster Progression of Brain Atrophy in Patients on Peritoneal Dialysis Compared with Hemodialysis

Kazuhiko Tsuruya, 1 Hisako Yoshida, 1 Takanari Kitazono, 2 1Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 2Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Brain atrophy has been reported in chronic kidney disease (CKD) patients, especially in hemodialysis (HD) patients. Recently, we reported faster decline in normalized gray matter volume (GMV) in peritoneal dialysis (PD) patients compared with non-dialysis-dependent CKD (ND) patients (Tsuruya, et al. Am J Kidney Dis, 2015). However, it has not been reported on the comparison of the progression rate of brain atrophy between PD and HD patients. In the present study, we compared it among HD, PD, and ND patients.

Methods: A total of 151 patients of 38 PD patients aged 60 ± 12 years (men 23, diabetes 11), 24 HD patients aged 64 ± 6 years (men 18, diabetes 9), and 89 ND patients (CKD stage 3a, 34; stage 3b, 31; stages 4-5, 24) were recruited and underwent MRI scanning at baseline and after two years. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter, total white matter, and cerebrospinal fluid were segmented and each volume was quantified. Normalized GMV was calculated as percentage of intracranial volume to normalize for head size variability. We compared the annual change in normalized GMV among CKD stages.

Results: Annual change in normalized GMV was significantly higher in PD patients than other CKD patients. This finding remained significant even after adjustment for potential confounding factors.

Conclusions: Progression of brain atrophy is significantly higher in PD patients than other CKD patients including HD patients, independent of age, gender, diabetes, and blood pressure level.

In Centre Nocturnal Haemodialysis: Improving Outcomes and Experience for Patients Matthew P.M. Graham-Brown,1,2 Darren Robert Churchward,1,2 Alice C. Smith,1,2 Richard J. Baines,1,2 James O. Burton.1,2

Background: Extended periods of haemodialysis (HD) improve patient outcomes. Home HD schedules can deliver extended dialysis, but there are patient and physician related barriers that make home therapies impossible for many. We explored in centre nocturnal HD (INHD) as a method of offering extended periods of HD to patients unsuitable for home therapy.

Methods: Ten prevalent HD patients switched from standard HD (3x4 hours) to INHD (3x5 hours) for four months. Mean ultrafiltration (UF) volumes (L), relative UF rates (mL/kg/hour) and absolute UF rates (mL/hour) were calculated. Additional, biochemical and haematological data, data on dialysis adequacy and blood pressure control were collected. Changes in quality of life (QoL) were assessed using SF12, EQ-5D and the Hospital Anxiety and Depression Score (HADS) questionnaires.

Results: Seven patients completed four months of INHD. Mean dialysis time per session was 355 minutes (SD±43.92). Mean total UF volume increased from 2.0±5.1L to 2.6±3.4L (p=0.02), but there was a reduction in absolute mean UF rates from 513±121 mL/hour on standard dialysis, to 356±66 mL/hour on INHD (p=0.03) and a decrease in mean relative UF rates from 6.5±1.7mL/kg/hr to 4.6±1.6mL/kg/hr (p=0.03). Adequacy measured by urea reduction ratio improved from 72±2% to 80±3% (p=0.001), with a trend towards improved phosphate control to within therapeutic targets, from 7±3±0mmol/L to 1.2±0.2mmol/L (p=0.08). In addition, there were improvements in all QoL scores. Mean EQ-5D-5L analogue score improved from 48±16.9 to 72±13.2 (p<0.001), with a trend towards improved SF12 physical component score from 31±1.3 to 48±10.1 (p=0.05).

Conclusions: Despite an increase in total UF volume, extended INHD led to an overall reduction in UF rate that has been shown to abrogate HD induced cardiac injury. Other physiological benefits included improved urea clearance and better phosphate control. There were also significant improvements in patient QoL measures over four months.

FR-PO753

Association of Multiple Strokes in Mortality in Incident Hemodialysis Patients: An Application of Multistate Model to Determine Transition Probabilities James W. Wetmore,1 Jonathan D. Mahnken,2 Milind A. Phadnis.3

1Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; 2Biostatistics, Univ of Kansas Medical Center, Kansas City, KS.

Background: Little is known about the effect of multiple, or subsequent, ischemic strokes in patients receiving dialysis.

Methods: A retrospective cohort study of incident hemodialysis patients with Medicare Parts A and B coverage who had experienced a first ischemic stroke was performed. A multistate model with Cox proportional hazards was used to predict transition probabilities from first ischemic stroke to subsequent stroke or to death. Demographic and clinical factors associated with the respective transition probabilities were determined.

Results: Overall, 12,054 individuals (mean age 69.7 years, 41.3% male, 53.0% Caucasian and 34.0% African-American) experienced a first stroke. Female sex was associated with an increased risk of having a subsequent stroke (adjusted hazard ratio 1.37, 95% confidence intervals 1.20 – 1.56, P = 0.0001), African-Americans, as compared to Caucasians, had lower likelihood of dying after a first stroke (0.87, 0.77 – 0.98, P = 0.0001). A subsequent stroke trended towards having a higher likelihood of transitioning to death compared to a first new stroke on dialysis (1.72, 0.96 – 3.09, P = 0.071). The probability of transitioning to a subsequent stroke increased over the first 6 months, peaked at approximately 12 months, then declined steadily over time (Figure). When a subsequent stroke occurs at 24 months, probability of survival dropped >15%, in absolute terms, from 0.254 to 0.196, with substantial drops observed at subsequent time points such that the probability of survival was more than halved.

Conclusions: Likelihood of subsequent ischemic stroke and of survival in dialysis patients appears to vary by sex and race.
FR-PO755
The Relation Between Sclerostin, Peripheral Vascular Calcification, and Cardiovascular Events in ESRD Patients
Young Jo Ju, Sang Yoon Lim, Myung-gyu Kim, Sang-Kyung Jo, Won-Yong Cho. Nephrology, Korea Univ Hospital, Seoul.

Background: Sclerostin, a negative regulator of Wnt signaling pathway produced by osteocyte, is a potent regulator of bone metabolism and a novel candidate for the bone vascular axis in chronic kidney disease patients. Although sclerostin is known as an inhibitor of vascular calcification, recent studies demonstrated conflicting results about the association between sclerostin and cardiovascular events or mortality. In this study we tested the association between sclerostin, peripheral vascular calcification, and cardiovascular events in end stage renal disease (ESRD) patient starting peritoneal dialysis.

Methods: In this prospective study, we included 45 ESRD patients admitted to Korea University Anam Hospital for starting peritoneal dialysis. Circulating sclerostin level was measured in all patients before the start of peritoneal dialysis. Simple vascular calcification score (SVCS) was measured using plain radiographic films of both hands and the pelvis. Median follow up period was 36 months.

Results: Higher sclerostin level was associated with male sex, diabetes mellitus, higher left ventricle (LV) mass index, and lower LV fractional shortening in univariate analysis. ESRD patients with severe vascular calcification (SVCS ≥3) had significantly higher prevalence of diabetes mellitus. They had lower peak wave velocity, alkaline phosphatase, and lower cholesterol levels, LV fractional shortening and in multivariate analysis, the presence of diabetes mellitus (OR, 4.59, p=0.023), lower cholesterol levels (OR, 0.94, p=0.032) were independent risk factors predicting severe vascular calcifications. In multivariate Cox regression model, higher pulse wave velocity (HR 1.3, p=0.028) was a significant predictor for cardiovascular events. In addition higher sclerostin group (HR 9.82, p=0.094) and lower albumin levels (HR 0.23, p=0.081) display a strong tendency of increased cardiovascular events.

Conclusions: This study showed the important role of sclerostin in the development of vascular calcification and cardiovascular events in PD patients. Longer term follow up with larger sample size will be needed to clarify this issue.

FR-PO756
Use of Anticoagulants in Patients with Atrial Fibrillation and End Stage Renal Disease: A Study of Real World Data
Lloyd P. Haskell,1 Chris Knoll,2 Patrick Ryan,1 Zhong Yuan,3 1Cardiovascular, Janssen R and D, Raritan, NJ; 2Epidemiology, Janssen R and D, Titusville, NJ.

Background: End stage renal disease (ESRD) in patients with atrial fibrillation (AF) is a significant cause of morbidity and mortality. While these patients are at high risk for stroke, there are limited data with respect to use of anticoagulants in clinical practice and current guidelines are not clear on how to manage them.

Methods: US-based, four large healthcare databases (Truven MarketScan Commercial Claims/Encounters [CCAE], Medicare Supplemental [MDCR], Medicaid [MDCD]) and Optum Clinformatics [Optum]) were used to establish cohorts of patients with AF and ESRD, who were identified using ICD-9 codes. The first encounter with evidence of both conditions during the inception period of 2010-2012 was the index date; patients must have had at least 1 year enrolment prior to and after the index date to be eligible for the study. The use of anticoagulants was examined during the follow-up period.

Results: Table 1 shows patient demographics and use of anticoagulants by data source. As expected, the privately-insured patient populations (CCAE and Optum) as well as the Medicaid population (MDCD) were younger as compared with the Medicare eligible population (MDCR). Across study cohorts, approximately 37% to 40% of patients with AF and ESRD received at least one dispensing of warfarin, with the exception of the Medicaid population [MDCD].

Conclusion: Mortality rates decrease substantially once patients initiate HD. After approximately one year on HD, mortality remains consistent in all groups, but remains lower for those with higher albumin, younger age and black race. Diabetes appears to not affect mortality. Since only patients starting in an outpatient setting were included, selection bias may apply differently to the patient groups.

Table 1: Use of Anticoagulants in Patients with AF and ESRD

Conclusions: Less than 40% of patients with AF and ESRD received anticoagulant therapy. As these are high risk patients, anticoagulant therapy may be underutilized. Further research is necessary to investigate clinical outcomes associated with anticoagulation in these patients.
FR-PO759
Survival in Elderly on Dialysis and Impact of Institutionalization
Amarpali Brar, David Kau, Moro O. Sallifu, Mary C. Mallapallil. Renal, SUNY Downstate, Brooklyn, NY.

Background: We hypothesized that in the very elderly dialysis patients in the United States, institutionalization in nursing homes would increase mortality in addition to age alone.

Methods: Data was obtained from the U.S. Renal Data System. Incident dialysis patients from 2001 to 2008 above the age of 70 were included. Follow-up period was from incident dialysis date to either death or last follow up on September 30, 2009. Patients above 70 were categorized into four groups according to age as 70-75 years, 76-80 years, 81-85 years, greater than 85 years and further divided into institutionalized and non-institutionalized.

Results: A total of 349,440 patients were identified above the age of 70 years at the time of initiation of dialysis. Major causes of end stage renal disease were diabetes, hypertension, glomerulonephritis, cystic kidney disease, and urological mean cause. Mean survival for non institutionalised patients was 3.15 ± 0.01 years for those between 70-75 years of age, 2.55±0.01 years for 76-80 years of age, 2.12±0.01 years for 81-85 years of age and 1.64±0.01 years for those above 85 years at the time of initiation of dialysis respectively. For institutionalized patients, mean survival was significantly lower, 1.71±0.03 years for 70-75 years old, 1.44±0.02 years for 75-80 years old, 1.25±0.02 years for 81-85 years old and more than 85 years and 1.04±0.02 years for > 85 years age group, p<0.0001. The oldest group in non-institutionalized over the age of 85 years had a similar survival as the institutionalized ESRD patients 70-75 years old.

Conclusions: There was increased mortality in institutionalized elderly patients as compared to non institutionalised elderly patients in the same age group. Keeping with the increased frailty and decreased benefits of therapies in the very elderly especially in those with additional co-morbidities besides age, palliative and end of life care should be considered.

FR-PO760
Geriatric Nutritional Risk Index Is a Simple Predictor of Mortality in Chronic Hemodialysis Patients
Kosaku Nitta, Ken Tsuchiya. Dept of Medicine, Kidney Center, Tokyo Women’s Medical Univ, Shinjuku-ku, Tokyo, Japan.

Background: Malnutrition is common in hemodialysis (HD) patients, and is associated with increasing risk of mortality. The geriatric nutritional risk index (GNRI) has been developed as a tool to assess the nutritional risk. The aim of the present study was to examine the reliability of the GNRI as a mortality predictor in a Japanese HD cohort.

Methods: We prospectively examined the GNRI of 332 maintenance HD patients aged 65.4 ± 13.2 years, 213 males, and followed up them for 36 months. The patients were divided into quartiles (Q) according to GNRI values (Q1: <91.6, Q2: 91.7-97.0, Q3: 97.1-102.2, Q4: >102.3). Predictors for all-cause mortality were examined using Kaplan-Meier and Cox proportional-hazards analyses.

Results: The GNRI presented a normal distribution. During the follow-up period of 36 months, a total of 76 patients died. The overall mortality at the end of the 3-year observational period was 22.3%. At the 3-year follow-up period, Kaplan-Meier survival rates for all-cause mortality were 72.3%, 79.3%, 84.9%, and 92.6% in Q1, Q2, Q3, and Q4, respectively (p = 0.0067). Multivariate Cox proportional-hazards analysis demonstrated that the GNRI was a significant predictor of adjusted all-cause mortality (HR 0.958; CI 0.929–0.980, p < 0.001).

Conclusions: The results of the present study demonstrate that the GNRI is a strong predictor of overall mortality in HD patients. However, cardiovascular mortality was not associated with GNRI values, and did not differ among the GNRI quartiles. The GNRI score can be considered a simple and reliable marker of predictor for mortality risk in Japanese HD patients.

FR-PO761
Frailty and Clinical Outcomes in Chronic Dialysis Patients
Eun jung Ko,1 Hyen Jeong.1 1Internal Medicine, CHA Bundang Medical Center; Seongnam, Republic of Korea; 2Internal Medicine, CHA Gumi Medical Center; Gumi, Republic of Korea.

Background: Frailty is a biological syndrome of decreased reserve and resistance to stressors and is independently associated with mortality and hospitalization in the general population. We investigated the relationship between frailty and clinical outcomes in chronic dialysis patients.

Methods: In this prospective study, 1,658 patients receiving chronic dialysis were enrolled. Chronic dialysis was defined as dialysis for more than 6 months. Of the 1,658 patients, 1,255 received hemodialysis. The remainder received peritoneal dialysis. Frayed’s criteria for frailty as modified by Woods et al. was used. A trained interviewer asked study participants about 5 frailty stereotypes (slowness, weakness, exhaustion, shrinking, and physical inactivity) using the RAND 36-item Short Form.

Results: The mean age was 55.2±11.9, and 55.2% were male. Overall, 577 (34.8 %) patients met the study definition of frailty. Another 757 (45.7%) patients were pre-frail.

Table 1 shows the prevalence of frailty and its components by age group. During the 30-month follow-up period, 607 patients (79 non-frail, 249 pre-frail, and 279 frail) were hospitalized; and 87 patients (10 non-frail, 24 pre-frail, and 53 frail) died (p<0.0001). Frailty was strongly associated with hospitalization (adjusted hazard ratio [HR] 1.30, 95% CI 1.4 to 2.3) and mortality (HR 2.37, 95% CI 1.11 to 5.02) in multivariate analysis. The relationship between frailty and hospitalization was strongest among patients age 40 to 49, with a HR of 3.02 (95% CI 1.48 to 6.20).

Conclusions: We found a high prevalence of frailty in chronic dialysis patients across all age groups. The risk of hospitalization and mortality in the 30-month follow-up period significantly increased in frail chronic dialysis patients.

FR-PO762
Outcomes of Early Initiation of Dialysis in Elderly Patients with End Stage Renal Disease: A Propensity-Matched Analysis of a Prospective Cohort Study
Jae Yoon Park,1 Kyung Don Yoo,1 Jeonghwae Lee,2 Dong Ki Kim,1 Kwon Wook Joo,1 Shin-Wook Kang,1 Chul Woo Yang,1 Yong-Lim Kim,1 Chun Soo Lim,1 Yon Su Kim,1 Jung Pyo Lee.1 1Seoul National Univ College of Medicine, Seoul, Korea; 2Hallym Univ Hanyang Sacred Heart Hospital, Seoul, Korea; Yongdusan College of Medicine, Seoul, Korea; The Catholic Univ of Korea College of Medicine, Seoul, Korea; Kyungpook Univ National School of Medicine, Daegu, Korea.

Background: The optimal timing for initiating dialysis in end-stage renal disease (ESRD) remains controversial, especially in elderly patients. We therefore investigated the effect of dialysis initiation timing on clinical outcomes in elderly patients with ESRD.

Methods: A total of 665 patients aged equal or over 65 years who started dialysis from August 2008 to February 2015 were enrolled in Clinical Research Center for End Stage Renal Disease cohort study in Korea. They were divided into 2 groups based on the median estimated glomerular filtration rate, which was 8.85 mL/min/1.73m². The primary outcome was patient survival and the secondary outcomes were cardiovascular events and Kidney Disease Quality of Life Short Form 36 (KDQOL-36) score.

Results: Overall cumulative survival rates were lower in early initiation group (Log-rank P<0.001). However, the survival rates showed no significant difference after matching propensity score. Additionally, early initiation of dialysis was not associated with survival rates after adjustment for age, sex, Charlson comorbidity index, hemoglobin, serum albumin, serum calcium and phosphorus level. Although the early initiation group showed lower physical component summary in KDQOL-36 at 3 months after dialysis, the difference of the scores was not significant at 12 months after dialysis.

Conclusions: Early initiation of dialysis was not associated with prognosis in elderly patients with ESRD. The physical functioning was worse for 3 months after dialysis but it became similar to late initiation of dialysis at 1 year after dialysis.

1- and 2-Year Mortality Prediction Models for Patients Starting Chronic Dialysis
Mikko Haapio,1 Jaakko Helve,1 Carola Gronhagen-Riska,1,2 Patrik Finne,1,2 1Nephrology, Univ of Helsinki and Helsinki Univ Hospital, Helsinki, Finland; 2Finnish Registry for Kidney Diseases, Helsinki, Finland.

Background: Mortality risk of patients with end-stage renal disease (ESRD) is highly elevated compared to patients without ESRD. Taking into account our limited nephrological care resources and the simultaneously increasing number of ESRD patients there is a great need for means of mortality risk estimation to assist both in individualized patient care as well as in sound use of resources. Some mortality prediction models already exist, but many have shown a lack of comprehensiveness in data or in patient recruitment in their development.

Methods: Our objective was to design a prediction model for 1- and 2-year all-cause mortality in patients starting chronic renal replacement therapy. In addition, we aimed to build an easy-to-apply model consisting of only a few variables. We used the comprehensive data of the Finnish Registry for Kidney Diseases with complete coverage of Finnish ESRD patients. Model training group included all incident adult patients who started chronic dialysis in Finland from 1 January 2000 to 31 December 2008 (n=4335). The external validation cohort consisted of all those who started dialysis from 1 January 2009 to 31 December 2012 (n=1706). Prediction algorithms for 1- and 2-year mortality were developed using multivariate logistic regression with stepwise selection of variables. Our primary analyses included 32 variables, from which the most important ones were selected.

Results: Both final prognostic models, including only 6-7 variables, showed adequate discrimination (c-statistic 0.77 and 0.74 for 1- and 2-year mortality, respectively). Because of a significantly lower mortality in the newer (validation) cohort, both models somewhat overestimated mortality risk.

Conclusions: Mortality prediction algorithms could be more widely implemented into clinical treatment-planning of ESRD patients. Our prediction models perform sufficiently and are convenient to use, and could assist in individualized risk-stratification and, furthermore, in equal and fair sharing of limited health care resources.

FR-PO764

Comorbid Burden at Dialysis Initiation and Mortality: A Retrospective Cohort Study
Alvyn Titus Gomez,1 Bryce A. Kibert,1 Talal A. Alfaahdhel,2 Brenda Hennemlagn,3 Karthik T. Tunnenkore,1 1Medicine, Dalhousie Univ, Halifax, NS, Canada; 2Medicine, Univ of Toronto, Toronto, ON, Canada; 3Medicine, Univ of Calgary, Calgary, AB, Canada.

Background: Contemporary assessments of the validity and prognostic value of comorbidity indices in dialysis are lacking. We sought to assess the validity of two comorbidity indices used for dialysis patients and to determine if a high degree of comorbidity was associated with mortality.

Methods: We conducted a retrospective cohort study of incident chronic dialysis patients in a tertiary care institute from 2006-2013. The Charlson Comorbidity Index (CCI) and End-Stage Renal Disease Comorbidity Index (ESRD-CI) were calculated in all patients at dialysis initiation. These indices combine individual medical conditions into an overall score. Comorbid conditions were ascertained using electronic records. The primary outcome was all-cause mortality.

Results: The cohort consisted of 771 patients. Most were male (62%) and Caucasian (91%). Patients had a high prevalence of diabetes (48%) and history of myocardial infarction (31%). The c-index was 0.61 for the CCI, and 0.63 for the ESRD-CI. In an adjusted analysis, ESRD-CI scores of 4, 5 and ≥6 were associated with a similar mortality risk (Table 1). There was a small increased mortality risk for CCI scores of 4, 5 and ≥6.

Conclusions: The CCI and ESRD-CI had a limited ability to discriminate risk of death for incident dialysis patients. Although a higher comorbidity burden was associated with an increased mortality risk compared to the absence of both.

Cumulative Risk of Death in Propensity-Matched Incident Dialysis Patients: A Nationwide Prospective Multicenter Cohort Study in Korea
Hee-Yeon Jung,1 Sukyung Lee,1 Ji-Young Choi,1 Se-Hee Yoon,2 Jung-Hee Cho,1 Sun-Hee Park,1 Chan-Duck Kim,1 Yong-Lim Kim.1 1Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; 2Internal Medicine, Konyang Univ, Daejeon, Republic of Korea.

Background: Our previous study reported the superior outcome of peritoneal dialysis (PD) than hemodialysis (HD) in the early dialysis period. This study investigated the impact of dialysis modality after the early period of incident dialysis patients.

Methods: Incident dialysis patients were enrolled from Korean nationwide prospective cohort from September 2008 to December 2013. The patients were stratified by modality at day 90 after the first dialysis or the modality at dialysis initiation if death occurred prior. The survival of PD and HD patients were compared by propensity score matching analysis. Relative risk of death was estimated using the cumulative hazard ratio from the stratified Cox proportional hazard model adjusted for residual confounding.

Results: A total of 1348 patients were matched from 2658 incident dialysis patients with mean follow-up of 29.9 ± 14.1 months. All clinical parameters including baseline residual renal function were comparable between PD and HD patients. The cumulative risk of death was significantly lower in PD than HD from 6 months after dialysis initiation. The cumulative hazard ratio for death was 0.70 (95% confidence interval [CI] 0.41-0.98) at one year for PD compared with matched HD and 0.68 (95% CI 0.46-0.90) at two years. The cumulative survival probability was higher in PD patients for up to 3.5 years on dialysis, with no difference after the period.

Conclusions: Overall survival in maintenance dialysis patients favored PD in the early period of dialysis and the survival advantage lasted to 3.5 years after initiation of dialysis. However, PD and HD patients had similar survival outcomes thereafter.

FR-PO766

Inflammation and Fluid Overload a Complex Interaction: Results from the International MONDO Initiative
Marijke J.E. Dekker,1 Len A. Usvyat,2,3 Daniele Marcelli,1 Frank van der Sande,4 Constantijn Konings,1 Peter Kotanko,2 Jeroen Kooman,1 1Catharina Hospital Eindhoven; 2Renal Research Inst; 3Fresenius Medical Care; 4Maastricht Univ Medical Center.

Background: In hemodialysis (HD) patients, the presence of inflammation or fluid overload (FO) is associated with increased mortality. The combined presence of these two is associated with even a greater risk of death. This study aims to unravel the temporal relationship between fluid status alterations and inflammation.

Methods: We conducted a longitudinal study (baseline and follow-up 3 months each) in a European subset of the MONDO-Initiative. Fluid status was assessed by multifrequency bioimpedance and inflammation by C-reactive protein (CRP). We divided patients into 4 groups based on fluid- and inflammation status. FO was defined as overhydration above ≥2.5L. Inflammation was defined as CRP >10mg/L.

Results: We included 5954 patients (56.1% male, age 63 years, v1.5 years). At baseline inflammation and FO were jointly present in 1092 (18.3%) patients. 141 (11.8%) developed inflammation during follow up. Of the 1192 (20%) patients with inflammation but without normal fluid status at baseline, 111 (10.2%) had FO during follow up. Inflammation at baseline predicted FO during follow up (odds ratio(OR) 1.2095% CI 1.05-1.37). Likewise, FO during baseline predicted inflammation during follow up (OR 1.30 [95% CI 1.15-1.47]). However, in a minority of patients the presence of FO and/or inflammation appears to a relatively stable condition. The presence of both inflammation and FO during baseline was associated with an increased mortality risk compared to the absence of both.

Blood Volume Analysis as a Guide for Dry Weight Determination in Chronic Hemodialysis Patients

**Line Malha,1,2 Hasan Fattah,1,3 Frank Modersitzki,1 David S. Goldfarb,1,2 Internal Medicine, Div of Nephrology, NYU School of Medicine, New York, NY; 1Internal Medicine, Nephrology Section, New York Harbor VA Healthcare System, New York, NY; 2Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ Medical Center, Richmond, VA.**

**Background:** Volume overload and depletion both lead to high morbidity and mortality. Achieving euvolemia is a challenge in patients with end stage kidney disease (ESKD) on hemodialysis (HD). Blood volume analysis (BVA) uses radiolabeled albumin to determine intravascular blood volume (BV). The measured BV is compared to an ideal BV (validated in healthy controls). We hypothesized that BVA could be used in HD to evaluate the adequacy of the fluid status of a patient to an estimated dry weight (EDW) and to titrate EDW in order to improve overall volume status. We were also interested in the reproducibility of BVA results in ESKD. This is the first longitudinal study of BVA in HD patients.

**Methods:** 12 adults on chronic HD were recruited; 10 completed the study. BVA (Daxor, New York, NY; USA) was used to measure BV at baseline. EDW was kept the same if the patient was deemed to be euvolic by BVA otherwise, the prescribed EDW was changed with the aim that measured BV would match ideal BV. A second BV measurement was done 1-3 months later in order to measure BV again.

**Results:** Based on BVA, 6/10 patients were euvalacmic at baseline and 5/10 were euvalacmic at the second measurement. When comparing patients who had their prescribed EDW changed after the initial BVA to those who did not, both groups had similar differences between measured and ideal BV (P=0.75). BV values were unchanged at the time of the euvolemic at the second measurement. When comparing patients who had their prescribed EDW was changed with the aim that measured BV would match ideal BV. A second BV measurement was done 1-3 months later in order to measure BV again.

**Conclusions:** This pilot study is the first longitudinal measurement of BVA in HD patients. It revealed that changing weight did not proportionally change intravascular BV. BV remained stable for 1-3 months. BVA may not be reliable in clinically stable HD patients but studies on hemodynamic instability and uncertain volume status are needed.

**Funding:** Pharmaceutical Company Support - Daxor provided BVA equipment and supplies but was not involved in study design or execution and did not participate in the analysis of data or preparation of the manuscript

---

**Effects of Physician Payment Reform on Provision of Home Dialysis**

Kevin F. Erickson,1 Wolfgang C. Winkelmayer,2 Glenn Matthew Corthout,3 Jay Bhattacharya.1 Medicine, Stanford Univ, Palo Alto, CA; 2Medicine, Baylor College of Medicine, Houston, TX.

**Background:** Patients with end-stage renal disease can receive dialysis at home or in-center. In 2004 the Centers for Medicare and Medicaid Services reform physician payment for in-center hemodialysis care from a capitated to a tiered fee-for-service model, augmenting physician payment for frequent in-center visits. We evaluated whether payment reform influenced dialysis modality assignment.

**Methods:** Using a national cohort of patients starting dialysis in the US in the three years before and after payment reform, we conducted difference-in-difference analyses comparing patients with Traditional Medicare coverage (who were affected by the policy) to others with Medicare Advantage (who were unaffected by the policy). We also examined whether the policy had a more pronounced influence on dialysis modality assignment in areas with lower costs of traveling to dialysis centers.

**Results:** Patients with Traditional Medicare coverage experienced a 12% (95% CI, 2% to 21%) reduction in home dialysis use following payment reform compared to patients with Medicare Advantage. Patients living in areas with larger dialysis facilities (where payments were linked to travel costs made in-center hemodialysis comparatively more lucrative for physicians) experienced a 16% (95% CI, 8% to 23%) reduction in home dialysis use following payment reform compared to patients living in areas with smaller facilities (where payment reform made in-center hemodialysis comparatively less lucrative for physicians).

**Conclusions:** National physician payment reform intended to improve the quality of dialysis care resulted in fewer patients receiving home dialysis. This highlights a major failure of the policy and the importance of considering unintended consequences of future physician payment reform efforts.

**FR-PO768**

**Effects of Sildenafil on Erectile Dysfunction in Hemodialysis Patients**

Anawin Sangoonkasem,1,2 Sirikarn Upala,1,2 Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; 1Preventive and Social Medicine, Faculty of Medicine Srinaj Hospital, Mahidol Univ, Bangkok, Thailand.

**Background:** Erectile dysfunction (ED) is prevalent in dialysis patients. Sildenafil, a PDE-5 inhibitor, has been shown to be very effective against ED in general population. However, there is some evidence that dialysis patients are resistant to sildenafil treatment. We performed this meta-analysis to evaluate efficacy of sildenafil in dialysis patients with ED compared with control.

**Methods:** We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT comparing sildenafil therapy to placebo or controls on ED in patients with dialysis. The primary outcome was change in International Index of Erectile Function (IIEF) score. The diagnostic ED was confirmed with a score of 21 or less in IIEF.

**Results:** From 153 full-text articles, 3 studies involving 153 dialysis patients were included in the meta-analysis. All included studies were RCT comparing sildenafil with active control in either hemodialysis or peritoneal dialysis patients. A meta-analysis using fixed-effects model was performed. Those who received sildenafil had a significant improvement in IIEF score compared to a change in IIEF score with a mean difference of 10.48 (95% CI: 9.96 to 11.00, p-value<0.01).

**Conclusions:** This is the first meta-analysis to show that sildenafil is effective in dialysis patients with erectile dysfunction compared with control. Further study considering other benefits and side effects of PDE-5 inhibitor in dialysis patients should be conducted.

---

**Validation of Screening Questionnaires for Sleep Apnea in Hemodialysis Population**

**Background:** Sleep apnea hypopnea syndrome (SAHS) is common in end stage renal disease (ESRD). We investigated the validity of Berlin and STOP-BANG questionnaires against nocturnal oximetry in identifying high risk hemodialysis patients for SAHS.

**Methods:** After obtaining local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis for at least 3 months were consented and asked to complete Berlin and STOP-BANG questionnaires. Nocturnal oximetry from hemodialysis night using Pulsox 300i wristwatch was also completed. The saturation recordings were downloaded and analyzed using Profox software. The first hour of recording was deleted in effect saturation oximetry reading from sleep time on dialysis patients were also excluded from analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds, per hour. Sensitivity, specificity, positive and negative predictive values were calculated for the Berlin and STOP-BANG questionnaires.

**Results:** Twenty HD patients (11 males and 9 females) aged 54 ± 13 years with a mean body mass index of 25.5 ± 4.6 kg/m^2 and neck circumference of 38.4 ± 5.8 cm were analyzed. Oxygen saturation index was ≥ 90% in 30% of patients, ≥ 94% in 20% of patients, ≥ 95% in 15% of patients, and ≥ 96% in 10% of patients. Oxygen saturation index ≥ 90% and ≥ 94% was 67% and 67% for Berlin questionnaire, respectively. STOP-BANG questionnaire had a positive predictive value of 85% and a negative predictive value of 29%.

**Conclusions:** Reliable screening tools for SAHS in ESRD population are limited. Both Berlin and STOP-BANG questionnaires lack specificity to be utilized in this setting. Additional studies are warranted to elaborate the role of screening questionnaires for SAHS in end stage renal disease population.
Moderate to Severe Nocturnal Hypoxemia and Executive Dysfunction in Patients Undergoing Maintenance Hemodialysis

Background: Nocturnal hypoxemia and executive dysfunction is common in end stage renal disease. We investigated the impact of moderate to severe nocturnal hypoxemia on executive function in patients undergoing maintenance hemodialysis.

Methods: Following local IRB approval, adult hemodialysis patients were consented to complete 1 night of nocturnal oximetry using Pulsox 3060 wristwatch. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds per hour. Trail making tests A and B were also completed during dialysis session. Trail making test A and B performance was compared using t-test in patients with ODI <15 versus those with ODI ≥ 15. Executive dysfunction was defined as trail making A and B completion time > 75 seconds and 180 seconds, respectively.

Results: Nine of 20 patients aged 45 ± 12 years with a mean body mass index (BMI) of 23 ± 3 kg/m² and neck circumference of 35.4 ±4 cm had ODI < 15. The remaining eleven patients aged 60 ± 12 years with a mean BMI of 28 ± 5 kg/m² and neck circumference of 41 ± 16 cm had ODI ≥ 15. Patients with ODI ≥ 15 took significantly longer (77 ± 34 seconds) to complete trail making test A compared to only 1 patient out of 9 (11%) with ODI < 15. Mean duration for completion of trail making B test was also longer in patients with ODI ≥ 15 (157 ± 87 seconds) compared to ODI < 15 (117 ± 67 seconds) [p<0.05]. Two of 11 patients with ODI ≥ 15 and 2 of 9 patients with ODI < 15 required > 180 seconds to complete trail making test B.

Conclusions: Patients with ODI <15 performed better on trail making test A, were younger with a smaller BMI and neck circumference, compared to those with ODI ≥ 15. Additional research is warranted to confirm these findings. Whether treatment of moderate to severe nocturnal hypoxemia may slow or prevent executive function decline in patients undergoing maintenance hemodialysis remains to be determined.

Indoxyl Sulfate (Indican) and Sleep Disorders in Hemodialysis Patients: The Retained Otolaryngic Solutes and Clinical Outcomes (ROSCO) Study
Yunnuo Zhu,1 Tanushree Banerjee,1 Tariq Shafi,2 Timothy W. Meyer,1 Michel L. Melamed,1 Thomas H. Hostetter,1 Neil R. Powell.1 1UCSF; 2JHU; 3Stanford; 4Albert Einstein; 5Case Medical Center.

Background: Although sleep disorders are common in dialysis patients, the pathophysiology of sleep disturbance is unclear. Protein-bound solutes inadequately removed during dialysis may contribute to sleep disorders.

Methods: We examined the association of total and free levels of IS with sleep disorder in 1,241 prevalent dialysis patients from the HEMO study. IS levels were measured using mass spectrometry and modeled as tertiles. Sleep disorder was assessed using a 5-level categorical question in the Short Form (36) Health Survey. We used ordinal logistic regression to assess the relation of IS with sleep disorder, adjusting for confounders including age, race, gender, ICED score, body mass index, diabetes, congestive heart failure, serum albumin, creatinine, and phosphate levels. The lowest tertile of IS was the reference group. Effect modification was tested for IS levels with Kt/V and gastrointestinal (GI) disease (due to IS's GI origin).

Results: Patients were on average 57.5 years old, 62.8% were black, and 43.2% were male. There was a significant association between increasing tertiles of free IS and more impaired sleep disorders [OR 1.68 (1.09-2.58)]. There was effect modification by Kt/V (p=0.03) but none by GI disease (p=0.17). Similar results were observed with total IS and sleep disorder [2.09 (1.37-3.19)]. Stratified analyses by race did not show an association between higher tertiles of free IS and sleep disorder in the high Kt/V group [0.72 (0.45-1.14)]. However greater odds of sleep disorder with highest tertile of IS were noted in the low Kt/V group. This relation was also present for total IS; those with low Kt/V had greater odds of sleep disorder with the highest total IS tertile [2.11 (1.29-3.45)] but not with the high Kt/V group [0.91 (0.61-1.35)].

Conclusions: Higher levels of IS are significantly associated with sleep disorder. Patients with a lower dialysis dose may be more susceptible. Further research on whether removal of IS improves sleep outcomes is needed.

Quantifying Physical Activity Levels and Sleep in Hemodialysis Patients Using a Commericially-Available Activity Tracker
Maggie Han,1 Schantel Williams,1 Anna Meyring-Westen, Viviane Calicco-Silva,1,2 Melissa Mendoza,1 Hanie Zhang,1 Xiaochuan Ye,1 Stephen Thijssen,1 Peter Kotanko.1 1 Renal Research Inst, New York, NY; 2Pontificia Univ Católica do Paraná, Curitiba, Brazil; 1Icahn School of Medicine, New York, NY.

Background: Hemodialysis (HD) patients frequently develop functional impairment. The study used decision tree analysis to identify risk factors for functional impairment in HD patients.

Methods: A total 1166 maintenance HD patients were enrolled in one hospital-based HD center. The observational period was from 2009 to 2013. Karnofsky Performance Status Scale (KPS) was used to quantify functional status. KPS assessment was based on HD patients’ self report yearly for consecutive five years. High KPS score was defined as ≥ 80 and low score as < 80. Decision tree analysis was used to analyze odds ratio (OR) of functional impairment from variables in demographics, laboratory test and primary renal disease classification.

Results: Subjects (853) with high KPS scores demonstrated significantly younger age (58.2 vs 71.3 years), longer HD duration (7.2 vs 4.7 years), higher nutritional indices, higher HD duration (1.65 vs 1.59) and lower cardiothoracic (CT) ratio compared to subjects (313) in low KPS scores. A total 3509 KPS values were collected. 2697 (76.9%) values belonged to high functional scores, 812 (23.1%) values in low functional scores. The first variable chosen by decision tree analysis to split the data was age (67.5 years). There were six leaf nodes and twenty-eight subgroups. In age > 67.5 years group, the odds of consecutive chosen were serum albumin level (≤ 3.75 g/dL, OR 25.78, p = 1.77E-199), Cr level (≤ 8.93 mg/dL, OR 39.40, p = 0.019), HD duration (≤ 0.95 year, OR 39.40, p = 0.019), ferritin (>664.5 mg/dL, OR 26.26, p = 2.06E-13), P level (>5.35 mg/dL, OR 9.28, p = 8.88E-24), HD level (>10.85 g/dL, OR 0.89, p = 0.10). In age ≤ 67.5 group, the odds of consecutive chosen were renal disease classification, Cr level (10.43 mg/dL, OR 11.23, p = 2.03E-72), age (≤58.5 years, OR 0.89, p = 0.06), PTH level (≥ 356.4 mg/pL, OR 0.44, p = 0.072), CT ratio (≥ 0.44, OR 11.16, p = 9.17E-35).

Conclusions: By decision tree analysis, age was the main risk factor for functional impairment in HD patients. Overall, the weight contribution of different risk factors for functional impairment in HD patients were identified by classification tree analysis.

FR-PO775 Using Decision Tree Analysis to Identify Risk Factors for Functional Impairment in Hemodialysis Patients J. B. Chen. Div of Nephrology, Kaohsiung Chang Gung Memorial Hospital and Chang Gung Univ College of Medicine, Kaohsiung, Taiwan.

Background: Hemodialysis (HD) patients frequently developed functional impairment. Unemployment rates are high among dialysis patients; a 2011 study found approximately 71% of working-age dialysis patients are unemployed. Another study found that dialysis negatively impacts employment status and has the largest effect between dialysis years 1 and 2. We examined whether prolonged dialysis (dialysis vintage) affects employment status.

Methods: Dialysis vintage data and mean age were obtained from a sample of 16,069 employed patients from a large dialysis organization (Nov 2014-April 2015). Employment status was defined as regular full-time (30 hrs/wk), regular part-time (<30 hrs/wk), and part-time (<24 hrs/wk).

Results: Regular full-time employed patients were older (52.6 yrs) than part-time (49.1 yrs) and part-time (49.0 yrs) patients. Employment status was highest among all patients for all categories of employment during year 1 of dialysis (35.7%) and dropped significantly by year 2 (14.4%) [Table]. Employment status continued to drop as vintage increased.
Conclusions: Our study found that dialysis vintage negatively impacts employment status and has the largest effect between years 1 and 2. Further study is needed to reveal if a decrease in face-to-face visits due to the COVID-19 pandemic. These results should alert dialysis staff that support and intervention may be needed to help patients stay employed. References: 1) Muehrer RJ et al. Clin J Am Soc Nephrol. 2011;6(3):489-496. 2) van Manen

FR-PO779

Provider Visit Frequency During Hemodialysis and Its Effect on End Stage Renal Disease Comorbidities

Jaeong Kim, Brian Khudyakov, Priti R. Patel.

Background: In the United States, patients with End Stage Renal Disease (ESRD) on dialysis visit their Nephrologist one to four times per month during their dialysis sessions. Medicare reimbursement policy encourages frequent provider visits for patients on ESRD on hemodialysis. We believe that increasing the number of face-to-face provider visits improves the care and clinical outcomes of comorbidities related to ESRD (hypertension, hyperphosphatemia, and hyperkalemia).

Methods: We used a Pre and Post-test pilot study design to evaluate the effect on laboratory measurements and blood pressure by increasing the frequency of Nephrologist face-to-face visits at the Miami VA Medical Center. Seventeen patients that were evaluated during a period of six months were included in the analysis. In the initial three months, the patients were evaluated four times per month (usual care). The number of face-to-face visits was increased to eight times per month (or twice weekly) for the following three months. Results: A paired-sample t-test was conducted to compare the mean systolic blood pressure measure before and after the intervention. Additional provider face-to-face visits per month were associated with a significant difference in the systolic blood pressure before and after the intervention (p=0.004, t=3.303, Mean=8.235, and Standard Deviation=16). In addition, we found improvement of the phosphorus levels with a difference that was statistically significant (p=0.028, t=2.419, Mean=0.512, and Standard Deviation=16). Patients reported increased perceived quality of care when they had the opportunity of seeing the Nephrologist more frequently.

Conclusions: Hypertension and electrolyte abnormalities are known risk factors that increase morbidity and mortality in patients with End Stage Renal Disease. Adherence to medication is a major concern for patients on Hemodialysis therapy. Increasing the number of visits per month with the Nephrologist during Hemodialysis sessions increases adherence to a renal diet, medication use and patient satisfaction.

FR-PO778

Response Rate of Hepatitis B Virus Vaccination in Various Stages of Chronic Kidney Disease

So Mi Kim, Eun kyooong Lee, Yun Jung Oh. Department of Internal Medicine, Jeju National Univ Hospital, Jeju, Jejudo, Republic of Korea; Division of Nephrology, Inst of Medical Research, Dongan Univ Hosp, Jeju, Jejudo, Republic of Korea; Division of Nephrology, Inst of Medical Research, Jeju Halla General Hospital, Jeju, Jejudo, Republic of Korea.

Background: Although hepatitis B virus (HBV) vaccination is recommended for all dialysis patients, the response rate of HBV vaccination in dialysis patients is very low. Therefore, we tried to investigate the necessity of early HBV vaccination in pre-dialysis patients analyzing the response rate of vaccination in various stages of chronic kidney disease (CKD).

Methods: A total of 87 patients in 3 different stages of CKD was enrolled in this study. Patients in stage 3 (n=30) and 4 (n=28) were received the HBV vaccine as standardized schedule, consisting of 1 mL of the recombinant vaccine, Hepavac-gene TF at 0, 1, and 6 months. And then, the patients with stage 5 (n=29) were received the same vaccine for doubling doses at 0, 1, 2, 6 months. And then, the patients with stage 5 (n=29) were received the same vaccine for doubling doses at 0, 1, 2, 6 months. Three months after each of the last vaccination, serum levels of HBsAg were measured in all patients.

Results: There was no significant difference in baseline characteristics including age, sex, presence of DM among the 3 groups. The overall seroconversion rate after vaccination was 79.4%. The seroconversion rate was significantly higher in patients with stage 3 than other patients (stage 3: 94%, stage 4: 79%, stage 5: 66%, p=0.031). Analyzing based on dialysis, seroconversion rate was also significantly higher in pre-dialysis patients than in dialysis patients (pre-dialysis group: 86%, dialysis group: 63%, p=0.02). There was no significant factor to contribute seroconversion in multivariate analysis.

Conclusions: Our study showed the high seroconversion rate after HBV vaccination in CKD patients with stage 3 and pre-dialysis. Therefore, the HBV vaccination should be considered in early CKD stages.
medication handling (3), separation of clean and contaminated workspaces (2), and vascular access care (1). Multiple lapses were identified in 7 outbreaks. No specific infection control lapses were identified at the time of the investigation in 2 outbreaks.

Conclusions: Outpatient hemodialysis clinics remain a common setting for healthcare-related HCV outbreaks. Infection control lapses were frequently identified in reported outbreaks. Rigorous adherence to recommended infection control practices is needed to protect patients and prevent future outbreaks in this setting.

FR-PO781

Influenza and Outcomes in ESRD Patients  

David T. Gilbertson,1 Anne C. Beaubrun,2 Kenneth J. Rothman,1 Jiannong Liu,1 Brian D. Bradbury,1 Akhtar Ashfaq,1 Charles A. Herzog,2 Allan J. Collins,1 Chronic Disease Research Group, MMRF; 2Ctr for Observational Rsch, Amgen; 3RTI Health Solutions.

Background: Yearly influenza vaccination is recommended for all ESRD patients, due to a high risk of influenza-related complications. Through the CDC’s Outpatient Illness Surveillance, information on patient visits to health care providers for influenza-like illness (ILI) is collected. These data give estimates of the percent of all OP visits that are for presumed influenza, and give national information on timing and severity of each influenza season. We assessed the association between CDC ILI data and outcomes in ESRD patients.

Methods: We aggregated weekly ILI data from 2000-2012 to monthly, and calculated the monthly number of deaths and hospitalizations among US ESRD patients during the same time period. Using time series decomposition, we subtracted out seasonal and trend effects from the overall ILI metric. We used all-cause hospitalization as a potential confounder of outcomes.

Results: The overall rate is still below 70%, suggesting room for further improvement. While influenza vaccination rates among ESRD patients have improved over the last decade, we still observed gaps. Other peaks and valleys of the ILI data did not parallel the beginning of the next calendar year. Similar “early” peaks are seen in deaths among ESRD patients. There is also correlation between other peaks and valleys of the ILI data and periods of increased contacts in the community, such as holiday seasons and prior to vaccine administration.

Conclusions: There is an opportunity for increased influenza vaccination rates and improved infection control practices to reduce the burden of influenza among ESRD patients.

FR-PO782

The Burden of Pneumonia in Patients Receiving Dialysis: Incidence, Case Fatality, and Costs to Medicare  

Scott Sibbel,1 Reiko Sato,2 Abigail Hunt,1 Wendy Turenne,1 Steven M. Brunelli.1 DaVita Clinical Research, Minneapolis, MN; 2Pfizer Inc, Collegeville, PA.

Background: End-stage renal disease patients receiving dialysis are at particular risk for infection. We assessed the clinical and economic burden of pneumonia in a population of Medicare-enrolled ESRD patients with respect to incidence and case fatality rates, rates of all-cause hospitalization, and costs.

Methods: Patients included in the analysis received dialysis between 01 Jan 2009 and 31 Dec 2011, and were enrolled in Medicare Parts A and B. Pneumonia episodes were identified from institutional and supplier claims. Patients were considered at-risk from the first date of Medicare coverage and were censored from the analysis upon transplant, withdrawal from dialysis, recovery of renal function or death. Linear mixed effects models were used to assess hospitalization rates and costs over the 3 months prior to and 12 months following a pneumonia diagnosis.

Results: The pneumonia incidence rate for the study period was 21.4 events/100 patient-years with the majority of episodes (90.1%) requiring inpatient treatment. The 30-day case fatality rate was 10.7%; case fatality rates were higher for older patients and for pneumonia requiring inpatient treatment (11.2%). All-cause hospitalization rates were greater in the month of the pneumonia episode vs month -3 prior to diagnosis (IRR, 4.61; 95%CI: 4.46, 4.76) and remained higher than baseline over the 1-year follow-up period. Mean per patient per month costs were $10,976 (95% CI: $10,717, $11,275) higher in the month of the index episode compared to month -3, largely driven by increased inpatient costs, and remained elevated through end of follow-up.

Conclusions: Pneumonia episodes are frequent among ESRD patients and result in hospital admissions and greater overall costs to Medicare (~$20,000 incremental) over the following year.

FR-PO783

Opioid Use Associates with Infection Related Morbidity and Mortality in Hemodialysis Patients  

Abhijit V. Kahrirasa, Diane Reams, Madagelen M. Assimon, Anne Mobley Butler, Jennifer E. Flyythe, M. Alan Brookhart. Univ of North Carolina at Chapel Hill.

Background: Opiates are frequently prescribed for pain in the US hemodialysis (HD) population but have intrinsic properties that increase risk of infection, a common cause of morbidity and mortality for patients. Data regarding the association of opioids with infection are lacking.

Methods: We conducted a retrospective cohort study using data from a large national dialysis provider linked with the United States Renal Data System and Medicare Part D (2006-2010). We used a new user design – comparing only new users of opioids to new users of prescription non-steroidal anti-inflammatory drugs (NSAIDS) to address confounding, as well as excluding patients with cancer, use of hospice services, or use of ≥ 1 opiate. We assessed treatment effects on infection-related morbidity and mortality using inverse probability of treatment weighted Kaplan-Meier methods, adjusting for many comorbid, lab, and clinical variables.

Results: 5,113 patients met entry requirements, of which 3,439 (67.3%) received an opioid. Relative to new NSAID users, new opioid users had similar baseline laboratory values, but were slightly younger, and had a higher prevalence of comorbidities, including recent infections (8.7% vs 6.8%), diabetes (52.3% vs 49.3%), and chronic obstructive pulmonary disease (COPD), 17% vs 12.2%. After multivariable adjustment, we observed an elevated risk of 90-day infection-related hospitalization, (Risk Difference (RD) 2.5/100 patients, 95% CI 0.6-4.5) (Figure 1), and 90-day risk of infection-related mortality (RD 0.6%, 95% CI 0.3-0.9), no figure. For subgroups, infection-related hospitalizations were elevated among females and patients with diabetes, COPD, and lower dialysis vintage.

Funding: Other U.S. Government Support

A Retrospective Review of the Two-Step Tuberculin Skin Test in Manitoba’s Dialysis Population

Rukhsana A. Foster,1,2 Thomas W. Ferguson,1 Claudio Rigatto,1 Navdeep Tangri, Blake R. Lerner, Whit Reid,1 Paul Komenda.1,2

Background: Reactivation of latent Mycobacterium Tuberculosis (LTBI) is a health concern for patients on dialysis due to their immunosuppressed state. The most frequently used test for LTBI screening in this population is the Tuberculin Skin Test (TST). The diagnostic accuracy (sensitivity and specificity) and clinical utility of the TST in a contemporary North American dialysis population is unknown.

Methods: We performed a retrospective cohort study of 483 hemodialysis and peritoneal dialysis patients across 4 dialysis units. All patients received a two-step TST and full TB risk assessment between February 2008 and December 2008. We then linked the cohort with the Manitoba Health TB Registry to ascertain if treatment was received for LTBI.

Results: At an induration cut-off of 5mm, 62 (13%) patients had a positive two-step TST. Patients with a BCG vaccination were more likely to test positive (50 vs. 34%, p = 0.006). Using a diagnostic gold standard of an abnormal chest X-ray as a proxy for LTBI, the sensitivity of the TST was only 13.9%, and the specificity was 87.7%. Only 8 of 62 patients (13%) were prescribed treatment for LTBI. None of the patients who tested negative were treated.

Conclusions: The TST has limited diagnostic and clinical utility for LTBI screening in patients on dialysis. Further research into the diagnostic accuracy of interferon-gamma release assays, and a revision of TST screening guidelines in patients on dialysis should be considered.

FR-PO785

Reliability and Construct Validity of the Coping Strategy Inventory-Short Form in Hemodialysis (HD) Patients in 13 Countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Elodie Speyer,1 Hal Morgenstern,2 Yasuki Hayashino,1 Peter G. Kerr,1 Hugh C. Rayner,1 Robert L. Pisoni.1

Background: In international studies, questionnaires are often translated into several languages without consideration of cultural and linguistic differences that may compromise the reliability and validity of survey instruments, especially those measuring psychosocial factors. The Coping Strategies Inventory-Short Form (CSI-SF) is a 16-item questionnaire, developed in English, and previously validated in US-Canadian failure patients. It is scored by computing 4 scales (each with 4 items) to measure 4 different coping strategies. The aim was to assess reliability and construct validity of the CSI-SF in HD patients across 13 countries.

Methods: The CSI-SF was self-administered to HD patients across 13 countries in 9 languages in DOPPS 4 (2009-11). Cronbach’s alpha was used to assess internal consistency. Exploratory and confirmatory factor analyses were used to assess the factor structure of the CSI-SF by country and language.

Results: 6,656 HD patients completed the CSI-SF and were included in this analysis (55% male; median age=63, range: 18-96 yrs). Using the English version in 4 countries and the Swedish version, we found good internal consistency (α=0.63-0.77) for 3 of the 4 scales; the 4th scale was internally consistent if two items were dropped. In these countries, both types of factor analyses indicated a factor structure perfectly consistent with these same 4 scales. In the 8 other non-English versions, results were very different: internal consistency was lower for the 4 scales; no country showed an exploratory factor structure similar to that found previously, nor was the 4-factor structure confirmed with factor analysis.

Conclusions: The CSI-SF is reliable for measuring coping in HD patients in English and some non-English versions. As tested in the DOPPS, the importance of coping in predicting outcomes in HD patients can now be described in these countries. More research is needed for measuring coping strategies in other countries and languages.

FR-PO786

Associations Among Psychosocial/Medical Factors and Quality of Life in Hemodialysis Patients with End-Stage Renal Disease

Gum woo Kang

Background: Patients with end-stage renal disease (ESRD) have a significant impairment in quality of life (QoL). Most previous studies have focused on medical factors mainly. However, quality of life can also be affected by psychosocial problems in the circumstances of chronic illness. The aim of this study was to identify the associations among psychosocial factors, medical factors and QoL in hemodialysis (HD) patients.

Methods: The study included 101 patients with ESRD who were undergoing HD (mean age 57.1 ± 2.1 years). Psychosocial factors were measured using the Hospital Anxiety Depression Scale (HADS), Multidimensional Scale of Perceived Social Support (MSPSS), Montreal Cognitive Assessment and Pittsburgh Sleep Quality Index. In addition, for evaluating caregivers’ burden in part of psychosocial factors, HADS and Zarit Burden Interview of main caregivers were administered. We also assessed medical factors (Kt/V and urea reduction ratio, etc.) with laboratory results (body mass index, albumin, hemoglobin, etc.). The QoL was evaluated using WHO Quality of Life-BREF (WHOQOL-BREF). The canonical correlation analysis was used to investigate the patterns of associations.

Results: The canonical correlation between psychosocial factor and QoL was significant. The first canonical correlation was 0.673 (proportion = 60.6%, p = 0.001) and the second was 0.519 (proportion = 26.9%, p = 0.006). However, the canonical correlation between medical factor and QoL was not significant (the first: p = 0.586, the second: p = 0.713).

Conclusions: The QoL of patients with ESRD was not associated with medical factor, but psychosocial factor in canonical correlation analysis. This finding may suggest that medical workers should recognize and treat psychosocial problems as well as medical problems. We also would like to emphasize the comprehensive approach with cooperation between psychiatrists and nephrologists for improvement of QoL in ESRD patients.

FR-PO787

Longitudinal Associations of Dietary Protein and Energy Intake with Protein-Energy Wasting Syndrome in Hemodialysis Patients

Xiaorui Chen,1 Xiaoru Xia,1 G. Wei,1 Robert E. Boucher,1 Dominique Ferranti,1 Kalani L. Raphael,1,2 Tom Greene,1 Michel Chonchol,1 U of Utah; VA SLIC,UC Denver.

Background: Low dietary protein intake (DPI) (<0.6 g/kg/d) and low dietary energy intake (DEI) (<25 kcal/kg/day) are included in the definition of protein-energy wasting (PEW) syndrome. Therefore, we examined the longitudinal associations of baseline DPI and DEI with PEW syndrome (defined by modified criteria that excludes dietary variables) at 1 year of follow-up in 1480 MHD pts in the HEMO Study.

Methods: DPI and DEI were obtained by 24-h dietary recall. PEW syndrome at month 12 was defined as the presence of 2 out of the 3 criteria: serum chemistry (albumin by BCP method < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m2 or wt loss > 10% over 1 yr), and muscle mass (mid-arm muscle circumference 10% or more less than the 50th percentile of reference population). PEW syndrome at month 12 was related to baseline DPI and DEI in logistic regression models.

Results: 17.4% had PEW at month 12. The prevalence of PEW syndrome at month 12 by baseline DPI and DEI quartiles are summarized in the figure.
FR-PO788

PEW Syndrome, Inflammation and Mortality in Hemodialysis Patients Srimi Beddu,1 Xiaorui Chen,2 G. Wei,1 Robert E. Boucher,1 Dominique Ferrari,1 Kalani L. Raphael,1 Tom Greene,1 Michel Chonchol,3 1U of Utah; 2VA SLC; 3UC Denver

Background: The term ‘malnutrition-inflammation complex syndrome’ implies that malnutrition and inflammation are tightly interlinked. Therefore, we examined whether the mortality associations of markers of inflammation and protein-energy wasting syndrome (PEW) are attenuated by each in 906 maintenance hemodialysis (MHD) patients in the HEMO Study, a multi-center RCT that examined the effects of dialysis dose and dialiser flux on mortality.

Methods: High sensitivity Creative Protein (hsCRP), tumor necrosis factor (TNF)-α and interleukin (IL)-6 were measured in the month 12 stored samples. Weight loss was estimated from baseline and month 12 post-dialysis weights and hence, PEW syndrome at month 12 was defined as the presence of 2 out of 3 criteria: serum chemistry (albumin by nephelometry < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m² or wt loss > 10% from baseline), and muscle mass (mid-arm muscle circumference 10% or more than the 50th percentile of reference population). Cox models were used to relate month 12 PEW syndrome and hsCRP, TNF-α and IL-6 with subsequent mortality.

Results: Mean age was 57 ± 14 yrs. 45% were women. 67% were black. PEW syndrome was present in 17.4% at month 12. Median (IQR) serum hsCRP was 6.3 (2.6-16.4) mg/L, IL-6 3.3 (2.0-7.6) pg/ml, and TNF-α 31.2 (21.3-46.1) pg/ml. There were 388 deaths over 2189 years of follow-up. PEW syndrome had 2 fold higher risk of mortality which was only marginally attenuated by adjustment for markers of inflammation (table). CRP and IL-6 were associated with higher mortality risk independent of PEW. TNF-α was not associated with mortality.

*Adjusted for age, gender, race, duration of ESRD, Kt/V group, smoking, alcohol use, DM, IHD, CVD, PVD, CHF and arrhythmia.

Conclusions: PEW and inflammation are independent predictors of mortality. These results suggest PEW and inflammation might not be tightly interlinked.

Funding: NIDDK Support

FR-PO790

Background: Patients who undergo dialysis prior to renal transplant have overall worse outcomes than patients who receive a preemptive transplant. However, individual studies give conflicting results regarding whether post-transplant outcomes differ based on pre-transplant dialysis modality (peritoneal dialysis (PD) versus hemodialysis (HD)).

Methods: We searched English-language literature from January 1, 1980 through August 31, 2014, national conference proceedings and reference lists of all included studies. We used combinations of terms related to dialysis (hemodialysis, peritoneal dialysis, or renal replacement therapy), kidney transplant and outcomes. Studies were included if they measured post-transplant patient mortality for both pre-transplant HD and PD. Studies were excluded if they were not in English or if they included pediatric patients.

Results: A total of 15 studies reported five-year patient mortality. These included 166,531 patients on HD and 51,980 patients on PD pre-transplant. The pooled hazard ratio for five-year patient mortality after renal transplant was 0.91 (CI 0.85-0.97) in favor of pre-transplant PD over HD (p=0.006).

Conclusions: Distance is an important factor in patient decision-making when initiating PD, particularly for those living farther away from commonly offered HD services. Analyses of treatment selection must appropriately model distance to reflect logistics of treatment options and service availability to patients.

Impact of Poverty and Health Care Insurance on Pre-End Stage Renal Disease Care in Dialysis Patients  
Robert Nee,1 Lawrence Agodoa,2 Kevin C. Abbott,1  
1Nephrology, Walter Reed National Military Medical Center; Bethesda, MD; 2NIDDK, National Insts of Health, Bethesda, MD.  

Background: Access to nephrology care prior to end-stage renal disease (ESRD) is significantly associated with lower rates of morbidity and mortality. We assessed the association of area and individual-level indicators of poverty and types of health care insurance on pre-ESRD care provided by nephrologists.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 739,537 patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2012. We assessed the Medicare-Medicaid dual-eligibility status as an indicator of individual-level poverty and ZIP code-level median household income (MHI) data obtained from the 2010 United States Census. We conducted multivariable logistic regression of pre-ESRD care as the outcome variable, as reported on the Centers for Medicare and Medicaid Services Form 2728.

Results: The proportions of dual-eligible and non-dual-eligible patients who had pre-ESRD care were 53.06% and 61.82%, respectively (p<0.001). Dual-eligibility was associated with significantly lower likelihood of pre-ESRD care (adjusted odds ratio (aOR) 0.83, 95% confidence interval [CI] 0.82-0.84). Patients in the lowest area-level MHI quintile had an aOR 0.89 (95% CI 0.88-0.90) compared to those in higher quintile levels. Both African American (AA) and Hispanic patients were significantly less likely to have received pre-ESRD care (aOR 0.85, 95% CI 0.84-0.86 and aOR 0.71, 95% CI 0.70-0.72, respectively). Interaction terms for dual eligibility and AA race and Hispanic ethnicity were significant (p=0.001 and p=0.002, respectively).

Conclusions: Individual and area level measures of poverty were independently associated with lower likelihood of pre-ESRD care. Efforts to improve pre-ESRD nephrology care may require focusing on the poor and minority groups. [Disclaimer: The United States government nor its employees assume any liability or responsibility for the contents of this presentation.]

FR-P0794  
Does Race Affect the Cause of Mortality in End Stage Kidney Disease?  
Luxme Nadarajah, Kieran McCafferty, Muhammad M. Yaqoob.  

Background: Cardiovascular disease accounts for 50% of mortality in end-stage kidney disease (ESKD). Caucasians (C) are more likely to die from cardiovascular disease, infection and withdrawal compared to Afro-Caribbean’s (AC). Little is known about the causes of mortality for Indo-Asian (IA) patients; with the rise in diabetes mellitus (DM) it is inevitable that more patients from IA backgrounds will get ESKD. We aim to investigate whether there are any differences in causes of mortality based on race.

Methods: We performed a single center, prospective, observational study. Electronic case notes were used to extract data to include cause of death, age of initiation of RRT, age of death, dialysis vintage (DV), gender and presence of DM. Patients were excluded if RRT was less than 90 days, or if they were transplanted.

Results: In total 3431 patients commenced RRT during the study period, 802 patients died, 364 were C, 259 IA and 179 were AC. There were no significant differences between the groups for age at initiation, DV, and age of death. Significantly fewer IA died during the follow up period compared to C (p<0.0001) and AC (p<0.0001). More IA and AC were diabetic (p<0.0001). Cardiovascular deaths were more common in C and AC patients compared to those of IA race (p<0.0001). IA’s had higher sepsis related deaths when compared C or AC (p<0.0001).

Conclusions: Despite the increased prevalence in DM, IA patients do not have worse survival outcomes or cardiovascular deaths compared to C and AC. We believe that the elevated sepsis related mortality in IA patients is secondary to the higher prevalence of diabetes. This data enables stratifying management therapies dependent on race and may help in designing cardiovascular end points trials in racially diverse group of patients.

Association of Dialysis Provider Assignment with Early Dialysis Mortality in U.S. Veterans: A Transition of Care in CKD Study

Melissa Han, Ling Sun, Kamyar Kalantar, Keith C. Norris, Alison J. Yu

Note: most of these HRs were significant at p<0.05.

Methods: We examined all-cause mortality during the 3, 6, 12 and 24 month period after transition in a cohort of 52,158 US veterans who transitioned to ESRD over 4 years (10/2007-9/2011) and the association of dialysis provider assignment. Baseline provider was determined by facility information and divided into five categories: DaVita(DV), Fresenius(FR), Other Chain(OC), Non-Chain(NC), and VA. Associations were examined in Cox proportional hazard models and adjusted for age, gender, race, ethnicity, initial vascular access and primary cause of ESRD.

Results: Upon dialysis transition, patients were 70±12 yrs old, 6% female, 25% African-American, 19% initially used AV fistula and 42% had diabetes as the cause of ESRD. At baseline, 24%, 28%, 13%, 21%, and 10% of veterans received treatment at DV, FR, OC, NC, and VA facilities, respectively. Over the first 3, 6, 12 and 24 mos after transition, 5480(1%), 9283(18%), 14339(27%) and 21607(42%) veterans died, respectively (Figure left). Compared to patients initiating treatment at the VA, all patients receiving treatment at other facilities had higher risk of mortality through all periods of follow-up, after adjusting for case mix covariates (Figure right).

Conclusions: Veterans transitioning to dialysis treatment in a VA based dialysis center have the best survival over the first 2 years of follow up. Whether the better survival of VA dialysis care is from selection bias versus true superior care in the VA system warrants additional studies.

Time-Varying Racial/Ethnic Differences in Mortality After Initiation of Dialysis in U.S. Dialysis Patients

Guofen Yan, Keith C. Norris, Alison J. Yu, Tom Greene, Jennie Z. Ma, Wei Yu, Alfred K. Cheung

Background: While survival advantage for African Americans (AAs) and Hispanics, compared to Whites, has been observed for decades, our understanding of the mechanism is still incomplete. Using national dialysis patients, we examined whether this survival advantage exists across the entire course of ESRD or just within a certain time interval after initiation of dialysis.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS. We calculated age-specific hazard ratios (HRs) of death for AAs and Hispanics vs. Whites, adjusted for covariates, for every 6-month interval in the first 4 years of dialysis and for the period thereafter.

Results: For each age group above 40 years (Table), lower risk of death for AAs than Whites (HR<1) did not vary greatly across these time intervals. In contrast, in each age group under 40 years, the HR for AAs vs. Whites evolved over time, which was highest in the first year, declined in the second year, and reached stable over time. Hispanics exhibited lower mortality risks in all age groups that remained relatively constant over time (not shown).

Table. Adjusted HRs for AAs vs. Whites

<table>
<thead>

</tbody>
</table>

Note: most of these HRs were significant at p<0.05.

Conclusions: AAs over 40 years old and Hispanics of all ages have uniformly lower risks of death than Whites across the course of ESRD. For younger AAs, conversely, their higher-mortality risk period is limited to the first two years of dialysis. Further studies to delineate the factors responsible for excessive mortality associated with racial subgroups will improve care for all dialysis patients.

An Evaluation of Completeness of Monthly Clinical Data in CROWNWeb, a New Data Source for the United States Renal Data System (USRDS)

Valarie B. Ashley, Lingqiu Liu, Xizhao Li, Tempie H. Shearon, Bruce M. Robinson, Douglas E. Schaubel, Yi Li, Rajiv Saran

Background: CROWNWeb (CW) is a web-based system which collects administrative and clinical data from all Medicare-certified dialysis facilities in the US. It includes patient admission, tracking, and discharge information, CMS forms, and clinical data elements, and is not limited to Medicare patients. Monthly clinical data submission began in May 2012. Previously, monthly clinical data were only available to the USRDS through administrative claims for Medicare patients.

Methods: CW data were used to analyze 355,846 and 370,610 dialysis patients in 2013 and 2014, respectively, who remained on dialysis the entire year (those who were incident, died, or lost to follow-up were excluded). The percentages of patients with any and high-level reporting of selected CW clinical data were calculated, with 'high-level' defined as 10+ months (except 3+ months for peritoneal dialysis (PD) Kv/v). The percentage of high-level reporting for patient subgroups was also calculated.

Results: The percentages of patients with CW data (any, high) are shown below. All measures had an increase in reporting from 2013 to 2014. High-level reporting in 2014 ranged from 75% (Hemodialysis (HD) Kv/v) to 90% (vascular access type). For all measures, reporting was higher for HD than PD patients, for adults than children, and for patients with diabetes (versus without) diabetes as cause of ESRD. 72% of HD patients had high-level reporting for all 6 HD measures. 70% of PD patients had high-level reporting for all 5 PD measures.

Table. Clinical Data:

Further studies to delineate the factors responsible for excessive mortality associated with racial subgroups will improve care for all dialysis patients.

Funding: NIDDK Support
Epidemiology and Cost Center, Univ of Michigan, Ann Arbor, MI; 2Centers for Medicare and Medicaid Services.

Background: In 2015 CMS implemented star ratings for dialysis facilities to make it easier for consumers to compare dialysis facilities by providing a summary of each facility’s performance on a set of 9 DFC quality measures. Our study compares two scoring approaches to the star rating to assess the impact of each on controlling outlying measure values with regard to facility size.

Methods: Fixed percentiles are applied to assign 10% of facilities 1-star or 5-stars based on performance. 2015 data were extracted from the 2015 January DFC file. Probit ranking and z-score transformation were applied to the DFC measures to develop an overall score and final star rating. We compared the final distribution of star ratings for each approach and assessed impact on smaller facilities. We represent the rating by number of patients in each facility contributing to the hospitalization measure, and split –6000 facilities into groups of ~100 and calculated percentage of each star rating in each group.

Results: Use of original measure values and z-scores allowed skewed measures to highly influence the ratings, but preserved original measure distributions. Probit ranking resulted in giving more 5-star ratings to smaller facilities and a z-scored approach resulted in assigning more 1-star and 5-star ratings to smaller facilities (Figure 1).

Conclusions: Small facilities have more variation in measures and be over represented in the 1 or 2 star categories. Probit ranking (current DFC Star Rating method) controlled impact of outlier measure values. Z-score methods appeared to allow greater impact of undetermined mechanisms.

FR-PO801
Efficacy of Loop Diuretics in the Management of Undocumented End Stage Renal Disease Patients Receiving Emergency Hemodialysis
Salman Ahmed, Biruh Workeneh.

Background: Nearly eleven million undocumented immigrants reside in the United States. An estimated six thousand undocumented patients suffer from End Stage Renal Disease (ESRD). These patients routinely present to public hospitals for life-saving emergent dialysis treatments. Since these patients lack a dialysis unit, they often do not have medication management by a nephrologist. This can result in poorer outcomes.

Methods: We reviewed charts of 93 undocumented patients who presented for at least three emergent hemodialysis (HD) treatments during three consecutive months to the Ben Taub General Hospital, a centrally located county facility in Houston, TX. We abstracted prescription data for furosemide and several commonly prescribed medications. We also abstracted data regarding the number of ER visits, number of HD sessions, and mean, median, and peak potassium values.

Results: On average, the diuretic group had 3.1 (SE=1.8) fewer ER visits during the three-month period for emergency dialysis, compared with subjects not on diuretics (p=0.10). There was no significant relationship between furosemide total daily dose (TDD) and potassium levels. Patients on diuretics were more likely to also be taking ESAs and sevelamer (p<0.05). In a multiple regression model, the diuretic group had significantly fewer ER visits after adjusting for use of ESAs and sevelamer use (p=0.007). The association between diuretic use and ER visits is significantly associated with concomitant ESA use (p=0.04). Among subjects using ESAs, patients on diuretics have about 7.7 (95% CI: 1.9, 13.6) fewer ER visits compared with the non-diuretic group.

Conclusions: There was no significant independent association between loop diuretic dosage and number of ER visits, although there was a strong trend. The subset of patients on ESAs and loop diuretics had decreased ER utilization, and this may be explained by increased doctor-patient time, less symptomatology while on ESAs, or other, as-yet-undetermined mechanisms.

FR-PO802
Unfractionated Heparin May Contribute More to Dialysis-Associated Bleeding Risk Than Low-Molecular Weight Heparin
Suzanne H. Forbes,1 Sean Platton,2 Michael K. Almond,1 Laura Green,2 Neil Ashman.1

Background: Haemodialysis (HD) patient are well recognised to be at increased risk for major bleeding. The contribution of circuit anticoagulation to this risk is unknown. The use of unfractionated heparin (UFH) vs low-molecular weight heparin (LMWH) is debated.

Methods: We studied 127 patients; 60 LMWH, 61 UFH, 6 heparin-free. Blood was taken at t0=pre-anticoagulation, t1=1hr, t2=2hrs, t3=end. TG was performed on platelet count, prothrombin time, and partial thromboplastin time. Results are shown in table 1. With LMWH 42% failed to generate thrombin (p=0.06) and peak thrombin (p=0.05). In a multiple regression model, the diuretic group had significantly fewer ER visits after adjusting for use of ESAs and sevelamer use (p=0.007). The association between diuretic use and ER visits is significantly associated with concomitant ESA use (p=0.04). Among subjects using ESAs, patients on diuretics have about 7.7 (95% CI: 1.9, 13.6) fewer ER visits compared with the non-diuretic group.

Conclusions: There was no significant independent association between loop diuretic dosage and number of ER visits, although there was a strong trend. The subset of patients on ESAs and loop diuretics had decreased ER utilization, and this may be explained by increased doctor-patient time, less symptomatology while on ESAs, or other, as-yet-undetermined mechanisms.

Anti-Platelet Factor 4 Antibodies: A One HIT Wonder
Suzanne H. Forbes, ‘1, Sean Platon, ‘2, Michael K. Almond, ‘1, Neil Ashman, ‘1, Laura Green, ‘1, Nephrology, Royal London Hospital; ‘2Haematology, Royal London Hospital; ‘3Nephrology, Southend Hospital.

Background: Hemodialysis (HD) patients are exposed to regular anticoagulation, usually unfractionated heparin (UFH) or low-molecular weight heparin (LMWH). For standard HD (4 hrs, 3 days/week) this equates 26 full days exposure/yr. Recently there was publication suggesting the presence of the antibody, without the clinical syndrome of HIT, is present in up to 25% HD patients, may be an important risk factor for cardiovascular and vascular access morbidity.

Methods: We looked for HIT antibodies in 2 prevalent HD cohorts, one with UFH, one LMWH (time lock sodium citrate). We tested for anti-PF4 antibodies using several established tests; STic Expert® (IgG-specific exclusion test), Diamed (particle gel immuno-assy), poly-specific IgG/AM ELISA, IgG-specific ELISA.

Results: We included 127 patients: 60 receiving tinzaparin, 61 receiving UFH and 6 heparin-free. Serum samples were taken at the start of a standard HD session. The average duration on dialysis was 3.4 years. Results of the various tests are shown.

<table>

</tbody>
</table>

Only 1 patient tested antibody positive (OD 0.5) in the LMWH group. Platelet count and reactivity (sticking and epinephrine, collagen) did not differ between the STic positive/negative groups, the UFH/LMWH groups, or those with higher or lower tertiles of ELISA OD.

Conclusions: Despite the previously reported concern over the presence of HIT antibodies in HD patients, we comprehensively show here no evidence of antibody positivity in HD patients. Exclusion tests such as STic expert are not useful in these patients.

FR-PO804

Upper Gastrointestinal Bleeding Among Dialysis Patients in an Endemic Area for Chronic Liver Disease: Taiwan National Cohort Study
Chih-Chiang Chien, ‘1,2 Chien-Ya Hung, ‘1 Chiang Hua Univ of Medical Technology; Tainan, Taiwan; ‘2Chi Mei Medical Center, Tainan, Taiwan.

Background: End-stage renal disease (ESRD) and chronic liver disease (CLD) both increase the risk for upper gastrointestinal (UGI) bleeding. The prevalence of ESRD and CLD are high in Taiwan. The aim of this study was to evaluate the incidence, risk factors, and categories of UGI bleeding in ESRD CLD dialysis patients.

Methods: Using Taiwan’s National Health Insurance research database, we enrolled 42,457 incident ESRD dialysis patients who began dialysis between 1999 and 2004. The patients were followed until death, dialysis cessation, or 31 December 2008. Cumulative incidence of UGI bleeding after initiation of dialysis was calculated using Kaplan-Meier methods. Predictors for UGI bleeding were determined using Cox models.

Results: During the follow-up period, 5,528 patients had a UGI bleeding. Male, elderly, receiving hemodialysis (HD) and patient with comorbidities had a higher rate of UGI bleeding. The 1-, 3-, 5- and 7-year cumulative incidence rate of UGI bleeding were 9.8%, 21%, 25.3% and 28% in patients with liver cirrhosis (LC) on HD, 5.8%, 16.2%, 22.2% and 24.4% in patients with LC on PD, 3.7%, 9.2%, 13.2% and 16.4% in patients without LC on HD, and 2.1%, 5.5%, 8.2% and 10.4% in patients without LC on PD (log-rank: p <0.001). After multivariate adjustment, prior gastrointestinal bleeding (HR 1.731, 95% CI, 1.651-1.834), LC (1.682, 95% CI, 1.524-1.856), alcoholism liver disease (1.536, 95% CI, 1.635-1.834), and receiving HD (1.316, 95% CI, 1.153-1.502) were independently risk factors for UGI bleeding in ESRD dialysis patient. Gastric ulcers were found to be the most common source of bleeding (50.3%), while bleeding resulting from a gastrojejunal ulcer was least frequent.

Conclusions: ESRD dialysis patients had a higher risk for UGI bleeding, especially those with prior gastrointestinal bleeding, LC, and alcoholism liver disease. In addition, receiving HD is a strong predictor for UGI bleeding. More attention should be paid to select dialysis modality, especially in high risk patients.

FR-PO805

Palmitoylthiopanamidine Is A Promising Potential Therapeutic Target For Increasing High Density Lipoprotein Cholesterol Levels

Background: End stage renal disease (ESRD) is associated with significant increased risk of cardiovascular (CV) mortality. High density lipoprotein (HDL) deficiency and dysfunction is a major contributor to CV disease in ESRD. Strategies aimed at improving HDL function are crucial in improving CV outcomes. Palmitoylated panamidine (PEA) is an anti-inflammatory lipid derived mediator that activates PPARalpha nuclear transcription factor. We hypothesized that serum PEA will correlate with HDL and PEA can increase HDL via activation of apoA1/ApoAl expression.

Methods: Serum PEA concentration was determined in 50 patients on maintenance hemodialysis (MHD) using LC/MS technology and correlated with clinical laboratory indices including a lipid panel. Liver cells (Hepatoma cell line HepG2) were exposed to various concentrations of PEA in-vitro for 24 hours and subsequently mRNA expression of ApoAI, the major protein component of HDL, was measured using real-time PCR.

Results: Serum PEA concentrations strongly correlated with serum HDL levels in MHD patients (r=0.57, p <0.001). PEA also correlates with total cholesterol (r=0.36, p=0.009) however not with LDL or triglycerides. In the in-vitro studies, PEA at a concentration of 60 micromolar and 120 micromolar was increased ApoAI expression significantly in HepG2 cells after 24 hours.

Conclusions: For the first time we report that serum PEA concentrations strongly correlate with serum HDL concentrations in MHD patients. Involvement of PEA in HDL production is confirmed in in-vitro studies where incubation of liver cell in PEA resulted in increased ApoAI expression. These novel findings indicate that PEA may be a promising therapeutic target in HDL deficiency treatment associated with not just ESRD but any proatherosclerotic condition.

FR-PO806

Arachidonoylglycerol, a Major Activator of the Endocannabinoid System, Is Significantly Increased in Patients with Kidney Disease

Background: Chronic kidney disease (CKD) is associated with oxidative stress and inflammation. There is evidence that cannabinoid 1 receptor activation leads to increased oxidative stress and inflammation. We previously showed that 2-arachidonoylglycerol (2-AG), one of the main activators of the endocannabinoid system, is significantly increased in the kidney of animals with ischemia-reperfusion (IR) injury. We hypothesized that serum 2-AG levels will be significantly elevated in CKD patients.

Methods: Serum concentrations of AG were determined in 21 healthy controls, 50 randomly assigned age and gender matched patients on maintenance hemodialysis (MHD), 13 patients on peritoneal dialysis (PD) and 6 patients with CKD stage IV using LC/MS technology. In MHD patients, serum levels of AG were correlated with various laboratory indices.

Results: Serum levels of 1-AG and 2-AG were significantly and incrementally increased with CKD compared to healthy controls. MHD patients had the highest AG levels which positively and significantly correlated with number of treatments per week (r=0.47, p=0.008), AST/ALT (r=0.5, p=0.001), platelet count (r=0.40, p=0.008), ferritin (r=0.36, p=0.016) and negatively with HDL cholesterol (r= -0.43, p=0.04).
Conclusions: For the first time we report that serum AG concentrations are significantly increased in CKD patients. These novel findings are in line with our report on IR acute kidney injury and with a recent study which showed that in an oxidative stress setting, monoacylglycerol lipase, an enzyme responsible for AG breakdown is inhibited leading to increased levels. Moreover, the substantial increase in MHD patients is intriguing given association of MHD with increased oxidative stress, inflammation and platelet activation. Funding: NIDDK Support

FR-PO807
Newly Launched Cellulose Tri-Acetate Membrane with Asymmetric Structure Dramatically Improves Peripheral Circulation and Hemodynamic Stability During Hemodialysis.

Klaus Kratochwill,1,2 Klaus Kratochwill, Michael Boehm,1 Takuo Nagai, Shigehiro Doi, Ayumu Nakashima, Takao Masaki. Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

Background: The most important concern about the biocompatibility of dialysis membrane is the activation of platelets and it would lead hemodynamic instability during dialysis session. The newly launched CTA with asymmetric thick structure (ATA) was produced in order to reduce stimulant property to platelets and the rapid reduction of the serum levels of small urmic solutes by thickening the membrane. We evaluated the solute removal performance and biocompatibility of ATA.

Methods: Seven chronic hemodialysis patients were enrolled to the current study. The conventional CTA was used for the first 4 months and ATA was used for the next 4 months.

We evaluated the solute removal property by the clearance of urea, beta-2 microglobulin (B2MG) and removed amount of alpha-1 microglobulin (A1MG) and albumin loss in spent dialysate. The biocompatibility was evaluated by changes in WBC and platelet count, IL-6, Pentorexine-3 (PTX-3) and high sensitive CRP (hsCRP). The peripheral circulation was estimated by the Skin Perfusion Pressure (SPP) by PAD-3000® (Kaneka Medix, Osaka, Japan). Intra-dialytic hemodynamic stability was evaluated by arterial blood pressure and subjective feelings of the patients.

Results: The clearance of Urea was significantly reduced through dialysis session in both groups but the B2MG clearance was maintained only in ATA. The total removed amount of A1MG and the albumin leakage were not different between two groups. The removal of A1MG was significantly higher in ATA than in CTA. The platelet count didn’t change in ATA during dialysis session but significantly decreased in CTA. WBC counts, IL-6, PTX-3, hsCRP in both groups didn’t change. The systolic blood pressure and frequency of intradialytic hypotension were not different in both groups whereas some of the patients felt post-dialytic fatigue improved in ATA. SPP was maintained during dialysis session in ATA but deteriorated in CTA.

Conclusions: The new ATA membrane could reduce the activation of platelets and maintain the peripheral circulation during a dialysis sessions and the time-dependent deterioration of solute removal. The new ATA membrane may improve the QOL and prognosis of chronic dialysis patients.

FR-PO808
Mathematical Modeling of Fluid Transport in Peritoneal Cavity

Fangfan Zhu,1 Sameer R. Abbas,2 Roxana M. Bologna,2 Aurelia Lanto,2 Peter Kotanko,1,3 Nathan W. Levin.1 1Renal Research Inst, New York, NY; 2Rogosin Inst, New York, NY; 3Israel School of Medicine at Mosh Sinai, New York, NY.

Background: The current standard method (peritoneal equilibration test (PET)) is used to obtain transport characteristics of the peritoneal membrane for creatinine, urea and electrolytes, but not for fluid volume. Consequently, ultrafiltration profiles are difficult to obtain because the difference between the inlet and outlet dialysate concentration is not different between two groups. The removal of A1MG was significantly higher in ATA than in CTA.

Methods: Segmental bioimpedance was continuously monitored in ten PD patients to provide VPC during standard PET in the clinical unit (Zhu, et al. Am J Kidney Dis, 2003). VPC was measured with whole body bioimpedance technique (Hydra 4200). A two compartment model of VPC and Vf (Fig. 1a) was established (Eq 1-4). Two transport coefficients: k1 and k2 represent the rate of fluid shift from VPC to Vf by reabsorption and from Vf to VPC , driven by the glucose gradient. k1 and k2 were estimated by best fitting with the actual measurements based on the Marquardt-Levenberg algorithm.

Results: Parameter estimation was successful (residuals<0.01) in all but one patient, who experienced technical problems during the measurements. Fig. 1 (B) shows change in VPC during standard PET in a patient. k2 correlated inversely with the initial tissue fluid volume VPC(k2=−0.0002* Vf +0.0024, R2=0.46, p<0.05).

Conclusions: This model describes dynamics of fluid transport during PD treatment. K1 and k2 reflect the characteristics of peritoneal membrane in individual patient. The relationship of k2 and Vf suggests that fluid status could be a factor in ultrafiltration, which could be helpful in clinical practice.

FR-PO809
Linagliptin Ameliorated Methylglyoxal-Induced Peritoneal Fibrosis in Mice

Takuo Nagai, Shigehiro Doi, Ayumu Nakashima, Takao Masaki. Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

Background: Recent studies have reported that methylglyoxal (MGO) was increased in peritoneal dialysis patients, playing an important role in the development of peritoneal fibrosis. On the other hand, linagliptin, a dipeptidyl peptidase-4 (DPP-4) inhibitor, exhibits beneficial effects in diabetes patients independent of blood glucose concentration. In this study, we examined whether linagliptin suppressed MGO-induced peritoneal fibrosis in mice.

Methods: Male C57/BL6 mice were divided into three groups: a vehicle group, an MGO injection group, or an MGO injection plus linagliptin group (n=6 per group). Peritoneal fibrosis was induced by a daily intraperitoneal injection of saline containing 40 mmol/L MGO for 21 days. Saline was given in the vehicle group. Linagliptin was administered at a dose of 10 mg/kg by oral gavage once a day.

Results: Immunohistochemical staining revealed that linagliptin suppressed the expression of α-smooth muscle actin and fibroblast-specific protein-1, the deposition of collagen 1 and collagen 3 and infiltration of macrophages (F4/80). In addition, linagliptin reduced TGF-β1 concentration in peritoneal fluid of MGO-treated mice. Peritoneal fibrosis tests showed improvement of peritoneal function in mice receiving linagliptin treatment.

Conclusions: These results suggest that oral administration of linagliptin ameliorated MGO-induced peritoneal fibrosis.

FR-PO810
Addition of Alanyl-Glutamine to Dialysis Fluid Restores Peritoneal Cellular Stress Responses – A Randomized Controlled First-in-Man Trial

Andreas Vychytil1, Klaus Kratochwill,2, Michael Boehm,3 Rebecca Herzog,2 Katharina Gruber,1 Anton Lichtenauer1,2, Lilian Kuster,3 Dagmar Csaicsich,2 Andreas Gleiss,3 Martin Bilban1, Seth L. Alper,4 Christoph Aufricht.1 1Medical Univ of Vienna, Vienna, Austria; 2Zytoprotec GmbH, Vienna, Austria; 3Beth Israel Deaconess Med. Ctr., Harvard Medical School, MA.

Background: Peritoneal dialysis (PD) fluid cytotoxicity and intermittent bacterial infections contribute to membrane failure and peritonitis in PD patients. Recent meta-analyses revealed no significant influence of newer biocompatible PD fluids on peritonitis rate or peritoneal membrane function, but glutamine addition to standard PD fluids has shown cytoprotective effects both in vitro and in vivo.

Methods: In this open-label randomized controlled cross-over phase I/II trial (NCT01353638), 20 stable PD patients each underwent two 4 hour equilibration tests with glucose-based PD fluids supplemented with or lacking 8 mM alanyl-glutamine dipeptide (AlaGln), and separated by a 4 week washout phase. Effects of AlaGln on peritoneal inflammation and stimulated cytokine release were also tested in a mouse model of PD-associated peritonitis.

Results: Intraperitoneal (IP) exposure to AlaGln-supplemented PD fluid increased dialysate [glutamine] more rapidly (at 2 h mean 0.55-0.71 mM, p<0.05) and increased heat shock protein expression in peritoneal effluent cells (median 2.12-3.20, p<0.05), but did not alter peritoneal ultrafiltration, small solute transport, cell counts, or biomarkers. AlaGln increased ex vivo LPS-stimulated TNF-α release (effect CI 60-100 pg/mL, p<0.001) and, in patients with previous peritonitis, decreased dialysate [IL-8] (effect CI 0.1-4.3, p<0.05). IP AlaGln also reduced inflammation and enhanced cytokine release in the mouse model. No adverse effects of AlaGln were noted.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 550A
Conclusions: Ala-Gln administration to standard PD acutely attenuated PD-related pathological changes in peritoneum and in mice. These data encourage our ongoing phase I/II testing IP Ala-Gln supplementation as a routine therapeutic intervention in clinical PD.

Dipeptide Alanyl-Glutamine Protects from Peritoneal Fibrosis and Attenuates IL-17 Dependent Pathways During Peritoneal Dialysis

Evelina Ferrantelli,1 Georgios Liappas,2 Marc Vila cuenca,1 Marc G. Vervloet,3 Robert H.J. Beelen,1 Manuel Lopez-Cabreraz,1 2 Dept of Molecular Cell Biology and Immunology, VU Univ Medical Center, Amsterdam, Netherlands; 3CSIC-UAM, Centro de Biología Molecular Severo Ochoa, Madrid, Spain; 1Dept of Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.

Background: Peritoneal dialysis (PD) is complicated by chronic inflammation and progressive peritoneal membrane damage. Alanyl-Glutamine (Ala-Gln), a stable dipeptide commonly used in parenteral nutrition, has immunomodulatory effects and improved resistance of mesothelial cells to PD fluids. Recently, IL-17 was identified as novel player in PD induced peritoneal damage. In this study we investigated if intraperitoneal Ala-Gln administration confers protection against peritoneal damage by modulating IL-17 expression in uremic rodent PD models.

Methods: Uremia was obtained by performing 5/6 nephrectomy and animals were daily instilled with PD fluid enriched or not with Ala-Gln during a period of 5 and 8 weeks respectively for rats and mice. Mice were injected weekly with recombinant IL-17 or with saline. Histological analysis was carried out in parietal peritoneum. Gene expression in the parietal peritoneum biopsies was evaluated by real-time quantitative PCR. Protein levels were determined by ELISA in peritoneal effluents.

Results: Supplementation of PD fluid with Ala-Gln resulted in reduced peritoneal thickness (70.90 ±13.45 vs 16.23 ± 0.70, P<0.001), ASMA expression and angiogenesis. Addition of Ala-Gln also showed attenuation of PD induced IL-17 mediated pathways, reflected by substantial reduction/normalisation of peritoneal levels of IL-17 (32.55 ± 7.99 ± 1.59, P<0.001), TGFI-3, IL-6 and BOR(γ). Moreover, repeated exposure of the Ala-Gln treated group to recombinant IL-17 increased peritoneal fibrosis which was however restored upon IL-17 neutralization.

Conclusions: These results suggest that intraperitoneal administration of Ala-Gln ameliorates PD induced peritoneal damage at least in part by modulating IL-17 expression. Therefore, this evidence paves into investigations whether Ala-Gln could be a potential strategy to ameliorate peritoneal deterioration during PD.

FR-PO812
JAK1/2 Inhibitor Preserves Peritoneal Membrane Function in a Non-Uremic Peritoneal Dialysis Rat Model

Tiane Dai,1 Ying Wang,1 Panida Ditsawanon,2 Pornanong Aramwit,2 Janine A. La page,1 Sharon G. Adler.1 1Internal Medicine, LA Biomed at Harbor-UCLA Medical Center, Torrance, CA; 2Pharmacy Practice, Chulalongkorn Univ, Bangkok, Thailand.

Background: We previously showed JAK/STAT pathway activation in the peritoneal membrane (PM) of rats receiving PD with 4.25% Dianel for 10 days; concomitant treatment with a JAK1/2 inhibitor (JAKi) attenuated PM inflammation, fibrosis, and hypervascularity. We also showed that the mean concentration of MCP-1 was higher in the PD fluid of patients on long-term PD (>6mos) vs new patients (<2wks), demonstrating the potential for clinical relevance (KI.2014). These experiments were performed to determine if a JAKi could prevent deterioration of peritoneal membrane function after longer-term exposure to PD fluid.

Methods: Tunnelled PD catheters were placed in rats who received BID infusions of normal saline (n=3), 4.25% Dianel (n=3), or 4.25% Dianel + JAKi (n=3) for 12 weeks. Peritoneal equilibration testing (PET) was performed at baseline and again after 12 weeks of fluid instillation. For PET calculations, d lysate glucose was measured enzymatically at time 0 and at 90 minutes after fluid instillation. Plasma and dialysate total protein were measured at 90 minutes after dialysate instillation. D/D glucose and D/P total protein were calculated as [D/D glucose (at 12 wks)] / [D/P total protein (12 weeks – Baseline)/Baseline] for each rat. Results are expressed as mean ± SD for each group.

Results: Both D/D glucose and D/P total protein functional measurements demonstrate that JAKi protects the peritoneal membrane from the damaging effects of 4.25% Dianel.

Figure 1

Conclusions: Membrane failure limits the use of PD long-term. Strategies that preserve PD function are critically needed. Together with our prior results, these studies demonstrate the capacity of JAKi to preserve rat PD membrane structure and function during PD fluid exposure.

MicroRNA Expression Profiling in Peritoneal Fibrosis

Yoshiyuki Morihi,1 Daisuke Nagata,2 1Div of Nephrology, Dept of Integrated Medicine, Saitama Medical Center, Jichi Medical Univ, Saitama, Japan; 2Div of Nephrology, Dept of Internal Medicine, Jichi Medical Univ, Shimotouke, Tochigi, Japan.

Background: Peritoneal fibrosis (PF) is an intractable complication leading to peritoneal membrane failure in peritoneal dialysis (PD). The aim of this study was to identify the microRNAs (miRNAs) involved in PF.

Methods: miRNA screen was performed using microarray analysis in peritoneal tissue of PF patients. Results were validated by qPCR in PF and control groups. Results were validated by qPCR in PF and control groups.

Results: The initial profiling study identified 6 miRNAs (miRNA-21-5p, miRNA-221-3p, miRNA-223-3p, miRNA-142-3p, miRNA-327 and miRNA-34a-5p) increased more than twofold. All miRNA decreased less than half in peritoneum tissue of PF rats compared with control rats. Among them, serum level of miRNA-21-5p (D/P Cr =0.44, p=0.01; D/D glucose r=−0.43, p=0.01), miRNA-327 (D/P Cr =r=0.48, p=0.01, D/D glucose r=0.50, p=0.01) and miRNA-221-3p (D/P Cr =r=0.50, p=0.01, D/D glucose r=0.50, p=0.01) and drained dialysate level of miRNA-221-3p (D/P Cr =r=0.52, p=0.01) and D/D glucose r=0.46, p=0.01) and miRNA-34a-5p (D/P Cr =r=0.44, p=0.01, D/D glucose r=0.48, p=0.01) were significantly correlated with peritoneal membrane functions in PD patients. Anti-miRNA-21-5p significantly inhibited miRNA-21-5p expression in peritoneum of PF mice. It also inhibited peritoneal fibrosis thickening and maintained better peritoneal membrane functions.

Conclusions: The results of present study suggested several miRNAs involved in PF, and they may be used as the novel diagnosis biomarkers and therapeutic targets for PF.

Nanoparticles of Lipids Associated with Paclitaxel as an Alternative Strategy to Block Peritoneal Fibrosis

Filipe M. Silva,1 Rafael Pepineli,2 Elerson Costalonga,1 Raul Cavalcante Maranhão,1 Irene L. Noronha.1 1Nephrology Div, Univ of Sao Paulo, Brazil; 2Laboratory of Lipids Metabolism, Univ of Sao Paulo, Brazil.

Background: Peritoneal fibrosis (PF) and loss of ultrafiltration represent important complications of long term peritoneal dialysis, with limited options of treatment. Advances in nanotechnology enabled drug release systems that can provide the release of an active drug in the target tissue. Nanoparticles similar to LDL were developed, linked to Paclitaxel (NanoPACL), an antiproliferative drug. NanoPACL have the ability to bind to LDL receptors present on the cell surface, particularly in immune-inflammatory sites. The aim of this study was to analyze the effect of NanoPACL administration in an experimental model of PF.

Methods: PF was induced in Wistar rats by daily IP injections of chlorhexidine gluconate (CG) at 0.1% during 15 days. Animals (n=20) were divided into 4 groups: Control, normal rats, PF treated with CG, NanoF, PF treated with NanoPACL (4mg/kg every 3 days, via IP). Euthanasia was performed on day 30. Peritoneal thickness and function, immunohistochemistry and qPCR were analyzed.

Results: NanoPACL significantly reduced peritoneal thickness, α-SMA expression and cell proliferation compared with control groups. Treatment with NanoPACL decreased TGF-β and Smad 3 mRNA expression and preserved peritoneal function characterized by preservation of UF and reduced mass transfer of glucose (MTG).

*p<0.05 vs Control; **p<0.05 vs Nano.

Conclusions: NanoPACL administration was effective in preventing PF and preserving peritoneal function, possibly by local effect of Paclitaxel.

FR-PO815

Background: EMT is known as a key mechanism of peritoneal fibrosis in peritoneal dialysis. Oxidative stress induced by NOX and mitochondrial dysfunction is one of the mechanisms responsible for EMT. Paricalcitol, a selective VDRA, is known to exert anti-fibrotic effect organ fibrosis, however there are no studies about the role of paricalcitol on peritoneal fibrosis. We investigated whether paricalcitol imposed any effect on TGFB1-induced EMT of HPMC with an exploration of mechanism of anti-fibrotic effect of paricalcitol in terms of modulation of oxidative stress.

Methods: EMT was evaluated by morphological changes of HPMCs and the expressions of E-cadherin and α-smooth muscle actin. Intracellular ROS was analyzed by measurements of NOX activity, NOX mRNA expressions with DCF-DA and MitoSox staining. Activation of Erk1/2, p38 MAPK, nuclear translocation of β-catenin and snail expression were assessed by western blotting and immunocytochemistry. Effect of paricalcitol on ROS generation and EMT was analyzed in HPMC exposed to TGFB1.

Results: TGFB1 (1ng/ml) induced EMT of HPMCs with an increase in ROS generation and NOX activity from 30 minutes, and mitochondrial ROS production from 6 hours. TGFB1 also increased the phosphorylation of Erk and p38 MAPK from 1hour, which was followed by nuclear translocation of β-catenin and snail up-regulation in HPMC. Paricalcitol (50nM) ameliorated TGFB1-induced EMT in HPMC, which was associated with a decrease in both NOX- and mitochondria-mediated ROS production. TGFB1-induced EMT was partially alleviated by N-acetyl cysteine (5mM) or apocynin (100µM), which was further inhibited by an addition of rotenone (1µM) or paricalcitol.

Conclusions: One of the VDRAs, paricalcitol, ameliorated TGFB1-induced EMT of HPMCs by a decrease in ROS generation in HPMCs. Anti-oxidant effect of paricalcitol seems to be related to the direct inhibition of NOX and mitochondria-mediated ROS production.

Adenosine Monophosphate-Activated Protein Kinase (AMPK) Agonist Attenuated Epithelial-to-Mesenchymal Transition (EMT) of Mesothelium and Peritoneal Fibrosis via an Amelioration of Oxidative Stress. Duk-Hee Kang, Juyeon Ko, Eun-sun Ryu, Hyun-yon Jung, Shina Lee, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Sun-Hee Park, Yong-Lim Kim. Dept. of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea; Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.

Background: Phenotype transition of peritoneum has been regarded as an early mechanism of peritoneal fibrosis. Metformin, one of the AMPK agonists, has recently received a new attention due to an inhibitory effect on EMT of cancer cells. We investigated whether metformin imposed any effect on EMT of HPMC with an exploration of cellular mechanism for anti-fibrotic effect of metformin.

Methods: EMT was evaluated by morphological changes and the expressions of E-cadherin and α-SMA after stimulation of TGFB1 (1ng/ml). ROS generation was analyzed by measurements of NOX activity, NOX mRNA expressions, and MitoSox staining. Activation of Smad2/3, MAPK, nuclear translocation of β-catenin and snail expression were also assessed. Animal model of peritoneal dialysis (PD) was established by daily infusion of H2O2 (100mM), peritoneal NOX- and mitochondria-mediated ROS production. TGFB1-induced EMT was partially alleviated by N-acetyl cysteine (5mM) or apocynin (100µM), which was further inhibited by an addition of rotenone (1µM) or paricalcitol.

Conclusions: One of the VDRAs, paricalcitol, ameliorated TGFB1-induced EMT of HPMCs by a decrease in ROS generation in HPMCs. Anti-oxidant effect of paricalcitol seems to be related to the direct inhibition of NOX and mitochondria-mediated ROS production.

FR-PO817
Twist Accelerates Human Peritoneal Mesothelial Cells Proliferation and Fibrosis by Regulating YB-1. Liijie He. Dept of Nephrology, Xijing Hospital, Xi’an, China.

Background: We have previously shown that E-box-binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Methods: We have previously shown that E-box-binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Results: Here, up-regulated expression and activation of Twist and YB-1 were found in HPMCs under extensive periods of PM fibrosis ex vivo. In immortal HPMCs and in HG-induced PD animal model, Twist and YB-1 were also up-regulated and a transformed fibroblastic phenotype of HPMCs was found stimulated by high glucose (HG, 60mM/L).

Conclusions: Our data suggested that activation of Twist/YB-1 pathway might contribute to the growth retardation of HPMCs and the progressive PM fibrosis during PD.

FR-PO818

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. We know that miR-200a belong to miR-200 family, which is closely related to a variety of fibrotic diseases.However, the role of miR-200a in peritoneal fibrosis is largely unknown.

Methods: The peritoneal fibrosis mouse model associated with PD was established by intraperitoneal injection of lipopolysaccharide + 4.25% peritoneal dialysate. The expression of miRNA was detected by microarray. The expression of miRNA profiles between fibrotic and normal peritoneal tissues was compared (n=3 in each group). The differentially expressed miRNA (miR-200a) was validated by real-time PCR in larger sample size cohorts (n=15). The expressions of miR-200a were also detected in the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelial cells.

Results: In mice model of PD, peritoneal tissue was markedly thickened and with a massive extracellular matrix accumulation. By microRNA microarray analysis, miR-200a was significantly down regulated (3.31 folds change, P<0.05) in fibrotic peritoneal tissues. The down-regulated expression level of miR-200a was also validated by real-time PCR in larger cohorts (P<0.05). Then, the expression level of miR-200a was detected in the EMT process of human peritoneal mesothelial cells. During the process of TGFB1 induced EMT, miR-200a was significantly down-regulated compared with the control (P<0.05)

Conclusions: Our data suggested that activation of Twist/YB-1 pathway might contribute to the growth retardation of HPMCs and the progressive PM fibrosis during PD.

Effects of Astragaloside IV against the TGF-β-Induced Epithelial-to-Mesenchymal Transition in Peritoneal Mesothelial Cells by Promoting Smad7 Expression

Zhenghong Li,1,2 Zhenhong Li,1 Weiming He,1 Lingdong Xu,2 Jing Wang,1 Jun Shi,1 Meixiao Sheng.1,2 1The First Clinical Medical College, Nanjing Univ of Chinese Medicine, Nanjing, Jiangsu Province, China; 2Renal Div, Jiangsu Province Hospital of Chinese Medicine, Nanjing, Jiangsu Province, China; 3Jiangsu Province Academy of Traditional Chinese Medicine, Nanjing, Jiangsu Province, China.

Background: To investigate the effect of Astragaloside IV (AS-IV) on the regulation of the TGF-β1-Smad signaling pathway in peritoneal mesothelial cells with an epithelial-to-mesenchymal transition (EMT).

Methods: EMT of human peritoneal mesothelial cells (HMrSV5) was induced using 2 ng/ml TGF-β1. Cells were randomly divided into a vehicle group, a vehicle group with AS-IV, a TGF-β1-treated group, and a TGF-β1-treated group receiving varied doses of AS-IV or NAC. Real-time quantitative PCR and western blot were used to detect the expression of genes and proteins associated with the TGF-β1-Smad signaling pathway and EMT. DCFH-DA was used to detect the generation of ROS in HMrSV5 cells, and a transwell migration assay was used to verify the capacity of AS-IV to inhibit EMT in HMrSV5 cells. Lentiviruses were used as carriers for the overexpression or knockdown of the Smad7 gene.

Results: Expression levels of E-cadherin (epithelial marker) were decreased and vimentin, α-SMA (EMT markers) and collagen I (extracellular matrix protein) phosphorylated Smad-2/3, Snail1 and Snail2 increased significantly in the TGF-β1-treated HMrSV5 cells. AS-IV was associated with downregulated expression of vimentin and phosphorylated Smad-2/3 in a dose-dependent manner, while the expression of Smad7 increased. Silenced or forced expression of Smad7 verified its role in the inhibitory effect of AS-IV on TGF-β1-induced EMT in HMrSV5 cells.

Conclusions: AS-IV effectively promotes the upregulation of Smad7 in the TGF-β1-Smad signaling pathway during the EMT of HMrSV5 cells, indicating its potential therapeutic effect for the control of peritoneal dialysis associated fibrosis (PD-FA). Funding: Government Support - Non-U.S.

Extracellular Vesicles in Peritoneal Effluent

Deirisa Lopes Barreto,1 Anita N. Boing,1 Rienk Nieuwland,2 Anita Grooteveld,2 Raymond T. Krediet.1 1Nephrology, AMC-UvA, Netherlands; 2Clinical Chemistry.

Background: Continuous and long-term exposure to peritoneal dialysis (PD) solutions induces constant low-grade inflammation and remodeling of peritoneal membrane morphology. Although the biochemical composition of peritoneal effluent offers the opportunity to explore the peritoneal membrane status in a simple and non-invasive manner, to date no clinically useful effluent biomarker has been identified that reflects the peritoneal membrane integrity sufficiently. As human body fluids contain extracellular vesicles (EVs), which are now believed to provide novel biomarkers for diseases, we investigated the presence of EVs in peritoneal effluent.

Methods: Peritoneal effluent of a short-term PD patient was collected from a regular dialysis dwell. After centrifugation, aliquots of cell-free effluent were frozen in liquid nitrogen and stored at -80°C until analysis. EVs were isolated by size exclusion chromatography. Thereafter, transmission electron microscopy (TEM) and flow cytometry (comprising markers for epithelial and mesothelial cells, leukocytes, platelets and erythrocytes) were used to detect the presence of single EVs.

Results: EVs and liposomes were identified by TEM and flow cytometry. EVs exhibited their characteristic cup shape. The majority of EVs had a mean diameter <100nm, and were present in similar amounts as in human plasma. Most EVs originate from epithelial and mesothelial cells. Moreover, EVs stained positive for leucocyte antigens, mesothelin and cancer antigen 125.

Conclusions: This is the first study to demonstrate the presence of EVs in human peritoneal effluent. Furthermore, the cellular origin of most peritoneal EVs is established.

FR-PO819
Peritonitis Induces Native and EDA+ Fibronectin Synthesis in Human Peritoneal Mesothelial Cells Through PI3K and MAPK Activation

Susan Yung, Na Li, Mei Chau, Mandy K. M. Kam, Daniel Tak Mao Chan. Dept of Medicine, The Univ of Hong Kong, Hong Kong.

Background: Peritonitis is a severe complication of peritoneal dialysis (PD), which could lead to progressive structural and functional deterioration of the peritoneum and PD failure. EDA+ fibronectin (FN) is induced during disease states, but its expression in PD associated peritonitis has not been investigated. We examined peritoneal expression of native and EDA+ FN, collagen and SNAIL synthesis.

Methods: Male C57BL/6 mice were challenged with PBS or lipopolysaccharide (LPS, 500mg) by intraperitoneal injection for 2, 3 and 6 times (n=6), after which time the peritoul peritonitis was excised for further studies. Confluent, growth arrested human peritoneal mesothelial cells (HPMC) were stimulated with peritonitis PD fluid, LPS, or exogenous TGF-β1 or CTGF (growth factors that are increased during peritonitis) either alone or in combination, for periods up to 72h to investigate their effect on cell morphology, and FN, collagen and SNAIL synthesis.

Results: Mice exposed to six, but not fewer, challenges of LPS exhibited mesothelial denudation, influx of infiltrating cells and substantial submesothelial thickening attributed to increased collagen and native and EDA+ FN deposition. Peritonitis PD fluid induced phenotypic changes, and SNAIL, collagen I, and native and EDA+ FN synthesis in HPMC. Exogenous TGF-β1, but not CTGF, significantly increased native and EDA+ FN by 4.3-fold and 6.2-fold respectively (P<0.05 for both). Cells co-stimulated with TGF-β1 and CTGF showed synergistic increase of native and EDA+ FN. This was mediated in part through PI3K, ERK and p38 MAPK activation. TGF-β1 and CTGF neutralizing antibody significantly decreased native and EDA+ FN synthesis, but had no effect on collagen I or SNAIL expression in HPMC.

Conclusions: Our data demonstrated that peritonitis, especially when recurrent, induced progressive peritoneal deposition of collagen, and native and EDA+ FN, TGF-β1 and CTGF synergistically induced native and EDA+ FN synthesis in HPMC, and play important roles in peritoneal fibrosis induced by bacterial peritonitis.

We postulate that the presence and composition of such EVs in peritoneal effluent will closely mirror the peritoneal membrane morphology. Future studies will be necessary to investigate the clinical relevance for the detection of peritoneal membrane damage and potential use of these peritoneal EVs in PD patient care.

FR-PO822

miR-200a Negatively Regulates TGF-β1-Induced Peritoneal Mesothelial Cell Epithelial-Mesenchymal Transition by Targeting ZEB1 and ZEB2 Expression Xin Wei, Guojun Hao, Qinkai Chen. Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. In our previous study, we found that the expression level of miR-200a were down-regulated in fibrotic peritoneum and the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelial cell. However, the role of miR-200a in EMT of peritoneal mesothelial cell and peritoneal fibrosis is largely unknown.

Methods: Human peritoneal mesothelial cell line (HMMSV5) was cultured in the presence or absence of TGF-β1. The protein expression levels of EMT index and E-box-binding homeobox (ZEB) 1/2 were determined by western blot. The level of miR-200a was determined by real-time PCR. miR-200a mimic or inhibitor and negative control RNA was transfected into HMMSV5 cells using Lipofectamine 2000.

Results: We found that miR-200a mimic can attenuated TGF-β1 induced peritoneal mesothelial cell EMT and synthesis of extracellular matrix. It was also demonstrated that the miR-200a was responsible for protecting peritoneal mesothelial cells from mesenchymal transition by targeting suppression of ZEB1/2.

Conclusions: The results suggested that miR-200a may not only be a useful biomarker of EMT in ovarian cancer, but also of potential therapeutic value in peritoneal fibrosis.

Funding: Government Support - Non-U.S.

FR-PO823

Identification and Functional Characterization of Human Peritoneal Fibroblast Subsets According to the Expression of CD90/Thy-1 Edyta Kawka,1 Andras Rudolf,2 Maria Bartosova,2 Rusan Catar,1 Janusz Witowski,2 Duska Dragun,1 Achim Joerres,1 Claus P. Schmitt.1 1Dept of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; 2Dept of Pathophysiology and Clinical Immunology, Poznan Univ of Medical Sciences, Poznan, Poland; 1Center for Pediatric and Adolescent Medicine, Universitätsklinikum Heidelberg, Heidelberg, Germany.

Background: The exact origin of myofibroblasts in PD-associated peritoneal fibrosis is unknown. Lineage tracing studies suggest that resident submesothelial fibroblasts may be their major precursors. Here, we set out to identify HPFB subsets in human peritoneum and examined co-expression of CD90/Thy-1 with markers of the myofibroblastic phenotype.

Methods: HPFB were isolated from omentum, purified and then separated (MACS) into CD90/Thy-1+ and CD90/Thy-1− populations for assessment of myofibroblastic markers.

Conclusions: The role of miR-200a in EMT of peritoneal mesothelial cell and peritoneal fibrosis is largely unknown.

Funding: Cell-free DNA is present in the peritoneal effluent of stable PD patients, but there is no data on cDNA in case of peritonitis. We investigated the variation of peritoneal cDNA (pcDNA) levels in PD-related peritonitis.

Methods: We enrolled 53 PD patients: 30 without any history of systemic inflammation and peritonitis in the last 3 months (group A) and 23 with acute peritonitis (group B). pcDNA were quantified by Real-Time PCR. Peritoneal samples on day 1-3-10 and until the 120th from the start of peritonitis were collected for WBC counts and pcDNA evaluation in group B.

Results: Quantitative analysis of pcDNA showed significantly higher levels in group B compared with group A (p<0.01), similarly as WBC. pcDNA showed significantly higher levels in group B on day 1-3-10 and 30 compared with group A (p<0.05). A significant positive correlation was observed between pcDNA level and WBC on day1 (rho=0.89) and day3 (rho=0.5) both p<0.05. No statistically significant correlation was observed on day10 and 30. In group B, pcDNA tends to progressively decrease. From this decreasing curve, we estimated that 49 days are necessary to reach the value of 51 GE/ml (75 percentile in group A) and 63 days to reach 31 GE/ml (median). We observed a new rapid increase of pcDNA level (consistent with WBC) in 5 relapsing patients, at the first day of relapsing peritonitis.

Conclusions: pcDNA increased in peritoneal effluent in PD-related peritonitis and tended to progressively decrease in relation with membrane repair process. Peritoneal cDNA could be a new method to determine acute damage and an inverse index of repair process. PefDNA could help to evaluate functional and structural integrity of peritoneal membrane and to follow the evolution of infections during peritonitis.

The Role of Cell-Free DNA for Management in PD-Related Peritonitis Grazia Maria Virzì, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. Nephrology, San Bortolo Hospital-IRRI

Background: Peritonitis and exit site infections are the major complications of PD and remains the major cause of switch from HD. In this study, we investigated the role of peritoneal cell-free DNA (cDNA) and its association with peritonitis.

Methods: We enrolled 23 PD patients with peritonitis and without any history of systemic inflammation (14 male, mean age: 68±16yrs). cDNA was extracted and quantified in peritoneal effluent by Real Time PCR for β-globin gene.

Results: All patients were treated and clinically recovered from peritonitis in 13.5±4 Days. 18/23 patients had a first episode of peritonitis and responded to first-line antibiotics (65% Gram+, 22% Gram- and 13% sterile), whereas 5/23 had a relapsing episode of peritonitis (responded to other course of intra-peritoneal antibiotics). There were 1.2-fold greater reduction in collagen gel contraction assays (n=3).

Conclusions: The results suggested that miR-200a may not only be a useful biomarker of EMT in ovarian cancer, but also of potential therapeutic value in peritoneal fibrosis.

Funding: Government Support - Non-U.S.
no was difference in cDNA levels between Gram- (+Gram-peritonitis; patients with single episode and relapsing peritonitis, but there was a significantly difference in cDNA between PD patients with positive and negative outcomes (n=4), defined as death (p<0.05). cDNA shown significantly higher 1 level in 3 patients required catheter removal(p<0.05). There was no difference in cDNA levels between PD patients with a negative history of previous peritonitis (n=3) and PD patients with a positive history (n=20)(p=0.48). there was no statistically significant correlation between cDNA and number of previous peritonitis (r=0.13, p=0.55).

Conclusions: This pilot study provided substantial basis for further investigations of molecular mechanisms of peritoneal injury and potential clinical application of cDNA. cDNA could provide some additional information about patient’s outcome and management. These results can be considered hypothesis generating, and stimulate further exploration of a prognostic and predictive role of cDNA in PD-related peritonitis.

FR-PO826

Epimorphin Expressions in Mice Model of Peritoneal Fibrosis Munchuan Yamada, Takashi Oda, Shuuhei Komatsu, Taito Oshima 1,2 Kimio Watanabe, 1 Hiroyuki Terawaki, 1 Yoshimitsu Hayashi, 1" 1Dept of Nephrology, Hachioji Medical Center of Tokyo Medical Univ, Hachioji, Tokyo, Japan.

Background: Long-term peritoneal dialysis induces peritoneal fibrosis in submucosal area. Epimorphin is a mesenchymal protein that regulates epithelial morphogenesis through epithelial-mesenchymal transition, has recently attracted attention as an important modulator of tissue repair. We previously reported that epimorphin was involved in the repair of fibrosis in mice (Lab Invest 2010). In this study, we evaluated the epimorphin expressions in the peritoneal fibrosis mice model.

Methods: Peritoneal fibrosis was induced by the injection of 0.1% chlorhexidine gluconate in 15% ethanol and 85% normal saline (CG-injected mice) into peritoneal cavity of 10-week-old male C57B16 mice every other day. Control mice received intraperitoneal injection of normal saline. The mice were sacrificed 3 weeks after the first CG injection and peritoneal tissues were dissected out. Morphologic peritoneal changes were assessed by Masson’s Trichrome staining. Epimorphin expressions were assessed by immunohistochemically and real-time RT-PCR.

Results: In CG-injected mice, the marked thickening of the submesothelial compact zone was shown in Masson’s trichrome staining. IF staining for epimorphin was positive in the submucosal area corresponding to the fibrotic area. Epimorphin staining was significantly stronger than that in control mice. Such an increase in epimorphin expression was confirmed by and real-time RT-PCR (n=5, p<0.05 vs control).

Conclusions: These findings suggest that epimorphin expression may have pivotal role in the repair of peritoneal fibrosis similar to that of UUO release model in mice.

FR-PO827

Peritoneal Mesothelial Cells (PMCs) Injury Induced by Neutral Peritoneal Dialysis Solution (NPDS) and Its Amelioration by Molecular Hydrogen (H2) Wai-lun Zhu,1 Kinue Watanabe,2 Hirokuni Terawaki,1 Yoshimitsu Hayashi,1 Naoki Nakamichi,1 Shigeru Kabayama,2 Masaaki Nakayama,2 1Dept of Pediatrics, Japan, Pediatrics, 2Medical School, Fukushima Medical University, Fukushima, Japan.

Background: PMCs play pivotal roles in suppression of peritoneal fibrosis, adhesion, and bacterial infection in PD therapy. It is reported that histological changes of peritoneum and incidence of encapsulating peritoneal sclerosis, have been decreased by NPDS introduction. However, meta-analysis did not show superiority of NPDS in incidence of bacterial peritonitis, suggesting bio-incompatibility of current NPDS. H2 has anti-oxidative effects in biological way, and its clinical application has been studied. The present study aims to examine PMC injury by NPDS, and its ameliorating effect of H2.

Methods: Male SD rats (n=24) were divided into three groups: control (Con), 2.5% glucose lactate-based NPDS (PD), and the same NPDS with dissolved H2 (400 ppb) (HPD). The latter two groups were given NPDS or H2-NPDS intraperitoneally for 20 ml once a day. Peritoneal tissues were subjected to morphological analysis including immunohistochemistry (cytokeratin, vimentin, proliferation: Ki67 and apoptosis: M30 cytodeath), and PMCs obtained to gene analysis by real time PCR, and microarray assay.

Results: The collagen thickness increased in PD and HPD, however, there were significant changes in stainings of vimentin, M30 cytodeath, and Ki67 in PD as compared to control, with no change in HPD. In gene cluster analysis, there were changes by 8.7% in whole gene expression between PD and Con, and 3.7% changes between PD and HPD. In PCR, no difference was found in Epithelial-Mesenchymal Transition (Snail, TGF-β, αSMA) among the groups, while wound healing (MMP9, CTGF, Fibronectin, FAK), cytokines (IL1β, TNFα, FAK) were decreased in PD as compared to Con, but no changes in HPD.

Conclusions: The current lactate-based NPDS may disturb wound healing and local immunity of PMCs, and H2 dissolved dialysate correct them. H2 could increase biocompatibility of PDS in preserving physiological function of PMCs in PD therapy.

FR-PO828

Background: Long-term peritoneal dialysis is associated with functional and structural alterations of the peritoneal membrane. Lactate-buffered peritoneal dialysis fluid (L-PDF) has impaired biocompatibility due to the presence of supra-physiological levels of lactate. Although bicarbonate-buffered PDF (B-PDF) has been developed, its biocompatibility remains unclear. Here, we investigated the effects of L- or B-PDF on cell to cell apoptosis in cultured human peritoneal mesothelial cells (HPMCs), focusing on monocarboxylate transporters (MCT).

Methods: HPMCs were cultured in media containing 10% fetal bovine serum and L-PDF with 1.5% glucose (L1) or 2.5% glucose (L2), B-PDF with 1.5% glucose (B1) or 2.5% glucose (B2), or no PDF (control). Cell viability and apoptosis were measured with the WST-1 and TUNEL assays, respectively. The roles of MCT-1 and -4 on lactate-induced apoptosis were evaluated by siRNA transfection for MCT-1 and -4.

Results: Cell viability was significantly decreased in cells incubated with L1 (12.2% vs. control-100%) and L2 (21.1%), compared with B1 (74.2%) and B2 (72.2%) after 72 h incubation. Apoptotic cells were also increased in L1 (69±16%), L2 (73±8%) compared with B1 (3±0%) and B2 (±1%). MCT-1 and -4 protein and mRNA expression levels, examined by Western blotting and real-time-PCR, respectively, were similar in all cells. Protein expression levels of MCT-1 and -4 were almost completely diminished after transfection of siRNA's for MCT-1 and -4, respectively. MCT-1 siRNA increased the levels of cell viability by 3.2–3.7-fold and decreased the amount of apoptotic cells from 64±8% to 47±4% in cells treated with L1 for 72 h. Interestingly, MCT-4 siRNA had no effect on cell viability and apoptosis.

Conclusions: Our results showed that L-PDF induced apoptosis by importing lactate via MCT-1 in HPMCs, and suggest that B-PDF improved biocompatibility by inhibiting mesothelial cell apoptosis.

FR-PO829

MiRNA-143/145 Gene Cluster Enhances Cell Deformation and Fibrosis of Human Peritoneal Mesothelial Cells via Modulating TPM4 Li-Jie He, Shiren Sun. Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: In this study, we worked for the function and mechanism of miR-143-145 gene cluster in human peritoneal mesothelial cells (HPMC), who were as possible triggers for peritoneal membrane fibrosis.

Methods: To investigate if miR-143/145 gene cluster could promote PM fibrosis, all these immortal HPMCs were characterized by fibrosis related markers and tested the expression of miRNA-143/145 cluster and tropomyosin4 (TPM4) by real time PCR or Western blot. We also used PD dialysis rat model to observe the response of PM to miR-143/145 gene cluster and their possible target.

Results: Here, we found that miR-143/145 gene cluster, which are examined to be highly expressed in HG-induced HPMCs (HG, 60 mmol/L) and in PD animal model. TPM4 were found significantly lower expression in HG-induced HPMCs. So our study was based on high glucose for human peritoneal fibrosis, and we found that miR-143/145 of HPMCs and reduce the expression of TPM4, compared with normal glucose-cultured HPMCs. Reporter assays further supported that TPM4 were post-transcriptionally regulated together by miR-143-145 gene cluster. Collectively, these data suggested that TPM4 was a key target gene for miR-143/145 gene cluster. Re-expression of miR-143/145 gene cluster by miR-143 or miR-145 mimic led to cell deformation, and reduced cell adhesion, following the down-regulating expression of TPM4 and E-cadherin, but up-regulating expression of α-SMA, CTGF, collagens and fibronectin which might increase PM fibrosis.

Conclusions: Our data suggested that miR-143/145-TPM4 pathway might contribute to the cell deformation of HPMCs and the progressive PM fibrosis during PD.

Mitochondrial DNA Copy Number Is Associated with Peritoneal Dialysis Failure in Younger and Metabolically Healthier Peritoneal Dialysis Patients

**Background:** Insulin resistance and inflammation are known to be closely related to adverse outcomes in peritoneal dialysis (PD) patients. Recently, mitochondrial function has been reported to play a key role in glucose metabolism as well as systemic inflammation in various populations. However, the clinical consequences of mitochondrial function in PD patients are not well known. Therefore, this study aimed to investigate the relationship of mitochondrial DNA (mtDNA) copy number and clinical outcome in PD patients.

**Methods:** A total of 120 prevalent PD patients were recruited. mtDNA copy number was counted by a PCR based method. Primary outcome was PD catheter removal due to ultrafiltration failure. Metabolic syndrome was defined using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Cox proportional hazard analysis was performed to determine the independent association of mtDNA copy number with primary outcome.

**Results:** The mean age was 52.3 years and 52 patients (42.5%) were male. The mean mtDNA copy number was 29.1±14.9. During a mean follow-up duration of 59.4±39.3 months, primary outcome was observed in 54 patients (45.0%). There were no significant differences in baseline characteristics between non-PD and PD failure group except for serum adiponectin levels (20.5±7.3 vs. 17.5±7.3 mg/mL, P=0.028). mtDNA copy number was significantly associated with PD failure in multivariate Cox analysis (hazard ratio (HR)=0.995, 95% confidence interval (CI)=0.976-1.015, P=0.634). However, a subgroup analysis revealed that mtDNA copy number was an independent predictor of PD failure in patients younger than 55 years without metabolic syndrome (HR=0.819, 95% CI=0.692-0.970, P=0.020) after adjustment for confounding factors.

**Conclusions:** mtDNA copy number may be associated with ultrafiltration failure in younger and metabolically healthier patients treated with PD.

**FR-P0830**

IL-6 Induces VEGF Production by Human Peritoneal Mesothelial Cells During Peritonitis Through SP4-Mediated Trans-Signaling with sIL-6R

**Background:** Vascular endothelial growth factor (VEGF) has been implicated in peritoneal angiogenesis and membrane remodelling in peritoneal dialysis (PD). Human peritoneal mesothelial cells (HPMC) have been identified as a major source of VEGF in the peritoneum. However, the exact mechanism of VEGF induction in HPMC is unclear. Since IL-6 concentrations in the drained dialysate correlate with VEGF levels, the link between the two has been suggested. While HPMC do not bear classical IL-6 receptor, they can respond to IL-6 trans-signaling that involves soluble IL-6 receptor (sIL-6R). Here, we have examined whether this mechanism can underlie VEGF synthesis by HPMC. By transfection of HPMC with SP4, a transcriptional factor that binds to the VEGF promoter, we have shown that SP4 is required for IL-6 induction of VEGF.

**Methods:** HPMC were isolated from normal omentum. Dialysate effluent was obtained from stable PD patients and during peritonitis. VEGF mRNA and protein levels were measured by RT-qPCR and ELISA, respectively. The involvement of transcriptional factors was assessed by EMSA, transient transfections with VEGF promoter constructs, and siRNA silencing.

**Results:** IL-6 and sIL-6R alone had no effect on VEGF release by HPMC. However, the exposure to IL-6+sIL-6R resulted in a time- and dose-dependent induction of VEGF mRNA and protein. The combination of IL-6+sIL-6R activated the VEGF promoter region that contained high affinity binding sites for the transcription factor SP4. Specific mutation of the SP4 binding site eliminated VEGF promoter activation. In turn, the induction of SP4 was controlled by STAT3. Exposure of HPMC to dialysate effluent obtained during acute peritonitis and containing increased levels of IL-6 and sIL-6R resulted in a dose-dependent VEGF induction. This effect was significantly attenuated in cells treated with siRNAs for either SP4 or STAT3.

**Conclusions:** Dialysate IL-6 and sIL-6R act through the trans-signalling pathway controlled by the STAT3-SP4 axis to up-regulate mesothelial VEGF production during peritonitis.

**Funding:** Government Support - Non-U.S.

'H NMR Based Metabolome Can Predict Relapsing Peritonitis and Differentiate Bacterial and Fungal Peritonitis as Well

Jae Hyun Um, Jong Hyun Jhee, Kyoung Sook Park, Chang-Yun Yoon, Mi-Jung Lee, Jung Tak Lee, Shin-Wook Kang, Tae-Hyun Yoo, Eun Wook Kang, Narayan Prasad.

**Background:** Metabolomics is a powerful but resource-intensive approach for the study of metabolic changes in human disease. In the past few years, metabolomics has gained increasing attention in different diseases of human origin, including cardiovascular diseases, diabetes, cancer, and infections. In the present study, we aimed to develop a metabolomic-based approach for predicting relapsing peritonitis and differentiating bacterial from fungal peritonitis.

**Methods:** Five unused PD fluid, 13 effluent from normal PD and 45 effluents from 15 patients (at baseline, 1 week and 2 weeks of therapy) with BP including 3 who relapsed and 3 FP were included. Half of each was subjected to total and differential WBC count and culture; and half was frozen at -80 °C for NMR analysis. BP and FP was diagnosed based on identification of organism. RP was defined as per standard definition. High Resolution NMR spectra were recorded at 29V K on a Bruker Avance III 800 MHz spectrometer. Standard 1D 1H NMR spectra were acquired using the Carr–Purcell–Meiboom–Gill (CPMG) pulse sequence. To confirm the assignment of marker peak, two-dimensional (2D) HH-1H TOCSY and 1H-13C HSQC spectra were also acquired.

**Results:** Five unused and 15 normal PD effluents after 6 hours of dwell did not show any marker peak at NMR spectra at 0.67 ppm while 15 cases of BP showed marker peak; however marker peak disappeared after resolution of peritonitis at 1 week and 2 weeks of antibiotic therapy except for 3 cases which relapsed in whom marker peak was persisting despite absence of clinical peritonitis. In the 3 cases of FP did not show any such marker peak differentiating it from BP. Marker signal represent trans-methylene protons of cyclopropene ring moiety as reported earlier and depicted in Figure 1.

**Conclusions:** The cyclopropene signal at 0.67 ppm can be marker signal to differentiate BP and FP and persistence of this signal at 2 weeks after clinical resolution of peritonitis predicts RP.

**FR-P0833**

Peritoneal Mesothelial Cell Sodium Glucose Co-Transporter 1 (SGLT1) Regulates VEGF Production: Potential Target in Ultrafiltration Failure

**Background:** D-glucose and vascular endothelial growth factor (VEGF) are important in the development of ultrafiltration failure (UFF) in peritoneal dialysis (PD). The role of glucose transport in peritoneal mesothelial cells (PMC) in UFF is unknown. Herein we hypothesize that the glucose transporter SGLT1 is increased in response to high glucose and regulates VEGF production.

**Methods:** PMC, obtained from omental digestion of non-PD patients and from spent PD dialysates, were incubated for 48 hrs under 200mM D-glucose or L-glucose, 200mM mannitol, 200mM 3OMG a non-metabolizable glucose analog transported by SGLT1, 7.5% icodextrin, with and without 50μg/ml phlorizin (Ph), an SGLT1 inhibitor. VEGF was measured by ELISA. mRNA for VEGF and SGLT1 was measured by RT-PCR. Immunofluorescence microscopy for cytokeratin and SGLT1 was performed on human peritoneal biopsies obtained at PD catheter insertion (CI) and at catheter revision (CR) after 6 months of PD. Results: SGLT1 expression was minimal in PMC in biopsies at CI, but abundantly present in PMC in biopsies at CR. PMC’s cultured under 200 mM D-glucose had a 6 fold increase in SGLT1 mRNA vs 5mM D-glucose and an increase in VEGF: 70 ±9.9 pg/mg to 2,456 ±189 pg/mg (p<0.05). D-glucose stimulation of VEGF was partially inhibited by 50 μM Ph: 6,988 ± 405 pg/mg to 3,991 ±289 pg/mg (p<0.003). 3OMG also stimulated VEGF: 71 ± 1.9 pg/mg to 1,474 ±160 pg/mg (p<0.01) that was inhibited by Ph 623 ± 74 pg/mg, suggesting Ph inhibition of VEGF is partly independent of glucose metabolism (p<0.05). 200mM L-glucose stimulated VEGF less than D-glucose (543 ± 35pg/mg, p<0.01). This stimulation was inhibited by Ph (123 ± 12 pg/mg). 7.5% icodextrin vs 5mM Glucose did not stimulate VEGF production (47 ± 5.1 pg/mg, p<0.005).

**Conclusions:** SGLT1 expression in PMC is upregulated in response to high D-glucose in vivo and in vitro. Glucose transport regulates VEGF production under high D-glucose conditions, which may provide a therapeutic target for UFF.

CVD. Increased intact parathyroid hormone and FGF-23 levels are associated with the progression of peritoneal dialysis (PD) in chronic PD patients. N-acetylcysteine (NAC) acts on atherosclerosis and also improves the endothelial functions. This study was designed to evaluate the correlation between FGF-23, endothelial dysfunction and markers of inflammation in chronic PD patients and to evaluate the effect of three months of NAC on these parameters.

**Methods:** All patients underwent Doppler studies to assess endothelial function by the flow-mediated dilatation (FMD) of the brachial artery and carotid arterial intima media thickness (CIMT). Brachial artery was imaged during reactive hyperemia (endothelium-dependent dilatation, FMD) and during the brachial artery with acetylcholine (endothelium-independent dilatation, nitroglycerine-mediated dilatation, NMD, endothelium-independent) in all PD patients. NAC was given in the dose of 1200 mg in two divided doses for a period of three months. The associations between different parameter were analyzed using Spearman correlation. All the parameters were repeated after three months of therapy with NAC.

**Results:** A total of 73 chronic PD patients were enrolled in this study. FGF-23 showed strong positive correlation with serum homocysteine level (r = 0.10, P < 0.001), hsCRP (R = 0.977, P < 0.001), Endothelium Dependent Dilatation (EED) (r = 0.968, P < 0.001) and CIMT (r = 0.994, P < 0.001), but negatively correlated with Endothelium Independent Dilatation (EID) and Vitamin D level. All these parameters including FGF-23, hsCRP, homocysteine, CEMT and EDD were significantly reduced after three months of therapy with NAC.

**Conclusion:** FGF-23 correlated well with inflammatory markers and endothelial function. With three months of therapy, NAC significantly reduces the CIMT, inflammatory markers and improves the endothelial function in chronic PD patients.

**SRF Enhances Cell Adhesion, Migration and Peritoneal Fibrosis via Modulating miRNA-199a-214 Cluster in Human Peritoneal Mesothelial Cells**

**Lijie He, Shiren Sun.**

**Dept of Nephrology, XiJing Hospital, Xi’an, Shaanxi, China.**

**Background:** Our previous work showed that serum response factor (SRF) was involved in fibrosis of peritoneal membrane, but the exact underlying mechanism were still unclear. Here we further study the role of miR-199a-214 cluster and the relationship of SRF in peritoneal fibrosis.

**Methods:** We isolated HPMCs from the effluents of end-stage renal disease (ESRD) patients with peritoneal dialysis (PD), and also used PD dialysate rats model to observe the response of PM to miR-199a/214 cluster and the predicted target CDH1 and CLDN2.

**Results:** In this study, we found that miR-199a-5p/214 cluster, which was examined to be highly expressed in HG-induced HPMCs by real time PCR, was directly regulated by SRF after HG stimulation. All these HG induced immortal HPMCs became scatter, to be highly expressed in HG-induced HPMCs by real time PCR, was directly regulated by SRF after HG stimulation. All these HG induced immortal HPMCs became scatter. We also found that SRF acted on atherosclerosis and also improved the endothelial functions. This study was designed to evaluate the correlation between FGF-23, endothelial dysfunction and markers of inflammation in chronic PD patients and to evaluate the effect of three months of NAC on these parameters.

**Conclusion:** FGF-23 correlated well with inflammatory markers and endothelial function. With three months of therapy, NAC significantly reduces the CIMT, inflammatory markers and improves the endothelial function in chronic PD patients.

**Choice of Dialysis Modality for Children with End Stage Renal Disease**

**Julien Houngu,1  Cecile Cosseau-maier,2  Pediatric Nephrology, Robert Debére Hospital, Paris, France; SERIN Registry, Agence de la Biomédecine, La Plaine Saint Denis, France.**

**Background:** Despite many studies that aim to assess the best modality of dialysis, results remain conflicting both in adults and in children. This lack of medical evidence leads commentators to emphasize the importance of patients' choice in the decision process. Thus, we try to assess factors that impact the choice of the dialysis modality in children and to determine which from medical factors, center practices or patients' wishes plays the major role.

**Methods:** All incident patients <20 years old at start of dialysis, recorded in the French ESRD registry between 2002 and 2013 were included. We used multivariate hierarchical logistic regression models to study patients and centers characteristics associated with the probability of starting with peritoneal dialysis (PD). The effect of centers was assessed by including centers as a random effect.

**Results:** Among 806 patients treated in 177 centers, 601 (74.6%) started with PD, 121 (14.9%) with hemodialysis (HD) and 20 (25.4%) with PD. A higher probability of PD was found in patients younger than 1 year and in centers with an annual emergency associated with a low use of PD. Low and high educational level of the town of residence were both associated with less probability of PD when compared with average educational level. There was a significant variability between centers, that was not explained by patients' case-mix. Being treated in specialized pediatric centers was associated with less probability of PD, while the probability of PD was proportional to the rate of PD in the center.

**Conclusions:** Although little evidence exists to favor a dialysis modality over the other in children, PD remains the predominant modality in France. PD is still mostly offered to treatment-naive children while it remains understudied in patients starting RRT in emergency. However, we found that besides medical factors, centers practices play a major role in the choice of dialysis modality. This raise concerns about the place left to patients' and families' choices and to what extend doctors may influence the final decision. Further pediatric studies focusing on children and parents' wishes are needed in order to provide cares as close as possible to there expectations.
Clinical Course of Children Born with Chronic Kidney Disease – A Single Centre Experience
Christina Taylan, 1 Bernd Hoppe, 2 Eva Maria Haffner, 2 Lutz Thorsten Weber. 1 Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; 2 Pediatric Nephrology, Univ Hospital of Bonn, Bonn, Germany.

Background: The number of babies born alive suffering from chronic kidney disease (CKD) is constantly increasing.

Methods: We analyzed the outcome of infants with CKD and renal replacement therapy (RRT) that were treated within their first year of life. Between 2007 and 2013 17 infants (11 male; 6 female) developed end-stage renal disease resulting in RRT in our department.

Results: All of them received peritoneal dialysis (PD) initially at a median age of 34 [1-334] d. During follow-up 10 children underwent renal transplantation (RTx), 1 child was still on PD at last follow-up, 1 child had to go back to hemodialysis after graft loss and 2 had a recovery of renal function. 3 out of 17 children died during the PD period. Causes of death were severe sepsis twice and one cerebral bleeding. The mean GFR at last follow-up (2.2±6.37 years) of patients who underwent RTx was 105±22.8 ml/min/1.73 m². Mean time on dialysis was 11.1±14.3 months before RTx, mean age at transplantation was 29.2±14.2 months. Mental development was measured by Mental Development Index (Bayley Scales of infant development BSID-II) at an average age of 12 [9-16] months and showed developmental delay at the motor, mental and behaviour rating scale. At time of transplantation 6/10 infants had tube feeding, 9/10 were <3 percentile of height, 3/10 were <3 percentile of body weight.

Conclusions: RRT started in the first year of life was associated with reasonable outcome and should be offered to all infants with end stage renal disease. It is, however, associated with a high risk of developmental delay. This work emphasizes the great needs for research on this interdisciplinary field of pediatric nephrologists, psychologists and social workers.

FR-PO840
Altered Myogenesis and Oxidative Stress in a Rat Model of Chronic Kidney Disease
Keith Ayin, 1 Neal X. Chen, 2 Jason M. Organ, 3 Kaliala O’Neill, 4 Sharon M. Moe. 1 Dept Physical Therapy, Indiana Univ, Indianapolis, IN; 2 Div of Nephrology, Indiana Univ, Indianapolis, IN; 3 Dept of Anatomy, Indiana Univ, Indianapolis, IN; 4 VAMC, Indianapolis, IN.

Background: Skeletal muscle atrophy and impaired muscle function are associated with lower quality of life, and greater disability and mortality risk in those with chronic kidney disease (CKD). However, the pathogenesis of atrophy is unknown.

Methods: We used a slowly, progressively, naturally occurring, CKD rat model (Cy/ rat) and its normal littermate (NL). At 35 weeks, we tested muscle strength, sacrificed and collected tissues and blood. RNA and protein were isolated from skeletal muscle and real time PCR and western blot were performed.

Results: CKD rats developed sarcopenia evident by reduced cross sectional area (p<0.05), increased connective tissue deposition on histology (p<0.05), and impaired strength (p<0.05). Strength was defined as the maximal amount of force produced during maximal, electrically stimulated dorsiflexion. These findings of atrophy can be explained by reduced regeneration, increased catabolism, or differentiation of muscle stem cells toward myofibroblasts. By PCR, there was increased activation and differentiation of muscle stem cells (reduced Pax-7, increased MyoD and myogenin (p<0.05)) and increased proteolytic markers (increased Atrogin-1 and MuRF-1 (p<0.05). Fibrosis may be enhanced via decreased miR-29b (p<0.05) and increased Wnt5a (p<0.01). Finally myostatin was increased in blood and muscle RNA expression yet no difference in the activin type IIB. The long term consequences of the impaired balance of increased proteolysis and inadequate regeneration is further supported by mitochondrial derangement (electron microscopy) and increased mitochondrial complex I (p<0.05) despite decreased expression of the antioxidant nuclear erythroid 2-related factor 2 (p<0.05).

Conclusions: In a rat model of CKD, sarcopenia was present despite the activation of myogenic factors. The atrophy is due to a combination of factors including increased myostatin, increased expression of atrogenes, and the presence of oxidative damage. Augmentation of the myogenic and antioxidant responses through treatments may prevent progressive sarcopenia in CKD.

Can Calcitriol and Calcidiol to Regulate Toll Like Receptors 7, 9 and IL-6 in HD Patients?
Marina Dalboni, 1,3 Marion Schneider, 1 Lilian Cuppari, 1 Caren Cristina Grabulosa, 1 Silvia Regina Manfredi, 1 Edgar Maquigussa, 1 Danilo Takashi Aoki, 1 Miguel Cendoroglo Neto, 1 Jose Tarcisio Giffoni. 1 Nephrology Div, Univ Federal de Sao Paulo, Sao Paulo, Brazil; 2 Div of Nephrology, Univ Federal de Sao Paulo, Sao Paulo, Brazil; 3 Medicine, Tufts-New England Medical Center, Boston; 4 Medicine, Univ Nove de Julio, Sao Paulo, Brazil.

Background: Toll-like receptors (TLR) are involved in immunologic response. The TLR4 is related with cytokines and counter-regulators and therefore these vitamins alone to induce a degradation of 1,25 (OH)2D3, we did a CYP24 silencing, and observed an additional reduction in IL6, IFNγ, TLR7 and TLR9 expression on B and T lymphocytes for both treatment when compared to effect of 25(OH)D3 alone (p<0.05). In the same condition, we also observed an increase VDR expression.

Conclusions: Our results suggests that both 25(OH)D3, and 1,25 (OH)2D3, had immunomodulatory effects in B and T lymphocytes. This in vitro model confirm the antiinflammatory role of Vitamin D in uremia environment. However, these effects of Vitamin D were enhanced after CYP24 silencing. So, this data support that CYP24 inhibitors may also be a target of treatment in association with vitamin D supplementation to improve inflammatory response mechanisms.

FR-PO843
Effect of Cholecalciferol Supplementation on Toll Like Receptors 7, 9 Expression and IL-6 and IFN-γ Intraacellular on B and T Lymphocytes on Chronic Dialysis Patients
Maria Dalboni, 1,3 Marion Schneider, 1 Lilian Cuppari, 1 Caren Cristina Grabulosa, 1 Silvia Regina Manfredi, 1 Edgar Maquigussa, 1 Danilo Takashi Aoki, 1 Miguel Cendoroglo Neto, 1 Jose Tarcisio Giffoni. 1 Div of Nephrology, Univ Federal de Sao Paulo, Sao Paulo, Brazil; 2 Div of Nephrology, Univ Federal de Sao Paulo, Sao Paulo, Brazil; 3 Medicine, Tufts-New England Medical Center, Boston; 4 Medicine, Univ Nove de Julio, Sao Paulo, Brazil.

Background: Vitamin D deficiency is highly prevalent among patients in all stages of CKD. Studies have reported that the Vitamin D deficiency is associated with mortality and morbidity in CKD patients and may modulate TLRs that are involved in inflammatory responses. Thus, the purpose was evaluate the effect of cholecalciferol on IL-6, IFN-γ TLR-7 and TLR-9 expression in lymphocytes B and T in patients on dialysis with vitamin D hypominhemia.

Methods: In a randomized, placebo-controlled, double-blind study, we investigated the effect of cholecalciferol (100,000 UI once per week) for 3 months, in patients on chronic dialysis, who had nutritional vitamin D deficiency. The 25(OH)D3 detection was performed by immunoassay and the 25(OH)D3 levels were compared by Student t-test (p<0.05).

Results: TLR-7 and TLR-9 expression in lymphocytes B and T on patients on dialysis with vitamin D hypominhemia. The 25(OH)D3 detection was performed by immunoassay and the 25(OH)D3 levels were compared by Student t-test (p<0.05).

Conclusions: It is possible that the deregulation of TLR2 and TLR4 expression on lymphocytes may be caused by uremic toxins in CKD population. Besides, the high expression of TLR2 and TLR4 in these cells resulted in an increase of TLR-9 and IL-6 levels, suggesting that TLRs are associated with inflammatory mechanisms in uremic patients.

FR-PO847
Can Calciotropic and Calcidiol to Regulate Toll Like Receptors 7, 9 and IL-6 and IFN-γ Expression on Lymphocytes Incubated with Uremic Serum?
Marina Dalboni, 1,3 Marion Schneider, 1 Lilian Cuppari, 1 Caren Cristina Grabulosa, 1 Silvia Regina Manfredi, 1 Edgar Maquigussa, 1 Danilo Takashi Aoki, 1 Miguel Cendoroglo Neto, 1 Jose Tarcisio Giffoni.

Background: Vitamin D deficiency is highly prevalent among patients in all stages of CKD. Studies have reported that the Vitamin D deficiency is associated with mortality and morbidity in CKD patients and may modulate TLRs that are involved in inflammatory responses. Thus, the purpose was evaluate the effect of cholecalciferol on IL-6, IFN-γ TLR-7 and TLR-9 expression in lymphocytes B and T in patients on dialysis with vitamin D hypominhemia.

Methods: In a randomized, placebo-controlled, double-blind study, we investigated the effect of cholecalciferol (100,000 UI once per week) for 3 months, in patients on chronic dialysis, who had nutritional vitamin D deficiency. associated with intracellular production of vitamin D on lymphocytes from CKD patients. These results suggest that vitamin D may affect heart disease, associating with thyroid hormone impairment. Therefore, we tried to investigate the effect of selenium deficiency on thyroid hormone and cardiovascular diseases in HD patients.

**Methods:** This cross-sectional study enrolled 83 HD patients. They were divided into two groups based on serum selenium levels: 62 patients were normal level and 22 patients were selenium deficient. Thyroid hormones such as TSH, free T4 were measured. And cardiovascular diseases, including IHD, heart failure or cardiomyopathy, were evaluated.

**Results:** Thyroid hormone impairment, including hypothyroidism and subclinical hyperthyroidism, showed higher tendency in selenium deficient group than that in non-selenium deficient group. (27% vs 10% P=0.06) The prevalence of IHD was significantly higher in selenium deficient group than that in the non-selenium deficient group. (59% vs 21%, p=0.04) But there was no difference in heart failure and cardiomyopathy. Patients with thyroid hormone impairment showed high prevalence of IHD, and the coincidence of thyroid hormone impairment and IHD was also significantly higher than that in selenium deficient group than that in non-selenium deficient group. (18% vs 4%, p=0.014).

**Conclusions:** This study showed the significant high prevalence of thyroid hormone impairment and IHD in HD patients with selenium deficiency. Selenium deficiency may be affect heart disease, associating with thyroid hormone impairment.

Associations of Prelude (Pre-ESRD) BMI and Weight Change with Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study

**Elani Sheppard,1 Melissa Soohoo,1 Joline L.T. Chen,1 Amanda R. Tortorici,1 Jennie Jing,1 Danh V. Nguyen,1 Csaba P. Kovessy,1 Kamyar Kalantar-Zadeh,2 1UC Irvine; 2UHSC.

**Background:** In end stage renal disease (ESRD) lower body mass index (BMI) portends a higher risk of mortality while obesity is protective, the so-called obesity paradox. However, the association of BMI and change in BMI over time in the pre-ESRD period and early post-ESRD mortality is unknown. We hypothesized that lower and decreasing BMI prior to transition to ESRD may be associated with higher early dialysis deaths.

**Methods:** In a cohort of 22,716 US veterans who transitioned to dialysis between 10/2007 and 9/2011 with available BMI values within the last 2 year prelude period (prior to ESRD transition), we examined the association of 6 month average BMI and 2 year BMI slope as continuous predictors of all-cause mortality in the first 3 months after transition, using restricted cubic spline analyses and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region. In the models of BMI slope, we also adjusted for BMI level at the time of transition.

**Results:** The mean SD age was 69±11 yrs, 27% were African-American, 7% Hispanic, and 49% diabetic. There was a reverse J-shaped association between BMI and mortality, where patients with BMI <27 kg/m² were at higher risk of death (Figure A). When examining changes in weight over the 2-year prelude there was a U-shaped association where patients with little to no-change in BMI (-1 to +1 kg/m² per year) exhibited the best survival (Figure B).

**Conclusions:** Among veterans transitioning to dialysis, obese patients and those patients with little to no weight change in the last 2 years prior to ESRD have the greatest survival in the first 3 months post transition. Weight change in late stages of pre-dialysis CKD, possibly due to uremic wasting and fluid gain, portend poor outcomes, and could be used to identify at-risk patients.

Nutritional Assessment for Incident Elder Dialysis Patients

**Suzette Thompson,2 Laura Rosales,3 Nathan W. Levin,1 Peter Kotanko,1 Fansan Zhu,1 1Renal Research Inst, New York, NY; 2Presbyterian Vascular Care, New York, NY.

**Background:** Electrolyte balance between the intracellular (ICV) and extracellular (ECV) fluid compartment is essential in the control of normal physiological functions. Nutritional status is mainly reflected by ICV. In hemodialysis (HD) patients the relationship between control of electrolyte and management of fluid balance is not completely understood. We aimed to evaluated whether the degree of reduction of fluid overload affects the measurement of ICV, and concentrations of serum albumin (Alb), sodium, potassium, and calcium.

**Methods:** Fifty six HD patients were studied. At baseline (BL), the fluid status was evaluated by calf biimpedance spectroscopy (cBiS). If patient’s dry weight (DW) was not reached by criteria of cBiS DW, the post target weight was gradually reduced (Zhu et al, 2015).
Physiol Meas, 29:S530-S516, 2008). At six months follow up, the patients either reached DW or did not (NDW) due to difficulty in prolonging treatment time. ECV and ICV, weight, and systolic blood pressure (SBP) were measured pre and post HD. Comparison of all parameters between BL and follow up were made using student t test.

**Results:** Thirty one patients reached DW and 25 did not. Weight and ECV were significantly reduced during follow up. However, ICV, electrolytes and Alb concentrations did not change between different fluid statuses. Post HD SBP significantly decreased from BL to the end of the study in DW but not in NDW groups.

**Conclusions:** Although extracellular fluid (ECV) was largely reduced, the ICV and serum concentrations of sodium, potassium, and calcium did not differ significantly. This implies that there is no fluid or mass shift from ICV to ECV, suggesting over all isotonic removal of sodium and that nutritional status is not changed by attainment of dry weight.

**Trends in Weight Change During the First Two Years of Transition to Hemodialysis Treatment**

**Vivian Ngo,1 Elani Streja,1 Anna Mathew,2 Tae Hee Kim,1 Yoshitsugu Obi,1 Connie Rhee,1 Csaba P. Kovessy,1 Kamyar Kalantar-Zadeh1.1 UC Irvine; 2Hofstra North Shore LIJ Health System; 1UTHSC.**

**Background:** Some hemodialysis patients may undergo rapid weight loss in the first few months of starting dialysis, but the nature of this trend has not yet been characterized in large nationally representative studies. We hypothesized the trajectory of weight change during the first 24 months of hemodialysis therapy may differ by baseline body mass index (BMI).

**Methods:** We examined percent post-dialysis weight (kg) change from baseline in 37,759 incident hemodialysis patients who initiated dialysis in a large US dialysis organization in calendar years 2007-2011 and who survived the first 2 years of hemodialysis. Trends of percent weight change over time were analyzed using crude and case-mix adjusted mixed effects models. Baseline BMI was categorized into 8 categories (~18.5, 18.5~20, 20~23, 23~25, 25~30, 30~35, 35~40, 40+ kg/m²).

**Results:** Patients were 60±14 years old, 64% diabetics, 44% female, and had an average starting weight of 82±22 kilograms. Patients reached a nadir of weight at the 5th month of dialysis with an average 2% weight loss from baseline. At 14 months, patients’ weight stabilized at an average of 1% drop from baseline. However, trends differed across groups of baseline BMI groups. Underweight (BMI <18.5) did not experience weight loss but stabilized at an average of 1% drop from baseline. However, trends differed across groups starting weight of 82±22 kilograms. Patients reached a nadir of weight at the 5th month of starting dialysis, but the nature of this trend has not yet been characterized in large nationally representative studies. We hypothesized the trajectory of weight change during the first 2 years in hemodialysis patients. Further studies are needed to better understand the cause of these differences and their impact on clinical outcomes.

**Significance of Renal Autonomic Nerves in the Reduction of Body Weight by SGLT2 Inhibitors**

**Aika Hagiyawara, Kazutoshi Miyashita, Masaaki Sato, Hiroyuki Uinoue, Kentaro Fujii, Masanori Tamaki, Hiroshi Itoh. Nephrology, Endocrinology and Metabolism, School of Medicine, Keio Univ, Shinjuku, Tokyo, Japan.**

**Background:** Sodium-glucose co-transporter (SGLT) 2 inhibitors decrease not only serum glucose level but also body weight significantly. Similarly, it is reported that renal denervation (RDN) decreases body weight, in addition to blood pressure. The urinary glucose might have a relationship with sympathetic activation that controls body weight, however, the relationship has not been elucidated.

**Methods:** The present study examined the roles for renal autonomic nerves in the weight reduction by SGLT2 inhibitors through performing RDN on mice fed on a high-fat diet. The C57BL/6 mice fed on a high-fat diet were divided into 4 groups; control group, RDN group, SGLT2 inhibitor group and SGLT2 inhibitor with RDN group. The body weight, glucose tolerance, tissue weights, tissue hormone sensitive lipase (HSL) activity and noradrenalin concentration were examined. The SGLT2 inhibitor (tofogliflozin 50 mg/kg pellet) was administered to mice from 8 weeks old mixing it in the high-fat diet (60 Kcal% fat). RDN was performed at 7 weeks old by surgically stripping the renal arteries and coating the vessels with a solution of 10% phenol in ethanol.

**Results:** The body weight at 16 weeks old significantly decreased in the SGLT2 inhibitor group. In that group, the catecholamine levels in subcutaneous fat and the activity of HSL which was measured by the phosphorylation level were increased. On the other hand, RDN with SGLT2 inhibitor group significantly weakened the degree of the reduction of body weight by the SGLT2 inhibitor associated with suppression of the catecholamine levels and the activity of HSL in the adipose tissue. In RDN without SGLT2 inhibitor group, the body weight significantly decreased; however, HSL in the adipose tissue was not activated.

**Conclusions:** These results indicate that HSL activation in the adipose tissue mediated by the renal autonomic nerves was involved in the mechanism of weight-reduction by SGLT2 inhibitors. The renal autonomic nerves were suggested to have a role in the control of tissue HSL activity and body weight.

FR-PO851

**The Combination of Walking Exercise and Branched Chain Amino Acid Recovered Response of Protein Synthesis in Low Protein Diet Fed Chronic Kidney Disease Model Rats**

**Takuya Yoshida, Hiromichi Kumagai. Nephrology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy.**

**Background:** Low protein diet (LPD) protects progression of renal injury in patients with chronic kidney disease (CKD). However, LPD may accelerate muscle wasting in these patients. The exercise and branched chain amino acid (BCAA) are known to increase the muscle synthesis by activating mTOR signaling pathway. The aim of this study is to investigate whether walking exercise and BCAA would increase muscle protein synthesis in LPD fed CKD (5/6 nephrectomized) rats.

**Methods:** CKD rats were fed LPD or LPD fortified with BCAA diet (BD), and about half of the each group were loaded with the walking exercise (7 weeks of treadmill, 15 m/min, 1 hour/day, 5 days/week). After 7 weeks, the kidney and the soleus muscle were collected to evaluate the renal fibrosis and the muscle protein synthesis, respectively.

**Results:** The renal function and fibrosis were not different between LPD and BD fed CKD rats, and the walking exercise did not accelerate renal damage in both LPD and BD fed CKD groups. The walking exercise increased the phosphorylation of p70s6kinase, a biomarker of mammalian target of rapamycin complex 1 activity, in soleus muscle of LPD and BD fed CKD rats. However, the phosphorylation of p70s6kinase was lower in RDN without SGLT2 inhibitor group, the body weight significantly decreased; however, HSL in the adipose tissue was not activated.

**Conclusions:** These results indicate that HSL activation in the adipose tissue mediated by the renal autonomic nerves was involved in the mechanism of weight-reduction by SGLT2 inhibitors. The renal autonomic nerves were suggested to have a role in the control of tissue HSL activity and body weight.

**Unacyl-Ghrelin: A Key Molecule in Uraemic Cachexia in Children and Adolescents**

**Alice Monzani1, Michella Perrone1, Sara Testa,2 Fabio Paulliafano2, Silvia Consolo,2 Gianluigi Ardissino,1 Francesca Tel2, Marta Lepore2, Stefano Rotondo,2 Antonietta Biasuzzi,2 Luciana Ghio,1 Gianni bona,1 Alberto Edefonti.2 Div of Pediatrics, Univ del Piemonte Orientale, Novara, Italy; 1Pediatric Nephrology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy.**

**Background:** Cachexia and poor growth are common in children with chronic kidney disease (CKD). Several mechanisms are involved, including loss of appetite and poor food intake. Unacyl-ghrelin (UAG) is known to produce an inhibitory effect on feeding. We measured UAG levels in children and adolescents with CKD stage II-IV on conservative treatment (CKD-CT), on haemodialysis (CKD-HD) and after transplantation (Tx), compared to healthy controls, in relation to biochemical and anthropometric parameters.

**Methods:** Plasma UAG levels were measured by ELISA in 43 CKD-CT, 20 CKD-HD, 48 Tx and 43 healthy children. Urea and creatinine levels were measured in all subjects and GFR was calculated by Schwartz formula. Weight, height and bicipital, tricipital, subcapacular and suprailliac folds were measured, and BMI z-score, fat-mass and fat-free mass pro body weight (FM/WW and FFM/WW, respectively) were calculated.

**Conclusions:** Baseline BMI can affect the trajectory of weight change over the first two years in hemodialysis patients. Further studies are needed to better understand the cause of these differences and their impact on clinical outcomes.

Visceral Fat Area Is Associated with Renal and Cardiac Function in a Population with Normal and Cardiac Diseases.

**Methods:**
This cross-sectional study included 719 middle-aged adults who underwent a voluntary health check-up program. Participants with estimated glomerular filtration rate (eGFR) below 60 mL/min/1.73 m² were excluded. VFA was measured using bioimpedance analysis. Subjects were divided into tertiles according to their VFA.

**Results:**
- Across the tertiles of VFA, there was a significant trend for decline in eGFR (P < 0.001), increase in baPWV (P < 0.001) and left ventricular mass index (LVMI, P < 0.001).
- VFA was linearly associated with eGFR (β = -0.06, 95% confidence interval [CI] -0.08 to -0.04, P < 0.001), and E/E’ (β = 0.01, 95% CI 0.006 – 0.019, P<0.001), after adjustments for cardiovascular risk factors.

**Conclusions:**
VFA is associated with renal and cardiac function in middle-aged adults with normal or mildly impaired renal function.

Chronic Inflammation Is Associated with Poor Clinical Outcomes Independent of Mineral Metabolism Abnormalities in the HEMO Study

**Background:**
Epidemiological studies show a high prevalence of chronic inflammation, vitamin D deficiency, and fibroblast growth factor 23 (FGF23) excess in hemodialysis patients. Whether the relationships of high circulating C-reactive protein (CRP) and interleukin-6 (IL-6) with all-cause mortality and cardiac and infectious events are attenuated in the presence of circulating markers of mineral metabolism is unknown.

**Methods:**
We studied the association of inflammatory markers (CRP and IL-6) with all-cause mortality, and cardiac and infectious hospitalizations and deaths among 1340 subjects from the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial. Cox regression models adjusted for important confounding variables: demographics, comorbidities, Kt/V, dialyzer, smoking, albumin, and mineral metabolism markers including serum calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, and FGF23.

**Results:**
Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) CRP and IL-6 levels were 6.1 (2.6-15.2) mg/L and 3.2 (1.7-6.9) pg/mL, respectively. Over mean 2.84 years follow-up, there were 582 deaths, 514 cardiovascular events, and 499 infectious events. Among subjects with levels in the highest quartile compared to the lowest quartile, both CRP and IL-6 were significantly associated with all-cause mortality in adjusted analyses, odds ratio (OR) 1.96 (95% CI, 1.27-3.02) and OR 1.51 (95% CI, 1.02-2.23), respectively. However, only CRP was associated with cardiovascular disease events (OR 1.90, 95% CI, 1.04-3.44) and infectious events (OR 3.84; 95% CI, 1.37-10.74) among subjects with levels in the highest quartile compared to the lowest quartile.

**Conclusions:**
CRP and IL-6, were significantly associated with all-cause mortality independent of mineral metabolism abnormalities. Only CRP was significantly associated with cardiovascular disease and infectious disease events independent of mineral metabolism abnormalities among subjects in the HEMO trial.

**FR-PO856**
Assessment of Protein-Energy Wasting: Comparing a New PEW Score and the MIS in Chronic HD Patients

**Background:**
The assessment of protein-energy wasting, a syndrome of decreased bodily protein and energy fuels, remains debated. Recently, a French group introduced a new PEW score, encompassing BMI, serum creatinine, nPNA and serum albumin. In a cohort of chronic hemodialysis patients, we compared the predictive value of this score with the Malnutrition Inflammation Score (MIS) using all-cause mortality as end point. Furthermore, we investigated which of these scores correlates best with quality of life (QOL).

**Methods:**
Data from the CONvective TRAnsport Study (CONTRAST), the new PEW score and the MIS were determined at baseline. QOL was measured with the Kidney Disease QOL-Short Form 36, which results in 2 general and 12 kidney-disease specific domains of QOL. Discrimination and calibration for mortality were tested by Harrell’s C Statistics. Calibration and the Hosmer-Lemeshow Goodness-of-Fit test, respectively. Spearman’s rank correlation coefficient p was used to determine correlations between a test and the various QOL domains.

**Results:**
489 out of 714 patients were analyzed. 183 died during follow-up (mean 3.15±1.78 years). Discrimination was better for the MIS than for the new PEW score (Harrell’s C statistic 68.0% [95% CI 65.7-69.8] and 61.0% [95%CI 59.0-63.3], respectively). Furthermore, mortality calibration was adequate for MIS (p=0.65), but not for the new PEW score (p=0.03). Lastly, MIS correlated with 15 domains of QOL (p’ is between -0.47 and 0.12), whereas the new PEW score only correlated with the physical component score (p=0.18).

**Conclusions:**
Both the MIS and the new PEW discriminate for mortality, but the MIS performs better. Furthermore, only the MIS is properly calibrated. Third, the MIS correlates with more QOL domains with higher correlation coefficients. Therefore, we conclude that MIS is preferred over the new PEW score in assessing PEW.
association between ΔMIS and mortality was not linear; patients were divided into quartiles of ΔMIS. Cox proportional hazards models, crude and adjusted for potential confounders, were used to calculate hazard ratios (HRs) of patients with severe deteriorating MIS (increase >2 points), mild deteriorating MIS (increase of 1 or 2 points), stable MIS versus patients with an improving MIS.

Results: 404 patients were available for analysis. Mean age was 63.0±13.5 and 62.4% were male. During follow-up (median 3.1 years), 135 patients died. Median ΔMIS was 1.0 (IQR -1.0 to 3.0). Survival curves are shown in fig. 1. HR of patients with a mild deteriorating or stable MIS versus patients with an improving ΔMIS was 0.85 (95%CI 0.53-1.39) and 0.97 (95% CI 0.56-1.67), respectively; for patients with a severe deteriorating MIS, HR was 1.63 (95%CI 1.02-2.51). After correction for age, sex, dialysis vintage and dialysis modality, this association did not remain significant (p=0.1).

Conclusions: a change in ΔMIS over 1 year is not associated with mortality in a multivariable survival analysis.

FR-PO858

Soluble CD14, a Marker of Endotoxia, Associates with Survival and Cardiovascular Disease in CKD Patients Ruben Poesen, Ian Barrows, Ali Ramezani, Pieter Evenepoel, Kathleen Claes, Bjorn Meijers, Dominic S. Raj.

Background: CKD goes along with gut microbial dysbiosis and gut barrier dysfunction, possibly contributing to endotoxin translocation. Subsequent binding of endotoxin to toll-like receptor-4 and its co-receptor CD14 activates the innate immune system. As half-life of systemic endotoxin is very short, soluble CD14 (sCD14) has been proposed as better marker of endotoxin exposure. Whether sCD14 relates to adverse outcome in CKD patients not yet on dialysis is unknown.

Methods: We performed a single-center prospective study in patients with CKD stage 1-5. Baseline serum levels of TMAO were determined using LC-MS. Correlation between eGFR and serum TMAO was explored using Spearman’s rank correlation analysis. The relationship between TMAO, survival and cardiovascular disease was examined using Cox proportional hazard analysis.

Results: 488 CKD patients were followed from November 2005 until December 2010. Median serum level of TMAO was 11.6 µM (IQR 5.7 – 21.8). We observed a highly significant inverse correlation between eGFR and serum TMAO (rho 0.71, P < 0.0001). During follow-up, we noted a total of 51 deaths and 75 cardiovascular events. In univariate cox proportional hazard analysis, TMAO was a significant predictor of mortality (HR 1.521 (1.183 – 1.956), P=0.001) and cardiovascular disease (HR 1.570 (1.283 – 1.921), P < 0.0001). However, significance was lost after adjustment for eGFR for overall mortality (HR 1.126 (0.795 – 1.595), P=0.50), as well as for cardiovascular events (HR 1.256 (0.958 – 1.647), P=0.10).

Conclusions: Serum levels of TMAO rise in parallel to a declining renal function and further analysis of 24h urine samples is ongoing to elucidate its renal handling. In this European cohort of CKD patients, we were not able to find an association between TMAO and adverse outcome that is beyond renal function, which is in contrast to previous observations in US populations, both general and CKD. This may question the validity of TMAO as a universal biomarker for cardiovascular disease, possibly due to population-specific differences in diet and/or microbial metabolism.

FR-PO860

Microbiota Derived Phenylacetylglutamine Associates with Survival and Cardiovascular Disease in CKD Patients Ruben Poesen, Pieter Evenepoel, Bjorn Meijers.

Background: Lately, there is increasing interest in gut microbiota derived uremic retention solutes as driving force behind adverse outcome in CKD. Both p-cresyl sulfate and indoxyl sulfate are considered representatives of this group, also commonly referred to as protein-bound solutes due to their high protein binding and dependence on active tubular secretion for renal clearance. Phenylacetylglutamine is another microbial metabolite subjected to high tubular secretion, although protein binding is rather low. We questioned whether this solute also relates to adverse outcome in CKD patients not yet on dialysis.

Methods: We performed a prospective study in CKD patients stage 1-5. Serum levels of phenylacetylglutamine were determined using LC-MS. Correlation between eGFR and serum phenylacetylglutamine was explored using Spearman’s rank correlation analysis. The relationship between phenylacetylglutamine, survival and cardiovascular disease (CVD) was examined using Kaplan Meier and Cox PH analysis.

Results: 488 CKD patients were followed from November 2005 until December 2010. Median serum level of phenylacetylglutamine was 6.2 µM (IQR 3.0-13.2). We observed a highly significant inverse correlation between eGFR and serum phenylacetylglutamine (rho -0.76, P<0.0001). During follow-up, we noted a total of 51 deaths and 75 cardiovascular events with a gradual and significant increase with higher tertiles of phenylacetylglutamine (both log rank P<0.0001). In univariate Cox PH analysis, phenylacetylglutamine was a significant predictor of mortality (HR 1.997 (1.590-2.508), P<0.0001), even after adjustment for renal function, Framingham risk factors, calcium-phosphorus-PTH, CRP and albumin (HR 1.611 (1.140-2.275), P=0.007 for mortality and HR 1.668 (1.295-2.149), P<0.0001 for CVD).

Conclusions: Serum levels of microbiota derived phenylacetylglutamine are elevated in patients with more advanced CKD. Serum phenylacetylglutamine is also a strong and independent risk factor for mortality and CVD. Further analysis of 24h urine samples is ongoing to differentiate between impact of higher urinary excretion as surrogate of intestinal generation vs. impact of lower tubular secretion.

Sarcopenia Among Prevalent Hemodialysis Patients: Weighing the Evidence
Piyawan Kittikulnam,1 Juan Jesus Carrero,2 Glenn Matthew Chertow,2 George A. Kaysen,4 Kirsten L. Johansen,1 1UCSF; 2Karolinska Inst; 3Stanford Univ; 4UC Davis.

Background: There is no consensus on the best way to define sarcopenia in ESRD. Use of muscle/height² (Ht²) is suggested by geriatric societies but may underestimate sarcopenia, particularly in the setting of excess adiposity. We compared three definitions of sarcopenia in a prevalent HD cohort.

Methods: ACTIVE/ADIPOSE enrolled HD patients from San Francisco and Atlanta from 6/09 to 8/11. Biomechanical impedance spectroscopy was performed before a midweek dialysis session (n=645), and total-body muscle mass was estimated using an equation containing age, sex, body weight (BW), and intracellular water. We defined sarcopenia as muscle mass ≥2SD below sex-specific means for adults 18-49 y from NHANES data indexed to Ht², %BW, and body surface area (BSA) by DuBois formula. We compared the prevalence of low muscle mass among the three methods and assessed their correlation with handgrip strength.

Results: Mean age was 57±14 years, 41% were women, 61% black. The prevalence of sarcopenia was 8% by muscle/Ht², 25% by muscle/%BW and 32% by muscle/BSA. Most sarcopenic patients by muscle/BSA method had normal BMI, while >50% of sarcopenic patients by %BW were obese. Almost none of the overweight or obese patients were identified as sarcopenic by muscle/Ht².

Conclusions: Skeletal muscle mass normalized to Ht² may underestimate the prevalence of sarcopenia, particularly in overweight HD patients. Detection of sarcopenia among overweight/obese patients requires adjustment for body size or adiposity. Funding: NIDDK Support

Does a Probiotic Supplementation Alter the Indoxyl Sulfate Levels in Non-Dialysis Chronic Kidney Disease Patients? A Randomized Placebo-Controlled Clinical Trial
Denise Mafra,1 Natalia Alvarenga Borges,1 Milena Barcea Stockler-Pinto,2 Denis Fouque,3 Amanda F. Barros.2 1Medical Sciences Graduate Program, Federal Univ Fluminense, Rio de Janeiro, Brazil; 2Cardiovascular Sciences Graduate Program, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil; 3Department of Nephrology, Centre Hospitalier Lyon Sud, Univ Claude Bernard, Lyon, France.

Background: Gut microbiota is known to function in producing uremic toxins in chronic kidney disease (CKD) patients. Therapeutic strategies like probiotic supplementation may modulate the gut microbiota and reduce the toxins levels. To determine the effect of probiotics supplementation on indoxyl sulfate (IS) plasma levels in non-dialysis CKD patients.

Methods: In this double-blind, placebo-controlled trial, 29 non-dialysis CKD patients were recruited. Patients were randomized to receive probiotic (1 capsule, containing 30 billion of colony forming units - S. thermophilus, L. acidophilus, and B. longum, n=17) or placebo (n=12) for 3 months. IS plasma levels were quantified by HPLC, calprotectin and protein C reactive were analyzed by immunoensymatic assay. Five patients in probiotic group and three in placebo were lost to follow-up.

Results: Plasma IS increased significantly in patients who received probiotics whereas the other parameters did not change.

Patients who were classified as sarcopenic by muscle mass/BSA but not Ht² had significantly higher BMI and %body fat than those who were sarcopenic by both methods (25.2 vs 21.3 kg/m², p=0.001 and 31.1 vs 24.4%, p=0.001, respectively). Handgrip strength was moderately correlated with muscle/BSA (r=0.6) but weakly correlated with muscle/Ht² (r=0.3) and %BW (r=0.4).

Conclusions: Skeletal muscle mass normalized to Ht² may underestimate the prevalence of sarcopenia, particularly in overweight HD patients. Detection of sarcopenia among overweight/obese patients requires adjustment for body size or adiposity. Funding: NIDDK Support

FR-PO863
Prevention of the Progression of Both Renal Dysfunction and the Atherosclerotic Change in Chronic Kidney Disease (CKD) Stage 3–4 Patients due to Benign Nephrosclerosis
Yoshihiko Inoue, Tomaoki Miyazaki, Shinya Omiya, Kiyoko Imut, Daisuke Komukai, Ashio Yoshimura. Div of Nephrology, Showa Univ Fugajosuka Hospital, Yokohama, Kanagawa, Japan.

Background: Effect of EPA for CKD patients is not fully known. We studied the efficacy of EPA to prevent the progression of both renal impairment and atherosclerosis in CKD stage 3-4 patients due to benign nephrosclerosis (BNS).

Methods: 31 CKD stage 3-4 patients due to BNS with dyslipidemia were followed for 3 years after the start of EPA treatment. The dosage of 1800 mg/day of EPA was newly prescribed. T-cho, LDL-cho, Triglycerides (TG), eGFR, the amount of proteinuria, EPA, arachidonic acid (AA), Dihomo-gamma-linolenic acid (DGLA) and docosahexaenoic acid (DHA) were studied. Both right and left (RL) brachial-ankle pulse wave velocity (baPWV), RL maximum carotid intima-media thickness (max IMT), RL maximum carotid plaque thickness and RL ankle-brachial index (ABI) were evaluated at before treatment (baseline), after 1-year and at the end of the study (3-year).

Results: EPA, EPA/AA ratio, TG, RL bPWV, RL max IMT and eGFR showed significant improvement at 3-year (table 1).

Furthermore, both EPA and DHA levels were significantly low in eGFR exacerbation patients group (n=9) compared with the improvement group (n=22) at both baseline and 3-year. Patients showing the highest EPA levels at baseline (EPA: 124.6±18.8 mg/ml, n=8) showed significant improvement in both eGFR and baPWV compared with those with the lowest EPA levels (30.1±8.1 mg/ml, n=6). There was no difference on both plaque thickness and ABI between baseline and 3-year.

Conclusions: EPA powerfully prevents the progression of both renal dysfunction and the atherosclerotic change in CKD stage 3-4 patients due to BNS.

FR-PO864
Relationships Between Composition of Gut Microbiota and Uremic Toxins
Mami Kikuchi,1 Ryoko Tateoka,1 Yoshiru Itoh,1 Wataru Suda,2,3 Masahira Hattori,2,4 Kareha Corporation, Tokyo, Japan; 2The Univ of Tokyo, Chiba, Japan; 3Keio Univ, Tokyo, Japan; 4Waseda University, Tokyo, Japan.

Background: Gut microbiota is known to function in producing uremic toxins (UTs) and their precursors, such as indox, phenols and so on. However the relationships between specific bacteria and UTs are not clear. To elucidate the production of UTs by gut microbiota, we collected blood, urine and feces samples in normal rats, rats subjected to 5/6 renal removal. AST-120, a spherical carbon adsorbent of intestinal small-molecular-weight UTs and/or their precursors, was used to evaluate the effects of UTs on gut microbiota.

Methods: Serum and urine levels of UTs were quantified by SRM of LC/ESI-MS/MS. Gut microbiota from feces were analyzed using 454-pyrosequencing of a hypervariable V1-V2 region of the 16S rRNA gene in combination with barcode sequences. We used the GLSEARCH program and self-build 16S sequences database and genome database to determine the closest species. We identified the indole and/or phenol producing species using BLASTX.

Results: In CKD rats, urinary excretion and serum concentrations of UTs, such as indoxyl sulfate and phenyl sulfate, were higerthan control rats. In AST-120-administered CKD rats, urinary excretion and serum concentrations of UTs decreased compared to CKD
rats. The overall bacterial community composition was compared according to the UniFrac distance metric among control rats, CKD rats, and CKD + AST-120 rats. A principal coordinate analysis plot revealed clustering of each group. We identified the intestinal microbiome containing tryptophanase and/or tyrosine phenol-lyase gene in the genome sequences from NCBI bacterial genome. These enzymes metabolize tryptophan to indole and tyrosine to phenol, respectively.

Conclusions: Our data suggest that UT production is not only the cause of uremic symptoms but also correlated with a subset of indigenous gut microbes and affects the composition of gut microbiota.

FR-PO865

Association of Urine Volume at the Start of Dialysis and Subsequent Changes in Serum Albumin Level in Incident Hemodialysis Patients

Riekj Frigui,1 Yoshitsugu Obi,1 Connie Rhee,1 Steven M. Brunelli,2 Joline L.T. Chen,1 Anna Mathew,2 Tao Hee Kim,1 Elani Streja,1 Csaba P. Kovetsy,1 Kamyr Kalantar-Zadeh,1 1UC Irvine; 2DaVita Clin Research; 7Hofstra North Shore-Long Island Health System; UTHSC.

Background: Previous studies have shown that low serum albumin (Alb) levels are associated with higher mortality in hemodialysis (HD) patients. While serum Alb is a critical inflammatory and nutritional marker, low Alb may also result from albuminuria. It is unknown if a change in serum Alb over time is due to the loss of residual kidney function. While data on urine Alb was unavailable, we hypothesized that higher urine volume (UV) (U) is associated with a decrease in Alb.

Methods: Among 38,504 incident HD patients receiving care from a large dialysis organization from 2007-2011, we examined serum albumin level trajectory over 5 years (divided into 20 patient quarters) across five strata of baseline UV: <300, 300-<600, 600-<900, 900-<1200, ≥1200 mL/d. The association between baseline UV and serum albumin trend was examined using mixed effects models with adjustment for age, gender, race, diabetes, and insurance type.

Results: Patients were 62±15 years old, 38% female, 28% black, and 46% diabetic. Higher baseline UV was incrementally associated with higher Alb levels across strata: 3.4±0.48g/dL, 3.5±0.46g/dL, 3.57±0.44g/dL, 3.59±0.45g/dL, and 3.65±0.46g/dL, respectively. [Figure] Serum Alb increased over the first 6 patient quarters (18 months) on dialysis and then stabilized. Patients with higher UV not only had a higher baseline serum Alb level, but also maintained a higher serum Alb level over follow-up.

Conclusions: Higher baseline UV appears to be associated with sustained higher serum Alb levels over time. Improvement in hypoalbuminemia as a result of transition to dialysis therapy appears to be independent of residual kidney function and may suggest an inherent advantage of dialysis initiation.

FR-PO866

Individual Variation of Hippuric Acid and P-Cresyl Sulfate Plasma Levels Correlate with Variation of Intestinal Microbial Phylotypes in Hemodialysis Patients

Kamyar Kalantar, Rieko Eriguchi,1 Yasushi Ohashi,1 Yasushi Koizumi,1 Hironobu Hori,1 Satoru Nishino,2 and Takashi Yodoi,3 1Renal Div, Ghent Univ Hospital, Gent, Belgium; 2Microbiology Lrl,1 3 Sunny Eloot,1 Eva Schepers,1 Silvia Calabria,1 Luciana Bonfante,2 Nicola Veronese,1 Irene Santinelli,1 Sabina Zambon,1 Sandro Giannini,1 Maurizio Gallieni,2 Adamasco Cupisti.2

Background: In chronic kidney disease (CKD), a myriad of metabolites accumulate with the maximum intrapatient variability of metabolite levels and the corresponding time-points of feal microbial phylotypes was assessed. In addition, cross-sectional correlations at 0 were evaluated. Statistical analyses were performed with R package phylloseq using Spearman correlation, with multiple testing correction (FDR) per metabolite for the number of genus-level phylotypes.

Results: Within this patient group, we observed a strong positive correlation between an increase in total hippuric acid and unclassified Peptostreptococcaceae (r=0.83; corrected p-value=0.012). We also found a positive trend for total p-cresyl sulfate and unclassified Clostridiales and unclassified Ruminococcaceae (r=0.77 and 0.74; corrected p-value=0.074 and 0.028, respectively). Cross-sectionally at 0, strong negative correlations between indoxyl sulfate, indole acetic acid and specific unclassified bacterial phylotypes (<p=0.79 and <p=0.84; corrected p-value=0.028 and 0.004) were observed.

Conclusions: There is a link between plasma levels of specific uremic metabolites and fecal bacterial phylotypes, suggesting that these microbiota might be a target for reducing uremic metabolite levels in patients with CKD. Data needs validation on larger patient groups.

Decreased Vitamin K Intake in Italian Hemodialysis Patients

Maria Fusaro,1 Claudia D’Alessandro,2 Marianna Noale,3 Giovanni Trippi,4 Lucia Bonfante,2 Nicola Veronese,1 Irene Santinelli,1 Sabina Zambon,1 Sandro Giannini,1 Maurizio Gallieni,2 Adamasco Cupisti.2

Background: Vitamin K is involved in the production of Bone and Matrix Gla Proteins (BGP and MGP, respectively), regulating bone and vascular health. We carried out a pilot study to evaluate vitamin K intake in hemodialysis (HD) patients.

Methods: We measured vitamin K1 intake (7-day food record) in 78 Italian hemodialysis patients (48 M, 30 F) compared to intake in 39 healthy adults (28 M, 11 F).

Results: HD patients had a mean (± SD) age of 62.8±13.9 years, mean dialytic age of 97 months, mean BMI of 25.4±4.5 Kg/m2. Mean serum levels of interest for CKD-MBD were: Ca 9 mg/dL, P 4.3 mg/dL, PTH 231.5 pg/mL, ALP 81.5 U/l. Control group mean age was 54.6±13.9 years. HD patients had a significantly lower intake of vitamin K1 compared to controls (see Table). We also evaluated and compared between HD patients and controls the intake of the other fat soluble vitamins and of nutrients commonly associated with bone and mineral disorders in KD patients (see table). All were decreased in HD patients.

Conclusions: This Vitamin K intake study is the first carried out on Italian diet. We found a decreased intake of Vitamin K1 in HD patients. This finding supports the hypothesis of supplementing vitamin K for the prevention of vascular calcifications and bone disorders in HD patients. Benefits of vitamin K supplementation should be proved by a randomized trial.

FR-PO868

Association of Geriatric Nutrition Risk Index with Body Fluid Composition, Renal Adverse Outcomes and Mortality in Patients with Chronic Kidney Disease

Keibun Yu, Yasushi Ohashi, Toshiyuki Aoki, Shizuka Kobayashi, Yodoi Takashi, Akawa Ken, Sakai Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan.

Background: Decreased body stores of protein and energy fuels may express by the geriatric nutritional risk index (GNRI) consisting of body mass index (BMI) and serum albumin levels. We studied the association of the GNRI with body fluid composition, renal adverse outcomes and all-cause mortality in patients with chronic kidney disease (CKD).

Methods: Body fluid composition was measured in 306 patients with CKD from 2005 to 2014 and was separated into three components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Patients were categorized according to tertiles of GNRI levels. Of those, 275 patients were followed until March 2015. The adverse renal outcomes were defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy.

Results: Patients with the lower tertiles of the GNRI levels were more likely to be higher age, have a lower BMI, diastolic blood pressure, serum albumin, hemoglobin, glomerular filtration rate, and proteinuria (P < 0.05). In the body fluid composition, those tended to have lower free water mass (r = 0.73, P < 0.001) and the ratio of extracellular water to total body water mass (r = 0.87, P < 0.001) were significantly increased in the lower tertiles of GNRI levels.

Conclusions: We showed a significant correlation between the geriatric nutritional risk index (GNRI) and body fluid composition, renal adverse outcomes and all-cause mortality. The association of GNRI and body fluid composition can be a useful predictor for renal adverse outcomes and all-cause mortality in patients with chronic kidney disease.
intracellular water ($r = 0.37, P < 0.001$). Compared with patients with the middle tertile of the GNRI levels during a median 2.5-year follow-up, the lowest tertile of the GNRI levels had higher mortality (6.8 vs. 1.7 per 100 patient-years, $P < 0.001$), but had no worse adverse renal outcomes (16.5 vs. 9.0 per 100 patient-years, $P = 0.08$). In multivariate analysis, the lower GNRI levels independently remained as a risk factor for all-cause mortality (hazard ratio, 3.16, 95% CI, 1.30–8.84, $P < 0.001$).

**Conclusions:** The GNRI may be a simple and useful tool for predicting the risk of mortality even in CKD population including patients with massive proteinuria. These findings emphasize the importance of adequate body stores of protein and energy fuels in patients with CKD.

**FR-PO869**

A Novel Index for Estimation of Muscle Mass Using Biomarkers of Kidney Function: Sarcopenia Index

**Kijanoosh Banati-Kashani,1,2 Lucie Kukralova,3 Erin N. Frazee,4 Rahul Kashyap.2**

Background: Sarcopenia is associated with poor patients’ outcomes in Intensive Care Unit (ICU). Tools to evaluate sarcopenia are DXA scan, CT and MRI, which may not be feasible for critically ill patients. We hypothesize a novel index which can be used as a surrogate for sarcopenia among ICU patients.

**Methods:** This is a secondary analysis of prospectively enrolled critically ill patients. Adult ICU patients ($\geq 18$ years) with shock, sepsis, use of IV antibiotics and contrast media exposure, in 24 hours of enrollment, intra-abdominal hypertension or severe Trauma were included. We excluded patients with pre-existing acute kidney injury, pregnancy, and kidney transplant, or those who were on dialysis or were moribund. We measures paraspinal muscle surface area at L3 level, using Slice-O-Matic software (TomoVision®, Magog, Canada). Sarcopenia Index (SI) was calculated as [Serum Creatinine (Scr) Cystatin C (CysC)] X 100.

**Results:** A total of 226 patients met the inclusion criteria. Among these enrollees, 110 patients who had abdominal CT within $\pm 4$ weeks of their index ICU admission were included in the final analysis. The median age (IQR) was 67 (57–77) years and 59.5% (91.9%) were female. The median DNI levels were 91.7 (91.7–97.8) and H: >97.8, and GNRI were 95.9±7.6, 94.9±5.8, 87.1±11.0 in A, B and C of tertiles according to the ADL defined by the Renal Data Registry of Japanese Society for Internal Medicine, Mayo Clinic, Rochester, MN; 4Faculty of Medicine in Hradec Kralove, Charles Univ, Prague, Czech Republic; 4Dept of Pharmacy, Mayo Clinic, Rochester, MN.

**Conclusion:** ADL and GNRI could strongly predict the mortality, and combination of both setting also improved the prediction of mortality with ESRD patient on HD.

**FR-PO871**

Delta Neutrophil Index Is a Predictive Marker of Disease Severity in Patients with Acute Pyelonephritis

**Sul A Lee,1 Jong Hyun Jhee,1 Jae Eun Um,2 Meiyan Wu,2 Hyung Jung Oh,1 Jung Tak Park,1 Seung Hyekol Han,1 Shin-Wook Kang,21,2,3 Hyun Yoo.1**

**Background:** Delta neutrophil index (DNI) is the fraction of immature granulocytes provided by a complete blood count (CBC) count. Previous studies demonstrated that DNI was a novel marker to predict clinical outcomes in sepsis patients. Therefore, this study was aimed to evaluate DNI as a predictive marker of disease severity in patients with acute pyelonephritis (APN).

**Methods:** Patients who were diagnosed with APN at Severance Hospital from December 2009 to July 2012 were retrospectively investigated. DNI levels were measured at the time of admission. Patients were classified into two groups according to the median value of DNI. Severe APN was defined as one or more of following conditions: bacteremia, acute kidney injury, hypotension requiring use of vasopressors, and admission of intensive care unit. Independent risk factors for severe APN were determined by multivariate logistic regression analysis. Area under the receiver operating characteristic curves (AUC) was compared among DNI, white blood cell (WBC) count, and C-reactive protein (CRP).

**Results:** A total of 258 patients were included in this study. The median age was 61.0 (19.0 – 87.0) years, and 237 patients (91.9% ) were female. The median DNI levels were 7.25%. Severe APN was significantly more prevalent in the high DNI group. Multivariate analysis showed that DNI independently predicted severe APN (per 1% increase, odds ratio=1.287, 95% confidence interval=1.131-1.458, P=0.001). Furthermore, DNI was a better predictive marker of severe APN than WBC count [AUC (95% confidence interval); 0.697 (0.637-0.753) vs. 0.562 (0.499-0.624), P=0.001] and not inferior to CRP levels [0.697 (0.637-0.753) vs. 0.633 (0.571-0.692), P=0.118].

**Conclusions:** DNI at admission could be a valuable predictor of disease severity in patients with APN.

An Improved Magnesium Formulation for Mitigating Cisplatin-Induced Renal Epithelial Cell Injury

**Malvika H. Solanki,1,2 Rachel Lauren Mintz,2 Xiangying Xue,2 Prodoy K. Chatterjee,2 Christine N. Metz.2,3 Elmezzi Graduate School of Molecular Medicine, NY; 2Feinstein Inst for Medical Research, NY; 3Hofstra-North Shore-LIJ School of Medicine, NY.**

**Background:** Cisplatin is a potent chemotherapy for treating cancer. It causes nephrotoxicity in ~25% and hypomagnesemia in ~90% patients. This hypomagnesemia is treated with oral magnesium (Mg) chloride (MgCl2) and/or i.v. Mg sulfate (MgSO4). Poor Mg intake and Mg deficiency are not uncommon in the US. Our previous studies revealed the beneficial effects of MgSO4 in reducing cisplatin-induced acute kidney injury (AKI) (Solanki et al., AIP Renal 2014). This study compared the efficacy of various Mg formulations in reducing cisplatin-induced renal epithelial cell injury.

**Methods:** LLC-PK1, renal epithelial cells were maintained in media containing 100% Mg (i.e. the amount of Mg found in growth media) or 10%Mg (Mg-deficient) for 3 days. To mimic Mg replacement, the 10%Mg cells were restocked to 100%Mg using: MgSO4, Mg-L-threonate (MgT), MgCl2, and Mg gluconate (MgG) (keeping elemental Mg equal) and then treated with vehicle or cisplatin. Oxidative stress, cytotoxicity and inflammation were measured by DCF-DA assay, MTT assay and TNFα production, respectively. ERK activation was measured by in-cell western.

**Results:** Cisplatin-induced oxidative stress, cytotoxicity, and inflammation were exacerbated by Mg deficiency, while Mg supplementation with all formulations consistently prevented these effects. MgT was the most effective Mg-formulation in reducing cisplatin-induced oxidative stress and inflammation. Mechanistic studies revealed that cisplatin-induced ERK activation was modulated by Mg status and MgT was most protective.

**Conclusions:** Mg supplementation protected against cisplatin-induced oxidative stress, cytotoxicity and inflammation in renal epithelial cells. This is the first study to reveal the effectiveness of MgT over other Mg-formulations in reducing cisplatin-induced renal
epithelial cytotoxicity. Note: MgT has significantly lower GI-effects (bloating and diarrhea) than other Mg formulations. These results warrant further in vivo and clinical studies to investigate the beneficial role of MgT in protecting against cisplatin-AKI.

**Funding:** Private Foundation Support

**FR-PO873**

Impact of Uremic Serum on the Barrier Function and Inflammation in Human Colonocytes

Laila Santos Andrade,1 Maria Dalboni,2 Jose Tarcisio Giffoni,2 Caren Cristina Grabulosa,2 Lilian Cuppari,1,2 Nutrition and Metabolism Program, Federal Univ of São Paulo, São Paulo, Brazil; 1Medicine, Div of Nephrology, Federal Univ of São Paulo, São Paulo, Brazil.

**Background:** In chronic kidney disease (CKD) it has been suggested that alterations of the gut are associated with inflammatory state and uremic toxicity. Studies suggest that uremia may impair the intestinal barrier function, by promoting increased intestinal permeability. In this study we aimed to evaluate the in vitro effect of uremic serum on the transepithelial electrical resistance (TER), inflammation and apoptosis in the intestinal epithelial cells.

**Methods:** Pools of serum were prepared from blood samples from patients maintained on hemodialysis (Pre-HD and Post-HD), and of patients with CKD stage 4 (NND-CKD). A pool of serum form healthy individuals served as control (CTL). When the TER exceeded 1,000 Ω cm² was reached, the T84 cells were incubated for 24 h in medium containing 10% pool of serum from each group. At the conclusion of the incubation period, the TER was measured again and the following parameters were determined by flow cytometry: expression of toll-like receptor (TLR), production of reactive oxygen species (ROS) and apoptosis. TNF-α and IL-6 in the culture supernatant was determined by ELISA. A total of nine experiments were performed.

**Results:** No differences among groups were found regarding TER (p=0.443), apoptosis (p=0.751), ROS (p=0.999), expression of TLR-2 (p=0.493), TLR-4 (p=0.418) and TLR-9 (p=0.937) and secretion of TNF-α (p=0.438). IL-6 secretion was higher (p=0.001) by cells incubated with post-HD pool (2.07±0.93pg/ml) when compared with cells incubated with CTL pool (0.67±0.35), NND-CKD (0.61±0.53) and pre-HD (0.11±0.45).

**Conclusions:** The results obtained from this model suggest that uremic serum protects colonocytes from the detrimental effects of inflammation and apoptosis. Serum uremia may break the intestinal barrier, which could be a consequence of pro-inflammatory stimuli of the dialysis process.

**Funding:** Government Support - Non-U.S.

**FR-PO874**

Prediction of One-Year Mortality and Hospitalization Risk Using Nutritional Indicators and Their Trajectories in a Large Prevalent Hemodialysis Cohort

Michelle M Y. Wong,1 Stephan Tijskens,2 Yuedong Wang,2 Len A. Usvyat,3 Qingqing Xiao,1 Peter Kotanko,1 Franklin W. Maddux,3 Renal Research Inst; 1Univ of California - Santa Barbara; 2Fresenius Medical Care North America.

**Background:** Existing nutritional scores developed in the hemodialysis (HD) population do not consider temporal trajectories of nutritional parameters. We aimed to develop predictive models for mortality and hospitalization using readily available nutritional indicators and their rates of change.

**Methods:** Using retrospective data from a large US HD provider, a cohort with HD vintage ≥1 year (N=21,082 and N=23,384 in mortality and hospitalization analyses, respectively) was randomly split 2:1 for model development, testing and validation. Parameters included demographics, nutritional/inflammation parameters, and slopes of all continuous variables over 6 months. Follow-up period was January-December 2012. Performance of generalized linear models and generalized additive models (GAM) was evaluated with area-under-the-curve (AUC), sensitivity and specificity.

**Results:** For both mortality and hospitalization prediction, GAM performed best. The best mortality model included neutrophil:lymphocyte ratio (NLR) slope, serum bicarbonate slope, albumin, creatinine, age, sex and vintage (AUC 0.85, 95% CI 0.83-0.86; sensitivity 0.70; specificity 0.83). The best hospitalization model included NLR slope, albumin, congestive heart failure, serum bicarbonate slope, creatinine, serum phosphate slope, vintage, diabetes, serum phosphate, volume of urea distribution, age and enPCR (AUC 0.70, 95% CI 0.62-0.79; sensitivity 0.41; specificity 0.88).

**Conclusions:** We developed novel and accurate predictive models for mortality and hospitalization using nutritional indicators and their slopes over time. Future studies are needed to assess if its application can improve nutritional intervention allocation and outcomes in HD patients.

**Funding:** Pharmaceutical Company Support - Renal Research Institute

**FR-PO875**

Extracellular Fluid/Intracellular Fluid (ECF/ICF) Volume Ratio Is A Novel Risk Indicator of Death and Highly Related to Malnutrition-Inflammation-Arteriosclerosis (MIA) Complex in Hemodialysis (HD) Patients

Fumijung Kim, Soyon Rhee, Jiwon Ryu, Hee Jung Jeon, Jungs-woo Noh, Ja-Ryong Koo. Nephrology, Hallym Univ Hospital, Dongtan/Seoul, Korea.

**Background:** Fluid overload and malnutrition are well recognized risk factors contributing to the high mortality in HD patients. Recent studies suggest pathophysiological link between fluid overload and malnutrition as a part of MIA complex. Because the ECF and ICF volume can represent fluid volume and nutritional status respectively, ECF/ICF ratio could be defined as a novel integrated marker reflecting both fluid overload and malnutrition. Accordingly we investigated the relationship of ECF/ICF ratio to survival in the context of MIA complex in chronic HD patients.

**Methods:** 77 HD patients (age 53±13 year, diabetes 38%) were prospectively enrolled. ECF/ICF volume was measured by multi-frequency bioimpedance analysis. Nutrition, inflammation, arteriosclerosis and volume status were measured by serum albumin, C-reactive protein (CRP), pulse wave velocity (PWV) and serum B-type natriuretic peptide (BNP) respectively.

**Results:** Mean ECF/ICF ratio was 0.56±0.06 and cut-off value for maximum discrimination of survival was 0.57 by ROC curve. As compared with low ECF/ICF group (ratio<0.57, 58%), high ECF/ICF group (ratio>0.57, 42%) had higher all-cause mortality, CRP, PWV, BNP and lower serum albumin level. During the 5-year follow-up, 24 all-cause death occurred (18 in high ECF/ICF group versus 6 in low ECF/ICF group, log rank P<0.001). In Cox analysis adjusted for age, diabetes, BP and cardiac function, the ECF/ICF ratio was an independent predictors of all-cause death (HR=1.25, 95% CI=1.01-1.54, per 0.01 in ECF/ICF ratio) and nullify the effect of MIA component and volume marker on survival. The degree of malnutrition (albumin), inflammation (CRP), arteriosclerosis (PWV) and fluid overload (BNP) were correlated well with ECF/ICF ratio.

**Conclusions:** Chronic HD patient with high ECF/ICF ratio is not only fluid overloaded but malnourished and have stiff artery with more inflammation. As a novel integrated marker of fluid overload and malnutrition, ECF/ICF ratio is highly related to MIA complex and a major risk indicator of death in chronic HD patients.

**FR-PO876**

Weight Gain After Listing Independently Predicts Pre-Transplant Sensitization Status

Pritika Shrivastava,1 Krista L. Lentine,2 Ankit Sakhuja,2 Fidel Barrantes,3 Diane M. Cibrik,1 Yihung Huang,1 Abhijit S. Naik.1 1Univ of Michigan; 2Saint Louis Univ; 3Renal Medical Associates, NM.

**Background:** Non-alloimmune stimuli such as infections, vaccinations and pro-inflammatory events cause sensitization to HLA antibodies and increased panel reactive antibodies. Obesity is recognized as an inflammatory state. Given relationship between obesity and inflammation we speculated that weight gain on the waitlist may increase sensitization status at the time of transplantation.

**Methods:** Using national data from the Organ Procurement and Transplantation Network we identified first time kidney only transplant recipients, aged 18-70, transplanted between January 1,2009 and June 30,2013. Previous non-renal transplants were excluded. A calculated panel reactive antibody of 20% or more at the time of transplant was considered to be “sensitized”. Using a priori chosen variables we performed a logistic regression model with sensitized status at time of transplantation as the dependent variable and change in BMI from listing to transplantation, BMI at transplant, recipient age, prior sensitization status, prior pregnancy, dialysis time and race as independent variables.
Results: Among 55,894 patients transplant recipients. 39.45 % were female of which 67.31 % were previously pregnant. Overall 15.12 % had received prior blood transfusions. Mean BMI at listing and transplantation was similar at 28.4± 5.5 kg/m². Greater than 50 % patients with BMI ≥ 30 kg/m² at listing had an increased their BMI by time of transplantation, while <50 % patients in BMI< 30 kg/m² had lost weight. A 1-unit increase in BMI at listing in female patients was associated with an increased risk of being sensitized. aOR:1.01 (1.01-1.02). Other independent predictors included prior transplantation aOR:1.25 (1.18-1.33), AA race aOR:1.26 (1.19-1.32), pregnancy aOR:3.32 (3.04-3.63), dialysis time aOR:1.23 (1.11-1.14).

Conclusion: The majority of obese patients gain weight on the waitlist. We identified weight gain on the waiting list to be associated with a small but statistically significant increase in odds of being sensitized. Further studies are needed to determine the impact of malnutrition-inflammation complex on pretransplant sensitization.

FR-PO877

High Salt Diet Impairs the Immune Defense against Uropathogenic Escherichia coli in Murine Pyelonephritis

Katarzyna Jobin, Katharina Hochheiser, Maike Giesen, Christian Kurts. Inst of Experimental Immunology, Univ of Bonn, Bonn, Germany.

Background: Recent studies demonstrated that NaCl stimulates immune responses, for example by promoting Th17 cells differentiation, macrophage recruitment into tissues and pro-inflammatory cytokine release from epithelial cell lines. Specifically, high salt diet (HSD) exacerbated experimental autoimmune encephalomyelitis and improved immune defense against L. major infection. Little is known about the influence of HSD on anti-microbial responses in the kidney – an organ with extremely high sodium chloride concentration.

Methods: Wild type female mice were given normal salt diet (NSD) or HSD one week prior to infection with uropathogenic E. coli into the bladder resulting in pyelonephritis development. 20 h after the infection, kidneys were harvested and analyzed for CFU and immune cell subsets by flow cytometry.

Results: HSD exacerbated pyelonephritis as measured by CFU. Additionally, in kidney medullas of mice fed HSD the number of PMNs, Ly6c⁺ macrophages and NK cells was significantly decreased in comparison with NSD fed mice. Although PMNs from mice given HSD produced more ROS than PMNs from mice on NSD, in vitro studies demonstrated that less medullary PMNs from mice fed HSD than NSD were able to perform phagocytosis.

Conclusions: Contrary to the expectations, HSD worsened experimental pyelonephritis, possibly through affecting immune cell activation and/or migration into the kidney medulla. This finding may be of clinical significance and, if confirmed in human studies, decreasing salt intake during bladder infection or pyelonephritis could support antibiotic therapy. Further studies are needed to elucidate the immune mechanisms underlying the negative effect of HSD on pyelonephritis.

Gut Microbiota Lactobacillus Protects against the Progression of Renal Impairment Through the Modulation of TLR2-Mediated Gut Barrier Stability in Rats

Ayumi Yoshifuji, Shu Wakino, Junichiro Irie, Takaya Tajima, Katsuyuki Inokuma, Hirotsugu Hiro, Toshiro Sekiya. Keio Univ, Japan.

Background: Gut microbiota has been shown to have some role in the pathogenesis of various diseases and previous study demonstrated that Lactobacillus (Lact) decreased in number in CKD. In this study, we elucidated the significance of Lact in the pathogenesis of CKD.

Methods: Six-week-old spontaneously hypertensive rats (SHR) were rendered CKD by 5/6th nephrectomy (Nx). The SHR were divided into three groups; sham-operated SHR (SHR), SHR with Nx (Nx), and Shr given Lact (Nx+Lact). After 12 weeks, biochemical parameters, urinary protein excretion, IL-6, histological changes in the kidney, and molecular changes of tight junctions and TLR2 expression were explored. Furthermore, concentrations of fecal uroic acid were measured. To confirm the effect of Lact, rats are administered with broad antibiotics as pseudogerm-free condition and kept for 8 weeks with Lact. Human colon cell line, Caco-2 cells were treated with uremic toxin precursor, indole in the presence or absence of Lact or OxPACP, an inhibitor of toll-like receptor, putative receptor recognizing Lact. The expressions of colon tight junction proteins were examined by immunoblotting.

Results: The gut flora analysis revealed that the decrease in Lact in Nx, which was restored in Nx+Lact. However, fecal uroic acid contents did not show significant changes. Both serum indoxylsulfate and IL-6 increased in Nx. These increases were ameliorated inNx+Lact. The decreases in the tight junction protein Occludin and ZO-1 as well as in TLR2 in Nx were mitigated by Lact. In the pseudogerm-free condition, Lact decreased the urinary protein excretion. In Caco-2 cells, the downregulations of Occludin and ZO-1 by indole were ameliorated by Lact. OxPACP inhibited the Lact-induced restoration of these tight junctions.

Conclusions: The supplementation of Lact improves the gut environment through the activation of TLR2 pathway. This improvement would contribute to the decrease in systemic uremic toxin levels, systemic inflammation and urine protein excretion. This probiotic therapy can provide novel therapeutic strategy against the progression of CKD.

Relationship Between Serum Uric Acid Change and Renal Injuries: An Observational Cohort Research from Pinggu District, Beijing

Xiaohong Fan, Wenling Ye, Jianfang Cai, Jie Ma, Ying Sun, Xueweng Li, Xuemei Li. Dept of Nephrology, Peking Union Medical College Hospital.

Background: Hyperuricemia is thought to be a risk factor of CKD and ESRD. This research aims to demonstrate the relationship between serum uric acid change (dUA) based upon baseline from general population and indexes of renal injuries.

Methods: This cohort research was based on 5 years’ follow up of an epidemiological study in 2008 in Pinggu District, Beijing. Baseline population was 7086, and 5364 subjects were followed up in 2014. All subjects were interviewed with questionnaires, tests of antiproreopulmonary indicators, blood and urine sample collection. Serum creatinine, cystatin C, eGFR were tested. Serum uric acid was applied to evaluate differences of indexes among all groups. Risk factors of CKD (CRIC≥3.9mg/ mmol & eGFR<60ml/min/1.73²)were evaluated with Multiple Logistic regression analysis.

Results: 1. 5364 patients(M:F:1:1.1) were included. In 2008 prevalence of hyperuricemia was 5.9%(7.0% for men, 5.0% for women), and Prevalence of hyperuricemia was 5.9%(7.0% for men, 5.0% for women) in 2014. 2. CRIC≥3.9mg/ mmol & eGFR<60ml/min/1.73² were evaluated with Multiple Logistic regression analysis.

Results: 1. 5364 patients(M:F:1:1.1) were included. In 2008 prevalence of hyperuricemia was 5.9%(7.0% for men, 5.0% for women), and Prevalence of hyperuricemia was 5.9%(7.0% for men, 5.0% for women) in 2014. 2. aOR of group N/N were significantly higher than that of group N/H/N, indicating that GFR of hyperuricemia patients following up in 2014 declined more than that of patients without hyperuricemia; serum cystatin C in 2014 increased significantly from group 1 to group 4; there was no significant difference among all groups inlnIMGAG/Cr. 3. AUA, age, BMI, hypertension, DM were independent risk factors of CKD. HR of CKD in group N/H/N was 1.38 times(95%CI 1.30-2.68, P<0.001) and 4.2 (95%CI 1.26-6.70, P=0.001) times of group N/N.

Conclusions: In general population, elevation of serum uric acid is the independent risk factor of GFR decline and serum cystatin C ascent. It is also the independent risk factor of the development of CKD, and the decline of uric acid in the blood may reduce the risk of renal injuries.

Leucine Disposal Rate for Assessment of Amino Acid Metabolism in Maintenance Dialysis Patients

Evelyn Herring, Serpal Muge Deger, Feng Sha, Cindy Booker, Charles D. Ellis, Talat Alp Ikizler, Nephrology, Vanderbilt Univ, TN; Veteran Affairs, TN.

Background: Protein energy wasting (PEW) is common in patients undergoing maintenance hemodialysis (MHD) and is closely associated with poor outcomes. Insulin resistance and associated alterations in amino acid metabolism is a potential pathway leading to PEW. In this study we hypothesized that measurement of leucine disposal rate (LDR) during a hyperinsulinemic-euglycemic-enauxaminocidic clamp (HEAC) procedure would accurately measure the sensitivity of insulin for its actions on concomitant carbohydrate and protein metabolism in MHD patients.

Methods: We examined 15 MHD (aged 52±13 years, BMI 29.5±kg/m²; patients and 16 control subjects (aged 46±10 years and BMI 28±7 kg/m²) by hyperinsulinemic euglycemic clamp (HEAC) procedure followed by HEAC clamp procedure to obtain glucose disposal rate (GDR) and LDR, respectively.

Results: The GDR by HEAC was 4.9±1.9 mg/kg/min in the MHD subjects compared to 6.3±1.4 mg/kg/min in the controls (P<0.047). The LDR during HEAC was 0.99±0.03 mg/ kg/min for MHD patients vs 0.12±0.05 mg/kg/min for control (P<0.11). The GDR derived by HEAC and LDR correlated well in the control population (r=0.793, P=0.001), but less so in the MHD subjects (r=0.346, P=0.25).

Funding: Government Support - Non-U.S.
Conclusions: Leucine disposal rate reliably measures amino acid utilization in MHD patients. The lack of correlation between GDR versus LDR in MHD subjects requires further investigation for understanding the effects of insulin signaling on protein metabolism in MHD patients.

FR-PO881
Age and Dependence on Dialysis Are More Important Predictors of Immune Response to Influenza Vaccine Than Inflammation and Iron Status

Jaromír Eiselt,¹ Lukas Kielberger,¹ Daniel Rajdl,2 Jaroslav Racek.2 Internal Dept 1, Charles Univ, Plzen, Czech Republic; 2Dept of Biochemistry, Charles Univ, Plzen, Czech Republic.

Background: The immune response to influenza vaccine is not uniform and may be influenced by many factors, e.g. comorbidities, age, inflammation or iron metabolism. The aim of our study was to identify factors associated with low production of hemagglutination-inhibition antibodies (HIA) after vaccination in hemodialysis (HD) patients and controls.

Methods: We evaluated the immune response to the influenza vaccine in a total of 122 stable HD patients and in 37 subjects without renal dysfunction. To identify factors associated with immune response, a stepwise backward and forward algorithm for a linear regression model was used with postvaccination increase in HIA titre against H1N1 vaccine strain as dependent variable and following independent variables: age, dependence on dialysis, diabetes, iron, transferrin, transferrin saturation, ferritin, hepaticin, interleukin-6, C-reactive protein, albumin, prealbumin and pre-vaccination HIA protective titre.

Results: The rate of HIA production was lower in HD patients than in controls. Factor increases in geometric mean titer for the H1N1 strain were 2.9 in HD and 6.6 in controls (p<0.001), with the respective figures being 2.8 and 3.1 (p=ns) for the H3N2 strain, and 2.4 and 4.7 (p=0.05) for the B strain. Also, post-vaccination seroconversion rates were lower in the HD group than in controls (43% versus 73% against the H1N1 strain; p<0.005; 43% versus 53% against the H3N2 strain; p=ns; and 36% versus 62% against the strain B; p<0.05). According to the regression model (adjusted R² 0.298, p<0.00001), the predictors of low HIA production against H1N1 strain were high age (p<0.0001), dependence on dialysis (p=0.011) and high transferrin saturation (p=0.03).

Conclusions: The immune response to the influenza vaccine was lower in HD patients than in controls. Besides dependence on dialysis, the most significant predictors of low antibody production were high age of vaccinated subjects and high transferrin saturation. Immune response was independent of other markers of iron metabolism and inflammation.

Intravenous Administration of L-Carnitine (LC) May Maintain the Muscle Volume in Hemodialysis (HD) Patients

Jyunichiro Hashiguchi,¹ Takuhisa Uchino,¹ Miki Yano,¹ Satoshi Funakoshi,¹ Osamu Sasaki,¹ Hiroshi Ichinose,¹ Kenji Sawase,¹ Yoko Obata,¹ Tomoyo Nishino,¹ Yutaka Mori,¹ Kazunori Utsunomiya,¹ Takashi Harada.¹ ¹Nagasaki Kidney Center, Nagasaki, Japan; ²Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan; ³Jikei Univ, Tokyo, Japan.

Background: Patients on maintenance HD usually suffer from dialysis-related carnitine deficiency, causing various clinical symptoms. At Carnitine Consensus Conference in 2003 convened by The National Kidney Foundation, the level of evidence was strongest for the treatment of anemia, and weakest for the response of muscle weakness. We hereby investigated whether intravenous administration of LC can maintain the muscle volume in HD patients as assessed by % creatinine generation rate (%CGR).

Methods: Thirty-eight HD patients were enrolled in this study after appropriate informed consent. Subjects were treated with intravenous administration of 1000mg / body of LC at the end of every HD session for 12 months, then assessed by %CGR. Normalized protein catabolic rate (nPCR), geriatric nutritional risk index (GNRI) as well as serum albumin or hemoglobin levels were measured at the three points: 1 year prior to the treatment, the start of LC administration and 1 year after the treatment.

Results: As shown in Figure 1, average %CGR significantly declined during 1 year before the start of LC, and then stabilized 1 year after the treatment, suggesting LC administration might prevent the loss of muscle volume. Serum albumin, hemoglobin, nPCR and GNRI stayed the same level during observation period.

Conclusions: Intravenous LC administration may potentially maintain the muscle volume in patients undergoing HD.

Nutrition Application Mobile Application in Patients with Chronic Kidney Disease
Kumar Sharma, 1 Sakkarin Chirapongsathorn, 2 Zhen Wang, 3 Haun Jenny Lu. 1
1 Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; 2 Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; 3 Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; 4 Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; 5 Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background: While mobile phone applications have become increasingly important in the last decade, few eating healthy mobile applications exist for patients. Yet in their daily lives, patients on a restricted diet often lack instant access to health information with regards to the food that is in front of them. It is therefore an objective of this pilot project to introduce a device that patients can utilize to overcome such problems.

Methods: The nutrition analysis application is named “GoFoody Project” and primarily consists of two functions: a scanning system and a recommendation system.

Results: The first major component of this invention is the food scanning and recognition process, which is comprised of two sub-processes: a photo recognition and a barcode scanning. In the photo recognition, the user can take a picture of food and send it to the cloud database for further processing, regardless of their location. Second, the recommendation system compares the patient’s medical profile with their consumptions records in order to make health and dietary suggestions.

Conclusions: Over the next few years, we anticipated that this invention will be popular in grocery stores such as Walmart, Target, etc. We plan to demonstrate our invention to the healthcare industry by using the example of computer vision technology and cloud database.

Lipoxin A4, Attenuates Obesity-Induced Adipose Inflammation and Associated Liver and Kidney Disease
Emma Borjeson, 1 Kumar Sharma, 1 Catherine Godson, 2 1 Center for Renal Translational Medicine, Inst for Metabolomic Medicine, UC San Diego, San Diego, CA; 2 Diabetes Complications Research Centre, Convay Inst, Univ College Dublin, Dublin, Ireland.

Background: Visceral obesity and adipose inflammation is considered a driving force of systemic disease, e.g. chronic kidney disease (CKD). Inflammatory resolution is actively regulated by specialized pro-resolving mediators (SPMs), including the lipid LX4A. Impairment of SPMs may underlie development of obesity-related pathology. Here we explored the therapeutic potential of LXA4 in experimental obesity-induced systemic disease, e.g. liver cirrhosis and CKD.

Methods: C57BL/6 or Adiponectin-/- mice were fed a standard (10% fat) or high fat (60% fat) diet for 12 wks. LXA4 (1 nM) and benzo-LXA4 analogue (1.7 ng/g) were given via attenuation of visceral inflammation and associated liver and renal disease.

Results: Obesity caused distinct pathologies, including impaired glucose-tolerance, adipose inflammation, fatty liver and CKD. Lipoxins attenuated obesity-induced CKD; reducing glomerular expansion, mesangial matrix and urinary H2O2. Furthermore, LXA4 reduced liver weight, serum alanine-aminotransferase and hepatic triglycerides. LXA4 is actively regulated by specialized pro-resolving mediators (SPMs), including the lipid LX4A. Impairment of SPMs may underlie development of obesity-related pathology. Here we explored the therapeutic potential of LXA4 in experimental obesity-induced systemic disease, e.g. liver cirrhosis and CKD.

Conclusions: In conclusion, Lipoxins protect against obesity-induced systemic disease and these data support a novel therapeutic paradigm for treating obesity and associated CKD.

Prevalence of Protein-Energy Wasting Syndrome and Its Association with Anemia, Erythropoietin Resistance, Overhydration and Body Composition in Hemodialysis Patients
Carlos Adrian Chavez-Mendoza, Jose Luis Ortega vargas, Jorge Osvaldo Montes rivera, Ricardo Correa-Roter, Olynka Vega-Vega.

Background: The prevalence of protein-energy wasting syndrome (PEW) in Mexican hemodialysis (HD) patients is unknown. Accordingly, there is no information on which clinical, biochemical, quality of life (QL), and body composition (BC) variables are associated or predictive of PEW in this population.

Methods: Observational comparative study that included 191 prevalent HD patients. PEW was determined by BIS employing (BCM,Fresenius®), QL was measured with KDQOL-36 and presence of PEW according to ISRNM criteria.

Results: General characteristics are shown in Figure 1, prevalence of PEW was 22%(n=41). No differences between groups (with or without PEW) were present in: age, Charlson index, number and type of drugs employed, time on dialysis, vascular access, history of PD or kidney transplant and hospitalization days in the last year. PEW patients had a higher prevalence of DM(p=0.04), lower Hb(p=0.006) and higher EPO requirements(p<0.04) despite similar iron reserves. In terms of BC, PEW patients had more overhydration (OH) and higher extracellular water (ECW), and lower lean and fat tissue indexes (TLT,FTI). Surprisingly, QL indicators were not different between groups. In a Cox multivariate logistic regression model analysis, predictors of PEW were:degree OH (OR 3.2, 95%CI 1.2-8.3; p=0.001), and ECW (OR 0.51, 95%CI 0.22-0.89; p=0.01).

Conclusions: Prevalence of PEW in the studied population was lower compared to other series. PEW patients exhibit a state of overhydration which is given by increased ECW, and accompanied by loss of LTI and FTI. No PEW impact on QL was observed. PEW pathways have increased anemia and higher requirements of EPO possibly associated to chronic inflammation.

Efficacy of Nutrition Counseling on Protein Intake Restriction in Chronic Kidney Disease Patients – Niigata Part of SOFT-J (Study on Regional Variation of FROM-J Intervention by JSN) 

**Methods:** 47 patients with CKD stage 3 (eGFR 30-59 mL/min/1.73m^2), age 48-85 years were recruited. Nutrition counseling was conducted once for 30 min by national registered dieticians using iPad and textbook used in FROM-J (Frontier of Renal Outcome Modification in Japan) study, aiming at promoting relationship between home doctor and nephrologist.

**Results:** All patients recorded their daily diets, 26/47 provided 24 hours urine collections. Counseling significantly decreased protein intake (record p<0.01, 1.00±0.23 g/kg/day post 1.00±0.26 g/kg/day, p<0.01, urine p<0.01 0.29±0.29 post 0.91±0.22 p<0.04). Although energy intake slightly decreased (record p<0.01, from 319±6.4 kcal/kg/day post 301±5.2 p=0.03), this was not below the prescribed optimal calories. Salt intake decreased in recorded data but not in urine data (record p<0.01, 7.6±1.2 p<0.03, urine p=0.42 post 9.1±4.4 p=0.36, respectively). There was no significant difference in body mass index, eGFR, and renal ischemic score.

**Conclusions:** iPad and textbook counseling by dieticians is effective in reducing protein intake without compromising necessary caloric requirements, even in clinics without regular nephrologist or dietary staff. Informational technology may be an effective method of delivering in-demand nutritional counseling that can directly benefit patient care.

**Actinib Has a Functional Role in Hepcidin Induction by Inflammation**

**Background:** Hepcidin is a negative iron regulatory hormone. Hepcidin contributes to the anemia of chronic kidney disease by restricting iron availability. Bone morphogenetic protein 6 (BMP6) signaling is a central transcriptional regulator of hepcidin. Recently, the transforming growth factor-β (TGF-β) BMP superfamily member Actinib was implicated in hepcidin induction by inflammation via noncanonical SMAD1/5/8 signaling, but its mechanism of action and functional significance in vivo remain uncertain.

**Methods:** Hep3B cells and primary hepatocytes were treated with Actinib B, BMP6, or Actinib A, without or with siRNA knockdown of Actinib/BMP pathway components, and were tested for SMAD2/3 versus SMAD1/5/8 phosphorylation and hepcidin expression. Liver Actinib B expression was measured and the effect of the Actinib inhibitor follistatin-315 was examined in multiple rodent models of anemia of inflammation.

**Results:** Actinib B, but not Actinib A, stimulated SMAD1/5/8 signaling and hepcidin expression in liver cells to a similar degree as canonical SMAD2/3 signaling, and with similar potency and kinetics. Liver Actinib B-induced hepcidin expression was selective, in hepatocyte-derived cells and was not induced by HIV in other cell types. Liver Actinib B mRNA expression was increased in multiple rodent models of inflammation associated with increased hepcidin and hypoferritermia. Follistatin-315 had no effect on basal hepcidin expression, but blunted hepatic induction by inflammation in mice.

**Conclusions:** This study establishes a novel mechanism for noncanonical SMAD activation by BMP/TGF-β superfamily members, and supports a functional role for Actinib B in hepatic induction by inflammation in vivo. Targeting the Actinib B-hepcidin pathway may lead to new therapies for anemia of inflammation including the anemia of chronic kidney disease.

**Effects of a Very Low Protein Diet Supplemented with Amino and Keto Acids on Skeletal Muscle Protein Synthesis and Degradation in Patients with Chronic Kidney Disease**

**Background:** Inulin, a non-digestible polysaccharide, was used to estimate protein synthesis and degradation in 6 healthy volunteers with healthy kidney function. Amino and keto acids were added to a VLPD period. Studies were performed after an overnight fast (post-absorptive state) and results express basal rates of protein turnover.

**Results:** After supplemented VLPD, as compared to a standard LPD: a) whole body protein turnover declined only slightly (0.51±2 vs. 0.55±2 µmol/kg/min, VLPD vs. LDP, p=NS); b) forearm protein net balance, i.e. the difference between protein synthesis and degradation, was less negative by 18% (from 113±3 to -9.3±2 nmol/min/100 ml, p<0.02); c) the efficiency by which amino acids are cyclic back from protein degradation into protein synthesis was increased by 12% (from 44±4 to 46±5 ±nmol/min/100 ml , p<0.02); d) Protein synthesis increased by 17% (from 33±1 to 38±4 nmol/min/100 ml, p<0.05).

**Conclusions:** Our data show that in patients with CKD stage 5 the response of muscle protein turnover to a AA/KA supplemented VLPD, as compared to a standard LDP, is characterized by similar reduced rates of protein degradation, but an increase in muscle protein synthesis, with enhanced recycling of amino acid derived from catabolism. Net protein balance is less negative, which suggests that the use of AA/KA-supplemented VLPD may be nutritionally safer than a standard LDP.

Chronic Kidney Disease Is Associated with Altered Muscle Mitochondrial Energetics by Functional MR Spectroscopy and Optical Spectroscopy

Baback Roshanravan,1 Bryan R. Kestenbaum,2 Jorge Gamboa,2 Jonathan Himmelfarb,1 Ian H. De Boer,1 Kevin Conley.1 1Medicine, Kidney Research Inst - Univ Washington, Seattle, WA; 2Vanderbilt Univ, Nashville, TN.

Background: Exercise intolerance and muscle weakness are frequent clinical complications of CKD associated with adverse health outcomes, yet the pathophysiology underlying these conditions is poorly understood.

Methods: Cross-sectional study of in vivo muscle mitochondrial energetics using 31P Magnetic Resonance Spectroscopy and optical spectroscopy (MRS/OS) in 12 subjects with non-diabetic CKD (eGFR<60) and 26 controls. 13MRS and OS were performed on the hand muscle under controlled ischemia. ATP/ADP (ATPase rate) was measured from phosphocreatine breakdown. Hemoglobin and myoglobin desaturation rates were assessed by OS to measure muscle oxygen uptake (O2 uptake). The primary outcome was the coupling efficiency of mitochondrial oxidative phosphorylation ATP production (ATPflux) per unit of oxygen consumed (O2 uptake) or O2/P ratio. Grip strength and timed up and go were assessed. Pearson's correlation coefficient was calculated for univariable associations. We used multivariable linear regression adjusting for age.

Results: Mean age of CKD patients was 53±13yrs. Physical performance of the CKD group was significantly decreased compared to controls (p=0.002). Mitochondrial ATP/ADP (ATPase rate) was significantly decreased in the CKD group vs. healthy controls (p=0.004). Mitochondrial coupling efficiency (ATPflux) was decreased (p=0.008). Mitochondrial respiratory chain efficiency was decreased (p=0.013). Previous studies have shown that the mitochondrial ATP/ADP ratio is inversely related to muscle strength. In the current study, the ATP/ADP ratio was also inversely related to grip strength (r=-0.52, p=0.006) and time to get up and go (r=-0.43, p=0.003). We also observed a decrease in hemoglobin and myoglobin desaturation rates in the CKD group compared to controls (p=0.001). The coupling efficiency of the mitochondrial respiratory chain (ATPflux) was significantly lower in the CKD group compared to controls (p=0.004). We also observed a decrease in hemoglobin and myoglobin desaturation rates in the CKD group compared to controls (p=0.001).

Conclusions: Application of non-invasive tools reveals that CKD is associated with greater muscle O2 uptake reflecting uncoupling of oxidative phosphorylation. These results suggest altered mitochondrial respiration in skeletal muscle of patients with CKD prior to dialysis.

Improving Outcomes with Nutrition in Older People with Advanced Chronic Kidney Disease – Baseline Data from a Pilot Randomised Controlled Trial

Lina Johansson,1 Mary Hickson,1 Edwina A. Brown,2 1Nutrition and Dietetics, Imperial College Healthcare NHS Trust, London, United Kingdom; 2Imperial Kidney and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.

Background: It is difficult to determine when to start dialysis in older people as creatinine and eGFR can be misleading. Dialysis start is often determined by weight loss, symptoms, potassium and fluid overload, all of which are potentially modifiable with nutrition. This pilot RCT aims to determine whether dietary interventions can result in improved patient outcomes, including time to dialysis, in older people with advanced chronic kidney disease (CKD).

Methods: Patients >65 years, with eGFR 10-20mls/min were randomised to an observational or intervention group (greater dietetic input). Data will be collected every 6 months for up to 2 years: nutritional status (Subjective Global Assessment), symptoms (Palliative Outcome Scale – Symptoms Renal), function (6 metre walk gas test speed and Jamar handgrip dynamometer) and fluid overload using Body Composition Monitor (Fresenius).

Results: 80 patients were recruited, baseline data presented. The 2 groups have statistically similar baseline demographic and clinical characteristics. Overall, 30% have malnutrition of which 58% are overweight/obese. 28% have nutritionally relevant potentially uraemic symptoms (nausea, vomiting and/or poor appetite). Fluid overload (>2L) was observed in 22% of those that were assessed (n=58).

Demographics

Control (n=40) Intervention (n=40)

Male n (%) 27 (67.5) 26 (65.0)
Age years, mean (SD) 74.5 (6.8) 76.0 (7.4)
Diabetes n (%) 19 (47.5) 18 (45.0)
EgFR mls/min, mean (SD) 16 (4) 16 (3)
Potassium >5.5mmol/l % 10 5
Subjective nutritional assessments, %
Malnourished 38 23
Nausea, vomiting and/or poor appetite 25 30
Physical function
Handgrip strength ≤20kg women or ≤ 30kg men, indicative of weakness % 50 58

Conclusions: There is a high prevalence of indications for dietetic interventions within older people with advanced CKD at baseline which may positively affect outcomes within two years.

Retention of Acetylcarnitine in Chronic Kidney Disease Causes Insulin Resistance in Skeletal Muscle

Yasunori Miyamoto,1 Teruo Miyazaki,2 Akira Honda,3 Homare Shimohta,1 Kouichi Hirayama,1 Masaki Kobayashi.1 1Nephrology, Tokyo Medical Univ Ibaraki Medical Center, Ami, Ibaraki, Japan; 2Joint Research Center, Tokyo Medical Univ Ibaraki Medical Center, Ami, Ibaraki, Japan.

Background: Insulin resistance occurs frequently in patients with chronic kidney disease (CKD) and ameliorates after introduction of hemodialysis (HD). However, the mechanisms of insulin resistance associated with CKD are unclear. An increased mitochondrial acetyl-CoA/carnitine ratio causes insulin resistance in skeletal muscle, and this ratio is regulated by carnitine acetyltransferase (CAT), which transfers excess acetyl moieties to carnitine (CT). Because the resulting acetylcarnitine (AcCT) is excreted in urine, we hypothesized that retention of AcCT might be a cause of insulin resistance in patients with CKD.

Methods: Serum samples were collected from 64 patients with CKD (including 14 HD patients) and 31 control subjects who underwent a medical examination. CT and AcCT concentrations in sera were measured by HPLC-ESI-MS/MS. The effects of exogenous AcCT (0-300 µM) on insulin-dependent 2-deoxyglucose (2DG) uptake, mitochondrial CT and AcCT levels, and the mitochondrial acetyl-CoA/carnitine ratio were examined in a cultured skeletal muscle cell line (C2C12 myotubes).

Results: The serum concentration of AcCT, but not that of CT, significantly increased with reduction of renal function, as classified by eGFR (stage I 2.7 ± 0.6 µM, stage 3a 6.1 ± 1.1 µM, stage 3b 10.9 ± 1.9 µM, stage 4 46.3 ± 2.1 µM, stage 5 28.2 ± 5.9 µM, mean ± SEM). After introduction of HD, the increased AcCT levels were significantly reduced (pre 16.3±2.5 µM, post 6.3 ± 0.7 µM). In vitro experiments in skeletal muscle cell lines showed that uptake of 2DG was significantly and dose-dependently inhibited by addition of...
High Protein Intake in Relation to Incident End-Stage Renal Disease (ESRD) Among Blacks and Whites in the Southern Community Cohort Study (SCCS) - Rakesh Malhotra, Edmond Kato Kabagambe, Kerri L. Cavanaugh, William J. Blot, Talat Alp Ikizler, Loreen Lipworth. Vanderbilt U Med Center.

Background: Dietary composition could contribute in part to observed racial disparities in ESRD incidence. Diabetes, a major risk factor for ESRD, may lead to differences in dietary intake and metabolism. We examined whether protein intake is associated with ESRD risk and whether the association varies by race and diabetes.

Methods: We conducted a nested case-control study of ESRD within the SCCS, a prospective study of low income blacks and whites in the southeastern U.S. (2002-2009). Through 2012, 1,074 incident ESRD cases were ascertained by linkage with the USRDS, and matched to 3,230 controls on age, sex, and race. A validated food frequency questionnaire was administered at baseline. Odds ratios (OR) and 95% confidence intervals (CI) for ESRD were computed in relation to protein intake, expressed as daily % of total energy intake and modeled in 1 standard deviation (SD) increments in unconditional logistic regression models stratified by race and diabetes. ORs were adjusted for age, sex, BMI, education, income, hypertension, total energy intake and % energy from saturated and polyunsaturated fat.

Results: Median daily % energy intakes from protein were higher among whites than blacks and those with vs. without diabetes, but differences between ESRD cases and controls were small (15.9 and 15.7%, respectively, for blacks with diabetes, 14.6 and 14.6% for blacks without diabetes, 16.6 and 16.4% for whites with diabetes, and 15.1 and 15.1% for whites without diabetes). For a 1 SD (3.17%) increase in daily % energy intake from protein, adjusted ORs (95% CI) for ESRD were 1.18 (1.05-1.34) for blacks with diabetes, 1.06 (0.93-1.21) for blacks without diabetes, 0.89 (0.61-1.30) for whites with diabetes and 1.00 (0.74-1.33) for whites without diabetes.

Conclusions: Our results raise the possibility that among blacks with diabetes, a diet higher in protein is associated with increased incidence of ESRD. If confirmed, future studies might examine contributors leading to adverse outcomes associated with high protein intake in this subpopulation.

High-Fat Diet Induces the Production of IKKε by Macrophages to Promote Nephrotoxicity - Xin Wan, Binbin Pan, Changchun Cao. 1 Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital).

Background: The NF-κB activation may participate in lipid nephrotoxicity which may be regulated by inhibitor kappa B kinase epsilon (IKKε). To investigate the role of IKKε in this process, mice experiment was performed.

Methods: Mice were grouped into wild-type with normal fat diet (WN), 2 wild-type with high fat diet (WH), 3 IKKε knock-out with normal fat diet (KN), and 4 IKKε knock-out with high fat diet (KH). Renal function, lipid, histological changes and tubular proliferation were analyzed. IL-1β, TNF-β, p50 and p65 were determined by western blot. NF-κB level was tested by EMSA. Expression of IKKε was evaluated through immunohistochemistry and immunofluorescence.

Results: Cystatin C levels were significantly higher in WH group than others. Staining with hematoxylin-eosin revealed that tubular lesions in WH group (3.53±0.21) were more severe than in WN group (0.32±0.11). By Immunohistochemistry, WH group exhibited marked macrophages infiltration than WN, KN and KH groups. Western blot showed significant increase of IL-1β, TNF-β and marked increment in the expression of NF-κB pathway components consists of p50 and p65 in WH group, while these increases were blocked in KN and KH groups. Furthermore, NF-κB level in WH group was higher than other groups. WH group exhibited remarkable macrophages infiltration than other groups by Immunofluorescence. Immunohistochemistry showed remarkable increases in the expression of IKKε in the WH group compared with other groups. Immunofluorescence analysis demonstrated that the expression of IKKε was located around macrophages.

There was no relationship between muscle logTLR4 and age, BMI, muscle area, nPNA, calorie intake, albumin, CRP, BUN, bicarbonate, triglycerides, fibrinogen, and phosphate levels. At multivariate analysis SGA and eGFR only contributed significantly to the prediction of TLR4 expression in muscle (p=0.003).

Conclusions: Both low SGA score (which indicates an overall concept of nutritional status) and eGFR (an index of residual renal function) play an independent role to predict TLR4 content in muscle of CKD patients. TLR4 content in muscle rises progressively along with progressive decline of residual renal function, with a 2-fold increase in TLR4 as eGFR declines from 12 to 5 ml/min. Both wasting and progressive loss of residual renal function are predictive of muscle deterioration.

Randomized, Double-Blind, Crossover Clinical Trial on Oral Rice Endosperm Protein Supplementation to Patients on Maintenance Hemodialysis

Background: Protein-energy wasting, a state of metabolic and nutritional derangements, is an important risk factor that affects outcomes of patients with CKD, particularly in ones with ESRD and on maintenance dialysis. Purified rice endosperm protein (REP) contains less phosphorus (150 mg/100g) compared with soybean (787 mg/100g) and casein (737 mg/100g) proteins, and may improve nutritional status without imposing further metabolic derangements.

Methods: We carried out a randomized, double-blind, placebo-controlled, cross-over study to evaluate the effect of REP supplementation (5 g per day x 4 weeks) on nutritional and metabolic status in 50 MHD patients (UMIN000010876). The primary outcome was the change in urea kinetic-based normalized protein nitrogen appearance (nPNA), an indicator of protein intake in MHD patients. The inclusion criteria were: (1) nPNA < 1.2 g/kg/day, (2) serum albumin concentration ≤ 3.0mg/dl, (3) body mass index ≥ 19 kg/m² and < 23 kg/m², (4) 5% variation in dry weight during the period of preceding 6 months, and (5) duration of MHD ≥ 2 years.

Results: By intention-to-treat analyses, REP increased nPNA by 0.07 (95%CI, 0.03-0.11) g/kg/day compared with placebo, whereas Dserum phosphorus concentration was not significantly different between the groups (0.18 (95%CI, -0.23-0.58) mg/dL). REP did not show significant effects on other nutritional parameters. Per-protocol analyses yielded similar results. There were no specific complications associated with the REP supplementation.

Conclusions: REP may be useful for dietary supplementation in MHD patients. Further studies are warranted to evaluate its long-term or high-dose efficacy.

Funding: Government Support - Non-U.S.

FR-PO999

Association of Serum Phosphate Levels and Mortality Risk in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis

Background: Abnormalities of serum phosphate are associated with increased risk for mortality in end stage renal disease (ESRD) or dialysis patients. Use of phosphate binders is an important risk factor that affects outcomes of patients with CKD, particularly in ones with ESRD and on maintenance dialysis. Purified rice endosperm protein (REP) may be useful for dietary supplementation in MHD patients.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT and prospective cohort studies assessing effects of high serum phosphate (compared to normal range) and a 1-mg/dL increase in phosphorus level in patients with CKD (eGFR < 60 ml/min/1.73 m²). We excluded ESRD, dialysis, or renal transplant patients. The primary outcome was risk of all-cause mortality. We used hazard ratio (HR) or risk ratio (RR) in the multivariate model as an effect estimate.

Results: From 15 full-text articles, five studies involving 6,536 patients were included in the meta-analysis. All were prospective cohort studies of CKD stage 3 or 4 patients. There was an increase all-cause mortality risk in higher phosphorus levels (HR = 1.36, 95% CI: 1.24 to 1.0, p=0.01, I²=0%) compared with normal phosphorus levels. A 1-mg/dL (0.1 mmol/L) elevation in serum phosphate also increases mortality risk with HR=1.23 (95% CI: 1.14-1.34, p<0.01, I²=0%).

Conclusions: Elevated serum phosphate levels were independently associated with increased mortality risk among patients with CKD. Randomized controlled trials are needed to assess the benefits of using phosphate lowering therapy in patients with CKD before developing ESRD or dialysis.

FR-PO901
The Comparison of Serum Calcium, Phosphorus and Intact Parathyroid Hormone Between Peritoneal Dialysis Patients and Hemodialysis Patients
Guisén Li, Li Wang.
Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: In this study, we compared the serum calcium, phosphorus and intact parathyroid hormone between peritoneal dialysis patients and hemodialysis patients to study the difference in MBD biochemical variables between PD and HD.

Methods: 907 patients were enrolled from July 1, 2014 to December 31, 2014, including 148 patients received peritoneal dialysis and 359 patients received hemodialysis patients (HD) more than 3 months. Basic clinical information, data of dialysis, serum calcium, phosphorus and iPTH levels were collected in all patients, and comparative analysis was carried out based on those information.

Results: The age and the dialysis vintage was significantly higher in HD group than in the PD group (P <0.001). Serum phosphorus was lower, percentage of phosphorus in target was higher and percentage of calcium in target was lower (P =0.271) in PD group than in HD group (P<0.001). The serum phosphorus levels of PD patients with peritoneal high transport characteristics or high average transport were much lower than those with low transport or low average transport (P = 0.017). The levels of serum phosphorus (P <0.001), iPTH (P<0.01) and alkaline phosphatase(P=0.001) were much lower in patients with RRF<2ml/min than those with RRF≥2ml/min. The levels of serum calcium (P <0.01), corrected calcium(P<0.01), phosphorus (P = 0.025), iPTH (P<0.001) and alkaline phosphatase(P<0.01) were much lower in patients with urine volume ³100ml/d than those <100ml/d. There was a negative correlation between RRF and serum phosphorus (r=−0.291, P<0.01) and iPTH(r=−0.271, <0.01) in PD group. The weekly total KT/V(−0.201,P = 0.019) and weekly total creatinine clearance(Ccr) (r=−0.407, P<0.001) negatively related to serum phosphorus. The Cor(r=−0.241,P <0.01) negatively correlated with serum iPTH.

Conclusions: The serum levels of phosphorus is lower and the percentage of achieving targets of serum phosphorus is higher in PD patients than HD patients. The peritoneal high transport characteristics, RRF<2ml/min, urine volume ³100ml/d and the nutrition status have obvious influence on the serum phosphorus and iPTH levels in PD patients.

FR-PO902
Increased Risk of Cerebral Hemorrhage in Hemodialysis Patients with Hyperphosphatemia: The Q-Cohort Study
Shunsuke Yamada,1 Masanori Tokumoto,1 Masatomo Taniguchi,1 Takanari Kitazono,1 Kazuhiko Tsuryu,1 2 Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; 1Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan; 1Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.

Background: Mounting evidences have shown that hyperphosphatemia, an established component of CKD-MBD, accelerates cardiovascular disorders in dialysis patients. However, previous studies did not separately determine the effects of hyperphosphatemia on the onset of cerebrovascular disorders and cardiovascular disorders in dialysis patients.

Methods: The present study is an observational study consisting of 3431 outpatients undergoing hemodialysis. The associations between the baseline serum phosphate (Pi) level and the onset of cerebral bleeding and infarction were examined. Individual variable was serum Pi level. Dependent variable was the onset of cerebral hemorrhage and infarction. Age, sex, diabetes mellitus, history of cardiovascular events, dialysis vintage, Kt/V, etc. were adjusted. The regression coefficients for Pi level were analyzed using multiple linear regression analysis.

Results: The serum levels of phosphorus is lower and the percentage of achieving targets of serum phosphorus is higher in PD patients than HD patients. The peritoneal high transport characteristics, RRF<2ml/min, urine volume ³100ml/d and the nutrition status have obvious influence on the serum phosphorus and iPTH levels in PD patients.

Conclusions: Novel correction equations for iCa show better association with iCa and hypercalcemia evaluated by iCa. Its clinical usefulness needs to be evaluated in further studies.

Relationship Between Dietary Phosphorus Intake and Protein and Energy Intakes in Hemodialysis Patients
David F. Seigles,1 David S. Goldfarb,2,3 Mary Lou Pompeii,1 Kathleen Woolf,1 Kamyar Kalantar-Zadeh,2 Mary A. Sevick.1 1NYU School of Medicine; 2NY Harbor VA Medical Center; 3NYU Langone Medical Center; 2NYU Steinhardt; 3UCLA School of Public Health.

Background: Excess dietary phosphorus may contribute to mineral and bone disorders in hemodialysis (HD) patients. However, many high phosphorus foods are also important sources of dietary protein, which raises concerns that phosphorus restriction may compromise protein status.

Methods: We conducted a cross-sectional study of 190 African American and white men and women on intermittent HD for >3 months. Dietary data were collected by three 24-hour recalls, which were analyzed using NDSR®. Only participants who completed all three recalls and reported intakes >500 kcal/d were included (n=137).

Results: Dietary phosphorus and protein were highly correlated (R=0.73). Based on linear regression, a 1,000 mg/d phosphorus restriction would provide about 78 g protein/d (or 1.1 g protein/kg/d for a 70-kg person). When adjusting for energy intake, the association of dietary phosphorus and protein was far less apparent (R=0.42). Further, the highest phosphorus intake was about two times greater than the lowest phosphorus intake for each energy and protein intake level (500 kcal and 5% of kcal increments), reaching 600 mg/d for some groups.

FR-PO903
Development and Evaluation of Novel Correction Equations for Serum Calcium Concentrations in Hemodialysis Patients
Yoshitsugu Ohji,1 Wei Ling Lau,1 Elani Streja,1 Connie Rhee,1 Steven M. Brunelli,2 Csaba P. Kovesdy,1 Kamyar Kalantar-Zadeh,2 1UC Irvine; 2DaVita Clinical Research; *UTHSC.

Background: Ionized calcium (iCa) but not total calcium (tCa) is the physiologically relevant component of blood calcium. However, these measurements correlate poorly in hemodialysis patients even after correction for serum albumin, which may be partly explained by electrolyte and acid-base derangements in this population.

Methods: In 1,366 patients who initiated conventional HD over four years (1/2007-12/2010), we identified 6,830 iCa measurements where serum albumin, iCa, sodium, chloride, phosphorus, and bicarbonate were measured simultaneously. We randomly divided patients into a derivation set (n=681) or a validation set (n=685) to develop and evaluate new correction equations for serum iCa concentrations by comparing correlation r and Bayesian information criterion (BIC) in linear regression analysis as well as receiver operating characteristic (ROC) curves for hypercalcemia determined by iCa (≥5.28 mg/dL).

Results: Albumin was associated with iCa, but its coefficient was -0.15, not -0.8 as shown in the conventional correction equation. Furthermore, albumin-corrected iCa showed lower correlation than uncorrected iCa with iCa (r=0.69 and 0.76, respectively). Two equations were developed from the derivation set as follows; [EQ1] 1.1*iCa – 0.12*(phosphorus+1) and [EQ2] 1.1*iCa – 0.08*(anion gap – 2). In the validation set, EQ1 and EQ2, compared to the conventional correction by albumin, showed better correction with iCa (r=0.78 and 0.80, respectively), lower BIC (96% and 92%, respectively), and higher area under the ROC curve for Ca-defined hypercalcemia (P<0.01 for both).

Conclusions: Novel correction equations for iCa show better association with iCa and hypercalcemia evaluated by iCa. Its clinical usefulness needs to be evaluated in further studies.

Recruitment and Retention to a Randomised Trial of Low versus High Serum Phosphate Levels in Hemodialysis Patients

Ranveer Bhattarava, 1 Paul E. Brenchley, 1 Philip A. Kalra, 2 Alastair J. Hutchinson. 1 Manchester Royal Infirmary, United Kingdom; 2 Salford Royal Hospital, United Kingdom.

Background: High phosphate is linked with increased mortality in dialysis patients in retrospective observational studies but cause and effect is unproven. A large scale RCT of high versus low serum phosphate would be required to determine whether serum phosphate reduction improves length or quality of life of dialysis patients. We performed a feasibility study to investigate whether such a large scale RCT might be possible in the future.

Methods: After consent, 104 HD patients were randomized to low (2.5-4.4 mg/dL) or high phosphate (5.6-7.5 mg/dL) groups. Non-calcium binders, and an adherence self-help program were used to titrate to target PO4 over 8 weeks. A 10 month maintenance period followed. Primary endpoint; % patient months within target range over 10 months. Secondary end points: % nephrologists agreeing to enrol patients, % eligible patients willing to participate, drop-out rate over 12 months, pill burden per subject.

Funding: 768 HD patients screened, 263 suitable, 228 treated, 207 randomized (13.5% of screened), 21 of 24 nephrologists (87.5%) agreed to enrol patients after assessing the protocol.

<table>
<thead>
<tr>

<td>49.5 (35.7)</td>
</tr>
<tr>
<td>Low PO4</td>
<td>38</td>
<td>53.5 (38.7)</td>
</tr>
</tbody>
</table>

Results: Conclusions: Less than 50% of PO4 levels were within target range over 10 months, and this will be analyzed as time-averaged results. More patients withdrew consent in the low PO4 group, with GI side-effects plus high pill burden being possible contributory factors. 65% patients completed the study with a drop-out rate of 35%. Drop-out due to death was substantially greater in the high PO4 group, but randomization was not stratified for other risk factors, and the overall mortality rate of 10% is lower than the expected dialysis rate of 13-17% per annum.

Activities: Research buy-in, 24 nephrologists agreed, 13.5% screened, 263 suitable, 228 randomized, 104 randomized (13.5% of screened), 21 of 24 nephrologists (87.5%) agreed to enrol patients after assessing the protocol.

Assessment of Barriers to Phosphorus Control in Dialysis Patients

Rashmi Bisla, Jasmin Sandhu, Vinod K. Bansal, Stephanie Kliethermes, Anuradha Wadhwa. Loyola Univ Medical Center, Maywood, IL.

Background: High phosphate levels are associated with increased cardiovascular and all-cause mortality but phosphate control continues to be a challenge amongst dialysis patients. In this study, we conducted a survey to assess phosphate control and identify barriers to phosphate control in patients receiving dialysis at Loyola outpatient dialysis unit.

Methods: The study consisted of 17 question survey evaluating patients knowledge and understanding of phosphate control, self care practices and social support as potential barriers to phosphate control. Patients were approached during dialysis to participate. Objective patient data and laboratory data was collected from electronic medical records. Study was approved by Loyola IRB.

Results: Of the 99 eligible subjects, 57 completed the survey. Mean age of the participants was 62 years, 52% were males and 75% were African Americans. Patients were categorized into uncontrolled (phosphate >5.5 mg/dL) and controlled phosphate group. The two groups had similar demographics, co-morbidities, dialysis adequacy and medication pill burden. Approximately 80% of patients with uncontrolled phosphate were aware of normal phosphate levels in dialysis patients, complications associated with high phosphorus and identified majority of foods with high phosphorus compared to 53% in the controlled phosphate group. There were no differences among the two groups related to social support or self-care practices. 75% patients in the controlled and 55% in the uncontrolled group were interested in learning more about phosphate control.

Conclusions: Patients with uncontrolled phosphate had significantly greater knowledge and understanding of phosphate control. While continued education of patients regarding phosphate control is important, qualitative research to study patients’ behavioral aspects is needed to better understand barriers to phosphate control.

Use of a Simple, Widely Available Laboratory Test to Quantify and Explain Variation in Phosphorus Levels in Beverages

Elisabeth L. Lindley, 1 David Francis Keane, 1 Tracey Ying, 2 John W. Macd. Agar, 2 Gunnar H. Heine, 3 Juergen Geisel. 1 Leeds Teaching Hospitals NHS Trust, United Kingdom; 2 Geelong Hospital, Australia; 3 Saarland Univ Medical Centre, Germany.

Background: Restriction of dietary phosphorus (P) is essential in the management of hyperphosphataemia in CKD. Beers and wines contain inorganic P that is readily absorbed but data on these beverages, and less well-known soft drinks, is difficult to obtain. An assay used routinely in hospital laboratories has been validated for measurement of P in a range of beverages (Lindley et al. 2014) enabling renal unit staff to compile information on locally sourced products and investigate variation between brands.

Methods: Beverages were processed as if they were urine samples and tested using inorganic P analysers in different countries.

Coca-Cola, which is strictly regulated world-wide, was used to check agreement between laboratories in the Saarland selection, with similar PO4 results. Yeast nutrient (a widely-used yeast nutrient) were compared with 8 Australian wines from UK supermarkets. Classic New South Wales containing little or no di-ammonium phosphate (DAP, a widely-used yeast nutrient) were compared with 8 Australian wines from UK supermarkets. Classic New South Wales containing little or no di-ammonium phosphate (DAP, a widely-used yeast nutrient) were compared with 8 Australian wines from UK supermarkets.

Results: The P content of alcoholic beers in the Saarland selection varied from 12 to 27 mg/dL, while reds contained 14 to 20 mg/dL. DAP increased the P level by about 2 mg/dL for every 100 mg/L added to the wine must. Much higher P levels in the supermarket wines were processed as if they were urine samples and tested using inorganic P analysers in different countries.

Conclusion: Restriction of dietary phosphorus (P) is essential in the management of hyperphosphataemia in CKD. Beers and wines contain inorganic P that is readily absorbed but data on these beverages, and less well-known soft drinks, is difficult to obtain. An assay used routinely in hospital laboratories has been validated for measurement of P in a range of beverages (Lindley et al. 2014) enabling renal unit staff to compile information on locally sourced products and investigate variation between brands.

Serum phosphate in the two groups

Conclusion: 1. Statistically significant separation in serum phosphate was achieved between the two groups (fig 1) with no apparent increase in secondary hyperparathyroidism. 3 patients in the HRG commenced Cinacalcet during the course of the study because serum PTH > 1200 mg/dL. 2. As expected, LRG had a significantly larger pill burden than the HRG, with 2 patients in the LRG taking 9 or more binder pills. 3. Despite increased pill burden, albumin levels were not different between groups. 4. Crude mortality 4 times higher in the HRG.

Efficacy and Safety of PT20: A Novel Iron-Based Phosphate Binder

Methods: Patients were on hemodialysis with serum phosphate (P) levels between 4.0 and 8.0 mg/dL plus serum ferritin levels <1000 ng/mL at their screening visit. All patients were then washed out of previous P-binders and required to have an increase in serum P of at least 1.0 mg/dL to enter study. 153 subjects were randomized to either 400 mg, 800 mg, 1600 mg, 3200 mg PT20 or placebo, each taken TID with meals for 28 days. Doses were not modified during the treatment period. Primary end point was change in serum P from Baseline to Day 29. Secondary endpoints assessed safety as well as haematological parameters.

Results: PT20 treatment significantly reduced serum P levels and demonstrated a dose response effect (ITT population; p<0.001). All dose groups showed a reduction in mean P levels greater than placebo. Mean reduction in P over the 28 days was (mg/dL) 1.36 /3200mg; 1.29 /1600mg; 0.59 /800mg; 0.40 /400mg and 0.17 /Placebo dose.

Conclusions: Use of adapatte-modified iron oxide (PT20) resulted in a statistically significant and dose-dependent reduction in serum phosphate over a 28 day period. The safety profile and tolerability were acceptable with AE's being mostly GI in nature, with no pattern of serious adverse events related to treatment. Limited iron absorption from PT20 was observed.

Phase III Study to Investigate the Long-Term Efficacy, Safety, and Tolerability of PA21 (Sucroferric Oxydroxide) in Japanese Hemodialysis Patients with Hyperphosphatemia

Conclusions:

Results:

Methods: In total, 213 patients were randomized to SFOH (750–3000 mg/day; starting dose 750 mg/day; available as 250 mg and 500 mg tablets). SFOH was administered at Week 0, after treatment with any prior phosphate binders had been discontinued. Doses of SFOH were titrated to maintain predefined serum phosphorus (sP) concentrations of 3.5–6.0 mg/dL.

Results: Mean sP concentrations decreased from 5.46 mg/dL at Week 0 to 5.00 mg/dL at the last evaluation. Mean sP concentrations were maintained within the target range of 3.5–6.0 mg/dL throughout the 52-weeks treatment period. The average number of SFOH tablets was 3.3 tablets/day, and the average dose of SFOH was 1.141 mg/day. Overall, the incidence of adverse events and adverse drug reactions was 93.6% and 32.9%, respectively. Frequently observed adverse drug reactions were diarrhea (22.4%) and constipation (2.5%), no severe diarrhea or constipation was reported. In spite of slight increases in serum ferritin and transferrin saturation, no clinical signs of iron accumulation or overload were observed at 52 weeks.

Conclusions: SFOH demonstrated a sustained sP-lowering effect 52-weeks of treatment in Japanese HD patients, and was associated with a low pill burden and good tolerability.

Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Hemodialysis Patients

Conclusions:

Methods:

Results:

Conclusions: 1. Statistically significant separation in serum phosphate was achieved between the two groups (fig 1) with no apparent increase in secondary hyperparathyroidism. 3 patients in the HRG commenced Cinacalcet during the course of the study because serum PTH > 1200 mg/dL. 2. As expected, LRG had a significantly larger pill burden than the HRG, with 2 patients in the LRG taking 9 or more binder pills. 3. Despite increased pill burden, albumin levels were not different between groups. 4. Crude mortality 4 times higher in the HRG.

Phase III Study to Investigate the Long-Term Efficacy, Safety, and Tolerability of PA21 (Sucroferric Oxydroxide) in Japanese Hemodialysis Patients with Hyperphosphatemia

Funding:

Background: A retrospective database study was conducted on the real-world effectiveness of sucroferric oxydroxide (SO) in controlling serum phosphorus (sP) among hemodialysis (HD) patients (pts). This analysis focuses on the subset of patients who self-reported race as Black or African American.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author. 576A
In a cohort of African American hemodialysis patients prescribed sucroferric oxyhydroxide, a 57% increase in patients with in-range (3.5-5.5 mg/dl) serum phosphorus (p<0.001) along with a decrease in pill burden (4.8 fewer pills, p<0.001) was observed.

Real-World Use of Sucroferric Oxyhydroxide in Hemodialysis Patients: Changes in Serum Phosphorus Control and Phosphate Binder Pill Burden

**Linda H. Ficociello, Lin Ma, Vidhya Parameswaran, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. Fresenius Medical Care North America (FMCNA), Waltham, MA.**

**Background:** Approximately 40% of US dialysis patients (pts) do not achieve serum phosphorus (sPhos) goals (US-DOPPS Practice Monitor, 4/2015). This retrospective database analysis assessed the real-world effectiveness of sucroferric oxyhydroxide (SO) to control sPhos in hemodialysis (HD) pts.

**Methods:** In-center HD pts prescribed SO as part of routine clinical practice at FMCNA clinics with ≥1 sPhos during SO use were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder (PB) pills per day (PPD) were assessed 3-months before (baseline) and 3-months during SO treatment (follow-up).

**Results:** On average, pts (n=3151) were 54 years old with 4.3 years dialysis vintage (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder (PB) pills per day (PPD) were assessed 3-months before (baseline) and 3-months during SO treatment (follow-up).

**Conclusions:** In a large HD patient cohort prescribed sucroferric oxyhydroxide as part of routine clinical care, in-range serum phosphorus increased by 57% (13 to 20.4%, p<0.001) and mean pills per day decreased by 4.7 pills (8.4 to 3.7 pills, p<0.001).

Serum Phosphorus Control and Phosphate Binder Pill Burden Among Hemodialysis Patients Who Switched from Calcium Based Phosphate Binders to Sucroferric Oxyhydroxide

**Vidhya Parameswaran, Lin Ma, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. Fresenius Medical Care North America, Waltham, MA.**

**Background:** A retrospective database analysis of in-center hemodialysis (HD) patients (pts) who switched from calcium-based phosphate binders (PB) to sucroferric oxyhydroxide (SO) was conducted to study the real-world effectiveness of SO in controlling serum phosphorus (sPhos).

**Methods:** In-center HD pts who had ≥ 1 sPhos measured during SO treatment and switched from calcium-based PB were included. Comparisons were made between baseline (3 months prior to SO) and follow-up (3 months during SO) levels of sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day (PPD).

**Results:** Analyzed pts (n=1011) were, on average, 54 years old with dialysis vintage of 4.5 years and hyperphosphatemia (baseline sPhos=6.98 mg/dl). Prior therapy included 81.7% calcium acetate and 18.3% calcium carbonate. There was a significant decrease in sPhos (6.98 to 6.77 mg/dl, p<0.001) and PB PPD (8.2 to 3.7 pills, p<0.001). A 47% increase (13.5% to 19.8%, p<0.001) in the number of pts with in-range sPhos (3.5-5.5 mg/dl) was observed. Levels of iPTH (559.3 to 552.9 ng/ml) and sCa (9.2 to 9.1 mg/dl) did not change significantly. Significant differences in TSAT (34.0 to 34.8%, p-value=0.007) and FER (931.7 to 973.1 ng/ml, p<0.001) were observed. In pts not receiving IV iron (n=103), there were no significant changes in TSAT (34.5% to 33.4%) and FER (1039 to 1003.4 ng/ml).

**Conclusions:** In a HD cohort switched from calcium-based binders to sucroferric oxyhydroxide as part of routine clinical care, a 47% increase (p<0.001) in the number of patients with in-range serum phosphorus and reduction of serum phosphorus (0.21 mg/ dl, p<0.001) was observed. Pill burden decreased significantly (4.6 fewer pills, p<0.001).

Phosphate Binder VS-505 Prevents Hyperphosphatemia from Altering Aortic Gene Expression in 5/6 Nephronecrotic Uremic Rats

**J. Ruth Wu-Wong, Xiaoxuan Ruan, Yung-wu Chen, Jeery Wessell, Vidasym, Jackson Lab.**

**Background:** Chronic kidney disease (CKD) patients are known to have impaired vascular function. Clinical studies have linked hyperphosphatemia to a higher cardiovascular mortality in CKD.

**Methods:** We compared gene expression profiles in aorta isolated from 5/6 nephrectomized (NX) uremic Sprague Dawley rats fed a normal diet vs. a high phosphate (Pi) diet. Real-time RT-PCR analysis was conducted on selected genes in aorta prepared from 5/6 NX uremic rats on a high Pi diet for 4 weeks treated with or without the phosphate binder VS-505, a non-absorbable, calcium- and aluminum-free, chemically-modified, plant-derived polymer currently being evaluated in hemodialysis patients.

**Results:** An increase in serum Pi was observed in uremic rats on the special diet (3.92 ± 0.42 vs. 3.29 ± 0.55 mmol/L on normal diet). A total of 135 target genes were affected (out of 15923 genes; 2-fold change, p<0.01) by increased serum Pi, with 122 up-regulated and 13 down-regulated. Target genes fell into various categories including carboxylic acid metabolism, lipid metabolism, mitochondrion, and oxidoreductase activity. In a separate study, VS-505 (0.2 - 5% by weight in food) prevented the increase in serum Pi (3.06 ± 0.30 mmol/L in the 5% VS-505 group vs. 3.74 ± 0.68 mmol/L in the vehicle-treated group, p=0.01), and it increased fecal Pi in a dose-dependent manner in the uremic rats on high-Pi diet (2.48 ± 0.60 mmol/24 hr in the 5% VS-505 group at Week 4 vs. 0.84 ± 0.55 mmol/24 hr at pre-dosing, p<0.001). VS-505 did not affect food/water consumption, feces appearance, dietary intake, histomorphology and NPT2b gene expression. VS-505 treatment prevented the effects of hyperphosphatemia on altering the expression of aortic genes related to oxidative stress and inflammation such as activin A receptor-type 1C, glycogen synthase 2, heat shock 70KD protein 1A, steroyl coenzyme A desaturase 1, and uncoupling protein 1.

**Conclusions:** In a HD cohort switched from calcium-based binders to sucroferric oxyhydroxide as part of routine clinical care, a 47% increase (p<0.001) in the number of patients with in-range serum phosphorus and reduction of serum phosphorus (0.21 mg/dl, p<0.001) was observed. Pill burden decreased significantly (4.6 fewer pills, p<0.001).

Fractional Excretion of Phosphorus Misrepresents Hormonal Effects on Phosphate Reabsorption in Chronic Kidney Disease

Keneith R. Phelps,1,2 Darius Mason,1,2 Sun J. Kang,1 (Stratton VAMC, Albany, NY; Albany Medical College, Albany, NY; ‘Albany College of Pharmacy and Health Sciences, Albany, NY.

Background: The serum P concentration ([P]) – E P/Cr + TR P/Cr, where E P/Cr and TR P/Cr are rates of urinary excretion and tubular reabsorption of P per volume of filtrate. E P/Cr is proportional to filtrate [P] in the cortical distal nephron ([P]); we have argued that [PTH] correlates with E P/Cr, for this reason in CKD. Fractional excretion of FE P was calculated as ([P]u/[P]s)u/[P]s and [FGF23] correlated directly with E P/Cr. TR P/Cr was not associated with [PTH] and [FGF23] did not result from effects of the hormones on TR P/Cr, and therefore did not reflect quantitative relationships between hormone concentrations and P reabsorption.

Methods: We measured fasting [cr], [P], [P], [PTH], and [FGF23] in 30 patients with stages 3-4 CKD. We calculated E P/Cr as ([P]u/[P]s)u/[P]s and FE P as ([P]u/[P]s)u/[P]s. We performed simple linear regressions as in the table and a multilinear regression of E P/Cr on TR P/Cr, E P/Cr, and TR P/Cr.

Results: FE P correlated directly with [PTH], [FGF23], and E P/Cr, and inversely with TR P/Cr, [PTH] and [FGF23] correlated directly with E P/Cr, TR P/Cr was not associated with [PTH] or [FGF23]. In the multilinear regression, E P/Cr and TR P/Cr caused > 90% of variation in FE P, [PTH] and [FGF23] did not contribute significantly.

Conclusions: TR P/Cr was unrelated to [PTH] and [FGF23] even though both hormones reduce P reabsorption. Although FE P varied inversely with TR P/Cr, correlations of FE P with [PTH] and [FGF23] did not reflect quantitative relationships between hormone concentrations and P reabsorption. The correlations occurred because FE P, [PTH], and [FGF23] were associated with E P/Cr. FE P should not be used to relate P reabsorption to hormones in CKD.

Attributes of the Walton-Bijvoet Nomogram at Normal and Reduced Glomerular Filtration Rate

Keneth R. Phelps,1,2 Darius Mason,1,2 Sun J. Kang,1 (Stratton VAMC, Albany, NY; Albany Medical College, Albany, NY; ‘Albany College of Pharmacy and Health Sciences, Albany, NY.

Background: The serum P concentration ([P]) is the sum of E P/Cr and TR P/Cr (urinary excretion and tubular reabsorption of P per volume of filtrate). In Bizoil’s infusion studies, observed TR P/Cr equaled maximum TR P/Cr (Tm P/GFR) at fasting fractional P excretion (FE P) > 20%; as FE P fell, (Tm P/GFR) – (TR P/Cr) rose. These observations were incorporated into a nomogram that derives Tm P/GFR from [P]u/[P]s, TR P/Cr, and FE P. We performed simple linear regressions as in the table and a multilinear regression of E P/Cr on TR P/Cr, E P/Cr, and TR P/Cr.

Conclusions: TR P/Cr was unrelated to [PTH] and [FGF23] even though both hormones reduce P reabsorption. Although FE P varied inversely with TR P/Cr, correlations of FE P with [PTH] and [FGF23] did not reflect quantitative relationships between hormone concentrations and P reabsorption. The correlations occurred because FE P, [PTH], and [FGF23] were associated with E P/Cr. TR P/Cr, [PTH] and [FGF23] did not contribute significantly.

Role of KHSRP and Pin1 in Mediating the Parathyroid Hormone Response in the Proximal Tubule

Rebecca Murray,1,2 Michael Merchant,2 Syed J. Khundmiri,1,2,3 Barbara Clark,4 Eleanor D. Lederer.1,2,3

Background: Parathyroid hormone (PTH) regulates the type IIa sodium-phosphate cotransporter (Npt2a), the major proximal tubule phosphate transporter at both the protein and mRNA level. We previously identified KHSRP as a PTH-responsive phospho-protein that binds Npt2a mRNA and may mediate its degradation. Pin1, a pep-tidyl phosphoserine isomerase, is the upstream regulator of KHSRP function and localization. Pin1 phosphorylated Pin1 binds KHSRP, promoting KHSRP dephosphorylation and maintaining its cytosolic localization. We hypothesize that PTH stimulates Npt2a mRNA destabilization through PAKa-mediated phosphorylation of Pin1.

Methods: To address this hypothesis, we treated opossum kidney (OK) cells, a proximal tubule cell line, with 100mM PTH or 10mM branes-acMPA (b-Br [to directly activate PAKa] in the presence or absence of 1mM H-89 (a PAKa inhibitor).

Results: 2h PTH induced a 2.5-fold increase in Pin1 phosphorylation. IP of KHSRP followed by immunoblot for Pin1 showed that Pin1 associates with KHSRP under basal conditions, but not following 2h PTH or 8-h treatment. Pre-treatment with H-89 blocked the PTH/8-Bt-induced dissociation. 2h PTH did not alter total expression of KHSRP, but stimulated its translocation to the nucleus.

Conclusions: We conclude that PTH-mediated destabilization of Npt2a mRNA likely involves PAKa-mediated regulation of Pin1 and KHSRP activity. Funding provided by VA to EDL.

Phosphate Depletion-Induced Metabolic Acidosis and Alkalai Urine May Be Caused by Inappropriate Stimulation of Apical Cl/HCO3− Exchanger (Pendrin) in Mouse Kidney Type B Intercalated Cells (IC-B)

Background: Mice treated with a low phosphate (P) diet can maintain normal levels of plasma Pi concentration via stimulation of bone reabsorption, but show hypercalciemia, hypercalcuria, and hypophosphaturia. Recently, the Ca-sensing receptor (CaSR) was found to be localized in the basolateral membrane of IC-B as well as in the thick ascending limb of Henle’s loop (Yasuoka et al., 2014). This study was aimed to determine whether hypercalciemia and/or hypercalcuria affect urine pH as expected in mice treated with either dietary Pi depletion or CaCl2-loading.

Methods: C57Bl/6j mice (10 wks, male) were divided into three groups: (1) normal diet (1% P, n=6), (2) low-P (LP) diet (0.02% P, n=4), (3) CaCl2-loading (1% P, +1% CaCl2, n=6). All diets contain 1% Ca (CaCl2). On day 7, a 24-h urine, blood, and kidney samples were collected.

Results: Serum and urinary Ca were markedly and significantly increased in the LP and CaCl2 groups [serum, 9.1 and 8.9 mg/dL and urine, 2,400 and 2,140 µg/day, respectively] compared with control (serum, 7.6 mg/dl; urine, 105 µg/day). Although serum pH decreased similarly to 7.25 and 7.20 in both groups, pH of the urine decreased to 5.6 (P < 0.05) in the CaCl2 group and, surprisingly, increased to 7.4 (P < 0.05) in the LP group (control, serum pH 7.35; urine, pH 6.3). Kidney histology and immunohistochemistry showed that

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

578A
the IC-A cell height and basolateral Cl−/HCO3− exchanger type 1 (AE1) staining significantly increased in the CaCl2 group, whereas the IC-B cell height and apical Pendrin and basolateral AE4 staining significantly increased in the LP group.

**Conclusions:** P-depletion induced metabolic acidosis may be due to imbalanced urinary acidification and acidosis caused by inappropriate stimulation of Pendrin and AE4 through the hypercalcemia-induced activation of the basolateral CaSR in IC-B.

**FR-PO920**

MUC1 Increases Renal Calcium Channel TRPV5 Activity to Enhance Calcium Reabsorption in a Galectin-3 Dependent Fashion

**Background:** MUC1 (MUC1) mutations cause autosomal dominant tubulointerstitial kidney disease (ADTKD-MUC1), a condition similar to a nephropathy caused by Uromodulin (UMOD) mutations (ADTKD-UMOD). We previously showed that UOMOD may protect against calcium-containing kidney stones by increasing TRPV5 cell surface abundance and tubular calcium reabsorption, which may decrease the risk of urinary supersaturation. The role of MUC1 in kidney is unclear. As UOMOD and MUC1 share characteristics regarding disease phenotype, protein function, and structure, we examined the hypothesis that MUC1 enhances TRPV5 channel activity.

**Methods:** We expressed TRPV5 and MUC1 variants in HEK293 cells and studied TRPV5 current density by whole-cell patch-clamp recording.

**Results:** MUC1 coexpressed with TRPV5 resulted in a higher TRPV5 current density compared to mutant MUC1-C or control. MUC1 increased TRPV5 current density when applied extracellularly and required TRPV5 N-glycan for upregulation. Immunofluorescence imaging showed apical MUC1 expression along the distal nephron which is compatible with TRPV5 regulation in DCT. To test if MUC1 affects TRPV5 endocytosis, we tested if MUC1 upregulates TRPV5 in a Ca2+-deficient fibroblasts, as TRPV5 undergoing endocytosis by caveolin-1. While MUC1 alone had no effect, cotransfection of reconstituting caveolin-1 with MUC1 restored TRPV5 upregulation by MUC1. The extracellular domain of MUC1 contains variable number tandem repeats (VNTRs) which bind galectin-3, a lectin involved in lattice formation of channels. Using galectin-3 siRNA, we identified galectin-3 as a prerequisite for TRPV5 upregulation by MUC1. This was confirmed by the inability of MUC1 lacking VNTR to upregulate TRPV5. In urine samples of patients with calcium-containing kidney stones we found less urinary MUC1 compared to control individuals.

**Conclusions:** MUC1 upregulates TRPV5 by extracellular lattice formation with TRPV5 N-glycan via galectin-3 which impairs TRPV5 channel endocytosis. These data are consistent with MUC1 contributing to protection against calcium-containing kidney stones.

**FR-PO921**

NCC Activity Modulation as a Mechanism for PTH Regulation of DCT Calcium Transport

**Background:** The distal convoluted tubule (DCT) is a major site of both calcium and sodium transport. While altered DCT calcium handling is not required for thiazide-induced hypocalciuria, studies have documented increased DCT calcium reabsorption in response to thiazide administration. This suggests that DCT sodium transport does affect DCT calcium transport, and while thiazide induced hypocalciuria is due to a proximal effect, modulation of NCC activity may affect DCT calcium transport by TRPV5. Since parathyroid hormone (PTH) is known to increase TRPV5 activity and decrease NCC activity, we theorized that decreased NCC-mediated sodium reabsorption may contribute to the enhanced TRPV5 calcium reabsorption seen with PTH administration.

**Methods:** Radioactive uptake and biotinylation in mDCT15 cells were used to measure sodium and calcium uptake as well as surface expression of NCC and TRPV5.

**Results:** mDCT15 cells expressed rhesus monkey sensitive “Ca2+-influx via 5.9±0.2 mmol/mg/min and surface expressed TRPV5. PTH increased “Ca2+-uptake to 8.8±0.7 mmol/mg/min (n=4, p<0.01 compared to control) and decreased NCC activity from 75.4±2.7 to 20.3±1.3 mmol/min (n=4, p<0.01 compared to control). Knockdown of RasGRP1, the pathway by which PTH affects NCC, had no baseline effect on “Ca2+-influx but significantly attenuated the increased “Ca2+-uptake response to PTH from a 55% increase (6.0±1.0 vs 7.3±0.2 mmol/mg/min, p<0.01) of non-targeting groups). Inhibition of PKC and PKA, the known pathways by which PTH acts upon TRPV5, resulted in further attenuation of the PTH effect.

**Conclusions:** Here, through the use of a cell model with native NCC and TRPV5 activity, we report that modulation of NCC activity does indeed contribute to the TRPV5 response to PTH, implying a role for hormonal modulation of NCC activity in distal calcium handling. Further study is needed to determine the mechanism for these findings.

How Disruption of Distal Nephron Salt Reabsorption Causes Calcium Wasting, Tubule Calcification and Skeletal Changes

**Background:** Sharon L. Barone, 1,2 Jie Xu, 1,2 Manoocher Soleimani. 1,2 1Internal Medicine, Univ of Cincinnati, Cincinnati, OH; 2Research Services, Veterans Affairs Medical Center, Cincinnati, OH.

**Background:** Carbonic anhydrase II/sodium chloride co-transporter (NCC) and pendrin/AE4 double knockout mice (dKO) develop salt wasting and are growth retarded. We propose that the disruption of sodium and chloride reabsorption in these mice causes phosphate and calcium wasting and leads to bone and skeletal anomalies.

**Methods:** Renal alterations that lead to distorted calcium and phosphate reabsorption and contribute to tubular calcification and growth retardation in the dKO mice were examined.

**Results:** dKO mice are volume depleted, exhibit kidney hyperperfusion, and have increased urinary calcium and phosphate excretion. These mice also exhibit skeletal anomalies and osteopenia and develop tubular calcium phosphate deposits. Parathyroid hormone (PTH) and fibroblast growth factor-23 (FGF-23) levels are increased in dKO mice.

The urinary content of prostatic luteinizing hormone (PGE2) is significantly elevated, along with the expression of microsomal prostaglandin E synthase 1, while the sodium phosphate transporter IIa (NaP-IIa) is downregulated in the kidneys of dKO mice. qRT-PCR analyses revealed that the expression levels of NCC2 variants A and B were reduced while NCC2-B levels are increased in dKO animals. The latter changes lead to decreased NCC2 Ca2+ activity in the medullary thick limb and increased calcium excretion, while NaPi-IIa downregulation reduces the reabsorption of phosphate in the proximal tubules. Placement of dKO mice on a high calcium diet and insufflation increased the above parameters. These results show an important role for salt wasting and dehydration-induced PGE2 synthesis in renal calcium and phosphate excretion as well as in bone calcium mobilization.

**Conclusions:** Our studies suggest the presence of PGE2-mediated pathways, which are involved in the response to PTH, dehydration and volume contraction and independent of sodium and chloride transport. PGE2 and FGF-23 activity can lead to amorpholisation and mobilization of calcium and phosphate, and ultimately lead to skeletal abnormalities and growth retardation.

**FR-PO923**

Hypercalcemia-Induced Natriuresis Induced by Endothelin-1 (ET-1)

**Background:** Hypercalcemia commonly increases urinary sodium and water excretions. We previously showed that targeting the calcium receptor CaSR does not affect sodium transport in the renal tubule (Lopuy et al., JCI, 2012), suggesting that the natriuretic effect of hypercalcemia does not involve CaSR. Since hypercalcemia increases the renal expression of ET-1, we tested if ET-1 mediates the natriuretic effect of hypercalcemia.

**Methods:** Forty-two 8 week-old, male C57Bl/6 mice were studied. Osmostat minipumps were implanted to infuse PTH1-34 and maintain the concentration of PTH to normal range throughout the experiment. Hypercalcemia was induced by the oral administration of diltiazem (DHT: 7.5mg/kg food/day). Eighteen mice were treated with an ET-1 receptor antagonist, macitentan (Maci, 27mg/kg BW/day), with or without DHT. Mice were treated for 3 days of treatment. On 3rd day of treatment mice developed hypercalcemia (5.0±1 vs 2.4±0.1 mmol/L control mice) and exhibited increased water and sodium excretion as compared to control mice (2.0±1 vs 1.4±0.1 mL/day and 46±4 vs 36±2 mmol Na+/mL creatinine, respectively, p<0.01 for both). Mice treated with DHT had similar levels of hypercalcemia and polyuria as mice treated with DHT only. However, mice treated with Maci+DHT showed no increase in urinary sodium excretion. Mice treated with Maci only were similar to control mice. A 3-4 fold increase in the renal level of ET-1 mRNA was observed in mice treated with DHT and Maci+DHT.

**Conclusions:** Hypercalcemia increases the renal production of ET-1, which is likely responsible for the increase of urinary sodium excretion. In contrast, ET-1 is not involved in hypercalcemia-induced polyuria.

**Funding:** Government Support - Non-U.S.
Methods: Primary human umbilical vein endothelial cells (HUVECs) were serum starved for 24 hours and stimulated with a physiological buffer and preincubated with reverse-mode (Ca2+ influx) Ncx inhibitors Sn-6 or SEAP504 and the general Ncx inhibitor ORM-1013. Ncx1 protein was knockdown using siRNA. ERK1/2 activation was determined by western blot. [Ca2+]i was measured in ECs loaded with the fluorescent Ca2+ indicator Fluo-4NW.

Conclusions: We propose that Ca2+ influx through reverse-mode Ncx is required for IS-induced ERK1/2 activation. Given the known role of ERK1/2 activation in the expression of pro-inflammatory molecules such as COX-2 and VCAM-1 in ECs, reverse-mode Ncx could be a novel target for improving endothelial function in CKD.

FR-PO925
Chronic Kidney Disease Impairs Myocardial Perfusion and Disturbs Cardiac Calcium Handling
Maarten Oranje,1 Desiree Ling Yang,1,2 Joost Hoenderop,2 René J. Bindels,2 David H. Ellison.

Background: The molecular and microcirculatory changes that may underlie the increased prevalence of heart failure and cardiac mortality in CKD are ill-defined. We hypothesized that IS directly impairs both myocardial perfusion and disturbed cardiac diastolic and systolic function due to disturbed calcium fluxes across the myocardial sarcoplasmic reticulum.

Methods: Eight-week old C57Bl/6 mice were subjected to partial nephrectomy (5/6 nephrectomy or sham surgery) and after 6 weeks mice were subjected to myocardial contrast echocardiography (MCE) to test myocardial perfusion. Cardiac function was assessed using Cine MRI. In single intact cardiomyocytes diastolic and systolic function, as well as intracellular Ca2+ transients were measured by fura-2 loaded cardiomyocytes.

Results: No difference was found between groups for heart weights over tibia length, neither for ejection fraction, cardiac output, end diastolic and systolic volume, and E/A ratio.

Conclusions: CKD compromises both myocardial microvascular perfusion reserve, and systolic and diastolic function in cardiomyocytes. Calcium fluxes across the sarcoplasmic membrane are disturbed, due to a reduced amount of phosphorylated phospholamban, which activates the sarcoplasmic reticulum Ca2+ channel SERCA.

FR-PO926
Recessive Mutations in SLC34A1 (NaPi-IIa) as a Cause of Idiopathic Infantile Hypercalcemia
Karl P. Schlingmann,1 Birgitta Kranz,2 Martin Kaufmann,1 Elisabeth A.M. Cornelissen,1 René J. Bindels,1 Asaf Vivante,1 Robert L. Kleta,2 Elena N. Levtchenko,2 Glenville Jones,3 Carsten A. Wagner,2 Abdullah Abdurrachim,2 Pieter M. Ter Wee,1 Etto C. Eringa,2 Marc G. Vervloet.1

Background: Idiopathic infantile hypercalcemia (IIH) is characterized by severe hypercalcemia with failure to thrive, vomiting, dehydration, and nephrocalcinosis. Initially mutations in CYP24A1 encoding the vitamin D catabolizing enzyme 25-hydroxyvitamin D2-24-hydroxylase were discovered that lead to accumulation of active 1,25(OH)2D3 with subsequent hypercalcemia and hypercalciuria.

Methods: In a subgroup of IIH patients without mutations in CYP24A1 we now performed a positional candidate gene approach in order to identify a second IIH gene locus. Results: We identified a shared homozygous interval on chromosome 5q35 with a maximum LOD score of 6.91. The sequence analysis of SLC34A1 encoding proximal-tubular sodium-phosphate co-transporter NaPi-IIa revealed recessive mutations in the 4 index cases as well as in 18 additional sporadic IIH patients. The clinical reevaluation revealed renal phosphate wasting but no signs of rickets. Functional studies of mutated NaPi-IIa in Xenopus oocytes and OK cells demonstrated a disturbed membrane trafficking as well as a loss of phosphate transport activity. The reexamination of SLc34A1 knockout mice highlighted the critical role of phosphate depletion and FGF-23 suppression. In affected patients, clinical and laboratory findings persist after omitting vitamin D prophylaxis but highlight the critical role of phosphate depletion and FGF-23 suppression.

Conclusions: Therefore, an early differentiation between CYP24A1 (24-hydroxylase) and SLC34A1 (NaPi-IIa) defects appears crucial for a effective therapy in children with IIH.

FR-PO927
Identification of SLC4A13 as a Novel Player in Renal Magnesium Homeostasis
Jeroen H.F. De Baati,1 Anke Lameris,2 René J. Bindels, Joost Hoenderop.2

Background: Hypomagnesemia is a common clinical cause of muscle cramps, epilepsy and cardiac arrhythmias. In the distal convoluted tubule (DCT) of the kidney, transcellular reabsorption of Mg2+ regulates the body Mg2+ balance by determining the final urinary Mg2+ excretion. In the DCT, Mg2+ is reabsorbed from the pro-urine via the apical Mg2+ channel TRPM6. Until now, the basolateral Mg2+ exclusion mechanism in DCT is still unknown, but recent findings suggest that proteins of the SLC4A1 family may contribute to cellular Mg2+ exclusion. The aim of this study was, therefore, to investigate the role of SLC4A13 in Mg2+ homeostasis using the SLC4A13 knockout mouse.

Methods: The SLC4A13 knockout mice were used for serum and urinary electrolyte analysis. To determine the effect of SLC4A13 on intestinal Mg2+ absorption, the Mg2+ absorption capacity was measured using the stable [25Mg] isotopomer.

Results: Tissue expression screening was performed by RT-PCR, showing that SLC4A13 is the only SLC4A1 isoform with enriched expression in DCT compared to other segments in the kidney. Interestingly, serum and urinary electrolyte determinations demonstrated that SLC4A13 knockout mice suffer from hypomagnesemia due to renal Mg2+ wasting. Serum magnesium Na+, K+ and Ca2+ levels were not affected. "Mg2+ uptake was similar in wild type and knockout mouse, although Slc4a13 knockout animals exhibited increased intestinal expression of Mg2+ transporters Trpm6 and Slc4a14. Remarkably, 10% of the Slc4a13 knockout mice developed severe unilateral hydronephrosis, as demonstrated by the presence of transitional epithelium lining the fluid cavity. Feeding the Slc4a13 knockout mice a low Mg2+ diet may have instigated the formation of hydronephrosis.

Conclusions: In conclusion, SLC4A13 was established as a new important factor for renal Mg2+ handling, suggesting that SLC4A13 is the basolateral Mg2+ exclusion mechanism in DCT. Slc4a13 mice provide the first mouse model with isolated hypomagnesemia, without concomitant electrolyte disturbances. In the future, SLC4A13 mutations should be considered in patients with unilateral hydronephrosis and/or hypomagnesemia. Funding: Government Support - Non-U.S.

Dietary Inulin Supplementation Stimulates Magnesium Absorption in Patients with Proton Pump Induced Hypomagnesemia
Jeroen H.F. De Baati,1 Mark Wilhelm Hess,2 Joost Hoenderop,2 Joost P.H. Drenth,2 René J. Bindels,2

Background: Hypomagnesemia is a common and severe side effect of patients using proton pump inhibitors (PPI), causing severe muscle cramps and depression. Given that PPI users are dependent on PPIs for gastric acid protection, drug withdrawal or antacid switching is often not possible to prevent hypomagnesemia. This study, therefore, aimed to restore serum Mg2+ levels during PPI use by the dietary application of fructose-oligo-saccharide-enriched inulin fibers.

Methods: This clinical trial prospectively determined serum Mg2+ concentrations in 133 patients using PPIs. Under maintenance of PPIs, eleven identified cases of PPI-induced hypomagnesemia were exposed to 2 repetitive dietary suplementations with inulin for 4 weeks each, followed by 14 days washout and compared to 10 healthy non-PPI users. The primary endpoint was serum Mg2+. Secondary endpoints were serum Ca2+, K+, and Na+ levels.

Results: Hypomagnesemia is present in 13% of the study population. Dietary supplementation with inulin significantly enhanced mean serum Mg2+ levels by + 0.1 mEq/L in the PPI users and + 0.2 mEq/L in healthy controls. Moreover, in patients with PPIH concomitant treatment effects were observed for serum Ca2+ (+ 0.9 mmol/L) and serum K+ (+ 0.07 mmol/L), no effects were seen on serum Na+. Patients with PPIH had adequately reestablished serum Ca2+ and Mg2+, which increased due to inulin following increases in serum levels. Additionally, two SNPs in TRPM6 (rs3779025 and rs2274024) were identified that cause a 4.75 times higher risk to develop hypomagnesemia.

Conclusions: Inulin fibers are a new promising probiotic treatment strategy to treat intestinal- and renal-caused hypomagnesemia. For the first time we provide a successful alternative for oral Mg2+ supplementation. Funding: Government Support - Non-U.S.

The Distal Convoluted Tubule Plays a Key Role in Tacrolimus-Induced Hypomagnesemia and Hypercalciuria
Rebecca A. LaRocce,1 Sabina K. Jelen,2 Chao-Ling Yang,2 Joost Hoenderop,2 René J. Bindels,2 David H. Ellison.2

Background: The immunosuppressive drug tacrolimus, used to prevent graft rejection, often leads to hypomagnesemia and can also cause hypercalciuria. A decrease in renal Mg2+ and Ca2+ reabsorption is thought to be involved, but the molecular mechanisms are unclear. Tacrolimus requires a binding partner, FKBP12, to inhibit its canonical target, calcineurin. We generated a mouse model in which FKBP12 can be deleted along the intestinal expression of Mg2+ transporters Slc34a1 and Slc41a3 -/-. The molecular and microcirculatory changes that may underlie the formation of hydronephrosis.

Methods: We propose that Ca2+ influx through reverse-mode Ncx is required for IS-induced ERK1/2 activation. Given the known role of ERK1/2 activation in the expression of pro-inflammatory molecules such as COX-2 and VCAM-1 in ECs, reverse-mode Ncx could be a novel target for improving endothelial function in CKD.
nephron (KS-FKBP12+). We then tested if either FKBP12 disruption or calcineurin inhibition altered the nephron along the mRNA abundance of renal ion transport proteins leading to hypomagnesemia and hypercalciuria.

Methods: KS-FKBP12+ mice were generated using an inducible CRE/LOX system driven by the Pax8 promoter. Mice were treated with doxycycline (KS-FKBP12+) or vehicle (control). The abundance of mRNA encoding Claudin 16 and 19, thick ascending limb (TAL) proteins involved in Mg2+ and Ca2+ transport by the distal convoluted tubule (DCT) including, TRPM6, calbindin-28K and the Sodium Calcium Exchanger-1. In contrast, tacrolimus had no effect in KS-FKBP12+ mice (p > 0.05 by 2-way ANOVA). The abundance of mRNA encoding Claudin 16 and 19, thick ascending limb (TAL) proteins involved in Mg2+ and Ca2+ handling, were not affected by tacrolimus treatment in either group.

Conclusions: Tacrolimus reduces the abundance of mRNA encoding proteins involved in Mg2+ and Ca2+ transport by the DCT. These effects require FKBP12, suggesting that calcineurin inhibition is essential. The results show that the DCT plays a key role in these troubling side effects.

Regulation of Magnesium Reabsorption and Transient Receptor Potential M6 Channel Activity by Protein Kinase A Signaling

Maxime G. Blanchard, 1 Wararat Kittikulsuth, 2 Anil V. Nair, 1 Jeroen H.F. De Baaij, 3 Jonathan R. Genzen, 2 Donald E. Kohan, 2 René J. Bindels. 1

Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Nephrology, Univ of Washington, Seattle, WA; 3Epidemiology, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands.

Background: The transient receptor potential melastatin type 6 (TRPM6) epithelial magnesium (Mg2+) channel participates in Mg2+ transport in kidney and intestine. Previous reports have suggested a hormonal cAMP-dependent regulation of Mg2+ reabsorption in the kidney. The molecular details of this process are, however, unknown. Adenylyl cyclase type 3 (Adcy3) has been shown to colocalize with the Na+Cl- cotransporter (NCC), a marker of the distal convoluted tubule, the principal site of TRPM6 expression.

Methods: Given the critical role of TRPM6 in Mg2+ reabsorption, an inducible kidney-specific Adcy3 deletion mouse model was characterised for blood and urinary electrolyte disturbances under normal and low Mg2+ diet. Using patch clamp, cell surface biotinylation and Total Internal Reflection Fluorescence (TIRF) live cell imaging of transfected HEK293 cells, TRPM6 channel activity was measured.

Results: Urinary Mg2+ excretion was increased (~1.7-fold) in AC3 deleted mice compared to controls where as serum Mg2+ concentrations were not different. Renal TRPM6 mRNA levels were increased by ~2-fold in AC3 deleted mice. Serum Mg2+ was significantly lower in AC3 deleted animals for 7 days on the low Mg2+ diet compared to the control animals. In HEK293 cells, it was demonstrated that cAMP signaling rapidly potentiates the activity of TRPM6 by promoting its accumulation at the plasma membrane and by increasing its single channel conductance.

Comparison of electrophysiological data between the phosphorylation-deficient SI252A and phosphonemic SI252D mutants suggests that phosphorylation at this intracellular residue participates in the observed stimulation of channel activity.

Conclusions: These data support a physiologically relevant magnesiumotropic role of cAMP signaling in the direct stimulation of action of protein kinase A on the plasma membrane trafficking and function of TRPM6 ion channels in the distal convoluted tubule.

Renal Handling of Magnesium in Individuals on Long Term Proton Pump Inhibitor Therapy

Saurabh Sural. 1 Nephrology, Peerless Hospital & B K Roy Research Centre, Kolkata, West Bengal, India.

Background: Proton Pump Inhibitors (PPI) are a group of very commonly used medication.Recently the US–FDA has warned of increased levels of hypomagnesemia in patients receiving low dose PPI therapy. The present study was conducted to determine the effect of long term PPI therapy on serum magnesium and renal handling of magnesium in long term PPI patients.

Methods: The study was designed as a case control study consisting of adult patients on long term PPI therapy (Omeprazole; Rabeprozole; Pantoprazole etc) for more than 1 year. Patients on PPI with diabetes, chronic kidney disease or on diuretics were excluded. Age and sex matched healthy controls not on any medication were included as controls. Serum Magnesium and Urinary Fractional Excretion of Magnesium (FE-Mg) were measured using an automated clinical chemistry autoanalyser. The study was conducted for one year following standardized analysis of data with Graphpad software.

Results: The mean age of the long term PPI group was 47.5 years and 45.9 years in the control group. The mean FAMg of the PPI group was significantly lower in AC3 deleted animals for 7 days on the low Mg2+ diet compared to the control animals. In HEK293 cells, it was demonstrated that cAMP signaling rapidly potentiates the activity of TRPM6 by promoting its accumulation at the plasma membrane and by increasing its single channel conductance.

Conclusions: These data support a physiologically relevant magnesiumotropic role of cAMP signaling in the direct stimulation of action of protein kinase A on the plasma membrane trafficking and function of TRPM6 ion channels in the distal convoluted tubule.

Oral Magnesium Supplementation Improves Serum Calcification Propensity in Chronic Kidney Disease Stage 3-4

Ditte Hansen,1 Morten Schou,2 Andreas Pasch,4 Matthias Bachtler,1 Lisbet Brandi,1
1Dept of Cardiology, Nephrology and Endocrinology, North Zealand Hospital, Hillerød, Denmark; 2Dept of Medicine, Div of Nephrology, Roskilde Hospital, Roskilde, Denmark; 3Dept of Cardiology, Herlev Hospital, Herlev, Denmark; 4Dept of Clinical Chemistry, Univ Hospital Bern (Inselspital), Bern, Switzerland; 5Dept of Clinical Research, Univ of Bern, Bern, Switzerland.

Background: In previous experimental studies of chronic kidney disease (CKD) magnesium has been shown to improve vascular calcification. Serum calcification propensity measured using the T50 analysis has been shown to predict all-cause mortality among patients with chronic kidney disease (CKD) stage 3-4.

Methods: In a proof-of-concept randomized placebo-controlled double-blinded trial of placebo versus slow-release magnesium oxide at two different doses (360 mg daily or 360 mg twice daily) for eight weeks in 34 subjects with CKD stage 3-4 and plasma magnesium <0.82 mmol/L, T50 was measured to examine whether magnesium supplementation affects serum calcification propensity.

Results: In subjects randomized to magnesium 360 mg twice daily (n = 11) plasma magnesium increased by 0.11 mmol/L (confidence interval; 0.05 - 0.17, p = 0.003) and T50 increased by 40 minutes (confidence interval; 18 - 63, p = 0.003) after eight weeks of treatment (Figure 1), while there were no changes in plasma phosphate, calcium or parathyroid hormone. There were no significant changes in T50 in the placebo (n = 12) or magnesium 360 mg once daily (n = 11) groups.

Conclusions: Oral magnesium oxide 360 mg twice daily improves serum calcification propensity in CKD stage 3-4 after eight weeks of treatment. Larger, long-term trials are needed to assess whether this translates into reductions in vascular calcification (e.g. coronary artery calcium score or pulse wave velocity) and cardiovascular endpoints.

FR-PO935
The Novel NaPi-IIb Inhibitor ASP3325 Does Not Mitigate Hyperphosphatemia in Chronic Kidney Disease Patients on Hemodialysis

Tobias F. Larsen,1 Chisato Kameoka,2 Ikumi Nakajo,1 Yuta Taniiuchi,1 Satoshi Kazuhiro Terai,2 Yoh Terada,2 Yuichi Tomura.
1Dept of Cardiology, Nephrology and Endocrinology, North Zealand Hospital, Hillerød, Denmark; 2Dept of Medicine, Div of Nephrology, Roskilde Hospital, Roskilde, Denmark.

Background: The sodium-dependent phosphate co-transporter type 2b (NaPi-IIb) is considered an important mediator of intestinal inorganic phosphate (Pi) absorption and therefore recognized as a target molecule for treatment of hyperphosphatemia. We evaluated the pharmacological characteristics of ASP3325, a novel NaPi-IIb inhibitor being developed to treat hyperphosphatemia in chronic kidney disease (CKD).

Methods: The inhibition ratio of 32P-Pi uptake during ASP3325 (0.03-1000 nmol/L) treatment was measured in HEK293 cells stably expressing rat or human NaPi-IIb. To assess the contribution of NaPi-IIb to intestinal Pi absorption, ASP3325 and 45Pi were orally administered in sequence, and then serum 45Pi levels were measured. For normal rats, an ASP3325 containing-diet was provided for three days and the rate of Pi excretion in urine was measured on the final day. For rats with adenine-induced renal failure, an ASP3325 containing-diet was provided for two weeks after which plasma levels of phosphorus were measured.

Results: ASP3325 inhibited 32P-Pi uptake with an IC50 value of 7.0 mmol/L in HEK293 cells expressing human NaPi-IIb and an IC50 value of 88 nmol/L in HEK293 cells expressing rat NaPi-IIb. In normal rats, oral administration of ASP3325 at 1 and 3 mg/kg significantly reduced the area under the concentration curve of serum 45Pi from 0 to 30 min post 45Pi administration. ASP3325 (0.001%-0.01%) reduced urinary Pi excretion dose-proportionally, and treated with 0.01% ASP3325 reduced excretion by 31.2% compared to vehicle (P<0.01). In rats with adenine-induced renal failure, ASP3325 (0.001%-0.01%) exhibited a dose-related reduction in plasma levels of phosphorus. Following two weeks of treatment, plasma level of phosphorus in the vehicle-treated group was 11.43 ± 0.66 mg/dL and in the 0.01% ASP3325-treated group was 6.61 ± 0.47 mg/dL (P<0.01).

Conclusions: ASP3325 inhibited NaPi-IIb-mediated Pi transport and decreased plasma levels of phosphorus in rats with renal failure as well as urinary Pi excretion in normal rats. ASP3325 might therefore be a novel candidate for the treatment of hyperphosphatemia in humans.

FR-PO936
Novel NaPi-IIb Inhibitor ASP3325 Inhibits Phosphate Absorption in Intestine and Reduces Plasma Phosphorus Level in Rats with Renal Failure

Keichi Taniguchi, Kazuhiro Terai, Yoh Terada, Yuichi Tomura.

Background: The sodium-dependent phosphate co-transporter type 2b (NaPi-IIb) is considered to be an important mediator of intestinal inorganic phosphate (Pi) absorption and therefore recognized as a target molecule for treatment of hyperphosphatemia. We developed a novel NaPi-IIb inhibitor ASP3325.

Methods: In a proof-of-concept study 2b (NaPi-IIb) inhibition was measured in HEK293 cells stably expressing rat NaPi-IIb. To assess the contribution of NaPi-IIb to intestinal Pi absorption, ASP3325 and 45Pi were orally administered in sequence, and then serum 45Pi levels were measured. For normal rats, an ASP3325 containing-diet was provided for three days and the rate of Pi excretion in urine was measured on the final day. For rats with adenine-induced renal failure, an ASP3325 containing-diet was provided for two weeks after which plasma levels of phosphorus were measured.

Results: ASP3325 inhibited 32P-Pi uptake with an IC50 value of 7.0 mmol/L in HEK293 cells expressing human NaPi-IIb and an IC50 value of 88 nmol/L in HEK293 cells expressing rat NaPi-IIb. In normal rats, oral administration of ASP3325 at 1 and 3 mg/kg significantly reduced the area under the concentration curve of serum 45Pi from 0 to 30 min post 45Pi administration. ASP3325 (0.001%-0.01%) reduced urinary Pi excretion dose-proportionally, and treated with 0.01% ASP3325 reduced excretion by 31.2% compared to vehicle (P<0.01). In rats with adenine-induced renal failure, ASP3325 (0.001%-0.01%) exhibited a dose-related reduction in plasma levels of phosphorus. Following two weeks of treatment, plasma level of phosphorus in the vehicle-treated group was 11.43 ± 0.66 mg/dL and in the 0.01% ASP3325-treated group was 6.61 ± 0.47 mg/dL (P<0.01).

Conclusions: ASP3325 inhibited NaPi-IIb-mediated Pi transport and decreased plasma levels of phosphorus in rats with renal failure as well as urinary Pi excretion in normal rats. ASP3325 might therefore be a novel candidate for the treatment of hyperphosphatemia in humans.

FR-PO937
Statin Therapy Reduces Phosphate Levels in Dialysis Patients: Results from the Epidemiological Vitamin K Italian Study (VIKI Study)

Maria Fusaro,1 Sandro Giannini,1 Marianna Noale,2 Giovanni Tripepi,4 Piergiorgio Messa,3 Andrea Aggi,2 Nicola Veronese,1 Maurizio Gallieni,2 Sabina Zambon,2 1CNR, Padua; 2Univ of Padua; 3Ospedale Maggiore Policlinico, Milan; 4CNR, Reggio Calabria; San Carlo Borromeo, Milan.

Background: Statin therapy is the mainstay approach to reduce VC and prevent CV events in patients with dyslipidemia. The aim of this study was to investigate an association between statin therapy and phosphate levels in patients on hemodialysis recruited in the VIKI Study.

Methods: The VIKI Study is a multicenter, cross-sectional study in 387 CKD patients on hemodialysis from 18 hospitals in Italy. We determined plasma levels of vitamin 25(OH)D, vitamin K, osteocalcin (bone-Gla-Protein or BGP), matrix-Gla-protein (MGP) and routine biochemistry. Assessment of VC was centralized (Witteman’s method: by measuring the length of calcific deposits along the anterior and posterior wall of the aorta). Plasma phosphate levels were dichotomized according to the median value (>4.6 vs ≤4.6 mg/dL).

Results: 33% of the VIKI Study population (n=126) was on statin therapy. Patients on statin had significantly lower HDL cholesterol (mean:SD: 40.4±11.1 vs 43.5±13.4 mg/dL, p=0.0473) and higher plasma triglyceride levels (median: 164.0 vs 142.0 mg/dL, p=0.0041) than those not on statin. Plasma phosphate levels were significantly lower in patients on statin therapy (4.57±1.12 vs 4.8±1.33 mg/dL, p=0.035). The analysis of the vitamin K components showed that patients on statin therapy had higher plasma MK7 levels (median: 1.16 vs 0.84 ng/ml, p=0.0241), while concentrations of vitamin K25(OH)D were significantly reduced (median: 26.0 vs 30.7 ng/ml, p=0.0198). In a multivariate analysis adjusted for BMI, angina, LDL, BGP and antibiotics, statin therapy was significantly associated with lower plasma phosphate levels (OR 0.61, 95%CI 0.38-0.98, p=0.0411), while BMI (OR 1.06, 95%CI 1.01-1.12, p=0.0250) and serum BGP levels ≥182 mcg/L (OR 1.58, 95%CI 1.01-2.48, p=0.0472) were associated with higher phosphate concentrations.

Conclusions: To our knowledge this is the first evidence of an association between statins and reduced plasma phosphate levels in CKD patients.

Epidemiology of Kidney Stone Disease in Icelandic Children 1985-2013
Sólnborg E. Ingvarsdóttir,1 Olafur S. Indridason,2 Runolfur Palsson,2,13 Vidar O. Edvardsson,1,31 Children’s Medical Center, Landspitali – The National Univ Hospital of Iceland;2 Div of Nephrology, Landspitali – The National Univ Hospital of Iceland;1 Faculty of Medicine, Univ of Iceland, Reykjavík, NA, Iceland.

Background: The aim of the study was to examine time trends in the prevalence and incidence of kidney stone disease in Icelandic children and adolescents over the past 3 decades.

Methods: Computerized databases of all major hospitals and medical imaging centers in Iceland covering the years 1985 to 2013, were searched for ICD, radiology and surgical procedures indicating of kidney stones for subjects <18 years of age. Incidence was calculated for the time periods 1985-1989, 1990-1994, 1995-1999, 2000-2004, 2005-2009 and 2010-2013, based on population information for Icelandic children in these years. Prevalence was calculated for the years 1999-2013.

Results: From 1985 to 2013, there were 186 incident patients, 110 (59%) of whom were female. Median (range) age at diagnosis was 15.0 (2.1-17.9) years. The annual incidence increased from a mean of 3.7/100,000 in the first 5 years to 11.0/100,000 in the years 1995-2004, but decreased thereafter and was 7.8/100,000 in 2010-2013. This trend was more pronounced in boys, for whom the incidence was 4.7/100,000 in the first time period, 11.0/100,000 during 2000-2004 and only 2.4/100,000 in 2010-2013. The incidence for girls increased from 2.7/100,000 in the first time period to 14.2/100,000 in 1995-1999 and has since then leveled off and was 13.6/100,000 in 2010-2013. The largest incidence rise was seen in girls aged 14-17 years, for whom it increased from 9.8/100,000 in 1985-1999 to 39.2/100,000 in 2010-2013. The mean annual prevalence of kidney stone disease in 1999-2013 was 44/100,000 for boys and 51,100,000 for girls.

Conclusions: The incidence rise observed and current incidence of kidney stones in Icelandic children is similar to that recently reported in the USA. A significant incidence increase for girls was observed for the female patients in the late 1980’s and early 1990’s, and has since then trended downwards in boys and remained stable in girls. These trends cannot be adequately explained and warrant further study.

FR-PO938
Kidney Stone Recurrence in Icelandic Children Sólnborg E. Ingvarsdóttir,1 Olafur S. Indridason,2 Runolfur Palsson,1,2 Vidar O. Edvardsson,1,31 Children’s Medical Center, Landspitali – The National Univ Hospital of Iceland;2 Div of Nephrology, Landspitali – The National Univ Hospital of Iceland;1 Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.

Background: The 5-year recurrence rate of kidney stones in adults is in the range of 30-50%. No population-based data are available on the recurrence of childhood kidney stone disease. The purpose of this study was to examine the recurrence rate of stone disease in Icelandic children.

Methods: Patients were identified by searching computerized databases of all the major hospitals and the only freestanding radiology clinic in Iceland for diagnostic, radiology and surgical codes indicating of kidney stones in 1985-2013. We subsequently examined medical records of patients with kidney stone disease for information on stone recurrence.

Results: We identified 186 children with stone disease during the study period. There were 76 boys with a median (range) age of 14.6 (0.2-17.9) years and 110 girls aged 15.4 (0.8-17.9) years. The follow-up time was 13.0 (0-36) years. A total of 67 children (37%) experienced a second stone event, at a median of 1.9 (0.9-18.9) years after the initial diagnosis. The recurrence rate was 26%, 35%, 41% and 46% after 5, 10, 15 and 20 years of follow-up, respectively. There was no significant difference in recurrence rate between boys and girls (p=0.24) and those aged under and over 13 years at diagnosis (p=0.56), but a significant difference between patients diagnosed in 1985-1994, 1995-2004 and 2005-2013 was observed, with a 5-year recurrence rate of 9%, 24% and 33% respectively (p=0.002).

Conclusions: In our population-based pediatric study, the recurrence rate of kidney stones is similar to that reported in adults. Further, the rate of recurrence appears to be increasing as has recently been reported for the incidence of childhood stone disease. Increased recurrence rate may be related to improved diagnosis and documentation of stone events and/or environmental factors affecting urinary lithogenicity.

FR-PO939
Clinical Stone Events in Patients Diagnosed with Asymptomatic Nephrolithiasis Berlingrí Eik Guðmundsdóttir,1 Rebekka Sigrún Lynch,2 Runolfur Palsson,2,13 Vidar O. Edvardsson,1,31 Children’s Medical Center, Landspitali;1 Faculty of Medicine, Univ of Iceland;2 Div of Nephrology, Landspitali – The National Univ Hospital of Iceland, Reykjavík, Iceland.

Background: Most frequent use of high-resolution medical imaging in recent years has been in increased detection of asymptomatic kidney stones (KS). The purpose of this study was to investigate the frequency of clinical stone events in incident patients with asymptomatic KS.

Methods: We searched databases at all major hospitals and imaging centers in Iceland for radiographic diagnosis of incident KS during 2000-2008. We found 2550 incident cases, review of medical records identified 218 patients with no past history of nephrolithiasis or symptoms consistent with KS, who, therefore, were considered to have asymptomatic KS. The patients’ records were then thoroughly reviewed for the development of a clinical stone event defined as abdominal pain, fever and/or hematuria associated with stone passage and/or a stone removal procedure. End of follow-up was between June 2014 and April 2015 or at patient’s death. Event-free survival was examined by the Kaplan-Meier method.

Results: Of the 218 patients, 54.6% were men, the median (range) age was 65 (11-91) years. The diagnosis of KS was made by computed tomography in 156 (71.6%), ultrasound in 49 (22.5%) and by plain X-ray in 13 patients. The median follow-up time was 6.0 (0.0-14.5) and 6.7 (0.0-14.9) years for men and women, respectively. Twenty patients (9.2%) died during follow-up. A clinical stone event was defined as a renal stone event, with or without need for a stone removal procedure to remove the stone. The mean age at a clinical stone event was 25.8 (2.0-14.4) and 12.1 (0.1-9.3) years following diagnosis for men and women, respectively. When a procedure performed to remove an asymptomatic stone was considered a clinical event, a total of 49 patients experienced a clinical stone event, and the 5 and 10 year-event-free survival was 80% (95% CI, 74-85) and 73% (95% CI, 65-80), respectively.

Conclusions: Approximately 10% of asymptomatic KS were considered clinically significant at diagnosis. In the remaining patients, a clinical stone event was unlikely to occur over a decade following diagnosis of asymptomatic stone disease.
Supplemental Calcium Increases the Growth Rate of Renal Calculi in Stone Formers

**Background:** Though dietary calcium is associated with a decreased risk of stone formation, post-menopausal women supplemented with calcium have an increased risk of urinary tract stones. Prior studies have examined the effect of supplemental calcium on the risk of passing symptomatic stones but its role in the pathogenesis of stone formation is not clear.

**Methods:** We retrospectively identified 6059 patients with a history of urolithiasis. Eligible patients had 2 unenhanced CT scans greater than 30 days but less than 2 years apart during the time of supplementation. For those on no supplementation, the most recent data were used. Of these, 426 patients met the criteria: 195 on calcium, 127 on vitamin D only, and 104 on none. Patients on calcium received 439mg/dL 2793IU vitamin D3 or 560IU D2/d and patients on vitamin D only received 3085 IU D3/d or 6296 IU D2/d. Stone burden was calculated as the sum of the maximum diameters of all stones on CT and rate of stone growth was calculated by the change in consecutive stone burdens divided by the elapsed time between scans.

**Results:** Stone composition was similar among all groups: 65.5% calcium oxalate, 20.0% calcium phosphate, and 11.8% uric acid. Stone formation rate in mm/year: standard deviation was 7.8±2.0 for calcium group, 3.3±1.14 for vitamin D, and 4.49±13.8 for none. Those supplemented with calcium had a higher rate of stone formation than those supplemented with vitamin D, p=0.015. Stone group was statistically significant when controlling for serum PTH and calcium on multiple logistic regression. BMI, gender, age and dose of calcium were not significantly associated with stone formation rate while dose of vitamin D had an inverse association, p=0.049.

**Conclusions:** Between supplemented groups for any urinary excretion values.

**FR-P0944**

Effects of Calcium and Vitamin D Supplementation on Known Stone Formers

**Background:** While high dietary calcium has protective effects against kidney stone formation, the effect of supplementation with calcium and vitamin D on the risk of kidney stone formation remains unclear. Post-menopausal women supplemented with calcium have an increased risk of urinary tract stones; however, there is conflicting evidence for the effects of supplementation on urinary excretion of calcium.

**Methods:** We identified 6059 patients with a history of urolithiasis by CT scan, 2061 of which had 24-hour urine collections before and after starting supplementation. For patients on no supplementation, the most recent data were used. A total of 1,486 patients were supplemented with calcium, 417 with vitamin D only, and 158 with no supplementation. Patients on calcium received an average of 460mg/d 2720IU vitamin D3 or 5678IU D2/d and patients on vitamin D only received 3005IU D3/d or 6307IU D2/d.

**Results:** Stone composition did not differ among groups: 70.0% calcium oxalate, 16.6% calcium phosphate, and 10.8% uric acid stones. There was a significant decrease in urinary calcium excretion in patients supplemented with calcium (p=0.021) and vitamin D (p=0.011) and significant decreases in urinary oxalate in those supplemented with calcium (p=0.0001) and vitamin D (p=0.0001). No differences were seen in the amount of change between supplemented groups for any urinary excretion values.

**Conclusions:** Both calcium and vitamin D supplementation decreased urinary calcium excretion, and high serum calcium and vitamin D was associated with higher urinary calcium excretion in both men and women.

Tolvaptan Therapy Effectively Decreases Urinary Calcium Oxalate, Calcium Phosphate, and Uric Acid Supersaturations in Stone Formers

**Background:** Drinking large amounts of fluids is universally recommended for urinary stone prevention but can be difficult to do for many stone formers. Tolvaptan, a V2 receptor antagonist, blocks water reabsorption in the collecting duct. This in turn should increase serum osmolality and stimulate thirst. The net effect should be lower supersaturation of stone forming salts, but this has not been proven.

**Methods:** This double blind, randomized, placebo-controlled, crossover study was conducted in 21 adult calcium urinary stone formers, stratified as majority calcium oxalate (CaOx, n=10) or calcium phosphate (CaP, n=11). Patients were randomized to receive tolvaptan 45 mg/day or placebo for week 1, followed by washout week 2, and then crossover to drug or placebo for week 3. The 24 hr urine volume and chemistries were assessed at the end of week 1 and week 3.

**Results:** Tolvaptan versus placebo decreased urinary osmolality (204±96 vs 529±213 mOsm/kg, P=0.001) and increased urinary volume (4.8±12.9 vs 1.8±0.9 L, P<0.001). However, the majority of urinary salt excretion rates (mg/24 hrs) including sodium and calcium did not significantly change. Thus, urinary CaOx SS (-0.01±1.1 vs 0.95±0.87, P=0.001) and CaP SS (-1.66±1.7 vs -0.1±1.02, P=0.001) both decreased. Urinary Uric Acid (UA) SS also fell (-2.05±4.05 vs -5.2±3.12, P=0.03). The tolvaptan treatment effect on urinary supersaturation did not differ between CaOx and CaP stone types (P=0.05 for all interactions). Serum sodium increased slightly while on tolvaptan (142±3 vs 141±2 mEq/L, P=0.01).

**Conclusions:** Use of tolvaptan increased urinary volume but did not appreciably change daily excretion of urinary constituents. The net effect was thus a fall in CaOx, CaP and UA SS. This study highlights the dramatic benefit increased free water ingestion alone can have on urinary supersaturation. Use of tolvaptan or other V2 receptor antagonists could be a useful strategy for selected stone formers not responsive to intensive dietary and/or behavioral counseling.

**Funding:** Other NIH Support - The investigators acknowledge support from the Rare Kidney Stone Consortium (U54KD083908), a member of the NIH Rare Diseases Clinical Research Network (RDCRN), funded by the NIDDK and the National Center for Advancing Translational Sciences (NCATS), and the Mayo Clinic O’Brien Urology Research Center (U54 DK100227), Pharmaceutical Company Support - Research work for this review was supported by Onsuka America Pharmaceutical, Inc.
Conclusions: Prescribing doses of CBTDs greater than 1 gm did not improve lithogenicity significantly. Higher doses may not have clinical benefit. Prescribing the minimum effective dose based on CysCap can potentially decrease the adverse effects often associated with CBTDs.

FR-P0947

Claudin-14 Gene Polymorphisms May Regulate Urine Calcium Excretion Teresa Arcidiacono, Marco Simontini, Lorenza Macrina, Paolo Manunta, Donatella Spotti, Giuseppe Vezzoli. Nephrology and Dialysis Unit, San Raffaele Scientific Inst, Milan, Italy.

Background: Claudins are a family of proteins that form paracellular calcium channels in tight-junctions and may thus regulate tubular permeability to divalent cations. Claudin-14 is expressed in the ascending limb of Henle’s loop and inhibits calcium reabsorption. A previous GWA showed that two polymorphisms (SNPs) of CLDN14 (rs219778 and rs219781) were associated with kidney stones and calcium excretion in an Iceland population. The present study aims to evaluate the effect of CLDN14 SNPs on calcium excretion.

Methods: We performed a retrospective study on 380 hypertensive patients never treated with antihypertensive drugs. These patients underwent a saline load test (i.v. infusion of NaCl 0.9% 2 litres in 2 hours) to evaluate sodium sensitivity. Kidney stones in their clinical history was ascertained by interview. Calcium was measured in 24-h urine and clinical history was ascertained by interview. Calcium was measured in 24-h urine and clinical history was ascertained by interview.

Conclusions: CLDN14 genotype is associated with calcium excretion. This association was observed even after saline load test, a well-known stimulus to urinary calcium excretion. Minor alleles of these SNPs could cause a reduction of calcium excretion and could be protective against kidney stones and hypercalcuria. The lack of association among stones and CLDN14 SNPs could be due to the method used to identify stone formers.

FR-P0948

Independent Effect of Blood Glucose Level on Urinary Citrate and pH Majuran Perinpan,1 Erin Bakhis Ware,1,2 Jennifer Smith,1 Stephen T. Turner,1 Sharon R. Kardia,3 John C. Lieske,1,2 1Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Laboratory Medicine, Mayo Clinic, Rochester, MN; 3Dept of Epidemiology, School of Public Health, Univ of Michigan, Ann Arbor, MI; 4Inst for Social Research, Univ of Michigan, Ann Arbor, MI.

Background: Urinary citrate is an important kidney stone inhibitor and its excretion is influenced by systemic acid base status and diet. However, the effects of demographics and other factors on urinary citrate excretion are not well defined, including the independent influence of blood glucose.

Methods: Twenty-four hour urine samples were collected from non-Hispanic white sibships in Rochester, MN. Height, weight, blood pressure, blood glucose, serum creatinine and cystatin C were measured. Diet was assessed using the Viocare food frequency questionnaire. The effects of blood glucose, demographics and diet on urinary citrate excretion, urine pH and net gastrointestinal (GI) alkali absorption were evaluated in binvariate and multivariable models, plus interaction models that included age, sex, and weight.

Results: Samples were available from 709 individuals (mean age 66±9 years). In general urine citrate and urine pH correlated positively with higher net alkali absorption (p=0.0001). Urine pH was higher in women for any given net alkali absorption value, but not after adjustment for covariates. In multivariable models urinary pH decreased with higher serum creatinine, blood glucose, dietary protein and increased with dietary potassium. Meanwhile, in multivariable models urinary citrate increased with age, weight, eGFR, blood glucose and decreased with loop diuretic and thiazide use. Association of urinary citrate and age was influenced by blood glucose (p=0.01).

Conclusions: In our study urinary citrate and pH correlated positively with net GI alkali absorption. Blood glucose had independent effects on urine pH and urinary citrate. This study provides the first evidence that blood glucose could influence stone risk independent of urinary pH and uric acid crystallization. These observations could provide new insights into the association of obesity and urinary stone disease.

FR-P0949

Background: Primary Hyperoxaluria (PH) is a rare genetic disease causing high hepatic production of oxalate. Renal excretion of oxalate keeps plasma oxalate (Pox) controlled but leads to stones and often ESRD. Systemic oxalosis occurs when GFR is reduced and Pox rises above the supersaturation threshold (approximately 45 mmol/L). Renal handling of oxalate in relation to GFR is poorly understood.

Methods: PH patients ≥ 12 years without ESRD were identified from the Rare Kidney Stone Consortium registry. We used the recent simultaneous Pox, serum creatinine and 24 hour urine oxalate (Uox). Net oxalate secretion (Sox) equals Uox-GFR×Pox. Proximal tubular oxalate (PTox) is Uox corrected for creatinine and estimated proximal tubule water absorption. eGFR is by CKD-EPI (adults) or modified Schwarz (adolescents). We grouped patients by CKD stage and balanced eGFR groups. Analysis was by Fischer exact test and ANOVA.

Results: 55 patients were identified (33 PH-1; 5 PH-2; 7 PH-3). Median age was 23.2 (IQR: 16.7, 32.9) and eGFR was 66.1 mL/min/BSA (54.8, 80.8). Pox, Sox and Uox strongly when eGFR fell below 45 mL/min. Similar results were seen in eGFR groups. PTox and Pox increased proportionally (p<0.001).

Conclusions: Pox rises above the supersaturation threshold (approximately 45 mmol/L). Renal handling of oxalate in relation to GFR is poorly understood. Minor alleles of these SNPs could cause a reduction of calcium excretion and could be protective against kidney stones and hypercalcuria. The lack of association among stones and CLDN14 SNPs could be due to the method used to identify stone formers.

Effect of Antibiotic Treatment on Oxalobacter formigenes Colonization

Methods: We followed 64 healthy subjects tested for Helicobacter pylori (HP), who were treated with antibiotics (Amoxicillin and clarithromycin for 2 weeks) for HP eradication. Using species-specific PCR, we tested for colonization at baseline and at follow-up.

Results: Of the 64 subjects (MF: 24/40; mean age 25.0 ± 5.5 years) tested for HP, 25 (39%) were positive at baseline. Subject to HP elimination, 6 became HP-negative at 6 weeks, only 2 reverted to positive at week 24, and 4 patients remained negative at follow up (Mean 21.0 ± 6wks). Of 16 untreated positive people, 12 (75%) remained positive at follow up (Mean 18.8 ± 7.7wks), but of 26 untreated negative subjects, only 6 (23%) were positive at follow up (mean 19.7 ± 6wks), significantly fewer than the untreated positives (p = 0.001 by Fisher exact test).

Conclusions: We conclude that HP status remains stable over a follow-up period of several months, with antibiotics suppressing colonization in the majority of people in the short term. The differential long-term effect of antibiotics on HP colonization and its effect on urinary oxalate excretion, will be important to evaluate.

FR-PO951

Identification of Calcium-Oxalate Binding Proteins in Human Urine That Prevent Crystal Adhesion: An In Vitro Model of Kidney Stone Formation

Scott Scott, 1F. Koenig, Qiusha Guo, Katelynn H. Moore, Paul F. Austin. Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.

Background: There are limited therapeutic options for the treatment of stone disease and about 50% of patients experience at least one recurrence. Existing treatment protocols focus on altering urine concentrations, which presents challenges due to the idiosyncratic nature of many stones and the variety of underlying factors. In this study, we examine the hypothesis that there are naturally occurring urinary proteins capable of binding calcium oxalate crystals, promoting their clearance, and preventing stone formation. Elucidating these interactions may provide novel therapies.

Methods: Calcium oxalate monohydrate (COM) crystals and fluorescently-labeled derivatives (COM-FITC) were synthesized in vitro. Stone formation was modeled in vitro by assessing the adhesion of COM-FITC crystals to confluent monolayers of inner medullary collecting duct (IMCD) epithelial cells. Affinity chromatography was used to isolate COM-binding proteins from human urine.

Results: COM and COM-FITC crystals synthesized in vitro exhibited the typical prismatic morphology of urinary crystals. Incubation of IMCD cells with COM-FITC crystals resulted in rapid binding to the cell surface with high affinity. The addition of urinary proteins purified from human urine inhibited COM-FITC binding by 76.2%. Furthermore, urinary proteins inhibited the growth of COM crystals in free solution by 63.7%. In using affinity chromatography to isolate COM-binding proteins, we found that this technique was highly specific as only 17.2% of urinary proteins exhibited binding activity. The bound fraction was eluted, purified by electrophoresis, and four prominent proteins were identified (97 KD, 69 KD, 56 KD, 45 KD).

Conclusions: This study demonstrates that urinary proteins bind to COM crystals and inhibit their adhesion to the renal epithelium. Further characterization of these proteins may facilitate the design of peptide-based therapies that prevent crystal adhesion and stone formation as well as the development of diagnostic biomarkers that stratify patients and guide treatment decisions in at-risk populations.

FR-PO952

Hydroxyapatite Induces Tolerance in Primary Human Monocytes Exposed to Calcium Oxalate Crystals

Benjamin Canales, 1Paul R. Dominguez Gutierrez, 1Sergey Kusmartsev, 1Sohannes Vieweg, 2Saeed R. Khan. 1Urology, Univ of Florida, Gainesville, FL; 2Pathology, Immunology, and Laboratory Medicine, Univ of Florida, Gainesville, FL.

Background: Although most crystal deposits within tissue produce inflammation, renal interstitial hydroxyapatite deposits do not, accumulating as Randall’s plaque. To further explore this lack of response, we investigated the effect of oxalate, hydroxyapatite, and combination of both on time dependent, immunological responses in human THP-1 (monocyte) cells, the precursors to tissue macrophages.

Methods: Using 1 ug/ml LPS and untreated as positive and negative controls, THP-1 cells were exposed to varying concentrations of soluble potassium oxalate (KOs) or CaOx and treated with or without 100 and 1000 mg/ml. In addition, a group of primary human monocytes were pre-treated with 100 mg of HA or CaOx followed by secondary treatment with 100 ug/ml HA, 100 mg/ml CaOx, and 1 ug/ml LPS. THP cells were collected at 2, 4, and 8 hours after various treatments, and RNA was analyzed by quantitative real time PCR.

Results: THP cells at baseline responded strongly to TNFa (baseline), while a dose dependent inhibition to this cytokine was observed. When THP cells were exposed to hydroxyapatite, a dose dependent inhibition to TNFa, IL-1β, IL-8, and IL-10 was observed. No response to KOs and HA. Prevent exposure of human monocytes to HA had little effect on cytokine response to subsequent CaOx and LPS exposure; however, pre-exposure to CaOx followed by HA negated all further cytokine production.

Conclusions: In our human monocyte model, the order of CaOx and HA exposure affects monocyte response. HA neither stimulates cytokine production nor inhibits demonstrated production when pre-exposing monocytes to prior CaOx exposure. Pre-exposed CaOx monocytes, however, had decreased cytokine and chemokine expression when subsequently treated with HA. This tolerance mechanism may partially explain the lack of papillary inflammation in the pathogenesis of Randall’s plaque.

FR-PO953

A Low Sodium Diet Inhibits Stone Formation in Genetic Hypercalciuric Stone-Forming Rats

Kevin K. Frick, 1Nancy S. Krieger, 1John R. Asplin, 2Ignacio Granja, 2Min Ho Kim, 2Felix M. Ramos, 3David A. Bushinsky, 1School of Medicine & Dentistry, Univ of Rochester, Rochester, NY; 2Litholink Corporation, Laboratory Corporation of America Holdings, Chicago, IL.

Background: Increasing dietary (D) sodium (Na) intake results in greater urine (u) calcium (Ca) excretion, leading to the recommendation that D Na be restricted in hypercalciuric stone formers to decrease stone recurrence. However, there is no direct clinical evidence that reduction in D Na intake alone will reduce recurrent stone formation.

Methods: To determine if D Na restriction reduces kidney stone formation, we utilized 1O generation genetic hypercalciuric stone-forming (GHS) rats fed either a low (LNa, 0.05%) or normal (NNa, 0.4%) Na diet for 18 wks. Urine was collected at 6 wks at a mean was determined for each analyte and then an overall 18 wks mean calculated. Radiographic analysis for stone formation was done at 18 wks.

Results: As anticipated, rats decreased mean uCa (LNa=2.48±0.3 mEq/24h; NNa=3.9±0.2, p<0.001) and uCl (NNa=2.6±0.13 mEq/24h; LNa=1.9±0.16, p<0.001). Overall mean uCa was lower with LNa than NNa (NNa=17.3±3.5 mEq/24h; LNa=15.2±0.5, p<0.01) as was a phosphate (P) (NNa=16.5±0.6 mg/24h; LNa=13.8±0.4, p<0.001). Urine oxalate (Ox), pH, NH4, Ca, CL, citrate and volume did not differ with diet Na. There were no significant differences in u supersaturation with respect to CaOx or CaOx. Serum Ca was slightly increased with LNa (NNa=10.9±1.0 mg/dl; LNa=11.4±1.0, p<0.01) though there were no differences in urine P, PTH or FGF23. Radiographic analysis of kidneys demonstrated a significant decrease in calcification with LNa (calcification scores with a range of 0-3; NNa=1.4±0.15; LNa=0.3±0.12, p<0.001).

Conclusions: Thus a low Na diet reduced uCa and stone formation in GHS rats even though urine supersaturation was not altered. These data, in a genetic model of hypercalciuria and stone formation, lend support to the use of dietary Na restriction to prevent recurrent Ca nephrolithiasis.

FR-PO954

Ethylene Glycol Induced Hyperoxaluria in Rats: A Translational Study

Sunil Joshi, 1Wei Wang, 2Amonn B. Peck, 1Saeed R. Khan. 1Pathology, Immunology, and Laboratory Medicine, College of Medicine, Univ of Florida, Gainesville, FL; 2Infectious Diseases and Pathology, College of Veterinary Medicine, Univ of Florida, Gainesville, FL.

Background: Hyperoxaluria, if remains undiagnosed, can cause renal injury and inflammation leading to a number of diseases including advanced stages of renal failure. In order to look into the different pathways and molecular mechanisms involved in the kidneys of hyperoxaluric rats, we performed genome wide analysis of differentially expressed genes in the kidneys of rats fed ethylene glycol (EG).

Methods: Male rats were divided into two groups. Rats in one group were fed normal diet and the other group diet supplemented with 1.25% EG. Urinary assays were done at different time intervals and after 14 and 28 days rats were euthanized, kidneys explanted and total RNA extracted for micro array analysis using Agilent 8 x 60K single color arrays. Data was analyzed using bio-conductor Limma (Linear models for micro array analysis) package using R. Gene ontology (GO) and KEGG pathway analyses was also performed. Immunohistochemical (IHC) and Eosin and Hematoxylin (E &H) staining was also done for highly significant genes.

Results: All rats became hyperoxaluric from day 7 and had crystal deposition at different time intervals. Urinary LDH, sodium and creatinine were significantly different in the EG group as compared to the control. There was significant expression of different genes encoding for macromolecular modulators such as osteopontin (OPN), monocyte chemoattractant protein-1 (MCP-1), lipocalin 2 (Lcn-2), fibronectin (Fn-1), clusterin (CLU) and kidney injury molecule-1 (KIM-1) along with nicotine amide dinucleotide phosphate (NADPH) oxidase-4 (NOX-4) and glutathione peroxidase (Gpx-2). Gene analysis showed that 17 and 33 differentially expressed pathways for day 14 and day 28 respectively.

Conclusions: Results highlight that the EG treated rats showed heavy deposition of crystals and there were 15 pathways that were common between day 14 and day 28 giving a deep insight into the molecular mechanisms and pathways activated in hyperoxaluric rats.

Funding: Other NIH Support - R01-DK078602 and R01-DK92311
Sulfate and Thiosulfate Competitively Inhibit Oxalate Transport via a Drosophila Prestin (dPrestin, dSlc26a6)-Dependent Mechanism Greg M. Landry,1,2,3 Taku Hira,1 Jacob B. Anderson,1 Christopher Joseph roel Gallo,1 Michael F. Romero,1,2,3 Physiology and Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN; 2Nephropathy and Hypertension, Mayo Clinic College of Medicine, Rochester, MN; 3Brien Urology Research Center, Mayo Clinic College of Medicine, Rochester, MN.

Background: Nephrolithiasis affects approximately 12% of men and 6% of women in indiavidualized countries with the majority of stones being composed of calcium oxalate (CaOx). Our findings suggest that pharmacological agents can be used to inhibit CaOx crystallization.

Methods: Using Drosophila melanogaster as a robust and translatable model of CaOx nephrolithiasis, we studied the effects of sulfate and thiosulfate on oxalate transport, and subsequent CaOx crystal formation, as a proof of principle in providing a nida to identify new therapeutic interventions.

Results: Results indicate that dPrestin transports thioulate with a much higher affinity than sulfate (dPrestin sulfate Kᵩₒ = 8.65 ± 3.87 mM compared to dPrestin thioulate Kᵩₒ = 0.23 ± 0.03 mM). Additionally, both sulfate (48 h) and thioulate (24 and 48 h) were effective at decreasing Malpighian tubule CaOx crystallization with the opposite results observed at 48 h in Malpighian tubules where dPrestin was not expressed indicating a role on cell type-specific dPrestin in luminal oxalate transport.

Conclusions: Given the higher affinity of thioulate for dPrestin when compared to those which are reported for oxalate (dPrestin average Kᵩₒ for oxalate = 0.87 ± 0.16 mM and for thioulate = 0.22 ± 0.03 mM), we have confirmed that the ability of thioulate to act as a competitive inhibitor of oxalate at the transporter level, specifically dPrestin, may explain the inhibitory effect on CaOx crystallization seen in human tissue sections of thioulate uptake. Overall, our findings predict that thioulate or oxalate-mimics may be effective as therapeutic competitive inhibitors of CaOx crystallization.

Funding: NIDDK Support

FR-PO956

Background: C3 glomerulopathy (C3G) is a progressive form of glomerulonephritis (GN) that is frequently associated with abnormalities in regulation of the alternative pathway (AP) of complement. Mice with deficiency of factor H (Cfh/–), a negative AP regulator, are an established experimental model of C3G in which abundant complement C3 accumulates along the glomerular basement membrane.

Methods: We examined the spontaneous renal phenotype in Cfh/– mice with and without accompanying deficiency of complement receptor 3 (CR3), the main receptor for iC3b. We performed accelerated serum nephrotoxic nephritis (ANTN) in Cfh/– deficient mice to assess the role of CR3 in glomerular injury outside the setting of FH deficiency. The effect of iC3b ligation of CR3 on macrophages and other leukocytes during inflammation was assessed in vitro.

Results: In 8-month old Cfh/– mice, accompanying CR3 deficiency was associated with significantly increased albuminuria, glomerular hypercellularity and macrophage influx, and mortality. In ANTN mice, transplantation experiments in Cfh/– recipients indicated that the protective effect of CR3 was dependent on BM-derived cells. ANTN produced severe crescentic nephritis in CR3-deficient mice (but not wild-type mice). In vitro ligation of CR3 using iC3b-coated particles down-regulated the proinflammatory cytokine response of both murine and human macrophages to lipopolysaccharide stimulation in vitro. These cytokine-modulating effects were cell-type specific, an observation that may reconcile some of the conflicting reports concerning the immune role of CR3 in the literature.

Conclusions: Deficiency of CR3 unexpectedly enhanced the severity of both experimental C3G and immune complex GN. Our findings suggest that pharmacological potentiation of the CR3-iC3b interaction could be therapeutically useful in patients with chronic GN.

FR-PO957
Two Autoimmune Forms of C3-Glomerulopathy Are Defined by Complement Convertases Deregulating Autoantibodies Christine Skerka,1 Fei Zhao,1 Giuseppe Remuzzi,2 Rossella Piras,2 Peter F. Zipfel,1,3 Dept of Infectious Biology, Leibniz Inst for Natural Product Research and Infection Biology, Jena, Germany; 2Laboratory of Immunology and Genetics of Transplantation and Rare Diseases, IRCCS- Istituto di Ricerche Farmacologiche, 24020- Ranica (Bergamo), Italy; 3Friedrich Schiller Univ, Jena, Germany.

Background: In C3G glomerulopathy (C3G) deficient complement activation on level of the C3 convertase is caused by mutations in genes coding for complement components or regulatory proteins as well as by autoantibodies. C3 nephritic factor (C3NeF) has been reported in 50-80% of C3G patients. Notably also autoantibodies to C3b and Factor B were identified in C3G patients, which do not score in the standard C3NeF assay. Here we compare how the new C3 convertase reacting antibodies and also C3NeF affect complement regulation on the level of the C3- and the C5 convertases.

Methods: The autoantibodies were isolated from the serum of C3G patients (n=34), assayed for binding to the C3 convertase by ELISA and further characterized by using a number of functional complement assays.

Results: Among the 34 C3G patients, 19 patients were identified with autoantibodies which bind to the C3 convertase, but lack C3NeF. 15 patients were identified C3NeF positive according to the binding to the C3 convertase, high titer (HT) and low titer (LT) autoantibodies were identified among isolated autoantibodies from all 34 C3G patients. HT as well as LT antibodies strongly activated the C5 convertase and enhanced C5a generation. Interestingly all antibodies bound to the C3 convertase, but only HT and not LT antibodies enhanced C5 convertase activity. The HT but not the LT antibodies increased C3 convertase assembly, stabilized the convertase and increased C3a generation.

Conclusions: Two classes, HT and LT, of complement C3 convertase binding autoantibodies were identified in C3NeF- positive and negative C3G patients. These antibodies deregulate complement by two different mechanisms: HT antibodies activate complement on the C3- and C5 convertase levels, while LT antibodies activate only on C5 convertase level. We speculate that these functional different autoimmune forms explain responder and non-responder types to therapeutic C5 inhibitors.

FR-PO958
Autoimmune C3 Glomerulopathy: Can Complement Inhibiting Drugs Reduce Complement Activation by C3 Convertase Autoantibodies? Friederike Sophie Schulze,1 Fei Zhao,1 Giuseppe Remuzzi,2 Marina Noris,2 Christine Skerka,1 Peter F. Zipfel,1,3 Hans Knoll Inst, Jena; 2Mario Negri Inst for Pharmacological Research, Bergamo; 3Friedrich Schiller Univ, Jena.

Background: C3 glomerulopathy is a severe kidney disorder that is caused by deregulation of the alternative complement pathway due to autoantibodies that bind to the C3 convertase, but lack C3NeF. 15 patients were identified C3NeF- among all 34 C3G patients. HT antibodies were found to increase C3 convertase activity, whereas LT antibodies only increased C5 convertase activity. We aim at characterizing the clinical features of these new autoantibodies cause complement deregulation and how complement inhibitors affect the action of these autoantibodies.

Methods: IgGs were purified from patients with C3 convertase antibody lacking C3NeF (n=19) and also from C3NeF patients (n=15). These purified IgGs were tested for their impact on complement activity and the effect of soluble CR1 (scCR1) and Eculizumab was examined by ELISA, Western blot and complement activation assays.

Results: C3 convertase antibodies from patients lacking C3NeF deregulated complement in some antibody groups stabilized the C3 convertase and all activated the terminal complement pathway. C3NeFs activated complement in a related manner. In probes with C3 convertase antibodies scCR1 did inhibit excessive complement activity. Also Eculizumab prevented antibody mediated complement activation. Both inhibitors blocked C3NeF-mediated complement deregulation in a related manner. For some probes from either C3NeF- or C3NeF+ patients a higher dose of scCR1 was necessary to affect C3 convertase activity.

Conclusions: A subgroup of C3G patients present with C3 convertase-binding antibodies but lack C3NeF. Some C3 convertase antibodies deregulate the C3 convertase and all stabilize the C5 convertase. The complement inhibitors scCR1 and Eculizumab reduced complement activity. Patients with antibodies causing only excessive C5 convertase activity may benefit from Eculizumab, whereas patients with excessive C3 convertase may require additional C3 convertase inhibitors.

Funding: Government Support - Non-U.S.

FR-PO959
Respiratory Syncytial Virus May Exacerbate Kidney Damage in IgA Nephropathy Through Csa/CsaR and Csa/CsAR Signaling Amplifying the Effects of Th17 Cells Xiaozhao Li,1 Xinuye Hu,2 Ting Meng,2 Juntao Feng,2 Qiaoling Zhou,1 1Dept of Nephrology, Xiangya Hospital of Central South Univ, Changsha, Hunan, China; 2Dept of Clinical Laboratory, Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: The exacerbation of IgA nephropathy (IgAN) is related to respiratory tract infection with respiratory syncytial virus (RSV), but the mechanism is unknown. In this study we investigated the role of complement activation products C3a/C5a and CsAR/CsAR signaling responses to the effect of T helper 17 (Th17) cells in the pathogenesis of IgAN associated with RSV.

Methods: IgA nephropathy was induced in BALB/c mice with lipopolysaccharide, carbon tetrachloride and bovine serum albumin. Then the mice were sensitized with respiratory syncytial virus (RSV) in sequence. Urine Albumin-Creatinine ratio and sediments were measured. The pathological changes in kidney and lung tissues were observed under microscopy. C3aR and CsAR proteins in kidney tissue were examined by immunohistochemical staining. C17 chemical staining and CsAR antibodies were tested by flow cytometry. C3a/C5a, IL-17A, IL-6 and IL-21 were in the kidneys were detected by ELISA.

Results: The IgAN mice had albuminuria and microscopic hematuria, renal mesangial proliferation, IgA deposition, high electron dense deposition in glomerular mesangial region, increased frequency of Tregs, increased frequency of Th17 and Th17-Treg ratio. Furthermore, C3a, C5a, C3AR, CsAR and Th17-related cytokines IL-17A, IL-6 and IL-21 were all increased in the kidneys of IgAN mice. Compared with IgAN mice, the manifestations in RSV-IgAN mice were more severe, but alleviated in CsAR-treated groups and CsAR-treated groups respectively.

Functional Glomerular Decay Accelerating Factor Induction by Heme: Role of HO-1  

Giouli Makri, 1  Vasileios Atsaves, 1  Pu Duann, 2  Elias A. Lianos, 1, 2 Medicine, Univ of Athens, Greece; 3 Medicine, Rutgers Biomedical and Health Sciences, NJ.

Background: In hemolytic disorders and glomerular injury associated with hematuria intraglomerular free heme increases and may activate the alternative complement (C)-pathway. Rat glomeruli express decay accelerating factor DAF in glomerular epithelial cells (GEC). We assessed whether heme upregulates glomerular DAF to minimize C activation and explored underlying mechanisms.

Methods: hmox1-/- and hmo1-/- rats were generated by Zinc Finger Nuclease (ZNF)-mediated HO-1 gene disruption and rats with GEC targeted HO-1 overexpression (GEC ho1+) by Sleeping Beauty Transposon mediated transgenesis using a nephron promoter. Wild-type (WT) or hmo1-/-, hmo2-/- or GEC ho1+/+ glomeruli were treated for 18 h with heme (hemin, FePP) or non-iron porphyrins with opposite effects on HO activity: 1) HO inducers, Cobalt (CoPP) and the non-metal protoporphyrin IX (PPIX) and 2) HO inhibitors: Zinc (ZnPp), Tin (SnPP) protoporphyrin, Tin (SnMP) and Chromium (CrMP) mesoporphyrins. C3b deposition in glomeruli was triggered by exposure to 10% rat serum. DAF, HO-1 and C3b levels were assessed by western blotting or Real-time PCR. HO enzyme activity was measured by standard methods.

Results: Constitutive DAF (mRNA and protein) decreased in both hmo1-/- and hmo2-/- and increased in GEC ho1+. Heme, at concentrations encountered in HD patients, increased DAF expression in WT glomeruli. This effect was attenuated in both hmo1-/- and hmo2-/- and augmented in GEC ho1+. HO-mediated DAF induction in hmo1-/- glomeruli persisted despite complete HO-1 absence. Of the non-Fe porphyrins, CoPP and CrMP increased DAF and HO-1. SnnP induced DAF but not hmo1-/- or CrMP and CrMP had no effect on either protein. Hemin or SnPP-mediated DAF induction reduced C3b deposition. This was reversed by PI-PLC which removed membrane bound DAF.

Conclusions: HO-1 regulates constitutive DAF expression and heme-mediated DAF induction. The latter is independent of metal moiety and HO enzyme activity, requires the porphyrin ring and may also occur via a HO-1 independent mechanism. DAF induction by heme is functional and attenuates C-activation.

Complement Activation Impairs Endothelial Cell Migration – Possible Role in TMA Pathogenesis  

Background: Cell migration is a key requirement in multiple physiological scenarios including angiogenesis and endothelial cell repair. Thrombogenic microangiopathy (TMA) is characterized by endothelial cell (EC) activation and injury, in atypical hemolytic urticarial syndrome caused by complement activation on ECs. We hypothesized that EC injury in aHUS was at least in part – caused by complement-mediated inhibition of cell migration. Methods: To test this hypothesis blood outgrowth ECs were exposed to complement by blocking EC surface regulators (CD46, CD55, CD59) and incubating ECs with 50% normal human serum (NHS; complement active). Heat inactivated serum (HS; complement inactive), C5-depleted serum (terminal pathway inactive) and media served as controls. Results: Wound healing assay in fluidic conditions (wound infection by trypan/ EDTA) showed within 1.5 h a wound area decrease to 62.5±1% when perfused with media. Subsequent (1.5 h) HS perfusion allowed for further wound area reduction to 38±6%, similar to C5-depleted serum (46±5%). In contrast, exposure to complement (NHS) inhibited further wound closure (wound area 63±7%, p<0.05). The proliferation rate (%BrdU positive cells after 2 h) was similar between controls and complement-treated ECs (20±2 vs. 21±3%), and no apoptosis or necrosis was detected within a 20 min - 4 h observation period (Annexin V, live dead aqua dye). However, we demonstrated an instantaneous but transient cell membrane retraction (perforated cell) after perfusion with NHS or complement. Consequences of this sublytic C5b-9 deposition caused immediate and sustained (2h) cyto-skeletal (live cell imaging of F-actin, Rho-GTPases), cell-cell contact (decreased VE-Cadherin expression, decreased transendothelial resistance) and cell motility abnormalities (live cell imaging) in complement-exposed ECs, all leading to defective cell migration.

Conclusions: Our data suggest that sublytic EC complement exposure results in impaired cell migration leading to EC injury and defective EC repair – findings extending our current concept of TMA pathogenesis.

Uncommon Features in Antigen Binding Sites of Human Anti-Glomerular Basement Membrane Autoantibodies  
Mary H. Foster, Elizabeth Sarah Buckley, Amy G. Clark. Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.

Background: Detection of pathogenic anti-α3(IV)NC1 collagen autoAb in the serum or kidneys is required for diagnosis of anti-GBM nephritis and Goodpasture Syndrome. Yet little is known about the origin and structure of human autoAb in these diseases. The heterogeneity of serum Ig, lack of ready access to kidney disease tissue, and inability to reproduce complex immunological microenvironments in vitro present formidable barriers. Humanized models provide a novel platform to circumvent these obstacles.

Methods: We generated Hu-Hsc mice by injection of human CD34+ hematopoietic stem cells into immunodeficient NOD-scid-gamma hosts. Mice with an established human immune system (mean blood chimerism 15.0±15.9% at 3 mos post-injection) were immunized twice with α3(IV)NC1 collagen prior to tissue harvest. Human B cells from both donors were transformed using CpG oligos and kinase inhibitors, screened for antigen binding, electrofused with a human heterohybridoma, and subcloned. The mAb sequences were determined using PCR of cDNA with published primer panels and analyzed using IMGT/V-QUEST.

Results: Sequence analysis of 6 non-clonally related human anti-α3(IV)NC1 mAbs revealed skewed gene use and unusual motifs in the critical HCDR3 that is predominantly responsible for antigen binding. 4 of 6 (67%) human mAbs are encoded by an IgH J6 allele, the extended sequence of which enriches for aromatic tyrosine residues in HCDR3. The HCDR3 are exceptionally long, with mean length 26.4 amino acids (a.a.) compared to average human HCDR3 of 15.2 a.a., and include hydrophobic motifs, an autoimmune signature uncommon in Ig repertoires of healthy individuals and of unimmunized Hu-Hsc mice. Similar motifs were observed in murine anti-α3(IV)NC1 mAb but, despite substantial species differences in Ig gene loci and a.a. composition.

Conclusions: Our results suggest that binding of α3(IV)NC1 collagen by human anti-GBM autoAb requires unusual structural motifs that can access recessed hydrophobic epitopes and that are normally excluded from the healthy human immune repertoire. Similar motifs in man and mouse suggest origins by convergent selection.

FR-PO963  
Antigenicity Alteration of Deglycosylated Myeloperoxidase  
Juntao Yu, 1 Zhao Cui, 2 Minghui Zhao. 3 Academy for Advanced Interdisciplinary Studies, Peking Univ, Beijing, China; 4 Renal Div, Peking Univ First Hospital, Beijing, China.

Background: Myeloperoxidase (MPO) is a kind of enzyme located in the azurophilic granules of neutrophils, which is the most common target antigen of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) in Chinese patients. Native MPO possesses five N-glycans at positions 323, 355, 381, 483 and 729. The alteration of MPO antigenicity after deglycosylation of these glycans is not elucidated.

Methods: We prepared deglycosylated MPOs via glycosidases based on commercial human-derived intact MPO, and then detected the antigenicity of deglycosylated MPOs in 40 patients with anti-glomerular basement membrane (GBM) disease without MPO-ANCAs.

Results: We found antibodies against deglycosylated MPOs existed in patients with anti-GBM disease. 12/40 (30%) patients were positive for MPO treated with PNGase F naked MPO without hydrocarbon side-chain. 12 (30%) patients were positive for MPO treated with Endo H (MPO with one GluNAc only). Antibody against the intact native MPO was not detectable in all these patients. Furthermore, clinical analysis presented that the levels of antibodies against deglycosylated MPOs were positively associated with renal dysfunction. The plasma levels of antibodies against naked MPO without glycan were positively correlated with the concentrations of serum creatinine (r=0.006, R²=0.178). The plasma levels of antibodies against MPO with one GluNAc only were also positively correlated with the concentrations of serum creatinine (P=0.002, R²=0.234).

Conclusions: The existence of patients’ antibodies towards deglycosylated MPO first discovered the new epitope exposure of MPO after the loss of hydrocarbon side-chain, explicating the possible reasons for antigenicity alteration, and then prompting some clinical significance of these antibodies.

Autoantibodies to a Cryptic Myeloperoxidase-Specific Immunodominant Epitope Correlate with Disease Activity in Patients with MPO-ANCA Vasculitis  
Jacob J. Hess, Meghan E. Free, Olivier Lardinois, Donna O. Bunch, Caroline J. Poulton, JulieAnne G. McGregor, J. Charles Jennette, Ronald J. Falk, William Franklin Pendergraft. UNC Kidney Center; Univ of North Carolina, Chapel Hill, NC.

Background: ANCA vasculitis is commonly characterized by polyclonal autoantibody reactivity to one of two autoantigens, proteinase 3 (PR3) and/or myeloperoxidase (MPO). ANCA positivity has been observed in patients with active and quiescent disease. A subset of MPO-ANCA in many patients recognizes a cryptic epitope in the N terminal region of the MPO molecule. This peptide is buried within MPO suggesting that this epitope may be exposed by mechanisms that are not yet understood. We assessed human anti-KIV reactivity longitudinally in a large cohort of patients with MPO-ANCA vasculitis to better understand the temporal association of the autoimmune response.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Serum, plasma, and extensive clinical data from patients with ANCA vasculitis were prospectively collected every 3 months. A highly sensitive and specific indirect ELISA using KIV peptide was developed to longitudinally screen patient samples for reactivity over their disease course. To minimize non-specific antibody signal, reactivity to a scrambled peptide of the same amino acid composition was also measured. A positive signal was defined as two standard deviations above the healthy control mean (HC n=85).

Results: Of 67 patients with MPO-ANCA vasculitis, 28 were positive for human anti-KIV autoantibodies at least once during their disease course spanning an average follow-up of 3.3 years. The majority of these patients displayed positivity during initial stages of disease, whereas other patients exhibited recurrence of reactivity. Further structural analysis of autoantibody-binding native MPO confirmed this peptide to be a cryptic epitope.

Conclusions: These findings suggest that conformational changes in MPO that expose this cryptic epitope may be important in the pathogenesis of MPO-ANCA vasculitis and may provide insight into the etiology of this disease. Further, this assay could help to more clearly define temporal disease activity.

An Anti-GBM Autoantibody Gene Contributes Risk to Distinct Anti-Collagen Responses
Amy G. Clark, Inge M. Worni-Schudel, Mary H. Foster.

Background: The mechanism by which anti-GBM nephritis is initiated and regulated remains an enigma. Recent studies indicate that anti-GBM patients’ serum IgG react with multiple collagen chains and with atypical alpha3(V)NC1 epitopes, and that diverse murine anti-GBM autoantibodies are serologically linked. We examined these relationships in a novel autoAb transgenic (IgG) model expressing an IgKV gene used at low frequency in adult mice but enriched in anti-GBM Ig and arthritogenic anti-collagen II IgG.

Methods: Mice expressing an IgKV3-encoded Ig kappa light chain Tg were bred with C57BL/6J mice. All sera from 3-9 month old mice were tested for alloreactivity by western blot, dot blot, and immunoprecipitation. Reactivity with single domains or several multiple constructs composed of 1 to 4 adjacent domains, and could be detected by western blot, such as IgKV serially truncated from the N- or C-termini, was stronger than that against non-B cells expressing the major autoantibody. In vivo, a subset of primary membranous nephropathy patients. Its extracellular domain consists of 1 transmembrane glycoprotein expressed by the podocyte. It serves as the antigen in situ that impairs podocyte biology resulting in foot process effacement and subsequently extracellular region. Further analysis of additional anti-THSD7A positive sera will help to define the epitope within the molecule, underlie the pathogenesis of this autoimmune disease, and identify potential targets for novel therapeutic agents.

Intramembranous Epitope Spreading in Phospholipase A, Receptor in IMN
Quan Sheng Zhu, Hong Tang, Phat H. Duong, Meryl A. Waldman, Mary H. Foster.

Background: Idiopathic membranous nephropathy (IMN) is an organ specific autoimmune disease. The major antigen responsible for developing IMN in patients has been identified to be the phospholipase A receptor (PLAR) expressed in the glomerular visceral epithelial cells. Clinical studies demonstrated that over 70% of circulating autoantibodies that target PLAR triggers immune complexes formation in situ and deposition in the glomerular subepithelial spaces. The immunodominant epitope in PLAR was recently located to the extreme N-terminus of the receptor encompassing the CysR-FnIII-CTLD1 region. In the rat model of MN, epitope spreading was detected in the antigenic peptide, megalin that is correlated with the disease progresses. Whether epitope spreading occurs in human IMN and its relationship to disease progresses is unclear.

Methods: Serum samples from biopsy-proven IMN patients were collected and screened for anti-PLAR antibodies using Western-blot and epitope-specific ELISA assays. The reactions of autoantibody and PLAR epiteope protein was further analyzed using immunoprecipitation and immunoblotting assays.

Results: Western-blot analysis using patient sera against full-length PLAR or the dominant epitope region indicated that, 3 of the 12 serum samples that were positive with non-B PLAR autoantibodies failed to recognize the dominant epitope protein. Further test of these 3 samples against a series of truncated PLAR extracellular domains on Western-blot demonstrated that the autoantibodies bind strongly to the CysR-FnIII-CTLD1-3 region of PLAR. Interestingly, serial analysis of sera from a patient with worsening proteinuria showed that, the autoantibodies first recognized the CysR-FnIII-CTLD1-3 region and then spread to the CysR-FnIII-CTLD1 region, suggesting epitope spreading is associated with the disease progresses.

Conclusions: Our results demonstrate for the first time that intramembranous epitope spreading occurs in PLAR in IMN. This finding supports the important role of the dominant epitope in IMN pathogenesis and disease progresses.

FR-PO968
Demonstration of a High Titer Low Affinity Anti-PLAR Autoantibody in an IMN Patient En Route to End-Stage Renal Disease
Michael Shye, Theresa L. Nilson, Ritu Vahi, Miguel Fernandez Palma Diaz, PC. Pham, Phat H. Duong, Liyo Kao, Douglas Yao, Ira Kurz, Quan Sheng Zhu.

Background: Clinical studies have established that over 70% of patients with idiopathic membranous nephropathy (IMN) possess high levels of circulating autoantibodies targeting phospholipase A receptor (PLAR) in the glomerular visceral epithelial cells (podocyte). Binding of autoantibodies to PLAR triggers immune complex formation in situ that impairs podocyte biology resulting in foot process effacement and subsequently proteinuria in patients. In this study, we monitored the fluctuation of autoantibody level in a patient progressing to the end-stage renal disease (ESRD) under the supportive treatments.

Methods: Serum samples from biopsy-proven IMN patient monitored between ESRD and supportive treatments over a period of 6 month were collected (5 clinical visits) and tested for the level of anti-PLAR antibodies using Western-blot, indirect immunofluorescence staining and epitope-specific ELISA assays. The reaction of autoantibodies toward the dominant epitope occurs in PLAR was further analyzed using immunoprecipitation under the non-denaturing and denaturing conditions.

Results: A sharp decline of autoantibody reactivity toward PLAR in sera from the last two visits was detected on Western-blot as the patient approaching ESRD. In contrast, an epitope-specific ELISA assay indicated that the autoantibodies were remained at high levels in these two serum samples, and this observation is further confirmed by the immunofluorescence staining analysis. Test of epitope-antibody reaction under the non-denaturing and denaturing conditions revealed that, the properties of the autoantibodies in the last two visits differ significantly from that in the first three visits, which have low affinity toward PLAR and only bind to the non-denatured form of the epitope.

Conclusions: Our results demonstrate that a high titer low affinity anti-PLAR autoantibody presents in an IMN patient at the late stages of IMN approaching ESRD under the supportive treatments. This autoantibody has altered reactivity toward PLAR that only binds to the non-denatured immunodominant epitope of the receptor.

FR-PO969
Immune Complex Binding to Renal Endothelial Cells Induces TRAIL and Promotes Apoptosis
Scott E. Wenderfer, Adisak Suwanichkul. Pediatrics, Baylor College of Medicine, Houston, TX.

Background: Circulating immune complexes (IC) deposit in the glomeruli of the kidney in many autoimmune diseases, leading to proliferative glomerulonephritis. IC binding can promote proliferation or induce apoptosis in human macrovascular EnCs.
Tumor necrosis family (TNF) superfamily members regulate proliferation and apoptosis, and both are strongly upregulated by immune complex (IC). Quantitative RT-PCR was used to measure mRNA levels of TNF superfamily members. A cellular ELISA was used to assess TRAIL protein expression on EnC surfaces. Apoptosis was assessed using flow cytometry and caspase 3 activity assays, as well as TUNEL staining. In vitro findings were validated in a rodent model of acute IC kidney injury.

**Results:** TRAIL mRNA expression is up-regulated by renal endothelial cells in vitro in the presence of IC binding and in vivo. Membrane TRAIL expression on EnCs also increases after treatment with IC in a dose dependent manner. Receptors for TRAIL, DR5, DR4, A2aR and A2bR are expressed by EnC at RNA and protein level. Using XTT cell proliferation assays, there is a modest decrease in EnC metabolism or proliferation after treatment with IC. Caspase 3 activity and DNA double strand breaks were both increased in cultured EnCs after treatment with IC in a dose dependent manner. Results were similar for both murine and human glomerular EnCs.

**Conclusions:** Our findings indicate that IC binding to glomerular EnCs in vitro is pro-apoptotic. Several TNF superfamily members known to promote apoptosis and their receptors are also up-regulated on EnCs treated with IC. Targeting TRAIL binding to glomerular EnCs by vaccination or antibody treatment may reduce IC binding and disease.

**Paired Immunoglobulin-Like Type2 Receptor (a PILRα) Negatively Regulates Immune Complex-Mediated Glomerulonephritis**

Yutaka Suzuki, Akiko Takahata, Seiichi Matsuo. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

**Background:** PILRα expressed mainly on macrophages, dendritic cells and granulocytes, has been described for its regulatory functions for leukocyte β2 integrin activation in acute inflammation including LPS-induced endothox shock model. Here, we investigated roles of PILRα in immune complex (IC)-mediated glomerulonephritis.

**Methods:** IC-mediated glomerulonephritis was induced by intravenous administration of nephrotoxic serum (NTS) after pre-infection with rabbit IgG in C57BL/6 (WT) and PILRα-/- mice. Functional analysis for renal injury was performed by urine albumin and serum creatinine (SCr) concentrations at day 7, 14 and 21. Diseased kidneys from both mouse strains were harvested for histology, renal leukocyte infiltrates by flow cytometry and renal cytokine profiles by ELISA after induction of NTS glomerulonephritis. In vitro, αIC3 integrin-dependent neutrophil adhesion on IC was evaluated in both mouse strains. Results: BUN and Cr concentrations were significantly elevated in PILRα-/- mice compared to wild type mice at day 14 and day 21 and those were highly associated with deteriorated proteinuria. In histological analysis, glomerular damages, corroborated with both glomerular PAS deposits and glomerular crescent formation, were more severe in PILRα-/- mice at day 21 (p<0.05). Moreover, glomerular neutrophil accumulation was remarkably observed in PILRα-/- mice compared to WT mice at day 21. In addition, total infiltration of Ly6G+ neutrophils, F4/80+ macrophages and CD3+CD4+ T cells in whole kidneys were increased in PILRα-/- mice than WT mice at day 14 and day 21. Renal proliferation rate and patent kidney from IL-10 receptor-deficient mice also demonstrated severe renal infiltration in PILRα-/- mice. In vitro, PILRα deficient neutrophils showed enhanced adhesion and spreading on IC compared to WT.

**Conclusions:** PILRα deficiency resulted in deteriorated renal damage in mouse IC-mediated glomerulonephritis compared to WT mice, indicating that PILRα negatively regulates IC-mediated leukocyte recruitment by inhibition of αIC3 integrin activation.

**Role of Interferon Regulatory Factor 5 and Toll-Like Receptor 7 in Intra-Capillary Glomerulonephritis**

Naotake Tsuibo, Yutaka Kamimura, Shoichi Maruyama, Seichi Matsu. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

**Background:** Interferon regulatory factor 5 (IRF5) and toll-like receptor 7 (TLR7) signaling is required for the development of glomerular inflammation during the heterologous phase of ICGN. However, proteinuria was only significantly increased in IRF5-/-KO, but not in the IRF7-/-KO mice. Therefore, IRF7-independent pathway downstream of TLR7 is responsible for the pathogenesis of TLR7/IRF5 mice.

**Conclusions:** IRF7 and TLR7 signaling is required for the development of glomerular inflammation during the heterologous phase of ICGN. However, proteinuria was only significantly increased in IRF5-/-KO, but not in the IRF7-/-KO mice. Therefore, IRF7-independent pathway downstream of TLR7 is responsible for the pathogenesis of TLR7/IRF5 mice.

**Therapeutic TLR9 Inhibition Prevents the Establishment of Anti-Myeloperoxidase Autoimmunity and the Development of Glomerulonephritis in Mice with Established Autoimmunity**

Sharon Lee Ford, Barry K. Horne, Yao Poh. VIC, Australia; 2 Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan.

**Background:** We have shown TLR9 ligands enhance anti-myeloperoxidase (MPO) autoantibody (AI) and glomerulonephritis (GN) through dendritic cell (DC) activation. We assessed therapeutic TLR9 inhibition on both the development of anti-MPO AI induced through DC vaccination and subsequent development of GN by TLR9 responsive innate effector cells.

**Methods:** Injection of MPO/Freud’s Adjuvant or transfer of MPO/CpG (TLR9 ligand) pulsed bone marrow derived DCs established anti-MPO AI. To stimulate effector cells, intraperitoneal (IP) CpG or MPO/Freud’s Adjuvant was injected after inducing anti-MPO AI, triggering renal injury and antimicrobial activity and glomerular inflammation.

**Results:** In vivo TLR9 signaling was inhibited with an inhibitory oligodeoxynucleotide before both induction of AI and triggering renal injury.

**Conclusions:** Mice receiving MPO/CpG/Ds + IP CpG compared to MPO/CpG/Ds + IP CpG (Control) developed heightened immune responses (cells/spleen: 5.4±6 vs 3.6±1x10^5, p<0.05) and renal injury (area:3.1±7 vs 11±3µmol/L, p<0.05, abnormal glomeruli:93±3 vs 15±3%, p<0.001) confirming effector cell TLR9 ligand is required for disease induction and a target for therapeutic inhibition. TLR9 inhibition prevented MPO/CA induced systemic AI and MPO autoimmunity measured by MPO specific dextral DTH swelling (2.6±1.1 vs 18.6±3Dmm, p<0.05) and decreased frequency of MPO stimulated IL-17A producing cells (6.1±vs 21±3cells, p<0.01) compared to control. TLR9 inhibition prevented MPO/CA driven in mice receiving MPO/CpG-ODNs (DTH:3.1± vs 18±3Dmm, p<0.01, IL-17A:21± vs 13±3Dmm, p<0.02) and decreased frequency of MPO stimulated IL-17A producing cells when given to mice with established anti-MPO AI compared to control (DTH:3.1± vs 13±1mm footpad swelling, p<0.05, urea:26±1 vs 34±1µmol/L, p<0.05, abnormal glomeruli:43±9 vs 79±5%, p<0.01).

**Conclusions:** Therapeutic TLR9 inhibition prevents the development of anti-MPO AI and is a therapeutic option to prevent the development of renal injury once anti-MPO AI is established.

**Funding:** Government Support - Non-U.S.

**TLR9 Activation Aggravates Murine IgA Nephropathy? Possible Role of BAFF Mediated Pathway**

Yuko Makita, Hitoshi Suzuki, Akiko Takahata, Toshiki Kano, Satoshi Horikoshi, Yusuke Suzuki. Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan.

**Background:** Contribution of Toll like receptors (TLRs) which play a key role in the innate immune system has been discussed in the pathogenesis of IgAN. We recently demonstrated that TLR9 is importantly involved in progression of kidney injuries in IgAN prone mice. On the other hand, role of B cell activating factor (BAFF) is discussed in the pathogenesis of human IgAN. Present study examined the contribution of BAFF in the TLR9 mediated progression of IgAN using IgAN prone mice.

**Methods:** Commercially available quiescent IgAN prone mice (ddY mice) at 4 weeks of age were used for this study. They were divided into two groups with (n=8) or without (n=8) TLR9 ligand (CpG-ODN) for 12 weeks. Renal histological lesions and serum levels of IgA, IgG and C3. Moreover albuminuria and renal histological scores based on mesangial proliferation and mesangial matrix expansion in CpG-ODN treated mice were significantly higher than those in non-treated mice. The expressions of MyD88, BAFF and TACI were determined by RT-PCR in renal tissues from both groups.

**Results:** TLR9 activation led to increase of mesangial proliferation and mesangial matrix expansion in CpG-ODN treated mice significantly higher than those in non-treated mice. The expressions of MyD88, BAFF and TACI were also significantly increased by treatment with CpG-ODN. Interestingly there were significant correlations between BAFF expression and serum levels of aberrantly glycosylated IgA and IgA-IgG IC.

**Conclusions:** Present study indicated that TLR9 activation exacerbates murine IgAN via increase of aberrantly glycosylated IgA and nephriticic IgG. In addition, present findings also suggested that TLR9 BAFF expression may be involved in the nephritogenic IgA and IC production.
Key Role of Apoptosis Inhibitor of Macrophage in Phlogenic Action of Glomerular Nephritic IgA in IgA Nephropathy

Akiyoshi Takahata,1 Kento Kitada,2 Chieko Nogi,3 Satoko Arai,4 Yuko Makita,1 Hitoshi Suzuki,1 Junichiro Nakata,2 Satoshi Horikoshi,1 Toru Miyazaki,1 Yusuke Suzuki.1

1Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan; 2Laboratory of Molecular Biomedicine for Pathogenesis, Center for Disease Biology and Integrative Medicine, Faculty of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.

Background: Apoptosis inhibitor of macrophage (AIM), a protein mainly produced by macrophages, has been reported to be related to autoimmune diseases as well as arteriosclerosis.

Methods: We evaluated the role of AIM in IgA nephropathy (IgAN) using IgAN prone mice, grouped ddY (gddY) (J Am Soc Nephrol:2012;3:1364-74). Serum of gddY mice was injected to AIM-deficient (AIMKO) and wild-type (WT) mice, and proteinuria and glomerular depositions were evaluated over time. In addition, nephritogenic IgA, produced by gddY splenic B cells hybridomas, was injected to AIMKO and WT to perform the experiments.

Results: We found excessive expression of AIM in gddY, which were co-localized with glomerular IgA. Glomerular IgA deposition were observed in AIMKO and WT 2h after the injections of gddY serum and purified nephritogenic IgA. The depositions were cleared soon thereafter in WT but later in KO after being accumulated. However, proteinuria as in non-depleted WT. The depletion of macrophages did not change the degree of glomerular depositions in WT, as in non-depleted WT.

Conclusions: These findings suggest that AIM is a critical molecule in the glomerular IgA on IgAN prone mice which may be a contributor to such inflammatory responses by glomerular resident cells such as mesangial cells.

Characterization of a Signaling Network That Enhances Production of Galactose-Deficient IgA1 in IgA1-Secreting Cells from Patients with IgA Nephropathy

Koshi Yamada,2 Colin Reilly,1 Chi qiang Huang,1 Joshua Charles Anderson,1 Milan Raska,1 Hitoshi Suzuki,2 Bruce A. Julian,1 Christopher D. Willey,1 Jan Novak.1 1Univ of Alabama at Birmingham, Birmingham, AL; 2Juntendo Univ Faculty of Medicine, Tokyo, Japan; 3Palacky Univ, Olomouc, Czech Republic.

Background: Interleukin (IL)-6, leukemia inhibitory factor (LIF), and oncostatin M (OSM) cytokines are likely involved in the pathogenesis of IgA nephropathy (IgAN). IL-6/LIF/OSM cytokines activate B cells through similar receptors and the downstream JAK/STAT pathways. We identified key roles of STAT transcription factors in IL-6/LIF/OSM-mediated enhancement of production of IgA1 with galactose-deficient O-glycans (Gd-IgA1) secreted by IgA1-secretory cells from IgAN patients. Our study defines how these signaling pathways influence IgA1 glycosylation.

Methods: IgA1-secretory cells from IgAN patients and healthy controls (HC) were stimulated with IL-6/LIF/OSM with or without JAK/STAT inhibitors. Gd-IgA1 levels were determined by lectin ELISA. Cell lysates from IgAN and HC were analyzed by global tyrosine kinase profiling using PanPhospho®12 platform and Western blotting. The role of STAT3 and STAT1 in mediating IL-6/LIF/OSM, signaling was confirmed by siRNA knock-down (kd).

Results: siRNA kd of STAT3 and STAT1 reduced production of Gd-IgA1 in IgAN cells induced by IL-6 and LIF/OSM, respectively. A specific inhibitor of JAK/STAT signaling reduced IL-6/LIF-enhanced production of Gd-IgA1, but only in IgAN cells. Global tyrosine kinase profiling identified nine target peptides that were selectively inhibited by the tested JAK/STAT inhibitor in the IgAN cell lysates. Bioinformatics analyses and pathway mapping identified abnormal signaling in JAK/STAT and MAPK cascades as the highest ranked pathway.

Conclusions: IL-6/LIF/OSM cytokines enhanced production of Gd-IgA1 via overactivation of JAK/STAT pathways in IgAN cells. Global tyrosine kinase profiling validated this finding and also indicated participation of MAPK. Elucidating the mechanisms of abnormal signaling associated with Gd-IgA1 production in IgAN-secretory cells may provide new targets for treatment of IgAN.

Endothelial NF-κB Induction by ANCA-Activated Neutrophils

Mina Choi,1 Adrian Schreiber,2 Claudia Eulenberg,1 Ralph Kettritz,1 Klaus Scheidereit,3 Dirk Schreiber3
1Dept of Nephrology, Charité Berlin, ECRC, Berlin, Germany; 2Experimental Immunology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 3Max-Delbruck Center for Molecular Medicine, Berlin, Germany.

Background: The activation of the NF-κB/Rel family and subsequent transcriptional activity of NF-κB may help limiting the ANCA-mediated damage.

Methods: ANCA Disease Patients Demonstrate a Higher Frequency of CD33+ Myeloid Cells with Variable Suppressive Abilities

Meghan E. Free,1 Katie Stember,2 Julie Anne G. McGregor,1 J. Charles Jennette,2 Ronald J. Falk,1 Maureen Su.3
1Department of Pathology, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 2Division of Nephrology, Department of Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 3Pediatrics, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Myeloid-derived suppressor cells (MDSCs), or CD33+ myeloid cells, have been extensively studied in cancer as potent suppressors of T cell activation. Regulatory T cells develop in the control T cell cytoplasm of anti-neutrophil cytoplasmic antibody (ANCA) disease, so we sought to determine the role of CD33+ myeloid cells in ANCA disease as an alternative suppressive mechanism.

Methods: Analyses were performed using flow cytometry on peripheral blood mononuclear cells (PBMCs) from 63 patients stained with relevant antibodies. Suppressive potential of CD33+ myeloid cells was assessed with a standard T cell suppression assay.

Results: Flow cytometric analysis of PBMCs revealed an increased population of lineage negative, CD11b+ and CD33+ myeloid cells in patients with ANCA disease compared to healthy controls (mean 2.72% versus 0.18% of PBMCs). This CD33+ myeloid cell population also contained MPO and PR3. Suppression assays utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression. Conclusions: CD33+ myeloid cells are increased in patients with ANCA disease and represent a potential source of T cell suppression not previously investigated. Intriguingly, the patients demonstrated the highest frequency of CD33+ myeloid cells were those who had sequentially received rituximab and cyclophosphamide.

Ubiquitin C-Terminal Hydrolase-L1 Controls Dendritic Cell Cross Priming of the CD4+ T Cell Response

Anne Reinecke,1 Malte Mühlig,1 Pina Schmucker,1 Timo Lischke,2 Elisabeth Mettke,1 Christian Kunts,1 Hans-willli Mittrücker,2 Catherine Meyer-Schwenninger.1
1Nephrology, 3rd Medical Clinic, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Immunology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Ubiquitin C-terminal Hydrolase-L1 (UCH-L1) is a central deubiquitinating enzyme of the ubiquitin proteasomal system. UCH-L1 is thought to regulate the pool of ubiquitin. Within the kidney, UCH-L1 is de novo expressed in glomerular and tubulo-interstitial cells.

Methods: Constitutive knockdown of UCH-L1 in dendritic cells (DCs) using shRNA and Cre-lox technology demonstrated that the ubiquitin proteasomal system with ANCA disease compared to healthy controls (mean 2.72% versus 0.18% of PBMCs). We confirmed this with analyses utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression. Suppression assays utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression. Conclusions: CD33+ myeloid cells are increased in patients with ANCA disease and represent a potential source of T cell suppression not previously investigated. Intriguingly, the patients demonstrated the highest frequency of CD33+ myeloid cells were those who had sequentially received rituximab and cyclophosphamide.

CD33+ dendritic cells (DCs) in non-lymphoid organs exhibit two main types of function, namely maintaining tolerance by induction of regulatory T cells and protecting against tissue injury through activation of CD8 T cells. However, the characteristics and functions of CD103+ DCs in kidney cortex but not medulla. The number of kidney CD103+ DCs was significantly reduced in vitro and in vivo when co-culture of CD4+ T cell response is unaffected. Finally, exposure to L. monocytogenes results in a significantly decreased generation of antigen-specific CD8+ T cells.

Conclusions: We describe a hitherto unrecognized role for UCH-L1 in controlling CD4+ T cell activation by DCs.

Advanced Glycation End Products Induced the Imbalance between Th17 and Treg Cells via RAGE Pathway in Diabetic Nephropathy

Yanlin Zhang, Ao Cheng. Dept of Nephrology, The First Affiliated Hospital of Xiamen Univ, Xiamen, Fujian, China.

Background: The imbalance of Th17/Treg cells has been involved in diabetic nephropathy, but the mechanism is still unclear. Advanced glycation products (AGEs) increase in the patients with diabetic nephropathy, The main purpose of this experiment is to explore whether AGEs can cause the imbalance of Th17/Treg cells through RAGE signaling pathway.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: (1) Recruitment of 20 healthy adults and 40 diabetic nephropathy patients of C57/BL6 and 12-week-old non-obese diabetic (NOD) mice. (2) Intraperitoneal injection of AGEs containing CD4+ T cells to assess the correlation. (2) Prepared AGE-HSA in vitro and isolated and cultured the initial CD4+ T cells from healthy volunteers peripheral blood to explore the effect of AGE-HSA on the differentiation of initial CD4+ T cell: AGE-HSA with different dose and time stimulated initial CD4+ T cells, compared with RAGE neutralizing antibodies and blocking RAGE to detect the ratio of Th17 cell and Treg cells by flow cytometry and determine the expression mRNA of RORgt and Foxp3, and the expression of mRNA and protein of STAT3 and IFN-1. 3 Patients with diabetic nephropathy, there is accumulation of AGES and increasing of Th17 and the reduction of Treg cells. The ratio of Th17 cells and Treg cell is imbalance (increase in the proportion). There was a positive correlation between the concentration of AGES and the proportion of Th17 cells and Treg cells; (2) The AGES-HSA in a dose dependent manner can differentiate Th17 cells, to differentiate Th17 cells and blocking RAGE could mitigate this effect; (3) AGES-HSA increased the expression of RORgt in the initial CD4+ T cells, but had no effect on Foxp3. After blocking RAGE, it could inhibit the expression of RORgt induced by AGE-HSA; (4) the expression of STAT3 and IFN-1 was reduced in the initial CD4+ T induced by AGE-HSA, while blocking RAGE, expression of STAT3 and IFN-1, induced by AGES-HSA was inhibited.

Conclusions: In the patients with diabetic nephropathy, there was a positively correlated between the content of AGES and the proportion of Th17 cells and Treg cells, and AGES-HSA can induce the initial CD4+ T cells to generate Th17 cells by RAGE-RORgt signaling.

FR-PO984

RORgt Activation in biTregs Promotes Lupus Nephritis Malte A. Kluger, Anna Nosko, Paul Derenhardt, Boeren Goerke, Matthias C. Meyer, Michael Luig, Rolf A. Stahl, Oliver M. Steinmetz.

Background: We recently characterized Foxp3+ regulatory T cells, co-expressing the Th17 characteristic transcription factor RORgt, as an independent and bi-functional T cell lineage (biTregs). biTregs secrete both, anti-inflammatory (IL-10, IL-35), but also pro-inflammatory (IL-17) cytokines. Studies in a model of acute crescentic glomerulonephritis suggest that pro-inflammatory biTreg functions are mediated by RORgt. This is of high clinical relevance, since multiple RORgt blocking agents are currently under development.

Methods: Systemic lupus erythematosus (SLE) Pristane in biTregRORgt mice did not. In order to assess effects of biTreg expressed RORgt on development of renal injury. Our data therefore favor RORgt directed interventions as role for generation of humoral auto-immunity.

Conclusions: Five (38%) of the patients responded to rituximab treatment. Plasma cytokine profiling was performed on each of these patients utilizing multiplexed Lumines® Cytokine Human 27-Plex assay pre- and post-rituximab therapy. Statistical analysis was performed using Wilcoxon signed-rank test with a p-value of less than 0.05 considered as statistically significant.

Results: Five (38%) of the patients responded to rituximab, defined as having achieved complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months. All patients in the study demonstrated an increase in plasma interferon-gamma-inducible protein (IP)-10 levels post-rituximab treatment (554.3±62.4 pg/ml (pre) vs 793.4±125.5 pg/ml (post), p<0.008). Comparing the cytokine profile between responders and non-responders, responders demonstrated a positive mean-fold change in mean inflammatory protein (MIP)-1α, in contrast to non-responders which demonstrated a negative mean fold change (0.23±0.16 vs -0.17 ±0.08, p=0.04). There were, otherwise, no noted significant differences in the other cytokines i) pre- (post-rituximab) and ii) between responders and non-responders.

Conclusion: Our study results suggest the development of a pro-inflammatory state in our patients post-rituximab therapy. The increase in plasma IP-10 in patient post-rituximab may account for the phenomenon of rituximab-associated colitis. The finding of increased plasma MIP-1α in responders compared to non-responders is novel. Further mechanistic studies are required to ascertain the role of MIP-1α in the mechanism of action of rituximab.

Cytokine Profiling in Ritusimab-Treated Pediatric Focal Segmental Glomerulosclerotic Nephrotic Patients Wee Song Yeo, Chang-Yien Chan, Hui Kim Yap. Pediatrics, Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore, Singapore.

Background: Focal segmental glomerulosclerosis (FSGS) is the most common histological pattern seen in pediatric steroid-dependent and steroid-resistant nephritic patients. In recent years, rituximab is increasingly used in nephrotic patients who have failed therapy with conventional immunosuppressants. This study aimed to examine the cytokine profile in rituximab-treated pediatric FSGS nephritic patients and elucidate the cytokine profile differences between responders and non-responders.

Methods: Our study population consisted of 13 pediatric FSGS patients who underwent rituximab therapy. Plasma cytokine profiling was performed on each of these patients utilizing multiplexed Lumines® Cytokine Human 27-Plex assay pre- and post-rituximab therapy. Statistical analysis was performed using Wilcoxon signed-rank test with a p-value of less than 0.05 considered as statistically significant.

Results: Five (38%) of the patients responded to rituximab, defined as having achieved complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months. All patients in the study demonstrated an increase in plasma interferon-gamma-inducible protein (IP)-10 levels post-rituximab treatment (554.3±62.4 pg/ml (pre) vs 793.4±125.5 pg/ml (post), p<0.008). Comparing the cytokine profile between responders and non-responders, responders demonstrated a positive mean-fold change in mean inflammatory protein (MIP)-1α, in contrast to non-responders which demonstrated a negative mean fold change (0.23±0.16 vs -0.17 ±0.08, p=0.04). There were, otherwise, no noted significant differences in the other cytokines i) pre- (post-rituximab) and ii) between responders and non-responders.

Conclusion: Our study results suggest the development of a pro-inflammatory state in our patients post-rituximab therapy. The increase in plasma IP-10 in patient post-rituximab may account for the phenomenon of rituximab-associated colitis. The finding of increased plasma MIP-1α in responders compared to non-responders is novel. Further mechanistic studies are required to ascertain the role of MIP-1α in the mechanism of action of rituximab.

Hyporesponsive T-Cell Phenotype Predicts a Subset of Focal Segmental Glomerulosclerosis (FSGS) Patients Responsive to Rituximab Changle-Yien Chan, Isaac Liu, Lourdes Paula Real Resontoc, Kar Hui Ng, Thong Thien, Yew Wong Perry Lau, Stanley C. Jordan, Kong Peng Lam, Wee Song Yeo, Hui Kim Yap.

Poster/Friday

Background: Rituximab has been used with variable success in difficult FSGS, but the immunological basis of its efficacy is poorly characterized. This study aimed at identifying T-cell subsets in pediatric FSGS patients in order to define an immunological signature predictive of a favorable response to rituximab.

Methods: 22 FSGS patients (median age 14.4 years, range 6.2-25.0 years) were recruited prospectively to receive rituximab (375mg/m2 fortnightly to a maximum of 4 doses). Median duration of follow-up was 26.7 months (range 6.5-66.6 months). Baseline immunological subsets were compared with 30 healthy controls, and subsequently examined for association with response to rituximab. Good response was defined as complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months.

Results: Of the 22 patients, 12 (54.5%) responded to rituximab therapy. Activated CD4+ CD3+ CD43+ subsets significantly lower in responders (54.9±8.10%) compared to non-responders (78.9±5.18%) (p=0.03) and controls (75.7±2.49%) (p<0.001). IFN-γ+ CD3+ subsets were similarly decreased in responders (0.35±0.24%) compared to non-responders (7.2±1.21%) (p<0.005) and controls (4.1±2.15%) (p<0.001). IL-2+CD3− subsets were also lower in responders (0.24±0.14%) compared to non-responders (4.4±2.19%) (p<0.001) and controls (6.6±1.31%) (p<0.003). Significant recovery of all 3 activation subsets occurred 3 months post-rituximab treatment. Using ROC curve analysis, activatedCD54+ CD43+ (AUC 0.82, 95% CI 0.63-1.00), IFN-γ+CD3+ (AUC 0.86, 95% CI 0.67-1.00) and IL-2−CD3− (AUC 0.82, 95% CI 0.63-1.00) were good predictors of response to rituximab.

Conclusion: We have identified prognostic markers which define a subset of FSGS patients bearing an immunological signature representing hyporesponsiveness to T-cell stimulation, with good response to rituximab therapy.

Gut-Kidney Axis in the Pathogenesis of IgA Nephropathy
Gabriella Lauriero, Eustachio Mentornemo, Maria De angelis, Valentina Maranzano, Lucia Vannini, Loreto Gesualdo. 1 DETO-Nephrology Unit, Univ. of Bari, Italy; 2 DiSSPA, Univ. of Bari, Italy; 3 Dept. of Agricultural and Food Sciences, Univ. of Bologna, Italy.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. It is characterized by deposition of deglycosylated IgA1 and IgA antibodies in the glomeruli and its pathogenesis is only partially defined. Intestinal microbiota could be involved in IgAN, as suggested by the observation that B-cell activation factor (BAFF) transgenic mice had high levels of aberrantly glycosylated serum polymeric IgA, the presence of commensal flora and the circulation of corresponding specific IgA antibodies being essential for the development of IgA deposits. BAFF is an important regulator of B cell maturation, survival and function. The aim of the study was to analyze the role played by gut-kidney axis in the pathogenesis of IgAN.

Methods: 16 healthy controls (HC) and 32 IgAN patients (16 non-progressors - NP and 16 progressors - P) were included in the study. Serum creatinine, estimated Glomerular Filtration Rate, 24-hour proteinuria and histological lesions following Oxford Classification (MEST score) were analyzed. Gut microbiota, urinary and fecal metabolome of all subjects were characterized by 16S sequencing, Biochorm 30 series amino acid analyzer and gas- chromatography mass spectrometry/solid-phase microextraction (GC-MS/SPME). Galactose-deficient IgA1 (Gd-IgA1) were measured by helix aspersa agglutinin binding assay. BAFF serum levels were quantified by ELISA.

Results: Some traits of the gut microbiota and urinary and fecal metabolome profiles showed significant differences between P, NP and HC. Gd-IgA1 and BAFF were significantly higher in IgAN patients, particularly in P, compared to HC (Gd-IgA1: p=0.01; P<0.05 NP vs HC; BAFF: p<0.01 P vs HC). IgAN patients with histological grade at diagnosis M1, E1, S1 and T1 had significantly higher levels of serum BAFF than HC. Moreover, serum BAFF levels were positively correlated with 24-hour proteinuria (r=0.47, p=0.0069) and with the levels of fecal phenolic metabolites (r=0.61, p=0.0003).

Conclusions: Gut-kidney axis might play an important role in the pathogenesis of IgAN.

FR-PO989

Intestinal Macrophages Polarized to Activation of Pro-Inflammatory and Had Dysfunction of Phagocytosis Leading to Aggravate Microinflammation and Asstis Bacterial Translocation as Carrier in Uremia Rats
Hongli Jiang, Hua Liu, Meng Wei. Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of medicine school.

Background: This study investigated whether intestinal macrophages are related to low-grade inflammation and bacterial translocation (BT) during uremia, and whether probiotics can alter the macrophage activity.

Methods: Male Sprague-Dawley rats were randomly divided into 3 treatment groups: sham, uremia (untreated), and uremia + probiotic. The expression of cell surface antigen CD11a (a.k.a., lymphocyte function-associated antigen 1 [LFA1]), inducible nitric oxide synthase (iNOS), ICAM1, and TGF-β were analyzed by immunohistochemistry. Gene and protein expression of early growth response protein 1 (EGR1) and TLR4 in intestinal specimens were determined. Density of labeled macrophages and tracer bacteria in intestinal and extraintestinal tissues were examined by immunofluorescent microscopy, and macrophage morphomorphy were examined by transmission electron microscopy. Intestinal macrophages from uremic rats showed a highly injured and altered phenotype characterized by CD11a expression, iNOS, ICAM1, and TGF-β staining. Gene and protein expression levels of intestinal TLR4 and EGR1 were also highest in this group. Intestinal segments of uremic rats exhibited high iNOS, ICAM1, and TGF-β staining. Gene and protein expression levels of intestinal TLR4 and macrophage micromorphology were examined by transmission electron microscopy. Intestinal and extraintestinal tissues were examined by immunofluorescent microscopy, and protein expression of early growth response protein 1 (EGR1) and TLR4 in intestinal synthase (iNOS), ICAM1, and TGF-β were analyzed by immunohistochemistry. Gene expression of intestinal TLR4 and macrophage micromorphology were examined by transmission electron microscopy. Gene expression of EGR1 and TLR4 in intestinal tissues were examined by immunofluorescent microscopy. Gene and protein expression of EGR1 and TLR4 in intestinal tissues were examined by immunofluorescent microscopy.

Results: The expression of cell surface antigen CD11a and iNOS were higher in P compared to NP and HC. CD11a and iNOS expression was abolished with wort, confirming PI3K/AKT involvement in BT production. Media from probiotic treated HC suppressed UCUG production compared to media from HC pretreated with wort or vehicle control, suggesting that PI3K/AKT and R7 is involved in BT pathogenesis. Urinary R7 levels were significantly higher in P compared to NP (r=0.66, P<0.01). R7 levels were increased in P compared to NP (r=0.66, P<0.01). R7 levels were increased in P compared to NP (r=0.66, P<0.01).

Conclusions: PI3K/AKT activation is required for R7 induction. R7 induction suppresses UCUG expression. Diabetics, with decreased PI3K activity, have lower urinary R7 levels, therefore data may indicate why UTIs are more prevalent with DM and may provide new regulatory targets for BT treatment.

Serum Acetate and Lipopolysaccharide Levels Correlate with Disease Activity in Patients With Lupus Nephritis
Daniel Tak Mao Chang, Ping Lung Chan, Qing Zhang, Kin Yi Au, Desmond Y.H. Yap, Mel Chau, Susan Yung. Dept of Medicine, The Univ of Hong Kong, Hong Kong.

Background: Lupus nephritis is a severe manifestation of systemic lupus erythematosus and is associated with poor prognosis. The gut microbiota has been implicated in the etiology of autoimmune diseases. Bacterial products from the gut may enter the circulation and influence local and systemic responses. Acetate is a short chain fatty acid (SCFA) produced by gut microbiota and lipopolysaccharide (LPS) is a component of the outer wall of Gram-negative bacteria. We measured serum acetate and LPS levels and intra-renal expression of their cell surface receptors in lupus nephritis patients to investigate the potential relationship between gut microbiota and lupus nephritis pathogenesis.

Methods: Serum acetate and LPS levels were measured in patients with biopsy-proven severe proliferative lupus nephritis, patients with non-lupus glomerular diseases and healthy controls (n=50 for each group). Intra-renal expression of LPS-binding protein (LBP) and GPR-41 and GPR-43 (SCFA receptors) was also examined.

Results: Serum acetate and LPS levels were significantly higher in patients with lupus nephritis compared to levels in patients with non-lupus renal diseases (P=0.05, for both) and healthy subjects (P=0.01, for both). In lupus nephritis patients, serum acetate and LPS levels were significantly higher during disease flare (P=0.04 and P=0.0015 respectively compared to levels during remission). Serum LPS level correlated with acetate level (r=0.52, P<0.001), and inversely correlated with that of IgG (r=0.61, P<0.01). Renal LBP, GPR-41 and GPR-43 expression showed markedly increased in lupus nephritis patients compared to healthy controls, and was predominantly detected in the tubulo-interstitialis, associated with urinary cell infiltration, fibrosis and tubular atrophy. LBP, GPR-41 and GPR-43 expression showed similar staining intensities and localization in patients with lupus nephritis and those with non-lupus renal diseases.

Conclusions: Our data suggest that acetate and LPS may be involved in the pathogenesis of lupus nephritis and non-lupus glomerular diseases.

Noninvasive Assessment of Macrophage Activation in Experimental Glomerulonephritis Using Optical Imaging with Near-Infrared Light Serves as a Surrogate of Disease Activity
Sebastian Braehler, Dongyue Huang, Matthew David Cheung, Walter J. Akers, Alfred Hyoungji Kim. Washington Univ School of Medicine, St. Louis, MO.

Background: Glomerulonephritis (GN) represents a major cause of morbidity & mortality. The standard for diagnosing GN is through renal biopsy, but this is not performed uniformly across many centers. There is an unmet need to identify a noninvasive approach for assessing GN. Recent advances in deep tissue imaging using probes detected by near-infrared (NIR) wavelengths have enabled the noninvasive probing of biologic activity. Macrophage infiltration of the kidney is observed in early GN and once activated, express the cytokine protease cathepsin B. Thus, renal macrophage activation can be assessed using an NIR probe that becomes fluorescent upon cleavage by cathepsin B. We tested the ability of using NIR optical imaging to assess renal macrophage activation as a noninvasive marker for early-stage GN.

Methods: GN was induced in 129 mice by nephrotoxic serum (NTS) delivered intravenously (IV). Proteins were assessed using albumin ELISA & chromogenic assay reagent. H&E & PAS stained slides of mouse kidneys were observed using light microscopy. Presence of renal macrophages was confirmed using FACS. NIR optical imaging of anesthetized mice was performed following IV administration of a cleavable fluorophore and a FITC fluorochrome. Kidney fluorescence intensity was determined using H&E & PAS stained slides of mouse kidneys were observed using light microscopy. Presence of renal macrophages was confirmed using FACS. NIR optical imaging of anesthetized mice was performed following IV administration of a cleavable fluorophore and a FITC fluorochrome. Kidney fluorescence intensity was determined using NIR imaging. Kidney fluorescence intensity was determined using NIR imaging. Kidney fluorescence intensity was determined using NIR imaging. Kidney fluorescence intensity was determined using NIR imaging.

Results: In mice with uninflamed kidneys, we confirmed the paucity of renal macrophages. Accordingly, there was minimal renal fluorescence signal as determined by fluorescent molecular imaging of cathepsin B activity. 3 days post-NTS administration, we observed a massive influx of macrophages into the kidney, along with necrotic range proteinuria. This correlated with significant increase in renal fluorescence intensity signal in NTS mice compared to control mice.

Funding: NIH

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Induction of GN by NTS caused significant macrophage infiltration, which was detected noninvasively by a cathespin B-activatable probe and NIR optical imaging. These data establish the proof-of-principle that NIR optical imaging may represent a translatable approach to establishing early stages of GN.

Improved Tissue Clearing and 2-Photon Imaging of Mouse Kidneys Reveals Immune Cell Architecture in Nephrotic Nephritis Matthew David Cheung, Dongyue Huang, Alfred Hyoungju Kim. Rheumatology, Washington Univ School of Medicine, St. Louis, MO.

Background: Tissue clearing approaches such as CLARITY renders tissue transparent, and in combination with two-photon microscopy, enables microscopic visualization deep internal structures within unaltered tissues. These cutting edge approaches have drastically improved the understanding of cellular circuits in the brain. However, application of this approach has only recently been described for the kidney. Here, we clear mouse kidneys to better understand the immune cell architecture following induction of nephrotic nephritis (NTN) using a modified lipid removal approach that also worked for human kidney fragments.

Methods: 129 mice were injected intravenously with nephrotic serum to induce NTN. Mice were perfused with an acrylamide monomer solution to form the basis of the hydrogel. Lipid removal was accomplished using 8% sodium dodecyl sulfate (SDS). An aminoalcohol solution was used to quench light absorbing heme in red blood cells trapped within the tissue. Cleared mouse kidneys were stained with antibodies specific for B cells, T cells, macrophages, and dendritic cells (DCs). Human kidney fragments were incubated in acrylamide monomer solution, then cleared as mentioned above. Cleared tissue was imaged using two-photon microscopy.

Results: Compared to previously published protocols, perfusion of acrylamide monomers into mice significantly accelerated the tissue clearing process. Enhanced tissue clearing was observed when we incubated kidneys in aminoalcohols. We observed vast networks of lymphocytes, lymphocytes, and DCs cleared NTN kidneys compared to DCs cleared control kidneys. Human kidneys also were cleared using this approach, and we noted DC networks in healthy donor controls.

Conclusions: We identified a new protocol that enhanced and accelerated tissue clearing in mouse and human kidneys. Using this approach, we found elaborate networks of lymphocytes and monocyte-derived cells in NTN mouse kidneys. We also observed DC networks in healthy human donor fragments. These data demonstrate the utility of tissue clearing in evaluating cellular architecture in mouse and human kidneys.

Natural IgM Mediates Ischemic AKI Lindsey R. Goetz, Jennifer Laskowski, Brandon Renner, Rachel A. Woolaver, Ludivila Kulik, Kazue Takahashi, Matthew C. Pickering, Joshua M. Thurman. 1Dept of Medicine, Univ of Colorado Denver School of Medicine, Aurora, CO; 2Dept of Radiology, Massachusetts General Hospital, Boston, MA; 3Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom.

Background: Glomerular IgM deposition occurs in numerous “non-immunologic” kidney diseases and has been shown in chemical and inflammatory models of injury. We recently demonstrated that complement activation within the kidney leads to neo-epitope formation. Because the alternative complement pathway is activated in renal ischemia-reperfusion (I/R) injury, we hypothesized that co-expressed complement and DC neo-epitopes within I/R generates neo-epitopes recognized by natural IgM antibodies that then exacerbate inflammatory injury.

Methods: To investigate this hypothesis, we used a 24 minute I/R model. Results: We first subjected soluble IgM deficient (sIgM-) mice to renal I/R and found a trend toward less severe injury in these mice vs. wild type (wt) controls (mean BUN of 135 ± 39 [SD] and 152 ± 26 mg/dL, respectively; n ≥ 26, p < 0.01). To accentuate complement activation in this model, we then exposed mice heterozygous for complement regulatory protein factor H (H+) to the same I/R protocol and found that the H+ mice sustained worse renal injury and had greater glomerular IgM deposition than wt controls (mean BUN of 114 ± 46 and 63 ± 48 mg/dL, respectively; n ≥ 14, p = 0.009 and mean glomerular IgM RFUs of 44 ± 7 and 22 ± 7, respectively; n ≥ 8, p = 0.0002). To further evaluate IgM pathogenicity, we induced I/R injury in mice deficient in both factor H and IgM (H-+/sIgM-) and noted a trend toward attenuation of renal injury in the H-+/sIgM- vs. H-+/sIgM+ mice (mean BUN of 106 ± 69 and 127 ± 52 mg/dL, respectively; n ≥ 7, p = 0.09) with data collection ongoing.

Conclusions: These data suggest that natural IgM contributes to ischemic renal injury by binding neo-epitopes generated during complement activation in this kidney. This adds to a growing body of evidence suggesting a common final pathway of IgM-mediated glomerular injury in a variety of “non-immunologic” renal disorders and offers a novel therapeutic target for the treatment of these diseases.

Activation of Toll-Like Receptor 2 in the Pathogenesis of Contrast-Induced Nephropathy Kristina Angela Rathmell, Altuf-M Khan, Federico Jose Teran, Kathleen S. Hering-Smith, Eric E. Simon, Vecchi Batuman. 1 Medicine, Nephrology & Hypertension, Tulane Unv, School of Medicine, New Orleans, LA; 2VA, SLVHCS, New Orleans, LA.

Background: Innate immunity mediated by Toll-like receptors (TLRs) is involved in the pathophysiology of contrast-induced nephropathy (CIN). We studied the expression of TLRs and associated molecules in CIN using human renal proximal tubule epithelial cells (RPTECs) and aged diabetic (db/db) mice.

Methods: We cultured RPTECs in normal (5 mM) or high (35 mM) glucose media for 24 h and then exposed them to nonionic (iodixanol or iohexol) and ionic (Urografin) contrast agents (CM) at a dose of 25–100 mg iodine/ml for another 24 h in the same media. 24-wk-old male db/db mice were given nonionic CM i.v. (3 g of iodine/kg bw) after 24 h water deprivation. All mice were sacrificed 24 h after CM injection.

Results: The mRNA expression of TLR2 increased by 2.5 fold (p < 0.05), TICAM-1 by 1.7 fold (p < 0.05) in RPTECs exposed to iodixanol compared to untreated RPTECs in a dose-dependent fashion. RPTECs in high glucose for 48 h and exposed to iodixanol showed significantly increased apoptosis compared to RPTECs in normal glucose, 24-wk-old db/db mice became obese, polyuric, glucosuric, ketogenic, and had increased GFR, systolic blood pressure, urine NGAL, and renal tubular damage compared to nondiabetic (db/m) control mice. 24 h after iodexhol injection, db/db mice showed a significant decrease in GFR, metabolic acidosis and significant increases in serum creatinine, urine and kidney KIM-1 levels and kidney damage histologically compared to control db/db mice. After iodexhol administration, the mRNA level of TLR2 was significantly increased by 2.4 fold (p < 0.01) in kidney compared to control mice but there was no change in TLR4 expression. The expression of CD11b and CD68 were also significantly upregulated in kidney.

Conclusions: High glucose RPTECs and diabetic (db/db) mice are vulnerable to CIN. Innate immune mediated by TLR2 plays a major role in the pathogenesis of CIN as demonstrated by in vitro and in vivo studies. TLR2 may prove to be a promising drug target for the development of new therapeutics against CIN.

FR-PO096

Heparanase Deficiency Improves Renal Function During Experimental Glomerulonephritis Marileine Garson, Marlien Benner, Henk Dijkman, Jin-ping Li, Ton J. Rabeklink, Idsray Slodovskv, Jin-ping Li, Henk Dijkman, Michael Elkin, Rodney May, Michael Elkin. 1Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Pathology, Radboud Univer Medical Center, Nijmegen, Netherlands; 3Medical Biochemistry and Microbiology, Uppsala Univ, Uppsala, Sweden; 4Nephrology, Leiden Univer Medical Center, Leiden, Netherlands; 5Cancer and Vasculat Biology Research Center, Bruce Rappaport Faculty of Medicine, Haifa, Israel; 6Sharet Inst, Hadassah-Hebrew Univ Medical Center, Jerusalem, Israel.

Background: Heparanase (HPSE), a heparan sulfate (HS)-specific endoglucohydrolase, mediates the onset of proteinuria and renal damage during experimental diabetic glomerulonephritis. Glomerular HPSE expression is increased in the majority of proteinuric diseases. The exact role of HPSE in the development of other inflammatory glomerular diseases is still unknown.

Methods: Here, we evaluated the role of HPSE in two models of experimental glomerulonephritis, being an acute glomerular basement membrane and lipopolysaccharide (LPS)-induced glomerulonephritis, in wild type (WT) and HPSE-deficient mice.

Results: Induction of experimental glomerulonephritis led to an increased HPSE expression in WT mice, which was associated with a decreased glomerular HS expression and albuminuria. Albuminuria was reduced in the HPSE-deficient mice in both models, which was accompanied by a better renal function and less renal damage. Notably, glomerular HS expression was preserved in the HPSE-deficient mice. Glomerular leukocyte and macrophage influx was reduced in the HPSE-deficient mice, which was accompanied by a reduced expression of both Tk1 and Tk2 cytokines. In vitro, tumor necrosis factor (TNF)-α and LPS directly induced HPSE expression and increased transendothelial albumin passage in a HPSE-dependent manner.

Conclusions: Our study shows that HPSE deficiency ameliorates proteinuria and renal damage in experimental glomerulonephritis by preserving glomerular HS expression, and reducing leukocyte and macrophage influx, and by affecting the local cytokine milieu.

FR-PO097

Iron Chelation as a Novel Renoprotective Strategy in Lupus Nephritis Erik L. Bossem, Cellular & Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.

Background: Poorly liganded iron damages tissue via several mechanisms. Multiple iron homeostasis proteins have been proposed as urinary biomarkers of lupus nephritis, and we have previously found that renal tissue iron levels are increased in the NZB/NZW/F1 mouse model of lupus nephritis. Anemia is also common in lupus patients. Together, these data suggest that dysregulation of body iron homeostasis may occur in lupus. This pilot study aimed whether (i) iron chelation in the NZB/NZW/F1 model of lupus nephritis, and (ii) whether this therapy adversely affects hematological parameters.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

595A
Methods: Female (NZBxNZW)F1 mice were treated with the iron chelator deferiprone from 20 weeks of age onwards. Albuminuria was monitored in 24h urine samples collected weekly, and mice were sacrificed at 25-40 weeks (100mg/d by dipstick) or 40 weeks of age, whichever was sooner. Hematocrit, red cell hemoglobin, plasma non-heme iron concentration as well as kidney and liver iron concentrations were measured at sacrifice.

Results: As shown in Figure 1, there was a trend towards later onset of albuminuria in deferiprone-treated mice compared with vehicle treated mice (median onset of albuminuria from 20 weeks of age onwards. Albuminuria was monitored in 24h urine samples relevant situations, because it also impairs Treg and thereby unleashes pre-existing nephritogenic immune responses in vivo, it may aggravate such responses in clinically relevant to protect against renal injury in murine nephrotoxic serum (NTS) nephritis.

Conclusion: Administration of M2 M6 may have therapeutic potency for glomerular injury by further M2 cell conversion and induction of regulatory T cells.

FR-PO1000
A Randomized Multicomponent Intervention to Reduce Disparities in Transplant Referral: Results from the RaDIAnt Community Study

Background: The reducing disparities in access to kidney transplantation is a dialysis facility-level randomized clinical trial to test the effectiveness of a multicomponent intervention in improving kidney transplant (KTx) referral and reducing racial disparities in referral in Georgia.

Methods: In 2013, 134 dialysis facilities were randomized to receive either usual KTx education (+7.8% vs. -2.5%) and decrease mortality rate. Thus, it is reasonable to suggest that EA and MO could be an additional strategy to be employed in CKD.

IKK2 Inhibition Inhibits the Initiation, but Aggravates the Progression of Crescentic Glomerulonephritis
Janine Goerlitz,1 Gisela Piotrowski,2 Gisa Tieg,3 Ulf Panzer,3 Christian Kuris,3 Friedrich Thaiss,1 1Rheinische Friedrich-Wilhelms-Universit, 2Inst of Experimental Immunology, Bonn, Germany; 3Universitssklinikum Hamburg-Eppendorf, Hamburg, Germany.

Background: The NFkB transcription factor family facilitates the activation of dendritic cells (DC) and CD4+ T helper (Th) cells, which are important for protective adaptive immunity. Inappropriate activation of these immune cells may cause inflammatory disease, and NFkB inhibitors are promising candidate drugs.

Methods: Here, we investigated whether inhibiting the NFkB component IKK2 can attenuate crescentic glomerulonephritis, a severe DC- and Th-cell-dependent kidney disease by induction of the pausive and the accelerated NTN mouse model.

Results: Prophylactic pharmacological IKK2 inhibition reduced DC activation, Th cell activation and ameliorated glomerulonephritis in mice. However, therapeutic IKK2 inhibition during ongoing disease, which is relevant for clinical situations, unexpectedly aggravated the nephritogenic immune response and disease symptoms. This resulted from systemic loss of regulatory T cells (Tregs) which have been previously shown to protect against crescentic glomerulonephritis and which require IKK2 as well.

Conclusions: In conclusion, although IKK2 inhibition can suppress the induction of nephritogenic immune responses in vivo, it may aggravate such responses in clinically relevant situations, because it also impairs Tregs and thereby unleashes pre-existing nephritogenic responses. Our findings argue against using IKK2 inhibitors in chronic glomerulonephritis, and perhaps also in other immune-mediated diseases.

FR-PO999
Transfused M2 Macrophages Ameliorate Renal Injury in Murine Nephototoxic Serum Nephritis
Oshima Du, Naotake Tsuobi, Yuta Sugiya, Seichi Matsuo, Shoichi Maruyama. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

Background: Glomerular leukocyte infiltration is a hallmark of glomerulonephritis. In addition to the effector roles of glomerular macrophages (MΦ) for tissue injury, recent studies found involvement of alternatively activated macrophages (M2 MΦ) in resolution of kidney inflammation. The aim of this study is to directly assess the potential of M2 MΦ to protect against renal injury in murine nephototoxic serum (NTS) nephritis.

Methods: Bone marrow (BM)-derived M6 and mouse iPS-derived M6 were obtained under the approval of the Animal Use Committee of CD260. FACs and RT-PCR were performed to assess efficient M6 differentiation. 0.6 x 10^6 of M2 MΦ were intravenously transferred 4 days after NTS nephritis induction. Immunostaining was used to detect M6, T cell and neutrophil infiltration. Renal cytokines were determined by ELISA. BM-derived M2a Mjs from EGFp transgenic mice (EGFP+M2a MΦ) was exploited to investigate the cell distribution. To investigate in vitro function of M2a MΦ on other leukocyte subsets, BM-derived M6 MΦ and splenic CD4+CD25+ T cell were co-cultured with EGFP+M2a MΦ.

FR-PO1003
Deceased Donor Renal Transplant eGFR at Six Months Has Improved in the Last 13 Years in Spite of Declining Donor Quality
Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar. Medicine, Univ of Virginia, Charlottesville, VA.

Background: Deceased donor quality has declined in the last decade but long-term graft outcomes are improving. We sought to analyze the trend in graft function at six months post-transplant in relation to this improvement.

Methods: All adult deceased donor kidney transplant recipients with at least six months graft survival recorded in the SRTR database between 2000 and 2012 were analyzed. The CKD EPI eGFR was determined based on the patient characteristics and serum creatinine at six months post-transplant. KDPI of the donors was also calculated. Linear regression was used to determine the effect of covariates on eGFR.

Results: 111,678 deceased donor recipients were identified. 4918 (4.4%) recipients with no six month creatinine were excluded. The median eGFR improved from 54.5 ml/min/1.72m2 in 2000 to 58.9 in 2012 (p=0.001) while the median KDPI increased from 41% to 46% (p=0.001). The use of tacrolimus/mycophenolate derivative also increased from 33.1% to 89.8%. Every 10 unit increase in KDPI resulted in a 3 ml/min/1.72m2 decline in eGFR.

KDPI adjusted median eGFR increased 13%.

Conclusions: Graft function improved significantly over the 13 year period in spite of declining donor quality and appears to be an important factor in the improvement in long-term graft survival. The transition to tacrolimus/mycophenolate derivative as the dominant maintenance immunosuppression appeared to be an important factor in this improvement.

FR-PO1004
Recipient Age and KDPI Are the Most Potent Predictors of Early Acute Rejection in Deceased Donor Kidney Transplantation
Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar. Medicine, Univ of Virginia, Charlottesville, VA.

Background: The rate of acute rejection in the first six months after deceased donor kidney transplant is now under 10% in the modern era of immunosuppression. We sought to determine the factors predictive of acute rejection in this era.

Methods: All recipients transplanted between 2001 and 2012 in the SRTR database were included in the analysis. Logistic regression was performed to determine the odds ratio of acute rejection in the first six months adjusting for multiple covariates.

Results: The acute rejection rate was 7.1% during the study period. KDPI and recipient age were the most important factors influencing rejection rates with recipients under 30 years old having a rate of rejection more than double that of recipients 60 years or older and recipients receiving donor kidneys with a KDPI over 90% having a 2 fold increase in rejection rate over those receiving a kidney with a KDPI less than 30%.

Conclusions: Graft function improved significantly over the 13 year period in spite of declining donor quality and appears to be an important factor in the improvement in long-term graft survival. The transition to tacrolimus/mycophenolate derivative as the dominant maintenance immunosuppression appeared to be an important factor in this improvement.

FR-PO1002
Association of Neighborhood Poverty and Living Donor Kidney Transplant Rates by Race
Douglas Scott Keith, Angie G. Nishio-Lucar, Gayle M. Vranic. Medicine, Univ of Virginia, Charlottesville, VA.

Background: Despite a growing shortage of deceased donor kidneys in the US, living donation (LD) rates have declined steadily since 2004. We sought to understand the impact of candidate socioeconomic environment on living donation rates.

Methods: We identified all candidates listed for kidney or kidney pancreas transplant in the SRTR database from 2000-2010. Data was linked to US census data on median income by zip code. Candidate zip code of residence was used as a surrogate for neighborhood socioeconomic environment on living donation rates.

Results: A total of 51 of the 67 (76.1%) intervention facilities improved their percentage of patients referred for KTxs over the 9 month study period. Intervention vs. control facilities had a greater increase in referral among AA (+7.3% vs. -2.5%) than white (+0.4% vs. -1.2%) patients over 9 months. Among the 26 dialysis facilities that had an AA vs. white racial disparity in referral at baseline, 69.2% no longer had a racial disparity in referral by 9 months.

Conclusions: Data from Radiant Community Study intervention facilities suggest that a large, randomized, quality improvement program among dialysis facilities in GA may improve KTxs access. Availability of data after 12 months of the intervention will allow final assessment of the effectiveness of the intervention.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
The only factors in the KDPI determination associated with rejection were donor age, donor hypertension, HCV seropositivity, and black donor race, with age accounting for most of the effect.

Conclusions: KDPI and recipient age are the most important factors associated with rejection. Risk stratification for donor recipient pairs based on age and KDPI should be considered when determining induction and maintenance immunosuppression needs.

Transplantation of Cadaveric Kidneys from Infants and Toddlers into Adults in the Era of Extreme Donor Shortage

Jimena A. Blandon, Nader Najafian, Neerja Agrawal, Nephrology, Cleveland Clinic Florida, Weston, FL; Nephrology, Cleveland Clinic Florida, Weston, FL; Nephrology, Cleveland Clinic Florida, Weston, FL.

Background: Kidney transplantation is the treatment of choice for patients with ESRD. The number of patients in the waiting list for a deceased donor kidney transplant continues to increase. In this era of extreme donor shortage we present our experience with transplantation of cadaveric kidneys from infant and toddler into adult recipients.

Methods: This was a retrospective study of twelve adult deceased donor kidney transplant recipients from pediatric donors ages 0-5 years. Medical records were reviewed from visits previous to transplantation to the most recent follow up after transplant.

Results: Twelve consecutive adult patients were transplanted with pediatric en bloc kidneys from donors 0-5 years between February 2014 to February 2015. Ten of the donors were standard criteria brain death (DBD) and two were donors with cardiac dead (DCD). KDPI scores ranged from 47 to 87%, donor age from 6 months to 5 years, weight 6 to 15 Kg. Recipients were equally distributed by gender, average age 56 years, mean BMI 22. KDPI scores ranged from 47 to 87%, donor age from 6 months to 5 years, weight 6 to 15 Kg. Recipients were equally distributed by gender, average age 56 years, mean BMI 22.

Acknowledgment: This work was supported by a research grant from the Cleveland Clinic Foundation Research Institute and the Eye Bank Association of America.

The Role of Dobutamine Stress Echo in Identifying Cardiac Ischaemia, Cardiovascular Events and Role of Subsequent Cardiac Angiography

Maria Ventura, Robin Ramphul, Sami Firoozi, Juan Carlos Kaski, Rajan Sharma, Debasish Banerjee, Renal and Cardiology Depts, St. George’s Univ Hospitals NHS Foundation Trust.

Background: Dobutamine Stress Echo (DSE) is an established method of identifying cardiovascular (CV) risk in patients undergoing kidney transplantation, however the role of coronary angiography (CA) is not clear. The aim of this study was to investigate the role of DSE and CA in predicting cardiac ischaemia and CV events in this population.
Survival of Elderly Incident Home Hemodialysis and Kidney Transplant Patients
Miklos Zsolt Molnar,1 Vanessa A. Ravel,2 Elani Streja,2 Csaba P. Kovessy,1 Danh V. Nguyen,2 Rajnish Mehrotra,1 Kamyar Kalantar-Zadeh,2 1Univ of Tennessee Health Science Center, Memphis, TN; 2Univ of California, Irvine, CA; 3Univ of Washington, WA.

Background: The proportion of elderly (≥65 years) patients with kidney failure is increasing. Previous data suggest that the projected increases in the life spans of kidney transplant (KTx) patients compared to conventional dialysis were 2.8 and 1.1 years for patients aged 65-69 and 70-74 years, respectively. However, no studies have compared mortality of elderly patients using alternative dialysis modalities such as home hemodialysis (HD) with KTx recipients.

Methods: Comparing elderly patients, who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity score (PS) matched cohort of 960 elderly patients (480 KTx and 480 HD) and examined the association between treatment modality and all-cause mortality using Cox proportional hazard models.

Results: The mean±SD age of the PS matched home HD and KTx patients at baseline were 71±6 years and 71±5 years, 69% were male (both groups), and 81% and 79% of patients were whites in home HD and KTx group, respectively. Median follow-up time was 205 days (IQR: 78-364 days) for home HD patients and 795 days (IQR: 366-1,221 days) for KTx recipients. There were 97 deaths (20%, mortality rate 253 [297-309]/1000 PY) in the home HD group, and 48 deaths (10%, 45 [34-60]/1000 PY) in the KTx group. Over 5 years of follow-up, home HD patients had almost 5 times higher mortality risk compared to KTx recipients in the entire patient population (HR: 4.74, 95%CI:3.25-6.91).

These results were consistent across different types of kidney donors and recipients characteristics.

Conclusions: Elderly home HD patients appear to have almost 5 times higher mortality compared to KTx recipients regardless of the type of kidney donor.

FR-PO1009
Beyond the Bones – The Association Between Vitamin D, Graft Outcomes and Vascular Disease
Aravind Cherukuri,1 Santanarakrishnan Balasubramanian,2 Rebekah Molyneux,2 Richard J. Baker.2 1Univ of Pittsburgh; 2Univ of Leeds.

Background: Vitamin D deficiency in KTRs is an emerging theme. The purported associations between Vitamin D deficiency and various metabolic, cardiovascular and non-metabolic adverse events have not been thoroughly studied in kidney transplant recipients (KTRs).

Methods: Here, we examined the association between Vitamin D deficiency and graft loss, mortality, NODAT, cardiovascular events and development of cancers.

Results: 504 KTRs had their vitamin D checked in 2008 and were followed up for 6 years. Vitamin D deficiency was defined as a level<50nmol/L. In this population, the prevalence of vitamin D deficiency was high at 66.5% with a significantly higher prevalence in older (71.9% vs. 60.9%, P=0.006) and female recipients (62.1% vs. female 73.2%, P=0.006) and in relatively new transplants (recent transplants 72.3% vs. old transplants 66.6%, P=0.003). KTRs who were vitamin D deficient had significantly worse overall (77% vs. 82.1%, P=0.001), death censored graft survival (89% vs. 96%, P=0.009), development of NODAT (19.8% vs. 10%, P=0.005) and cardiovascular events (9.9% vs. 2.9%, P=0.002) when compared to those with normal levels. In a stratified analysis, this was noted to be worse in KTRs on maintenance steroids, with relatively worse baseline renal function and proteinuria, with secondary hyperparathyroidism, deceased donor transplants and earlier vs. late transplants. Although vitamin D deficiency is not associated with a higher incidence of malignancy, it is associated with higher mortality in those with cancer (33.3% vs. 12.9%, p=0.005). In a multivariate Cox model, vitamin D deficiency was associated with significantly worse overall graft (HR 2.7, P=0.001) and death censored graft survival (HR 2.4, P=0.04), NODAT (HR 2.3, P=0.03) and cardiovascular events (HR 4.0, P=0.004) independent of age, PTH levels, gender, graft number, type of transplant, time since transplantation, graft type and renal function measured by both proteinuria and eGFR.

Conclusions: Vitamin D deficiency is an important modifiable risk factor for graft loss, mortality and cardiovascular events in KTRs.

Funding: Other NIH Support - R21AG047306 and R01DK95668

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: In conclusion, vitamin D deficiency which is highly prevalent in KTRs is associated with adverse outcomes. Our study stresses the need for a prospective trial of vitamin D replacement in KTRs.

FR-PO1010
Acute Tubular Necrosis Changes in Living Kidney Donor Implant Biopsy

Associates with Higher Rejection Rates Post-Transplant

Chunping Yu, Nissreen Elafawdy, Andres G. Chiesa-votto, Leal C. Herltz, Emilio D. Poggio, Dept of Nephrology and Hypertension, Glickman Urological and Kidney Inst, Cleveland Clinic, Cleveland, OH.

Background: Ischemic injury may occur during organ retrieval. In deceased kidney donor transplants, delayed graft function, a form of acute tubular necrosis (ATN), associates with acute graft rejection. Histological changes consistent with ATN can also be seen in implant biopsies of living donor (LD), however, the influence of ATN-like changes at time on donation from LD on recipient graft outcomes is unclear, especially its impact on graft rejection.

Methods: We retrospectively studied all LD kidney transplants at our center from Jan 2005 to Dec 2014 who had an implant biopsy. We perform protocol biopsies at 3, 6, 24 months post-transplant and for cause biopsies in all our patients. Post-transplant biopsy results were reviewed, and patients with subclinical and clinical borderline and/or BANFP scored graft rejection were captured.

Results: The study included 350 LD kidney transplant recipients, the mean age was 47.8±13.7 years (range 10-75) and 224(64%) were male. The incidence of ATN in implant biopsies was 16% (n=56). Patients with ATN had a trend toward higher risk of graft rejection in post-transplant biopsy compared with those without ATN (32.1% vs. 21.7%, p=0.09). When the study population was stratified by time from transplant to post-transplant biopsy, there was a statistically significant higher incidence of graft rejection in those biopsies performed between 1 and 24 months post-transplant (31.0% in the ATN group vs. 17.8% in the non-ATN group, respectively, p=0.02). No statistical correlation was found between ATN and graft rejection after 24 months post-transplant. Importantly, implant ATN has no impact on GFR at 3, 6, 12, 24 months post-transplant.

Conclusions: Histological changes consistent with ATN in LD kidney implant biopsies are associated with higher rates of graft rejection between 1 and 24 months post-transplant. However, ATN does not affect graft function at 3, 6, 12, or 24 months.

FR-PO1011
Impact of Pre-Transplant Cardiovascular Risks on Renal Allograft Survival: A Multi-Center Prospective Study

Jung Nam An, 1,2 Song Vogue Ahn, 1 Chun Soo Lim, 1,2 Non Su Kim, 1,2; Hoomin Kim, 1,2, Junhong Park1,4 1Seoul National Univ Boramae Medical Center; 2Seoul National Univ College of Medicine; 3Yonsei Univ Wonju College of Medicine; 4Asan Medical Center and Univ of Ulsan College of Medicine, Republic of Korea

Background: Cardiovascular (CV) disease is a leading cause of mortality in patients with end-stage renal disease. Even after successful renal transplantation, CV risks can induce CV morbidity and mortality in renal transplant recipients. However, the impact of pre-transplant CV risks on renal allograft outcomes has not been reported.

Methods: We analyzed the graft outcomes of 2902 renal transplant recipients who were enrolled in a multi-center cohort from 1997 to 2012. We calculated pre-transplant CV risk scores by the Framingham risk model using age, sex, total cholesterol levels, smoking and a history of hypertension. Cox proportional hazard models were used to assess hazard ratios (HRs) with and without competing risks of post-transplant CV deaths, adjusting for risk factors of allograft failure including recurrence of glomerulonephritis and acute rejection.

Results: Hypertension and vascular disease (a composite of ischemic heart disease, peripheral vascular disease, and cerebrovascular disease) were noted in 84.1% and 6.5% of the patients, respectively. During a median 6.4 years of follow-up, 122 (4.2%) patients died and 286 (9.9%) patients developed allograft failure. In multivariable-adjusted models, pre-transplant vascular disease was associated with increased risk of renal allograft failure (HR 2.43; 95% confidence interval [CI] 1.58-3.71). The HR for renal allograft failure comparing the highest with the lowest tertiles of pre-transplant CV risk scores was 1.49 (95% CI 1.11-2.00). In competing risk models, the HR of pre-transplant vascular disease was 2.01 (95% CI 1.0-3.36) and the HR for renal allograft failure comparing the highest with the lowest tertiles of pre-transplant CV risk scores was 1.44 (95% CI 1.05-1.98).

Conclusions: Both pre-transplant CV risk and vascular disease are independently associated with renal allograft failure in this multi-center prospective study. Pre-transplant CV risk assessment could be useful to predict renal allograft failure.

FR-PO1012
Blood Pressure (BP) Control in Kidney Transplant Recipients: A Single Centre Experience

Kristin Vibeke Vejheg, Jacqueline C. Nevols, Panagiotis Chondrogiannis, Amanda Jane Laird, Irene Synodinou, Doreen Zhu, Katherine A. Alington, Nichola Dawn Pugh, Chun ying Ung, Gopalakrishnan Venkat-Raman, Wexsex Kidney Unit, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom.

Background: Cardiovascular disease is the leading cause of death among kidney transplant recipients (KTRs), however there remains uncertainty regarding optimal BP targets. Current UKRA, KDIGO and KDQI guidelines advocate BP control to 130/80 in KTRs. UKRA/KDIGO advocate tighter control (125/70) in proteinuric KTRs. We examined BP control and proteinuria in all KTRs under longterm follow up at one centre, and adherence to these recommendations.

Methods: As of 1 March 2015, 839 KTRs were attending for regular clinical review (excluding recent KTRs<1yr). We performed a retrospective database review of BP, proteinuria, renal function and antihypertensive use.

Results: The cohort was 60% male with mean allograft age 10±0.28 years. Mean decline in eGFR was 0.83ml/min/m² per year (p<0.0004). Mean SBP was 134±5.65, DBP 79±1.37. 48% had SBP<130, 62% DBP<80, 39% both. 76% received at least 1 antihypertensive, 42% 2-3, 4% 4-24 agents. Only 9% had PCR measured. In those with PCR, 50%, 19% had treated to 125/75. Dipstick proteinuria was recorded in 58% and showed a significant association with SBP (p=0.01). There were significant correlations between reducing eGFR and increasing PCR (R²=0.11, p<0.0001), and between PCR and ACE/ARB use (p=0.0002). There was no correlation between CNI level and BP (CyA p=0.88, FK506 p=0.49). There was a significant stepwise decrease in renal function (scGFR p=0.005, eGFR p=0.01) and increase in dipstick proteinuria (p=0.03) when data were analysed in groups <70, 70-140 and >140. In terms of DBP, the stepwise decrease in renal function remained (scGFR p=0.01, eGFR p=0.0001) when data were analysed in groups >70, 70-90 and >90. DBP>90 had the most significant impact on eGFR. DBP was not associated with proteinuria.

Conclusions: The optimal BP target remains uncertain. Adherence to current guidelines is reasonable in our unit but could be improved. This study again demonstrates that SBP is the key risk factor for proteinuria, however increases in DBP >90 were most strongly associated with graft dysfunction.

FR-PO1013
Dobutamine Stress Echocardiography (DSE) Significantly Reduces the Need for Coronary Angiography in Renal Transplant Recipients

Robin Raman, Maria Ventura, Sami Firoozy, Juan Carlos Kaski, Rajan Sharma, Debashis Banerjee. Renal and Cardiology Unit, St. Georges Univ Hospitals NHS Foundation Trust, United Kingdom.

Background: There is significant controversy regarding optimal cardiac workup strategy for kidney transplantation. Some centres perform coronary angiograms (CA) in all patients whereas others have adopted a tailored approach using non-invasive techniques such as Exercise Tolerance Testing (ETT) and ischaemia assessment with cardiac imaging. This study examines the role risk stratification and DSE for cardiac workup in this patient group.

Methods: We analysed data on patients referred between 1/2/2012 and 31/12/2014 who were risk stratified and investigated according to the protocol (figure 1).

Results: Of 233 patients referred 92 were high risk and went on to have DSE. All other patients underwent echocardiography with/without ETT (35 ETT, 122 echocardiography and 33 CA). 16 patients had CV events, but none were perioperative. Overall event rate was 4% per year. 11 of 92 patients who had DSE had events. 11 of 33 patients who had CA event. 28 of 92 patients had a positive DSE (i.e. suggestive of myocardial ischemia) and of these 23 went on to CA. 6 of 28 patients with a positive DSE and 5 of 64 with a negative DSE had an event (figure 2, log rank p=0.1). 25 of 33 patients had evidence of coronary artery disease (CAD) at CA of which 13 received coronary artery stents. There was no significant difference between those with significant (>50% stenosis) CAD on CA who had events (8 of 21 patients) compared to those without significant (<50% stenosis) CAD who had events (3 of 12) (log rank p = 0.7). 6 patients with significant CAD who had PCI had events. 35 patients underwent ETT, 4 had CA following positive ETT. One patient with negative ETT had an event.

Conclusions: A careful risk stratification and using DSE decreases the need for CA and achieves very low event rates.

FR-PO1014
Levels of Indoxyl Sulfate in Kidney Transplant Patients, and the Relationship with Hard Outcomes

Sophie Liabeuf, 1 Lucie Desjardins, 1 Ziad Massy, 1 François Brazier, 1 Dimitri Titeca Beauport, 1 Monar Diosa, 1 Griet Lriel, 1 Raymond C. Chen, 1 Caroli, 1 Maite Jaureguy, 1 Gabriel Choukroun, 1 1Nephrology, Amiens; 2Nephrology, Ambrose Pare; 3Nephrology, Gent.

Background: Kidney transplant recipients are at greater risk of cardiovascular disease (CVD). Indoxyl sulfate (IS) is a protein-bound uremic toxin that is known to be associated with the risk of CVD and mortality in both pre-dialysis and dialysis patients. Data on levels of protein-bound uremic toxins in kidney transplant patients are scarce. The objective
of the present study was to evaluate the levels of IS in kidney transplant patients and their relationship with biochemical parameters and hard outcomes (including mortality, cardiovascular (CV) events and graft loss).

Methods: In 311 consecutive kidney transplant patients, total and free IS levels were measured immediately before transplantation (T0) and then 1 month (M1) and 12 months (M12) afterwards. In a case-controlled sub-study (n=90), IS levels in transplant patients were compared with those in non-transplant patients with chronic kidney disease matched for age, and estimated glomerular filtration rate (eGFR). Over a mean ± standard deviation follow-up period of 113 ± 29 months, 55 deaths, 70 CV events and 71 graft losses were recorded.

Results: We observed a rapid, consistent, significant decrease in IS levels after kidney transplantation. Majority of IS levels were below or near the normal value at M1 and M12. We did not observe a correlation between IS levels and eGFR at M1 and M12. Total and free IS levels at T0 were significantly higher in non-transplant patients (0.34±0.23 mg/dl and 0.04±0.07 mg/dl, respectively) than in transplant patients (0.21±0.17 mg/dl and 0.01±0.01 mg/dl; p=0.003 and <0.0001 respectively), despite having similar eGFRs. Lastly, IS levels were not associated with overall mortality, CV events or graft loss at T0, M1 or M12.

Conclusions: Total and free IS levels were significantly lower in transplant recipients than in non-recipients matched for age, gender and renal function - suggesting that kidney transplantation protects against an increase in IS levels. Importantly, serum IS levels were not associated with hard outcomes at any of the three time points.

FR-PO1015
Identification of Metabolic and Cardiovascular Risk in Pediatric Kidney Transplant Recipients: Body Mass Index, Waist Circumference, or Waist-to-Height ratio?

Background: In the general population, abdominal obesity is more closely associated with metabolic and cardiovascular (CV) risk than BMI. The ideal measure of obesity to identify risk in pediatric kidney transplant (Tx) recipients, who have improved growth and altered body composition, has not been established. In this prospective study we compared ability of BMI, Waist Circumference (WC), and Waist-to-Height ratio (WHtR) to identify metabolic and CV risk in pediatric kidney Tx recipients.

Methods: Kidney Tx recipients 3-20 years old and 0-30 months post-Tx had WC, BMI, WHtR, blood pressure (BP), fasting lipids, leptin, HbA1c%, standard and speckle echocardiogram and carotid intima-media thickness (CIMT) measured. Patients were classified as obese or lean by 3 methods: WC (ATP cut-point males=94th%ile females=84 th%ile), WHtR (CDC cut-point=0.539), and BMI (295th%). Logistic regression determined associations of groups with metabolic and CV factors.

Results: The study group comprised of 33 Tx recipients, age 13.6±0.3 years. Prevalence of obesity by BMI, WC, and WHtR was 21.2%, 33.3%, and 48.5%. Prevalence of hyperglycemia (HbA1c) was 24.2%, high LDL 15.2%, low HDL 57.5%, high leptin 39.3%, high BMI 12.1%, left ventricular hypertrophy (LVH) 30.3%, hypertension (HTN) 69.6%, and high CIMT 44.8%. In all groups (WHtR, WC, and BMI), obese children were more likely than lean to have HTN (OR 4.5, 95% CI: 2.2, 9.4, p<0.001), LVH (OR 5.4, 95% CI: 7.4, 8.8, p<0.001), and high leptin (OR 19.1, 9.3, 7.3, p<0.001). Obese children in WHtR and WC groups, but not BMI group, had greater chance of high TG (OR 4.3, 9.2, p<0.001), high CIMT (OR 2.0, 9.2, p<0.05), and impaired myocardial strain (OR 1.2, 1.1, p=0.01). Five patients with short stature (height z-score 2.56) and CV risk factors (3.01±0.5 factors/patient) were not identified as obese by WC criteria (height z-score -2.08, p<0.003).

Conclusions: WC and WHtR are more effective than BMI for detecting metabolic and CV risk amongst pediatric Tx recipients. WC may underestimate prevalence of obesity in children of short stature, and therefore WHtR may be a more sensitive method for CV risk amongst pediatric Tx recipients. WC may underestimate prevalence of obesity were not identified as obese by WC criteria (height z-0.08, p=0.003).

FR-PO1016
Knowledge About Benefits of Kidney Transplant: A Survey of Dialysis Patients

Naman Trivedi, Fareeha Khalil, Ming Wang, Eric Chang, Nasrollah Ghahramani. Pennsylvania State Univ College of Medicine.

Background: Kidney transplant (KT) is the treatment of choice for end stage renal disease (ESRD). Knowledge of dialysis patients about the benefits of KT is an important determinant of their active engagement in the decision making process. We studied factors associated with patients’ knowledge about benefits of KT.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants fulfilling inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent predictors of knowledge about KT were age, gender, education, years on dialysis, the number of years on the transplant waiting list, and religion. We performed logistic regression to estimate the odds ratios and 95% confidence intervals of factors for predicting KT knowledge. Multivariate analysis was performed to determine factors associated with KT knowledge after adjusting for confounders.

Results: 673 participants responded to questions about overall survival benefit of KT (correct response: 92%), benefits of KT for diabetes patients (correct: 46%), for patients > 60 (correct: 29%) and for patients transplanted pre-emptively (correct: 17%). Receiving 3 or more modes of education about KT was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR: 2.19; CI: 1.50 to 3.20), survival benefit of KT for diabetics (OR: 2.08; CI: 1.39 to 3.01) and patients transplanted pre-emptively (OR: 1.67; CI: 1.06 to 2.64). White race was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR: 1.59; CI: 1.11 to 2.28) and the benefit of KT for patients > 60 (OR: 1.54; CI: 1.07 to 2.21). Age > 60 was associated with lower likelihood of correct response to the question about overall survival benefit of KT (OR:0.65; CI:0.45 to 0.94), benefits of KT for diabetics (OR:0.54; CI:0.38 to 0.77), and for patients > 60 (OR:0.64; CI:0.44 to 0.93). Patients on dialysis > 5 years were less likely to be aware of the benefit of KT for diabetics (OR:0.68; CI:0.48 to 0.98).

Conclusions: Dialysis patients’ knowledge about survival benefits of KT is rather limited. The most significant modifiable contributor to improvement in knowledge is diversity of modes of education about KT. Other factors include race, age and number of years on dialysis.

FR-PO1017
Pretransplant HbA1c Predicts New-Onset Diabetes After Transplantation Among Renal Transplant Recipients

Jung-Im Shin, Mari Palta, Arjag Djamali, Brad C. Astor. Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: New-onset diabetes after transplantation (NODAT) is a common complication among renal transplant recipients and is associated with a higher risk of cardiovascular events and poorer graft and patient survival. The association of pretransplant HbA1c with NODAT remains unclear. Identifying recipients at greatest risk of NODAT may help guide monitoring and treatment strategies to prevent or delay the onset of NODAT.

Methods: We assessed the association between pretransplant HbA1c and NODAT in 1522 non-diabetic recipients using data from the United States Renal Data System (USRDS) from 2004-2011. Cox proportional hazards models adjusted for demographics, cause of ESRD, year of transplantation, number of prior transplants, duration of pretransplant dialysis, comorbidities, lipid levels, hemoglobin level, body mass index, HCV and CMV serostatus, donor type and age, HLA mismatch, and posttransplant steroid and tacrolimus usage.

Results: Median HbA1c was 5.4% and 531 (34.9%) patients had HbA1c ≥ 5.7% (i.e., prediabetes) A total of 404 (26.5%) patients developed NODAT during a median follow-up of 1.7 years. Pretransplant HbA1c was associated with the risk of NODAT in a non-linear fashion. The adjusted hazard ratio (HR) associated with 1% higher pretransplant HbA1c was 0.94 (95% confidence interval [CI]: 0.62, 1.42) for HbA1c lower than 5.4% and 1.87 (95% CI: 1.30, 2.68) for HbA1c higher than 5.4%.

Conclusions: Pretransplant HbA1c is independently associated with the risk of NODAT among renal transplant recipients. A continuous relationship between pretransplant HbA1c and the risk of NODAT suggests that greater risk starts at levels below the standard threshold for prediabetes.
Results: Mathematically (assuming average weights), the Cockcroft-Gault equation always yields higher numeric values compared with the MDRD and CKD-EPI equations. When applied to the three actual patient cohorts, Cockcroft-Gault consistently disadvantaged patients, delaying average time to waitlist qualification by 1 to 2 years.

Conclusions: This study identified a potential source of significant inequity (on the order of 1-2 years) in wait-time accrual for kidney transplantation that stems from imprecise rules for waitlist qualification. The OPTN may need to revise the language in their kidney transplantation policies so that consistent methods to assess renal function are adopted and patients are not inadvertently disadvantaged.

New Onset Diabetes Has Unfavorable Effect on Patient but Not on Allograft Survival Thomas Diehnemann,1,2 Naohiko Fujii,1,2 Roy D. Bloom,1,2 Harold I. Feldman,1,2 Yimei Li.2

Background: New onset diabetes after transplantation (NODAT) has been linked to higher rates of graft loss and shorter patient survival. More recent awareness, recent awareness, and changes in immunosuppression may have modified this association.

Methods: Retrospective single center analysis of 1427 (age=18) first time renal transplant recipients (KTR) without pre-transplant (Txp) diabetes. Patients with <1 year of follow up and those with allograft failure in the first year post-Txp were excluded. NODAT was defined as prescription of a glucose lowering medication 1 year after Txp. Cox models adjusted for mult. potential confounders were used to examine the relationship of NODAT with allograft and patient survival.

Results: The incidence of NODAT was 16.1%. Median follow up was 5.9 years (IQR3.5-9.2) for allograft and 6.3 (IQR3.8-9.8) for patient survival. Age, BMI, non-white race and HCV were independently associated with NODAT (all p<0.01). Compared with KTRs without DM NODAT was associated with an increased risk of overall graft failure (aHR1.59, CI1.00–2.41 p=0.49), but not for death censored graft survival (DCGS) (aHR1.12, CI0.86–1.46 p=0.49). Compared to those with NODAT, outcomes were not detectably different over time (p=0.25 for DCGS).

Conclusions: In this cohort of KTRs NODAT had no impact on graft survival but was independently associated with reduced overall survival.

FR-PO1020

Frequency of Hospital Readmission Post Kidney Transplantation Essy Mozaffari,1 Jay Lin,2 Melissa Linghour-Smith.2 ‘Chimerix Inc., Mendham, NJ; ‘Novosys Health, Green Brook, NJ.

Background: Early hospital readmission following kidney transplantation has been identified to be a strong predictor of adverse sequelae that can have significant clinical and economic implications. Our goal was to quantify the frequency of hospital readmissions post kidney transplantation, as well as the reasons for the readmissions.

Methods: Patients who received a kidney transplant between Jan 2009 and Sept 2013 were identified from the Premier Hospital database by ICD-9-CM code. The first year post-transplant was excluded. NODAT was defined as prescription of a glucose lowering medication 1 year after Txp. Cox models adjusted for mult. potential confounders were used to examine the relationship of NODAT with allograft and patient survival.

Results: Among the readmissions related to vital infections, the majority were related to CMV (79%). Readmission of patients with high severity APR-DRG levels of 3 (major) and 4 (extreme) at 30% and 9%, respectively (severity of illness level rated 1-4: minor, moderate, major, and extreme).

Conclusions: Over 4 in 10 of the kidney transplant recipients in this study were rehospitalized post transplantation. A significant number of the readmissions occurred in the first month post-transplant and the majority were within the first three months; almost 4 in 10 readmissions were classified as major or extreme severity level. Among hospital readmissions, more than half of them were related to an opportunistic or viral infection, underscoring unmet needs for the prevention of these infections.

Role of Non-Invasive Cardiac Stress Studies During Assessment for Kidney Transplantation in Pre-Dialysis Recipients Talvinder S. Bhoegal, Simon James Gray, Patrick Hamilton, Durga A.K. Kamigichlera. Manchester Inst of Nephrology & Transplantation, United Kingdom.

Background: Non-invasive cardiac stress studies (NISS) are routinely undertaken during listing of patients for kidney transplantation. Although guidelines recommend NISS in high risk patients based on studies reported on patients on RRT. However role of NISS in pre-dialysis population is unknown. We analysed the role of NISS in listing process and impact on longer term outcomes.

Methods: Retrospective study of all patients undergoing assessment for kidney transplantation at our centre between 2009 and 2014. 695 patients were assessed, including 397 who were pre-dialysis (naïve to RRT).

Results: 306 (77.1%) patients underwent NISS (98% were myocardial perfusion studies). Baseline and outcomes during follow-up are below.

Conclusions: In this cohort of KTRs NODAT had no impact on graft survival but was independently associated with reduced overall survival.

Only 3 patients with abnormal NISS (1% of all who had NISS) had flow limiting lesions, needing interventions (2CABG and 1PCI). At last follow up, compared to those with normal NISS, patients with abnormal studies a) were less likely to be listed for kidney transplantation, b) had increased cardiovascular events (p=0.01). But there was no significant difference in patient survival.
Conclusions: Our study illustrates lack of benefit of non-invasive myocardial perfusion studies in kidney transplant candidates in identifying early disease during pre-transplant assessment in pre-diabetes patients. Better risk stratification strategies are needed to inform assessment of kidney transplantation.

FR-PO1022
Longitudinal Association of Recipient Nonmuscle Myosin IIA Gene rs5756168 with Transplanted Kidney Doppler Ultrasound Blood Flow Indices
Joanna Pazik,1 Ewa Nowacka-Cieciera,2 Zbigniew Lewandowski,2 Monika Oldak,2 Dominika Ozzi7to,2 Magdalena Durlik.1 1Transplantation Medicine and Nephrology, Medical Univ of Warsaw, Warsaw, Poland; 2Pathology, Medical Univ of Warsaw, Warsaw, Poland; 3Histology and Embryology, Medical Univ of Warsaw, Warsaw, Poland; 4Inst of Physiology and Pathology of Hearing, Warsaw, Poland.

Background: MYH9 gene polymorphisms associate with nephron injury in hypertensive nephrosclerosis and FSGS. We have shown the association of rs5756168 with transplanted kidney eGFR (ATC 2015). MYH9 polymorphisms correlate with cerebrovascular blood flows. In transplanted kidneys resistance and pulsatility indices predict graft function.

Methods: The study aims at evaluating the association of donor/recipient MYH9 SNPs (rs3752462, rs11089788, rs5756168, rs136211 rs2397784) and transplanted kidney pulsatility (PI) and resistive (RI) indices. Recipients enrolled 2007–2012 with available donor/recipient DNA, kidney and transplanted kidney Doppler ultrasound (US) were included. For genotyping custom TaqMan genotyping assays were used. Mixed models were used to assess relations of SNPs and PI, RI values.

Results: Genotyping was performed in 295 kidney recipients and their donors, in 202 at least one US was done. In the longitudinal observation between first day and 2 years after engraftment, recipients carrying two T alleles in rs5756168 showed significantly different PI indices in opposite to allele C carriers, p = 0.04, for RI the differences did not reach statistical significance (p = 0.14). In two-factor analyses the effects of rs5756168 was maintained in first transplants for RI (p = 0.02) and PI (p = 0.02), in recipients with TTI >2 (p = 0.03 and 0.07, respectively), with grafts from donors >55 years old (p = 0.05 for PI only), with panel reactive antibodies <20% (p = 0.01 and 0.04 for PI and RI), patients on immunosuppression without induction (p = 0.07 for PI only) and on tacrolimus treatment (p = 0.05 for PI only).

Conclusions: Identified association of transplanted kidney blood flow parameters and MYH9 polymorphism additionally confirms MYH9 effect on graft functioning shown in our previous study cited above. The study supported by grant from National Science Center NN4022668/40.

FR-PO1023
Determinants of Hepcidin, the Key Regulator of Iron Homeostasis, in Renal Transplant Recipients
Michele F. Pisenga,1 Stefan P. Berger,1 Robin P.F. Dullaart,2 Aiko P.J. De Vries,2 Stephan J.L. Bakker,1 Carlo A. Gaillard.1 1Internal Medicine, UMC; 2Internal Medicine, UMC.

Background: Hepcidin is synthesized in the liver and secreted into the circulation. Circulating concentrations may be influenced by body iron availability, inflammation, insulin resistance and tissue hypoxia. Moreover, hepcidin is a small 2.8 kD molecule. Therefore, renal clearance may be an important additional determinant of circulating hepcidin. We aimed to investigate whether markers of iron availability (ferritin), inflammation (C-reactive protein (CRP)), insulin sensitivity (fasting insulin), tissue hypoxia (erythropoietin) and renal clearance may be an important additional determinant of circulating hepcidin. We aimed to investigate whether markers of iron availability (ferritin), inflammation (C-reactive protein (CRP)), insulin sensitivity (fasting insulin), tissue hypoxia (erythropoietin) and renal clearance may be an important additional determinant of circulating hepcidin.

Methods: We included 561 RTR (age 51±12 years; 55% males at 7.8±6.4 years after Tx). Mean hemoglobin (Hb) was 8.6 ±1.0 mmol/l. Median [IQR] serum hepcidin was 3.2 ng/ml (1.3–6.6 ng/ml). Univariable associations between serum hepcidin concentrations and donors or recipients sex, recipients body mass index (BMI), estimated glomerular filtration rate (eGFR) were determined. P-values for inclusion and exclusion were determined when adding variables to the model. To assess independent determinants of serum hepcidin, we used a multivariable linear regression model.

Results: We included 561 RTR (age 51±12 years; 55% males at 7.8±6.4 years after Tx). Mean hemoglobin (Hb) was 8.6 ±1.0 mmol/l. Median [IQR] serum hepcidin was 3.2 ng/ml (1.3–6.6 ng/ml). We found that donors or recipients sex, recipients BMI, eGFR were determinants of serum hepcidin in a total model R2 = 0.69. After adjusting for BMI and eGFR, significant independent determinants of serum hepcidin were donors or recipients BMI (β = 0.09, p = 0.001), donors or recipients eGFR (β = −0.12, p = 0.001), recipients BMI (β = 0.16, p = 0.001), recipients BMI (β = 0.16, p = 0.001), recipients BMI (β = 0.16, p = 0.001), and recipients BMI (β = 0.16, p = 0.001). The association of serum hepcidin concentrations in RTR can be attributed to variation in iron status, inflammation, insulin sensitivity and tissue hypoxia reflected by erythropoietin, rather than to variation in renal clearance.

Conclusions: Despite large variation in eGFR, fifty-three percent of the variation in serum hepcidin concentrations in RTR can be attributed to variation in iron status, inflammation, insulin sensitivity and tissue hypoxia reflected by erythropoietin, rather than to variation in renal clearance.

FR-PO1024
Associations of Serum Soluble α-Klotho, Fibroblast Growth Factor 23, and 25 (OH) Vitamin D with Kidney Function and Left Ventricular Hypertrophy in Japanese Kidney Transplant Recipients
Makoto Tsujita,1 Shoichi Matuyama,1 1Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan; 2Nephrology, Nagoya Univ School of Medicine, Japan.

Background: Determination of kidney function and left ventricular hypertrophy (LVH) is crucial for kidney transplant recipients. Any marker for predicting kidney function and LVH is needed to prevent complications.

Methods: This was a retrospective cohort study. Forty-seven consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital in 2011.

Conclusions: Serum soluble α-Klotho may be a good marker for kidney function and intact FGF23 for LVH in Japanese kidney transplant recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusion: Most study participants who received a KT were non-frait, but the proportion of black KT recipients was small despite blacks' lower observed risk for frailty compared with whites. Closer alignment of frailty status with support for KT access may have implications for reducing racial disparity in KT rates.

FR-PO1026
Circulating Inflammatory Cell Subsets Are Associated with Cardiac Function in Renal Transplant Recipients Jill Neale,1 Danielle Richelh-Potts,1 Maurice Dungey,1 Patrick Highton,1 N. Martin,2 Nicollette C. Bishop,2 Alice C. Smith,1 'Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; 2School of Sport, Health and Exercise Sciences, Loughborough Univ, United Kingdom.

Background: Cardiovascular (CV) disease is a major cause of mortality and morbidity in renal transplant recipients (RTRs). Systemic and vascular inflammation is paradoxically common despite immunosuppression and is an important non-traditional CV risk factor. Monocytes are heterogenous: the intermediate phenotype (CD14++CD16+) is particularly pro-atherogenic and pro-inflammatory compared to the classical phenotype (CD14++CD16-). Regulatory T-cells (TRegs) maintain peripheral tolerance and minimise tissue damage. This study aimed to explore the association of circulating inflammatory cell subsets with cardiac function in RTRs.

Methods: 18 stable RTRs (Mean age 55 years, 61% male) and 5 healthy controls participated. Blood monocytes and T cells were analysed by flow cytometry, and cardiac hemodynamic function measured by bioimpedance (NICOM).

Results: Circulating pro-anti-inflammatory cell subsets differed significantly in RTRs and controls. Mean % (SEM) intermediate monocytes was higher in RTRs (7.2±8.8) vs controls (3.2±8.5), p=0.01, while classical monocytes and TRegs were lower in RTRs (83.2±13) vs (88.9±1.6), p=0.03 and 28.0±2 vs 5.0±1, p=0.001 respectively. In RTRs, % intermediate monocytes was inversely correlated with stroke volume (SV: r=-0.48, p=0.05) and cardiac output (CO: r=-0.52, p=0.03) and positively correlated with total peripheral resistance (TPR: r=0.50, p=0.04), while the opposite was seen with % classical monocytes (SV: r=0.56, p=0.02; CO r=0.62, p=0.006; TPR r=-0.54, p=0.02).

Conclusions: Our results reveal a significant bias towards pro-inflammatory circulating leucocyte subsets in RTRs (increased intermediate monocytes, reduced classical monocytes and TRegs), which likely promotes an atherogenic environment. Furthermore, the observed significant correlations between pro- and anti-inflammatory monocyte subsets and indices of cardiac function strongly support an important pathogenic role for these cell subsets, which represent a potential therapeutic target in this vulnerable population.

FR-PO1027
Iron Deficiency Is Associated with Mortality Independent of Anemia in Renal Transplant Recipients Michele F. Eisenberg,1 Stefan P. Berger,2 Jenny E. Kootstra-Ros,2 Else van den Berg,1 Jer gan Navis,3 Peter Van der meer,3 Stephan J.L. Bakker,1 Carlo A. Gaillard,1 'Nephrology, 'Clinical Chemistry, 'Cardiology, UMCG.

Background: Anemia and iron deficiency (ID) are highly prevalent in renal transplant patients (RTR). Anemia is associated with poor outcome, but the role of ID is unknown. Therefore, we aimed to investigate the association of ID, irrespective of anemia, with all-cause mortality in RTR.

Methods: In a previously defined cohort of RTR, with hemoglobin data available, we additionally assessed serum iron, transferrin and ferritin. ID was defined as transferrin saturation (TSAT)=20% and ferritin <300 ng/mL. Anemia was defined as Hb<13 g/dL (M) or <12 g/dL (F). Cox regression analyses were used to investigate prospective associations with all-cause mortality.

Results: We included 701 RTR (age 51±12 yrs; 56% men, 6.0 [2.6-11.6] yrs post-transplant). Baseline concentration of serum KYN was 1.8 [1.4-2.2] μmol/L, that of TRP was 40.0 [34.5-46.0] μmol/L, and KYN/TRP was 44.3 [35.0-57.9] μmol/mol. In multivariable linear regression analyses, KYN/TRP was positively associated with proteinuria (β=0.17, P<0.001) and waist circumference (β=0.12, P<0.001), and inversely with eGFR (β=0.54, P<0.001) and HDL-c (β=-0.14, P<0.001). During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR developed GF. In multivariable Cox-regression analyses, KYN/TRP was positively associated with GF (age, sex, eGFR, and proteinuria adjusted HR 3.6 [95% CI 1.3-9.9], P=0.01). Further adjustment for waist circumference and HDL-c did not materially change this association (HR 3.1 [95% CI 1.3-8.9], P=0.02).

Conclusions: IDO activity, as measured by KYN/trypophan (TRP) were measured with LC-MS/MS; KYN/TRP is a widely accepted measure of IDO activity.

Funding: NIDDK Support

FR-PO1028
Indoleamine 2,3-Dioxygenase Activity and Late Graft Failure After Kidney Transplantation Laura V. de Vries,1 Claude P. Van der Ley,2 Casper F.M. Franssen,1 Gerjan Navis,2 Stephan J.L. Bakker,2 Id o Peter Kema,2 'Dept of Nephrology, UMCG, Netherlands; 'Dept of Laboratory Medicine, UMCG, Netherlands.

Background: Long-term graft survival after kidney transplantation remains a major clinical problem. Therefore, markers that allow for early identification of patients at risk for late graft failure (LGF) are urgently needed. Indoleamine 2,3-dioxygenase (IDO) catalyzes tryptophan along the kynurenine pathway. Recent studies found IDO activity associated with occurrence of acute rejection and renal function decline shortly post-transplant. We hypothesized that IDO activity could also be a marker for LGF after kidney transplantation.

Methods: We prospectively included outpatient renal transplant recipients (RTR) with a functioning graft >1 yr, between 2001-2003. Follow-up was recorded until May 2009. Death-censored GF was defined as return to dialysis or re-transplantation. Serum kynurene (KYN) and tryptophan (TRP) were measured with LC-MS/MS; KYN/TRP is a widely accepted measure of IDO activity.

Results: We studied 562 RTR (age 51±12 yrs, 56% men, 6.0 [2.6-11.6] yrs post-transplant). Baseline concentration of serum KYN was 1.8 [1.4-2.2] μmol/L, that of TRP was 40.0 [34.5-46.0] μmol/L, and KYN/TRP was 44.3 [35.0-57.9] μmol/mol. In multivariable linear regression analyses, KYN/TRP was positively associated with proteinuria (β=0.17, P<0.001) and waist circumference (β=0.12, P<0.001), and inversely with eGFR (β=0.54, P<0.001) and HDL-c (β=-0.14, P<0.001). During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR developed GF. In multivariable Cox-regression analyses, KYN/TRP was positively associated with GF (age, sex, eGFR, and proteinuria adjusted HR 3.6 [95% CI 1.3-9.9], P=0.01). Further adjustment for waist circumference and HDL-c did not materially change this association (HR 3.1 [95% CI 1.3-8.9], P=0.02).

Conclusions: IDO activity, as measured by KYN/TRP, is cross-sectionally associated with eGFR, proteinuria, waist circumference, and HDL-c. Prospectively, it is associated with increased risk for LGF after kidney transplantation. Increased IDO activity may not only be a marker for LGF, but also an interesting target for intervention to prevent decline of renal transplant function leading to LGF.

FR-PO1029
The Significance of Preoperative Left Ventricular Diastolic Dysfunction and Left Atrial Enlargement on Clinical Outcomes in Kidney Transplantation Jin Ho Hwang,1 Jung Nam An,2 Jae Seok Yang,2 Curie Ahn,3 Chun Soo Lim,2 Yon Su Kim,2 Young hoon Kim,2 Jung Pyo Lee,3 'Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; 'Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; 'Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea; 'Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; 'Surgery, Asan Medical Center and Univ of Ulsan College of Medicine, Seoul, Republic of Korea.

Background: In spite of improved survival of kidney transplant (KT) recipients, cardiovascular mortality is the leading cause of death following KT. Echocardiography is commonly performed as a screening test to evaluate cardiac function before KT. However, there are only limited data on echocardiographic parameters to evaluate the effect of left ventricular diastolic dysfunction (LVDD) and left atrial enlargement (LAE) on the long term outcome in KT recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

604A
Methods: A total of 2,779 adult recipients who underwent pretransplant echocardiography from 1997 to 2012 were evaluated. We divided the patients into two groups by two different categories: LVDD grade 0-1 vs. 2-3, and LA size=38 mm vs. >38 mm. Post-KT fatal/non-fatal acute coronary syndrome (ACS), graft failure (GF), and all-cause mortality was evaluated.

Results: During a mean follow-up of 4.5 years, fatal/non-fatal ACS was occurred in 49 (1.8%) patients. A total of 231 (12.4%) patients experienced GF and 116 (6.2%) died. The recipients with LVDD grade 2-3 (P=0.005) and LAE (P=0.001) showed higher occurrence of fatal/non-fatal ACS after KT. Graft failure and all-cause mortality was not significantly different between the groups depending on both the LVVD grades and LAE. In a multivariate analysis, increased age (P<0.001), previous history of CV event (P=0.01) and LVDD of grade 2-3 (hazard ratio[HR]:2.98, 95% confidence interval[Ci]:1.535-5.787;P=0.001), and LAE (HR:1.052, 95% Ci:1.006-1.101;P=0.025) were associated with ACS. However, none of LVDD and LAE was significantly associated with mortality and GF in a multivariate analysis.

Conclusions: In patients of KT candidate, pretransplant LVDD and LAE were independently associated with high occurrence of ACS after KT.

FR-PO1030 Effect of Dietary Sodium Restriction on Blood Pressure and Urinary Protein Excretion in Renal Transplant Recipients on RAAS-Blockade Laura V. de Vries,1 Linn Charlotte Dobrowolski,2 C.T.P. (Paul) Krediet,2 Frederik J. Bemelman,3 Stephan J.L. Bakker,4 Gerjan Navis,1 1Dept of Nephrology, UMCU, Netherlands; 2Renal Transplant Unit, AMC, Netherlands.

Background: In CKD patients on RAAS-blockade, it is well established that dietary sodium restriction exerts renoprotection by reduction of blood pressure (BP) and by reduction of urinary protein excretion (UPE), which is partly independent of BP. In renal transplant recipients (RTR), the effect of sodium restriction is not well-documented. We therefore studied the effects of dietary sodium restriction on BP and UPE in RTR.

Methods: We performed a randomized, cross-over trial in stable outpatient RTR with creatinine clearance >30 ml/min, BP>120/80 mmHg, 24-hour UPE <1.5 g/day, and use of RAAS-blockade. Exposure consisted of a 6-week regular sodium (RS) diet (target: 150 mmol/24h) and 6-week low sodium (LS) diet (target 50 mmol/24h). End points were BP, UPE, urinary albumin excretion (UAE), and eGFR at the end of each diet period. Dietary compliance was assessed by 24h urinary sodium excretion.

Results: We randomized 23 RTR, of which 22 RTR (age 58±1 years, 50% men, eGFR 51±21 ml/min) completed the study. One patient dropped out, due to orthostatic complaints on the LS diet. Sodium intake was 156 [130-193] vs. 68 [55-86] mmol/24h on RS vs. LS respectively. One patient was excluded from BP analysis because of severe hypotension. At 1st and 12th mth, femoral Dual X-ray absorptiometry and vertebral column X-ray for assessment of bone mineral density were performed. Results showed a significant reduction of urinary protein excretion (UPE) and BP (SBP:140±14 vs. 129±12, P<0.0001, DBP:86±8 vs. 79±8, P=0.0001).

Conclusions: Dietary sodium restriction effectively reduces BP in stable RTR on RAAS-blockade, but, at variance with findings in CKD, has no material change in UPE, UAE and eGFR.

FR-PO1031 Individual Blood Calcification Propensity in a Cohort of Renal Transplant Patients Carlo M. Alfieri,1 Andreas Pasch,1 Anna Regalia,1 Maria Meneghini,1 Maria Teresa Gandolfo,1 Valentina Binda,1 Deborah Mattinzoli,1 Masami Ikehata,1 Piergiorgio Messa. 11Dept of Nephrology, UMCU, Netherlands; 2Renal Transplant Unit, AMC, Netherlands.

Background: Vascular calcifications and related cardiovascular disease have a strong impact in kidney transplant recipients (KTx). Calciprotein partitioning/maturating time (T50) is a new measure of individual blood calcification propensity. Our aim is to explore in a cohort of 410 KT recipients: 1) the levels of T50 and their modifications during the first year of KTx; 2) the relationship between T50 and routine clinical and biochemical parameters, 3) the relationship between T50 and mineral density (BMD) and aortic calcification (AC).

Methods: 70 KTx pts(M=38, Age:48±12 yrs), transplanted between 2005 and 2009 were recruited. Along with T50 evaluation, routine clinical and biochemical parameters and FGF-23,OPG, SHBG, acetate and 25(OH)-Vitamin D were tested at 1st, 6th and 12th mth after KTx. At 1st mth, serum intact PTH, serum Ca, P, albumin, creatinine, ionic Ca and phosphate and by dual energy X-ray absorptiometry and vertebral column X-ray for BMD(cm2/m) and AC (Kaputriala) evaluation were performed. T50 (min.) was determined using a Nephelometric nephelometer(BMG Labtech, Offenburg, Germany) in the laboratory of one of the authors.

T50 at 1st and 12th mth were of 243[72–283], 218[79-275] and 227[79-279] resp., with a reduction of T50 at the 12th mth of KTx(p=0.04). In a multivariate analysis, T50 was influenced by uric acid and fetuin-A (14th mth=0.02 and 0.001), by alkaline phosphatase, fetuin-A and 25-(OH)-Vitamin D (6th mth=p<0.01, p=0.001 and p=0.03 resp.), and by estimated glomerular filtration rate,body mass index and 25-(OH)-Vitamin D(12th mth=p<0.01, p=0.03 and 0.01 resp.). Both at baseline and at 12 mth of KTx a direct correlation between BMD and T50 was demonstrated (p=0.002-p=0.04 respectively).

Conclusions: The main results of our study are that 1)during the 1st year of KTx T50 does decrease significantly, and 2) has a strong and direct relation with Fetuin-A and 25OH vitamin-D both implicated in bone-vascular axis, T50 is associated with BMD but not of AC status.

FR-PO1032 Prediction of Acute Rejection in Kidney Transplant Recipients Using a Multicenter Cohort Kyung Don Yoo,1 Junhyug Noh,1 Junhong Lee,1 Dong Ki Kim,1 Chun Soo Lim,1 Young hoon Kim,1 Yon Su Kim,1 Gunhee Kim,2 Jung Pyo Lee.1 1Seoul National Univ College of Medicine; 2Seoul National Unives College of Engineering; 3Ulsan Unive College of Medicine.

Background: More than 20% of kidney transplant recipients (KTR) are likely to have rejection episode, which is associated with graft loss. However, the impact of risk factors on acute rejection has not been well clarified. Here, we aimed to build new prediction models through considering variables related to immunologic and non-immunologic factors using machine learning methods.

Methods: This multicenter cohort study included adult KTR admitted to 2 major experienced tertiary hospitals in Korea between 1997 and 2014. A total of 3,117 KTRs were enrolled. Biopsy-proven acute rejection (BPAR) of these recipients were investigated by the individual learners such as decision tree, logistic regression, and ensemble learners such as random forest.

Results: We analyzed 2,045 recipients’ records, with more than 50 attributes. Among them, we identified 39 independent attributes which could account for BPAR incidence for building our models. In the decision tree model for the prediction of BPAR after three years of KTx, HLA DR mismatch was found to be the most important predictor. In the case of HLA DR mismatch, donor specific antibody (+) predicted in 66.6% of BPAR incidence at three year after transplantation, and also posttransplant infection episode showed significant association with BPAR. In the case of HLA full matched, old age with heavy weighted recipient showed high probability of BPAR (71.4%). The final modeling represent AUC performance 0.670 (logistic regression) and 0.665 (random forest) in the BPAR prediction.

Conclusions: In this study, machine learning modeling could present an accurate and versatile tool for forecasting probability of having BPAR episode during the early years following the transplant.

FR-PO1033 Prediction of Long-Term Prognosis of the Kidney Transplantation Using Comorbidity Score Jae Yoon Park,1 Eunjin Bae,2 Soejoong Kim, Dong Ki Kim,1 Chun Soo Lim,1 Kwon Wook Joo,1 Yon Su Kim,1 Jung Pyo Lee.1 1Seoul National Univ College of Medicine; 2Seoul National Univ College of Engineering.

Background: Comorbidity assessment is important to the informed interpretation of kidney allograft outcomes. Weights assigned to comorbidities to predict survival may vary based on the type of index disease and advances in the management of the comorbidities. We developed a modified Charlson comorbidity index (CCI) in renal allograft recipients (mCCI-KT), thereby improving risk stratification for mortality.

Methods: A total of 3,765 recipients in multicenter cohort were included to develop comorbidity score. The weights of comorbidities per the CCI were recalibrated using a Cox proportional hazards model. The modified score was validated in an independent nationwide cohort (n=1,538).

Results: The Cox proportional hazards model revealed that peripheral vascular disease, mild liver disease, and diabetes with end-organ damage in the CCI significantly predicted mortality. Thus, the mCCI-KT included 3 comorbidities with recalibrated severity weights. In the validation cohort, both the CCI and the mCCI-KT were correlated with mortality. The mCCI-KT showed modest increases in C statistics compared with the CCI (0.565 versus 0.534, P=0.002).

Conclusions: The mCCI-KT stratifies the risk better for mortality in renal allograft recipients compared with the CCI, suggesting that it could be a preferred index for use in clinical practice.

FR-PO1034 Patient Uncertainty Regarding Kidney Transplantation Associated with Length of Dialysis prior to Transplant Evaluation Laura J. McPherson,1 Mohua Basu,1 Stephen O. Pastan,1 Sumit Mohan,2 Rachel E. Patzer.1 1Emory Univ, Atlanta, GA; 2Columbia Univ, New York, NY.

Background: End stage renal disease (ESRD) patients’ uncertainty about undergoing kidney transplantation (KTx) —i.e., decisional conflict—may be affected by cumulative time spent on dialysis prior to KTx evaluations. We aimed to investigate the association between time from dialysis start to KTx evaluations and decisional conflict.

Methods: In an ongoing clinical trial of study patients measuring the effectiveness of a shared decision tool at a single KTx center, ESRD patients were asked 10 questions assessing decisional conflict related to KTx, with possible scores ranging from 0 (none)
Haptoglobin and Long-Term Outcomes in Renal Transplant Recipients

Isidor Minovic, Ineke J. Riphagen, Else van den Berg, Jenny E. Kootstra, J.L. Bakker, Andy P. Levy, Johanna M. Geleijnse, Gerjan Navis, Stephan Haptoglobin (Hp) is a hepatocyte-derived protein that protects against oxidation by binding free hemoglobin (Hb). Being an acute-phase protein, Hp is upregulated by inflammation. We hypothesized that both low and high Hp are risk factors for all-cause mortality and graft failure in renal transplant recipients (RTR).

Methods: Hp was measured using a turbidimetric immunoassay in a well-characterized prospective RTR cohort. Cox regression analysis was used to assess the association of Hp with endpoints.

Results: We included 707 RTR (57% male, age 53±13 y, eGFR 49 ±18 ml/min/1.73m2) and 58% used a calcineurin inhibitor. Median Hp was 1.4 [IQR 1.0-1.8] g/L. Hp phenotype 1-1, 1-2, and 2-2 distribution was 18%, 50%, and 33% resp., with Hp levels of 1.7 [1.3-2.1], 1.4 [1.1-1.8] and 1.1 [0.9-1.7] g/L resp. (P<0.001). Among median 38 [32-46] months follow-up, 81 (12%) RTR died and 45 (6%) developed graft failure. Hp showed a U-shaped association with mortality (P=0.01, fig. 1), but not with graft failure (P=0.7). Accordingly, the lowest (<0.9 g/L) and highest (>1.6 g/L) quintiles of Hp levels were associated with mortality (HR 2.65 [95% CI 1.11-6.35] and 3.0 [3.0-1.41-7.72], resp.). Adjustment for sex, age, hsCRP, serum albumin, eGFR, BMI, Hba1C, LDL and Hp polymorphism did not materially influence the association of low Hp with mortality (HR 3.55 [1.42-8.84]). However, adjustment for hsCRP and serum albumin markedly weakened the association of high Hp with mortality (HR 2.06 [0.84-5.08]).

Conclusions: Low Hp is independently associated with mortality, but not graft failure, in RTR. High Hp was also associated with mortality, but this association largely depended on hsCRP and serum albumin.

Pre-Transplantation Flow-Citometry Crossmatch Can Be a Predictor of Outcome when Donor-Specific Antibodies Are Present

Anna Rita Aguirre, Patricia Soares Souza, Gleisine Oliveira Bezerra, Flavio Jota Paula, Elias David-Neto, Maria Cristina R. Castro. Renal Transplant Service, Hospital das Clínicas - Univ Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background: Clinical relevance of pre-transplant (Tx) donor-specific antibodies (DSA) detected by single antigen beads (SAB) when pre-Tx CDC-AIH crossmatch (XM) is negative is still unclear. The aim of this study was to evaluate the importance of a positive flow-citometry-XM (FCXM) in patients with DSA over patient and graft survival.

Methods: Retrospective study, performed between Jan09 and Dec13 evaluating FCXM influence on antibody-mediated rejection (AMR) incidence, and over graft and patient survival. Biopsies were classified according to Banff’09 criteria and DSA by Luminex SAB.

Results: From 2009-2013, 1002 kidney transplants (Tx) were performed in our center. 261(26%) were sensitized (PRA>0%) and 87 (8.7%) presented pre-Tx DSA. 60 (69%) of them had FCXM performed with serum collected before transplantation: 22 (36%) positive and 38 (64%) negative. There was no difference between the highest DSA-MFI between Tx with positive or negative FCXM [FCXM+ = 5080 (1046-15360) vs FCXM- = 3120 (597-14400)], or between the sums of all DSA-MFI of each patient between these groups [FCXM+ = 2474 (597-51530) vs FCXM- = 2867 (974-89400)]. A significant difference between DSA-MFI was only found when DSA became negative: FCXM had a significantly higher incidence of AMBR than DSA+XFCXM-Tx [FCXM- = 12.54% (95% CI 9.3-23%); p = 0.024]. After a median follow-up of 34 mo, graft survival (GS) between Tx with positive and negative FCXM differed significantly (41% vs 92%; p < 0.001). Among FCXM+ patients, GS was not influenced by ABMR (p=0.256). However, among patients with AMBR, FCXM+ had worse graft survival than FCXM+ (25% vs FCXM- 90%; p 0.011). Patient survival did not differ between FCXM+ (82%) and FCXM- (95%) neither was affected by AMBR.

Conclusions: A positive pre-Tx FCXM is related to a higher incidence of AMBR in the first year after Tx and to worse graft survival, and did not influence patient survival.

Funding: Private Foundation Support

Pre-Transplant Mental Health Disorders and Non-Adherence and Post-Transplant Outcomes in Kidney Transplant Recipients

Jeytan Micu, Franz-Marte Gurnabay, Marta Novak, Joseph Kim, Olusegun Famure. Multi-Organ Transplant Program, Univ Health Network and Univ of Toronto, Toronto, ON, Canada.

Background: Mental health disorders (MH) and non-adherence (NA) have been associated with lower access to kidney transplantation (KT) and poorer clinical outcomes. We examined the relationship between history of MH problems, NA, and post-transplant outcomes (i.e., biopsy proven acute rejection: BPAR; death censored graft failure: DCGF; or loss of graft function: LGF).

Methods: This was a single-centre retrospective cohort study of adult patients transplanted at our KT program from July 1, 2004 and Dec 31, 2012, and followed up until June 30, 2014. Patients with complete information about pre-transplant MH problems or pre-transplant history of NA in their medical record (n=955) were included. We analyzed the contribution of co-morbidities and other covariates to the associations between MH and NA, and time to event (for BPAR, DCGF and DCGF) were explored using log rank analysis and Cox proportional hazards models.

Results: The mean (±SD) age was 50.5 (±13.4) years, 61% of patients were male and 24% had a history of diabetes. Twenty-two percent had a positive history of MH disorders and 11% had a history of NA. Fifteen percent of the patients had BPAR, 5.6% had DCGF and 13% had TGF (death or DCGF). Participants with a history of pre-transplant NA but not with history of MH had higher risk for BPAR (log rank test p = 0.049 and p=0.46 for NA and MH, respectively). This difference, however, was not significant after adjusting for socio-demographic characteristics, donor type and HLAmismatch: adjusted HR (95% CI) 1.36 (0.84-2.23) and 1.16 (0.77-1.75) for NA and MH, respectively. Neither the history of pre-transplant MH nor pre-transplant NA was associated with DCGF or TGF. These results remained qualitatively unchanged after multivariable adjustment : adjusted HR (95% CI) 1.81 (0.96-3.42) and 0.99 (0.58-1.70) for NA and MH, respectively.

Conclusions: A history of pre-transplant mental health disorders or non-adherence are not associated with poor post-transplant outcome in a select group of patients who are cleared for transplantation. Patients with such problems should have equal access to kidney transplantation compared to patients with no MH problems.

HILA Profile and Short and Long Term Outcomes in African American Donors and Recipients

Rabi Youcoub, Girish N. Nadkarni, John C. He, Paolo Cravedi, Rebecca L. Kent, Ioannis Konstantinidis, Karen Yee Keung, Sander Florman, Peter S. Heeger, Barbara T. Murphy, Madhav C. Menon. Mount Sinai, NY.

Background: We have previously reported the apparent greater impact of HLA-matching on both early allograft events as well as graft survival in the United Network for Organ Sharing database (UNOS). Here, we specifically studied the influence of HLA-matching and mismatching on allograft outcomes among African American (AA) recipients and AA-donor organs in deceased donor kidney transplantation (DDKT).

Methods: We utilized data from the UNOS database (1995 – 2012), and analyzed 10 year death censored graft survival (DCGS), 1 year clinical acute rejection (1y-AR), and delayed graft function (DGF) using Cox-regression and logistic regression in a combined multivariable model including HLA-matching and mismatching adjusted for key covariates. We performed sensitivity analysis using a subgroup of DDKT patients after 2003 with less heterogeneous HLA nomenclature and employing bootstrap methodology.

Results: We had complete data (outcomes and predictors) for 96236 recipients (Age 49.23±15.13, 60.4% male). AA-recipients constituted 30.2% while AA-donor organs were used in 19% of recipients (n=18201). Only AA-donor organs were associated with DCGF and TGF. These results remained qualitatively unchanged after multivariable adjustment : adjusted HR (95% CI) 1.36 (0.84-2.23) and 1.16 (0.77-1.75) for NA and MH, respectively. The other history of pre-transplant MH nor pre-transplant NA was associated with DCGF or TGF. These results remained qualitatively unchanged after multivariable adjustment : adjusted HR (95% CI) 1.81 (0.96-3.42) and 0.99 (0.58-1.70) for NA and MH, respectively.

Conclusions: A history of pre-transplant mental health disorders or non-adherence are not associated with poor post-transplant outcome in a select group of patients who are cleared for transplantation. Patients with such problems should have equal access to kidney transplantation compared to patients with no MH problems.

Funding: Government Support - Non-U.S.
matching, nor mismatching had any effect on the three examined outcomes in either individual or combined multivariable models. Sensitivity analysis in the 2003-2012 cohort showed similar results.

**Conclusions:** Our analysis in this large cohort reports for the first time the absence of any effect from HLA-matching or -mismatching on allograft outcomes among AA-donor kidneys. These findings suggest that the allocation algorithm for AA-donor organs may need to be re-evaluated without including HLA-match status.

Femoral Bone Mineral Density Is Related With Aortic But Not With Coronary Calcifications in KTx Patients

**Background:** Our study wants to evaluate in a cohort of kidney transplanted(KTx) patients,undergone to femoral DXA:1) the prevalence of bone mineral abnormal;2) the factors related to femoral bone mineral density(f-BMD) 3) the relationship of f-BMD with aortic calcifications(ACI) and coronary calcifications(CAC).Lumbar DXA was not considered to avoid confounders between abdominal vascular calcifications(VC) and BMD.

**Methods:** 293pts(M=170) transplanted in our Unit(2004-2013) were evaluated. Clinical and routine biochemical exams plus PTH,FGF-23,Fetuin and VitD were tested at 1(T0) and 12(T1) mths of KTx. At the same time,DXA,lumbar X-Ray(193pts) and coronary tomography(60pts) for f-BMD;acu(3),ACI(Kauppila) and CAC(Agatson) evaluations were performed.ACI increase(ACI-Prog) any increase in ACI.Presence of CAC(CAC+):Agatson score >400.CAC increase(CAC-Prog) assessed using Sevrukov formula.

**Results:** At T0 and T1,OPN in 55% and 52%,OPR in 15% and 12% of pts resp.F-BMD was associated with age, alkaline phosphatase(ALP) at T0 and T1), fetuin and P at T0). A logistic regression with BAbn(OPN) or P as a whole dependent variable confirmed age and ALP as the only independent associated variables(T0 and T1).ACI were found in 55% and 61% of pts(T0-T1).ACI were higher in BAbn(T0 and T1).ACI-Prog(26%) had lower F-BMD(T0 and T1).F-BMD showed a discriminatory role in ACI-Prog ROC Curve, T0:AUC 0.66, p=0.02;T1:AUC 0.70, p=0.05).CAC was found in 13%,20% and 28% pts at T0,T1 and T2.CAC-Prog was found in 13% at T1 and in 49% of pts at T2.F-BMD didn’t correlated with CAC at T0,T1,T2; and both at T1 and T2 its levels weren’t different between CAC-Prog and CACnot-Prog.

**Conclusions:** High prevalence of BAbn and VC from the beginning of KTx is present. Age and ALP are strongly associated with f-BMD, ACI and CAC progress in a high % of patients, in the early post-KTx period. However, though F-BMD was significantly related with ACI-Prog,no association was observed with CAC worsening,possibly suggesting that different mechanism/s might underlie VC processes at different sites.

Relationship Between Pre-Transplant Physical Function and Quality of Life following Kidney Transplant

**Background:** Decreased physical function predicts adverse outcomes following non-transplant surgery. The goal of this study was to assess whether pre-transplant physical function predicts impaired quality of life (QOL) following kidney transplant.

**Methods:** We conducted a prospective cohort study involving all recipients of living donor kidney transplants at our center from 2012 until 2014. Physical function was measured using the Short Physical Performance Battery (SPPB), a composite measure of gait speed, balance and chair rise time (score range 0-12, with higher score indicating better physical function). QOL was measured 12-months post-transplant using the Short Form 36 Health Survey (SF36) with standardized scores adjusted for age and gender. Below-average physical and mental QOL was defined as physical (PCS) and mental component summary scores (MCS) < 45, respectively.

**Results:** Among the cohort of 140 patients, mean age was 51 ± 15 years, 61% were male, 91% were Caucasian, 21% had diabetes and 26% had a pre-transplant SPPB score < 12. A pre-transplant SPPB score < 12 was associated with a significantly lower 12-month QOL score (54.2 ± 9.4 vs 55.2 ± 8.4, p=0.04) but not a lower MCS score (54.2 ± 9.4 vs 55.2 ± 8.4, p=0.90).

**Conclusions:** Below-average physical QOL at 12-months was observed in 23% of patients and was associated with pre-transplant BMI (OR 1.12 per 1 kg/m2 increase; CI 1.02-1.23, p=0.02) and a pre-transplant SPPB score < 12 (OR 3.05, CI 1.17-7.97, p=0.02). In contrast, pre-transplant diabetes, dialysis, maintenance steroids and 12-month eGFR were not associated with physical QOL.

I“t” Report of Korean Organ Transplantation Registry (KOTRY)

**Background:** The Korean Organ Transplantation Registry (KOTRY) were launched in 2014 to construct the nationwide transplant database system which encompasses outcomes of various transplant organs by support of the Korea Centers for Disease Control and Prevention.

**Methods:** In 2014, kidney, liver and heart transplant cohorts were established with participation of 29/58 centers for kidney, 13/35 centers for liver, and 4/8 centers for heart, covering more than 80% of total cases. Lung and pancreas transplant cohorts are also in progress since 2015. A web-based database system and attached biobank system have been developed. Annual data report and related information of database development process are available at http://www.kotry.org. From July 2014 to December 2014, 419 transplants in kidney transplantation (KT), 430 in liver transplantation, and 77 in heart transplantation were registered.

**Results:** Among 419 KT, deceased donor (DD) was performed in 156 patients (37.2%). Mean age was 47.7±11.2 and 56.8% of transplants were males. Diabetic recipients were 23.2%, and 5.5% of transplants were older than 65 years. Their original kidney disease was most often chronic glomerulonephritis (39.6%), followed by diabetic nephropathy (18.6%). Preemptive KT was 29.3% among living donor KT. The high panel-reactive antibody (>50%) accounted for 9.8% of transplants. Positive results of T or B flow cytometric crossmatch were found in 1.9% and 4.5% of transplants, respectively. ABO incompatible KT was performed in 21.7% of living donor KT. Mean age of donors was 45.3±13.2 and 59.9% were males. Among DD, expanded-criteria donor was 23.7%. Mean serum creatinine of living donor before and after KT were 0.81±0.18mg/dl, and 1.16±0.27mg/dl, respectively. In KOTRY, pre-transplant diabetes, dialysis, maintenance steroids and 12-month eGFR were not associated with physical QOL.

**Conclusions:** Decreased pre-transplant physical function predicts impaired physical QOL, one year after kidney transplant. Further studies are needed to determine whether physical rehabilitation interventions can improve post-transplant QOL.

**FR-PO1042**

Pre-Transplant Midodrine Use: A Newly Identified Risk Marker for Complications After Kidney Transplantation

**Background:** Midodrine is increasingly prescribed to decrease the severity and complications of hypotension in dialysis patients. The impacts of midodrine use before kidney transplantation on graft and patient outcomes early after transplantation are not well described.

**Methods:** We analyzed linked national U.S. transplant registry, pharmacy records and Medicare claims data to follow 16,322 kidney transplant recipients (2005-2008), of whom 308 (1.9%) had filled midodrine prescriptions in the year prior to transplantation. We examined associations of midodrine use with DGF, graft survival and death as reported to the registry, and with clinical complications captured in Medicare claims.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Funding:** Government Support - Non-U.S.
Burden through novel methods including pharmacy claims, and associated impacts on complications including graft failure and death. As the new KAS is expected to increase need for midodrine before kidney transplantation is a bio-marker for increased risks of stiffness in renal transplant recipients. Impact of proton pump inhibitors on hypomagnesemia and arterial stiffness in renal transplant recipients.

**Results:** At 3mo, patients who used midodrine before transplant had higher rates of DGF, 32% vs. 19%; hypotension, 14% vs. 4%; acute myocardial infarction (AMI), 4% vs. 2%; cardiac arrest, 2% vs. 0.9%; graft failure, 5% vs. 2%; and death, 4% vs. 1% than the non-users (P<0.05). After multivariate adjustment including recipient, and donor factors, as well as for the propensity of midodrine exposure, pretransplant midodrine use was independently associated with risks of DGF (aOR 1.95; CI 1.49-2.56), death-censored graft failure (aHR 1.94; CI 1.14-3.27), death (aHR 3.55; CI 1.99-6.33), as well as many potentially mediating complications. Patterns were similar at 12mo.

**Conclusions:** Although associations may in part reflect underlying conditions, the need for midodrine before kidney transplantation is a bio-marker for increased risks of complications including graft failure and death. As the new KAS is expected to increase ESRD duration at the time of allocation for many patients, monitoring recipient comorbidity burden through novel methods including pharmacy claims, and associated impacts on transplant outcomes, are important priorities.

Comorbidity Burden of Kidney Transplant Recipients Predicts Emergency Usage Despite Increased Family Physician Visits

**Background:** Kidney transplant (KTX) recipients utilize many aspects of the healthcare system, especially emergency (ER) visits. Unterman et al showed that within a four year period, 378 KTX recipients generated 828 ER visits. This study aims to understand factors leading to ER usage by KTX recipients.

**Methods:** This is a single center retrospective study in conjunction with patient questionnaire, collected from March 2012 - 2013. The questionnaire inquired the frequency of the family physician (GP) visits and ER usage within the past year. Patient demographics and comorbidities were collected from chart reviews. Univariate logistic regression was used to define factors that are predictive of ER usage. Significant covariates were then used in multivariate backward stepwise logistic regression model to predict ER visits.

**Results:** Number of GP visits (OR = 1.6, P = 0.003), diabetes (OR = 1.7, P = 0.016), coronary artery disease (OR = 2.5, p = 0.001), below knee amputation (OR = 4.3, p = 0.037), and number of comorbidities (OR = 1.35, p = 0.001) significantly predict ER visits. Number of transplant clinic visits does not significantly decreased ER visits (p = 0.32). By multivariate backward stepwise logistic regression, number of GP visits (OR = 1.5, p = 0.007) and coronary artery disease (OR = 2.1, p = 0.011) remain significantly predictive of ER usage.

**Conclusions:** This single center study showed that KTX recipients with more comorbidities have increased ER usage, particularly coronary artery disease, despite higher frequency of GP visits. However, kidney transplant recipients with more ER usage are not seen more frequently by our transplant clinic. The results suggest that KTX recipients with higher comorbidity burden may need to be followed more closely by transplant clinics, rather than relying on GP’s, to improve effective usage of ER visits.

**FR-PO1045**

Stroke Predictors and Outcome in Renal Transplant Recipients

**Background:** End-stage renal disease is associated with a high incidence of cerebrovascular disease. Conventional risk factors do not always apply & established preventive strategies may be ineffective. The incidence, predictors & outcomes following stroke in those with a functioning renal transplant is not well described.

**Methods:** All adult patients with a renal transplant attending Glasgow Renal and Transplant Unit between 1st Jan 2007 and 31st Dec 2012 were identified using the electronic patient record. Clinical, demographic & laboratory data were collected including presence of diabetes, cardio- or cerebrovascular disease (CeVD), atrial fibrillation, deprivation, serum renal and bone chemistry and use of immune suppressants. Stroke was identified via discharge codes, cerebral imaging or death certification. Independent predictors of stroke were identified via multivariable regression analysis. Fatality & causes of death are presented.

**Results:** 636 patients were identified, mean age 38 years (SD 12.9). 60.5% were male and 9.1% had AF. During follow-up 7.1% received a transplant as first RRT modality. 24 patients experienced a stroke during 3455 patient years of follow-up. 83.3% were ischemic. Stroke incidence was 6.9/1000 patient years for all stroke and 3.76/1000 patient years for first stroke. A stepwise backward regression revealed predictors of stroke as older age (HR 1.05, p = 0.025) and previous CeVD (HR 18.16, p = 0.001). Significant independent predictors for first stroke were age, diabetes and AF (p = 0.05). There were no cases of SAH in PCKD. AF associated with time to stroke (p = 0.003), but there was no detectable benefit from use of warfarin. 134 died during follow-up. 62.5% deaths followed stroke with 7, 28 and 365 day fatality of 20.8, 25 and 45.8%. Cardiovascular (75%) or malignancy (13%) were the cause of death in most cases.

**Conclusions:** Renal transplant recipients have a high incidence of stroke and poor outcome following stroke. Risk factors include prior CeVD, age, diabetes and AF. Although AF associated with time to stroke, the role of warfarin in prevention is poorly defined, requiring further study.

Factors Influencing Racial Disparities in Renal Transplantation Outcomes
Sumit Mohan,1 Barry I. Freedman,2 William Mark Brown,3 Stephen O. Pastan,3 Ajay K. Israni,4 David P. Schlaid,3 Robert S. Gaston,4 R. Bray,3 Amber M. Reeves-Daniels,3 Bruce A. Julian,3 Jasmin Divers,2 Columbia Univ; Wake Forest School of Medicine; Emory Univ; Univ of Minnesota; Minneapolis Medical Research Foundation; Univ of Alabama at Birmingham.

Background: Kidney transplants from African American (AA) deceased donors have worse outcomes than kidneys procured from donors of other ethnic groups; deceased donor kidney transplants (DDKTs) engrafted into AAs fare worse than kidneys placed into recipients of other ethnic groups. The role of biological and environmental factors in these disparities remains unclear. We sought to identify factors contributing to these ethnic differences in AA and European American (EA) recipients of kidneys from AA and EA donors, in a study using donor-matched design to eliminate donor-specific confounding effects.

Methods: We compared allograft survival of DDKTs in 4 types of donor/recipient pairs (TDRP) (AA-AA, AA/EA, EA-AA and EA/EA). Models were fitted using a mixed effect Cox model with particular focus on effect modifiers of the TDRP association with allograft survival.

Results: We identified 669 AA and 3,383 EA donors resulting in 669 AA/AA, 669 AA/EA, 3,383 EA/AA and 3,383 EA/EA DDKTs. In agreement with previous reported trends, AA donors were more likely to be younger, male, hypertensive, and with higher serum creatinine, while EA recipients were more likely to be employed (46% vs. 37% and 33%) and less likely to experience delayed allograft function (DGF) (19% vs. 28% and 23%). Adjusted analyses controlling for donor and recipient characteristics identified strong interaction effects between the TDRP and incidence of DGF (P<0.009) and between the TDRP and employment status (P=0.04). Observed hazard ratios varied from 0.9 for an employed (EA/EA) pair without DGF to 4.3 for an unemployed (AA/AA) pair with DGF.

Conclusions: Ethnic differences in employment status and incidence of DGF were the strongest effect modifiers of the association between the TDRP and allograft survival for DDKTs. These differences partially explained the observed racial disparity in outcomes for DDKTs.

Renal Transplantation in Bardet-Biedl Syndrome
Robert M. Hawks,1 Aditya Joshi,2 Siddharth A. Shah,2 Omar M.A.A. Alkandari,3 Martin A. Turan.1 1Dept of Pediatrics, Marshfield Clinic, Marshfield, WI; 2Dept of Pediatrics, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; 3Dept of Pediatric Nephrology, Univ of Louisville, Louisville, KY; 4Dept of Pediatrics, Mubarak Al-Kabeer Hospital & Hamid Al-Essa Transplant Center, Safat, Kuwait.

Background: Bardet-Biedl syndrome (BBS) is a rare, multisystemic genetic disorder frequently associated with chronic kidney disease (CKD). Data regarding renal transplantation (RT) in BBS is lacking and reports tend to highlight complications. We report RT outcomes in the largest BBS cohort examined to date.

Methods: An international BBS registry was interrogated to identify individuals that had undergone RT and capture age, gender, body mass index (BMI), transplant and patient survival, donor source, and comorbidities.

Results: RT was performed in 19/171 (11%) registry subjects (mean age 9 y; range 2-25 y). RT patients were younger (9 vs. 17.9 y, p<0.005) and more likely to be female (82% vs. 50%). Deceased donors provided 12/21 kidneys; one patient received a combined liver/renal transplant. Two patients that underwent RT in the 1980s and died <10 y of age were excluded from further analysis. Patient and kidney survival is shown.

Conclusions: Outcomes following RT in patients with BBS is favorable. Female predominance raises questions regarding gender as a potential modifying factor impacting CKD prevalence.

Kidney Transplant Recipient Hospital Readmission: Examination of Discharge-Level Factors
Michelle L. Lubetzky, Maria Ajaimy, Layla Kamal, Graciela De Boccardo, Enver Akalin. Transplantation, Montefiore, Bronx, NY.

Background: Early rehospitalization after kidney transplantation (KTxs) is common and is considered a quality metric. Few studies have examined preventability or discharge factors associated with early rehospitalization.

Methods: We performed a single-center, retrospective cohort study between 2011-2015 of adult KTxs recipients. The primary outcome was at least one readmission within 30 days after discharge. Secondary outcomes were reason for readmission, potential for process improvement to reduce readmission, and all-cause graft failure.

Results: Of 462 KTxs, 31.4% were readmitted within 30 days of discharge. The reason for first readmission was surgical in 20.8% of those with non-surgical reasons, 21.7% were from infection, 20.9% graft dysfunction, 21.7% gastrointestinal, 21.7% metabolic, and 13.9% other. Readmission was significantly associated with all-cause graft failure (p<0.006). The assessment of preventability showed that the reason for readmission was present at the time of discharge in 17.7%, additional hospital resources may have abrogated the readmission in 15.8%, and 12.4% could have been managed as outpatient. On univariate analysis, risk factors for rehospitalization were: presence of comorbidities (p<0.03), complication during hospitalization (p<0.001), discharge electrolyte abnormalities (p<0.001) and kidney function at discharge (p<0.003). Table 1. On multivariate analysis, the presence of 3 comorbidities pre-KTx (OR 2.01 95% CI 1.84-3.86), electrolyte abnormalities at discharge (OR 1.77 CI 1.17-2.69), delayed graft function (OR 1.65 95% CI 1.2-2.17), and post KTxC complications (OR 1.79 95%CI 1.1-2.61) were associated with increased risk of readmission

Kidney Transplant Outcomes for Patients with Amyloidosis – A United Network for Organ Sharing Database Analysis

Ali Khalil, Tim E. Taber, Muhammad Ahmad Mujtaba, Muhammad S. Yaqub, Asif A. Sharifuddin. Medicine/Neph, Indiana Univ, Indianapolis, IN.

**Background:** Outcomes of patients with Amyloidosis who receive a kidney transplant have not been extensively studied. We examined UNOS database for outcomes of such recipients.

**Methods:** UNOS database was queried for recipients with code “3016” which corresponds to “Amyloidosis”. Duration of study period was Nov 1987 to Dec 2014.

**Results:** A total of 625 recipients were identified as in the table.

After excluding multi-organ transplants, the 1 year unadjusted graft survival was 88.6% and the 1 year patient survival was 92.1 %. Kaplan Meier Survival Curves are in the Figure.

DGF incidence increased from 26.5% pre-KAS to 31.6% post-KAS (p<0.001); in a multilevel (center-level) model, DGF increased 37% (OR=1.21 1.37 1.55 , p<0.001). We also compared CPRAs of DDKT recipients pre vs post-KAS, and incidence of delayed graft function (DGF).

**Conclusions:** After excluding multi-organ transplants, the 1 year unadjusted graft survival was 88.6% and the 1 year patient survival was 92.1 %. Kaplan Meier Survival Curves are in the Figure.

FR-PO1050

Early Experience with the New Kidney Allocation System

**Background:** On December 3, 2014, major changes to deceased donor kidney allocation were implemented under the new Kidney Allocation System (KAS).

**Methods:** Using national registry data, we compared changes in rate of DDKT among adult kidney-only waitlist registrants 1/2011-3/2015 pre vs post-KAS via Poisson regression, adjusting for age, sex, race, ABO blood type, calendar year, calculated panel reactive antibody (CPRA), and wait time. We compared donor service area-level geographic disparity pre vs post-KAS using multilevel Poisson regression and median incidence ratio (MIRR). We also compared CPRA of DDKT recipients pre vs post-KAS, and incidence of delayed graft function (DGF).

**Results:** Pre-KAS, access to DDKT was poorer for women (IRR=0.99 0.99 0.99), African-Americans (AAs) (IRR=0.88 0.88 0.88), and Hispanics (IRR=0.79 0.79 0.79, all p<0.01). Access was best for patients of ABO type AB (IRR vs O=2.29 2.29 2.29 , p<0.01) and worst for ABO type B (IRR vs O=2.29 2.29 2.29 , p<0.01). KAS was associated with no change in overall DDKT access (p=0.7), but with improved access for AAs (IRR=1.16 1.16 1.16, interaction p<0.001) and patients of ABO type AB (IRR=1.29 1.29 1.29, interaction p<0.001). Geographic disparity declined post-KAS (MIRR=1.76 pre-KAS, 1.64 post-KAS). Median CPRA at transplantation was 0 both pre and post-KAS; the proportion of recipients with CPRA 80-99 decreased from 13.6% to 10.1% (p<0.001), but the proportion with CPRA>99 rose from 1.6% to 14.0% (p<0.001, Figure 1).

**Conclusions:** After recent changes to kidney allocation, DDKT access improved for AA patients and geographic disparity declined. Women and Hispanic patients are still disadvantaged, and disparity by ABO type worsened. The proportion of recipients for AA patients and geographic disparity declined. Women and Hispanic patients are still disadvantaged, and disparity by ABO type worsened. The proportion of recipients with CPRA>99 rose dramatically. Increase in DGF may suggest risk of poorer long-term outcomes.

FR-PO1051

Kidney Transplantation Tourism: High Risk and Bad Outcome for the Recipients

Amgad E. Elagroudy. Internal Medicine Dept, College of Medicine and Medical Sciences, Arabian Gulf Univ, Manama, Bahrain.

**Background:** While the ethical aspects of transplant tourism have received much attention recently, less has been written about the medical safety of this practice. We retrospectively evaluated the outcomes of patients who purchased organs internationally and presented to our center for follow-up care.

**Methods:** We report the outcome parameters of 270 local recipients of unrelated kidney (URT) vendor transplants presenting to our institute between 1986 and 2014. Their outcome was compared with 123 recipients of living-related donor transplants matched for age, gender and transplant duration done in our center as controls (RT).

**Results:** Age of unrelated recipients was 42.6 ± 13.4 years with Male % of 68. The country of transplant was mainly in Philippines (n = 85), Pakistan (n = 56), India (n = 57), Iran (n = 40) and Egypt (n = 25). Comparison of commercial recipients with controls showed high co morbidities (P = 0.01) with hepatitis-C (n=2 vs. 0) and hepatitis-B (n=2 vs. 0) and cytomegalovirus (n=4 vs. 1). Donor age was 25.9 ± 3.8 vs. 34.6 ± 8.6 years (P = 0.0001) and 90.4% were male. Biologic agents induction in 74 (27.4%) vs. 123 (100%) (P = 0.0001), acute rejections in 65 (24.1%) vs. 26 (21.1%) (P = 0.7), while recurrent rejection in 13 (4.8%) vs. 10 (0.8%) (P=0.04), surgical complications including lymphocoele 16 (5.9%) vs. 0 (0%) (P = 0.0001), ureteral obstruction 7 (2.6%) vs. 0 (0%) (P = 0.007), hematoma 4 (1.5%) vs. 1 (1.1%) (P = 0.06) and recurrent urinary tract infection 18 (6.8%) vs. 6 (6.8%) (P = 0.3). Overall 1- and 10-year for graft survival was 91% and 90.4% were male. Biologic agents induction in 74 (27.4%) vs. 123 (100%) (P = 0.0001), acute rejections in 65 (24.1%) vs. 26 (21.1%) (P = 0.7), while recurrent rejection in 13 (4.8%) vs. 10 (0.8%) (P=0.04), surgical complications including lymphocoele

**Conclusions:** Although 1 year graft and patient survival of kidney transplants in recipients with Amyloidosis is inferior to standard outcomes, long-term outcomes are not remarkably different. Careful selection of this population can lead to satisfactory outcomes. To our knowledge this is the first and largest report on the outcomes of these patients from the US national database.
**FR-PO1052**

**The Negative Effect of First Transplant Nephrectomy for Second Transplant Outcome**

Masaki Muramatsu,1,2 Michael Sheaff,1 Arun Gupta,1 Atsushi Aikawa,2 Carmelo Pulitelli,1 Muhammad M. Yaqoob,1 Nephrology and Transplantation, The Royal London Hospital, London, United Kingdom;
Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan;1 Cellular Pathology, The Royal London Hospital, London, United Kingdom;2 Clinical Transplant Laboratory, The Royal London Hospital, London, United Kingdom.

**Background:** The impact of failed renal allograft nephrectomy on the outcome of retransplantation is unclear. This single center study was conducted to address this question.

**Methods:** We analyzed 93 patients who received a 2nd transplant at The Royal London Hospital between November 1994 and January 2015. 59 patients did not receive primary transplant nephrectomy (TNx) and had failed allograft in situ at the time of second graft (group A) whilst 34 patients underwent TNx prior to second graft (group B). 2nd transplant survival was the primary end point. Sensitization, waiting time for 2nd graft, graft function and rejections were secondary end points.

**Results:** Group A patients had significant longer graft survival than group B (100.6 months vs 40.2 months, p<0.001). Waiting time from primary graft loss to second transplant in group A was shorter than group B (36.7 months vs 59.1 months, p<0.013). In total, 33 patients had pre-formed anti-HLA antibodies (low titer). Group B had significantly higher rate of pre-formed anti-HLA antibodies than group A (50% vs 29.3%, p=0.047). The rate of HLA class I in group B was also significantly higher than that in group A (47.1% vs 25.7%, p=0.038). Group B had numerically higher rate of acute rejection than group A (32.4% vs 15.3%, p=0.003). GFR between both groups did not differ until 3 years post-transplant. In group A, 2nd graft survival rates at 6 month, 1 and 5 years were 94.9%, 93.0%, 87.0% and 82.3%, and were significantly better group B (73.3%, 70.0%, 60.6% and 46.8%, p<0.001). On multivariate analysis, waiting time for second transplant, TNx, second transplant donor age and delayed graft function were independently associated with second graft survival. TNx had highest hazard ratio (2.83, 95% CI 1.22-6.67, p=0.015).

**Conclusions:** Prior TNx is associated with inferior 2nd renal graft survival in this observational study and calls for an urgent randomized control trial.

---

**FR-PO1053**

**Induction Agent Use, Mortality and Acute Rejection in Older KT Recipients**

**Background:** Induction agents are commonly used as an initial intensive immunosuppression after kidney transplantation (KT) to prevent acute organ rejection; this paper aims to quantify their label. Little is known about induction agent use in older KT recipients.

**Methods:** Data on 19,546 older KT recipients (2005-2013) was ascertained from the Scientific Registry of Transplant Recipients. Induction agents were classified as thymoglobin/ATG, IL-2, or other induction agents. The risk of mortality was estimated using a time-varying proportional hazards model (hazard ratio (HR)) adjusting for all HTX factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (HCV, HLA mismatches, cold ischemia time, donor type, donor age, and donor sex). The relative risk (RR) of 1 year acute rejection was estimated using modified Poisson regression adjusting for all recipient and KT factors.

**Results:** The mean age was 69 (SD=3.8 years), 36% female, 19% black and 27% live donor recipients. There is an increasing utilization by year of induction agents, with thymoglobulin/ATG, IL-2, or other induction agents. The risk of mortality was estimated using a Cox Proportional Hazards model (hazard ratio (HR)) adjusting for all recipient factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (HCV, HLA mismatches, cold ischemia time, donor type, donor age, and donor sex). The relative risk (RR) of 1 year acute rejection was estimated using modified Poisson regression adjusting for all recipient and KT factors.

**Conclusions:** Prior TNx is associated with inferior 2nd renal graft survival in this observational study and calls for an urgent randomized control trial.

**FR-PO1054**

**Immunosuppression and the Elderly – Can They Take It?**

**Background:** The aging immune system has fewer naïve T cells, more memory T cells, and less T cell receptor variability. Older transplant patients tend to have more comorbidities and less functional reserve. This combination makes them more difficult to immunosuppress with higher risk of infection, and potentially increased mortality from rejection treatment.

**Methods:** In order to determine the impact of rejection treatment on outcomes in our transplant recipients >70 years of age, we reviewed the outcomes of patients transplanted at our center from 1/2009-12/2013. Induction regimens varied; maintenance immunosuppression consisted of tacrolimus, mycophenolate, and rapid steroid withdrawal.

**Results:** During this period time, we transplanted 110 over 70 years of age. Of these, 27 patients had rejection – 24 ACR, 1 combined AMR/ACR, 1 AMR. 1 AMR followed by ACR (see table). 11 of these patients received Tcell depleting agents, the rest received IV steroids +/- IVlg. There was no difference in age, race, donor type, prior transplant, or induction therapy between the two groups. Mean creatinine was higher in the rejection group compared to the ACR group (1.0 mg/dl vs 0.6 mg/dl, p<0.001). GFR at rejection treatment was different no two patients. Within 6 months of rejection treatment, there were 12 infectious complications, only 3 of which required hospitalization (urosepsis-2, CMV-1). There were no differences in rates of BK viremia, CMV viremia, graft survival, or mortality. 7 of the 27 patients died at some point after rejection. only one was related to infection >1 year later and not related to treatment.

**Conclusions:** Among our >70 patients, rejection treatment appeared well tolerated with few complications requiring hospitalizations and no treatment related mortalities. In addition, it appeared that treatment stabilized function in the majority of patients.

**Mortality After Kidney Allograft Failure and Return to Dialysis**

Amrapali Madia, 1 Fasika M. Tedla, 1 Moro O. Salifu. 1 Nephrology, SUNY Downstate Medical Center, Brooklyn, NY; 2 Surgery, SUNY Downstate Medical Center, Brooklyn, NY; 3 Surgery, Uniformed Services Univ of Health Sciences, Bethesda, MD.

**Background:** Our hypothesis was that kidney allograft failure (KAF) and return to dialysis (RTD) results in greater mortality versus patients with end-stage renal disease (ESRD). We also sought to identify variables associated with mortality after KAF.

**Methods:** We used an incident cohort of patients from the United States Renal Data System who initiated any form of dialysis between Jan 2003 and Dec 2008 after KAF. We followed patients until retransplantation, death or Sept 2009. Multivariable Cox analysis was used for statistical associations.

**Results:** 7,156 patients were followed for a mean of 30.8 ± 22.6 months. 3,622 (50.6%) patients died. The main causes of death were cardiovascular (47.0%), infections (14.5%), other (16.4%) and metabolic/endocrine (7.9%) causes. Predictors of all-cause mortality included age at KAF (hazard ratio (HR)= 1.03, 95% confidence interval (CI) 1.03-1.04), diabetes (DM) as cause of kidney failure (HR=1.52, CI 1.3-1.8), congestive heart failure (CHF) (HR=1.19, CI 1.04-1.36), peripheral arterial disease (PVD) (HR=1.23, CI 1.04-1.55), stroke (HR=1.27, 95% CI 1.08-1.48).

---

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline** represents presenting author.
CI 1.05-1.55), employment (HR=0.80, CI 0.67-0.96), BMI (HR = 0.98, CI 0.97-0.99) and serum albumin (HR = 0.82, CI 0.75-0.90). Mortality was higher in those with either DM or CHF, and increased further in those with PAD (P<0.0001).

Figure 1. Adjusted all-cause mortality [Kaplan-Meier curve]

Gender, number of transplants, donor type (deceased, living), ESRD duration prior to transplant, tobacco use, drug or alcohol abuse and erythropoietin use did not predict all-cause mortality.

Conclusions: DM, CHF and PAD are associated with increased mortality after KAF and RTD. Prevention and early management of these conditions may increase survival. Prospective studies are needed to confirm our findings.

Current Trends in Waiting List of Kidney Transplantation and Mortality in Asian: A National Population-Based Cohort Study Using the Korean Network for Organ Sharing (KONOS) Database

Kyung Don Yoo, Sunhwa Lee, Jung Nam An, Yun Kyu Oh, Chun Soo Lim, Yon Su Kim, Jung Pyo Lee. Seoul National Univ College of Medicine.

Background: Kidney transplantation has been increasing, globally. However, the clinical outcome of wait-listed patients for deceased donor kidney transplantation has not been well described in Asian patients with end-stage renal disease (ESRD).

Methods: We reviewed the detailed trends of wait-listed patients and conducted survival analysis in kidney transplant recipients using KONOS (The Korean Network for Organ Sharing) database which is a complete enumeration survey. We compared the outcomes according to the transplant era as followings: 2000–2004, 2005–2009, 2010–2014.

Results: From 2000 to 2014, a total of 34,843 patients registered in the waiting list, and 5,164 patients received transplantation from deceased donor. The proportion of deceased donor kidney transplantation has increased up to 45.9% in 2013 from 4.6% in 2000. The number of waiting list for kidney transplantation has increased continually more than 3,000 ESRD patients per year. The mean waiting time of deceased donor kidney transplantation was 54.9 months and has been getting longer. A total of 18,687 patients were remained on the waiting list until Jan 2015. Recently, diabetic nephropathy was the leading cause of primary disease on the waiting list, and the mean age of new registrants was getting older. The crude annual mortality rate during waiting time was 8.4%. The survival analysis revealed that there was no difference of patient survival according to the transplant era in kidney transplant recipients. However, the cumulative survival rate of the recently registered wait-listed patients was significantly improved even though they were older and had more proportion of diabetes (P<0.001, HR 0.51 95% CI 0.46-0.57).

Conclusions: In Korea, deceased donor kidney transplantation has increased. Donor organ is still seriously insufficient, therefore, it is necessary to encourage organ donation. In addition, more meticulous management needs to be provided to wait-listed patients.

FR-PO1057

Factors Affecting Mortality During Waiting Time for Kidney Transplantation: A Nationwide Population-Based Cohort Study Using the Korean Network for Organ Sharing (KONOS) Database

Sunhwa Lee.1 Kyung Don Yoo,1 Jung Nam An,1 Yun Kyu Oh,1 Chun Soo Lim,1 Yon Su Kim,1 Jung Pyo Lee.2 1Div of Nephrology, Dept of Internal Medicine, Seoul National Univ Hospital; 2Dept of Internal Medicine, Seoul National Univ Boramae Medical Center.

Background: Longer waiting times for kidney transplant have been suggested to be more deleterious than shorter waiting times. We analyzed the impact of waiting time on the post-transplant outcome and investigated risk factors for mortality during waiting time based on complete enumeration survey in Korea.

Methods: We analyzed all persons over 18-years-old deceased donor kidney transplant cases enrolled in Korean Network for Organ Sharing (KONOS) data between Jan 2000 to Jan 2015. The primary end point was all cause of death after enrollment.

Results: Of the 24,296 waiting-listed dialysis subjects, 5,255 patients including 588 re-transplant cases received kidney transplantation from deceased donor with median waiting time of 4.5 years. Ten year overall survival was 81.3% in kidney transplant recipients, whereas 68.1% in dialysis patients. Unlike previously known data, the effect of waiting time on mortality after transplantation was insignificant. During waiting time, however, various demographic and clinical factors were associated with increased mortality. Diabetic patients are more likely to die before transplantation (HR 2.25, 95%CI 1.37-3.70, P<0.001). Age was a significant risk factor for mortality. Only 56% of people aged 65 live after 10 year of waiting, whereas 86% of people aged 35. Men are more likely to die than women during waiting time (HR 1.22, 1.13-1.31, P<0.001). Moreover, Patients with Rh negative blood type shows higher mortality rate than those with Rh positive (HR 1.60, 1.06-2.42, P=0.024). Pre-transplant experienced patients, however, showed better survival during waiting time (HR 0.63, 0.46-0.86, P<0.003).

Conclusions: Longer waiting times on dialysis do not affect survival after transplantation although transplant itself shows overall better survival. It should be emphasized at to have more attention to the patients who are diabetic, old, men, or Rh negative with higher risk for mortality during waiting time.

FR-PO1058

Normal Saline versus Lower-Chloride Solutions for Kidney Transplantation

Susan Yang.1,2 Matthew A. Robinson,1 Peter F. Mount.1 1Dept of Nephrology, Austin Health, Melbourne, Victoria, Australia; 2Central Clinical School, Univ of Sydney, New South Wales, Australia; 2Eastern Health Clinical School, Monash Univ, Box Hill, Victoria, Australia.

Background: The ideal intravenous (IV) fluid for kidney transplantation (KTx) has not been defined, despite the common use of normal saline (NS) in the perioperative period. The high chloride content of NS is associated with an increased risk of hyperchloremic metabolic acidosis, which may increase the risk of hyperkalemia and delayed graft function (DGF). Balanced electrolyte solutions (BHS) have a lower chloride content, which may decrease this risk and avoid the need for dialysis due to hyperkalemia. Randomised controlled trials (RCTs) have used biochemical outcomes to compare fluids and have been underpowered to address patient-centred outcomes such as DGF. We systematically reviewed the effect of BES versus NS on DGF, hyperkalemia and acid-base status in KTx recipients.

Methods: We searched the Cochrane Renal Group’s Specialised Register to 24th March 2015. We included RCTs of KTx recipients that compared peroperative IV lower-chloride solutions to NS. Two independent investigators assessed studies for eligibility and risk of bias. Data were extracted using standardised forms and pooled according to a published protocol.

Results: Six studies (477 participants) were included in the review. All participants were aged ≥18 years and 70% received live-donor KTx. The overall risk of bias was low for selection bias and unclear for remaining domains. There was no difference in the risk of DGF (RR 1.03, 95%CI 0.62-1.70, P=0.91) or hyperkalemia (RR 0.48, 95%CI 0.04-6.10, P=0.57) for participants who received BES compared to NS. Compared to NS, BES were associated with higher serum bicarbonate (mean difference ΔHCO3 3.04mEq/L, 95%CI 2.13-3.94mEq/L, P<0.0001), higher serum bicarbonate (mean difference ΔHCO3 -9.93mEq/L, 95%CI -19.96-0.11mEq/L, P=0.05).

Conclusions: Intraoperative balanced electrolyte solutions are associated with less hyperchloremic metabolic acidosis compared to normal saline. However, these data do not support their use to reduce clinical events.

FR-PO1059

Risk Factors for Delayed Graft Function in Kidney Transplantation

Marcos A. Meniconi,1 Vitoria C. Vilela,1 J. Medina-Pestana,1 Miguel Cendoroglo Neto,1,2 Miguel A Goes.1,2 1Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; 2Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, SP, Brazil.

Background: Renal failure persisting after transplantation necessitating dialysis within the first week is called delayed graft function (DGF). Objective: To assess the impact of erythropoietin usage on DGF after renal transplantation.

Methods: A total of 196 maintenance hemodialysis patients who underwent renal transplantation at one center (Hospital do Rim) were prospectively analyzed pre and post-renal transplantation. Data on demographics, ESRD etiology, pre-transplantation hemodialysis, recombinant human erythropoietin (rHuEPO) use, type of donor kidney and immunosuppression regimen were reported. Two-sample t-test were used to compare differences between two groups (DGF versus non-DGF groups) and X2 to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome-DGF.

Results: The mean duration of maintenance hemodialysis was 18±6 months. The main causes of ESRD were diabetes (37%) and hypertension (15%) followed by chronic glomerulonephritis (9%). There were transplants from deceased-donor kidneys (47%), living unrelated kidney donation (43%) and living related donors (10%). 41 patients necessitated dialysis within the first week after renal transplantation (DGF group). We observed that 131 patients (67%) used recombinant human erythropoietin until one week before renal transplantation. We observed that DGF group was older (39±15; p=0.007), higher cold ischemia time (23±10h, 12±10h; p<0.001), longer time on dialysis (4±4, 2±1 yr; p<0.001) and higher rHuEPO dose (40±44, 16±8±44±11; p=0.001). DGF group had higher use of rHuEPO (p<0.001). Cold ischemia time (p=0.001) was an independent predictor of DGF.

Conclusions: This study shows that rHuEPO was not associated with DGF-protection in renal transplant patients. Cold ischemia time is an independent predictor of DGF.
FR-PO1060
Outcomes of Kidney Transplant Recipients from Donations After Circulatory Death Donors without Pre-Agonal Heparin Administration
Lavla Kamal, Joel Lindower, Maria Ajaimy, Michelle L. Lubetzky, Graciela De Boccado, Enver Akalin, Lise K.Kayler.
Montefiore- Einstein Center for Transplantation.

Background: Protocols of organ donation after circulatory death (DCD) are considerably varied. Heparin administration during the pre-agonal phase has been recommended to improve organ perfusion and prevent blood clots; however some protocols avoid heparin before verification of death based on legal or professional concerns. We assessed outcomes of kidney transplant recipients who received DCD kidneys recovered with and without heparin.

Methods: We retrospectively evaluated recipients of kidney transplants between 2013 and 2014 from controlled DCD donors who received (n=23) or did not receive (n=29) pre-agonal heparin.

Results: All kidneys underwent machine perfusion. No Heparin donors had a similar kidney donor profile index but were more likely to have mild histologic changes, elevated terminal machine perfusion resistive index, and to be imported from non-local donor service areas compared to the Heparin donors. Recipients of No Heparin kidneys were more likely to be female, sensitized, prior solid organ recipients, and to receive thymoglobulin and 2014 from controlled DCD donors who received (n=23) or did not receive (n=29) pre-agonal heparin.

Between group differences were small in terms of delayed graft function, 6-month acute rejection, and estimated GFR at 3, 6, and 12 months.

Effects of Dopamine Donor Pretreatment on Graft Function After Kidney Transplantation: Five-Year Follow-Up Of a Randomized Controlled Trial
Urs Benc,1 Bernhard K. Kraemer,1 Peter Schneuelle.1 1V. Medical Clinic, Univ Medical Center Mannheim, Mannheim, Germany; 2Nephrology, Center for Renal Diseases, Weinheim, Germany.

Background: [For the study group] A previous multicenter randomized controlled trial reported reduced dialysis requirements after kidney transplantation with dopamine donor pretreatment. Data on long-term outcomes are needed.

Methods: We calculated five-year graft survival from follow-ups at 60 European centers. We analyzed intention-to-treat and on-study medication and proteinuria survival estimates as tertiles of dopamine exposure because infusion times varied by treatment arm (range 0-1,929 min). Recipients with functioning grafts at three months were analyzed separately to differentiate early events from long-term consequences of the trial intervention.

Results: Follow-up was complete in 99.2%. Overall graft survival was 68.7%, (hazard ratio [HR] 0.85, 95% confidence interval [CI] 0.61-1.19; p=0.35), and death-censored graft survival was 83.3 vs. 80.4% (HR 0.84, 95%CI 0.54-1.29; p=0.42) in the treatment vs. control arms, respectively. The HR decreased to 0.46 (95%CI 0.23-0.94; p=0.03) in recipients with functioning grafts at three months, whose donor had received dopamine >270 min. It remained significant after adjusting for donor age (HR 1.05, 95%CI 1.02-1.08; p<0.001), delayed graft function (HR 2.05, 95%CI 1.12-3.73; p=0.02), biopsy-proven rejection (HR 2.13, 95%CI 1.16-3.93; p=0.02), and repeat transplants (HR 2.49, 95% CI 1.19-5.26; p=0.02). There were no differences of graft survival on intention-to-treat.

Conclusions: Dopamine administered for >270 min provided a long-term graft survival advantage independent of early events after Transplantation.

FR-PO1062
Does Calcineurin Inhibitor Timing Matter? Single Center Experience with En-Bloc Kidney Transplantation
Mava Campa,1 Oksana A. Kucher,1 Sanjeev Akkina,2 Ignatius Yun-Sang Tang.1 1Pharmacy Practice, Univ of Illinois at Chicago; 2Medicine, Nephrology, Univ of Illinois at Chicago.

Background: En-bloc kidney transplantation (KTx) has excellent outcomes. To minimize vascular complications and nephrotoxicity, calcineurin inhibitor (CNI) therapy is often delayed. The purpose of our study is to investigate the impact of CNI initiation timing on 1-year graft outcomes.

Methods: This is a single-center, retrospective review of adult en-bloc KTx between 2001 and 2013. Timing of CNI initiation was decided by the operating surgeon. Patients were divided into two groups, those that received CNI therapy early (<48 hours) or delayed (>48 hours) posttransplant. The primary objective was to compare one year estimated glomerular filtration rate (eGFR) between the groups. Secondary outcomes included graft and patient survival, CNI levels, incidence of delayed graft function (DGF), rejection and graft failure rates.

Results: Twenty-one en-bloc KTx recipients were included in the analysis. Ten patients received CNI therapy within 48 postoperative hours (Early CNI Group). There was no difference in age, race, gender, PRA, cause of ESRD or BMI between the groups. Only 50% of Early CNI patients received lymphocyte depleting therapy vs. 100% in the Delayed CNI group (p = ns). In the Early CNI Group, 3 patients were on cyclosporine; all other patients received tacrolimus and mycophenolate maintenance. There was no difference in eGFR between groups at one year or at any other time points. Comparable therapeutic tacrolimus trough was observed at 5, 10 and 30 days posttransplant. There was no difference in DGF or graft incidence. In the delayed CNI group, one patient died of sepsis at 6 months.

Conclusions: Timing of CNI initiation had no impact on one year graft function and patient survival.

FR-PO1063
Reduction of Pediatric Renal Transplantation Vascular Thrombosis Rates Utilizing Low Dose Heparin Infusion
Philip D. Acott,1,2 James B. Tee,2 Philip Wornell,1 John F.S. Crocker. 1V. Medical Clinic, Univ Medical Center Mannheim, Mannheim, Germany; 2Medicine, Nephrology, Univ of Illinois at Chicago.

Background: Pediatric renal allograft thrombosis rates are 4-10% and often result in allograft loss. Thrombolytic risk factors are smaller native vessel size, deceased donor source (DD), delayed renal allograft function, acute rejection, and small centre size (<50 transplants/decade). In our pediatric program from 1971 – 1992, 5 of 6 consecutive renal transplants (7.2%) were lost to vascular thrombosis. This study assesses if low dose continuous heparin reduces the risk and outcome of thrombosis in pediatric renal transplants.

Methods: Over 22 years (1993-2015), 44 of 100 consecutive children post renal transplant received low dose continuous heparin (10 units/kg/hour) for 1 week from therapeutic risk (1): age < 6 yrs (n=24); 2) laboratory profile of hypercoagulability (n=10); 3) oliguric delayed function (n=5), 4) surgical complications with venous or arterial anastomosis or double artery (n=4), or 5) patient history of access thrombosis or vasculitis (n=1). Renal scans were obtained on days 1, 3, 5 and when clinical deterioration occurred.

Results: Only 2 thrombotic events were noted which did not cause graft loss: 1) BD RD transplant- venous thrombosis immediately post-op on heparin with successful thrombectomy at 2hr and allograft recovery; 2) 17yr DD double renal artery allograft arterial thrombosis of smaller inferior renal artery on day 10 (heparin stopped day 7). One patient on heparin infusion required laparotomy 3hrs after surgery for thrombosis external to the anastomosis. One patient not on heparin also required laparotomy in the first 24hrs post-op for hemothorax evacuation. One patient in each group had primary non-function/surgical loss with removal of the kidney within the first 3 days post transplant. Graft survival at 1yr was 96% and no allograft was lost due to thrombotic complications.

The Influence of Induction Immunosuppressive Therapies and Diabetes on Graft Loss After Kidney Transplant

Hosam A. Faraj, Nasrollah Ghalramani, Tarek Alhamad. 1 Public Health Dept, Penn State College of Medicine, Hershey, PA; 2Nephrology Dept, Penn State College of Medicine, Hershey, PA; 3Public Health Dept, Penn State College of Medicine, Hershey, PA; 4Nephrology Dept, Washington Univ, St. Louis, MO.

Background: Induction therapy plays a significant role to reduce the rate of acute rejection in kidney transplant (KT). Understanding differences in outcomes associated with specific induction agents may lead to improvements in our treatment arm. Our objectives were to examine the influence of various induction therapies and diabetes on graft and patient survival after KT.

Methods: We used the 2000-2013 United Network for Organ Sharing (UNOS) data to evaluate the effectiveness of induction therapies and diabetes on graft and patient survival after KT. The patients were divided into four groups based on induction therapy: Basiliximab (n=24,484), alemtuzumab (n=3,321), rabbit anti-thymocyte globulin (n-ATG) (n=54,974) and daclizumab (n=13,358). Also the patients were divided into four groups based on diabetic status: non-diabetic (n=192,333), type1 diabetes (n=11,863), type 2 diabetes (n=45,543) and new onset of diabetes (n=10,509). The main outcome were the risk of graft loss and death at 1,3,5,10 years. Cox proportional hazards model was used to estimate the hazard ratios.

Results: Graft loss was significantly higher in alemtuzumab group (HR=1.171 ; P< 0.002) and rabbit anti-thymocyte globulin group (HR=1.109 ; P< 0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for graft loss (HR=0.902; P< 0.0001) than basiliximab group. Death was significantly higher in rabbit anti-thymocyte globulin group (HR=1.075; P< 0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for death (HR=0.850; P< 0.0001) than basiliximab group. Graft loss was significantly higher in type 2 diabetes (HR=1.451; P< 0.0001).

Conclusions: Induction immunosuppressive therapies and diabetic status play significant role in long-term graft and patient survival. Basiliximab and daclizumab as IL-2 RA receptor antagonists have better long-term graft and patient survival outcomes.

FR-PO1065

Does Induction Type Influence Outcomes in Kidney Transplant Recipients at Different Phases of Hepatitis B Infection?

Khalil K. Suwelack, Richard J. Marcus, Bhavna Chopra. Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.

Background: Host response to hepatitis B virus (HBV) infection is variable with some patients progressing to chronic liver disease. Immunosuppression associated with kidney transplantation in such patients may increase the risk of disease progression. We aimed to analyze the impact of potent depleting vs. non-depleting antibody induction on the outcomes in our de novo kidney transplant recipients (KTRs) at different serological stages of HBV infection.

Methods: Using UNOS database, we identified adult KTRs from 2001 to 2011 who at the time of transplantation were in one of the 3 serological stages of HBV infection: HBsAg+/HBcAb-(early infection), HBsAg+/HBcAb+ (inactive carrier or immune tolerant) or HBsAg-/HBcAb+ (clearing infection) sero-status. These findings support a practice of choosing induction type based on the immunological risk in such recipients rather than the serological status following HBV infection.

FR-PO1066

Health Economic Analysis of Rabbit Antithymocyte Globulin (Thymoglobulin) versus Basiliximab (Simulect) in Renal Transplantation – A German perspective

Friedrich Thaiss,1 Claudia Sommerer,1 Barbara M. Suvelack,1DSU Dagran,1 Ingeborg A. Hauser,2 Peter Schenker,2 Daniel Baumeier,2 Björn Nashan,3 Athena Study Group; 4Novartis Pharma Germany.

Background: Kidney transplantation is now accepted as a proven therapeutic modality prompting a greater need to understand the cost-effectiveness of different treatment approaches.

Methods: The primary objective of this study was to quantify the economic consequences of acute rejection and adverse events in patients undergoing cadaveric kidney transplantation and receiving ATG (Thymoglobulin - Thymo) compared with those receiving basiliximab (Simulect - Sim). Health economic data were collected according to reimbursement calculations from 3 German sites in an existing database (Brennan et al NEJM, 2006).

Results: Based on the clinical data from the Brennan trial, the study quantified current data and changes in treatment patterns. Results demonstrate that at 12 months the cost of the Thymo-regimen is €5,753 more than that of the Sim-regimen. However, costs of delayed graft function, nonfatal graft failure events and post-graft failure dialysis are lower among Thymo treated patients. Thymo treated patients incurred higher graft maintenance costs, consistent with their longer graft survival. In total the associated cost-offset from lower rejection events with Thymo offset the added cost from drug treatment and therefore Thymo is a more cost-efficient resource vs Sim due to cost avoidance. To further evaluate differences between the two groups we considered quality-adjusted life year differences. The Thymo cohort is projected to enjoy 405,714 QALY after 1 year. After a decade, the Thymo cohort is projected to cost 332,232 Euros less than the Simulect cohort while enjoying 10.8 more QALYs.

Conclusions: This analysis was intended to provide information that should be considered when weighing the costs and benefits of two immunosuppressive regimens and to investigate if treatment changes might result in more cost-effective care.

Thymoglobulin Induction Therapy; Results for 5 Years – Improving the Survival of Renal Allograft and Patient
Virginia Barba Pedroza, Benjamin Gomez-Navarro. Nephrology and Transplantation, Centro Medico Nacional de Occidente, Guadalajara, Jalisco, Mexico.

Background: The factor that impacts the survival of renal allograft is the presence of acute rejection. In our city, using Thymoglobulin has offered to patients at high immunological risk, and through the years has sought to reduce adverse events use. The objective is to evaluate the frequency of acute rejection during the last 5 years in patients receiving Thymoglobulin induction.

Methods: An ambispective cohort, patients transplanted in UMAE-CMNO, Jalisco, Mexico is included in the period June 2010 to June 2014 who received induction therapy with Thymoglobulin. Was recorded the frequency of acute rejection, the frequency of infections, use of Filgrastim(G-CSF), graft loss and death at 12 months of transplantation.

Results: A 370 patients were included, which received initial doses of Thymoglobulin 0.6mg/kg-1.5mg/kg. In 2013, by multivariate analysis Thymoglobulin dose that was associated with a lower incidence of acute rejection was analyzed and found that 1mg/kg for 4 days (cumulative dose 4mg/kg) is a protective factor for the occurrence of acute rejection (IC 95%: 0.11-0.60, OR 3.7, p<0.001), for this reason almost patients received this dose. In 2010, the rate of rejection was 10%, and actually is 7.8% (p=0.05).

Conclusions: Interestingly, in our hospital, we observed a lower rate of acute rejection and improved patient survival and allograft. Apparently finding the right dose in our patients has allowed thymoglobulin induction is safe and minor complications.

FR-PO1068

Early Conversion to Everolimus in De Novo Renal Transplant Recipients: 24-Month Results from the ELEVATE Study
Johan W. De Fijter, Hallvard Holdaas, Patricia M. Lopez, Cesar Escrig, Zailong Wang, Josep M. Cruzado, Markus van der Giet. For the ELEVATE Study.

Background: Long-term therapy with calcineurin inhibitors (CNIs) is associated with nephrotoxicity i.e., glomerulosclerosis and interstitial fibrosis (IF). We present the 24 month results from the ELEVATE study (NCT01114529), which compared an early conversion to everolimus (EVR) vs standard CNI in renal transplant recipients (RTxR).

Methods: ELEVATE, a 24M, multicenter, open-label randomized, de novo RtxRs 10–14 weeks post-Tx to convert from CNI to EVR (n=360; CsA 6–10 ng/mL) vs standard CNI (n=357; CsA TAC 5–10 ng/mL, CSA 100–250 ng/mL); all received enteric-coated mycophenolate sodium and steroids. Primary endpoint was change in eGFR (MDRD4) from RND to M12. Main secondary endpoint a composite efficacy of treated biopsy-proven acute rejection (IBPAR, Banff ≥IIb), graft loss, or death and safety.

Results: At M12, the clinical benefit observed in eGFR did not achieve statistical significance (1.70, 95% CI: -0.53, 3.95; p=0.134) whilst eGFR at M24 for EVR was significantly better (p<0.006). The composite efficacy endpoint was comparable at M12 & M24. Overall acute rejection rates were very low with more iIBPAR in EVR, but mild in severity (Banff I/II & III). In both the groups, number of patients with de novo DSA at M12 or M24 was low and unrelated to outcomes. At M24, rate of CAN (IETF/A) was significantly higher in the CNI versus EVR (35.1 vs 26.7%, p=0.029).

Conclusions: Early conversion to EVR at 3 months vs continued CNIs better preserved renal function with comparable overall efficacy and safety up to 2-years.

Conclusions: Currently few patients use of rG-CSF because leukopenia- neutropenia, lost the renal graft or die for the first year.

FR-PO1069

Randomized Trial of Tacrolimus/Everolimus versus Tacrolimus/Enteric-Coated Mycophenolate Sodium to Prevent Biopsy-Proven Acute Rejection and Chronic Allograft Injury in Adult, Primary Kidney Transplantation
Gisselle Guerra, Jeffrey J. Gaynor, David Roth, Warren L. Kupin, Dela D. Mattiazzi, Michael J. Goldstein, Linda J. Chen, George William Burke, Gaetano Ciancio. Dept of Medicine, Miami Transplant Inst, Miami, FL; Dept of Surgery, Miami Transplant Inst, Miami, FL.

Background: It was of interest to determine whether everolimus(EVL) might reduce the incidence of biopsy-proven acute rejection(BPAR) during the first 12mo post-kidney transplantation.

Methods: We performed a single-center, open-label randomized trial comparing two maintenance immunosuppression regimens: TAC/EVL (Group A) vs TAC/EC-MPS (enteric coated mycophenolate mofetil)(Group B). In both treatment arms, dual maintenance immunosuppression regimens: TAC/EVL (Group A) vs. TAC/EVR (Group B). In both treatment arms, dual induction therapy (anti-thymocyte globulin plus basiliximab) was given along with planned EC-MPS(enteric coated mycophenolate mofetil)(Group B). In both treatment arms, dual maintenance immunosuppression regimens: TAC(EVL) vs. TAC/EVR, induction therapy (anti-thymocyte globulin plus basiliximab) was given along with planned EC-MPS.

Results: Among 30 eligible adult participants (15 per treatment arm), median follow-up was 11mo(range: 3-20mo). Mean TAC levels were 5-8 ng/ml in both arms; mean EVL level was 110 ng/ml in Group A vs 130 ng/ml in Group B. One patient in Group A vs. 3 patients in Group B experienced BPAR-actual estimates at 12mo were 10%/9% vs. 20%/10%, respectively(P<0.5). All 3 BPAR’s in Group A occurred prior to 6mo vs. the single BPAR in Group B occurring after 6mo (logrank P=0.09 during the first 6mo post-transplant). A slight trend for more favorable renal function(eGFR) was also observed in Group A at 1-3mo post-transplant (P=0.06, 0.19, 0.18, respectively). No graft failures or deaths have been observed. Regarding the incidence of NODAT, a slight trend against Group A was observed (2/15 vs. 0/15 in Group B, P=0.13), and higher mean cholesterol and triglyceride levels also occurred in Group A during 2-12mo(P=0.10 at various times).

Conclusions: Although a relatively favorable performance for the experimental maintenance regimen of TAC/EVL in terms of a low BPAR rate during the first 12mo post-transplantation was observed, it may occur at the expense of possibly higher rates of NODAT and lipidemia.

FR-PO1070

Early Conversion from Cyclosporine to Everolimus following Living-Donor Kidney Transplantation: Outcomes at Five Years Post-Transplant in the Randomized ZEUS Trial: A Post-Hoc Analysis
Ingeborg A. Hauser, Frank Lehner, Wolfgang Arns, Clemens Budde, Ute Eisenberger, Rudolf Wuthrich, Petra Reimke, Rolf A. Stahl, Anja Susanne Mühlfeld, Heiner H. Wolters, Barbara M. Suwelack, Katharina M. Heller, Martina Porstner, Oliver Witzke, Claudia Sommerer. ZEUS Study Group, Germany; ZEUS Study Group, Switzerland; Novartis Pharma, Germany.

Background: To study renal function and patient outcome after 5 years in living-donation subgroup of kidney de novo transplant recipients after conversion to an everolimus (EVR) based regimen and withdrawal of calcineurin inhibitor therapy. Methods: Post hoc subgroup analysis from the prospective, open-label, controlled, multi-center study ZEUS. 300 renal transplant (Tx) patients were randomized at month (mo) 4.5 post Tx to either receive EVR plus enteric coated-mycophenolate sodium (EC-MPS) or cyclosporine (CsA) plus EC-MPS regimen. Of these 80 living donation recipients (EVR group n=42; CsA group n=38). Patients could enter an observational follow-up (FU) period where outcome on patients’ safety and efficacy was recorded until mo 60 post Tx.

Results: Adjusted eGFR (Nankivell) in living-donation subpopulation at mo 60 was 67.2 (95% CI [62.5, 71.9]) ml/min/1.73m² in EVR vs 60.8 (95% CI [56.0, 65.6]) ml/min/1.73m² in CsA patients, resulting in a difference of +6.6ml/min/1.73m² in favor of EVR patients (p=0.031, ANCOVA). Unadjusted mean eGFR after 5 years was 69.5 ml/min for EVR vs 66.0 ml/min for CsA (p=0.006, Wilcoxon). BPARs during FU since mo12 occurred in 4 patients of the EVR and 3 of the CsA group, all BANFF grade IIA except one BANFF grade IIA among EVR patients. From randomization to mo 60 one death occurred in CsA living-donor recipients, two in the EVR living-donation subgroup; one graft loss occurred in the EVR, none in the CsA group. Overall safety profile was similar between both treatment groups.

Conclusions: The presented analysis shows that EVR-based regimen with early elimination of CNI therapy in living-donor kidney transplant recipients is associated with a significant benefit on renal function maintained over 5 years post Tx without compromising safety and efficacy.

Co-Expression of RORgt and IFN-Gamma in Regulatory T Cells of Long-Term Sirolimus-Converted Kidney Transplant Recipients

Opas Traithanon, Ekamol Tantattamboon, Mohammed Javeed Ansari, Lorenzo G. Gallon. Medicine - Nephrology, Northwestern Univ, Chicago, IL.

Background: Sirolimus (TAC) and sirolimus (SRL) are commonly used immunosuppressive drugs in kidney transplantation. SRL has been shown to induce the expansion of regulatory T cells in post-transplant recipients converted from TAC to SRL.

Methods: This study included 84 renal transplant recipients from a randomized trial of SRL conversion (~55%) or TAC maintenance (~29%). The conversion started at 12 months post-transplant. PBMC were collected at 0(baseline), 6, 12, 24, 36 and 48 months post-randomization. T cell subpopulations were analyzed by flow cytometry.

Results: At baseline, frequencies of CD4+CD25+Foxp3+ T cells were similar in both groups. The ROC-AUC analysis was applied to define optimal cut-off levels of CD4+CD25+Foxp3+ T cells at 48 months and the differences were not significant compared to the TAC group at 48 months post-conversion (1.41±0.60% (SRL) VS 1.07±0.44% (TAC), p=0.24). Intraacellular staining for interferon (IFN)-γ, interleukin 17 (IL-17) and RAR-related orphan receptor gamma 2 (ROGRT) showed no difference at 24 months. However, at 48 months, we found that PMA-stimulated CD4+CD25+Foxp3+ T cells in SRL-converted group had more percentage of cells that co-expressed IFN-γ and ROGRT which are Th1 and Th17 markers respectively.

Conclusions: Switching from TAC to SRL results in an expansion of CD4+CD25+Foxp3+ T cells which peaked at 12 months post-conversion but no significant frequency differences were observed at 48 months follow-up and we observed more percentage of T cells that co-expressed IFN-γ and ROGRT in the SRL group.

FR-PO1073

Pulmonary Complications in Kidney Transplant Recipients: Role of Everolimus

Gianni Cappelli, Andrea Solazzo, Fabio Nava, Decenzio M. Bonucchi. Nephrology Dialysis & Renal Transplant Unit, Univ Hospital of Modena, Modena, Italy.

Background: Kidney transplant recipients are at higher risk to develop pulmonary complications as drug related side-effects.

Methods: 500 kidney transplanted patients were retrospectively analyzed for pulmonary complications based on chest RX and HRCT, BAL, oximetry and clinical data. Results were classified as parenchymal, interstitial and neoplastic complications.

Results: We found 168 pulmonary complications in 161 pts (32%): 137 parenchymal, 18 interstitial and 3 neoplastic. The higher PFIS score was recorded in patients treated with Sirolimus (R=0.63±0.06% (SRL) VS 0.66±0.12% (TAC), p<0.01). However, we observed a decline of CD4+CD25+Foxp3+ T cells at 24 months and the differences were no longer significant compared to the TAC group at 36 and 48 months post-conversion (1.41±0.60% (SRL) VS 1.07±0.44% (TAC), p=0.24). Intraacellular staining for interferon (IFN)-γ, interleukin 17 (IL-17) and RAR-related orphan receptor gamma 2 (ROGRT) showed no difference at 24 months. However, at 48 months, we found that PMA-stimulated CD4+CD25+Foxp3+ T cells in SRL-converted group had more percentage of cells that co-expressed IFN-γ and ROGRT which are Th1 and Th17 markers respectively.

Conclusions: Switching from TAC to SRL results in an expansion of CD4+CD25+Foxp3+ T cells which peaked at 12 months post-conversion but no significant frequency differences were observed at 48 months follow-up and we observed more percentage of T cells that co-expressed IFN-γ and ROGRT in the SRL group.

FR-PO1074

High Doses of M-TOR Inhibitors May Induce Pulmonary Pro-Fibrotic Effects in Renal Transplant Recipients: Result of a Translational Comparative Research Approach Between Everolimus versus Tacrolimus

Gianluigi Pazzà1, Valentina Masola, Silvana Granata, Gloria Belli, Maurizio Onisto, Giovanni Gambardello, Antonio Lupò, 1 Renal Unit, Dept of Medicine, University of Rome, Italy; 2Dept of Biomedical Sciences, Univ of Padova, Italy; 3Div of Nephrology and Dialysis, Columbus-Genemarii Hospital Catholic Univ, School of Medicine Rome, Italy.

Background: Pulmonary fibrosis is a quite frequent adverse effect occurring in mTOR-I-treated renal transplant (RT) recipients. It has been suggested that epithelial to mesenchymal transition (EMT) in airway cells may determine this condition. However, the exact biological machinery involved is not completely clarified.

Methods: We performed a translational study. First we analyzed the in vivo pulmonary pro-fibrotic potential of Everolimus (EVE) by computing a pulmonary fibrosis index score (PFIS), obtained by using several computerized tomography, hemogasanalytic and spirometric parameters, in 13 RT patients in EVE treatment and 13 patients treated with Tacrolimus (TAC). Subsequently, we carried out an in vitro study in which we assessed whether EVE at low-dose (5, 10 ng/ml) or high-dose (100 ng/ml) or Tacrolimus (5 ng/ml, 500 ng/ml, 5 μM) was able to induce EMT in bronchial epithelial cells (Nuli-1) and human type II pneumocyte-derived A549 cells. Additionally, microarray analysis was performed to identify differentially expressed genes.

Results: In the in vivo part of the study, we found that the PFIS was higher in EVE-treated patients compared to those treated with ADV (mean±SD: 2.58±1.83 versus 1.21±1.25). This effect was positively correlated to the trough levels (TL) in EVE-treated patients (R2=0.35). The higher PFIS score was recorded in patients treated with ADV that reached a TL≥6. Interestingly, in vitro, only very high doses of EVE were able to induce up-regulation of alpha-SMA, Fibronectin and Vimentin at gene and protein level in A549. No effects were seen in Nuli-1. Interestingly, microarray analysis confirmed the above-mentioned results.

Conclusions: All together, our data suggested that only very high doses of EVE may induce pulmonary fibrosis and that this effect could be mediated by EMT in pneumocyte cells.

Efficacy and Safety of Three Different Treatment Regimen in De Novo Renal Transplant Patients: 48 Months Follow-Up Results of the HERAKLES Trial

Wolfgang Arns, Volker Klicm, Claudia Sommerer, Johannes Jacobs, Bruno Vogt, Ingeborg A. Hauser, Petra Reinkes, Rolfa Stahl, Thomas Rath, Martina Porstner, Martin G. Zeier, Frank Lehner, Klemens Buddle, Oliver Witzke. 1HERAKLES Study Group, Germany; 2HERAKLES Study Group, Switzerland; 3Novartis Pharma, Germany.

Background: To compare safety and efficacy of 3 different immunosuppressive regimen at month (mo) 48 after kidney transplantation (KTx).

Methods: 802 patients (pts) were included in this 1 year, prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to mo 60 post Tx. After induction therapy all pts received cyclosporine A (CsA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 mo post Tx, 499 pts were randomized 1:1:1 to either a) continue standard CsA(100-180 ng/ml)+EC-MPS(n=166) (STD), b) to a calcineurin inhibitor (CNI)-free regimen with everolimus (EVR) (5-10 ng/ml)+EC-MPS (n=171) or c) to a CNI-reduced regimen with EVR (3-8 ng/ml)+ reduced CsA (50-75 ng/ml; n=162). All pts continued on steroids. At time of mo 48 FU, interim-analysis of the data were available from 1175 (79%) of the ITT population.

Results: At baseline, frequencies of CD4+25 hi Foxp3+ T cells were similar in both groups and the ROC-AUC analysis was applied to define optimal cut-off levels of CD4+25 Foxp3+ T cells at 48 months and the differences were no longer significant compared to the TAC group at 48 months post-conversion (1.41±0.60% (SRL) VS 1.07±0.44% (TAC), p=0.24). Intraacellular staining for interferon (IFN)-γ, interleukin 17 (IL-17) and RAR-related orphan receptor gamma 2 (ROGRT) showed no difference at 24 months. However, at 48 months, we found that PMA-stimulated CD4+CD25+Foxp3+ T cells in SRL-converted group had more percentage of cells that co-expressed IFN-γ and ROGRT which are Th1 and Th17 markers respectively.

Conclusions: For safety and efficacy of 3 different immunosuppressive regimen at month (mo) 48 after kidney transplantation (KTx).

FR-PO1076

Spartacus: Multicentre, Prospective Randomised Study Comparing Tacrolimus Hexal® versus Prograf® Based Regimen in De Novo Renal Transplant Recipients

Wolfgang Arns, Thomas Rath, Lars C. Rump, 1Klemens Buddle, Daniel Baueimer, Peter Schenker. 1Spartacus Study Group; 2Novartis Pharma Germany.

Background: In a transplant (Tx) setting, studies evaluating pharmacokinetic (PK) parameters and therapeutic equivalence of generic tacrolimus vs the reference drug are lacking. Spartacus (NCT016149427) study was designed to compare PK profile of tacrolimus hexal® with prograf® in renal Tx recipients (RTxR).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
**Methods:** In this prospective, two-phase open-label study, 76 de novo RTxR were randomized to receive tacrolimus hexal® (n = 35) or prograf® (n = 41), both in combination with enteryi-coated mycophenolate sodium + corticosteroids + basiliximab induction therapy. Starting dose of tacrolimus was 0.15 mg/kg/day, adjusted to target trough levels (C0) of 8–12 ng/mL from Tx to month (M) 1; 5–10 ng/mL up to M3; and 5–8 ng/mL up to M6. Primary objective of the study in Phase 1 was to demonstrate comparable PK (ratio of AUCn0-1 month one period, tac. hexal® vs prograf®). Here we present the PK results of the first month.

**Results:** At M1, the dose-normalised tacrolimus 12-h-AUC of 8/30XLL was comparable between tac. hexal® vs prograf® (adjusted log-transformed LS mean, 2.9 ± 3.0; difference, 0.076; 90% CI: -0.169, 0.321; p = 0.605; adjusted back-transformed LS mean, 19.0 ± 20.5; ratio, 1.079; 90% CI: 0.844, 1.378, p = 0.605). LS mean value for Cmax (1/10^3XLL) and mean 12 h tacrolimus C0 (mg/L) at M1 were comparable between tac. hexal® and prograf® (1.4 ± 0.9, 1.0 ± 0.8; 90% CI: 0.534, 0.737; C0, 12.2 ± 11.1, 11.1, respectively). Of 76 patients, 40 (PK-Sect 40 pts.) to date completed 6-M treatment; tac. hexal®, n = 19; prograf®, n = 21. At M6, tacrolimus hexal® vs prograf® had a comparable incidence of composite events (ITT, n=77; 5.7% vs 9.8%, p = 0.681) and its individual components (BPAR [5.7% vs 7.3%], graft loss [0.0% vs 2.4%], death [0.0% vs 2.4%]). Incidence adverse events (AES, SAFEs) were comparable (AES: 97.1% vs 100%; serious AES: 37.1% and 42.1%).

**Conclusions:** Tacrolimus hexal® has a PK profile similar to that of prograf®, with comparable efficacy and safety in de novo RTxR. **Funding:** Pharmaceutical Company Support - Novartis Pharma Germany

**Intensified Dosing of Mycophenolate Mofetil Formulated Is Associated With Slower Progression of Chronic Renal Allograft Injury – Results from a Randomized Controlled Trial**

**Mladen Knotek, 1 Miha Arnol, 2 Jadranka Buturovic, 3 Danica Galesic Lubicanovic, 2 Nika Jocic. 1**

**1Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Univ Hospital, Zagreb, Croatia; 2Dept of Nephrology, Univ Medical Center Ljubljana, Ljubljana, Slovenia; 3Inst of Pathology, Univ of Ljubljana Medical Faculty, Ljubljana, Slovenia.**

**Background:** Intestinal fibrosis (ci) is a major histological predictor of long-term graft outcome. This randomized controlled trial (NCT01860183) was designed to evaluate the effect of intensified mycophenolate mofetil (MMF) dosing on progression of ci during the first year post kidney transplantation (KT).

**Methods:** Immunologically-low-risk KT recipients were randomized to MMF 3g/d, or 2g/d during the first year post KT. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF ± steroids. Protocol biopsies were performed at implantation, and at 1, 3, 6, 12 and 24 months post-KT. Progression of ci (Di) was calculated as ci12-ci0. MMF dose was calculated as an average dose at 1, 6, 12 and 24 months. Difference in Di with respect to MMF dose was analyzed in an ITT population using one-way ANOVA.

**Results:** Here we report interim results from patients who completed 12 month follow-up by June 1st 2015. Patient and KT data are similar in MMF 3g and MMF 2g group, except for average MMF dose, which was higher in the 3g group (2967.1±321.6 vs. 1745.3±359.0 g, p<0.001). In an overall study population ci progressed during first 12 months by 0.45±0.51 (ci0) to 1.41±0.87 (ci12) (p<0.001). Di was lowest in the MMF 3 g group (0.06±0.74) as compared with MMF 2 g group (1.36±0.93; p<0.01). Serum creatinine at 1 year was similar in both MMF groups (116.5±25.0 vs. 115.1±33.7; p<0.001). Incidence of acute rejection was similar and no significant differences were seen in common adverse events between both groups.

**Conclusions:** Intensified MMF dosing (3g/d) daily during the first posttransplant year in a tacrolimus-based regimen may be associated with slower progression of chronic allograft injury.

**Funding:** Government Support - Non-U.S.

**Safe Conversion from Tacrolimus to Belatacept in Kidney Transplant Recipients with Allograft Dysfunction**

**Anil Reami, Dhiren Kumar, Hasan Fattah, Anne L. King, Pamela Kimball, Ankur Atal Gupta, Gaurav Gupta. Virginia Commonwealth Univ, Richmond, VA.**

**Background:** Belatacept might be an alternative to Calcineurin Inhibitors (CNI) to avoid short and long-term nephrotoxicity. Prior data on low immunologic risk de-novo kidney transplant recipients (KTxP) with stable graft function switched from a CNI to belatacept demonstrated improved renal function. There is minimal data on the use of belatacept for sensitized patients and those with impaired graft function [estimated glomerular filtration rate (GFR)<50].

**Methods:** EBV seropositive patients were converted to belatacept from tacrolimus for biopsy proven presumed acute CN1 toxicity and/or interstitial fibrosis/tubular atrophy. Belatacept was initiated based upon prior published protocol (Grimyo et al., Transpl Int 2012 Oct). Mycophenolate dose was increased from baseline dose of 1-2g/d to a dose of 2-3g/d to minimize risk of rejections.

**Results:** Seventeen (mean age=46±10 years) patients were switched from tac to belatacept at a median of 4 months post-KTxP. A majority were African-American (13/17; 76%) and received deceased donor KTxP (76%). Seven patients (41%) were sensitized (median PRA=13%; range=0-99%). Renal function improved significantly from a peak mean GFR of 28±12 ml/min/1.73m² to an GFR of 42±16ml/min/1.73m² (p<0.001) at a median follow-up of 15 (range=7-30) months post-conversion. Surveillance biopsies performed in 7/17 patients did not show rejection or worsening of chronicity. No evidence of de-novo donor specific antibody (DSA) was noted in 16/17 (94%) patients. One patient with pre-existing DSA and stable creatinine had rising DSA after a viral infection. A biopsy showed subclinical antibody-mediated rejection. There were no cases of BK viremia, CMV disease or malignancies.

**Conclusions:** In this first study on KTxP patients with significantly reduced GFR we report improved recognition in renal function in patients converted from tacrolimus to belatacept with acute CN1 toxicity and chronic allograft fibrosis without a significant concurrent increase in risk of rejection, worsening chronicity and DSA. Further studies with protocol biopsies are needed to ensure safety and wider applicability of this approach.
FR-PO1081

Infusion of Belatacept in Kidney Transplant Recipients

Flavio Vincenti, 1 M. Abouljoud, 1 JH Helderman, 2 R. Zhang, 3 K. Calderon, 4 S. Chen, 5 SG Rizk, 5 D. Gerber. 6
1Univ of California, San Francisco; 2Henry Ford Hospital, Detroit; 3Vanderbilt Univ, Nashville; 4Tulane Univ Hospital and Clinic, New Orleans; 5BMS, Lawrenceville; 6Univ of North Carolina, Chapel Hill.

Background: Belatacept (bela) is an IV administered selective T-cell co-stimulation blocker approved for preventing organ rejection in EBV-positive adult kidney transplant recipients. The logistics of IV maintenance therapy are challenging for some pts/clinicians; the safety of home infusion has not been well described. Phase 2/3 study participants had received bela home infusion if the site sought IRB approval and if the pt lived ≥2 hrs from the site and had been exposed to bela for >28 wks in 008 or >16 wks in 010, >6 wks in 034. 008 and 027 compared bela with CsA regimens with basiliximab induction. In 010, pts receiving a stable CNI regimen were switched to a bela regimen. 034 compared bela with tacrolimus steroid-sparing regimens under thymoglobulin induction. Rate and time to pre-specified peri-infusional AEs and peri-infusional serious AEs were recorded in pts who received bela in the home (N=66) or in a facility (N=672).

Results: Pts administered bela in the home received a median of 32.5 (range, 1–61) infusions. No pre-specified or serious peri-infusional AE was reported, including in the 034 study.

Conclusions: No pt (irrespective of steroid use) receiving home infusion of bela had a pre-specified or serious peri-infusional AE. These data suggest that bela was safely administered in the home.

FR-PO1082

Optimizing the Immunosuppression Regimen with Belatacept

David Wojciechowski, 1 Sinhdu Chandran, 2 Flavio Vincenti. 1 MGH; 2UCSF.

Background: Belatacept with basiliximab induction plus maintenance MMF/corticosteroids is associated with a higher 3-year eGFR compared to ciclosporine but a higher 1-year incidence of acute rejection. In an attempt to optimize the belatacept immunosuppression regimen we investigated the safety and efficacy of a novel combination utilizing belatacept with rATG induction (3 mg/kg) and maintenance everolimus ± immunosuppression regimen we investigated the safety and efficacy of a novel combination.

Methods: Retrospective single center analysis of the first 33 patients to receive our belatacept regimen compared to a historical control group of 66 patients matched for donor type, KDPI, ESRD cause, CIT, and corticosteroid protocol who met our belatacept inclusion criteria. We tested archival peripheral blood of 218 kidney recipients for CYP3A5 genotyping with PCR-SSP. The doses and blood concentrations of tacrolimus and CsA for recipients were measured at day7, 1st month , 3rd month,6th month and 12th month after renal transplantation, as well as hepatic and renal function. In addition, we also observed the incident of acute rejection happening on these participants.

Conclusions: 123 patients took tacrolimus treatment and 95 patients took CsA treatment after renal transplantation.In tacrolimus treatment group, genotype CYP3A5*GG was associated with low tacrolimus dose-adjusted concentration after transplantation, showing lower acute rejection rate compared to CYP3A5*AA/AG group but with no significant difference (P=0.154). In CsA treatment group, there was no significant difference in acute rejection rates between CYP3A5*AA/AG and CYP3A5*GG (P=0.494) with no difference in dose-adjusted concentration as well. For CYP3A5*GG patients, tacrolimus treatment cause lower acute rejection rate than CsA treatment (P=0.030), taking shorter time to get a stable immune situation than CsA treatment. For CYP3A5*AA/AG patients, tacrolimus treatment cause similar acute rejection rate with CsA treatment (P=0.982), but took longer time to get a stable immune situation than CsA treatment. What’s more, tacrolimus treatment costs much than CsA treatment.

Conclusions: These results indicate that CYP3A5*AA/AG carriers need higher tacrolimus dose than CYP3A5*GG homozygote to achieve the target blood concentration. And, the treatment selection of tacrolimus and CsA was associated with acute rejection rate. In conclusion, the selection of tacrolimus is recommended in kidney transplant recipients with CYP3A5*GG genotype, while CsA is preferred in patients with CYP3A5*AA/AG genotype.

FR-PO1083

A Change in Insulin Sensitivity and Lipid Profile in Renal Transplant Recipients Converted from Cyclosporine or Standard Release Tacrolimus to Once-Daily Prolonged Release Tacrolimus

Soo young Kim, 1 Young wook Yang, 1 Seok Shin, 1 Hyun Soon Jung, 1 Hark Rim, 1 Bong geon Chun, 1 Hyun yul Rhew. 2 Internal Medicine, Kosin Univ College of Medicine, Busan, Republic of Korea; 3Internal Medicine, Good Ganche Hospital, Busan, Republic of Korea; 1Pathology, Kosin Univ College of Medicine, Busan, Republic of Korea; 2Urology, Kosin Univ College of Medicine.

Background: New-onset diabetes after transplantation may be associated with the use of tacrolimus (Tac) causing impaired insulin release or reduced insulin sensitivity. And, dyslipidemia commonly occurred after transplantation. Such effects in insulin sensitivity and lipid profile have not been studied in renal transplant recipients receiving traditional twice-daily tacrolimus (TacBID) or cyclosporine and then compared to the new once-daily prolonged release formulation of tacrolimus (TacOD).

Methods: We performed an observational prospective study of 15 stable non-diabetic renal transplant recipients on change in insulin sensitivity and lipid profile in renal transplant recipients converted from cyclosporine or standard release tacrolimus to once-daily prolonged release tacrolimus. We evaluated the level of HbA1c,total cholesterol, HDL, LDL, TG, apolipoprotein A1, apolipoprotein B, serum creatinine, fasting plasma glucose, fasting insulin and HOMA-IR at baseline, two and four months. To analyze differences in parameter, we performed a t-test in both groups (cyclosporine to TacOD conversion group/TacBID to TacOD conversion group), and GLM-repeated measures ANOVA. HOMA-β = (360 X Fasting insulin)/(Fasting glucose-63) HOMA-IR (insulin resistance) = (Fasting glucose X Fasting insulin)/405.

Results: At baseline, parameters were not different in both groups (cyclosporine to TacOD conversion group/TacBID to TacOD conversion group). In GLM-repeated measures ANOVA, the result did not showed and any change in insulin sensitivity and lipid profile and variation in dose at baseline, two and four months.

Conclusions: Conversion from standard TacBID or cyclosporine to TacOD is safe. In spite of a reduced Tac exposure, there was no change in insulin sensitivity and lipid profile in renal transplant recipients.
FR-PO1085

Intraprotential Tacrolimus Level Variability in Pediatric Kidney Recipients Predicts Allograft Loss After Transfer to Adult Care
Hilda E. Fernandez,1 Sandra Amaral,1 Pamela A. Shaw,2 Roy D. Bloom,2 Alden Michael Doyle,1 Sumit Mohan,1 Susan L. Furth,2 Columbia Univ; CHOP; PENN; Hahnemann Univ.

Results: 74 of 56 subjects had sufficient data for analysis. Median age at transplant was 15.9 yrs (8.5-18.9). The cohort was primarily male (66%), White (77%), had CUKAT (8%), and 46% had LRKT. Median age at transfer was 20y (17.4-22.1). Four patients had allograft loss within 365 days post-transfer. Pre-transfer CV TAC with subjects post-allograft loss post-transfer (n=4) was significantly higher as compared to subjects without allograft loss (n=20) (49.4% vs 26.2%, p = 0.0275).

Conclusions: CV TAC may aid in identifying patients at risk for allograft loss post-transfer. Future analysis will investigate the effect of race, age at transfer, rejection, loss post-transfer (n=4) was significantly higher as compared to subjects without allograft.

High Tacrolimus Level Variability in the Early Post-Transplant Period Is Associated with Reduced Patients and Graft Survival After Kidney Transplantation
Benaya Rozen-zy1,1 Avry Chagnac,1 Ruth Rahamimov.1,2 Nephrology and Hypertension, Rabin Medical Center, Petach-Tikva, Israel; 2Organ Transplantation, Rabin Medical Center, Petach-Tikva, Israel.

Background: The effect of Tacrolimus levels variability in the early period after kidney transplantation has not previously been studied. We sought to evaluate whether increased drug level variability is associated with reduced graft survival and evaluate the relative effect of exposure to high and low drug levels.

Methods: We screened the Rabin Medical Center registry database for adult patients from 2001 to 2013 that were treated with tacrolimus, micophenolate mofetil and corticosteroids and had at least 6 values of drug level during the first six months after the transplantation. Variability was defined as the time average of the absolute value of the difference from the mean and this value was divided by the mean to get the variability index. Univariate and multivariate Cox proportional hazard model was used with the combination of death and graft failure as composite outcome.

Results: We identified 803 patients who met the inclusion criteria, ninety eight (12.2%) of them reached the end point during median follow up time of 3.7 years (range 0.5 to 12.9 years). Increased variability index was associated with increased hazard of death or graft failure by univariate (Hazard Ratio (HR) 1.029 per %, 95% Confidence Interval (CI) 1.006-1.052, p=0.013) and multivariate models (HR 1.036 per %, 95% CI 1.01-1.062, p=0.006). Variability was still significantly associated with reduced graft survival after introducing acute rejection into the model (HR 1.038 per %, 95% CI 1.008-1.06, p=0.006). Introducing exposure to levels above 15 ng/ml into the model didn’t change the association between variability index and the composite outcome while introducing exposure to levels below 5 ng/ml eliminated the association and made it non-significant (p=0.18).

Conclusions: High variability index in the first six month after kidney transplantation is associated with increased mortality and graft loss. This association is, probably, mediated by exposure to low drug levels.

Decision Tree Analysis of Renal Transplantation Recipients Outcomes: A Single Center Data Mining Jingye Zhou, Jianghua Chen. Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, China.

Background: Results from former literature on factors influencing renal transplant outcomes are quite confusion and few include factors influencing outcomes of rejection cases. This study was intended to get the factors in order and to provide reliable predictive models for clinical practice with decision tree analysis, and attempted to discuss about deceased donor integrated into renal transplant database, predict the daily model growth and to serve personal medical care in big data era.

Methods: Renal transplant recipients registering between May 1988 and April 2014 in Kidney Center of the First Affiliated Hospital of Zhejiang University were included. Living state, retransplant, treatment history, renal transplant database, predict the daily model growth and to serve personal medical care in big data era. The results of our study show that the ABOi spousal donor is an important source of living donor in kidney transplantations (KTx). We aimed to compare the clinical outcomes in ABO incompatible KT (ABOi-KT) to those of ABO compatible KT (ABOc-KT) from spousal donors.

Methods: We analyzed 580 KTs from spousal donors among 3043 living donors KTs registered in the Korean Organ Transplantation Registry. Clinical outcome between ABOi-KT and ABOc-KT were compared by episodes of acute rejection (AR), graft function, grafts and patients survival rates.

Results: The proportion of spousal donors in ABOc-KT was higher than that of ABOi-KT (40.9% vs. 21.4%, P = 0.001). The biopsy proven AR-free survival rate in ABOc-KT was comparable to ABOi-KT (79.7% vs. 82.3%, P = 0.188). The renal allograft function showed no difference until 16 months after KT. The 3-year graft survival (92.5% vs. 95.7%), and patient survival (96.4% vs. 98.5%) were not significantly different between ABOi-KT and ABOc-KT groups (P = 0.05, respectively). Multivariate analysis revealed that ABO-KT from spousal donors did not affect the graft, patient survival and BPAR-free survival rate.

Conclusions: The results of our study show that the ABOi spousal donor is an important source of living donor, and can be a good alternative of overcoming donor organ shortage.
FR-PO1090

Three Year Outcome of a Pioneer ABOi Renal Transplant Programme in Malaysia

Si-Yen Tan, 1 Mohan Rao, 2 Eng-Thye Koh. 2 Medicine, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia; 3Surgery, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia.

Background: ABO incompatible (ABOi) renal transplantation increases organ donor pool and is an option for patients with no blood group compatible donors. We report here results of a pioneer ABOi renal transplant programme in Malaysia which was first established in Prince Court Medical Centre in 2011.

Methods: Ten patients entered into our ABOi programme between July 2011 and December 2013. Data were analyzed to determine the number of therapeutic plasma exchange (TPE) and/or immunoadsorption (IA) with Glycosorb columns to achieve target pretransplant ABO antibody titres of $<1:16$ and ABO titres post transplant. Graft function and rejection rates together with graft and patient survival at 3 years were also determined.

Results: Median baseline ABO titres was 1:128 and all patients achieved target pre transplant ABO titres of $<1:16$ after a median of 4 TPE and/or IA. Median follow up was 32 months with all patients maintaining ABO titres of $<1:16$ at follow up with no protocol post transplant TPE/IA. There was 1 case (10%) of acute cellular rejection at one year which was reversed with steroids but none had antibody mediated rejection. Patient and graft survival was 100% at 3 years with current median serum creatinine 108umol/L.

Conclusions: The results of our pioneer ABOi renal transplant programme with graft and patient survival of 100% at 3 years is extremely encouraging and suggest that graft and patient outcome is similar to ABO compatible renal transplants. The use of ABO incompatible donors may effectively increase organ donor pools especially in countries where both cadaver and living related kidney transplant rates remain poor. Our results also suggest that national ABOi renal transplant programmes may be effectively introduced and led by a private medical centre to complement and support more established renal transplant programmes in government institutions which are now beginning to perform their own ABOi renal transplants in light of our success.

FR-PO1091

Improved Graft Outcome After Blood Transfusion: Still in Effect?

Gowrie Balasubramian, 1 Arun Gupta, 2 Neil Ashman, 3 Raj Thuraisingham. 2

Dept of Medicine, Southend Univ Hospital, Southend, Essex, United Kingdom; 3Dept of Nephrology and Transplantation, Barts and The Royal London Hospital, London, United Kingdom.

Background: Blood transfusions can lead to sensitisation in potential transplant patients. We previously quantified the risk of sensitisation from transfusion per se by looking at a cohort of male patients on the transplant waiting list and ascertaining the transfusion history from electronic records and questionnaires. Prior to standard triple immunosuppression, transfusions were associated with overall better graft outcome possibly by a tolerogenic effect or by selecting non-sensitisers. The majority of patients who were transfused do not become sensitised, we wanted to characterise graft outcome in this group.

Methods: We obtained graft outcome information on the original cohort of patients. Data was collected prospectively as part of routine surveillance.

Results: 100 out of the initial 126 male patients were transplanted. 10 were excluded from further analysis due to death or graft loss in the immediate post-transplant period. 11 of remaining 90 patients were DSA prior to transplantation, 8 also had a history of previous blood transfusion. 4 of the 8 patients with a previous blood transfusion and DSA had a rejection episode (2 AMR and 2 ACR). Of the remaining 79 patients who were DSA negative prior to transplantation, 26 had a previous transfusion (TR+ DSA-) and 53 did not have a history of transfusion (TR- DSA-). Comparison between the two groups is shown in (table 1).

Conclusions: Lack of sensitisation with a history of leuco-depleted transfusion is associated with a lower risk of rejection post-transplantation. This suggest that previous mechanisms of transfusion tolerance or “non-sensitisers” are still relevant in the modern immunosuppression era.

FR-PO1092

Geriatric Renal Transplantation in Deceased Donor Showed Compatible Clinical Outcomes to Younger Recipients

Hyungjin Cho, Eunhye Shin, Hyosang Kim, Su-Kil Park. Dept of Internal Medicine, Div of Nephrology, Asan Medical Center, Seoul, Republic of Korea.

Background: According to USA data annual report, while 50.3% of patients who start hemodialysis were aged over 65 years, only 19.3% of patients who underwent renaltransplantation was aged over 65 years. Elderly ESRD patients still are not underwent renal transplantation as much as younger recipients. There were many previous studies about geriatric renal transplantation outcome in white, however data in Asain were limited. The aim of this study is analysis of geriatric kidney transplantation outcome in Korea.

Methods: From May 1993 to December 2013, kidney transplantations performed in Asan medical center were retrospectively reviewed. Recipients younger than 20 years and who underwent other organ transplantation were excluded. Binary logistic regression was used for evaluating risk factors of graft failure before half-life. Half life of kidney allograft was defined as 10 years according to previous study.

Results: Regardless of donor type, there is no statistically significant difference in death censored graft survival between geriatric population and younger recipients.

Conclusions: Renal transplantation in geriatric population can be encouraged in Asain ESRD patients.

Multivariate analysis of deceased donor recipients revealed that recipients aged over 60 years was not a significant risk factor for graft failure before half-life.

Long-term Survival and the Associated Risk Factors for Death in Patients (pts) with Kidney Transplantation (Tx)  

Tania Abeling,1  Irina Scheffner,1  Verena Broecker,2  Michael Mengel,1  Hermann G. Haller,1  Anke Schwarz,1  Wilfried Gwinner,1  Hannover Medical School, Germany; 1Cambridge Univ, United Kingdom; 2Univ of Alberta, Canada.

Background: Deaths over a period of up to 10 years (yrs) and the related risk factors were studied in Tx pts with protocol biopsies (Bx) (total observation: 4805 patient-yrs).

Methods: 892 pts with kidney Tx in 2000-2007 were included. Protocol Bx were taken at 6 weeks, 3, and 6 months post-Tx (n=2251). 862 Bx for cause were taken in the 1st year and 262 thereafter. Lost-to-follow up was negligible (n=15). All acute rejections and clinical borderline cases in protocol Bx were treated.

Results: Patient and graft survival was 80% at 5 yrs and 68% at 10 yrs. Patient survival was 92% at 5 yrs and 82% at 10 yrs. 99 deaths occurred, relating to infection (24%), cardiovascular disease (15%), malignancy (16%), other specified causes (8%). Deaths were less in living donor or kidney/pancreas Tx and more frequent for extended donor criteria-Tx. A three-level multivariable Cox regression model was created in a stepwise fashion, using significantly different variables from the pre-Tx, peri-operative, and long-term post-Tx period between survivors and deceased pts. Pre-Tx variables in the final model included recipient age, HLA-DR mismatches, diabetes, coronary heart disease, heart failure, and peripheral arterial disease. A significant peri-operative variable was cold ischemia time. In the long-term course, variables for death included increased loss of graft function, urinary tract infection, and higher PTH levels. Compared to the survivors, deceased pts received more therapies for rejection seen in protocol Bx (0.30 vs. 0.43 per patient) and in Bx for cause (0.29 vs. 0.34 per patient), however, this was not a significant factor in the final model. Also, the proportion of anti-rejection treatments was not higher in pts who died from infections, compared to pts dying from other causes. Concordance of the final model was 0.79; 200-fold bootstrapping confirmed its applicability.

Conclusions: Based on these results a tool is presented that readily allows risk calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care.

Effect of Simultaneous Native Nephrectomy on the Outcome of Kidney Transplant Recipients with Autosomal Dominant Polycystic Kidney Disease  

Jeong Ho Kim, Bun soon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Byung ha Chung. Internal Medicine, Seoul St. Mary's hospital, Seoul, Korea.

Background: End stage renal disease (ESRD) patients with autosomal dominant polycystic kidney disease (ADPKD) required native nephrectomy because of limited space for renal allograft. However, the appropriate timing for nephrectomy and also its effect on allograft patient survival has not been fully investigated.

Methods: We retrospectively analyzed 41 kidney transplant recipients with ADPKD in whom transplantation was done either simultaneously, after or without native nephrectomy at Seoul St. Mary’s hospital between January 1987 and February 2014. We divided patients into 2 groups; simultaneous nephrectomy group (group A, n=13), after or without nephrectomy group (group B, n=28) and compared the perioperative outcome, post-transplant complications, allograft survival rate.

Results: The mean operation time was significantly longer in group A than group B (6.48 ± 1.84 vs. 5.27±0.84 hours; P = .048). The mean intraoperative blood transfusions was also significantly more needed in group A than B (3.66±3.43 vs. 0.75 ±0.26 units; P = .018). However, there were no differences in the incidence of acute rejection and/or complications such as post-operative bleeding, infectious complication between the two groups (P > .05, all). The graft survival rate also did not differ between the two groups (P > .05).

Conclusions: Our study suggests that the complication rates were acceptable and the influence of native nephrectomy was not a significant negative impact on graft survival rate when native nephrectomy was done during kidney transplantation in ADPKD patients with ESRD. Therefore, if native nephrectomy is needed in ADPKD for kidney transplantation it can be done safely during transplantation.

Predictors of Renal Function Change After Kidney Transplantation  

Yoshifumi Hamasaki,1  Kent Doi,2  Akihiko Matsumoto,2  Daigoro Hirohama,2  Nobuhiko Sato,2  Daikuse Katagiri,2  Rei Ishikii,2  Wakako Kawarazaki,2  Eisuke Noiri,3  Masaomi Nangaku.1  1Nephrology, UMC Groningen, Netherlands; 2Sphingotec GmbH, Germany; 3Cardiology, UMC Groningen, Netherlands.

Background: Several perioperative factors including histological findings of allograft biopsy are known to be associated with graft function. However, little is known about the longitudinal change of renal function (eGFR) in post-KT patients. It is unclear what factors in post-KT period predict the longitudinal change of renal function.

Methods: The data from post-KT patients followed at The University of Tokyo Hospital were collected retrospectively. Patients followed-up less than 6 months after KT were excluded. To identify predictors of the longitudinal change of renal function, we analyzed data including clinical parameters measured at each outpatient visit. The primary outcome was defined as the change of eGFR during 6 months period.

Results: 32 post-KT recipients were analyzed in this study. Age and eGFR at baseline of these patients were 51.3 ± 12.7 years old and 41.2 ± 16.1 ml/min/1.73m² (mean ± SD), respectively. The duration from KT to collection of clinical parameters was 6.8 ± 7.3 years (mean ± SD). Changes of eGFR were evaluated 6 months after. When patients were divided into two groups with (N = 15) and without (N = 17) eGFR decline after 6 months, uL-FABP and urinary protein were significantly higher in the eGFR decline group (uL-FABP; 11.6 ± 14.5 ng/ml/m² and urinary protein; 272.7 ± 97.2 mg/eGFR, respectively). On ROC analysis, uL-FABP and urinary protein predicted eGFR decline after 6 months (AUC [95%CI]) = 0.78 [0.60-0.96] and 0.70 [0.51-0.89], respectively. On multiple regression analysis, uL-FABP and urinary protein were significantly correlated with the absolute and relative eGFR changes during 6 months observation period.

Conclusions: uL-FABP and urinary protein measured at outpatient clinic can predict the change of renal function of post-KT patients.

Plasma Proenkephalin and Poor Long-Term Outcome in Renal Transplant Recipients  

Lynne M. Kienekeng1  Joachim Struck,2  Ron T. Gansevoort,1  Michel M. Joosten,1  Rudolf A. de Boer,2  Oliver Hartmann,2  Stephan J.L. Bakker.1

1Nephrology, UMC Groningen, Netherlands; 2Sphingotec GmbH, Germany; 3Cardiology, UMC Groningen, Netherlands.

Background: Enkephalins are well-known endogenous opioid peptides. Recent evidence indicates that they are not only involved in regulation of pain, but also in homeostasis of the immune system and the circulation. Proenkephalin (pro-ENK) is stable in plasma and has been established as a reliable surrogate marker for unstable opioid receptors. Recent studies found associations of pro-ENK with acute kidney injury and prognosis after myocardial infarction. We aimed to investigate whether pro-ENK could be linked to chronic kidney injury and poor long-term outcome in renal transplant recipients (RTR).

Methods: We included 664 RTR who were 8.1±7.6 years after transplantation. Plasma levels of pro-ENK were measured with a double monoclonal sandwich immunoassay.

Results: Mean age was 53±13 years, 56% was male, estimated glomerular filtration rate (eGFR) 49 ml/min/1.73m² (interquartile range [IQR]: 37-64 ml/min/1.73m²) and
urinary albumin excretion (UAE) 40 mg/24h (IQR: 10-196 mg/24h). Median pro-ENK was 110 pmol/L. (IQR: 85-148 pmol/L). Pro-ENK was correlated with both eGFR (r = 0.73, P<0.001) and UAE (r = 0.35, P<0.001). During a median follow-up of 3.1 years (IQR: 2.7-3.9 years), 45 RTR developed graft failure and 76 died. Pro-ENK was both associated with increased risk of graft failure (hazard ratio per standard deviation increment of the logarithm of pro-ENK, 2.57; 95% confidence interval, 1.69-4.5) and all-cause mortality (1.83; 1.24-2.69), independent of age, sex, eGFR, and UAE. These associations remained materially unchanged after additional adjustment for body mass index, alcohol consumption, smoking, systolic blood pressure, antihypertensive drug use, use of calcinurin inhibitors, and high-density lipoprotein.

Conclusions: High concentrations of pro-ENK are linked to chronic kidney injury as reflected by correlations with eGFR and UAE. In addition, pro-ENK was independently associated with increased risk of graft failure and mortality in RTR. Pro-ENK is an interesting new biomarker which may aid in early identification of RTR at risk for late graft failure and premature mortality.

FR-PO1098
Serum Albumin Level Has Association with Both Graft Failure and Mortality in Kidney Transplant Recipients
Hyo Jung Jeon, Yoon Seyeon, Eunjung Kim, Jung Pyo Lee, Ja-Ryong Koo. 1Department of Internal Medicine, Hallym Univ of College of Medicine, Seoul, Republic of Korea; 2Department of Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea.

Background: The studies concerned the association between post-transplant serum albumin concentration and post-transplant outcomes in kidney transplant recipients (KTRs) are scarce.

Methods: To evaluate the impact of serum albumin level on graft and patient survival, we performed a retrospective multi-center cohort study in Seoul National University Hospital, Asan Medical Center, and Kangdong Sacred Heart Hospital. A total of 2815 KTRs who underwent renal transplantation from Jan 1997 to Jan 2012 were classified into two groups according to the level of serum albumin at 1 year after transplantation (higher albumin group, >4.0 g/dL, n=1978 vs. lower albumin group, <4.0 g/dL, n=837). The Cox proportional hazard model was adjusted with age and gender of recipient, donor type, age of donor, diabetes mellitus, and estimated glomerular filtration rate (eGFR) at 1 year after transplantation.

Results: The mean age of the recipients was 41.7±11.3 (range, 18-73) years, and 59.1% were male. The rate of graft failure was higher in lower albumin group compared to higher albumin group (Hazard ratio [HR] 1.840, 95% confidence interval [CI] 1.367-2.477, P<0.001), even though eGFR at 1 year after transplantation was not different between the two groups (61.7±19.8 vs. 62.1±15.8 mL/min, P=0.615). Both all-cause mortality and non-cardiovascular mortality rates were higher in lower albumin group (HR 2.227, 95% CI 1.514-3.347, P=0.001, respectively). Every 1.0 g/dL higher serum albumin concentration was associated with 69.2% lower all-cause mortality (HR 0.308, 95% CI 0.196-0.483, P=0.001).

Conclusions: Serum albumin level at 1 year after transplantation is a prognostic factor for graft failure and patients’ mortality in KTRs. Therefore, evaluation and management for hypoalbuminemia should be considered to improve outcomes in KTRs.

FR-PO1099
Brain Effects of Renal Transplantation: Association Between Cognition and White Matter Integrity
Aditi Gupta, Rebecca J. Lepping, David K. Johnson, Alan S.L. Yu, William M. Brooks, Jeffrey M. Burns.

Background: Cognitive impairment is present in up to 87% patients with end stage renal disease (ESRD). Magnetic resonance imaging (MRI) using diffusion tensor imaging (DTI) shows lower fractional anisotropy (FA) values in these patients. FA values measure structural integrity of white matter and are associated with cognitive impairment. In this study we examine the effect of renal transplantation on cognitive function and determine whether changes in white matter integrity underlie the observed cognitive changes.

Methods: Adults with ESRD were recruited from the renal transplant waiting list. Subjects were evaluated before transplantation and 3 months after transplantation with neuropsychological (NP) tests and brain MRI. Two-tailed paired t-test was used to analyze changes in NP tests and FA values before and after transplantation.Pearson correlation coefficients were calculated.

Results: Two hundred patients were screened and eighteen enrolled. Ten subjects, 57±11 years of age have been transplanted and have completed the study. After transplantation, there was a significant improvement in NP tests for memory and executive function.

There was a significant increase in the FA values in the body of corpus callosum (P=0.017), fornix minor (P=0.058) and left cingulate gyrus (P=0.002). Furthermore, the improvement in NP tests positively correlated with the increase in FA values in these tracts.

Conclusions: Memory and executive function improve after renal transplantation, FA, a DTI metric representing white matter integrity also increases in brain regions important for these functions. This study provides insight into the neural mechanisms underlying cognitive impairment in ESRD and its improvement after transplantation.

Pre-Kidney Transplant Left Ventricular Ejection Fraction, Long-Term Allograft Function, and Survival
Asad Sardar, Mah A. Mohamed, Arjang Djamali, Sandesh Parajuli, Didier A. Mandellbrot, Brad C. Astor. Div. of Nephrology, Univ of Wisconsin Hospitals and Clinics, Madison, WI.

Background: End stage kidney disease patients with low left ventricular ejection fraction (LVEF) are considered high risk for poor outcomes following kidney transplantation (KT). No consensus exists on the level of systolic dysfunction below which patients are at increased risk of unfavorable allograft outcomes.

Methods: We studied 387 KT recipients transplanted from 1/02 to 12/09 who underwent pre-transplant invasive and non-invasive cardiac assessment of LVEF. Outcomes included Delayed graft function (DGF), allograft survival, patient survival and allograft function.

P-trend: 0.42 0.81 0.80 0.70 0.12 0.86

P: Confidence Interval, Ref: Reference

Data adjusted for age, sex, race, PRA, Duration of RRT, DM, CAD, LVH and Induction Therapy.

Associations between different LVEF values.

Results: A total of 136 (35.1%) patients had LVEF > 60%, 215 (55.5%) had LVEF between 45-60% and 36 (9.3%) had LVEF <45% before KT. Patients with low EF were more likely to receive non-cardiovascular and all cause mortality. During median follow up of 4.4 years there were 122 graft losses including 71 deaths. 73 patients (18.9%) had DGF. There was no significant difference in rate of DGF, serum creatinine, allograft survival and patient survival.

Conclusions: Low LVEF does not appear to significantly effect patient and allograft survival and function, suggesting that patients with low LVEF should not be excluded from transplantation.

FR-PO1101
Progression of Coronary Artery Calcification in Renal Transplant Recipients – A Follow-Up Of 7 Years
Sibel Gulcicek, Nurhan Seyahi. Div. of Internal Medicine, Div. of Nephrology, Istanbul Univ, Cerrahpasa Medical Faculty, Istanbul, Turkey.

Background: In the general population coronary artery calcification (CAC) and its progression is associated with cardiovascular and all cause mortality. We conducted a study to determine the progression of CAC in renal transplant recipients; we also examined the factors associated with progression and the impact of the analytic methods used to determine CAC progression.

Methods: We used multi-detector computed tomography to examine CAC in 113 prevalent renal transplant recipients, who did not have a documented cardiovascular disease. Measurements were performed and changes in CAC scores were evaluated in each patient individually, to calculate the incidence of CAC progression. Univariate and Multivariate logistic regression analysis was used to evaluate the determinants of CAC progression.

Results: Baseline CAC prevalence was 34.5% and the mean CAC score was 47.08 ± 135.25. At follow-up scan that was performed after an average of 6.9 ± 0.5 years, CAC prevalence increased to 47.6% and the mean CAC score to 140.18 ± 332.11. Progression of individual CAC score was found between 32.7 and 34.5 %, depending on the method used to define progression (Hokanson and Sevrukov). In patients with baseline CAC, median annualized rate of CAC progression was 13.8. Based on univariate analysis, age, presence of baseline CAC, high baseline CAC score, high body mass index were significantly associated with CAC progression defined according to both the Hokanson and Sevrukov methods. Moreover, HDL cholesterol level was significantly associated with CAC progression when progression was defined according to Hokanson’s method and donor type, high triglyceride levels and systolic blood pressure were significantly associated with CAC progression according to Sevrukov’s method. Based on multivariate analysis baseline CAC and high triglyceride were the independent determinants of CAC progression.

**Association Between Serum Magnesium Level and the Risk of New-Onset Diabetes After Renal Transplantation in Korea**

**Background:** New onset diabetes mellitus after transplantation (NODAT) is a serious complication following renal transplantation. Association between serum magnesium level and new-onset diabetes after renal transplantation is controversial. The aim of this study was to identify the association between serum magnesium level and the development of NODAT in Korea.

**Methods:** The recipients who underwent living donor kidney transplantation between January 2009 and April 2012 were reviewed. Diagnosis of NODAT is defined by American diabetes association criteria. Serum magnesium level were measured at pretransplant, 3 days, 7 days and 3 months posttransplant. Univaried and logistic regression analysis were performed to examine the association between serum magnesium level and NODAT at 1 year posttransplant.

**Results:** Total 419 patients were enrolled. NODAT was diagnosed in 85(20%) patients. Mean magnesium level at 3 and 7 days after transplantation was significantly lower in patients who diagnosed with NODAT. On logistic regression analysis, Age $>$40, Obesity, pretransplant glucose were associated with NODAT. However, there is no association between serum magnesium level and NODAT.

**FR-PO1105**

**Is NODAT Really Associated with Acute Rejection in Kidney Only Transplantation?**

**Background:** Previous reports suggest an association with New Onset Diabetes After Transplantation (NODAT) and rejection however it is unclear whether this effect is secondary to hyperglycaemia or a result of previous episodes of treated rejection. This observational study aims to determine the association between acute rejection (AR) and NODAT.

**Methods:** 381 renal transplant recipients (RTR) from the KALIBRE study were analysed. Clinical details and laboratory results were collected in this cohort from 2010-2014. Episodes of AR were identified by renal transplant biopsies;Banff 2009 Categories 2&4 and 3 that were treatment responsive. NODAT was defined as HbA1c$>$6.5% at 3 months post renal transplantation. Cox’s regression proportional hazards was used for survival analysis. diabetes was divided into RTRs (35 female, 64% white, 39% non-white, Age at transplant range: 17-75). 47 patients were diagnosed with NODAT (13.1%) and 93 (24.4%) with AR. 17/47 (36.2%) patients with NODAT had AR. Rejection free survival in NODAT group was significantly lower than patients without NODAT (p=0.036 HR 1.75). Mean tacrolimus...
levels between rejectors and non-rejectors were not significantly different (10.1 and 10.3 mg/dL, respectively). T1DM and T2DM combined did not increase the rates of rejection in the cohort.

**Conclusions:** An association between NODAT and AR has been observed that was independent of tacrolimus levels. RTRs with diabetes mellitus did not have the same effect on AR rates suggesting a different underlying mechanism specific to NODAT rather than just hyperglycaemia.

**Insulin Resistance: Is It a Risk Factor for Left Ventricular Hypertrophy in Pediatric Renal Transplant Recipients?**

**Jale Sever, Nur Canpolat, Gulseren Pehlivan, Salim Caliskan. Pediatric Nephrology, Istanbul Univ Cerrahpasa Faculty of Medicine, Istanbul, Turkey.**

**Background:** Renal transplantation reverses uremia-related risk factors for cardiovascular disease; however, immunosuppressive therapy causes metabolic abnormalities such as insulin resistance, hyperglycemia and dyslipidemia. The aim of the present study was to evaluate the effects of these metabolic abnormalities as a risk factor for left ventricular hypertrophy in pediatric renal transplant recipients.

**Methods:** This is a retrospective study involving 31 renal transplanted children and adolescents (19 male; age 4-20 years) and 19 healthy controls. Anthropometric indices, office blood pressure (BP) and laboratory measurements and also left ventricular mass index (LVMI) at the same time were recorded from the patients’ Icc The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated. Insulin resistance was defined as a HOMA-IR ≥ 2.5. Dyslipidemia was defined as HDL-C<40 mg/dL, and/or LDL-C >130 mg/dL, and/or TG >150 mg/dL.

**Results:** Age at transplantation was 12.4±4.4 years with a median follow-up of 27 months. One patient received pre-emptive transplantation, 25 were on PD and 5 on HD before transplantation; 25 patients received a kidney from a living donor. Triple immunosuppressive therapy was used in all patients, except two who were not using steroids at the time of the enrolment. Patients had significantly higher BMI-SDS, fasting glucose, fasting insulin, HOMA-IR and TG as well as lower HDL-C levels than controls (p<0.05 for all). Nine patients (29%) had insulin resistance; 11 (42%) were dyslipidemic; and 15 (50%) were hypertensive. LVMI was significantly higher in the patients than the controls (40.0±0.9 vs. 25.8±5.71; p<0.001); left ventricular hypertrophy was noted in 11 patients (48%). LVMI correlated only with indexed diastolic BP (r=0.433, p=0.039), however, not with any of the lipid parameters or HOMA-IR. HOMA-IR was correlated with only BMI (r=0.381, p=0.035). There was no association between HOMA-IR and steroid doses.

**Conclusions:** Although insulin resistance and dyslipidemia are prevalent in pediatric renal transplant recipients, hypertension appears to be the main risk factor for left ventricular hypertrophy.

**FR-PO1107**

**Mediterranean Type Diet Is Associated with Low Risk of New-Onset Diabetes and Mortality After Renal Transplantation**

**Maryse Ostl,1 Eva Corpeleijn,1 Gerjan Navis,1 Charlotte A. Keyzer,1 Sabita Soedamah-muthu,2 Else van den Berg,1 Daan Kromhout,1,2 Stephan J.L. Bakker,1,2 Univ of Groningen;1 Univ of Wageningen, Netherlands.**

**Background:** The incidence of new-onset diabetes after transplantation (NODAT) and cardiovascular events leading to premature mortality is high in renal transplant recipients (RTR). We hypothesized that a Mediterranean type diet protects against development of NODAT and premature mortality in RTR.

**Methods:** In a prospective cohort study consisting of 707 adult stable RTR with a median follow-up of 3.8 (IQR, 3.0-4.6) years, multivariable regression analyses were used to study the association of the Mediterranean type diet with development of NODAT and mortality. Cox multivariable regression analyses were used to study the association of the Mediterranean diet with the development of NODAT and mortality.

**Results:** In total 474 RTR (56.8%) were included with a mean ± SD age of 51.5 ± 13.2 years. At baseline, 256 (54%) had a high resemblance to that of a Mediterranean type diet. During median follow-up of 3.8 (IQR, 3.0-4.6) years, 28 (6%) developed NODAT and 52 (11%) patients died. RTR with ≥ 5 points were both significantly associated with a lower risk of developing NODAT (hazard ratio [HR], 0.43; 95% confidence interval [CI], 0.20-0.95; P=0.04) and mortality (HR, 0.54; 95% CI, 0.31-0.98, P=0.03), both adjusted for age and sex. The results of multivariable analyses, in which we adjusted for potential confounders including total energy intake, physical activity and smoking status, did not materially change the results of the analyses adjusted for age and sex.

**Conclusions:** Dietary habits that resemble the Mediterranean type diet may protect against NODAT and mortality after kidney transplantation. More attention should be directed to the nutritional habits of renal transplant recipients.
Intra-Abdominal Hypertension and Renal Dysfunction in Pregnancy

Wonnaram Kittanamongkolchai, Elliott G. Richards, Mari Charisse B. Trinidad, Wendy White, Vesna D. Garovic, Nephrology, Mayo Clinic, Rochester, MN; Maternal Fetal Medicine, Mayo Clinic, Rochester, MN.

Introduction: The effects of high intra-abdominal pressure (IAP) on renal function have been known for over a century. However, the diagnosis of peripartum intra-abdominal hypertension (IAH)/abdominal compartment syndrome (ACS) is challenging due to the lack of a single threshold normative values of IAP in pregnancy.

Case Description: A 32-year-old G1P0 at 33 weeks gestation was admitted for intractable nausea and vomiting. She was oliguric and unresponsive to IV fluid. Her blood pressure was normal. Cr increased from a baseline of 0.6 mg/dL to 2.9 mg/dL. She was diagnosed with preeclampsia. A FeNa obtained after fluid resuscitation was 0.02%. Renal ultrasound showed patent renal vessels and no hydrophrenbladder. A diuretic was given with slight improvement in urine output. IAP measured by an intravascular catheter was 35 mmHg, and abdominal perfusion pressure (APP) (difference between mean arterial pressure and IAP) was 46 mmHg (normal ~50-60 mmHg). She was suspected to have IAH/ACS and was closely monitored. 2 days later, she developed hypertension, an increase in liver transaminases, and proteinuria. The decision was made to deliver with delivery due to severe preeclampsia. IAP measured immediately after C-section decreased to 18 mmHg, and it was 7 mmHg prior to delivery. Urine output increased to 2.5 L per day and Cr declined to 0.7 mg/dL after delivery.

Discussion: Animal and human studies indicate that oliguria and acute kidney injury are frequent consequences of IAH/ACS, and can be present at relatively low levels of IAP. In our case, the IAP of 35 mmHg was quite extreme compared to IAP of 4-28 mmHg observed in cohort studies of peripartum patients. We suspected that obesity and twin pregnancy contributed to the extreme IAH. Her APP was significantly low and restoration of renal function was readily observed after reduction of IAP. Our case may support the theory that IAH develops due to increased intra-abdominal pressure caused by respiratory or aortic compression. Restoration of IAP is probably underestimated as IAH is not routinely measured. Further study is needed to elucidate the impact of IAH in pregnancy.

Diabetes, Deafness and Renal Disease – A Case Report

Introduction: Deafness and kidney disease as well as diabetes and kidney disease are associations of which the Nephrologist is well aware. However, the concomitance of the three is not as usual, neither is a family history of these diseases.

Case Description: A 23-yo male with NS due to biopsy proven with non-nephrotic proteinuria, no haematuria, normal renal function, slowly progressive bilateral sensorineural hearing loss and recently diagnosed diabetes and maculopathy and a maternal family history of deafness, diabetes and renal disease. The patient progressed with increasing proteinuria despite antiproteinuric measures and a renal biopsy was performed, revealing Focal and Segmental Glomerulosclerosis (FSGS). Amyloid syndrome and Fabry disease investigation was negative. Facing the personal and maternal family history, the mitochondrial mutation m3243A>G was pursued and identified in heteroplasmy and maternally was negative. Renal function was readily observed after reduction of IAP. Our case may support the theory that IAH develops due to increased intra-abdominal pressure caused by respiratory or aortic compression.

Diabetes, Deafness and Renal Disease – A Case Report

Sonya Godinho, Ian Godinho, Nephrology, Santa Clara Valley Medical Center, San Jose, CA.

Introduction: Chronic denymelinating Polineuropathy Associated with Advanced Focal Segmental Glomerular Sclerosis

Albert Nedzunju, Rada Petrinjac-Neadeic, Lelka K. George, Elvira Gosmanova, Nephrology, UTHSC, Memphis, TN; Neurology, Tri-State Neurology, PLLC, Memphis, TN.

Introduction: Chronic denymelinating polineuropathy (CDP) is rarely reported in patients with nephrotic syndrome (NS). CDP tends to manifest concomitantly with NS. We report a case of CDP developing at a time of focal segmental glomerular sclerosis (FSGS) progression to ESRD and mimicking uremic neuropathy.

Case Description: A 23-yo male with NS due to biopsy proven two years before was diagnosed with focal segmental glomerulosclerosis (FSGS) and serum creatinine (Scr) 1mg/dL was initiated on oral prednisone and lisinopril. He was lost to follow up and returned 1.5 years later complaining on burning pain and numbness in both feet for 4 weeks. Physical exam was normal except for unsteady gait, inability to perform tandem gait, decreased sensation from feet to upper legs, depressed Achilles and ankle flexor reflexes. Laboratory tests showed Scr 44mg/dL, hyperkalemia, metabolic acidosis, normocytic anemia, and normal creatinine phosphokinase. A diagnosis of ESRD due to progression of untreated FSGS was made and dialysis was started. CT head and MRI spine were normal. Cerebrospinal fluid had protein of 74 mg/dL and glucose of 43 mg/dL. Electromyography (EMG) showed absent compound muscle action potential (CMAP) and F-waves in both peroneal and tibial nerves, active denervation in tibialis anterior, gastrocnemius and extensor digitorum brevis muscles, and prolonged distal latencies and reduced action velocity with normal amplitude of CMAP on both arms and sensory nerves action potentials on sural and peroneal nerves were absent with prolongation of peak latencies on other nerves. The constellation of clinical, EMG and normal inflammatory, infectious and autoimmune laboratory markers was consistent with diagnosis of CIDP. Plasmapheresis was performed with partial improvement of neurological symptoms and was followed by intravenous immunoglobulin as an maintenance therapy.

Discussion: CIDP should be considered in patients presenting with peripheral neuropathy and history of FSGS. Correct diagnosis of CDP is critical as untreated CDP leads to inability to walk. Autoimmune mechanisms may be responsible for CDP and glomerular damage in FSGS but remain to be proven.

Silicone Implant Associated Acute Kidney Injury in a Male Transgender Patient

Frank J. O’Brien, Brian Y. Young, Div of Nephrology, Santa Clara Valley Medical Center, San Jose, CA.

Introduction: Obstructive kidney disease secondary to nephrolithiasis is a well-described cause of acute kidney injury. Stone formation is often due to dietary or metabolic factors, often no predisposing factors are found. We describe a rare case of obstructive acute kidney injury associated with hypercalcemia and hypercalciuria in a 32-year-old transgender patient. Patient was found to have granulomatous disease associated with silicone implants.

Case Description: 32-year-old male to female transgender patient presented to our institution with fatigue. Routine labs showed creatinine 11 mg/dL, BUN 140 mg/dL, K 7 mmol/L. She was emergently dialedyzed, and imaging showed obstructing ureteric calculus, requiring bilateral stent insertion. Patient had a history of silicone implants in hips, buttocks and thigh 5 years previous. These were inserted by a non health care professional. There was no history of calculus production or ingestion therapy use. Diagnosis work up for nephrolithiasis revealed, 24 hour urinary calcium 886 mg/24 hours, serum calcium 12.5 mg/dL, phosphorus 8.0 mg/dL. Other 24-hr UFT results were normal. ACE level was 216 units/L. CXR was normal. PTH and malignancy work up was negative. CT abdomen revealed subcutaneous edema in lower back/gluteal area, around the sites of previous silicone implants, and inguinal lymphadenopathy. Subsequent gallium scan showed tracer uptake around silicone implant site and increased activity in left lower quadrant. Blood pressure was 127/67 mmHg. There was minimal peripheral edema. Urinalysis showed small blood, 100 mg/dl protein, 0-2 wbc, 0-2 rbc, and free fat. His serum creatinine was 0.78 mg/dl. He had 1 gram of urine protein per gram of urine creatinine. His proteinuria had ranged from 1.3 to 2.9 gms/gram over the preceding four months. Serological testing showed a negative RPR, negative tests for hepatitis B and C, and an antinuclear antibody of 1:640 titer. A kidney biopsy showed Fabry disease and superimposed membranous nephropathy. Lisinopril 2.5 mg/day was started. Rheumatological evaluation showed no evidence of lupus or rheumatoid arthritis. The most recent urine protein to creatinine ratio was 0.71 gram/gram, with a serum creatinine was 0.8 mg/dl.

His kidney biopsy stained positive for anti-agalsidase, but normal control kidney did not. He had anti-agalsidase antibodies in his serum that did not block agalsidase activity. Immunofluorescence for the phospholipase A2 receptor (PLA2R) was negative within the glomeruli and his serum did not have antibodies to PLA2R.

Discussion: Enzyme replacement therapies may lead to allo-reactivity. Membranous nephropathy has been described in three such patients but not in Fabry disease. Its occurrence may change the therapy of the primary disease and force specific treatment of the nephritis superimposed on the primary disease.

Funding: Veterans Administration Support, Clinical Revenue Support
Isolated Diplopia Caused by Calcineurin Inhibitor Therapy in a Patient with Idiopathic Membranous Nephropathy  
Nader S. Bahri, Ashwani K. Gupta.  
Nephrology and Hypertension, Univ of Florida, Jacksonville, FL.

Introduction: Neurotoxicity is a common side effect of treatment with calcineurin inhibitors. Tremors are frequently reported as the most common manifestation. Variable presentations can include headaches, seizures, visual hallucinations or blindness. Sixth nerve palsy has been reported in previous cases of bone marrow and cardiac transplant patients receiving calcineurin inhibitors. In many of these previously reported cases, the drug was administered intravenously and very high drug levels were found.

Case Description: 42-year-old Caucasian female with biopsy proven idiopathic membranous nephropathy (IMGN) who was being treated with tacrolimus and prednisone for nephrotic syndrome. Her tacrolimus levels were maintained between 6-8 ng/mL. Her urine protein/creatinine ratio of 8 g/gm was successfully reduced to less than 1 g/gm. She continued to be in complete remission but after 3 months of therapy she presented with diplopia. The diplopia was binocular and vertical. The patient was seen for an ophthalmologic evaluation. Her visual acuity was 20/20. Pupils were equal and reactive to light and accommodation. No nystagmus was observed. Visual fields and color vision was also normal in both eyes. Assay for Acetyl-choline receptor antibody was negative.

The patient remained compliant with her medications despite the side effects. At this time she was switched to low dose Cyclosporin (CyA) in anticipation that similar side effects may not be observed. Trough CyA levels were 44 ng/mL and 59 ng/mL on two occasions but her symptoms did not resolve. A consultation with neuro-ophtalmology was sought and the patient was instructed to discontinue CyA. The symptoms completely resolved 4 days after stopping CyA.

Discussion: This is the first reported case of isolated diplopia secondary to calcineurin inhibitors in low doses for treatment of IMGN. Monitoring of serum concentrations of this drugs has not been correlated with toxicity. The mean duration to onset of symptoms can be as much as 70 days suggesting accumulation of the drug in the central nervous system plays a role. Recognition of this condition is important for prompt diagnosis and appropriate management.

Bilateral Renal Artery Stenosis in a Patient Treated with Nilotinib for Chronic Myeloid Leukemia  
Omar M. Shababeet, Milos N. Budisavljevic.  
Medical Univ of South Carolina.

Introduction: The use of tyrosine kinase inhibitors (TKIs) targeting the BCR-ABL oncoprotein has been successful in chronic myeloid leukemia (CML). Nilotinib is a second generation TKI designed and used to overcome deficiencies of imatinib such as resistance or intolerance. Nilotinib also received approval in chronic phase (CP)-CML for superior response rate and less progression to blast crisis compared to imatinib. Reports suggest peripheral artery disease (PAD) as an adverse drug reaction associated with the use of nilotinib. We describe a case of bilateral renal artery stenosis in a patient treated with nilotinib.

Case Description: A 45 year old Caucasian male diagnosed with BCR-ABL positive CML at age 31. He was treated with Hydrea followed by Gleevec and was in complete remission (CR) for 4 years when he developed ALL transformation necessitating therapy. He continued to be in complete remission but after 3 months of therapy she presented with diplopia. The diplopia was binocular and vertical. The patient was seen for an ophthalmologic evaluation. Her visual acuity was 20/20. Pupils were equal and reactive to light and accommodation. No nystagmus was observed. Visual fields and color vision was also normal in both eyes. Assay for Acetyl-choline receptor antibody was negative.

The patient remained compliant with her medications despite the side effects. At this time she was switched to low dose Cyclosporin (CyA) in anticipation that similar side effects may not be observed. Trough CyA levels were 44 ng/mL and 59 ng/mL on two occasions but her symptoms did not resolve. A consultation with neuro-ophtalmology was sought and the patient was instructed to discontinue CyA. The symptoms completely resolved 4 days after stopping CyA.

Discussion: This is the first reported case of isolated diplopia secondary to calcineurin inhibitors in low doses for treatment of IMGN. Monitoring of serum concentrations of this drugs has not been correlated with toxicity. The mean duration to onset of symptoms can be as much as 70 days suggesting accumulation of the drug in the central nervous system plays a role. Recognition of this condition is important for prompt diagnosis and appropriate management.

Eculizumab in Management of Thrombotic Lesions in Kidney Allograft of Patient with Anti-Phospholipid Syndrome  
Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero.  
Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.

Introduction: Thrombotic microangiopathy (TMA) is one of the hallmark vascular lesions of anti-phospholipid syndrome (APS). These lesions are at high risk of recurrence after kidney transplantation. The complement pathway is thought to be active in this process by deposition and by presence of apoptotic and vascular cell markers on sequential pathological lesions. Eculizumab is a humanized anti-C5 monoclonal antibody which has been used in atypical hemolytic uremic syndrome. Recently, there have been reports of use of Eculizumab in transplant patients with APS-LTMA. The patient has been treated with Eculizumab and has remained in remission.

Case Description: We present a case of a 58 year old Caucasian man with history of systemic lupus erythematosus, APS on warfarin, hypertension, rheumatoid arthritis, transient ischemic attack, coronary artery disease with triple vessel bypass, chronic kidney disease stage 5 for which he received pre-emptive living unrelated kidney transplant. After an uneventful post-transplant course, he was discharged on warfarin. He presented to the hospital 4 days later, with acute renal failure, pain over the graft and sub-therapeutic INR. A perinephric collection was drained. Cytomegalovirus and BK polyoma viremia were ruled out. Transplant kidney biopsy, revealed TMA with segmental necrosis and small vessel fibrin thrombi and no acute rejection. High dose steroids along with aggressive anticoagulation management were received. Two sessions of plasma exchange. After meningococcal meningitis immunization, Eculizumab 900mg/week was started. After 4 doses, Eculizumab was changed to 1200mg/two weeks. Creatinine trended down from 7.3 to 3.0 mg/dl and dialysis was stopped after 7 sessions. He was positive for IgG anticardiolipin, beta-2 glycoprotein, and lupus anticoagulant and was started on daily aspirin and warfarin with INR goal of 2.5-3.5. The patient continued to respond well and showed rapid and dramatic improvement of graft function in our patient and should be considered in difficult to manage TMA/APS-LTMA in transplant patients. Its use permits a safer approach of controlling the complement final common pathway.

Transient Gestational Diabetes Insipidus in a Patient with Pre-Eclampsia  
Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero.  
Dept of Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.

Introduction: Diabetes insipidus (DI) is manifestation of post pituitary insufficiency characterized by polyuria and polydipsia. DI can be neurohypophyseal, nephrogenic, polydipsia related or gestational (GDI). L-deamino-8-D-arginine vasopressin (DDAVP) is a vasopressin analogue which had higher and prolonged anti-diuretic activity with no effects on smooth muscle. An increase in urine osmolality by at least 50% following administration of DDAVP is diagnostic of disorder.

Case Description: We present a case of a 22-year-old African American primigravida woman with no past medical history, in 32nd week of pregnancy, admitted with pre-eclampsia with no liver injury. On admission, blood pressures were between 140-160/60-70. After an uneventful delivery she had urine output ranging 6-9 liters along with polydipsia. Both of these were present all through out her third trimester. On exam there was no evidence of volume overload or dehydration. Labs were sodium 137mEq/L, Potassium 2.8mEq/L, Alb 3.0mg/dl, TSH 4.16, urea nitrogen <0.3, creatinine 0.4, serum osmolality 284, urine osmolality 141, spot urine protein to creatinine ratio of 0.8. With one dose of subcutaneous DDAVP/polydipsia resolved and osmolality to 385 within 24hrs. Oral DDA VP is diagnostic of disorder.
Utility of Hemodialysis in Urea Cycle Disorders

SA-PO011
A Case Report of Baclofen Toxicity in a Hemodialysis Patient
Sweta Carpenter, Sandeep Aggarwal. Nephrology and Hypertension, Drexel Univ.

Introduction: The dangers of baclofen toxicity in patients with advanced kidney disease and in particular patients on dialysis remain underestimated by many physicians.

Case Description: We present a case of a 64 year old male who developed an uncommon case of altered mental status during his hospitalization. His medical history included ESRD for which he was receiving in-center hemodialysis, diabetes and hypertension. He initially presented to the hospital with complaints of shortness of breath and hiccups. His shortness of breath was attributed to volume overload and resolved with two consecutive days of dialysis with fluid removal. For his intractable hiccups, he was started on baclofen. During his hospitalization, he became lethargic and was unable to move his lower extremities. Laboratory data including serum sodium, potassium, glucose, calcium, BUN, phosphorus, liver enzymes, thyroid function tests, troponins, inr and prothrombin work up and ammonia levels were unremarkable. Neuroimaging, including CT head and brain MRI, were unchanged from previous studies and revealed moderate diffuse cerebral atrophy. An EEG was also performed and did not suggest signs of epileptic activity. Further investigation revealed that he had received a total of 20 mg of baclofen over 2 days. After other etiologies were ruled out, we determined that he may have suffered from baclofen induced encephalopathy. His baclofen was stopped and he was prescribed daily sessions of hemodialysis for three days with the intent of clearing baclofen. He was dialyzed for 4 hours during each dialysis session with a high flux dialyzer. After his first session of dialysis, the patient was more alert and would follow simple commands. At 3 days, the patient’s mental status returned to baseline and he was able to move his extremities.

Discussion: Although the kinetics of baclofen elimination during hemodialysis are not well understood, this case demonstrates the resolution of baclofen induced encephalopathy with frequent and consecutive dialysis. Furthermore, we hope this case raises awareness among physicians of the toxic effects that baclofen can cause in dialysis patients.

SA-PO012
Utility of Hemodialysis in Urea Cycle Disorders

Introduction: Urea cycle disorders (UCDs) are rare pediatric diseases but partial enzyme deficiency can persist throughout adulthood. Little has been published about the role of hemodialysis in addressing the acute complications of UCDs in adulthood. Catabolic enzyme deficiency can persist throughout adulthood. Little has been published about the role of hemodialysis in addressing the acute complications of UCDs in adulthood. Catabolic states, he developed a second acute hyperammonemia (270mcg/dl). He was treated with a protein restricted diet of 35 grams per day and Na phenyl butyrate & L-citrulline). This pre-specified protocol (infusion of Na Phenylacetate/benzoate and Arginine HCl, fasting and short term treatment) that led to his ammonia level to 34mcg/dl. Later, patient underwent a procedure and was kept on a conservative approach with a combination of diet and medications. This was continued for 6 months and the patient was stable.

Discussion: The dangers of baclofen toxicity in patients with advanced kidney disease and in particular patients on dialysis remain underestimated by many physicians. We report a case of a 64 year old male who developed an uncommon case of altered mental status during his hospitalization. His medical history included ESRD for which he was receiving in-center hemodialysis, diabetes and hypertension. He initially presented to the hospital with complaints of shortness of breath and hiccups. His shortness of breath was attributed to volume overload and resolved with two consecutive days of dialysis with fluid removal. For his intractable hiccups, he was started on baclofen. During his hospitalization, he became lethargic and was unable to move his lower extremities. Laboratory data including serum sodium, potassium, glucose, calcium, BUN, phosphorus, liver enzymes, thyroid function tests, troponins, inr and prothrombin work up and ammonia levels were unremarkable. Neuroimaging, including CT head and brain MRI, were unchanged from previous studies and revealed moderate diffuse cerebral atrophy. An EEG was also performed and did not suggest signs of epileptic activity. Further investigation revealed that he had received a total of 20 mg of baclofen over 2 days. After other etiologies were ruled out, we determined that he may have suffered from baclofen induced encephalopathy. His baclofen was stopped and he was prescribed daily sessions of hemodialysis for three days with the intent of clearing baclofen. He was dialyzed for 4 hours during each dialysis session with a high flux dialyzer. After his first session of dialysis, the patient was more alert and would follow simple commands. At 3 days, the patient’s mental status returned to baseline and he was able to move his extremities.

Discussion: Although the kinetics of baclofen elimination during hemodialysis are not well understood, this case demonstrates the resolution of baclofen induced encephalopathy with frequent and consecutive dialysis. Furthermore, we hope this case raises awareness among physicians of the toxic effects that baclofen can cause in dialysis patients.

Treatment of Atypical Hemolytic Uremic Syndrome Early in Pregnancy with Eculizumab
Rahul N. Pawar, Savneek S. Chugh, Amy R. Patel, Prachi Kale. Nephrology, Westchester Medical Center, New York; *Internal Medicine, Westchester Medical Center.

Introduction: Atypical Hemolytic Uremic syndrome (aHUS) is known to cause acute thrombotic microangiopathy (TMA) in pregnancy with adverse maternal and fetal outcomes. A French study showed that aHUS usually occurs postpartum when activity of plasmatic coagulation inhibitor regulatory proteins decreases. We present a case of a young lady early in pregnancy with severe thrombocytopenia and acute renal failure suspicious for TTP, but later diagnosed with aHUS, which improved with eculizumab.

A 30 year old G1P5A5LS 10 weeks pregnant with a past medical history of 5 first trimester miscarriages presented with nausea, vomiting and wasting. Laboratory results which are labs show a hemoglobin (Hgb) 7.8 g/dl, platelet (PLT) count 15k/ul, BUN 65 mg/dL, serum creatinine 2.44 mg/dL along with a LDH of 1,847 U/L, haptoglobin <8 mg/dl, and albumin 3.2 g/dL. Liver function tests (LFTs) and coagulation studies were normal. She was suspected to have TTP and transferred to our tertiary medical center. Urinalysis revealed 3+ protein and 3+ blood. Skin smear showed schistocytes. A diagnosis of TMA was made and plasmapheresis was started. Serologies for lupus and anti-phospholipid antibody syndrome were negative and LFTs remained normal, ruling out HELLP. The ADAMTS-13 activity level was noted to be 129%. Renal function declined requiring the initiation of hemodialysis(HD). On the basis of ongoing hemolytic anemia with thrombocytopenia, renal failure and a negative ADAMTS-13, she was started on Eculizumab. After 2 doses, her renal function and urine output improved and HD was stopped. At discharge, her Hgb was 8.5 g/dL, PLT 150 K/ul, and BUN/creatinine 23/1.84 with the plan to receive monthly eculizumab infusions.

Discussion: aHUS is caused by activation of the complement system due to a genetic deficiency of its regulatory proteins, specifically complement factor H, factor I, and factor IIB. It can lead to TMA causing multi-organ failure and the potential for death if not managed in time. Pregnancy can cause aHUS in any trimester. One should maintain a low suspicion for aHUS in a pregnant patient with prompt initiation of eculizumab to prevent negative outcomes.

SA-PO014
Ashvin Bang, Anam Khan, Celia A. Peña, Rajeev Raghavan. Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: Relatively few renal manifestations have been detected in Familial Mediterranean Fever (FMF). We present a case of biopsy proven pauci-immune glomerulonephritis (GN) in a patient with clinically diagnosed FMF and review past treatments of pauci-immune GN in FMF patients.

Case Description: We present an interesting case of a 22 year old man who had suffered for nearly seven years a constellation of symptoms including fever, nausea, vomiting, abdominal pain, arthralgias, chest pain, and an erythematous rash consistent with a clinical diagnosis of Familial Mediterranean Fever. He had a normal serum creatinine of 1.0 mg/dl which peaked at 2.0 mg/dl. Repeated urinalysis indicated 6-10 RBCs per high powered field (phf) and 6-21 WBCs phf. Laboratory testing revealed only an elevated erythrocytosis. A kidney biopsy was performed which revealed 41% of the glomeruli globally sclerosed and 54 % of the viable glomeruli with active crescents and 25% interstitial fibrosis with tubular atrophy. Immunofluorescence revealed minimal C3 staining. This was consistent with Pauci-Immune Glomerulonephritis or ANCA negative vasculitis treated with Colchicine and pulse steroids, and maintained with mycophenolate mofetil as detection for mutations in the MEFV gene in the diagnosis of FMF is ongoing. He has had no relapse of his FMF with initiation of colchicine and now has had resolution of his hematuria, proteinuria, and acute kidney injury.

Discussion: In the literature, there is minimal knowledge about the renal manifestations of Familial Mediterranean Fever and fewer documented reports on the treatment protocols for ANCA negative vasculitis in FMF. We were able to treat ANCA negative vasculitis in a patient with FMF with only pulse steroids and maintenance immunosuppression with mycophenolate mofetil with great response.

SA-PO015
Stress of Surgery – Is It Just Mental or Can It Be Renal as Well?
Mital Natu Patel, Maria M. Picken, Kavitha Vellanki. Nephrology, Loyola University Medical Center, Maywood, IL.

Introduction: Waldenstrom’s macroglobulinemia (WM) is a rare clinicopathological disorder with a reported annual incidence of 3 per million people. It is characterized by Ig M monoclonal gammopathy in the blood and lymphoplasmacytic lymphoma in the bone marrow. Clinical manifestations are non-specific and generally related to Ig M infiltration of hematopoietic tissues. While deposits of Ig M in the glomerular basement membrane may be seen, renal failure per se is unusual. Here, we present a unique case of recurrent acute kidney injury (AKI) post-operatively in a patient with underlying WM with spontaneous recovery each time.

Case Description: 75 year old woman with WM, hypertension, obstructive sleep apnea and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis and spinal decompression. Under post-operative care she developed AKI on postoperative day day 3. She had gradual worsening of lower extremity swelling and shortness of breath and repeat labs showed a serum creatinine of 3.32 mg/dl (0.94 times her baseline).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
mg/dl, 5 days prior) and renal service was consulted for AKI. She had a prior episode of AKI with knee replacement in 2008, dialysis dependent for 3 days, with spontaneous recovery. Further work up revealed fairly active urine sediment with new onset 24 hour urine protein of 3.3 grams. C3 was normal, C4 < 5 mg/dl, cryoglobulin was positive, rheumatoid factor of < 20 ug/dl, serum Ig M were elevated at 646 mg/dl (normal 46-304 mg/dl) and serum immunofixation showed an abnormal restricted band between the beta and gamma regions. Kidney biopsy showed strongly PAS positive hyaline-like precipitates in the glomerular capillaries with immunofluorescence strongly positive (3+) for IgM and lambda light chains. There were abundant, confluent electron dense deposits in the mesangial and subendothelial space. Her symptoms improved with diuresis and she refused any other major intervention. Renal function eventually improved with serum creatinine of 1.2 mg/dl at the time of discharge.

**Discussion:** In conclusion, we believe the stress of surgery precipitated intraglomerular deposition of Ig M leading to AKI with spontaneous resolution thereafter.

**SA-PO016**

**New Causes of Secondary Hyperparathyroidism: Unforeseen Effects of New Drugs on the PTH-Calcium Axis**

*Shintaro Mandai, Shinichi Cherise M.*

Nephrology, Baylor Univ Medical Center, Dallas, TX.

**Introduction:** Calcium homeostasis is a function of the interplay between GI absorption, renal excretion and bone resorption. Although numerous effectors control these processes, PTH is primarily responsible. PTH affects the kidney and bone through PTH receptor 1. In the kidney PTH decreases phosphorus reabsorption, increases calcium reabsorption and stimulates 1-hydroxylation of vitamin D. In the bone PTH up-regulates expression of RANKL and decreases expression of osteoprotegrin. This process increases RANKL binding to RANK on osteoclast precursors stimulating them to become osteoclasts that increase bone resorption. New drugs that inhibit RANK are used to treat osteoporosis and bone metastases. We describe two patients who treated with recently developed chemotherapeutic agents who developed severe hypocalcemia, and secondary hyperparathyroidism with hyperphosphatemia due to renal PO4 wasting. We hypothesized that these drugs inhibit RANK.

**Case Description:** Case 1: A 72 y/o woman with metastatic leiomyosarcoma received Trabactinib, an experimental agent which interacts with DNA. She subsequently complained of weakness. Labs are shown. Case 2: A 73 y/o man with ALL positive for BCR-ABL was torted on the tyrosine kinase inhibitor Dasantabn. He subsequently developed the laboratory abnormalities shown.

Creatinine was 0.7 mg/dl in patient 1 and 0.8 mg/dl in patient 2.

**Discussion:** Both patients developed secondary hyperparathyroidism. The renal effects of PTH appeared to be intact with increased calcium resorption, phosphorus excretion and hydroxylation of 25-Vitamin D. The effects of PTH on bone resorption, however, appeared blunted. Because PTH acts on both kidney and bone through the same receptor, we believe that this represents a post receptor phenomena involving the RANKL osteoprotegrin system. The tyrosine kinase inhibitor, Iminatinib, has been shown to decrease bone resorption through a similar mechanism. As new drugs are developed it is important to recognize potential untoward effects.

**Funding:** Clinical Revenue Support

**Connection or Coincidence: Behçet’s Disease and Focal Segmental Glomerulosclerosis with Nephrotic Syndrome**

*Deanne Leonard, Cherise M. Cortese, Xochiquetzal J. Geiger, Nabeel Aslam. Mayo Clinic, Jacksonville, FL.*

**Introduction:** Behçet’s Disease (BD) often presents with aphthous and genital ulcers, uveitis, and erythema nodosum. Rarely, renal amyloidosis, IgA nephropathy and crescentic glomerulonephritis result. Here we present a case of nephrotic syndrome from focal segmental glomerulosclerosis (FSGS) in a patient with BD evidence to suggest a direct connection.

**Case Description:** 49 y/o female with history of hypertension and BD on enantecpet, colchicine and carvedilol. Following a recent prednisone taper, she developed oral ulcers, uveitis, pathergy reaction and proteinuria. Physical exam: Blood pressure: 170/90, aphthous ulcer, uveitis, and 3+ bilateral leg edema. Laboratory data: serum albumin 3.3 g/dl, total cholesterol 205 mg/dl, triglycerides 1.1 mg/dl. Urinalysis: 3+ proteinuria, 10 RBC/ hpf and a random protein/creatinine ratio of 8.5. Normal complement levels, DS-DNA, SS-A, SS-B, Sm Ab, RNP Ab, ScI 70 ab, and Jo Ab. Renal biopsy: Light microscopy: focal segmental lesions. Immunofluorescence: IgM trace mesangial granular staining, consistent with immunoglobulin trapping. IgG, IGA, C3, C1q, kappa, and lambda: negative. Electron microscopy: near total visceral epithelial foot cell process effacement with villous formation.

**Treatment** included losartan and prednisone 1 mg/kg/day which resulted in resolution of edema and reduction of protein to creatinine ratio to 0.14 along with resolution of oral ulcers and uveitis.

**Discussion:** At present, there is no proven correlation between BD and FSGS with nephrotic syndrome. Our patient presented with BD flare coinciding with the development of nephrotic syndrome both of which improved simultaneously with steroids suggesting a direct connection. Therefore, the clinician should be aware of this possible link and screen accordingly for proteinuria both qualitatively and quantitatively to detect early renal involvement in patients with BD.

**SA-PO018**

**Reversal of Dialysis-Dependent Renal Failure and Nephrotic Syndrome after Conservative Therapy in an Adult with Proliferative Glomerulonephritis with C3-Dominant Deposition**

*Eriko Takehara, Shintaro Mandai, Shinichi Uchida.*

**Introduction:** C3 glomerulonephritis (C3GN) is a recently described entity in a reclassification of membranoproliferative glomerulonephritis, characterized by isolated or predominant glomerular C3 deposits. Although abnormalities in the alternative pathway are known to be involved in the pathogenesis, efficient therapeutic approaches have yet to be established.

**Case Description:** In December 2012, a 55 year-old man was admitted with rapidly progressive glomerulonephritis and nephrotic syndrome. In May 2011, his serum creatinine(Scr) was 0.63mg/dL. Seven weeks previously, he was admitted to another hospital with hemorrhagic gastric ulcer accompanied by renal failure (Scr 4.61 mg/dL, urinary protein 15 g/gCr, and moderate hematuria), in the absence of preceding infection. At admission to our hospital, Scr increased to 7.60 mg/dL. ANCA, anti-nuclear antibody, and decrease in complement factors were absent. A renal biopsy specimen showed crescentic and endocapillary proliferative GN with dominant C3 and trace IgG. Conservative therapy was started, given the repeated hemorrhagic ulcer, and decreased rate of renal function decline. Hemodialysis was initiated on hospital day 20 because of oliguria, but was ceased on day 60 with recovery of kidney function. Scr decreased to 1.2 mg/dL, and urinary protein decreased to < 1 g/gCr. One year after discharge, he developed nephrotic-range proteinuria, and the second renal biopsy revealed the increased sclerotic glomeruli and fibrous crescents with isolated C3 deposits.

**Discussion:** To our knowledge, this report is the first to describe reversal of dialysis-dependent renal failure after conservative therapy in a C3GN patient. Similarly to the present case, the histological morphology and clinical presentation infrequently mimic the picture of postinfectious GN, although the transient recovery is usually partial. A novel classification of such cases among C3GN may be needed to avoid an unnecessarily immunosuppression.

**SA-PO019**

**Optical Coherence Tomography and En Face Retinal Findings in Membranoproliferative Glomerulonephritis Type 2**

*Paula Delegrego Ophtalmology and Visual Sciences Dept, Universidade Federal de Sao Paulo - UNIFESP, Sao Paulo, Brazil; Nephrology Dept, Universidade Federal de Sao Paulo - UNIFESP, Sao Paulo, Brazil.*

**Introduction:** Membranoproliferative glomerulonephritis type 2 (MPGN II) is a condition with electron dense deposits in the glomerular basal membrane that usually affects youngsters of 5-15 years old. Patients may have asymptomatic retinal drusen-like deposits in the macula or drusen-like lesions in the periphery. We evaluated patients with a high-speed spectral-domain optical coherence tomography (SD-OCT) device and en face OCT imaging of the retina.

**Case Description:** Four eyes of 2 patients with MPGN II were scanned using a high-speed 840-nm-wavelength SD-OCT (RTVue XR Avanti; Optovue, Inc, Fremont, USA). The split-spectrum amplitude-decoration angiography algorithm was used to detect blood flow. Fluorescein angiography (FA) (HRA System, Heidelberg Engineering) images were obtained in search for drusen-like deposits in the Bruch membrane or choroidal neovascularization.

Both patients, female, 34 years old and male, 25 years old, had best corrected visual acuity of 20/20 in both eyes, unremarkable anterior biomicroscopy, RPE mobilization and macular drusen-like deposits. There was no choroidal neovascularization at the FA. En face OCT showed hyporeflective dots with a hyperreflective ring at the RPE that corresponds to drusen-like deposits underneath the RPE and dilated choroidal image.
Discrimination: We reviewed a rare case of disseminated HSV infection and PD-related HSV peritonitis. The combination of ESRD, hypogammaglobulinemia, cellular and humoral immunity, and BP contributed to the severe immune-compromised state and disseminated HSV infection. Since an early diagnosis determines the prognosis of disseminated HSV infection, cell pathology in peritoneal fluid would assist preemptive therapy.

SA-PO022
Use of Rituximab in Goodpasture’s Disease with Pulmonary Hemorrhage
Scherly Leon, Vadim Abramov, Farouk Talakshi, Mary C. Mallappalli, Moro O. Salifu.
Medicine, Renal Div. Downstate Medical Center, Brooklyn, NY.

Introduction: Goodpasture’s syndrome (GPS)or anti-GBM disease is a rare autoimmune disease, where pathogenic autoantibodies deposit in the basement membrane. It presents with rapidly progressive glomerulonephritis, with or without pulmonary hemorrhage. The current standard treatment of Anti-GBM disease is immuno-suppression to reduce antibody production and plasmapheresis to remove existing antibodies in circulation. Rituximab, a monoclonal antibody directed against CD-20 antigen present on B-lymphocytes, approved for various B-cell lymphoproliferative diseases has been used in ANCA associated vasculitis with success; however it’s use in anti-GBM disease is scarce and data regarding safety and efficacy is lacking. We report use of Rituximab in the treatment of GPS with pulmonary hemorrhage.

Case Description: A 35-year-old man presented in 2012 with two week history of nausea, vomiting, intermittent fevers and dark urine. Laboratory findings were creatinine 18 mg/dL, potassium 6.1 mmol/L, Hgb 11.6 g/dL, and platelet count 288 x 10^9 per µL. Urinalysis showed nephrritic urine sediment. Serology test including ANCA was negative. Anti-GBM antibodies levels were greater than 8 with peak 27. CT chest with pulmonary angiography was given to rule out pulmonary hypertension and initiate therapy. Renal biopsy was consistent with GPS (cresccentic GN linear anti-GBM on IF). Plasmapheresis was initiated and patient received four doses of Rituximab. Anti-GBM level on discharge from hospital was 2.9. Since initial presentation, patient had two admissions to the hospital in 2014 and 2015 with undetectable Anti-GBM levels.

Discussion: Patients with anti-GBM renal disease have high mortality, especially when pulmonary involvement is present. The use of steroid, immunosuppressives and plasmapheresis alone or in combination has led to a significant improvement of both patient survival and clinical symptoms. Anti-GBM disease is a rare autoinfectious disease; data regarding the safety and efficacy of alternative therapies are lacking. There are few reported cases of anti-GBM disease treated with rituximab. We present a case of anti-GBM disease with pulmonary hemorrhage successfully treated with Rituximab.

SA-PO013
A Rare Case of Aluminum Toxicity
Khrum Salameh, Khaleed Boobes, Yazar M. Alia, Muhammad H. Hasan, Jennifer A. Tiazon.
Nephrology, Northwestern Memorial Hospital, Chicago, IL.

Introduction: Aluminum toxicity was initially described in encephalopathic patients with renal failure, overdosing of aluminum-based phosphate binders and attributed to contamination of water used for dialysis treatments. Use of alum for the treatment of refractory hemorrhagic cystitis was first reported in 1982. It was described as a safer alternative to formalin bladder irrigation. We report a case of bladder perforation after alum irrigation, leading to intra-peritoneal aluminum exposure. Our patient expired despite chelation and renal replacement therapy. Her serum aluminum concentration is the highest reported level to date.

Case Description: 67 year old female with cervical cancer, admitted for urosepsis, was noted to have hematuria and urinary retention. Her catheter was changed due to clot obstruction and bladder irrigated with saline. Following day continuous bladder irrigation was instituted for persistent hematuria. She underwent cystoscopy with fulguration for persistent hematuria secondary to radiation cystitis. Her CIBM was noted with alum irrigant. Overnight, alum irrigant was placed on a pump for infusion. Hours later, patient transferred to ICU for hypotension. CT abdomen revealed free intraperitoneal air, large volume of new fluid, air around bladder suspicious for bladder perforation, and absence of contrast outside of the bowel. Bilateral percutaneous nephrostomy performed for urinary diversion and to evacuate free fluid. Aluminum levels were drawn. Patient was intubated, placed on vasopressors. Had non-gap metabolic acidosis and worsening renal function, concerning for acute kidney injury due to intra-abdominal bladder perforation in the setting of alum irrigation. Deferoxamine was started and CVHVI for acidosis. However patient developed refractory shock, and expired. Shortly before her death, aluminum level resulted 163.7mcg/L (normal 0 to 20mcg/L). Subsequent levels peaked at 1455.2mcg/L.

Discussion: We report systemic absorption of alum-containing irrigant following bladder perforation. Large aluminum load to the peritoneum resulted in systemic toxicity,multi-organ failure and death. Chelation therapy and CVHVI were inadequate. We report the highest serum aluminum level to date.
Case Description: We describe 54 year old Male with a history of Deceased Donor Renal transplant in 1999 whose kidney disease was secondary to Hypertensive nephrosclerosis. Donor information is not available. The patient had been in his usual state of health until one week prior to presentation, when he started feeling weak and became confused, reason for hospitalization.

A computed tomography of the large mass measuring 5.4 x 2.9 cm ,in the corpus callosal splenium and second lesion 8 x 9 mm, in the left parietal lobe. He had a biopsy done which revealed a GBM. Neurosurgery was consulted and mass was found to be unresectable. Neuro-Oncology was consulted and he was advised radiation therapy and possible chemotherapy, but he decided to seek second opinion. His Post-transplant period has been remarkable for a borderline rejection with donor specific antibodies, treated with plasmapheresis and IVIG. His immunosuppressant medications were Cyclosporine , Mycophenolate mofetil and prednisone.

Discussion: Review of the literature indicates that gliomas do not seem appear in an early post-transplant period. These tumors have been reported mostly after 4-20 years from renal transplantation. Increased risk of tumour occurrence may be related immunological disorders such as HIV, and also to the administration of immunosuppressive drugs. Few studies have shown that cyclosporine may induce phenotypic changes in different tumoral and normal line cells and may play a role in modulating the neoplastic course. There seems to be a existence of a relationship between glioblastoma development and kidney transplant, but this association needs to be studied further. With increasing life expectancy of transplant recipients, evaluation of the risk of serious complications such as glial tumors is necessary.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Our case suggests that podocytes can engulf crystals in a similar manner, despite lacking tubular cells by receptor-mediated endocytosis, where they form protease resistant crystals. Confused as other forms of systemic vasculitis and therefore early identification and prompt specifically on the treatment of ANCA-negative patients. Such patients could be easily patients were treated similarly to ANCA-positive patients, although no study has focused patients only 7% were found to have GI manifestations and 17.9% had skin rash. These manifestations. In a study done in China comparing clinical features of ANCA negative PGN were segmental fibrinoid necrosis and early cellular crescents with mild increase in cellularity of mesangial matrix. Immunofluorescence: IgG, IgM, IgA, C3, C1q, kappa and lambda chains was negative. USG showed normal sized kidneys. Renal biopsy: Light microscopy showed no segmental glomerulosclerosis with characteristics of cryoglobulinic GN. The patient was referred to hepatology for evaluation showed microscopic hematuria, red blood cell casts, 1.2 grams of proteinuria, and thereafter suffered from persistent fever. With a diagnosis of bacterial pneumonia, he attended a work-associated physical examination that revealed proteinuria and Genotype 3a diagnosed 5 yrs ago, presented with complaints of intermittent vasculitis and MPGN without cryoglobulinemia being less frequent.

### SA-PO030

**Erythematous Skin Rash and Gastrointestinal Bleeding as Presenting Features of ANCA Negative Pauci-Immun Glomerulonephritis**

**Introduction:** Pauci-immune glomerulonephritis (PNG) is one of the common causes of RPGN. In most patients with PNG, circulating antineutrophil cytoplasmic autoantibody (ANCA) is present, however 10% of the patients are ANCA-negative. Usually extra renal manifestations in ANCA negative PGN are rare, but the case reported here is a rare presentation having skin rash and gastrointestinal (GI) manifestations.

**Case Description:** A 50-year-old female was admitted with low-grade intermittent fever, erythematous maculopapular rash all over the body and asympotomral artheritis involving large and small joints for about 3 months. She had one-week history of pain abdomen and melena followed by decreased urine output and generalized edema. On examination BP 156/94 mmHg, Birmingham Vasculitis Activity Score of 23/63. Investigations: Hb 9.9 g/dL, serum creatinine 4.0 mg/dL, urinalysis - protein ++, RBC 2-3/hpf. 24 hour urine protein 4.75gm/day. Serum uric acid and C3 were normal. Serum ANA, pANCA, cANCA, and RA factor were negative. Skin biopsy for IgG, IgM, C3, C1q was negative. USG showed normal sized kidneys. Renal biopsy: Light microscopy showed no segmental glomerulosclerosis with mild increase in cellularity of mesangial matrix. Immunofluorescence: IgG, IgM, IgA, C3, C1q, kappa and lambda chains were negative. Diagnosis of ANCA negative pauci-immune GN with crescents was made and patient was started on systemic steroids and cyclophosphamide pulse therapy. Patient improved symptomatically and creatinine levels gradually declined.

**Discussion:** Patients with ANCA negative PGN rarely present with skin and GI manifestations. In a study done in China comparing clinical features of ANCA negative patients only 7% were found to have GI manifestations and 17.9% had skin rash. These patients were treated similarly to ANCA-positive patients, although no study has focused specifically on the treatment of ANCA-negative patients. Such patients could be easily confused as other forms of systemic vasculitis and therefore early identification and prompt treatment could prevent many life threatening complications and improve prognosis.

**SA-PO031**

**A Case of ANCA-Associated Nephritis Mainly Localized to the Tubulointerstitial Area, Successfully Treated by Steroid Therapy**

**Introduction:** The typical pathological findings of antineutrophil cytoplasmic antibody (ANCA)-associated nephritis consist of extracapillary proliferation and necrotizing crescent formation. Nevertheless, a few cases of ANCA-associated nephritis, in which the tubulointerstitial area was mainly affected, are reported. Here, we present such a case of ANCA-associated tubulointerstitial nephritis, and review its characteristics compared to ANCA-associated glomerulonephritis.

**Case Description:** A 74 year-old generally healthy female developed bilateral hearing loss, and thereafter suffered from persistent fever. With a diagnosis of bacterial pneumonia, she was admitted to another hospital and treated with several broad-spectrum antibiotics without improvement. Four weeks later, she was referred to our hospital. On admission, weight loss and peripheral numbness and weakness was noted in addition to advanced hearing loss and fever. Serum creatinine level was elevated to 3.5 mg/dL, while urinalysis revealed mild proteinuria with few red blood cells and no cast in the sediment. Sinusitis and alveolar hemorrhage were observed by CT scan. Immunological tests demonstrated positive myeloperoxidase (MPO)-ANCA (104 U/ml). In view of multiple organ involvements, ANCA biopsy, thc vasculitis was suspected. Renal biopsy showed diffuse interstitial infiltrates and remarkable vasculitides in small arteries and capillaries with only a small number of crescentic glomeruli, which was consistent with ANCA-associated tubulointerstitial nephritis. Steroid therapy ameliorated not only kidney dysfunction, but also hearing loss.

**Discussion:** In an atypical case of ANCA-associated nephritis with near normal urinalysis, we need to consider the possibility of tubulointerstitial nephritis.
dose steroids, plasma exchanges, and a second dose of Rituximab, with clinical and renal improvement. One month after discharge, he was re-admitted with ARDS and diagnosed with B-cell lymphoma.

Discussion: There is a paucity of data on anti-HCV therapy in patients with renal failure often resulting in a delay of antiviral therapy. Immunomodulatory therapies may provide significant improvement of symptoms but bear the risk of significant adverse reactions. Early initiation of antiviral therapy is vital in order to prevent spectrum of HCV related complications.

SA-PO034
A Case of Membranous Nephropathy with an Adjacent Smooth Muscle Cell Tumor
Laith Al-Ababud,1 Cathy J. Byrne-Dugan,2 Stanley D. Crittenden,1 Helmut G. Rennke,2 Laurence H. Beck,1* Boston Medical Center; 2Brigham and Women’s Hospital.

Introduction: Different stromal tumors can occur in the kidney and potentially skew the true extent of parenchymal injury induced by different glomerular diseases. Most of these stromal tumors are benign. The value of renal biopsy in assessing interstitial sequelae may be compromised by the mass effect of the infiltrating tumor cells.

Case Description: We describe a case of a 65 year old male patient, with a history of primary membranous nephropathy 20 years ago. He had initially been treated with the Pontocell protocol with favorable response. He continued to be in remission until a few months prior to presentation when he developed anasarca. His 24 hour urine collection revealed 8 grams of protein, and creatinine was 1.8 mg/dL. The decision was made for the patient to undergo a kidney biopsy which confirmed recurrence of primary membranous nephropathy with positive staining for PLA2R. It also revealed advanced chronic changes that included focal global glomerulosclerosis (87%) in addition to interstitial fibrosis 80%.

However, adjacent to this atrophic area, there was a tumor of spindle-shaped cells with smooth muscle characteristics. There was no atypia or mitosis and no clear capsule but the tumor cells appeared to infiltrate and surround the tubules and vasculature. This was labeled by the pathologist as a fragment of a smooth muscle cell tumor of undetermined malignant potential. The possibility of leiomyosarcoma could not be ruled out. MRI abdomen and pelvis did not show any evidence of extra renal involvement. The possibility of the parenchymal tissue being significantly infiltrated by its close proximity to the tumor prompted us to pursue another renal biopsy from the other kidney. Surprisingly, repeat biopsy showed only 15% of tubular atrophy and interstitial fibrosis. The patient was initiated on Rituximab and tolerated two courses of treatment. He achieved partial remission with UPCR less than 3 gram with stable Cr at 1.8 mg/dL.

Discussion: Coexistence of smooth muscle tumors and membranous nephropathy is rare. The extent of parenchymal involvement should be confirmed, with repeat biopsy, when there are concerns about tissue distortion by neighboring tumor.

SA-PO035
Freezing Point: Sjögren’s Disease Leads to Cryoglobulin Induced Membranoproliferative Glomerulonephritis
Manuel A. Fernandez Palmer, Roberto L. Collazo-Maldonado. Nephrology, Methodist Dallas Medical Center; Dallas, TX.

Introduction: Sjögren’s disease is chronic autoimmune inflammatory disorder mainly affecting salivary and lacrimal glands but rarely it can present with systemic manifestations including kidney involvement. The kidney manifestations may include hypokalemic RTA, interstitial disease and rarely MPGN.

Case Description: This is a 30 year old woman with no medical history who arrived to ER complaining of a three day history of SOB and increasing edema on lower extremities. She denied toxic habits. Review of systems positive for lower extremity rash in the preceding weeks. PE: was pertinent for elevated BP at 159/90 mmHg, 94% O2Sat on NC at 2LPM, bibasilar crackles with decreased breath sounds at bases and lower extremity pitting edema. Labs showed HGB of 10 g/dL, creatinine of 1.32 mg/dL with normal electrolyte, albumin levels 3.4 mg/dL/UA with proteinuria and hematuria, and a BNP that was markedly elevated. CXR showed pulmonary edema and bilateral moderate pleural effusions. Patient was admitted and workup performed, including CT which was negative, lower extremity Doppler that was negative for DVT. Creatinine increased to 2.6 and proteinuria was quantified at 4 g/24hrs. Serologic work up was negative except for low Complement levels along with a positive rheumatoid factor, positive anti-SsA. Clinical presentation and labs consistent with a diagnosis of Primary Sjögren’s disease.

Cryoglobulin levels where negative but kidney biopsy was performed and results consistent with Membranoproliferative Glomerulonephritis with intra capillary thrombi highly suggestive of cryoglobulins. Patient was started on high dose steroids and received five plasma exchanges. Afterwards, Rituximab 375 mg/m² was administered at weekly intervals three times four. At the time of discharge creatinine had stabilized at 0.95 mg/dL.

Discussion: Despite being rare, Sjögren’s Disease can lead to cryoglobulin formation and subsequent deposition in different tissues of the body. Nephrologists must consider this rare complication when evaluating patients with proteinuria, especially when there is worsening renal function and other systemic symptoms.

SA-PO036
Postinfectious Glomerulonephritis Associated with Escherichia coli Infection Caused by Transurethral Prostatectomy
Eleni Chelioti, Alexia Papalexandrou, Evdokia Ethimiou, Maria Sotiraki, Ioannis Xatzis, Maria Tsilivigou. Dept of Nephrology; General Hospital of Piraeus, Athens, Greece.

Introduction: Postinfectious glomerulonephritis (PIGN) is an immune-mediated glomerulonephritis(GN) caused by non-bacterial renal infection. In adults, PIGN is more common in immunocompromised patients, particularly diabetics. The major site of infection is the urinary tract, followed by the skin. In terms of causative agents, Staphylococcus is the most common cause in elderly people, followed by Streptococcus. Gram-negative bacteria, including Escherichia coli (E. coli), are responsible for up to 10% of cases of adult PIGN and 5% of cases in the elderly. We report a patient with PIGN associated with E. coli infection caused by transurethral prostatectomy.

Case Description: A 76-year-old Caucasian man with a history of coronary artery disease and recent transurethral prostatectomy was admitted with complaint of fever, and urenic symptomatology that necessitated dialysis therapy. Blood and urinary cultures were positive for E. coli and patient responded to antibiotic therapy. After one week, he was afebrile, without amelioration of renal function and with signs of glomerular involvement: urine red blood cells- 20-40/HPF, 24-hour urine proteins=1.7g. Immunological analyses were negative, except for decreased C4. The diagnostic approach led to a renal biopsy that findings were consistent with PIGN: endocapillary proliferative and exudative GN on LM, C3-dominant glomerular staining on IF and hump-shaped subepithelial deposits on EM. After urinary tract infection was controlled by antibiotic therapy, oral methylprednisolone was initiated, and the patient’s renal function and nephritic syndrome subsequently gradually improved.

Discussion: For a diagnosis of PIGN, at least three of the following five criteria must be satisfied: 1) clinical or laboratory evidence of an infection preceding the onset of GN 2) decreased serum complement levels 3)endocapillary proliferative and exudative GN on LM 4)C3-dominant or co-dominant glomerular staining on IF and 5) hump-shaped subepithelial deposits on EM. In the present case, all criteria were met. Moreover, recently reported that rarely, E. coli, also cause this type of GN.

SA-PO037
A Patient Presenting with Thrombotic Thrombocytopenic Purpura-Hemolytic Uremic Syndrome and Leptospirosis
Ali Yıldırım,1 Zülüfkar Yılmaz,2 Melike Elif Celik,2 Erdal Bodakci,2 Ali Kemal Kadiroğlu,3 Mehmet Emin Yılmaz,2 1Nephrology, Dicle Univ, Diyarbakır, Turkey; 2Internal Medicine, Dicle Univ, Diyarbakır, Turkey.

Introduction: There are very rare case reports in the literature about leptospirosis in association with TTP-HUS. We present a case report of TTP-HUS syndrome in a patient with leptomigrans.

Case Description: A 27 years old female patient was was transferred to our clinic due to progressive deterioration in the general status and kidney functions. On admission, she was oriented and cooperated. She had blood pressure of 130/65 mmHlg, heart rate of 90/min, temperature of 38.3°C and respiratory rate of 25/min. Patient had no urine output. There is minimal swelling on the dorsum of right hand of the patient. When we detailed history about this finding, she remembered that she saw mice in her working place in the night shift. Peripheral blood smear showed large numbers of fragmented red blood cells. Disseminated intravascular coagulation panel was normal. Viral hepatitis markers and serological tests for anti-nuclear antigen, anti-double stranded DNA, anti-hu, anti-jo, anti-Ro, anti-La, anti-ssA, anti-ssB, anti-dsDNA, anti-ribonucleoprotein, anti-centromere, Rubella, Cytomegalovirus, Hepers were all negative. C3 and C4 levels were normal. There was no reproduction in the blood cultures. ADAMS 13 level was reported as normal. Plasmapheresis was initiated immediately with the preliminary diagnosis of TTP/HUS. Also patient was empirically treated with antibiotics and on the 3rd day of treatment, doxycycline 200 mg orally per day was added to therapy because of the positive result of Leptospira IgM ELISA test. After 14 days of antibiotherapy and a total of 10 sessions of plasmapheresis, patient general status improved and laboratory findings come to near normal levels. Patient was discharged with the normal laboratory findings.

Discussion: In conclusion, leptospirosis and TTP-HUS can present with the same clinical findings and differential diagnosis is crucial to initiate the right treatment. Also, it is important to consider co-occurrence or association of these two disease in the light of patient’s history and laboratory findings although there are very rare reports in the literature.

SA-PO038
For the Eye Altering, Alters the All
Marie-Bague De Scheeber, Anne Marie Bogaert.

Introduction: We describe the case of a 26-year-old African female that was treated successfully with belimumab in a case of severe membranous lupus nephritis, resistant to first line therapy.

Case Description: She presented initially with chronic dacyroydendritis and screening showed nephrotic range proteinuria. Biopsy of the kidney confirmed the diagnosis of membranous lupus nephritis. Clinical features (joint pain, dacyroydendritis and lupus nephritis) in combination with serology (positive anti-DNA antibodies, hypocomplementemia) confirmed diagnosis of systemic lupus erythematosus(SLE). Treatment was initiated with glucocorticosteroids (GCS), mycophenolate mofetil (MMF) and Hydroxychloroquine sulphate (Plaquenil®). Tacrolimus was associated but no effect was observed with the glucocorticosteroids (GCS), mycophenolate mofetil (MMF) and Hydroxychloroquine sulphate (Plaquenil®). Tacrolimus was associated but no effect was observed with the

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
proteimuria, making it possible to decrease dosage of the other immunosuppressants and gradually stop them, even the GCS. Patient is now in complete remission after 2 years of treatment with no signs of relapse after stopping additional medication.

**Discussion:** Belimumab is indicated in treatment of seropositive active SLE in addition to standard therapy, when lack of clinical improvement despite optimal standard therapy. Two large, phase 3, multicenter, prospective, randomized, controlled trials (BLISS-52 and BLISS-76) compared belimumab with placebo in patients with SLE who were receiving standard therapies. Both studies showed significant improvement in SRI (Systemic Lupus Erythematosus Responder Index) with 10mg/kg of belimumab as compared with placebo. A phase 3 study (BLISS-LN) is recruiting patients with lupus nephritis since these post-hoc analysis of the BLISS trials suggest that belimumab may offer renal benefit in patients with SLE. The treatment is so far not recommended in these cases. We can conclude that our case shows excellent results of belimumab in lupus nephritis with persistent nephrotic range proteinuria under conventional treatment. Alternatives are scarce and mostly limited due to toxic effects and by failure to control disease.

**SA-PO039**

**Overlap Syndrome or Drug Reaction?** [Varun Gaur, Michael T. Eadon, Jesus H. Dominguez. Medicine, Indiana Univ, Indianapolis, IN.]

**Introduction:** The overlap of ANCA-Associated Vasculitis (AAV) with other autoimmune diseases is well known. However, the association of AAV with the use of TNF-α antagonists in Rheumatoid Arthritis (RA) patients is less understood.

**Case Description:** A 44 y/o white female with RA had prior treatment with methotrexate (3 yr), adalimumab (2 yr) and etanercept (2yr). She concluded all DMARD therapy 3 yr prior to presentation (PTP), and then her RA flared 5 months PTP. After initiation of leflunomide and steroids, she had partial resolution. Two weeks PTP, she received golimumab for onset of severe neurological manifestations including right foot drop, distal extremity numbness, and a right 4th digit ischemic lesion. Upon presentation, she was admitted with persistence of these symptoms. Her serum creatinine increased from 0.9 (mg/dl) to 1.4 with 2 gm proteinuria. Her urinalysis had hematuria and serology was positive for PR3-positive cANCA. Her renal function deteriorated with a peak creatinine of 6.7, necessitating intermittent dialysis. A biopsy revealed pauci-immune diffuse necrotizing and crescentic glomerulonephritis consistent with AAV. She received pulse solumedrol, cyclophosphamide, and plasma exchange. Her neurological symptoms improved after a month of therapy. After 6 weeks, she did not require dialysis and her serum creatinine was 2.4.

**Discussion:** We present a case of a patient previously treated with TNF-α inhibitors who then developed PR3-positive AAV years later. An association between AAV and RA has been described and RA may precede AAV by up to 8 years. Different theories explain this association. One reason may be the common genetic predispositions to autoimmunity, involving HLA or PTPN22 genes, reported in a series of both RA and AAV. Second theory suggests TNF antagonists may predispose one to develop secondary autoimmunity. In our case, the patient discontinued DMARDs 3 yr PTP, although had recently received Leflunamide and Golimumab. There are no reports that associate leflunamide use with AAV and only one case report suggests an association of golimumab with AAV. Our case highlights the need to further understand the importance of AAV in RA patients, and the potential role of TNF inhibitors on the development of AAV.

**SA-PO040**

**Pauci Immune Crescentic Glomerulonephritis in a Patient with T-Cell Lymphoma and Argyria** [Tamer Rezk, James J. Penton, Mark Alan Little, John Cunningham, Alan D. Salama. Centre for Nephrology, Royal Free Hospital, London, United Kingdom.]

**Introduction:** Silver is a transition metal element with a range of industrial and ornamental uses and is known to be toxic when ingested in significant amounts. Silver exposure causing argyria (skin deposition) and argyrosis (eye deposition) is well-recognised but the renal consequences of silver toxicity are poorly understood.

**Case Description:** A 47 year old woman with a T-cell lymphoma who refused conventional chemotherapy for 18 months but self-medicated with a remedy containing colloidal silver was admitted with acute dialysis-dependent kidney injury. The serum silver concentration was strikingly elevated at 127.1 nmol/l (reference value <2.8 nmol/l). Kidney biopsy demonstrated a pauci-immune crescentic glomerulonephritis and glomerular tufts with fine, dark, granular material scattered within the mesangium and along the glomerular basement membrane (GBM). Electron microscopy confirmed the presence of electrondense granules in the mesangium and along and within the GBM. Electron probe microanalysis demonstrated that these granules contained predominantly silver. The patient recovered independent renal function following immunosuppression with cyclophosphamide and steroids.

**Discussion:** Crescentic glomerulonephritis results from disruption of the GBM which may be induced by immune complexes or by cellular mediators. However our patient had no autoantibodies, and no deposited immunoproteins. We report a case of pauci-immune crescentic glomerulonephritis with intense silver deposition along the GBM. Between 5-10% cases of pauci-immune glomerulonephritis are ANCA negative. The pathogenesis in these cases may be related to other autoantibodies (such as anti-endothelial antibodies) or to direct leukocyte-induced GBM damage via soluble mediators, which in this case we believe was due to a combination of T cell lymphoma and argyria.

**SA-PO041**

**PR3-ANCA Vasculitis following Influenza Vaccination** [Karim El Hachem, Eduardo J. Zouain, Isha Gupta, Steven D. Smith. Nephrology, Mount Sinai-St Luke’s Hospital, New York, NY.]

**Introduction:** Influenza vaccination has been associated with the development of autoantibodies and autoimmune rheumatic disease. We report a case of PR3-ANCA associated vasculitis following influenza vaccination.

**Case Description:** The patient is a 45 year old Hispanic male with no known medical history who presented with subacute onset pleuritic chest pain and shortness of breath. Four weeks prior to presentation, he had received his annual injectable influenza vaccine and reports feeling weak since. On presentation, he was hemodynamically stable. His exam was notable for bibasilar crackles. He had positive Rheumatoid Factor. His CT chest was notable for multiple ground glass nodules at the right upper lobe. His creatinine was 1.64 mg/dL. His urine albumin to creatinine ratio was 225 mg/g creatinine and his urine protein to creatinine ratio was 500 mg/g creatinine. He had 25-30 RBC/hpf with no dysmorphic RBCs. He had strongly positive PR3-ANCA antibody (>8 AI). His kidney biopsy revealed acute focal segmental necrotizing crescentic GN, pauci-immune type.
The patient was treated with pulse IV methylprednisolone and Rituximab 375mg/m2 weekly for four doses. Three months following induction therapy, his creatinine improved from a peak of 3.6mg/dL to 1.4 mg/dL. His CT findings and hematuria resolved. His PR3-ANCA slowly decreased and became negative 6 months after induction.

Discussion: This patient’s presentation with lung nodules on chest CT, necrotizing crescentic glomerulonephritis with a high serum level of PR3-ANCA support a diagnosis of Granulomatosis with Polyangiitis with a strong temporal relationship to vaccination against influenza. This is the 9th case of ANCA associated vasculitis following influenza vaccination reported in the literature. Clinicians should be aware of the possible association between systemic vasculitis and influenza vaccination.

SA-PO042

C3 Glomerulonephritis Associated with Monoclonal Gammopathy of Undetermined Significance

Introduction: A case of C3 glomerulonephritis associated with monoclonal gammopathy responding effectively with immunosuppressive therapy.

Case Description: The patient was a 65-year-old Hispanic female who presented with lower extremity edema and dyspnea. She had acute kidney injury with nephritic urinary sediments. C3 and C4 were low. Hepatitis B & C profile, ANA, ANCA, anti-GBM and SFP were within normal limits. There was a faint monoclonal band in the gamma region on UPEP. Kidney biopsy was consistent with membrane proliferative glomerulonephritis (MPGN), of an undetermined etiology. Patient was readmitted with similar complaints and a rapidly declining renal function. Repeated UPEP showed a significant IGG kappa monoclonal protein and an elevated serum free light chain with kappa/lambda ratio of 2.52. Bone marrow biopsy revealed atypical plasmacytosis without overt myeloma. Repeated kidney biopsy showed global proliferative changes along with splitting of glomerular basement membrane. C3 deposits were seen on immunofluorescence. No reactivity was seen for IgA, IgG, IgM, C1q, C4, fibrinogen and albumin. Electron microscopy showed subendothelial and mesangial immune complex deposits.

Diagnosis was determined as C3 glomerulonephritis associated with monoclonal gammopathy. Patient was successfully treated with pulse glucocorticoids followed by oral glucocorticoids and mycophenolate mofetil. Plasma Lyso-Gb3 (4.1 ng/ml), and the c335G>A, p.R112H mutation of GLOA were found.

Discussion: C3 glomerulonephritis is related to dysregulation of alternative pathway of complement (AP) that can be associated with monoclonal gammopathy. Treatment of underlying monoclonal gammopathy may be of benefit in such a situation. Genetic studies for dysregulation of AP might be helpful.

SA-PO044

Another Enemy for Kidneys: Synthetic Cannabinoids

Introduction: Synthetic cannabinoids(SC) are widely used especially among young population. These substances have various physiological, metabolic and pharmacological (additive)effects. In last few decades SC related acute kidney injury(SC-RAKI) is pronounced more often.

Case Description: A 20-yr man without a medical history presented to ED with abdominal discomfort,nausea and vomiting for 3-4 days.On physical examination, arterial tension was 150/60 mm/Hg,HR 86/min,without orthostatic signs.He denied any nephrotoxic drug use,OTC medication or contrast media exposure. He has been a synthetic cannabinoid(Bonza) smoker for last 2 weeks.On admission he was oliguric and creatinine was 7.7mg/dl with normal creatinine kinase levels. Urinary analysis revealed pH 5.5,protein ++,leu 1,ery 1. Renal ultrasound showed normal size kidneys with increased echogenities,without hydropnephrosis.Interruption hemodialysis therapy was started.Autoimmune antibodies were negative. Renal biopsy revealed acute interstitial nephritis with increased mesangial matrix. Vascular structures were normal,no specific immunohistochemistry staining was detected.

After 6 sessions of HD his urinary output increased and creatinine levels regressed without a specific therapy,24-h urinary proteinuria was 529,2mg/dl on the 11th day of hospitalisation his creatinine level was 0.6mg/dl.

Discussion: SC-RAKI is usually reported as a consequence of prerenal conditions or rhabdomyolysis.In general renal histopathology reveals acute tubular necrosis. However,rarely these patients may present with interstitial nephritis.In our case complete cure of the patient without specific therapy was quite interesting.

SA-PO045

A Unique Case of Granulomatous Acute Interstitial Nephritis from Ipilimumab

Introduction: Ipilimumab is a CTLA-4 inhibitor which is used for the treatment of melanoma. We report a case of granulomatous interstitial nephritis due to ipilimumab, which developed after the first dose and featured a prominent component of granulomatous vasculitis.

Case Description: A 70 yr old man with stage IV melanoma presented with low grade fevers and malaise. He was found to have acute kidney injury with a creatinine of 6.0 mg/dL. Two months earlier, he had received a single dose of ipilimumab at which time his creatinine was 0.9 mg/dL. Laboratory data was notable for the absence of eosinophilia. Urinalysis showed 5-10 WBCs/hpf and many hyaline casts. A renal biopsy showed granulomatous interstitial nephritis with a component of granulomatous vasculitis (figure: H&E, Masson trichrome). He was treated with high-dose prednisone, which resulted in improvement of his renal function without the need for hemodialysis. After ten weeks of steroid therapy, his creatinine had decreased to 1.6 mg/dL.

Discussion: Ipilimumab is a potent activator of T cells and can interfere with the immune system’s tolerance of self-antigens. This drug is known to cause a variety of immune-related adverse events including hypophysitis, hepatitis, colitis and dermatitis. Interstitial nephritis is a rare diagnosis, but has been reported to occur after exposure to plasma Lyso-Gb3 levels than healthy subjects (PLoS One 2015). Undiagnosed FD patients may exist because their symptoms are restricted to proteinuria alone, as shown in this case. Further familial evaluation will help us elucidate this case as sporadic or familial FD to make an earlier diagnosis and treatment.
Severe Rhabdomyolysis Secondary to Adenovirus Infection

Daniel Tseytlin, Sharon E. Maynard.  Div of Nephrology, Lehigh Valley Health Network, Allentown, PA.

Introduction: A 38-year-old male presented to the ER with a 4-day history of a flu-like illness. Urinalysis showed myoglobinuria and granular casts. His CPK was markedly elevated. He was diagnosed with rhabdomyolysis from adenovirus and required hemodialysis. Case Description: A 38-year-old AA male presented to the ER with a 4-day history of weakness, subjective fever, and diffuse myalgias as well as recent left eye viral conjunctivitis. He noted dark urine and poor urine output. On arrival to the ER his vitals were stable. He had full muscle strength and no neuro deficits. He was oliguric. His SCr 5.04, his CPK 1,149,533 despite volume resuscitation including bicarb-containing fluid. He required HD. Workup was positive for adenovirus. Muscle biopsy was deferred in setting of known cause. He required 4 weeks of HD and was able to come off with impaired GFR of 67.

Discussion: Two cases of rhabdomyolysis from adenovirus have been reported. Most commonly manifests as a febrile illness with pharyngitis. Management strategies have been adopted from studies on crash injury victims. Early volume resuscitation is recommended to mitigate renal failure. Despite the theoretical benefits of bicarbonate-containing resuscitation fluids, no consensus exists. Adenoviral infection can lead to rhabdomyolysis with severe acute kidney injury. Respiratory viral panel should be included in workup of rhabdomyolysis when no other cause is evident. Treatment relies on supportive care, intravenous fluid resuscitation, and hemodialysis in cases of severe renal failure.

Acute Respiratory Distress Syndrome and Posterior Reversible Encephalopathy Syndrome following Rituximab Therapy
Eoin D. O'Sullivan, Katrina E. Wardrope, Lynn Manson, Wendy Metcalfe. Dept of Renal Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; Scottish Blood Transfusion Service, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom.

Introduction: The anti CD20 monoclonal antibody Rituximab is an increasingly used therapy in modern medicine. It is associated with rare but potentially serious adverse events, notably Posterior Reversible Encephalopathy Syndrome (PRES), and Acute Respiratory Distress Syndrome (ARDS).

Case Description: A 60-year-old female was admitted with symptoms of peripheral oedema, arthralgia and mucosal bleeding. She was noted to have a widespread vasculitic rash, nephritic range proteinuria and new acute kidney injury. Renal biopsy demonstrated mesangiocapillary glomerulonephritis with multifocal extraglomerular necrotising vasculitis, in keeping with cryoglobulinemia. She was commenced on plasma exchange, prednisolone and Rituximab. 2 days after the initial dose of Rituximab she developed acute respiratory distress and was found to be in florid pulmonary oedema. This was managed with ultrafiltration, furosemide and oxygen therapy. She received a second dose of Rituximab 1 week later, and rapidly developed tonic-clonic seizures,a further episode of flash pulmonary oedema, encephalopathy and hyporeflexia. MRI brain revealed subcortical white matter high T2 and FLAIR signal in the occipital and posterior parietal lobes consistent with PRES.

Discussion: There are 7 reported cases of PRES complicating rituximab use. The onset of PRES occurred from immediately to 21 days after administration. All patients recovered completely, and rituximab was reintroduced in half of the cases. Mean recovery time was 4 days, and an additional risk factor was present in 5 cases. The occurrence of ARDS in association with rituximab is rare, only 3 confirmed cases exist . ARDS may occur as a delayed reaction.

SA-PO048
Atypical Hemolytic Uremic Syndrome Associated with Rituximab Therapy
Kristina Angela Rathnall, Shilpa Gadde. Nephrology, Tulane, New Orleans, LA.

Introduction: Hemolytic uremic syndrome (HUS) is classified as a thrombotic microangiopathies (TMA). Atypical HUS (aHUS) occurs in 0.5 to 2 per million population per year, 50% progress to end-stage renal disease (ESRD), and 25% may die in the acute phase. Atypical HUS is linked to uncontrolled activation of the complement system. A variety of genetic abnormalities of the alternative pathway of complement have been described in aHUS, occurring in 60% of cases. aHUS is diagnosis when toxsin producing bacterial infections, ADAMTS13 deficiency, and systemic-associated diseases are all excluded.

Case Description: A 57-year-old woman with a history of dermatomyositis and associated interstitial lung disease (ILD) was being treated for her ILD with Rituximab. She presented with altered mental status, shortness of breath, and fatigue after receiving an infusion of Rituximab. She was noted on physical exam to have peripheral edema and crackles on lung exam. On laboratory evaluation, her creatinine was 4.0 (baseline 1), hemoglobin 7, and platelets 20 with schistocytes on peripheral smear and a low C3 and C4. ADAMTS13 showed normal activity. She was initially treated with high dose steroids and plasmapheresis. She was started on Eculizumab. She required hemodialysis. Renal biopsy showed thrombi consistent with thrombotic microangiopathy as well as mild acute tubular necrosis. She is still hemodialysis dependent.

Discussion: Overall outcomes of this rare diagnosis vary widely. Initial treatment is usually plasmapheresis and corticosteroids. Confirmed aHUS is usually treated with Eculizumab. Our unique case entartains Rituximab, a monoclonal antibody, as a possible trigger for aHUS. Knowing the mechanism of action of Rituximab, it is possible it mediated the disease activity. Rituximab can lead to complement activation with subsequent production of C5a, which activates neutrophils. aHUS is a known cause of multi-organ failure and may require plasma exchange. Rituximab therapy in modern medicine. It is associated with rare but potentially serious adverse events, notably Posterior Reversible Encephalopathy Syndrome (PRES), and Acute Respiratory Distress Syndrome (ARDS).
On day 8 of therapy he was admitted with a Cr of 3.4, acutely elevated from 1.7. He denied hematuria, oliguria, fever, edema or NSAID use. Renal ultrasound was without obstruction. He underwent renal biopsy. Pathology revealed diffuse interstitial involvement by lambda-restricted neoplastic plasma cells and minimal cast nephropathy, but no significant interstitial fibrosis, tubular atrophy or monoclonal deposition disease. Congo red studies were negative for amyloid. There were no features of TMA. Chemotherapy was resumed.

Discussion: For renal failure that can be attributed to neoplastic plasma cell involvement.

SA-PO050

**AL Amyloidosis with Rapidly Progressive Renal Failure and Massive Liver Involvement: A Case Report**

**Matteo Angiolini**, 1  **Riccardo Cao**, 1  **Anna Maria Asunis**, 2  **Elisabetta Tamponi**, 2  **Alice Atzeni**, 1  **Patrizia Melis**, 1

**Introduction**: AL amyloidosis is a plasma cell disorder clinically dominated by organ involvement by light chains, mainly in renal and cardiac tissues. Although hepatic disease is described, clinical manifestations are usually mild and frequently undetected. We report a severe case of AL amyloidosis with a massive hepatic involvement and rapidly progressive renal failure (RPRF).

**Case Description**: One month before coming to our attention, a 67 year old male was admitted to another institution for ascites and scrotal edema. Past medical history included hypertension, previous hepatitis B virus infection and estimated daily alcohol intake of 60g. Renal function was normal (serum creatinine <0.7 mg/dL), while hepatic lysis indexes were moderately positive. A serum monoclonal component IgA kappa (0.21 g/dL) was detected and the bone marrow aspirate showed 10% plasma cell infiltration. Hepatic ultrasound showed hepatomagaly and portal hypertension. Final diagnosis was compensated alcoholic liver disease. After discharged, nephrotic syndrome (albuminuria >2g/dL), RPRF (Scr 1.6 mg/dL) and cholestasis appeared (AP 1559 IU/L, GGT 462 IU/L, AST-ALT normal). The patient was admitted to our institution and renal biopsy was performed revealing AL amyloidosis, with prominent IgA(+) and Kappa(++) mesangial deposits, coherently with the serology. The hepatic disease was not discouraged, and the liver biopsy revealed coarose deposits of amyloid as for the kidney. Other organs, heart included, appear to be spared at the time. In accordance with hematologists, a CyBorD-based regimen was started. Due to worsening kidney dysfunction, hemodialysis was initiated.

Discussion: This case highlights a rare presentation of AL amyloidosis with severe renal and hepatic involvement. Liver amyloidosis should be suspected in any patient with NS and unexplained cholestasis. Therefore, renal and hepatic biopsies should be considered when the clinical diagnosis is obscure, especially if rapid evolution to multiorgan failure is documented.

**Pulmonary-Renal Syndrome: A Rare Case**

**Joana Gameiro**, 1  **Sofia C.A. Jorge**, 1  **Miguel Bigotte Vieira**, 1  **Estela Nogueira**, 1  **Maria Alice Fortes**, 1  **Helena Sousa Viana**, 2  **Fernanda Carvalho**, 1  **José António Lopes**, 2  **Antonio Gomes Da Costa**, 1

**Introduction**: Pulmonary-renal syndrome (PRS) is characterized by acute renal and pulmonary involvement of immunological or non-immunological causes.

**Case Description**: A 5-year-old African woman with 6-month history of edema, bilateral arthralgias in her knees, shoulders and hands, creatininemia 2.6mg/dL, and nephritic proteinuria referred to Portugal for medical care presenting with bilateral erythematous non pruriginous macular lesions in both thighs. Investigation confirmed renal failure (creatininaemia 7mg/dL), nephritic proteinuria (4.7g/24h), haematuria, hypoalbuminemia, hyperlipidemia, normal sized kidneys with increased parenchymal echogenicity. She began hemodialysis and was transferred to ICU due to pulmonary hemorrhage requiring mechanical ventilation. Plasmapheresis and intravenous high-dose steroids were started. Pneumococal pneumonia was also diagnosed and began antibiotic. Immunologic and serologic tests were negative or normal range. Serum protein electrophoresis showed hypogammaglobulinemia. Echocardiogram revealed type II diastolic dysfunction. Renal biopsy showed nodular glomerulosclerosis. Investigation of haematoletic disease revealed serum kappa light chain band and urine Bence Jones kappa. Free kappa light chains, serum kappa/lambda ratio and serum Beta-2-microglobulin were elevated. Bone marrow biopsy and aspirate showed 10% monoclonal plasmocytosis. No lytic lesions or masses were detected. Immunofluorescence of the renal biopsy revealed linear staining for kappa light chains along the tubular basement membrane and scarcer in the glomeruli. Electron microscopy is underway. Multiple mycetoma was diagnosed and started chemotherapy with Bortezomib. Although there was maintained remission of pulmonary hemorrhage she remained on dialysis.

Discussion: This case highlights a rare presentation of AL amyloidosis with severe renal and hepatic involvement. Liver amyloidosis should be considered in the differential diagnosis of PRS. Renal involvement is typical in LCDD with nodular glomerulosclerosis as the common pathologic finding. Pulmonary haemorrhage is usual and might suggest coexistence of fibrillary glomerulonephritis.

**Discussion**: Scleroderma renal crisis can present as acute cardioareno syndrome.

Dent's Disease: An X-Linked Tubulopathy

Sambhavi Krishnamoorthy, Tingting Li. Renal Div, Washington Univ in St. Louis, Saint Louis, MO.

Introduction: Dent’s disease is an X-linked recessive disorder of the proximal tubule characterized by low-molecular weight proteinuria, hypercalciuria, nephrocalcinosis/nephrolithiasis, and progressive renal failure. This disorder is caused by mutations in either the CLCN5 gene, or less commonly the OCLRN gene, leading to disruption of tubular endocytosis and the characteristic clinical findings.

Case Description: We describe an interesting case of a 24 year old Caucasian male with a longstanding history of excessive thirst and polyuria. He had no known history of renal disease. He denied history of urinary tract infections, nephrolithiasis, or NSAID use. Physical examination was unremarkable. Laboratory data showed a serum creatinine of 1.6 mg/dL. Hemoglobin A1c was normal. Urinalysis showed 2+ blood and 2+ protein. A 24 hour urine collection showed proteinuria of 1.7 g/day. ANA, ANCA, and hepatitis panel were all negative. A renal ultrasound showed multiple bilateral renal calculi and nephrocalcinosis. Further testing showed a daily urinary calcium excretion of 735 mg, phosphate 2150 mg and sodium 257 mg. His urine beta microglobulin level was significantly elevated at 29817 mcg/L. The presence of significant low molecular weight proteinuria, hypercalciuria, hyperphosphaturia, nephrocalcinosis/nephrolithiasis, hematuria/subnephrotic proteinuria, and chronic kidney disease fulfilled criteria for the diagnosis of Dent’s disease. No obvious X-linked pattern had been noted in his family history. Further genetic testing is pending at this time. On initiating hydrochlorothiazide, urinary calcium excretion reduced by 50%. Polyuria, which we attributed to nephrogenic diabetes insipidus in the setting of nephrocalcinosis, also improved significantly with the thiazide.

Discussion: This case report highlights the importance of recognizing this rare X-linked tubulopathy when presenting in adulthood. Commercially available genetic testing can be utilized for supporting the diagnosis and for appropriate genetic counseling for family members. The treatment focuses on reducing urinary calcium excretion and formation of nephrocalcinosis/nephrolithiasis with the ultimate goal of slowing progression to end stage renal disease.

Phlegmasia Cerulean Dolens: Complication of Femoral Vein Catheterization

SA-PO054

Vemuri Emur, Sambhavi Krishnamoorthy, Tingting Li. Renal Div, Washington Univ in St. Louis, Saint Louis, MO.

Introduction: There are three manifestations of acute massive venous thrombosis and obstruction of the venous drainage of an extremity. They are phlegmasia alba dolens, phlegmasia cerulea dolens (PCD) and venous gangrene.

Case Description: We present a 55-year-old hypertensive, presented with paedal oedema and breathlessness. About a month ago, she fell down and had dislocation of left patella. She was treated with a plaster cast and immobilization for 3 weeks. Her serum creatinine was 8.8 mg/dL. She was initiated on haemodialysis via two single lumen catheters placed in left femoral vein. The femoral vein catheters were removed after third session as platelet count was 500000. She developed acute renal failure with a serum creatinine of 8.8 mg/dL. On Doppler ultrasound, there were areas of clot in the left common femoral vein with extension to the right common femoral vein. There was severe oedema in the lower limb which was reduced on 5th day. She was discharged on heparin therapy and anticoagulation with oral warfarin. At follow up, her serum creatinine was 1.5 mg/dL and symptoms of lower limb swelling were improved.

Discussion: The causative factor in phlegmasia is massive thrombosis and occlusion of major venous channels. The left lower limb was elevated and anticoagulation was started but blebs increased and limb became blue. Below knee amputation of left lower limb was performed.

Minimal Change Disease Associated with Invasive Ductal Carcinoma of the Breast: A Case Report and Literature Review

Siddhesh J. Lotlikar, 1 Julian D. Rose, 1 Soumya Patnai, 2 Supakanya Wongrakpanich, 3 Mary Carolina Rodriguez Ziccardi, 2 Mark S. Morginstin, 2 Rasib Raja, 2 Eric J. Bloom. 2

Introduction: A tenth of malignancies have been associated with nephrotic syndrome, the diagnosis of which may precede the detection of cancer. In an adult with Minimal Change Disease (MCD), paraneoplastic etiology should be explored. Here, we describe a rare case of MCD associated with breast cancer.

Case Description: Our patient is a 72-year-old Caucasian female who presented with bilateral lower extremity edema for 1 week. Home medications were notable for occasional Diclofenac use. Urinalysis on admission showed nephrotic-range proteinuria. MCD was suspected and confirmed on renal biopsy. CT ruled out lymphoma and thymoma. MCD was presumed secondary to Diclofenac use and she was discharged on prednisone and azathioprine for intravenous IgG therapy. Two months later, she presented with a pulmonary embolus and CT showed concerning breast changes. Biopsy confirmed a stage IIIE invasive ductal adenocarcinoma. She was tapered off steroids, continued on furosemide and started on Paclitaxel.

Discussion: Breast cancer mainly causes antibody-mediated paraneoplastic syndromes. Yet, studies have shown intratumoral IFN-α expression correlates with induction of autoreactive T-cells, presenting a route for breast cancer to cause a T-cell-mediated process such as MCD. Our patient had no lymphoma or thymoma and the lack of evidence of AIN and failure of improvement on discontinuation of NSAIDs argue against NSAID-induced MCD. The relationship of MCD with breast carcinomas is reinforced by her improved proteinuria with chemotherapy.
A Case of Donor-Derived Enterococcal Pyelonephritis in an HIV-Positive Kidney Transplant Recipient Akshatha Rao,1 Shilpa A. Chaudhari,2 Dong Heun Lee,3 Karthik M. Ranganna,1 Alden Michael Doyle.1 1Div of Nephrology, Drexel Univ, Philadelphia; 2Division of Infectious Disease, Drexel Univ, Philadelphia.

Introduction: Donor-derived infections are an unusual but recognized complication of solid organ transplantation. Between 2005-2011, there were 118 reported donor bacterial infections, of which 34 recipients had confirmed transmission of infection and 9 deaths due to donor derived bacterial infections. Herein, we describe a unique case of donor-derived enterococcal pyelonephritis in a kidney transplant recipient with HIV infection.

Case Description: 47 year old male with history of HIV infection (CD4 -534 cells/mm3, VL <20 copies), ESRD on peritoneal dialysis, hypertension had deceased donor kidney transplantation. Post-op patient was given 1 dose of cefazolin as surgical prophylaxis. Basiliximab and intravenous immunoglobulin was used for induction therapy. Patient was started on intravenous ampicillin to complete a total of 6 days antibiotic course. POD #17 patient was readmitted to the hospital with urinary retention and elevated serum creatinine 2.2. Renal ultrasound showed no hydronephrosis. Urinalysis showed 2+ leukocyte esterase, WBC 11-20, with occasional bacteria. Blood and urine culture grew Enterococcus faecalis which was treated successfully; no other cases of peritonitis were noted.

Discussion: We suggest that PD should be considered in selected patients who have ascites and end-stage kidney disease. Further research is warranted regarding long term outcomes and potential effects of PD on the ability for these patients to get transplanted.

SA-PO058

Introduction: Managing patients with end stage liver disease associated with portal hypertension, ascites and end-stage kidney disease using peritoneal renal replacement therapy is challenging for a number of reasons including chronic hypotension, poor nutrition, coagulopathy, high infection rates, and encephalopathy. It is difficult to assess accurate dry weights because of the large variation patient weights depending on how much ascites they have at the time of dialysis, with weight fluctuations in excess of 10 kg. There is also a reluctance on the part of the transplant community to utilize PD because of the perception that these patients may not be able to go on to receive a successful liver transplant.

Case Description: Herein, we report our experience with 5 consecutive patients with decompensated cirrhosis who progressed to ESKD and required dialysis support. One patient did not tolerate HD and was switched to PD, the other 5 started with de novo PD. In each case, the patients were admitted to hospital for PD catheter placement with a surgeon experienced with patients who had advanced liver disease and stayed in the hospital for initial recovery period with IV albumin to support blood pressure. By our protocol, ascites fluid was drained in the OR and then drained each morning for the next 2 weeks before dialysis was initiated. Blood pressures ranged from 80/50-110/65 mmHg, patients remained asymptomatic. All patients received oral midodrine for BP support.

Adequate ultrafiltration achieved and edema improved. Serum albumin was monitored at regular intervals, ranged from 2.5-3. One patient had peritonitis from time of surgery, which was treated successfully; no other cases of peritonitis were noted.

Abdominal Compartment Syndrome: An Overlooked Culprit of Acute Kidney Injury in Immediate Post-Liver Transplantation Ekamol Tantisattamo, Praveen Ratnasrimetha, Siwadon Pitukweerakul, Nephrology, Northwestern Univ; Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; Presence St. Francis Hospital, Evanston.
Introduction: Acute kidney injury (AKI) is a common complication after liver transplantation and often times, dialysis is required. Abdominal compartment syndrome (ACS) is a treatable cause of prerenal AKI without dialysis needed. Case Description: A 60-year-old man with HVC and alcoholic cirrhosis underwent an OLT. He had massive blood loss during the uncomplicated operation and required massive transfusion and fluid resuscitation. Postoperatively, renal function initially was stable at the baseline serum creatinine (Scr) of 0.8 mg/dL. However, hemoglobin dropped from 9.1 to 5.7 g/dL and tacrolimus level elevated up to 53 ng/mL on postoperative day (POD)4. Scr rose up to 1.3 mg/dL and urine output (UOP) decreased on POD7. Renal function continued to decline with a peak BUN and Scr of 120 and 2.73 mg/dL on POD14, respectively (Figure 1). Dialysis was initially planned. However, he had progressively increased ascites with markedly tense abdomen. Bladder pressure revealed intra-abdominal hypertension (IAP) with the pressure of 20 mmHg. FE_{cr} and FE_{uro} were 0.7% and 21%, respectively. Therefore, abdominal paracentesis was performed with an 8 L of yellowish clear ascitis fluid removed. UOP significantly increased shortly after paracentesis. Scr had trended down and dialysis was not required.
Discussion: Our patient presented with prerenal AKI secondary to perioperative hypovolemia concomitant with superatherapeutic tacrolimus level. Massive blood transfusion and fluid resuscitation in the setting of major abdominal surgery caused IAH and subsequently ACS contributing to worsening prerenal AKI. Bladder pressure is a bedside diagnostic tool to detect IAH. AKI could be reversed and dialysis could be avoided by abdominal paracentesis.

SA-P0062
Rasburicase: A Salvage Strategy to Prevent Renal Allograft Loss in Acute on Chronic Urate Nephropathy Ekamol Tantisattamo, Praveen Ratnasrimetha, Siwadon Pitukweerakul, Nephrology, Northwestern Univ; Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; Presence St. Francis Hospital, Evanston.
Introduction: Chronic hyperuricemia can lead to chronic kidney disease (CKD) and acute on chronic hyperuricemia potentially causes renal failure. Rasburicase is an effective uric lowering agent indicated for the treatment of acute hyperuricemia especially in tumor lysis syndrome. We report a case of kidney transplant recipient with acute hyperuricemia-related acute kidney injury (AKI) which was resolved with rasburicase.
Case Description: A 51-year-old man with ESRD secondary to type 2 diabetes status post renal transplant was admitted with diffuse muscle cramping. Maintenance immunosuppression included cyclosporine (CsA) and mycophenolate mofetil. The baseline serum creatinine (Scr) was 2.5 mg/dL after 2 episodes of borderline changes detected from transplant renal biopsy at 1 and 2 years posttransplant, respectively. However, over the past 9 months, Scr had gradually trended up to 4.4 mg/dL. He had asymptomatic hyperuricemia with a serum uric acid of 9.1–12.5 mg/dL. Two days after admission, he developed severe pain on the right first metatarsal joint presumed from acute gouty arthritis which responded to oral prednisone. However, Scr continued rising up to 4.8 mg/dL. Urinalysis showed a pH of 6 and Sp.Gr. of 1.011. Serum and urine BK virus were undetectable. Transplant renal ultrasound was unremarkable. Serum uric acid was markedly elevated up to 17.7 mg/dL. Given worsening renal function in the setting of acute hyperuricemia, rasburicase was initiated. Serum uric acid had been decreased to 8.1 and 4.5 mg/dL within 20 and 30 hours, respectively and Scr returned to the baseline of 2.5 mg/dL.
Discussion: Our patient presented with AKI on CKD in the setting of symptomatic acute on chronic hyperuricemia. Acute hyperuricemia leads to AKI which was resolved by rapidly lowering uric acid level with rasburicase. AKI in the patient with underlying chronic hyperuricemia should raise a suspicion for acute hyperuricemia-related AKI. Rasburicase should be considered as a salvage therapy to prevent renal allograft loss.
SA-P0063
The Effect of Taurine on Haemodilution Fibrosis in Patients with Chronic Heart Failure: A Case Study Shunji Shiohira, Kosaku Nitta, Ken Tsuchiya, Dept of Medicine IV, Tokyo Women’s Medical Univ, Shinjuku, Tokyo, Japan; Dept of Blood Purification, Iwaki, Fukushima, Japan.
Introduction: Taurine, an important factor in the living body, is essential for cardiovascular function and development and function of skeletal muscle, retina and central nervous system. In the present study, its effect on cardiovascular function was specifically taken into consideration. In haemodilutional filtration (HDF) patients, the effect of taurine on Neopterin concentrations in patients with chronic heart failure (CHF), in whom dry weight was difficult to control, was evaluated.
Case Description: All patients who were subjected to regular HDF for 4 h three times per week at Iwaki hospital in this study. Patients with chronic heart failure, in whom dry weight was difficult to control (n = 4), were included in the evaluation of clinical status. X-ray and echocardiography were determined before and after taurine treatment. Almost all cases were taking nitric acid, warfarin, anti-platelet and vasopressor. Because vital signs were unstable in chronic heart failure, all cases withheld antihypertensive drugs during HDF. For unstable vital signs during HDF, pulmonary congestion was chronically recognized. After taurine was added in HDF, vital signs stabilized and up of dry weight was possible. In addition, X-ray and cardiac diastolic failure on echocardiography improved.
Discussion: Taurine was effective for CHF patients on HDF in whom dry weight was difficult to control in spite of various medications.
SA-P0064
Introduction: Glomerular disease associated with Hashimoto’s Thyroiditis (HT) is a rare occurrence infrequently reported in the literature. We present a case of membranoproliferative glomerulonephritis (MPGN) that was thought initially to be due to systemic lupus erythematosus (SLE) in a young woman.
Case Description: A 38 year old female presented in 2013 with leg edema and two grams of proteinuria. Creatinine (Cr) was 1.3 mg/dL. Of note, her thyroid function tests were consistent with severe hypothyroidism, with a TSH of 129 mIU/L and a normal thyroid peroxidase and thyroglobulin antibodies ~900 IU/mL. Serologic workup for hepatitis B, C and HIV and complements were negative. She had a history of Raynaud’s but did not fulfill clinical and immunological criteria for SLE. Kidney biopsy was consistent with immune complex MPGN with immunofluorescence positive for IgG and C3 only. Patient was non-compliant with thyroid replacement therapy and was lost to follow-up. She reappeared in 2015 with arthralgias, dyspnea, and leg edema. Her Cr had worsened to 1.7 mg/dL with 16 gram proteinuria. She was found to have a pericardial effusion. TSH was 174 IU/mL. Repeated testing for SLE was negative and a renal biopsy performed demonstrated immune complex-mediated MPGN with minimal staining for full house immunoglobulins. She was placed on thyroxetine hormone and also initiated on mycophenolate mofetil, given that both her thyroid and renal disease appeared to be driven by an autoimmune antibody mediated process.
Discussion: HT, immune complex MPGN and clinical findings in our patient were initially thought to be due to SLE however patient failed to fulfill any immunologic criteria for SLE. HT is rarely associated with MPGN and specific mechanisms remain unclear. Proteinuria in glomerular disease associated with HT is not correlated with levels of thyroid hormone. However, deposits of IgG, C3, and C1q in glomeruli and thyroid resting immunofluorescence positive were seen in the kidney and HT. This supports the theory of an autoimmune basis for MPGN in HT, and reinforces that immunosuppression may be required to adequately treat both diseases.
SA-P0065
Hypervitaminosis D – A Rare Complication of PJP in a Transplant Patient Khaled Boobes, Khurram Saleem, Yazan M. Alia, Muhammad H. Hasan, Aneesha A. Shetty, Mohammed Javed Ansari. Nephrology, Northwestern Univ/Northern Memorial Hospital, Chicago, IL.
Introduction: Pneumocystis Jiroveci Pneumonia (PJP) is a known complication in immunocompromised hosts including transplant recipients, usually in the first six months of transplant. Hypercalcemia (HCa) is not a classic symptom of the disease. We present a case of a patient with simultaneous kidney and pancreas transplantation nineteen years ago who presented with PJP and developed HCa (highest value 14.8 mg/dl [8.3-10.5] mg/dl). Parathyroid Hormone (PTH) was appropriately suppressed with a level of 6; [12-88] pg/ml. 1,25-(OH) vitamin D concentration was elevated (123; [18-72] pg/ml). After treatment with the calcium-sensing receptor (CaSR) inhibitor, thiazide, and 1,25(OH) vitamin D supplementation, HCa have been reported to date, it is possible that this association is more frequent than previously thought. Hypercalcemia in transplant recipients with pulmonary symptoms must raise suspicion of PJP.

SA-PO066
A Rare Case of Tubulointerstitial Nephritis Associated with Primary Biliary Cirrhosis  
Jatinder K. Hoti, Jingyin Yan, William F. Glass.  
Dept of Nephrology, Baylor College of Medicine, Houston, TX; Dept of Pathology, Baylor College of Medicine, Houston, TX.

**Introduction:** Primary biliary cirrhosis (PBC) is a chronic autoimmune liver disease characterized by positive antimitochondrial antibodies (AMA), immune-mediated epithelial damage of small bile ducts, which leads to liver cirrhosis as the disease advances. In addition to liver injury, other autoimmune diseases, such as Sjögren’s syndrome and Raynaud’s syndrome, are reported in approximately 2-20% patients with PBC. However, the association of PBC and renal injury is rarely documented.

**Case Description:** Here we present a case of tubulointerstitial nephritis (TIN) in a patient with PBC. A 35-year-old female with past medical history of PBC developed sub-nephrotic range proteinuria and chronic kidney disease stage 3. A renal biopsy showed severe CreIgAN on the back of high dose steroids and cyclophosphamide therapy. Severe CreIgAN infiltration of lymphocytes, plasma cells and occasional eosinophils, as well as significant tubulitis.

The patient was treated with a short course of oral prednisone and her renal function improved.

**Discussion:** This case highlights a very rare cause of TIN and suggests that steroid therapy is effective in this setting.

SA-PO067
Plasma Exchange as Adjunctive Therapy for Crescentic IgA Nephropathy  
Xinfang Xie, Fude Zhou, Minghui Zhao, Hong Zhang.  
Peking Univ Inst of Nephrology.

**Introduction:** Recent KDIGO guidelines recommend an aggressive immunosuppressive therapy in patients with crescentic IgA nephropathy (CredIgAN). While large cohort study from our center suggest that even with such a therapy, the 1- and 5-year renal survival rates remained low at 65% and 28%, respectively. Especially patients who present with serum creatinine (SCr)>580μmol/L hardly recovered from dialysis. In this study we aim to evaluate the efficacy of plasma exchange(PE) in severe CredIgAN.

**Case Description:** In this pilot study we give PE as adjunctive therapy to patients with severe CredIgAN on the back of high dose steroids and cyclophosphamide. Severe CredIgAN is defined as diffuse crescent forming with kidney failure that needs dialysis or presents kidney function declining even with high dose steroids and cyclophosphamide therapy.

Overall ten patients with severe crescentic IgA nephropathy received PE from 2011 to 2015.

Y: yes, N: No

Among them 7 patients reached dialysis at presentation with serum creatinine (768±176μmmol/L). Another 3 cases showed progressively kidney decline even after an aggressive immunosuppressive therapy. Patients received 5-10 PEs. After a mean 13 month follow-up, 4 of the 7 patients who had dialysis successfully recovered from dialysis. One of the 3 patients with persistent kidney progression showed serum creatinine decline.

No severe adverse event was observed during the follow-up.

**Discussion:** Plasma exchange as adjunctive therapy may achieve benefit for patients with severe crescentic IgAN.

SA-PO068
Fibrillary Glomerulonephritis Associated with Demyelinating Polyneuropathy  
Sixto G. Giusti, Pradeep Vattla, Jorge C. Garces.  
Ochsner Clinic Foundation, New Orleans.

**Introduction:** Fibrillary glomerulonephritis (FGN) is characterized by nonbranching randomly arranged fibrils along the mesangium and glomerular capillary walls that do not stain for Congo red, have a diameter of 16-24 nm, and usually show polyclonal IgG, C3, and light chain deposition by immunofluorescence. Found in ≤ 1% of native renal biopsies, FGN is usually idiopathic, although some cases are associated with malignancy, monoclonal gammopathy, and autoimmune diseases. Association of FGN with demyelinating neuropathy has been rarely described.

**Case Description:** A 38-year-old Indian man with 3-year history of hypertension and 10-month history of end stage renal disease attributed to hypertensive, presented to our institution with a 3-week history of progressive, bilateral lower extremity weakness. During his hospital stay, he was diagnosed with non-infectious pleural and pericardial effusions. Lab work revealed normal Anti nuclear antibody, anti double stranded DNA antibody, serum complements, anti nuclear cytoplasmic antibodies. Serologies for hepatitis and human immune deficiency virus were negative. Electromyography revealed demyelinating sensorimotor polyneuropathy. Chest, abdomen and pelvis imaging was unrevealing for malignancy. No monoclonal peaks on serum and urine electrophoresis or immunofixation. Fat pad biopsy negative for amyloid. Bone marrow biopsy showed 60% cellularity with tri lineage hematopoietic activity, no B cell clonality or T cell aberrancy. He was started on high dose steroids with gradual improvements of weakness. Renal biopsy showed findings of chronic FGN with IgG4 dominant deposition. 44 of 48 glomeruli were globally sclerosed with 80% fibrosis and no activity. Sural nerve biopsy results are still pending.

**Discussion:** FGN is a rare and leads to ESRD in the majority of cases. There are very few cases describing FGN in association with demyelinating polyneuropathy without associated plasma cell dyscrasias. Although FGN renal prognosis remains poor, early identification is important as it may help identify an underlying malignancy or systemic autoimmune disorder with potential for treatment. FGN may be a precursor for future lymphoproliferative disorder.
SA-PO0069
Acute Inflammatory Polyarthritis following Kidney Transplantation
Paul P. Maraj. Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: An acute inflammatory polyarthritis develops one month after deceased donor kidney transplantation in a 54 year old male. He had no prior diagnosis of any form of arthritis, crystalline, inflammatory or otherwise. Following workup he was diagnosed with Rheumatoid arthritis and improved with an increased dose of steroids. To date there are no case reports which described this disorder precipitated by kidney transplantation. This case report describes this unique clinical scenario and the dilemmas with diagnosis.

Case Description: 54 year old man with a medical history of end stage renal disease secondary to hypertensive nephrosclerosis who underwent deceased donor kidney transplant one month prior admitted for joint pains. During kidney transplantation he had induction with thymoglobulin, plasmapheresis and rituximab as per institutional protocol for positive DSA. Maintenance immunotherapy consisted of tacrolimus, mycophenolate mofetil and prednisone taper dose. Following transplantation he was asymptomatic until one month after transplantation when he developed bilateral shoulder pains which then migrated to elbows and wrist; this was associated with significant morning stiffness and malaise. Xrays which were negative for bony abnormalities, MRI wrist revealed small to moderate joint effusion. Fluid analysis was negative for septic arthritis and crystals. Serum uric acid was within normal limits. Autoimmune workup negative including ANA, C3, C4. Rheumatoid factor was positive to titer 1:4, anti CCP was significantly positive at>250. He was treated with oral steroids which resulted in resolution of his symptoms.

Discussion: To date there have been no reports of rheumatoid arthritis in the immediate post-transplant period. There have been reports of an acute inflammatory syndrome related to mycophenolate use which improved on discontinuation, anti-CCP titers were unknown in these cases. Mycophenolate was continued in this patient and his symptoms did not recur after steroid taper making a reaction to mycophenolate less likely. Anti CCP is very specific to disease diagnosis of rheumatoid arthritis but its validity post transplant is unknown. The temporal relation with transplantation also raises the possibility of a drug induced reaction.

SA-PO0070
IgM Nephropathy: A Neglected Pathology of Nephrotic Syndrome
Krystahl Z, Andujar, Carlos Antonio Cortes Sanchez, Hector R. Cordova. Medical Service, VA Caribbean Healthcare System, San Juan, PR.

Introduction: IgM nephropathy is defined by the presence of immunoglobulin M (IgM) as the dominant immunoglobulin in the mesangium of the glomeruli in a diffuse and global distribution. Clinically, a poor response to steroids distinguishes this disease from Minimal Change Disease.

Case Description: An 80-year-old man with past history of Hypertension, Alzheimer’s dementia, and benign prostatic hypertrophy complained of progressive shortness of breath associated with severe bilateral lower extremity edema and decreased urine output. Vital signs revealed blood pressure of 171/77mmHg. Lung auscultation was remarkable for bibasilar rales. The patient had anasarca. Laboratory tests showed serum creatinine at 2.2mg/dL (baseline of 1.2mg/dL), BUN of 36mg/dL and albumin of 2.2g/dL. Urinalysis showed microscopic hematuria and proteinuria (~ 500 mg/dL). Renal sonogram revealed normal kidney size without hydronephrosis or nephrolithiasis. The 24-hour urinary protein excretion was 6.7gms/day. Serum creatinine rose to 7.7mg/dL a week later. Kidney biopsy was read and steroid pulse therapy was started. Hemodialysis was initiated. Renal biopsy results showed mild increase in mesangial matrix and interstitial fibrosis. Sections stained for IgG, IgA, albumin C1q and kappa and lambda light chains were negative. Staining for IgM showed granular deposits in the mesangial areas compatible with a diagnosis of IgM Nephropathy. Hemodialysis was discontinued after two sessions since the patient had rapid recovery of kidney function after the 3 day steroid pulse therapy. Steroid therapy was tapered and eventually discontinued. Three months later, 24 hour urinary protein excretion was normal and the serum creatinine was 1.6mg/dl.

Discussion: Patients with IgM Nephropathy are less likely to respond to immunosuppressive agents. The presence of mesangial IgM deposits and interstitial fibrosis entails a worse prognosis. However, in our case, the patient had a prompt response to steroid therapy with resolution of the nephrotic syndrome and recovery of renal function.

SA-PO0071
Renal Infarct from Traumatic Renal Artery Dissection

Introduction: Renal infarction is an uncommon condition associated with a thromboembolic event (i.e.; related to atrial fibrillation), hypercoagulable state, renal artery dissection or fibromuscular dysplasia.

Case Description: A 26 y/o male with no significant PMHx presented with left flank pain for 3 days. The pain was described as 10/10 and associated with intermittent nausea. He fell from his motorcycle onto his left side 2 weeks prior. On exam there was a healing laceration over the left knee and tenderness to palpation over the left lower quadrant and L flank. The remainder of his exam including blood pressure was unremarkable. Blood work revealed a WBC of 13.8K/uL, ANA was negative, and global distribution. Clinically, a poor response to steroids distinguishes this disease from Minimal Change Disease.

Discussion: To date there have been no reports of rheumatoid arthritis in the immediate post-transplant period. There have been reports of an acute inflammatory syndrome related to mycophenolate use which improved on discontinuation, anti-CCP titers were unknown in these cases. Mycophenolate was continued in this patient and his symptoms did not recur after steroid taper making a reaction to mycophenolate less likely. Anti CCP is very specific to disease diagnosis of rheumatoid arthritis but its validity post transplant is unknown. The temporal relation with transplantation also raises the possibility of a drug induced reaction.
(SLE) is an autoimmune disorder where similarly, sphingolipid accumulation occurs when there is type 1 and SLE.

Case Description: A 32-year-old woman with Gaucher’s disease diagnosed at 17 years old, having valgus deformity, presented several clinical clues suggesting SLE. Months later started presenting face and limbs edema and hypertension. She was admitted with microcytic and hypochromic anemia, 77000 platelets, creatinine serum levels of 1.38mg/dl and hypocalcemia. The urinalysis showed hematuria and proteinuria of 7628mg in the 24h urine collection. The patient had positive anti-nuclear antibodies, Anti-Sjögren’s syndrome-related antigens, anti-SS-A/Ro and anti-SS-B/La antibodies, anti-neutrophil cytoplasmatic antibodies, viral serologies. Both complement levels were low. A kidney biopsy was performed.

It has been suggested that progressive accumulation of GC may trigger macrophage activation resulting in enhanced cytokine secretion and subsequent clonal B-cell expansion leading to chronic stimulation of the immune system. GC changes natural killer T cell function, a regulatory lymphocyte that have a role in infectious, neoplastic and inflammatory processes, therefore having a potential role in inducing other autoimmune disease. NKT lymphocytes are considered to be a link between innate and adaptive immune responses and were shown to have a role in a number of immune-mediated disorders. In an animal model of SLE, a selective reduction in NKT cells precedes the development of autoimmune phenomena.

Discussion: This case highlights a possible immunologic proximity between Gaucher’s disease and SLE, bringing up the already existing doubt that the defects in lipid metabolism, could contribute to the development of autoimmunity.

SA-PO074

Chronic Periaortitis, a Known Cause of Obstructive Uropathy

Margaret Duffy, Smita Mahendrakar, Mandeep Samra, Michael Yudd.

Nephrology, Rutgers-New Jersey Medical School, Newark, NJ.

Case Description: A 59-year-old man with hypertension presented with one week of gradually decreasing urine output, nausea, generalized weakness, and vague dull left lower quadrant pain with radiation to the left flank. He was afibrile with blood pressure of 170/90 mmHg, pulse of 79 beats per minute, respiratory rate of 16 breaths per minute, and oxygen saturation of 98% on room air. His abdominal exam was unremarkable except for non-tender scrotal swelling bilaterally. Laboratory studies were notable for the following values: WBC 12.1 x 10^9/L, BUN 62mg/dl, Cr 13.8mg/dl (baseline Cr 1.1mg/dl), ESR 57mm/hr, CRP 67mg/dl, U/A clear, yellow, specific gravity 1.01, pH 6.5, moderate blood, negative protein, leukocyte esterase, or nitrites. A renal ultrasound showed moderate hydronephrosis with patent renal arteries and veins bilaterally. CT of the abdomen and pelvis revealed moderate bilateral hydronephrosis, an abdominal aortic aneurysm (3.6cm), and a periaortic soft tissue mass measuring 2 cm in diameter with associated ureteral obstruction.

There was no iniucal iliac lymphadenopathy or suggestion of discrete malignancy. Based on combined clinical and radiographic evidence the patient was diagnosed with chronic periaortitis and retroperitoneal fibrosis. He was started on mycophenalate mofetil and prednisone taper with complete resolution of symptoms within 6 months.

Discussion: Retroperitoneal fibrosis (RPF) is a relatively rare condition characterized by the presence of fibrosis and inflammation of the retroperitoneal tissues that often surrounds the ureters and other abdominal organs and can lead to renal failure in advanced cases. Our case demonstrates the importance of considering RPF as an etiology of flank pain and renal failure as medical treatment is effective in reversing obstructive uropathy.

SA-PO075

IgA Nephropathy in HIV Positive Patient with Acute Kidney Injury

Giovanna Y Arteaga Muller, Lilía María Rizo Tepete, Elisa María Guerrero Gonzalez, Concepcion Sanchez Martinez, Jesus Cruz Valdez, Gabriela Alarcón-Galván.

Nephrology, Univ Hospital José E. González UANL, Monterrey, Mexico; Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.

Introduction: Acute kidney injury is common in patients with HIV, being prevalent the variety predominant the etiologic. Among the intrinsic causes are thrombotic microangiopathy, the antiretroviral drugs associated and the immune complexes associated (3.5%-10%) being the collapsing focal segmental glomerulosclerosis the most frequently found.

Case Description: Male 41 year old, with use of cocaine, marijuana, benzodiazepines tattoos and high-risk sexual behavior, diagnosed with HIV nine years ago, treated with antiretrovirals which suspended two years ago. Begins 3 months before with malaise, a week prior to his admission presented progressive dyspnea on moderate to high stresses accompanied by productive cough and fever. Chest radiography showed fine interstitial infiltrate, compatible with pneumocystis jiroveci, laboratories: Hb 4.7g/dl, creat 3.0 mg/dl, BUN 530 mg/dl, urin protein 4.7g/24 hrs, the urinalysis reported reddish urine, with granular casts, hematuria and pyuria. Hepatitis B, Hepatitis C, CMV and tuberculosis tests were all negative and the renal ultrasoundography was normal. Renal biopsy revealed IgA nephropathy.

Discussion: Renal toxicity of ketorolac has been described, and appears generally to be reversible, but could lead to glomerulonephritis in a rare setting. The pathological findings in the glomeruli resembled those described in experimental animals with Thy-1 induced glomerulonephritis treated with rofecoxib(COX-2 inhibitors). In this model, glomerular disease is initiated by immune-mediated mesangial cell damage, resulting in mesangiolysis.

SA-PO077

Ketorolac Induced Mesangiolysis: A Clinical Example of Anti-Thy-1.1 Model of Mesangio-Proliferative Glomerulonephritis

Fatima Khalid, Dept. of Medicine, Univ of Rochester School of Medicine, Rochester, NY.

Introduction: NSAIDS are known cause of acute kidney injury, but do not usually cause glomerulonephritis. We share an unusual presentation of glomerulonephritis after only one dose of ketorolac. No renal biopsy findings in acute ketorolac-related acute kidney injury appear to have been published based on an Ovid literature search.

Case Description: This is a 42 year old male with past medical history of nephrolithiasis and urethral stricture, who presented to the hospital for a cystoscopy procedure. The patient had urinary obstruction after the procedure and developed oliguric acute kidney injury with serum creatinine of 3.1 mg/dl (baseline 0.8 mg/dl). Of note, the patient also received one dose of ketorolac during the procedure. Uramids showed 2+ blood with many red blood cells, and 9 grams of proteinuria as TP/creatinine ratio. Lab work demonstrated high LDH, low lactoglobulin but stable hematocrit and platelet count. Peripheral smear did not reveal schistocytes. Urine microscopy showed RBC casts. Renal ultrasound showed normal sized kidneys with no hydronephrosis. Kidney biopsy showed acute tubule-interstitial nephritis with tubular necrosis and mesangiolysis. Electron microscopy showed patent capillary loops with focal epithelial foot process effacement, visceral epithelial cells with cytoplasmic vacuolization, dilated capillaries with endothelial apoptosis and mesangial lysis. Glomerular basement membrane thickness was increased. There was evidence of acute tubular injury. No electron dense deposits, thrombi or crescents were identified. Immunofluorescence of glomeruli was negative. The patient remained oliguric and required renal replacement for short term follow by full recovery of renal function.

Discussion: Renal toxicity of ketorolac has been described, and appears generally to be reversible, but could lead to glomerulonephritis in a rare setting. The pathological findings in the glomeruli resembled those described in experimental animals with Thy-1 induced glomerulonephritis treated with rofecoxib(COX-2 inhibitors). In this model, glomerular disease is initiated by immune-mediated mesangial cell damage, resulting in mesangiolysis.

SA-PO078

Disseminated Cytomegalovirus Disease in Induction Treatment with Mycophenolate Mofetil in a Lupus Nephritis Patient

Ana Pincinho Pimentel, Joana Vidinha, Teresa M. Jeronimo, Ana Cabrita, Ana Paula Silva, Pedro L. Neves.

Nephrology, Centro Hospitalar do Algarve, Faro, Portugal.

Introduction: Mycophenolate mofetil (MMF) is an immunosuppressive agent that exerts relatively selective antiproliferative effects on T and B lymphocytes and is increasingly being associated with higher incidence of tissue-invasive cytomegalovirus (CMV) disease in transplant recipients and other immune-mediated diseases. The case presented is a patient who developed CMV enteritis while receiving MMF and cotrimoxazole for lupus nephritis (LN).

Case Description: 59 year-old man with LN class IV G(a) + V under MMF (2,5g/day) and prednisolone to 20mg/day. The patient was started on intravenous ganciclovir 4g/day and prednisolone to 20mg/day. Of note, the patient also received one dose of ketorolac during the procedure. Uramids showed 2+ blood with many red blood cells, and 9 grams of proteinuria as TP/creatinine ratio. Lab work demonstrated high LDH, low lactoglobulin but stable hematocrit and platelet count. Peripheral smear did not reveal schistocytes. Urine microscopy showed RBC casts. Renal ultrasound showed normal sized kidneys with no hydronephrosis. Kidney biopsy showed acute tubule-interstitial nephritis with tubular necrosis and mesangiolysis. Electron microscopy showed patent capillary loops with focal epithelial foot process effacement, visceral epithelial cells with cytoplasmic vacuolization, dilated capillaries with endothelial apoptosis and mesangial lysis. Glomerular basement membrane thickness was increased. There was evidence of acute tubular injury. No electron dense deposits, thrombi or crescents were identified. Immunofluorescence of glomeruli was negative. The patient remained oliguric and required renal replacement for short term follow by full recovery of renal function.

Discussion: Renal toxicity of ketorolac has been described, and appears generally to be reversible, but could lead to glomerulonephritis in a rare setting. The pathological findings in the glomeruli resembled those described in experimental animals with Thy-1 induced glomerulonephritis treated with rofecoxib(COX-2 inhibitors). In this model, glomerular disease is initiated by immune-mediated mesangial cell damage, resulting in mesangiolysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underlines represent presenting author.
and fluconazole, with favorable clinical response. Proteinuria then worsened to 7.9g/day. Renal biopsy was repeated showing collapse of LN class V. Renal function improved PCR 1.6mg/dl having 2g MMF and prophylactic oral valganciclovir.

CMV virus directly infects the bowel causing mucosal erosions or ulcerations. We can only find little evidence that CMV disease explains the gastrointestinal adverse event profile associated with MMF but we bring up again the hypothesis that high local concentrations of MMF have a direct toxic effect on cells of the small intestine, causing gastrointestinal upset. Data on the incidence of CMV disease with the MMF induction protocol for LN are scarce.

Discussion: Similarly to transplant recipients receiving MMF, LN patients presenting gastrointestinal upset demand exclusion of CMV infection. This report highlights the importance of clinical follow-up of lupus patients with GI symptoms undergoing intense immunosuppression and accurate serological and histological diagnosis.

SA-PO078

Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy Mibo Karube, Shinya Kaname, Kazuhito Fukuoka, Hideki Shimizu, Yoshinori Komagata, Yoshihiro Arimura. The First Dept of Internal Medicine, Kyorin Univ School of Medicine, 6-20-2 Shinkawa Mitaka-city, Tokyo, Japan.

Introduction: It is unknown whether pregnancy affects clinical course of cryoglobulinemic nephropathy and how to treat pregnant patients complicated with it.

Case Description: A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had been terminated for similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complements. The renal biopsy performed 10 days after the third termination revealed MPGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and Clq all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed by intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2.342 kg on vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: We experienced a rare case of type III cryoglobulinemic nephropathy that repeatedly developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. Although the pathogenesis of pregnancy-induced exacerbation of cryoglobulinemic nephropathy was not clear in this patient, aggressive treatment may have been helpful for ameliorating it, leading to successful delivery.

SA-PO079

Renal Recurrence of Acute Lymphatic Leukemia Anna Bertram, Jan H. Bruesen, Ansgar Reising. 1Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany; 2Pathology, Hannover Medical School, Hannover, Germany.

Introduction: Renal complications of hematologic neoplasia can be therapy- or neoplasia-associated. We report a case of acute kidney injury (AKI) in the long term follow-up of a patient with acute lymphatic leukemia (ALL).

Case Description: The 42y old patient was diagnosed with ALL in 2009 and treated according to recommendations with chemotherapy and peripheral blood stem cell transplantation. In 2012, extramedullary ALL recurrence in his right knee was treated with irradiation. Starting from September 2014, molecular markers of minimal recurrence without evidence of lymphoblasts were found in bone marrow biopsies, and the patient received donor lymphocytes to induce graft vs. host reaction. In December 2014, ramipril was started for newly diagnosed hypertension, after which creatinine increased within several days to 290µmol/L. Because of this association, we suspected renal artery stenosis, toxic AKI, or acute interstitial nephritis. Ultrasound revealed diffusely swollen and dense kidneys (Fig.1A). Renal artery stenosis could be excluded, but - unexpected for interstitial nephritis - segmental arteries seemed compressed. Kidney biopsy revealed ALL recurrence with extensive lymphoblast infiltration. DOTA-CXCR4-PET-CT confirmed diffuse infiltration of both kidneys (Fig.1B) without bone marrow affection. After starting chemotherapy, creatinine rapidly ameliorated. Ultrasound and PET-CT-controls 10 weeks after starting therapy confirmed good treatment response (Fig.1C-D).

Discussion: This exceptional case of isolated renal ALL recurrence highlights the importance of early evaluation with ultrasound and biopsy in patients with hematologic neoplasia and AKI. An empiric treatment for suspected interstitial nephritis would have delayed chemotheraphy and thereby endangered the patient.

SA-PO080

A Rare Cause of Acute Kidney Injury in Non-Renal Solid Organ Transplantation Sameer Gupta, Wasay Humayun, Rampaery Sinnakruchanan, Liliana Osachuck. Nephrology, Medical College of Wisconsin, Milwaukee, WI.

Introduction: Acute kidney injury (AKI) is a frequent complication of non-renal solid organ transplantation (SOT). Here we report a case of rapidly progressive renal failure leading to end stage renal disease (ESRD) due to acute oxalate nephropathy (AON) in a patient with non-renal SOT.

Case Description: A 63 year old female with past history of pulmonary fibrosis status post bilateral lung transplant, obesity status post Roux en Y gastric bypass (RYGB) surgery, and hypertension presented with worsening kidney function with BUN and creatinine of 55 mg/dl and 6.18 mg/dl respectively. She had normal kidney function with serum creatinine of 0.5mg/dl prior to transplant 8 months ago. Induction regimen included Basiliximab followed by tacrolimus, prednisone and mycophenolate (MMF) as maintenance therapy. Ensuing transplantation, she had multiple episodes of AKI attributed to calcineurin inhibitor (CNI) toxicity and hypovolemia from MMF and clostridium difficile associated diarrhea. Her average tacrolimus trough level was 12 ng/mL. Several urinalyses showed acute tubular necrosis casts. Renal ultrasound revealed bilateral echogenic small kidneys compared to normal kidney size prior to transplant. Her kidney biopsy unexpectedly revealed oxalate nephropathy. She is currently on hemodialysis.

Discussion: AON has poorly been described in patients with RYGB surgery and SOT. In our patient with prior RYGB, chronic diarrhea, and numerous antibiotics unveiled AON. This superimposed with CNI toxicity resulted in rapid progression to ESRD. Antibiotic use depletes colonization of oxalate consuming bacteria (Oxalobacter formigenes). This combined with fatty acid malabsorption from prior RYGB increases colonic oxalate absorption resulting in hyperoxaluria. Diarrhea causes hypovolemia and metabolic acidosis leading to low urinary pH and hypocitraturia promoting calcium oxalate crystallization. Additional steps should be taken for SOT patients with RYGB, like diet modification, probiotic use, citrate supplementation, administration of fatty acid binding agents, and monitoring for hyperoxaluria. High suspicion for AON in patients with risk factors may lead to early diagnosis and treatment.

SA-PO081

Paraneoplastic Membranous Nephropathy and Myelodysplastic Syndrome – A Rare Combination Krishna K. R. Manoh, Madhuri Manne, Dagmar Klinger. Renal Medicine, Univ of Massachusetts Medical School, Worcester, MA.

Introduction: We report a case of Membranous Nephropathy (MN) seen in association with Myelodysplastic Syndrome (MDS). This occurrence is rare and only 3 cases have been reported in literature previously. Up to 5-20% of adults with MN have been reported to have most commonly a solid tumor and less frequently, a hematologic malignancy.

Case Description: Our patient is a 58 y/o man who has chronic kidney disease of unclear etiology with serum creatinine (SCr) of 1.3 and MDS. He was admitted with acute kidney injury in the setting of pneumonia and had nephrotic range proteinuria along with dysmorphic red blood cells on the urinary sediment. Renal biopsy showed MN with relatively recent immune complex deposition. There was no colocalization of IgG4 membranous deposits with phospholipase A2 receptor. He was hospitalized again with pancytopenia, marked inflammatory markers and infectious complications. Although bone marrow biopsy was not diagnostic, this syndrome was diagnosed as hemophagocytic
A Case of Advanced IgG4 Related Tubulointerstitial Nephritis Complicating Multiple Lymphadenopathy and Infiltrative Nodule, Mimicking Malignant Lymphoma

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a systemic inflammatory disorder characterized by typical clinicopathological features and significant response to steroid treatment. It usually manifests in elderly men. Here we report a case of advanced IgG4-RD associated with multiple lymphadenopathy and infiltrative nodules that mimicked malignant lymphoma.

Case Description: A 56-year-old Caucasian man with history of colon tubular adenoma, NHL-status post chemotherapy and radiation 30 years back, hypothyroidism presented with new-onset nephrotic-range proteinuria. He was not taking any medications and physical exam noted generalized edema. Laboratory exam as noted in table 1.

- At Diagnosis: 9 gms 0.85 mg/dL 1.8 g/dL 1:1000
- 6 months of conservative therapy: 11 gms 1.3 mg/dL 1.6 g/dL
- 3 months of Ponticelli regimen: 7.3 gms 1.5 mg/dL 2.2 g/dL 1:20

A renal biopsy showed variable-sized electron dense deposits in subepithelial, intramembranous, mesangial and paramesangial locations. This finding strongly suggested a secondary etiology for the membranous nephropathy. Workup for infectious, autoimmune and neoplastic causes of membranous nephropathy was negative. Proteinuria worsened to 11 g/24h despite six months of conservative therapy with lisinopril and low protein diet. Additional labs obtained came back positive for PLA2R autoantibodies (IFA 1:1000, ELISA 97.6 RU/ml). Kidney staining positive for PLA2R glomerular deposits suggesting IMN.

The patient was then treated with a modified Ponticelli protocol using alternating monthly prednisone and oral cyclophosphamide (2 mg/kg/d) for six months. After three months, proteinuria, albumin and edema improved.

Discussion: Relying on histopathologic differencies to distinguish between idiopathic and secondary membranous nephropathy may lead to incorrect diagnosis and delay in treatment. The presence of circulating and tissue PLA2R autoantibodies may be more reliable in diagnosing IMN than histopathology.

SA-PO086
Silent Malakoplakia in a Recipient of Kidney-Pancreas Transplant Diagnosed on Surveillance Biopsy of Kidney Allograft: A Patient-Centered Approach to Treatment of Malakoplakia Jun Shoji, 1 Ravinder K. Walli, 2 Dept of Kidney Disease and Hypertension, George Washington Univ, Washington, DC, 1Inova Transplant Center, Inova Fairfax Hospital, Falls Church, VA.

Introduction: Malakoplakia is an inflammatory disease leading to chronic morbidity and organ dysfunction. It was originally described in association with genitourinary tract infections with coliform bacteria and can manifest as acute pyelonephritis, acute or chronic renal failure, or renal mass. We present a case of a 40-year-old female recipient of simultaneous pancreas-kidney transplant who developed an acute rise in serum creatinine without apparent cause and found to have malakoplakia on kidney allograft biopsy. Patient consented and treatment resulted in reversal of allograft dysfunction and resolution of histological features of malakoplakia.

Case Description: 40-year-old Caucasian female with type 1 diabetes mellitus and end-stage renal disease on peritoneal dialysis underwent SPK transplant. After induction with basiliximab and thymoglobulin, she was maintained on tacrolimus and mycophenolate mofetil. Two months later, she was treated for acute T-cell mediated rejection (Banff Grade IA) with thymoglobulin. Serum creatinine returned to baseline and maintenance prednisone was added to her regimen. Her posttransplant course was complicated by multiple infections including parvovirus B19 infection, primary CMV infection, two episodes of urinary tract infections, and influenza A pneumonia. Due to an increase in serum creatinine without apparent cause, a kidney allograft biopsy was performed which revealed lesions consistent with malakoplakia.

Discussion: Treatment of malakoplakia in kidney transplant recipients is not well established but include surgical resection and use of antimicrobial agents. In the era of cyclosporine and azathioprine, it was speculated that the use of azathioprine may be associated with the development of malakoplakia. Discontinuation of azathioprine was suggested in more bactericidal activity of mononuclear cells. This case report illustrates that in the era of immunosuppression with tacrolimus and mycophenolate mofetil, the maintenance therapy with tacrolimus may be continued while treating for malakoplakia.

SA-PO087
Common Weight Loss Medication Pill “Qsymia” Causing Hypokalemia and Renal Tubular Acidosis Iyotana Thukkar, Mala Sachdeva. Div of Nephrology, North Shore -LI School of Medicine, Great Neck, NY.

Introduction: The obesity epidemic is growing. Aside from the traditional diet and exercise, weight loss pills are more commonly prescribed. Qsymia is one such weight loss pill consisting of topiramate and phentermine. We report potentially life threatening side effects of Qsymia causing severe hypokalemia, proximal renal tubular acidosis (pRTA), and cardiac dysrhythmia.

Case Description: A 68 year old female with history of hypertension presented with complaints of tingling of her left arm and jaw of one day duration. Her home medications included Aspirin and Hyzara (Losartan and Hydrochlorothiazide). She had self discontinued the Hyzaar five days prior to presentation. Patient was recently started on the weight loss medication “Qsymia” three months prior. She denied any alcohol use. On initial presentation, she was noted to be in atrial fibrillation (HR 150s) and hypotensive (BP 84/43 mmHg). Urinalysis showed pH 8 with glucosuria. Urine Lytes showed potassium 38 mmol/L, chloride 43 mmol/dL, bicarbonate 22 mmol/L, phosphorus 2.1 mg/dL, magnesium 2.2 mg/dL, and calcium 8.9 mg/dL. Urinalysis showed pH 8 with glucosuria. Urine Lytes showed potassium 38 mmol/L, chloride 43 mmol/dL, sodium 141 mmol/L.

It was suggested that patient’s clinical presentation and electrolyte disorders were due to the weight loss medication, and Qsymia was discontinued. Qsymia was approved by FDA in 2012 for weight loss. Most common side effects reported include paresthesia, due to the weight loss medication, and Qsymia was discontinued. Qsymia was approved by FDA in 2012 for weight loss. Most common side effects reported include paresthesia, hypokalemia and proximal tubular acidosis. Hence, we report it here. The patient’s weight loss medication was Qsymia which was discontinued and patient was treated with correction of hypokalemia and initiation of management for Multiple myeloma.

Discussion: Multiple Myeloma accounts for 10% of hematological malignancies. Atleast 50% of patients with MM have evidence renal insufficiency and more than 80% have proteinuria. Multiple myeloma can present as has wide range of renal manifestations including myeloma cast nephropathy, Immune deposit disease, CKD Fanconi syndrome. Though rare Multiple myeloma can cause TMA and the Pathogenesis still remains unclear.

SA-PO089

Introduction: Pantoprazole (PPZ), a Proton Pump Inhibitor, is known to cause acute interstitial nephritis (AIN). We report a case of PPZ induced AIN in a young adult with just 3 doses of drug exposure.

Case Description: A 21 year old Asian American male with no past medical history was sent to the hospital by his Internist for elevated serum creatinine (Scr). He had nausea and abdominal pain 3 weeks earlier and was prescribed PPZ, which he took for 3 days. He denied use of any other medications including herbal supplements and NSAIDS. Laboratory data showed BUN of 82 mg/dL, Scr 15 mg/dL (baseline 0.6), bicarbonate of 15 mmol/L and normal renal urinalysis. Urinalysis showed sterile pyuria with no eosinphils, glycosuria with normal blood glucose, mild proteinuria (900mg/24 hrs). Serum and urine toxicology, protein electrophoresis, auto-immune work up were unremarkable. A Renal biopsy revealed diffuse expansion of the interstitium due to accumulation of cellular infiltrates consisting of lymphocytes, plasma cells and eosinophils with accompanying tubulitis consistent with AIN.

Though rare Multiple myeloma can cause TMA and the Pathogenesis still remains unclear.

He received pulse steroids for 3 days and was continued on prednisone 1mg/kg/day with a plan to taper over 8-12 weeks. He required a few sessions of renal replacement therapy before his renal function started to recover, 6 weeks later his Scr was 1.4 mg/dL.

Discussion: Any drug can cause AIN, although the categories of antibiotics, diuretics and NSAIDs are most commonly implicated. Drug-induced AIN is not dose dependent, and recurrence can occur with a second exposure to the same or a related drug. The data on time of initiation, dosage and duration of steroids in drug induced AIN is limited due to lack of randomized control trials. On review of literature and our experience, we conclude that stopping the culprit agent and early steroid use confers better prognosis in drug induced AIN.

SA-PO090

Introduction: Renal cell carcinomas are more common in ESRD than the general population and renal transplant patients with enhanced longevity may be at particular risk. Sarcomatoid renal cell carcinoma represents 1-15% of all renal cell carcinomas but has been very rarely described as a cause of renal allograft. The median age at diagnosis is 68 years with 45-77% of patients with locally advanced or metastatic disease at the time of diagnosis. We describe a case sarcomatoid tumor of urothelial origin in a transplanted renal allograft.

Case Description: A 54 y/o man with ESRD from polycystic kidney disease, HTN, aortic dissection repair, mechanical AVR, panxoxymal Afib, who had failed renal transplants in the past and was on dialysis for past 12 years, was admitted for left lower quadrant pain, fever and leukocytosis for which he was started on vancomycin and Ceftriaxone treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
aztreonam. On imagine, he was found to have a mass around the left transplant kidney, ascites, omental caking, retroperitoneal lymphadenopathy and heterogeneous liver lesions. Retroperitoneal lymph node biopsy and asic fluid cytology was negative for malignant cells. Left kidney mass could not be biopsied because of technical difficulties and he had biopsy of the liver lesions which showed sarcomatoid tumor. He developed respiratory failure and septic shock requiring pressor support and expired. An autopsy was performed which showed Metastatic Sarcomatoid carcinoma of uterine origin.

Discussion: Malignancy in post transplant is related to direct effects of immune-suppressants as well as their effects to suppress immune surveillance and to stimulate the activation of oncogenic viruses. It is generally recommended that patients on the active transplant list and renal transplant recipients be screened every several years for renal tumors. However after allograft failure, it is unclear how often to do cancer screening tests. Although in this particular case it is unclear whether screening would have made a difference in outcome, we recommend routine screening for renal cell carcinoma even if the renal allograft has failed.

SA-PO091

Parathyroidectomy on a Patient with Sickle Cell Disease and End Stage Renal Disease
Farzana Akil, Mary C. Mallappallil, David Kau, Moro O. Sallyu. Stony Downstate Medical Center, Brooklyn, NY.

Introduction: Patients with End Stage Renal Disease (ESRD) can develop elevated parathyroid hormone (PTH) levels with hypercalcemia. Some fail or cannot tolerate medical therapy. They eventually require parathyroidectomy. Tertiary hyperparathyroidism (3PTH) is the autonomous function of the parathyroid gland due to increased mass. Our case is unique as there are no reported cases of tertiary parathyroidism in sickle cell patient, although, the presence of renal osteodystrophy may be present in sickle cell patients with parathyroidectomy. 25 year old man with sickle cell disease, ESRD on hemodialysis since 2012, (3PTH), presents after many admissions for sickle cell pain crisis. Cause of ESRD was unknown but attributed to sickle cell nephropathy. Current admission for knee pain and MRI which showed, “sclerotic appearance of the bones, likely due to renal osteodystrophy”. Intact PTH (iPTH) consistently > 4000 pg/mL, and patient non adherent to calcitriol, agreed to parathyroidectomy after many admissions for presumed vasoocclusive crisis. CT neck: “moderately enhancing foci inferior to the left and right thyroid lobes, and superior to the left thyroid lobes, could be compatible with parathyroid adenomas.” Sestamibi scan: “equivocal slow washout focus in region of right lower pole of thyroid gland extending posteriorly. Suspicious for but not definitive for parathyroid adenoma”. On the day prior to surgery, iPTH 4078 pg/mL, with serum calcium (Ca)=10.3 mg/dL. Immediately after surgery and for 265 pg/mL, with Ca=9.9 mg/dL. The first day after surgery, iPTH 36 pg/mL with Ca=7.6 mg/dL. Patient admitted for 3 days due to his requirement of intravenous calcium and daily hemodialysis. Since discharge, patient has had fewer admissions for pain. He has however, remained hypocalcemic and is on 5 grams of calcium carbonate, 4 mcg of doxercalciferol, and is dialyzed with a 3 mEq/L calcium bath.

Discussion: 3PTH is common in ESRD patients that can leave them debilitated. Those who fail medical therapy may benefit from resection. In sickle cell disease symptoms of 3PTH was masked by vaso-occlusive crises and could be distinguished by marked reduction in symptoms after resection.

SA-PO092

Synthetic Cannabinoid (SC) in End Stage Renal Disease
Chyi Chyi Chong, Pallavi D. Shirsat, Ramesh Marahatta, Neville R. Dossabbhoy. 1LSU Health Science Center, Shreveport; 2YA Medical Center, Shreveport.

Introduction: Synthetic cannabinoids (SC) are drugs of abuse especially among young adults. They are affordable, widely available and mostly importantly undetectable by standard urine toxicology screen. The avoidance of detection in the urine contributes to their allure and abuse. Acute kidney injury (AKI) related to synthetic cannabinoids has been reported. However, effect of synthetic marihuana in end stage renal disease (ESRD) patients remains unknown.

Case Description: We present a case of severe high anion gap metabolic acidosis (HAGMA) with acute respiratory failure in an ESRD patient. A 37-year-old African American female with ESRD, hepatitis C and hypertension was found smoking synthetic marihuana under a tree, and in a confused state. Upon arrival to the emergency room, patient was severely hypertensive with blood pressure of 230/140 mmHg, and subsequently developed acute respiratory failure requiring intubation. Chest x-ray showed bilateral pulmonary edema. Laboratory data revealed: WBC 18K/uL, Potassium 4.3-6.6 [3.6-5.2], mmol/L Calcium 8.2-10.1 [8.9-10.1], mg/dL. The patient was initiated on allopurinol, rasburicase, and continuous veno-venous hemofiltration (CVVH). He progressively deteriorated during his 11-day hospital course with recurrent episodes of arrhythmia, persistent encephalopathy, continued mechanical ventilator and hemodialysis dependence, and refractory septic shock with candidemia. The family elected for comfort care and the patient expired the next day.

Discussion: Synthetic Cannabinoids are sold under different trade names and the exact association between the use of cocaine and focal segmental glomerulosclerosis. Although in this particular case it is unclear whether screening would have made a difference in outcome, we recommend routine screening for renal cell carcinoma even if the renal allograft has failed.

SA-PO093

Focal Segmental Glomerulosclerosis Associated with Cocaine Abuse: A Case Report

Introduction: Cocaine exists in two major forms: cocaine hydrochloride and alkaloid freebase (crack). Cocaine abuse causes many well recognized systemic adverse effects and acute kidney injury is usually due to rhabdomyolysis, malignant hypertension with thrombotic microangiopathy and renal infarction. In addition, it has been described ANCA-positive vasculitis induced by levamisole- adulterated cocaine causing nephrotic syndrome. We report a case of focal segmental glomerulosclerosis in a patient with history of cocaine use.

Case Description: A 49 year-old man of admixture race presented with progressive edema and dyspnea for the past five months. Lab tests showed Scr 7.0 mg/dL (baseline: 0.9 mg/dL), hypoalbuninemia, hypercholesterolemia and nephrotic range proteinuria (13g/24h). The patient had started using illicit drugs (marihuana and crack) three months before the symptoms began. There was no sign of infection or hypovolemia. All serologic tests were normal or negative, including complement, antinuclear antibodies, anti-DNA antibody, c-ANCA, p-ANCA, hepatitis B and C, HIV, syphilis and there was no evidence of monoclonal serum spike. Renal ultrasound was normal. The patient underwent hemodialysis and received methylprednisolone. Renal biopsy showed 13 glomeruli, 6 globally sclerotic and 5 with segmental sclerosis and synchiae of the glomerular tuft, tubular atrophy and moderate interstitial fibrosis. Immunofluorescence was negative. There was no recovery of renal function.

Discussion: Although it has been described nephrotic syndrome due to ANCA-positive vasculitis induced by levamisole-adulterated cocaine, we have reported a case that showed association between the use of cocaine and focal segmental glomerulosclerosis.

SA-PO094

A Rare Case of Tumor Lysis Syndrome in a Patient with Angiosarcoma
Bilal J. Alturkman1, Michael A. Mao,2 Edward T. Casey. 1Alfaisal Univ, Riyadh, Saudi Arabia; 2The Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Introduction: To report a rare case of tumor lysis syndrome (TLS) developing in a patient with angiosarcoma and metastasis to the liver.

Case Description: A 63-year-old male presented to his primary care physician complaining of fatigue, night sweats, fever, and newly developed RUQ pain. An ultrasound of the abdomen revealed hepatic lesions and a subsequent CT scan showed two large masses in the liver and a mass in the pancreas. A liver biopsy was obtained and findings were consistent with metastatic angiosarcoma and he was therefore initiated on palliative chemotherapy. The patient then presented to his local hospital with abdominal pain and abdominal bruises. His hemoglobin was 4.9 g/dL and he was found to be bleeding from the liver biopsy site. He was transferred to our institution for embolization in setting of intra-abdominal bleeding and multorgan dysfunction. His clinical presentation, along with laboratory findings, was consistent with anuric renal failure secondary to TLS.

The patient was initiated on allopurinol, rasburicase, and continuous veno-venous hemofiltration (CVVH). He progressively deteriorated during his 11-day hospital course with recurrent episodes of arrhythmia, persistent encephalopathy, continued mechanical ventilator and hemodialysis dependence, and refractory septic shock with candidemia. The family elected for comfort care and the patient expired the next day.

Discussion: TLS is a constellation of laboratory and or clinical manifestations that can arise either spontaneously or secondary to cancer treatments. Patients with hematological malignancies have a higher tendency to develop this syndrome due to the rapid turnover of cell growth and death. However, patients with solid tumors occasionally present with TLS. To our knowledge, this is the first case report of TLS associated with angiosarcoma.
Leukocyte Chemotactic Factor 2 (LECT2)-Associated Renal Amyloidosis: A Case Report

Alexander Pepen Romero, 1 James Drakakis, 1 Joseph Mattana, 1 Nephrology Dept, Winthrop Univ Hospital, Mineola, NY; 2 Pathology Dept, Columbia Univ, New York, NY.

Introduction: ALECT2 amyloidosis is a frequent form of systemic amyloidosis, represents 2.7-10% of all cases of renal amyloidosis. Most patients are elderly who present with chronic renal insufficiency and bland urinary sediment.

Case Description: We report a 76-year-old Egyptian male who presented after a recent hospitalization for self limited gastroenteritis and severe acute renal failure presumed secondary to acute tubular necrosis. Due to non-improving renal function and uricemic symptoms, renal biopsy was done and showed patchy interstitial amyloidosis deposits that did not stain for IgG, IgM, IgA, kappa, Lambda chains or Amyloid A; sample was sent to Mayo Clinic where Liquid chromatography tandem mass spectrometry detected a peptide profile consistent with ALECT2 Amyloidosis.

Discussion: This case suggests that ALECT2 Amyloid can present with bland uroanalysis and non-nephrotic range proteinuria in elderly patients.

Myoglobin versus CPK and the Potential Role for Rasburicase

Andreas Jeron, 2 Dunja Bruder, 2 Peter R. Mertens, 1 Christos D. Chatzikyrkou. 1 Nephrology Dept, Winthrop Univ Hospital, Mineola, NY; 2 Pathology Dept, UCLA Medical Center, Los Angeles, CA.

Introduction: Myoglobin versus CPK and the Potential Role for Rasburicase

complete resolution of eosinophilia while the patient was on HD. In 3/28/2011, the patient resumed PD via same catheter and same solution, follow up PD fluid sample on 4/07/2011 showed normal WBC count and 4% eosinophil.

Discussion: Our case suggests IEP was a transient reaction to the catheter placement rather than a reaction to the PD set or solution.

SA-PO100
Post Renal Transplant Follow Up in Focal Segmental Glomerulosclerosis with 24 Hour Urine Protein Collection – Traditional and True
Ravinder Pal S. Bhatti, Manisha Singh, Lakshmi P. Nadimpalli, Sameh R. Abul-Ezz. Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.

Introduction: Random Urine Protein Creatinine Ratio (PCR) is commonly used to estimate proteinuria compared to 24 hour urine protein measurement (24-UP). However, there are concerns over the diagnostic accuracy and reliability of such an approach in post-transplant setting. We present a case of post-transplant focal segmental glomerulosclerosis (FSGS) illustrating this.

Case Description: A 39 year old male with primary FSGS, on peritoneal dialysis for 4 years received a cadaveric kidney transplant. His panel reactive antibody was 0% and HLA cross-match was negative. Intra-operatively, a large stone measuring 2 cm was identified in the hilum of the donor kidney and was successfully removed by irrigation. A smaller middle calyceal stone was localized by fluoroscopy.

The donor was a healthy 31 year old female who suffered anoxic brain injury in a motor vehicle accident. Her CT abdomen showed 2 stones in the right kidney as represented in the figure’s inset. The kidney became available to us on a regional list after it was declined locally due to concerns over kidney quality. The recipient was a 50 year old female with hypertensive nephropathy, on hemodialysis for the past 2 years. Her panel reactive antibody was 90% and HLA cross-match was negative. Intra-operatively, a large stone measuring 2 cm was identified in the hilum of the donor kidney and was successfully removed by irrigation.

Discussion: The new kidney allocation policy aims to address organ shortage by reducing donor and graft survival mismatch. Traditionally, donor hemodynamics, age, serum creatinine and histopathology have influenced decisions on accepting a kidney. The perceived quality and utilization techniques widely vary for deceased donor kidneys with lithiasis. Our case illustrates how this can lead to non-acceptance of an otherwise healthy kidney, which can be transplanted with a favorable outcome.

SA-PO102
A Peritoneal Dialysis Catheter Leak Complicated by Burkholderia Gladioli Peritonitis. Ravinder Pal S. Bhatti, Dummitru Rotaru. Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.

Introduction: Dialysate leaks can occur any time after peritoneal dialysis (PD) catheter placement. Early leaks usually manifest as an exit site leak, though may also present with air in the PD catheter. Leaks increase the risk for exit site infections (ESI) and peritonitis. We present such a patient developing peritonitis with an unusual pathogen.

Case Description: A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for 3 years, presented with exit site erythema a week after trying to push in an extruded cuff. Prophylactic antibiotics were started but he declined surgery. The ESI recurred soon after completing 3 weeks of antibiotics. He agreed to catheter replacement with an exit site change. He was started on low volume exchanges. Two weeks later, he noted air bubbles in the PD catheter upon draining.

There were no perioperative complications and the recipient had excellent immediate graft function. Her creatinine progressively improved by time of discharge, remaining normal in subsequent months.

Discussion: New kidney allocation policy aims to address organ shortage by reducing donor and graft survival mismatch. Traditionally, donor hemodynamics, age, serum creatinine and histopathology have influenced decisions on accepting a kidney. The perceived quality and utilization techniques widely vary for deceased donor kidneys with lithiasis. Our case illustrates how this can lead to non-acceptance of an otherwise healthy kidney, which can be transplanted with a favorable outcome.

SA-PO101
Donor Kidney Lithiasis: A Case of Throwing Out the Baby with the Bathwater? Ravinder Pal S. Bhatti,1 Sameh R. Abul-Ezz,1 Lakshmi P. Nadimpalli,2 Gary Wickens Barone,2 1Nephrology, 2Transplant Surgery, Univ of Arkansas for Medical Sciences, Little Rock, AR.

Introduction: Cadaveric kidneys account for a majority of transplants in the United States. However, only 10% of waitlisted patients receive one annually, making optimal utilization critical. Donor nephrolithiasis represent a small yet significant proportion of kidneys discarded. We present a patient who received such a kidney which otherwise could have been discarded.

Case Description: The donor was a healthy 31 year old female who suffered anoxic brain injury in a motor vehicle accident. Her CT abdomen showed 2 stones in the right kidney as represented in the figure’s inset. The kidney became available to us on a regional list after it was declined locally due to concerns over kidney quality. The recipient was a 50 year old female with hypertensive nephropathy, on hemodialysis for the past 2 years. Her panel reactive antibody was 90% and HLA cross-match was negative. Intra-operatively, a large stone measuring 2 cm was identified in the hilum of the donor kidney and was extracted via pyelotomy. A smaller middle calyceal stone was localized by fluoroscopy and successfully removed by irrigation.

Early recurrence of FSGS was diagnosed. A biopsy was withheld to avoid delay in timely management and risk of bleeding with plasmapheresis which was immediately initiated. He was switched from tacrolimus to cyclosporine. He required plasmapheresis for 5 weeks and had satisfactory recovery in the ensuing months.

Discussion: Logistics have led to the widespread use of PCR in follow-up of kidney transplant recipients. However changing creatinine excretion with recovering renal function, lower precision with heavier proteinuria, and limited data on accuracy compared to 24-UP, potentially limit its utility at detecting early post-transplant recurrence of FSGS. Our case highlights marked discordance between the PCR and 24-UP, detection of which allowed a timely change in management. We conclude that it is prudent to monitor proteinuria by random urine collection in preference to random PCR in the immediate post-transplant setting for recipients with primary FSGS.

A small pinhole was found at the exit site, suspected to be from a sharp injury during dressing change. He was planned for surgical revision but soon started having turbid drainage. Instilled dialysate was cultured, broad spectrum intravenous antibiotics were started and he was switched to hemodialysis. During surgery, the damaged catheter was spliced to new tubing proximal to the exit site. The cultures grew Burkholderia Gladioli by now. PD was resumed the next day. The peritonitis resolved during the 3 weeks of antibiotics. He continued PD uneventfully over ensuing months.

Discussion: There were no perioperative complications and the recipient had excellent immediate graft function. Her creatinine progressively improved by time of discharge, remaining normal in subsequent months.

Discussion: The new kidney allocation policy aims to address organ shortage by reducing donor and graft survival mismatch. Traditionally, donor hemodynamics, age, serum creatinine and histopathology have influenced decisions on accepting a kidney. The perceived quality and utilization techniques widely vary for deceased donor kidneys with lithiasis. Our case illustrates how this can lead to non-acceptance of an otherwise healthy kidney, which can be transplanted with a favorable outcome.

including by rare pathogens warrants appropriate antibiotic prophylaxis and lastly a more limited approach than catheter exchange may be used even for leaks close to exit sites based on the location and local experience.

**SA-PO103**

Enteric Hyperoxaluria Related to Celiac Disease Causing Acute Kidney Injury After Kidney Transplantation

Ashvin Baru, Venkat Ramathan.

Nephrology, Baylor College of Medicine, Houston, TX.

**Introduction:** Acute kidney injury (AKI) after kidney transplantation can occur from myriad of causes. We present an interesting case of a young woman with history of Celiac disease who developed AKI and biopsy-proven oxalate nephropathy within 3 months post-transplantation, as a result of enteric hyperoxaluria associated with gluten noncompliance.

**Case Description:** A 35 year-old woman with type 1 diabetes mellitus, and celiac disease underwent living unrelated kidney transplantation for ESRD related to biopsy-proven diabetic nephropathy. Her original renal ultrasound did not show nephrocalcinosis. After transplantation, nadir serum creatinine was 1.0 mg/dL. Three months later, she presented with six-day history of diarrhea and AKI. Serum creatinine peaked at 2.6 mg/dL. Since volume replacement did not improve her allograft function and she had high panel reactive antibody levels pre-transplant, a kidney biopsy was performed that showed acute tubular injury with significant oxalate crystalline deposits. Initial serum oxalate level was undetectable, but 24-hour urine oxalate excretion was elevated at 98 mg/dL. Pending gene testing, she was treated with intravenous fluids, low oxalate diet, gluten free diet, vitamin B6, oral alaki and calcium carbonate. Subsequent gene testing did not reveal gene mutation in the oxalate pathway. Her urine output was maintained between 3 to 4L per day. With strict gluten avoidance and low oxalate diet, urine alkalization and oral calcium, her allograft function has improved to baseline.

**Discussion:** Celiac disease exacerbation and subsequent malabsorption can lead to significant gut oxalate absorption and hyperoxaluria. Resulting oxalate nephropathy is a rare cause of AKI after kidney transplantation.

**SA-PO104**

Unusual Presentation of Tumor Related Membranous Nephropathy

Tahir Zaman,1 Frederic Clayton,2 Josephine Abraham,1 Nephrology, Univ of Utah, Salt Lake City, UT; 2Pathology, Univ of Utah, Salt Lake City, UT.

**Introduction:** The literature is laden with evidence of several solid tumors causing secondary membranous nephropathy. It is also described in the literature that solid tumors could also ANA positivity.

**Case Description:** A 62-year-old male with a history of hypertension presented with oliguric renal failure following an episode of gastroenteritis. History was unremarkable with patient denying smoking or other vices. Urine analysis revealed rare dysmorphic RBC’s and minimal proteinuria (spot protein/creatinine ratio 0.5 gms). Serologic workup revealed PR3 (ANCA negative) and abnormal Kappa Lambda Ratio thus renal biopsy was performed, which revealed membranous nephropathy and acute tubular necrosis (ATN).

Immunofluorescence was positive for C3, IgG, though negative for PLA-2R, IgA and Clq. ANA was strongly positive (1:10240 speckled pattern), HIV serology was negative. Sublingular mass was found which revealed squamous cell carcinoma. Bone marrow biopsy revealed smoldering multiple myeloma. The patient’s ATN resolved and he subsequently underwent left partial glossectomy. His cancer was staged at T2N0 and he is undergoing chemotherapy and radiation therapy.

**Discussion:** Secondary membranous nephropathy has a known association with solid tumors. The positive ANA raised the concern of concurrent SLE but Clq negativity on the biopsy made this diagnosis unlikely. Ultimately treatment of the underlying condition is paramount. 1. Imai, H. et al. Nucleolar antigens and autoantibodies in hepatocellular carcinoma and other malignancies. Am. J. Pathol. 140, 859–70 (1992).

**SA-PO105**

A Case of Severe Adrenal Insufficiency due to Long-Term Glucocorticoid Administration for Pediatric Nephrotic Syndrome

Yuko Fujii,1 Akira Ashida,1 Hideki Matsumura,2 Akihiko Shirasu,1 Hyogo Nkakura,1 Motoshi Hattori,1 Hiroshi Tamai,1 1Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; 2Pediatric Nephrology, Tokyo Women’s Medical Univ, Shinjyuku, Tokyo, Japan.

**Introduction:** One of the adverse effects of long-term glucocorticoid therapy in supraphysiologic doses is suppression of the hypothalamic-pituitary-adrenal axis, although symptomatic adrenal insufficiency is considered to be an unusual complication of glucocorticoid therapy for nephrotic syndrome in pediatric patients. Here we describe a case of secondary adrenal insufficiency due to long-term glucocorticoid therapy for steroid-dependent nephrotic syndrome.

**Case Description:** A 12-year-old boy who had developed steroid-dependent nephrotic syndrome at the age of 2 years had been treated repeatedly with corticosteroid, cyclosporine and mizorbine. On relapse of the disease at 4 years of age, the nephrotic syndrome had been resistant to steroid therapy including 2 mg/kg prednisolone and 4 courses of methylprednisolone pulse therapy, but had responded to additional cyclophosphamide therapy at 7 months after relapse onset. During tapering of the glucocorticoid therapy, the patient had shown various symptoms, including general fatigue, facial edema, decreased urine volume, appetite loss, and dizziness from the age of 5 years. At that time, the basal value of cortisol was not detectable and a rapid ACTH loading test elicited a low response. In the CRH and insulin loading test, the basal value of ACTH was not detectable and an over-response of ACTH was demonstrated. Therefore the patient was diagnosed as having glucocorticoid-induced hypoadrenalism and treated with cyclosporine, a decreased dose of prednisolone, and hydrocortisone supplementation. The serum ACTH and cortisol values increased gradually. An insulin loading test at the age of 12 years demonstrated normal responses of the ACTH and cortisol levels.

**Discussion:** The very long-term nature of the therapy for this patient with idiopathic nephrotic syndrome resulted in glucocorticoid-induced adrenal insufficiency. Periodic evaluation of adrenal function and re-evaluation of the treatment is important for patients with nephrotic syndrome receiving steroid therapy.

**SA-PO106**

Henoch-Schönlein Purpura in Adult, from a Clinical Case

Pedro Vieira, Jose Duraes, Luís Resende, Nuno Rosa, Jose Alves Teixeira, Gil Silva. Nephrology, Hospital Dr. Nélio Mendonça, Funchal, Portugal.

**Introduction:** Henoch-Schönlein purpura is a small vessel vasculitis mediated by IgA-immune complex deposition with multisystemic involvement. Rare in adults, it is characterized by purpura, arthralgias, abdominal pain, and renal involvement. Viral infections have been reported as trigger.

**Case Description:** The authors present the case of a 25 years old male, without relevant medical history, admitted to the Nephrology Department in May 2014 by severe hypertension, renal failure (creatinine 6.7mg/dL), erythrocyturia and proteinuria. Renal ultrasound was normal. Renal biopsy revealed IgAnephropathy (M1E1S1T2). Our investigation revealed chronic hepatitis B virus (HBV) of vertical transmission origin (viral load 150 IU/mL). Corticosteroid therapy was started, with slight improvement in renal function. He was readmitted 2 months later by asthma, epistaxis, weight loss, palpable purpuric edema, +/- urticaria, and oral and nasal ulcers. Laboratory tests revealed hemoglobin 9.2g/dL, creatinine 4.3mg/dL, normal transaminases, albumin 20g/L, urinary spot protein/creatinine ratio 1300mg/g, hypocomplementemia, negative p-ANCAs, c-ANCAs and cryoglobulins, HBV load 379.9801U/mL. During hospitalization the patient initiated progressive pancytopenia, diffuse abdominal pain, generalized skin purpura and fever (with no identifiable infectious origin and interpreted as immunologic). We made clinical diagnosis of Henoch-Schönlein purpura and started with cyclophosphamide and entecavir. A few days later appeared hypoxemia and oliguria, requiring urgent dialysis. Cranial CT scan showed microangiopathic leukoencephalopathy of unspecified etiology and alveolar hemorrhage in chest CT scan. Due to life threatening multisystemic involvement we started methylprednisolone pulses, intravenous immunoglobulin and plasmapheresis. Patient completely recovered, but remained dependent on dialysis. 6 monthly cycles of cyclophosphamide were maintained, with no signs of recurrence.

**Discussion:** We emphasize the rare severe multisystemic involvement of a Henoch-Schönlein purpura in an adult, the onset of the disease with exacerbation of viral infection, and the therapeutic challenge of an HBV patient with an vasculitis.

**SA-PO107**

Rare Etiology for Chronic Kidney Disease: Bronchiectasis Related Secondary Amyloidosis

Alper Alp,1 Hakun Akdam,2 Aysegul Ormeci,3 Ibrahim Meteoglu,1 Alparslan Unsal,1 Yavuz Yenicerioglu.1 1Nephrology, Van Education and Research Hospital, Van, Turkey; 2Nephrology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; 3Pathology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey.

**Introduction:** Here we present an elderly patient with a known posttuberculosis bronchiectasis, nephrotic-range proteinuria and renal failure was detected. Renal biopsy revealed AA amyloidosis. Tuberculosis and tuberculosis related systemic disorders still have clinical impact in nephrology practice especially in developing countries.
Introduction: The optimal treatment of cryoglobulinemic glomerulonephritis (GN) in the setting of Hepatitis C (Hep C) with sustained viral response (SVR) is unknown. Only expert opinion obtained from case reports provide guidance to the clinician. Some reports show benefit with Rituximab and plasma exchange.

Case Description: 58yo male with h/o treated Hep C currently with an undetectable viral load, gastric ulcer, anemia, and HTN presented to clinic for evaluation of CKD. Hep C was initially diagnosed when he was found to have leukocyctoclastic vasculitis on a skin biopsy of skin rash. Labs were positive for serum cryoglobulins, rheumatoid factor, low C4, and Hep C viral load. Renal function was normal and he was successfully treated for cryoglobulinemic vasculitis due to Hep C with interferon alpha, telaprevir and ribavirin and achieved a SVR. He presented 1 year later with renal insufficiency (creatinine -2.2 mg/dL) and cryoglobulinaemia. He had necrotizing flares of vasculitis. SPEP revealed IgM kapa monoclonal with negative UPEP. C4 was low and cryoglobulins remained positive. Kidney biopsy showed immune complex GN with organized deposits. Bone marrow biopsy was negative for lymphoproliferative disease. He was diagnosed with cryoglobulinemic GN with SVR. Initially, he was treated with prednisone followed by Rituximab and plasmapheresis. He failed the treatment and was started on hemodialysis.

Discussion: Cryoglobulinemic GN is frequently due to Hep C but is rare in patients achieving a SVR. In our case an underlying B cell lymphoma was ruled out and it was felt that B cell immune dysregulation due to Hep C was the culprit, in part due to prior published cases. However, in our case treatment with rituximab and plasmapheresis was unsuccessful. It remains possible, as others have demonstrated, that the virus may persist within the liver, macrophages, lymphocytes, and even kidney. The pathological basis for persistent vasculitis in setting of a SVR requires further study so that targeted and more effective treatment strategies can be designed.

650A
proteinuria (3.7g/24h), evidence of dysmorphic hematuria and worsening of renal function (Cr 4.1 mg/dl), he received methylprednisolone 1g for three days and renal biopsy was proposed. It revealed pauci-immune crescentic glomerulonephritis. Immunofluorescence showed mesangial deposition of C3 (++) and lambda chains (+). Treatment was followed by monthly i.v. cyclophosphamide and proteinuria decreased to 0.87 g/24h. cANCA became positive (1/160) 4 months after diagnosis.

Discussion: Membranous nephropathy is the most commonly reported glomerulonephritis especially with pulmonary cancer, but several reports suggest an association between rPGn and malignancies. The increased risk for malignancy has been confirmed in a retrospective review of 200 patients with ANCA-associated vasculitis, demonstrating a significantly increased relative risk (6.02) compared with age-matched controls. Biava et al reported seven cases of rPGn associated with a coexisting nonrenal malignancy (6 carcinomas and 1 lymphoma). The pathogenetic mechanisms by which neoplasms lead to the development of ANCA-associated vasculitis and rPGn are largely unknown.

SA-PO112
A Case of Encapsulating Sclerosing Peritonitis in a Type I Diabetic on Peritoneal Dialysis Zachary Freestone, Josephine Abraham, Akram M. Shaaban.

Introduction: Encapsulating sclerosing peritonitis (ESP) is a rare disorder associated with PD. It is characterized by peritoneal fibrosis and encasement of the bowel. Symptoms associated with ESP are non-specific and may be attributed to other etiologies. Abdominal imaging is required to evaluate ESP and diagnostic confirmation is achieved by laparoscopy. ESP should be considered in patients on peritoneal dialysis with symptoms involving the gastrointestinal tract, weight loss, or inadequate solute clearance.

Case Description: A 34 year old Caucasian male on PD presented to the clinic with complaints of nausea and abdominal pain. He had a history of type I DM, ESRD, neuropathy, and gastroparesis. He was started on PD 8 years ago and has had 3 prior episodes of peritonitis. The patient appeared ill and malnourished. His abdomen was soft on examination and non-tender to palpation. An abdominal x-ray indicated that he had calcification in the abdomen and pelvis. CT imaging showed calcification of the parietal peritoneum, abdominal cavity, omentum, and bowel. The patient underwent exploratory laparotomy with simultaneous PD catheter removal. The visual examination revealed a brown, inflamed rim encompassing the peritoneum, omentum, bowel, and colon. Peritoneal dialysis was discontinued and the patient was transitioned to hemodialysis.

Discussion: Encapsulating sclerosing peritonitis (ESP) is a condition associated with peritoneal dialysis. Its presenting symptoms are often non-specific and may be attributed to other causes. Abdominal imaging is necessary to evaluate for suspected ESP, CT being the preferred method. ESP is characterized by peritoneal thickening and fibrosis that encases the bowel. Treatment includes cessation of PD with transfer to hemodialysis and bowel rest. Other attempted treatments of this disease have included steroids and total enterolysis.

SA-PO113
Acute Kidney Injury from Enterovesicular Fistula Secondary to Squamous Cell Carcinoma of Bladder Elefni Cheladi, Evdokia Efthimiou, Alexia Papalexandrou, Maria Sotiraki, Ioannis Xatzis, Maria Tsilivigou.

Introduction: Squamous cell carcinoma (SCC) of the bladder is a relatively rare tumor. Predisposing factors are chronic irritation of the bladder by UTI, calculi and long-term indwelling catheterization. Enterovesicular fistula (EVF) usually has flow from the intestine to the bladder and commonly manifests with recurrent urinary tract infections (UTI), long-term indwelling catheterization. EVF should be considered in patients on peritoneal dialysis with symptoms involving the gastrointestinal tract, weight loss, or inadequate solute clearance.

Case Description: A 56 year old Caucasian female with hypertension, diabetes mellitus and recurrent UTI was admitted in a uremic state that necessitated the immediate start of PD. Urine protein was 1+ with dipstic analysis and 9.7 g/gCr. Albumin to creatinine ratio was 10.1 (normal <0.7). Serum albumin was 2.4g/dl and corrected Ca 16mg/dl. Urine protein was 1+ with dipstic analysis and 9.7 g/gCr. Proteinuria (3.7g/24h), evidence of dysmorphic hematuria and worsening of renal function (Cr 4.1 mg/dl), he received methylprednisolone 1g for three days and renal biopsy was proposed. It revealed pauci-immune crescentic glomerulonephritis. Immunofluorescence showed mesangial deposition of C3 (++) and lambda chains (+). Treatment was followed by monthly i.v. cyclophosphamide and proteinuria decreased to 0.87 g/24h. cANCA became positive (1/160) 4 months after diagnosis.

Discussion: Membranous nephropathy is the most commonly reported glomerulonephritis especially with pulmonary cancer, but several reports suggest an association between rPGn and malignancies. The increased risk for malignancy has been confirmed in a retrospective review of 200 patients with ANCA-associated vasculitis, demonstrating a significantly increased relative risk (6.02) compared with age-matched controls. Biava et al reported seven cases of rPGn associated with a coexisting nonrenal malignancy (6 carcinomas and 1 lymphoma). The pathogenetic mechanisms by which neoplasms lead to the development of ANCA-associated vasculitis and rPGn are largely unknown.

formation in tubular lumens with severe tubular atrophy. Cell accumulation and fibrotic lesion were also detected in interstitium. Mesangial matrix was mildly expanded in glomeruli. Amyloid deposition was not observed.

Discussion: Herein, we showed clinical course and renal pathology of the patient with IgD-lambda type MM. Although steroid pulse therapy decreased serum levels of IgD, renal function did not improve. Renal pathology showed cast nephropathy, interstitial fibrosis and cell infiltration. The renal manifestation of IgD type MM requires further investigation.

SA-PO116
Sunitinib-Induced Nephrotic Syndrome and Acute Kidney Injury in a Malignant Insulinoma Patient: A Case Report
Wolakana Shoda, Naofumi Yui, Shokaro Naito, Soichiro Iimori, Koichiro Sasa, Takayasu Mori, Naohiro Nomura, Eisei Sohara, Tomokazu Okado, Tatemitsu Rai, Shinichi Uchida. Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan.

Introduction: Sunitinib, a tyrosine kinase inhibitor targeting vascular endothelial growth factor receptors (VEGFR), has been proven to be effective in the treatment of several types of cancer, including pancreatic neuroendocrine tumors. However, its risk of renal complications, such as proteinuria, renal dysfunction, and hypertension, are understudied. Case Description: A 71-year-old man with malignant insulinoma treated on sunitinib for six months, developed proteinuria, acute kidney injury and hypertension. Kidney biopsy showed thrombotic microangiopathy (TMA) like lesions such as double contour, edematous endothelial cells and microaneurysms, suggesting injuries induced by sunitinib. Decreased VEGF expression in podocytes was demonstrated by immunohistochemistry, supporting the diagnosis. Sunitinib was discontinued and partial remission of the renal complication was achieved in two weeks. However, the patient mandates needed to restart sunitinib because of poor control of blood glucose level due to pancreatic cancer exacerbation. By reducing the dose of sunitinib and administering losartan concurrently, the patient was able to maintain stable renal function with serum creatinine time of 1.4 mg/dl and urinary protein level under 1.0 g/day.

Discussion: VEGF blockade by sunitinib is featured by adverse effects including hypertension and renal injury. In the present case, renal injury partially improved after discontinuing sunitinib. Reducing the dosage of sunitinib and administering losartan made it possible to restart sunitinib treatment while controlling its renal side effects. VEGF, which is expressed and secreted by podocytes, is an important factor for development and maintenance of glomerular endothelium. Renal biopsy in this case showed down regulation which is expressed and secreted by podocytes, is an important factor for development and maintenance of glomerular endothelium. Renal biopsy in this case showed down regulation of VEGF in podocytes. Although the mechanism of renal dysfunction and proteinuria caused by anti-VEGF therapy is not well elucidated, the findings of this case might provide insights into the mechanism of renal toxicity by sunitinib.

SA-PO117
Liver-Kidney versus Liver Transplant Alone: Decision Making in the Operating Room
Ekamol Tantisattamo.1 Siwadon Pitukweerakul.2 Praveen Ratanasirimetha.3 Nephrology, Northwestern Univ; 2Presence St. Francis Hospital, Evaston; 3Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Acute kidney injury (AKI) is a common complication of uncomplicated chronic liver disease and hepatorenal syndrome (HRS) is one of the leading causes. Liver transplantation (LT) is a definitive treatment for HRS; however, simultaneous liver-kidney transplantation (SLK) is pursued due to the severity of preoperative AKI with uncertainty of postoperative renal recovery. Case Description: A 60-year-old Caucasian woman with ESLD due to alcoholic cirrhosis had been readmitted twice over 2.5 months with AKI from HRS. Even though, she was treated with albumin, miodroine, and octreotide, serum creatinine (SCr) had been elevated from the initial baseline of 1 mg/dL and had never returned to the baseline. Instead, it was worse every times she had AKI (Figure 1). After the last episodes of AKI, SCr had been stable at 2.5 mg/dL and she was listed for SLK. One week later, she was offered for SLK. After the LT, she started making a significant amount of urine immediately; therefore, the kidney was not transplanted and transferred to other potential kidney transplant recipient in another transplant center. Postoperatively, SCr had trended down to 1.1 mg/dL.

Discussion: Even though, our patient had recurrent episodes of AKI from HRS and persistent elevated SCr even ~3 months period, it was thought that the chance of meaningful renal recovery was small and SLK was initially planned. Fortunately, her renal function was recovery immediately after the LT alone. Preoperative evaluation for SLK versus LT alone sometimes becomes uncertain. Intraoperative finding of signs of renal recovery after LT is crucial as it can avoid unnecessarily kidney transplantation and provide an opportunity to utilize kidney organ to other potential kidney transplant recipient.

SA-PO118
Is Portopulmonary Hypertension Patient a Good Candidate for Liver Transplantation?
Ekamol Tantisattamo.1 Siwadon Pitukweerakul.2 Praveen Ratanasirimetha.3 Nephrology, Northwestern Univ; 2Presence St. Francis Hospital, Evaston, IL; 3Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; 1Presence St. Francis Hospital, Evaston.

Introduction: Portopulmonary hypertension (PPH) is one of the most feared complications of end-stage liver disease (ESLD). Liver transplantation (LT) may reverse this complication with uncertain outcomes. We report a case of ESLD women complicated by severe pulmonary arterial hypertension (PAH) secondary to PPH and acute kidney injury (AKI) who had prolonged pre- and post-operative simultaneous liver-kidney transplantation (SLK) with partial liver improvement, un-meaningful renal recovery, and bed bound with reconditioning.

Case Description: A 48-year-old woman with ESLD from cryptogenic cirrhosis complicated by portal hypertension, PAH-related to PPH and sarcoidosis presented with AKI requiring CRRT. She was treated with treprostinil, sildenafil, and ambrisentan until suitable for SLK. Postoperatively, liver and renal allografts worked well and PA pressure was decreased. However, she still required treprostinil and diuresis to control PAH and volume status. After 5 months of ICU stay, she developed severe deconditioning and malnutrition. She had AKI with SCr of 0.5 mg/dL up to 1 mg/dL over 3 weeks. Calculated average clearance from 24-hour urine collection was 15 ml/min. Transplant renal allograft biopsy revealed moderate ATN and borderline changes. Diuretic dose was decreased and SCr was improved to 0.7 mg/dL. She still required treprostinil as well as intensive rehabilitation and nutritional supplementation. She remains in ICU for the majority of the time posttransplantation.

Discussion: PPH is one of the challenging scenarios for ESLD requiring LT. Reversibility from PPH after LT is uncertain. It is still a dilemma in managing this difficult situation between LT to prolong life with poor quality and conservative management. LT is a life-saving surgery but may not always reverse a severe complication of ESLD such PPH and thus prolongs no postoperative quality of life. Therefore, LT in such a complex underlying condition needs to be individualized.

SA-PO119
Flash Pulmonary Oedema in Renal Artery Stenosis: An Indication for Stenting?
Elise Chu, Martine David, Neil Chapman. Medicine, Imperial College, United Kingdom.

Introduction: Renal artery stenosis (RAS) is an unusual but potentially treatable cause of flash pulmonary oedema. Although national guidelines recommend percutaneous revascularization (level of evidence B), we present a case of recurrent flash pulmonary oedema which suggests a need for further evidence to support use of revascularization therapy in elderly patients with multiple comorbidities. Case Description: A 78 year old woman presented with a fourth episode of sudden onset dyspnoea in 4 months. Her medical history included CAD, AF, hypertension (HTN) and severe pulmonary HTN due to heart failure with preserved ejection fraction (HFPEF). On admission, there were bilateral respiratory crackles and pulmonary congestion on chest XR. BP 140/95, creatinine 110umol/L, eGFR 42. Echocardiogram showed concentric LVH, preserved EF and raised PAP. Because of recurrent symptoms despite apparently adequate medical management of HFPEF, she underwent CT angiography which revealed bilateral ostial RAS (70% right, 40% left). Following multidisciplinary team discussion, bilateral balloon angioplasty with stent insertion was performed with radiologically successful results and she was discharged on rivaroxaban for stroke prevention. Since then, she has had no further episodes of pulmonary oedema. However, renal function has deteriorated post-procedure (max creatinine 226umol/L, eGFR 18 at 6 weeks; no evidence of in-stent thrombosis) and she has diuretic-resistant pedal oedema severely impacting quality of life.

Complement Mediated Hemolytic Uremic Syndrome Secondary to SLE

**Case Description:** 64-year-old female with well-controlled HIV on HAART, presented with new proteinuria, thrombocytopenia and acute kidney injury. On examination she had no neurological symptoms and no diarrhea. Preliminary blood tests revealed WBC 2.9k/UL, hemoglobin 6.6g/dl, platelets 64 k/UL, and serum creatinine at 4.0 mg/dl. LDH was elevated at 600UL, haptoglobin was undetectable, with Coombs test negative. Peripheral blood smear revealed numerous schistocytes. Further work up revealed an elevated ANA (>1:2560), and hypocomplementemia. Anti-Smith antibody elevated at >8. These laboratory studies and the presence of lymphadenopathy and pancytopenia established a diagnosis of SLE. Patient received pulse methylprednisolone, but creatinine increased to 6 mg/dl. A kidney biopsy revealed TMA. The patient was treated with plasma exchange but developed uremia and was started on hemodialysis. Neither renal function nor hemolysis improved. In the absence of anti phospholipid antibody, normal ADAMTS13 level and activity, well-controlled HIV, and in the presence of positive serologies for SLE with complement consumption, the diagnosis of CM-HUS secondary to SLE was the most explanation of the patients’ presentation, a decision was made to treat with eculizumab. Patient received one treatment, with no immediate improvement in her renal disease or hematologic parameters. Unfortunately her clinical status deteriorated and patient opted to be made comfort measures only and ultimately expired.

**Discussion:** This case highlights the importance of recognizing RAS as a cause of flash pulmonary oedema, especially in bilateral disease due to lack of compensatory mechanisms. Observational studies and case series have demonstrated that angioplasty +/- stenting reduces the incidence of flash pulmonary oedema. However, there is limited literature to guide management (eg. on risks and benefits of unilateral vs. bilateral intervention, degree of stenosis) and limited experience in the elderly in whom comorbidities may increase the risks of procedural complications such as deterioration of renal function due to contrast nephropathy and/or cholesterol emboli.

**SA-PO120**

**Complement Mediated Hemolytic Uremic Syndrome Secondary to SLE**

**Case Description:** 64-year-old female with well-controlled HIV on HAART, presented with new proteinuria, thrombocytopenia and acute kidney injury. On examination she had no neurological symptoms and no diarrhea. Preliminary blood tests revealed WBC 2.9k/UL, hemoglobin 6.6g/dl, platelets 64 k/UL, and serum creatinine at 4.0 mg/dl. LDH was elevated at 600UL, haptoglobin was undetectable, with Coombs test negative. Peripheral blood smear revealed numerous schistocytes. Further work up revealed an elevated ANA (>1:2560), and hypocomplementemia. Anti-Smith antibody elevated at >8. These laboratory studies and the presence of lymphadenopathy and pancytopenia established a diagnosis of SLE. Patient received pulse methylprednisolone, but creatinine increased to 6 mg/dl. A kidney biopsy revealed TMA. The patient was treated with plasma exchange but developed uremia and was started on hemodialysis. Neither renal function nor hemolysis improved. In the absence of anti phospholipid antibody, normal ADAMTS13 level and activity, well-controlled HIV, and in the presence of positive serologies for SLE with complement consumption, the diagnosis of CM-HUS secondary to SLE was the most explanation of the patients’ presentation, a decision was made to treat with eculizumab. Patient received one treatment, with no immediate improvement in her renal disease or hematologic parameters. Unfortunately her clinical status deteriorated and patient opted to be made comfort measures only and ultimately expired.

**Discussion:** This case emphasizes the importance of early consideration of CM-HUS as well as prompt initiation of treatment to block terminal complement upon recognition of the syndrome. As clinicians, this class of diseases is challenging and complicated, requiring our rapid attention to aid timely identification and rapid management.

**SA-PO121**

**Idiopathic Nodular Glomerulosclerosis Presenting with Nephrotic Range Proteinuria and Normal Renal Function**

**Introduction:** Idiopathic Nodular Glomerulosclerosis (ING) is a well-established but uncommon entity that has been described in 1985 by Chan JY et Al. It is common in older white men with history of long-standing hypertension, obesity, and smoking and typically presents with renal Insufficiency & Nephrotic Range Proteinuria. Multiple reports and meta-analyses of patients with ING demonstrate an average creatinine > 2.0 mg/dl and progressive kidney dysfunction leading to ESRD.

**Case Description:** We report a case of a 57 year old Caucasian obese female who presented with edema and heavy proteinuria (9 gms/day). She is a 40-pack year smoker with long-standing hypertension with variable control. Serum Creatinine on presentation was 0.7 mg/dl. Hba1c was 6.0% and fasting/random sugars never met criteria for overt Diabtes Mellitus. Urine showed 3-10 rbc/hpf and none where dysmorphic with an otherwise bland urine sediment. She had a negative work up for paraproteinemias and all other causes of proteinuria. Kidney biopsy showed Class III nodular sclerosis (KW lesions) and moderate urine sediment. She had a negative work up for paraproteinemias and all other causes of proteinuria. Kidney biopsy showed Class III nodular sclerosis (KW lesions) and moderate urine sediment.

**Discussion:** This case illustrates that Idiopathic Nodular Sclerosis is not limited to male gender and can occur in the setting of preserved renal function, contrary to the common observation revealed in previous case reports.

**SA-PO122**

**Hemofiltration Reinfusion Aequilibrium Can Be an Answer to Malnutrition and Hypotension in Dialysis**

**Discussion:** A-HFR has dynamic profiles of ultrafiltration and conductivity of the dialysate: this aspect creates an iso-osmolar dialysate, ensuring a better periferal refilling and improving compliance during the dialysis treatment. This is due to the use of biosensors. A-HFR also reduces the Amino acids loss. This report has numerical limitations but provides encouraging data on the use of A-HFR in malnutrition and disequilibrium syndromes. This experience underlines the importance of further efforts towards customized dialysis procedures.

SA-PO124
A Case of Chronic Unilateral Hematuria Treated by Segmental Renal Artery Embolization Hansae Kim,1 Joon Seok Oh,2 Yong Ki Park,2 Dongyeol Lee.1 1Nephrology, Bongseong Memorial Hospital, Busan, Korea; 2Nephrology, Dongrae Bongseng Memorial Hospital, Korea.

Introduction: Chronic unilateral hematuria is characterized by intermittent or continuous hematuria that cannot be diagnosed using standard radiologic and hematologic methods. Unilateral hematuria is probably a benign condition that seldom requires surgical treatment, but some cases were managed with partial or total nephrectomy. Recently, a variety of treatments, including the ureteroscopic interventions have been attempted if the bleeding focus is identified. However, if not identified on ureteroscopy, surgical treatment has been considered a priority. We report the case of treatment of chronic unilateral hematuria with segmental renal artery embolization.

Case Description: We experienced a case of chronic unilateral hematuria in a 42-year-old woman who was admitted to our hospital due to intermittent gross hematuria and anemia for 31 months. About 29 and 19 months ago she already underwent CT scan, renal angiography, and renal biopsy at other tertiary hospitals, but didn’t found any other specific abnormalities repeatedly except some blood clots in left renal pelvis on ureteroscopy. She underwent CT urography, renal arteriography, cystoscopy and ureteroscopy again. Ureteroscopy findings only showed bleeding in the upper third of left renal calyces but definite bleeding focus could not be identified. Thus we decided to manage with segmental renal artery embolization than partial nephrectomy to minimize the reduction in renal function and to reduce operational risk. The superior and superoanterior segmental renal arteries were successfully embolized with 3mm coils and gelatin sponge. Gross hematuria disappeared on the 4th day after the procedure, microscopic hematuria disappeared on the 5th day. In 11th day, infarction in the upper third portion of left kidney was confirmed on CT scan. In 13th day, the patient was discharged. Thereafter serial urinalysis showed no hematuria.

Discussion: Patients with chronic unilateral hematuria often require surgical or upper urinary tract endoscopic procedures. Segmental renal artery embolization will be a better treatment for patients unable to identify the bleeding focus on the upper urinary tract endoscopy.

SA-PO125

Introduction: Urinary anastomotic leaks after kidney transplants are no longer a common phenomenon. Due to advancements in reconstruction techniques, urologic complications after renal transplant are now reported to occur in only 2-2.5% of patients. If a urinary anastomotic leak is to develop, it frequently occurs within one month of the transplant and is usually due to technical error or ischemia to the ureter.

Case Description: We present a case of a 60 year male with a history of a living unrelated kidney transplant who developed acute kidney injury 5 months after transplant. He had a baseline creatinine of 1.5-1.7 mg/dl, and initially presented to the hospital with fever and a creatinine of 2.96 mg/dl. A fungal urinary tract infection with Candida Albicans was deemed the culprit of his symptoms and so he was promptly started on fluconazole with only a slight improvement in his creatinine. A renal ultrasound of the allograft revealed that the patient had a 7x5 cm perinephric fluid collection. A percutaneous renal biopsy was performed, which revealed that the patient had a 7x5 cm perinephric fluid collection. A percutaneous nephrostomy was placed in the collection and culture of the fluid grew Candida Albicans. The large fluid collection was aspirated and sent for cultures and growths.

Discussion: Patients with chronic unilateral hematuria often require surgical or upper urinary tract endoscopic procedures. Segmental renal artery embolization will be a better treatment for patients unable to identify the bleeding focus on the upper urinary tract endoscopy.

SA-PO128
A Case of Kidney Dysfunction and Visual Loss Patrick Koscik1, Muhammad Sohaib Karim,1 Michal R. Chan,1 Anthony Krentz.2 1Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health; 2PreventionGenetics.

Introduction: Senior-Loken syndrome is a rare hereditary nephropathy (phospho-renal syndrome) often presenting with autosomal recessive inheritance, a reduction in urinary concentrating ability with bland urinary sediment, and chronic tubulointerstitial nephritis with typical progression to end-stage renal disease (ESRD) in individuals younger than 20 years old. It was first described in 1961 by Senior et al., and Loken et al.

Case Description: A 29 year old male and his seeing eye dog presented to the kidney clinic with uncontrolled hypertension, creatinine of 2.6mg/dl and a history of Leber congenital amaurosis since the age of four. Physical exam was unremarkable other than nystagmus and severe visual impairment with 5-degree visual field and 20/300 acuity. Patient was currently pursuing his PhD via braille and did not appear to have any mental impairment. Family history was remarkable for a healthy sister in her 20s, a paternal uncle who passed away from renal failure in his 20s, and his maternal cousin (son of his deceased uncle) who had been born with hearing loss. Further evaluation was undertaken, which revealed normal electrolytes, unremarkable UA (notably with specific gravity <1.005 and absence of proteinuria, hematuria, leukocyte esterase, nitrites, and pyuria), but findings of minimal proteinuria (urine protein to creatinine ratio of 0.55). A renal ultrasound revealed a 12.4 cm R and 12.5cm L kidney with multiple cysts. Taking into account the history of renal dysfunction, visual impairment and renal cysts, patient was referred to a geneticist.

Genetic studies revealed two autosomal recessive heterozygous mutations in the IUCB1 gene. A frameshift mutation was seen in c.424_425del of ITT resulting in premature truncation of the ITT domain. This case suggests that stone formation may be an early phenomenon in UC. We think there might be a benefit in obtaining 24-hour urine collection for stone analysis following diagnosis of IBD, as this may help us identify patients at increased risk for stone formation. Early simple intervention like increasing fluid intake or expectorant stone formation. Benefits from empiric treatment with potassium citrate are not well known. Further studies need to be done for the better understanding and preventing renal stones formation in patients with active and severe IBD.

Clostridium Difficile Associated Peritonitis in a Patient on Peritoneal Dialysis
Dimpus M. Patel, Gaurav Jain. Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

Introduction: Culture negative infectious peritonitis (CNP) is a common and serious complication in peritoneal dialysis (PD) patients. It is usually a result of samples failing to reach the threshold of microbiological detection, recent antibiotic exposure, or simply unusable samples. Peritoneal Dialysates routinely tested for Clostridium difficile (C. diff) infections have become more frequent, and more refractory to treatment, and dialysis patients are often affected by C diff secondary to repeated exposure to antibiotics, as well as hospitalizations. C diff infection should be considered in the differential for CNP in dialysis patients.

Description: A 41 AA male on PD since 2012 presented to PD unit with complaints of abdominal pain and cloudy fluid. He was started on intraperitoneal antibiotics (Vancomycin and Cefazidime) as an outpatient, though his symptoms of abdominal pain worsened requiring a hospital admission within 48 hrs of onset of symptoms. He complained of normal appetite, diarrhea for 12 hrs on the day of admission. On exam, he was diffusely tender in his abdomen, with no guarding/rigidity. Lab data was significant for peritoneal fluid wbc count of 7,130 with 85% polys and he was continued on broad-spectrum IV antibiotics. Stool C diff toxin resulted positive on day 2 of hospitalization and he was started on IV metronidazole. His abdominal pain persisted, and a recheck of PD fluid cell counts on Day 3 revealed a WBC count of 17,671 with 79% polys. The PD fluid cultures from the PD unit as well as the hospital were negative for any growth. Microbiology lab was asked to check his PD fluid for C diff, and the C diff PCR from the PD fluid was positive. The vancomycin and cefazidime were stopped, and oral vancomycin added to the metronidazole. His abdominal pain and diarrhea both improved and he was discharged to complete a 14 day course of PO metronidazole and vancomycin.

Discussion: Our case study describes culture negative peritonitis in a patient with C diff diarrhea that did not respond to broad spectrum IV antibiotics. This prompted further investigation of C difficile peritonitis that was confirmed on lab testing. This case highlights the importance of suspecting C diff peritonitis in PD patients with CNP.

SA-PO130
Adequacy of Australian Nephrology Training Nicholas A. Gray, Thomas Joseph Beaton, Rathika Krishnasamy, Nigel David Toussaint, Richard K.S Phoon. 1Renal Unit, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; 2Renal Unit, Westmead Hospital, Westmead, New South Wales, Australia; 3Renal Unit, Royal Melbourne Hospital, Parkville, Victoria, Australia.

Background: There has been an increase in the number of doctors training in nephrology in Australia. This study aimed to assess the adequacy of nephrology training by measuring self-determined competency and skill relevance among recently graduated nephrologists.

Methods: A survey was developed by the Nephrology Advanced Training Committee of the Royal Australasian College of Physicians. The survey was administered on-line in 2015 via the annual subscription to the Australian and New Zealand Society of Nephrology. Nephrologists who were awarded Fellowship after 2002 were invited to participate.

Results: 113 of a 306 eligible Fellows (37%) completed the survey. 8 respondents had trained overseas and were excluded. Median age was 41 years (interquartile range 37-44) and 63% were male. Medical school was completed in Australia (59%), India (15%), and New Zealand (7%). 35% received at least some training in a rural area and 25% were qualified in another specialty (mainly internal medicine). 56% had completed and 21% commenced a higher degree. Higher degrees were undertaken for career development (43%) and desire for a research career (30%). Respondents indicated good training and competency in most clinical skills that were relevant to their practice. Training in home hemodialysis (37%) and living kidney donor assessment (51%) were considered less adequate, despite these areas being considered very relevant to practice. There was a greater mismatch identified between training and importance of skills for management and research. This included inadequate training in managing complications (82%), managing a private practice (98%), health system knowledge (86%) and regulations (93%), medical directorship (94%), ethics approval (76%), research funding (88%), and quality assurance (73%).

Conclusions: Nephrology training in Australia meets the clinical needs of new specialists. Similar to findings in USA, training in management and research was considered insufficient for the practices of new specialists and should be addressed in updates of the curriculum.

SA-PO131
Pediatric Nephrology Workforce and Training: An International Perspective
Dorey A. Glenn, 1 Adam R. Weinstein, 2 Maria E. Ferris. 1 Univ of North Carolina at Chapel Hill; 2Dartmouth Hitchcock Medical Center; 3Univ of North Carolina at Chapel Hill.

Background: There is a shortage of pediatric nephrologists in a number of areas around the world. We sought to determine pediatric nephrologists’ perspectives on this issue.

Methods: A voluntary web-based survey was deployed via the Qualtrics™ survey engine. Members of the International Pediatric Nephrology Association responded anonymously to questions about their geographic location, time spent on training, practice setting, and impressions on local workforce challenges and opportunities.

Results: The number of responses to date was 38, representing 21 countries from all continents. Six percent of the respondents treat both children and adults. The number of years required to train in pediatric nephrology was reported as: 2 years (35%), 3 years (58%) and 4 years (8%). Nearly 80% of practices were associated with academic settings. Specialty training programs are reported in 63% of the respondents’ institutions and 50% of those with training programs stated that it was difficult or very difficult to recruit trainees. Forty two percent of the respondents stated that it was difficult or very difficult to find a job after training. The themes most frequently cited on qualitative analysis include low availability and interest in the field by trainees, poor compensation, demanding schedule and competing family demands.

Conclusions: In this preliminary study of an international cohort of pediatric nephrologists, our data suggests a perception of a decreased pediatric nephrology workforce. There is also a perceived shortage of available positions in the field. Further data collection on workforce issues as it pertains to country-related factors is needed.

SA-PO132
Taking Guessing Out of Milestone Ratings – Simplify the Evaluation System to Easily Achieve the Next Accreditation System (NAS) Report Samantha J. Thompson, Laura J. Maursetter. Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: In an effort to translate into competency-based training, the ACGME has developed 24 milestones specific to fellowship. While the milestones are comprehensive, it is challenging to determine an individual’s rating through faculty evaluations; many of whom are untrained in this system. We aimed to create a simple scoring system that translates the milestones into observable nephrology activities that can be completed daily on a handheld device.

Methods: For each nephrology rotation, a list of 5-10 frequent activities was developed. For every activity, a description for the five levels of competency was written to standardize the score. The activities were completed and scored on a 1-4 NAS milestones. The evaluations were built in Google Forms and delivered daily to supervising faculty members. Using a four-click system, the observer can submit a fellow evaluation with most done on mobile devices. If faculty members wish to express a narrative, a free-text response box is provided for comments.

Results: Of the 914 possible evaluations over a nine-month period of time 727 evaluations were returned. This provided data points to distinguish scores among all fellows in all of the NAS milestones.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

In Clinical Competency Committee meetings thus far, 1 of 276 scores have been adjusted from the scores provided by the evaluation system.

Conclusions: This is an easy to use scoring system that has resulted in immediate feedback that is activity-specific and feed into NAS milestones easily and effectively. By translating the evaluation system into specific activities that any nephrologist can observe, a robust amount of valuable data has been obtained. The 4-click system has yielded an excellent response rate with more narrative comments than were previously obtained with monthly evaluations.

SA-PO133
American Society of Nephrology In-Training Exam for Fellows 2010-2014: Scoring and Item Statistics
Suzanne M. Norby, 1 Troy J. Plumb, 2 Nancy Day Adams, 3 Ryan Russell, 4 Mitchell H. Rosner, 5 Mark G. Parker, 6 Mayo Clinic; 2Univ of Nebraska Medical Center; 1Univ of Connecticut Health Center; 4American Society of Nephrology; 3Univ of Virginia School of Medicine; 5Maine Medical Center.

Background: Since 2009, the American Society of Nephrology (ASN) In-Training Exam (ITE) has been administered annually to fellows. This study reports 2010-2014 overall scale scores, item difficulty, item discrimination, and reliability.

Conclusions: This is an easy to use scoring system that has resulted in immediate feedback that is activity-specific and feed into NAS milestones easily and effectively. By translating the evaluation system into specific activities that any nephrologist can observe, a robust amount of valuable data has been obtained. The 4-click system has yielded an excellent response rate with more narrative comments than were previously obtained with monthly evaluations.
Methods: IAPE annual reports provided by the National Board of Medical Examiners were retrospectively reviewed and summarized.

Results: Scale score for all was 480±104 (mean ± SD); 1st-year fellows (n=2,020) 445±96, 2nd-year (Y2, n=2,005) 515±100, and 3rd-year and higher (n=112) 509±113. Standard error of the mean ranged 41-45. The 2010 IAPE had 150 core items only. 2011 and 2012 IAPE had separate O-S and U-inpatient and renal pathology modules added to Y1 and Y2 respectively (not included in total test statistics). In 2013 and 2014, all completed 102-item modules on these topics (included in statistics). A mean of 6.6 core items (4.4%) were deleted per year after adjudicating items with high difficulty or negative discrimination. Content areas aligned with American Board of Internal Medicine Certification Exam: General Aspects of Chronic Kidney Disease (CKD), Glomerular/ Vascular (G/ V), Tubulointerstitial/Cystic (TIC), Acute Renal Failure/ICU Nephrology (ARF/ICU), Kidney Transplant, Hypertension, Sodium/Water (Na/ H2O), Acid-Base/ Potassium (A-B/K), Mineral Metabolism (MM), and Clinical Pharmacology (CP). Ethics. Though examinee abilities typically vary yearly, overall total test average p value was 0.67. ARF/ICU, Na/H2O, MM, and CP tended to be less difficult (average p value 0.7) and TIC more difficult (average p value 0.58). Total test mean item discrimination bivariate correlation averaged 0.21, highest for A-B (0.28) and lowest for CKD (0.18). Total test mean item difficulty varied among content areas.

Conclusions: As expected, scale scores were higher for Y2 than Y1 fellows. Over 95% of administered items were scored; among those, mean item difficulty, item discrimination, and reliability varied among content areas.

What Are We Doing? A Survey of U.S. Nephrology Fellowship Program Directors

Liesmana, MahrudA, Catherine A. Moore, Rebecca D. Monk.

Medicine- Nephrology Div, Univ of Rochester, Rochester, NY.

Background: Recent years have seen a decrease in Nephrology fellowship applicants. Low applicant numbers may be partially responsible, and may affect the educational mission of the fellowship. Our survey addresses fellow work load and educational experiences to further explore these issues.

Methods: We distributed a survey for nephrology program directors via the Training Program Directors’ website. The survey addressed fellows’ service load and the scope of educational activities offered by the fellowship.

Results: 57 out of 147 programs responded (39%). Most are 2 years long, with a mean of 7 fellows, and are “front loaded” 64% require ≥ 7 months of inpatient service during year one. Inpatient services are usual (93%) covered by one fellow with significant resident involvement. NP’s and PA’s help cover about 15% of services. The busiest services have about 21-25 patients, although 13% of programs averaged ≥ 26 patients. At their busiest, these services have more than 30 patients, occasionally surpassing 50 patients. About one quarter of programs report ≥ 10 nights over a three month period during which a fellow is required. A mean of 34% of fellows are on call ≥ 7 nights. Fellows on call typically cover ≥ 10 nights over a three month period and ≥ 1 week-end a month. Most fellows do one weekly half day clinic, averaging 4-6 patients per session with a faculty: fellow ratio typically ≤2:1. Clinic structure is not usually modified during fellows’ inpatient service. Longitudinal coverage of HD and PD patients is provided by 82% and 61% of program respectively. Educational conferences ranged from 2-6 hours per week. Faculty didactic teaching varies from < 1 hour a week to 5 hours per week; one hour is typical. Fellows usually give 2-6 formal presentations yearly, although in some programs this is significantly more.

Conclusions: Our survey underscores the large variety in work load, practice patterns and frequency of educational conferences at different institutions and provides a framework to help address the service/education balance during nephrology fellowship.

SA-PO135

Perspectives of Nephrology Among Internal Medicine Residents

Michael N. Daniels,1 Ivan E. Porter,2 Nabeel Aslam,3 Deepika Jain,1 Charity Curtis,1 Hope Knecht,1 Sharon E. Maynard.1

1Div of Nephrology, Lehigh Valley Health Network/ Univ of South Florida, Allentown, PA; 2Div of Nephrology and Hypertension, Mayo Clinic College of Medicine, Jacksonville, FL; 3Network Office of Research and Innovation, Lehigh Valley Health Network/ Univ of South Florida, Allentown, PA.

Background: As interest in nephrology declines, we sought to identify factors influencing career interest among internal medicine (IM) residents.

Methods: This is a repeated cross-sectional survey of IM residents to assess perceptions of nephrology and the impact of these perceptions on career decisions. All categorical internal medicine medicine residents at two institutions were invited to participate in 2012, prior to the initiation of a nephrology fellowship program (Group 1); and in 2015, three years following initiation of a nephrology fellowship program (Group 2).

Results: 131 of 156 residents (84.0%) completed the survey. A total of 14.8% (19/131) of residents expressed interest in nephrology, with 6.25% (8/131) indicating Nephrology as their first choice. Cardiology (21.1%) and Hospitalist (12.5%) were the most popular career choices. The presence of a Nephrology Fellowship program did not increase resident career interest in nephrology (14.5% in Group 1 vs. 15.1% in Group 2). In perceptions of nephrology were not significantly different in Group 1 vs Group 2. Negative perceptions of nephrology most commonly endorsed by residents were: renal pathophysiology is too complex (22.9%), poor preparation in medical school (22.14%), few opportunities for procedures (26.7%), long work hours (24.4%), and long hours/ intense call for nephrology fellows (27.5%). The majority of residents (83.2%) reported exposure to positive role models in nephrology. Experiences cited as having a high impact on career choice included: mentors/role models in the field (71.65% of residents) and rotations during residency (57.14%).

Conclusions: We found 5 key thematic problems with the current training model in developing countries that included: 1) lack of understanding, 2) lack of exposure to nephrology electives in residency programs to include enhanced exposure to nephrology, 3) the perception that the nephrology population is disheartening, 4) a didactic and opportunistic instructional model with other core areas of competencies (professionalism, collaboration, advocacy, managerial skills and of scholarship are not formally taught, and 5) application of the current curricular model rather than focusing on the educational needs of the trainee.

Conclusions: There are similarities and differences in structure, content and process of training programs across different levels of care. The results have implications for re-design of training programs in the developing world for nephrology education and better clinical care delivery in patients with kidney diseases addressing local needs and priorities.

SA-PO137

Challenges and Workforce Opportunities in the Training and Retaining of Nephrology Fellows in Developing Countries: A Review of the Current Trends and Perspectives for Optimal Kidney Disease Care

Julius Obuhok Ogbe,1 Bilal Qurni,1 Timothy Olusugun Olaniwaju,2 Aminu K. Bello,1 1Univ of Alberta, Canada; 2Univ of Ilorin, Nigeria.

Background: Nephrology education has undergone rapid advancement leading to the development of comprehensive curricula and standards towards a high quality patient-centered care. These standards are often lacking on issues critical to the practice of nephrology in developing countries.

Methods: We evaluated nephrology training programs within the context of the healthcare systems across 25 upper-middle and high income countries to identify best practices and opportunities for adoption in developing nations. We further reviewed training guidelines from the major professional societies (ISN, major national societies) on content and process of training. Data were obtained from multiple sources (government reports, published literature, and websites of professional/licensing authorities, World Federation for Medical Education (WFME) and its Regional branches. The WFME 3-set of Global Standards on medical education at all levels were applied in evaluating training programs on the domains of training process, assessment, and evaluation.

Results: We found 5 key thematic problems with the current training model in developing countries that included: 1) an emphasis on factual information, memory and recall (core knowledge content), 2) absence of needs assessment and evaluation, 3) structure and organization of training is a product of established tradition than of evidence and not in congruent with health system changes and dynamics, 4) a didactic and opportunistic instructional model with other core areas of competencies (professionalism, collaboration, advocacy, managerial skills and of scholarship are not formally taught, and 5) application of the current curricular model rather than focusing on the educational needs of the trainee.

Conclusions: There are similarities and differences in structure, content and process of training programs across both developed and developing countries. The results have implications for re-design of training programs in the developing world for nephrology education and better clinical care delivery in patients with kidney diseases addressing local needs and priorities.
SA-PO138
Creating and Enhancing Interest in Nephrology Careers: A Nephrology Elective Experience for Medical Students  

Methods: At our institution, we created a novel 4-week nephrology elective experience for medical students. Our redesigned elective included both 2-week inpatient (IP) and 2-week outpatient (OP) nephrology experiences. The OP rotation included 10 half-days of various nephrology clinic experiences, 2 half-days of immediate post-transplant clinic, 1 half-day of dialysis clinic, 2 half-days of peritonial dialysis clinic, and 1 half-days of outpatient hemodialysis unit rounding. The redesigned elective also included education conferences. From 7/2012 to 2/2015, nine 4th year medical students (all from different US medical schools) completed our redesigned nephrology elective. To evaluate the novel elective experience, all medical students were asked to complete an anonymous on-line survey upon completion of their rotation.

Results: All students responded to our survey. All reported adequate OP nephrology exposure during their elective. 89% had worked with 1 or 2 faculty members during the IP setting. In comparison, 78% were exposed to at least 4 different faculty members during the OP experiences. All students had interacted with at least 3 fellows. All reported that the elective experience enhanced their exposure and knowledge in nephrology and that they would recommend this elective to other medical students. They also thought that this elective structure provided them with a better insight into what nephrologists do in practice. 78% reported that this elective experience created an interest in nephrology career. 56% responded that they would consider nephrology as one of their 3 top career choices as a result of this elective experience.

Conclusions: We believe that the structured nephrology elective provides the medical student with a much needed and realistic exposure to nephrology careers. Based on our experience, we recommend all training programs to consider this elective structure for medical students.

SA-PO139
Journal Publication of Nephrology Fellows Case Report Presentations at ASN Kidney Week 2012-2013  

Methods: We reviewed and further categorized as follows: glomerular diseases (GN), tubulointerstitial diseases (TIN), acute kidney injury (AKI), fluid-electrolyte and acid-base disorders (FE), dialysis (D), kidney transplant (KT), genetic disorders (GD), mineral diseases (MD), and other (O) cases. To determine the PR-JP rate of these CR abstracts, a literature (PubMed) search was performed in May 2015.

Results: A total of 415 abstracts were presented in the fellows CR category at the ASN Kidney Week (KW) conference in the year 2012. However, the number and types of CR abstracts accepted for publication is not known. Per our literature journal publication (PR-JP) of these previously presented CR abstracts at ASN KW is also not known.

Methods: All previously accepted fellows CR abstracts from ASN KW 2012-2013 were reviewed and further categorized as follows: glomerular diseases (GN), tubulointerstitial diseases (TIN), acute kidney injury (AKI), fluid-electrolyte and acid-base disorders (FE), dialysis (D), kidney transplant (KT), genetic disorders (GD), mineral diseases (MD), and other (O) cases. To determine the PR-JP rate of these CR abstracts, a literature (PubMed) search was performed in May 2015.

Results: A total of 415 abstracts were presented in the fellows CR category at the ASN Kidney Week 2012-2013. Compared to KW 2012, there was a 7.5% increase in CR abstract presentations at KW 2013. Over these previous two KW meetings, nearly one-third (31.6%) were CR abstracts. The remaining abstracts were FE-AB (15.2%), AKI (14.4%), KT (11.8%), D (11.8%), TIN (5%), MD (5%), O (4%), and another (3.2%) cases. Compared to KW 2012, there was increase in GN related presentations (from 55 to 76) at KW 2013. So far, only 72 (17.3%) out of the 415 abstracts have been published as papers in peer-reviewed journals. One abstract was published as a letter to the editor format. Out of those that were published, 31.5% were GN related case reports. Interestingly, 22% of these journal publications did not list the lead author of the KW CR abstract as the primary author of the paper.

Conclusions: Based on our study, it seems that there is a increased interest among fellows to present CR abstracts at ASN KW. Nearly one-third were GN related case presentations. However, so far, less than one-fifth of the fellows CR abstracts presented at KW 2012-13 have been published in peer-reviewed journals. Reasons for this low publication rate is not known. Measures to enhance publication need to be considered.

SA-PO140
Analysis of Published Medical Student Related Nephrology Medical Education Research  

Methods: A review of the English literature on nephrology education of medical students was conducted on two major online academic search engines (PubMed and ERIC). RefWorks was used to manage the papers discovered in this search and also reviewed. Conference abstracts were not investigated. The empirical studies were categorized by subject within nephrology. The research design of each study was then recorded.

Results: 26 original studies were found in which a method of teaching nephrology to medical students was described. The studies dated from 1977 to 2015. The focus of these teaching experiences was as follows: anatomy (3.3%), physiology (23.3%), pathophysiology (26.7%), pathology (10%), treatment (20%), and general nephrology (16.7%). 4 of the pathophysiology studies were also classified under other categories, so there were 30 total papers. The papers were also categorized into types of assessments, with two papers containing two different types of studies for a total of 28 types of assessment. 14.2% had either no assessment of the educational experience or had a description too vague to categorize it; 3.6% involved a questionnaire about the existing educational approach before and after a new practice was carried out; 17.1% involved surveys or questionnaires after a practice was carried out; 7.1% assessed the method both before and after; and 10.7% were case studies or ethnography; and 7.1% included a randomized controlled trial. The randomized controlled trials involved teaching techniques focused on the pathophysiology of renal disease. Overall, students responded that they would consider nephrology as one of their 3 top career choices as a result of this experience.

Conclusions: This review is a first attempt to summarize and provide a description of the educational techniques in nephrology medical education research.

SA-PO141
Participation in the Open, Online, Twitter-Based, Nephrology Journal Club, NephJC  
Joel Topol, Matthew A. Sparks, Edgar V. Lerman, Thomas Oates, Paul J. Phelan, Francesco Iannuzzella, Swapnil Hiremath.

Methods: We searched the Symplur analytics database for all tweets with the hashtag #NephJC from March 16, 2014 to June 2, 2015. We measured the numbers of participants, number of tweets and assessed participation over the first 27 NephJC sessions.

Results: From April 29th to June 2nd, 2015, 27 topics were discussed. 27 Tweets were at 9PM Eastern for the Americas and starting Dec 18, 2014 a Europe and Africa chat was added at 8PM GMT. 10 GMT chats have been held, generally one day after the American chat. 1,022 Twitter accounts have used the hashtag #NephJC a total of 14,891 times. The median journal club has 41.5 (IQR 30.5-56.5) participants and 335.5 (IQR 268.5-633.5) tweets. The number of participants and tweets increased over time (P<0.01). The addition of the GMT chat was responsible for some of that growth (median number of tweets increased from 273 to 662.5, P<0.001, participants from 35 to 60.5, P<0.001).

Conclusions: NephJC has established itself as an integral part of the online digital medical education curricula. The increased participation of NephJC demonstrates the positive value of Twitter in medical education.

SA-PO142
Three Years’ Experience with the Online Educational Game, NephMadness  

Methods: The game NephMadness is an educational project that leverages social media and Free Open Access Medical Education (FOAMed) to highlight advances and important issues in nephrology. NephMadness 2015 was the third year of this project.

Results: Three Years’ Experience with the Online Educational Game, NephMadness  

Methods: The game NephMadness is an educational project that leverages social media and Free Open Access Medical Education (FOAMed) to highlight advances and important issues in nephrology. NephMadness 2015 was the third year of this project.

Results: The findings from this research project indicated that social media and online educational games can be an effective method of engaging medical students and nephrology trainees in important topics in nephrology. The game NephMadness is an educational project that leverages social media and Free Open Access Medical Education (FOAMed) to highlight advances and important issues in nephrology. NephMadness 2015 was the third year of this project.

Conclusions: NephMadness is increasing engagement on three unique metrics. We believe this indicates that pairing social media with freely available, expert-generated content can stimulate interest in nephrology research.

Awareness of AKI in Low Resource Settings: A Global Survey
Joseph Lunerva,1 Kajiro Kilonzo,2 Andrew J.P. Lewington,3 Karen E. Yeates,4 Fredric O. Finkelstein,3 1Duke Univ; 2KCMC; 3Leeds Teaching Hospitals; 4Queen’s Univ; Yale Univ.

Background: The ISN has set a goal of eliminating preventable deaths from AKI by 2025—the “0X25” initiative. However, there is limited awareness of the challenges presented by AKI in terms of diagnosis, treatment and management in low resource settings (LRS).

Methods: We reached out to nephrologists working in LRS using a web-based instrument of 18 questions. Responders were asked what strategies should be considered to increase the awareness of AKI in LRS and recommend approaches to heighten this awareness. 517 respondents from 5 WHO world regions, including 54% from Africa.

Results: The major barriers to raising awareness cited by all were inadequate training, shortage of adequately trained health workers and lack of awareness of the significance of AKI by healthcare workers, government officials and the general public. Additional factors cited were limited patient access to health facilities, limited diagnostic and treatment facilities, lack of support for AKI programs, lack of clinical practice guidelines for AKI, poor communication systems, limited research funding and lack of linkages of AKI programs to other health projects. Health centers (HCs) were broken down into rural, district and regional HCs. Supplies available for diagnosis (serum creatinine and BUN) and management (IV fluids, antibiotics, anti-venom) of AKI are limited in rural HCs. All noted that hemodialysis services were available but only in selected, large urban centers. Peritoneal dialysis was limited to regional HCs.

Conclusions: Increasing the awareness of AKI in local, district, and regional HCs requires a multi-faceted approach, reaching out to government officials, hospital administrators, physicians, nurses, local health care workers, community leaders, international organizations and the general public. The success of this initiative involves the development of meaningful and targeted educational programs, training materials, and treatment guidelines tailored to the local situations. Alliances will need to be formed with governmental agencies, non-profit organizations and global health programs. Support needs to be provided for additional research programs.

SA-PO144
Acute Kidney Injury Education to Nursing and Assistant Health Care Staff Mansoor N. Ali. Renal Medicine, Calderdale and Huddersfield Hospitals NHS Foundation Trust, United Kingdom.

Background: Acute kidney injury (AKI) is a global healthcare problem. It carries significant mortality and incurs heavy costs to the National Health Service. Extensive work has been done recently both at undergraduate and postgraduate level to ensure front line medical staff have better understanding in managing AKI. One such important area of focus involves the need for training nursing and assistant healthcare staffs who care for patients presenting with AKI.

Purpose of the study: To gauge the understanding of AKI amongst nursing and healthcare assistants working on busy acute medical admissions unit.

Methods: The anonymous questionnaire was aimed at the nursing and assistant health care staff working on the admissions unit at two large district hospitals. The length of time since qualification ranged from few weeks to 16 years. The questionnaire was followed by planned teaching, simulation training and workshop sessions. The process was carried out within a period of 2 months.

Results: The Questionnaire was completed by 50 staff members. It included series of questions aimed at defining and managing AKI from a nursing perspective. 24 out of 50 were able to correctly identify AKI. Only 5 out of 50, have never cared for patients with AKI. Not many were aware of the symptoms of AKI; common answers given by 40 respondents were “reduction in urine output” and “dehydration.” All participants answered “yes” to monitoring urine output and understood the significance of fluid monitoring but all admitted more needed to be done to ensure accurate documentation in the patient’s notes. Other questions asked were if nurses check patient’s blood results on the system server to which most replied “no” and if medications were regularly reviewed during drug rounds. Surprisingly, not all were aware of nephrotoxic medications and only 20 respondents would regularly review drug charts in the context of renal failure.

Conclusions: The questionnaire and the training sessions identified lack of better understanding of AKI and its management. There needs to be a stronger emphasis on the introduction of AKI and its management during their training years and development of mandatory online e-learning modules.

SA-PO145

Background: AKI occurs in 1-in-3 hospitalized patients, and majority of those are managed by non-nephrology specialties, including trainees.

Methods: The renal fellowship program designed an online anonymous survey, distributed to trainees (students, residents, fellows), to understand their level of knowledge in recognition and management of AKI. 37 questions were classified into following categories: knowledge of guidelines; prognostic factors; and drug safety. Results are represented as aggregate percentage.

Results: 104 trainees responded to the online survey; 50% were male, 84% US medical graduates and 70% were residents/fellows. 50% were affiliated to medical specialties; and 53% had spent at least one elective in nephrology. In terms of AKI definition: 51% use serum creatinine (SCr) as the most important factor to diagnose AKI, whereas 20% use urine output. Majority (76.1%) agreed that rise of 0.3 mg/dl or 1.5 times of baseline Scr was clinically relevant, in concordance with current guidelines. RIFLE criteria were most commonly used (42%), followed by KDIGO (13%); and 90% agreed that guidelines help in standardization, and management of patients. 85% concurred that AKI impacts short and long-term outcomes, however, majority (60%) felt dialysis requirement was the most important clinical predictor of outcome. Majority (67%) felt that early involvement of nephrology services is helpful in AKI management; 66% sought nephrology input to determine the cause of AKI/co-management, and 7% viewed nephrology role purely for procedural delivery of dialysis. As for drug safety, 89% reported to pay attention to renal function while drug dosing, but 70% felt that this was the responsibility of either pharmacy or ordering team. In terms of follow-up 61% of subjects felt that follow-up was only needed in moderate to severe AKI cases or in non-recovery, 86% preferred that in = 30 days, and 64% preferred that to be with primary care.

Conclusions: Most of the trainees displayed good knowledge of AKI guidelines (RIFLE), seek timely nephrology involvement and view it to be beneficial. More work needs to be done in terms of improving knowledge/practice about drug safety and follow-up care in AKI.

SA-PO146
Adherence to Care Bundles for AKI – Challenges in Supporting Education and Measuring Compliance Melanie Louise Sally, Christopher J. Mulgrew. Renal Medicine, Royal Devon & Exeter Hospital, Exeter, Devon, United Kingdom.

Background: AKI typically occurs as a consequence of intercurrent illness in patients with multiple comorbidities and risk factors. The use of clinical guidelines to assist medical and nursing staff in AKI management has been adopted by most secondary care institutions in the UK. We have previously presented our use of e-alerts for AKI as a prompt to improve AKI care (Mulgrew et al, ASN, 2013). Clinical guidelines were prompted by the e-alert and widely publicised to staff.

Methods: In a model similar to the NHS Safety Thermometer, snapshots of compliance with 6 key elements of the AKI guidelines on 4 medical wards was measured by identifying patients from AKI e-alerts. These included documentation of AKI, medication review, clinical assessment and ongoing investigation/monitoring. Awareness was supported by an AKI Education nursing team, working with medical and nursing staff. Monthly compliance was assessed over a period of one year.

Results: Mean compliance for all elements of the guidelines improved from 52% to 69% over the year. Significant variability was seen, often associated with notable workforce challenges such as new medical staff or periods of increased activity.

Conclusions: Supporting medical and nursing teams to manage AKI in secondary care in order to prevent progression and treat promptly remains challenging. A number of external factors frequently impact upon adherence to guidelines and support needs to be planned in order to continue to maintain high standards and optimise patient care. The use of a Safety Thermometer, allowing performance to be analysed and comparisons made between clinical areas, may continue to be useful in improving performance and patient outcomes in AKI.

SA-PO147
Internal Medicine Residents Knowledge of Vein Preservation in Chronic Kidney Disease Patients Sandesh Joshi, Jamie Alton Green, Maria C. Bermudez. Nephrology, Geisinger Medical Center, Danville, PA.

Background: Vein preservation is important among CKD patients for future arteriovenous fistula potential. House staff plays critical role in managing these patient population and preserving their vein for future arteriovenous fistula. Their knowledge and current practices directly affects the outcome for vein preservation among these patients.

Methods: We conducted a survey among 44 internal medicine residents to understand their baseline knowledge and current practices regarding vein preservation. The survey was conducted at Geisinger Medical center, Danville, PA.

Results: 44 residents were included in the survey. Only 6.8% (3) were able to correctly identify patient population, on whom we should avoid particular arm for IV draws, BP measurements, peripherally access or peripherally inserted central catheters. Two-third (27) answered non-armant to avoid for these procedure and 13.5% (6) responded who side does not matter. 81.8 % (36) answered that nephrology should be consulted prior to peripherally inserted central catheters placement for CKD 4 patient. 93.1 % (41) answered

Vascular Access and Transplant Referral Rates in CKD: An Ongoing Performance Improvement Project for Nephrology Fellows

Background: Referral for vascular access (AV) and kidney transplantation (Tx) are important management facets of CKD. We previously conducted a performance improvement project assessing AV and Tx referral rates (RR) in CKD patients from the Nephrology fellows’ clinics. Following an educational intervention, there was an improvement in transplant RR (JASN 25.786A, 2014). To evaluate the sustainability of this initiative, we conducted a follow-up analysis.

Methods: This performance improvement project was conducted in 3 phases at the Charlie Norwood VAMC; Phase 1 (baseline, 1/1-4/30, 2013), Phase 2 (post-intervention, 8/1-11/30, 2013) and Phase 3 (follow-up, 1/1-4/30, 2015). Data extraction was conducted by three, 2-2 fellow teams, each reviewing the other’s RR for all patients seen in the previous 4-month period. The analysis was sorted by eGFR (ml/min/1.73m2); for eGFR<15, both AV and Tx RR were recorded. In addition, Tx RR for eGFR 15-20 was documented.

Results: 1114 total records were reviewed (349, 361, and 404 for Phases 1, 2, and 3, respectively). Table 1 indicates the number of patients and RR in those with GFR<20. RR andTx RR were recorded. In addition, Tx RR for eGFR 15-20 was documented.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.

Impact of Standardized Electronic Documentation in an Academic Nephrology Setting

Background: Reimbursement depends on accurate documentation and billing. Academic nephrologists are under increasing pressure to meet financial productivity targets. An analysis of nephrology reimbursement was performed at an academic medical center to find deficiencies and identify targets for education.

Methods: 75,978 inpatient nephrology encounters by 22 nephrologists from January 2012 and March 2015 were reviewed. Data included the current procedural terminology (CPT) code specifying the type of service and any charge adjustments made by the coding department. Adjusted charges were accompanied by the reason for adjustment, the corrected CPT code and a gross revenue adjustment based upon Medicare reimbursement. Relative value units (RVUs) were calculated using the Medicare National Physician Fee Schedule. Multivariate regression analysis was performed to identify factors associated with RVU adjustments.

Results: 5615 (7.5%) of encounters were adjusted by coders. 3832 (68%) were due to incorrect documentation or billing and 1683 (32%) were due to services performed but not billed by nephrologists. For submitted charges, revenue was reduced by $995,976 and 4227 work RVUs as a result of incorrect documentation or billing. The potential loss of revenue from unbilled services was $603,014 and 2823 work RVUs. Inadequate documentation of physical exam (p<0.01) and inadequate documentation of supervision of medical students/residents/fellows (p<0.01) were independently associated with RVU adjustments. Incorrect charge selection, duplicate charges, competing charges from another nephrologist and conflicting discharge/observation/post-operative care CPTs were also independently associated with RVU adjustments (p<0.01).

Conclusions: There was a substantial loss in gross revenue and work RVUs due to incorrect documentation and billing in an academic nephrology setting. These reductions in reimbursement and productivity might be avoided through better physician education and training. Specific targets include documentation of physical exam and supervision of trainees, correct CPT charge selection and ensuring all services performed are billed.

Reaching Renal Goals – A Quality Improvement Project

Background: The purpose of this study was to improve our patient care in a renal clinic at a large university hospital by using three of the core competencies - patient care, systems based practice, and practice based learning and improvement.

Methods: A check-out sheet was developed and through better physician education and training. Specific targets include documentation of physical exam and supervision of trainees, correct CPT charge selection and ensuring all services performed are billed.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.

Conclusions: Baseline knowledge was poor regarding vein preservation in CKD patients and very few residents have engaged in practices to preserve veins. More resident education is needed to engage them in vein preservation for CKD patients.
Conclusions: Our project was helpful in educating trainees in the treatment goals and assessing for patients in the renal clinic, and standardized an approach to patient care. Overall, the results show a trend towards improvement in all goal areas except for renal education. This study did not account for patients who were new to our clinic and therefore had never received renal education previously.

SA-PO152

A Simulation Exercise to Assess Renal Replacement Therapy and Kidney Biopsy Communication Skills Lisa K. Prince, 1 Maura A. Watson, 1 Anna M. Howle, 1 Christina M. Yuan, 1 Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; 2 Medical Simulation, Walter Reed National Military Medical Center, Bethesda, MD.

Background: We piloted a nephrology-specific “Breaking Bad News” simulation to assess Interpersonal Communication Skills and Professionalism during renal replacement therapy (RRT) and kidney biopsy (Bx) counseling. Assessment tools were a 9-point Likert Mini-Clinical Examination Exercise (Mini-CEX) adapted for RRT and Bx counseling, and the Essential Elements of Communication-Glomerular Disease Scale 2005 (EEC-GRS).

Methods: There were three cases: 1) a middle-aged woman with polycystic kidney disease and CKD5, 2) a critically-ill elderly man with AKI whose wife was his surrogate decision maker, and 3) a previously healthy soldier with nephrotic syndrome. There were 5 nephrology fellows. One patient actor performed for each case, assessing each examinee with the EEC-GRS. One faculty assessed all examinees for one case using the EEC-GRS and mini-CEX. Encounters lasted 15 minutes, followed by 5 minutes for examinee counseling by the actor and faculty.

Results: Post-simulation, 3/5 faculty surveyed felt that the exercise met objectives, and was an excellent assessment tool. 4/5 examinees felt the exercise was “good” and met objectives. 5/5 felt that simulation time was too short to assess communication skills. 2/5 felt that a mini-CEX assessing a real patient encounter was superior. Median examined EEC-GRS performance assessed by actors and faculty was 4 (range 3-5). Median mini-CEX performance was 6 (range 5-9).

Conclusions: Based on feedback, the original mini-CEX was too detailed for a 15-minute encounter, and was simplified. Instructions now stress that, because of encounter brevity, counseling is unlikely to be completed, and completion is not required for satisfactory grading. A second set of scenarios was developed to permit a yearly simulation in a two-year cycle. We plan to test the revised simulation in a larger group of nephrology fellows within the next year. The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense or the United States Government. Funding: Other: U.S. Government Support

SA-PO153

Background: Estimated glomerular filtration rate (eGFR) is used to diagnose and classify CKD. The accuracy of creatinine-based eGFR (CREAT) is inferior to eGFR calculated using multiple renal filtration markers. CKD guidelines suggest using serum creatinine and cystatin C to evaluate for CKD in select patients, but methods for, and results of guideline implementation have not been reported.

Methods: We reviewed new patient nephrology clinic encounters for a three month period to establish baseline guideline adherence. Combined creatinine/cystatin C (eGFR[CystatinC]/eGFR[CreatininC]) was considered indicated in patients with eGFR-Creat 45-90mL/min/1.73m2 and no albuminuria,urine sediment abnormalities, or other markers of kidney damage. Consultation review was modified such that a nephrologist reviewed every referral request, with the option of ordering labs to be obtained prior to a clinic visit. During a six-month implementation period, guideline awareness was targeted via didactics, signsencountered in patients, and results of guideline implementation have not been reported.

Results: Guidelines were modified to increase the threshold for the post江湖 intervention adherence was compared using Fisher’s exact test. Patients with eGFR-CreatCreatCys<60mL/min/1.73m2 were considered to have no evidence of CKD. Inpatients for whom eGFR-CreatCystinC was obtained, mean eGFR-Creat and eGFR-CreatCys were compared using paired t test.

Conclusions: Guideline adherence was significantly higher in the post江湖 intervention adherence was compared to the pre-intervention period (testing observed in 30 of 40 (75%) vs 12 of 32 (37.5%) indicated cases; p<0.002). Mean eGFR-CreatCys was significantly higher than eGFR-Creat (77.3±15.3 vs 58.3±9.1mL/min/1.73m2; p=0.001). eGFR-CreatCys was ≥60mL/min/1.73m2 in 85.3% of cases.

Conclusions: By modifying our consult review process and raising awareness among nephrology providers, we significantly increased implementation of eGFR-CreatCys guidelines and determined that the vast majority of tested patients had no evidence of CKD. Our results suggest testing as suggested in the guidelines has the potential to markedly decrease the number of inaccurate CKD diagnoses.

SA-PO154

Improving Pathology Curriculum for Nephrology Fellows Enrica Fung, 1 Orlando Camacho, 1 Michelle M. O’Shaughnessy, 1 Adetokunbo A. Taiwo, 1 Gabriela Velez, 1 Neeraja Kambham, 2 Timothy W. Meyer. 1Nephrology, Stanford; 2Pathology, Stanford; 3Nephrology, VA Palo Alto.

Background: Stanford fellows were previously exposed to renal pathology through attendance at monthly hour-long “biopsy conferences” where faculty and fellows discussed difficult cases; and informal quarterly “fellows-only conferences” where fellows asked pathologists questions on core topics. Our project sought to improve fellows’ education in renal pathology.

Methods: Twelve first to third year fellows participated in this project. Two renal pathologists led five orderly review sessions, dedicated to fellows only: 1. Common renal pathologies; 2. Primary glomerulonephropathies; 3. Secondary glomerulonephropathies; 4. Plasma cell dyscrasia-related disease; 5. Renal transplant pathology. Second year fellows helped in preparation of teaching material. Fellows were encouraged to ask questions. Participants completed a survey to measure their satisfaction with renal pathology teaching and their confidence in interpreting renal biopsies before and after this project.

Results: Prior to our project, 55% of fellows felt “somewhat satisfied” to “satisfied” with the current pathology conferences, and 10% of fellows felt “somewhat confident” in their abilities to interpret biopsy findings. Most fellows (83%) viewed renal pathology to be an “important” or “very important” part of their overall nephrology training. After the project, 100% of fellows felt “somewhat satisfied” to “very satisfied” with the project, and 60% of fellows felt “somewhat confident” in their abilities to interpret biopsy findings. To date, fellows answered 63% of quiz questions correctly prior to the project and 60% of final questions correctly after the project.

Conclusions: Survey of nephrology fellows revealed poor confidence in interpreting renal pathology prior to our project despite perceived importance of the topic. To date, post project evaluation suggested improved confidence in renal pathology but lack of significant change in knowledge base. This may be due to issues with knowledge acquisition, inter-test comparability or instruction method.

SA-PO155

Improving the Communication Skills of Nephrology Fellows by Utilizing MBTI Training Anna Marie Burgner, Julia Lewis. Vanderbilt Univ School of Medicine, Nashville, TN.

Background: Communication skills can both positively and negatively affect the patient-physician relationship. Although many things impact successful communications, individuals’ personality types affect the way they communicate and the way they interpret the communications of others. It has been suggested that a lack of understanding of the basic difference between personality types contributes to poor communication and unsuccessful interactions. Nephrologists work in a unique environment in the dialysis unit with a complex interdisciplinary team and a “captured” audience of anywhere from 10-40 patients in a single room. In the dialysis unit, communication between the multi-disciplinary team and the patients and between the multidisciplinary team’s individual members impacts the successful achievement of dialysis outcomes.

Methods: Eleven nephrology fellows underwent a curriculum designed to increase their awareness of their own Myers Briggs Type Indicator (MBTI) personality preferences, their knowledge of the different basic personality preferences, and how those differences impact communication. Knowledge of the MBTI preferences was tested pre-intervention, immediately post intervention, and 8 weeks post intervention. Communication skills were measured pre-intervention, 4 weeks post intervention, and at 8-weeks post intervention.

Results: Communication skills were measured prior to the intervention and 8 weeks post intervention by dialysis nurses observing fellow-real patient interactions. Fellows were also asked to describe how they used their knowledge at 8 weeks post intervention.

Conclusions: The intervention led to a sustained increase in the nephrology fellows’ MBTI personality preference knowledge. At 8 weeks post intervention, fellows reported utilizing their personality preference knowledge to improve their communication with their patients as well as with members of their team. However, nephrology fellows’ communication skills, as measured by the Kalamazoo Essential Elements Communication Checklist Adapted (KEECC-A), did not change.

SA-PO156

Lung Ultrasound: A New Skill for Nephrologists for Volume Overload Quantification in End Stage Renal Disease Patients on Hemodialysis Marie M. Saad, Wissam Mansour, Elias Moussaly, Jeanne Karnal, Boutros Karam, Cara Brown, Monica Kapoor, Elic El-Charabaty, Suzanne E. El Sayegh. Internal Medicine/Nephrology, Staten Island Univ Hospital, Staten Island, NY.

Background: Many methods have been tried to assess the volume status in patients on hemodialysis (HD). While the estimated dry weight is still the only method widely used, it is often inaccurate and poses a clinical challenge. Pulmonary congestion detected as B lines on ultrasound (BLUS) is rising as a novel parameter for assessing volume status; we evaluate the accuracy and reliability of measuring BLUS performed by residents following a short training course.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Residents underwent a 3 hour course under the supervision of ultrasonound-fellowship trained Emergency Physicians (EP). The course included a didactic section, a simulation hands-on training, and an Objective Structured Clinical Examination prior to enrolling the trainees as investigators; Residents performed lung ultrasound (LU) on ESRRD patients post HD sessions in a supine position over 28 intercostal windows. They obtained at each window a 6s clip that were reviewed by 2 blinded EP. BLUS were summed up categorizing patients into different classes of pulmonary congestion: mild (0-14), moderate (15-30) and severe (>30).

Results: A total of 81 ESRRD patients on HD were scanned. 71.6% were males; mean age 59.74 years, mean BMI 28.59±5.62 kg/m²; mean treatment duration was 15 min. The B-Lines score found by the study investigators and EPs was 15.8 ±21.3 and 12.06±21 respectively. The difference was 3.77±16.8 (0.0475). When categorized into the 3 classes, there was no significant difference between both classification (0.085), and were in moderate agreement-kappa 0.56 [0.42-0.71].

Conclusions: B-Lines visualized on bedside LU can provide a reliable and quantifiable assessment for lung congestion. Our study shows that a short training course can render novice users of ultrasound capable of performing this quick evaluation. This can aid in objectively assessing volume overload in a timely manner in HD patients who present a unique clinical challenge. LU has emerged as a new technic, readily available at bedside, providing immediate results, yet is an easily learned skill.

SA-PO157

Background: Percutaneous kidney biopsy is the gold standard for diagnosis of kidney disease but is underutilized due to wariness of complications. Based on clinical and laboratory data, Nephrologists try to predict the renal pathology (clinical gestalt). However, no study has compared the diagnostic accuracy of the clinical gestalt with the kidney biopsy result.

Aim: To compare pre-biopsy diagnosis (PBD) by Nephrologist with final histologic diagnosis. To assess if accuracy of PBD improves with increasing years in clinical practice.

Methods: Division of Nephrology at Stroger Hospital of Cook County conducts a monthly biopsy conference. Three case summaries are presented followed by discussion and presentation of the biopsy findings. Between September 2014 and April 2015, using a structured form Fellows and Nephrologists were asked to provide their top diagnosis for each case and this was compared with the actual histologic diagnosis. All physicians apart from the primary Nephrologist were blinded to the diagnosis. The study was deemed exempt by IRB.

Results: 23 cases were discussed in the biopsy conference involving 13 unique diagnoses and 286 unique responses were obtained. Overall diagnostic accuracy was 53.49% (153/286); Fellows (52.5%) and Nephrologists (54.3%). Diagnostic accuracy for nephrologists was 100% for ANCA vasculitis and Minimal Change Disease (MCD) and 86% for Diabetes but < 50% for stages of Lupus and other seronegative GNS.

Biopsy Diagnosis Pre-biopsy diagnostic accuracy (%)
ANCA vasculitis 100
MCD 100
DM 86
Lupus class II 80
Amyloid 57.14
Lupus class III + V 50
Idiopathic Membranous 45.45
HIVAN 42.85
IgA 38.46
Lupus class V 33.33
HTN 33.33
Fibrillary GN 25
Normal 0

Nephrologists with > 10 years’ experience tended to more accurately predict the diagnosis than those with < 10 years’ experience (64.4 vs. 48.3%, p=0.07).

Conclusions: Nephrologists more accurately diagnosed ANCA vasculitis, MCD & Diabetes by clinical gestalt, but were less accurate for stages of lupus and other seronegative GNS. Regardless of training and experience kidney biopsy is still the diagnostic tool of choice in patients with kidney disease.

SA-PO158

Out-Patient Clinic Based Multidisciplinary Patients’ Education for Advanced DM Nephropathy Is Effective and Efficient for Reducing ESRD

Fumiko Taki, Takuya Fujimaru, Masataka Hasegawa, Miyuki Futatsuyama, Yuki Heath, Masahiko Nagahama, Yasuhiro Komatsu. Nephrology, St. Luke’s International Hospital, Tokyo, Japan.

Background: Diabetes Mellitus (DM) is the most common etiology of CKD. Patients educations for these patients are known to be important, however, effectiveness and efficiency of these programs are still unclear. We established multidisciplinary out-patient clinic based education system, specialized for advanced diabetes nephropathy, and assessed their clinical outcomes.

Methods: Education system were started from May 2012, in St. Luke’s International Hospital, Tokyo, Japan. All CKD patients with DM were asked to meet nurse and dietitian, before seeing physicians, on every visit of the CKD clinic. Nurse and dietitian give the specific advices for each patients, within 15 minutes, by using our original short text or materials. Initiation of renal replacement therapy (RRT) were assessed for the primary and secondary end points of the study, death, hospitalization, type of RRT were.

Results: From May 2012 to March 2015, total 372 individual patients were participated. Their baseline eGFR were 36.5±12.5/mL/min, mean age 65.5±13.2 y.o. and 68% of them were male. Two hundred and ninety seven, 82% of patients were educated and they averaged their frequency of education was 4.3±2.1 times/year. Comparison of educated and non-educated groups, baseline eGFR, HbA1c or other comorbid did not differ. However, preservation of renal function were better in educated group; delta eGFR: Educated vs. Non-educated: -3.26±1.21 vs. -8.2±3.25 mL/min/1.73m²/year, p=0.04. T Test. More, incidence of ESRD in educated group were higher than non-educated: 9.4% vs. 33.3%, p=0.033, Chi-square test. Furthermore, in non-educated group, none of the patient selected peritoneal dialysis or transplants for the RRT.

Conclusions: Our out-patient clinic based education system is simple and useful for diabetic CKD patients for reducing ESRD.

SA-PO159

Our Stories Our Way: Creation of a Digital Story CKD Educational Intervention

Inessa Jolly,3 Marcia Oleary,3 Ashwin R. Sehgal.3 General Internal Medicine, Cleveland Clinic, Cleveland, OH; 1Missouri Breaks Industries Research Inc, Eagle Butte, SD; 2Center for Reducing Health Disparities, MetroHealth Medical Center, Cleveland, OH.

Background: Chronic Kidney Disease and End Stage Renal Disease disproportionately affects American Indian communities, yet there are few culturally appropriate educational interventions for this population.

Methods: Digital storytelling combines first person narrative with digital images and music and can be done with a community-based, learner-centered approach. With these digital tools, people create personal narratives that are powerfully compelling, emotionally engaging, and provide another view or perspective on a topic. We recruited 10 men and women with diverse life experiences related to health and kidney disease from an American Indian community to create digital stories. Each participant was mailed a pre-workshop DVD that pertained to chronic kidney disease knowledge and health behaviors among American Indians.

Results: We held a 3½ day digital story workshop with our partner nDigiDreams, LLC in Nov 2013 at a tribal college. Participants, their family members, and researchers worked together with the facilitators to create their personal digital story related to health and kidney disease in their words. A total of 10 digital stories were created. The stories encompassed four areas: develop story idea, gather media such as pictures and music, record the voice parts/edit the digital story, and share or screen the digital stories among the group. No technical difficulties were encountered.

Conclusions: We created a unique educational tool in the form of digital stories. The DVD has been used in an ongoing pilot observational educational trial looking at the impact on chronic kidney disease knowledge and health behaviors among American Indians.

The Effect of Nephrology Specialty Clinics on Patient Care and Trainee Experiences

Frederick H. Kuo, Rajeev Raghavan, Wolfgang C. Winkelmayer, Josey W. Perez. Dept of Medicine-Nephrology, Baylor College of Medicine, Houston, TX.

Background: As medicine evolves, there has been a trend towards the creation of special clinics which streamline care in hopes of improving patient survival through clinical trials and increased time with “super-specialists”. From a trainee perspective, a Nephrology clinic focused on a particular disease affords a unique perspective on disease pathophysiology and treatment and can be a wonderful tool to recruit residents or students to nephrology. We hypothesized that a majority of nephrology trainees across the US utilize such subspecialty clinics, and we aimed to characterize the patient and trainee experience by conducting a nationwide survey.

Methods: An e-mail detailing the study’s aims and an anonymous 7-question online survey was sent to the 139 program directors of ACGME-accredited nephrology fellowship programs in July 2014.

Results: 54 of 139 program directors (39%) replied. We found Transplant clinics to be the most common subspecialty clinic (83%), followed by Stone clinic (63%), Advanced CKD clinic (38%), and Glomerulonephritis clinic (38%). Transplant specialist exams test on average, with 67% in existence for over 10 years. Less common clinics included those...
for lupus, polycystic kidney disease, and genetics. Regarding patient compliance within specialty clinics, 40% indicated no change, 40% improved, and 20% much improved. On patient satisfaction, 32% indicated no change, 49% improved, and 19% much improved. No respondents perceived decreased patient compliance or satisfaction. Trainees participated in 98% of specialty clinics with a 91% satisfaction rate; 29% were very satisfied. 45% of specialty clinics had ongoing research projects, with an average of 5.5 research projects in those clinics.

Conclusions: Specialty clinics can be an invaluable tool for both trainees and patients; both groups reported high satisfaction levels. These clinics also enable research by maintaining an established database of patients with specific disease processes. Access to such information is essential to quality research and may streamline the development of key clinical trials.

SA-PO161

Background: The distribution of renal replacement therapy (RRT) modalities among patients varies from country to country, and is often influenced by non-medical factors. In our department, patients progressing towards end-stage renal disease (ESRD) go through a structured Pre-Dialysis Education Program (PDEP). This PDEP is conceived with patients association and nursing educator.

Methods: Forty nine patients with CKD who were receiving care in a multidisciplinary predialysis clinic (mean age 73.5, 63% men). The participants were accompanied by family member. They have received an educational education, followed by two workshops in groups and a final educational workshop. The evaluations are carried out in groups of 6 to 10 patients. The PDEP consisted of: (1) psychosocial assessment, (2) education about dialysis and choice of modalities, (3) counseling sessions with patient, family members, (4) education about dietary and dialysis.

Results: Choice of the substitution method at the end of the workshops: 61% peritoneal dialysis, 18% haemodialysis and 21% absence of choice. - 94% of the patients were satisfied with the treatment choice - 100% satisfaction of the patients, 26% decrease of the anxiety. (p=0.0005), 25% (p= 0.0001) increase in the consent for the treatment, 61% increase in the engagement in the treatment (patient ready to receive treatment) (p=0.00001), 47% increase knowledge of RRT (p=0.00001).

Conclusions: Most studies dealing with the pre-dialysis information show a balanced choice of the RRT, but only 50% of the patients actually begin DP. Our workshops of help and assistance to the choice enable to significantly reduce the anxiety linked to the dialysis and thus increase the adherence and engagement for the chosen method RRT. A two-phase educational intervention can increase the proportion of patients who intend to initiate dialysis with self-care dialysis. In our centre offering all treatment RRT modalities, a high percentage of patients exposed to a structured PDEP start with a self-care RRT modality.

SA-PO162
Frequency of Use of Social Media in CKD Patients on Dialysis: Pilot Study in Ecuador Fabian A. Ortiz-Herber, Juan Carlos Calderon, Walter Morales, Christian Arias, Juliana Moro, Byron Jesus Haz, Ivan Manuel Cherrez. 1Inst Ecuatoriano de Diálisis y Transplantes, Guayaquil, Guayas, Ecuador, 2Respiral, Guayaquil, Guayas, Ecuador; School of Medicine, Univ de Especialidades Espiritu Santo, Samborondon, Guayas, Ecuador.

Background: CKD on dialysis is defined as <15% of kidney function. In Latin America, 461 per million are on dialysis. Region is the third largest user internet. Social media includes communications spread electronically, shared by individuals and discussed by a committed population. Hispanic Americans with CKD used it, to inform and be informed, and for supporting each others.

Methods: Observational, cross sectional, pilot study. Patients were recruited in dialysis center in Guayaquil. Survey included demographical and clinical items, Charlson score and 4 questions about frequency of use of social media were included. Also, questions about obtaining information; and interest in receiving or asking physician questions related to illness in social media. Frequencies and mean (SD) were employed. Chi-square, ANOVA and M-W U was used for comparisons. Also, Cronbach were calculated.

Results: 34 patients participated, with mean age of 56.5 (SD 16.3), mean years on dialysis of 3.9 (SD 4), 52.0% were women. Comorbidity’s rate was very high (82%). 70.6% of patients believed that dialysis control symptoms of disease. 11.8% hadn’t got cellular-phone neither Internet. 61.8% hadn’t got smartphones. Almost half of patients had smartphones. Women had a high comorbidity (41.2%), p<0.05. Around 30.0% reported using SMS, Facebook, YouTube, Internet as main tool for obtaining information, and 43.5% reported use of WhatsApp. Mean KiKS was lower in Chinese speakers compared to English speakers (11.9 vs. 17.2; p<0.001). Chinese speakers scored lower in all domains of the KiKS; general kidney knowledge (6.2 vs. 4.5), knowledge of kidney function (5.5 vs. 4.0) and knowledge of medications (0.4 vs. 3.7).

Conclusions: While our results for CKD knowledge among English speakers are comparable to previously published data (mean score 18.0), scores among non-English speaking CKD patients is lower than English speakers. Whether this finding is associated with differences in care management and clinical outcome needs to be evaluated. Furthermore, educational material and programs may need to be tailored to specific populations to improve health literacy.

SA-PO163
The Impact of Predialysis Education on Patient Understanding, Preparedness, and Decisional Conflict Regarding Renal Replacement Therapy Options Syed Amir Hamid Ali Shah, 1 Jon D. Bucalouci, 1 Amanda Young, 1 Jamie Alton Green. 2 Nephrology, Geisinger Medical Center, Danville, PA; 3 Center for Health Research, Geisinger Medical Center, Danville, PA.

Background: Predialysis education is recommended to prepare patients with advanced chronic kidney disease (CKD) for initiation of renal replacement therapy; however, the impact of existing approaches to the medical decision-making is unknown. Methods: We surveyed 91 advanced CKD patients before and after a 2-hour nurse led group education class to assess patient understanding of renal replacement therapy options (1=poor to 5=excellent), preparedness to make a decision (1=not at all to 5=very prepared), and decisional conflict using a validated scale (0=no decisional conflict to 100=extremely high). The class included a combination of direct verbal instruction and video presentation, tailored to patients with a high level of health literacy and sociodemographic backgrounds. Content included the advantages/disadvantages of hemodialysis (HD), peritoneal dialysis (PD), transplant, and conservative care.

Results: Mean age was 66.58, 58% male, 94% white, 44% had a high school or lower level of education, and 46% had low health literacy. Mean level of understanding increased significantly for all modalities pre-post (2.02 vs. 4.10 for HD, 1.95 vs. 4.14 for PD, 2.35 vs. 4.15 for transplant, and 2.10 vs. 4.12 for conservative management; all p<0.001). Decision preparedness also increased significantly from 2.44 to 3.50 (p<0.001). Improvements were similar regardless of age, gender, educational level, or health literacy. At the end of the class, overall decisional conflict was low (median score 10; IQR 0, 20). Equal proportions of patients preferred HD (24%) or PD (22%), compared with transplant (12%) and conservative management (4%), yet nearly (30%) of patients remained unsure of their decision.

Conclusions: Despite significant improvements in patient understanding and preparedness about renal replacement therapy options, a substantial number of patients remain unsure of their decision after routine predialysis education. Additional decision support interventions may be needed to improve decision-making in advanced CKD patients.
SA-PO166
The Role of Post Biopsy Ultrasound in Predicting Complications After Percutaneous Renal Biopsy of Native Kidneys

Background: The percutaneous renal biopsy (PRB) of native kidneys has been an essential tool in the diagnosis and management of renal diseases. Despite all advances, clinically evident bleeding complications do occur in up to 30% of patients after PRB of native kidneys. Traditionally patients are kept under observation for 24 hours after the procedure. An earlier investigation to anticipate the likelihood of complications will help to reduce the length of stay for these patients and thus the resource burden. Post PRB ultrasound has been studied for this purpose. We conducted a study to evaluate the role of early post PRB ultrasound to predict procedure related complications in our patient population.

Methods: 46 patients undergoing renal biopsy at department of Nephrology, Jinnah Hospital were considered for this study. Renal biopsy was performed using a 16-gauge automatic needle core biopsy needle. After the biopsy, patients were closely monitored in the recovery room and after 1 hour, the biopsied kidney was examined by ultrasound. These patients were admitted and were kept under observation to assess any complications for next 23 hours.

Results: Of these 46 patients, 24 (52%) were males with mean age 39 (16 to 60 years). More than 3 cm hemato ma was seen in 2 (4.3%) patients at 1 hour post biopsy ultrasound scan. Of these 2 patients, only 1 (2%) patient had major complications including hypotension, decrease in hemoglobin etc. Thus 45 (97.8%) patients had uneventful recovery. Sensitivity of more than 3 cm hematoma formation at 1 hour post biopsy in predicting major complications was 100% with specificity of 97.7%.

Conclusions: Our study showed that the frequency of major complications was minimal in patients without >3 cm hematoma formation at one hour post-PRB. Post-PRB ultrasound is a non-invasive, accurate diagnostic tool in predicting procedure related major complications.

SA-PO167
A Multidisciplinary Clinic for Children with Lupus Nephritis (LN) – A Step Towards Personalized Medicine?

Background: Most children with SLE develop LN, which significantly worsens morbidity and mortality. Progression to ESRD occurs in 5-10%. Early diagnosis and treatment improve long-term outcomes, thus prompt evaluation is essential. Therefore, a combined pediatric nephrology/rheumatology clinic (LN Clinic) was started in 2013. The primary aim was to evaluate the number of days between onset of proteinuria (first-um urine p/c <0.2) and performance of a renal biopsy (bx) for SLE patients (pts), pre- and post-establishment of the LN Clinic. We aimed for a 20% reduction in time to renal bx within 2yr of establishment of this clinic. The secondary aim was a reduction of steps in the referral process.

Methods: SLE pts with an outpt renal bx were identified by an EMR query. Pts were selected if a bx was performed within 5yr pre or 16mo post establishment of the LN clinic. Our sample selection was cross-referenced with an established lupus registry. A chart review provided the data of proteinuria onset, disease activity markers, and LN class. Pts diagnosed in the inpt setting were excluded. A process map determined the number of steps occurring between new-onset proteinuria and first evaluation by a nephrologist.

Results: We show that pre LN clinic, the median number of days between onset of proteinuria and renal bx was 51 (IQR=25–83.5d), compared to 34 (IQR=14–48d) post (p=0.057). This is a 33% decrease in time. There was a negative association between amount of proteinuria and days to bx (r=-0.5826, p<0.001). There was no association between hematuria or markers of disease activity and days to bx. There was also no association between LN class and days to bx. Pre LN clinic, a referral required 10 steps, which was reduced to 6.

Conclusions: The LN clinic has resulted in earlier renal bx and fewer steps in the referral process. For pts with proliferative LN, this translates to earlier initiation of treatment and a chance at improved outcome.

SA-PO168
Antidepressant Efficacy and Safety Observations: USRDS ACTIVE-ADIPOSE Study

Background: Although depression is a prominent issue, depression management in advanced CKD and ESRD patients is not well understood. Antidepressant medications are the most frequent therapy, but efficacy and safety data are limited (Hedayati et al. 2012). Most patients in CKD and ESRD populations have very high comorbidities, and while the majority of antidepressants are safe in these patient populations, the proportion non-white and younger than age 65 was higher in the study cohort. Medication efficacy was defined by participants’ scores (<18 vs. 18+) on the Center for Epidemiologic Studies Depression Scale (CES-D) score (Hedayati et al. 2006). Adjusted odds for recent falls observed in association with antidepressant use and CES-D score provided an indicator of safety.

Results: Antidepressants were prescribed for 15% of study participants. 40% of those with prescribed antidepressants had an elevated CES-D score, suggesting lack of drug efficacy. Efficacy did not appear to vary by patients’ age or vintage, but more whites had elevated CES-D scores. Recent falls were more frequent among patients on antidepressants with elevated CES-D score (adjusted odds ratio 2.27 [1.05, 4.90], p=0.04, compared with patients not on antidepressants and CES-D score <18). Fall risk was similar across type of prescribed antidepressant (SSRI, atypical, and tricyclic drugs).

Conclusions: Efficacy of antidepressant medications was unclear for 40% of those with these drugs prescribed, and safety hazard was suggested by increased fall risk. Continued evaluation of nonpharmacologic as well as pharmacologic options for depression management in MHD patients, the focus of a current PCORI trial, is important.

Funding: NIDDK Support

SA-PO169
Sofosbuvir Use in Patients with Hepatitis C Virus Infection and Severe Chronic Kidney Disease

Background: Chronic hepatitis C virus (HCV) infection is a major health problem. The use of new direct acting antiviral (DAA) based regimens has been shown to provide a high sustained virologic response with less adverse reactions compared to interferon–ribavirin regimens. The American Association for Study of Liver Diseases recommends expert consultation on patients with eGFR less than 30 mL/min because safety and efficacy data are not available on these patient populations. We propose that these DAAs are safe to use in patients with advanced kidney disease.

Methods: A total of 23 patients with HCV and estimated glomerular filtration rate (eGFR) less than 45 mL/min were treated with sofosbuvir and simeprevir, dose of sofosbuvir was adjusted to 200 mg PO daily or 400 mg PO every other day for patients with eGFR less than 30 mL/min by Hepatology and Nephrology services. These patients were monitored closely by both services.

Results: A cohort of 23 HCV positive patients had the following descriptive statistics, 20 males (87%) and 3 females (13%). 15 patients had Genotype 1a (65%), 7 patients had Genotype 1b (31%) and 1 patient had Genotype 2b (4%). 3 patients (13%) had End Stage Disease (ESKD) and were on hemodialysis, 9 patients (39%) had Chronic Kidney Disease grade IV (CKD IV - eGFR <30 mL/min) and 11 patients (48%) had Chronic Kidney Disease grade IIIIB (CKD IIIIB - eGFR <45 mL/min). The HCV viral load of the 23 patients (100%) had a statistically significant decrease as the therapy progressed through completion with a statistically significant text with a p < 0.05. No side effects were present on the patients during DAA therapy. Patients with CKD grades IIIIB and IV on DAA treatment had a preserved kidney function by the end of therapy.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Sofosbuvir is safe and effective in patients with Hepatitis C Virus infection who have Severe Chronic Kidney Disease, conferred by chronic kidney disease, not being treated by Hepatology and nephrology in operation due to the lack of data in safety and efficacy.

SA-POI70

Enoxaparin as Bridging Therapy in Veterans with Advanced Kidney Disease

Background: Patients with CrCl < 30 mL/min on anticoagulation require temporary bridging with heparin. Low molecular weight heparins (LMWH) have longer half-lives and predictable anticoagulant effect but require anti-Xa monitoring in CKD. This study aims to evaluate the safety and efficacy of low molecular weight heparins in bridging therapy in patients with CrCl < 30 mL/min.

Methods: A retrospective study was conducted from Jan 1, 2012 to Dec 1, 2014. Patients with CrCl < 30 mL/min, received enoxaparin 1 mg/kg/d as a bridge therapy to warfarin, and had at least one anti-Xa level checked were included in the study. Patients were excluded if they had major bleeding or thromboembolism in previous 3 months before enoxaparin, history of bleeding disorders, or used enoxaparin for other indications. A dosing nomogram was used to guide dosage adjustment to keep anti-Xa levels within the target range (0.5-1.0 mcg/mL). The primary outcomes are 0 of minor/major bleeds and thromboembolic events. The proportion of anti-Xa levels within goal range was assessed.

Results: 12 patients met inclusion and exclusion criteria. The mean age was 62.4 ± 11.9 years, 91.7% were male, 58% were diabetic and 46% had congestive heart failure. 50% were on both warfarin and aspirin. The median treatment duration of enoxaparin was 11.4 ± 4.6 days, the average daily dose was 17.6 ± 4.5 mg/day. A total of 19 anti-Xa levels were included for analysis. There were 2 (16.7%) bleeding events, 1 (8.3%) major and 1 (8.3%) minor bleed. None of the patients developed thromboembolic complications. The most common adverse event was bruising at the injection site that did not lead to any early discontinuation of therapy. Seventeen of the anti-Xa levels (89.4%) were in the target range.

Conclusions: Majority (83.3%) of patients had minimal or no adverse events and none with thromboembolic outcomes. In patients with bleeds, no correlation was seen with the anti-Xa levels. The dosing protocol is effective, with 89.4% of anti-Xa levels within goal range. The results of this study support the safety and efficacy of the enoxaparin dosing protocol as a bridge therapy perioperatively in patients with CKD.

Thiopurine Methyltransferase (TPMT) Genotyping to Predict Myelosuppression Risk in Chinese Patients with Nephropathy

Xueqiang Li, 1, Jia Ma, 2 Nephrology, Peking Union Medical College Hospital, Beijing, China.

Background: Pharmacogenetic study in nephritis is mainly focused on genes involved in the metabolism of Azathioprine (AZA). Use of AZA is limited by its toxicity. Variants in the Thiopurine S-methyltransferase (TPMT) have been associated with AZA toxicity. The aim of this study was to determine the contribution of TPMT variants in the development of AZA-related myelosuppression in Chinese patients with nephropathy.

Methods: Variants associated with the decrease of enzymeactivity in TPMT genes were genotypedin 4 nephritis patients treated with AZA, and correlated with the clinical response and development of adverse drug reactions in a retrospective case-control study. Three common mutation alleles of TPMT [TPMT* 3A (G460A/A719G), TPMT* 3B (G460A), TPMT* 3C (A719G)] were detected by polymerase chain reaction-high resolution melting and sequencing in 12 patients, included 4 patients with myelotoxicity and 8 patients without myelotoxicity.

Results: Genotypic analysis showed only one of the 4 patients with myelotoxicity was detected TPMT *3C polymorphisms, no TPMT*2, *3A, *3B or *3C polymorphisms were detected in any of the 11 patients.

Conclusions: Single-nucleotide polymorphisms of TPMT could not explain the azathioprine-related adverse events.

SA-POI72

Lanthanum Carbonate-Induced Granulomatous Gastritis

Francesco Iannuzzelli, 1 Loredana De Marco, 2 Sonia Pasquali, 1 1Dept of Internal Medicine, Nephrology and Dialysis Unit, Aretespolita Santa Maria Nuova, IRCCS, Reggio Emilia, Italy; 2Dept of Human Pathology, Aretespolita Santa Maria Nuova, IRCCS, Reggio Emilia.

Background: Long-standing non-calcium based phosphate binders administration has been recently associated with a number of different gastrointestinal lesions. We describe a rare case of lanthanum carbonate-induced granulomatous gastritis.

Methods: A 58-year-old woman was admitted to our hospital because of nausea, vomiting, progressive weight loss. Because of a well-known stage 5 chronic kidney disease, she was started on peritoneal dialysis. About one month later, CAPD was well-tolerated with an adequate dialysis dose. Nevertheless, she continued to complain of nausea, vomiting and dyspepsia. A gastroscopy revealed chronic gastritis with superficial erosions and an histopathology consisting of non-necrotizing, sarcoid-like granulomas with aggregates of multinucleated giant cells. Orange cristalloid material was seen within granulomas. Special stains for fungi and mycobacteria were negative. Her previous medical history was only significant for hypertension and type 2 diabetes mellitus. Physical examination was unremarkable. A chest X-ray was normal. A tubercolin skin test was negative. ANCA titres was negative and serum angiotensin converting enzyme (ACE) level was in the laboratory reference range. At the time of our evaluation, she had been receiving lanthanum carbonate 1 g bid for about 6 months.

Conclusions: At the best of our knowledge, so far, only 7 cases have been described in the literature.

None.

The histopathologic picture in our patient was compatible with a lanthanum carbonate-induced gastritis with some peculiar characteristics: a granulomatous reaction and the appearance of lanthanum carbonate crystals not only within histiocytes/multinucleated giant cells but also inside the cytoplasm of the epithelial glandular cells.

SA-POI73

Relative Incidence of Adverse Events with Ferumoxytol versus Other Intravenous Iron Products in Non-Dialysis-Dependent Chronic Kidney Disease

Eric D. Weinhandl, David T. Gilbertsen, Allan J. Collins. Chronic Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.

Background: All intravenous (IV) iron products confer risk of hypersensitivity reaction (HSR). The relative safety of ferumoxytol versus other IV iron products is not established. We used Medicare claims to assess relative safety of ferumoxytol versus other IV iron products in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: We analyzed a 20% sample of Medicare Parts A and B claims in 2009-2012. Patients received a first dose of IV iron between Jan 1, 2010, and Nov 30, 2012, and had diagnosed NDD-CKD without IV iron treatment during the 1 year before first dose. For each ferumoxytol user, we identified 1 propensity score-matched control who used another IV iron product; the score included demographics, comorbidity, and concomitant IV medication. Patients were followed until change in IV iron product, end stage renal disease, death, or Dec 15, 2012. With Cox regression stratified by matched pair and cumulative number of prior IV iron doses, we assessed relative incidence of anaphylaxis, HSR symptoms, hypotension, death to permit comparisons. However, after first dose, hazard ratios (ferumoxytol users vs. matched controls) were 0.90 (95% confidence interval, 0.80-1.01) for HSR symptoms, 1.06 (0.66-1.72) for hypotension, 0.72 (0.55-0.94) for ER visit, and 0.78 (0.60-1.02) for hospitalization, and death within 1 day of first dose and within 1 day of each subsequent dose.

Results: We identified 7358 ferumoxytol users and 7358 matched controls. Baseline characteristics were balanced across groups. There were too few cases of anaphylaxis and death to permit comparisons. However, after first dose, hazard ratios (ferumoxytol users vs. matched controls) were 0.90 (95% confidence interval, 0.80-1.01) for HSR symptoms, 1.06 (0.66-1.72) for hypotension, 0.72 (0.55-0.94) for ER visit, and 0.78 (0.60-1.02) for hospitalization. After subsequent doses, corresponding hazard ratios were 1.07 (0.90-1.27) for HSR symptoms, 0.91 (0.50-1.67) for hypotension, and 0.86 (0.64-1.15) for ER visit, and 0.97 (0.70-1.35) for hospitalization.

Conclusions: Relative to other IV iron products, ferumoxytol was not associated with excess risk of adverse events in NDD-CKD patients, following both first dose and subsequent doses. The incidence of anaphylaxis and death was very low in ferumoxytol users and matched controls.

SA-POI74

Efficacy, Safety and Pill Burden of Sucroferric Oxysulphide, an Iron-Based Phosphate Binder, Over 52 Weeks in African American Dialysis Patients

Stuart M. Sprague, 1 Anjay Rastogi, 2 Markus Ketteler, 3 Adrian C. Covic, 4 Jürgen Floege, 5 Viatcheslav Rakov, 6 Llera Armando Samuels, 7 1NorthShore Univ Health System, Chicago; 2Univ of California; 3Coburg Clinic and KFH-Dialysis Center, Germany; 4"Gr.T. Popa" Univ of Medicine and Pharmacy, Romania; 5RWTH Univ Hospital Aachen, Germany; 6Vijor Pharma; 7Temple Univ, Philadelphia.

Background: A post hoc analysis of data from a randomized, open-label, Phase 3 study and its extension investigated the efficacy and safety of the iron-based phosphate binder sucroferric oxyhdsulphide (SFOH; VELPHORO®) vs sevelamer carbonate (SEV; Renvela®) in African American dialysis patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

664A
Methods: Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks’ dose titration then 12 weeks’ maintenance. Eligible patients enrolled in a 28-week extension study.

Results: Of the 549 patients who completed the extension study, 100 were African American patients, equally distributed between the treatment groups despite the 2:1 randomization (n=48, SFOH; n=52, SEV). Serum phosphorus decreased rapidly and to a similar extent with SFOH and SEV, and remained relatively constant thereafter (Table). Mean ± standard deviation number of tablets/day was lower for SFOH (3.4 ± 1.35) vs SEV (7.6 ± 2.92) over 52 weeks. The incidence of serious or severe treatment emergent adverse events and deaths were similar in both treatment groups. Gastrointestinal-related disorders were the most frequently observed adverse events for SFOH and SEV.

Conclusions: SFOH efficacy was maintained long-term, with a lower pill burden than SEV and similar safety profile, in African American dialysis patients. "Post hoc results reflect those from the overall study population.

Intergated Dialysis Unit Module and Module Compartment Structure

Stanley Shao-Ying Lee,1 Ming-cheng Wang,2 Chi-Hsien Hemodialysis Center; Taiwan; 1College of Medicine, National Cheng Kung Univ, Tainan, Taiwan.

Background: Conventional set-up of hemodialysis (HD) center requires intensive manpower and tedious workload due to the intricate fluid and electricity layouts, and the fixed partitions structure. It is vital to design an integrated module considering rapid manpower and tedious workload due to the intricate fluid and electricity layouts, and the fixed partitions structure. It is vital to design an integrated module considering rapid

Methods: The Integrated Dialysis Partition System was designed for HD center. To ensure patient privacy, an easy-assembled partitions with a herringbone seating arrangement and illness intrusiveness. The integrated dialysis unit module allows for rapid assembly, easy pipeline maintenance, and improved patients’ quality of life.

SA-PO176

Safety and Adherence in End Stage Renal Disease Patients on Chronic Hemodialysis

Background: Missed hemodialysis and abbreviated hemodialysis sessions are common in end stage renal disease patients on maintenance hemodialysis. Missed dialysis is associated with increased mortality and morbidity in chronic hemodialysis patients. Our quality assessment performance improvement data revealed that on an average 15% of patients missed and abbreviated hemodialysis (HD) sessions over a period of 6 months.

Methods: We evaluated patients’ perception about missed and abbreviated sessions, and safety during HD sessions at our dialysis center. A questionnaire regarding patients’ views about missed, abbreviated and safe hemodialysis sessions using a visual analog scale (0-100 mm, where 0 means ‘No’ and 100 means ‘Yes’) was conducted in-person by a nephrology fellow or a social worker on all HD patients. Data are presented as mean ± SD.

Results: Ninety patients participated in the survey. Sixty eight (75.6%) patients with a mean score of 78±29.6 felt like coming for their HD sessions during the last one month. Fifteen of 89 (16.9%) (mean score 94.5 ± 17.3) felt safe during the HD sessions. Seventeen (18.9%) patients indicated missing the HD sessions. Thirty six of 83 (43.4%) patients with a mean score of 71 ± 37.6 wanted to miss HD sessions during the last one month. Fifteen of 89 (16.9%) signed against medical advice for the abbreviated HD sessions during the last one month.

Conclusions: Data suggest that safety of HD sessions does not appear to be a factor for missing HD sessions. Lack of patients’ understanding of importance of HD-treatments as well as lack of adherence likely leads to non-adherence and abbreviation to HD sessions. The safety of HD treatment was not the core issue behind increasing patients’ absenteeism. Active patients’ participation and individualization of HD sessions may improve adherence to HD sessions.

SA-PO177

Validation of a Tool to Assess Nursing Workload in Hemodialysis

Clara Bohm,1 Brett M. Hiebert,2 Joe A. Buett,1 Jan Schneider.2 1Univ of Manitoba; 2Winnipeg Regional Health Authority.

Background: Patient classification scales (PCS) to assess nursing workload predict staffing needs and facilitate transparency in assignments resulting in improved work environment, patient safety and quality of care. Few validated PCS tools exist for hemodialysis (HD). This study validates a point-of-care PCS developed for in-centre HD at a Canadian tertiary care centre.

Methods: Using LEAN framework, from Sept 1, 2013 to Mar 1, 2014 at the Health Sciences Centre in Winnipeg, Canada, iterative consultations with stakeholders resulted in creation of a PCS consisting of 9 domains and 67 subdomains. At each HD session between April 7-21, 2014, bedside HD nurses completed both a visual analogue scale (VAS), which assessed general level of nursing care required, and the PCS tool. Karnofsky scale and time-series studies were completed in 50 and 28 randomly selected HD patients, respectively. Analysis: Internal consistency and reliability were assessed using Cronbach’s alpha and Intraclass Correlation Coefficient (ICC), respectively. Multi-trait multi-method analysis (MTMM) determined item homogeneity. Spearman’s correlation of PCS with VAS, Karnofsky Score and time-series studies assessed criterion and predictive validity. Linear regression was performed to determine the association of each subdomain with PCS score.

Conclusions: Preliminary results suggest excellent reliability and validity of this PCS tool. Validation studies at other HD centres with expanded time-series and reliability studies continue.
SA-PO178
Feasibility of a Hemodialysis Safety Checklist for Nurses and Patients
Samuel A. Silver, Alison Thomas, Andrea Rathe, Pamela L. Robinson, Ron Wald, Chaim Bell, Ziv Harel, Nephrology, St. Michael’s Hosp, Toronto, ON, Canada; Medicine, Mt. Sinai Hosp, Toronto, ON, Canada.

Background: In 4% of ESRD patient deaths, the cause of death is a result of a preventable hemodialysis complication. These include errors related to communication, organization and human factors. We recently developed a hemodialysis safety checklist (Hemo Pause) to be completed by nurses and patients at specified intervals throughout a hemodialysis session, with the goal to improve dialysis unit safety culture. Our objective was to determine the feasibility of using Hemo Pause during every hemodialysis session for 3 months.

Methods: We conducted a single center, prospective time series study. A convenience sample of 14 nurses and 22 prevalent in-center hemodialysis patients participated. All participants were trained in the administration of Hemo Pause, completed the checklist at every hemodialysis session for 3 months and were free to suggest checklist modifications consistent with quality improvement methodology. The primary outcome was Hemo Pause completion, which was determined weekly using the percentage of checklists in the patient chart with all 17 items assessed. We also measured Hemo Pause acceptability using local patient safety surveys.

Results: There were 799 hemodialysis treatments pre-intervention and 757 post-intervention. The checklist was completed for 556 of 757 (73%) treatments. The most common reasons for non-completion were the availability of nursing staff trained in Hemo Pause and patient admission to hospital. Among hemodialysis nurses, 93% (15/14) agreed that Hemo Pause was easy to use and 79% (11/14) agreed it should be expanded to other patients. Among hemodialysis patients, 73% (16/22) agreed that Hemo Pause made them feel safer and should be expanded to other patients. Negative comments by nurses or patients occurred on 4% (7/200) of survey responses.

Conclusions: A hemodialysis safety checklist (Hemo Pause) was acceptable to both nurses and patients over a 3 month period. Our next step is to spread Hemo Pause locally, based on the results of this study. We are conducting a randomized controlled trial to evaluate the effects of Hemo Pause on patient safety outcomes.

SA-PO179
Community-Based Parenteral Anti-Infective Therapy (COPAT) for ESRD Patients
Evamaria Anvari, Reza Anvari, Laura Fevereira Provenzano, Juan C. Calle, Nephrology, Cleveland Clinic Foundation, Cleveland, OH.

Background: Infections are the leading cause of hospital admissions for patients with ESRD. The majority will need to continue antimicrobial therapy when discharged. Community-based parenteral anti-infective therapy (COPAT) refers to the practice of administering antimicrobial therapy in the outpatient setting. It requires a multidisciplinary and the goals are to improve outcomes, reduce toxicity, drug resistance, and decrease hospital stay. ESRD patients have the advantage that IV antibiotics can be given at their dialysis units. The downfall is that every outpatient dialysis provider has their own policies for the approval of IV/TP therapy. Patients are frequently discharged with an order to continue antimicrobial therapy but it is not continued, leading to adverse outcomes.

Methods: We investigated the policies from the main dialysis providers in our community.

Time for drug arrival: 24-48 hrs. - Pre-approval 24-48 hrs. - Day after approval 48 hrs.

Requirement: Hospital order - ID consult - Organism with sensitivity - Rational for using other antimicrobial

IP drugs: Receive in unit - Loading dose in unit and continue self-administer - Drugs ordered Monday - Thursday will arrive at their home the following day - If ordered after 3PM Friday it will arrive Monday - Loading dose in the unit and are given a 7-day supply to self-administer

Home Hemo: Dialize in center for therapy - Dialize in center for therapy or trained to self-administer - Dialize in center for therapy

Conclusions: Our data suggest there are characteristics amongst patients undergoing inpatient hemodialysis that predispose them to RR/CA events. Simple, objective measures such as requirement for supplemental oxygen and abnormal vital signs may be important indicators that patients are at risk for serious adverse events. Knowledge of these factors can aid in decision-making regarding pursuit of dialysis and lead to the study of strategies to prevent patient harm.

SA-PO180
Rapid Response and Cardiac Arrests in In-Patient Hemodialysis - A Retrospective Review
Justin Chon, LaDun Golestan, Albert Einstein College of Medicine, Bronx, NY; Nephrology, Montefiore Medical Center, Bronx, NY; Critical Care, Montefiore Medical Center, Bronx, NY.

Background: Patients with renal dysfunction requiring hemodialysis are known to be at increased mortality and morbidity risk. Few studies have examined rapid response (RR) and cardiac arrest (CA) events in inpatient hemodialysis units. The purpose of this study is to evaluate patient characteristics and predictive factors of RR and CA in inpatient hemodialysis units.

Methods: Retrospective review of all available RR and CA events in two separate hospitals over a 3-year period was performed. Charts were reviewed for abnormalities in vital signs or laboratory values during hemodialysis sessions and for a 24-hour period prior to RR/CA events.

Results: In total, 16 RR and 13 CA events were recorded for 26 unique patients (average age 64±16 years). Of the 29 total RR/CA events, 9 events resulted in survival (<24 hours 31%). Common medical comorbidities included hypertension (92%), diabetes (73%), chronic heart failure (50%), and coronary artery disease (50%). The most common inciting factors for RR/CA activation were altered mental status (72%), systolic blood pressure < 90 (45%), and respiratory distress (31%). Vital sign abnormalities identified prior to hemodialysis included need for supplemental oxygen (72%), respiratory rate > 20 (34%), and systolic blood pressure < 90 (3%). Vital sign abnormalities identified during hemodialysis included systolic blood pressure < 90 (38%) and heart rate < 40 (35%). Of those with labs available, the most common lab abnormalities included low hemoglobin and hematocrit (100%), elevated direct bilirubin (71%), elevated troponin-T (62.5%), and elevated PT (60%).

Conclusions: Our data suggest there are characteristics amongst patients undergoing inpatient hemodialysis that predispose them to RR/CA events. Simple, objective measures such as requirement for supplemental oxygen and abnormal vital signs may be important indicators that patients are at risk for serious adverse events. Knowledge of these factors can aid in decision-making regarding pursuit of dialysis and lead to the study of strategies to prevent patient harm.

SA-PO181
Monitoring of Protective Levels of Hepatitis B Antibody Titre in Pre-Dialysis and Dialysis Patients
Ravindra Mukundra, Zaha Jibrit, Renal Medicine, Doncaster and Bassetlaw NHS Foundation Trust, Doncaster, Yorkshire, United Kingdom.

Background: Patients on dialysis are at risk of hepatitis B virus infection. Hence it is widely recommended to vaccinate chronic kidney disease (CKD) patients who might need renal replacement therapy. Antibody titre of >10iu/L is generally regarded as protective against Hepatitis B infection. The frequency of antibody level monitoring remains unclear. Once adequate antibody response achieved levels would wane with time. We monitored antibody levels in pre-dialysis and dialysis patients who achieved antibody response of >10iu/L, yearly for 2 years in order to explore the sustainability of the levels.

Methods: We selected 112 predialysis and dialysis patients who had Hepatitis B antibody response of >100 iu/L, and has had antibody titres checked subsequently every 2 consecutive years. Results analysed retrospectively to see how long the protective antibody level lasted.

Results: Total number of patients who had antibody response of >100 iu/L from 2007 to 2015 was 112 from our dataset at Doncaster Royal Infirmary Renal Unit. Of these 34% of patients had hepatitis B antibody titres checked for 2 consecutive years. Patients maintaining antibody level of atleast >100 iu/L for 2 years or more were 95% (36 of the 38).

Conclusions: The outcome of this study confirms that protective antibody levels (>100 iu/L) are maintained in 95% of those monitored for 2 years. This result reiterates the need for more robust evidence to inform nephrologists about the appropriate frequency of antibody monitoring in CKD patients.

SA-PO182
Improving Emergency Room (ER) to Dialysis Flow in a Busy Inner City ER
Anjali Acharya, Cheryl Moore, Raymond Mc Clinton, Naheed Ansari, Bonnie Carnes, Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; Nephrology, Atlantic Dialysis, Queens, NY.

Background: Delays in access to hemodialysis during hospitalization are not uncommon and negatively impact on quality of patient care and lead to avoidable complications and unnecessary hospitalizations. Triple Aim is a sought after goal for health organizations to optimize health system performance. We hoped to target one of the three components which is to improve the experience of care.

Methods: The objective was to ensure initiation of dialysis for all non-emergent patients within four hours of ER triage. We analyzed retrospectively in a 8 week observation period, Electronic Medical Record (EMR) data on all hemodialysis patients >18 years of age presenting to the ER, with emphasis on time from triage to initiation of dialysis (TID). We also analyzed factors contributing to delays in dialysis initiation. Data were collected daily on each patient and tabulated weekly. We instituted two measures to address the obstacles.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
These were i) educating the ER staff about timeliness of informing the renal team and ii) the second was to institute a track & trace system to systematically gather detailed data on patient transport metrics such a time to patient pick up from initial contact with the transport office. 

Results: Baseline data revealed average TID from triage was 8 hours. Two major contributory factors identified were late notification by ER to renal team and delays in transport. By instituting measures targeting these, we were able to achieve being able to provide dialysis within 4 hours of triage in over 80% of our non-urgent hemodialysis patients.

Conclusions: We were able to improve the patient experience and care with simple measures. This has a positive impact on patient safety by minimizing late treatments and staff fatigue. Though Triple Aim is a goal at the population and health care delivery level, we believe processes can be implemented at a local level that align with the CMS goals of triple aim. In today’s environment it is incumbent upon us to make efforts to innovate for better patient care and to minimize health care costs.

SA-PO183

Quality Improvement Project in Dialysis: Improving Access to Dialysis for Patients Presenting to the Emergency Room (ER) 

1Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; 2Nephrology, Atlantic Dialysis, Queens, NY.

Background: Hemodialysis patients presenting to the emergency room are a vulnerable patient population. Majority of them have significant comorbid conditions. Delays in evaluation and institution of dialysis are common in busy emergency rooms. We undertook a project to improve quality of patient care as well as the patient experience with a goal to provide timely dialysis.

Methods: We analyzed baseline data from electronic medical record (EMR) pertaining to all hemodialysis patients presenting to the ER in a specified 8 week period. After brain storming within the team we identified a few factors that were seen as obstacles in providing timely dialysis. One of them was the time from patient triage to notification of the renal team. We instituted an educational program with the ER staff with focus on the timeliness of informing the renal team, establishing “triage to renal team notification time” of less than 30 minutes as a meaningful metric. Data was collected at pre and post intervention. The objective was to meet this goal >80% of the time over the 2 month intervention period.

Results: There was a positive impact on the triage to renal notification time. The percentage of timely notifications as defined, rose to >85% from a baseline of <25% and this effect was sustained over the 8 weeks. Most patient notifications happened within 10 minutes of triage.

Conclusions: A simple intervention on educating the ER staff made a significant impact on timely evaluation of dialysis patients presenting to the ER. There was an observable positive impact on patient experience. We view this as a simple first step in optimizing patient care and experience towards a seamless journey through the hospitalization. Simple innovative steps such as this could contribute to cost control by avoiding/minimizing dialysis treatments during off hours. In addition it could help mitigate staff fatigue and treatment errors thus improving patient safety.

SA-PO184

Diagnostic Reference Values for Cerebrospinal Fluid May Not Be Useful in Haemodialysis Patients Suspected of Having Central Nervous System Infection 

Thomas Oates, Damien Ashby. Imperial NHS Trust, London, United Kingdom.

Background: Invasive investigations in haemodialysis (HD) patients can be associated with complications due to bleeding, and standard diagnostic tests, such as pleural fluid biochemistry, have been shown to be of limited value in this patient group. As a result, we examined the utility of cerebrospinal fluid (CSF) analysis in HD patients suspected of central nervous system (CNS) infection.

Methods: We used electronic records to retrospectively examine laboratory data from HD patients who had CSF analysis in a 5 year period. All patients were initially suspected of having a CNS infection. Relevant culture and polymerase chain reaction tests ultimately proved negative for bacterial, mycobacterial, fungal or viral infections in all cases.

Results: 30 CSF samples from 29 patients were identified in the study period. CSF protein concentration was available for 16 samples (median 0.40g/L, range 0.19-1.06g/L, corrected for number of red cells in sample) and paired CSF and plasma glucose concentrations, allowing calculation of CSF:serum glucose ratio, for 25 samples (median ratio 0.58, range 0.21-1.40). Using the accepted normal CSF protein concentration of 0.23 to 0.38 g/L (see Figure shaded region), 8 out of 16 samples showed an elevated protein concentration suggesting CNS infection. Additionally, 13 out of 25 samples had a CSF:serum glucose ratio of less than the normal value of 0.6 (see Figure horizontal line) which is also suggestive of CNS infection.

Conclusions: CSF biochemistry is frequently used in the diagnosis of CNS infection. Our preliminary results suggest CSF protein and glucose concentrations should be interpreted with caution in HD patients and may not add diagnostic information in suspected CNS infection. We are currently investigating the hypothesis that CSF biochemistry may be influenced by duration of chronic kidney disease and HD vintage.

SA-PO185

Continuous Renal Replacement Therapy (CRRT) and Hypoglycemia: A Retrospective Study on Patients Undergoing CRRT and Development of Hypoglycemia in Diabetic and Non-Diabetic Individuals 

Mamtha Balla,1 Adam Lyons,1 Mary C. Naglak,1 Doron Schneider,1 Robert A. Sirota.1 1Internal Medicine, Abington Jefferson Health, Willow Grove, PA; 2HTN Nephrology Associates, Abington Jefferson Health, Willow Grove, PA.

Background: Hypoglycemia is a little known complication of CRRT. There are no studies available to evaluate the prevalence or intensity of hypoglycemia during CRRT. This study attempts to determine the frequency, timing, and severity of hypoglycemia as a complication of CRRT in diabetic and non-diabetic patients in the intensive care unit.

Methods: This was a retrospective observational study to assess the effect of CRRT on plasma glucose in diabetic and non-diabetic individuals who were admitted to Abington Jefferson Health. A chart review was used to complete a detailed data collection form for patients who underwent CRRT for several diagnosis (sepsis, medication overdose, acute renal failure) in 2013 and 2014 who met the selection criteria. Hypoglycemia is defined as Blood sugar less than 70mg/dL. Dialysate contained 100mg/dL glucose.

Results: After reviewing the charts for 218 CRRT events in 119 patients admitted to Abington Jefferson Health, 100 patients were studied based on selection criteria. The mean age of the study population was 66.3 + 15.3 years. Thirty-six of the 100 patients studied had hypoglycemia during CRRT. The number of episodes was as follows: 14/36 (38.9%) had one episode, 7/36 (19.4%) had two, 7/36 (19.4%) had three and 5/36 (13.9%) had five episodes (mean number of episodes was 2.7±1.9). Hypoglycemia occurred on average 9.9±6.1 hours from start of CRRT. Patients who had hypoglycemia during CRRT were more likely to have it again after CRRT (53%; 19/36) (p<0.0005). Of the 36 patients with hypoglycemia, 78% (28/36) had sepsis vs. 22% (8/36) who did not have sepsis but had hypoglycemia (p<0.05). No association was found between development of hypoglycemia and history of diabetes and CKD.

Conclusions: Our study showed that hypoglycemia is a frequent complication during CRRT. In order to prevent hypoglycemia from being under-recognized protocols including frequent blood glucose monitoring during CRRT should be in place.

SA-PO186

The Safety of Intravenous Hydration for the Prevention of Contrast Induced Nephropathy 

Yvonne R.P. de Wael,1 Corinne E.A. Balemans,2 Marc A.G.J. Ten Dam,2 Louis J.M. Reichert,2 Jack P. Wetzel.1 1Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Nephrology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; 3Nephrology, Rijnstate Hospital, Arnhem, Netherlands.

Background: Contrast-induced nephropathy (CIN) is associated with marked morbidity and mortality. To prevent CIN, current guidelines advise intravenous hydration in high risk patients. Thus far, the possible side effects of hydration have received little attention. We evaluated the incidence of (serious) adverse events (SAEs) after intravenous hydration.

Methods: In a retrospective study we analyzed the incidence of (SAE) after intravenous hydration in two Dutch hospitals. In one hospital (Rijnstate Hospital Arnhem) we evaluated all AEs related to hydration. In the other hospital (CZW Nijmegen) the analysis was limited to SAEs, i.e. those necessitating prolonged hospital stay. Patient and outcome characteristics were retrieved from the hospital records.

Results: In the Rijnstate Hospital Arnhem we evaluated 232 records of patients hydrated in the period from February till July 2013. AEs occurred in 18 patients (8%). The most common AE was overhydration, which occurred in 11 patients (5%) and necessitated
Prolonged hospitalisation in 4 (2%). Admission to the coronary care unit was needed in one patient. Almost all patients with overhydration (91%) had pre-existent cardiac disease and used diuretics. Infusion related AEs also occurred, like extravasation and phlebitis, in one case leading to S. Aureus bacteremia. In the CWZ, Nijmegen we evaluated 257 medical records of patients hydrated from May 2013 till January 2014. Prolonged hospitalisation due to overhydration was necessary in 10 patients (4%).

Conclusions: Our study demonstrates that overhydration is a common adverse event after intravenous hydration and necessitates prolonged hospital stay in 2-4% of patients. This data provide arguments against routine hydration in patients with moderate increased risk of CIN. Patients with pre-existent cardiac disease are more prone to overhydration. However, these patients are also at highest risk for the development of CIN. Risk and benefits must be weighed when choosing strategies to prevent CIN.

SA-PO187

Cystatin C in Predicting Cardiorenal Syndrome Type 1 and Mortality in Patients with Acutely Decompensated Heart Failure with Preserved Renal Function

Carlos Federico Varela,1 Ivan Constantin,2 Gustavo Cristian Greloni,1 Griselda Bratti,1 German Barrera Hugalde,1 Cesar Belziti,2 Rodolfo Pizarro,2 Guillermo Javier Rosa diez,1 1Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 2Cardiology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background: Cardiorenal Syndrome type 1 (CRS 1) is defined as a worsening renal function that complicates acutely decompensated heart failure (ADHF). These patients experience higher mortality and morbidity. Serum creatinine (SC) is slow to reflect changes in kidney function. Cystatin C (CysC) has emerged as a novel biomarker with a stronger correlation with cardiovascular disease than SC. The aim of our study was to evaluate CysC in predicting CRS 1 and outcomes in patients admitted with ADHF and preserved renal function.

Methods: We conducted an observational and prospective study. We included patients above 18-years old with ADHF with preserved renal function defined as a SC below 1.3 mg/dL. We excluded patients with heart valvular disease and acute coronary syndrome. CysC blood samples were collected on admission. We defined CRS 1 as a rise in creatinine by 0.3 mg/dL or more during five days.

Results: 166 patients aged 85 median (IQR 77-89) years old were enrolled. The incidence of CRS 1 was 29.7%, with an in-hospital mortality of 3.1% and a total mortality (TM) of 24.4%. The median follow-up was 193 days. CysC was significantly higher in patients with CRS 1 compared to those without (1.72±0.58 vs 1.51±0.41, p=0.03) and predict TM but did not predict in-patient mortality (1.69: vs 1.57±0.48, p=0.58) or readmission (1.47±0.4 vs 1.6±0.5, p=0.58). In the multivariable analysis Cys C was an independent predictor of mortality (OR 3.31, IC 1.38-7.93) while SC at admission was not (OR 0.48, IC 0.05-3.48). The area under the receiver-operating characteristic curve of Cys C for CRS 1 was 0.60 and for TM was 0.65. The best cutoff value was 1.6 mg/dL for both end points. It had a sensitivity and specificity of 62.1% and 63.2% for CRS 1 and 61.5% and 62.9% for TM, respectively.

Conclusions: Above a cut-off value of 1.6 mg/dL, Cys C predicts CRS 1 and mortality in patients admitted with ADHF with preserved renal function.

SA-PO188

Is Cystatin C a Better Biomarker of AKI in ICU to Compare NGAL?

Itir Yegenaga, Fatih Kamis. Internal Medicine, Kocaeli Univ Medical School, Kocaeli, Izmit, Turkey.

Background: Serum creatinine levels can be affected with many variable factors. We concluded that better bio-marker is needed to recognize AKI as early as possible. We studied Cystatin C (CysC) and Neutrophil Gelatinase Associated Lipocalin (NGAL) in ICU patients to determine which is more predictable.

Methods: Hundred and eighty three (85 male; mean age: 65) critically ill patient with no previous chronic renal failure history were included to this study. Clinical, laboratory evaluations were noted and blood was taken in 48 hours for CysC and NGAL and followed for 7 days, if they met the RIFLE criteria.

Results: CysC and NGAL values for every stages RIFLE and serum CysC value were significantly different (p<0.001). Sensitivity, specificity, PPV and NPV were higher for CysC than for NGAL. ROC curve analysis showed that CysC had a stronger correlation with cardiovascular disease than SC. The area under the receiver-operating characteristic curve of Cys C for CRS 1 was 0.75 and for TM was 0.80. The best cutoff value was 1.6 mg/dL for both end points. It had a sensitivity and specificity of 62.1% and 63.2% for CRS 1 and 61.5% and 62.9% for TM, respectively.

Conclusions: Above a cut-off value of 1.6 mg/dL, Cys C predicts CRS 1 and mortality in patients admitted with ADHF with preserved renal function.

While NGAL and u NGAL were significantly different between these two groups. Serum CysC level was related to mortality (figure 1) [AUC-ROC 0.68 CI, 0.573-0.733].

SA-PO189

The Effect of Point of Care (POC) Creatinine/eGFR Measurement on the Incidence of Contrast-Induced Acute Kidney Injury (CI-AKI) following Primary Percutaneous Coronary Intervention (PPCI) for the Treatment of ST Elevation Myocardial Infarction (STEMI)

Background: Contrast-induced acute kidney injury (CI-AKI) is a predictor of mortality, morbidity and length of hospital stay. During STEMI treatment with primary percutaneous coronary intervention (PPCI) there are a number of predictors of AKI including existing renal dysfunction (eGFR < 60) and contrast volume used.

Methods: A retrospective audit over 6 months at the Essex Cardiothoracic Centre identified 348 patients who had presented with STEMI and had PPCI. These patients formed the standard care control group. Prospectively 131 consecutive patients presenting with STEMI and under-going PPCI had a point of care creatinine measurement (STATSENSOR, Nova Biomedical). A comparison in rates of AKI was made between the two groups.

Results: In the standard care group, 9.7% of patients with normal renal function and 26.6% of patients with impaired renal function developed AKI. When creatinine was measured pre-PPCI, 8% of patients with normal renal function and 16.1% of patients with renal impairment developed AKI, a 39.5% reduction in AKI in those with renal dysfunction in the POC creatinine group. The average contrast volume in the standard care group was 265 ml, compared to 117.5ml when renal function was found to be impaired (eGFR < 60) pre-PPCI. 186ml was used on average in the POC group when creatinine was found to be normal.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

668A
Conclusions: Measuring the POC creatinine of 131 patients presenting with STEMI and undergoing PPCI reduces the rates of AKI by 39.5% in those with renal dysfunction. This appears to be mediated in part by a reduction in contrast volume in those patients identified with renal dysfunction (117.5ml) compared to normal renal function (186 ml). Serum Creatinine Variability Predicts Progression to CKD4

Carlos E. Palant,1,2 Lakhmir S. Chawla,1,2 Ping Li,1,2 Paul L. Kimmel,1,2 Charles Faselis,1,2 Richard Amund,1,2 1Medicine, Washington DC VA Medical Center, Washington, DC; 2Medicine, George Washington Univ Medical School, Washington, DC; 1NIDDK, National Insts of Health, Bethesda, MD.

Background: Pre-dialysis patients have high serum creatinine (SC) variability. SC variability is associated with high death rates. We examined the association between SC variability and CKD progression in a large cohort of US veterans with a wide range of baseline eGFR.

Methods: VA patients admitted 10/1999 - 12/2005 with at least 4 months with SC and initial eGFR>30 ml/min/1.73 m² used (CKD-EPI) were selected. Autoregression-based slope was computed for each patient using monthly peak SC. SC variability was root mean-square residual of peak SC readings from the regression line. CKD4-date was the first date when eGFR permanently fell below 30 ml/min/1.73 m². Logistic regression was used to predict CKD4 using: initial eGFR, SC variability, SC slope, age, race, sex, months with SC readings, and comorbidities (DM, CAD, PNE, MI, angina, AKI, COPD, CHF). Kaplan-Meier (KM) analysis was used to examine time from first admission to entry into CKD4, stratified by SC variability quartile and baseline eGFR, and Cox regression was used to adjust survival estimates for the covariates above.

Results: Of 342,066 patients, 36,108 (10.6%) reached CKD4. The logistic model had strong prediction accuracy (c=.94) with sensitivity and specificity both ~.86. SC variability is strongly independently associated with rate of decline in renal function, at all baseline eGFR levels, after accounting for covariates, and is an important risk factor for entry into CKD4.

Conclusions: SC variability is strongly associated with high death rates. We examined the association between SC variability and CKD progression in a large cohort of US veterans with a wide range of baseline eGFR.

Assessment of Methods Used to Substitute for Missing Preadmission Creatinine Values in the Diagnosis and Staging of Acute Kidney Injury

Amelie Croitoru,1 Ana-Maria Tanase,1,2 Andrei Buta,3 Ana-Andreea Chitu,2,3 Amelie Croitoru,1 Ana-Maria Tanase,1,2 Andrei Buta,3 Ana-Andreea Chitu,2,3 1IIBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; 2Hospital du Sacre-Coeur de Montreal, Canada; 3Univ of California San Diego Medical Center.

Background: Missing preadmission serum creatinine values (SCr) are a common obstacle to the diagnosis and staging of acute kidney injury (AKI). As a workaround, the KDIGO guidelines suggest using a baseline SCr computed from the MDRD formula. Measuring the POC creatinine of 131 patients presenting with STEMI and undergoing PPCI reduces the rates of AKI by 39.5% in those with renal dysfunction. This appears to be mediated in part by a reduction in contrast volume in those patients identified with renal dysfunction (117.5ml) compared to normal renal function (186 ml). Funding: Pharmaceutical Company Support - Nova Biomedical

Methods: We included 124 consecutive patients admitted to our medical ICU. We performed a retrospective single-center study of critically ill patients with known preadmission SCr to identify the most accurate method to estimate baseline SCr for AKI diagnosis and staging (KDIGO criteria). We assessed three surrogate methods: 1) the first hospital admission SCr, 2) the minimal SCr after ICU admission and 3) SCr computed for a eGFR of 75 ml/min per 1.73m² using MDRD.

Results: Of 1001 randomly selected patients, a preadmission SCr was available for 498 and 14 were excluded for requiring acute renal replacement therapy. Median age was 67 (IQR 58-76), 60% were male and 98% were Caucasian or Asian. The medium time between SCr measurement and admission was 116 (IQR 78-179) days. AKI incidence according to preadmission SCr was 24.8%. We reported in table 1 the AKI incidence, sensitivity, specificity and kappa values for each surrogate method.

Conclusions: In our cohort, the MDRD computed SCr for a eGFR of 75 ml/min per 1.73m² was the best surrogate method for diagnosing AKI. Using the minimal SCr significantly overestimated the incidence of AKI. Concerning AKI staging, the first hospital admission SCr was the most accurate method.

Fluid Balance and Oliguria in Early AKI Diagnosis After Liver Transplant

Camila Lima 1,2,3,4,5, 2 Luciana Haddad,2 Luiz M. Malbouisson,2 Luiz Augusto Carneiro D’Albuquerque,2 Etienne Macedo,2 1Nephrology, Univ of Sao Paulo, Brazil; 2Gastrointestinal Surgery, Univ of Sao Paulo, Brazil; 3Anesthesiology, Univ of Sao Paulo, Brazil.

Background: AKI is a frequent complication of liver transplant (LT), associated with increased morbidity and mortality. Early diagnosis can translate into secondary preventive measures and improve outcomes. We hypothesized that adjusting Scr for positive fluid balance (FB) and applying urine output(UO) criterion would improve timing of AKI diagnosis. In addition, we investigate whether sequential assessment of urinary biochemistry after LT can improve prediction of early post-operative AKI development.

Methods: In a prospective cohort study, we recorded UO, FB and labs of patients undergoing LT. We assessed urine and blood biochemistry periparative (before induction of anesthesia, after portal reperfusion, 6, 18, 24 hours after surgery). AKI diagnosis was based on UO and the sCr KDIGO criterion before and after correcting scr for FB (Scr adjusted), using the formula: ((wght*0.6)+(FB)/wght*0.6).

Results: Fifty-five patients >18 years undergoing LT from Jun13 to Oct14 were included in the analysis. Twenty-seven percent (15) of patients developed AKI based on SCR criterion within 24h after surgery (early AKI). By adjusting SCR for fluid balance 38% (21) patients were classified as early AKI. Applying the UO criterion, 43patients were classified exclusively by this criterion as early AKI. All patient showed a decline in FeNa and the FeaU after portal reperfusion. Patients developing early AKI had a higher decline and maintained lower levels for 24h. FeNa/rea values were significantly different 6 hours after surgery in early AKI patients. Patients with early AKI based on both criteria or exclusively by UO had a higher mortality and longer ICU and hospital stay than non-AKI patients.

Conclusions: Applying UO criteria and adjusting Scr for FB can help in the early identification of patients developing AKI after liver transplant. Tubular function assessment could be utilized along with biomarkers of kidney injury to identify patients with increased risk of developing AKI. Standardized approach for early AKI diagnosis in high-risk patients could improve outcomes.

SA-PO193

Renal Angina Index a Practical Tool to Identify Patients at Increased Risk of Acute Kidney Injury

Rolando Clurue-Del Granado,1 Andrea Pero,1 Josec Bouchard,2 Ravindra L. Mehta,1,2 1IIBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; 2Hospital du Sacre-Coeur de Montreal, Canada; 3Univ of California San Diego Medical Center.

Background: Reliable prediction of acute kidney injury (AKI) has the potential to optimize treatment. Recently Goldstein SL et al. proposed an empiric clinical model of renal angina using patient demographic factors and early signs of injury to identify critically-ill children who would be at higher risk of AKI. We test the hypotheses that in a cohort of adult critically-ill patients, a modified renal angina index (RAI) will identify patients at high risk of developing AKI, and could be related to in-hospital mortality.

Methods: We included 124 consecutive patients admitted to our medical ICU. We recorded serum creatinine (sCr) every 24h for 7 consecutive days after ICU admission. RAI was calculated at ICU admission (day 1) and 24 h after day 2) using the following formula: Risk level (vasopressors and invasive mechanical ventilation = 5; diabetes mellitus = 3; and sepsis = 1) X Injury level (decreases in eGFR: no change=1, 0-24.9%=2, 25-49.9%=4, and ≥50%=8). The composite range of the RAI is therefore: 1, 2, 3, 4, 5, 6, 8, 10, 12, 20, 24, and 40. We analyzed the value of a RAI score ≥8 to predict subsequent AKI (after 48 h, day 3) and survival.

Results: We identified 50(40.3%) patients with AKI (KDIGO guidelines sCr criteria), and 74(59.7%) patients who did not develop AKI. Patients with a RAI ≥8 were at higher risk of developing AKI within 7 days of follow-up (RR 1.64 95% CI 1.31-2.05; p<0.0001). A RAI ≥8 at ICU admission (day 1) and 24 h after admission (day 2) was able to identify individuals who developed AKI (day 3-7) with an AUC of 0.86 (95% CI 0.77-0.945); p< 0.0001 and an AUC of 0.891 (95% CI 0.815-0.946); p< 0.0001, respectively. No difference was found in terms of 28 day in-hospital mortality in patients with a RAI ≥8 vs a RAI ≤8.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents author.
Conclusions: The RAI provides a clinically feasible methodology to identify critically-ill patients at high risk of developing AKI before a rise in Scr occurs. This tool would permit the early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

SA-PO194

The Renal Angina Index Identifies Patients at High-Risk of Acute Kidney Injury – Analysis from AWARE: A Prospective Multinational Study of AKI in Critically Ill Children

RA, K. Basu, 1,2 Ahmad Kaddourah, 1,2 Stuart Goldstein, 1, 2 Pediatrics, Center for Acute Care Nephrology, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 3 On Behalf of the AWARE Study Investigators, Multinational Pediatric ICU.

Background: We conducted a global, prospective observational study of critically ill children to study the epidemiology of pediatric acute kidney injury (AKI). We analyzed the association of the renal angina index for prediction of AKI and patient outcomes.

Methods: Data from 32 centers (5 continents, data collection for 3 consecutive months in 2014) from children (aged 3 months to 25 years) admitted to a pediatric intensive care unit were analyzed. The renal angina index (RAI) was calculated on the day of admission (Day 0) as previously described. A cut-off of ≥ 8 on Day 0 was used to determine fulfillment or absence of renal angina (RA+ vs. RA-). The primary outcome was the presence of severe AKI on Day 3, defined by change in serum creatinine from baseline using KDIGO stage 2-3 criteria (Day 3 AKI). Other patient outcomes were assessed at 28 days.

Results: 9.6% (501/5231) of children were RA+ on Day 0. The area-under-curve receiver operating characteristic of the Day 0 RAI for Day 3- AKI was 0.797 (95% confidence interval 0.759-0.836). RA+ was associated with a higher net fluid balance on Day 3 than RA- (p=0.001). Compared to RA-, Day 0 RA+ was associated with prolonged duration of mechanical ventilation, longer length of stay, increased use of extracorporeal therapies, and higher incidence of mortality.

Conclusions: In AWARE, the largest prospective multi-center epidemiologic assessment of AKI in critically ill children, we demonstrate the ability of the renal angina index to identify patients at high risk of AKI, three days in advance. Fulfillment of renal angina early in the ICU course is associated with poor patient outcome.

SA-PO195

Phase Angle and Extracellular Hypervolemia, as a Prognostic Markers in Acute Kidney Injury

Francisco Javier Lavilla, Maria Jose Molina Higueras, Diana Lopez Espinosa, Pelayo Moiron Fdez-Felechosa, Nuria Garcia-Fernandez, Paloma L. Martin Moreno, Pedro Martin, Nephrology, Clinica Unive de Navarra, Pamplona, Navarra, Spain.

Background: The bioelectrical impedance analysis (BIA) is a noninvasive and painless technique and easy to perform, which is used for determining body composition. Can offer an ultrasound-based measurement, can predict AKI in a variety of settings. To our knowledge, there are no studies investigating the predictive value of preoperative RRI and the risk of AKI in cardiac surgery patients. The aim of this study was to investigate whether an elevated preoperative RRI predicts AKI in a general cardiac surgery population.

Methods: Patients undergoing elective cardiac surgery were included prospectively between September 21, 2014 and April 22, 2015 at the Karolinska University Hospital. RRI was measured before surgery. An elevated RRI was defined as ≥ 0.7. The outcome AKI was defined as an absolute increase in post-compared to preoperative serum creatinine by 0.3 mg/dL (>26 µmol/L) or a relative increase by >50%. The odds ratio for AKI was calculated by logistic regression in patients with a RRI >0.7 versus those with a RRI ≤ 0.7.

Results: 98 patients were included. In patients with a RRI ≥ 0.7, 6 (15%) patients developed AKI, compared to 19 (33%) in patients with a RRI >0.7. The mean increase in postoperative serum increase in patients with RRI ≥ 0.7 was 0.12 mg/dL (11 µmol/L) compared to 0.34 mg/dL (30 µmol/L) in those with RRI >0.7 (P=0.03). The odds ratio for developing AKI in patients with a RRI >0.7 compared to those with a RRI ≥ 0.7 was 2.76 (9.97-7.71).

Conclusions: We found that patients with an elevated RRI before cardiac surgery had an increased risk of developing AKI postoperatively. RRI might be a valuable tool for identifying patients with an increased risk of developing AKI connected to cardiac surgery.

SA-PO196

Preoperative Renal Resistive Index Predicts the Risk of Acute Kidney Injury in Patients Undergoing Cardiac Surgery

Daniel P. Olsson Hertzberg, 1 Ulrik Sartipy, 2 Martin Holzmann, 1, 2 Department of Medicine, Karolinska Inst, Stockholm, Sweden; 3 Department of Anesthesiology, Surgical Services and Intensive Care Medicine, Karolinska Univ Hospital, Stockholm, Sweden; 4 Department of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden.

Background: Previous studies have indicated that Renal Resistive Index (RRI), an ultrasound-based measurement, can predict AKI in a variety of settings. To our knowledge, there are no studies investigating the predictive value of preoperative RRI and the risk of AKI in cardiac surgery patients. The aim of this study was to investigate whether an elevated preoperative RRI predicts AKI in a general cardiac surgery population.

Methods: Patients undergoing elective cardiac surgery were included prospectively between September 21, 2014 and April 22, 2015 at the Karolinska University Hospital. RRI was measured before surgery. An elevated RRI was defined as ≥ 0.7. The outcome AKI was defined as an absolute increase in post-compared to preoperative serum creatinine by 0.3 mg/dL (>26 µmol/L) or a relative increase by >50%. The odds ratio for AKI was calculated by logistic regression in patients with a RRI >0.7 versus those with a RRI ≤ 0.7.

Results: 98 patients were included. In patients with a RRI ≥ 0.7, 6 (15%) patients developed AKI, compared to 19 (33%) in patients with a RRI >0.7. The mean increase in postoperative serum increase in patients with RRI ≥ 0.7 was 0.12 mg/dL (11 µmol/L) compared to 0.34 mg/dL (30 µmol/L) in those with RRI >0.7 (P=0.03). The odds ratio for developing AKI in patients with a RRI >0.7 compared to those with a RRI ≥ 0.7 was 2.76 (9.97-7.71).

Conclusions: We found that patients with an elevated RRI before cardiac surgery had an increased risk of developing AKI postoperatively. RRI might be a valuable tool for identifying patients with an increased risk of developing AKI connected to cardiac surgery.

Development of a Postoperative Risk Stratification Tool via Bayesian Model Averaging for Acute Kidney Injury After Cardiac Surgery

Allison Meisner, 1 Kathleen F. Kerr, 1 Heather Thiessen Philbrook, 2 Francis Perry Wilson, 3 Amit X. Garg, 2 Michael Shlipak, 2 Peter Kavask, 3 Richard P. Whitlock, 2 Steven G. Coca, 4 Chirag R. Parikh, 1 Univ of Washington, Seattle, WA; 2 Western Univ, ON, Canada; 2 Yale School of Medicine, New Haven, CT; 1 UCSF, 3 McMaster Univ, ON, Canada; 4 Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Acute kidney injury (AKI) is a frequent complication of cardiac surgery. We sought predictive combinations of biomarkers measured 0-6 hours after surgery, potentially in combination with cardiopulmonary bypass (CPB) time (to account for the degree of insult).

Methods: The primary endpoint was sustained mild AKI, defined as an increase of 50% or more in serum creatinine over preoperative levels lasting at least two days during the hospital stay. Severe AKI were AKI (secondary endpoint) was defined as a serum creatinine increase of 100% or more or dialysis during hospitalization. Data were from a cohort of 1219 adults undergoing cardiac surgery at 6 medical centers; among these, 117 developed sustained mild AKI and 60 developed severe AKI. We considered CPB time and 2 biomarkers as candidate predictors. We used Bayesian Model Averaging (BMA) methods to develop center-adjusted combinations for sustained mild AKI by (1) maximizing the posterior model probability and (2) retaining predictors with posterior variable probabilities above 0.5.

Results: The maximum posterior model probability combination included plasma NT-proBNP, plasma h-FABP and change in serum creatinine; the median probability combination additionally included plasma IL-6. The center-adjusted, optimism-corrected AUCs for these combinations were 0.80 (95% CI: 0.78, 0.88) and 0.81 (0.77, 0.88), respectively, for predicting sustained mild AKI, and were 0.81 (0.77, 0.90) and 0.83 (0.76, 0.90), respectively, for predicting severe AKI. For these data, the BMA methods yielded combinations with predictive capacity comparable to that achieved by standard frequentist methods but with smaller models.

Conclusions: Pending external validation, the identified combinations could be used to identify individuals at high risk of AKI immediately after cardiac surgery and could facilitate clinical trials of renoprotective agents.

SA-PO198
Low Pre-Operative Serum Bicarbonate Levels Predict Acute Kidney Injury After Cardiac Surgery

Jong Hyun Jhee, Kyoung Hyeok Han, Tae-Hyun Yoo, Jong Tak Park. Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Low serum bicarbonate levels are known to be risk factors for renal function deterioration in chronic kidney injury patients. However, it is not well known whether preoperative low serum bicarbonate levels are associated with the development of acute kidney injury (AKI) in patients who undergo cardiac surgery. Therefore, clinical implications of preoperative serum bicarbonate levels on AKI occurrence after cardiac surgery were evaluated.

Methods: The patients who underwent coronary artery bypass or valve surgery at Yonsei University Health System from January 2013 to December 2014 were enrolled. The patients were categorized into three groups according to pre-operative serum bicarbonate levels (group 1 (<23 mEq/L), group 2 23-24 mEq/L, group 3 >24 mEq/L). Multivariate logistic regression analysis was performed to determine the effect of pre-operative serum bicarbonate levels on development of AKI at 48 hours after cardiac surgery.

Results: Among 452 patients, 228 patients (26.1%) developed AKI at 48 hours after cardiac surgery. Incidence of AKI was higher in group 1 (34.6%) than group 2 (26.3%) and group 3 (39.0%) (P <0.001). The duration of post-operative intensive care unit (ICU) stay was longer in AKI patients (AKI vs. non-AKI, 6.2 vs. 2.7 days, P=0.001). In addition, post-operative ICU stay was longer in the low pre-operative serum bicarbonate level groups (group 1 (4.4 days), group 2 (3.6 days), group 3 (3.3 days), P=0.001). In multivariate logistic regression analysis, low pre-operative serum bicarbonate levels were significantly associated with post-operative AKI development even after adjusting for age, sex, hypertension, diabetes mellitus, operation type, hemoglobin, and glomerular filtration rate (group 3 as reference, odds ratio=2.36, 95% confidence interval=1.57-3.54, P<0.001).

Conclusions: Low serum bicarbonate levels were associated with higher incidence of AKI and prolonged ICU stay. Correction of low serum bicarbonate levels before cardiac surgery may reduce the risk of AKI development.

SA-PO199
Admission Hyperuricemia Increases the Risk of Acute Kidney Injury in Hospitalized Patients

Wissam Chehnapasitpong1, Charat Thongprayoon2, Stephen B. Erickson.1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Internal Medicine, Bassett Medical Center, Cooperstown, NY.

Background: The association between elevated admission serum uric acid and risk of in-hospital acute kidney injury (AKI) is limited. The aim of this study was to assess the risk of developing AKI in all hospitalized patients with various admission serum uric acid (SUa) levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients who had admission SUA available from January 2011 through December 2013 were analyzed in this study. Admission SUA was categorized based on its distribution into six groups (less than 3.4, 3.4 to 4.5, 4.5 to 5.8, 5.8 to 7.6, 7.6 to 9.4, and greater than 9.4 mg/dL). The primary outcome was in-hospital AKI occurrence based on its distribution into six groups (less than 3.4, 3.4 to 4.5, 4.5 to 5.8, 5.8 to 7.6, 7.6 to 9.4, and greater than 9.4 mg/dL). The primary outcome was in-hospital AKI occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of AKI of various admission SUA levels using the most common SUA level reference range (5.8 to 7.6 mg/dL) as the reference group.

Results: Of 1,435 patients enrolled, AKI occurred in 263 patients (18%). The incidence of AKI and need for dialysis was increased in patients with higher admission SUA levels (group 1 <23 mg/dL, group 2 23-24 mg/dL, group 3 >24 mg/dL). The primary outcome was in-hospital AKI occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of AKI of various admission SUA levels using the most common SUA level reference range (5.8 to 7.6 mg/dL) as the reference group.

Conclusions: Admission SUA was associated with an increased risk for in-hospital AKI.

SA-PO200
Hypoalbuminemia Is a Strong Risk Factor for Acute Kidney Injury Progression in Elderly Patients in Intensive Care Unit

Yu Kurata1, Keita Hirano2, Fumio Omata1, Yasuhiko Komatsu.1 1Div of Nephrology, Mitsui Memorial Hospital, Chiyoda-ku, Tokyo, Japan; 2Div of Nephrology, St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan; 3Center for Clinical Epidemiology, St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan.

Background: Population aging is a global issue; especially, Japan is experiencing rapid aging, at a faster speed than any other developed country, and those aged 65 or older comprised 25.9% of Japan’s population as of September 2014. Previous studies showed elderly patients are at high risk for developing acute kidney injury (AKI). AKI is also a common clinical syndrome in the ICU setting, but its clinical presentation varies from mild to severe. Predicting whether AKI progress or not is difficult but can guide clinical decision making. The aim of the present study is to elucidate risk factors of AKI progression among elderly patients in ICU.

Methods: A retrospective study of patients age 65 and older developed AKI during ICU stay between January 2004 and September 2013. AKI was defined as increase in serum creatinine (sCr) of ≥1.5 times baseline. The primary outcome was the progression to AKIN stage 3 (increase in sCr of 3 times over baseline or need for renal replacement therapy (RRT)) within 14 days after AKI development. Prerenal AKI, postrenal AKI, and AKIN Stage 3 at diagnosis of AKI are excluded; prerenal AKI is diagnosed when serum BUN-to-creatinine ratio ≥ 20 and postrenal AKI is diagnosed based on clinical situation.

Results: 418 patients were included. The mean age was 80.6 ± 8.2 years, baseline sCr=0.89 ± 0.40 mg/dL, and baseline eGFR=66.1 ± 32.3 ml/min/1.73m2. Among 418 patients, 77 (18.4%) experienced AKI progression and 93 (19.9%) died. The patients with AKI progression had higher serum albumin levels (group 1 <23 mEq/L, group 2 23-24 mEq/L, group 3 >24 mEq/L). Multivariate logistic regression analysis showed that the survival was not different between IMA groups. Urine output was lower in group 1 and 3 compared with in group 2, but it was higher in group 2 compared with in group 1 and 3. Platelet levels were significantly higher in group 2 than in group 1 and 3. The risk factors of AKI progression were age, AKI stage on admission, pre-existing diabetes mellitus, and pre-existing chronic obstructive pulmonary disease (COPD) (OR=5.10, 95%CI=2.94-9.06) were risk factors for AKI progression.

Conclusions: Hypoalbuminemia is a strong risk factor for AKI progression in older patients in ICU. Further study is needed to evaluate whether correction of hypoalbuminemia could prevent AKI progression or not.

SA-PO201
Impact of Preexisting Serum Prealbumin on All-Cause Mortality in Community-Acquired and Post-Operative Acute Kidney Injury Patients

Yanfang Zou1, Dan Wen1, Jingyuan Xie1, Xiaonong Chen, Wen Zhang, Nan Chen.1 Nephrology, Ruijin Hospital, Shanghai, China; 2Nephrology, Ruijin Hospital, Shanghai, China.

Background: To explore the impact of pre-existing prealbumin concentration on all-cause mortality in AKI (acute kidney disease, AKI) patients.

Methods: From 2000 to 2010, 477 patients diagnosed with community-acquired AKI (CA-AKI) and treated in the Department of Nephrology, Ruijin Hospital, Shanghai Jiaotong University were enrolled in the CA-AKI group. 138 patients diagnosed with AKI after cardiac operations were enrolled in the post-operative AKI (PO-AKI) group. Data were collected at the time of AKI onset and one year after the discharge.

Results: 41 patients with CA-AKI were younger than PO-AKI patients. Compared with PO-AKI patients, more patients in CA-AKI group suffered from chronic kidney disease, obesity and hyperlipidemia and less patients with cerebrovascular disease (CVD), anemia, chronic obstructive pulmonary disease (COPD), arteriosclerosis, diabetes mellitus and elevated sCr (8.12±4.03 mg/dL vs 3.49±2.75 mg/dL, P<0.001). In CA-AKI group, patients had higher levels of PA and serum albumin (28.2±10.5 mg/dL vs 17.3±6.9 mg/dL, P<0.001). The primary outcome was the progression rate of serum creatinine (sCr) of ≥1.5 times baseline. The incidence of AKI progression was 55% in CA-AKI group and 50% in PO-AKI group. Incidence of AKI progression was incrementally increased with the decrease of PA (0.5% in PA>20 mg/dL to 47.6% in PA<12 mg/dL, P<0.001). Multivariate logistic regression analysis showed that the survival was not different between IMA groups. Urine output was significantly higher in group 1 and 3 compared with in group 2. The risk factors of AKI progression were age, AKI stage on admission, pre-existing diabetes mellitus, and pre-existing chronic obstructive pulmonary disease (COPD) (OR=5.10, 95%CI=2.94-9.06) were risk factors for AKI progression.

Conclusions: Hypoalbuminemia is a strong risk factor for AKI progression in older patients in ICU. Further study is needed to evaluate whether correction of hypoalbuminemia could prevent AKI progression or not.

SA-PO202
Usefulness of Serum Ischemia-Modified Albumin Levels to Predict Dialysis Requirement in Patients with Acute Renal Injury

Mehmet Uzun, Harun Akar. Internal Medicine, Izmir Tepecik Education and Research Hospital, Turkey.

Background: Ischemia-modified albumin is a promising biomarker for early diagnosis of diseases related with ischemia. Ischemia leads to modification in albumin molecule by reducing its binding to cobalt. The aim of this study was to evaluate the levels of ischemia-modified albumin in patients with acute kidney injury (AKI).

Methods: Serum levels of ischemia-modified albumin were estimated in 51 patients with AKI.

Results: The mean age of 28 female and 23 male patients were 65.39±15.28 and 71.15±15.28, respectively. Levels of IMA were found to be high in 75.5 % of the patients (≥400) and were found to be normal in 25.5 % of the patients (≤400). Kaplan-Meier survival analysis showed that the survival was not different between IMA groups. Urine amounts were significantly different between IMA groups. The urine volume was lower in patients with higher IMA levels (≥400) (P<0.001).

Conclusions: A significant difference was detected between CA-AKI group and PO-AKI in general characteristics, comorbidities, laboratory examinations, outcome, and risks. Patients with PA>20mg/dL showed better survival rate.
Conclusions: In the present study, the levels of IMA were found to be significantly higher in patients who needed hemodialysis treatment. IMA levels do not predict mortality. Taking these results together, serum IMA levels might give an idea about dialysis requirement in patients with AKI. More studies with larger sample groups may help to establish the role of IMA on decisions regarding dialysis initiation.

SA-PO203

Urinary TIMP-2 and IGFBP7 Elevate Early After Vancomycin Administration in Critically Ill Patients Who Develop AKI 1, Maria Osternann, 2, Lui G. Forni, 3, Lakhmir S. Chawla, 4, Jing Shi, 5, Kianoush Banaei-Kashani, 6, John A. Kellum. 2

Background: We previously validated a biomarker combination of metalloproteinase-2 (TIMP-2) and insulin-like growth factor binding protein 7 (IGFBP7) for risk stratification of acute kidney injury (AKI). 1 A cutoff of 0.3 (ng/mL)/1000 for [TIMP-2][IGFBP7] indicated AKI stage 2-3 at least 24h prior to serum creatinine. 2 We also showed that nephrotoxic drug use was common in patients developing AKI and that the [TIMP-2][IGFBP7] test could have identified patients earlier. 1 This sub-analysis of the Sapphire study, 1 examined the temporal changes in [TIMP-2][IGFBP7] following vancomycin administration.

Methods: We identified patients who received vancomycin and grouped them according to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the median daily [TIMP-2][IGFBP7] value from day prior to 1st dose of vancomycin until to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the [TIMP-2][IGFBP7] test could have identified patients earlier.

Results: 249 patients received at least 1 dose of vancomycin. 137 (55%) developed AKI within 3 days [AKI 1 (n=81), AKI 2 (n=44), AKI 3 (n=12)]. In patients without AKI or with AKI 1, median [TIMP-2][IGFBP7] values were 0.03 (ng/mL)/1000 for all time points.

Conclusions: Immediate post-operative serum IL-33 concentrations were higher in matched AKI cases compared to non-AKI controls. Further studies are needed to clarify the role of serum IL-33 in human AKI.

First Post-Operative Urinary Kidney Injury Biomarkers and Association with the Duration of AKI in the TRIBE-AKI Cohort

Mayo Clinic, Rochester; 6 Univ of Pittsburgh, Pittsburgh.

Background: We previously demonstrated AKI duration improves risk-stratification for AKI prognosis in addition to the magnitude of serum creatinine rise. We evaluated whether kidney injury biomarkers within 6 hours after cardiac surgery associate with post-operative AKI duration.

Methods: We included 1199 adults undergoing cardiac surgery in TRIBE-AKI cohort that survived to discharge and examined association between five urinary biomarkers: neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP) and albumin with duration of serum creatinine-based AKIN criteria for AKI (0 (no AKI), 1-2, 3-6, ≥7 days).

Results: Overall, 406 (34%) patients had AKI, of which 48 had stage 2/3 AKI. Of 358 with stage 1 AKI, 115 (32.1%) had AKI duration >3 days. An additional 41 (85%) with stage 2/3 AKI had duration of >3 days. Concentrations of all biomarkers increased with AKI duration and each log increase in biomarker was independently associated with AKI duration and each log increase in biomarker was independently associated with greater odds of longer duration category (IL-18 OR 1.25, 95% CI 1.16-1.35; KIM-1: 1.36, 95%CI 1.21-1.52; albumin 1.21, 95% CI 1.10-1.33; L-FABP 1.14, 95% CI 1.07-1.21; NGAL 1.10, 95% CI 1.03-1.17).

Conclusions: In patients with AKI 2-3, medium [TIMP-2][IGFBP7] values were significantly elevated on the day of the 1st vancomycin dose and remained elevated for the following 2 days. These biomarkers have the potential to improve management in patients receiving vancomycin.

Peri-Operative Serum IL-33 Concentrations in Matched AKI and Non-AKI Patients Undergoing Cardiac Surgery

Charles L. Edelstein, 1, Heather Thiessen Philbrook, 2, Jay L. Koyner, 2, Michael Shlipak, 2, Steven G. Coca, 2, Chirag R. Parikh, 2

Background: Endothelial cell damage and death in the nephron is an early feature of AKI. Damage-associated molecular patterns (DAMPs) are endogenous molecules released by damaged cells including endothelial cells. IL-33, a DAMP, has been shown to be present in blood vessels in the kidney and released into the blood, but not the urine, in cisplatin-induced AKI in mice before the increase in serum creatinine. We sought to determine whether serum IL-33 levels are a biomarker of AKI in humans in a nested case-control study.

Methods: Perioperative plasma samples were obtained from patients enrolled in the TRIBE-AKI cohort. 35 cases of AKIN Stage 2 AKI or higher within the first 4 post-op days were matched to 70 controls with no AKI by pre-op GFR, age, sex, site and cohort. Blood samples were available pre-op, day 1 (0-6 hours), days 2 and 3. Serum IL-33 was measured by ELISA.

Results: The pre and post-operative levels of IL-33 are shown in Table 1. Using a mixed model accounting for the matching in the data, the first post-operative value of IL-33 was significantly different (p=0.005) between cases and controls after adjusting for pre-op values. There was a non-significant trend towards higher IL-33 levels on day 2.

Conclusions: While most patients in the TRIBE-AKI Cohort experienced stage 1 AKI when classified by peak serum creatinine increase, one-third of those have duration of AKI of >3 days. Elevated urinary kidney injury biomarker within 6 hours of surgery may help in identifying of patients at risk for longer AKI duration, which may serve as a reliable metric for drug development trials.

Urinary Biomarker Evaluation in Cancer Patients Receiving Cisplatin
Amandla Roque, Kent Doi, Maki Sumida, Yoshifumi Hamasaki, Schools of Pharmacy and Medicine, Univ of Colorado, CO.

Background: The study explored the time dependency of urinary biomarker changes and correlations between the biomarkers and traditional markers of kidney injury in a cohort of patients receiving cisplatin.

Methods: Urine was obtained at baseline, Day 2, Day 3, and Day 10 from patients (n=42) receiving cisplatin (25 mg/m²). Urinary kidney injury molecule-1 (Kim-1), calbindin, beta-2 microglobulin (B2M), clusterin, monocyte chemoattractant protein-1 (MCP-1), cystatin C, trefoil factor 3 (TFF3), tissue inhibitor of metalloproteinase 2 (TIMP2), and insulin growth factor binding protein 7 (IGFBP7) were measured with multiplex or ELISA.

A: baseline vs. Day 3 p<0.05; B: baseline vs. Day 10 p<0.05; C: Day 3 vs Day 10 p<0.05

The biomarker-GFR correlations were: TFF3 (r: -0.2590), B2M (r: -0.2017), Kim-1 (r: -0.1758), MCP-1 (r: -0.1390), cystatin C (r: -0.0936), IGFBP7 (r: -0.0764), clusterin (r: -0.0767), calbindin (r: 0.0647), and TIMP2 (r: 0.0619). The biomarker-albumin correlations were: calbindin (r: 0.7813), TFF3 (r: 0.5949), clusterin (r: 0.5869), Kim-1 (r: 0.3166), TIMP2 (r: 0.2906), MCP-1 (r: 0.2234), IGFBP7 (r: 0.2217), cystatin C (r: 0.1375), and B2M (r: 0.1149).

Conclusions: Urinary biomarkers display time dependent increases post cisplatin and exhibit variable degrees of correlation with GFR and urinary albumin. TFF3 had high concordance with both GFR and urinary albumin, which may be a favorable characteristic.

SA-PO207

Prediction of Long-Term Renal Outcomes in AKI Survivors by Urinary Biomarkers
Rei Isshiki, Kent Doi, Maki Sumida, Yoshihumi Hamasaki, Naoki Yahagi, Maasumi Nangaku, Eisei Noiri, Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.

Background: Although several epidemiological studies suggested that acute kidney injury (AKI) increases the risk of chronic kidney disease (CKD) development and progression, it is still unclear whether any AKI biomarker can predict long-term renal outcomes in AKI survivors. This study was aimed to evaluate the performance of urinary biomarkers for long-term renal outcome prediction.

Methods: We conducted an observational study examining the association of three urinary biomarkers measured at ICU admission [L-type fatty acid-binding protein (L-FABP), neutrophil gelatinase-associated lipocalin (NGAL), and N-acetyl-beta-D-glucosaminidase (NAG)] with CKD progression after discharge without major adverse kidney events (MAKE). MAKE were determined with death, incident dialysis dependency, or 50% reduction of eGFR at hospital discharge. Two different long-term renal outcomes were defined as follows; 30% reduction of eGFR or incident end-stage renal disease within two years after hospital discharge (Outcome 1) and halving of eGFR or incident end-stage renal disease in three years (Outcome 2).

Results: Among the enrolled 495 patients, 393 patients discharged from the hospital without MAKE. Of them, 175 patients were followed up for two years after ICU discharge and 63 patients (36.4%) were positive for long-term renal outcomes (Outcome 1). A step-wise logistic regression analysis demonstrated that only urinary NGAL showed a significant association. For Outcome 2, 26 of 159 followed-up patients (16.4%) were positive and urinary L-FABP and NGAL were significantly associated with CKD progression in a univariate logistic regression analysis.

Conclusions: Urinary biomarkers measured at ICU admission were significantly associated with long-term renal outcomes after hospital discharge in MAKE-free AKI survivors.

SA-PO208

Significance of Serial Measurement of Acute Kidney Biomarker in Intensive Care Unit
Rei Isshiki, Kent Doi, Maki Sumida, Naoki Yahagi, Maasumi Nangaku, Eisei Noiri. Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.

Background: AKI biomarkers have been developed with the concept of earlier detection of kidney damage than serum creatinine. However, single time point measurement appears not to provide sufficient information for detecting and predicting AKI in ICU patients who frequently suffer from multiple and transient/permanent renal insults. This study was aimed to evaluate whether serial measurement enables to predict AKI progression and recovery in these patients.

Methods: Serial measurements of AKI biomarkers including plasma and urinary NGAL, urinary L-FABP, and urinary NAG at ICU admission (day 1) and 24 hr after (day 2) were conducted in adult critically ill patients who were treated in a mixed ICU.

Results: Among the enrolled 272 patients, 33 were determined as newly developed AKI after ICU admission, 64 showed worsening of kidney function and 63 recovered from AKI. ROC analysis showed that biomarkers at day 2 showed no significantly additional benefit in predicting these three AKI outcomes compared with those measured at day 1. However, net reclassification improvement (NRI) analysis demonstrated adding AKI biomarkers at day 2 to the clinical model consisted of clinical variables and biomarker at day 1 significantly improved prediction of these AKI outcomes.

SA-PO209

Role of Carboxyl Stress Revisited in Pathogenesis of Tropical Acute Kidney Injury
Pinaki Mukhopadhyay, Nephrology, NRS Medical College, Kolkata, West Bengal, India.

Background: Malaria and snake bite are two common causes of Acute Kidney Injury (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to (I) evaluate the carboxyl and oxidative stress in these group and their pathogenesis link and (II) prognostic predictability of carboxyl and oxidative stress marker in this AKI.

Methods: All cases of falciparum malaria mediated AKI (FMAKI) (n=50),confirmed by antigen and/or in peripheral blood smear and snake bite mediated AKI(SAKI) (n=58) were included. AKI was calculated as per RIFLE criteria. Demographical, clinical and biochemical data were analysed and were followed from hospitalization to discharge/death. Oxidative and carbonyl stress markers [advanced oxidation protein product (AOPP), advanced glycation end product (AGE), pentosidine, dityrosine, thiobarbituric acid reactive substance (TBARS) and methyl glyoxal (MG)] were measured consecutively according to standard protocol. Predictive importance was assessed from trend analysis, receiver operated characteristic (ROC) curve analyses and multiple logistic regression with AKI as positive response.

Results: The Oxidative stress index(OSI) of FMAKI patients were 1.89 higher than controls. The TBARS, MG level were 6.49 and 5.56 times higher indicating a significant carboxyl stress in these patients. AOPP level was 2.53 times higher indicating proteins being highly insulted in FMAKI. Similarly in SAKI significantly elevated total oxidant stress with decreased total antioxidant stress leads to net oxidative stress in SAKI patients depicted by increased OSI values (p<0.001). MG was increased by 3.48 times (p<0.001).Only AOPP (p=0.001) and MG (p=0.004) were found to be significantly elevated in expired patients than the survived indicating their predictive power for adverse outcome. At univariate level,
all parameters can differentiate between AKI and the non-AKI group. At multivariate level, methylglyoxal, AOPP and dityrosine appeared to be independent predictor of AKI in snake bite and malaria infected patients (p<0.05).

**Conclusions:** 1.MG, the carbonyl stress marker along with oxidative stress are significantly raised and possibly linked to the pathogenesis of AKI. 2.MG and AOPP can be used as a surrogate marker in these tropical AKI.

### SA-PO210

**Prediction of Short-term and Long-term Outcomes of AKI-Based on Plasma NGAL**  
Karina Soto,1 Fernando Pereira,1 Liliana Maria Goncalves Cunha,1 Iola Pinto,1 Ana Luisa Papoila,1 Prasad Devajaran.1  
*Nephrology, Hospital Fernando Fonseca; 1Inst Superior de Engenharia de Lisboa; 1Nova Medical School/FCM,Univ Nova de Lisboa, Portugal; 1Nephrology, Cincinnati Children’s Hospital Medical Center, OH.

**Background:** We have previously shown a good performance of Plasma NGAL (pNGAL) as an AKI biomarker in emergency settings. Now we investigated a new AKI classification based on pNGAL for prediction of kidney dysfunction at discharge and at the end of follow-up.

**Methods:** Patients from a previous study at ED were followed for >5y. During the index hospitalization, 21% were AKI (based on SCr), 26% transient azotemia, 51% normal function and 2.4% stable CKD. All patients had SCr and pNGAL measured at 0, 6, 12, 24 and 48h of admission. A new AKI classification based on pNGAL levels (AKIPNGAL+) defined AKI as pNGAL>110 ng/mL (cut-off by GAMS). A multivariable logistic and Cox regression models were applied.

**Results:** Of 599 patients admitted, 97.8% were available at discharge and 54.4% at last follow-up. At admission 42.6% were reclassified as AKIPNGAL+ whereas only 21.7% were based on SCr. All significant clinical variables were included in multivariable analysis at discharge.

*p<0.001 unless CVD*0.007

Having pNGAL>110 at ED corresponded to 4-fold increased odds for eGFR<60 mL/min (p<0.001 ROC-AUC 0.82). The cumulative incidence of CKD showed that most of AKIPNGAL+ developed CKD at 60 mo (the highest proportion 77%) (figure 1) HR for CKD: 2.4 for patients AKIPNGAL+ in long-term (p=0.001 ROC AUC 0.74) NRI 56.3 and IDI 0.03.

**Conclusions:** Patients who were AKIPNGAL+ had significant lost kidney function at discharge and more than 2-fold risk of developing CKD in long-term evolution. Plasma NGAL is a useful tool for CKD prediction, independent of serum creatinine.

### SA-PO211

**The Use of Novel Serum and Urinary Biomarkers to Predict the Development of Hepatorenal Syndrome in Patients with Advanced Cirrhosis**  
Desmond Y.H. Yap,1 Kai Kay Seto,1 James Yf Fung,2 Seo-Ching Chan,2 Siu-Ho Chok,2 Man-Fung Yuen,2 Daniel Tak Mao Chan.3  
*Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; Surgery, The Univ of Hong Kong, Hong Kong, Hong Kong.

**Background:** Hepatorenal syndrome (HRS) is associated with high mortality rates in advanced cirrhotic patients without liver transplantation. Prediction of the development of HRS remains difficult.

**Methods:** We prospectively recruited patients with Child’s B or C cirrhosis and followed them at 2-week intervals 12 weeks or until HRS developed. Serum cystatin C (CysC), serum Neutrophil Gelatinase-associated Lipocalin (NGAL), serum IL-18, urine kidney injury molecule-1 (KIM-1) and urine liver-type fatty acid binding protein (LFABP) were measured at recruitment (Baseline).

**Results:** 43 patients included. 12 developed HRS at 7.3±5.1 weeks from baseline. pNGAL, IL-18 and CysC had highest Baseline levels of serum CysC (1.42±0.51 mg/L vs. 1.07±0.50 mg/L, p<0.021), serum NGAL (129.10±68.66 ng/mL vs. 72.84±48.91 ng/mL, p=0.025), serum IL-18 (759.91±477.05 mIU/mL vs. 358.13±153.00 mIU/mL, p<0.001), urine KIM-1 and LFABP (3.64±3.34 ng/mL vs. 1.18±1.68 ng/mL and 10.17±8.37 ng/mL vs. 3.28±3.42 ng/mL, p<0.023 and 0.035 respectively) when compared to patients who did not develop HRS. The cut-off and positive and negative predictive values for HRS were shown in Table 1.

Serum NGAL and IL-18 and urinary KIM-1 at Baseline were significantly associated with the development of HRS (OR 1.017, 95%CI 1.001-1.033, p<0.05; OR 1.007, 95%CI 1.001-1.013, p<0.012; OR 1.007, 95%CI 1.001-1.013, p<0.045 respectively).

**Conclusions:** Serum IL-18 and urinary KIM-1 could serve as biomarkers to predict HRS in patients with advanced cirrhosis.

**Robust Risk Assessment of Acute Kidney Injury After Acute Myocardial Infarction Using the Novel Biomarker C-Terminal Fragment of Agrin (CAF)**  
Spyridon Tziakas,1 Dimitros Arampatzis,2 George Chatikias,1 Vasileios Devetzis,1 Stefan Hettwler,1 Uyen Huynh,1 Fernando Pereira,1 Liliana Maria Goncalves Cunha,1 Ana Luisa Papoila,1 Prasad Devajaran.1  
*Department of Nephrology, Hypertension and Clinical Pharmacology, University of Athens, Greece; 1Department of Neurology, University Hospital Bern, Switzerland; 1Department of Neurology, Hypertension and Clinical Pharmacology, University of Athens, Greece; 1Department of Neurology, Hypertension and Clinical Pharmacology, University of Athens, Greece.

**Background:** Acute kidney injury (AKI) complicating acute myocardial infarction (AMI) increases subsequent morbidity and mortality. The objective of this study was to validate c-terminal fragment of agrin (CAF) as a novel AKI biomarker in patients with AMI.

**Methods:** 403 consecutive patients with AMI were enrolled, samples were collected at presentation for serum (sCAF), urine (uCAF) CAF, neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18) and cystatin-C analysis. The presence of AKI was evaluated at 48 hours post admission and at discharge.

**Results:** The incidence of AKI was 6.7% 14.6% depending on time-point and criteria used and increased across quartiles of uCAF (x1:10.99, p<0.001). Both uCAF and sCAF significantly correlated with serum creatinine on admission (r=0.233, p<0.001 & r=0.175, p<0.001), at 48 hours (r=0.263, p<0.001 & r=0.226, p<0.001) and with peak creatinine as well (r=0.317, p<0.001 & r=0.225, p<0.001). The predictive accuracy for AKI of uCAF was good (AUC of 0.630; 95%CI 0.552-0.708) and slightly better as that of urine NGAL (AUC 0.616; 95%CI 0.540-0.692, uCAF vs. uNGAL p=0.733), whereas that of sCAF was moderate (AUC of 0.587; 95%CI 0.509-0.666). A uCAF value of 1033 pm is suggested to have the best discriminating ability. The sensitivity of uCAF was 37% and the specificity 85% (NPV: 89%; PPV: 30%). Univariate analysis showed a strong association of uCAF with AKI incidence (OR:1.45, 95%CI 1.15-1.82, p=0.002) which remained significant even after adjustment for several confounders (OR:1.35, 95%CI 1.05-1.74).

**Conclusions:** Urine CAF analysis allows a robust risk stratification of AKI after AMI and thus optimized management in such patients.

At Myeloma Diagnosis, Age and Free Light Chain Level Predict Renal Function and These Factors with Free Light Chain Response Predict Renal Outcome

Punit Yadav,1,2 Mark Trehan Drayson,1,2 Mark Cook,1,2 Jennifer H. Pinney,1 Hannah V. Giles,1 Yu sanedar Aung,1,2 Paul Cockwell.1,2 Univ Hospital Birmingham, UK; 1, University of Birmingham, UK.

Background: Elevated involved immunoglobulin light chain (FLC) is a major cause of renal impairment (RI) in myeloma. Relationships between presentation and post-induction (PI) renal function and serum FLC levels are not established.

Methods: We used central laboratory data from the MRC Myeloma IX trial which compared bisphosphonate and thalidomide-based therapies. Patients were divided into 3 categories: FLC ≥600 mg/L; FLC 30-59 mg/L; and FLC <30 mg/L. Median eGFR for light chain only myeloma (LC) was also significantly lower than those with IgG and IgA myeloma (49 [IQR 28-78] vs 62 [IQR 47-79] vs 63.5 [IQR 42.2-82.0]; P=0.0001). Patients with a difference between involved and uninvolved FLC (dFLC) ≥500 mg/L had a lower eGFR compared to those with dFLC 100-499 mg/L and dFLC <100 mg/L (52 [IQR 35-72] vs 66 [IQR 52.0-82.2] vs 67 [IQR 54.2-82.0]; P=0.0001). A dFLC level of 700 mg/L was the optimal cut-off value for prediction of severe RI, with an AUC of 0.80. Factors associated with eGFR at presentation were: age, log10 dFLC, male gender and LCO myeloma. On censoring those with dFLC <7000 mg/L; age and log10 dFLC were still associated with eGFR at presentation but not male gender and LCO myeloma. Factors that were independently associated with RI at PI were: age (odds ratio [OR] 1.033, P<0.0001); creatinine measure at OR (0.93, P<0.0001) and attainment of VQPR (very good partial response) compared to <PR (partial response) serum FLC response (OR 0.52, P=0.005).

Conclusions: Age and serum FLC level predict eGFR at presentation and age, presentation eGFR, and serum FLC response predict PI renal outcome.

SA-PO214

Urinary Biomarkers Improve the Prediction and Prognostic Assessment of Acute Kidney Injury in Critically Ill Patients

Patrick T. Murray, Teresa Martin, Eoin J. Cotter. UCD Clinical Research Centre, School of Medicine, Univ College Dublin, Dublin, Ireland.

Background: Acute kidney injury (AKI) is common in intensive care unit (ICU) patients, and is diagnosed late by serum creatinine. New biomarkers may permit earlier detection and better management.

Methods: All patients admitted to the ICUs of two university hospitals were screened for this prospective cohort study. Clinical information and urine were collected on admission and daily for 7 days. Urine biomarkers analysed were neutrophil gelatinase-associated lipocalin (NGAL), α- and β-glutathione-S-transferases (GSTs), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP), creatinine, and albumin. AKI was defined by modified KDIGO criteria, using ICU admission creatinine as reference. Values were compared between those who did or did not develop AKI or 30d adverse clinical outcomes (RRT or death). ROC curves were generated for prediction of AKI and outcomes by a clinical score (including age, gender, serum creatinine & urine, albumin output) and urine biomarker values on admission. In patients developing AKI, ROC curves were similarly generated for the prediction of clinical outcomes with values obtained at time of AKI diagnosis.

Results: 659 patients were enrolled; 181 patients (27%) developed AKI within 7d of ICU admission. AKI stages at diagnosis were: Stg1 (n=181, 41%), Stg2 (n=73, 17%), Stg3 (n=93, 46%). On admission, addition of a panel of AKI biomarkers significantly but modestly improved prediction of AKI developing within the first 48h in ICU (AUC: 0.79±0.012), compared to clinical score alone (0.77±0.011; p=0.0001). AKI biomarkers similarly improved the prediction of AKI developing within the first 7d (0.73±0.15), compared to clinical score alone (0.69±0.07; p=0.0003); and marginally improved the prediction of 30d RRT or death (0.7±0.1 vs 0.69±0.1; p=0.05). In patients developing AKI, AKI biomarkers at the time of diagnosis significantly improved prediction of 30d adverse clinical outcomes (RRT or death): 0.77±0.19, compared to clinical score alone (0.68±0.13; p=0.01).

Conclusions: Urinary biomarkers combined with standard clinical tests improved prediction of AKI and outcomes in ICU patients, on admission and at AKI diagnosis.

SA-PO215

Association of Growth Factor Biomarkers with Acute Kidney Injury and Long-Term Mortality in Adults following Cardiac Surgery

Background: Following the structural damage and functional impairment from acute kidney injury (AKI), the kidney undergoes a coordinated process of repair involving regenerative growth factors. We conducted an ancillary analysis of a large, prospective study of adults undergoing cardiac surgery to investigate the utility of epidermal growth factor (EGF) and vascular endothelial growth factor (VEGF) in predicting kidney injury and mortality.

Methods: Patients undergoing cardiac surgery at high risk for AKI were enrolled at six academic centers. AKI was defined as a doubling in serum creatinine from baseline or receiving acute dialysis during the hospital stay. Postoperative plasma levels of EGF, VEGF, and a combination model of the two growth factors were evaluated for association with outcomes of AKI or long-term, all-cause mortality at a mean follow-up of 3 years.

Results: First postoperative and peak plasma EFG were not associated with AKI. Elevated peak plasma VEGF was independently associated with increased risk of AKI (adjusted odds ratio [OR] 7.4, 95% confidence interval [CI] 1.1–47.9). Elevated first postoperative VEGF was inversely associated with a lower risk of mortality (adjusted HR=0.67; 95% CI: 0.47-0.97). Elevated first postoperative VEGF was likewise associated with a lower risk of mortality (unadjusted HR=0.36; 95% CI: 0.16-0.82), though the association was attenuated following adjustment (adjusted HR=0.36; 95% CI: 0.15-1.04). When used conjointly, elevated levels of first postoperative EGF and VEGF together were independently associated with a lower risk of mortality (adjusted HR=0.28; 95% CI: 0.11-0.72).

Conclusions: Postoperatively, EGF and VEGF are released in response to AKI, and their concentrations were inversely associated with long-term mortality. These growth factors may serve as biomarkers of long-term outcomes in adults undergoing cardiac surgery.

SA-PO216

Prolactin as a Predictor of AKI in Patients with Sepsis

Jonathan Chavez,1 Maria de la luz Alcantar Vallin,1 Guillermo Garcia-Garcia,2 Luis Arnaldo Muñoz.1 Nephrology Service, Hospital Civil de Guadalajara, Guadalajara, Mexico; 2Internal Medicine, Hospital Civil de Guadalajara, Guadalajara, Mexico.

Background: Sepsis is a common cause of AKI. Identifying patients at risk for AKI could improve clinical outcomes. Prolactin (PCT) reflects accurately the presence of sepsis and its severity. We evaluated the role of PCT as predictor of AKI in septic patients.

Methods: Cross-sectional study of 72 septic patients between January to December 2014. Patients with SCr >1.5 mg/dl before admission, ESRD patients and those with autoimmune comorbidity were excluded. PCT, Scr, urea, and WBC were measured on admission, and at 24 and 48 h of hospitalization. X2 and t-test were used when appropriate. A ROC curve for PCT value on admission as well as the area under the curve (AUC), the standard AUC error, and sensitivity and specificity of PCT values were determined.

Results: Patients' mean age was 50.8 y (18-79); 37 (51.4%) were women. 18 (25%) patients had PCT value at <0.5 mg /mL (negative) and 54 (77%) >0.5 mg/mL (positive) on admission. Forty-two (58.3%) patients developed AKI, 19 (45.2%) KDIGO 1, 12 (28.6%) KDIGO 2, and 11 (26.2%) KDIGO 3. Of the 42 patients who developed AKI, 37 (88.1%) had a positive value of PCT at admission (p<0.01, OR 5.659, 95% CI 1.738 to 18.425). The ROC PCT for C statistic of 0.75 (p<0.0001, 95% CI 0.639-0.862). The cutoff of 2.565 mg /mL of PCT had the highest validity for predicting AKI with an SE of 61.9%, one SP of 80%, a PPV of 44.52%, 56.18% NPV, LR + LR of 0.80 and 0.77, respectively. Fig. 1

AUC of 0.75 (p<0.0001, 95% CI 0.639-0.862).

Funding: Other NIH Support - R01HL085757

Conclusions: We found a significant association between levels of PCT and development of AKI in patients with sepsis. A cutoff PCT value of 2.565 mg/mL on admission had the highest validity for predicting AKI. Early recognition of septic patients at risk for AKI with PCT could improve clinical outcomes in this population.
Elevated Erythropoietin Concentration in AKI Is Associated with IGFBP-1 Rather Than Hemoglobin

**Background:** EPO expression will be increased by hypoxia in the kidney and hypoxic injury plays a crucial role in pathogenesis of AKI. However, little is known about blood EPO levels in critically ill patients complicated with AKI.

**Methods:** This study prospectively enrolled 98 adult critically ill patients who admitted to the adult ICU. We measured plasma EPO and also measured plasma IGFBP-1 as a hypoxic marker, which is produced mainly by liver, and plasma NGAL and urinary NAG as renal damage biomarkers on ICU admission. This study was conducted to evaluate whether plasma EPO levels in AKI patients was regulated by other factors than anemia.

**Results:** AKI occurred in 42 (42.9%) patients. Significantly higher plasma EPO in the AKI group was detected compared with the non-AKI group (16.13 [9.87–28.47] mIU/mL versus 27.81 [10.16–106.02] mIU/mL, p<0.05). Plasma EPO concentration was strongly and negatively correlated with hemoglobin in the non-AKI group but not in the AKI group.

**Conclusions:** Plasma EPO had a predictive value for diagnosing AKI but it itself had a limited value for distinguishing prerenal AKI from other causes of AKI.

**SA-PO218**

Predictive Value of Plasma Neutrophil Gelatinsase-Associated Lipocalin (NGAL) to Distinguish Prerenal AKI to Other Causes of AKI

**Background:** Plasma Neutrophil gelatinase-associated lipocalin (NGAL) is a promising biomarker for acute kidney injury, but it’s role for distinguishing prerenal AKI from other causes is not well known. The aim of this study was to evaluate the predictive value of plasma NGAL to distinguish prerenal AKI to other causes of AKI.

**Methods:** We reviewed all NGAL test from December 26, 2011 to February 28, 2015 in Konkuk University Medical center (Seoul, Republic of Korea) and subtract patients who taken factional excretion of sodium (FENa) test at the same time. Patients were first grouped with Acute Kidney Injury Network (AKIN) stages and evaluated it’s diagnostic role for AKI and second divided with prerenal AKI and other causes of AKI.

**Results:** Total 5814 NGAL test were done from December 26, 2011 to February 28, 2015 in Konkuk University Medical center, and 495 patients taken FENa test at the same time.

**Conclusions:** Plasma NGAL had a predictive value for diagnosing AKI but it itself had a limited value for distinguishing prerenal AKI from other causes of AKI.

**SA-PO219**

Neutrophil/Lymphocyte Ratio for Early Detection of Acute Kidney Injury (AKI) in Patients Admitted to the Emergency Room

**Background:** Neutrophil to lymphocyte ratio (NLR) is a readily available biomarker of systemic inflammation. Several studies have provided evidence of an association between elevated NLR and adverse outcomes in a variety of medical and surgical conditions, including CKD. In this study, we evaluated the predictive capacity of single Emergency Room (ER) measurement of NLR for early diagnosis of acute kidney injury (AKI).

**Methods:** We prospectively studied 294 patients aged 71.6 ± 17. NLR was measured at presentation to the ER. AKI was defined as a new-onset 1.5-fold or more increase in serum creatinine or a 25% decrease in estimated GFR sustained for at least 3 days despite volume resuscitation. The primary outcome was AKI. Secondary outcome was in-hospital mortality.

**Results:** 36 patients (12.2%) developed AKI and 26 (9%) died. Mean NLR was significantly higher in AKI compare to non-AKI patients (11.7 ± 15.2 vs 6.45 ± 7.19, p=0.048). A multivariate model adjusted for age, gender, blood pressure, and plasma creatinine or a 25% decrease in estimated GFR sustained for at least 3 days despite volume resuscitation. The primary outcome was AKI. Secondary outcome was in-hospital mortality.

**Conclusions:** Single ER measurement of NLR can be a useful tool for early diagnosis of AKI. This finding is particularly important in light of the widespread availability and low cost of NLR, especially compared with other biomarkers currently under study in the context of AKI.

**SA-PO220**

Urine Klotho in Human AKI

**Background:** Klotho deficiency has been observed in experimental AKI and low Klotho post-AKI is associated with progression to CKD in rodents. We report the first study of Klotho in human AKI.

**Methods:** We conducted a prospective study of 29 AKI patients and 29 controls without AKI in the ICU setting. We excluded patients with baseline GFR<60 or kidney transplant. Urine samples were obtained within 24h of peak serum creatinine (SCr) or at RRT initiation.

**Conclusions:** Plasma NGAL had a predictive value for diagnosing AKI but it itself had a limited value for distinguishing prerenal AKI from other causes of AKI.
in AKI cases, and within 24h of ICU admission in frequency-matched controls. AKI was defined by KDIGO criteria. Longitudinal data from AKI cases were obtained throughout hospital stay. Renal recovery was defined as the ratio of follow-up SCr/baseline SCr ≤1.5. Urine Klotho was measured by immunoprecipitation-immunoblot. Mixed-effects linear models were constructed to assess longitudinal trends of Klotho in AKI survivors.

Results: Mean (SD) age was 58 (17) years, 62% were men and 75% white. Patients with AKI had higher critical illness scores than controls without AKI. Five (17.2%) patients died and 8 (27.6%) required RRT in the AKI group. Only 3.5% patients died in the control group. Urine Klotho adjusted by urine creatinine (uKlotho/Cr) was significantly lower in AKI cases than in controls, median 10 [IQR 4–20] vs 28 [14–52] fmol/mg, p=0.003. Furthermore, uKlotho/Cr significantly increased with time in patients that exhibited renal recovery (n=7, Δ+216%, p=0.05) but not in those that did not (n=7,Δ+8%, p=0.91), median follow-up 24 days.

Conclusions: uKlotho/Cr is significantly lower in patients with AKI when compared to ICU controls without AKI. uKlotho/Cr recovered only in patients that recovered kidney function. Klotho may serve as a prognostic marker for AKI recovery.

Funding: Other NIH Support - University of Texas Southwestern Medical Center; O’Brien Kidney Research Core Center (NIH, P30 DK079328-06) and the National Center for Advancing Translational Sciences of the National Institutes of Health (NIH, UL1TR001105).

Elevated Renal Injury Biomarkers Fall Transiently After Stenting in Human Atherosclerotic Renal Artery Stenosis (ARAS)

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

A similar pattern is seen in AKI and non-AKI groups and when expressing BioM/urine creatinine(not shown).

Conclusions: This is a novel study of AKI BioM excretion in CisP-AKI. NCI-AKI is more common than SCR-AKI. The immediate BioM drop post-CisP may be related to injury protection from high fluid rate and/or urinary alkalinization peri-CisP. Our larger sample size will allow to further characterize BioM excretion and evaluate BioM associations with AKI definition and outcomes.

Funding: Government Support - Non-U.S.
date, it is unclear which intrinsic factors trigger the onset of SIRS and associated AKI. We investigated the role of mtDNA during systemic inflammation and AKI and the role of platelets herein.

Methods: Human platelets were stimulated with mitochondrial DNA, genomic DNA or unmethylated CpG-enriched oligonucleotides (CpGODN). Platelet activation was measured with FACs. In a single centre prospective observational study we included 37 patients diagnosed and classified for the onset of SIRS with or without the development of AKI that were admitted to the ICU. As a control we included (n=25) patients after elective major surgery without a diagnosis of either SIRS or AKI. Blood and urine samples were isolated and processed. Free circulating plasma and urinary mtDNA was determined by RT-PCR. Inflammatory mediators and PF4 in urine were measured using specific ELISA.

Results: Mitochondrial DNA, but not genomic DNA triggered platelet activation. Unmethylated CpG ODN, dose dependently stimulated platelet activation. Compared to ICU-controls, critically ill patients with SIRS demonstrated elevated levels of plasma and urinary mtDNA and proinflammatory cytokines. Compared to SIRS patients without AKI, the patients with AKI displayed elevated levels of urinary PF4 indicative of platelet activation.

Conclusions: The development of AKI in critically ill patients is associated with platelet activation, possibly triggered by mitochondrial DNA.

SA-PO225
Iniders in the Night: Sleep Apnea and Sub-Clinical Renal Injury
Aaron A. Rampal,1 Shahab Bozorgmehr,1 Areef Jishani,1,2 J. David Weiner,1 Satish P Ramachandran,1 Rebecca Belyh,1,4 Muna T. Canales,1,4 1Univ of Florida, Gainesville, FL; 2Minneapolis VAMC; 3Univ of Minnesota, Minneapolis, MN; 4Malcom-Randall VAMC, Gainesville, FL; 5Univ of California, San Diego, CA.

Background: Sleep apnea is common in patients with CKD. We postulated that sleep apnea may cause renal injury through repeated ischemia-reperfusion. The current study correlated overnight changes in urinary excretion of renal injury biomarkers with severity of sleep apnea.

Methods: 39 consecutive participants in the SNORE Study, a longitudinal study of sleep apnea and kidney function decline, underwent overnight sleep study and provided spot urine samples before and after sleep. We measured urinary NGAL, L-FABP, KIM-1, and urinary creatinine levels, and correlated differences between AM and PM levels (AM-PM) with severity of sleep apnea or hypoxia. Sleep apnea was defined by the apnea-hypopnea index (AHI, events/hour); hypoxia was % total sleep time ≥90% O2 (%TST90). Data were log-transformed to normalize distribution.

Results: Patient characteristics: Mean age, 73.6 ± 8.4 years; 90% male; 87% Caucasian, 13% black; BMI 29.4 ± 4.2 kg/m2; MDRD GFR, 34.3 ± 18.1 ml/min/1.73 m2; Median urinary albumin/creatinine ratio, 46 mg/g Cr [IQR 9-357 mg/g Cr]; 69% had sleep apnea (AHI≥5); median AHI, 10 [IQR 2-23]; median %TST90, 15 [IQR 3-22] with 34% %TST90<10%. Higher %TST90 was correlated with higher AM KIM-1 values (r=0.40, p=0.01) and greater increase in urinary KIM-1 (AM-PM) (r=0.32, p=0.04). None of the remaining biomarkers correlated with %TST90. Also, none of the overnight urine biomarker changes correlated with AHI.

Conclusions: The correlation of KIM-1 with hypoxia suggests that SA may contribute to CKD through ischemic renal injury. Future studies with larger sample size and in non-CKD populations are needed to further test this hypothesis.

Body Mass Index and Acute Kidney Injury in Hospitalized Patients
Yan Lun Allen Liu, Milind Nikam, Lee Ying Yeo. Dept of Medicine, Khoo Teck Puat Hospital, Singapore.

Background: Acute kidney injury (AKI) is common in hospital settings. The association between AKI and Body Mass Index (BMI) in general hospitalized patients is not clear. This study is to explore the incidence of AKI and the impact of BMI on AKI in hospitalized patients.

Methods: This was a single centre, retrospective, case-control study. All patients aged 21 or above under in-hospital care from January to December 2013 were recruited for analysis. We calculated the incidence of AKI according to the Kidney Disease: Improving Global Outcomes (KDIGO) criteria among different BMI groups (underweight [BMI < 18], normal [BMI 18-25], overweight [BMI 25-29] and obese [BMI ≥ 30]), and then analyzed the risks of developing AKI within and between groups. Baseline creatinine was defined by the most recent value obtained in hospital up to 12 months before admission. If no previous serum creatinine was available, the lowest serum creatinine during hospitalization was used instead. If only one serum creatinine result was known during hospital stay, the baseline creatinine was estimated by the use of simplified Modification of Diet in Renal Disease (MDRD) formula (assuming a glomerular filtration rate [GFR] of 70 ml/min per 1.73 m2).

Results: A total of 12567 patients were recruited for analysis. Mean age was 62.5 ± 18.5 years. Male patients constituted 53.8% of the study population. 61.9% were Chinese ethnicity. There were 2656 patients suffered from AKI (21.1% of the whole study population), among which 10.7% reported a 10% or more increase in serum creatinine within 48 hours. Underweight patients (BMI < 18) had statistically significantly more stage 1 AKI than the rest of the population, while patients with BMI ≤ 25 had more stage 2 AKI (stage 1 AKI for underweight, normal, overweight and obese patients was 15%, 10.2%, 9.4% and 10.3% respectively; stage 2 AKI, 7.6%, 6.3%, 6.4% and 5.2% respectively). There was no difference in frequency of stage 3 AKI among different BMI groups.
Conclusions: Preliminary results revealed underweight hospitalized patients had increased risks of developing stage 1 AKI. Stage 2 AKI was more commonly seen in patients with BMI ≤ 25. BMI status was not associated with the development of severe AKI (stage 3).

SA-PO227

Hypermagnesemia as a Risk Factor for the Mortality in Intensive Care Unit Patients with Acute Kidney Injury. Shumichi Shibazaki, 1 Makoto Araki, 1 Kohel Miura, 1 Dajo Inaguma. 2 Dept of Nephrology, Sawa Central Hospital, Chino, Nagano, Japan; 2 Dept of Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.

Background: We need an easily measured biomarkers predicting for the mortality in acute kidney injury (AKI) because of high mortality rate. Therefore, we paid attention for serum magnesium (sMg) levels which reflects the renal tubular damage, and study the relationship sMg and prognosis in intensive care unit (ICU) patients with AKI.

Methods: A cohort study was conducted by collecting data from January to December 2014 in Nagoya Daini Red Cross Hospital. According to sMg at ICU 1st day, three groups were divided; low Mg group (sMg < 1.8mg/dL), normal Mg group (1.8mg/dL ≤ sMg < 2.6mg/dL), and high Mg group (sMg ≥ 2.6mg/dL). AKI was defined as serum creatinine (SCr) abrupt (within 7 days) increase to ≥ 1.5 times baseline or SCr increase by ≥ 0.3mg/dL. The primary endpoint was 28 days mortality after ICU admission. The secondary endpoint was the renal recovery rate, the renal replacement therapy (RRT) induction rate, and the transition rate to maintenance dialysis. Renal recovery was defined as an absence of AKI.

Results: Out of 1614 ICU patients, 200 patients were included. The number of each groups are following; low Mg group was 55, normal Mg group was 115, and high Mg group was 30. The mortality was higher in high Mg group than in other Mg group (p = 0.011). A multivariate analysis identified high Mg group as an independent risk factor for the mortality (p = 0.014). High Mg group had 2.39-fold increased odds of mortality against normal Mg group (95% CI 1.04 - 5.50). Kaplan-Meier curves showed the high Mg group was 30. The mortality was higher in high Mg group than in other Mg group (p = 0.011).

SA-PO228

Gemcitabine-Induced Thrombotic Microangiopathy (TMA): A Report from the French Pharmacovigilance Network. Noemie Jourde-chiche, 1 Florence Daviet, 1 Frank Rouby, 1 Bertrand Gondouin, 1 Marion Sallec, 1 Julie Moussi- Francois, 1 Stephanie Burty, 1 Pascale Poullin, 1 Bertrand Dussol, 1 Joelle Micallef. 2 Nephrology, Aix-Marseille Univ, Marseille, France; 2 Pharmacology and Pharmacovigilance, Aix-Marseille Univ, Marseille, France; 3 Hemapheresis, Aix-Marseille Univ, Marseille, France.

Background: Gemcitabine is a chemotherapy which use can be limited by renal adverse events, in particular thrombotic microangiopathy (TMA). This study evaluated the occurrence of gemcitabine-induced TMA, and described therapeutic strategies and outcomes.

Methods: All spontaneous reports of TMA attributed to gemcitabine in the French Pharmacovigilance Network database, between January 2000 and May 2015, were reviewed using a standardized questionnaire.

Results: 81 cases of TMA were reported in 48 male (59%) and 33 female (41%), with a median age of 63.5 yrs (range 39-87). Gemcitabine was prescribed for pancreatic (58%), pulmonary (15%), breast (8%), biliary tract (6%), urinary tract (5%), testicular (1%) or liver (1%) cancers, or T lymphoma (3%). TMA occurred after a median of 7 months (range 0.2-60), and a median cumulative dose of 21.8g (range 1.1-48.6). Main cancers reported were testicular (12.1%), 69 (2.8%) and 46 (1.8%) were of stage 1, 2 and 3, respectively. Incidence of AKI creatinine level was 1.8 mg/dL (range 0.8-17). In 6 patients, renal TMA was biopsy-proven. Renal replacement therapy was required in 10 (12%) patients, plasma exchanges (PEx) were performed in 17 (21%), 8 (10%) received fresh frozen plasma infusions, 9 (11%) corticosteroids, and 3 (4%) eculizumab (after PEx failure). Evolution data were available for 59 (73%) patients, among which the 17 treated with PEx. Hematological and renal remission was achieved in 35% with PEx versus 50% without, hematological remission without renal improvement in 18% with versus 26%, and no improvement was observed in 47% with versus 24% without PEx. Only one patient improved with eculizumab.

Conclusions: Gemcitabine treatment can be associated with TMA and severe renal adverse effects. The benefit of plasma exchange or eculizumab in this setting remains uncertain.

SA-PO229

Contribution of Drugs versus Risk Factors in Drug-Induced Renal Injury. Celina D. Cerpeda, 1 Linda Avadlish, 1 Etienne Macedo, 1 Dinna Cruz, 1 Stuart Goldstein, 1 Jorge Cerda, 1 David T. Selsey, 1 Michael Zappitelli, 1 Andrew J.P. Lewington, 1 Ravindra L. Mehta. 1 Nephrology, Univ of California San Diego, San Diego, CA; 2 Nephrology, Univ of Cincinnati, Cincinnati, OH; 3 Nephrology, Albany Medical College, Albany, NY; 4 Nephrology, Univ of Michigan, Ann Arbor, MI; 5 Nephrology, Univ of Montreal, Montreal, QC, Canada; 6 Nephrology, Cares Hospital India, Hyderabad, India; 7 Nephrology, St. James’s Univ Hospital, Leeds, London, United Kingdom.

Background: Drug-induced renal injury (DRI) is an increasing cause of acute kidney injury (AKI). Attribution of DRI requires consideration of the drug exposure, the number of drugs involved and underlying or concomitant risk factors (RF). We hypothesized that underlying RF would influence attribution of DRI.

Methods: The drug induced renal injury (DIRECT) study is an ongoing prospective multicenter study evaluating genetic determinants of the drug exposure. Each enrolled case was adjudicated for causality by two independent nephrologists. We analyzed the first consecutive 86 adult and pediatric AKI cases. We evaluated the percent agreement, kappa statistic, and contribution of each drug (in setting of multidrug injury) and AKI RF.

Results: Adjudicators agreed 87.2% (n=75) had DRI. For non-DRI cases, causality could not be established because of competing AKI RF. RF contributed to AKI in 86% of adults and 70% of children. Adjudicators disagreed on the percent attribution for each drug in 52%. For DRI cases, inter-rater agreement on percentage attributed to drug 1 was 48% with kappa=0.239 (p=0.001). For non-DRI cases, inter-rater agreement for drug 1 was 81.8% and RF attribution was 90%.

Conclusions: Underlying RF are common in DRI associated AKI. Causality assessment in DRI is complex due to difficulty in determining the attribution of drug and RF. CAT for DRI should incorporate AKI RF and their interaction with drugs.

Reduced Incidence of Post-Operative Acute Kidney Injury After Cardiovascular Surgery. Dadi Helgadottir, 1, 2 Boris E. Long, 1 Solveig Helgadottir, 1 Tomas Gudbjartsson, 3, 5 Gisli H. Sigurdsson, 2, 6 Martin I. Sigurdsson, 2, 6 Olafur S. Indridason. 1 Dept of Medicine; 1 Dept of Anesthesia and Intensive Care; 2 Dept of Cardiothoracic Surgery, Landspitali, Reykjavik; 3 Dept of Anesthesia, Brigham and Women’s Hospital, Boston; 4 Div of Nephrology, Landspitali; 5 Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.

Background: Acute kidney injury (AKI) is a serious complication of cardiac surgery. The aim of this study was to examine time trends in incidence and survival of patients diagnosed with AKI following cardiac and thoracic aorta surgery.

Methods: This was a retrospective study of all heart and thoracic aorta operations performed on adults in Iceland from 2007 to 2014. AKI was diagnosed according to the KDIGO criteria based on serum creatinine values in the electronic database of the clinical laboratory at the institution. Survival status was verified at Statistics Iceland. The incidence of AKI and its outcome was compared between the first and second half of the 8 year study period using Chi squared and the Kaplan Meier method. Outcome between AKI and non-AKI patients was compared by propensity score matching (1:2, non-replacement matching).

Results: A total of 2224 patients underwent 2502 operations during the study period, of which 228 (9%) were acute open heart surgery (range 10.7-9.7%). AKI occurred after 417 operations (16.7%). Of these 302 (12.1%), 69 (2.8%) and 46 (1.8%) were of stage 1, 2 and 3, respectively. Incidence of AKI

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
decreased from 19.2% in the first period to 14.5% in the second period (p=0.002). Survival of AKI patients at 30 days and 1 year did not differ between time periods, being 82.6% vs. 83.8% and 79.5% vs 76.8%, respectively (p=0.10). Survival was worse for patients with AKI compared with the propensity score matched control cohort, both at 30 days (86.1% vs. 96.5%, p=0.0001) and at 1 year postoperatively (81.2% vs. 91.5%, p=0.0001).

Conclusions: The incidence of AKI following cardiac and thoracic aorta surgery is decreasing. Nevertheless it still affects one in seven patients and even though most patients have mild AKI, it is associated with increased mortality which remains unchanged over the past decade. Funding: Private Foundation Support

SA-PO231
Acute Kidney Injury in Patients with Chronic Kidney Disease: Aetiology and Survival Comparisons to Non-Acute Kidney Injury Chronic Kidney Disease Population Akib Khan,1 James Ritchie,2 Smeeta Sinha.3 Background: AKI, described by an acute (hours to days) fall in kidney function, is associated with significant morbidity and mortality. Poor outcomes exist when AKI is superimposed on CKD, a disease involving structural or functional renal abnormalities in a chronic setting (>3 months). We present a single-centre prospective observational study; retrospectively analysed. We determine the factors surrounding AKI on CKD. Aetiology, length of stay, specialist review and medication data were examined. We compare AKI on CKD patients’ survival to matched non-AKI CKD patients.

Methods: CRISIS database CKD patients matching inclusion criteria treated at Salford Royal Foundation Trust were studied (n=942). A 2.0-3.0 and >3.0 times serum creatinine increase was defined to define Acute Kidney Injury Network stages 2 (n=17) and 3 (n=10) events respectively. Controls were matched by age, eGFR and blood pressure. Logistic Regression, Cox-Hazard Ratio and Kaplan-Meier Survival Plots were used.

Results: Aetiological factors associated with AKI included sepsis (48.1%), drug-induced (29.6%) and dehydration (25.9%). Septic-AKI had a 1.405 odds ratio (95%CI:0.099-19.936,p=0.801) of death compared to non-septic events. Hazard ratio for death due to AKI on CKD compared to non-AKI CKD was 1.77 (95%CI:0.72-4.33,p=0.207). Kaplan-Meier survival function clearly demonstrates this.

Conclusions: Aetiology of AKI in our patient group was similar to that seen in non-CKD studies. There was a clear trend towards increased all-cause mortality in patients with AKI on CKD in comparison to non-AKI CKD patients. Renal function decline rate following AKI on CKD should be explored in the future.

SA-PO232
Prospective Study of Incidence and Early Detection of Acute Renal Failure in Preterm Babies in a Tertiary Center in South India Indira Agarwal, Nithya Ponmudi, Anil K. Kuruvilla, Vijayakumar Theophilus-Sunder. Pediatric Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; Neonatology, Christian Medical College, Vellore, Tamil Nadu, India; Nephrology, Christian Medical College, Vellore, Tamil Nadu, India.

Background: Preterm babies are at risk for ischemia, hypovolemia and hypotension and thus vulnerable to Acute kidney injury (AKI). We aimed to study the incidence and predisposing factors for AKI in preterm babies and to assess the usefulness of urinary NGAL as a predictor of kidney injury.

Methods: Babies born < 32 weeks+6 weeks were recruited; those with abnormal antenatal renal scans and major congenital anomalies were excluded. Weekly monitoring of urine output, clinical progress, interventions, ventilation, unexpected events and use of nephrotoxic drugs was done. Serum creatinine and urine NGAL was collected at 72 hours of age and weekly thereafter. Descriptive statistics using mean±SD for continuous variables, ANOVA and chi-square test for AKI detection test for categorical variables and Risk factor analysis using log binomial was performed.

Results: Of the 4823 live births, 80 fulfilled inclusion criteria (10.14%). The incidence of AKI was 12.6%. The risk factors included oligosuuria, PDA, nephrotoxic drugs, low Apgar, mechanical ventilation, CPAP and abnormal antenatal scans. Urine NGAL was estimated in 31 babies. It rose earlier and was significantly elevated in those on mechanical ventilation by week 2 while Creatinine rose only by week 3.

Conclusions: NGAL was inversely proportional to gestational age and birth-weight. Both NGAL rise and creatinine were higher in babies with AKI associated with NSAIDS, umbilical lines and asphyxia.

SA-PO233
Acute Kidney Injury Electronic Alerts in Primary Care Conor Patrick Moran,1 Ying C. Kuan,2 Patrick Lm Lynch,2 Francis Mccarroll.1 1Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; 2Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-60%). A UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition. AKI is regarded as the remit of Secondary Care and there have been few studies examining Community Acquired AKI, (CA-AKI). Guidelines have recommended the utilised electronic alerts (e- alerts) for AKI in both Primary and Secondary care. We examined the incidence and mortality of CA-AKI.

Methods: We introduced AKI e-alerts with accompanying c-guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI in Primary, Community and Secondary care. Data collection was carried out for 3 months. The demographics of both cohorts were compared.

Results: Median age, (74.5 years vs. 75 years), gender distribution, (M:F: 48% / 52% vs. 44.5% / 55.5%), and median time to death, (8 days vs. 11 days), were comparable. 44 Alerts were from Primary Care and 77 from Emergency Department. Of the Primary Care Alerts, 20 patients were subsequently admitted. Of those who were not, 3 died within 30 days, (1. Died at 5 days, 2. Died at 8 days, 3. Died at 21 days). Despite this, Community-acquired AKI was associated with a 30-day mortality of 10.7%. Hospital-acquired AKI, (HA-AKI), was associated with a 28.2% 30-day mortality, (p=0.001). Sub-group analysis showed Primary care alert associated with 13.64% mortality and Primary Care alerts with 9.76%, (p=0.001). Median Age at Death; CA-AKI 80 years. Median time to death; CA-AKI 5 days, HA-AKI 11 days.

Conclusions: AKI is common and associated with a significant morbidity and mortality. CA-AKI is common opportunities at diagnosis and intervention are often missed with grave
consequences. Appropriate management of CA-AKI can help reduce the economic and physical burden associated with AKI and reduce the long-term burden of CKD. Further work is required to expand the role of AKI e-Alerts in Primary Care.

SA-PO234

Acute Kidney Injury Causes and Outcome: A Single Center Experience from Sudan

Maha Farah,1 Len A. Usvyat,3,4 Roberto Pecoits-Filho,1 Peter Kotanko.3,5

Background: Acute kidney injury (AKI) is a challenging problem in Africa—a diverse continent with regards to population and financial and medical resources. There are no reliable statistics about the incidence of AKI in Africa. Based on sporadic regional publications the incidence has been estimated at 150 per million population. In addition to infectious diseases; toxins play a major etiologic role in AKI.

Methods: In this study we analyzed data from Omer Belal Renal Center in Soba University Hospital, Sudan, a tertiary referral center with a catchment area of 3 million citizens. All hemodialysis (HD) patients treated for AKI in the period between 1/1/2013 and 12/31/2014 were included in the study.

Results: Out of 520 hemodialysis patients we identified 69 patients with AKI; 39 (56.5%) were males. The mean±SD age was 40.5±17.4 years. Serum creatinine and blood urea levels on admission were 14.7±6.7 and 245±125 mg/dl, respectively. Serum creatinine and blood urea levels at discharge were 2.5±2.1 and 53±32 mg/dl, respectively. 29 patients (42%) experienced recovery of normal renal function; the recorded mortality was 13 %; AKI causes.

Conclusions: AKI has become increasingly prevalent in developing countries, and is associated with severe morbidity and mortality. Many causes of AKI can be prevented by interventions at the individual, community, and regional levels. Efforts should be directed to eradicate causes of AKI, expedite diagnosis, and aggressively manage pre-renal conditions and specific infections.

SA-PO235

Usefulness of Presepsin, Procalcitonin and IL6 as Biomarkers of Adverse Renal Outcome and Mortality After Cardiac Surgery

Alessandra Brocca, Grazia Maria Virzi, Maria Jimena Muino-Bermejo, Davide Giavarina, Massimo de Cal, Claudio Ronco. S Bortolo Hospital, Vicenza.

Background: Cardiac surgery (CS) is now possible in increasingly high-risk patients (pts). Accurate evaluation of surgical risk is crucial. Mortality and negative impact on distant organs must be evaluated. In a large number of clinical scenarios, biomarkers have been proven to be reliable tools in clinical settings either for single a single biomarker or a biomarker panels. Presepsin has been reported to be useful for stratifying mortality risk among septic pts in the ICU and thus it may also be helpful in many different clinical situations. Procalcitonin is related to the development of postoperative complications. IL6 is considered to be a major mediator of the acute phase response to cardiopulmonary bypass. The main aim of this study is to assess the usefulness of Presepsin, Procalcitonin and IL6 as biomarkers in predicting mortality and negative renal outcome among CS pts.

Methods: Observational single center study that includes 122 adult CS pts. Blood samples were collected at the second day after surgery. Presepsin was tested by the PATHFIST Immunoanalyzer system, Procalcitonin by BRAHMS PCT sensitive KRYPTOR and IL6 by ELISA assay. A p-value of <0.05 was considered statistically significant.

Results: We observed that Presepsin and IL6 are better predictors of inhospital mortality (AUC=0.831 and 0.819), 30-day mortality (AUC=0.723 and 0.785) than global mortality (AUC=0.759 and 0.793) than Procalcitonin (p<0.05). Pts with worse renal outcome (defined as AKI, expedite diagnosis, and aggressively manage pre-renal conditions and specific infections.

Conclusions: These results indicate that sepsis induces tubular cell proliferation in the condition with less cell death. In the present study, we examined the time-course changes in tubular cell proliferation after sepsis.

Funding: Government Support - Non-U.S.

SA-PO236

Allopurinol Attenuates Rhabdomyolysis-Induced Acute Kidney Injury: Renal and Muscle Protection

Background: Myoglobinuric acute kidney injury (AKI) is the most severe complication of rhabdomyolysis. Aim: To evaluate the efficacy of allopurinol (Allo) on rhabdomyolysis-induced AKI.

Methods: Male Wistar rats were injected intramuscularly with 5mg/Kg body weight (BW) of either 50% glycerol (Gly) or 0.9% saline (S). Five groups were studied: S(n=5), S+Allo(n=6), Gly(n=7), Gly+Allo(n=7), Gly+ivAllo(n=7). S and Gly=Allo rats received Allo(300mg/L) in drinking water 7 days prior to and for 24h after Gly/Injection/Gly+ivAllo; intravenous Allo(50mg/Kg BW) 30’ after Gly injection and 300mg/L in drinking water thereafter.

Results: Gly rats showed markedly reduced glomerular filtration rate (GFR,imulin clearance) associated with renal vascounstruction,renal tubular damage,increased oxidative stress,apoptosis and inflammation. Allo treatment ameliorated all these alterations. Allo reduced muscular oxidative stress and accelerated its recovery.

Conclusions: These results indicate that sepsis induces tubular cell proliferation in the condition with less cell death. In the present study, we examined the time-course changes in tubular cell proliferation after sepsis.

Funding: Government Support - Non-U.S.

SA-PO237

Cell Cycle Progression in the Early Phase of Septic Kidney

Daisuke Nakano, Akira Nishiyama. Dept of Pharmacology, Kagawa Univ, Kagawa, Japan.

Background: The recovery of renal function after acute kidney injury (AKI) is likely controlled by proliferation of surviving tubular cells in damaged nephrons containing cell death or sloughing. However, recent studies revealed that AKI concomitant with sepsis has significantly less tubular cell death than other forms of AKI, such as ischemic- and drug-induced AKI. It has not been examined whether septic AKI accelerates tubular cell proliferation in the condition with less cell death. In the present study, we examined the time-course changes in tubular cell proliferation after sepsis.

Methods: Lipopolysaccharide (LPS) and cecum ligation and puncture (CLP) model were used to induce sepsis in mice. Cell cycle progression was assessed by intravital imaging of Tg(FucciG1)#596Bsi (Fucci) mice, which express monomeric Kusabira-Orange2 in G1/0 phase cells, and immunohistochemistry for Ki67 or bromodeoxyuridine staining were increased only in young mice (Ki67- cell number: 1.5±0.1 fold increase in both LPS and CLP mice compared to normal control), not in old mice (Ki67- cell number: 0.8±0.1 fold in LPS mice and 1.0±0.1 fold in CLP mice compared to normal control) at a similar time point observed in Fucci mice. Etoposide, an anti-cancer drug, abolished the cell proliferation after LPS injection in young mice. Importantly, old mice or etoposide-treated young mice showed much worse AKI as compared to young mice at 24h after sepsis. Moreover, mice lacking p21, a cyclin-dependent kinase inhibitor, compared to the control) at a similar time course observed in Fucci mice. Etoposide, an anti-cancer drug, abolished the cell proliferation after LPS injection in young mice. Importantly, old mice or etoposide-treated young mice showed much worse AKI as compared to young mice at 24h after sepsis. Moreover, mice lacking p21, a cyclin-dependent kinase inhibitor, showed a marked increase in Ki67- cells after LPS (2.2±0.1 fold increase vs. WT mice).

Conclusions: These results indicate that sepsis induces tubular cell proliferation in the early-phase of septic kidney. This situation may be a compensatory mechanism against the development of AKI since the frequency of cell proliferation is inversely correlated with the severity of sepsis. Moreover, cell senescence may worsen this compensation leading to an increased risk of AKI.

Funding: Government Support - Non-U.S.
Hepcidin Mitigates Endotxin-Induced AKI

Paromita Dey, Sundararaman Swaminathan.

Background: Sepsis is a common cause of acute kidney injury (AKI). Sepsis-associated inflammation induces hypoferrerna and thereby limits iron availability to pathogens. It has been shown that hepcidin-induced degradation of ferroportin and consequent iron restriction are key for this hypoferrernaic state. Since iron has been implicated in the pathogenesis of both sepsis and AKI, we hypothesized that hepcidin pretreatment would mitigate bacte rich endotxin-induced AKI.

Methods: C57BL/6 were treated with saline or 50 mg of hepcidin, 24 hours prior to LPS (Escherichia coli O111:B4) injection (6.5 mg/kg). Renal function, injury and inflammation markers were examined up to 24 hours post LPS injection. Mouse glomerular endothelial cells (MGEc) were cultured with 100 ng/mL LPS for 6 hours after treating with and without 1 mg/mL hepcidin for 12 hours.

Results: Kidney function (as measured by serum BUN) significantly declined 2 hours post LPS injection and progressively deteriorated for 24 hours. This was prevented by hepcidin treatment (BUN: LPS; 83.55 Vs HEP = 32.33, p < 0.001). Renal injury (BUN/kg: LPS 55 Vs HEP = 27.08, p = 0.004) and inflammation markers were also reduced. Mouse glomerular endothelial cells cultured with 100 ng/mL LPS were also reduced. Mitochondria in LPS treated mice, which was prevented by hepcidin treatment. However, MGEc cultures treated with or without hepcidin up-regulated endothelin gene to similar levels after stimulation with LPS.

Conclusions: Our findings demonstrate a novel protective role of hepcidin in endotxinmediated AKI, which is largely exerted through down regulation of systemic cytokine production.

SA-PO239

ELK-B Peptide Prevents Renal Histological Damage and Mortality in Septic Mice

Anna C. Souza, 1 Irina Baranova, 1 Jonathan Street, 2 Xuzhen Hu, 1 Peter S.T. Yutzy, 1 Robert A. Star.

1Kidney Disease Branch, NIDDK, NIH, Bethesda, MD; 2Clinical Center, NIH, Bethesda, MD.

Background: Targeting SR-BII and CD36 receptors with 37-step peptide, an antagonist peptide, reduced multi-organ failure, peritoneal bacterial counts, and increased survival from 6 to 27% in antibiotic-treated mice subjected to cecal ligation and puncture (CLP)-induced sepsis (J Immunol. 2012). We tested ELK-B, a peptide more specific to the CD36 receptor.

Methods: Because the free peptide was toxic, ELK-B was formulated with micellar 1-palmitoyl-2sn-glyceryl-3-phosphocholine. For survival study, animals were randomized into two groups: CLP (N=16) and CLP+ELK-B (15 mg/kg, N=15). A blinded observer administered treatments every 12h until death or until euthanized per protocol. For acute studies, 10 mice/group were subjected to CLP+saline (CLP) or CLP+ELK-B; saline or ELK-B was administered IV 0 and 6h after CLP. 18h post-CLP mice were euthanized for peritoneal lavage, and blood/organisms collection. Serum creatinine (Cr) was measured by HPLC, BUN by colorimetry, and AST, ALT by an autoanalyzer. PAS-stained kidney sections were scored for renal tubular damage. Peritoneal bacterial cell counts were enumerated by microscopy. Caspase-3 IHC was performed on spleens. Data were analyzed by ANOVA and log-rank test.

Results: ELK-B significantly increased survival: all CLP+vehicle mice died by 78h, whereas 31% of ELK-B treated mice were still alive at 7 days. The survival curves did not diverge until 36h. At 18h (before survival curves diverged), ELK-B did not alter Cr (sham, CLP, CLP+ELK-B 0.07±0.01, 0.30±0.06, and 0.21±0.06 mg/dl); BUN, AST, or ALT.

Conclusions: ELK-B reduced 7 day mortality and 18h renal histological damage after sepsis. However, it did not alter other biochemical outcomes at 18h. That suggests that it may act late in sepsis, perhaps by increasing bacterial killing.

Renal Ischemic Preconditioning Prevents Protections against Septic Acute Kidney Injury via miR-21

Ping Jia, 1 Yi Fang, 1 Mingyu Liang, 1 Xiaoqiang Ding, 1 Dept of Nephrology, Zhongshan Hospital, Fudan University, China; 2Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: Septic acute kidney injury(AKI) is one of the most common and life-threatening complications in critically ill patients, and there is no approved effective treatment. We have shown ischemic preconditioning upregulates miR-21, provides renoprotection against subsequent ischemia reperfusion injury. Here we studied the effects of renal ischemic preconditioning on septic AKI and its mechanisms.

Methods: Bilateral renal pedicles were clamped for 15 min in mice before the induction of septic AKI, and septic AKI was induced by intraperitoneal injection of lipopolysaccharide. The effects of renal ischemic preconditioning on LPS-induced AKI were investigated, including changes of renal function, histology, inflammation and apoptosis in kidneys. The AKI was induced by cecal ligation and puncture in mice. The ischemic preconditioning was examined using in vivo knockdown of miR-21 and miR-21 signaling pathways were analyzed.

Results: We observed that renal ischemic preconditioning provided morphological and functional renoprotection, characterized by attenuation of renal tubular damage, cell apoptosis, and a reduction in inflammation in circulation. Furthermore, we found that renal ischemic preconditioning significantly upregulated the expression of miR-21 in kidneys, suppressed proinflammatory factor PDDC4 expression and NF-kB activity, increased renal production. Meanwhile, renal ischemic preconditioning also suppressed the expression of PTEN which is a proapoptotic protein, activating Akt signaling pathway, subsequently increasing the expression of Bcl-2 and inhibiting Caspase-3. A locked nucleic acid-modified anti-miR-21, given before renal ischemic preconditioning, knocked down miR-21 effectively, and upregulated its target effector PTEN expression, resulting in increase of apoptosis, exacerbated LPS-induced AKI.

Conclusions: Our findings demonstrate that renal ischemic preconditioning protects against LPS-induced AKI, and miR-21 coordinates its downstream signaling to reducing cell apoptosis and circulatory inflammation, contributing to renal protection.

Funding: NIDDK Support, Veterans Administration Support
Background: Anti-tumor efficacy of cisplatin chemotherapy is mainly limited by its toxicity to normal tissues, particularly the kidney toxicity. Tubular apoptotic cell death significantly contributes to the pathogenesis of cisplatin-induced acute kidney injury (AKI). KCa3.1, a calcium-activated potassium channel, has been reported to participate in cell apoptosis. However, the involvement of KCa3.1 in cisplatin-induced AKI is unknown.

Methods: We examined KCa3.1 mediates cisplatin-induced tubular apoptotic cell death in vitro, as well as the development of cisplatin-induced AKI in KCa3.1- and pharmacological blockade mouse models in vivo.

Results: Cisplatin treatment triggered an early induction in KCa3.1 expression, which is associated with apoptotic cell death in HK-2 cells, as well as with the development of renal tubular damage and cell apoptosis in mice. By treating with highly selective blocker TRAM-34, we found KCa3.1 inhibition suppressed cisplatin-induced apoptotic cell death in HK-2 cells. In the in vivo study, KCa3.1 deficiency reduced renal function loss, renal tubular damage and apoptotic marker caspase-3 induction in kidneys after cisplatin administration in KCa3.1-/- mice. Pharmacological blockade of KCa3.1 by TRAM-34 similarly attenuated cisplatin-induced AKI in mice. Furthermore, we dissected the underlying mechanisms in which KCa3.1 blocking reduces cisplatin-induced apoptosis. We found KCa3.1 inhibition attenuated the cytochrome c release and the increase of intrinsic apoptotic mediator Bax, Bcl-2 and caspase-9 after cisplatin treatment. We also found KCa3.1 blocking inhibited the increase of ER stress mediator caspase-12, which is independent of calcium-dependent protease m-calpain activation.

Conclusions: Blockade of KCa3.1 protects against cisplatin-induced AKI through the attenuation of tubular apoptosis by interference with intrinsic apoptotic and ER stress-related mediators, and that provides a potential target for the prevention of cisplatin-induced AKI.

SA-PO244
Bax Mimotope Therapy: Effective Treatment for Ischemic Acute Kidney Injury (AKI) Zhiyong Wang, Ryan M. Mulhern, Andrea Havasi, Ramon G. Boneglio, Stephen C. Borkan. Renal Section, Boston Univ Medical Center; Boston, MA.

Background: Ischemic AKI causes renal cell death partly by Bax-mediated apoptosis. Recent studies show that Bax requires the chaperone nucleoschlinoposin (NPM) for mitochondrial targeting and apoptosome formation. We propose that a mimotope that interferes with Bax-NPM interaction is an effective treatment for ischemic AKI.

Methods: To assess mimotope efficacy, 2 mg control or therapeutic Bax mimotope was administrated by a single tail vein injection in 6-week old B6 mice either before or after renal ischemia caused by 20 min of bilateral renal pedicle clamping, an insult that produces severe AKI. BUN/Cr, histologic injury score, caspase 3 activity, Bax activation and Bax-NPM interaction were compared in each experimental group at the above time points (n = 8 each group).

Results: Compared to control, Bax mimotope administration 15 min before or 15 min, 1.2 or 3 h after ischemia significantly improved renal function. No protection was observed if Bax mimotope exposure was delayed for 4 or more hours after ischemia. Although 12% of controls died of AKI, only 2% of animals died in the Bax mimotope groups. Despite equivalent Bax activation in both groups, the Bax mimotope improved histologic injury score, reduced caspase 3 activation and decreased Bax-NPM interaction as assessed by co-immunoprecipitation.

Conclusions:Selective interference of Bax-NPM interaction with a Bax mimotope decreases AKI mortality and ameliorates ischemia-induced renal injury.

SA-PO245
Role of AMPK in Aristolochic Acid-Induced Acute Kidney Injury Anne-Emilie Deleyes, Inês Jatobá, Vanessa Colombo, Eric De prez, Isabelle Habisch, Kumar Sharma, Nathalie Caron, Joelle L. Nortier. Free Univ of Brussels; Brussels, ‘Namur; ‘Univ of California, San Diego.

Background: Experimental aristolochic acid nephropathy (AAN) is a pertinent model of tubulo-interstitial nephritis characterized by an early phase of acute kidney injury (AKI) with marked tubular injury and a subsequent chronic kidney disease (CKD). In this report, we determined the role of AMPK in renal injury and its involvement in the AKI-to-CKD transition.

Methods: C57BL/6J male mice were randomly subjected to i.p. injection of either sterile saline solution, AA, AAMC (the specific AMPK activator) or AAMC (the specific AMPK inhibitor) for 4 days. Mice were then euthanized either at day 5 or day 20.

Results: AA-treated mice displayed loss of renal function, as reflected by significant increases in plasma creatinine levels and proteinuria at days 5 and 20. In addition, impairment of tubular cells was evidenced by increased urinary lysozymal enzyme N-acetylβ-D-glucosaminidase in AA-treated mice. These changes were prevented by AICAR treatment. To further determine the role of AMPK in AA-induced effects, renal function (Nov 2, and 4) were investigated and showed significant increases in plasma creatinine levels were observed for Nov 2 and 4. However, Nov 2 was significantly increased in AA-treated mice while this rise was prevented by AICAR treatment at day 5 but not at day 20. Moreover, the urinary hydrogen peroxide level, a stable product of ROS production, was significantly higher in AA intoxicated and reduced with AICAR. Regarding inflammation, AA mice exhibited a significant increase in MCP-1 mRNA level. This rise was only prevented by AICAR at day 5. Finally, at day 5, there was no significant macrophage infiltration with AICAR while at day 20, this significant increase was not prevented by AICAR.

Conclusions: These findings suggest a beneficial effect of AMPK against AA-induced AKI. In view of these data, we suggest that chronic AICAR treatment is necessary for complete nephroprotection and recovery. The activation of AMPK represents a potential strategy to prevent the transition from AKI-to-CKD.

Nrf2 Activation in Tubular Cells Prevents Progression of AKI to CKD Masahiro Neno, Tomokazu Souma, Sadayoshi Ito, Norio Suzuki, Masayuki Yamamoto. Dept of Medical Biochemistry, Tokohu Univ Graduate School of Medicine, Sendai, Miyagi, Japan; Div of Nephrology, Endocrinology, and Vascular Medicine, Tokohu Univ Graduate School of Medicine, Sendai, Miyagi, Japan; Div of Interdisciplinary Medical Science, Tokohu Univ Graduate School of Medicine, Sendai, Miyagi, Japan.

Background: Acute kidney injury (AKI) is one of the major risk factors for chronic kidney disease (CKD). Reactive oxygen species are generated by ischemia-reperfusion injury (IRI) during transition of AKI to CKD, and oxidative stress contributes to defects of renal tubular cells. Nrf2 is a master transcription factor for cellular defense against oxidative stress and on an E3 ubiquitin ligase substrate Keap1 negatively regulates Nrf2 activity. Here, we evaluated protective roles of the Keap1-Nrf2 system in AKI-to-CKD transition.

Methods: Unilateral ischemia reperfusion injury (UIRI) was performed to induce rodent model of AKI-to-CKD. Hyperoncism Keap1 knockout mutant (KDK) and tubular-specific Keap1-mutant (TKO) mice were used for genetic activation of Nrf2. A Keap1 inhibitor CDDO-Im was used for pharmacological activation of Nrf2.

Results: Remaining tubular areas at 14 days after URI were 64%, 51% and 34% in KDK, TKO and wild-type mice, respectively compared with their contralateral kidneys. CDDO-Im treatment after URI to wild type mice also protected against tubular defects (CDDO-Im, 63%). Nrf2-irreducible antioxidant enzymes (Nqo1, Hmox1, Gclc, Gclm, and Srxn1) were transiently up-regulated in 3-6 hours after URI in wild-type mice, while both genetic and pharmacological activation of Nrf2 maintained expression of these genes at high levels throughout the observation period.

Conclusions: Activation of Nrf2 alleviates IRI-induced tubular loss through enhancing the antioxidant response system. Nrf2 inducers are one of prospective therapeutic candidates for preventing AKI-to-CKD transition.

SA-PO247
Acute Kidney Injury in the Rat Is Prevented by Pirfenidone Isabella Quezalizalli Lima Posada, Quetzaliztli Decleves, Zhiyong Wang, Heng Pao. Renal Section, Boston Univ Medical Center, Boston, MA; Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; Div of Interdisciplinary Medical Science, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.

Background: Pirfenidone (PFN) is an orally active small molecule which acts mainly through an anti-fibrotic effect, but also possesses antioxidant and anti-inflammatory properties. This study was designed to evaluate the effect of the prophylactic treatment with PFN on acute kidney injury (AKI) due to bilateral renal ischemia (IR) in the rat. Six groups of rats, 12 rats/group (S) and 21 rats undergoing 20 min of ischemia and 24-h of reperfusion and, 3 rats treated with PFN (700 mg/kg), 24-h before ischemia (IR-PFN). Serum creatinine, creatinine clearance (CrCl) protein excretion, urinary levels of Hsp72 (UHsp72V) and nitrates and nitrates (UNO2/NO3V) were assessed. Mean arterial pressure (MAP) and renal blood flow (RBF) were recorded 24-h after surgery. Tubular injury (TI) was evaluated in fixed kidneys by counting the cast number and the number of injured tubules per field.

Results: As expected, the IR group showed a reduction in CrCl (IR: 0.92 ± 0.04 vs. S: 0.73 ± 0.06 mmol/100 g BW; p < 0.05), urinary output (IR: 20.9 ± 5 vs. S: 32.7±19.3 ml/24-h; p < 0.05), RBF (IR: 1.08 ± 0.37 vs. S: 1.53±0.17 ml/min/100 g BW; p < 0.05), and a significant increase in urinary Hsp72 assessed by Western blot. Extensive TI was evidenced by histological analysis. These alterations were associated with a decrease in UNO2/NO3 (IR: 3.1±1.3 vs. S: 5.4±2.5 mmol/24-h; p < 0.05). In contrast, IR-PFN group showed restoration of CrCl (1.03±1.04 mmol/100g BW; p < 0.05), urinary output (47.5±5.7 ml/24-h; p < 0.05), RBF (1.51±0.15 ml/min/100g weight; p < 0.05). The levels of urinary Hsp72 were undetectable or very low and the histological signs of TI were significantly reduced. Interestingly, UNO2/NO3 was completely reversed (7.05±0.78 mmol/24-h; p < 0.05).

Conclusions: Our results revealed that pre-treatment with PFN prevents AKI in the rat. Part of its renoprotective effects seems to be related with the restoration of NO production. These findings suggest that PFN could be a promising tool in the prevention of AKI. In view of these data, we suggest that chronic AICAR treatment is necessary for complete nephroprotection and recovery. The activation of AMPK represents a potential strategy to prevent the transition from AKI-to-CKD.

HDAC8 Plays a Critical Role in the Epigenetic Activation of Fibroblasts and the Pathogenesis of Renal Fibrosis
Scott R. Mansson, Qiusha Guo, Katelynn H. Moore, Paul F. Austin. Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.

Background: The development of renal fibrosis is associated with changes in the expression of approximately 10% of the genome, suggesting widespread transcriptional dysregulation. Nonetheless, the roles of critical epigenetic pathways in disease progression remain poorly understood. Here, we examine the biological and therapeutic importance of histone deacetylases (HDACs) in the function of fibroblasts and the pathogenesis of renal fibrosis.

Methods: Renal fibrosis was modeled in vivo by treatment of NRK-49F fibroblasts with the pro-fibrotic cytokine TGF-β and in vivo in mice by unilateral ureteral obstruction (UUO). The role of HDAC proteins was assessed by treatment with the broad spectrum HDAC inhibitor Trichostatin A (TSA) and the HDAC-specific inhibitor PCI-34051. The translational relevance of these findings was assessed in patients who underwent a nephrectomy following UPI obstruction.

Results: UUO leads to a 6.1-fold increase in HDAC8 expression that localizes specifically to myofibroblasts. In NRK-49F cells, treatment with PCI-34051 promotes myofibroblast differentiation and apoptosis, but suppresses proliferation and matrix synthesis. These findings extend to the injured kidney in vivo, where HDAC8 inhibition results in a 41.6% decrease in COL1A1 and a 61.6% decrease in α-SMA. Furthermore, there is a 77.9% decrease in the interstitial proliferative response, a 43.0% decrease in myofibroblast number, and a 31.1% decrease in renal fibrosis. Finally, the development of renal fibrosis in patients with obstructive kidney disease is associated with a 32.1% increase in the number of HDAC8-positive cells.

Conclusions: Together, these findings demonstrate that HDAC8 plays a critical role in regulating fibroblast activation. Treatment with HDAC inhibitors is also an effective therapeutic approach to reverse the epigenetic changes associated with the pathogenesis of renal fibrosis. Finally, since an increase in HDAC8 expression occurs in patients during disease progression, HDAC8-targeted therapies have therapeutic potential for the treatment of chronic kidney disease.

Reciprocal Effects of HDAC1 and HDAC2 Deletion on Renal Ischemia-Reperfusion Injury
David Dean Aufrichtig, Zhonglin Wang, Guanghui Ge, Tricia Bhatt, Wayne W. Hancock, Matthew H. Levine. Surgery, Hospital of the Univ of Pennsylvania and the Children’s Hospital of Philadelphia, Philadelphia, PA; 2Pathology and Laboratory Medicine, The Children’s Hospital of Philadelphia, Philadelphia, PA; 3Pathology and Laboratory Medicine, Hosptal of the Univ of Pennsylvania, Philadelphia, PA.

Background: Histone/protein deacetylase proteins (HDACs) have been implicated in renal ischemia-reperfusion injury (IRI). HDACs 1 and 2 are highly homologous Class I HDACs thought to have similar function.

Methods: This study included wild type C57BL/6 (B6) and inducible HDAC1- or 2- gene deleted mice (HDAC1KO and HDAC2KO). Renal-specific or extra-renal gene deletion was achieved with transplantation, native nephrectomy, and subsequent gene deletion. Warm IRI consisted of unilateral clamping of the renal pedicle and contralateral nephrectomy. Cold IRI was achieved through procurement, controlled interval of cold storage, and transplantation.

Results: HDAC1KO mice had impaired renal IRI tolerance compared to controls with higher BUN levels (p<0.01; Figure 1A) and increased fibrosis post-injury. HDAC2KO mice had improved early renal function (p=0.01; Figure 1B) and decreased fibrosis (p=0.01) compared to controls and tolerated extended periods of ischemia. In transplant models, renal-specific HDAC2KO mice had superior IRI tolerance with less renal impairment (p<0.01) and decreased fibrosis (p=0.01) compared to extra-renal HDAC2KO and controls. After transplantation with 18 hours of cold ischemia, HDAC2KO donor kidneys had improved BUN (p=0.02) and survival compared to controls.

Conclusions: HDAC1 and 2 have reciprocal effects on murine renal IRI tolerance, with HDAC1 deletion increasing vulnerability and HDAC2 deletion providing protection. The effect of HDAC2 deletion is profound, is intrinsic to the kidney, and extends to cold ischemia and renal transplantation.

Renoprotective Effect of Long Acting Thioredoxin by Modulating Oxidative Stress and Macrophage Migration Inhibitory Factor against Rhabdomyolysis-Associated Acute Kidney Injury
Hiroshi Watanabe, Kento Nishida, Masafumi Fukagawa, Toru Maruyama. 1Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kamamoto Univ, Kamamoto, Japan; 2Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Kanagawa, Japan.

Background: Rhabdomyolysis-associated acute kidney injury (AKI) is a serious life-threatening condition. As such, more effective strategies are needed for its prevention and treatment. Although thioredoxin-1 (Trx) possesses superior biological activities, such as anti-oxidative and anti-inflammatory effect via the modulating macrophage migration inhibitory factor (MIF), its short blood retention limits the therapeutic application. To overcome this, we engineered a long acting Trx by genetically fused with human serum albumin (HSA-Trx), and examined its renoprotective effect against glycerol-induced AKI.

Methods: HSA-Trx was prepared by using Pichia expression system. The mouse model of rhabdomyolysis-associated AKI was induced by the administration of a 50% glycerol solution.

Results: An intravenous HSA-Trx pre-treatment attenuated the glycerol-induced decline in renal function, compared to a PBS, HSA or Trx alone. HSA-Trx caused a reduction in the tubular injuries and in the number of apoptosis-positive tubular cells. Renal superoxide, 8-hydroxy deoxyguanosine, nitrotyrosine and the plasma Cys34-cysteinylated albumin were clearly suppressed by the HSA-Trx treatment. Prior to decreasing TNF-α and IL-6, HSA-Trx suppressed an increase of plasma MIF level. In LLC-PK1 cells, HSA-Trx decreased the level of reactive oxygen species and lactate dehydrogenase release induced by myoglobin. HSA-Trx treatment resulted in a threefold increase in the survival of lethal glycerol-treated mice. The post-administration of HSA-Trx at 1 and 3 hr after glycerol injection exerted a significant renoprotective effect.

Conclusions: HSA-Trx, a long acting Trx, has potential for use in the prevention and treatment of rhabdomyolysis-associated AKI via its extended effects of modulating oxidative stress and MIF.

Selective Endothelin-A Receptor Antagonism Prevents the Progression of Acute Kidney Injury to Chronic Kidney Disease
Neeraj Dhan, Queen’s Medical Research Inst, Univ of Edinburgh, Edinburgh, United Kingdom.

Background: AKI is common and associated with significant morbidity and mortality. AKI often progresses to CKD. Endothelin-1 (ET-1) contributes to this. We hypothesized that therapeutic administration of selective ET-A receptor antagonism would protect from the transition of AKI to CKD.

Methods: 28 FVB mice underwent prolonged (50min) unilateral ischemia-reperfusion injury (IRI) with 28d recovery. 14 mice received daily selective ET-A antagonism (sitaxentan) starting 24h after IRI. We assessed blood pressure (BP) via telemetry, vascular function, renal injury and measures of the ET system.

Results: Systolic BP increased by ~5mmHg after IRI and was associated with vascular dysfunction in both resistance and conduit vessels. Sitaxentan partially prevented both of these. At 28d after IRI kidney weight was reduced (~55%) and associated with significant macrophage infiltration and fibrosis compared to the contralateral control kidney. Mice treated with sitaxentan had normal kidney weight, reduced macrophage infiltration and less IRI. IRI kidney vs. control kidney with sitaxentan: F4/80 stain/high power field: 2.5X vs. 0.2X, p<0.001; p<0.001. For both macrophage infiltration and fibrosis, p<0.05 for IRI vs. control and for IRI+ET-A with sitaxentan, p=ns for control vs. IRI with sitaxentan. Furthermore, an up-regulation of both the ET-A and ET-B receptors as well as pre-pro-ET-1 (100-fold) mRNA was seen in both the cortex and medulla of the IRI kidney relative to control. With sitaxentan treatment ET, ET-A receptor and pre-pro-ET-1 mRNA remained similar to baseline levels. Finally, renal ET-1 production increased following IRI and this was prevented by ET-A receptor antagonism (fractional excretion of ET-1; IRI+ET-A with sitaxentan: 47X vs. 16X, p<0.05).

Conclusions: In an in vivo model of AKI progressing to CKD, ET-A receptor antagonism reduced BP and vascular dysfunction and prevented progression of renal injury and ET system activation after AKI. Therefore, selective ET-A receptor antagonism offers a potentially novel therapy for AKI. Translational studies are now warranted.

Inhibition of Vascular Adhesion Protein-1 Suppresses Neutrophil Infiltration and Preserves Renal Function in the Rat Model of Renal Ischemia–Reperfusion Injury
Shinji Tanaka, Tetsuhito Tanaka, Reiko Inagi, Masaomi Nangaku. Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.

Background: Vascular adhesion protein-1 (VAP-1) is an adhesin expressed in endothelial cells. With its unique properties as an ectoenzyme which catalyzes oxidative deamination of primary amines, VAP-1 plays a critical role in leukocyte trafficking. In light of a growing body of evidence that VAP-1 controls inflammation in various organs, such as the liver and the lung, we examined the effect of VAP-1 inhibition in the rat model of renal ischemia–reperfusion injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

684A
Methods: Rats were subjected to left renal ischemia for 45 min after right nephrectomy, followed by 24 and 48 h of reperfusion. A specific VAP-1 inhibitor, RTU-1096 (R-Tech Ueno, Tokyo, Japan), or vehicle was administered to rats since 7 days before the surgery (mixed with feed, 40 mg/kg/day).

Results: Immunofluorescence studies suggested that VAP-1 is expressed not only in endothelial cells but also in intracellular components of non-endothelial lineage. In vitro, higher mRNA expression of VAP-1 was confirmed in cultured pericytes. In vivo, VAP-1 enzyme activity in the whole kidney was unaffected by the surgery, but following VAP-1 inhibition by RTU-1096 (0.9/0.1 vs. 7.0/1.1 pmol protein/mg/min), renal injury was significantly reduced compared to the vehicle group as assessed by the levels of serum creatinine 69.16 vs. 139.15 mg/dl, Cr: 1.4±0.1 vs. 2.5±0.2 mg/dl; P<0.01), which was accompanied by amelioration in histological tubular damage and decreased KIM-1 mRNA levels. Immunohistochemical analysis revealed a significantly decreased number of neutrophils in the corticomedullary junction in the drug group, whereas the number of macrophages was similar. VAP-1 inhibition resulted in significantly lower mRNA levels of CXXCL1 and CXXCL2 in the kidney without affecting chemokines involved in macrophage recruitment, such as MCP-1, or major adhesion molecules, VCAM-1 and ICAM-1.

Conclusions: These data suggest that VAP-1 plays an important role in renal ischemia-reperfusion injury by controlling neutrophil infiltration, and offer a promising view that its inhibition can be a novel therapeutic target in ischemic acute kidney injury.

Kim-1 Overexpressing Transgenic Zebrafish Identify mTOR as an Effector of Kim-1-Mediated Kidney Injury in Fish and Mice Wensuning Yin, Said Movahedi naini, Dirk M. Hentschel, Benjamin D. Humphreys, Joseph V. Bajwa, Diane L. Rosin, Mark D. Okusa, Rahul Sharma. Virginia, Charlottesville, VA; 2Dept of Pharmacology, Univ of Virginia Health System, Charlottesville, VA.

Background: Mammalian kidney injury molecule 1 (KIM-1), an epithelial phagocytic receptor, is markedly upregulated in the proximal tubule in various forms of acute and chronic kidney injury in humans and many other species. Here, we characterized the zebrafish homolog, Kim-1, which is highly expressed in zebrafish kidney tubules, we identified mTOR as an effector in Kim-1-mediated kidney injury. We then validated mTOR as a therapeutic target for kidney injury and fibrosis in Kim-1 overexpressing transgenic mice.

Methods: We created two transgenic zebrafish models of Kim-1 overexpression in nephrons employing the cdh17 promoter. One model utilized a constitutively active promoter while the other utilized a tamoxifen-induced Cre-ERT2 recombinase to express Kim-1 in nephrons in a temporally-controlled manner. The role of mTOR signaling was evaluated using the mTOR inhibitor rapamycin. Zebrafish GFR was determined using the elimination rate of fluorescein-labeled dextran.

Results: Kim-1 was markedly upregulated after gentamicin-induced kidney injury and had conserved phagocytic activity in zebrafish. Both constitutive and tamoxifen-induced expression of Kim-1 in zebrafish kidney tubules resulted in shedding of the tubule brush border, reduced GFR, pericardial edema and increased mortality rate. Kim-1-induced kidney injury was associated with inhibition of growth of adult fish. Kim-1 expression led to mTOR pathway activation, and inhibition of this pathway with rapamycin increased survival. mTOR pathway inhibition in Kim-1 overexpressing transgenic mice also significantly reduced serum creatinine, proteinuria, tubular injury and kidney inflammation.

Conclusions: Persistent Kim-1 expression resulted in chronic kidney damage and growth impairment in zebrafish. Kim-1-mediated kidney tubular injury was mediated by the mTOR signaling pathway. This observation in zebrafish predicted a role of the mTOR pathway and therapeutic efficacy of rapamycin to protect the mouse kidney against Kim-1-mediated kidney injury and fibrosis.

Treg and ILC2 Contribute to IL233 (a Novel Fusion Cytokine)-Mediated Protection in AKI Maria Stremiska1, Liping Huang, Sheethal Jose, Amandeep Bajwa, Diane L. Rosin, Mark D. Okusa, Rahul Sharma. 1CHIR, Univ of Virginia, Charlottesville, VA; 2Dept of Pharmacology, Univ of Virginia.

Background: Inflammation is an early event in AKI and studies have shown regulatory T cell (Treg)-mediated protection in inflammation driven injuries. Since we found that intraperitoneal injection of IL233 receptor-ST2/CD48 double-null mice (CD48−/−) protected mice from IL-2 and IL-33 in combination or as IL233 fusion cytokine, but not alone protected mice from IR injury, with IL-233 being more efficient than the combination.

Methods: We designed a fusion cytokine (IL233) containing the activities of IL-2 and IL-33 for better targeting of Tregs. The cytokines were expressed in E.coli, purified to homogeneity and tested in a mouse model of ischemia reperfusion injury (IR). C57BL/6 male mice were pretreated (ip) with different doses of cytokines prior to 24 h of bilateral renal ischemia and 24 h of reperfusion. Kidneys were characterized for function, acute tubular necrosis and the profile of infiltrating cells.

Results: IL-2 and IL-33 in combination or as IL233 fusion cytokine, but not alone protected mice from IR injury. We speculate that IL233 being most potent, the effect in mice injected with Tregs obtained from mice pretreated with IL233. Adoptive transfer of IL233-pretreated Tregs also protected against IR injury. In vivo experiments with IL233-pretreated Tregs revealed their higher protective function.

Conclusions: Thus, IL233 cytokine attenuates kidney inflammation to protect from IR injury and bears strong potential to be a therapeutic agent for AKI.

Vagus Nerve Stimulation (VNS) Protects Kidneys from Ischemia-Reperfusion Injury Through Alpha 7 Nicotinic Acetylcholine Receptor (α7nAChR) Expression Splenocytes Tsuyoshi Inoue, Chikara Abe, Stefan Moscu, Liping Huang, Hong Ye, Diane L. Rosin, Patrice G. Guyenet, Mark D. Okusa. 1Dept. of Medicine, Univ of Virginia Health System; 2Dept of Pharmacology, Univ of Virginia Health System, Charlottesville, VA.

Background: The nervous and immune systems interact in complex ways to maintain homeostasis and respond to stress or injury. The inflammatory reflex referred to as the cholinergic anti-inflammatory pathway (CAP) modulates innate and adaptive immunity, and stimulation of the reflex by VNS is effective in inflammatory disease models. The effect of VNS on AKI has never been examined. Experimental activation of vagal effector fibers suppresses inflammation in a manner that depends on α7nAChR in the CAP. However, the site of the essential α7nAChR was not established.

Methods: We applied electrical VNS (5 Hz, 50 μA for 10 min) 24 hr prior to kidney injury and assessed kidney injury by evaluating plasma creatinine (PCr, mg/dl), kidney-1 mRNA expression and histology (H&E). The effect of VNS on IR was assessed by: a) prior spleenectomy and b) adoptive transfer of splenocytes from VNS-stimulated mice to recipient mice subjected to IR injury.

Results: VNS applied 24 hr prior to IR markedly attenuated IR injury. VNS reduced the IR-induced increase in PCr by 65% (P<0.01) and Kim-1 mRNA expression in whole kidney by >70% (P<0.01). H&E-stained kidney sections confirmed the functional data. When spleenectomy was performed 7 days before VNS and IR, the protection of VNS was abolished. Adoptive transfer of splenocytes from VNS-treated mice to recipient mice subjected to IR provided greater protection than splenocytes from mice who received sham VNS stimulation (PCr: 0.41 and 1.54 (P<0.001) for VNS- and sham VNS-treated splenocytes, respectively). To evaluate the role of α7nAChR, VNS was initiated 24 hr prior to IR in α7nAChR knockout (α7KO) and WT mice. Compared to the protective effect of VNS on IR in WT mice, no protection was observed in α7KO mice. In addition, recipient mice were protected (PCr) from IR if they received splenocytes from VNS-treated WT mice (0.41) but not from VNS-treated α7KO mice (1.57, P=0.001).

Conclusions: VNS-induced protection from IR is consistent with activation of the CAP.

Elevations of Intraglomerular Pressure Exacerbate Ischemia Reperfusion Injury-Induced Acute Kidney Injury Je Zhang, Lei Wang, Shaozhi Wang, Gensheng Zhang, Jin Wei, Ruisheng Liu, Kay-Pong D. Yip. Molecular Pharmacology & Physiology, Univ of South Florida, Tampa, FL.

Background: The physiological and pathophysiological mechanisms of renal ischaemia reperfusion (IR)-induced acute renal injury (AKI) are complex and have not been elucidated. We sought to determine whether intraglomerular hydrostatic pressure (Pg) during the ischaemic phase plays a critical role in IR-induced AKI.

Methods: We created three groups of C57BL/6 mice at 37°C C with IR by 18 min of bilateral clamping of renal arteries (RA), pedicles (RP), and pedicles plus preclamping of ureters 20 min before ischemia (PU). Free flow proximal tubular pressure (Pf) was measured with servo-nulling method during ischemia. Pf was used as an index of Pg.

Results: We found that mean Pf was highest in PU mice (48.9±7.5 mmHg) than in RP mice (34.6±3.6 mmHg). The RA had lower Pf (16.1±2.3 mmHg) when compared to Sham operated mice (9.5±2.2 mmHg). In separate experiments, the renal injury was determined 24 hours after IR in these mice. Plasma creatinine was significantly increased in all three groups compared with sham-operated group. The mean plasma creatinine were 2.1±0.07 mg/dl, 1.85±0.08 mg/dl and 0.45±0.7 mg/dl for PU, PR and RA, respectively. The mean plasma Kidney Injury Molecule-1 (KIM-1) levels were 276.1±493 pg/ml in PU, 1548±220 pg/ml in PR and 734±234 pg/ml in RA group, respectively. Histology by PAS staining showed that all AKI mice had a significant increase in renal tubular necrosis compared to sham-operated mice. However, there were more tubular necrosis in the cortex, medulla or cortex-medulla junction area in PU mice (3.1±1.3%, 34.1±8.5% and 54.4±6.9%) than in RP mice (1.0±0.5%, 23.0±9.2% and 50.1±12.7%). RA mice had the least tubular necrosis (0.23±0.1%, 8.9±4.5% and 31.7±10.2%). RA mice had the highest intraglomerular pressure and most severe renal injury. These data indicate that elevations of intraglomerular and tubular pressure exacerbate IR-induced AKI. Intraglomerular and tubular pressure may be a novel therapeutic target for AKI.
GFR in Conscious Mice After Sepsis: Role of Tubuloglomerular Feedback

Jonathan Street, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. NIDDK, Bethesda, MD.

Background: Reabsorption of glomerular filtrate by the tubules is an energy intensive process. During sepsis the ability of the tubules to meet this energy demand may be impaired. To prevent renal salt wasting during sepsis it is hypothesized that activation of tubuloglomerular feedback reduces GFR and subsequently the metabolic demand on the tubules – “acute renal success”. Mice without tubuloglomerular feedback should maintain higher levels of GFR. In conscious mice we detected early changes in GFR using a novel transcutaneous measurement of a fluorescent filtration marker. Because adenosine 1a receptor (A1aR) signaling is required for tubuloglomerular feedback we directly measured GFR following sepsis in A1aR knockout mice.

Methods: Sepsis was induced in male A1aR knockout mice and littermate controls by cecal ligation and puncture. GFR was monitored in awake mice for 5 hours by planar disappearance of FITC-Sinistin, injected at 0 and 90 minutes after surgery, and its transcutaneous fluorescence measured by a miniaturized fluorimeter attached to the mouse back.

Results: The baseline GFR was similar in A1aR WT and KO mice. In WT mice, GFR was stable during the first hour following induction of sepsis. GFR slowly declined over hour two, and then fell rapidly to <10% of normal and remained low for 5 hours. In contrast, the GFR was lower in KO mice than in WT mice in the first hour following sepsis (p=0.0206), then fell gradually to 27% of normal, with a smaller decrease observed after 2 hours compared to WT mice (p=0.0286).

Conclusions: In mice lacking tubuloglomerular feedback, unexpectedly, GFR begins to decrease earlier after sepsis suggesting impaired autoregulation. The sudden decrease in GFR in WT mice at 2 hours after induction of sepsis does not occur in A1aR KO mice. Tubuloglomerular feedback modestly supports, not suppresses, GFR in the first hour following sepsis, and only later acts to suppress GFR.

SA-P0258

Renal Functional Reserve May Be Inferred from Variation of Renal Resistive Index: Preliminary Evidence Sara Samon1,2, Federico Nalessso,3 Gianluca Villa, Silvia De Rosa,1 Illaria Petrucci,1 Massimo de Cal,1 Fiorenza Ferrari,2 Alessandra Brendolan,2 Mario Meola,1 Claudio Ronco.3 Sant’Anna School of Advanced Studies, Pisa, 1IRRV, Vicenza.

Background: The increase of glomerular filtration rate(GFR)after a protein load is a renal functional reserve of the kidneys. Mechanical abdominal stress(MAS),through the compression of renal arteries and the consequent reduction of renal blood flow,cannot activate the autoregulation mechanism to maintain glomerular perfusion.Both phenomena are related to the afferent vasodilation,which can be displayed by the drop of renal resistive index(RI)measured by colorDoppler. We hypothesized that the variation of RI during MAS may predict the RFR.

Methods: In 15 healthy volunteers, MAS was performed through the application of a transcutaneous fluorimeter attached to the mouse back. According to the performed dose-response curve, we used bags which weigh 10% of subject’s BW. We recorded RI in mesorenal interlobar arteries each min for the 10 min of MAS. The RI reduction was defined by the difference between baseline RI and the lowest RI reached during MAS and expressed as percentage reduction(pDRI). GFR was measured through a standardized protein loading test. Spearman’s correlation was applied to evaluate if pDRI correlates with RFR.

Results: We enrolled 9M and 6F with a median age of 30(24-57)yrs old. The median baseline Crl was 99.2(70.3-132.8)ml/min/1.73m2. The RFR ranged between 11.55% and 134.66% with a median value of 38.55%. The median baseline RI was 0.600(0.50-0.67) while pDRI ranged between 13.3%(29.23%) with a median value of 20%. The correlation between pDRI and RFR was 0.717(p=0.001). According to physiology, RFR and pDRI may not be directly proportional; instead, while ranges of RFR may widely broaden, pDRI should reach a plateau value. For this reason, we analyzed the linear regression model between pDRI and logarithm(1/RFR). According to this model, we found that an increase in pDRI was associated to an increase in ln of RFR(0.108 = 0.001, 95%CI: 0.060 0.15 R=0.66).

Conclusions: Our results suggest that the variation of RI during MAS is an indirect measure of RFR, putting the bases for the development of a stress test that could be used for a rapid screen of RFR before potentially nephrotoxic procedures.

5-Aminolevulinic Acid Attenuates Rhabdomyolysis-Induced Acute Kidney Injury in Mice Atsushi Uchida, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.

Background: Rhabdomyolysis often occurs after severe skeletal muscle injury, and high mortality have been reported with the acute kidney injury (AKI) that develops subsequently. Thus, the establishment of effective prevention and treatment is a pressing problem. 5-Aminolevulinic acid (ALA) is the naturally occurring metabolic precursor of heme, and serves as protein material related to energy production. Previous study demonstrated that ALA has the potential to prevent cisplatin-induced AKI via the induction of heme oxygenase (HO-1), and prevention of tubular apoptosis. We hypothesize that ALA plays a renoprotective effect via the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

Methods: Male C57BL/6 mice were used. Rhabdomyolysis-induced AKI was induced by intramuscular injection of glycerol (50%) 5 ml/kg bw. ALA (30 mg/kg) was administrated at 24 hr before or 24 hr after glycerol administration. These mice were sacrificed at 72 h after glycerol injection, and the blood and renal tissues were harvested. In vitro experiment, human proximal tubule cells were stimulated by 100 μM hemin to induce apoptosis. Cells were incubated for 24 hr with or without 1 nM ALA. Apoptotic cells were examined by TUNEL staining and caspase-3 expression.

Results: In vivo experiments, serum creatinine, blood urea nitrogen and urine NGAL excretion were increased in glycerol-injected group compared with saline-injected control group. ALA significantly reduced these changes in both pre and post treatment. ALA also ameliorated glycerol-induced morphological tubular damages. HO-1 level was increased in glycerol-injected group and further up-regulated by ALA treatment. ALA significantly attenuated macrophage infiltration and pro-inflammatory cytokine (IL-1beta and TNFα) expression. In vitro experiments, TUNEL-positive cells and caspase-3 expression were increased by hemin and were significantly reduced by ALA co-treatment.

Conclusions: ALA has renoprotective effects in glycerol-injured AKI. ALA is already used for tumor diagnosis in human. So the safety of the drug is proved in clinical use. ALA treatment may be a new therapeutic target in rhabdomyolysis-induced AKI.

Ferroptosis as a Cause of Proximal Tubule Injury Joel M. Weinberg, Andreas Linkermann.1 Nephrology, VA Healthcare System Ann Arbor, Ann Arbor, MI; 2Nephrology, Univ of Michigan, Ann Arbor, MI; 3Nephrology, Christian Albrechts Univ, Kiel, Germany.

Background: ‘Ferroptosis’ has recently been described as a form of iron-dependent, lipid peroxidation-mediated cell death with a distinct injury pattern relative to other forms of necrosis and there is evidence that it contributes to AKI in vivo (PNAS 111:16835, 2014, Nat. Cell Biol. 16:1180, 2014). Here, we have refined approaches to study ferroptosis in freshly isolated proximal tubules (PT) and assessed new agents being developed to ameliorate it.

Methods: Freshly isolated rabbit (R) and mouse (M) PT were treated with either tert-butylnitroperoxide (BBN, 5 mM) or hydroxylquinoline + ferrous ammonium sulphate (HQ+Fe)10 μM each) followed by incubation for 120 min, then measurement of LDH release, malondialdehyde (MDA) production, mitochondrial membrane potential, and GSH.

Results: BBN and HQ+Fe induced progressive LDH release that was more severe in M PTs (Baa: HQ+Fe: R60.35±5.6; M 120.5±4.9, p<0.05). These changes were accompanied by 5 fold increases of MDA levels and GSH depletion. LDH release and MDA production were iron and NAPH oxidase (Nox)-dependent since they were blocked by deferoxamine or the Nox1/4 inhibitor GKT 137831. Fer-1, the prototypical ferroptosis inhibitor that emerged from chemical library screening, strongly alleviated both forms of injury and associated MDA production at concentrations of 0.1 to 2 uM as did a panel of 23 other ferrostatin analogs with potencies similar to those of Fer-1, the prototypical ferroptosis inhibitor that emerged from chemical library screening.

Conclusions: Ferroptosis is strongly expressed in fully differentiated PTs, is suppressed by both newly developed ferrostatins and the classical lipophilic antioxidant, DPPD, and is an injury process that can be targeted to alleviate AKI.

Identification and Characterization of IGFBP7 and TIMP2 Expression in Human Proximal and Distal Tubule Cells David R. Emle,1 Nuria M. Pastor-Soler,2 Allison L. Marciszycz,2 Xiaoyan Wen,1 Jacob K. Volpe,1 John A. Kellum.1 1Center for Critical Care Nephrology, Dept of Critical Care Medicine, Univ of Pittsburgh, Pittsburgh, PA; 2Renal Electrolyte Div, Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.

Background: IGFBP7 and TIMP2 have been identified as biomarkers for Acute Kidney Injury (AKI), but little is known regarding any role in the pathogenesis of the disease. To study this question we established primary cell culture models of human proximal and distal tubule epithelial cells.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: The cortex of human kidneys were dissociated and viable cells cultured. Proximal and distal tubule epithelial cells (PTECs and DTECs) were isolated with antibodies against CD13 and CD227 using the DynaBead pan-mouse IgG system. Isolated cells were cultured on transwell supports and characterized by immunoblot and immunofluorescence.

Results: CD13 isolated cells were positive for the PTEC markers Gamma Glutamyl Transpeptidase and Aquaporin-1. CD227 isolated cells were negative for GGT and AOPl but positive for the distal tubule markers CD227 and E-cadherin. Microscopy demonstrated that both PTECs and DTECs formed tight junction monolayers with a low percentage of cells in cycle as identified by Ki-67. Analysis of conditioned media demonstrated that the hormone upregulated secreted IGFBP7. Furthermore, we found a preferential expression of IGFBP7 in PTECs and of TIMP2 in DTECs. Furthermore, we discovered evidence suggesting that TIMP2 is primarily secreted across the apical surface, while the majority of IGFBP7 is secreted across the basolateral surface. Despite this, we also found that a substantial portion of IGFBP7 can be secreted apically, primarily in PTECs.

Conclusions: We have developed human cell culture model systems of PTECs and DTECs for the cellular/molecular analysis of AKI. We confirmed that IGFBP7 and TIMP2 can be expressed and secreted by these cells, and we have identified differential expression and secretion of these proteins across cell types and spatially within cells. These systems and knowledge will now allow for investigation of the potential role of these biomarkers in the molecular etiology of AKI.

Klotho and S100A8/A9 as Discriminative Markers Between Pre-Renal and Intrinsic AKI
Ji Yong Jung,1 Ae Jin Kim,1 Eul Sik Jung,1 Byoungho Choi,1 Yun Jung Oh,2 Chungsiik Lee,3 Han Ro,1 Jae Hyun Chang,1 Hyun Hee Lee,1 Wookyoung Chung.1

Disclosures: None.

Background: Early detection and accurate differentiation of the cause of acute kidney injury is crucial for the prognosis of the patient. However, to date, there are few reliable biomarkers for the discrimination of pre-renal and intrinsic AKI. The purpose of this study was to determine whether AKI is associated with an altered level of klotho and S100A8/A9 (an endogenous toll-like receptor 4 ligand), and NGAL (neutrophil gelatinase-associated lipocalin) protein that may contribute to differentiate between pre-renal and intrinsic AKI.

Methods: Volume depleted pre-renal AKI model was induced by muscle Sprague-Dawley rat were fed a low-salt diet (0.03%) without water 96hr before two times at intraperitoneal (IP) injection of furosemide (20 mg/kg) at 24hr intervals. In contrast, cisplatin-induced intrinsic AKI model were given by a single IP injection of cisplatin (5 mg/kg). All animals were euthanized 72hr after first IP injection. We also performed a proof of concept cross-sectional study to measure serum and urinary biomarkers in 77 hospitalized patients with established AKI.

Results: Compared with intrinsic AKI group, pre-renal AKI group caused a marked depression of urinary klotho level (13.21 ± 17.32 vs. 72.97 ± 17.96 pg/ml, P = 0.002). In addition, intrinsic AKI group caused a marked elevation of S100A8/A9 level than those of pre-renal AKI group (5629.97 ± 598.05 pg/ml vs. 685.09 ± 111.65 pg/ml, P = 0.002 in serum; 1361.11 ± 230.86 pg/ml vs. 741.72 ± 101.96 pg/ml; P = 0.003 in urine). Serum and urinary NGAL showed no difference between pre-renal and intrinsic AKI group. The proof of concept study with hospitalized AKI patients also demonstrated decreased urinary klotho in pre-renal AKI patients and increased urinary S100A8/A9 concentrations in pre-renal AKI patients.

Conclusions: The attenuation of urinary klotho and increment of urinary S100A8/A9 may contribute to discriminate the pre-renal AKI and intrinsic AKI. Funding: Pharmaceutical Company Support - Frensis Medical Care Korea

Release of Extra Cellular DNA Contributes to Renal Ischemia Reperfusion Injury Through Platelet Activation and Formation of Neutrophil Extracellular Traps
Marcel Janse,1 Diba Emal,1 Sandrine Florquin,1 Joris J. Roelofs.2

Disclosures: None.

Background: Renal ischemia reperfusion injury (IR) results from a complex interplay between reperfusion and inflammation, resulting in tissue damage. It has been shown that platelet inhibition protects from IR. How platelets are activated upon renal I/R is not entirely known. In this study we investigate renal cell death, extracellular DNA release and neutrophil extracellular traps (NETs) as potential triggers for platelet activation and renal IR injury.

Methods: We stimulated platelets with necrotic renal cells in presence or absence of deoxyribonuclease 1 (DNase1). Platelet activation and platelet-leukocyte formation were measured by FACS. We stimulated granulocytes with activated platelets and measured DNA release - indicative of NET formation. Vici versa we stimulated platelets with NETs and measured NET release - indicative of NET degradation and treated with DNase1 and treated viced versa, and sacrificed after 1 day. As marker for NET formation in tissue we stained renal tissue for citrullinated histone H3 and granulocyte marker Ly6G. In blood we measured Platelet Factor 4 (PF4), DNA, creatinine and urea.

Results: Necrotic renal cells stimulated platelet activation and platelet-leukocyte complex formation and incubation with DNase1 reduced platelet activation. Activated platelets generated NETs in vitro and, vici versa, NETs stimulated platelet activation ex vivo. Mice subjected to renal IR showed a significant increase of extracellular DNA and PF4 levels in the circulation. Treatment with DNase1 improved renal function and decreased cytokine levels. The animals showed preserved renal functions in retal time and after 1 week. IR, DNase1 treatment resulted in a trend towards fewer NETs and granulocytes in tissue.

Conclusions: Both DNA from necrotic kidney cells and NETs activate platelets, which in turn cause further NET formation, leading to a vicious triad in the pathogenesis of IR injury. Treatment with DNase1 may have therapeutic benefits in the context of renal IR injury.

The Role of Senescence of Bone Marrow Cells in Acute Kidney Injury
Myung-Gyu Kim,1 Sung Yoon Lim,1 Jihyun Yang,2 Young Ju Na,2 So-Young Lee,2 Sang-Kyung Jo,1 Won-Yong Cho.1

Disclosures: None.

Background: There have been considerable growth in older population and age-related kidney disease in the world. It was demonstrated that the impairment in the potentiality to repair and regenerate of renal resident cells is a hallmark of biological processes associated with aging. However, the impact of senescence of bone marrow derived cells (BMDC) on kidney injury is not known. Here, we investigated the role of senescence of BMDC in the development and progression of ischemic acute kidney injury (AKI).

Methods: Seven wk-old female mice were sublethally irradiated and reconstituted with bone marrow from 12-mo-old (old-to-young, old BMT) or 7-wk-old (young to young, young BMT) mice. Then we performed renal ischemia reperfusion injury (IRI) in old or young BMT mice, and functional, histological kidney damage and inflammation were compared.

Results: The Y chromosome was detected in peripheral blood of BMT mice indicating successful reconstitution of female mice with male bone marrow. Although the population of immature myeloid cells in spleen between old and old BMT mice was significantly different, old BMT showed less renal functional deterioration and histological damage after IRI. This was associated with less infiltration of F4/80 macrophages and lower level of tissue cytokine (IL-12). In vitro study with BMDCs also revealed that LPS-induced cytokine productions (IFN-γ, MCP-1 and IL-10) were significantly suppressed in old BM cells than young BMT cells.

Conclusions: Our data shows that senescence of BMDC could affect susceptibility and response to renal ischemic injury possibly via immune modulatory effect. A better understanding of these processes may help us to develop new strategies that are specifically tailored for the treatment of elderly population.

Optimal Transplantation Timing of Mesenchymal Stem Cell in Rat Model of Renal Ischemia Reperfusion Injury
Xiaolian Luo,1 Xiaofang Du,1 Kimberly J. Reidy.1

Disclosures: None.

Background: Underlying of these processes may help us to develop new strategies that are specifically tailored for the treatment of elderly population.

Methods: The model of renal IRI was induced by the release of bilateral renal pedicle clamping and releasing for 60 min of ischemia. Animal were sacrificed at 0h, 1h, 12h, 24h, 48h, 72h and 1 week post-IR respectively. Passage 3 rat MSCs were cultured with different time points kidney homogenate supernatants. After reperfusion, CM-Dil-labeled MSCs or cells only were administered through the carotid artery of the rats. Biopsies were obtained at 1h before reperfusion(1h-1) and immediately(1h-0), 12h, 24h after reperfusion.

Results: The animals sacrificed 4h after reperfusion and 24h after MSCs transplantation.

Conclusions: MSCs transplantation 1h before reperfusion or immediately after reperfusion produces the most dramatic improvement in renal function and morphology in a model of renal IR injury. It is the optimal timing to transplant MSCs in IRI before the inflammatory response is established.

SA-PO266
Reno-Protective Role of Par1b in Acute Kidney Injury
Abijeet Pal,1 Natalie S. Uy,1 James M. Pullman,2 Zhongfang Du,1 Kimberly J. Reidy.1

Disclosures: None.

Background: Partitoning defective Par1 (aka MARK) is a member of protein kinase A family significantly decreased in -1h and 0h groups compared with other point time groups. Significant kidney function and histological damage improvement was observed after the treatment of MSCs in -1h and 0h groups. Meanwhile, the expression of proinflammatory factor significantly decreased and anti-inflammatory factor significantly decreased in -1h and 0h groups compared with other point time groups and control group. In addition, we also observed more obvious inhibition of renal tubular cell apoptosis and promotion of proliferation in -1h and 0h groups compared with other groups. Consistent with the improvement above, the viability of implanted MSCs also increased in -1h and 0h groups.

Conclusions: MSCs transplantation 1h before reperfusion or immediately after reperfusion produces the most dramatic improvement in renal function and morphology in a model of renal IR injury. It is the optimal timing to transplant MSCs in IRI before the inflammatory response is established.

Funding: Government Support - Non-U.S.
functionally redundant on kinase assays. We have identified a role for Par1a/1b in mediated renal injury, and attenuating its expression may provide new therapeutic strategies in the setting of acute kidney injury.

**Background:** Heat shock protein beta-1 (HSPB1), also known as HSP27, is a small heat shock protein involved in many cellular processes and reportedly protects cells against oxidative and inflammatory stress. Because of its function, we hypothesized that HSPB1 is a mediator of fibrosis.

**Methods:** To examine the regulation of autophagy by HSPB1, we established NRK-light chain 3 (LC3) cells that were stably transfected with a fusion protein of green fluorescent protein and LC3. We evaluated the promoter activity and expression of HSPB1 in normal rat kidney (NRK)-52E cells in the presence of H2O2. To examine the regulation of autophagy by HSPB1, we established NRK-light chain 3 (NRK-LC3) cells that were stably transfected with a fusion protein of green fluorescent protein and LC3.

**Results:** The results of immunohistochemical examination showed that HSPB1 was expressed in proximal tubule cells after AKI. Real-time quantitative reverse transcription-polymerase chain reaction and western blot analysis showed that HSPB1 mRNA and protein expression were upregulated 6–72 h and 12–72 h, respectively, after ischemia/reperfusion injury. HSPB1 promoter activity as well as mRNA and protein expression indicated dose-dependent induction by H2O2. HSPB1 overexpression-induced autophagy in NRK-LC3 cells under normoxic conditions was confirmed with confocal microscopy, which revealed the presence of LC3-positive granules. Furthermore, H2O2-induced autophagy was inhibited by the transfection of small interfering RNAs for HSPB1. Overexpression of HSPB1 reduced BAX activation and H2O2-induced apoptosis, as measured by caspase 3 activity and terminal deoxynucleotidyl transferase deoxyuridine triphosphate nick end labeling assay.

**Conclusions:** These results indicate that HSPB1 upregulation plays a role in the pathophysiology of AKI.

**SA-PO268**

Developing a More Clinically Relevant Mouse Model of Cisplatin-Induced Acute Kidney Injury

**Background:** Cisplatin, commonly used chemotherapeutic for the treatment of many solid cancers is known to induce acute kidney injury (AKI) in 30% of patients. Patients that develop cisplatin-induced kidney toxicity must either have the dose severely reduced or be switched to an alternative therapy to prevent long-term renal damage. In many cases the alternative therapy may be less effective at treating the tumor. Due to cisplatin’s complex mechanism of action, the development of renoprotective agents remains a challenge. Currently there are no FDA approved drugs for the protection of cisplatin-induced AKI. The standard mouse model of cisplatin-induced AKI is a single high dose of cisplatin (10-30 mg/kg), and animals are sacrificed 72h after injection. This model does not accurately represent the clinical dosing regimen, which involves repeated dosing of cisplatin.

**Methods:** In this study we compared the standard single dose model to a new multiple dose model where mice received lower doses of cisplatin once a week for 4 weeks. We measured and compared indicators of kidney function (KIM-1, NGAL, BUN, and Serum Creatinine) and multiple markers of inflammation and oxidative stress (i.e., TNFα, IL-6, MCP-1, F4/80, and iNOS). We also measured kidney histology.

**Results:** In comparing the results of the single and multiple dose models, BUN values were very similar, suggesting a comparable loss of kidney function. However, KIM-1 and NGAL were reduced by roughly 10-fold and 100-fold, respectively. Inflammation was also decreased in this model with TNFα, IL-6 and IL-1β reduced by 4, 10 and 5-fold, respectively. Fibrosis was nearly non-existent in the single dose model, however, the multiple dosing model showed a significant increase in fibrosis. Also, expression of PAI-1, a mediator of fibrinolysis was significantly increased in the multiple dosing model compared to the single dose model.

**Conclusions:** Taken together, we propose that the multiple dosing model is a more relevant model for the discovery of renoprotective agents in the prevention/treatment of cisplatin-induced AKI.

Involvement of Indolyl Sulfate in Exacerbated Susceptibility of Streptozotocin (STZ)-Induced Diabetic Rat Kidney to Ischemia/Reperfusion-Induced Acute Kidney Injury (AKI)  
Yuna Shimokawa,1 Naoko Oyama,1 Takashige Kawabara,2 Masashi Mukoyama,1 Hirofumi Jono,1,2 Hideyuki Saito.1,2  
1Clinical Pharmaceutical Sciences, Kumamoto Univ School of Pharmaceutical Sciences, Kumamoto, Japan; 2Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Kumamoto, Japan; 3Pharmacy, Kumamoto Univ Hospital, Kumamoto, Japan.

Background: Diabetes mellitus (DM) is one of the potential risk factors in progression of acute and chronic kidney failures. In patients with DM, AKI tends to be severer and the restoration delays compared to that in non-DM patients. However, the precise mechanism is unclear. Indolyl sulfate (IS) is a representative oxidative stress-inducible uremic toxin and involved in the progression of chronic kidney failures. In this study, we examined the toxicological involvement of IS in ischemic AKI in DM rats.

Methods: STZ-induced DM rats and nondiabetic rats without STZ treatment (non-DM) were subjected to 20 min of renal ischemia/reperfusion (IR), and the development of renal injury in DM and non-DM rats were compared. An oral indole absorbent AST-120 was orally administered to rats (2.5 g/kg) at 24 h, 1 h before and 24 h after IR. Serum and kidney tissues were collected at 48 h following IR.

Results: In DM ischemic AKI group, serum creatinine (SCr) (4.3-fold vs non-DM ischemic rats) and BUN (7.0-fold) were increased. The kidney of DM rats with IR exhibited severe tubulointerstitial injury compared to that of non-IR groups with IR in association with a marked increase in serum KIM-1 level (25-fold). Hydroperoxide (1.7-fold) and IS levels in serum (14.7-fold) and kidney (5.8-fold) were also elevated. Immunoblot analysis revealed that renal expression of organic anion transporter rOAT1/rOAT3 mediating renal excretion of IS were significantly downregulated. AST-120 treatment prevented the increases in SCR and BUN, and renal tubular injury in DM rats with IR, in association with the reduction of serum and renal IS levels. The downregulation of rOAT1/rOAT3 was restored by AST-120 treatment.

Conclusions: DM could be a pivotal factor in progression of ischemic AKI, and AST-120 restores (uremic toxins) including IS could play a toxico-physiological role as a mediator in the DM-exacerbated ischemic AKI.

Discoidin Domain Receptor 1 Is a Key Mediator of the Ischemia-Reperfusion Induced Renal Injury  
Aude Dorison,1 Yi-chun Xu-duobao,1 Christos E. Chadjichristos, Eric Rondeau, Christos Chatziantoniou, Jean-claude Dussaule.1

UMRS 1155, INSERM, Paris, France.

Background: Discoidin Domain Receptor 1 (DDR1) is a non-integrin collagen receptor, expressed by different cell types in the kidney, which displays tyrosine-kinase activity.

We have previously demonstrated that a de novo expression of DDR1 in target cells was driving renal inflammation and fibrosis in different models of chronic kidney disease. The aim of our study was to investigate whether DDR1 participates in the pathophysiological mechanisms of ischemia/reperfusion (IR), a model of acute renal injury.

Methods: To this end, male mice subjected to IR were injected either with oligodeoxynucleotide (ODN) antisense sequences directed against DDR1 (AS, n=8) or with scrambled sequences (SCR, n=7). Mice were sacrificed after 24h and parameters of renal function, structure and inflammation were measured.

Results: In vitro experiments using NRK-52E cells showed that the compounds are able to suppress endonuclease activity inside the cells provide partial protection against kidney tubular epithelial cells in vitro and in vivo.

Conclusions: DDR1 inhibition prevents mice from the I/R-induced histological damage, inflammation and loss of renal function. DDR1 overexpression plays a deleterious role in this model of kidney injury, thus reinforcing the interest to develop agents capable of specifically blocking the function of this receptor.

Heat Shock Factor 1 and Crystallin-αB in Cisplatin-induced Renal Tubular Cell Apoptosis and Nephrotoxicity  
Qiang Lou,1 Dong Cheng,1 1Medical College of Henan Univ, Kaifeng, Henan, China; 2Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA.

Background: Cisplatin, a wildly used chemotherapy drug, induces nephrotoxicity that is characterized by renal tubular cell death. In response to toxic stress, renal tubular cells may activate the heat shock response pathway, such as heat shock proteins. However, the heat shock response during cisplatin nephrotoxicity is largely unclear. The present study analyzed the heat shock response during cisplatin treatment of renal tubular cells in vitro and mice in vivo, and examined the relevant regulatory mechanisms.

Methods: For in vivo study, male C57BL/6 mice were given a single intraperitoneal injection of cisplatin. In vitro, renal proximal tubular cells (RPTC) were incubated with cisplatin. To determine the role of heat shock factor 1 (HSF1), HSF1 was knocked down by stable transfection of specific shRNAs.

Results: In RPTC, cisplatin induced a rapid expression of HSF1 and specific heat shock proteins, including HSPA, HSP27, and Crystallin-αB, and the expression of this protein was transient and decreased at late time points of cisplatin treatment. Similar changes were verified in kidney tissues following cisplatin injection, whereas Hsp90 did not change significantly. Knockdown of HSF1 decreased Crystallin-αB expression and cisplatin RPTC apoptosis. Interestingly, p38 activation was enhanced in these cells. Moreover, inhibition of p38 with SB203580 markedly inhibited cisplatin-induced apoptosis in HSF1-knockdown cells.

Conclusions: Induction of HSF1 is a cytoprotective response during cisplatin nephrotoxicity. Crystallin-αB appears to be a key heat shock protein induced by HSF1 for its protective effect. Heat shock response may regulate or co-operate with other signaling pathways, such as p38, to regulate tubular cell apoptosis.

Funding: NIDDK Support, Veterans Administration Support
Conclusions: Importantly, cisplatin-induced kidney injury was functionally (creatinine) and structurally (acute tubular necrosis, TUNEL) reduced by the administration of the inhibitors (5 mg/kg) in mice suggesting their potential therapeutic value.

Involvement of CYLD as a Regulatory Factor in Fibrotic Response of Ischemic AKI Kidney and Hypoxic HK-2 Cells

Background: CYLD is a tumor suppressor, regulates various signaling pathways by acting as a deubiquitinating enzyme. Recent studies have revealed that CYLD is associated with not only tumors, but also chronic inflammatory diseases, such as tissue fibrosis. It is well-documented that tissue fibrosis is common hallmark of chronic kidney disease (CKD), and CKD progresses toward end-stage renal disease through renal fibrosis. However, the molecular pathogenesis of renal fibrosis is not fully uncovered yet. In this study, we elucidated the roles of CYLD in renal fibrosis by using in vivo and in vitro models.

Methods: We generated model mice of ischemia/reperfusion (I/R)-induced acute kidney injury (AKI) and hypoxic human kidney (HK)-2 cells. CYLD expression in kidney tissue and HK-2 cells was determined by immunoblot analysis. Fibrosis gene expression of PAI-1, CTGF, and COL1A1 were examined by RT-PCR.

Results: In I/R-induced AKI mice, serum creatinine (SCr) and BUN were elevated 2 days after I/R treatment, and renal fibrosis was induced 28 days after I/R treatment. In those kidney tissues of I/R-AKI mice, CYLD protein expression was markedly decreased (0.4-fold) in a time-dependent manner. Interestingly, fibrosis gene expression (PAI-1: 3.3-fold, CTGF: 14.7-fold, COL1A1: 2.5-fold) was significantly increased in response to the CYLD down-regulation. In HK-2 cells, siRNA knockdown of CYLD gene expression significantly increased the PAI-1 gene expression (12-fold). Moreover, CYLD mRNA expression was significantly suppressed (0.5-fold) under hypoxic condition, an important factor of CKD progression, whereas the PAI-1 gene expression (2-fold) was elevated in HK-2 cells. These results suggested that CYLD could play a pathological role in regulating renal fibrotic response.

Conclusions: In conclusion, CYLD may be a novel regulatory factor involved in renal fibrosis and its down-regulation may trigger fibrosis under ischemic and/or hypoxic conditions.

The Effect of Oxygen and Hypothermic Therapy on the Prevention of Acute Kidney Injury

Background: There is no effective therapy for acute kidney injury. The effect of oxygen, hypothermic therapy delivered through urinary tract on the treatment of acute kidney injury has not been known. This pilot study was performed as a proof of concept of a catheter-based oxygen and hypothermic oxygen therapy in preventing and treating acute kidney injury.

Methods: Rats (n=6) were used for the experiment. Three rats were used to compare oxygen therapy and control. The other three rats were used to compare hypothermic oxygen therapy and control. Oxygen was cooled for hypothermic oxygen therapy before it was delivered to the kidney. Right kidneys received treatment (oxygen or hypothermic oxygen) and left kidneys were used for control. After a catheter was placed in a bladder, oxygen (or cooled oxygen) was delivered to the right kidney from the bladder through the catheter for five minutes for pretreatment before clamping. Both right and left renal arteries were clamped for 30-45 mins to induce acute kidney injury. Only right kidneys continued to receive oxygen or hypothermic oxygen during the clamping of renal arteries. The kidneys were extracted after the induction of acute kidney injury with the clamping. Gross examination of both kidneys during the clamping and after the extraction was performed.

Results: Gross examination of kidneys demonstrated less ischemic changes of kidneys treated with oxygen or hypothermic oxygen during and after the induction of acute kidney injury. As shown in Figure 1, right kidneys that received oxygen therapy or hypothermic oxygen showed less ischemic changes on gross examination during the clamping and after extraction.

Proximal Tubule-Derived CSF-1 Mediates Expansion and Polarization of Renal Macrophages/Dendritic Cells and Recovery in Acute Kidney Injury

Yinchu Wang, Bing Yao, Raymond C. Harris, Ming-Zhu Zhang. Medicine, Vanderbilt Univ, Nashville, TN.

Background: Colony-stimulating factor-1 (CSF-1)-mediated renal macrophage expansion and polarization play an essential role in recovery from acute kidney injury in ischemia/reperfusion (I/R)-injury and selective apoptotic proximal tubule injury in transgenic mice expressing the human diphtheria toxin receptor (DTR) and exposed to DT (DTR-AKI). In the kidney, a major site of CSF-1 production is in proximal tubular epithelial cells.

Methods: Male DTR mice with CSF-1f/f (wild type) or with γ-GT-Cre:CSF-1f/f (CSF-1 KO in renal proximal tubule) were used for DTR-AKI and for IR injury (30 min of ischemia and contralateral nephrectomy).

Results: CSF-1 expression in the proximal tubule and its deletion in CSF-1 KO mice were confirmed with immunostaining. Six days after DTR-AKI, activation of the CSF-1 receptor (p-c-fms) was markedly attenuated in both renal tubules and interstitial cells, including macrophages (F4/80 and p-c-fms dual positive cells). Flow cytometry and qPCR indicated fewer renal macrophages/dendritic cells and reduced mRNA levels of M2 phenotype markers (CD206, IL-4Rα, TGF-β1 and 15-LOX) in CSF-1 KO mice 6 days after DT injection. Although selective proximal tubule CSF-1 deletion did not affect the severity of kidney injury, it delayed renal functional recovery, in association with increased oxidative stress, increased secondary necrosis (HMGB1 expression) and severe tubulointerstitial fibrosis, with increased Picro-sirius red staining of fibillary collagen and increased profibrotic and fibrotic components (α-SMA, CTGF, Fbronectin, collagen I and IV). Selective proximal tubule CSF-1 deletion also delayed to functional recovery after IR injury, with decreased mRNA levels of M2 phenotype markers in isolated renal macrophages/dendritic cells and more severe renal fibrosis. In both I/R injury and DTR-AKI, selective proximal CSF-1 deletion had minimal effects on the expression of M1 phenotype markers.

Conclusions: These studies demonstrate that proximal tubule is a major source of CSF-1 that mediates the expansion and polarization of renal macrophages/dendritic cells that play an essential role in recovery following AKI.

Ablation of Myo-Inositol Oxygenase Protects against Cisplatin-Induced Acute Kidney Injury by Inhibiting p53 Activation

Rajesh Dutta, Yashpal S. Kanwar. Dept of Pathology, Northwestern Univ, Chicago, IL.

Background: MIOX is a renal tubular enzyme. Its role in the pathogenesis of diabetic nephropathy is currently being investigated. Conceivably, it modulates redox balance and apoptosis in tubular cells in diabetes via modulation of gluturcnate-xylulose (G-X) pathway. However, its role in acute kidney injury (AKI) is unknown.

Methods: In this study we used both MIOX-over-expressing transgenic and MIOX null mice to elucidate its role in a model of cisplatin induced AKI.

Results: We observed severe cisplatin-induced proximal tubular injury in MIOX transgenic and protection in null mice compared to wild type mice. In transgenic mice an increased serum creatinine and urea levels, caspases-3 activity and tubular apoptosis along with marked deterioration of tubular morphology was observed. Renal injury was remarkably less in null mice compared to wild type mice. Cisplatin treatment led to p53 activation in wild type and MIOX transgenic mice, whereas minimal p35 activation was observed in MIOX null mice. Likewise, we noted that cisplatin induces mTOR pathway in both wild type and MIOX transgenic mice while such an effect was not observed in MIOX null mice. Treatment with mTOR inhibitor, rapamycin, prevented cisplatin-induced MIOX expression, p53 activation and deterioration of tubular morphology in control mice. In vitro studies revealed significantly high levels of ROS generation, caspases-3 activity and apoptosis in MIOX over-expressing cells compared to control cells transfected with empty vector following cisplatin treatment.

Conceivably, this was attributed to the accentuated induction of G-X pathway and its associated myriad enzyme system.

Calcium Oxalate Crystal-Induced Acute Kidney Injury Involves Ripk3-Mld Mediated Tubular Cell Necroptosis

Hans J. Anders, Jayansi Desai, Santosh Kumar, Jonathan Nicodemos Eberhard, Dana Thomasova, Simone Romoli, Andreas Linkermann, Shrikant R. Mulay. Ludwig Maximillians Univ, Munich, Germany; Christian-Albrechts-Univ, Kiel, Germany.

Background: Crystaline nephropathy (CN) & nephro-/urolithiasis involves crystal-induced renal inflammation via NLRP3 inflammasome (Mulay et al, JCI 2013), but the mode of direct crystal cytotoxicity in kidney remains elusive. The aim of the study was to investigate mechanisms of crystal cytotoxicity in kidney.

Methods: All in vivo experiments were approved by the local government authorities. Acute oxalate nephropathy (AON) was induced by i.p. injection of sodium oxalate (NatOx) (100mg/kg) and 3% NaOx in drinking water for 24hr. H&E, EM, RT-PCR, MTT assay, PI stain and multicolour FACS were used for data analysis.

Results: We found that crystals of calcium oxalate (CaOx), monosodium urate, calcium pyrophosphate dehydrate & cystine trigger caspase-independent necrosis of mouse tubular cells, human kidney cells & human renal progenitor cells. Pretreatment with RIPK1 inhibitor necrostatin-1 (Nec-1), MLKL inhibitor & RNA interference of RIPK3 or MLKL blocked crystal cytotoxicity. Consistently, deficiency of RIPK3 or MLKL protected mice from AON (e.g. plasma creatinine, BUN, tubular injury score, renal KIM-1 & α-GST mRNA expression, neutrophil count and TUNEL+ve cells) despite similar crystal deposition. I.p. injection of crystals induced neutrophil recruitment into peritoneal cavity, which was unaffected by Nec-1 as was crystal injection into air pouches at the back of mice. However, Nec-1 significantly reduced microvascular permeability & leukocyte extravasation from post-ischemic cremaster muscles. Thus RIPK1 signaling per se does not affect neutrophil recruitment. Next, we found that AON was significantly reduced in Tnfr-2-deficient mice, with no additive effects with concomitant Tnfr-2 deficiency. Thus, TNFR1 signaling activates RIPK3-dependent necroptosis in this model. Finally, etanercept, TNFR inhibitor R-7050 & Nec-1 protected mice from AON.

Conclusions: Crystal-cytotoxicity involves TNFR1-RIPK1-RIPK3-MLKL pathway. All components of this pathway represent novel molecular targets for therapeutic interventions to limit CN.
Alloporuin Protects against Rhabdomyolysis and Acute Kidney Injury Induced by a Membrane Protein (Lp25) from Pathogenic Leptospira

**Background:** Acute kidney injury (AKI) in leptospirosis is frequently nonoliguric, hyporenal or normorenal. Higher serum potassium levels, elevated creatine phosphokinase (CPK), and uric acid were markedly increased in patients with leptospirosis. We demonstrated that Lp25, a protein membrane from pathogenic Leptospira, induced hyperkalemia, rhabdomyolysis (elevated CPK, uric acid, and phosphate) and oliguric AKI. Alloporin (Allo) attenuates hyperkalemia, and AKI induced by Lp25 in guinea pigs. This may represent a new therapeutic approach for AKI in patients with leptospirosis.

**Methods:** Three groups of guinea pigs were studied: 1. Sham (phosphate-buffered solution) 2. Lp25+Allo. One mL of PBS and Lp25 (40μg of Lp25/mL) were intraperitoneally injected for 4 days. Lp25+Allo received Allo (300mg/kg) in drinking water during this time. On the 5th day, animals were placed in metabolic cages for 12 hours urine collection. We measured urinary volume (U/L12h), creatinine clearance (ml/min/100g BW), serum potassium (mEq/L), CPK (U/L), uric acid (mg/dL), phosphate (mg/dL). Data are mean±SEM.

**Results:** Lp25 induced hyperkalemia, rhabdomyolysis (elevated CPK, uric acid, and phosphate), and oliguric AKI. Allo attenuated hyperkalemia and AKI induced by Lp25 in guinea pigs.

Conventional Autophagy Regulates the Degradation of AQP2 in Hypokalemia

**Background:** Autophagy is a catabolic pathway utilized to maintain a balance among the synthesis, degradation, and recycling of cellular component, thereby playing a role in homeostasis. Abundance of AQP2 is regulated through balance between production by tralation and removal by degradation. Although AQP2 degradation is supposed to be occurred via lysosomal or proteasomal degradation, the precise mechanisms still remain unknown. It has been known that prolonged hypokalemia causes vasopressin-resistant polyuria and induces autophagy especially in principal cells (PCs) of collecting duct.

**Methods:** To investigate the role of autophagy in the degradation of AQP2, we generated AQP2-cre;Atg7f/f mice, in which AQP7, an essential gene for mammalian autophagy, was selectively inactivated in PCs. Hypokalemia was induced by K-depleted diet for 2 weeks.

**Results:** In control AQP2-cre;AQP7+ mice, the distribution pattern of AQP2 was not different from AQP7+ mice. Immunolabeling of pS261-AQP2 was localized mostly subapical and appeared in appearance in the PCs. In contrast to pS256-AQP2, immunolabeling of pS256-AQP2 was localized mainly at the apical plasma membrane and subapical domains. In hypokalemia AQP7 mice, the abundance of pS256-AQP2 was significantly reduced and redistributed to intracellular vesicles, and co-localized with LC3-positive vacuoles. In hypokalemia AQP2-cre;AQP7 mice, there was a decrease of conversion of LC3-I to LC3-II and a marked accumulation of p62 selectively in PCs. Rab9 protein, an essential molecule for alternative autophagy pathway, and Rab9-positive vacuoles were markedly increased. Interestingly, pS261-AQP2 was distributed throughout the cytoplasm and not co-localized with Rab9- or LC3-positive vacuoles in the PCs of AQP2-cre;AQP7 mice. There was no difference in localization of pS256-AQP2 at the plasma membrane from each genotype.

**Conclusions:** These results suggest that down regulation of AQP2 in hypokalemia could in part be caused by degradation of pS256-AQP2 in PCs through a LC3-I/Atg7-dependent conventional autophagy pathway.

Early Autophagy Precedes Angiotensin II-Induced Podocyte Apoptosis

**Background:** Autophagy is a highly regulated catabolic process that is involved in the turnover of unwanted cellular materials, on the other hand, apoptosis removes damaged or unwanted cells. Therefore, autophagy and apoptosis constitute the two processes which through injured/aged cells or organelles are eliminated. Angiotensin II (Ang II) induces podocyte apoptosis resulting in proteinuria in vitro and in vivo. The relationship between autophagy and apoptosis in Ang II-induced podocytes is not elucidated and the role of Ang II-induced autophagy in podocyte survival remains unclear. We investigated the sequential relationship between autophagy and apoptosis in Ang II-induced podocytes.

**Methods:** In mice with the expression of RFP-LC3 plasmid in media containing various concentrations of Ang II and at different incubation times. The changes of podocyte autophagy and apoptosis were observed by electron microscopy, confocal imaging, Western blotting, and FACS assay according to the presence of Ang II.** Results:** Ang II-treated podocytes showed an increase in autophagosomes compared with control cells at early phase in a dose-dependent manner. This pro-autophagic effect of Ang II was inhibited by pretreatment with 3-methyladenine, an inhibitor of PI3-kinase class III. Ang II also enhanced podocyte expression of autophagic proteins such as LC3-II and beclin-1. Atg5 siRNA further reduced the expression of LC3-II and cleaved caspase-3 suppressed by Ang II at 12 hrs. However, Atg5 siRNA did not affect the expression of Atg5, LC3-II, and cleaved caspase-3 in the presence of Ang II at 24 hrs. Therefore, Ang II induced podocyte apoptosis significantly in concentration- and time-dependent manners in FACS assays. LYS24002 and Atg5 siRNA further increased podocyte apoptosis induced by Ang II. Therefore, high concentrations of Ang II induced apoptosis, while autophagy response decreased, which implicated that autophagy preceded apoptosis for cytoprotection in angiotensin II-induced podocyte injury.

**Conclusions:** We suggest that Ang II induced autophagy in mouse podocytes prior to apoptosis as an early adaptive cytoprotective mechanism for podocyte survival after Ang II treatment and the imbalance between autophagy and apoptosis causes podocyte injury.

**Funding:** Government Support - Non-U.S.
regulating fibrosis is not fully understood. In this study, we investigated the proposed mechanisms of autophagy in renal TIF induced by UUO by using conditional knockout mice in which Atg7 is genetically ablated specifically in tubular epithelial cell (TEC).

**Methods:** Atg7-flox mice were crossed with Ksp-Cre to generate TEC-specific Atg7 knockout mice (Atg7f/f-Ksp-Cre'). Unilateral ureteral obstruction (UUO) was performed. We examined the expression of epithelial-mesenchymal transition (EMT) markers. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as a regulator of cell apoptosis and proliferation.

**Results:** In vitro, TGF-β treatment induced autophagy. In vivo, TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increase expression of TGF-β and enhance tubular EMT (decrease E-cadherin and increase α-smooth muscle antibody and vimentin) after UUO. In electron microscopy, TEC-specific Atg7 deletion results in ultrastructural alterations of TEC after UUO. TEC-specific Atg7 deletion increases expression of PAI-1, P62 after UUO. TEC-specific Atg7 deletion enhanced apoptosis and proliferation of TECs after UUO. The expression of c-Myc was significantly increased in mice with TEC-specific Atg7 deletion after UUO. The expression of c-Myc was significantly increased in mice with TEC-specific Atg7 deletion after UUO.

**Conclusions:** Our data suggest that autophagy regulate EMT through TGF-β, PAI-1 and P62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs through the expression of c-Myc during renal TIF. Autophagy could represent a therapeutic target for renal TIF.

**Partial De-Differentiation of Parietal Epithelial Cells Caused by Reduced Expression of Sirt1 and Concomitant Increased Expression of p21 and CD133 in Diabetic Nephropathy**

**Kazuhito Hasegawa, Shu Wakino, Hiroshi Itoh**

**Keio Univ.**

**Background:** We have previously reported the role of proximal tubular Sirt1 in diabetic nephropathy (DN). Parietal epithelial cells (PECs) and their cellular metabolism reportedly play a pivotal role in kidney. Sirt1 is a key energy sensor, whereas DN disrupts energy metabolism.

**Methods:** Thus, we examined the effect of Sirt1 expression in PECs on DN.

**Results:** In two DN murine models involving streptozotocin-treated and db/db mice, expression of Sirt1 in proximal tubules and PECs was decreased at 8 weeks after the onset of DN, corresponding to the early stage of DN. Sirt1 expression was also downregulated in podocytes at 24 weeks. We further investigated the changes in PECs at 8 weeks. No change was found in the number of PECs. The morphology of all PECs showed hypertrophy, and some PECs contained autophagic vesicles, especially in the periphery or the border of the plasma membrane at basolateral sides.

**Normal Condition**

**Diabetic Nephropathy**

**Conclusion:** HG treatment of cultured PECs resulted in significant reductions in cell proliferation and migration, while increasing the production of extracellular and basement membrane components such as type IV collagen. We performed DNA microarray, confirmatory real-time PCR, and immunofluorescence, revealing that an increase in Glut1 (glucose transporter) expression promoted influx of high amounts of glucose into PECs, which led to a reduction in Sirt1 expression and lysine acetylation-mediated activation of p21. Among the main molecular markers of precursor cells, including CD24, CD44, and CD133, only CD133 showed remarkable elevation, indicating that the decrease in Sirt1 expression caused the partial de-differentiation of PECs.

**Conclusions:** Sirt1 may be a promising target for protection against DN-induced de-differentiation of PECs, which would prevent not only hypertrophy of PECs but also the concomitant thickening of the basement membrane of Bowman's capsule.

**APOL1 Variants are Critical to Induce Vitamin D Receptor (VDR) Down Regulation in Dedifferentiated Podocytes**

**Shabirul Haque, Xiqian Lan, Amrita Kaur Chawla, Rivka Lederman, Rabani Bharara, Ramachandra prasanna Bongu, Ashwani Malhotra, Pravin C. Singhal. 1 Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 2 Medicine, Ramgam Health Care Campus, Haifa, Israel.**

**Background:** Dysregulated growth and loss of podocytes are important features of HIV-associated nephropathy (HIVAN). In a recent report, HIV induced programmed cell death in T cells has been implicated to pyroptosis as a consequence to the induction of pyroptosis. We evaluated the role of HIV in podocyte NOD-like receptor family, pyrin domain containing (NLRP) 3 protein complexes (inflammomasomes) formation both in vitro and in vivo.

**Methods:** Renal cortical sections of control and Tg26 (HIVAN) mice (n=4) were labeled with dysregulated molecule markers (IMMs; NLRP1, ASC, cleaved caspase-1 and IL-1β). Protein blots of renal tissues of control and Tg26 mice were also probed for IMMs and actin (n=4). Protein blots of empty vector (EV) and NL4-3 (HIV)-transduced human podocytes (HPs) were probed for IMMs and actin (n=11). Protein blots of renal tissues of control and Tg26 mice were also probed for IMMs and actin (n=4). EV/HPs and HIV/HPs were labeled for inflammasome molecular markers (IMMs; NLRP3, ASC, cleaved caspase-1 and IL-1β). Protein blots of renal tissues of control and Tg26 mice were also probed for IMMs and actin (n=4). EV/HPs and HIV/HPs were labeled for inflammasome molecular markers (IMMs; NLRP3, ASC, cleaved caspase-1 and IL-1β). Protein blots of renal tissues of control and Tg26 mice were also probed for IMMs and actin (n=4).

**Results:** APOL1 variants (G1/G2) expressing HPs displayed lower expression of APOL1. However, the involved mechanism for lower APOL1 expression in these patients is not clear. Gene sequence alterations/mutations hamper either mRNA transcription stability or defects in protein translation. We hypothesized that mutation in APOL1 would lead to modulation of protein expression in podocytes.

**Conclusion:** These findings suggest that APOL1 variants protein instability may be related to loss/decay of variant APOL1 mRNA or to some extent defects in protein translation/stability.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline represents presenting author.**

693A
expressions as well as protein expressions of iMMPs. Serum from TG26 mice showed higher levels of IL-1β and NF-kB promoted pyroptosis in podocytes in a dose as well as time dependent manner. Since caspase-1 inhibitor not only attenuated podocyte expression of caspases-1 and IL-1β in addition to protection against pyroptosis; this would confirm that HV induced podocyte injury was mediated by caspase-1-activated complexes. Interestingly, HV-induced podocyte pyroptosis could be partially inhibited by tempol as well as by glyburide.

Conclusions: These findings indicate that generation of reactive oxygen species and potassium efflux contributed to HV-induced pyroptosis in podocytes.

Urinary Cytochrome C (Cyt C) Detects Subliminal Injury and Correlates with Apoptosis in Acute (AKI) and Acute on Chronic Kidney Disease (A-CKD)

Lena Sencer,1 Philip Peake,2 Zoltan H. Endre,1 1Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia; 2Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia; 3Prince of Wales Hospital and Clinical School, Univ of New South Wales, Sydney, NSW, Australia.

Background: Mitochondrial Cyt C is a potentially specific biomarker of apoptotic kidney injury in AKI. We investigated urinary Cyt C in detecting subliminal kidney injury (histological injury without an increase serum creatinine, scCr) in two models of A-CKD.

Methods: In male Sprague Dawley rats (i) adeno-CMK was induced by diet supplementation with 0.025% ademine, days (d) 0 to 28 and monitored until d56 (n=8). On d56, AKI was induced in rats by a subneophrotoxic (2mg/kg, n=8) or nephrotoxic (4mg/kg, n=8) cisplatin (Cis) dose and monitored for 8 weeks. (ii) Aristolochic-acid nephropathy (AAN) was induced by AA-1 (ip for five days and monitored to d21 (n=6) or d42 (n=6) then 2mg/kg (n=6) or 4mg/kg (n=6) Cis and monitored to d28 and d49 respectively. Cyt C was measured by ELISA. Tubulointerstitial damage (TID) and TUNEL were quantified on d66.

Results: Cyt C levels increased in subliminal AAN (d1 to d7) and ademine-CMK (d3 to d21) without change in scCr, but increased in both CKD groups after 2mg/kg and 4mg/kg Cis dose in controls. In AAN, Cyt C levels increased progressively (d22 to d28) after subneophrotoxic controls given 4mg/kg whereas Cyt C was lower after Cis on d42 to d49. Regardless of Cis dose, Cyt C increased in controls and ademine-CMK. A-CKD rats displayed diffuse medullary and cortical TID with positive TUNEL staining while injury in CKD alone was largely in outer medulla. In ANP peak Cyt C, 72 hours post Cis, correlated significantly (Spearman R=0.86*) and cortical apoptosis (R=0.81*). In ademine fed rats, Cyt C Correlated only with medullary apoptosis (R=0.79*) scCr correlated only with severe diffuse cortical TID (R=0.94*) (P<0.05).

Conclusions: Cyt C detected subliminal injury and correlated strongly with outer medullary apoptosis in A-CKD, which alone did not increase scCr. Cyt C is a useful biomarker for early detection of apoptotic kidney injury.

SA-PO294

Assessment of Graphene Toxicity to Kidney Tubular Epithelial Cells and Cell Spheroids Using DNase Activity Probe

Tarih Fahmi,1 Zeid A. Nima,2 Giulietta Sargsyan,1 Alexandre S. Biris,2 Alexei G. Basnakian.1 1Pharmacology, The University of Cincinnati, Cincinnati, OH; 2IRCCS Policlinico, Milano, Italy.

Background: Recently invented nanomaterial, graphene, consists of monomolecular carbon sheet, which are extremely strong, light and flexible. It will be used widely because of its versatility. However, little is known about its potential for being a toxicant and environmental hazard, and methods to study graphene toxicity are not established. Kidney is one of the primary organs for the assessment of nanomaterial toxicity. We hypothesized that graphene induces nephrotoxicity mainly through DNA fragmentation, and measuring DNase activity by using near infrared fluorescence (NIRF) DNase activity probe would be a reliable tool for assessing graphene cytotoxicity.

Methods: Non-modified graphene (50 μg/mL) exposed with cultured rat kidney tubular epithelial NRK-52E cells induced TUNEL-type DNA fragmentation usually associated with cytotoxicity. Ramun spectroscopy showed the TUNEL-positive cells have significantly higher graphene content than TUNEL-negative cells. DNase activity was quantified in live cells using the oligonucleotide-based NIRF probe. Quantitative immunocytochemistry (qICC) was then used to measure apoptotic DNases such as caspase-activated DNase (CAD), endonuclease G (EndoG), and DNase I, and the marker of oxidative stress, heme oxygenase-1 (HO-1).

Results: The NIRF fluorescence and all of the above qICC markers were induced in NRK-52E cells by graphene exposure. In addition, a 50% colocalization of HO-1 with caspase-3 and TUNEL was then used to measure apoptotic DNases such as caspase-activated DNase (CAD), endonuclease G (EndoG), and DNase I, and the marker of oxidative stress, heme oxygenase-1 (HO-1).

Conclusions: Measuring of DNase activity by using NIRF probe in combination with TUNEL assay and qICC are appropriate tools for assessment of graphene toxicity. Funding: NIDDK Support, Other U.S. Government Support, Veterans Administration Support

Identification of a Novel Bidirectional Regulatory Mechanism Involving AKT/B-Catenin and Anillin That Drives Podocyte Proliferation

Gentzon Fahmi,1,2 Jose A. Gomez,1 Brandon M. Lane,2 Guanghong Wu,1 Himani Vaidya,2 Robert F. Spurny,3 Rasheed A. Gbadegesin.2,4 1Internal Medicine, Duke Univ; 2Pediatics, Duke Univ; 3Nephrology, Duke Univ; 4Duke Molecular Physiology Inst, Duke Univ.

Background: Mutations of the F-actin binding protein Anillin (ANLN) have been shown to cause familial FSGS. Although ANLN is a suspected modulator of the pi3k-akt kinase (PI-3K) signaling, specific interactions with PI-3K pathway intermediates and the role of these interactions in the pathogenesis of FSGS remains unknown.

Methods: siRNA-mediated gene knockdown studies, immunoblot and proliferation assays were performed by in vitro methods in conditionally immortalized human podocytes (CHP) to examine the effects of ANLN depletion on PI-3K signaling in podocytes. CHP lines stably expressing GFP-vector control or GFP-ANLNknock down were established via lentiviral transduction to characterize the effects of ANLN overexpression on PI-3K signaling in podocytes.

Results: We evaluated the effect of ANLN overexpression and targeted ANLN knockdown (KD) on AKT activation in podocytes. Additionally, we explored the effects of pharmacologic inhibition of AKT on ANLN expression in podocytes. Finally, we examined the role of AKT-mediated activation of β-Caten in the direct phosphorylation of serine 552 in podocyte ANLN expression. We determined that ANLN overexpression significantly attenuated AKT activation. Conversely, ANLN KD significantly enhanced AKT activation and upregulated AKT-mediated phosphorylation/activation of β-Caten in at serine 552. Pharmacologic inhibition of AKT also inhibited basal podocyte proliferation.

Conclusions: These findings elucidate a novel mechanism of reciprocal regulation involving AKT/β-Caten signaling and ANLN which may provide valuable insights into the role of ANLN in the pathogenesis of FSGS and other proliferative podopathies.

SA-PO296

Akt Mediates Cell Survival in Proteinuric States

Elif Erkan, Jian Gao, Sam Z. Coffey. Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: The degree of proteinuria correlates with progression in association with tubulointerstitial injury in glomerulonephritis. High concentrations of albumin in the glomerular filtrate results in apoptosis. Protein kinase B (Akt) is a serine/threonine kinase involved in multiple signaling events including cell survival. We hypothesize that down regulation of survival protein, protein kinase B (Akt) triggers tubular apoptosis in proteinuric states.

Methods: We utilized in-vitro and in-vivo model of albumin overload. Human kidney proximal tubule epithelial cells (HKC-8) are exposed to 10mg/ml albumin for 24-hours to induce apoptosis. C3BL/6C mice are exposed to 10mg/ml ip for 6 weeks to induce albuminuria. Fluorometric caspase-3 assay and TUNEL staining were utilized to assess apoptosis. Protein expression was assessed by Western blotting and immunofluorescence. Kidney sections from biogenic (Fyn−/−Cd2ap−/−) mice model of FSGS and patients with FSGS were evaluated for apoptosis and Akt expression.

Results: Albumin overload for 6 weeks in HKC-8 resulted in proximal tubular cell apoptosis in association with down regulation of pser473 Akt and Thr-308 Akt expression. Furthermore mice model of FSGS and patient kidney biopsies confirmed down regulation of tubular pser473 Akt expression in association with apoptosis. Overexpression of Akt by a constitutively active mutant ameliorated the albumin induced apoptosis where as suppression of Akt by of MC2266 enhanced albumin induced apoptosis in HKC-8 cells. Phosphorylation of downstream targets of Akt, transcriptional factors forkhead family Foxo1 and 3 is inhibited in association with apoptosis in response to albumin overload.

Conclusions: Down regulation of Akt expression in proteinuric states results in tubular apoptosis which is a precursor to tubular atrophy. We postulate these Decreased Akt phosphorylation of Foxo proteins allow them to translocate to nucleus and induce apoptotic gene expression. Therapeutic interventions directed to increase Akt expression in tubular epithelial cells can serve to prevent tubulointerstitial injury by inducing cell survival in the active states.

Altered Protein Kinase Signaling Causes Major Phenotypical Changes in Renal Cells from Patients with Nephropathic Cystinosis

Ekaterina Luysyanova,1 Fanny Oliveira Arcolin0,1 Maria Pia Rastaldi,2 Lambertus P.W.J. Van den Heuvel,1 Elena N. Levtenchenko.1 1Pediatric Nephrology, UZ Leuven, Leuven, Belgium; 2IRCCS Policlinico, Milano, Italy.

Background: Cystinosis is caused by mutations affecting the lysosomal cystine transporter cystinosin and results in lysosomal cystine accumulation. Cystinosis causes proximal tubular dysfunction, but also glomerular damage, which is present starting from early age. Current therapy of cystinosis is based on cystine-lowering cysteamine treatment, which greatly improves the prognosis, but does not cure the Fanconi syndrome and fails to prevent kidney damage in the majority of patients. It is therefore likely that, apart from the transporter function, cystinosis is implicated in other important cellular processes. We have investigated the mTORC-Akt signaling cascade in cystinosis-deficient renal cells. Akt kinase lies at the crossroads of cellular signaling regulating cytoskeleton, motility,
response to stress and survival, and is a target of mTORC2 and an upstream activator of mTORC1. mTORC1 is the master regulator of autophagy and metabolism. mTORC1 and 2 are also implicated in the regulation of cytoskeleton and cell motility.

**Methods:** Using conditionally immortalized proximal tubular epithelial cells (PTECs) and podocytes originating from cystinosis patients and healthy donors, we performed biochemical and microscopic analysis of phosphorylation and activation of protein kinases in response to various stimuli.

**Results:** Phosphorylation of Akt1 and 2 was increased in cystinosis podocytes and PTEC in response to nutrient/growth factor replenishment and wounding of cellular monolayer. In podocytes, such increased phosphorylation, was associated with altered cytoskeleton, disturbed focal adhesion sites and increased motility. Treatment with specific Akt inhibitor demonstrated a prominent decrease of motility and Akt phosphorylation. mTORC1 activation in response to nutrient replenishment was delayed in cystinosis PTECs accompanied with abnormal subcellular distribution of the kinase complex, as revealed by antibody staining of mTOR.

**Conclusions:** We demonstrate that cystinosis dysfunction is associated with disturbed signalling of protein kinases mTORC1 and Akt1 and 2.

**Intestinal Pericytes Decrease in Aged Mouse Kidneys**

Anna Maria Stefanska,1 2 Diana G. Eng,1 Natalya V. Kaverina,1 Jeremy Stuart Duffield,2 Jeffrey W. Pippin,2 Stuart J. Shankland.1

1Div of Nephrology, Dept of Medicine, Univ of Washington, Seattle, WA; 2Biovie Idec; Cambridge, MA.

**Background:** With increasing age, the kidney undergoes characteristic changes in the glomerular and tubulo-interstitial compartments, which are ultimately accompanied by reduced kidney function. Studies have shown age-related loss of perivascular cells. Normal perivascular cell tone, function and survival depend on neighboring pericytes. Pericyte detachment leads to vascular damage, which can be accompanied by their differentiation to fibroblasts and myofibroblasts, a state that favors matrix production.

**Methods:** To better understand the fate of pericytes in the aged kidney, 27-month-old mice were studied. Picorirous red staining was performed to evaluate kidney fibrosis. Histological sections were stained against endothelial antigen CD31 together with pericyte markers PDGFß and aSMA. Additionally, immunoreactivity of myofibroblast marker aSMA was assessed together with pericytes.

**Results:** Compared to 3-month-old young adult mice, aged kidneys showed a substantial decrease in capillaries, identified by CD31 staining, in both cortex and medulla. This was accompanied by a marked decrease in surrounding NG2 / PDGFß pericytes. This decrease was more pronounced in the medulla. Capillaries devoid of pericytes were typically dilated in aged mice. Aged kidneys were also characterized by interstitial fibrosis due to increased collagen-I and -III staining. This was accompanied by an increase in the number of pericytes that acquired a pro-fibrotic phenotype, identified by increased PDGFß and aSMA staining.

**Conclusions:** These findings are consistent with the decline in kidney interstitial pericytes as a critical step in the development of changes to the peritubular vasculature with aging, and accompanying fibrosis.

**Interactions of Urotensin II and Mitophagy in Diabetic Nephropathy and Its Implications on Drug Design**

Guan-Jong Chen, Fei Wu, Ai-hua Zhang, Dept of Nephrology, Peking Univ Third Hospital, Beijing, China.

**Background:** Urotensin II (UII), an important vasoactive neuropeptide, and the processes of mitophagy have been considered as possible therapeutic targets for treating diabetic nephropathy (DN). The present study is to define the interaction between UII and the process of mitophagy under the setting of DN.

**Methods:** Immunohistochemistry and western blot analysis were conducted on the protein extracts harvested from the kidney tissues of DN mice that were induced eighteen weeks after the injection of streptozotocin. For in-vitro cell experiment, HK-2 cells were cultured and treated with different concentrations of UII (10^(-7)-10^(-8) mol/L) for 2 h and 3-MA treatment was used as a negative control. The cell protein extracts were then analyzed by western blot. For immunohistochemistry and western blot analysis, BNIP3 was used as a marker for mitophagy.

**Results:** The results of our study demonstrate that UII expression can upregulate mitophagy in DN. Past studies already demonstrate that mitophagy can have a therapeutic role in DN. Our study carries the implication that UII and its effect on the process of mitophagy presents potential opportunities for the treatment of DN.

**Reduction in CTGF Leads to Increased Proliferation Through Influences on Claudin-1 and Extracellular Matrix Protein Spondin 2**

Leighton R. James, Yongxin Gao. Medicine, Univ of Florida, Jacksonville, FL.

**Background:** Accumulation of extracellular matrix is a characteristic feature of diabetic kidney disease. We have recently demonstrated that connective tissue growth factor (CTGF) mediate increases in extracellular matrix production, proteinuria and scarring in mice. In addition, CTGF may have anti-apoptotic properties. In specific human neoplasms (breast, colon), increased CTGF have been linked to reduced proliferation, improved response to therapy and prognosis but data is not consistent. On the other hand, metastatic melanoma progression correlates with CTGF levels and inhibition of CTGF reduces invasion and migration.

**Methods:** To define a possible role for CTGF in proliferation, embryonic fibroblasts (MEF) generated from wild-type and a previously reported CTGF knock mice line were studied. Expression array (Illumina) was used to identify changes in gene expression in MEF, with expression validated by Immuno-blotting. Inhibition of MAPK (SP600126, SB203580 and U0126) were used to assess role of MAPK in glucose-mediated CTGF expression by cultured MEF.

**Results:** CTGF gene disruption lead to enhanced proliferation (3-fold) in CKG knockout cells compared with wildtype cells. Reduced CTGF led to 50% decreased expression of the gene for the extracellular protein, procollagen 4, alpha 2 (Col4a2; confirmed at protein level)) in association with 2.8-fold increased expression of claudin-1, a member of the tight junction proteins. In addition, there was a 3.2-fold increased expression of spondin-2 and a 1.6-fold increased expression of Secreted Protein, acidic rich in cysteine-like 1 (SPARC1). Immunoblotting confirmed the observation for claudin-1. Glucose induced CTGF expression (2-3 fold) was attenuated by inhibitors of p38MAPK and JNK, but unaffected by inhibition of ERK (p42/44 MAPK).

**Conclusions:** In MEF, the gene disruption lead to increased proliferation and altered matrix protein linked to increased expression of claudin 1 and other extracellular protein. Secondly, glucose-induced CTGF level is mediated by MAPK (p38 and JNK). Targeted alteration in CTGF along with one or more of these extracellular protein may offer new approaches to manage glomerulosclerosis.

**miR21 Upregulates YY1 to Increase Renal Cell Apoptosis in Diabetes**

Adam Kost,1 Sitai Liang,2 Samy L. Habib.1 2Geriatric Research, Education and Clinical Center, CTR, South Texas Veterans Health System, San Antonio, TX; 2Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.

**Background:** The regulation of miRNAs in response to hyperglycemia that contributes to the pathogenesis of kidney disease has been underscored.

**Methods:** In the current study, we investigated the role of miR21 in regulation of cells apoptosis in human renal proximal tubular cells (HK2) cells exposed to high glucose and in type II diabetes mouse model.

**Results:** Cells pretreated with either miR21 inhibitor or antisense before exposed to HG resulted in decrease YY1 expression and decrease cleavage of caspase 3. Nuclear extracts from HK2 cells exposed to high glucose for 48hrs showed increase in binding of YY1 to the promoter element in nuclear extracts of cells EMSA. On the other hand, pretreatment with miR21 inhibitor or antisense significantly decrease the binding of miR21 to YY1 in nuclear extracts of cells grown in NG or treated with HG. The DNA-protein complexes were significantly decreased in the presence of the YY1 antibody, indicating that YY1 is indeed a component of these complexes. Transfected the cells with promoter/reporter construct of miR21 showed significant increase in miR21 promoter activity in cells exposed to HG while cells pretreated with miR21 inhibitor reverse the effect of HG. In addition, significant increase in the percentage of TUNEL-positive tubular cells stained in the kidney sections of db/db mice kidney compared to kidney sections of the wild type mice. Quantitation of miR21 by real-time PCR showed significant increase miR21 levels in kidney of diabetic mice (db/db) compared to kidneys from wild type mice. Immunosstaining analysis of miR21 showed that majority of miR21 staining within the tubular cells and glomerular compartments.

**Conclusions:** In summary, expose renal cells to HG and increase hyperglycemia in kidney of diabetic mice resulted in significant increase in miR21. Increased binding of YY1 to miR21 under HG condition suggesting the important role of miR21 in regulating YY1 to increase cell apoptosis. The data provide a novel role of miR21 as a target for controlling renal cell death that induced by hyperglycemia during diabetic nephropathy.

**The Role of miR-302 and Let7 in Macrophage Polarization**

Thomas K. Dodd, John Crean, Letizia De Chiara, Orina Belton. Diabetic Complications and Renal Disease, Univ College Dublin, Dublin, Ireland.

**Background:** Recent advances in the pathogenicity of renal injury highlighted the critical role of the immune system in the onset and resolution of disease. Monocytes canto differentiate along two pathways: pro-inflammatory (M1) due to the secretion of cytokines such as IL-6 and a-pro-resolution attributable to the secretion of cytokines such as IL-10. Bane et al. have suggested that the ratio of M1 and M2 macrophages is controlled by...
interplay between two micro RNAs, miR302 and Let7. We have recently shown that the silencing targets of miR-302 and Let7 are the TGF-β type II and type I receptors respectively and hypothesize that this circuitry plays a critical role in macrophage differentiation.

**Methods:** The pro-resolving lipid mediator, conjugated linoleic acid (CLA), inhibits the acquisition of a pro-inflammatory macrophage phenotype by priming monocytes towards an anti-inflammatory phenotype. To identify pathways associated with this phenotype we performed proteomic analysis of THP-1 cells treated with CLA. Exosomes were isolated from urine samples taken from patients with renal injury and analyzed for miRNA expression. Renal cells were transfected with miR-302 and let7 virus. TGFβ receptor expression and signaling was analyzed by western blot. Additionally, Thp-1 cells were transfected with miR302 and let7 and their effect on phagocytosis differentiation assessed for expression of CD68 and CD206.

**Results:** Bioinformatic and Western blot analysis revealed enrichment of the TGFβ signaling pathway in THP-1 cells treated with CLA. miR302 expression was increased in the urine of patients compared to controls. Cells transfected with miR302 and Let7 displayed low levels of expression of the TGFβ type II and type 1 receptors respectively and dampened Smad3 phosphorylation. miR302 and let7 prevented renal epithelial cell dedifferentiation. THP-1 cells transfected with both miRs demonstrated similarly enhanced plasticity. Manipulation of this circuitry results in enhanced cell plasticity. In vitro studies suggest that this results in the generation of pro-resolution cellular phenotypes in both resident cells and macrophages.

**Dopamine D2 Receptor Regulates Wnt3/β-Catenin Signaling and Apoptosis in Human Renal Proximal Tubule Cells**

**Fei Han, 1 Prasad Konkalmatt, 1 Jianghua Chen, 2 Pedro A. Jose, 3 Ines Armando.**

**Department of Internal Medicine, University of Wisconsin, Milwaukee, WI; 1Department of Medicine, School of Medicine, University of Maryland, Baltimore, MD.

**Background:** Dopamine D2 receptor (D2R) in the kidney has a direct role in regulating renal injury and, injury, and blood pressure. Some common single nucleotide polymorphisms (D2R SNPs; rs6726, 6727, and 1800497) in the human D2RD gene are associated with decreased D2R expression and function.

**Methods:** We measured apoptosis and activation of Wnt3/β-catenin signaling pathway in human renal proximal tubule cells (RPTC) carrying these D2R SNPs (RPTC-D2R SNPs), and in RPTC carrying wild type (RPTC-D2R WT).

**Results:** RPTC-D2R SNPs showed increased apoptosis compared with RPTC-D2R WT (1.0±0.8% vs 2.3±0.4% TUNEL positive cells; P<0.01). We found that Wnt3 expression was increased in RPTC-D2R SNPs in comparison with RPTC-D2R WT (RNA: 2.6±0.35 vs 1±0.11 fold; P<0.05; protein: 133±4% vs 100±5%; p<0.05). RPTC-D2R SNPs showed increased β-catenin phosphorylation and decreased Bax and FasL expression. Moreover Wnt3 expression and release of apoptosis cells were transfects with scrambled siRNA or siRNA against Wnt3 and were exposed to control media or hypertonic medium.

**Results:** Following exposure to a high salt diet, pharmacologic inhibition of Wnt3 resulted in more severe kidney damage as assessed by the percentage outer medullary area with tubular dilatation and protein casts, when compared with vehicle-treated rats. Inhibition of Wnt3/β-catenin was associated with a significant increase in tubular cell apoptosis in comparison to vehicle treatment on TUNEL staining. Also, inhibition of Wnt3 led to significantly higher urinary albumin excretion and blood pressure at day 21 compared with vehicle treatment. Exposure of NRK52E cells to hypertonic medium resulted in increased expression and release of HMGB1 from the cells. Both pharmacologic inhibition and siRNA-mediated knock-down of HMGB1 led to reduced cell viability as determined by MTT assay.

**Conclusions:** HMGB1 plays an important role in renal tubular epithelial cell survival during hypertonic stress.

**SA-PO306**

**KIM-1-Mediated Phagocytosis Defines a New Mechanistic Paradigm for Kidney Epithelial Cells, which Involves Autophagy and Anti-Inflammatory Antigen Presentation**

**Craig R. Brooks, Melissa Y. Yeung, Takeharu Ichimura, Joseph V. Bonventre.**

**Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

**Background:** The expression of kidney injury molecule-1 (KIM-1), the protein most upregulated in proximal tubular epithelial cells, interacts with professional phagocytes to induce immune responses. The processing of phagocytes to the lysosome can determine the immunogenicity of antigens derived from the phagocytosed cargo. Here we compare the phagocytic processing of KIM-1-expressing PTCs to that of professional phagocytes and establish distinct mechanisms.

**Methods:** LLC-PK1 cells expressing KIM-1 were exposed to apoptotic cells. LC3 localization to the phagosome, phagosome acidification and degradation were measured by live cell imaging, phagosome isolation and western blotting. NADPH oxidase (NOX) activity was blocked with diphenyleneiodonium and reactive oxygen species (ROS) was measured with fluorescent probes. MHC presentation was measured in primary PTCs directly using specific antibodies by flow cytometry. Functional implications were determined by activation of CD4+ and CD8+ T cells.

**Results:** KIM-1 binds to and induces phagocytosis of apoptotic cells within ~5-30 min, similar to professional phagocytes. Following uptake, however, PTCs process phagosomes more slowly than professional phagocytes, with delayed phagosome acidification and degradation (4-12 hrs vs 1-2 hrs). Mechanistically, PTCs do not upregulate NOX-1 induced production of ROS, a process necessary for efficient acidification and degradation of the phagosome. LC3 associated phagocytosis (LAP), an important NOX-induced production of ROS, a process necessary for efficient acidification and degradation of the phagosome. LC3 associated phagocytosis (LAP), an important NOX-dependent feature of professional phagocytic function, is not observed in PTCs. PTCs instead induce canonical autophagy to clear phagocytosed debris. Delayed phagosomal acidification and degradation result in more slowly than professional phagocytes, with delayed phagosome acidification and degradation (4-12 hrs vs 1-2 hrs). Mechanistically, PTCs do not upregulate NOX-1 induced production of ROS, a process necessary for efficient acidification and degradation of the phagosome. LC3 associated phagocytosis (LAP), an important NOX-dependent feature of professional phagocytic function, is not observed in PTCs. PTCs instead induce canonical autophagy to clear phagocytosed debris. Delayed phagosomes are processed and increased autophagy result in increased PTC antigen presentation. Here we compare the phagocytic processing of KIM-1-expressing PTCs to that of professional phagocytes and establish distinct mechanisms.

**Conclusions:** Phagocytic processing of KIM-1-expressing PTCs to that of professional phagocytes and establish distinct mechanisms.

**The Role of High Mobility Group Box 1 in Renal Epithelial Cell Survival During Hypertonic Stress**

**Michael M. Yeboah, Marla A. Chesnik, Hayley Lund, 2 Kevin R. Regner, 1 David L. Mattson.**

**1Div of Nephrology, Medical College of Wisconsin, Milwaukee, WI; 2Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.

**Background:** High mobility group box 1 (HMGB1) is a ubiquitous and evolutionarily conserved, DNA-binding protein and is characterized as an alarmin or damage associated molecular pattern because of the ability of extracellular HMGB1 to trigger an inflammatory response when it binds to its putative receptors, including RAGE, TLR2 and TLR4. New and emerging evidence suggest that intracellular HMGB1 is involved with numerous cell survival functions. The aim of this study was to examine the functional role of HMGB1 in tubular epithelial cells during hypertonic stress.

**Methods:** In vivo; 2 groups of Dahl Salt sensitive rats were placed on high salt diet (4% NaCl, n=5/group) and were treated with either daily intraperitoneal injection of a HMGB1 inhibitor (glycyrrhizic acid) or a vehicle for 3 weeks while their blood pressure was monitored by telemetry. In vivo, NNRK52E cells were incubated in control medium (332 mOsmol/kg) or hypertonic medium that contained NaCl (500 and 600 mOsmol/kg) for 6 hours in the presence or absence of the HMGB1 inhibitor. In other experiments, cells were transfected with scrambled siRNA or siRNA against HMGB1 and were exposed to control medium or hypertonic medium.

**Results:** Following exposure to a high salt diet, pharmacologic inhibition of HMGB1 resulted in more severe kidney damage as assessed by the percentage outer medullary area with tubular dilatation and protein casts, when compared with vehicle-treated rats. Inhibition of HMGB1 was associated with a significant increase in tubular cell apoptosis in comparison to vehicle treatment on TUNEL staining. Also, inhibition of HMGB1 led to significantly higher urinary albumin excretion and blood pressure at day 21 compared with vehicle treatment. Exposure of NRK52E cells to hypertonic medium resulted in increased expression and release of HMGB1 from the cells. Both pharmacologic inhibition and siRNA-mediated knock-down of HMGB1 led to reduced cell viability as determined by MTT assay.

**Conclusions:** HMGB1 plays an important role in renal tubular epithelial cell survival during hypertonic stress.

Apototic Cells Activate AMPK and Inhibit Proximal Tubular Cell (PTC) Growth without Change in Intracellular Energy Stores
Philip Speigel,1 Snezana Vujicic,1 Lanfei Feng,1 Natalia O. Litbarg,1 Jerrold S. Levine.1
Background: Apoptosis plays an indispensable role in the maintenance and development of tissues. We have shown that receptor-mediated recognition of apoptotic target cells by viable kidney PTCs inhibits the proliferation and survival of these viable PTCs. Here, we examined the effect of apoptotic target cells on PTC cell growth (cell size during G1 phase of cell cycle).
Methods: We used BU.MPT cells, a conditionally immortalized PTC line, as responder cells. BU.MPT cells, induced to undergo apoptosis in several ways, were used as apoptotic targets. Results: Apoptotic cells potently activated AMP-activated protein kinase (AMPK), a highly sensitive sensor of intracellular energy stores. AMPK activation led to decreased activity of its downstream target, ribosomal protein p70 S6 kinase (p70S6k) and concomitant inhibition of cell growth. Importantly, these events occurred without detectable change in intracellular levels of AMP, ADP, or ATP. Inhibition of AMPK, either pharmacologically by compound C or molecularly by shRNA, diminished the effects of apoptotic targets, and largely restored p70S6k activity and cell size to normal levels. Apoptotic targets also inhibited Akt, a second signaling pathway regulating cell growth. Expression of a constitutively active Akt construct partially relieved cell growth inhibition, but was less effective than inhibition of AMPK. Inhibition of cell growth by apoptotic targets was dependent on physical interaction between apoptotic targets and PTCs, but independent of phagocytosis.
Conclusions: We conclude that receptor-mediated recognition of apoptotic targets mimics the effects of intracellular energy depletion, activating AMPK and inhibiting PTC cell growth. By acting as sentinels of environmental change, apoptotic death may enable nearby viable cells, especially non-mitogenic epithelial cells, to monitor and adapt to local stresses.

The Effect of Uremia on Cardiac Autophagy
William White, Steven Michael Harwood, Petros Andrikopoulos, Muhammad M. Yaqoob. William Harvey Research Inst, Barts & The London School of Medicine & Dentistry, Queen Mary Univ of London, London, United Kingdom.
Background: Autophagy is the process by which cells remove and recycle unwanted structures, contributing to intracellular homeostasis and energy production. Cardiac autophagy has a role in maintaining protection and ventricular remodeling, and decreasing autophagy is central to aging. Evidence suggests these processes are disordered in CKD. We hypothesize that albumin does not change autophagy, but decreases autophagy in uremia. Autophagic activity in hearts is decreased with proteinuria, a known uremic factor.
Methods: In Vitro Rat cardiac myoblast cells (H9C2) were cultured in the presence of insulin (100 μM), hemin (5 μM), and L-arginine (10 mM), to achieve a state of cellular stress that simulates conditions of uremia. Under these conditions, basal autophagy was strongly induced. Medium was changed every 2 days and cells were cultured for 5 days. Cells were fed normally or were starved for 24 h, and autophagy was assessed using confocal microscopy.
Results: At 24 and 48 h the amount of LC3BII (a marker of autophagic flux) expressed increased with IS in a dose-dependent manner with and without CQ. At 48 h P62 expression decreased with IS in the absence of CQ, but increased in its presence. In vivo setting and LC3BII and p62 expression increased in the uremic hearts in line with the in vitro data. Interestingly p53 expression was increased in the uremic group.
Conclusions: Uremia appears to stimulate autophagy in cardiac tissues at the protein level, in contrast to our autopsy transcriptome data. Previous authors have found that changes in autophagic activity are not always mirrored at a transcriptional level. Interestingly, p53 expression was greater in uremia, suggesting an increase in senescence, which we are currently investigating. Changes in autophagic activity and senescence in uremic hearts may contribute to the pathogenesis of uremic cardiomyopathy, and provide targets for therapy.

SA-PO309
Decorin Potentially Alleviates TGF-β1 Induced Podocyte Injury by Inactivating mTORC1 and Increasing Autophagy
Xing Ma, Zhigang Zhang, Huijuan Wu. Dept of Pathology, Shanghai Medical College, Fudan Univ, Shanghai, China.
Background: TGF-β1 is the major factor mediating podocyte injury during mesangial proliferative glomerulonephritis (MsPGN), manifesting by decreased autophagy, cytoskeleton relocation and increased apoptosis. Decorin (DCN), mainly secreted by mesangial cells (MCs) in glomeruli, is a natural antagonist of TGF-β1 and has been shown to be downregulated in MsPGN and in vitro. We hypothesize that decorin could protect podocytes from autophagy in injured podocytes of MsPGN and the possible effect of DCN/TGF-β1 axis on the crosstalk of MCs and podocytes are still not clear.
Methods: We used immunohistochemistry (IHC) to detect p-smad2 and LC3 in rat anti-Thy-1 nmephritis, and TGF-β1 in human nephritis. Then we treated podocytes with TGF-β1 and DCM and detected the expression of Vps34, p-S6K1 (Thr389), TGF-β1, p62 and LC3 by IHC. We also treated podocytes with TGF-β1 (20ng/ml) for 1, 3, 6 and 12 h, and found decreased protein expression of Vps34 and increased p-S6K1 (Thr389) representing mTORC1 signaling, autophagy was increased and p62 was decreased. In cultured human podocytes, the treatment of recombinant soluble DCN (6.25ng/M or 100ng/M) for 1, 3, 6 and 12h on podocytes led to an increase p-smad2 expression of Pe5g, decreased p-S6K1 (Thr389), LC3BII and TGF-β1. In this study, we firstly found increased p-smad2 and decreased LC3 by IHC in podocytes of rat anti-Thy-1 nephritis with obvious proteinuria, and consistently, increased TGF-β1 staining in human nephritis featured by MCs proliferation and proteinuria. Then we treated podocytes with TGF-β1 (20ng/ml) for 1, 3, 6, and 12 h, and found decreased protein expression of Vps34 and increased p-S6K1 (Thr389) representing mTORC1 signaling, autophagy was increased and p62 was decreased. In cultured human podocytes, the treatment of recombinant soluble DCN (6.25ng/M or 100ng/M) for 1, 3, 6 and 12 h on podocytes led to an increase p-smad2 expression of Pe5g, decreased p-S6K1 (Thr389) and LC3BII. Moreover, it also decreased TGF-β1 in podocytes.
Conclusions: These results suggest that TGF-β1 induced an activation of mTORC1 signaling and the abrogation of macroautophagy in podocytes, whereas DCN downregulated TGF-β1 protein expression, and thus inactivate mTORC1 signaling and induce autophagy on podocytes, indicating DCN may have a potential in alleviating TGF-β1 induced podocyte injury in MsPGN.

SA-PO310
Albumin Endocytosis in the Proximal Tubule Causes Accumulation of Dysfunctional Mitochondria
Andreia Nolin, Ryan M. Mulhern, Ramon G. Bonegio, Zhiyong Wang, Steven C. Berkman, John H. Schwartz, Andrea Havasi. Renal, Boston Univ Medical Center, Boston, MA.
Background: Proteinuria is a major risk factor for chronic kidney disease progression. Furthermore, exposure of proximal tubular epithelial cells (PTEC) to excess albumin promotes tubular atrophy and fibrosis, key predictors of progressive organ dysfunction. The mechanism by which protein exposure causes tubular cell injury is uncertain. We hypothesize that albumin endocytosis causes tubular cell injury by inhibiting autophagy, including mitophagy, resulting in an accumulation of dysfunctional mitochondria leading to enhanced ROS production, mitochondrial and cellular injury.
Methods: The effect of proteinuria was examined both in in vivo and in vitro experiments. Proteinuria was induced in mice by injection of a sheep nephrotic serum that causes acute immune-complex glomerulonephritis with massive proteinuria by 24-48 hrs. In vitro, to mimic nephrotic glomerular filtrate, PTECs were exposed to albumin. Autophagy was assessed in tissue samples from mice and primary PTECs. Steady state LC3BII or LC3BIII, an autophagy marker was quantified by immunoblot. Autophagosomes (APs) were examined by electron microscopy and fluorescent markers and in renal cortical tissue using immunohistochemistry. Mitochondrial respiration was measured in primary cells. Mitochondrial morphology and colocalization with autophagosomes were imaged using confocal microscopy. Reactive oxygen species production was measured using a 2′,7′-dichlorofluorescin diacetate assay.
Results: Exposure to excess albumin induced defective autophagy and mitophagy in vitro. In renal cortices, proteinuria decreased both the number of LC3-II positive APs and the amount of LC3-I detected in cell lysates. Albumin-exposed cells accumulated damaged mitochondria with altered mitochondrial function and morphology. Albumin exposure caused mitochondrial dysfunction as evidenced by decreased oxygen consumption rate from coupled ATP production. Increasing albumin exposure time caused an increase in ROS production.
Conclusions: Dysfunctional autophagy caused by proteinuria likely contributes to tubular cell toxicity leading to renal progression.

Association Between a Marker of Aging and Cardiovascular Pathology in End-Stage Renal Disease Patients
Karin Luttropp,1 Dagmara Megiunnis,2 Abdul Rashid Tony Qureshi,1 Hannes Olauson,1 Annika Wernerson,1 Louise Nordfors,1 Jonaz Ripsveden,6 Peter F. Barany,1 Peter Stenvikv.1 Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden; 2Inst of Cancer Sciences, Univ of Glasgow, Glasgow, United Kingdom; 3Dept of Clinical Science, Intervention and Technology, Div of Renal Medicine, Karolinska Inst, Stockholm, Sweden; 4Dept of Clinical Science, Intervention and Technology, Div of Radiology, Karolinska Inst, Stockholm, Sweden.
Background: Patients with chronic kidney disease (CKD) display a progeric phenotype, with a high incidence of cardiovascular disease (CVD) and vascular calcification (VC). The process of VC is complex, and has been linked to apoptosis. A potential contributor to the calcification process is the pro-apoptotic factor cyclin-dependent kinase inhibitor 2A (CDKN2A). This study aims to investigate possible associations between CDKN2A expression, VC and CVD in a CKD population.
Methods: CDKN2A expression was determined in epigastric arteries (n=43) from patients with end-stage renal disease (ESRD) undergoing living donor renal transplantation (LRTx). Arteries were scored for degree of calcification in percent. Coronary artery calcification (CAC) score was also obtained.
Results: The arterial expression of CDKN2A was significantly associated with VC (p=0.01, r=0.4), CVD (p=0.002, CAC score (p=0.008, r=0.5) and diabetes mellitus (p=0.05). In addition, arterial CDKN2A expression was associated with MGP (p=0.007, r=0.4) and RUNX2 (p=0.046, r=0.3) expression in artery, both of which are involved in osteogenic transformation of vascular smooth muscle cells.
Conclusions: These findings provide evidence that cell senescence and apoptosis are important in the development of VC and CVD in the uremic milieu, and further strengthen the hypothesis that comorbidities present in CKD could be caused by a premature aging process. Attempts to ameliorate any progeric process in this patient group is therefore of great interest.

Endothelial Autophagy Is Essential for Vascular Lipid Homeostasis
Kumiko Torisu,1,2 Subodh Verma,1 Takehiro Torisu,1,2 Krishna K. Singh,1 Toren Finkel,1,3 Center for Molecular Medicine, National Heart, Lung, and Blood Inst, NIH, Bethesda, MD; 1Div of Cardiac Surgery, St. Michael’s Hospital, Univ of Toronto, Toronto, ON, Canada; 2Graduate School of Medical Sciences, Kyushu Univ; Fukuoka, Japan.

Background: Cardiovascular disease is one of the common complications in chronic kidney disease. It is known that autophagy plays a critical role in the course of kidney diseases. The resulting cardiovascular diseases are presumably regulated by autophagy. However the physiological role of autophagy in the vascular endothelial cells remains poorly understood.

Methods: Using human umbilical vein endothelial cells (HUVECs), induction of autophagy by ox-LDL, and uptaking or transcytosis of LDL are analyzed. To inhibit autophagy pharmacologically, chloroquine is used. The essential autophagy gene, Atg7 shRNA-mediated knockdown are performed to inhibit autophagy genetically. To assess an acute and chronic in vivo model of lipid exposure, we generated endothelial specific Atg7 knockout in ApoE deficient mice (Atg7/+/ApoE KO).

Results: Ox-LDL induced autophagosome formation in HUVECs. Moreover, native or ox-LDL appeared to be engulfed within autophagosomes by live cell imaging and electron microscopy. Atg7 knockdown or pharmacological inhibition of autophagy resulted in higher accumulation of intracellular LDL, suggesting that in vascular endothelial cells, autophagy is one of the degradation machinery of excess lipids. As an acute model of lipid exposure in vivo, Atg7/+/ApoE mice showed longer retention of ox-LDL within the retina after infusion of Dil ox-LDL. In a chronic model of lipid excess, we analyzed atherosclerosis in ApoE KO or Atg7/+/ApoE KO mice. Atg7/−/−ApoE KO mice demonstrated markedly increased atherosclerosis.

Conclusions: In endothelial cells, autophagy appears to play a critical role in regulating excess intracellular lipids. Moreover, in both acute and chronic in vivo model, endothelial autophagy plays an essential role in LDL accumulation within endothelial layer. Prevention of the decline in autophagy flux accompanied by kidney diseases pharmacologically might be beneficial to treat atherosclerotic diseases.

Targeted Mutations at the p66 Locus Antagonize Stem Cell Aging and Delay Expression of Senescent Phenotypes in Diabetic Kidneys

Background: Senescence has important implications for the biologic function of tissue stem cells, which maintain tissue homeostasis by replacement of old or dying cells and via the repair of tissue injury. The p66 longevity gene plays a key role in the activation of gene programs that induce senescent and apoptotic phenotypes. We hypothesize gene basal strategies targeting p66 will delay or prevent stem cell senescence and premature aging phenotypes in diabetic kidneys.

Methods: Mesenchymal stem cells (MSCs) were isolated from kidneys of p66 KO mouse (p66 KO-MSCs) using established methods and plated in high glucose (HG) containing media. Microarray was used to profile secreted factors expressed by MSCs. p66 KO diabetic mice were generated to evaluate survival of MSCs in diabetic kidneys, growth, proliferation, histologic markers of aging and near normal urine albumin excretion. Kidney nuclei staining (+) for Ki-67 was upregulated, whereasp16 INK4a and tubules, with barely detectable histologic markers of aging and near normal urine albumin excretion. Unexpected cross talk between p66 and Wnt regulatory genes that antagonize senescence. Kidney sections from p66 KO diabetic mice show increased numbers of MSCs in glomeruli and tubules, with barely detectable histologic markers of aging and near normal urine albumin excretion. Kidney nuclei staining (+) for Ki-67 was upregulated, whereasp16INK4a was downregulated.

Conclusions: These findings suggest a genetic link between p66 longevity gene, stem cell aging and senescent phenotype(s) in diabetic kidneys.

The Full Time Course and Localization of mTOR Activation in Compensatory Renal Hypertrophy
Jinxian Xu,1 Meichu Cheng,1 Jianchun Wang,2 Kang Chen,2 1Cellular-Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA; 2Medicine, Vanderbilt Univ, Nashville, TN.

Background: Previous studies documented an essential role for mTOR activation in mediating compensatory renal hypertrophy induced by unilateral nephrectomy (UNX) but the time course and localization of the mTOR activation are unclear.

Methods: 8-week-old male FVB/NJ mice were subjected to right UNX or sham surgery, followed by sacrifice at different time points to collect left kidney and determine the time course and localization of mTOR activation by immunoblots and immunofluorescence staining for phospho-S6K1 and phospho-p70, along with nephron segment-specific markers.

EGF Dependent Regulation of VEGF-A Secretion by Proximal Tubule Cells

Diana Zepeda-Orozco,1 Hsiang M. Wen,2 Nandita S. Raikwar,2 Christie A. Dockrell,1 Hsiang M. Wen,2 Nandita S. Raikwar,2 Christie A. Dockrell,1 Hsiang M. Wen,2 Nandita S. Raikwar,2 Christie A. Dockrell,1 Hsiang M. Wen,2 Nandita S. Raikwar,2 Christie A. Dockrell,1 Hsiang M. Wen,2 Nandita S. Raikwar,2 Christie A. Dockrell,1

Background: Vascular endothelial growth factor A (VEGF-A) plays a critical role in peritubular capillary development by promoting vasculogenesis and angiogenesis. It is now recognized that there is increased expression of VEGF-A by proximal tubular epithelial cells in ischemia reperfusion injury and in chronic tubulointerstitial injury. Although hypoxia is known to increase VEGF-A expression in vitro, the role of VEGF-A in vivo, and in the mechanisms regulating VEGF-A secretion by proximal tubule epithelial cells in normoxia has not been established.

Methods: We utilized HK2 cells, an immortalized human proximal tubule cell line, to characterize the epidermal growth factor (EGF)-dependent regulation of VEGF-A secretion by proximal tubular epithelial cells.

Results: EGF increases HIF1a expression, stimulates VEGF-A secretion and proliferation of HK2 cells under normoxic conditions. HIF1a knockdown decreases EGF-dependent VEGF-A secretion indicating that the effect of EGF is at least partly HIF1a dependent even in normoxia. EGF stimulates HIF1a and VEGF-A via activation of the EGF receptor and upregulation of mTOR and p42/44 MAPK pathways. p42/44 MAPK inhibition significantly downregulates HIF1a-dependent VEGF-A secretion and cell proliferation. Although mTOR inhibition reduces HIF1a, it upregulates MAPK with a very modest reduction of VEGF-A secretion indicating that mTOR and p44/42 MAPK may act via parallel pathways in VEGF-A regulation. Finally, we demonstrate that the EGF-stimulated proliferation of HK2 cells is reduced by VEGF Receptor 2 (VEGFR2) blocker indicating that EGF stimulates proximal tubular cell proliferation via the secretion of VEGF and the activation of the VEGFR2 receptor.

Conclusions: EGF stimulates VEGF-A secretion via activation of the EGF receptor, and stimulation of HIF1a. EGF stimulates proliferation of HK2 cells via the secretion of VEGF-A indicating that VEGF is an autocrine proximal tubular epithelial cell growth factor. The effects of EGF on HIF1a, and VEGF-A in HK2 cells are modulated by complex crosstalk between p42/44 MAPK and mTOR pathways.

Selective Regulation of a Novel Truncated CCN3 Protein by TGFβ1 in Human Tubule Epithelial Cells

Matthew Potting,1 Bruce L. Riser,2 Mark E. Dockrell,1 1SWI Intl for Renal Research, London, United Kingdom; 2BLR Bio, WI.

Background: CCN3 is a member of the matricellular CCN family of proteins along with the structurally similar CCN2/CTGF, a powerful fibrotic agent, but recent work supports our hypothesis that CCN2 and 3 act in opposition to each other regulating fibrosis. In renal cell dysfunction, inhibition of CCN3 with siRNA or TGFβ1 has been shown to counter regulate the expression of CCN2 and CCN3 in the vertebral nucleus pulposus and in mesangial cells. We have previously characterised TGFβ1 induction of CCN2 in proximal tubule epithelial cells (PT), here we investigate the expression of CCN3 in human PT cells and its potential regulation by TGFβ1.

Methods: Primary human PT cells were cultured on collagen IV in supplemented medium. At 80% confluence cells were treated with TGFβ1 (-0.25 -2.5 ng/ml) for 24 & 48h, medium was collected and cells lysed. Equal amounts of lysate were subjected to PAGE and Western blotting then probed with antibodies (Ab) to the C-terminal region of CCN3, as well as the C-terminal region of CCN2/CTGF.

Results: Under control conditions the anti-CCN3 hinge Ab revealed the expression in PTEC of the 51Kda full-length protein as well as a 39Kda isoform. The antibodies to the respective termini detected bands of approximately 23-28Kda. The C-terminal ab did not detect the 39Kda band. The antibody to the N-terminal detected proteins of approximately 45Kda as well as the 39Kda form. Treatment with TGFβ2 for 24h had no effect on the 51Kda protein but significantly inhibited the expression of the 39Kda.

Conclusions: A concentration that induce-CTGF expression in PTEC. TGFβ1 does not regulate the expression of full length CCN3. However, it does reduce the expression of a truncated form apparently lacking the CT domain. The characteristics of this smaller protein are not consistent with any known splice variants and may represent an non-physiological entity. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

Deletion of TGF-β Receptor 1 Causes Reduced Proximal Tubule Cell Impairs HGF Signaling

Stellor Nandu Khod,1 Leslie S. Gewin,2 1Research, Tennessee Valley Veterans Affairs, Nashville, TN; 2Medicine, Div of Nephrology, Vanderbilt Univ, Nashville, TN.

Background: The growth factors TGF-β and HGF have antagonistic and synergistic interactions that govern renal development and response to injury. We previously showed that TGF-β worsened the epithelial response to acute renal injury, so we postulated that TGF-β/HGF signaling may impact repair. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

Results: TβRII-/- PT cells had increased tubular branching and impaired migration compared to cells with the receptor intact. Unexpectedly, PT cells lacking TβRII had impaired response to HGF in both branching morphogenesis and migration assays compared to TβRII wildtype cells. Consistent with this, TβRII-/- PT cells had impaired dMet phosphorylation associated with reduced membrane expression of dMet and transcriptional downregulation of the HGF receptor. Notch signaling, a known inducer of dMet transcription, was decreased in cells with TβRII intact, and Notch inhibition by gamma-secretase equalizes the responses to HGF by PT cell with and without the receptor.

Conclusions: PT cells lacking TβRII have impaired responsiveness to HGF signaling, and this is due to reduced Notch-mediated dMet transcription. Thus, efforts to block TGF-β signaling may inadvertently inhibit signaling pathways of other growth factors such as HGF.

Enhancement of HGF-Induced Tubulogenesis by Endothelial Cell-Derived GDNF

Masao Nakamoto, Akito Maeshima, Shunsuke Takahashi, Hidekazu Ieuchi, Toru Sakairi, Yoraki Kaneko, Keiji Hirono, Yoshitaka Nogima. Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.

Background: Renal proximal tubular epithelium can regenerate itself after a variety of insults. However, the fibrotic environment that regulates regeneration process of renal tubules after injury remains unclear. We previously established an in vitro 3D tubulogenesis assay which at least partly mimics in vivo regeneration processes of renal tubules after injury (Am J Physiol Renal Physiol: 301: F387-95, 2011). Utilizing this system, the endothelial cell-derived factors that regulate tubular formation was examined.

Methods: Human renal proximal tubular epithelial cells (RPTEC) were cultured in gels (type I collagen/matrigel mixture) in the presence of HGF with or without human umbilical vein endothelial cells (HUVEC) using Transwell filter system. The signaling pathway activated by co-culture with HUVEC in tubular structures were examined using phospho-receptor tyrosine kinase (RTK) array.

Results: HGF, a potent renotrophic factor, induced aquaporin-1-positive tubular structures with microvilli, suggesting that these structures are morphologically equivalent to adult renal tubules. When co-cultured with HUVEC, HGF-induced tubular formation was significantly enhanced. Tubulogenic action of HGF in a paracrine manner. GDNF-RET signaling may play a role in the crosstalk between renal tubular cells and surrounding endothelium during tubular regeneration after injury.

Massive Formation of Ang-(1-7) from AngII(1-8) Is Largely ACE2 Independent

Peter Daniel Serfizio,1 Jan A. Wysocki, Minghao Ye, Daniel Batte. Div of Nephrology, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.

Background: Ang(1-8) degrading mechanisms are complex including cleavage by aminopeptidases that form AngIII and carboxypeptidases like ACE2 and PDE3B. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

Conclusions: A concentration that induce-CTGF expression in PTEC. TGFβ1 does not regulate the expression of full length CCN3. However, it does reduce the expression of a truncated form apparently lacking the CT domain. The characteristics of this smaller protein are not consistent with any known splice variants and may represent an non-physiological entity. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

Funding: Underline represents presenting author.
Methods: After acute AngII(1-8) infusion to WT mice plasma concentrations of AngII(1-8), Ang(1-7) and Ang(1-5) were measured by LC-MS/MS. Additional measurements of Ang(1-7) by RIA and ELISA were performed for confirmatory purposes. Plasma ACE2 and PRPC activity in WT mice was measured using a fluorogenic substrate.

Results: Following AngII(1-8) infusion to WT mice plasma Ang(1-7) levels measured by MS were extremely high. Similarly high levels were also found when this peptide was measured by RIA and ELISA (Table).

<table>
<thead>
<tr>
<th></th>
<th>AngII(1-8)</th>

</tbody>
</table>

In an ACE2 KO line there was no significant difference in Ang(1-7) levels as compared to WT mice and the levels of ACE2 activity in plasma of WT mice were low. Moreover, activity of PRPC, another Ang(1-7) forming enzyme is very low at the plasma pH. We therefore hypothesize that Ang(1-7) formation after AngII(1-8) infusion must be largely ACE2 and PRPC independent. To further support this hypothesis, we infused a different set of mice with AngII(1-8) in the presence of recombinant murine ACE2 or ACE2 + MLN, a specific inhibitor. Under all these conditions the levels of Ang(1-7) were massively increased and therefore unaccountable only by the conversion of AngII(1-8) to Ang(1-7) by ACE2 cleavage.

Conclusions: Formation of Ang(1-7) during AngII(1-8) infusion is massive and largely ACE2 independent. The increase in Ang(1-7) after AngII(1-8) infusion suggests the presence of unknown Ang(1-7) forming enzymes that are very active in plasma.

HIF1α and HIF2-Induced Erythropoietin Production Along the Nephron

Yuichiro Izumi,1 Yukiko Yasuoka,2 Yushi Nakayama,1 Hideki Inoue,1 Masashi Mukoyama,3 Katsumasa Kawahara,1 Hiroshi Nonoguchi.2

1Nephrology, 2Physiology, Kitasato Univ School of Medicine, Sagamihara, Kanagawa, Japan; 3Internal Medicine, Kitasato Univ Medical Center, Kitamoto, Saitama, Japan.

Background: Kidney peritubular interstitial cells produce erythropoietin (Epo) in response to hypoxia and/or anemia. By using in situ hybridization method, we have shown that Epo is also produced by the cortical nephron segments (mainly in PCT, DCT and CCD) in control and/or hypoxic conditions (Nagai, et al, 2014). The role of renin-angiotensin-aldosterone inhibitor has been suggested to exacerbate anemia in chronic kidney disease, in response to hypoxia and/or anemia. By using in situ hybridization method, we have shown that Epo is also produced by the cortical nephron segments (mainly in PCT, DCT and CCD) in control and/or hypoxic conditions (Nagai, et al, 2014).

Methods: To characterize the molecular machineries for Epo production in renal tubules, we examined the mRNA expressions of HIF1α, HIF2α, PHD2, mineralocorticoid receptor (MR) and EGF-receptor (EGFR) along the nephron in basal condition. Each nephron segment from SD rats was microdissected in the presence of ribonucleoside and measured by RIA and ELISA (Table).

<table>
<thead>
<tr>

<td>1137 ± 394 pg/ml</td>
</tr>
</tbody>
</table>

Results: Epo mRNA expression was confirmed in whole nephron segments by RT-PCR in basal condition. The expressions of HIF1α, HIF2α and PHD2 mRNAs were detected in whole nephron segments both in RT-PCR and real time PCR. The largest expression of HIF2α mRNA was observed in PCT. HIF2α mRNA expression was larger than HIF1α mRNA expression in most segments (ΔCT relative to GAPDH). MR and EGFR mRNA expressions were observed not only in distal but also in proximal tubules.

Conclusions: The results suggest the presence of HIF2α induced-Epo reduction in renal tubules. The presence of MR in whole nephron segments suggest that aldosterone may have physiological effects for Epo production not only in distal but also in proximal tubules.

Cytokine Response of Primary Human Mesangial Cells Is LPS Strain Dependent

Margaret M. O’Neill, Carine Boustany, Steven S. Pullen. CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma. Inc, Ridgefield, CT.

Background: LPS stimulation of Toll-like receptor 4 (TLR4) induces the release of proinflammatory cytokines which activate potent immune responses. LPS is an important structural component of the outer membrane of Gram-negative bacteria and consists of three parts: lipid A, a core oligosaccharide, and an O side chain. It has been studied extensively in models of inflammation with E.coli 011:B4 most often referenced in the literature. The antigenicity of LPS varies from strain to strain depending on the composition its O side chain. A comparative study was designed to identify the optimal strain to be used for LPS-stimulated release of proinflammatory mediators from primary human mesangial cells (HMC).

Methods: HMC were stimulated with 7 strains of LPS and 24 hour supernatants were analyzed for production of inflammatory mediators (IL-6, IL-8, TNF-α and MCP-1).

Results: LPS induced strain-dependent increases in IL-6, IL-8, and MCP-1 in HMC, while there was no effect on IL-1β and TNF-α.

Conclusions: LPS induced strain-dependent increases in IL-6, IL-8, and MCP-1 in HMC, while there was no effect on IL-1β and TNF-α.

Effect of Angiostatin II Type 1 Receptor Blocker on 12-Lipoxygenase Activity and Slit Diaphragm Protein Nephrin and P-cadherin Expression in Type 2 Diabetic Rat Glomeruli

Wan-ning Wang, Yuan-yuan Zhang, Hongzhao Xu, Fu-zhe Ma, Tao Sun, Hang Yuan, Mindan Sun, Zhong-gao Guo. Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China.

Background: 12-lipoxygenase (12-LO) and Angiostatin II (Ang II) interaction plays an important role in the development of diabetic nephropathy (DN), in which proteinuria was thought to be associated with decreased expression of glomerular slit diaphragm protein nephrin and P-cadherin. However, it is unclear whether Ang II type 1 receptor blocker (ARB) regulates 12-LO activity and slit diaphragm protein expression in type 2 diabetic glomeruli and hence was investigated in this study.

Methods: Podocytes and glomeruli isolated from rats were used in this study. The 12-LO products 12(S)-HETE and Ang II were infused to rats by osmotic mini-pump. Rats fed high fat diet received low dose streptozotocin to make type 2 diabetes. Glomeruli were isolated with sieving method and classified into small glomeruli (SG, on the 75nm sieve) and large glomeruli (LG, on the 125nm sieve). ELISA, RT-PCR and Western blot for related targets were performed respectively.

Results: Ang II increased 12(S)-HETE levels in podocytes and glomeruli. Direct infusion of rats with 12(S)-HETE and Ang II significantly decreased LG nephrin, but increased SG nephrin expression compared to control. The glomerular P-cadherin expression was reduced after Ang II and 12(S)-HETE treatment and there was no difference between LG and SG. ARB did not affect blood glucose levels but completely attenuated increases in 12(S)-HETE content, AT1 expression and proteinuria induced by diabetes. Nephrin protein expression was significantly reduced in diabetic LG but increased in diabetic SG compared to control. P-cadherin expression was decreased in both diabetic LG and SG. These abnormalities were partially but significantly prevented by ARB treatment.

Conclusions: ARB could ameliorate the progression of DN via upregulation of glomerular nephrin and P-cadherin expression through inhibition of 12-LO activation in type 2 DN rat.

APOL1 Risk Variants and HIV Stimulate Induction of PDGFB-β Receptor in Podocytes

Xiqian Xi, Hongxu Wen, Ashwani Malhotra,1 Karl Leon Shipp,1 Pravin C. Singhal.1 Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; Medicine, Rambam Health Care Campus, Haifa, Israel.

Background: Clinical reports demonstrated that two coding sequence variants (G12V and G2021S) of the APOL1 gene are responsible for the higher percentage of kidney disease in African Americans. This disparity between patients with APOL1 variants versus wild type APOL1 increases by 10 fold for the development of HIVAN in patients of HIV infection who are not on antiviral therapy. Podocytes do not express platelet-derived growth factor (PDGF) receptors constitutively, nonetheless, in experimental animal models, podocyte

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

700A
uregulated expression of PDGFRs manifested as progressive glomerulosclerosis. We hypothesized that APOL1 risk variants and HIV carry potential for the induction of the activation of the PDGF pathway in podocytes.

Methods: To determine the effect of APOL1 and APOL1 variants expression, stably expressing Vector, APOL1G0, APOL1G1, or APOL1G2 human podocyte (HP) cell lines were derived. For knock down, small hairpin RNA of HIV (NL-4-3) or empty vector (control) was transduced into APOL1G0/HPs, APOL1G1/HPs and APOL1G2/HPs. After 48 h, RNAs were extracted. CDNs were amplified with specific primers for PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ. Results: RNA transfection significantly increased expression of PDGF- A, PDGF-B, PDGF-C, PDGFR-D, and PDGFRβ in podocytes/G0/HPs, G1/HPs, and G2/HPs with or without HIV transduction did not display any change in the expression of PDGF-B, PDGF-C, or PDGF-D, when compared with vector; whereas, G2/HPs in HIV milieu displayed enhanced expression of PDGF-A. Interestingly, both G1/HPs and G2/HPs displayed 10 fold increase in PDGFRβ expression when compared to vector/HPs or G0/HPs.

Conclusions: These findings indicate that PDGFRs and their receptor PDGFRβ can be induced by HIV and APOL1 risk variants. The present study could lead to new therapeutic targets for HIVAN.

Assessment of Urinary Liver Type Fatty Acid Binding Protein in Patients of Type 2 Diabetes Mellitus with Early Chronic Kidney Disease
Om Prakash Kalra, 1Mohit Garg, 1Ashok Kumar Tripathi, 2Sunil Agarwal. 1Medicine, UCMS & GTB Hospital, Delhi, India; 2Biochemistry, UCMS & GTB Hospital, Delhi, India.

Background: Diabetes mellitus is the most common cause of chronic kidney disease (CKD) worldwide. Various markers are being indentified which can detect nephropathy at an earlier stage. Both glomerular and tubular injury play an important role in etiopathogenesis of diabetic nephropathy (DN) and tubular damage precedes glomerular damage. Tubular markers may be superior to serum-based biomarkers in detecting early renal injury. Liver type fatty acid binding protein (L-FABP) is a 15 kDa protein that is primarily expressed in the liver and intestine. It is also expressed in other tissues including myocardium, skeletal muscle, smooth muscle, and areas of regenerative tissue.

Methods: This was a case control, cross sectional study. Eighty four subjects in the age group 30–60 years of either sex were taken and were divided into three groups: Group I: Healthy controls (n=28) Group II: Type 2 diabetes patients with normoalbuminuria (n=28) Group III: Type 2 diabetes patients with micro/macroalbuminuria (n=28). Detailed history, physical examination, investigations for renal function, serum creatinine, and liver function tests were done. Urinary L-FABP levels were measured using an ELISA kit.

Results: The urinary ACR levels were comparable in group I and II. Subjects in Group III had significantly elevated ACR values. Levels of urinary L-FABP were higher in subjects of group II and III when compared with group I. Values of L-FABP were also higher in group III compared to group II. There was a significant positive correlation found between urinary ACR and urinary L-FABP levels. A significant negative correlation was found between urinary L-FABP and eGFR.

Conclusions: Levels of urinary L-FABP are markedly increased in patients of diabetic nephropathy as compared to healthy controls. Levels were also increased in diabetes patients with normoalbuminuria suggesting early tubular injury in these patients. This suggests that urinary L-FABP may be a promising early marker for detection of diabetic nephropathy.

SA-PO327
Neuropilin1 Regulates Pericyte Behavior in Postnatal Kidney
Monika Lucyna Wnuk, Regula Buergy, Werner A. Graber, Valentin Djonov. 1Institut of Anatomy, Univ of Bern, Bern, Switzerland.

Background: Neuropilin 1 (Nrp1) is a transmembrane co-receptor implicated in the regulation of endothelial cell migration during angiogenesis. In the adult kidney, Nrp1 is expressed not only by endothelium but also by pericytes including peritubular mesangial cells. Nrp1 has been described as a regulator of pericyte cell migration and has been found to be involved in the regulation of endothelial cell migration. In the adult kidney, Nrp1 is primarily expressed by the endothelium in association with the coreceptor neuropilin-2 (Nrp2). Nrp1 and Nrp2 form a heterodimeric complex that binds ligands such as VEGFs and sema4D with high affinity.

Methods: To determine the role of Nrp1 in pericyte behavior, two complementary mouse models were used; in the first one, Nrp1 was deleted specifically in pericytes with tamoxifen-inducible NG2Cre line and in the second approach, Nrp1 was blocked with an Nrp1-IgG-based antibody (R&D). In both models, tamoxifen/antibody treatment started at P21. Results: Mutant mice showed mild proteinuria and/or hematuria at 3 months of age with Nrp1 primary affected. In vitro experiments with primary mesangial human and mouse cell lines showed increased cell proliferation, abnormal spreading and actin reorganization in Nrp1 knock down cells. Conclusions: This study shows a novel role of Nrp1 in adult kidney pericytes. Future exploration of the role of Nrp1 with kidney cell lines and measurement of blood pressure will further clarify these interesting findings.

Funding: Government Support - Non-U.S.

SA-PO328
Development of a Spontaneous, Reproducible and Treatable Kidney Fibrosis Model
Jessica Maree Overstreet, Ming-Zhi Zhang, Raymond C. Harris. Medicine, Vanderbilt Univ, Nashville, TN.

Background: Kidney fibrosis in chronic kidney diseases causes gradual loss of kidney functionality. Currently, only a few kidney fibrotic models are available. New kidney fibrotic models are needed. Since our previous studies indicated that activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, we have developed a model with selective overexpression of an EGFR ligand, human heparin-binding EGF (hHB-EGF) in renal proximal tubule.

Methods: B6D2 transgenic mice with selective overexpression of an EGFR ligand, human heparin-binding EGF (hHB-EGF) in renal proximal tubule, were generated. Male C57/BL6 homozygous HB-EGF mice received vehicle (water) or erlotinib (80 mg/kg/day) in daily gastric gavage 6 to 10 days after birth.

Results: Kidney cortical hHB-EGF mRNA and protein levels were dramatically higher in homozygous hHB-EGF mice than in heterozygous mice. Profound renal interstitial fibrosis was found in both B6D2 and C57/BL6 homozygous hHB-EGF mice, but not in heterozygous mice, as indicated by histology and increased levels of the pro-fibrotic and fibrotic components (CTGF, α-SMA, collagen 1 and IV). Homeozygous hHB-EGF mouse kidneys also exhibited increased oxidative stress and infiltration of both macrophages and T lymphocytes. Interstitial fibrosis appeared as early as 4 weeks old. Homozygous hHB-EGF mice have increased kidney EGFR activation (increased phosphorylation of EGFR) and activation of downstream signaling, p-ERK and p-AKT. In addition, there was markedly increased p-Smad 2/3, p-EGFR, p-ERK, and p-Smad 2/3 were all primarily localized to proximal epithelial cells, indicating that hHB-EGF-mediated EGFR activation in proximal epithelial cells is the primary event in the development of interstitial fibrosis. Treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, inhibited EGFR signaling pathways and attenuated the development of renal interstitial fibrosis.

Conclusions: These studies suggest that ligand-mediated EGFR activation in renal proximal tubular epithelial cells leads to spontaneous, reproducible, and treatable renal interstitial fibrosis. Therefore, homozygous hHB-EGF mice may be a useful renal fibrosis model to test the effectiveness of anti-fibrotic agents.

LPA-LPA1 Signaling Regulates Fibroblast Proliferation and Myofibroblast Differentiation Dependent on Epithelial Cell-Fibroblast Interaction
Norihiko Sakai, Yasutaka Kamikawa, Akihiro Sagara, Yasuyuki Shinozaki, Shijni Kitajima, Akinori Hara, Yasunori Iwata, Milho Shimizu, Kengo Furuchi, Takashi Wada. Div of Nephrology, Kanazawa Univ, Kanazawa, Japan.

Background: Renal fibrosis is a common pathway of progressive renal diseases, resulting in renal failure regardless of its cause. The accumulation of fibroblasts and myofibroblasts has been recognized as a hallmark of renal fibrosis. However, the precise mechanisms driving it remain to be determined. We have previously found the lipid mediator lysophosphatidic acid (LPA) and one of its receptors, LPA1, stimulates peritubular mesothelial cells to induce fibroblast proliferation through connective tissue growth factor (CTGF) production, suggesting the involvement of epithelial cell-fibroblast interaction regulated by LPA-LPA1 signaling in the pathogenesis of organ fibrosis.

Methods: In this study, we focused on the effects of LPA-LPA1 signaling on the interaction between renal tubular epithelial cells (RTEC) and renal fibroblasts (RFB). The stimulation with LPA induced CTGF expression in both RTEC and RFB in a time- and dose-dependent manner. The induction of CTGF in both cells was suppressed by the treatment with LPA, antagonist (AM095). In addition to that, LPA-induced CTGF expression in both cells was diminished by the treatment with Rho inhibitor (C3 toxin) and Rho kinase inhibitor (Y27632). In both cells, LPA enhanced the nuclear translocation of myocardin-related transcription factor (MRTF)-A/B and the transcriptional activity of MRTF-serum response factor (SRF), whereas Y27632 treatment inhibited those. The inhibition of MRTF-A/B-SRF pathway by the treatment with siRNA or a chemical inhibitor of Rho kinase abolished LPA-induced CTGF expression.

Conclusions: In conclusion, LPA-LPA1 signaling regulates epithelial cell-fibroblast interaction to induce fibroblast proliferation and differentiation into myofibroblasts through CTGF production dependent on Rho/Rho kinase/MRTF-SRF pathway.

TWEAK/Fn14 Signaling Promotes Kidney Disease by Driving Myofibroblast Activation, Inflammation and Vascular Instability
Ivan G. Gomez, 1 Allison M. Roach, 1 Ganme Karaca, 1 Linda Burky, 1 Jeremy Stewart Duffield, 1 Research & Development, Biogen, Cambridge, MA; 2Medicine, Univ of Washington, Seattle, WA.

Background: We identified Fibroblast growth factor-inducible 14 (Fn14) as a receptor on pericytes, which is strongly upregulated as they differentiate into myofibroblasts in vivo in kidney disease. TNF-related weak inducer of apoptosis (TWEAK), a TNF-family
cytokine produced predominantly by myeloid leukocytes has been reported to activate NF-κB signaling and that NF-κB signaling was activated in myofibroblasts in vivo and hypothesized that TWEAK/Fn14 signaling might be an important driver of pathological myofibroblasts in kidney disease.

**Results:** Fn14 deficiency ameliorates myofibroblast appearance, fibrosis, and myofibroblast survival. TWEAK/Fn14 signaling activates primary murine cultured kidney fibroblasts in response to TGF-beta1 and Angiotensin II is suggestive of cross-talk among Hippo cells suggesting that these cytokines likely disable core Hippo signaling. TAZ stable gene Angiotensin II stimulation, moreover, promoted TAZ and pSMAD3 nuclear entry in HK-2 cells. TWEAK signaling in disease progression was evaluated in the mouse Alport model of chronic kidney disease. Anti-TWEAK antibodies preserve organ function and significantly attenuate disease progression.

**Conclusions:** These findings suggest that targeting the TNF superfamily TWEAK/Fn14 pathway is an approach to modulate myofibroblast activation and a novel way to block both inflammatory and fibrotic aspects of chronic kidney disease.

**Deregulation of Hippo-TAZ Pathway During Renal Injury Promotes Fibrotic Phenotype**

**Rohan Samarakoon,**1 Lucas Falka,2 Roel Goldschmeding,2 Paul J. Higgins,2 1Center for Cell Biology and Cancer Research, Albany Medical Center, Albany, NY; 2Dept of Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands.

**Background:** Hippo pathway is the principal regulator of organ size. Transcriptional co-activator with PDZ-binding motif (TAZ), a nuclear transducer of Hippo pathway, is activated by loss of cellular polarity, tension forces, or soluble factors. TAZ has been implicated in the progression of lung fibrosis and cancer. However, role of Hippo-TAZ pathway in chronic kidney disease (CKD) is unknown.

**Methods:** We utilized three mouse models of renal injury [ureteral ligation (UUO), aristolochic acid nephropathy (AAN), streptozotocin (STZ)-driven diabetic nephropathy] and TAZ genetic manipulation in HK-2 tubular epithelial cells and NRK-49F renal fibroblasts to investigate role of TAZ in renal fibrosis.

**Results:** TAZ is activated [as evident by increased nuclear accumulation (4-40 fold) and expression (2.5-5 fold) at both in the tubular and interstitial cells and decreased TAZ mRNA and protein expression] in the UOO kidney compared to contralateral controls. TAZ expression is also upregulated in AAN and STZ-induced renal diabetic injury models. TAZ activation correlated with increased pSmad3 in the fibrotic kidney. TGF-beta1 and Angiontsin II stimulation, moreover, promoted TAZ and pSmad3 nuclear entry in HK-2 cells suggesting that these cytokines likely disable core Hippo signaling. TAZ stable gene silencing in HK-2 cells, indeed, suppressed TGF-beta1 and Angiontsin II induced CTGF, PAI-1 and fibronectin expression. Stable TAZ overexpression in HK-2 cells promoted epithelial dedifferentiation and proliferative arrest.

**Conclusions:** Activated during renal injury, TAZ is a novel profibrotic effector of TGF-beta1 and Angiontsin II induced profibrotic responses. TAZ nuclear accumulation in response to TGF-beta1 and Angiontsin II is suggestive of cross-talk among Hippo pathway and these cytokines.

**Design and Characterisation of Novel BMP Agonists and Antagonists**

**Daniel Cremona,** Satnam Surace, Finian Martin, Catherine Godson. UCD; UCD; UCD.

**Background:** We have previously reported a role for the Bone Morphogenetic Protein (BMP) antagonist Gremlin in a driver of diabetic nephropy pathology and fibrosis in both kidney and lung. Bone Morphogenetic Proteins are integral regulators of bone and organ development. BMPs are secreted proteins and signal by associating with membrane bound receptors. The activity of BMP agonists is modulated by a family of secreted protein antagonists, including Noggin and Crossveinless-2 (BMP-2 only) and Noggin (BMP-2 only). Crossveinless-2 (BMP-2 only) and Noggin (BMP-2 only) and antagonists of BMP-7.

**Results:** The free energy calculations identified the key contributions of BMP residues to both binding events and suggested mutations that might generate super-agonist and dominant negative molecules. Further in silico analysis was performed by mutating each residue to each of the other 19 amino acids. From this we identified potential super-agonists and dominant negative mutants for both BMP-2: L51V and N102T (super-agonists) and S88G and L92D (dominant negatives), and BMP-7: E60T, D119I, L244A and K127E (super-agonists) and F117E and V122D (dominant negatives). The super-agonists will bind and activate the receptor but will be resistant to binding by antagonist; in contrast, the dominant negatives, bind antagonist but not receptor.

**Conclusions:** Data will be presented from our investigations of these molecules as potential therapeutic leads for treating fibrotic diseases including DN.

**Engaged Growth Factors to Treat Acute Kidney Injury**

**Shawdeeh Fahbi,** Fuk Haruta, Tim Stowe, Matt Onsum. Silver Creek Pharmaceuticals, San Francisco, CA.

**Background:** Acute kidney injury remains a major unmet medical need and economic burden. Currently there are no therapies that act directly on damaged kidney cells to promote survival. At Silver Creek Pharmaceuticals, we are engineering a new class of therapeutics called Smart Growth Factors that act selectively on damaged kidney cells to safely deliver pro-survival signals and restore kidney function.

**Methods:** We harness the power of pro-survival and mitogenic signaling of growth factors and engineer more desirable drug-like properties, including extended half-life and cell type-specific targeting. Our first SGF, designed to reduce cardiomyocyte death following acute myocardial infarction, has shown positive pre-clinical efficacy and is being prepared for an Investigational New Drug Application. We are now designing an SGF to treat acute kidney injury, where apoptosis of proximal tubule cells is a leading mechanism of pathology. We developed an in vitro model of tubule cell apoptosis using hypoxia to screen wild type growth factors for the ability to restore cell viability and promote proliferation. We then used computational models to design SGFs that could maximize pro-survival signaling and targeting in damaged kidney tubule cells.

**Results:** SGF variants were built, expressed and purified in-house, and screened for their ability to activate prosurvival and proliferative signals selectively in damaged cells using the in vitro hypoxia model. SGFs with favorable rescue ability, selectivity and pharmacokinetics will be tested in a rodent AKI model using bilateral ischemia.

**Conclusions:** Smart growth factors have the potential to transform the treatment of acute kidney injury, but safely delivering potent pro-survival and mitogenic signals specifically to damaged cells, hopefully leading to better outcomes for this patient population.

**SA-PO334**

**Loss of the Podocyte Glucocorticoid Receptor Exacerbates Proteinuria**

**Julie Goodwin,** Xuefei Tian,2 Shuta Ishibe,1 1Pediatrics, Yale Univ School of Medicine, New Haven, CT; 2Internal Medicine, Yale Univ School of Medicine, New Haven, CT.

**Background:** Nephrotic syndrome is one of the most common renal diseases in children and podocyte foot process effacement is its histologic hallmark. Glucocorticoids (GC) are the mainstay of treatment. Podocytes express the glucocorticoid receptor (GR) and new evidence suggests that podocyte-specific GC effects may be central to controlling proteinuria.

**Methods:** Mice with knockout of GR in podocytes were generated by crossing GR null mice with podocin Cre mice. Proteinuria was induced using both a systemic stimulus (LPS) and a renal-specific insult (nephrotic serum (NTS)). Urine protein/creatinine ratios, serum albumin, and GFR were measured at baseline and on day 1 of treatment following LPS or NTS injection. In vitro, wound healing assays and analysis of stress fiber formation after stimulation with LPS in the presence or absence of dexamethasone (DEX) were performed in primary podocytes isolated from animals of both genotypes.

**Results:** Podocyte GR knockout mice did not have a phenotype at baseline. Their weight, serum creatinine, serum albumin, urine protein/creatinine ratios and foot process morphology were similar to controls. When challenged with low-dose LPS (12.5 mg/kg, IP), knockout mice developed significantly more proteinuria (2.11 ± 0.77 vs. 0.60 ± 0.21, p<0.05, n=5/group) than did controls. Knockout mice also showed greater foot process effacement and impaired wound healing after LPS treatment compared to control podocytes. Administration of DEX could rescue the in vitro phenotype in control, but not GR knockout, podocytes.

**Conclusions:** These results demonstrate that (1) loss of podocyte GR exacerbates proteinuria in two different models in vivo, (2) podocytes lacking GR are more intolerant to injury, and (3) DEX administration ameliorates cellular injury in control, but not GR-deficient, podocytes. We conclude that the podocyte GR plays a key role in maintaining the integrity of the slit diaphragm after injury.

**Deletion of Inositol-Requiring Enzyme-1α in Podocytes Disrupts Glomerular Capillary Integrity and Autophagy**

**Daniel Robert Kaufman,**1 Joan Papillon,2 Takao Iwawaki,2 Andrey V. Cybulsky,3 1Physiology, McGill Univ, Montreal, QC, Canada; 2Medicine, McGill Univ, Montreal, QC, Canada; 3Medicine, Gunn University, Maebashi, Japan.

**Background:** Inositol-requiring enzyme-1α (IRE1α) is an endoplasmic reticulum (ER)-transmembrane endoribonuclease-kinase, which plays an essential function in numerous cellular and tissue during normal development, and is activated during ER stress. IRE1α may be involved in upregulating genes associated with the unfolded protein response and

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.**
ER-associated degradation, as well as in the activation of c-Jun N-terminal kinase (JNK)-1, and induction of apoptosis and autophagy. In this study, we address the functional role of mir-192 in podocytes.

Methods: Podocyte-specific mir-192 knockdown (KO) mice were produced by breeding mice with loxP-site surrounding exons 20-21 with podocin (NPHS2)-Cre mice. MirP-mediating excision in podocytes was confirmed.

Results: In male mice, deletion of mir-192 in podocytes resulted in albuminuria beginning at 5 months of age, and worsening with time. Electron microscopy revealed focal podocyte foot process effacement starting at 5 months, and worsening with time. Electron microscopy revealed focal podocyte foot process effacement in 9 month old male KO mice, as well as microvillous transformation of podocyte plasma membranes and cytosolic vacuolation. By light microscopy, glomerular cross-sectional area (an indicator of hypertrophy) was greater in KO males, compared with control, and capillary lumens occupied a higher fractional area of KO glomeruli, suggesting formation of anurysms. By immunofluorescence microscopy, WT- podocytes were comparable in KO and control males. Immunoblotting showed reduced LC3B-II expression and JNK-1 phosphorylation in KO glomeruli, in keeping with reduced autophagy. There was also a reduction in nephrin maturation in KO glomeruli, suggesting impaired ER function. Finally, expression of mir-1 in KO mice was confirmed.

Conclusions: Podocyte-specific deletion of mir-1 leads to albuminuria and morphologic evidence of podocyte injury. Thus, mir-1 is essential to the maintenance of podocyte integrity as well as age. The mechanism may, at least in part, relate to disruption of autophagy.

SA-PO336 Consistent Downregulation of Autophagy Gene Atg12 Through MicroRNA-192 in Diabetic Nephropathy Supriya Deshpande, Mitsuo Kato, Mei Wang, Rama Natarajan. City of Hope; City of Hope; City of Hope.

Background: Autophagy (Atg) plays a key role in the pathogenesis of kidney diseases, however its role in Diabetic Nephropathy (DN), and particularly in mesangial cells (MC) is not clear. TGF-b1, a key player in the pathogenesis of DN, regulates expression of various microRNAs (miRs) including miR-192. Also, several miRs regulate expression of various Atg genes. We hypothesized that miR-192 plays an important role in Atg regulation in DN.

Methods: Atg gene expression was analyzed in type-2 diabetic (db/db) and in STZ-injected type-1 diabetic mice. To analyze the role of miR-192 in Atg regulation, STZ-injected mice were treated with control locked-nucleic-acid (LNA) oligonucleotides (oligos) or LNA oligos targeting miR-192 (anti-mir-192-LNA), and Atg gene expression was analyzed in kidneys. Activation of caspase-12 was also analyzed in kidneys of WT and STZ-injected miR-192 knock-out (KO) mice. The effect of TGF-b1 on Atg gene expression and GFP-RFP-LC3 puncta formation was analyzed using mouse MC (MMC).

Results: Expression of several Atg genes was decreased in kidneys of type-1 and type-2 diabetic mice compared to controls. Treatment with LNA-anti-mir-192 reversed the effect of diabetes on some of the Atg genes. Further, Atg gene expression was not affected in kidneys of diabetic mirR-192 KO mice compared to controls. In vitro studies using MMC treated with TGF-b1 also showed a decrease in Atg gene expression compared to control. Transfection of MMC with mir-192 mimic oligos decreased expression of certain Atg genes. In addition, transfection of MMC with a GFP-RFP-LC3 plasmid decreased the average number of GFP-RFP-LC3 puncta/cell following TGF-b treatment, and this effect was reversed in MMC from mirR-192 KO mice. All Atg genes analyzed, except Atg12 expression was consistently decreased in these mouse models, and its decrease was reversed by anti-mir-192 LNA oligos as well as in mirR-192 KO mice.

Conclusions: These results demonstrate that consistent downregulation of Atg12 through mir-192 contributes to an overall decrease in autophagy and subsequent increase in cellular hypertrophy in response to TGF-b1 in MC and in glomeruli of diabetic mice leading to DN.

SA-PO337 mTOR Dependent Regulation of the Podocyte Metabolic Profile Tillmann Bork, Wei Liang, Tobias B. Huber. Renal Div Univ Hospital Freiburg, Freiburg, Baden-Wuerttemberg, Germany.

Background: Podocytes play a critical role in the formation and maintenance of the kidney filtration barrier. Previous studies have highlighted the role of mTOR signaling as regulator of podocyte adaption, differentiation and size-control. However, the eventual link between podocyte size control and the regulation of podocyte metabolism by mTOR remains elusive.

Methods: Mice models of mTOR hyperactivation (Tsc1 -PckO) and mTOR loss of function (Raptor -PckO) were crossed to a Tomato/GFP reporter line to efficiently isolate podocytes for primary cell culture studies. Mitochondrial respiration and ATP synthesis were assessed using Seahorse bioanalyzer with specific inhibitors of glycolysis and oxidative phosphorylation.

Results: Lipids are the main source for ATP synthesis due to oxidative phosphorylation in podocytes. Anerobic glycolysis is the dominating pathway to use glucose. Active mTOR signaling pathway massively enhances basal metabolic activity and the capacity for oxidative phosphorylation compared with anaerobic glycolysis.

Conclusions: Podocyte metabolism relies on 0-oxidation of lipids and anerobic glycolysis. mTOR signaling regulates metabolic activity without affecting the preferences for the used metabolic pathways. Targeting the predominant metabolic pathways of podocytes might help to ameliorate diabetic nephropathy or podocyte ageing.

Funding: Government Support - Non-U.S.

SA-PO338 Derlin-2 Knockout Mice Unravel an Essential Role for Protein Dislocation in Podocytes Guohui Ren, Kwi Hye Koh, Jing Li, Changli Wei, Mehmet M. Altintas, Jochen Reiser. Dept of Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Protein quality control plays a critical role in the information in podocytes and is associated with cellular injury. mTOR-2, a component that regulates cellular dislocation machinery, has been identified as an important element in skeletal and matrix producing cells.

Methods: Western blot and immunofluorescence staining were used for detection of protein expression. Derlin-2 knockout or overexpression in podocytes was achieved with transfection of lentiviruses containing shRNA or CNDA. Podocyte-specific Derlin-2 knockout mice were generated by crossing Derlin-2-flox mice with podocin-Cre mice. Autophagy was detected with the conversion of LC3-1 to LC3-II. Activation of caspase-12 was measured by cleavage of procaspase-12.

Results: Derlin-2 was expressed in both mouse and human podocytes. Derlin-2 deficiency in podocytes could be compensated for by insitol-requiring enzyme 1 (IRE1) induced autophagy at basal conditions. However, in situations where induced ER stress was involved in diabetes, cell damage or in other conditions, the compensatory response of autophagy was overwhelmed. Meanwhile, caspase-12 mediated apoptosis pathway was activated, and severe cellular injury ensued, leading to heavy proteinuria in podocyte-specific Derlin-2 knockout mice, as compared with wild type C57BL/6J control mice. In contrast, Derlin-2 overexpression in vitro attenuated podocyte injury. Derlin-2 expression was induced in cultured podocytes during segmental glomerulosclerosis (FGS) and diabetic nephropathy (DN) as well as in ADR nephropathy in BALB/cJ mice, streptozocin (STZ)-induced diabetic mice and B6.B1B1.D2/D2J mice.

Conclusions: Podocytes like osteoclasts and chondrocytes emerge from mesenchyme and belong to a group of cells that employ Derlin-2 to guarantee protein quality and minimize ER stress for cellular homeostasis. Overexpression of Derlin-2 may be a mechanism to rescue damaged podocytes. Induction of Derlin-2 expression in vivo may have applications for prevention and therapy of glomerular diseases.

SA-PO339 Protein O-GlcNAcylation Is Essential for Normal Podocyte Structure and Function Shinya Ono, Mako Yasuda, Shinnji Kume, Osamu Sekine, Jun Nakazawa, Hisazumi Araki, Masami Kanasaki, Shin-ichi Araki, Daisuke Koya, Masakazu Haneda, Takashi Uzu, Hiroshi Maegawa. Dept of Medicine, University of Chicago, Chicago, IL; Division of Diabetes, Endocrinology, Kanazawa Medical Univ, Kanazawa, Japan; Division of Metabolism and Biohythosystems Science, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.

Background: Podocytes play a critical role in the formation and maintenance of the kidney filtration barrier. Previous studies have highlighted the role of O-glycosylation of podocytes for proper protein folding, and belong to a group of cells that employ Derlin-2 to guarantee protein quality and minimize ER stress for cellular homeostasis. Overexpression of Derlin-2 may be a mechanism to rescue damaged podocytes. Induction of Derlin-2 expression in vivo may have applications for prevention and therapy of glomerular diseases.

Methods: O-GlcNAc is a critical enzyme for O-GlcNAcylation in mammals, and resides on the X chromosome. To examine the physiological role of O-GlcNAcylation in podocytes, we analyzed the renal phenotype of male podocyte-specific Ogt-knockout (Podo-OgtKO) mice, which were generated by crossing breeding Ogt-flox mice with podocyte-specific Cre-line transgenic mice.

Results: O-GlcNAc was immunochemically observed in the nuclei of podocytes in wild-type mice, and was completely absent in Podo-OGTKO mice. Podo-OGTKO mice showed normal birth rate and growth up to 32 weeks of age. Proteinuria was first apparent at 8 weeks of age and increased with age up to 32 weeks. Scanning transmission electron microscopy showed disruption of podocyte foot processes in Podo-OGTKO mice after 8 weeks of age. Immunofluorescence showed podocytes to have a punctate distribution in Podo-OGTKO podocytes and to be at a reduced level compared with wild-type mice. Furthermore, the numbers of podocytes in 16-week-old Podo-OGTKO mice were significantly decreased compared with wild-type mice. Finally, severe glomerular sclerosis with tubulointerstitial damage was observed in Podo-OGTKO mice at 32 weeks of age.

Conclusions: O-GlcNAc/Ylation of intracellular proteins by OGT is necessary to maintain podocyte numbers and normal foot process structure. Our results provide new insight into podocyte biology.

SA-PO340 Identification of Novel Gene Products That Regulate Podocyte Function Davide Pietro Cina, 1, 2 Chengjin Li, 1 Jason Moffatt, 1, 2 Susan E. Quaggin. 1, 2 Div of Nephrology, Northwestern University, Chicago, IL; 2 Feinberg Cardiovascular Research Inst, Northwestern University, Chicago, IL; 7Tannenbaum-Lunenfeld Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; 2Donnelly Centre and Banting and Best Dept of Medical Research, Univ of Toronto, Toronto, ON, Canada.

Background: Podocyte function is linked to the organization of its cytoskeleton and adhesion to the glomerular basement membrane. To identify genes that regulate podocyte function, we designed an in vivo genome-wide screen for factors involved in podocyte adhesion to fibronectin, an integrin mediated pathway, or fliT1/Fc, a heparin sensitive pathway, using a pooled 9000 shRNA library.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

703A
Methods: A pool of knockdown podocytes was generated using this library and plated on both coverslips followed by separation of the adherent and floating fractions and deconvolution by illumina sequencing. We developed a stringent method for statistical analysis and ‘hit’ determination and performed a small-scale validation of this method by interrogating top candidate genes individually. We also performed a larger scale validation using a secondary, focused pooled Cas9 mediated knockdown screen.

Results: We identified 121 genes that increased adhesion to fibronectin and 145 genes that increased adhesion to sFLT1/Fc. We also identified 66 genes that decreased adhesion to fibronectin and 106 genes that decreased adhesion to sFLT1/Fc, DP1, DP112, DP115 and DP117. The top five hits in the top ten hits for increased adhesion to both fibronectin and sFLT1/Fc were in the top five dynamin-related GTPases, including Oma1, mitofusin, and Drp1. Drp1 is an evolutionary conserved protein whose loss results in elongated mitochondria. We have previously reported that Rock1-mediated Drp1 activation leads to increased mitochondrial fragmentation and podocyte apoptosis. We hypothesized that attenuation of Drp1 expression and activity in podocytes may ameliorate features of DN.

Methods: To investigate the role of Drp1 in podocytes, we deployed a genetic and pharmacological approach using a model of Type 2 diabetes (LepRdb). First, we crossed conditional Drp1 (Dbm/Dp1f/v) mice with a Podocyte-specific tamoxifen, inducible Cre recombinase (Dbm/Dp1f/v, Dbm/Dp1f/v, Pod-Drap1f/v). Second, we employed the Drp1 GTase activity inhibitor, Mdivi-1, to pharmacologically assess the therapeutic potential of targeting Drp1 in diabetic mice.

Results: Both Drp1-specific, Drp1−/− and pharmacological inhibition of Drp1 by Mdivi-1 in diabetic mice exhibited significantly attenuated albuminuria, mesangial matrix expansion, increased podocyte numbers, reduced podocyte foot process effacement and attenuated glomerular basement membrane thickening. Ultrastructure analysis revealed significantly elongated mitochondria in Drp1−/− diabetic mice compared to non-induced diabetic mice. Drp1−/− diabetic mice displayed increased cell proliferation, as evidenced by BrdU pulse studies. Analysis of the phosphorylation of proteins was carried out by western blot analysis and deconvolution by illumina sequencing. We developed a stringent method for statistical analysis and ‘hit’ determination and performed a small-scale validation of this method by interrogating top candidate genes individually. We also performed a larger scale validation using a secondary, focused pooled Cas9 mediated knockdown screen.

Conclusions: Our Data Suggest that Drp1 as a key regulator of mitochondrial dynamics in podocytes, and point to Drp1 as a potential therapeutic target in DN.

SA-PO343

Cytosolic Phospholipase A2 Alpha Regulates G1 Progression Through Modulating Forhead Box Protein 01 Activity. Sayd Movahedi nasi1, Gabriel Choukroun,2 Dirk M. Hentschel, Joseph V. Bonventre.1,2 Brigham and Women Hospital, Renal Division, Boston, MA;1 Amiens Southern Hospital, Renal Division, Amiens, Picardie, France.

Background: Mesangial cell (MC) proliferation is characteristic of a number of chronic progressive glomerular diseases. cPLA2α is expressed in MCs and plays a role in cellular proliferation, however the mechanisms involved remain unclear. Here, we show for the first time a novel regulatory role for cPLA2α in the regulation of G1 phase of the cell cycle that is conserved in zebrafish and mammals.

Methods: Mouse embryonic fibroblasts (MEFs) and MCs were derived from cplaα−/− mice. cPLA2α was knocked down in zebrafish using morpholinos (MOs). Cell cycle progression was assessed by flow cytometry in zebrafish larvae and in G0, synchronized cells after stimulation with PDGF. S phase population was assessed in zebrafish and MEFs by BrdU pulse studies. Analysis of the phosphorylation of proteins was carried out by western blot assays using phosphospecific antibodies.

Results: We identified two zebrafish cplaα genes, termed zcplaαa and zcplaαb, with conserved phospholipase activity. In zebrafish and MEFs cPLA2α promotes G1 progression via its phospholipase activity and through PGE, production. PGE, through the PI3′-K/AKT pathway, regulates FOXO1 phosphorylation and FOXO1 nuclear export. This, in turn, inactivates FOXO1 resulting in upregulation of cyclin D1 and downregulation of p27Kip1, thus promoting G1 progression. These data indicate an evolutionary conserved mechanism between lower vertebrates and mammals. Further, using pharmacological inhibitors, we show that cPLA2α, RAFT/M203 in development (using the podocin cre driver) pharmacologically cooperatively regulate G1 progression in response to mitogenic stimulation.

Conclusions: cPLA2α is a critical effector of the G1 phase of the cell cycle through its phospholipase activity. Pharmacological targeting of this enzyme may have important therapeutic benefits in disease mechanisms that involve excessive cell proliferation including progressive acute and chronic glomerulonephritis.

SA-PO344

Podocyte Specific Glycogen Synthase Kinase 3 Is Critical for Neonatal Survival and for Renal Function in Maturity. Jenny Hurcombe1, Abigail Charlotte Lay2, Gavin Iain Welsh3, Peter D Matheson, Satish Patel, Susan E Quaggin, James R. Woodgett, Richard Coward,1 Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom;2 Samuel Lunenfeld Research Inst, Univ of Toronto, Toronto, ON, Canada;3 Feinberg School of Medicine, North Western Univ, Chicago, IL.

Background: GSK3 is a multi-functional serine/threonine kinase existing as two distinct isoforms, GSK3α and GSK3β. Knockout mouse models suggest that the GSK3 isoforms have different and cell type specific functions. This study aims to examine the importance of GSK3 in the podocyte.

Methods: We have used Cre/LoxP technology to generate mice with podocyte-specific ablation of GSK3α and/or GSK3β. Knockout mouse models suggest that the GSK3 isoforms have different and cell type specific functions. This study aims to examine the importance of GSK3 in the podocyte.

Conclusions: Mice developmentally lacking either GSK3α or GSK3β specifically in the podocyte are viable with normal life span (up to 2 years) and normal renal histology. In contrast, mice null for both GSK3α isoforms, born at normal Mendelian frequency, die at 10-16 days with massive albuminuria and acidosis. These mice have vacuolated glomeruli and glomerulosclerosis. Knockout of GSK3α and β after full glomerular development, at 4 weeks of age, also results in significant renal disease which develops within 2 weeks of knockdown. It consists of significant albuminuria with renal failure in some mice. Furthermore, there is evidence of a crescentic proliferative glomerulopathy, together with massive fibrosis and glomerulosclerosis. Mechanistically the wnt signalling pathway is up-regulated and β-catenin activated throughout the kidney. Contemporaneous knockdown of β-catenin in the developmental model dramatically improves albuminuria and renal histology but not acidosis or survival indicating the involvement of other pathways. These are currently being investigated through a glomerular transcriptomic approach.

Conclusions: Podocyte specific GSK3 is critical for glomerular and renal function in development and full maturity. Loss of single isoforms can be compensated throughout life but loss of both is catastrophic.

Funding: Government Support - Non-U.S.
Podocyte Oxidative Stress Coupled with Ubiquitin C-Terminal Hydrolase Deletion Exacerbates Renal Damage

**Background:** Ubiquitin C-terminal hydrolase L1 (UCHL1) may promote antioxidation by degrading oxidized proteins and by the enzymatic activity of UCHL1. Podocytes show increased oxidative stress and downregulated UCHL1 expression in FSGS. Expression of podocyte UCHL1 may be a disease modifier in FSGS, and the role of UCHL1 in FSGS remains to be determined.

**Methods:** UCHL1 was detected by immunoblot analysis of FSGS biopsies. Renal UCHL1 levels were assessed in podocyte cultures stimulated with siRNAs to UCHL1 or by treatment with NOX5 interference. Podocytes from UCHL1 knockout mice were compared with wild-type podocytes. Podocyte injury was evaluated using cell retraction, cell density, and cell hypertrophy.

**Results:** UCHL1 levels were significantly lower in FSGS biopsies compared to normal kidneys. Podocyte UCHL1 expression was reduced by NOX5 interference. Podocytes from UCHL1 knockout mice showed increased retraction, cell density, and cell hypertrophy compared to wild-type podocytes.

**Conclusions:** These findings suggest that UCHL1 protects podocytes from oxidative stress and that UCHL1 expression is a potential therapeutic target for FSGS.

Insulin Receptor Isoform A Is Implicated in Podocyte Injury in Diabetic Kidney Disease

**Background:** Podocytes are the key players in maintaining glomerular integrity and function. Perturbations in podocyte injury and proliferation have been linked to diabetic kidney disease (DKD). The insulin receptor (IR) is a key player in insulin signaling, and its isoforms are expressed in podocytes. The role of IR isoforms in podocyte injury in DKD remains unclear.

**Methods:** Podocyte injury was assessed in a mouse model of DKD using a surgical protocol that results in diabetes, insulin resistance, and podocyte injury. Podocytes from wild-type and insulin receptor isoform A (IRA) knockout mice were cultured and subjected to hyperglycemic conditions. Podocyte injury was assessed using cell retraction, cell density, and cell hypertrophy.

**Results:** Podocytes from IRA knockout mice showed increased cell retraction, cell density, and cell hypertrophy compared to wild-type podocytes. Podocytes from IRA overexpression mice showed decreased cell retraction, cell density, and cell hypertrophy compared to wild-type podocytes.

**Conclusions:** These findings suggest that IRA expression plays a crucial role in podocyte injury in DKD, and targeting IRA may represent a potential therapeutic strategy for the prevention of podocyte injury in DKD.

SMPDL3b overexpression augments IRA/Cav1 interaction and suppresses IRB/Cav1 interaction.

**Background:** SMPDL3b is a sphingomyelinase that regulates lipid rafts and contributes to podocyte injury. IRA and IRB are two isoforms of the insulin receptor that play different roles in podocyte function. The interaction between IRA and IRB with Cav1, a key component of lipid rafts, has been shown to be crucial for podocyte function.

**Methods:** Podocytes were treated with SMPDL3b overexpression or control vectors, and the interaction between IRA/Cav1 and IRB/Cav1 was assessed using co-immunoprecipitation (co-IP). The effects of SMPDL3b overexpression on podocyte function were assessed using cell retraction, cell density, and cell hypertrophy.

**Results:** SMPDL3b overexpression augmented IRA/Cav1 interaction and suppressed IRB/Cav1 interaction. Podocytes with SMPDL3b overexpression showed decreased cell retraction, cell density, and cell hypertrophy compared to control cells.

**Conclusions:** These findings suggest that SMPDL3b overexpression augments IRA/Cav1 interaction and suppresses IRB/Cav1 interaction, potentially contributing to podocyte injury in diabetes.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

ORO staining and prevented the development of mesangial expansion in KO+CD group compared to KO+Vehicle. A significant reduction in ACR was observed after 3 weeks of CD treatment in KO+CD compared to KO+Vehicle mice (p < 0.001), as shown by a trend in reduced serum creatinine. CD treatment did not affect ACR, renal function or mesangial expansion in WT mice.

Conclusions: Based on these results, we conclude that CD improves renal function in a mouse model for AS and could be a new therapeutic strategy for the treatment of AS patients.

The Glomerular Matrisome in Alport Syndrome Is Altered prior to the Onset of Albuminuria

Sophie C. Collinson, Jeffrey H. Miner, Rachel Lennon, 1,2  Welcome Trust Centre for Cell Matrix Research; Faculty of Life Sciences, Univ of Manchester, Manchester, United Kingdom, 1Dept of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester, Manchester, United Kingdom; 2Renal Div, Washington Univ School of Medicine, St. Louis, MO.

Background: Alport Syndrome is caused by genetic defects in COL4A3, COL4A4 or COL4A5, but despite this knowledge there are currently no targeted therapies. We aimed to build our basic understanding about the glomerular extracellular matrix (ECM) in Alport syndrome and performed global analysis of composition and ultrastructural imaging in the Col4a3/-/- mouse.

Methods: Cellular and extracellular matrix (ECM) fractions from wild type and Col4a3/-/- mice of at least 6 and 16 weeks of age were analysed by mass spectrometry (MS) and imaged using serial block face-scanning electron microscopy (SBF-SEM).

Results: MS analysis revealed moderate changes in the composition of glomerular ECM at 6 weeks, even prior to the onset of barrier dysfunction. These included complete absence of type IV collagen α1-3, α4-6, and upregulation of type VI collagen α1, α2, and type V1 collagen. At 16 weeks more dramatic changes were detected including elevated type IV collagen α1, α2, fibronectin, type I collagen, laminin α2 and fibronectin. Global and pathway analysis of cellular fractions indicated changes in actin regulating proteins at 6 weeks and mitochondrial dysfunction at 16 weeks. SBFSEM demonstrated thickened and irregular glomerular basement membranes with evidence of podocyte protrusions into this ECM.

Conclusions: Our data demonstrate that Alport syndrome progresses with distinct early changes in ECM followed by more profound ECM accumulation, disruption and thickened and irregular glomerular basement membranes with evidence of podocyte dysfunction prior to the onset of albuminuria.

Creation and Analysis of Mouse Models of Human Nephrotic Syndrome Caused by the Laminin b2 (LAMB2) S80R Mutation

Steven Daniel Funk, Jeffrey H. Miner. Renal Div, Washington Univ School of Medicine, St. Louis, MO.

Background: Most cases of congenital nephrotic syndrome in the first year of life are due to mutations in 4 genes expressed in podocytes: NPHS1, NPHS2, WT1, and Lamb2. LAMB2 encodes laminin b2, a glomerular basement membrane component critical for glomerular filtration. We previously created transgenic mice using the urinary promoter to study missense mutations discovered in patients with congenital nephrotic syndrome, including R246Q and C321R, which inhibit laminin β2 secretion and/or induce podocyte ER stress. Here we aimed to characterize a new mutation (S80R) in Lamb2 mice (BMC Nephrology 2014, 15:54). Here, we explored whether CLIC4 regulates ERM protein activation, similar to CLIC5A.

Methods: Confocal immunofluorescence (cIF) microscopy was used to visualize CLIC4 expression in mouse kidney sections. Western blot analysis (WB) was used to study total and cytoskeletal fractions from isolated mouse glomeruli and cultured human glomerular endothelial cells (EC).

Results: By cIF CLIC4 colocalized exclusively with moesin in mouse glomerular endothelial cells (EC). WB showed that CLIC4 is absent from LAMB2-/- mice, and that the ratio of pERM : tubulin is lower in CLIC4+/- compared to LAMB2-/- (1.28 ± 0.11 vs. 2.26 ± 0.30, respectively, p < 0.01, mean ± SD, n=3). Total ERM protein was also reduced, and much less ERM protein was observed in the cytoskeletal fraction of CLIC4+, compared to LAMB2-/-. In cultured human glomerular EC, CLIC4 siRNA reduced LAMB2-/- protein by >90% and resulted in ERM dephosphorylation and dissociation from the cytoskeleton, all rescued by over-expression of CLIC4. CLIC4-induced ERM phosphorylation was abolished by PLC activation with m-3M3FBS, indicating that PI4,5P2 dependence.

Conclusions: Hence, CLIC4 co-localizes with moesin in glomerular EC in vivo. Like CLIC5A, CLIC4 promotes ERM phosphorylation in a PI4,5P2-dependent fashion. We speculate that defective ERM phosphorylation may be responsible, in part, for the morphological and physiological abnormalities in LAMB2-/- mice.

Differential Roles of Cell Surface Proteoglycans in Podocyte-Glomerular Basement Membrane Adhesion

Angela C. DiPoto-Brahmbhatt, Deborah J. McCarthy, Kevin J. McCarthy. Pathology and Translational Pathobiology, LSU Health Sciences Center-Shreveport, Shreveport, LA.

Background: Cell surface proteoglycans (PG), via their heparan sulfate (HS) chains, work in a cooperative fashion alongside integrins to mediate podocyte (PG)-glomerular basement membrane (GBM) interactions. Results of our previous studies have shown that complete loss of HS at the POD cell surface leads to reduced cell attachment to the GBM. However, the mechanism by which HS contributes to these interactions is unknown. The purpose of this study was to determine the effects of selective depletion of the cell surface PG, syndecan-1 (Sdc1) or syndecan-4 (Sdc4) on POD in vivo.

Methods: Frozen tissue sections of POD-knockout (KO) mice were immunostained with antibodies against the core proteins of Sdc1 and Sdc4, HS (antibody HS4C3), syndapinin (SYN), nephrin, and α-actinin-4. To determine the potential for loss of anionic charge associated with HS, 500 nm sections of unfixed kidneys from POD-KO mice were treated with polyethyleneimine (PEI) followed by fixation and processing for transmission electron microscopy.

Results: TEM studies showed that the GBMs of both Sdc1 and 4 KO mice had GBP irregularities. The POD in Sdc4 KO mice showed moderate foot process effacement. Immunostaining for HS did not show differences in staining intensity for HS between Sdc1 and Sdc4 KO mice. However, PEI labeling showed that the GBMs in Sdc4 KO mice had larger aggregates of PEI than those found in the GBM of Sdc1 KO mice. Immunostaining showed that a compensatory increase in Sdc4 expression in Sdc4 KO glomeruli or Sdc1 expression in Sdc4 KO glomeruli did not occur. The glomeruli of Sdc1 KO mice showed disruption of nephrin organization compared to Sdc4 and WT mice. Immunostaining for α-actinin-4 in both Sdc1 KO and Sdc4 KO glomeruli was also disrupted compared to control.

Conclusions: The data show that disruption of either Sdc1 or Sdc4 interactions with the GBM significantly affect the manner by which POD interact with the GBM. Although loss of Sdc4 was associated with the development of foot process effacement, the loss of either Sdc1 or Sdc4 has effects on POD cytoskeletal organization.

ERG Protein Activation by CLIC4 in Glomerular Endothelial Cells

Abbas Almomany, Mahtab Tavasoli, Laiji Li, John C. Edwards, Barbara J. Ballermann, Medicine, Univ of Alberta, Edmonton, AB, Canada; Internal Medicine, St. Louis Univ, St. Louis, MO.

Background: We reported (J. Cell Sci. 2014, 127:1564) that the podocyte-predominant CLIC5A stimulates PI4,5P2 production and consequent ER (rins, radixin, moesin) protein phosphorylation (pERM). CLIC4, a homolog of CLIC5A, is expressed at high levels in glomerular and peritubular capillary endothelial cells (EC), and in proximal tubule brush border and basolateral membranes. CLIC4 deficient mice (CLIC4−/-) have fewer glomeruli and a lower peritubular capillary density than wild-type mice (BMC Nephrology 2014, 15:54). Here, we explored whether CLIC4 regulates ERM protein activation, similar to CLIC5A.

Methods: Confocal immunofluorescence (cIF) microscopy was used to visualize CLIC4 expression in mouse kidney sections. Western blot analysis (WB) was used to study total and cytoskeletal fractions from isolated mouse glomeruli and cultured human glomerular endothelial cells (EC). In cultured human glomerular EC, CLIC4 was silenced with CLIC4-specific siRNA ± CLIC4 cDNA rescue.

Results: By cIF CLIC4 co-localized exclusively with moesin in mouse glomerular endothelial cells (EC). WB showed that CLIC4 is absent from LAMB2−/- mice, and that the ratio of pERM : tubulin is lower in CLIC4−/- compared to LAMB2−/- (1.28 ± 0.11 vs. 2.26 ± 0.30, respectively, p < 0.01, mean ± SD, n=3). Total ERM protein was also reduced, and much less ERM protein was observed in the cytoskeletal fraction of CLIC4−/- compared to LAMB2−/-. In cultured human glomerular EC, CLIC4 siRNA reduced LAMB2−/− protein by >90% and resulted in ERM dephosphorylation and dissociation from the cytoskeleton, all rescued by over-expression of CLIC4. CLIC4-induced ERM phosphorylation was abolished by PLC activation with m-3M3FBS, indicating that PI4,5P2 dependence.

Conclusions: Hence, CLIC4 co-localizes with moesin in glomerular EC in vivo. Like CLIC5A, CLIC4 promotes ERM phosphorylation in a PI4,5P2-dependent fashion. We speculate that defective ERM phosphorylation may be responsible, in part, for the morphological and physiological abnormalities in CLIC4−/− mice.

Vascular Glycoalyx Syndeac (SDC) 4 Loss Coincides with Albuminuria in Diabetic Nephropathy

Raina D. Ramirez, Amy Russell, Rebecca R. Foster, Gavin Iain Welsh, Andy Salmon, Simon C. Jackson. 1Renal Unit, Univ of Bristol, Bristol, United Kingdom.

Background: The endothelial glycoalyx is a critical determinant of vascular health and a key regulator of vascular permeability. Increasing evidence points to disruption of the endothelial glycoalyx as a contributor to development of albuminuria (albumin in the urine) and eventually DN. TNFα which is important in the development of microvascular disease in diabetes caused a disruption of the glomerular endothelial cells (GEC)}
glycosylated through shedding of SDC4 and heparan sulphate (HS). We seek to investigate the role of vascular endothelial glycosylation in DN and determine the mechanisms involved in its disruption in DN.

**Methods:** DN was induced in DBA2 mice by giving daily intraperitoneal injection of streptozotocin (STZ) at 50mg/kg for 5 days. The mice became hyperglycemic at 2 weeks and significantly albuminuria in glomeruli in DN, suggesting that MMP2 could mediate SDC4 shedding. My in vitro data in human EHS showed that gelatinase MMP9 was upregulated and resulted in the shedding of SDC4 and HS. This resulted in an increase in BSA permeability across the monolayer.

**Conclusions:** MMP2,9-mediated shedding of SDC4 is likely to contribute to vascular endothelial glycosylation disruption and albuminuria observed in DN. Potential therapies targeted at glycosylation protection will be of benefit not only in DN but also in ameliorating systemic vascular disease in diabetes.

**Blood Cell Velocities in Glomerular Capillaries Measured by 2-Photon In Vivo Microscopy Reveal Heterogeneous Blood-Flow**

Deimarin Pedoto,1,2 Eugenio Gutierrez,1 Luca Bordoni,1 Sara Damiano,1 Francesco Trepiccio,1 Giovanni Rota Capurro,1,2 Sebastian Frische.1,3

1Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; 2Dept of Cardio-Thoracic and Respiratory Science, Second Univ of Naples, Napoli, Italy; 3Center for Functionally Integrative Neuroscience, Aarhus Univ, Aarhus, Denmark; 4Biogem, Ariano Irpino, Italy.

**Background:** Theoretical models have shown that the blood-flow within a glomerulus may be heterogeneous and that flow heterogeneity may affect the ultrafiltration coefficient and thus GFR. The aim of this study is to provide experimental data to test these model predictions by measuring glomerular capillary flow velocities by in vivo 2-photon microscopy.

**Methods:** Male Munich-Wistar rats were intubated, anesthetized with isoflurane, and mechanically ventilated. Blood pressure and heart-rate were monitored. The left kidney was externalized and the rat placed in the 2-photon microscope. Blood plasma was labeled by incubation with 6-carboxyfluorescein succinimidyl ester (CFSE) for 1 hour. The blood flow in superficial glomeruli was scanned at a frequency of >700 Hz. The axial movement of single blood cells was measured. 308 different capillaries were analyzed in 17 glomeruli from 5 different rats.

**Results:** Blood cell velocity was 2.99 μm/ms ±0.54. A Gaussian distribution and a Gamma-distribution were fitted to data from 13 glomeruli in which >12 capillaries were studied. C-tests (α=0.05) showed 5 of 13 datasets not to follow a Gaussian distribution and 1 of 13 not to follow a Gamma-distribution. The data from all 308 capillaries normalized to the mean of the respective glomerulus did not follow a Gaussian distribution (P<0.05). The Gamma-distribution allows an asymmetrical distribution around the mean and provided the best description.

**Conclusions:** This study provides experimental evidence of heterogeneity and an asymmetrical distribution of blood cell velocity in glomerular capillaries. This new experimental evidence calls for refinement of current models of glomerular blood flow heterogeneity and invokes the possibility to investigate the potential regulatory control of the ultrafiltration coefficient by regulation of capillary flow heterogeneity, e.g. by the action of mesangial cells.

**Axl Receptor Tyrosine Kinase Is Involved in Proliferation of Human Mesangial Cells Activated by PDGF**

Qi Bian,1,2 Joshua Charles Anderson,1 Xiaoan Chen,2,3 Xiubing Fan,1,2 Shanrong Zhao,1 Xiaowen Zhang,1 Zhi Qiang Huang,1 Kerstin Ebeforo,4 Jenny C. Nyström,5 Stacy D. Hall,1 Bruce A. Julian,1 Christopher D. Willey,1 Jan Novak.1

1Univ of Alabama at Birmingham, Birmingham, AL; 2Changhai Hospital, Second Military Medical Univ, Shanghai, China; 3Univ of Gothenburg, Sweden.

**Background:** Proliferation of mesangial cells (MC) is an important feature in many glomerular diseases, including IgA nephropathy (IgAN). Platelet-derived growth factor (PDGF) is a potent stimulator of MC, activating multiple signaling pathways associated with proliferation of MC. Our global kinomic profiling revealed that activity of multiple kinases in MC increased after PDGF stimulation, including tyrosine kinase Axl. As there is limited information on the association of PDGF signaling and activation of Axl in human MC, we studied details of Axl involvement in human MC stimulated by PDGF.

**Methods:** MC were obtained from a commercial source or isolated from biopsy specimens of patients with IgAN or other glomerular diseases. Quiescent primary human MC were stimulated by PDGF AB in the presence or absence of different inhibitors. MC lysates were analyzed by global tyrosine-kinome profiling using PamsStation®12 platform and Western blotting. MC proliferation was measured by BrdU incorporation. The expression and distribution of Axl in MC were assessed by immunofluorescence.

**Results:** Tyrosine-kinome profiling indicated that PDGF AB increased Tyr30, Abl, and Lck kinase activities. Further data analyses predicted Axl as one of the key upstream kinases activated in PDGF-AB-stimulated MC. We found that Axl was expressed in all tested primary human MC. PDGF AB stimulated proliferation of MC; this effect was inhibited by Axl-specific inhibitor R428. Signaling studies revealed that PDGF AB increased phosphorylation of multiple signaling proteins, including Axl, PDGFR-β, AKT1, and ERK1/2. R428 significantly inhibited phosphorylation of Axl and Axl1, and, to a lesser extent, also of ERK1/2 and PDGFR-β. MEK1/2 inhibitor U0126 and PI3K inhibitor LY294002 did not affect phosphorylation of Axl.

**Conclusions:** Axl is involved in PDGF-induced proliferation of cultured MC through multiple signaling pathways. Targeting Axl may provide a new therapeutic strategy for IgAN.

**Different Effects and Mechanisms of Prostaglandin E2 Receptor Subtypes EP2/EP4 in TGF-β1 Induced Mesangial Cell Injury**

Chen Xiao Lan,1 Yuan Li.2

1Affiliated Hospital of Nantong Univ; 2Affiliated Hospital of Nantong Univ.

**Background:** To study effects of prostaglandin E2 receptor subtypes 2 and 4 (EP2 and EP4) in mesangial cell injury by transforming growth factor-β1 (TGF-β1) and relevant signal pathways.

**Methods:** 1. The primary cultures of EP2 gene knockout (EP2-/-), EP4 gene knockout (EP4flox/flox) and wild type (WT) mice mesangial cells were established; 2. grouping: A: Q WT; WT + TGF-β1; B: EP2-/-; EP2-/- + TGF-β1; C: EP4flox/flox + AD-CRE (EP4KO); D: EP4flox/flox + AD-CRE (EP4KO) + TGF-β1; Group F: EP2-/-; EP2-/-+ TGF-β1; EP4flox/flox + AD-CRE (EP4KO) + TGF-β1 as control; 3. the level of PGE2 ,cAMP ,the PKA activity of mesangial cell was tested ; PKA (H89) and ERK (PD98059) inhibitors were used to interdict PKA activity and ERK pathway in WT mesangial cell; EP2 or EP4 receptor agonist was used to pretest WT MCs.

**Results:** 1. After TGF-β1 stimulation, expression of FN and CTGF increased; the expression of FN and CTGF in Group EP2KO increased; the expression of FN and CTGF in EP4KO decreased; 3. after TGF-β1 stimulation, the Smad3 phosphorylation level in EP2KO increased; while the Smad3 phosphorylation level markedly decreased in EP4KO; 4. the PGE2 level of WT mesangial cell increased at 12h after TGF-β1 treatment; 5. the AMP content in EP2KO was less than that of the control; PAKa activity obviously declined; the cAMP content has no obvious changes in EP4KO; after stimulation with TGF-β1, the PAKa activity increased; 6. ERK inhibitor blocks the function caused by agonist EP4; while PAKa inhibitor block the inhibition function of agonist EP4.**

**Conclusions:** EP2 and EP4 have different regulating effects on injury and renal fibrosis of mesangial cells: EP2 receptor mediated PGE2 induced up-regulation of the level of cAMP and PAKa activity, as to inhibit interaction effects of TGF-β1/Smad3 pathway and reduced the occurrence of injury and fibrosis of mesangial cell; while EP4 may mediate the promotional effect of mesangial cell injury induced by TGF-β1 by activating phosphorylation ERK pathway, resulting in regulating effects different from that of EP2.

**Funding:** Government Support - Non-U.S.
Mesenchymal Stem Cells in the Repair of the Damaged Mesangium: A Step by Step Ultrastructural Account of the Events Taking Place

**Background:** Not much is known about repairing the damaged mesangium. The use of mesenchymal stem cells (MSCs) to repair the injured mesangium is a rather novel concept. The present study aimed at analyzing the entire process using transmission electron microscopy in an effort to better understand the various steps involved.

**Methods:** Mesangial cells (MCs) cultured single layer in dish (2D) and on Matrigel (3D), MCs were first cultured to confluent and quiescent for 48 hours. Then they were incubated with glomerulopathic light chains (GLCs) (10 ug/ml) purified from the urine of patients with FSGS. After incubation with renal biopsy-proven light chain-related amyloidosis (AL-Am) (n=3) and light chain deposition disease (LCDD) (n=3) for 4 days and subsequently labeled MSCs were added. Samples were collected 10 days after the introduction of the MSCs (day 14) and processed for light and transmission electron microscopy.

Results: MSCs revealed evidence of direct damage by the GLCs including apoptosis with apoptotic bodies released. MSCs identified and migrate to areas where cellular damage was present. When MSCs became activated they acquired a "macrophage" phenotype. They then became active in phagocytosing cell debris, apoptotic bodies damaged extracellular matrix and non-extracellular matrix material. Their process of cleaning the damaged mesangium resulted in MSCs full of cellular debris and eventually disposing of the internalized material. After performing this function, they proceeded to differentiate into mature MCs.

**Conclusions:** MSCs actively clean the injured mesangium by phagocytosing apoptotic cells and other material. They do so by transforming into a macrophage phenotype. Once the cleaning process is completed, they differentiate into MCs acquiring their characteristic smooth muscle morphology and functional properties. The entire sequence of events was documented by transmission electron microscopy providing an added dimension to the understanding of MSCs in repair of the damaged mesangium.

Characterization of Circulating APOL1 Complexes and Their Kidney Distribution in African Americans

**Background:** The apolipoprotein L1 gene (APOL1) G1 and G2 renal-risk variants associate with non-diabetic nephropathy and cardiovascular disease in African Americans (AAs). Although substantial APOL1 protein is present in the circulation, with enrichment in podocytes compared to other renal cells, little is known about circulating APOL1 protein.

**Methods:** Total serum APOL1 levels were examined by Western blot in a cohort of healthy AAs who had a 1st degree relative with kidney disease. APOL1 protein complexes were isolated from fast protein liquid chromatography (FPLC) peak fractions and characterized by proteomic analyses. Results were subsequently verified by co-immunoprecipitation and Western blot.

**Results:** No significant differences were detected in serum APOL1 protein concentration based on APOL1 genotypes. However, serum APOL1 protein binds to other protein complexes. Non-denaturing gel electrophoresis and FPLC demonstrated that serum APOL1 protein existed in two non-overlapping peaks (12.2nm and 20.0nm in diameter, respectively). The smaller complex was labeled complex A and the larger complex B. Density gradient ultracentrifugation and agarose gel electrophoresis confirmed that neither APOL1 protein complex was associated with HDL or LDL cholesterol. The exposure of APOL1 complex A surface epitopes appeared to be altered by G1/G2 renal-risk variants based on avidity to a specific monoclonal antibody from a non-G1/G2 associated immunogen (p=0.01). APOL1, haplotype-related protein (HPR), and complement C3 were present in APOL1 complex A. APOL1, HPR, IgM, and fibronectin were present in APOL1 complex B. In APOL1 complex A, HPR-α was more abundant in those with G1 and G2 renal-risk variants, relative to G0 (GENMOD p=0.04, total N=12). Serum HPR-α was only present in APOL1 complexes. Small amounts of HPR protein were detected in renal tubule cells but not glomeruli, whereas HPR mRNA was absent in the kidney.

**Conclusions:** Results provide unique insights on the composition of circulating APOL1 complexes. The role of circulating APOL1 in kidney and cardiovascular disease in AAs requires further investigation.

Deep Mapping of the Native Mouse Podocyte Proteome

**Background:** The identity of proteins expressed within a podocyte is still not known.

**Methods:** We performed mass spectrometry based absolute and relative quantification of the proteome of FACS-sorted native mouse podocytes.

**Results:** We resolved the podocyte proteome at a near-comprehensive resolution (more than 8000 identified proteins). Absolute copy numbers of proteins correlated with copy numbers obtained from deep-sequencing transcriptomic analysis. The dataset indicates agreement between transcriptome and proteome regarding expression of proteins which are mutated in hereditary forms of proteinuria and FSGS in humans. 541 proteins were enriched within podocytes at very high ratios and significance. This study suggests that the podocyte is not only target to inflammatory stimuli such as TNFalpha and IFNgamma, but also unanticipated other stimuli. In addition, this study delineates podocyte enriched tyrosine kinases, a few of these are drugable. Protein domains significantly enriched in podocyte proteins comprise not only PDZ and Fn3 domains, but also i-set domain, an adhesion domain. The majority of podocyte specific proteins also contain positive findings for homology in human samples, with a weak correlation between staining intensity and absolute protein abundance measured by MS/MS.

**Conclusions:** This initial, near comprehensive draft of the podocyte proteome reveals untapped molecules and mechanisms. This dataset will be of benefit to understand podocyte physiology, pathobiology and develop potential therapeutic strategies.

Maternal Obesity Is a Significant Risk Factor for the Development of Diabetic Nephropathy

**Background:** We have studied whether a second-hit such as diabetes may further exacerbate diabetic nephropathy in offspring exposed to maternal obesity.

**Methods:** Female C57Bl6 mice were fed either normal or high-fat diet (HFD) for 6 weeks prior to pregnancy, during pregnancy and weaning and their offspring were weaned to chow diet or HFD. At Week 8, the male offspring were randomized to streptozotocin (STZ) 55mg/kg/day for five consecutive days, 100 mg/kg once only or placebo. Weight and glucose levels were tested fortnightly. 24 h urine collection was performed at Week 20 and 30. The kidneys were harvested at Week 32. The renal structure was observed.

**Results:** Development levels of podocyte, inflammatory and oxidative stress markers were measured by real time PCR and confirmed with protein quantification with Western blot and/or immunohistochemistry.

**Conclusions:** Offspring exposure to maternal obesity accelerates the severity of damage to the kidney caused by diabetes. Fetal programming of renal inflammation and oxidative stress may be a key component to the accelerated risk. Offspring diet has a powerful effect on renal outcome.

**Funding:** Government Support - Non-U.S.

Leucine-Rich Glycoprotein 1: A Candidate Biomarker for Early Renal Function Decline in Type 2 Diabetes

**Background:** Identification of patients with type 2 diabetes and early renal function decline may improve our ability to intervene and slow progression to end-stage renal disease. In a Phase I preclinical exploratory study, we tested whether leucine rich glycoprotein-1 (LRG1), a candidate biomarker discovered in db/db mice, would identify patients with early decline in renal function.

**Methods:** Patients with type 2 diabetes were recruited into training (n=56) and independent, non-overlapping test (n=37) groups (median baseline eGFR = 80.3 ± 29.5 ml/min/1.73m²). LRG1 was measured in spot urine collections by ELISA, and performance was assessed as area under the receiver operating characteristic curve (AUC) with adjustment for clinical covariates of DKD.

**Results:** Urine LRG1 was associated inversely with eGFR (r = -0.546, P<0.001) and positively with ACR (r = 0.283, P = 0.034). The AUC of LRG1 for identifying participants with baseline eGFR < 60 was 0.815 ± 0.103; in contrast, the AUC of the albumin/creatinine ratio was 0.465 ± 0.093 (P < 0.01 versus LRG1). Adjustment for age, sex, race, duration of diabetes, and HbA1c, did not alter the AUC for LRG1, and these results were replicated in the test group. In participants with eGFR >= 60 ml/min/1.73m² at baseline, LRG1 predicted a 5-year outcome of eGFR < 60 or ESRD better than ACR (0.702 ± 0.085, P = 0.01 versus ACR, 0.520 ± 0.119).

**Conclusions:** Taken together, these results suggest LRG1 may identify patients with early renal function decline more accurately than ACR. Evaluation of LRG1 in prospective cohort studies of type 2 diabetes may lead to a better biomarker for identifying and monitoring DKD.

A Longitudinal Study on Kidney Function, Pathology, and Multiple Urinary Biomarkers in ZSF1 Rat Model of Type II Diabetic Nephropathy  
Renal Discovery, Abbiev, North Chicago, IL.

**Background:** Obese ZSF1 rats display many clinical features of human type II diabetic nephropathy (DN). To further understand this model and to identify relevant biomarkers of disease progression, we followed the development of DN by measuring glomerular filtration rate (mGFR), histopathology, and a variety of urine and tissue biomarkers over 24 weeks after uninephrectomy (Unx). Correlations between mGFR and individual urinary biomarkers were assessed.

**Methods:** Male rats (9-week old) underwent either a sham or Unx (right kidney) surgery and were fed a high carbohydrate diet. GFR was measured by transradial clearance of FITC-sinistrin. Urine samples were collected once every 2-4 weeks for biomarker analysis, and renal tissue was examined for collagen deposition as well as for the levels of key inflammatory and fibrotic genes.

**Results:** Kidney hypertrophy was observed (2.0-3.0 fold increase in mGFR) in obese rats 2-week after surgery lasting until week 4. The mGFR subsequently declined over time in these rats and was 2-fold lower than control rats by end of study. Compared to lean rats, obese rats also demonstrated time-dependent increases in urinary excretion of protein, KIM-1, L-FABP, NGAL, Cystatin C, Cluseterin, Betaz-2-microglobulin, alpha-1-acid glycoprotein, VEGF, MCP-1, TIMP-1, Collagen IV, TGF-b, and TGF-b2. A significant correlation was found between mGFR and a number of urinary biomarkers (L-FABP, KIM-1, TIMP-1, Cystatin C, and TGF-b2). Kidney fibrosis was significantly elevated by week 12 post surgery and continued to expand in the following weeks. Unx increased the weight and glomerulosclerosis of the remaining kidney and accelerated the decline of mGFR in obese rats during late weeks of observation.

**Conclusions:** ZSF1 rats showed a progressive increase of fibrosis and loss of mGFR over the 24-week study. A number of urinary biomarkers demonstrated a strong inverse correlation with the time-dependent changes in mGFR. Additionally, Unx significantly increased glomerulosclerosis and loss of GFR in obese rats.

Resistance Exercise Training Prevents Kidney Hypertrophy and Increases the Biogenesis Mitochondrial in Diabetic Rats  
Luciana Jorge, Kleiton Augusto Santos Silva, Rafael Luiz, Rodolfos Rosseto Rampasso, Janaina Paulini Aguiar, Nestor Schor.

**Background:** Diabetic nephropathy(DN) is a progressive complication arising from diabetes. kidney cell response to injury includes cell division, cell hypertrophy and apoptosis. Increasing evidence indicates that the disruption of mitochondrial bioenergetics and structural change in the kidney may be important in the development and progression of DN. Therefore, is fundamental the understand of a non pharmacological intervention as exercise training to prevent those complications. We investigated the effect of resistance training(RT) on the DN pathogenesis.

**Methods:** Male Wistar rats were divided into control(C), control trained(CT), diabetic(D) and diabetic trained (DT). DM was induced by STZ. Trained groups were submitted to a resistance exercise training on Ladder climb (8wk). Urinary volume and proteinuria were evaluated. Tissue weight/tibial length ratio was used as kidney hypertrophic index.

**Results:** RT induced renal parameters in DT group show a decreased urinary volume(D=160;DT=120;C=130;CT=140)proteinuria(D=45;DT=32;C=18;CT=7 mg/24h) (p<0.05). Diabetes resulted in increased hypertrophic index (50%)and RT prevented it. Renal expression of PAMPK and MF2N was reduced in D group and RT normalized this expression(p<0.05). Moreover, the renal expression of PAKT and PmTOR were increased in the DM and the RT influence on it(p<0.05). Histological analysis showed glomerular hypertrophy in D and RT prevent this complication.

**Conclusions:** RT attenuated progression of diabetic nephropathy; Those improvements could be a result of increased AMPK/MF2N pathway, an important pathway to biogenesis mitochondrial; and inhibition of AKT/mTOR pathway, responsible for hypertrophic response, demonstrating that those complications were prevented by exercise training. Our findings demonstrated that RT is an important approach to avoid, both molecular and functional complications in diabetic kidney.Funds from FAPESP,CNPq and CAPES.

Aerobic Exercise Training Improves Proteinuria and Renal Inflammatory Factors in Rats with Diabetic Nephropathy

Rodolfo Rosseto Rampasso, Rafael Luiz, Kleiton Augusto Santos Silva, Luciana Jorge, Edison Andrade Pessoa, Mario Luis Ribeiro Cesaretti, Nestor Schor.

**Background:** The objective of this study was to evaluate the effects of aerobic exercise training in controlling the progression of diabetic nephropathy, inflammatory factors, and its possible renoprotective effects.

**Methods:** Adult male Wistar rats/4 groups, n=8/group: Sedentary controls (C-SED), Diabetes/Sedentary (DM-SED), Diabetes/Exercise (DM-EXE) and control exercise (C-EXE). Diabetes was induced with STZ, 50 mg/kg. The exercise training were conducted on a treadmill 60min/day, 5 days/week/8 weeks. Weekly certain, maximal exercise test(set on 65-70% of MEtest). Glycemia after post 24 education(24 glycemiapt), MEtest, creatinine clearance/BW(CrCl/BW), arterial pressure(AP), proteinuria(uProt), renal inflammatory factors IL-6, IL-10 and TNF-α were measured. Data as mean ± SD.

P<0.05 VS C-SED and DM-EXE VS C-EXE

**Conclusions:** Reductions in blood glucose and AP –11% comparing DM-EXE vs DM-SED. The DM-EXE controlled weight loss ~40% compared to DM-SED, but did not prevent change in CrCl/BW with this protocol. However, the effect was surprisingly observed EXE reduction in both exercise through uProt ~60% and ~25% in MD-inflammatory factors comparing SED vs DM-EXE. Therefore, preliminary data suggests that aerobic exercise can reduce proteinuria and inflammatory factors in diabetic animals and hence reduce the potential effects caused by diabetic nephropathy and could reduce the progression of renal failure.
Inhibition of miR-25 Processing Mediated by MeCP2 Phosphorylated by HIPK2 Can Upregulate NOX4 in Early Diabetic Nephropathy

Hyung Jung Oh, Mitsuo Kato, Supriya Deshpande, Mei Wang, Linda L. Lanting, Rama Natarajan, Diabetes and Metabolism, Beckman Research Inst of City of Hope, Duarte, CA.

Background: Altered microRNA (miR) levels play key roles in the pathogenesis of diabetic nephropathy (DN), but it is unclear if miR processing is involved. Phosphorylated methyl-CpG binding protein2 (p-MeCP2), known to act as a transcriptional repressor, was recently reported to suppress the processing of several miRs. Homeo-domain interacting protein kinase2 (HIPK2) can bind to and phosphorylate MeCP2. However, it is not known if MeCP2 and HIPK2 are involved in processing and expression of candidate miRs in DN.

Methods: p-MeCP2 and HIPK2 staining in kidney sections from 4-week streptozotocin (STZ) injected diabetic and control mice, was studied immunohistochemistry. Protein, mRNA and miR levels were examined by Western blotting (WB) or RT-qPCRs in TGF-b1- or high glucose (HG)-treated mouse mesangial cells (MMCs).

Results: p-MeCP2 and HIPK2 immunostaining, and their protein levels were significantly higher in renal glomeruli (but not cortex) of STZ mice than control. Moreover, Seven in Absentia Homolog 1 (SIAH1), which mediates proteosomal degradation of HIPK2, was decreased in STZ mice compared with control. Among several regulated miRs, miR-25 and -93 levels were significantly decreased in STZ mice relative to control. The precursors of miR-25 and -93 were also significantly decreased in STZ mice, while conversely, NADPH oxidase4 (NOX4), a target of miR-25 that is associated with renal fibrosis and DN, was significantly increased in STZ mice. Protein levels of p-MeCP2 and HIPK2 were also increased in vitro in TGF-b1- or HG-treated MMCs compared to control. Moreover, mRNA levels of the genes mentioned above in vivo were similarly regulated in MMCs in vitro, although only miR-25 and its precursor were significantly decreased in the treated MMCs.

Conclusions: Our data suggest that epigenetic changes lead to persistent increase of SHP-1 expression despite systemic hyperglycaemia. Emerging evidence indicates that multiple factors involved in the aetiology of diabetes can alter epigenetic mechanisms and regulate susceptibility to microvascular complications.

Ursolic Acid Attenuated High Glucose Induced Podocyte Injury by Inhibition of miR-25 Expression Mediated by Mecp2 Phosphorylated

Targeting the Polycystic Repressive Complex Chromatin Remodeling Machinery for Therapeutic Benefit in Diabetic Nephropathy

Letizia De Chiara, Hayley Beaton, Catherine Godson, John Crean. UCD School of Biomolecular and Biomedical Science, Diabetes Complications Research Centre, Univ College Dublin, Dublin, Ireland.

Background: Diabetic Nephropathy (DN) manifests as renal microvascular abnormalities, mesangial sclerosis and tubulointerstitial fibrosis as a result of longstanding hyperglycaemia. Emerging evidence indicates that multiple factors involved in the aetiology of diabetes can alter epigenetic mechanisms and regulate susceptibility to microvascular complications.

Methods: Immunoprecipitation, ChIP, Western Blot, miR302 overexpression, luciferase assay.

Results: We have previously identified SMAD3 and EZH2 as part of a context dependent switch enhancing complex that regulates cell fate during fibrotic processes. Here we describe the further characterisation of this interaction and delineate its potential pathogenic significance. Comparative analysis of gene expression data from patients, animals and cell models of diabetic kidney disease revealed a subset of genes that are potentially regulated by the interaction between Smad3 and EZH2, including critical regulators of epithelial fate such as E-Cadherin. Endogenous immunoprecipitation and luciferase experiments performed in renal epithelial cells demonstrated that the interaction is disrupted by downregulation of EZH2 and recruits EZH2 to the E-Cadherin promoter causing its down-regulation during Epithelial to Mesenchymal Transition. We further demonstrated that this interaction is disrupted by mutating SMAD3 protein sequence. Perturbation of the interaction between SMAD3 and EZH2 was facilitated by viral overexpression of miR302. Human renal mesangial cells transduced with miR302 undergo profound changes in gene expression exhibiting de novo expression of SNAIL and EZH2 and start to express de novo E-Cadherin.

Conclusions: Our results suggest that SMAD3 and EZH2 control the repression of E-Cadherin during DN, opening the possibility for therapeutic manipulation of this nexus during the progression of renal disease. Understanding the processes through which dynamic epigenetic silencing is controlled in adults will allow us to address the epigenetic state of acquired disease and whether original states, regenerative in nature, can be restored with therapy.

Effects of DPPIV Inhibitor versus Combined Treatment with DPPIV Inhibitor and ARB on Renal Function in Type 2 Diabetic Mice

Hye Sook Min, Jin Joa Cha, Sung Jin Kim, Kiue Kim, Jung Eun Kim, Jungyeon Ghee, Ji Eun Lee, Hyunwoo Kim, Jee Young Han, Young Sun Kang, Dae R. Cha. Internal Medicine, Korea Univ Ansan Hospital; Nephrology, Sam Hospital, Anyang; Internal Medicine, Wonkwang Univ Sanbon Hospital; Pathology, Inha Univ, Incheon, Republic of Korea.

Background: Recent evidence has shown that DPPIV is involved in all steps leading to renal dysfunction, such as inflammatory response, cell apoptosis and fibrosis. The aim of our study was to investigate the mechanism and effects of DPPIV inhibitor (DA1229) alone and combined treatment with DPPIV inhibitor and ARB (LC158809) on renal injury in db/db mice.

Methods: The mice were divided into five groups as follows: non-diabetic db/m mice (control), untreated db/db mice, db/db mice treated with DA1229 (300mg/kg/d), db/db mice treated with LC158809 (1.5mg/kg/d) and db/db mice combined treatment with DA1229 and LC158809 for 12 weeks.

Results: 12week HbA1c level was significantly decreased in combined treatment group. Oxidative stress markers were not different from each other. Activity of serum DPPIV was significantly reduced with DA1229, 24h albuminuria significantly decreased with LC158809 treatment at 8 weeks and with DA1229 at 12 weeks in diabetic mice. However, no additive effect on albuminuria was observed with combined treatment. Administration of DA1229 or LC158809 significantly decreased accumulation of ECM protein, TLR4 and NOX4 expressions in glomerulus. No additive effects were measured in Smad3 deficiency mutant group. Urinary excretion of nephrin was increased in diabetic mice and was decreased in combined treatment with DA1229 and LC158809. In vitro, DPPIV was expressed on the
podocyte membrane and its expression was activated by angiotensin-II. Nephrin expression in cultured podocyte was attenuated by high glucose and angiotensin-II. This attenuation was recovered with DA1229 treatment, but not with other DPPIV inhibitors.

Conclusions: Our data suggest that renoprotective effects of DA1229 in experimental diabetic mice might be associated with protective effect of podocyte injury. DA1229 might be a potential therapeutic agent to slow the progression of diabetic nephropathy.

SA-PO373
PBI-4425, a Novel Anti-Inflammatory/Fibrotic Compound, Improves Kidney Function and Structure in the Diabetic db/db Mouse Model

Background: Kidney disease associated with diabetes mellitus is a major health problem worldwide. Glomerular injury plays a pivotal role in the development of diabetic nephropathy. PBI-4425 possesses a pleiotropic mechanism of action with anti-inflammatory, antioxidant and anti-fibrotic properties. The aim of this study was to investigate the protective effect of PBI-4425 on kidney function and structure in uninephrectomized (NX) diabetic (db/db) mice.

Methods: Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4425 (100 mg/kg, oral once a day) from day 1 through 103. Kidney function (GFR), kidney mesangial lesions, modulation of gene expression, and serum cytokines were investigated.

Results: GFR assessed by inulin clearance was significantly reduced in NX-db/db mice compared to NX-C57BL/6 negative control mice, and PBI-4425 treatment significantly improved GFR. As shown by PAS staining, NX-db/db mice had larger glomeruli with increased mesangial lesions scores were significantly reduced by PBI-4425 treatment. Gene expression of inflammation, fibrosis, oxidative stress, and extracellular matrix remodeling markers were assessed. Kidney MCP-1, IL-6, Collagen I, NOS, MMP2, and Timp1 mRNA expression were markedly increased in NX-db/db mice, and PBI-4425 treatment induced a significant decrease of these markers. Glomerular response to injury was accompanied by activation of kidney development-related genes, such as glomerular epithelial protein 1 (GLEPP1); expression of GLEPP1 was significantly increased in NX-db/db mice, and restored to the negative control level following treatment with PBI-4425. Moreover, PBI-4425 significantly reduced serum pro-inflammatory cytokines IL-6, IL-12p70, as well as THp-type pro-inflammatory cytokines IL-9.

Conclusions: These results suggest that PBI-4425 offers the potential as a novel therapy for diabetic nephropathy by improving kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

The Effect of Nox Inhibitor APX-15 on Diabetic Kidney Disease

Jin Jun Cha, Hye Sook Min, Ji Hee Lim, Min Young Kim, Hyung Wook Kim, Jung Eun Kim, Jungyeon Ghee. 1 Medicine, UCSD, La Jolla, CA; 2 Medicine, UCSD, La Jolla, CA; 3 Medicine, UCSD, La Jolla, CA.

Background: The NADPH oxidase isoform NOX4 has been linked with diabetic kidney disease (DKD), however a mechanistic understanding of the downstream effects of NOX4 remains to be established.

Methods: To clarify the role of increased NOX4, we examined the role of NOX4 in the podocyte-specific NOX4 transgenic mouse. We also treated F1 Akita (DBA/2 J x C57BL/6J) INS2 Akita (db/db) mice with food pellets containing KGT137831, a NOX1/4 inhibitor from week 12 to week 28, and examined the effectiveness of treatment with the NOX1/4 inhibitor on the development of chronic kidney disease (CKD) and on the urine metabolome in a model of progressive DKD.

Results: Podocyte-specific induction of NOX4 in vivo was sufficient to recapitulate the characteristic glomerular changes noted with DKD, including glomerular hydropathy, mesangial matrix accumulation, GBM thickening, albuminuria, and podocyte dropout. Intervention with a NOX1/4 inhibitor reduced albuminuria, glomerular hydropathy, and mesangial matrix accumulation in the F1 Akita model of DKD. Metabolicomic analysis from the mouse studies revealed that TCA related urinary metabolites were increased in DKD and were uniquely reduced by the NOX1/4 inhibitor. TCA cycle enzyme runate hydratase (FH) reduction has been linked to regulating urine runat and indeed, FH was reduced in the diabetic kidney (in mice and human tissue) and the NOx4 inhibitor increased FH levels. Induction of NOx4 both in vitro and in the podocyte-specific NOX4 transgenic mouse led to reduced FH levels. The potential role of runate of FKD to DKD was confirmed as runate was found to stimulate ER stress, matrix gene expression and regulate HIF-1α and TGF-β.

Conclusions: Our data suggest that NOX4 is a major mediator of glomerular dysfunction with diabetes and renal FH is a key enzyme regulated in DKD and targeted by NOX4. FKD is a key enzyme that connects metabolic pathways to DKD pathogenesis and may have application to monitor renal NOX4 activity.

The Prostaglandin E2 EP3 Receptor Regulates Diet Induced Obesity

Ryan Patrick Ceddia, Richard M. Breyer. 1 Div of Nephrology and Hypertension, Dept of Veterans Affairs and Vanderbilt Univ, Nashville, TN; 2 Dept of Pharmacology, Vanderbilt Univ, Nashville, TN.

Background: Obesity is associated with a number of co-morbidities including diabetes, dyslipidemia and nonalcoholic fatty liver disease. Deletion of the PGE2, E-prostanoid (EP) 3 receptor gene has been shown to reduce the development of obesity and associated co-morbidities, such as dyslipidemia and nonalcoholic fatty liver disease.

Methods: To further characterize the effects PGE2-EP3 signaling on diabetes in a setting of diet induced obesity, EP3-/- mice were fed a high-fat diet (HFD; 45% calories from fat) or a control diet (10% calories from fat).

Results: Though no differences in body weight were observed in mice fed control diet, when fed a HFD, EP3-/- mice became heavier relative to EP3 +/+ mice (41.1±0.38 vs. 36.6±0.98 g; P<0.0001). EP3 -/- mice fed HFD had increased epididymal fat mass (1407±177 vs. 2401±167 mg; P<0.0001) and adipocyte size (6530±573 vs. 4330±469 μm²; P=0.005) compared to HFD fed EP3 +/- mice; paradoxically a relative decrease in both epididymal fat mass (P <0.0001) and adipocyte size (P=0.0055) was observed in the heaviest EP3 +/+ mice. EP3 -/- mice had increased macrophage infiltration (P<0.0001) and necrosis (P<0.001) in epididymal fat pads as compared to EP3 +/+ mice. Adipocytes isolated from EP3 -/- mice lacked PGE2-evoked inhibition of isoproterenol stimulated lipolysis compared to EP3 +/+ mice (1 nM ISO, ±100nM PGE2; EP3 +/+ : 10.2±1.4 vs. 4.8±1.84, P = 0.0036; EP3 -/ -: 11.8±1.20 vs. 10.3±0.68 nmol glycerol/10,000 cells, P>0.9999). EP3 -/- mice fed HFD had ecopic lipid accumulation in skeletal muscle (7.5±1.24 vs. 7.17±1.82 mg triglyceride/mg; P=0.0001) and liver (14.6±2.83 vs. 7.8±1.30 mg triglyceride/mg; P=0.0001), with evidence of hepatic steatosis. When fed HFD, EP3 +/+ mice became hyperglycemic (107 ±8.80 vs. 158±17.4 mg/dl; P<0.0001) and hyperinsulinemic (0.598±0.079 vs. 1.55±0.241 mg/ ml; P<0.0001) when compared to EP3 -/- fed HFD, demonstrating a more severe insulin resistance phenotype in EP3 +/+ mice (4.77±0.931 vs. 18.1±3.50 HOMA-IR, P=0.0001).

Conclusions: These results demonstrate that when fed a HFD, EP3 +/+ mice have abnormal lipid distribution, developing excessive ecopic lipid accumulation and associated insulin resistance.

Resveratrol Activates Renal Expressions of Adiponectin Receptor 1 and 2 in db/db Mice

Y aieni Kim, Jin Hee Lim, Min Young Kim, Hyung Wook Kim, Cheol Whee Park. Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Republic of Korea.

Background: Adiponectin is an adipocyte-derived adipokine that binds to adiponectin receptors (AdipoR1 and AdipoR2) and exhibits antidiabetic effects via activation of AMPK and PPAR-δ. Our previous study investigated the renoprotective role of resveratrol by decreasing lipotoxicity and inhibiting mesangial cell glucotoxicity in a manner dependent on the AMPK-SIRT1-PPARγ axis in diabetic mouse model. The common pathway shared by both interventions suggested us to explore the favorable effect of resveratrol on renal physiology through activation of AdipoR.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

71A
Methods: Male db/db mice at 8 weeks of age were fed resveratrol (20 mg/kg/day) via gavage for 8 weeks. Serum and renal tissue were obtained to analyze for changes in metabolic parameters, molecular levels and renal structure.

Results: Resveratrol treatment showed favorable effects on albuminuria, glomerular matrix expansion and inflammatory cell infiltration. Increased expressions of AdipoR1 and Adiponectin decreased NOS expression in patients. Adiponectin inhibited inflammation and AMPK-a level. It also ameliorated free fatty acid and triacylglycerol accumulation in the kidney which was related to the increases in phosphorylation of AMPK and PPAR-a level. They related to decreases in the phosphorylation of AMPK and the activation of SIRT1-PGC-1α signaling and of the key downstream effectors, the PPARα-Forkhead box O (FoxO3) / FoxO1 pathway. Adiponectin induced anti-oxidative elements (ERB)-Iα and nicotinamide adenine dinucleotide (NADH) 1 (SREBP1)/acyetyl coenzyme A carboxylase (ACC). Furthermore, resveratrol increased eNOS phosphorylation and Bcl-2/Bax ratio which were associated with decreased apoptotic cells and oxidative stress as reflected by renal 8-hydroxy-deoxyguanosine (8-OHdG) and uric acid, and increased anti-oxidant concentrations. Resveratrol prevented high glucose induced oxidative stress and apoptosis in cultured human glomerular endothelial cells (HGECs) through activation of both AdipoR1 and subsequent phosphorylation of AMPK and the downstream effectors.

Conclusions: In conclusion, our results suggest that resveratrol exerts its renoprotective effects through activation of both AdipoR1 which prevent lipotoxicity related apoptosis and oxidative stress in the kidney.

SA-PO378
Oral Treatment with PBI-4547, a Novel Anti-Diabetic and Anti-Fibrotic Compound, Ameliorates Kidney Function and Glomerular Integrity in the Diabetic db/db Mouse Model

Background: Diabetic nephropathy is the most common complication of longstanding diabetes affecting up to 30% of all diabetic patients, and is the main cause of end-stage kidney disease. This study examined the long-term nephroprotective effects of PBI-4547 in uninephrectomized (NX) diabetic (db/db) mice, a model of type 2 diabetes.

Methods: Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4547 (10 and 50 mg/kg, oral once a day) from day 1 through 105. Kidney function (GFR and structure (mesangium lesions, glomerular integrity), regulation of pro-inflammatory/fibrotic gene expression in the kidney, as well as serum pro-inflammatory cytokine levels were examined.

Results: Kidney function assessed by GFR was significantly reduced in NX-db/db mice compared to NX-CT controls, and PBI-4547 treatment significantly improved GFR in NX-db/db mice. As shown by PAS staining, mesangial matrix expansion and inflammatory cell infiltration. Increased expressions of AdipoR1 and the downstream effectors.

Conclusions: These data suggest that PBI-4547 is a potential novel therapy for diabetic nephropathy by decreasing kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

SA-PO379
Prostaglandin E2 Receptor 3 (EP3) Inhibits Vasopressin-Stimulated Water Reabsorption and Contributes to Diabetic Renal Dysfunction in Mice
Ramzi Hassounieh, Rania Nasrallah, Joe A. Zimpelmann, Kevin D. Burns, Yuanyuan Wu, Yufeng Huang. Daisuke Nakano, Wararat Kittikulsuth. Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Background: We have shown in a diabetic model that prostaglandin-E2 (PGE2) may contribute to increased renal cyclic GMP (cGMP) levels and fluid retention. The EP3 receptor mediates the vasopressin-induced cGMP increase. We examined the role of EP3 in the regulation of water reabsorption in diabetes.

Methods: Male EP3-/- and wild-type (WT) C57BL/6 mice were injected with vehicle or streptozotocin (STZ) and after 12 weeks, animals were treated with vehicle or PBI-4547 (10 mg/kg, oral once a day). Urinary albumin, blood glucose, and light-period mean arterial pressure (MAP) were measured. The cumulative loop was assessed by Western blotting.

Results: Untreated uninephrectomized db/db mice developed progressive albuminuria (P<0.01), decreased body weight and increased blood pressure compared to wild-type controls. In contrast, PBI-4547 treatment prevented the increases in urinary albumin and blood pressure and reduced body weight. These data suggest that a SGLT2 inhibitor elicits its beneficial effects on glucose metabolism and hypertension in subjects with metabolic syndrome undergoing treatment with SGLT2 inhibitors.

SA-PO380
Effects of Diuretics on SGLT2 Inhibitor-Induced Changes in Blood Pressure and Natriuresis in Obese Rats Suffering from the Metabolic Syndrome
Akira Nishiyama, Daisuke Nakano, Wararat Kittikulsuth. Dept of Pharmacology, Kagawa Univ Medical School, Kagawa, Japan.

Background: In experimental and clinical studies, SGLT2 inhibitors (SGLT2i) have been shown to reduce the risk of cardiovascular and renal events in patients with type 2 diabetes (T2DM), but evidence on the impact of SGLT2i on blood pressure (BP) remains limited.

Methods: Male 13-week-old SHRcp were treated with: (i) vehicle; (ii) the SGLT2 inhibitor luseogliflozin (10 mg/kg/d, p.o.); (iii) diuretics (hydrochlorothiazide; 10 mg/kg/d + spironolactone; 25 mg/kg/d, p.o.); or (iv) luseogliflozin (5 mg/kg/d, p.o.) + diuretics for 5 weeks (n = 5–8 for each group). BP response and urine volume were measured by telemetry system and oral glucose tolerance test, respectively.

Results: Vehicle-treated SHRcp developed non-dipper type hypertension (dark-light period mean arterial pressure (MAP) 148±0.7 and 148±0.7 mmHg, respectively, P<0.01) which were associated with a significant increase in urinary excretion of sodium. Addition of diuretics did not influence luseogliflozin-induced improvement of glucose metabolism and circadian rhythm of blood pressure in SHRcp.

Conclusions: These data suggest that a SGLT2 inhibitor elicits its beneficial effects on glucose metabolism and hypertension in subjects with metabolic syndrome undergoing treatment with SGLT2 inhibitors.

SA-PO381
SGLT2 Inhibition Slows the Progression of Diabetic Nephropathy in the db/ db Mouse
Liang Tang, Yuanuyan Wu, Yufeng Huang. Fibrosis Research Laboratory, Div of Nephrology, Univ of Utah, Salt Lake City, UT.

Background: It has been shown that SGLT2 inhibitor not only enhanced renal glucose excretion and lowered blood glucose (BG) but also reduced albuminuria in patients with Type 2 diabetes (T2DM). However, the renoprotective effect of SGLT2 inhibition in diabetic nephropathy has not yet been established.

Methods: This study sought to determine whether dapagliflozin, a selective SGLT2 inhibitor, could slow the progression of glomerulosclerosis in the uninephrectomized db/db mouse, a model of T2DM.

Results: Untreated uninephrectomized db/db mice developed progressive albuminuria and glomerulosclerosis between wks 18 and 22, associated with increased renal expression of TGFβ1, PAI-1, type IV collagen and fibrinone. Treatment with dapagliflozin (1mg/kg/d) via gel diet from wks 18 to 22 did not affect body weight but reduced BG (from 573±62.1 to 367±146.5 mg/dL, P<0.05) and HbA1c levels. Of note, treatment with dapagliflozin arrested the increases in albuminuria, body weight and markers of glomerulosclerosis seen in db/db mice between wks 18 to 22. Renal expressions of TGFβ1, PAI-1 and FN were reduced by 50% in STZ and restored to control levels in PBI-4547-treated NX-db/db mice. Moreover, qPCR analysis of the expression of MCP-1, IL-6, Collagen I, MMP2, Timp1, and iNOS showed that PBI-4547 downregulated diabetes-induced inflammation, fibrosis, oxidative stress, and expression of MCP-1, IL-6, Collagen I, MMP2, Timp1, and iNOS showed that PBI-4547 downregulated diabetes-induced inflammation, fibrosis, oxidative stress, and expression of MCP-1, IL-6, Collagen I, MMP2, Timp1, and iNOS.

Conclusions: Despite elevated VP levels in STZ, the CCD response to VP stimulation was no different than in WT, while SNP suppressed VP-induced Jv in both groups. In the absence of VP, the SNP-induced Jv was unchanged by SNP, confirming the importance of EP3 in this process. During diabetes, EP3 inhibition of VP-induced Jv may lead to polyuria and a sustained increase in VP, which may be injurious to the kidney.

Up-Regulated Sglt2 Reduces Proximal Tubular Sirt1 and Augments Renal GlucoseEosis in Early Stage Diabetic Nephropathy
Hiroki Umino, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. 1

Background: Sodium-glucose cotransporter (SGLT) 2 inhibitors are new antidiabetic drugs that increase urinary glucose excretion (UGE) by inhibiting renal SGLT2. SGLT2 inhibitors may induce body fluid reduction due to the increase in urine volume and Na excretion, but the details remain unclear.

Methods: Spontaneously Diabetic Torii (DM) rat, a non-obese type 2 diabetic model was used in this study. At the onset of diabetes (blood glucose ≥ 250 mg/dl), DM rats and age-matched Sprague-Dawley (non-DM) rats were separated to vehicle (Veh) and 0.01% Ipragliflozin. At the onset of diabetes (blood glucose ≥ 250 mg/dl), DM rats and age-matched Sprague-Dawley (non-DM) rats were separated to vehicle (Veh) and 0.01% Ipragliflozin. At the onset of diabetes (blood glucose ≥ 250 mg/dl), DM rats and age-matched Sprague-Dawley (non-DM) rats were separated to vehicle (Veh) and 0.01% Ipragliflozin. At the onset of diabetes (blood glucose ≥ 250 mg/dl), DM rats and age-matched Sprague-Dawley (non-DM) rats were separated to vehicle (Veh) and 0.01% Ipragliflozin.

Results: Renal membrane protein expression of SGLT2 was significantly higher in DM rats compared with non-DM rats. Ipragliflozin reduced the expression of SGLT2. However, Sglt2 inhibitors blocked these changes.

Conclusions: These results suggest that SGLT2 inhibitor not only reduces albuminuria but also slows the progression of glomerulosclerosis resulting from T2DM by improving hyperglycemia and renal inflammation and oxidative stress. Decreasing glomerular hyperfiltration and negatively regulating renal Na activity by SGLT2 inhibitor may be also renoprotective.

Funding: Pharmaceutical company support - AstraZeneca R&D.

References:

Background: SGLT2 inhibitors have recently been approved in type 2 diabetes and long-term clinical trials are ongoing to further establish efficacy and safety. Humans with familial renal glycosuria due to mutations in SGLT2 do not show signs of general renal tubular dysfunction or other pathological changes, and they seem to have normal life expectancies. Here we compared the phenotype of non-diabetic aged male mice at (24 months) that lack SGLT2 (Sglt2-/-) with their wild-type littermates (WT).

Methods: In awake mice, blood pressure (BP) and heart rate (HR) was measured by an arterial catheter-tail cuff system and GFR by FITC-inulin plasma eliminations kinetics.

Results: Out of initially 11 Sglt2-/- and 14 WT, 2 mice per genotype died for unknown reasons before reaching an age of 24 months; thus 9 Sglt2/-/- and 12 WT mice were analyzed. Consistent with results previously reported in young adult mice (3.5 months): aged sglt2-/-/ and wt increased similar both body weight (30±6.6 vs 32±10.9 g) and blood glucose (105±6 vs 116±10 mg/dl), and GFR (329±36 vs 370±20 ml/min); sglt2-/- had higher urinary glucose excretion (381±1 vs 51±1 mmol/mg creatinine) associated with higher intake of food (3.8±0.1 vs 3.2±0.1 g/day) and fluid (8.9±0.2 vs 5.1±0.1 ml/day) and smaller adipocytes in subcutaneous and epididymal fat tissue (4790±44 vs 638±130 and 8093±990 vs 11811±778 mm²/each (P<0.01); urine pH was similar (6.2±1 vs 6.5±0.2) and no bacterial growth detected in bladder urine. Different from previous findings in young adult mice: aged sglt2-/- had modestly higher kidney weight (14.5±0.9 vs 12.6±0.4 g body wt), BP (105±22 vs 93±1 mm Hg) and HR (666±7 vs 625±151/min) than WT and lower hematocrit (31±1 vs 41.3±0.4%) (each P<0.01).

Conclusions: Aged SGLT2-/- mice show many of the expected phenotypes previously observed in young adult mice, and have preserved GFR and no evidence for ascending branch stenosis. An increase in kidney weight has previously been reported in 7.5 months old SGLT2-/- mice. Further analyses aim to better understand the latter findings and the observed modest changes in BP and hematocrit.

Funding: NIDDK support.

References:
Results: Inhibiting SGLT2 shifts Na⁺ transport to downstream nephron segments, possibly increasing their QₘG. Particular concerns are the S3 segment and medullary thick ascending limb (mTAL), which are at risk for hypoxic injury. Dual SGLT1-SGLT2 inhibition protects the S3 segment, but could further reduce mTAL oxygenation. Model simulations suggest that SGLT2 inhibition substantially increases S3 QₘG. Together with elevated renin-angiotensin system (RAS) expression of Na-K-cotransporter (NCC2), SGLT2 inhibition also increases mTAL QₘG. Additionally, we used the model to determine the optimal combination of SGLT1 and SGLT2 inhibition, in terms of suppressing tubular glucose uptake and maintaining sufficiently low S3 and mTAL QₘG.

Conclusions: In conclusion, SGLT inhibition significantly increases oxygen consumption of the mTAL. This research was supported in part by NIH grant DK-89666. Funding: NIDDK Support

SGLT2 Expression Is Increased in Human Diabetic Nephropathy: SGLT2 Inhibition Decreases Renal Lipid Metabolism, Inflammation and the Development of Nephropathy in Diabetic Mice Xiaoxin Wang, 1 Jonathan Levi, 2 Yuhuan Luo, 1 Evgenia Dobrinskikh, 1 Almett Grozn, 1 Michal Herman-Edelstein, 2 Uzi Gafter, 2 Avry Chagnac, 1 Hermann Koeppeli, 2 Jeffrey B. Kopp, 2, 3, 4 A. Rosenberg, 2 Moshe Levi, 2 1Univ of Colorado Denver; 2NIDDK; 3Rabin Medical Center; 4Univ of Warsaw

Background: The renal sodium gradient dependent glucose protein SGLT2 expression is increased in renal biopsies from human subjects with diabetic nephropathy. Methods: To determine the potential mechanisms of beneficial effects of SGLT2 inhibition in progression of diabetic renal disease we treated db/db mice with a selective SGLT1 inhibitor.

Results: We found that SGLT2 inhibition caused marked decreases in systolic blood pressure, kidney weight/body weight ratio, urinary albumin (745±36 mg/dl in db/db vs. 207±5 mg/g in treated db/db, p<0.001) and urinary thiorheritance acid-reacting substances (TBARS). SGLT2 inhibition also a) prevented renal lipid accumulation via inhibition of LPL, SCD-1 and DAGAT1, key enzymes that mediate fatty acid and triglyceride synthesis, b) decreased inflammation via inhibition of CD68 macrophage accumulation, and expression of p65, TLR4, MCP-1 and 1NP, and c) increased CD73 and decreased adenosine A receptors Ador1, Ador2a, and Ador2b mRNA. These effects were associated with prevention of mesangial expansion, accumulation of extracellular matrix proteins fibronectin and type IV collagen, as well as loss of podocyte markers WT1 and synaptopodin, as determined by quantitative immunofluorescence microscopy.

Conclusions: In summary, our study showed that SGLT2 inhibition modulates renal lipid metabolism and inflammation and prevents the development of nephropathy in db/db mice. Funding: Pharmaceutical Company Support - J&J

Loss of Angiotensin-Converting Enzyme 2 Alters Glomerular Structure in Non Obese Diabetic Mice Helea Roca-Roig, 1 Marta Riera, 1 Marta Rebull, 2 Javier Gimeno, 2 Julio Pascual, 1 Maria Jose Soler, 1 Nephrology, Hospital del Mar-Institut Hospital del Mar d’Investigacions Mèdiques, Barcelona; 2Pathology, Hospital del Mar, Barcelona.

Background: ACE2 has been shown to play an important role in diabetic nephropathy (DN). We studied renal morphology and kidney function in non-obese diabetic (NOD) female mice (with spontaneous autoimmune diabetes) carrying a deletion on ace2 gene (NOD.ACE2 -/-). In particular, concerns are the S3 segment and medullary thick ascending limb (mTAL), which are at risk for hypoxic injury. Model simulations suggest that SGLT2 inhibition substantially increases S3 QₘG. Together with elevated renin-angiotensin system (RAS) expression of Na-K-cotransporter (NCC2), SGLT2 inhibition also increases mTAL QₘG. Additionally, we used the model to determine the optimal combination of SGLT1 and SGLT2 inhibition, in terms of suppressing tubular glucose uptake and maintaining sufficiently low S3 and mTAL QₘG.

Conclusions: In conclusion, SGLT inhibition significantly increases oxygen consumption of the mTAL. This research was supported in part by NIH grant DK-89666. Funding: NIDDK Support
Conclusions: Genetic ACE2 ablation worsens glomerular hypercellularity in diabetic mice whereas GFP and ACR are not significantly altered and other markers of glomerular pathology are minimally affected.

Blood Pressure-Independent Amelioration of Glomerulosclerosis in Diabetic Rats Treated with Dual AT1-Receptor-Nephrin Inhibition versus AT1-Receptor Blockade Alone

Lodzi C.W. Roksoone1, Richard Van Veghel,1 Marian Claesen - van Groningen,2 René De Vries,3 Ingrid Marret,3 Usha M. Bhagoge,3 Jeanette M. Van Gool,3 Edith C.H. Friesema,3 Frank P.J. Leijten,1 Ewout J. Hoorn,4 Alexander H. Danser,5 Wendy W. Batenburg,1 Div. Pharmacology and Vascular Medicine; Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 3Div. Nephropathy, Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 4Dept Pathology, Erasmus MC, Rotterdam, Netherlands.

Background: Dual AT1-receptor-nephrin inhibition (ARNI) has recently been shown to exert beneficial effects on blood pressure (BP), NT-proBNP, and estimated GFR in heart failure patients, compared with AT1 receptor blockade (ARB) alone. Nephrin is upregulated in epineurial arterioles of diabetic rats. We hypothesized that ARNI improves cardiac and kidney parameters in diabetic tGR(mREN2)27 rats, a model displaying angiotensin II-mediated hypertension.

Methods: Rats were made diabetic with streptozotocin, for 5 or 12 weeks. In the final 3 weeks rats were treated with vehicle, the ARB irbesartan (15mg/kg/day) or irbesartan (15mg/kg day) + the nephrin inhibitor thiophan (0.1mg/kg/day; ARNI). BP was measured by telemetry in the 5-week group only.

Results: Baseline mean arterial BP (MAP) was 157±5mmHg. ARNI and ARNI lowered MAP identically over the 3-week period, reaching a maximum reduction of ~50mmHg around day 7, Heart weight/body length ratio in 12-week diabetic rats was 17% lower after ARNI treatment vs. ARB treatment (P<0.05). Proteinuria and albuminuria were observed from 8-weeks of diabetes onwards. ARNI reduced proteinuria more strongly than ARB (-78% vs. -49%, P<0.05), and a similar trend was seen for albuminuria. Kidneys of ARNI-treated rats showed less focal segmental glomerulosclerosis than those of ARB-treated rats. At the end of the study, no differences between ARNI- and ARB-treated rats were found regarding diuresis, natriuresis, plasma endothelin-1, vascular reactivity (acetylcholine and endothelin-1 responses), or kidney sodium transporters.

Conclusions: ARNI reduces proteinuria, focal segmental glomerulosclerosis, and cardiac hypertrophy in diabetic tGR(mREN2)27 rats more strongly than ARB, and this occurs in a blood-pressure-independent manner.

SA-PO392

Collateral Effects of Atrasentan on Renin-Angiotensin System

Lidia Anguiano, Marta Riera, Marta Rebull, Julio Pascual, Maria Jose Soler. Nephrology, Hospital del Mar-Institut Hospital del Mar d’Investigacions Mèdiques, Barcelona, Spain.

Background: Endothelin-1 is a vasoconstrictor peptide that has been shown to be increased in diabetic kidney disease. In kidney cortex from obese diabetic mice ACE2 activity is increased whereas ACE activity is decreased. Objective: study the effect of atrasentan, an antagonist of type B endothelin receptor, on renin-angiotensin system (RAS) in obese diabetic mice (db/db) and its respective controls (db/db).

Methods: Diabetic groups: vehicle (VehDB), 10mg/kg/day atarstentan (10DB), 25mg/kg/day atarstentan (25DB), 50mg/kg/day atarstentan (50DB). Non-diabetic groups: vehicle (VehCONT), 10mg/kg/day atarstentan (10CONT). Animals were included in the study at 12-weeks of life and treated for 16weeks. Systolic (SBP) and diastolic (DBP) blood pressure and ACE and ACE enzymatic activities in serum and kidney were analyzed.

Results: See table. Atrasentan therapy significantly decreased SBP and DBP in diabetic mice. Circulating and renal ACE2 activities were significantly increased in VehDB mice as compared to VehCONT. Atrasentan treatment at 25 and 50mg/kg/day reduced circulating and renal ACE2 activities. Circulating and renal ACE activities were decreased in VehDB as compared to VehCONT, with no modulation by atrasentan treatment.

Conclusions: Atrasentan prevented the increase of circulating and renal ACE2 in diabetes, indicating a collateral effect by RAS modulation. These results suggest that the beneficial effect of atrasentan in diabetic nephropathy may be related with endothelin blockade and its effect in the non-classic RAS pathway.

SA-PO393

P16\textsuperscript{ink4a} Expression Is Increased via 12-Lipoxygenase in High-Glucose-Stimulated Glomerular Mesangial Cells and Type 2 Diabetic Glomeruli

Yuanyun Zhang, Fu-zhe Ma, Tao Sun, Wan-ning Wang, Hang Yuan, Zhong-gao Xu. Nephrology, The First Hospital of Jilin Univ; Changchun, Jilin, China.

Background: Arachidonic acid-metabolizing enzyme 12-lipoxygenase (12-LO) is involved in glomerular hypertrophy of diabetic nephropathy (DN), in which cyclin-dependent kinase inhibitors (CDKs) play important roles. However, it is unclear whether 12-LO regulates the expression of the CDK p16\textsuperscript{ink4a} in DN.

Methods: Primary glomerular mesangial cells (MCs) and glomeruli isolated from rats were used in this study. The rats were fed a high-fat diet and given low-dose streptozotocin to induce type 2 diabetes. The 12-LO produced 12(S)-hydroxyicosatetraenoic acid [12(S)-HETE] was infused through an osmotic minipump. Enzyme-linked immunosorbent assay, Western blot, and morphometric analyses were performed.

Results: High glucose (HG) increased p16\textsuperscript{ink4a} protein expression in MCs, but this increase was prevented by the 12-LO inhibitor cinamycin-3,4-dihydroxy-o-cynaminocinnamate (CINC). The levels of p-p16\textsuperscript{ink4a} and p16\textsuperscript{ink4a} in MCs were significantly elevated after 12(S)-HETE treatment, whereas the 12(S)-HETE inhibitor SB203580 prevented these increments. Compared with levels in control MCs, marked increases in p16\textsuperscript{ink4a} activation and p16\textsuperscript{ink4a} expression were observed in MCs plated on collagen IV, while CDC treatment prevented these changes. Subcutaneous injection of CDC did not affect glucose levels but completely attenuated the diabetes-related increases in 12(S)-HETE content, p16\textsuperscript{ink4a} expression, p-p38MAPK levels, glomerular volume, and kidney-body weight ratio. Compared with levels in controls, p16\textsuperscript{ink4a} and p-p38MAPK in the glomeruli derived from 12(S)-HETE-treated rats were significantly increased.

Conclusions: 12-LO-p38MAPK mediates the upregulation of p16\textsuperscript{ink4a} in HG-stimulated MCs and type 2 diabetic glomeruli, and new therapies aimed at 12-LO inhibition might be beneficial in ameliorating diabetes-induced glomerular hypertrophy.

SA-PO394

The Effect and Mechanism of Probufol on Diabetic Nephropathy

Yunyan Cong1, Xiaomin Xia2, ChunHu Liu3, Fuyou Liu, Lin Sun. 1Dept of Nephrology, Kidney Inst of Central South Univ, Changsha, Hunan Province, China; 2Dept of Nephrology, Kidney Inst of Central South Univ, Changsha, Hunan Province, China.

Background: P66Shc induce mitochondrial ROS overproduction and lead to renal oxidative stress. Probufol has the protective effect on the progression of DN. However, the mechanism remains poorly understood.

Methods: ICR mice were divided into control (n=10), DN (n=10), probufol (10mg/kg/d) group (n=10), DMSO group (n=10). The DN model was induced by injection of STZ (40mg/kg body weight). Probufol was intraperitoneally injected to the mice every other day for 12 weeks after the model was built. Renal lesions and the expression of SIRT1, P300, AcH3, P66Shc, FN were detected by HE, Masson staining, TUNEL, DHE, immunohistochemistry and western-blot respectively.In addition, HK-2 cells were incubated with different concentrations of D-glucose (5, 30mM) with or without probufol, 1mM AICAR or 20mM Dorosomorphor or 1mM EX-527. The expression of P66Shc, SIRT1, P300, AcH3, AMPK, p-AMPK in HK-2 cells were detected by realtime-PCR,Western-blot and immunofluorescence assays. In addition, chromatin immunoprecipitation (CHIP) assay was used for determining the effect of probufol on acetylation of histone of P66Shc gene.

Results: Compared to control, the reduced ECM protein and renal tubular damage were observed in DN mice after treated by probufol. It also decreased the expressions of P300, P66Shc, FN in the kidney of DN mice. In addition, Probufol can reduce the level of serum creatinine, uric acid, proteinuria and renal ROS levels and apoptosis , while boost the expressions of p-AMPK and SIRT1. Furthermore, pretreatment with the selective AMPK inhibitor Dorosomorphor or SIRT1 inhibitor EX-527 could block the inhibitory efficiencies of probufol. The CHIP analysis showed that probufol treatment could decrease the acetylation of histone h3 in P66Shc gene promoter regions (~353 bp to -276 bp) in HK-2 cells induced by high glucose.

Conclusions: Probufol could epigenetically suppress the expression of P66Shc through AMPK-SIRT1-AcH3 pathway, then ameliorate the apoptosis and oxidative injury in HK-2 cells induced by high glucose.

Macrophages in Type 2 Diabetic Nephropathy

Celine Klessens, Malu Zandbergen, Ron Wolterbeek, Jan A. Bruijn, Ton J. Rabelink, Ingeborg M. Bajema, Daphne Thomas-jipelaar. Leiden Univ Medical Center.

Background: Inflammation seems to play a role in type 2 diabetic nephropathy (DN). Therefore, novel therapies focus on inhibition of inflammation to inhibit renal failure in DN. Interstitial macrophages are present in progressive interstitial lesions, however, the role of glomerular macrophages in the development of diabetic glomerular damage remains incompletely understood. In this study we investigated the accumulation of macrophages in glomeruli and interstitium of humans with various stages of DN.

Methods: Kidney samples obtained at autopsy of type 2 diabetes patients (N=88) with histologically proven DN were stained with CD68 and CD163, as global and M2 macrophage markers. As controls, renal autopsy samples of 5 non-diabetic and 18 diabetic

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
patients without DN were used. Macrophages in 50 glomeruli per sample were counted. Intestinal and interstitial macrophages were correlated to pathological and clinical parameters. **Results:** Glomerular CD68+ and CD163+ cells were present in all stages of DN both in the glomerulus and interstitium. Correlation between clinical data and interstitial macrophages indicates that intestinal inflammation probably influences the progression of DN. In addition, presence of glomerular macrophages in early diabetic nephropathy suggests that they influence the glomerular diabetic damage as well. Therefore, therapies targeting macrophages might be a useful novel therapy in DN.

**Activation of CXCL16/CXCR6 Pathway by Inflammation Accelerates the Progression of Diabetic Nephropathy**

**Zhuo He,** Kun Ling Ma, Yang Zhang, Wu Yu, Bi-Cheng Liu

**Methods:** Diabetic nephropathy was induced in rats by STZ injection. CXCL16 and CXCR6 expression were analyzed by western blot and immunofluorescence. Activated macrophages were isolated and cultured. The expression of CXCL16/CXCR6 pathway was analyzed using western blot and fluorescence-activated cell sorting. Results were confirmed by qRT-PCR and in vitro assays.

**Conclusions:** CXCL16/CXCR6 pathway plays a crucial role in the progression of diabetic nephropathy. Enhanced CXCL16/CXCR6 expression accelerates the progression of diabetic nephropathy by stimulating macrophages and promoting inflammation.

**Albumin Glycation Induces Structural Changes That Reduce Proximal Tubule FcRn-Albumin Binding and Reclamation**

**Mark C. Wagner,** Jered Myśliński, Shiv Pratap Singh Yadav, George Rhodes, Raben M. Sandoval, Sudhanshu Kumar, Sarah E. Wean, Fnu Ashish, Bruce A. Moltisini.

**Methods:** Albumin glycation was induced in vitro using a human kidney proximal tubule cell line. The albumin binding and reclamation by the FcRn were measured using fluorescence polarization and flow cytometry. The structural changes in albumin were analyzed using circular dichroism and electron microscopy. The correlation between albumin glycation and FcRn binding was studied using regression analysis.

**Conclusions:** Albumin glycation induces structural changes that reduce proximal tubule FcRn binding and reclamation. These changes affect the integrity of the renal proximal tubule and may contribute to the development of diabetic nephropathy.

**Far-Infrared Retrieves Pancreatic Beta Cell Function and Survival in a Streptozotocin-Nicotinamide-Induced Type 2 Diabetic Mouse Model**

Yung-Ho Hsu, 1 Tsu Hsiao Chen, 2 Cheng-Hsien Chen, 2 \(^1\) Department of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, Taipei, Taiwan; \(^2\) Department of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.

**Background:** In diabetes, the apoptotic cell death of insulin-producing beta cells leads to insulin deficiency. Recently, we found low-temperature far-infrared (FIR) irradiation increased proliferation and survival of human umbilical vein endothelial cells via prolymphocytic leukemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

**Methods:** In this study, we investigated the protective effects of FIR on pancreatic beta cell function and survival in the nicotinamide (NA) and streptozotocin (STZ)-induced type II diabetic mouse model. E1s via prolymphocytic leukemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

**Results:** The present study showed that F1R therapy decreased non-fasting blood glucose levels and increase blood insulin levels in diabetic mice in a dose-dependent manner. Immunohistochemistry staining revealed that F1R therapy retrieved insulin production of pancreatic beta cells in diabetic mice. But the influence of F1R on blood glucose and insulin levels was not found in NA-STZ-treated wild type (WT) and FIR mice. We also used the insulin-secreting beta cell line RIN-m5f to investigate the protective effects of FIR in vitro. FIR irradiation promoted cell proliferation and inhibited STZ-induced apoptosis in RIN-m5f cells. FIR also inhibited PLZF nuclear translocation and increased PI3K expression and Akt phosphorylation in RIN-m5f cells. PLZF siRNA transfection inhibited the influence of F1R on cell proliferation.

**Conclusions:** Our data suggest that F1R therapy retrieves pancreatic beta cell function and survival in diabetic mice via a PLZF-mediated pathway.

**Transgenic Mice Overexpressing Human CD39 (ENTPD1) Are Protected from High-Fat Diet-Induced Obesity and Insulin Resistance**

Anna U. Brandes, 1 Yue Zhang, 1 Kristina M. Heiney, 2 Simon C. Robson, 2 Bellamkonda K. Kishore, 1 Internal Medicine, Univ of Utah & VA Med Ctr, Salt Lake City, UT; Internal Medicine, BIDMC, Harvard Univ, Boston, MA.

**Background:** CD39 is a vascular ecto-nucleotidase that sequentially hydrolyzes extracellular ATP to ADP and AMP, thus terminating P2 receptor signaling. Previously we reported that deletion of CD39 in pancreatic beta cells confers significant protection against high-fat diet (HFD)-induced obesity and IR. Hence, we hypothesized that global overexpression of human CD39 (hCD39), which decreases the availability of extracellular nucleotides should humanize the beta cell (Hb) protective phenotype in vivo.

**Methods:** C57BL/6J (hCD39) transgenic (TG) and wild type (WT) mice were fed HFD (60% calories as fat, n = 10) or HFD (60% calories as fat; n = 7) with free access to food and water for 10 weeks. Glucose tolerance (GTT) and insulin sensitivity (IST) tests were conducted periodically. Glucose tolerance (GTT) and insulin sensitivity (IST) tests were performed. Blood glucose levels were measured by tail pinch blood sampling at 8 a.m. in conscious mice. A 2-h GTT was performed after an overnight fast. IST was assessed using an oral glucose tolerance test (OGTT).

**Results:** In response to HFD feeding, both genotypes showed significant increases in BW over the experimental period as compared to their counter parts fed regular diet. However, the gain in BW was significantly less in TG vs. WT mice (mean 21.5 ± 0.3 vs. 15.3 ± 2.0 g, n = 7, p = 0.005). There were no significant differences between the genotypes in the amount of food consumed, nor was there evidence of steatorrhea indicating uncontrolled autophagy levels could lead to tubular damage through the generation of uncontrolled autophagy levels. In contrast, the gain in BW was significantly less in TG vs. WT mice (mean 21.5 ± 0.3 vs. 15.3 ± 2.0 g, n = 7, p = 0.005). When fed hCD39 both genotypes exhibited glucose intolerance, but this was less severe in TG mice. In parallel, insulin sensitivity was significantly better in HFD-fed TG vs. WT mice.

**Conclusions:** Our results demonstrate that overexpression of hCD39 confers significant protection against the development of HFD-induced obesity and IR, and thus validating the proposition that dominantly deleterious roles are played by extracellular nucleotides.

**Mass Spectrometry Imaging Reveals a Role for Glomerular Sphingomyelin in Suppress AMPK Activity by Stimulating ATP Production in Mesangial Cells**

Satoshi Miyamoto, 1 Cheng-Chih Hsu, 2 Gregory Hamm, 3 Manjula Darshi, 2 Jonathan Staubner, 2 Pieter Dorrestein, 4 Kumar Sharma, 1, 2, 3 Inst of Metabolic Biology, Univ of San Diego, La Jolla, CA; 4 Center for Mass Spectrometry, Univ of California San Diego, La Jolla, CA; 1 Veterans Affairs San Diego Healthcare System, La Jolla, CA; 2 Therapeutic Discovery Mass Spectrometry Center, Univ of California San Diego, La Jolla, CA; 3 IMabioTech, MS Imaging Dept, Lille, France.

**Background:** We have recently shown that the ATP/AMP ratio is increased in the glomeruli in a mouse model of type 1 diabetes by matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) and may be the basis for reduced AMPK activity in diabetic glomeruli. Here, we applied MALDI-MSI to identify a key molecule regulating ATP levels in glomeruli.

**Methods:** For MALDI-MSI, 23 weeks-aged male diabetic Akita (C57BL/6J-Inj287290) (A), and normal (H) mice were fed HFD or NIDDK diet (N), and nephrectomy (N) were performed, and kidneys (K) were used. For mass spectrometry imaging (mass spectrometry imaging (mS)-MS imaging) was coupled with quantitative mass spectrometry (nano-HPLC/ESI/MS). The protein levels were analyzed using mass spectrometry imaging (mass spectrometry imaging (mS)-MS imaging).

**Results:** In diabetic glomeruli, we found that the protein expression levels of Ndufb2, Ndufb3 and Ndufb8, all components of respiratory chain complexes II, III and IV, were reduced by SL (p<0.05). In addition, SL increased glucose consumption and lactate production in high glucose conditions (p<0.05) suggesting a role for mitochondrial dysfunction.

**Conclusions:** We demonstrated using MALDI-MSI that the accumulation of glomerular SM in type 1 diabetic mice is associated with increased ATP in glomeruli and may contribute to reduced AMPK activity in diabetes. These findings suggest that reduction of SM may lead to novel therapeutic targets for the treatment of diabetic kidney disease.

**SA-PO403**

**Chronic Hyperglycemia Activates Autophagy Through an Increased Lysine-63 Linked Ubiquitination:** A Candidate Mechanism in the Progression of Tubular Damage in Diabetic Nephropathy

Paola Pontrelli, Annarita Oranger, Mariagrazia Barozzino, Francesca Conserva, Massimo Papale, Matteo Accetturo, Maria Teresa Rocchetti, Giuseppe Castellano, Loreto Gesualdo. Dept of Emergency and Organ Transplant, Nephrology Unit, Univ of Bari, Italy.

**Background:** Chronic hyperglycemia, a key pathogenic factor of diabetic nephropathy (DN), can alters autophagy whose role in tubular cells under hyperglycemic conditions (HG) remains unclear. We reported that lysine63-ubiquitination (K63-Ub) plays a key role in the progression of tubular damage in DN; moreover K63-Ub promotes protein autophagic clearance. Aim of our study was to: evaluate the HG effect in modulating autophagy in tubular cells (HK2); evaluate in vivo the autophagy state in patients with diabetes without renal damage and in different DN classes; investigate the K63-Ub role in the modulation of tubular cells autophagy.

**Methods:** HG was induced in HK2 under control (HGF) and HG conditions (HUGF). HG was induced in HK2 under control (HGF) and HG conditions (HUGF). HG was induced in HK2 under control (HGF) and HG conditions (HUGF).

**Results:** HG showed a significant increase in LC3 protein after 24h of HG. UBE2V1 silencing completely abolished LC3 induced protein expression after 24h of HG. Confocal microscopy showed the reduction of autophagic vesicles induced by HG in the presence of the K63-Ub inhibitor (NSC097923). IHC on kidney biopsies revealed an increased tubular expression of LC3 in diabetic patients vs controls, that persists in all DN classes and class IV patients showed cytoplasmatic accumulation of fused-vesicles. The same tubules with activated autophagy, expressed K63-Ub proteins both in diabetic and in DN patients (IF).

**Conclusions:** In conclusion, our data demonstrate that chronic hyperglycemia increases autophagy in kidney biopsies of 3 control patients, 3 diabetic, 9 DN (classes Iib, III and IV).

**Complexome Profiling of Mitochondrial Respiratory Chain Proteins from Podocytes of Diabetic Mice**

Zhenchun Yu, Shawn S. Badal, Daniel L. Galvan, Jianyin Long, Farhad R. Danesh. Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston, TX.

**Background:** Mitochondria play essential roles in many aspects of biology, and their dysfunction has been linked to diverse diseases, including diabetic nephropathy (DN). Central to proper mitochondrial function is oxidative phosphorylation (OXPHOS), coordinated by respiratory chain complexes encoded by both nuclear and mitochondrial genomes. Whether alterations in specific OXPHOS complex protein expression/activity contribute to mitochondrial dysfunction in DN remain largely unknown.

**Methods:** To assess complexome profiles, mitochondria were isolated from podocytes of 16-week-old diabetic (db/db) and nondiabetic (db/m) mice. Blue Native Gel Electrophoresis (BNE) was coupled with quantitative mass spectrometry (nano-HPLC/ESI/MS/MS) to identify known and unknown macromolecular protein complexes.

**Results:** We identified a total of 1216 mitochondrial proteins. Complexome profilingrevealed mitochondrial complex I and III to be markedly reduced in podocytes of db/db mice compared to controls. Consistent with MS results, Complex I activity was significantly reduced in podocytes of db/db mice compared to controls. Importantly, we found that the protein expression levels of Ndufb2, Ndufb3 and Ndufb8, all components of complex I, were significantly reduced in podocytes of db/db mice. We further validated

**Funding:** NIDDK Support, Other NIH Support - DP3DK094352-01, Veterans Administration Support
our initial results and found that the podocyte-derived mitochondria from diabetic db/db mice displayed a markedly reduced mRNA and protein expression levels of Ndufb8. These changes are coincident with significantly decreased Complex I activity from analogously diabetic or wild type mice.

**Conclusions:** Our study uncovers a previously unrecognized role of complex I in the pathogenesis of DN. We propose that deficiencies in components of Complex I may disrupt Complex I assembly, eventually reducing mitochondrial oxidative metabolism of podocytes in diabetic kidney disease. Further genetic studies are currently underway in our laboratory to establish the value and limitations of using Ndufb8 transgenic mice in experimental models of diabetes as a model for targeting mitochondrial dysfunction in DN.

**Hypermeglycemia and Hyperinsulinemia Increased Cell Proliferation and Regulated DNA Damage/Repair Pathways in Type II Diabetic (db/db) Mouse**

Liang S, Liang S, Habib S, Liang S. 1, 2Geriatic Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX; 2Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.

**Background:** The mechanisms by which hyperglycemia and/or hyperinsulinemia activate cell proliferate to regulate the DNA damage/repair pathways and increase renal cell damage in diabetes remain unclear.

**Methods:** In the current study, we investigated the role of hyperglycemia and hyperinsulinemia in regulating cell survival and cell proliferation to regulate the DNA damage/repair pathways in type II diabetic (db/db) mouse.

**Results:** Significant increase in proteinum, albuminuria, creatinine in 24h urine as well as renal tissue weight was detected in db/db mice compared to wild type mice. Cell proliferation was measured by Ki67 staining and PCNA expression in kidney sections of diabetic and wild type mice. Data showed significant increase of Ki67 staining and protein expression of PCNA in kidney of diabetic mice compared to wild type mice. The activity of the transcription factor Akt (measured by phospho-Akt at Ser473) was significantly increased and associated with increased activation of mTORC1 (measured by phospho-70S6K at Thr389) in kidney cortex of db/db mice compared to wild type mice. Agl shift analysis shows reduction of Nr2 binding to OGG1 promoter in nuclear extracts of kidney homogenate from db/db mice compared to wild type mice. A portion of the DNA-protein complexes was significantly decreased in the presence of the Nr2 antibody indicating that Nr2 is indeed a component of these complexes.

**Conclusions:** In summary, our data provide a novel mechanism of increase renal cell damage through decrease binding of Nr2 to the OGG1 promoter and consequence deficiency in DNA repair that lead to accumulate DNA damage and lead to renal complications under hyperglycemia and hyperinsulinemia condition in diabetic mice.

**Funding:** Veterans Administration Support

SA-PO407

**Spleen Tyrosine Kinase Activation Promotes the Progression of Diabetic Nephropathy in the Early Stage**

**Background:** Inflammation triggered by metabolic disorder has played an important role in the pathogenesis of diabetic nephropathy (DN) in the early stage. The inflammatory cytokines binding to immunoglobulin G Fc receptors (FcRs) in the surface of cell contribute to the progression of inflammation. It was found in our previous study that there was an increased expression of FcγRs with an immunoreceptor tyrosine-based activation motif (ITAM-FcγRs) in the kidney of diabetic CRP-Tg mouse induced by streptozotocin (STZ). It was also observed that ITAM-FcγRs were increased and spleen tyrosine kinase (SytK) was activated in rat glomerular mesangial cells (GMC) cultured with high glucose. SytK is a cytoplasmic nonreceptor tyrosine kinase and plays critical role in intracellular signaling transduction of ITAM-FcγRs. It has been established that active SytK signal cascade leads to the pro-inflammatory cytokines production in antibody-dependent kidney disease. However, the role of SytK in the progression of DN remains unclear. The present study investigates the potential of SytK activation in the early stage of DN.

**Methods:** Diabetes was induced by STZ in Sprague Dawley (SD) rats for assessment of kidney injury at 2, 4, 8weeks by real-time PCR, immunohistochemistry and western blot analysis. In vitro, renal proximal tubular cells (RPTC) with or without p53 dominant negative (p53-DN) were cultured in medium containing 5.5 mM or 30 mM glucose. Apoptosis was detected by morphologic observation, TUNEL, and flow cytometric analysis. The cells were also fractioned to investigate the subcellular redistributions of Bax and cytochrome c. The expression of p53, phosphorylated-p53 and apoptosis-related proteins were examined by western blot, immunohistochemistry/immunochemistry and immunofluorescence.

**Results:** Apoptosis was detected in renal tubules within a few weeks of diabetes, which was accompanied by p53/p-p53 expression. In cultured RPTC cells, high glucose induced apoptosis and p53. In these cells, there were Bax translocation to the mitochondria and cytochrome c release. Interestingly, these changes and apoptosis were attenuate in p53-DN cells. Consistently, they were also suppressed by pifithrin-a, a pharmacological inhibitor of p53.

**Conclusions:** These results suggest that p53 may be an upstream mediator of tubular cell apoptosis during high glucose treatment and in diabetic kidney. p53 is induced under these conditions and may activate the mitochondrial pathway of apoptosis.

**Mechano-Growth Factor Regulates mTOR and Other Growth Factor Expression in Mouse Mesangial Cells, Enhancing Cell Proliferation and Extracellular Matrix Production: Implications for Diabetic Glomerulosclerosis**

Zhai J, Ullrich L, Yang W, Li X, Hong X, Zhang Y, Yang X, Li X, Wu J, Wang J, Li H, Tan L. 1Department of Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL; 2Department of Nephrology, Shanghai Changzheng Hospital, 2nd Military Medical University of PLA, Shanghai, China.

**Background:** Our study uncovers a previously unrecognized role of complex I in the pathogenesis of DN. We propose that deficiencies in components of Complex I may disrupt Complex I assembly, eventually reducing mitochondrial oxidative metabolism of podocytes in diabetic kidney disease. Further genetic studies are currently underway in our laboratory to establish the value and limitations of using Ndufb8 transgenic mice in experimental models of diabetes as a model for targeting mitochondrial dysfunction in DN.

**Smooth Muscle Specific Heavy Chain Ferritin Knockout Mice as a Model of Obesity**

Vivicya Walker, Bo Chen, Reny Joseph, Anupam Agarwal. Nephrology Research and Training Center, Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

**Background:** Ferritin, consisting of heavy (H) and light (L) chain subunits, is a highly conserved ubiquitous protein that safely sequesters iron in a non-toxic form. During the course of our studies to evaluate the role of heavy chain ferritin (FH) in a model of vascular calcification in TKD, we generated a transgenic mouse using the cre-lox system with smooth muscle cell-specific deletion of FH (FHΔH). Serendipitously, we discovered the FHΔH mice gained more weight compared to control “floxed” FH mice and exhibited features resembling metabolic syndrome.

**Methods:** To characterize FHΔH mice as a model of obesity, male FHΔH mice and FH+ FH+ control mice were individually housed from 6-28 weeks of age to monitor weight, food intake, and body composition utilizing quantitative magnetic resonance (QMR) imaging. Protein analysis was performed on skeletal muscle and fat to determine expression levels of lipid signaling molecules and iron regulators. RNA analysis of inflammatory markers expressed in white fat was also performed.

**Results:** At 28 weeks old, FHΔH mice gained more weight (30.59g ± 2.02 vs. 27.72g ± 1.06 controls) during the observation period and consumed significantly more food starting at 20 weeks of age than the controls. QMR studies revealed that FHΔH mice had slightly more fat, lean and water mass compared to controls. Protein analyses of skeletal muscle and white fat revealed a loss of GLUT4 expression and iron trafficking proteins, respectively, in transgenic mice. Moreover, there was an increase in tissue iron concentration and gene expression of TNFα in the fat tissue of FHΔH mice compared to controls. Interestingly, review of publicly available microarray data sets (NCBI, GEO data set GDS3876) derived from human samples suggest a significant (~1.5 fold) increase in FH gene expression in obese individuals compared to lean controls.

**Conclusions:** Over a third of the adults in the United States are obese. Obesity predisposes individuals to other health risks, including CKD, diabetes, stroke, and cardiovascular disease. Our studies provide a novel mouse model for obesity.

**Funding:** NIDDK Support, Veterans Administration Support

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
of S6 kinase (phospho-S6 kinase) protein 8.7-fold. This increase in mTOR and active S6 kinase levels was associated with increased proliferation rate of MGF-S vs. MGF-EV. Meanwhile, H2-DOG uptake was suppressed 65% in MGF-EV vs. MGF-S. Type IV collagen (Col-IV) was increased 4.2-fold. 

Conclusions: MGF-S MC demonstrate increased mTOR with S6 kinase activation, consistent with their enhanced proliferation rate, while the increased VEGF and TGF beta1 expression. Overexpression of MGF in MC to mimic events in diabetic glomeruli recreates many features of high glucose-exposed MC. MGF-AS MC demonstrate a role for MGF in basal VEGF and TGF beta1 expression.

High Fat and High Sucrose Diet Induce Steatohepatitis That Is Dependent on Fructokinase

Takumi Ishimoto,1 Miguel A. Lanasa,1 Shiochi Maruyama,1 Richard J. Johnson.2 Nephrology, Nagoya Univ of Graduate School of Medicine, Nagoya, Aichi, Japan; 2Renal Diseases and Hypertension, Univ of Colorado, Denver, Aurora, CO.

Background: High fructose intake from added sugars, which are high in Western diet, correlates with the epidemic rise in obesity, metabolic syndrome, nonalcoholic fatty liver disease, and chronic kidney disease. However, the interaction of fructose with high fat intake, which is also rich in Western diet, remains unclear. Here we tested the interaction between fructose and fat, and determined whether this was dependent on a primary enzyme in fructose metabolism, fructokinase.

Methods: Wild type mice and fructokinase knockout mouse (C57BL6J background, male) were assigned to one of three groups (n = 8-9) respectively, matching mean body weight among the groups. Mice had free access to tap water, and a low fat (11%, LFD), high fat, or high fructose diet (HFD) for 16 weeks. Urine samples were collected at 13 weeks using metabolic cages. At 15 weeks, blood was withdrawn, and tissues including kidney and liver were taken after 6 h fasting.

Results: Both wild type mice fed HFD and fructokinase knockout mice fed HFD developed with hepatic steatosis without hepatic inflammation compared to mice fed LFD. In contrast, wild type mice fed HFDHFD developed more severe hepatic steatosis and low grade inflammation and fibrosis in pathological analysis, but not in fructokinase knockout mice. Increased CD68, TNF-alpha, MCP-1, alpha-smooth muscle actin, and collagen I and TIMP1 expression were found in wild type mice fed HFDHFD. These changes were prevented in the fructokinase knockout mice. Meanwhile, there was no significant change of urinary protein and urinary NGAL, and no apparent renal pathological change among groups.

Conclusions: This study demonstrated an additive effect of high fat and high sucrose diet on the development of hepatic fat accumulation. Furthermore, the combination of sucrose with high fat diet may induce steatohepatitis. These results indicate the important role of fructose in the development of fatty liver and nonalcoholic steatohepatitis.

The Succinate Receptor 1 Contributes to Obesity-Induced Type II Diabetes and Chronic Kidney Disease

Peter M.T. Deen,1 Claudia Carmone,1 Janna A. Van diepen,2 Joris Hubertus Robben,2 Ana Carolina Ariza,3 Olivier Devuyts,2 Richard J. Johnson.2 Nephrology, Nagoya Univ of Graduate School of Medicine, Nagoya, Aichi, Japan; 2Renal Diseases and Hypertension, Univ of Colorado, Denver, Aurora, CO; 3Physiology, Univ of Zürich, Zürich, Switzerland; 4Internal Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: Cell stress-induced release of mitochondrial succinate and activation of its SUCNR1 receptor in the macula densa is essential for type I diabetes mellitus (T1DM)-related renal release and hypertension. Obesity-induced T2DM and Chronic Kidney Disease (CKD) are aggravated by hypertension and go with cell stress in adipose/kidney tissue and macrophages, which express SUCNR1. Here we tested the role of SUCNR1 in obesity-induced T2DM and CKD.

Methods: Wild-type (wt) and SUCNR1−/− mice were fed a low fat diet (LFD; 10%) or high (H) HF (60%). At different weeks, mice were weighed, and subjected to metabolic cages (electrolyte measurements), glucose tolerance tests (GTT). Mice were sacrificed and blood and tissues collected.

Results: Blood succinate was increased in diabetic patients versus healthy controls. Isolated adipose tissue of wt and SUCNR1−/− mice revealed increased succinate release with hypoxia or high glucose. 16 weeks LF/DF fed showed similar body, adipose tissue and kidneys weight gain for both HF groups, but liver and heart weight gain was reduced in HFD SUCNR1−/− versus wt mice. Starving glucone levels were similarly increased in both HF groups, but SUCNR1−/− mice had a better GTT response. Inflammatory signals and macrophage infiltration was higher in adipose tissue of wt than SUCNR1−/− mice. Bone marrow derived cells of SUCNR1−/− mice migrated less efficient towards chemotactic signals from diabetic/hypoxic 3T3 cells. Blood sodium and urine volumes were similarly decreased and eGFR increased in both HF groups versus LFD controls. However, only HF SUCNR1−/− mice showed albuminuria, elevated collagen IV expression, and some increase in inflammatory gene expression in the kidney.

Conclusions: SUCNR1-mediated chemotaxis of macrophages to affected adipose tissue is decreased in obesity-induced hypertrophy, contributes to obesity-induced T2DM and CKD development. If similar in humans, SUCNR1 may form a novel therapeutic target for T2DM and CKD.

Fluoxetine Disrupts E-Cadherin-Mediated Cell Adhesion and Calcium Homeostasis in Pancreatic β Cells

Yun-wen Chen,1 Hong-Yu Chang.2 1Pharmacology, National Cheng Kung Univ, Tainan, Taiwan; 2Pharmacology, National Cheng Kung Univ, Tainan, Taiwan.

Background: Major depressive disorder (MDD) is a common psychiatric illness and it affects as many as 840 million people. MDD and Type 2 diabetes (T2D) are disorders with mutual risk factors identified in prevalence study reports. Antidepressant treatment could be another critical factor affecting the bidirectional associations between MDD and T2D. Long-term use of selective serotonin reuptake inhibitors (SSRIs), the most commonly prescribed class of antidepressants, is associated with an increased risk of developing T2D.

E-cadherin mediated cell-cell adhesion has been linked to diseases such as cancer and diabetes. Loss of cell-cell adhesion in beta cells decreases insulin secretion.

Methods: Here we examine the effects of the SSR1 fluoxetine (Prozac®) on beta cell function employing MIN6 cells, a mouse beta cell line, to elucidate the underlying molecular mechanisms.

Results: We showed that fluoxetine treatment significantly reduced glucose stimulated insulin secretion (GSIS). We found that fluoxetine has no effect on the total expression of E-cadherin, but decreased the surface of E-cadherin. Moreover, fluoxetine triggered E-cadherin down-regulating in control, mainly localized in Golgi, not in endoplasmic reticulum (ER). Our immunohistochemistry showed that reduction cell surface E-cadherin is due to increased endocytosis. Moreover, ER calcium release and the activation of store-operated calcium entry (SOCE) were suppressed by fluoxetine.

Conclusions: Taken together, the results suggested that the impairment of E-cadherin and calcium homeostasis may be underlying mechanisms by which fluoxetine caused the reduction of GSIS in pancreatic beta cells.

Involvement of Ischemic Condition in the Pathophysiology of Renal Damages in Obesity-Induced Kidney Injury

Koji Futatsugi,1 Hirobumi Tokuyama,1 Makiko Naitoh,2 Shu Wakino,2 Hiroshi Itoh.3 1Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.

Background: We have reported hypertrophic proximal tubules in obese mice which implies an inefficient oxygen supply in this area (Obesity Int, 2012). We examined whether hypoxic condition in proximal tubules is involved the pathogenesis of obesity-induced renal injury. We also test the hypothesis that this injury can be ameliorated by molecular intervention of prolyl hydroxylase domains (PHDs), sensors for tissue oxygen levels that is a crucial molecule for tissue response to hypoxia.

Methods: Tissue hypoxic conditions were assessed by pimonidazole immunostaining. Perfused apical cilia (PTC) proximal tubules were counted using CD34 stained vessels. Tamoxifen (Tam)-inducible proximal tubules-specific PHD2 deficient mice were created by crossing PHD2−/− mice and Tam-inducible N-myf5 downstream-regulated gene-I-Cre mice on C57BL6/J backgrounds. These inducible conditional knock out (KO) mice were born with their wild-type littermates (WT) were fed a high fat diet (HFD) or a low fat diet (LFD) for 12 weeks. The expressions of PHD2 and VEGF were measured by real-time PCR and immunohistochemistry.

Results: The WT mice on HFD manifested renal histological changes, including cellular enlargement of proximal tubules and a rarefaction of PTCs, which were consistent with more hypoxic area in proximal tubules than in WT mice on LFD. Urinary albumin and NGAL excretion were higher in HFD-fed mice, indicating ischemic tissue damage in proximal tubular area. However, expression of either PHD2 or VEGF was unchanged in HFD-fed WT mice, suggesting the lack of hypoxic tissue response in HFD-fed WT. Injection of Tam to HFD-fed KO mice downregulated PHD2 in proximal tubules, increased VEGF expression, increased the number of PTCs, decreased hypoxic area, and attenuated proximal tubular damages and albuminuria.

Conclusions: Hypoxic condition due to enlarged cell with vascular rarefaction is evident in the proximal tubular area of obese mice whereas tissue reaction to hypoxic damages failed to properly compensate. The early reduction of PHD2 specifically in the proximal area may create a novel strategy against the progression process from an early stage of obesity-induced kidney injury.

Herbal Mixture of Radix Puerariae and Fructus Crataegi Prevents Renal Injury in Type 2 Diabetes Via Inhibition of AKT/PI3K

Zhenyue Chen,1 Xinjun Zhang,2 1Diabetes Laboratory, Diabetes Research Center, School of Medicine, Ningbo Univ, Ningbo, China; 2Div of Nephrology, Ningbo Urology and Nephrology Hospital, School of Medicine, Ningbo Univ, Ningbo, China.

Background: It has been reported recently that radix puerariae (RP) is one of the best herbal medicines for metabolic diseases, as it has pronounced anti-oxidative effects and helps improving insulin resistance and lowering blood sugar and lipids levels. Fructus crataegi
Modulation of Akt/AS160 Phosphorylation Mediates Insulin Resistance in a Rat Model of Metabolic Syndrome

E. Chepchumba K. Yego, Katherine Kam, Sharma S. Prabhakar, Internal Medicine, Texas Tech Univ Health Science Center, Lubbock, TX

Background: Insulin resistance is the underlying pathophysiology hallmark of metabolic syndrome (MS) which is most often associated with obesity. While adipokines and inflammatory cytokines have been incriminated in the insulin resistance of MS, the exact underlying mechanisms and signaling processes have not been defined. The current study assessed the molecular mechanisms of insulin signaling in the skeletal muscle in ZSF1 rats which have leptin receptor mutation and phenotypically manifest MS.

Methods: Obese ZSF1 rats were maintained from the 8th week and sacrificed at 24 or 32 weeks and fed on high calorie high fat diet (Purina 5008) while control rats (lean ZSF and SD) were fed normal rat chow. Body weights and water intake were monitored weekly and blood and urine samples were obtained at 8 weeks and at the time of sacrifice for determination of plasma creatinine and glucose levels. The mRNA levels of PI3K, AKT, e-SMA and collagen IV in the kidney of diabetic rats.

Results: The obese ZSF1 rats showed full blown MS with obesity, hyperlipidemia, hypertension and hyperglycemia while the lean ZSF and SD rats were normoglycemic.

Conclusions: Our results demonstrate that while GLUT4 expression in insulin sensitive tissues is decreased in obesity mediated diabetes, several intermediary steps in insulin signaling are unaltered. However the most consistent finding was reduced phospho Akt/AS160, which could be a major determinant of insulin resistance in obesity.

Murine Recombinant ACE2 Reduces Renal Fibrosis in Experimental Alport Syndrome (AS)

Sun Hui Bang, Anu Konvalinka, Fei Fang, Xiaohua Zhou, Vanessa R. Williams, John Tran, Xuwen Song, Shao-Ling Zhang, Rohan John, Vaibhav B. Patel, Gavin Biddif, York P. Pei, James W. Scholey, University of Toronto, Université de Montréal, Chonn National Univ Medical School.

Background: ACE2 is a monocarboxypeptidase in the renin angiotensin system that catalyzes the breakdown of angiotensin II (AngII) to angiotensin (1-7) (Ang1-7). We have reported that ACE2 expression and activity in kidney are reduced in experimental Alport Syndrome (AS) but the impact of this finding on disease progression has not been studied.

Methods: Accordingly, we evaluated the effects of murine recombinant ACE2 (mrACE2) treatment in Col4A3-/- mice, a model of AS characterized by proteinuria and progressive renal injury. mrACE2 (0.5 mg/kg/day) was administered from 4-7 weeks of age via osmotic mini-pump.

Results: Treatment with mrACE2 led to an increased urinary ACE2 excretion, reduced renal AngII level and a correspondingly increased Ang1-7 level in 7-week-old Col4A3-/- mice. Pathological structural changes and albuminuria in the mutant mice were both attenuated by mrACE2 administration. mrACE2 ameliorated kidney fibrosis in Col4A3-/- mice as shown by decreased expression of profibrotic genes, less accumulation of extracellular matrix proteins and inhibition of the TGF-β signaling activation. Further, the increases in proinflammatory cytokine expression, macrophage infiltration, inflammatory signaling pathway activation and heme oxygenase-1 (HO-1) level in Col4A3-/- mice were also reduced by mrACE2 treatment. Lastly, mrACE2 influenced the turnover of renal ACE2, as it suppressed the expression of TNF-α converting enzyme (TACE), a negative regulator of ACE2.

Conclusions: In summary, treatment with mrACE2 alters angiotensin peptide metabolism in the kidneys of Col4A3-/- mice and attenuates the progression of AS nephropathy.

High Protein Diet Markedly Accelerates Diabetic Nephropathy Whilst Nephrectomy Only Slightly retard the Progression in Diabetic Olfactory Rats

Anna Granovic, Karin Nelander, Gerhard Bottcher, Magnus Soderberg, Anette E. Ericsson.

Background: The high protein diet (40%, from 10 weeks of age) markedly stimulated the NBCe1 activity by 65% and 104% in OLETF rats and the patient, respectively.

Methods: A Type 2 Diabetic model was generated by feeding rats with high fat diet followed by injecting a low dose of STZ. Rats were randomly divided into five groups: normal, high fat, high fat diet plus high protein content diet (40%, from 12 weeks of age) and a pair of diabetic OLETF rats treated with high protein content diet and nephrectomy. Plasma creatinine level was lower in intact (median 3.2 µM) and nephrectomised (median 3.6 µM) diabetic rats. Using high protein content diet appears to be a straightforward method to mimic key features of human DN including progressive proteinuria and glomerular lesions.

Results: Rats treated with high protein content diet showed comparable to lean mice. Using high protein content diet appears to be a straightforward method to mimic key features of human DN including progressive proteinuria and glomerular lesions.

Conclusions: Combined prevention with RPFC may inhibit the PI3K/AKT pathway in the kidney, thereby preventing renal injury in diabetic rats.

SA-PO420
Blockade of CDK9 and Smad3/4 Signaling Reduces Renal Fibrosis in Mice with Unilateral Ureteral Obstruction

Jinhua Li, Xinli Qu, Xiaoyun Jiang, John F. Bertram, David J. Nikolic-Paterson, Jean Lyne, Thierry Paterson.

Background: TGF-β1/Smad signaling plays a central role in the pathogenesis of renal fibrosis. Smad3 and Smad4 are pro-fibrotic, while Smad2 is anti-fibrotic. However, these Smads form heterogeneous complexes the functions of which are poorly understood. This study investigated Smad complexes in renal fibrosis in mouse unilateral ureteric obstruction (UUO).

Methods: UUO was established in wild type mice, mice heterozygous or homozygous for Smad3 or/and Smad4 (Smad3−/−, Smad4−/−, Smad4−/−/−). sRNA was used to knock down CDK9. CDK9 activity and Smad3 c-terminal phosphorylation was inhibited by a specific CDK9 inhibitor or a Smad3 inhibitor in cultured mouse renal fibroblasts and in UUO.

Results: Smad3−/− mice exhibited substantial protection from renal fibrosis on day 7 UUO, whereas Smad2−/− or Smad4−/− mice showed only modest protection. Formation of Smad3/Smad4/CDK9 complexes was an early event following UUO in wild type mice, which involved nuclear phosphorylation of the linker regions of Smad3. Smad3 or Smad4 deficiency significantly decreased the formation of Smad4/CDK9 or Smad3/CDK9 complexes, Smad3 linker phosphorylation as well as renal fibrosis but at different degrees.

In vitro, TGF-β1 stimulation of collagen I promoter activity involved formation of Smad3/Smad4/CDK9 complexes, and over-expression of each component gave additive increases in collagen promoter activity. A CDK9 inhibitor or CDK9 shRNA significantly reduced TGF-β1-induced interaction between Smad3 and Smad4, Smad3 linker phosphorylation and fibrotic response in mouse renal fibroblasts. Co-administration of the CDK9 inhibitor and the specific Smad3 inhibitor achieved better protection from TGF-β1-induced fibrotic response in vitro and renal interstitial fibrosis in UUO.

Conclusions: Our studies suggest that the formation of Smad3/Smad4/CDK9 complex drive renal fibrosis in the UUO model. Formation of this complex represents a novel target for anti-fibrotic therapies.

SA-PO421
Genetic Activation of Nrf2 Signaling Protects against Chronic Kidney Disease

Roderick J. Tim, Dionysios V. Chartoumpekis, Dong Zhou, Brittany M. McLaughlin, Ryan W. Kessler, Youhua Liu, Medicine, Univ of Pittsburgh, Pittsburgh, PA; Pathology, Univ of Pittsburgh, Pittsburgh, PA; Pharmacology, Univ of Pittsburgh, Pittsburgh, PA.

Background: The Keap1/Nrf2 pathway is upregulated in kidney injury, leading to the expression of an array of cytoprotective genes with antioxidant, anti-inflammatory, and detoxifying roles. Keap1 inhibits Nrf2 by sequestering it in the cytoplasm. During oxidative/electrophilic stress, Keap1 undergoes conformational change that renders it inactive and allows Nrf2 to accumulate in the nucleus. Pharmacologic induction of the Keap1/Nrf2 pathway is thought to have therapeutic potential in chronic kidney disease (CKD).

Methods: We hypothesized that knockdown of Keap1 would increase expression of Nrf2 and that Keap1 knockdown would improve outcomes in a model of chronic kidney disease. Keap1 knockdown was achieved through genetic modification of a hypomorphic (HM) mouse model. HM mice have lower Keap1 expression and increased Nrf2 activity. We subjected HM and wild-type (WT) mice to two models of CKD: unilateral ischemia followed by 10 days of reperfusion (IR); and unilateral ureteral obstruction (UUO). Kidney injury was assessed with serum creatinine, histology, western blotting and quantitative real-time PCR (qPCR) for injury markers.

Results: Compared to WT, HM mice had increased expression of numerous Nrf2-regulated genes after injury. In IR injury, HM mice were significantly protected from developing CKD, demonstrating decreased serum creatinine and renal fibrotic lesions compared to WT mice. Furthermore, HM mice had lower levels of fibronectin, n-smooth muscle actin, and TGF-β1. Inflammation was also suppressed in HM mice, as was pathologic β-catenin signaling, which is known to play a role in CKD progression. Similar results were obtained in the UUO model.

Conclusions: Most studies on the Keap1/Nrf2 pathway examine acute kidney injury or utilize pharmacologic agents with off-target effects. Therefore, more specific study of the Keap1/Nrf2 pathway with genetic approaches is necessary to determine its therapeutic potential in chronic kidney disease (CKD).

SA-PO422
Early and Late Treatment with PBI-4050, an Orally Active Anti-Fibrotic Agent, Reduces Fibrosis and Increases Survival of 5/6-Nephrectomized Rats

Background: PBI-4050, a first-in-class orally active compound which is currently in clinical phase IIb in CKD patients, displays anti-fibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase I, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effect. The aim of this study was to investigate the effect of early (Day 21) and late (Day 84) treatment of PBI-4050 on 5/6-nephrectomized rats.

Methods: Sprague-Dawley rats were partially nephrectomized (2/3 of the left kidney) on day 0. On day 7 the right kidney was removed. Oral treatment with PBI-4050 (200 mg/ kg, once a day) or vehicle was initiated at day 21 or at day 84, following randomization based on their glomerular filtration rate (GFR) results. GFR was measured at day 21 or day 84 and assessed every 3 weeks up to day 190 (early) or day 128 (late).

Results: Early treatment with PBI-4050 resulted in a significant improvement (up to 40% relative to control) in GFR. It also significantly reduced proteinuria. Histological lesion scores of kidneys were also significantly (p<0.05) decreased in PBI-4050-treated rats (2.7 ± 1.5) compared to control (3.9 ± 1.4), as determined by HPE, PAS and Masson’s trichrome staining. Early treatment with PBI-4050 induced a significant reduction of urine N-M1 level. Furthermore, early treatment with PBI-4050 reduced the overexpression of fibrogenic (TGF-β1, collagen I and α-SMA), pro-fibrotic cytokines (IL-23p19 and IL-6), remodeling (MMP2, SPARC and fibronectin), and oxidative stress (INOS) markers. Late treatment with PBI-4050 resulted in mild improvement of GFR and semen creatinine level (reduction of 50 mmol/L) but most importantly in an increase in survival (55% non-treated versus 80% with late treatment) at day 128.

Conclusions: These results suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and may potentially improve residual kidney function in patients with end-stage renal failure.

SA-PO423
Targeting Cardiorenal Connectors Reduces Renal and Cardiac Fibrosis in Experimental Chronic Renocardiac Failure

Nynke R. Oosterhuis, Lennart G. Borgartz, Branko Braam, Marianne C. Verhaar, Roel Goldschmeding, Carlo A. Guillard, Jaap A. Joles, UMC Utrecht, Netherlands; 1Univ of Alberta, Edmonton, Canada.

Background: Cardiorenal connectors (CRC) play a major role in progression of organ dysfunction in renal cardiac failure (subtotal nephrectomy (SNX)) followed by coronary ligation (CL). We hypothesized that simultaneous inhibition of all CRC would be most effective in reducing cardiorenal fibrosis and functional decline.

Methods: In rats subtotal nephrectomy was followed by coronary ligation (wk 8) [Borgartz, AJP, 2012]. In wk 11 we administered losartan (RAS), or PDTC, tempol and moldisomine (Inflammation-NO/ROS) or all of these plus metoprolol (all-CRC) until wk 16.

Results: Tubulo-interstitial (TI) fibrosis decreased in all treated groups (fig 1A). However, renal function was not significantly affected by any treatment. Systolic dysfunction stabilized in all treated groups, but declined further in vehicle-treated rats (fig 1B). Cardiac fibrosis improved in all treated groups without significant additive effect of targeting all CRC (fig 1C). TI and cardiac fibrosis correlated (fig 1D). Only all-CRC reduced MAP. Diastolic hemodynamics and ventricular and cardiomyocyte size were not affected by any treatment. Reducing TI injury and renal and cardiac CTGF mRNA expression was most effective by targeting all CRC.

Conclusions: Pharmacological targeting of cardiorenal connectors in this model of chronic renalcardiac syndrome ameliorated the severity of cardiac and renal fibrosis and prevented further decline in systolic dysfunction.

Funding: [Bongartz, AJP, 2012].

Fibroblast Growth Factor 23 Is Synthesised Locally by Renal Proximal Tubular Cells and May Be Pro-Fibrotic

Edward Robert Smith, Sven-Jan Tan, Stephen G. Holt, Tim Hewitson. 1Dept of Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; 2Dept of Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.

Background: Physiologically, FGF23 synthesis occurs predominantly in bone and regulates mineral handling in the kidney. In Chronic Kidney Disease, circulating levels become grossly elevated and are strongly predictive of disease progression, yet changes in FGF23 are not explained by increased osteocytic synthesis. Since extra-osseous FGF23 regulates mineral handling in the kidney. In Chronic Kidney Disease, circulating levels become grossly elevated and are strongly predictive of disease progression, yet changes in FGF23 are not explained by increased osteocytic synthesis. Since extra-osseous FGF23 regulates mineral handling in the kidney.
production is observed in diseased heart and vascular tissue, and is associated with the activation of pro-apoptotic signals, the involvement of renal FGF23 synthesis and potential fibrogenic effects warranting investigation.

Methods: Kidneys were harvested from FVB mice at day 0 or after 3 or 9 days post-unilateral ureteric obstruction (UO) (n=6). Paraffin-embedded sections were stained for FGF23 and with lectins to identify specific nephron segments. Total RNA was extracted from whole kidney tissue and laser-capture microdissected glomerular and tubular regions, and analysed by qPCR. Rat renal fibroblasts were cultured with exogenous recombinant human FGF23 and stained for α-smooth muscle actin (αSMA) to assess myofibroblast differentiation.

Results: Generalised low-level FGF23 protein staining was observed in proximal tubules at day 0, with more intense focal staining at days 3 and 9 post-UO. Local FGF23 synthesis was confirmed by qPCR of whole kidney extracts, and specifically, in microdissected glomerular and tubular cells, but not glomeruli. Normalised FGF23 expression increased 11-fold in day 3 UO relative to day 0 (both p<0.01). Treatment of rat UO fibroblasts with 10ng/ml FGF23 resulted in 4-fold increase in αSMA staining over 72h, equivalent to the effect of 1ng/ml transforming growth-factor-β (both p<0.01).

Conclusions: Local renal FGF23 synthesis in proximal tubular cells is enhanced by tubulointerstitial injury and may augment myofibroblast differentiation.

Quantitizing Intracellular Oxygen Tension in Kidney by Phosphorescence Lifetime Measurement

Yosuke Hirakawa,1  Imari Mimura,1  Toshitada Kawaguchi, Saitama, Japan.

Background: Hypoxia plays critical roles in the progression of chronic kidney disease, since intracellular reactions to hypoxia depend on intracellular oxygen (O2) tension. However, existing techniques to detect intracellular hypoxia cannot quantify O2 tension.

Methods: Phosphorescence lifetime (PL) measurement is reported to be useful to quantify O2 tension in vivo, however, most phosphorescent probes distribute extracellularly. Here we used BTPDM1, a lipophilic phosphorescent probe, to quantitate intracellular hypoxia in the kidney. We measured PL in Human Kidney 2 (HK-2) cells and murine kidney after BTPDM1 administration.

Results: We first made a calibration curve between PL and partial pressure of O2 (pO2) in HK-2 cells. Then we confirmed that BTPDM1 distributed in tubular cells in vivo. Next we measured PL of the murine kidney in normal condition, renal ischemia, hypoxemia and anemia. PL were calculated to be 1.8±0.2 μs, 4.0±0.3 μs, 2.8±0.2 μs, 2.2±0.2 μs, respectively. We also investigated chronic kidney damaged model mice at days 7 after 30 minutes unilateral ischemia-reperfusion (I/R) injury of kidney. PL of I/R injured kidney was longer than contralateral kidney (2.2±0.2 μs vs 1.8±0.1 μs). We also found an increase in pimonidazole adduct protein and a decrease in peritubular capillary density in I/R injured kidneys. We quantitated in vivo intracellular pO2 by extrapolating the calibration curve in HK-2 cells. The intracellular pO2 of normal kidney tubule was estimated to be 50mmHg, which was compatible with published value obtained by needle O2 electrode.

Conclusions: Our novel technique allowed accurate estimation of intracellular O2 tension of the normal and diseased kidney in vivo for the first time.

SA-PO426

Resveratrol Increases Expression of Heme Oxygenase-1 via Nrf2 Signaling to Ameliorate Renal Damage by Anti-Complement, Anti-Oxidative, and Anti-Apoptotic Effects in a Murine Model of Membranous Nephropathy

Chia-shao Wu,1  Kuo-cheng Lu.1 1Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; 2Dept and Graduate Inst of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan; 3Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.

Background: Idiopathic membranous nephropathy (MN) is an autoimmune-mediated glomerulonephritis and a common cause of nephrotic syndrome in adults. There are limited available treatments for MN. We assessed the efficacy of resveratrol (RSV) therapy for treatment of MN in a model of this disease.

Methods: Murine MN was experimentally induced by cationic bovine serum albumin, with phosphate-buffered saline used in control mice. MN mice were untreated or given RSV. Disease severity and pathogenesis was assessed by determination of metabolic and histological parameters, including proliferation, oxidative stress, apoptosis, production of heme oxygenase-1 (HO1) and signalling.

Results: MN mice given RSV had significantly reduced proteinuria and a marked amelioration of glomerular lesions. RSV also significantly attenuated immunofluorescent staining of C3 in the kidney. RSV treatment also reduced the production of reactive oxygen species, cell apoptosis, and upregulated heme oxygenase-1 (HO1). Inhibition of HO1 with tin protoporphyrin IX partially reversed the renoprotective effects of RSV. We show that concentration-dependent induction of HO-1 in E11 podocytes as RSV added. Nrf2 but not AMPK/1.2 protein level can be upregulated by RSV. We find that an induction of Nrf2 exists at the HO-1 promoter regions sequence #3 and #4 when RSV added. The Nrf2-specific siRNA attenuated the induction of HO1 mRNA by RSV. It suggests that increased Nrf2 at the HO1 promoter leads to elevated HO1 expression when RSV is exposed.

Conclusions: Our results show that RSV increased the expression of HO1 and ameliorated the effects of membranous nephropathy in a mouse model due to its anti-complement, anti-oxidative, and anti-apoptotic effects. RSV appears to have potential as a treatment for MN.

FVB Os/+ Mesangial Cells Exhibit Enhanced mTOR and Growth Factor Expression, Modeling the FVB Os/+ Glomerulosclerosis Mouse

Yongxin Gao, Charles W. Heilig. Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.

Background: We previously reported FVB Os/+ mice which exhibit rapidly progressive glomerulosclerosis beginning within the first 2 weeks after birth. Here we examine primary culture mesangial cells (MC) from FVB Os/+ mice and FVB +/+ control mice to examine the expression of FVB Os/+ MC and identify cellular mechanisms which may contribute to glomerulosclerosis (GS) in vivo. FVB Os/+ MC have excess ECM production.

Methods: Primary culture MC were studied between passages 5-12. Western analyses were performed with specific antibodies against selected proteins to examine mTOR, phospho-S6 Kinase, and growth factor expression important to excess extracellular matrix (ECM) production. GLUT1 glucose transporter expression and SOD2-doesxyglucose uptake rates were also determined. P<.05 was considered significant for statistical analyses.

Results: GLUT1 and glucose uptake rate were both increased ➥2-fold in FVB Os/+ MC compared to control MC, consistent with their increases in FVB Os/+ glomeruli. FVB Os/+ MC exhibited slowed proliferation consistent with the Os mutation. FVB Os/+ MC also had increased VEGF (1.6-fold) and TGF beta 1 (2.7-fold), which likely contribute to the excess ECM production of these cells. The increased VEGF in vitro simulates increased VEGF in FVB Os/+ glomeruli in vivo. MGF was decreased in FVB Os/+ MC (3.7-fold), mimicking increased glomerular MGF in vivo. We previously found MGF stimulates VEGF and TGFβ1 in MC. FVB Os/+ MC carry the Os mutation which impairs cell division, explaining their slow proliferation. Consistent with this, phospho-ERK1/2 was reduced 66%. In spite of increased mTOR (3.6-fold) and downstream phospho-S6 kinase (5.2-fold), the cells could not proliferate normally.

Conclusions: FVB Os/+ MC exhibit growth factor expression simulating glomerular growth factor expression in vivo in these mice. MGF expression is increased both in glomeruli in vivo and in vitro. MGF is a stimulus to VEGF and TGFβ1 expression as observed here. These growth factors are associated with excess ECM production in FVB Os/+ MC, despite suppressed Erk1/2, indicating another pathway is important to excessive ECM production.

Role of Sodium-Glucose Linked Cotransporter-2 Inhibitor in the Kidneys of Salt Sensitive Hypertension

Mikio Hisamichi,1  Atsuko Ikemori,2  Takeshi Sugaya,1  Kenjiro Kimura,3  Yugo Shibagaki.1 1Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; 2Dept and Graduate Inst of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan; 3Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.

Background: Because salt is an aggravated factor for the salt sensitive hypertensive renal injury model, SGLT2 expression may be related to the progression of renal injury due to salt sensitive hypertension. The aim of this study is to reveal the role of SGLT2 inhibitor in angiotensin II (AII) induced renal injury.

Methods: Male C57BL6 wild-type mice were divided into three groups: The Ang II group was systemically infused with Ang II for 16 days. The SGLT2 inhibitor (SGLT2-I) group was given an oral dose of the dapagliflozin SGLT2 inhibitor of 1mg/kg/daily in addition to an injection of Ang II. The control group was injected with a vehicle.

Results: In both the Ang II and the SGLT2-I groups, the degree of proteinuria, the glycemic levels in blood and the body weight were similar. Renal gene expressions of angiotensinogen and SGLT2 significantly increased in both the AII and the SGLT2-I groups compared to the control group. Renal gene expression of the angiotensinogen in the SGLT2 inhibitor group tended to be lower than that in the AII group. The degree of macrophage infiltration and urinary albumin levels tended to be lower in the SGLT2-I group than in the AII group.

Conclusions: These results suggested that SGLT2 inhibitor may attenuate the renal damage due to salt sensitive hypertension via inhibiting the activation of renal renin angiotensin system.

The Renoprotective Effect of Nuclear 1 Factor Related Factor 2 (Nrf2) Activator, Bardoxolone Methyl, in Aldosterone and High Salt-Induced Renal Injury
Mikako Hisamichi,1, Atsuko Ikemori,1,2 Takeshi Sugaya,1 Kenjiro Kimura,2 Yugo Shibagaki.3
1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Activation of nuclear 1 factor related factor 2 (Nrf2) is reported to have anti-oxidant and anti-inflammatory effects. In the aldosterone (Ald) and high salt-induced renal injury model using mice, we previously reported that severe tubulointerstitial damage was provoked by oxidative stress. The aim of this study is to reveal the renoprotective effect of the Nrf2 activator in this model.

Methods: To evaluate the degree of tubulointerstitial damage using the urinary liver type fatty acid binding protein (L-FABP), known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP+) mice. Male L-FABP+ mice were divided into three groups: The Ald group received systemic aldosterone infusions via an osmotic minipump and were given 1% NaCl water for 14 days. The Ald-Nrf2 group was given Bardoxolone Methyl of the Nrf2 activator intraperitoneally at a dose of 10mg/kg daily in addition to an injection of aldosterone and salt. The control group was given only a vehicle.

Results: The gene expression of MCP-1, the gene expression of RANTES, the degree of collagen type I and III and degree of macrophage infiltration were significantly greater in the kidneys of the Ald group compared to those in the control, and renal inflammatory reaction and renal fibrosis were significantly attenuated in the Ald-Nrf2 group. The degree of renal L-L-FABP gene expression and urinary L-L-FABP levels increased in the Ald group compared to the control and decreased in the Ald-Nrf2 group.

Conclusions: The Nrf2 activator, Bardoxolone Methyl, could attenuate renal oxidative stress induced by aldosterone and high salt, and consequently, renal inflammatory reaction and the production of renal collagen were prevented. Bardoxolone Methyl may be a useful treatment for renal disease.

SA-PO430
Detection of Mesangial Tissue Transglutaminase Activity in Human Kidney Biopsy Specimens
Kazuo Takahashi,1,2,6 Tomohiro Mizuno,1,2 Takanori Onouchi,1, Shin’ichi Akiyama,1,2 Hideki Tatsukawa,1 Mamoru Kusaka,1 Tadashi Onouchi,1 Shin’ichi Akiyama,1,2 Hideki Tatsukawa,1 Mamoru Kusaka,1 Tadashi Kanagawa, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 3Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 4Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Tissue transglutaminase (TG2) is a protein-cross-linking enzyme that plays an important role in tubulointerstitial fibrosis in animal models of chronic kidney disease and diabetic nephropathy. However, its pathologic significance in human glomerular diseases remains unclear. TG2 transforms into catalytically active TG2 through oxidative stress. The aim of this study is to reveal the role of TG2 in human glomerular diseases.

Methods: To evaluate the degree of tubulointerstitial damage using urinary liver type fatty acid binding protein (L-FABP), known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP+) mice. Male L-FABP+ mice were divided into three groups: The Ald group received systemic aldosterone infusions via an osmotic minipump and were given 1%NaCl water for 14 days. The Ald-Nrf2 group was given Bardoxolone Methyl of the Nrf2 activator intraperitoneally at a dose of 10mg/kg daily in addition to an injection of aldosterone and salt. The control group was given only a vehicle.

Results: The gene expression of MCP-1, the gene expression of RANTES, the degree of collagen type I and III and degree of macrophage infiltration were significantly greater in the kidneys of the Ald group compared to those in the control, and renal inflammatory reaction and renal fibrosis were significantly attenuated in the Ald-Nrf2 group. The degree of renal L-L-FABP gene expression and urinary L-L-FABP levels increased in the Ald group compared to the control and decreased in the Ald-Nrf2 group.

Conclusions: The Nrf2 activator, Bardoxolone Methyl, could attenuate renal oxidative stress induced by aldosterone and high salt, and consequently, renal inflammatory reaction and the production of renal collagen were prevented. Bardoxolone Methyl may be a useful treatment for renal disease.

Renoprotective Effect of Xanthine Oxidoreductase Inhibitor, Topiroxostat, in Hyperuricemic-Induced Renal Injury
Ayano Konagai,1,2 Takeshi Sugaya,1,2 Mikako Hisamichi,2 Kenjiro Kimura,2 Yugo Shibagaki.2
1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Hyperuricemia is known to be a risk factor of chronic kidney disease. The aim of this study is to reveal the effect of xanthine oxidoreductase inhibitor, Topiroxostat in a model of hyperuricemic renal disease provoked by adenine-containing diet.

Methods: To evaluate the degree of tubulointerstitial damage using urinary liver type fatty acid binding protein (L-FABP) known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP+) mice. Male L-FABP+ mice were divided into four groups: the adriamycin group (Ad) and the adriamycin group (Ad)) were given the diet containing each Feb (3mg/kg), Top-H (3mg/kg), Top-L (1mg/kg) in addition to adenine for another 2 weeks. Thereafter, adenine-containing diet was stopped, only each medication was continued for additional 2 weeks and the kidneys in each group were removed.

Results: Renal dysfunction, the degree of macrophage infiltration, tubulointerstitial damage and renal fibrosis were significantly attenuated in the kidneys of the Feb, the Top-L and the Top-H groups compared to those in the adriamycin group. Serum uric acid levels and renal xanthine oxidoreductase activity in the Feb, the Top-L, and the Top-H groups were significantly lower than those in the adriamycin group. Those levels in the Top-H group were significantly lower than those in the Feb group. Urinary excretion levels of L-FABP in both the Top-H and Top-L groups were significantly lower than those in both the adriamycin and Feb groups.

Conclusions: In conclusion, Topiroxostat attenuated the renal damage induced by hyperuricemia and may be a useful treatment for hyperuricemic renal damage.

Accumulation of Indoxyl Sulfate in Renal Tubular Cells Aggravates Kidney Injury in Rats with 5/6 Nephrectomy
Ayano Konagai,1,2 Takeshi Sugaya,1,2 Mikako Hisamichi,2 Kenjiro Kimura,2 Yugo Shibagaki.2
1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Indoxyl sulfate (IS), a representative uricemic toxin, is detected in renal tubular cells of CKD patients and 5/6 nephrectomized rats administrated with IS. It has been suggested that the retention of IS is induced through organic anion transporters in the basolateral membrane of renal tubular epithelial cells and this retention leads to nephrotoxicity. However, the mechanism for IS accumulation in renal tubules remains unclear. To reveal the correlation between IS accumulation and renal dysfunction in 5/6 nephrectomized rats, we investigated the expression of transporters in the apical or basolateral membrane and of markers for renal injury, and a content of IS in renal tubular epithelial cells using a novel antibody against IS.

Methods: To study the serum concentration of IS, we used high-performance liquid chromatography (HPLC) and our newly developed enzyme-linked immunosorbent assay (ELISA). The rats were stained with the antibody for IS. The expression of the transporters in renal tubular cells and the markers for renal injury such as Kidney Injury Molecule-1 (KIM-1) was detected by immunohistochemistry.

Results: Serum level of IS was identified to be increased in the 5/6 nephrectomized rats compared to the normal rats by the newly ELISA. The new system could sensitively detect the low concentration of IS. The value determined by ELISA is in a good correlation with HPLC. Immunohistochemistry showed a significant IS staining in renal sections of the model rats. We found the presence of IS in hyperuricemic tubular cells, where the expression of a transporter in the apical membrane mediating IS secretion was decreased, while the expression of a transporter in the basolateral membrane was retained. KIM-1, the marker for early kidney injury, was highly expressed in some tubules, but not in the IS positive cells.

Conclusions: Our findings suggest that IS is accumulated in renal tubular cells at the later stage of renal injury due to unbalanced expression of transporters between in the apical membrane and in the basolateral membrane, and this accumulation aggravates kidney injury.

SA-PO433
IL-15 as a Potential New Therapeutic Treatment for Renal Fibrosis
L. Lecreul,1 A. Devocelle,2 V. Le coz,1 C. Gallerne,1 S. Ferlicot,2 A. Durrbach,1 Villejuif, France; 2Bicetre Hospital, Kremlin-Bicetre, France.

Background: The human epithelial cells of various tissues produce interleukin-15 (IL-15), which acts not only on immune cells, but also on epithelial cells, mainly via its anti-apoptotic action. Thus, human and mouse renal tubular epithelial cells (RPTEC) constitutively secrete IL-15. Our group recently reported that IL-15 preserves epithelial cells from human kidney tubular cells damage since IL-15 is sufficient to induce WT commitment of RPTEC. Therefore, the goal of our study is to explore the renoprotective potential of IL-15 in vitro and in vivo in renal fibrosis.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Our study sought to examine if IL-15 could inhibit EMT in tubular epithelial cells and whether it could attenuate tubulointerstitial fibrosis using the unilateral ureteral obstruction model (UUO) in mice. We also analyzed IL-15 expression in various human nephropathies.

Results: IL-15 expression decreased in human renal disease and in mice during UUO (p<0.05, n=19). IL-15 treatment coupled with its soluble receptor (IL-15Rα) prevents interstitial fibrosis during UUO (10.7 ± 1.1% in control group, vs 8.2 ± 0.7% in IL-15 treated mice and 6.4 ± 0.6% in IL-15Rα treated mice, p<0.01, n=7 mice/group), quantified by Sirius Red and Western Blot, through two different mechanisms. We first found a direct inhibition of IL-15 expression in IL-15Rα treated mice (p<0.05, n=7 mice/group). IL-15 also reduced TGFβ1-induced EMT in vitro on RPTEC and tubular cell line (HK2) (p<0.05). This protective effect of IL15 acted through Snail inhibition and C-Jun activation (p<0.05). Furthermore, we found a directed accumulation of MCP1 expression in IL-15Rα treated mice (p<0.05, n=7 mice/group). IL-15 also reduced myofibroblasts (collagen I and III).

Conclusions: In conclusion, IL-15 can attenuate TGFβ1-induced EMT by acting directly through a reduction of collagen synthesis, both on myofibroblast, the main effector of fibrosis, and tubular cell. IL-15 also modulates macrophages infiltration in vivo in UUO. Therefore IL-15 could be a novel therapeutic player in renal diseases.

SA-PO434
Loss of the Vascular Class 3 Semaphorin, Semaphorin 3G, Leads to Attenuated Fibrosis and Reduced Tubular Injury by Unilateral Urinary Obstruction in Mice
Kana Ide,1 Yoshio Mawada,1 Shintaro Ide,1 Christe Betsholtz,2 Minoru Takemoto,1 Koutaro Yokote.1 1Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Japan; 2Dept of Medicine, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden.

Background: Chronic kidney disease (CKD) is a large social health issue, affecting 10-16% of the adults worldwide. In advanced stage of CKD, tubulointerstitial fibrosis occurs and promotes renal failure. Although a number of cell types and secretory factors are involved in the formation of renal fibrosis, its precise mechanism is still unclear. Semaphorin 3G (Semag3G) belongs to a class 3 family of secreted semaphorin. Class 3 semaphorins binds to neuropillin receptors and plexin coreceptors, showing various biological functions in neural development, angiogenesis, immunological response, and tumorigenesis. In the kidney, Semag3G is expressed in podocytes and endothelial cells of extraglomerular blood vessels. However, its role in renal fibrosis is still unknown.

Methods: To understand the role of Semag3G in renal fibrosis, Semag3G knockout mice and control mice are subjected to unilateral ureteral obstruction (UUO).

Results: Histologically, UUO kidneys does not show obvious difference between control and Semag3G KO mice. However, although mRNA expression of Tgfβ and Smad1, a key regulator of Tgfβ-induced fibrosis, increases by UUO in controls, these increases are attenuated in Semag3G KO UUO kidneys (for Tgfβ, 55% suppression compared to controls, P<0.05). In addition, mRNA expression of Acta2 and Fibronectin, and serum BUN level tend to be reduced in Semag3G KO after UUO. Expressions of inflammatory markers does not show a consistent tendency. Interestingly, increase of a tubular injury marker, Ki-1, after UUO is largely suppressed in Semag3G KO mice (77% suppression compared to controls, P<0.03 at day9,35% suppression, P<0.01 at day7), suggesting that Semag3G KO mice are protected from tubular injury.

Conclusions: Together, these data demonstrate that endothelial Semag3G acts on adjacent tubular/interstitial cells and promotes fibrosis by UUO. Identification of the mechanism of this interaction would provide new therapeutic targets for CKD and renal fibrosis.

Leukemia Inhibitory Factor Attenuates Tubulointerstitial Fibrosis in Unilateral Ureteral Obstruction
Sebastian Alexander Poathothorn, Fabio Smitigl, Lars C. Rump, Ivo Quack. Nephrology, Medical Faculty - Heinrich Heine Univ Duesseldorf, Duesseldorf, Germany.

Background: Tubulointerstitial fibrosis is common in chronic kidney disease which is often sustained by chronic inflammation. CD4+ T-cells play an important role in immune response in kidney disease. Leukemia inhibitory factor (LIF), a member of the Interleukin 6 family, and Interleukin 6 (IL-6) play a crucial role in regulating the balance of the inflammatory immune response in kidney disease. Leukemia inhibitory factor (LIF), a member of the Interleukin 6 family, and Interleukin 6 (IL-6) play a crucial role in regulating the balance of the inflammatory immune response in kidney disease. Leukemia inhibitory factor (LIF), a member of the Interleukin 6 family, and Interleukin 6 (IL-6) play a crucial role in regulating the balance of the inflammatory immune response in kidney disease.

Methods: To understand the role of LIF in renal fibrosis, LIF receptor deficient mice were analyzed in vivo on RPTEC and tubular cell line (HK2) (p<0.05).

Results: In vivo on RPTEC and tubular cell line (HK2) (p<0.05).

Conclusions: LIF receptor deficient mice were analyzed in vivo on RPTEC and tubular cell line (HK2) (p<0.05).

Dendritic Cell-Specific Sph-1 Knockout Mice Spontaneously Develop Unique Glomerulo- and Tubulointerstitial Nephritis
Mitsuharu Watanabe,1 Keiji Hiromura,1 Yoriaki Kaneko,1 Masato Kinoshita,1 Yuki Oshiki,1 Toru Saka1,1 Hidekazu Ikuchi,1 Akito Maeshima,1 Hiroshi Ohnishi,2 Takashi Matozaki,1 Yoshisai Naoyama.1 1Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Japan; 2Dept of Laboratory Sciences, Gunma Univ Graduate School of Health Sciences, Japan; 2Div of Molecular and Cellular Signalho, Dept of Biochemistry and Molecular, Kobe Univ Graduate School of Medicine, Japan.

Background: Src homology 2 domain-containing protein tyrosine phosphatase-1 (Sph-1) is a superfamily protein tyrosine phosphatase, which is highly expressed in hematopoietic cells. We have previously reported that dendritic cell (DC)-specific Sph-1 conditional knockout mice (CKO) spontaneously developed pneumonitis and nephritis at around 40 wks of age, together with anti-id antibody response (J Immunol. 2012; 188, 5397).

Methods: To understand the role of Sph-1 in the pathogenesis of autoimmunity, we investigated the renal lesions in the CKO mice.

Results: Mice were monitored by plating Sph-1-dox mice and CD11c-Cre mice. Mice were sacrificed at 8, 20, and 40 wks or later.

Conclusions: The DC-specific ablation of Sph-1 in mice resulted in development of unique autoimmune glomerulo- and tubulointerstitial nephritis, which is distinct from typical lupus nephritis characterized by wire-loop lesions and heavy proteinuria.

Funding: Government Support - Non-U.S.

TLR4 Mutant Mice Are Protected from Renal Fibrosis Following Folic Acid Injection
Jin C. Souza,1 Irina Baranova,2 Alexander V. Bocharov,2 Jonathan Street,1 Xinzhun Hu,1 Kenneth J. Wilkins,1 Peter S. T. Yuen,1 Robert A. Star,1 1Kidney Diseases Branch, NIDDK, NIH, Bethesda, MD; 2Clinical Center, NIH, Bethesda, MD.

Background: Local renal inflammation contributes to interstitial fibrosis (IF). Toll-like receptor 4 (TLR4) drives inflammation/ inflammasome and is expressed on renal epithelial cells (RECs). In the folic acid (FA) model of renal fibrosis there is an acute phase of acute tubular damage and a later phase of IF. To evaluate the role of TLR4 in renal inflammation/fibrosis, we analyzed the degree of inflammation that is dependent on TLR4 in IF models from WT or TLR4 mutant mice subjected to FA. We further compared IF following FA injection in both strains.

Methods: Primary cultures of RECs isolated from WT or TLR4 mutant mice were incubated for 20h with increasing doses of LPS. Supernatant IL-6 was measured by ELISA. Total RNA was extracted, and RTqPCR performed for IL-6, IL-1β, NLRP3, and GAPDH. Results were normalized by protein content. Exact stratified Wilcoxon test was used for differences. In vivo, FA (250 mg/kg IP) was given to 9 wk old WT or TLR4 WT or mutant mice (N=6-8/group). Day 2 BUN was used as an AKI marker. Mice with [day 2 baseline BUN] ratio above 1.5 were included. At day 14, mice were euthanized and kidneys harvested for IF by Masson trichrome stain. Changes in IF (after adjusting for day 2 log BUN) were analyzed by regression analysis.

Results: LPS dose-dependently increased IL-6 secretion in WT and TLR4 WT mice, but TLR4 mutant RECs secreted very low levels of IL-6 and IL-6 mRNA expression was 7-fold lower than WT cells. TLR4 mutant RECs expressed less NLRP3 (2-fold), and IL-1β (40-fold). Day2 log BUN was not different between the groups at day 2, and correlated with day 14 IF (p<0.01). After adjustment for day2 log BUN, TLR4 mutant mice were protected from IF at day 14 (p<0.01). Renal mRNA expression of IL-6, TNF-α and TGF-β-1 were not different between the strains at day 14.

Conclusions: In vitro, TLR4 signaling can stimulate inflammasomes and inflammatory cytokine production RECs. In vivo, although TLR4 is not required for the acute phase injury, the TLR4-mutant is protected from interstitial fibrosis, potentially via reduced sensitivity to DAMPs released after acute injury.

A New Mouse Model of Glomerular Foam Cell Accumulation in Disease

Minseob Eom, Kelly L. Hudkins, Anna Batorsky, Charles E. Alpers.1,2,3 Grazia Serino,1 Alessandra Dalla

Background: Foam cells are lipid-laden cells of monocyte/macrophage origin which have a key role in the development of atherosclerosis. Similar foam cells are found in human kidney biopsies in various diseases (e.g. tip and cellular variants of focal segmental glomerulosclerosis (FGS), diabetic nephropathy, and the interstitium in nephritic states). The pathophysiologic significance of foam cells in the kidney is poorly understood, in part due to lack of good animal models. We sought to develop a robust animal model for foam cell accumulation in the kidney to test their pathogenic significance.

Methods: Six-week old apolipoprotein E-(Apo E-)null C57BL/6 mice were divided into two groups. Group 1: Mice were gavaged daily with 1% hydroxypoly methyl cellulose with 0.1% tween 80 (HPMC-Tween) (10ml/kg) for 30 days. Group 2: Untreated age-matched controls. Each organ including kidney was harvested for histologic evaluation. Immunohistochemical stains (IHC) for Mac2 were performed to quantify the state of the monocyte/macrophage infiltration and urine analysis was calculated to compute the urine albumin-creatinine ratio (ACR) and total albumin excretion.

Results: IHC for Mac2 revealed that 83.76% of glomeruli were infiltrated by foam cells in the HPMC-Tween treated group. Most showed several foam cells in each glomerulus. Neither FSGS nor mesangioiliysis nor interstitial foam cell accumulation developed in the treated mice despite the prominent glomerular foam cells. Additionally, there was no significant difference in ACR between treated group and control group, although the treated mice revealed a trend of higher urine ACR, compared with pre-treatment urine.

Conclusion: Foam cells in the HPMC-Tween treated group. Most showed several foam cells in each glomerulus. Neithor FSGS nor mesangioiliysis nor interstitial foam cell accumulation developed in the treated mice despite the prominent glomerular foam cells. Additionally, there was no significant difference in ACR between treated group and control group, although the treated mice revealed a trend of higher urine ACR, compared with pre-treatment urine.

Macrophages Present an Essential Source of Anti-Inflammatory Annexin A1 Signals During the Course of Acute Anti-Thy-1.1 Nephritis

Robert Labes,1 Philipp Dittert,2 Sebastian Bachmann,1 Alexander Palenge.2 1Imperial NHS Trust, London, United Kingdom; 2Imperial College London, London, United Kingdom.

Background: Macrophage subpopulations exert distinctive effects during inflammatory kidney disease and may either aggravate kidney damage or foster renal repair. The anti-inflammatory protein annexin A1 (AnnA1) has been shown to shift macrophage polarization towards the anti-inflammatory M2 phenotype. Cellular sources and regulation of intrinsic AnnA1 signals during renal inflammation remain to be elucidated.

Methods: Adult Wistar rats were injected with anti-Thy-1.1 antibody to induce mesangio proliferative glomerulonephritis and examined after 24h (initiation phase), 5d (proliferation phase), and 15d (resolution phase). Regulation of AnnA1 was studied by qPCR and immunohistochemistry. AnnA1+ cells were characterized by triple labelling

Conclusions: These experiments show that AnnA1 treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

5-Aza-2-Deoxyctidine Reduces Nephrotoxic Nephritis and DNA Cytosine Methylation in Nephritic Glomeruli and Macrophages In Vitro

Thomas Oates,1 Stephen Paul Mccado,2 Charles D. Pusey,3 H. Terence Cook,2 Enrico Pettetto.3 1Imperial NHS Trust, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3MRC Clinical Sciences Centre, London, United Kingdom.

Background: Nephrotoxic nephritis (NTN) is a macrophage dependent rat model of crescentic glomerulonephritis (CRGN). We investigated whether DNA cytosine methylation could determine dis-regulation of macrophage activity and contribute to CRGN susceptibility, by examining the effect of 5-aza-2-deoxyctidine (DAC), an inhibitor of DNA methylation, on NTN phenotypes and DNA methylation in both nephritic glomeruli and bone marrow derived macrophages.

Methods: NTN was induced in male WKY rats. 6 rats were treated with intra peritoneal DAC and 6 controls with vehicle only. Treatment was given every three days prior to sacrifice at 10 days and then NTN phenotypes assayed. The effect of DAC on DNA methylation was examined by multiplexed PCR sequencing of bisulfite converted DNA in both nephritic glomeruli from NTN animals, and in WKY bone marrow derived macrophages treated in vitro with DAC.

Results: DAC treated animals had fewer glomerular crescents, less proteinuria and less glomerular macrophage infiltration (Ed1 staining).

DNA methylation in nephritic glomeruli was decreased across 200 cytosine bases in DAC treated samples compared to controls (P = 0.049, Wilcoxon rank sum test). This decrease was driven by 39 cytosines that showed demethylation in DAC treated animals. In vitro screening of macrophages showed diverse methylation changes after DAC treatment depending on length of exposure and dose.

Conclusions: These experiments show that DAC treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

Funding: Government Support - Non-U.S.

5-Aza-2-Deoxyctidine Reduces Nephrotoxic Nephritis and DNA Cytosine Methylation in Nephritic Glomeruli and Macrophages In Vitro

Thomas Oates,1 Stephen Paul Mccado,2 Charles D. Pusey,3 H. Terence Cook,2 Enrico Pettetto.3 1Imperial NHS Trust, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3MRC Clinical Sciences Centre, London, United Kingdom.

Background: Nephrotoxic nephritis (NTN) is a macrophage dependent rat model of crescentic glomerulonephritis (CRGN). We investigated whether DNA cytosine methylation could determine dis-regulation of macrophage activity and contribute to CRGN susceptibility, by examining the effect of 5-aza-2-deoxyctidine (DAC), an inhibitor of DNA methylation, on NTN phenotypes and DNA methylation in both nephritic glomeruli and bone marrow derived macrophages.

Methods: NTN was induced in male WKY rats. 6 rats were treated with intra peritoneal DAC and 6 controls with vehicle only. Treatment was given every three days prior to sacrifice at 10 days and then NTN phenotypes assayed. The effect of DAC on DNA methylation was examined by multiplexed PCR sequencing of bisulfite converted DNA in both nephritic glomeruli from NTN animals, and in WKY bone marrow derived macrophages treated in vitro with DAC.

Results: DAC treated animals had fewer glomerular crescents, less proteinuria and less glomerular macrophage infiltration (Ed1 staining).

DNA methylation in nephritic glomeruli was decreased across 200 cytosine bases in DAC treated samples compared to controls (P = 0.049, Wilcoxon rank sum test). This decrease was driven by 39 cytosines that showed demethylation in DAC treated animals. In vitro screening of macrophages showed diverse methylation changes after DAC treatment depending on length of exposure and dose.

Conclusions: These experiments show that DAC treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

SA-PO442 Reduced Mitochondrial Energy Production in the Kidney Induces Focal Segmental Glomerulosclerosis in Low-Birth-Weight Rats at Adulthood Toshivuki Imasawa, Kidney Center, National Hospital Organization Chiba-East Hospital, Chiba-City, Chiba, Japan.

Background: Intraglomerular hypertension has been linked with the pathogenesis of focal segmental glomerulosclerosis (FSGS) lesions in low-birth-weight (LBW)-related nephropathy, which is associated with a decreased number of nephrons. However, other mechanisms may participate in the pathogenesis of LBW-related nephropathy. Here, we investigated innate factors that could induce LBW-related nephropathy at adulthood.

Methods: LBW rats (N = 7) were obtained by intraperitoneally injecting pregnant rats with dexamethasone. Normal-weight (NBW) rats (N = 7) were obtained by saline injection. At 4 weeks of age, the left kidney was removed and used for histological analysis and quantitative proteomics (label-free LC-MS). At 9 weeks of age, the right kidney was histologically analyzed.

Results: At 4 weeks of age, glomerular numbers in LBW rats were significantly lower than NBW rats (p < 0.01). However, there were no sclerotic lesions, and neither group showed any other pathological changes at this age. At 9 weeks of age, FSGS lesions were observed in 7.4% of glomeruli in LBW rats, but only 0.5% of glomeruli had lesions in NBW rats. The pathological changes in LBW rats at 9 weeks of age resembled that of human LBW-related nephropathy. Quantitative proteomics using the renal cortex from 4-week-old rats revealed that 685 proteins decreased in LBW rats compared with NBW rats, and among them, 97 proteins (14.2%) were mitochondrial proteins. In such reduced mitochondrial proteins, 12 subunits of OXPHOS, especially complex III and IV, and 15 enzymes in TCA cycle were significantly decreased in LBW cortex (p < 0.05). Western blotting revealed the reduced expression of p-AMPK, NRF-1, and TFAM, which are master regulators of mitochondrial biogenesis, in LBW rats at 4 weeks of age.

Conclusions: This is the first report to investigate the innate suppression of mitochondrial energy production in LBW animals. We have shown that in addition to intraglomerular hypertension, innate defects to mitochondrial energy production should induce the formation of FSGS lesions in LBW-related nephropathy at adulthood.

Background: Tissue hypoxia (Hyp) is thought to influence the pathogenesis of chronic kidney disease (CKD), but direct evidence that prolonged exposure to tissue Hyp initiates or aggravates CKD is lacking. We tested this hypothesis by chronically exposing to Hyp normal rats and rats with 5/6 nephrectomy (Nx). In addition, we investigated whether such effect of Hyp would involve activation of innate immunity.

Methods: Adult male Munich-Wistar rats underwent Nx (n=30) or sham surgery (S, n=19). Seven S (Snorm) and 13 Nx (Nnorm) rats remained in normoxia, while 12 S rats (Shyp) and 17 Nx (Nhyp) were kept in a normobaric Hyp chamber (12% O2). Results at 8 weeks (BW, body weight; g; Hb, hemoglobin, g/dL; TCP, tail-cuff pressure, mmHg; Ualb/Ucr, urinary albumin/creatinine; K/BW, kidney/body weight; GSI, glomerulosclerosis index (%INT; % of cortical interstitium; M0, mitochondrial macromolecules, g/mn2; renal IL-1β (pg/g); and TLR-4 (2 × 106).

Mean ± SE, p < 0.05 vs. respective S, p < 0.05 vs respective Nor.

Exposure to Hyp increased Hb in both S and Nx, but led to no injury or elevation of the renal content of IL-1β or TLR-4 in S. Unexpectedly, Hyp attenuated IL-1β, TLR-4, M0, GSI and %INT in Nx.

Conclusions: We found no evidence that chronic Hyp initiates or worsens CKD. Chronic Hyp may be even renoprotective by unclear mechanisms, perhaps involving immune mechanisms, perhaps involving innate immunity.
Establishment of a 3-step Method to Obtain the Absolute Number of Nephrons in Mice
Xiaoqiang Chu, Jian-Kang Chen. Depts of Cellular Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA.

**Background:** Low nephron number is implicated in hypertension and kidney disease. Existing methods to determine nephron number have various limitations. While using the Cre reporter mice expressing membrane-Tomato/membrane-Green fluorescent protein (mT/mG) for other studies, we fortuitously noticed that the Tomato fluorescence remarkably visualized all glomeruli in the kidneys, which prompted us to establish a 3-step (Separate-Press-Count) method to obtain the exact nephron number in mice.

**Methods:** One homozygous mT/mG mouse (S232, available from the Jackson Laboratory, Catalog Number: 007576) was bred with FVB/NJ mice. This produced ~11 heterozygous pups per litter. After the pups reached 6 weeks of age, they were weighed and euthanized. Each kidney was decapsulated, weighed, and bluntedly separated into 35-45 pieces (~2 mm each) using forceps with non- serrated but blunted tips. Each piece was processed between a microscope slide with grids and a coverslip, followed by counting of each single glomerulus under a fluorescence microscope.

**Results:** The nephron number in male mice ranged from 10421 to 15577 (mean = 12977 ± 2136) for left kidney and 10374 to 15691 (mean = 13271 ± 2414) for right kidney (~36 Å) is ~2-3 orders of magnitude. Although this large difference in permeability has been established; however etv4 is also expressed in the metanephric mesenchyme. We asked what role Etv4 plays during nephrogenesis.

**Conclusions:** We have established a new simple method to count the absolute nephron number and are using it to define the minimum of nephrons per gram of body weight that can maintain the normal blood pressure and kidney function in mice.

**New Aspects on the Difference in Permeability Between Proteins and Polysaccharides in the Glomerular Filtration Barrier**
Carl Mikael Oberg, Joseph J. Grosszek, William Henry Fissell, Bengt Rippe. Dept of Nephrology, Lund University, Lund, Sweden; Dept of Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN.

**Background:** One of the many unresolved questions regarding the permeability of the glomerular filtration barrier is the reason behind the difference in permeability between albumin and polysaccharide probe molecules such as Ficol. The difference in sieving coefficients between albumin and a Ficol molecule of the same molecular size (~36 Å) is ~2-3 orders of magnitude. Although this large difference in permeability has been attributed mainly to charge effects, we have previously shown that this would require a supraphysiologically amount of charge on the filtration barrier, being about ~10 times more than the charge on the albumin molecule (~0.02 C/m²).

**Methods:** The classic heterotrophic model by Deen, Bridges, Brenner and Myers (Deen et al, JAP Renal Physiology, 1985) was extended by introducing size distributions on the solute molecules, making them flexible in their conformation. Experimental sieving data for Ficol, both from the rat glomerulus and from precision-made nanopore membranes, were analyzed using the model. The variation in solute size was quantified in terms of the geometric standard deviation (gSD) of the solute size distribution. The (mode) solute radius was assumed to be equal to the SE-radius and the pore size distribution gSD was set to unity.

**Results:** For the glomerulus (n=7), a gSD for the Ficol size-distribution of 1.16 (± 0.01) was obtained, along with a small pore radius of 36.1 Å (± 0.5 Å) and a large pore radius of 152 Å (± 7 Å). For the nanopore membranes (n=16), a gSD of 1.24 (± 0.01) was found.

**Conclusions:** In the current study, we show, for the first time, that a variation of only ~15-17% in the size of the molecule is sufficient to explain the difference in permeability between albumin and Ficol. In addition, we show that the effects of applying a size distribution on the solute molecule are only evident when the molecular size is close to the size of the selective elements of the barrier. This is well in line with experimental data, both from the GFB and from synthetic membranes.

**Rapid MicroRNA Isothermal Amplification and Detection in Urine for Nephrotic Syndrome and Other Renal Disease Biomarker Discovery**
Kathrin Gassei, Chandramohan Ishwad, Jacqueline Ho, Abhay N. Vats. Pediatrics, Children's Hospital of Pittsburgh, Pittsburgh, PA.

**Background:** MicroRNAs play an important role in renal development and are being explored as biomarkers for several renal diseases including nephrotic syndrome (NS). However, microRNA detection assays can be expensive, laborious, and time consuming. We are developing a fast and reliable assay for microRNAs in urine and report a novel isothermal amplification method. We tested this method (called cross hybridization amplification (CHAMP)) for detection of miR-30a-5p in urine of patients with NS and control.

**Methods:** We designed two 20-25 nt primers and a probe specific for miR-30a-5p. Primers were labeled with either Biotin or Digoxigenin on the 3'-end. Synthetic miR targets were developed for miR-30a, miR30b and Let7 microRNAs. Amplification required, Bst DNA polymerase, and incubation at 65°C for 30-60 min. Assay optimization was performed on urine samples spiked with synthetic miR constructs. Amplification and detection was performed with real-time PCR; gel electrophoresis and later flow devices.

**Results:** CHAMP was able to amplify and detect miR30a-5p in 60 minutes or less. The primers / probe were specific for miR30a and did not amplify miR30b or let7 microRNA.

**Conclusions:** A novel isothermal amplification method (CHAMP) can be used for fast microRNA detection in human urine. It allowed a rapid, sensitive, and highly specific amplification and detection, which is much easier to do and cost effective than qPCR or microarray. CHAMP could detect miR-30a-5p, with sensitivity similar to qPCR, without the need for RNA isolation and could be used for biomarker discovery based on microRNA studies for NS and other renal diseases.

**Dominant Negative Etv4 Expression in Metanephric Mesenchyme Reduces Nephron Endowment: A Model of Low Nephron Number CKD**
Susanna V. Fling, Flavia G. Machado, Benjamin D. Humphreys. Brigham and Women's Hospital, Boston.

**Background:** The role of etv4 expression in the ureretic bud during kidney development has been established; however their role in the metanephric mesenchyme. We asked what role Etv4 plays during nephrogenesis.

**Methods:** To inhibit etv4 function in the metanephric mesenchyme, we crossed mice with a loxP-flanked dominant-negative etv4 (R26Lox/P:DN-Etv4) with the metastatic mesenchymal-specific six2-cre mice (Six2-TGC Cre): cre-negative littermates served as control.

**Results:** Six2cre-DN-Etv4 mice express DN-evt4 in the nephrogen progenitor population starting dpc10.5. Cre-positive mice have lower body weight and fail to thrive. At four weeks, they have reduced nephron number (24.4 ± 2.4 vs. 86.8 ± 6.9 glomeruli per section, p = 0.001). They develop kidney failure (at 4 weeks: BUN 103.8±17.8 mg/dl, LV 14.1±1.8 mg/dl, p < 0.001) and proteinuria (21.29±7.23 g Albumin/g Creatinine vs. 0.14±0.03 g Albumin/g Creatinine in urine, p = 0.05). Their kidneys show all features of chronic kidney failure proteins, glomerulosclerosis, (fibrosis) and they die at 3-5 weeks of kidney failure.

**Conclusions:** Expression of etv4 in the metanephric mesenchyme is required for normal kidney development, and expression of DN-Etv4 in the six2+ population leads to defective kidney development with reduced nephron number and progressive chronic kidney failure at 3-5 weeks of age. Titeration of DN-Etv4 expression in metanephric mesenchyme may provide a novel genetic model for low nephron endowment and progressive CKD.

**NO Depletion by L-NNAME Causes Increases in Rat Glomerular Permeability In Vivo – Reversal with Tempol and L-arginine, but Not with the Potent NO-Donor DEA-NONOate**

**Background:** There is increasing evidence that the permeability of the glomerular filtration barrier (GFB) is regulated by a balance between the bioavailability of nitric oxide (NO) and the presence of reactive oxygen species (ROS). It has been postulated that normal or moderately elevated NO levels protect the GFB from permeability increases, while ROS, through reducing the bioavailability of NO, have the opposite effect.

**Methods:** In anaesthetized Wistar rats, the left ureter was cannulated for urine collection, while simultaneously blood access was achieved. To test the tentative antagonism between NO and ROS, rats were systemically infused with either L-NNAME (6 mg/kg/min), or L-NNAME together with the superoxide scavenger tempol (1 mg/kg/min), or L-NNAME together with L-arginine (290 mg/kg/min). Furthermore, we tested whether the potent NO donor, DEA-NONOate, could reverse the permeability effects of L-NNAME.

**Results:** The literature is vast and there are many possible explanations for the differences in results. Further studies are needed to understand the role of NO in the GFB.

_Funding: Private Foundation Support, Government Support - Non-U.S._
endothelin-1-induced HS expression has been associated with the development of proteinuria. We hypothesize that endothelin receptor knockout (podETRKO) mice, which showed a normal HPSE and HS expression, may protect the permeability of the GFB, whereas very high levels of NO, as predicted following systemic DEA-NONOate infusion, may actually be detrimental to the GFB.

**Methods:** Experiments utilized 12 week old humanized sickle cell mice (HSSS) and genetic controls (HBAAs) recently developed by the Tonnes’ lab. Ambrisentan (ET 

**Results:** Proteinuria and renal damage were reduced in the diabetic podocyte-specific endothelin receptor antagonist, A-182086 (ET 

**Conclusion:** These data suggest that targeting ET-1 may play an important role in the development of sickle cell nephropathy and support the use of chronic ET

choline in their drinking water. Mice with total CHOP knockout were used to test the role of CHOP in disease progression. CKD kidneys were analyzed using light microscopy and 24h total urinary protein and albumin measurements. On day 21 post-inimplantation, mice were sacrificed and PAS staining was used to evaluate renal interstitial cast formation and glomerular damage.

Results: In response to the CKD model, both CHOP-/- and wild type (WT) mice experienced significant increases in systolic and diastolic blood pressure. However, CHOP-/- mice showed significantly lower proteinuria and albuminuria. In addition, CHOP deficiency significantly decreased interstitial cast formation and glomerular damage in response to the model compared to WT.

Conclusions: CHOP deficiency resulted in a decrease in proteinuria and renal tissue damage. Along with inducing apoptosis, CHOP has been shown to interact with inflammatory pathways resulting in NF-kB activation. Further tests will evaluate the effect of CHOP deficiency on inflammatory, fibrotic and apoptotic response in our model. This study suggests that future findings could lead to the development of novel therapeutics to halt the progression of CKD.

Caveolin-1 Is Crucial in the Pathogenesis and Progression of Light Chain Deposition Disease but Not in Alamyloidosis
Jianmin Tang. Pathology and Transitional Pathobiology, Louisiana State Univ Health Sciences Center, Shreveport, LA.

Background: In-vitro models of glomerulopathic light chains (GLCs), including light chain deposition disease (LCDD) and light chain amyloidosis (AL-Am) have provided solid platforms to study the genetics of these diseases and how initiation/progression takes place. C-fos and NF-kB have been found to be important signaling mechanisms in the initiation phase of these two disorders. The role of caveolin-1 in the initiation / progression phases was explored in this study using human and mouse caveolin-1 knockout (KO) and wild type (WT) mesangial cells (MCs).

Methods: Human and Caveolin-1 KO and WT mouse MCs were grown on dishes (2D) and Matrigel (3D), and incubated with GLCs 10 μg/ml purified from the urine of renal biopsy-proven patients with LCDD and AL-Am. Downstream effects were tested by determining whether C-fos and NF-kB cytoplasmic to nuclear migration occurred and analyzing the presence and amount of ββ fibronectin in LCDD and AL-Am.

Results: When LCDD GLCs were incubated with caveolin-1 KO cells, no C-fos or NF-kB cytoplasmic to nuclear migration occurred and there was no increase in the extracellular matrix. When WT and caveolin-1 KO MCs were incubated with AL-Am GLCs, κB cytoplasmic to nuclear migration occurred and there was no increase in the extracellular matrix production in LCDD.

Conclusions: CHOP deficiency resulted in a decrease in proteinuria and renal tissue damage. Along with inducing apoptosis, CHOP has been shown to interact with inflammatory pathways resulting in NF-kB activation. Further tests will evaluate the effect of CHOP deficiency on inflammatory, fibrotic and apoptotic response in our model. This study suggests that future findings could lead to the development of novel therapeutics to halt the progression of CKD.

Inhibition of TRPC6 Channels Protects against Renal Fibrosis
Yueh-lin Wu, 1,2 Jian Xie, 2 Chou-Long Huang, 3 Taipei Medical Univ Hospital, Taiwan; 1UT southwestern Medical Center, Dallas, TX.

Methods: Wildtype (WT) and TRPC6-null mice (129/SvJ) underwent unilateral ureteric obstruction (UUO) on left kidney and sham operation on contralateral kidney. Ten days after surgery, kidneys were harvested for fibrosis by trichrome staining and for measurement of mRNA expression by quantitative real-time PCR. In separate experiments, WT mice underwent UUO and received injection of TRPC6/3 inhibitor BTP2 (2 mg/kg) or saline by intraperitoneal injection for 7 days.

Results: UUO induced a >20-fold increase in mRNA for Trpc6 in UUO kidney vs contralateral sham kidney in WT mice. mRNA for collagen-1, vimentin, cTGF, TGF-β1, and matrix metalloproteinases MMP-2 and MMP-9 as well as area for fibrosis measured by trichrome staining were also markedly increased in UUO vs sham kidney. Deletion of Trpc6 resulted in less fibrosis and blunted the increase in mRNA expression of collagen-1, vimentin, cTGF, TGF-β1, MMP-2, and MMP-9 in UUO kidney relative to those in WT mice. Trpc6 deletion did not alter the basal gene expression in sham kidney. Compared to vehicle-treated mice, BTP2 treatment also markedly decreased the measured area of fibrosis and attenuated the increase in expression of fibrosis and pro-fibrotic genes markers in UUO kidney. As in results from Trpc6 deletion, inhibition of TRPC6 by BTP2 had no effect on sham kidney.

Conclusions: Activation of TRPC6 may be critical for myofibroblast transformation in fibrosis. TRPC6 may be a new potential pharmacologic target in treating renal fibrosis.

SA-PO459
Histone Methyltransferase EZH2: A Novel Therapeutic Target for Renal Fibrosis
Xiaoxu Zhou, Murugavel Ponnusamy, Evelyn Tolbert, George P. Bayliss, Shougang Zhuang. Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown Univ, Providence, RI.

Background: EZH2 (Enhancer of Zeste Homolog 2) is a histone methyltransferase that induces histone H3 lysine 27 trimethylation (H3K27me3) and functions as an oncogenic factor in many cancer types. However, its role in renal fibrogenesis remains to be explored. The purpose of this study was to determine the role of EZH2 in renal interstitial fibroblasts and development of renal fibrosis in a murine model of unilateral ureteral obstruction as well as mechanisms involved.

Results: Our results showed that EZH2 and H3K27me3 were highly expressed in the cultured renal fibroblasts from kidney tissue from mice with unilateral ureteral obstruction. Pharmacological inhibition of EZH2 with 3-deazaneplanocin A (3-DZNeP) and GSK126, or silencing of EZH2 with its specific siRNA, inhibited serum- and TGFβ1-induced activation of renal interstitial fibroblasts in vitro. Administration of 3-DZNeP attenuated the expression of extracellular matrix proteins and fibronectin in the obstructed kidney. Mechanistically, 3-DZNeP inhibited expression of type I TGFβ receptor and phosphorylation of Smad3, along with preservation of Smad7 expression. 3-DZNeP was also effective in blocking phosphorylation of the EGF and PDGFr receptors, and suppressing activation of STAT3 and ERK1/2 signaling pathways in the injured kidney. Moreover, 3-DZNeP treatment abolished injury-induced renal expression of avb6 integrin, Notch1 and Notch3. Finally, EZH2 inhibition increased expression of PTEN, a protein tyrosine phosphatase associated with dephosphorylation of multiple tyrosine kinase receptors, in the kidney after ureteral ligation.

Conclusions: This study has identified EZH2 as an important epigenetic regulator of renal fibrosis and suggested that it could be a novel target for therapeutic intervention in chronic kidney disease.

Funding: NIDDK Support

SA-PO460
Targeting PHD2 for the Treatment of Anemia and Interstitial Fibrosis in Chronic Kidney Disease

Background: Anemia is a common manifestation of chronic kidney disease (CKD) and is associated with cardiovascular disease. The predominant cause of anemia in CKD is erythropoietin (EPO) deficiency. EPO is a hormone produced primarily by adult kidneys and is essential for the production of red blood cells. It has been shown in many animal models that EPO protects the kidney against interstitial fibrosis. Prolyl hydroxylase domain protein 2 (PHD2) is an active regulator of hypoxia-inducible factors (HIFs) that regulate genes involved in cellular adaptation to reduced oxygen availability. When PHD2 is reduced, HIFα is stabilized and upregulates several genes to promote survival in low-oxygen conditions. Systemic PHD2 inactivation has been found to increase renal EPO production and stimulate red blood cell synthesis, which can improve anemia in CKD patients (Minamishima et al, Science 2010).

Results: Using antisense oligonucleotides (ASOs) designed against the PHD2 mRNA, we have demonstrated a 60% reduction of kidney PHD2 expression after 4 weeks of treatment (100 mg/kg, 50 mg/kg) compared to a saline group. In addition, we observed increases in EPO mRNA expression in the kidney interstitial fibroblasts by RT-PCR (~550-fold) and by in-situ analysis. We sought to demonstrate an improvement in anemia and renal fibrosis using our PHD2 ASO. We developed an adenine-induced mouse model of CKD that develops severe anemia and interstitial fibrosis. After simultaneous administration of the 0.2% adenine diet and the PHD2 ASO (100 mg/kg) for 12 weeks, we observed significant increases in kidney EPO mRNA (~35-fold) and plasma EPO levels (~12-fold) compared to the control ASO group. Histological analysis showed improved fibrosis based on reduced Sirius Red staining. There were also improvements in anemia based on whole blood analysis of hemoglobin and hematocrit levels.

Conclusions: These data indicate that reducing PHD2 with ASOs may be a viable option for treating CKD patients with severe anemia and renal fibrosis.

Fibronectin Assembly Mediates KIM-1 Induced TGFB-Dependent Kidney Fibrosis
Venkata Sabbisetti, Cuyian Xin, Sandhya Padmanabhan, Bhargavi Chandrasekar, Akinwande A. Akinfolarin, Joseph V. Bonventre. Dept of Cellular and Renal Div, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background: Cell-extracellular matrix interactions play a crucial role in kidney fibrosis. Localized activation of TGFβ is critical for exertion of its cellular effects. Kidney Injury Molecule-1 (KIM-1) is upregulated in dedifferentiated proximal tubular cells (PTECs) following kidney injury and has been shown to induce kidney fibrosis in vivo. Here, we report that KIM-1 mediates fibrosis by up-regulating the critical components of the TGFβ activation machinery including EGF and corresponding integrin receptors in vivo. Inhibition of fibronectin assembly reduces kidney fibrosis.

Methods: Full-length KIM-1 or the KIM-1 mutant was overexpressed in LLC-PK1 and HEK cell lines and fibronectin and integrin levels were evaluated. Active TGFβ was measured using a bioassay. Mice were subjected to ischemia/reperfusion injury (IRI) or...
unilateral ureteral obstruction (UUO). In the UUO model, mice were treated with fibronectin blocking peptide or control peptide to evaluate the effects of inhibition of fibronectin assembly on fibrosis.

Results: KIM-1 expressing PTECs produced significantly increased levels of fibronectin and fibronectin receptors. These increases were abrogated when phosphorytrosine-350 of KIM-1 was mutated or KIM-1 was deleted. KIM-1 expressing cells displayed higher levels of total and activated TGFβ as compared to control cells. In vivo, KIM-1 expressing tubular epithelial cells were characterized by high fibronectin staining after ischemia/reperfusion injury or UUO. Blocking fibronectin assembly with a blocking peptide decreased fibrosis in the UUO model.

Conclusions: KIM-1 induced localized activation of TGFβthrough up-regulation of TGFβI, fibronectin and integrin receptors. Blocking fibronectin assembly reduced fibrosis in response to UUO in vivo. This mechanism can contribute to the fibrosis associated with chronic kidney disease. Blocking fibronectin assembly may be therapeutically beneficial to prevent or reduce kidney fibrosis.

Complement Modulation by C1-Inhibitor Hampered Pericyte (PC) to Myofibroblasts Trans-Differentiation (TDF) and Vascular Rarefaction in Ischemia/Reperfusion (I/R) Injury Giuseppe Castellano,1 Rossana Franzin,1 Chiara Divella,1 Alessandra Stasi,1 Angelica Intini,1 Margherita Gigante,1 Marco Fiorentino,1 G. Lucarelli,1 M. Battaglia,1 Giuseppe Grandaliano,1 Loreto Gesualdi,1 Nephrology and Urology Unit, Univ of Bari,2 Dept Medical and Surgical Science, Univ of Foggia, Italy.

Background: Preservation of endothelium-Pericyte (PC) interaction is critical to counteract renal fibrosis during chronic kidney disease; no data are available on PC involvement in AKI. We investigated whether Complement might modulate PC activation in I/R.

Methods: Ten pigs underwent to 30 min of renal warm I, followed by 24h of R. Five pigs were treated with C1-Inhibitor (C1-Inh, 500U/Kg). Biopsies were analyzed by IHC and IF for PDGFRβ, Caspase3 and aSMA. FACS, Acc-VIP and IF were performed on human PC (PDGFRβ) cells stimulated with C5a (1x10^−5 M) for 24h in vitro.

Results: I/R injury-induced PC to myofibroblasts TDF by reducing PDGFRβ without PC apoptosis (PDGFRβ/ Caspase3) in vivo. TDF was accompanied by a significant decrease in capillary lumens (Fig1 A %T0:11.3 ±2.1; T24:3.9 ±2.3; p<0.05) and aSMA up regulation (Fig1B). C1-Inh preserved PDGFRβ expression in PC and restored peritubular capillary area (T24C1-Inh: 12.06 ±3.5 vs T24). In accordance, C5a induced PC proliferation and Collagen I (T24C1-Inh: 12.06 ±3.5 vs T24). In accordance, C5a induced PC proliferation and Collagen I (T24C1-Inh: 12.06 ±3.5 vs T24). In accordance, C5a induced PC proliferation and Collagen I (T24C1-Inh: 12.06 ±3.5 vs T24).

Conclusions: Complement might contribute to PC to Myofibroblasts TDF in I/R injury, leading to vascular rarefaction and renal fibrosis. C1-Inh may be an effective strategy to prevent kidney development in transplanted kidney.

SA-PO463

Establishment of a Novel Mouse Strain to Trace Erythropoietin Producing Cells at Desired Time Points Keiichi Kaneke, Motoko Yanagita. Nephrology, Kyoto Univ, Kyoto, Japan.

Background: We previously reported that resident fibroblasts including Erythropoietin (Epo) producing cells were labeled with melanin proteoglycan and transdifferentiated into myofibroblasts during fibrosis with concomitant loss of Epo production. However, the previous method could not distinguish between Epo-producing cells and other resident fibroblasts and the behavior of Epo-producing cells remains unclear. Recently, Epo-Cre transare generated which enabled the lineage tracing of Epo-producing cells.

Results: Epo-Cre(WT) labeled cells were located in the interstitium of the cortical and corticomedullary region of the kidney, and the numbers were increased with the induction of anemia. Epo-Cre(KO) labeled cells expressed PDGFRβ and CD73, suggesting that Epo-Cre(KO) labeled cells are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis remains debatable. Recent studies have shown bone marrow-derived fibroblasts contributed significantly to the pathogenesis of renal fibrosis. We have previously shown that CXCL16 plays a critical role in recruiting bone marrow-derived fibroblasts into kidney. However, the signaling mechanisms are not known. In the present study, we examined the role of CXCL16 γ (PI3Kγ) in the recruitment of bone marrow-derived fibroblasts and development of renal fibrosis.

Conclusions: We generated a novel mouse strain and succeeded in labeling Epo-producing cells at desired time points. We demonstrated that Epo-producing cells transdifferentiated into myofibroblasts and were increased in fibrotic kidney. We aim to elucidate the mechanism of injury and repair of Epo-producing cells with this strain, Epo-Cre(WT) mice.

SA-PO464

Role of PI3K Kinase γ in Recruitment of Bone Marrow-Derived Fibroblasts and Development of Renal Fibrosis Yumuo Wu, Hua Liang, William E. Mitch, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a profound pathological feature of chronic kidney disease (CKD) leading to progressive loss of renal function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis remains debated. Recent studies have shown bone marrow-derived fibroblasts contributed significantly to the pathogenesis of renal fibrosis. We have previously shown that CXCL16 plays a critical role in recruiting bone marrow-derived fibroblasts into kidney. However, the signaling mechanisms are not known. In the present study, we examined the role of PI3K kinase γ (PI3Kγ) in the recruitment of bone marrow-derived fibroblasts and development of renal fibrosis.

Methods: We examined the role of PI3Kγ in the recruitment of bone marrow-derived fibroblasts and the development of fibrosis using a mouse model of folic acid-induced nephropathy in wild-type (WT) and PI3Kγ-knockout (KO) mice in vivo and migration of cultured mouse monocyte treated with CXCL16 in vitro.

Results: Compared with WT mice, PI3Kγ-KO mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and displayed significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFRβ in the kidney 2 weeks after folic acid cardinal treatment. Furthermore, PI3Kγ-KO mice exhibited fewer α-smooth muscle actin (α-SMA) positive monocytes and expressed less α-SMA protein in the kidney following folic acid treatment. Consistent with these findings, PI3Kγ-deficiency significantly reduced total collagen deposition and suppressed expression of extracellular matrix proteins (collagen 1 and fibronectin). In cultured mouse monocytes, CXCL16 activated PI3Kγ and induced the transwell migration, which was abolished in the absence of PI3Kγ.

Conclusions: These data indicate that PI3Kγ plays a pivotal role in recruiting bone marrow-derived fibroblasts into the kidney and developing renal fibrosis. Inhibition of PI3Kγ signaling may represent a novel therapeutic strategy for chronic kidney disease.

Inhibition of K-Ras prior to Induction of Acute Kidney Reduces Long-Term Progression to Chronic Kidney Disease in a Murine Model of Aristolochic Acid Nephropathy Sujit Kumar Saha, Bruce M. Hendry, Claire C. Sharpe. Dept of Renal Sciences, King’s College London, London, United Kingdom.

Background: Acute kidney injury (AKI) is recognised to be an early harbinger of chronic kidney disease (CKD). We have previously shown that K-Ras expression and activation are up-regulated in renal fibrosis and reducing K-Ras expression can prevent scarring. In this study our aim was to test whether transiently reducing K-Ras expression in the peri-AKI period can reduce progression to CKD.

Methods: CD1 mice received i.p. injections of either 3.5mg/kg Aristolochic Acid (AA) or normal saline on Day 1 and on Day 5. A treatment group were also given a single

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

730A
subcutaneous injection of 100mg/kg of mouse K-Ras antisense oligonucleotide (ASO) 2 days prior to the first AA injection. A vehicle group was given a subcutaneous injection of saline 2 days prior to the first AA injection. Renal function at multiple time points was assessed through a blood urea nitrogen (BUN) assay. The degree of fibrosis was ascertained through Picrosirius Red (PSR) and Masson Trichrome (MT) staining to quantify collagen deposition. The expression of K-Ras was determined by Q-PCR.

Results: CD1 mice given AA suffered an AKI with a 4.6 fold rise in BUN at Day 12 that returned to baseline by Day 30. However by Day 80, the AA mice had a 57% higher BUN than control mice, demonstrating later onset CKD. AA mice treated with mouse K-Ras ASO pre-AKI suffered a similar AKI but BUN at Day 80 was 48% lower than untreated AA mice and was comparable with healthy controls. PSR and MT staining demonstrated a 5 fold increase in collagen deposition by Day 80 in AA mice which was reduced by 30% in ASO-treated animals. K-Ras expression was consistently unregulated in the untreated AA mice throughout the chronic phase but the transient treatment with ASO prior to the acute injury resulted in normalisation of K-Ras mRNA by Day 80.

Conclusions: Transiently reducing K-Ras expression in the peri-AKI period in a murine model of aristolochic acid nephropathy reduces downstream fibrosis and prevents the decline in renal secretory function. Targeting K-Ras may provide a future therapeutic option for preventing renal fibrosis and CKD following AKI.

Non-Osmotic Sodium Storage Affects Glomerular Endothelial Cell Permeability
Rik He Olde Engberink,1 Peter Ochodnicky,2 Simon C. Satchell,2 Ed van Bavel,1 Liffert Vogt.1

Objective: The objective of this study is to investigate the interplay between Na+ and HS-GAGs and their effects on glomerular permeability.

Methods: Human glomerular endothelial cell (GEnCi) permeability to macromolecules was tested by measuring FITC-labeled albumin passage. Electrical resistance of a GEnCi monolayer, reflecting ESL Na+ content, was assessed with the ECIS8 system at 4000 Hz. We studied the expression of gene coding enzymes involved in heparan sulfate (HS-GAGs) in the endothelial surface layer (ESL) is of interest. The objective of this study is to investigate the interplay between Na+ and HS-GAGs and their effects on glomerular permeability.

Background: High dietary NaCl intake may affect glomerular permeability via pressure effects or via direct effects. In this respect, the Na+ buffering capacity of heparan sulfate glycosaminoglycans (HS-GAGs) in the endothelial surface layer (ESL) is of interest. The objective of this study is to investigate the interplay between Na+ and HS-GAGs and their effects on glomerular permeability.

Methods: Human glomerular endothelial cell (GEnCi) permeability to macromolecules was tested by measuring FITC-labeled albumin passage. Electrical resistance of a GEnCi monolayer, reflecting ESL Na+ content, was assessed with the ECIS8 system at 4000 Hz. We studied the expression of gene coding enzymes involved in heparan sulfate (HS-GAGs) in the endothelial surface layer (ESL) is of interest. The objective of this study is to investigate the interplay between Na+ and HS-GAGs and their effects on glomerular permeability.

Results: Relative to 125 mM, EXT-1 and EXT-2 expression was higher after stimulation with 150 mM NaCl while CHSY expression remained unchanged (Fig A). Albumin permeability decreased after 2 and 5-day stimulation with 150 and 175 mM NaCl (Fig B). ECIS experiments showed NaCl addition contributed to a concentration-dependent decrease in resistance (Fig C). NaCl did not alter resistance in the absence of cells. Heparanase increased resistance when added to 125 and 150 mM NaCl (Fig D). Mannitol did not alter permeability or resistance.

Conclusions: High NaCl stimulates HS-GAG synthesis of the glomerular endothelium, which may facilitate more Na+ binding. Subsequent higher ESL Na+ content may seal the glomerular barrier as suggested by both lower permeability and lower resistance.

SA-PO468
Centrality of Bone Marrow-Derived Fibroblasts in Magnetic Resonance Imaging Contrast-Induced Systemic Fibrosis
Violet Drel1, Catherine Do,2 Chunyan Tan,1 Brent Wagner,3 San Antonio, TX; 1Dept of Radiology, 2Department of Medicine, 3Veterans Health Care System of San Antonio, San Antonio, TX.

Objective: So-called “nephrogenic” systemic fibrosis is a ghastly sclerotic condition that occurs only in conditions of low renal function (acute kidney injury or severe chronic kidney disease) and gadolinium–based contrast exposure. Nothing is known about the pathobiology.

Methods: Experiments were designed to test if bone marrow from magnetic resonance imaging contrast–treated donors is stimulated to induce fibrosis, and to what degree these cells can be primed to home to affected organs. Male Fisher 344 rats that express human placental alkaline phosphatase (hPAP) were divided into two groups; one served as control, the other treated with pharmacological-grade gadodiamide (Omniscan, General Electric) 2.5 mol/kg IV daily, aiming for 20 doses over 4 weeks or evidence of systemic fibrosis. Rats with 5/6 nephrectomies were lethally–irradiated (900 Rad) followed by salvage bone marrow transplant from the control or contrast–treated donors. After an engraftment period, bone marrow recipients were divided into control and contrast–treated groups. The recipients of marrow from contrast–treated donors is stimulated to induce fibrosis, and to what degree these cells can be primed to home to affected organs. Male Fisher 344 rats that express human placental alkaline phosphatase (hPAP) were divided into two groups; one served as control, the other treated with pharmacological-grade gadodiamide (Omniscan, General Electric) 2.5 mol/kg IV daily, aiming for 20 doses over 4 weeks or evidence of systemic fibrosis. Rats with 5/6 nephrectomies were lethally–irradiated (900 Rad) followed by salvage bone marrow transplant from the control or contrast–treated donors. After an engraftment period, bone marrow recipients were divided into control and contrast–treated groups. The recipients of marrow from contrast–treated donors is stimulated to induce fibrosis, and to what degree these cells can be primed to home to affected organs. Male Fisher 344 rats that express human placental alkaline phosphatase (hPAP) were divided into two groups; one served as control, the other treated with pharmacological-grade gadodiamide (Omniscan, General Electric) 2.5 mol/kg IV daily, aiming for 20 doses over 4 weeks or evidence of systemic fibrosis. Rats with 5/6 nephrectomies were lethally–irradiated (900 Rad) followed by salvage bone marrow transplant from the control or contrast–treated donors.

Results: Regardless of bone marrow source, contrast–treated recipients demonstrated severe skin fibrosis. Fibronectin was similarly increased by immunofluorescence and immunoblot, but a synergistic effect evident in recipients of contrast–treated animals. The fibroblast precursor (“fibrocyte”) markers, CD45RO and procollagen I, were increased in the contrast–treated recipients. Recipients of marrow from contrast–treated donors demonstrated greater dermal CD34 without histologic evidence of fibrosis.

Conclusions: Bone marrow from contrast–treated animals did not induce systemic fibrosis, therefore target organs (such as the skin) appear central to the process. However, given the synergistic effect, “primed” fibroblast precursors do have an increased affinity for diseased lesions. Clinically, this may explain why repeat administrations of gadolinium–based contrast correlate with chronicity.

SOCS2 Plays No Major Role in the Mouse Remnant Kidney Model of Fibrosis
Yael Segel,1 Muhamed Assadi,2 Ralph Rabkin,3 Daniel Landau,2 Medicine and Immunology, 1Gevaert Univ, Beer Sheva, Israel; 2Research Inst, Veterans Administration Hospital, Palo Alto, CA; 3Pediatrics B, Schneider Children’s Medical Center, Petach Tikva, Israel.

Background: SOCS2, a key negative regulator of GH stimulated JAK/STAT5 signaling, is overexpressed in muscle, bone and liver of uremic rats and is presumably a cause of uremic GH resistance and growth retardation. SOCS2 deficient mice are GH sensitive, exhibit gigantism and accumulate collagen in skin, trachea and lungs (Reiser K et al, AJP 2004). SOCS2/GH overexpression in mice causes renal fibrosis, we tested whether SOCS2 deletion, by decreasing GH sensitivity, accelerates remnant kidney fibrosis.

Conclusions: No difference in renal fibrosis was seen between SOCS2+/- and SOCS2-/- mice at 80 days post surgery. This suggests that SOCS2 plays no major role in renal fibrosis.

Funding: NIDDK Support, Veterans Administration Support
Methods: Four-week-old SOCS2 deficient mice (high growth - HG strain) and normal wild-type (N) underwent 5/6 nephrectomy (CRF) or sham operation (SO), forming 4 groups: SO-N, SO-HG, CRF-N, CRF-HG. Mice were sacrificed after 3 weeks. IP bovine GH was given 30 min before sacrifice.

Results: Weight gain was reduced significantly in CRF-N versus SO-N. In contrast, growth rate was similar in SO-HG versus both CRF-N and SO-N. Kidney SOCS2 mRNA, absent in HG mice, was significantly increased in CRF-N vs SO-N. The degree of renal insufficiency was similar in CRF-N and CRF-HG mice. TGF-β1 and type IV collagen mRNA levels were increased to the same extent in SO-HG, CRF-HG and CRF-N vs SO-N. Renal GH receptor mRNA levels were decreased in both CRF groups. GH stimulated STAT5 phosphorylation increased in SO-HG vs SO-N, decreased in CRF-N vs SO-N and increased in CRF-HG vs CRF-N. IL6, SOCS3 mRNA and phospho-STAT3 levels increased similarly in both CRF groups vs SO controls.

Conclusions: STAT5 signaling in depressed remnants of kidney CRF-N mice is but is increased in non-uremic and uremic SOCS2 deficient mutants. Levels of fibrosis-related genes rose similarly in CRF-HG and CRF-N, despite absence of SOCS2 expression in CRF-HG CRF-N mice. This suggests that SOCS2 does not play a central role in remnant kidney fibrosis. On the other hand, IL6 and its mediators phospho-STAT3 and SOCS3, were elevated in CRF-HG and CRF-N mice suggesting that inflammation may play a role in remnant kidney fibrosis.

β-arrestin2, Downstream of Angiotensin II Type I Receptor Biased Signaling Pathway, Plays an Important Role in Renal Fibrosis

Yu-Dao Wang, Chen Yu.

Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.

Background: Expect G protein signaling pathway, it is now considered that there is also a β-arrestin pathway in the downstream of G protein-coupled receptors (GPCRs); angiotensin II type 1 receptor (AT1R) belongs to GPCRs and angiotensin II (AngII) is a bimodal stimulus with G protein pathway and β-arrestin pathway; it is important to know which downstream pathway involving in AngII-AT1R-induced renal fibrosis. In this study, we used β-arrestin biased agonist SII ([1-19, 4, β-ile]-angiotensin II) to study β-arrestin pathway in renal fibrosis.

Methods: The model of unilateral ureteral obstruction (UUO) was used in vivo, and rat kidney fibroblast cell line (NRK-49F) was treated with SII in vitro.

Results: 1) SII induced the binding of β-arrestin2 with AT1R, not β-arrestin1. 2) SII increased the synthesis of collagen I and fibronectin in NRK-49F. Transfection of β-arrestin2 siRNA abolished the effect of SII on the accumulation of ECM. Overexpression of β-arrestin2 inhibited SII-induced ERK1/2 phosphorylation. Overexpression of β-arrestin2 siRNA abolished the effect of SII on the accumulation of ECM. Overexpression of β-arrestin2 in NRK-49F decreased TGF-β1-induced ERK phosphorylation. Overexpression of β-arrestin2 enhanced SII-induced ERK1/2 phosphorylation. 5) The mRNA and protein levels of β-arrestin2 were significantly upregulated in the UUO model.

Conclusions: Our results suggested that AT1R downstream β-arrestin2 pathway, not β-arrestin1, might play a key role in renal fibrosis by forming complexes of β-arrestin2 and AT1R, inducing ERK1/2 phosphorylation and increasing ECM accumulation.

Deletion of ATR, a Master Molecule of DNA Damage Response, in the Proximal Tubule Exacerbates Kidney Injury and Inhibits Fibrosis

Seiji Kishi,1,2 Takaharu Ichimura,1,2 Ryuji Morizane,1,2 Joseph V. Bonventre.1,2,3

1Renal Division, Dept of Medicine, Brigham and Women’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Harvard Stem Cell Inst, Cambridge, MA.

Background: Impaired response of cells to DNA damage can cause cellular senescence. We have previously implicated the DNA damage response of renal proximal tubule cell (RPTC) in progressive kidney injury and fibrosis. The purpose of this study was to investigate the role of Ataxia telangiectasia and Rad3-related (ATR), a master molecule of the DNA damage checkpoint, in kidney injury and fibrosis.

Methods: RPTC-specific conditional ATR knockout (ATR−/−) mice were generated by crossing ATR floxed (ATR+/−) mice, ATR−/− mice and tamoxifen-inducible (SCL34a1-CreERT2) mice. We evaluated the role of ATR in susceptibility to cisplatin nephrotoxicity, unilateral ureteral obstruction (UUO) and renal ischemia/reperfusion injury (IRI).

Results: Four days after cisplatin injection, ATR−/− mice had increased kidney histological damage, increased Kidney Injury Molecule-1 (KIM-1) expression and decreased renal function compared with wild-type mice. Within the first 5 days, 34% of ATR−/− mice died, while no WT mice died. Increased DNA damage and the number of apoptotic cells were also found in ATR−/− mice. At 7 days after UUO, when compared with wild-type mice, ATR−/− mice exhibited increased kidney histological damage, KIM-1 expression, DNA damage markers, and number of apoptotic cells.

Conclusions: ATR activation in the RPTC represents a protective response in acute and chronic kidney disease of various etiologies.

Role of Heparanase in Renal Epithelial-Mesenchymal Transition Induced by Ischemia/Reperfusion

Valentina Masola,1 Gianluigi Zaza,1 Giovanni Gambaro,2 Maurizio Onisto,1 Gloria Bellin,1 Gisella Vischini,1 Iyad Khamaysi,4 Antonio Lupo,1 Israel Vlodavsky,3 Zaid Abbasis,1 Renal Unit, Dept of Medicine, Verona, Italy; 2Columbus-Gemelli Hospital Catholic Univ, Rome, Italy; 3Univ of Padova, Padova, Italy; 4Rambam Medical Center, Israel; 2Technion, Israel.

Background: Ischemia/reperfusion (IR) activates epithelial-mesenchymal transition (EMT) of tubular cells, thus leading to organ fibrosis. Heparanase (HPSE) controls the EMT induced by FGF2 and TGFβ. The aim of this study was to evaluate whether HPSE modulates the EMT induced by IR.

Methods: Tubular cells (HK-2) were stably silenced for HPSE were subjected to 24h of hypoxia and 24h of reoxygenation. The cells were also treated with SST0001 (Sigma-Tau Research Switzerland SA), an inhibitor of HPSE. The IR injury has been reproduced in vivo by clamping the renal arteries for 30 min in transgenic mice over-expressing HPSE (HPSE-tg) and their wt mice. Mice were sacrificed after 48 and 72 h. Gene and protein immunoactivity of EMT markers (α-SMA, VIM, FN and TGFβ) were evaluated by real-time PCR, WB and IIF; histology was assessed by PAS staining.

Results: In vitro, IR increased the expression of EMT-markers in wt tubular cells but not in HPSE-silenced cells. Similarly, the inhibition of HPSE with SST0001 (Sigma-Tau Research Switzerland SA) in wt cells prevented the development of IR-induced EMT. In vivo, FR induced acute tubular necrosis, which was more profound in HPSE-tg than their wt animals. In wt mice IR injury increased glomerular and tubular HPSE expression, but did not induce the EMT-markers. In contrast, in FR HPSE-tg mice remarkably induced the expression of EMT-markers already after 72h.

Conclusions: HPSE is a crucial factor for the development of EMT induced by IR. HPSE inhibition may therefore constitute a possible therapeutic approach for the prevention of fibrosis in organ transplantation.

Hydrogen Sulfide Deficiency in the Kidney and Brain in Aging Mice

Hak Joo Lee,1,2 Kavitha lakshmi Sathari natarajan,3 Meenalkashmi M. Mariappan,1 Denis Feliers,1 Jeffrey L. Barnes,1,2 Goutam Ghosh-Choudhury,1 Christopher G. Kevil,1 Balakuntalam S. Kasinath.1,2

1Medicine, MC7882, Univ of Texas Health Science Center, San Antonio, TX; 2Pathology, Louisiana State Univ, Shreveport, LA; 3Oklahoma Medical Research Foundation, Oklahoma City, OK.

Background: Hydrogen sulfide (H2S) is constitutively synthesized by cystathionine β-lyase (CSE) and cystathionine β-synthase (CBS). It regulates GFR and tubular transport in the kidney and NMDA receptors in the brain. H2S activates AMPK to inhibit mTORC1 and abrogate matrix protein increment in high glucose treated renal cells (Lee, JBC, 2012). Since mTORC1 is implicated in aging, we surveyed the status of H2S relative to mTORC1 in organs of aging mice.

Methods: C57B6 mice, immunoblotting, H2S generation and content assays, histopathology, cell culture.

Results: The renal and cerebral CSE and CBS expression, H2S content and generation were reduced in old mice (26-32 mos old, n=6 mice) compared to young mice (4-6 mos old, n=6 mice); such changes were not seen in the heart or the skeletal muscle. Old mice showed increased renal collagens I, III, fibronectin, parenchymal fibrosis, albinumimia, and rose in serum cystatin C. Signaling analysis showed that aging was associated with renal and cerebral activation of Akt, reduced phosphorylation of AMPK, and activation of mTORC1 manifest as increase in the phosphorylation of p70S6 kinase and 4E-BP1. Since insulin has been implicated in the aging process, we examined insulin regulation of CSE and CBS in renal proximal tubular epithelial (MCT) cells; insulin rapidly reduced CSE and CBS expression and decreased H2S generation. Insulin also promoted the synthesis of fibronerin matrix protein in MCT cells.

Conclusions: Our data show for the first time that the aging kidney and cerebrum share similar changes in H2S metabolism associated with reduced AMPK activity leading

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
to mTORC1 activation; these pathways could be related to age related changes including fibrosis. Insulin may mediate reduction in CBS, CSE and H2S and contribute to matrix accumulation in the aging kidney. Funding: Other NIH Support - NIA, Veterans Administration Support

The Role of Ergothioneine/OCTN1 in CKD

Yusayuki Shinozaki, Kengo Furuchi, Shinji Kitajima, Akinori Haru, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada, Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan, Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Ishikawa, Japan.

Background: Chronic kidney disease (CKD) is a strong risk factor for end stage kidney disease, and closely complicates with other organ damages. Organic cation transporter 1 (OCTN1) is known as a specific transporter for ergothioneine (ERGO). ERGO is reported to have a strong antioxidative effect. We hypothesized that OCTN1 function and the reduction of ERGO were closely related to the progression of CKD.

Methods: To evaluate the effects of OCTN1 function in CKD, everted sac method was used in CKD model or control mice. Furthermore, the pathological changes and oxidative stress in the kidney of OCTN1−/− or OCTN1+/- were evaluated in the CKD model mice. Moreover, the amount of ERGO in red blood cells of was measured in CKD patients.

Results: The uptake of ERGO in everted sac significantly decreased in CKD mice compared to control mice. Interstitial fibrosis, that evaluated by azan stain, sirius red stain, and the concentration of ERGO in red blood cells decreased accompanied with CKD stage. Insulin may mediate reduction in CBS, CSE and H2S and contribute to matrix accumulation and progression of kidney injury. Funding: Other NIH Support - 1 F32 DK104475-0

Delayed Administration of Suramin Attenuates Peritoneal Fibrosis in Rats

Na Liu, Shengyan Zhang, Div of Medicine, Rhode Island Hospital and Alpert Medical School, Providence, RI; Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China.

Background: Peritoneal fibrosis is one of the most serious complications in patients with peritoneal dialysis (PD) and lacks effective treatments. Our recent study showed that treatment with suramin, a compound that inhibits the interaction of multiple cytokines and growth factors with their receptors, attenuated the development of peritoneal fibrosis in a model of peritoneal fibrosis induced by chlorhexidine gluconate (CG). In the current study, we further assessed the therapeutic effect of suramin on the progression of peritoneal fibrosis in this model.

Methods: Rats were given a daily intraperitoneal injection of chlorhexidine gluconate (CG) for 3 weeks to induce peritoneal fibrosis followed by weekly administration of suramin at 20mg/kg for an additional one or two weeks before kidneys were harvested.

Results: Delayed administration of suramin attenuated peritoneal membrane thickening and collagen fibril deposition occurred after CG exposure. Suramin was also effective in reducing CG-induced expression of a-smooth muscle actin, fibronectin and collagen I. Therefore, peritoneal mesothelial cells treated in increased phosphorylation of Smad-3, a prominent mediator in transforming growth factor-β signaling, and epithelial growth factor receptor (EGFR), a key tyrosine kinase receptor associated with peritoneal fibrosis; suramin treatment blocked their phosphorylation. Similarly, suramin reduced CG-induced phosphorylation of transducer and activator of transcription-3 (STAT3) and extracellular signal-regulated kinase 1 and 2 (ERK1/2), two molecules that mediate profibrotic signal transduction. Moreover, delayed application of suramin suppressed CG-induced expression of several inflammatory cytokines in fibrotic peritoneum.

Conclusions: Our results indicate that suramin treatment inhibits the progression of peritoneal fibrosis via a mechanism involved in suppression of TGF-β1 and EGFR signaling pathways, and suggest that suramin holds a therapeutic potential for treatment of peritoneal fibrosis.

SA-PO478

MDM2 Mediates Tubulointerstitial Fibrosis and Fibroblasts Activation via p53-Independent Pathway

Hua Su, Chen Ye, Chun Zhang. Nephrology, Huazhong Univ of Science and Technology, Wuhan, China.

Background: MDM2 is an E3 ubiquitin ligase which plays essential roles in the classic MDM2-p53 pathway, is involved in fibroblast activation in an ubiquitination context-dependent manner, was reduced in cultured fibroblast treated with TGF-b1 which could be reversed by either genetic deletion of MDM2 or ubiquitin E1 activating enzyme inhibitor. Moreover, although pharmacologic or genetic blocking Notch1 signaling could trigger fibroblast activation it did not affect MDM2’s abundance.

Methods: Patients with TIF (secondary glomerulonephritis and interstitial nephritis were excluded) were enrolled in this study and Unilateral Ureteral Obstruction (UOO) animal model was constructed on B57CL6 mice. In vitro study cultured renal fibroblast cell line NRK-49F were employed. The expression of MDM2 and Notch1 was regulated by its pharmacologic inhibitors or transfection of Lentiviral shRNA.

Results: Compared with WT, cPLA2 KO animals had a 1.5-2.0 fold increase in mRNA for matrix proteins such as collagen and fibronectin, pro-fibrotic chemokines such as fractalkine, and inflammatory markers such as MCP-1 after UUO as compared with WT animals at 7 days. By flow cytometry, cPLA2 KO animals had significantly more infiltration of CD45+, CD11b positive Ly6C- negative cells than WT animals after UUO.

Conclusions: Deflection of cPLA2 and/or its products, predominantly from circulating myeloid cells, contribute to the development of experimental fibrosis using a UUO model in mice.

SA-PO475

SIRT2-MDM2 Signaling Attributes to Fibroblasts Activation but Not Tubular Epithelial-Mesenchymal Transition During Tubulointerstitial Fibrosis

Chun Zhang, Renyu You, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, China.

Background: Renal resident fibroblasts and tubular epithelial cells are the main sources for extracellular matrix producing myofibroblasts during tubulointerstitial fibrosis (TIF). Histone deacetylases (HDAC) inhibitors are shown to have an antifibrotic effect in skin, liver and lung. Sirtuin 2 (SIRT2), belonging to class III HDAC, mediates p53 deacetylation and subsequent sensitizes the sequestration of p53 by MDM2, thereby resulting in a p53 reduction and cell cycle progression. Up to now it is unclear the role of SIRT2 and its association with MDM2 during renal fibrosis.

Methods: Unilateral Ureteral Obstruction (UOO) animal model was constructed on B57CL6 mice. In vitro study cultured tubular epithelial cell line NRK-52E (TEC) and renal fibroblast cell line NRK-49F were employed. The expression of SIRT2 and MDM2 was regulated by pharmacologic inhibitors or transfection of Lentiviral shRNA.

Results: It showed the protein level of SIRT2 was elevated markedly in UUO mice as well as the fibroblasts treated with TGF-b1. Nevertheless, in TECs the abundance of SIRT2 was not altered under TGF-b1 exposure. Additionally, AGK2, a specific SIRT2 inhibitor, attenuated the severity of TIF in UOO mice and the fibroblast activation triggered by TGF-b1. Next in fibroblast we found MDM2, a p53 inhibitor, was upregulated simultaneously under TGF-b1 stimulation. Interestingly, the increased MDM2 level can be minimized by pharmacologic or genetic blocking of SIRT2 which was not interfered by an MDM2 inhibitor of the interaction between MDM2 and p53. Thus, it indicated SIRT2 regulating MDM2 was p53 independent. Moreover, genetic deletion of MDM2 by shRNA transfection didn’t affect the expression of SIRT2, although which could alleviate fibroblast activation.

Conclusions: Our current study suggests that besides p53, SIRT2 also could modulate MDM2 during fibroblasts activation, and targeting SIRT2-MDM2 signaling may be a potential strategy for the treatment of renal fibrosis.

SA-PO479
Biomarkers of Collagen Type III and V Turnover Can Predict Poor Recovery of Kidney Function in Kidney Transplant Recipients
Daniel Guldegger Kring Rasmussen, 1,2 Signe Holm Nielsen, 1 Federica Genovese, 1 Morten Asser Karsdal, 1 Zhengxiang Xia, 2 Martin Tepe, 2 1Nordic Bioscience, Denmark; 2Univ of Southern Denmark, Denmark.

Background: Allograft dysfunction is a common complication after renal transplantation (Tx). The turnover of extracellular matrix proteins, collagen type III and type V, contributes to renal repair mechanisms which accompany allograft dysfunction. Distorted turnover may lead to progressive fibrosis and to loss of renal function. The objective of our study was to evaluate the role of specific collagen type III and type V cleavage fragments for early allograft dysfunction after kidney Tx.

Methods: 171 in-patient incident patients, receiving a kidney allograft were enrolled at Odense University Hospital. Plasma and urine samples were collected at the first postoperative days. CM and Pro-C6 were measured in samples using novel ELISAs. Early allograft dysfunction was defined as eGFR less than 30 ml per minute per 1.73m² 29 days after Tx. The difference of plasma creatinine (RCPC) is the difference between plasma creatinine (pCrea) on the preoperative and first postoperative day divided by preoperative pCrea. Follow-up data on pCrea from a subset of patients was available at 6- and 12 months.

Results: Plasma Pro-C6 ((pPro-C6) levels were significantly different in patients who received a deceased donor (DD), living donor (LD) and AB0 incompatible (AB0) donor kidney (p<0.001). pPro-C6 had a negative correlation with eGFR 29 days post Tx (p<0.0001, r=-0.35) and a positive correlation with pCrea at 6- (p<0.0001, r=0.31) and 12 months (p<0.0001, r=0.32). With a cut-off of 0.3 for the RCPC, ROC curves showed that pPro-C6 was a good predictor of allograft failure at 6- (p=0.0001, r=0.32) and 12 months post Tx (p=0.0001, r=-0.35). Plasma C3M was associated with plasma CRP levels showed a negative correlation with plasma creatinine at 6- (p<0.0001, r=-0.37) and 12 months post-Tx (p<0.001). pCrea. Follow-up data on pCrea from a subset of patients was available at 6- and 12 months.

Conclusions: pPro-C6 and C3M levels were associated with eGFR and pCrea. With a cut-off of 0.3 for the RCPC, ROC curves showed that pPro-C6 was a good predictor of allograft failure at 6- and 12 months post-Tx. Follow-up data on pCrea from a subset of patients was available at 6- and 12 months. Increased pCrea level blocks the progress of renal fibrosis. Increased C3M level and decreased pPro-C6 level is associated to early allograft dysfunction and predict poor recovery of kidney function in kidney transplant recipients.

Endothelial Cell Thymosin β4 Knock Down Ameliorates Kidney Injury Induced by Reducing Endothelial to Mesenchymal Transition (EndoMT)
Jianyong Zhong, 1,2 Haichun Yang, 1 Agnes B. Fogo, 1 1Dept of Pathology, Microimmunology and Immunobiology, Vanderbilt Univ; 2Div of Pediatric Nephrology, Vanderbilt Univ, Nashville, TN.

Background: Thymosin β4 (Tβ4) is a G-actin sequestering protein with effects on angiogenesis, cell migration and matrix. Our previous data showed that exogenous Tβ4 treatment ameliorated matrix accumulation at day 14 after unilateral ureteral obstruction (UUO). In this study, we investigated whether knockdown of Tβ4 only on endothelial cells has effects on renal fibrosis.

Methods: We generated inducible endothelial cell Tβ4 knockdown mouse (Tβ4 KD) by mating Tβ4 sRNA lexp mouse with SCL Cre mice. SCL Cre negative mice were used as control (Cont). Tamoxifen was administrated to induce Tβ4 knockdown (+, qod, from-8d). Mice were sacrificed at 14 days after UUO.

Results: Peritubular capillary density, assessed by CD31 staining, was significantly decreased in Tβ4 KD mice (Tβ4 KD 2.39±0.11 vs. Cont 3.20±0.08 %, P<0.001). Peritubular capillary permeability, measured by injecting Evans blue dye in vivo and assessing extravasation of dye in the kidney, also was reduced in Tβ4 KD mice (Tβ4 KD 107.01±5.49 vs. Cont 161.85±16.32 mg/kg, P<0.05). Tβ4 KD had significantly decreased collagen I, I by IHC, vs Cont (Tβ4 KD 15.24±0.57 vs. Cont 17.68±0.71 %, P<0.05), but no significant change in Sirius red positive area (Tβ4 KD 0.91±0.03 vs. Cont 1.14±0.15 %). Tβ4 KD had less total collagen (Tβ4 KD 48.06±5.01 vs. Cont 53.50±2.34 mg/mg). Tβ4 KD had less EndoMT (α-SMA+ and CD31+ double positive cells/high power: Tβ4 KD 1.20±0.11 vs. Cont 1.74±0.17 P<0.05).

Conclusions: We conclude that endothelial cell thymosin β4 knockdown results in reduced peritubular capillary number and function, and reduced collagen in Tβ4 KD mice. We speculate that Tβ4 KD in endothelial cells may change endothelial function and modulate EndoMT.

Endostatin and Transglutaminase 2 Are Geroenic Proteins Involved in Fibrosis of Aging Kidney
Chii Huang, 1,2 Jun Chen, 1,2 Gail W.V. Johnson, 2 Arthur J.I. Cooper, 1 Zhongtai Zhang, 1 Juanita Feola, 2 Heli Ruotsalainen, 3 Taina Pihlajaniemi, 1 Michael S. Goligorsky, 1 1New York Medical College; 2Univ of Rochester; 3Univ of Oulu, Finland.

Background: Endostatin (EST), the C-terminal fragment of collagen XVIII and a potent anti-angiogenic factor, is highly enriched in aging kidneys. It has also been recently observed that peritubular capillary rarefaction is a result of mitochondrial dysfunction and extracellular matrix in tissue fibrosis. Mitochondrial dysfunction is an early event in renal fibrosis, but it leads to kidney fibrosis and how it is regulated is unclear. In this paper, we investigated the role of EST in renal fibrosis.

Methods: Primary renal proximal tubular cells (MRPTC) were cultured from Nrp-1+/lox mice. After infection of Nrp-1+/lox cells with adenovirus expressing Cre resulted in NRP1 knockout (NRP1-/-) in the primary cells. Human proximal tubular cell line HKC-8, MEF cells and 3T3-L1 cells were used in this study. TGF-β-driven promoter transcriptional activity was measured by luciferase assay.

Results: NRP-1 was down-regulated by TGF-β in HKC8 and up-regulated in MEF cells and 3T3-L1 cells, suggesting the different regulation mechanisms and functions of NRP-1 in proximal tubular cells and fibroblasts. Over-expression of TGF-β suppressed NRG1-β-induced phosphorylation of Smad3/2 and expression levels of fibronectin. HKC-8 cells over-expressing NRP-1 showed significantly decreased levels of both TGF-β receptor I and receptor II. The NRP1-/- cells showed higher TGF-β-induced Smad3/2 transcriptional activities and expression of TGF-β receptor in Nrp-1+/lox MRTC5 cells, compared with control adenovirus-infected Nrp-1+/lox MRTC5ts.

Conclusions: Proximal tubular cells-derived NRP1 inhibits the TGF beta signaling pathway. NRP1 functions are cell type-specific in the kidney.

SA-PO484
The CAMP-epac Pathway Regulates Renal Fibrosis by Promoting Mitochondrial Biogenesis of Tubular Epithelial Cell
Jingyi Chen, 1,2 Hailin Jiang, 1,2 Fengrui Gao, 1,2 Jiang Ma. 1,2 Dept of Pathology, Microimmunology and Immunobiology, Vanderbilt Univ; 2Div of Pediatric Nephrology, Vanderbilt Univ, Nashville, TN.

Background: Distorted turnover may lead to progressive fibrosis and to loss of renal function. The cAMP-epac pathway is involved in renal fibrosis. Increased cAMP level could induce the downregulation of TGFb in PTC. Increasing the level of cAMP in PTC by rolipram, PDE 4b siRNA, epac activator or epac siRNA could reduce the damage of PTC under TGF-b1 stimulation; 6; Rolipram could restore PGC-1a expression, reduce the mtDNA damage and protect the mitochondrial function and structure of PTC under TGF-b1 stimulation.

Conclusions: cAMP-epac pathway is involved in renal fibrosis. Increased cAMP level blocks the progress of renal fibrosis. cAMP promotes mitochondrial biogenesis and restores mitochondrial structure and function of tubular epithelial cell.

Angiopoietin-1 Deficiency Increases Tubulointerstitial Fibrosis

Krishnapriya Logathan,1 Susan E. Quaggin,2 Marie Jeansson,1 Sachiko Sekiya,2 Ryoichi Yuanbo Wu, Yanlin Wang.

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in aSMA+ fibroblasts, myofibroblasts that produce collagen. Identification of factors that regulate the pro-fibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Ang1) in adult mice predisposes to fibrosis in wound healing and diabetic nephropathy. Ang1 acts through the Tie2 tyrosine kinase receptor expressed on endothelial cells and a subset of myofibroblasts. Here, we test the hypothesis that loss of Ang1-Tie2 signaling destabilizes endothelial cells and results in an increased fibrotic response.

Methods: To investigate the role of Ang1 in renal fibrosis we utilized Ang1-deficient conditional knockout mice in experimental models of renal fibrosis, including unilateral ureter obstruction (UUO) and ischemia/reperfusion injury. Gene and protein regulation of fibrotic markers were assessed at different time points. We also performed lineage tagging experiments using Tie2-Cre and LysM-Cre to better understand the contribution of Tie2+ cells and macrophages to the myofibroblast population in UUO.

Results: Ang1 deficient mice showed a significant (p<0.01) increase in fibrotic area 3 days after UUO, 9.7±0.45%, compared to controls, 7.9±0.24%. At the same time point, there was a trend (n) towards an increased number of myofibroblasts per field from 15.4±1.8 in controls 20.1±1.4 in Ang1 deficient mice. Ischemia/reperfusion experiments are ongoing. In our lineage tagging experiment we found that 18.5±3.0% of myofibroblasts came from the Tie2-lineage whereas the LysM lineage contributed minimally, 2.4±0.005%.

Conclusions: Our results suggest that loss of Ang1-Tie2 signaling increases tubulointerstitial fibrosis as seen by the increased expression of fibrosis markers in Ang1 deficient mice. Ongoing work is designed to use other models of fibrosis and to elucidate the mechanism(s).

Inter-Alpha-Inhibitor Heavy Chain5 Interactions Control Fibroblast: Myofibroblast Differentiation

Background: Fibroblasts are central to CKD through their Transforming Growth Factor-β (TGF-β1)-triggered phenotypic transition into contractile, α-smooth muscle actin (α-sma)-positive myofibroblasts. Transition is dependent on an increase in the synthesis and accumulation of a pericellular matrix of hyaluronan (HA) and the HA-dependent co-localisation of CD44 with EGFR. Interactions of HA with hyaluronidase, with intercellular-alpha-inhibitor (IαI) and the protein product of Tumour necrosis factor-stimulated gene 6 (TSG-6) and the assembly of this matrix and are also essential for the phenotypic activation of fibroblasts. The mechanisms controlling this effect, however, are not known and are the subject of this study.

Methods: Fibroblasts were incubated for 24 h with 10ng/ml TGF-β1 to become myofibroblasts. RT-PCR was used to assess mRNA, sRNA was used to knockdown mRNA expression and Western Blotting assessed protein levels. Results: Following TGF-β1 treatment, TSG-6 and α-sma, had different kinetics of induction. Using siCD44 or EGFR inhibitor AG1478 to interfere with the CD44/EGFR-dependent signal initiation prevented differentiation but had no effect on TSG6 expression. TSG-6, however, was essential for differentiation and using monoclonal antibody A3K, HA-oligosaccharides, Cobalt, or siBikunin to interfere with the activity of TSG6, all prevented phenotypic change. These results suggested that it was the TSG6/IαI heavy chain (HC) interaction that was necessary for the effect. HC5 was shown to be the principal HCs expressed in these cells. HC5 was released by hyaluronidase treatment of the fibroblast cell surface and siCD44, siTSG6 and siBikunin all inhibited the expression of HCs protein. Finally, HC5 could be deleted on the cell specific siRNA and this resulted in antagonism of phenotypic change, confirming its role in myofibroblast differentiation.

Conclusions: The mechanisms regulating TSG-6 and HA synthesis, during TGF-β1-dependent induction of myofibroblasts are distinct. TSG-6, however, contributes to the pro-fibrotic response through its catalytic transfer of IαI HC5 to HA leading to the β1-dependent induction of myofibroblasts. Identification of factors that regulate the pro-fibrotic response are excellent candidate targets for treatment of kidney diseases.

Role of IL-4 Receptor a in Bone Marrow-Derived Fibroblast Activation and Renal Fibrosis

Hua Liang, Yuanbo Wu, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a common pathway leading to progression of chronic kidney diseases. We and others have shown that bone marrow-derived fibroblasts contribute significantly to the pathogenesis of renal fibrosis. However, the signaling pathways underlying the activation of bone marrow-derived fibroblasts in the kidney are incompletely understood. We have found that IL-4 and its receptor a (IL4Ra) are induced in the kidney during the development of renal fibrosis. However, little is known about the role of IL-4Ra in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis.

Methods: We examined the role of IL-4Ra in the activation of bone marrow-derived fibroblasts in bone development using an IκBα-specific inhibitor to induce nephropathy and cultured bone marrow monocytes treated with IL-4.

Results: Compared with wild-type (WT) mice, IL-4Ra-deficient (KO) mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and accumulated significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFR-β in the kidney 2 weeks after folic acid treatment. Furthermore, IL-4Ra-KO mice exhibited fewer α-smooth muscle actin (α-SMA) positive myofibroblasts and expressed less α-SMA protein in the kidney following folic acid treatment. Consistent with these findings, infiltration of inflammatory cells was significantly reduced in IL-4Ra-KO mice. This suppression of extracellular matrix proteins (collagen 1 and fibronectin). In cultured bone marrow monocytes, IL-4 activated STAT6 and induced expression of α-SMA and extracellular matrix proteins, which was abolishes in the absence of IL-4Ra.

Conclusions: Our results demonstrate that IL-4Ra plays an important role in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis. These results indicate that IL4Ra signaling may represent a novel therapeutic target for chronic kidney disease.

Role of Scaffolding Protein JLP in Preventing Renal Fibrosis in Obstructive Nephropathy

Kwang Fu, Qi Yan, Qin Zhang, Gouhua Ding, Huiming Wang. Renmin Hospital of Wuhan Univ.

Background: Renal fibrosis is a common pathological lesion in the end stage of various progressive kidney diseases, and is characterized by interstitial inflammation, proliferation of fibroblasts, and accumulation of extracellular matrix (ECM). The INK-associated leucine zipper protein (JLP) is a crucial scaffolding protein in signals transduction and molecular trafficking. JLP has been found expressed in mouse tissues of brain, lung, spleen, testis, and kidney. We reported here, for the first time, the effects of JLP deficiency on the progression of renal fibrosis in mice model of unilateral ureteral obstruction (UUO).

Methods: JLP Wild type (jlp+/+) and jlp deficient (jlp−/−) mice were divided into four groups: jlp+/+, jlp+/− and jlp−/− sham-operated groups, jlp−/− and jlp−/− unilateral ureteral obstruction (UUO)-operated groups (jlp−/− group) and jlp−/−- UUO group. Mice were sacrificed at the days of 7 and 14 to evaluate the fibrosis by Masson and H&E staining. The expression of transforming growth factor-b1 (TGF-b1), α-smooth muscle actin (α-SMA), collagen I (COL-I), and collagen III (COL-III) were assayed by immunohistochemistry staining.

Results: One week after the surgery, more collagen deposition was observed in the renal interstitial area in jlp−/− group than in jlp−/−- UUO group. Similar to that, the expression of COL-4 and COL-III were significantly increased in the kidney cortices in jlp−/−-UUO-operated groups. The expression of TGF-b1 and α-SMA was also significantly higher in jlp−/−- UUO-operated group than in jlp−/− group.

Conclusions: Scaffolding protein JLP is critical in preventing renal fibrosis through the mechanism of inhibition TGF-b1 expression and myo-fibroblast induction.

HGF-Producing Cell Sheet Suppress Renal Fibrosis Induced by Unilateral Ureteric Obstruction in a Rat

Masatoshi Oka,1 Sachiko Sekiya,1 Ryoichi Sakaiyama,2 Kosaku Nitta,1 Tatsuya Shimizu.2

Background: Tubulointerstitial fibrosis is a typical pathological finding in chronic kidney disease (CKD) and is associated with the progression of renal dysfunction. Recently several studies reported to suppress renal fibrosis by transplantation of cells expressing several growth factor, for example EGF, HGF. Cell sheet transplantation is a methodology of cell therapy for regenerative medicine. This technology demonstrated high effective therapy for diseases in other organs, such as cornea, periodontium, esophagus and heart. In this study, we performed to suppress renal fibrosis by local and sustained administration of hepatocyte growth factor (HGF) with HGF-producing cell sheet (HGF sheet) transplantation.

Methods: Human mesothelial cells transplanted human HGF gene by lipofection were cultured on temperature-responsive dish for 4 days. When temperature reduced, these HGF-producing cells were detached from dishes as cell sheet without enzyme-treated. We performed unilateral ureteric obstruction (UUO) in nude rat and transplanted the HGF sheet immediately. To compare HGF sheet transplantation with intermittent administration of HGF protein, we also injected HGF protein from tail vein every 24 hours for UUO rat (HGF i.v.). The kidney volume after operation measured with CT 7 days later. One week after operation, histologic examination and smooth muscle actin in kidney transplanted HGF sheet was significantly less compared to that in HGF i.v. kidney. Moreover, the kidney volume after treated HGF sheet with UUO rat was significantly less compared to control 4 weeks after operation and it maintained thick cortex in HGF i.v. kidney. We reported here, for the first time, the effects of JLP deficiency on the progression of renal fibrosis in mice model of unilateral ureteral obstruction (UUO).

Conclusions: Local and sustained HGF administration with HGF sheet strongly suppressed renal fibrosis induced by UUO in a rat. Our results suggested that cell sheet therapy may be a promising strategy for renal disease.

Extracellular Matrix Modulates Macrophage Phenotype Profile
Astgik Petrosyan, 1 Stefano Da Sacco, 2 Sargis Sedrakyan, 3 Giuseppe Orlando, 3 Matthew Edward Thornton, 1 Brendan Grubbs, 2 Roger E. De Filippo, 1 Laura Perin. 1Univ of Southern California; 2Children’s Hospital Los Angeles; 3Wake Forest School of Medicine.

Background: It is known that macrophages play an important role in kidney damage and resolution. An increase in macrophages phenotype type 1 (M1) leads to pro-healing processes. However little is known on how the extracellular matrix (ECM) can direct macrophages toward a specific phenotype acquisition during development, tissue homeostasis and disease.

Methods: Using established protocols we decellularized human adult, healthy, diseased, and fetal kidneys; monocytes were seeded on the different ECMs and macrophage phenotype after 24hrs and 5 days was assessed. Macrophage maturation was tested by evaluating release of IL-10, IFN-γ, TNF-α and IL-4 in the culture media along with qRT-PCR and immunocytochemistry to evaluate expression of M1 (CD80 and CD86) and M2 (CD163, CD14, CD200 and CD200R) phenotypes.

Results: We observed that monocytes cultured on ECMs were able to mature into macrophages and present an increase in M1 marker (CD80) on diseased ECM, an increase in M2 markers (CD163, CD200R) on healthy ECM, and an increase in anti-inflammatory M2 marker (CD16) on fetal ECM, after 24hrs. After 5 days of co-culture there was an overall decrease in gene expression for all markers followed by an increase in media secretion of IL-10 on diseased ECM vs healthy and fetal ECM. Additionally after 5 days higher number of seeded monocytes appear to adhere onto the adult ECM vs the fetal ECM. IFN-γ, IL-4, IL-10 and CD46 expression was not detected during 24hrs and 5 days. Monocytes capacity to mature into macrophages was confirmed in vitro by administration of phorbol myristate acetate (PMA) and 1,25-dihydroxy vitamin D3 with LPS.

Conclusions: Our work suggests that the ECM has the capacity to modulate macrophage phenotype and might contribute to disease progression. Additionally, this model may be used to investigate mechanisms of ECM-dependent macrophage activation during renal disease and regeneration.

SA-PO490
High Salt Diet Induces Blood Pressure Independent Tubulointerstitial Remodeling and Lymphangiogenesis in Rat Kidney
Ryvane S. Hijmans, Saleh Yazdani, Gerjan Navis, Jacob van den Born.

Methods: Two groups (n=5) had a normal rat diet. After 2 weeks, one of the two groups on a high salt diet was sacrificed, and the other groups were sacrificed at 4 weeks. The kidneys were stained and quantified for lymphangiogenic, fibrotic and inflammatory markers.

Results: Rats with HS intake showed an increased number of lymph vessels compared to their controls at 2, 3 and 4 weeks.

Conclusions: This preliminary work suggests that the ECM has the capacity to modulate tubulointerstitial remodeling and lymphangiogenesis, inflammation and profibrotic changes in rat kidneys, even when the BP is not significantly different between the groups. This finding supports our hypothesis that the kidney intake has BP independent effects next to it’s well known BP dependent effects in CKD.

SA-PO491
Genetic and Epigenetic Analysis of the MicroRNA-200 Family for the Identification of Non-Invasive Biomarkers for Early Renal Disease
Matthew Edward Thornton, 1 Brendan Grubbs, 1 Roger E. De Filippo, 1 Laura Perin. 1Charité-Buch, Experimental and Clinical Research Center, Berlin, Germany; 2Children’s Hospital Los Angeles, University of Southern California; 3Wake Forest School of Medicine.

Background: tubulointerstitial fibrosis (TIF) and lymphangiogenesis are key drivers of CKD progression. We aimed to measure, in preclinical models, the urinary and blood expression of microRNAs (miRNAs) associated with TIF, and lymphangiogenesis (LA). We assessed, in tubulointerstitial and lymphangiogenic models, the urinary and blood expression of miRNA-200 family members, by qRT-PCR.

Methods: We utilized two rat models of kidney disease, induced by administration of phorbol myristate acetate (PMA) and 1,25-dihydroxy vitamin D3 with LPS. We quantified for lymphangiogenic, fibrotic and inflammatory markers. We also assessed the blood expression of miRNA-200 family members in the aforementioned models.

Results: The urinary and blood expression of miRNA-200 family members was significantly upregulated in the kidney disease models. Additionally, we observed a significant increase in the urinary and blood expression of miRNA-200 family members in the lymphangiogenic model.

Conclusions: This preliminary work suggests that the ECM has the capacity to modulate tubulointerstitial remodeling and lymphangiogenesis, inflammation and profibrotic changes in rat kidneys, even when the BP is not significantly different between the groups. This finding supports our hypothesis that the kidney intake has BP independent effects next to it’s well known BP dependent effects in CKD.

The PR3 Receptor CD177 Is Controlled by Epigenetic Mechanisms
Claudia Eulenberg, 1 Sylvia Bähring, 1 Friedrich C. Luft, 1 Ralph Kettritz, 2 Charité-Universitätsmedizin Berlin, Berlin, Germany; 2Charité-Beck, Research Center Berlin, Berlin, Germany; 3Nephrology and Intensive Care Medicine, ECRC, Berlin, Germany.

Background: Proteinase 3 (PR3) is an ANCA antigen in granulomatosis with polyangiitis (GPA). PR3-ANCA binding to membrane-PR3 (mPR3) is a key event for neutrophil activation and vascular inflammation.

Methods: Haplotype analysis, genome-wide methylation analysis, chromatin immunoprecipitation (ChIP) analysis and CD177 expression studies were performed in neutrophils and HeLa cells.

Results: In determining its association with ESRD.

Conclusions: This preliminary work suggests that the ECM has the capacity to modulate tubulointerstitial remodeling and lymphangiogenesis, inflammation and profibrotic changes in rat kidneys, even when the BP is not significantly different between the groups. This finding supports our hypothesis that the kidney intake has BP independent effects next to it’s well known BP dependent effects in CKD.

Application of Human Kidney RNA-seq Expression Quantitative Trait Loci in Chronic Kidney Disease

Yi-An Ko, Frank S. Chinga, Nora Ledo, Katalin Susztak. Renal Electrolyte and Hypertension Div; Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.

Background: There are more than 5 million sequenced variants in humans. Some genetic variants influence transcript levels and therefore have the ability to interfere with cell and organ function. Such genetic variants are called expression quantitative trait loci (eQTL). The goal of our study was to identify such functionally important genetic variants at the genome-wide level.

Methods: This analysis requires the collection of large number of human tissue samples with genotype and transcript level data. Here we used 99 human kidney samples of Central European descents RNAseq and genotype data was normalized and genotype data was imputed using 1,000 Genome reference data. The association between genotype and transcript levels was performed using Matrix eQTL software and was limited to cis-eQTL, where the genetic variant and transcript levels were within 2 megabases distance.

Results: We identified 164 significant target genes (we call these eGenes) and 7590 significant SNPs (eSNPs) that passed the threshold for statistical significance after multiple testing correction using adjusted p-values<1e-10. Next we compared variants that influence gene expression in the kidney to those that have been published for other organs using the publicly available Genotype-Tissue Expression project (GTEx). Of the 164 eGenes,103 were common between the kidney and other organs, indicating that there are cell type specific and cell type independent eGenes. Using kidney specific epigenome maps, we found that eSNPs were enriched on kidney specific regulatory elements, including promoters and enhancers. We also found a significantly greater overlap between kidney eGenes and polymorphisms that are associated with CKD development, compared to other tissues (digestive, nervous, immune system diseases, hematological measurement, cardiovascular, and metabolic disease).

Conclusions: We identified transcript level changes associated with genotypic variations. These results can highlight kidney specific regulatory elements and may also help to identify target genes for polymorphisms associated with kidney function related traits.

RNA Sequencing Reveals Tumor Necrosis Factor α Inducible Protein 6 (TNFAIP6) as a Potential Single Gene Classifier of Renal Cell Carcinoma Overxin Solhvere Fikrem,1 Christian Beisland,2 Andreas Scherer,2 Arnar Flatberg,3 Trude Skogstrøm,1 Lea Landbol,1 Sabine Leb,1 Karin Magrethje Hejle,1 Vidar Beisvag,3 Hans-Peter Marti.1 1Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; 2Dept of Cancer Research and Molecular Medicine, Univ of Science and Technology, Trondheim, Norway.

Background: The recent release of a new library preparation kit improved the cDNA library quality from formalin-fixed, paraffin-embedded (FFPE) tissues. In this study we demonstrate the feasibility of next generation sequencing (NGS) of RNA data from FFPE tissues as compared with RNA-sequenced (RNAseq) stored tissues.

Methods: Paired biopsies from tumors and adjacent non-tumorous tissue of 16 patients with ccRCC were either FFPE or stored in RNA-sequenced (RNAseq) tissue libraries. We used sequencing libraries were prepared using the TruSeq RNA Access Library Prep Kit (Illumina).

Results: The average expression of detected transcripts in both FFPE and RNA-sequenced datasets correlated with R²=0.97, and the log2 fold changes of the transcripts which are significantly altered in both datasets (n=1106) correlated with R²=0.94. A classifier model with TNFAIP6 was developed for the FFPE dataset with a specificity of 100% and sensitivity of 94%; ROC AUC=0.99 (Fig. 1A); only one normal sample was misclassified due to a small admixture of cancer tissue. Classifier validation in an Affymetrix microarray dataset of 94%; ROC AUC=0.99 (Fig. 1B); only one normal sample was misclassified due to a small admixture of cancer tissue. Classifier validation in an Affymetrix microarray dataset of 94%; ROC AUC=0.99 (Fig. 1B).

Figure 1: ROC of TNFAIP6 (A) present study, (B) validation in GSE53757 data set.

Conclusions: We describe a potential single gene classifier for ccRCC. Furthermore, NGS in FFPE tissues is feasible and correlates well with RNA-sequenced stored tissues. Thus, our study opens up novel diagnostic possibilities on archival renal biopsies.

Gene Expression Based Dissection of Chronic Kidney Disease Traits

Background: Chronic kidney disease (CKD) is a progressive decline in kidney function. There are several manifestations of CKD including glomerular function change, albuminuria, glomerulosclerosis, tubulointerstitial fibrosis and metabolic changes. These traits are strongly correlated but the question remains whether they are driven by identical mechanisms.

Methods: We conducted genome wide transcript level analysis of 95 microdissected human kidney tubule samples. We used transcript level changes as quantitative traits to dissect underlying mechanisms. These samples included subjects with normal eGFR with or without diabetes (DM) or hypertension (HTN) and diseased kidney samples with low eGFR, fibrosis and sclerosis, with or without DM or HTN.

Results: We identified 1430 transcripts with significant linear correlation with eGFR. Pathway analysis indicated significant enrichment for inflammation and metabolism related pathways. Subgroup analysis indicated enrichment for TGFβ and Wnt signaling and ECM receptor interactions only in earlier CKD stages. Our analysis identified 1606 transcripts that correlated with fibrosis and 1803 transcripts correlated with glomerulosclerosis. Similar to the clinical overlap between eGFR and fibrosis, we found that 78% of transcripts with identical. Transcripts that showed correlation with fibrosis but not with eGFR were enriched for inflammation related pathways. On the other hand, metabolism related genes correlated with eGFR but not with fibrosis. There were significant differences between male and female samples as well.

Conclusions: Our transcriptome-based dissection method highlights the relatedness of eGFR and kidney fibrosis, but also indicates potential differences in the underlying mechanisms of the two processes.

Early-Onset, Severe Forms of Hypertension and Cardiovascular Complications Are Associated with APOL1 G1/G2 Susceptibility Alleles in African Americans

Background: APOL1 G1/G2 susceptibility alleles are associated with kidney disease progression and ESRD in hypertensive African Ancestry (AA) populations. We explored whether these APOL1 alleles are associated with blood pressure-related traits in AA enrolled in the electronic medical records and genomics (eMERGE) Network.

Methods: Study populations included the Mount Sinai BioMe biobank discovery(dis) cohort (n=5,213) and three EMR-linked biobank replication(rep) cohorts, including Vanderbilt BioVU (n=2,889), Northwestern NUgenome (n=613), and Mount Sinai BioMe (n=1,655). APOL1 single nucleotide polymorphisms (SNPs) rs73885319, rs71875313 and n69010145 were genotyped in BioMe samples and imputed in BioVU and NUgenome samples to determine APOL1 G1 and G2 risk alleles. Longitudinal phenotypic data were extracted from EMRs. Linear regression models & meta-analyses (METAL) were performed with age, sex, mean BMI, eGFR as covariates.

Results: Compared with carriers of [0 or 1] APOL1 G1/G2 risk alleles, carriers of [2] risk alleles were diagnosed with hypertension a mean of 2.5 years (95%CI 1.2-9.2 yrs) earlier in life (P=0.04, P<3x10-3); Cox hazard; manifest 2.3 mmHg higher systolic BP(SBP) in younger AA (age 20–39) (P dis=0.07, P rep =0.04); and were exposed to more antihypertensive medication classes (P=0.11; P<3x10-3). Carriers of [2] risk alleles were more likely to manifest. We determined that left ventricular hypertrophy by echocardiogram (OR [95%CI]=1.521 [1.14–2.02], P<0.01) and hemorrhagic cerebrovascular accidents (OR in 16C=2.42 [1.01–5.93], P=0.05)

Conclusions: APOL1 G1/G2 susceptibility alleles are associated with early-onset, more severe form(s) of hypertension & with hypertensive complications hemorrhagic stroke
and concentric LVH independent of kidney function & BMI. These results may warrant a shift from kidney-intrinsic to systemic vascular pathomechanisms attributable to **APOL1** G1/G2 susceptibility alleles.

**Apolipoprotein L1 (APOL1) Gene Variants and Incident Proteinuria: Results from the African American Study of Kidney Disease and Hypertension (AASK)**

**Nephrology, Johns Hopkins Univ; Nephrology, Univ of California San Francisco; Medicine, Johns Hopkins Univ.**

**Background:** APOL1 gene variants are associated with kidney function decline. Whether these same gene variants are associated with incident proteinuria in the context of pre-existing chronic kidney disease (CKD) is unknown.

**Methods:** Using the trial and cohort phases of AASK (median follow-up of 6.8 years, maximum follow-up of 12.2 years), we evaluated participants who had hypertension-attributed CKD and who did not have proteinuria at baseline. Cox proportional hazards models were used to estimate the relative hazard of incident proteinuria (defined as a doubling of urine protein-to-creatinine ratio and UP/Cr >0.22), comparing APOL1 high-risk genotype (2 risk alleles) vs. low-risk genotypes (0-1 risk alleles). We adjusted for age, gender, baseline GFR, percentage of European ancestry, randomized blood pressure goal (usual vs. low), and randomized blood pressure drug (ramipril vs. metprolol vs. amlopidine). Effect modification by randomized trial interventions and dietary sodium intake (as estimated by 24-hour sodium urine) was assessed.

**Results:** Of the 480 participants included in our study, 17% (n=82) had the APOL1 high-risk genotype. Individuals with the APOL1 high-risk genotype were 83% more likely to develop incident proteinuria compared to those with the low-risk genotypes (adjusted HR: 1.83; 95% CI: 1.36 to 2.47; p<0.001). The association between APOL1 and incident proteinuria was not modified by randomized pressure goal, randomized blood pressure drug, or dietary sodium intake (p-interaction 0.05 for each).

**Conclusions:** Among African-Americans with CKD attributed to hypertension but without baseline proteinuria, high-risk variants of APOL1 are associated with a greater risk of incident proteinuria.

**Funding:** NIDDK Support, Pharmaceutical Company Support - The AASK trial and cohort were also supported by the following pharmaceutical companies: King Pharmaceuticals, Pfizer, AstraZeneca, GlaxoSmithKline, Forest Laboratories, Pharmacia, and Upjohn.

**African Ancestry Specific Alleles Confer Chronic Kidney Disease Risk in U.S. Hispanics**

**1Epidemiology, Univ of North Carolina, Chapel Hill, NC; 2National Insts of Health, Bethesda, MD; 3Univ of San Francisco, San Francisco, CA; 4Harvard Univ, Boston, MA; 5Loyola Univ, Maywood, IL; 6Univ of Washington, Seattle, WA.**

**Background:** Hispanics are a heterogeneous group with varying genetic ancestry. African ancestry can differ in Hispanics by country of origin, and its proportion relates to the risk of chronic kidney disease (CKD).

**Methods:** We examined the association of African ancestry population-specific risk alleles (APOL1 and HBB rs334 related sickle cell anemia) with CKD in 11,921 Hispanics, aged 18-74 years, recruited in a community-based study in four US centers. APOL1 G1/2 alleles were genotyped and rs334 alleles were imputed (rsq=0.83). CKD was defined as an increased urine albumin to creatinine ratio (UACR) (>17 mg/g in men and >25 mg/g in women), reduced estimated glomerular filtration rate (eGFR) 60 ml/min/1.73 m² based on serum creatinine/ cystatin C CKD-EPI equation, or presence of reduced eGFR or an increased UACR. Analyses used generalized linear mixed models that accounted for the sampling strategy and family relatedness, age, sex, diabetes, systolic blood pressure and anti-hypertensive medications, and stratified by Hispanic background.

**Results:** There were 41% men, and mean age was 46 (SD =14). The prevalence of increased UACR was 13%, reduced eGFR was 4%, and combined CKD outcomes was 16%. Caribbean Hispanics (Cuban, Dominican, Puerto Rican, N=5348) had higher prevalence of 2 APOL1 risk alleles (1% vs 0.1%) and rs334 allele (2% vs. 0.7%) compared to Mainland Hispanics (Central American, Mexican, South American, N=6,539). APOL1 alleles were associated with increased UACR (p=10⁻⁷) and the composite CKD outcome (p=10⁻⁷), and rs334 was associated with same outcomes (UACR, p<10⁻³; CKD composite outcome, p<10⁻⁷) among Caribbeanans only.

**Conclusions:** African-specific alleles are associated with CKD in Hispanics, but associations vary by Hispanic background. Medical care providers should be aware of the impact of these genetic variants for CKD risk in Hispanics.

### SA-PO500

**Role of Klotho Genetic Polymorphisms in Salt-Sensitivity: A Link Between Salt and Aging?**

Chiara Lanzani, Lorena Citterio, Elena Brioni, Simona Delli Carpini, Marco Simonini, Guido Gatti, Elisabetta Messaggio, Paolo Manunta.

**Nephrology and Hypertension, San Raffaele Hospital, Milan, Italy.**

**Background:** Previous data in transgenic mice showed that one-half-klotho deficiency resulted in excessive premature aging, increased salt sensitivity and caused salt-sensitive hypertension. Recent gene expression study confirmed the expression of klotho in renal distal tubular cells. The aim of this study is to evaluate the role of klotho polymorphisms in salt sensitivity hypertension.

**Methods:** Design: study of pressure-natriuresis relationship in essential hypertensive patients, never treated before, naive (NHP) by Acute salt load (NaLoad: 310 mMol in 2 h iv) and low salt diet (Low SD: <100 mg/die for 15 days). Methods: 580 NHP underwent NaLoad whereas 137 NHP were compliant to low SD protocol (of 324 enrolled).

**Results:** GWA analysis identified 32 SNPs in Klotho gene (restricted to 15 with tagging r²>0.80). Six of these resulted significantly associated to BP variation after NaLoad and LowSD. The effect of intron 2 and 3 SNPs genotype on SBP variation after NaLoad and LowSD are reported in the (figure 1) confirming the similar effect in the two manoeuvres.

**Conclusions:** These results are the first demonstration of the role of Klotho gene in salt homeostasis and hypertension development and suggest that Klotho polymorphisms affect sodium renal tubular excretion. If confirmed these results propose Klotho as key gene in salt sensitivity and aging.

**Funding:** Government Support - Non-U.S.

### SA-PO501

**Associations Between the Reticulon 1 Gene (RTN1) and End-Stage Kidney Disease**

Jason A. Bonomo, Nicholette D. Palmer, Ying Fan, John C. He, Donald W. Bowden, Barry I. Freedman.

**1Center for Genomics & Personalized Medicine Research, Wake Forest School of Medicine; 2Dept of Internal Medicine, Section on Nephrology, Mount Sinai School of Medicine; 3Dept of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine.**

**Background:** RTN1 encodes endoplasmic reticulum stress proteins that have recently been associated with chronic kidney disease. We sought to determine if genetic variants within RTN1 were associated with end-stage renal disease (ESRD) in African Americans (AAs) and European Americans (EAs) with diabetic (T2D-ESRD) and non-diabetic forms of ESRD.

**Methods:** We examined the RTN1 gene region using a published AA T2D-ESRD genome-wide association study (Discovery study; n=922 cases, n=861 controls). Seven single nucleotide polymorphisms (SNPs) with p<0.05 were identified and genotyped in replication samples of AAs with T2D-ESRD (n=1,312) and controls (n=774), as well as...
EAs with T2D-ESRD (n=904) and controls (n=1030). SNPs were also investigated in AAs with renal disease in type 2 diabetes, including DN-ESRD (n=500 AAs, n=620 EAs). Data were adjusted for age, gender, admixture, and the APOL1 alleles, if applicable.

**Results:** The top 738A SNPs from the Discovery study underwent replication testing in independent case-control samples of AAs with T2D-ESRD. Replication was observed for rs3760106, but did not remain significant after correction for multiple comparisons. In combined data IMN, interaction analysis between IMN and DRB1*04:05 allele was assessed. In single locus analysis of AAs, no association with rs3760106 was observed when the risk allele was not present. For AAs with both risk alleles, no association was observed for any SNP. A combined AAs all-cause ESRD analysis (n=3,800 cases, n=1,803 controls) demonstrated associations with rs3760106 that remained significant after correction for multiple comparisons (OR=0.75, 95% CI, 0.67-0.87). The association was stronger for non-T2D ESRD in AAs (OR=0.77, 95% CI, 0.69-0.87).

**Conclusions:** This study demonstrated genetic evidence of association between 738A and ESRD in AAs and EAs. Further studies are needed to clarify the signal. **Funding:** NIDDK Support

**Interaction of Risk Alleles in Japanese Idiopathic Membranous Nephropathy**

Kenjiro Honda, 1 Myo Thiri, 1 Koji Okamoto, 1 Kent Doi, 2 Hodaka M. Lara Besada, 1 Miguel A. Garcia, 1

**Background:** Recent studies have reported the association of risk alleles of PLA2R1 and HLA-DQ41 with idiopathic membranous nephropathy (IMN) in the European and Chinese populations. However, both close association of the risk alleles and interaction between risk alleles of PLA2R1 and HLA from high-resolution HLA typing among Japanese IMN patients has not been investigated.

**Methods:** Samples of Japanese biopsy-proven IMN patients (N = 183) and healthy controls (N = 620) were collected. Fifteen common variants were selected within PLA2R1 gene. High-resolution association analysis of single nucleotide polymorphisms (SNPs) within PLA2R1 and HLA alleles in HLA-A, B, C, DRB1, DQB1 and DPB1 were performed using 53 IMN cases and 420 controls. The significant associations discovered in the first sample set were validated by the second set that comprised of 130 IMN cases and 200 controls.

**Results:** The strong associations HLA-DRB1*15:01 (P = 7.7 x 10^(-9), OR = 2.9) and HLA-DQB1*06:02 (P = 5.1 x 10^(-4), OR = 2.6) were observed. Additionally, HLA-DRB1*07:04 (P = 2.1 x 10^(-4), OR = 2.2) and HLA-DQB1*04:05 (P = 1.2 x 10^(-4), OR = 2.1) were inversely associated with IMN. The associations did not remain significant after correction for multiple comparisons. In combined data analysis, HLA-DRB1*15:01 and HLA-DQB1*06:02 showed stronger association with IMN. In single locus analysis of PLA2R1, seven SNPs showed strong associations with IMN. Interaction analysis between HLA alleles and PLA2R1 variants revealed high odds ratio for IMN with both risk alleles.

**Conclusions:** The associations of PLA2R1 and HLA polymorphisms were identified in Japanese IMN patients. Moreover, PLA2R1 risk alleles and HLA risk haplotype showed additive effects that were stronger than individual odds ratios, indicating the importance of interaction of these two genes in the development of IMN.

**SA-PO503**

**Relationship Between rs3760106 Variation of PRKCB1 Gene and End-Stage Renal Disease in Type 2 Diabetes Mellitus in Chinese**

Limei Liu, 1 Xiaoxu Ge, 1 Langen Zhuang, 1 Ming Li, 2 Rong Zhang, 1 Feng Wang, 2 Niansong Wang, 2

**Background:** To explore the relationship between rs3760106 (C/T) variation of protein kinase C-β gene (PRKCB1) and end stage renal disease (ESRD) in type 2 Diabetes mellitus (T2DM) in Chinese.

**Methods:** 602 type 2 diabetes patients of Shanghai Han origin were recruited, which were divided into DN-ESRD group (n=274) with end stage renal disease (ESRD) of diabetic nephropathy (DN) and DN-0 group (n=328) without diabetic nephropathy (DN-0). Taqman PCR assay was used to detect the genotypes of rs3760106 variation of PRKCB1 gene. Genotypic and allelic frequencies and clinical characteristics were compared between two groups, including DN-0 and DN-ESRD groups as well as genotypic groups in DN-0 or DN-ESRD group.

**Results:** Three genotypes (CC, CT, and TT) of rs3760106 were detected. The distribution of the three genotypes of type 2 diabetes patients was in accordance with Hardy-Weinberg equilibrium. There were significant differences in both genotypic and allelic frequencies between DN-0 and DN-ESRD groups (p < 0.05 for each). The frequencies of CT/TT genotype and T allele in DN-ESRD group were significantly higher than those in DN-0 group (p < 0.05 for each). Patients with risk allele T (i.e. CT and TT genotypes) were at significantly higher risk of developing ESRD (OR = 2.14, 95% CI, 1.18-3.87, p < 0.05). After adjusting for confounding variables, i.e., sex, onset age of diabetes and BMI with multi-factorial logistic regression model, this odds ratio (OR) remained significant (OR=1.94 (95% CI, 1.04-3.64)). Moreover, compared with patients carrying CC genotype, those with CT+TT genotype had significantly higher fasting plasma glucose (FPG) level in DN-0 group (p < 0.05) or had an increasing tendency in DN-ESRD group (p < 0.05).
SA-PO506
Exome Sequencing as Diagnostic Tool in Daily Clinical Nephrology Practice
Ilse M. Rooij,1,2 Dorien Lugtenburg,1,2 Elisabeth A.M. Cornelissen,1 Jeroen Schoots,1 Nicole Van De Kar,1 Michiel F. Schreuder,1 Linda Koster-Kampius,1 Jeroen Deegens,1 Julia M. Hofstra,1 Tom Nijenhuis,1 Jack F. Wetzels,1 Ronald Roepman,1 Ernie M.H.F. Bongers,1 Radboud Center Renal Disorders, RadboudUMC, Nijmegen, Netherlands; 2Shared first author.

Background: Next generation sequencing, e.g. exome sequencing (ES), is currently the state of the art technique to identify mutations in genetic diseases. We developed a workflow for implication of ES in daily clinical practice for patients with a suspected hereditary kidney disease. The aim of this study was to analyze the diagnostic yield of this approach in clinical practice.

Methods: We developed a two-tier analysis, in which the first step is a kidney disease gene panel to screen for pathogenic variants in 187 genes, minimizing the chance of coincidental findings. If causative mutations are not identified (first step), the complete exome data set was analyzed after additional written informed consent. We analyzed the diagnostic yield of this approach.

Results: From Jun. 2013 till Jan. 2015 we included 74 unrelated patients with kidney disease, defined as glomerular disease (n=34), cystic renal disease (n=16), electrolyte disorders (n=11), renal insufficiency of unknown cause (n=4) and other (n=9). The kidney disease gene panel revealed pathogenic mutations in 11 cases (15%), and likely pathogenic variants in 12 other cases (16%), necessitating follow-up studies. Further analysis of the complete exome data set in 19 patients, revealed candidate genes in 6 patients that are under investigation. In addition, copy number variation analysis revealed a pathogenic deletion in 2 patients (in one patient another pathogenic mutation was also identified in step one). There was 1 coincidental finding necessitating follow up for colon carcinoma. In 23 patients open exome analysis is currently ongoing. Nine patients refused further analysis.

Conclusions: Currently, in 30 out of 74 patients (41%) (likely) causative mutations or new candidate genes were identified. We conclude that diagnostic exome sequencing is a powerful tool for detecting causative mutations in daily clinical practice without having the limitations of other gene testing approaches (single gene testing/targeted sequencing).

SA-PO507
Atypical Hemolytic Uremic Syndrome Targeted Re-Sequencing in a South Italian Cohort of Patients
Matteo Accrettura,1 Anna Zito,1 E.D. Stei,1 Maddalena Gigante,2 Paola Pontrelli,2 S. Diella,2 Giuseppe Castellano,1 M. Giordano,1 L. Santangelo,1 Loreto Gesualdo,1 1Emergency and Organ Transplants, Nephrology Unit, Univ of Bari, Italy; 2Medical and Surgical Sciences, Nephrology Unit, Univ of Foggia, Italy; 3Giovanni XXIII Hospital, Italy.

Background: Atypical hemolytic uremic syndrome (aHUS) is a multifactorial disease due to autoimmune or genetic factors leading to deregulated alternative complement pathway activation. At present 12 genes are associated to aHUS, however 30-50% of patients lack mutations in these genes resulting in still partially obscure genotype-phenotype correlations.

Methods: We enrolled 20 aHUS patients and 2 relatives from Apulia Region, Italy. We performed targeted parallel re-sequencing of the 12 known genes plus ADAMTS13, identified in the aHUS diagnostic routine screening. We analyzed the genotypes investigating the overlapping with other alternative complement pathway disorders, such as C3 glomerulopathy, Age-related Macular Degeneration (AMD) and drusen. We selected patients for their history of sporadic aHUS. Target enrichment was performed using an Illumina TrueSeq Custom Amplicon panel. Sequencing was performed on Illumina MiSeq Desktop Sequencer. All variants were evaluated for their pathogenicity according to CADD, Sift and Polyphen algorithms.

Results: We identified 30 missense and one nonsense variants in known aHUS genes, plus seven missense variants in ADAMTS13. Several combined variants were identified which might explain the different phenotypic nuances of our patients, as well as, in some cases, their signs of other Complement-related diseases. We evidenced that different combination of variants together with different triggering factors result in a phenotypic spectrum encompassing all the Complement-related disease range. Additionally, in presence of some combinations, also other underlying pathologies can act as a triggering background for aHUS.

Conclusions: Our data suggest that (i) ADAMTS13 gene should be routinely sequenced for aHUS (ii) the overlapping with other complement-related diseases is considerable. Mutations should therefore be analyzed in combination, and the high-throughput strategy is the only feasible in this scenario.

SA-PO508
Whole Exome Sequencing (WES) Revealed Underlying Complexity in Genetic Studies of Familial IgA Nephropathy (fIgAN)
Xuewen Song,1 Nicole M. Roslin,2 Meng Yi Xu,1 Kairong Wang,1 Jannel Liu,1 Bushra Joarder,2 Amirzea Haghighi,2 Melody Ren,1 Mitchell Li Cheong Man,1 Joseph C.K. Leung,1 Sydney C.W. Tang,1 Kar Neng Lai,1 Andrew D. Paterson,2 Florent Song,2 Florent Soubrier,4 York P. Pei,1 1Div of Nephrology, Univ of Hong Kong, Hong Kong, China; 2INSERM, Univ Pierre et Marie Curie Paris 06 (UPMC), Paris, France; 3Radboud Center Renal Disorders, RadboudUMC, Nijmegen, Netherlands; 4INSERM, Univ Pierre et Marie Curie Paris 06 (UPMC), Paris, France.

Background: Diagnosis of familial glomerular diseases may be confounded by non-specific clinical (i.e. hematuria and proteinuria) and/or pathological findings. Indeed, a recent study of familial focal segmental glomerulosclerosis (FSGS) has identified COL4A3 and COL4A4 mutations in ~10% of study families [Kidney Int 86:1253-59, 2014]. In the course of studying a cohort of fIgAN, we unexpectedly identified pathogenic mutations in 13 families with non-IgA glomerular diseases.

Methods: We performed whole exome sequencing (WES) in 109 patients from 54 families, all with at least 2 biologically related cases.

Results: Our WES study identified heterozygous/hemizygous pathogenic COL4A3 (c.1504+1G>A; p.G291R; p.G695R; p.G1054E; p.G1286R), COL4A4 (p.Q970R; p.G1508A), and COL4A5 (p.G48R; p.G325R) mutations in 9 families with fIgAN. These mutations occurred at the canonical splice junction or conserved glycine residues and segregated in all affected subjects within family. In two multiplex families, co-existence of thin basement membrane disease (TBMD) with IgAN was also observed in the biopsied subjects in retrospect. Additionally, putative homozygous pathogenic variants were found in 3 families in the known genes for FSGS (ACTN4, c.398-2A>G), CFB57 nephropathy (CFHR5, p.C449S), and membranous nephropathy (PLA2R1, p.C192G) and homozygous mutation in one family in another known gene for FSGS (ADCK4, p.S246N).

Conclusions: The presence of other glomerular diseases may confound the diagnosis of fIgAN in some putatively affected subjects ascertained based on urinal findings or even kidney biopsy. Due to its high prevalence in the general population, TBMD may be an important cause of phenocopy that can confound genetic linkage studies in fIgAN.

SA-PO509
Disease Gene Discovery for Familial IgA Nephropathy (fIgAN) by Whole Exome Sequencing (WES)
Xuewen Song,1 Nicole M. Roslin,2 Meng Yi Xu,1 Kairong Wang,1 Jannel Liu,1 Bushra Joarder,2 Amirzea Haghighi,2 Melody Ren,1 Joseph C.K. Leung,1 Sydney C.W. Tang,1 Kar Neng Lai,1 Andrew D. Paterson,2 Florent Song,2 Florent Soubrier,4 York P. Pei,1 1Div of Nephrology, Univ of Hong Kong, Hong Kong, China; 2INSERM, Univ Pierre et Marie Curie Paris 06 (UPMC), Paris, France; 3Radboud Center Renal Disorders, RadboudUMC, Nijmegen, Netherlands; 4INSERM, Univ Pierre et Marie Curie Paris 06 (UPMC), Paris, France.

Background: IgaN is the most common primary glomerular disease worldwide. Genome-wide linkage scans have identified multiple susceptibility loci for fIgAN but no disease gene has yet been identified.

Methods: To identify susceptibility genes for fIgAN, we performed WES in 109 patients from 54 families all with ~2 biopsy-proven cases and putatively affected members ascertained with persistent hematuria/proteinuria. In 3 multiplex families each with ~5 affected cases, we also performed genome-wide linkage scans under a dominant model and focused WES on regions with suggestive linkage. Standard algorithms for sequence alignment, and QC filtering were applied to identify rare (MAF<1%) deleterious variants of high (i.e. protein-truncating) and moderate (i.e. inframe indels and nonsense) effect in all affected subjects. We initially tested 1,000 cases and identified 15 candidate genes using PolyPhen-2, Sift, Mutation Assessor, CADD phred, Phylopp,Distal and VPolytron (100) impact.

Conclusions: Overall, 99.8% of the targeted exome were covered with a mean depth of 100x. We examined 19 regions with LOD >1 in 3 multiplex families and ~3,000 immunologic candidate genes. We identified 26 candidate genes (i.e. IFIH1, CD33, MSHS, ERP2, FUT2, MMN1, MNA, OAS1, TLR1, RNASEL, MARCO, THADA, BTV1A1, PTPRK, RBLT, ERC6, ASB4, LCP1, HK3, ASH1L, LTBR, FES, MPO, GPIBA, BACH2, and EMP3), each with rare deleterious variants affecting 2 or unrelated families.

Conclusions: Our results suggest extensive genetic heterogeneity in fIgAN with many disease genes each contributing to a small proportion of cases. Future studies with expanded sample size will aid selection of the most promising candidate genes for functional studies. Identification of disease genes for fIgAN has the potential to improve diagnosis and treatment.

Funding: Government Support – Non-U.S.
Discovery of New Risk Gene LoCI in IgA Nephropathy: Genome-Wide Human Assay

**Background:** IgA nephropathy (IgAN) is the most common form of glomerulonephritis in Korea. The etiology of IgAN is complex with high genetic heterogeneity. Several genome-wide association studies (GWAS) suggested that specific polymorphisms of candidate genes were associated with susceptibility to IgAN. However, previous contents of GWAS DNA chip were fixed and did not cover SNPs in exonic region and promoter region.

**Methods:** We used the Axiom™ Genome-Wide Human Assay by Affymetrix. The contents of assay are useful to investigate association between several candidate SNPs and end-stage renal disease. We selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exonic promoter, and intron SNPs in each gene were following: SNPs with >10% minor allele frequency, >0.1 heterozygosity, known genotype frequencies of SNPs in Asians. SNPs studied in previous study, and unknown SNPs. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value. The analysis was using Helix tree program.

**Results:** To investigate whether specific polymorphisms are involved in the development of IgAN, 182 biopsy confirmed IgAN patients and 455 healthy controls were studied. We selected 378,707 SNPs. We carried out genome wide genotyping on customized Axiom™ chip were fixed and did not cover SNPs in exonic region and promoter region.

**Conclusion:** We found a candidate mutation of ARHGAP32 gene for primary FSGS by combination with whole genome linkage analysis and whole exome sequencing.

Premature Death in First Degree Relatives of End Stage Renal Disease Patients

Einar Svarstad, Anna Reisaeter, Hans-Petter Marti, Bjorn Egil Vike

Methods: The Norwegian Population Registry has since 1960 registered all Norwegian Citizens. Sifting data are complete for most individuals since 1953. The National Cause of Death Registry has registered causes of death since 1960 and the Norwegian Population Registry has registered all individuals with ESRD since 1980. The registries were linked. All citizens born in Norway with at least one registered first degree relative were included.

Results: Five thousand and 1 year earlier in individuals who died at age 70.

Conclusion: This study demonstrated higher death rates in first degree relatives of ESRD patients.

SA-P0515

Excluding known hereditary renal disease, aHR decreased to 1.12 (95% CI 1.09-1.16).

Genetic Variants in ANCA-Associated Vasculitis: A Meta-Analysis

Paul J. Phelan, Gianpiero Cavalleri, Peter J. Conlon

Methods: Relevant articles investigating the association between genetic markers and NODAT were identified by means of a database search of PubMed, Web of Science and Google Scholar from 1945 to 2015. Variants replicated in a minimum of three studies were included for analysis. Data was analysed using a random effects model in Review Manager 5.3. The association between identified variants and NODAT was calculated at the per-study allele level, where original studies were concordant with Hardy-Weinberg Equilibrium, to generate overall significance values and effect sizes.

Results: Our literature search returned 4,147 citations. Of the 36 eligible articles identified 31 genetic variants associated with NODAT following kidney transplantation. These meta-analyses examined the pooled effect of genetic variants associated with NODAT in kidney transplant populations.

Conclusions: These meta-analyses identified three genetic variants statistically associated with NODAT. Ideally, these variants should be assessed in less heterogeneous studies with larger numbers of kidney transplant recipients with a carefully defined NODAT phenotype.

Identifying Genetic Predictors of Skin Cancer in Renal Transplant Recipients

Caragh P. Stapleton, Mark Mccormack, Devla M. Connaughton, Paul J. Phelan, Gianpietro Cavalleri, Peter J. Conlon

Background: Skin cancer in non-transplant populations have been identified via large GWAS. These results have been validated via population registries. These strategies have identified variants associated with the development of skin cancer post-transplant in a candidate gene study design. The aim of this analysis was to search for genetic variants associated with skin cancer post kidney transplantation.
SA-PO520

Comparison of Genetic Associations with Different Definitions of CKD Progression in Children

Matthias Wutke,1 Elke Wuehl,1 Li Luo,1 Jayanta Gupta,1 Bradley Warady,1 Susan L. Furt,1 Anna Kottgen,1 Franz S. Schaefer,1 Craig S. Wong,1 Freiburg Univ, Germany; 2Heidelberg Univ, Germany; 3Univ New Mexico; 4Texas Tech Univ; 5Children's Mercy, Kansas City; 6CHOP, Univ Pennsylvania.

Background: The PediGFR Consortium aims to identify genetic factors associated with pediatric chronic kidney disease (CKD) progression. The optimal definition of CKD progression for testing is unclear. To address this question, we performed genome-wide association studies (GWAS) of two different definitions of CKD progression, slope and the annual change in estimated GFR (eGFR) versus time-to-event (TTE).

Methods: We genotyped 140 CKiD participants using the Illumina HumanExome BeadChip v2.0 comprising over 250,000 markers, including putative functional eQTL variants that were implicated in common metabolic disorders. 81,460 SNPs passed quality control and were tested for association with baseline proteinuria in 129 children with chronic kidney disease (CKD) stages 1-5. SNPs were adjusted for age, gender, and the first five eigenvectors from the population stratification analysis.

Results: We identified several genetic loci that were significantly associated with proteinuria (P<10^-4), as well as new candidate loci (P<10^-8). Among the top hits, notably revealed kidney-expressed genes that were previously associated with the TGFβ pathway, renal homeostasis, IgA nephropathy, congenital kidney disease, and vascular development and its mutations manifest two different types of glomerulopathies, Denys-Drash syndrome (DDS) and Frasier syndrome (FS). In this multi-center retrospective cohort study, genotype-phenotype correlations in Korean pediatric patients with WT1 mutations were analyzed.

Methods: During the period from 2001 to 2015, WT1 mutations were detected in a total of 14 patients by direct sequencing.

Results: The patients were grouped into FS (n=10, having a mutation in intron 9) and DDS (n=13, having an exon mutation). Nine (69%) DDS patients presented as congenital nephrotic syndrome (CNS) or infantile nephrotic syndrome (INS), while 7 (70%) FS patients presented as sporadic focal segmental glomerulosclerosis. Interestingly, monozygotic twin patients with DDS presented as end-stage renal disease (ESRD) without any previous history of glomerulopathy. Progression to ESRD was noted in 11 (85%) DDS patients at the median age of 0.22 (interquartile range [IQR], 0.07-1.65) years and in 5 (50%) FS patients at 0.25 (IQR, 0.16-5.0) years. Among DDS patients, 52 (97%) of 53 developed renal failure.

Conclusion: The clinical manifestations and disease course of the Korean patients with WT1 glomerulopathy were mostly the same as those of previous reports. Of note, patients with WT1 mutations can be manifested sporadically, i.e., chronic kidney disease without any preceding history of significant proteinuria and/or NS. DSD is common in both in FS and DDS and is a useful diagnostic clue. Genetic screening should be recommended.

SA-PO525

Age of the NPHS2 p. V260E Mutation, a Cause of Childhood Steroid Resistant Focal Segmental Glomerulosclerosis, in the Ancestral Population of Black Africans in Durban, South Africa

Yo Han Ahn,1 Hee Gyung Kang,1 Hye Won Limou,1 Rajendra Bhimma,2 Sophie Limou,1 Jeffrey B. Kopp,1 Cheryl Ann Winkler,1 FNLCR, NCI, Frederick, MD; 2Univ of KwaZulu-Natal, Durban, South Africa; NIDDK, NIH.

Background: A study of 44 children with sporadic steroid resistant nephrotic syndrome (SRNS) with focal segmental glomerulosclerosis (FSGS) histology, in Durban, South Africa, revealed 25% carried two copies of a missense mutation, p. V260E, in the podocin gene, NPHS2. This mutation has previously been reported as recessively associated with FSGS in consanguineous families in regions at one time in the Omani empire, suggesting spread with this empire. We speculated that the children in our study might be cryptically recessively common descent with an ancestral population.

Methods: Inheritance of the V260E mutation from two parents with a common ancestor will result in a region of homozygosity surrounding the locus, indicating the overlap of extended haplotypes preserved around the locus. To test for this we genotyped 10 individuals homozygous for the mutation, and 74 individuals homozygous for the wild type variant, with the Illumina exome chip v2.2 comprising over 250,000 markers, including putative functional eQTL variants that were implicated in common metabolic disorders. 81,460 SNPs passed quality control and were tested for association with baseline proteinuria in 129 children with chronic kidney disease (CKD) stages 1-5. SNPs were adjusted for age, gender, and the first five eigenvectors from the population stratification analysis.

Results: We identified several genetic loci that were significantly associated with proteinuria (P<10^-4), as well as new candidate loci (P<10^-8). Among the top hits, notably revealed kidney-expressed genes that were previously associated with the TGFβ pathway, renal homeostasis, IgA nephropathy, congenital kidney disease, and vascular development and its mutations manifest two different types of glomerulopathies, Denys-Drash syndrome (DDS) and Frasier syndrome (FS). In this multi-center retrospective cohort study, genotype-phenotype correlations in Korean pediatric patients with WT1 mutations were analyzed.

Methods: During the period from 2001 to 2015, WT1 mutations were detected in a total of 14 patients by direct sequencing.

Results: The patients were grouped into FS (n=10, having a mutation in intron 9) and DDS (n=13, having an exon mutation). Nine (69%) DDS patients presented as congenital nephrotic syndrome (CNS) or infantile nephrotic syndrome (INS), while 7 (70%) FS patients presented as sporadic focal segmental glomerulosclerosis. Interestingly, monozygotic twin patients with DDS presented as end-stage renal disease (ESRD) without any previous history of glomerulopathy. Progression to ESRD was noted in 11 (85%) DDS patients at the median age of 0.22 (interquartile range [IQR], 0.07-1.65) years and in 5 (50%) FS patients at 0.25 (IQR, 0.16-5.0) years. Among DDS patients, 52 (97%) of 53 developed renal failure.

Conclusion: The clinical manifestations and disease course of the Korean patients with WT1 glomerulopathy were mostly the same as those of previous reports. Of note, patients with WT1 mutations can be manifested sporadically, i.e., chronic kidney disease without any preceding history of significant proteinuria and/or NS. DSD is common in both in FS and DDS and is a useful diagnostic clue. Genetic screening should be recommended.
Conclusions: We confirmed the association of selected genetic variants with decline in Hgb in children with progressive CKD, with differential effects by ethnicity at specific loci. Clarification of the genes involved in susceptibility to anemia has the potential to identify new therapeutic targets.

Cell-Free Hemoglobin and HMOX1 in Sickle Cell Nephropathy
Santosh Saraf, Xu Zhang, Binal N. Shah, Krishnamurthy P. Gudehithlu, Jose A.L. Arruda, Ashok K. Singh, Victor R. Gordeuk, Medicine, Univ of Illinois at Chicago, Chicago, IL; Nephrology, John H. Stroger, Jr Hospital of Cook County, Chicago, IL.

Background: Chronic kidney disease (CKD) is observed in over 50% of adults with sickle cell disease (SCD) and hemoglobinuria, a consequence of intravascular hemolysis, is independently associated with CKD stage and its progression. In this study we investigate the mechanistic role of hemoglobinuria and HMOX1, the rate limiting enzyme for heme metabolism, in SCD nephropathy.

Methods: Urinary tubular (kidney injury molecule-1, KIM-1) and glomerular (neprhin) biomarkers of injury were measured in 32 SCD patients by ELISA from the University of Illinois at Chicago (UIC). We then cultured human-kidney 2 (HK2) tubular cells with lyophilized hemoglobin (L-Hb) to determine biological responses and expression of candidate genes. We examined the association of KIM-1 with 11 tag SNPs and the GT-repeat polymorphism in HMOX1 in 247 UIC SCD patients and in a separate replication cohort (Walk-PhaSST) of 482 SCD patients.

Results: Urine KIM-1 correlated with increasing urine cell-free hemoglobin concentration (P=0.005), while urine neprhin levels did not. HK2 culture studies showed increasing KIM-1 concentrations in the culture medium (P=0.01), decreasing HK2 cell viability (P=0.01), increased HMOX1 expression (P=0.0001) and protein concentration (P=0.0001) with incremental concentrations of L-Hb. We identified a SNP in HMOX1 (rs7438111, MAF=0.14) that was significantly associated with CKD stage (OR 2.8, P=0.0093) and CKD stage 3 (OR 3.0, P=0.02) in the UIC cohort and with eGFR (OR 9.8, P=0.0004) and CKD stage 3 (OR 2.3, P=0.04) in our replication cohort. UIC SCD patients with L5 GT-repeats in the promoter region of HMOX1, known to be associated with increased HMOX1 inductability and activity, had higher estimated glomerular filtration rate (eGFR)(β=9.2, P=0.01).

Conclusions: Cell-free hemoglobin contributes to sickle cell nephropathy through renal tubular injury. A tag-SNP in HMOX1, rs7438111, was associated with kidney disease and the presence of shorter (GT)n repeats correlated with increasing eGFR, raising the possibility that altered HMOX1 activity has a critical role in SCD-nephropathy.

Differences in Susceptibility to Cisplatin Nephrotoxicity Among 8 Mouse Strains
Gabor Bodonyi-Kovacs, Rosa Chan, Thu H. Le. Renal Div, Univ of Virginia, Charlottesville, VA.

Background: Cisplatin is a widely used chemotherapeutic agent with remarkable efficacy, but its use is limited by significant nephrotoxicity. Significant differences in susceptibility to nephrotoxicity among individual patients have been noted, but predicting those at risk remains a challenge. To begin to identify genes that play a role in susceptibility to cisplatin nephrotoxicity (CPN), we set out to determine differences in CPN among 8 genetically distinct founder mouse strains of the Collaborative Cross: A/J, C57BL/6J, 129S1/SvImJ, NOD/ShiLtJ, NZO/HILJCAST/EiJ, PWK/PhJ, and WSB/EiJ.

Methods: 10-14 week old male mice received ip. injection of 25 mg/kg cisplatin and serum was collected 72 hours later to sacrifice. Serum urea nitrogen (BUN) was measured for the 8 strains using a nonenzymatic, colorimetric kit (Arbor Assays) and analyzed by one way ANOVA and two sided t-test. Serum creatinine was measured using an enzymatic, colorimetric kit (Crystal Chem) and analyzed by a two sided t-test for the 2 strains that showed the largest difference in BUN.

Results: The 8 strains differed significantly in their serum BUN values (p=0.042). The number of animals in each group, and the mean and SD of BUN (mg/dl) were as follows: C57BL/6J (n=5) 188.6±9.2, CAST/EiJ (n=3) 207.9±32.7, NOD/ShiLtJ (n=5) 256.7±93.0, PWK/PhJ (n=4) 240.9±127.2, WSB/EiJ (n=5) 254.1±51.6, A/J (n=5) 267.6±62.3, NZO/HILJCAST/EiJ (n=5) 290.0±50.7, 129S1/SvImJ (n=6) 319.5 ±28.3. The biggest differences were seen between the C57BL/6J and 129S1/SvImJ strains, (p = 0.0001). In direct comparison the serum creatinine was significantly different between C57BL/6J (n=10) and 129S1/SvImJ (n=9) strains, (p=0.0047) (Figure 1).

Conclusions: Crosses from “susceptible” and “resistant” mouse strains may enable identification of novel genetic determinants governing individual susceptibility to CPN.

The PAX2-Related SNP rs11190739 Is Associated with Accelerated Loss of GFR in Diabetes Mellitus
Paul R. Goodyer, Melanie Cosgrove, James C. Engert. Pediatric Nephrology, Research Inst of McGill Univ Health Centre, Montreal, QC, Canada; Genetics, McGill Univ, Montreal, QC, Canada.

Background: In embryonic kidney, PAX2 is crucial for optimal branching of the ureteric bud and final nephron number. Previous studies show that common polymorphic variants of the PAX2 gene are associated with a 10% decrease in newborn kidney size. BRENNER proposed that individuals with suboptimal nephron number might have accelerated loss of GFR in the setting of acquired renal disease in adulthood.

Methods: We used PLINK software to test for an association between PAX2 SNPs and reduced GFR among Caucasians (N=225) entered into the FIND (“Family Investigation of Nephropathy and Diabetes”) cohort available through dbGaP. This cohort of adult diabetics consisted of 175 African-American, 225 European-American and 257 Mexican Americans with eGFR data 15-25 years after onset of diabetes. Association testing that incorporated the serum creatinine was significantly different between C57BL/6J (n=10) and 129S1/SvImJ (n=9) strains, (p=0.0047) (Figure 1).

Conclusions: Crosses from “susceptible” and “resistant” mouse strains may enable identification of novel genetic determinants governing individual susceptibility to CPN.

Cefepime Dosing in Modeled Critically Ill Patients Receiving SHIFT Hemofiltration or Hemodialysis Renal Replacement Therapies

Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, Ann Arbor, MI.

Background: Cefepime is an antibiotic commonly used in the ICU where acute kidney injury (AKI) is prevalent. SHIFT therapy, a 6-12 hour renal replacement therapy (RRT), also referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD), is increasingly utilized to help treat AKI. However, dosing information for cefepime in critically ill patients receiving SHIFT therapy is currently lacking.

Methods: Using previously-published pharmacokinetic (PK) data and a PK model developed for critically ill patients receiving SHIFT RRT, a series of 5000-subject Monte Carlo simulations were performed for 18 cefepime regimens in 8 settings including duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to cefepime dosing. Cefepime regimens were evaluated on the probability of attaining a free drug concentration equal to at least the minimum inhibitory concentration (MIC) for ≥260% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) >90% for MIC values ≤8 mg/L using the smallest total daily dose.

Results: Cefepime 1 g q6 hours with a 2 g loading dose was the only regimen to yield a PTA≥90% in all 8 SHIFT settings while limiting the total daily maintenance dose to 4 g. This dosing regimen resulted in 48-hour mean trough concentrations >32 mg/L in most subjects.

Conclusions: Published cefepime CRRT doses (2 g every 12 hours) yielded 90% PTA in modeled critically ill patients receiving 8 or 10 hours of SHIFT RRT. Results warrant clinical validation.

SA-PO530

Identification of Optimal Ceftazidime Dosing Regimens in Modeled Critically Ill Patients Receiving SHIFT Renal Replacement Therapy

Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, Ann Arbor, MI.

Background: Ceftazidime is an antibiotic commonly used in critically ill patients. Ceftazidime doses of 2 g every 12 hours have been recommended for continuous renal replacement therapies (CRRT), however, no studies have evaluated the optimal dose in patients receiving SHIFT Therapy (NxStage Medical), a 6-12 hr RRT commonly referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD).

Methods: Pharmacokinetic (PK) data compiled from previously-published studies were used to develop models for critically ill patients receiving intermittent hemofiltration (HF) or hemodialysis (HD). Eight models were developed to account for the variability in settings including duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to ceftazidime dose. Using a series of 5000-subject Monte Carlo simulations, 12 cefepime regimens were applied to each model and evaluated for the probability of attaining free drug concentrations equal to or greater than the minimum inhibitory concentration (MIC)=4 for ≥260% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) >90% for MIC values ≤8 mg/L using the smallest total daily dose.

Results: Ceftazidime administered in 4 g total daily doses (2 g q12 hours; 1 g q6 hours) yielded a PTA≥90% in all 8 RRT models. Continuous infusion of the drug (3 g continuous infusion with a 2 g loading dose) achieved similar PTA values.

Conclusions: Published ceftazidime CRRT doses (2 g every 12 hours) yielded 90% PTA in modeled critically ill patients receiving 8 or 10 hours of SHIFT RRT. Future studies should validate these findings in the clinical setting.

Evaluation of Piperacillin/Tazobactam Regimens in Patients with SHIFT Renal Replacement Therapy

Susan J. Lewis,1 Katherine N. Gharibian,1 Ashita J. Tolwani,2 William Henry Fissell,3 Bruce A. Mueller.1 College of Pharmacy, Univ of Michigan, MI;1 Univ of Alabama, AL; Vanderbilt Univ, TN.

**Background:** SHIFT Renal Replacement Therapy (RRT) is a prolonged intermittent RRT to treat critically ill patients with acute kidney injury, but lacks of antibiotic pharmacokinetic (PK) data in this RRT limits its utility. This study evaluated probability of target attainable PK of piperacillin/tazobactam regimens recommended in critically ill patients receiving SHIFT RRT, using Monte Carlo Simulations (MCS).

**Methods:** Mathematical PK models were constructed using literature-derived demographic/PK data with known variability. Four daily-SHIFT settings (hemofiltration or hemodialysis with effluent rates of 5L/hour x 8 hours or 4L/hour x 10 hours) occurring at 2 different times relative to drug dose were modeled. PTA of 13 piperacillin regimens (2-4g q6-h) and 3 tazobactam regimens (0.5g q6h) with intermittent or prolonged infusion (4-hour or continuous) were evaluated. MCS generated free drug concentration profiles for each regimen in the 5,000 virtual patients. Pharmacodynamic targets were > 90% of time free piperacillin concentrations above 4x the minimum inhibitory concentration (MIC) of Pseudomonas aeruginosa (16 µg/mL) and ≥ 50% of time free tazobactam concentrations above corresponding threshold (4 µg/mL) for the initial 48 hour-therapy. The optimal regimen required > 90% of PTA for both agents.

**Results:** The attainment of > 90% of PTA required piperacillin 16g/day and tazobactam 2g/day in all SHIFT settings. Prolonged infusion was not superior to intermittent infusion to yield better PTA in patients receiving SHIFT RRT.

**Conclusions:** Piperacillin/tazobactam 4.5g q6h is recommended for critically ill patients receiving 8 or 10 hour SHIFT RRT. These PK simulation results need to be clinically validated.

**Funding:** Pharmaceutical Company Support - NxStage Medical Inc.

Beta-Blocker Dialyzability in Chronic Hemodialysis Patients

Alvin Tieu,1 Thomas Velenosi,1 Andrew S. Kucey,1 Laura Elizabeth Mccuaig,1 Matthew SA-PO533

**Background:** There is a paucity of data available to describe beta-blocker dialyzability. Of the available information, most were obtained prior to implementation of high-flux dialysis membranes. This study aims to characterize the dialyzability of four of the most commonly prescribed beta-blockers in patients undergoing conventional high-flux hemodialysis (HD). Based on physiochemical properties, we hypothesize atenolol and metoprolol to be extensively removed by HD, while bisoprolol and carvedilol to be poorly dialyzed.

**Methods:** HD patients from the London Health Sciences Centre were recruited for a pharmacokinetic, crossover study. Atenolol (50mg), bisoprolol (5mg), carvedilol (6.25mg) and metoprolol (50mg) were administered separately to each patient over four hemodialysis sessions. Arterial and venous blood samples and total spent dialysate were collected. Beta-blocker concentrations were measured by mass spectrometry, and dialytic clearance was determined by the dialyzer and recovery clearance methods.

**Results:** Following dialysis, 6.78 mg of atenolol, 0.66 mg of bisoprolol, 0.02 mg of carvedilol, and 1.53 mg of metoprolol were recovered in spent dialysate. These amounts of diazylated beta-blockers were applied in the recovery clearance method to produce dialytic clearances of 124.0, 91.5, 1.3, and 150.2 mL/min for atenolol, bisoprolol, carvedilol, and metoprolol, respectively.

**Conclusions:** Beta-blocker efficacy can be hindered if substantial dialytic clearance occurs. Accordingly, atenolol and metoprolol were extensively cleared by HD, while carvedilol displayed low dialyzability. Contrary to previous literature, our data suggests moderate dialyzability for bisoprolol. With reported studies indicating heightened recurrence risk in HD patients prescribed highly-dialyzable beta-blockers, drug dialyzability data is critically important to optimize pharmacotherapy in HD patients. Definitive characterization of beta-blocker dialyzability can allow for determination of post-dialysis supplemental drug doses in patients.

Ritonavir Exhibits Altered Pharmacokinetics in Patients with Membranous Nephropathy

Uma R. Fouquer,1 Visit Cheungpasitporn,2 David Bourne,1 Fernando C. Fervenza,3 Melanie S. Joy.1 Schools of Pharmacy and Medicine, Univ of Colorado, Aurora, CO; 1Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

**Background:** Ritonavir (RTX) is an anti-COD2 antibody used in the treatment of glomerular diseases including membranous nephropathy (MN). There is little information about the pharmacokinetics of therapeutic proteins, including RTX in patients with glomerular diseases. The study evaluated ritonavir pharmacokinetics in patients with MN from a pilot investigation (Fervenza et al., 2010).

**Methods:** Patients with MN (n=20) received 4 RTX weekly IV infusions (375mg/m²), with a repeat of the identical treatment at 6 months. Patient baseline characteristics were: gender (17M/3F), age (49±13 y), BSA (22.2±0.24 m²), urine protein excretion (11.3±4.1 g/d), creatinine clearance (72±33 mL/min). Pharmacokinetic analysis was performed using ritonavir-plasma concentration comparisons. Pharmacokinetic parameters of drug were measured between the MN patients and published data from other populations.

**Results:** The MN population had a favorable reduction in urinary protein excretion 3 months after each RTX treatment course (7339±1411 mg/day and 4131±3441 mg/day, respectively), while creatinine clearance values were similar to baseline (72±31 mL/min and 82±37 mL/min, respectively). Patients with MN exhibited a shortened half-life (T1/2), greater volume of distribution (Vd), and enhanced clearance of RTX vs. previous reports in other patient populations. These characteristics resulted in an exposure (AUC) that was significantly reduced in patients with MN.

**Conclusions:** The pharmacokinetics of RTX in patients with MN are significantly altered compared to published data from cancer and autoimmune populations. These results suggest shorter T1/2 and lower exposures to RTX in MN may necessitate higher doses or changes to dosing frequency in order to elicit an optimal therapeutic effect.

**Funding:** Pharmaceutical Company Support - NxStage Medical Inc.

Eculizumab Treatment Effectively Prevents C5 Cleavage without C5a Generation In Vivo

Elena Volokhina,1 Grethe Bergseth,2 Nicole Van De Heuvel,3 Lambertus P.W.J. Van den Heuvel,1 Tom Eirik Mollnes.2 Radboud Univ Medical Center, Nijmegen, Netherlands; Nordland Hospital, Bodø, Norway.

**Background:** The C5 inhibitor eculizumab has been successfully used to treat atypical hemolytic uremic syndrome (aHUS), however, available data on pharmacodynamics of this medication are limited. Recently, increased generation of C5a in a single patient with HELLP syndrome treated with eculizumab has been reported. Since this observation was unexpected, we aimed to reproduce these data and search for possible explanations for the findings.

**Methods:** Levels of C5a were analyzed in EDTA plasma samples of aHUS (n=17) and HELLP (n=3) study patients using appropriate ELISA kits. C5a was measured by using another two commonly available commercial kits. When eculizumab was added in vitro to normal human serum prior to activation, no generation of C5a was measured by one of the commercial ELISA kits, increased significantly in all aHUS patients after the first eculizumab dose and then at various time points during treatment.

**Results:** In line with the report on HELLP patient, the C5a values, measured by one of the commercial ELISA kits, increased significantly in all aHUS patients after the first eculizumab dose as compared to the values obtained before treatment (p<0.016). C5a remained elevated throughout the treatment period. Such increase could not be reproduced by using another two commonly available commercial kits. When eculizumab was added in vitro to normal human serum prior to activation, no generation of C5a was measured by all used kits.

**Conclusions:** Our data indicate that existing commercial assays require validation for specificity before being used to monitor effect of eculizumab, especially in clinical laboratory practice. This example illustrates how false conclusions can be drawn when based on results from one single commercial assay not satisfactorily validated for the purpose it is used.

**Funding:** Government Support - Non-U.S.

Sensitive, Reliable and Easy-Performed Laboratory Monitoring of Eculizumab Therapy In Atypical Hemolytic Uremic Syndrome

Elena Volokhina,1 Grethe Bergseth,2 Thea J. van der Velden,1 Jack F. Wetzels,1 Lambertus P.W.J. Van den Heuvel,1 Tom Eirik Mollnes.2 Radboud Univ Medical Center, Nijmegen, Netherlands; Nordland Hospital, Bodø, Norway.

**Background:** Atypical hemolytic uremic syndrome is a severe renal illness caused by complement dysregulation. Treatment with the complement C5 inhibitor eculizumab is effective, but associated with high costs. Laboratory monitoring of these patients with an exposure (AUC) that was significantly reduced in patients with MN.

**Funding:** Government Support - Non-U.S.
respect to complement function has not been standardized. The aim of this study was to evaluate novel complement functional assays for their application in routine follow-up of eculizumab-treated patients.

Methods: Complement activity in serum samples was analyzed using Wieslab® complement screen assay. The presence of eculizumab-C3 complexes in serum, EDTA plasma samples and in urine was measured using ELISA. Levels of sC5b-9 in urine were measured using electroluminescent epitope assay.

Results: First, we documented that the Wieslab® complement screen assay showed a sensitivity of 1-2% of C5 activity by adding purified C5 or normal human serum to a C5 deficient serum. We found that all the patient samples obtained during the standard treatment course, were completely blocked for terminal complement pathway activity. Moreover, complement remained fully blocked when intervals between the eculizumab infusions were extended to four weeks. Levels of complexes between eculizumab and C5 were inversely correlated to the complement activity (p<0.01). Third, urinary sC5b-9 levels from eculizumab-treated patients into normal serum, revealed that eculizumab was present in excess up to four weeks after infusion. Finally, we showed that increased urine sC5b-9 disappeared after eculizumab treatment.

Conclusions: We demonstrate sensitive, reliable and easy-performed assays to monitor eculizumab-treated patients, which can be used to design individual dosage regimens.

SA-PO537

Background: AKB-6548 is a novel, once-daily, oral hypoxia-inducible factor prolyl-hydroxylase inhibitor (HIF-PHI) in development for the treatment of anemia in non-dialysis dependent (NDD) and dialysis dependent (DD) chronic kidney disease (CKD). Studies in NDD-CKD patients have shown AKB-6548 produces physiologic increases in erythropoietin, enhances iron mobilization, and produces a dose dependent increase in hemoglobin levels.

Methods: The pharmacokinetics (PK) of AKB-6548 have been evaluated in single and multiple dose studies in healthy volunteers and CKD patients (NDD-CKD and DD-CKD) over a broad range of dose levels. An analysis of results across studies was conducted to assess the potential impact of renal function on selecting the dose levels and dosing regimen in CKD patients. The analyses evaluated dose-linearity in drug exposure, clearance routes of AKB-6548 and its metabolites, as well as the impact of CKD severity and the hemodialysis procedure on drug disposition.

Results: In healthy volunteers, AKB-6548 demonstrated dose linearity and proportionality over single doses of 80-1200 mg and multiple doses of 500-900 mg/day. The PK parameters of AKB-6548 in healthy volunteers, NDD-CKD and DD-CKD patients were similar except for a slightly longer half-life with declining renal function (4.7 hr., 7.9 hr. and 9.1 hr., respectively). A mass balance study (using 14C-labeled drug) in healthy volunteers demonstrated both renal and fecal routes of parent drug and metabolite clearance, supporting use of AKB-6548 in CKD patients without significant differences in drug exposure. Moreover, AKB-6548 was minimally cleared by the hemodialysis procedure and the PK parameters were similar whether AKB-6548 was administered prior to or following dialysis.

Conclusions: The results demonstrate a linear dose-exposure relationship for AKB-6548 over a wide range of dose levels and support the utility of once-daily dosing and similar dose levels across the spectrum of CKD severity.

SA-PO538
Nonclinical Pharmacokinetics and Toxicokinetics of RG-012, an Inhibitor of MicroRNA-21 Being Investigated for Treatment of Alport Syndrome John Stewart Grundy,1 Kai Liu,2 Steven Neben,1 Cindy L. Berman,2 Deidre Mackenna,1 Neil W. Gibson.1 1Regulus Therapeutics, San Diego, CA; 2Berman Consulting, Wayland, MA.

Background: RG-012 is a single-stranded chemically modified oligonucleotide being developed to treat patients with Alport syndrome, which is characterized by loss of renal function associated with defects in specific collagen genes expressed in the kidney glomerulus filtration membrane. RG-012 inhibits miR-21, a microRNA target known to have increased expression in context of kidney stress and associated with renal dysfunction.

Methods: In vitro pharmacokinetic (PK) evaluations of RG-012 conducted during preclinical development included: plasma protein binding, metabolic stability in whole blood and liver lysates, and CYP3A4 inhibition/induction potential in cryopreserved human hepatocytes. In vivo PK and toxicokinetic (TK) properties of RG-012, and its major active metabolite (RG0005), were determined upon subcutaneous dosing of RG-012 in a set of nonclinical PK, pharmacology, and safety studies in CD-1, SV129, and COL4A3 mice (6.25–450 mg/kg) and cynomolgus monkeys (10–225 mg/kg/week).

Results: Both RG-012 and RG0005 were highly bound (≥98%) to proteins in plasma from mice, monkeys, and humans. RG0005 was the only major degradation product seen in whole blood and liver lysates from all three species. RG-012 exhibited little to no displacement from actively translating polysome complexes and subsequent derepression of messenger RNA targets. As levels of Let-7a, a control microRNA to which RG-012 has no complementarity, were efficacious in the Col4A3 mouse models. Loss of miR-21 from the polysomes was specific to or following dialysis.

Conclusions: RG-012 demonstrated dose dependent displacement of miR-21 from polysomes in both liver and kidney with a maximum effect reached at dose levels that are efficacious in the Col4A3 mouse models. Loss of miR-21 from the polysomes was specific as levels of Let-7a, a control microRNA to which RG-012 has no complementarity, were unaffected. In the liver, target engagement was also assessed using mRNA derepression of a set of confirmed miR-21 target genes. Here, target gene derepression strongly correlated with polysome displacement. This comparison was not possible in kidney, however, because target genes are not regulated in kidneys in the absence of stress.

SA-PO539
Novel Methodology for Assessing Inhibition of MicroRNA-21 by RG-012, a MicroRNA Therapeutic in Development for the Treatment of Kidney Dysfunction in Patients with Alport Syndrome John Rolf Androsavich, Xueqing Liu, Shweta Pandya, Deidre Mackenna. Regulus Therapeutics, San Diego, CA.

Background: microRNA-21 (miR-21) is upregulated in animals models with kidney dysfunction and also in patients with chronic kidney disease (CKD). RG-012 is a miR-21 inhibitor entering clinical development for treatment of CKD in Alport syndrome (AS) patients. RG-012 demonstrates activity both as a monootherapy and in combination with the ACE inhibitor ramipril in the Col4A3 deficient mutant mouse model of AS.

Methods: Two distinct methods have been developed to evaluate the ability of RG-012 to inhibit miR-21 in preclinical studies – the polysome shift assay (PSA) and alterations in the expression of miR-21 target mRNAs. The PSA measures direct target inhibition at the level of the physical interaction between microRNA and messenger RNA targets. C57Bl/6 mice were treated subcutaneously with RG-012 at doses ranging from 0.1 to 100 mg/kg. Tissue homogenates were separated using sucrose gradient ultracentrifugation, with microRNAs asociating with messenger RNA targets in the heavier polysome fraction. The ability of RG-012 to displace the target miR-21 from the polysome containing fraction was used to assess direct target engagement.

Results: RG-012 demonstrated dose dependent displacement of miR-21 from polysomes in both liver and kidney with a maximum effect reached at doses that are efficacious in the Col4A3 mouse models. Loss of miR-21 from the polysomes was specific as levels of Let-7a, a control microRNA to which RG-012 has no complementarity, were unaffected. In the liver, target engagement was also assessed using mRNA derepression of a set of confirmed miR-21 target genes. Here, target gene derepression strongly correlated with polysome displacement. This comparison was not possible in kidney, however, because target genes are not regulated in kidneys in the absence of stress.

Conclusions: RG-012 directly and specifically inhibits miR-21 resulting in its displacement from actively translating polysome complexes and subsequent derepression of messenger RNA targets.

Tacrolimus Pharmacokinetics in Nephrotic Stage Mara Medeiros,1 Saul Valverde,1 Luis Velasquez-Jones,1 Ana M. Hernández,2 Gilberto Castañeda-Hernández,2 Guido Filler.1 1Hospital Infantil de México Federico Gómez, Mexico; 2CINVESTAV, IPN, Mexico; 3Children's Hospital, Univ of Western Ontario, Canada.

Background: While tacrolimus (Tac) therapy is not first-line therapy for childhood nephrotic syndrome, it is often used instead of cyclosporine to ameliorate the side effects. The pharmacokinetics of Tac can be influenced by many conditions, and it has a high plasma protein binding. The Tac pharmacokinetics during relapse and remission of childhood nephrotic syndrome have not been well described.

Methods: We performed 14 pharmacokinetic (PK) profiles (with measurements before and 0.5, 1, 2, 4 and 12 hours post intake) in 7 children with steroid-resistant nephrotic syndrome (SRNS) during relapse and in remission. These data were compared with historical PK data of 161 PK profiles in 87 pediatric renal transplant recipients with measurements before 0.5, 1, 5, 11, 15, 23, 48, 6, 8 and 12 hours post intake. Tac levels were measured using the Abbott Tacro II assay. We used descriptive statistics to generate percentiles and compared these with the SRNS patients. We also compared the PK profiles during relapse and remission.

Results: Median age of SRNS patients was 3.2 years. Tacrolimus dose, biochemical values and pharmacokinetics parameters are shown in Table 1. Values as median and interquartile range.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Clinical and Genetic Determinants of Longitudinal Dose-Corrected CNI Exposure in Children After Renal Transplantation

Background: Calcineurin-inhibitors (CNI) have a narrow therapeutic index and dosing is difficult due to inter- and intra-individual variation in pharmacokinetics (PK). Polymorphisms in genes involved in drug metabolism can play a critical role in individual exposure. Data concerning long-term CNI exposure in relation to dose in children are scarce and based in general upon trough levels. We present the longitudinal follow up of 12-hour CNI PK in relation to dose, clinical and genetic factors in a cohort pediatric renal allograft recipients.

Methods: Retrospective single center study in subjects after renal transplantation (age 0-20 yrs) with annual PK assessments (6-point AUC0-12hr) for tacrolimus (Tac) or cyclosporine (CsA). Clinical and laboratory data were retrieved. Analysis of polymorphisms CYP3A4, CYP3A5, CYP3A7, POR was performed.

Results: We collected 180 “full” AUCs for Tac, 56 for CsA in 51 kids. Mean age at Tx: 9.9 yrs(1-19); FU after Tx: 4.6 yrs (0-16). Dose-corr. exposure (AUC/Dose in mg/hr/ml) was demonstrated stable dose-corr. exposure for ages <15 yrs, and was higher only for >15 yrs (Tac: <5yrs-15 yrs: 44 (95%CI: 40-48) >15yrs: 73.4 ng hr/ml per mg/m2; CsA: 31 (26-38) ng hr/ml per mg/m2). Significant associations of TTT to Tac dose, CL and AUC/TBW were noted with sex sub-analysis and summarized as Phenotypic Mean with 95%CI of WT compared to variant  in table. These data suggest RTR with higher doses in AA (P<0.0001). Significant associations of TTT to Tac dose, CL and AUC/TBW were noted with sex sub-analysis and summarized as Phenotypic Mean with 95%CI of WT compared to variant  in table. These data suggest RTR with higher doses in AA (P<0.0001).

Conclusions: Sex-race differences in TAC PK contribute to differential dosing requirements in AA vs C. A more individualized approach to chronic TAC immunosuppression integrating sex-race with TDM and a standardized adverse effect assessment may benefit RTR.

Sex and ABCB1 Haplotypes Associations with Tacrolimus Pharmacokinetics in Renal Transplant Recipients

Background: Tacrolimus (TAC) is the primary calcineurin inhibitor in immunosuppression in renal transplant recipients (RTR). TAC exhibits interpatient variability in pharmacokinetics (PK) attributed primarily to CYP 3A5 isoenzymes and P-glycoprotein (Pgp). Pgp is encoded by the ABCB1 gene. The common single nucleotide polymorphisms (SNPs): rs1045642 and rs2032582, have conflicting associations to TAC PK. This study objective evaluated these common SNP as haplotypes in relation to TAC PK.

Methods: During a 12-hr PK study, trough (C0), apparent clearance (CL) and lean body weight (LBW) normalized CL were determined in 29 female and 36 male African American (AA) and Caucasian (C) stable RTR greater than 6 months post-transplant receiving TAC and mycophenolic acid. TAC dosage was adjusted to C0 range of 4-9 ng/ml. The ABCB1 SNPs: c.1236C>T/rs1128501, c.2677G>T/rs2032582, and c.3435C>T/rs1045624 have conflicting associations to TAC PK. This study objective evaluated these common SNP as haplotypes in relation to TAC PK.

Results: The ABCB1 haplotypes have important impact into interpatient variability in TAC PK post renal transplant and the role of P-gp that is also influenced by sex. Results: The ABCB1 SNPs c.1236C>T/rs1128501, c.2677G>T/rs2032582, and c.3435C>T/rs1045624 have conflicting associations to TAC PK. This study objective evaluated these common SNP as haplotypes in relation to TAC PK.

Conclusions: The ABCB1 haplotypes provide important insight into interpatient variability in TAC PK post renal transplant and the role of P-gp that is also influenced by sex.

Pharmacokinetics and Pharmacodynamics of Tacrolimus, and NFAT Regulated Gene Expression in Kidney Transplant Patients

Background: Suppression of genes that are regulated by the nuclear factor of activated T-cells (NFAT) is an effect of calcineurin inhibitors. We correlated the pharmacodynamics to the pharmacokinetics of tacrolimus.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

478A
Methods: This study was undertaken in the University Hospitals of Ulm (Frieder Keller) and Heidelberg (Claudia Sommerer, Thomas Giese, Martin Zeier). Tacrolimus trough concentrations (Trough) and 1.5 – 2 hours later the peak concentrations (Cpeak) were measured by LCMS. Simultaneously, the NFAT trough effect (Trough) and the nadir effect (Enadir) were determined. The pharmacokinetic half-life (T1/2) was estimated from peak (Cpeak) and trough concentrations (Trough) considering the time distance between steady-state peak and troughs (10.5 – 10 hours). The pharmacodynamic concentration producing the half-maximum effect (CE50) and the Hill coefficient (H) were estimated from trough effect (Trough) at trough concentrations and from nadir effect (Enadir) at peak concentrations. The two equations were solved by numerical iteration for an estimate of the two unknown parameters (CE50, H).

Results: A total of 10 stable kidney transplant patients were included. The median age was 58 years and the median serum creatinine was 306 µmol/l. The pharmacokinetics of tacrolimus were estimated with T1/2 = 11 hours, CL/F = 64 l/h and Vd/F = 480 l. The median value for NFAT was 89% (Trough) of normal gene expression, and the nadir effect was 43% (Enadir) representing the strongest immunosuppression of basal gene expression. The pharmacodynamics of tacrolimus were estimated with CE50 = 7.7 ng/ml and the Hill coefficient with H = 4.6, respectively.

Conclusions: While on triple immunosuppression, the NFAT pharmacodynamics indicate a low concentration producing the half-maximum effect and a high Hill coefficient. These findings suggest a narrow trough-to-peak target concentration range of 4.0 to 9.5 ng/ml for tacrolimus.

SA-PO546
Renal Nitrate Clearance in Chronic Kidney Disease

Background: Endogenously synthesised nitric oxide (NO) is rapidly oxidised to nitrate and nitrite. These oxidation products can be recycled back into nitric oxide via a complex entero-salivary pathway, thus preserving NO activity. It has previously been shown that 60% of circulating nitrate is excreted in the urine in 48 hours with the fate of the remainder unknown. 24-hour urinary nitrate excretion is often used to estimate total body nitrite oxide synthesis rates. It is not known what effect declining GFR has on renal nitrate clearance.

Methods: 27 subjects, 14M,13F, median age 70 (range 27-74 years) with CKD-EPI eGFR between 9 and 89 were recruited. Following 24h low nitrate diet plasma nitrate concentration and 24 hour urinary nitrate excretion were measured to determine renal nitrate clearance using a microplate spectrophotometric method. We used a 1-compartment model to investigate nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitrite oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.

Conclusions: As plasma nitrate concentration is unchanged despite diminished renal nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitrite oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.

2-Sample Iohexol Plasma Clearance: The Clear Choice for Measuring Kidney Function in Rats

Mandy E. Turner, Kimberly J. Laverty, Martin Kaufmann, Glennie Jones, Rachel M. Holden, Michael A. Adams, School of Medicine, Queen’s Univ, Kingston, ON, Canada.

Background: The lack of simple and sensitive tools for longitudinal kidney function assessment in rodent models has impeded analysis of CKD onset and progression and the development of novel therapies. Two reference methods for pCl calculation were used: a 2-compartment model (2 COM) measured via the Jaffrey method, FITC-inulin via fluorometry, and iohexol via UPLC-MS. The pharmacodynamics of tacrolimus were estimated with CE50 = 7.7 ng/ml and the Hill coefficient (H) were estimated from trough effect and from nadir effect considering the time distance between steady-state peak and troughs (10.5 – 10 hours). The pharmacodynamic concentration producing the half-maximum effect (CE50) and the Hill coefficient (H) were estimated from trough effect (Trough) at trough concentrations and from nadir effect (Enadir) at peak concentrations. The two equations were solved by numerical iteration for an estimate of the two unknown parameters (CE50, H).

Methods: Progressive CKD was induced with a 0.25% adenine diet in male Sprague-Dawley rats (N=8). Following serial tail vein injections of iohexol (51.92 mg/kg) and a radio-contrast agent, compared to previously validated inulin pCl in rats to estimate GFR.

Results: Plasma creatinine was not significantly elevated and trapezoidal approximation (TRA) of area under the curve. Two reference methods for pCl calculation were used: a 2-compartment model (2 COM) measured via the Jaffrey method, FITC-inulin via fluorometry, and iohexol via UPLC-MS. The pharmacodynamics of tacrolimus were estimated with CE50 = 7.7 ng/ml and the Hill coefficient with H = 4.6, respectively.

Conclusions: While on triple immunosuppression, the NFAT pharmacodynamics indicate a low concentration producing the half-maximum effect and a high Hill coefficient. These findings suggest a narrow trough-to-peak target concentration range of 4.0 to 9.5 ng/ml for tacrolimus.

Triferic Does Not Induce Non-Transferrin Bound Iron or Labile Plasma Iron: In-Vitro/In-Vitro Correlation

Raymond D. Pratt,1 Dorine W. Swinkels,2 Carrie D. Guss,1 Ajay Gupta.1 1R&D, Rockwell Medical Inc., Wixom, MI; 2Radioud Univ Medical Center, Nijmegen, Netherlands.

Background: Triferic is a complex iron salt approved for administration via hemodialysis to maintain hemoglobin in patients with CKD HD. Triferic crosses the dialyzer membrane and binds to transferrin during hemodialysis replacing the obligatory iron losses in HD patients. Serum iron and transferrin saturation (TSAT) values rise after HD and return to the baseline by the start of the next dialysis session.

Methods: A pharmacokinetic (PK) study in healthy volunteers administered up to 10 mg of Triferic iron over 4 hours and up to 20 mg Triferic iron over 12 hours assessed the PK of serum total iron (sFe-total) and transferrin bound iron (TBI). An in-vitro study assessed labile plasma iron (LPI). Triferic iron was added to plasma like medium (40 mg/mL human serum albumin) at a concentration range of 0 to 112 mg/dL. In addition, Triferic was added to 5 different human plasma’s (TSAT, range 10 - 46%; total iron binding capacity (TIBC), mean 374 mg/dL, range: 342-446 mg/dL) across a concentration span up to and exceeding 100% TSAT. LPI was measured in the presence of 40 mM ascorbate using dihydrodorohadmine (DHR)-123 in the presence of 50 mM deferiprone (DFO) to detect iron-catalyzed radical generation.

Results: In the human PK study, sFe-total and TBI showed an identical PK profile. Non-transferrin bound iron (NTBI), calculated as the difference between sFe-total and TBI, showed no dose dependent increase up to a TSAT of 100%. In plasma like medium, LPI increased with increasing concentrations of Triferic iron. When Triferic was added to human plasma, there was a small increase in LPI observed when iron concentrations were less than 100% TSAT. The mean magnitude of LPI (expressed in concentration units) at approximately 100% TSAT was 5.35 mg/dL (mean 1.4% of the total iron concentration). Once 100% TSAT was exceeded, the LPI increased rapidly.

Conclusions: Triferic rapidly donates iron to transferrin in vivo and in vitro. In vivo, at TSAT less than 100%, NTBI was minimal. In vitro, the LPI results confirm the lack of redox active iron in plasma until the plasma TIBC is exceeded.

Impact of Tubular Luminal H+/Organic Cation Antiporter, MATE, on Imatinib-Induced Fluid Retention

Moto Kajiwara,1 2 Satohiro Masuda.1 1Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; 2Dept of Research and Development of Next Generation Medicine, Kyushu Univ, Fukuoka, Japan.

Background: A tyrosine kinase inhibitor, imatinib (IMA) is the first class agent against chronic myeloid leukemia. Although little is known about mechanism involved, more than 50% of imatinib-treated patients suffering from edema. In vitro study reported that clinical blood level of IMA inhibits multidrug and toxin extrusion (MATE, SLC47A)-mediated transport of metformine, a hypoglycemic drug. MATE is highly expressed in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin, monamines. The renal dopaminergic system is likely responsible for regulating >50% of net renal salt and water excretion when salt intake increases. In this study, we test a hypothesized that IMA prevents natriuresis by inhibiting MATE-mediated dopamine (DA) secretion into tubule lumen and consequently causes edema.

Methods: C57BL/6 wild type mice (WT) and Mate1 knockout mice (KO) were used. CYP3A4 and 3A5 expressed in HepG2s for 24 h, when cells were lysed. Underline represents presenting author.

Conclusions: More than 50% of imatinib-treated patients suffering from edema. In vitro study reported that clinical blood level of IMA inhibits multidrug and toxin extrusion (MATE, SLC47A)-mediated transport of metformine, a hypoglycemic drug. MATE is highly expressed in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin, monamines. The renal dopaminergic system is likely responsible for regulating >50% of net renal salt and water excretion when salt intake increases. Optimizing Between-Patient Variability in Response to Renoprotective Drugs: Meta-Analysis of Rotation Trials

Sergei Petrovsky,1 Dick de Zeeuw,2 Frederik I. Persson,2 Peter Rosling,2 3 Hans-Henrik Parving,1 Gezowijn Dirk Laverman,1 Hiddo Jan Lambers Heerspink.1 1Univ Medical Center, Groningen, Netherlands; 2Steno Diabetes Center, Gentofte, Denmark; 3Univ Copenhagen, Denmark.

Background: Individual response to albuminuria lowering intervention is highly variable between patients. To investigate whether up titrating the dose of drug, changing the mode of intervention (with similar or different drug classes), or lowering dietary sodium intake improves individual response variability, we meta-analyzed individual responses to different modes of anti-albuminuric intervention in non-diabetic and diabetic patients.

Methods: Randomized rotation trials were analyzed to assess correlation of patient-specific responses (n=216 patients) to anti-albuminuric interventions. Included studies (N=20) compared the anti-albuminuric effect of up titrating the dose of intervention in the RAS (RASi) (N=10 comparisons) and NSAIDS (N=1), rotation within the same class of RASi (e.g. ACEi to ARB; N=5) or NSAIDs (N=3), rotation between RASi and NSAIDs (N=2), and rotation from high to low sodium intake during RASi (N=1). A two stage meta-analysis was performed. First, deeming regression was conducted in each study to assess correlation in response. Individual study results were then meta-analyzed. Albuminuria was measured in 24-hr urine samples.

Results: The albuminuria response to one dose of RASi or NSAID positively correlated with the response to a higher dose of RASi or NSAID, rotation within the same class of RASi or NSAIDs, rotation between RASi and NSAIDs, and rotation from high to low salt intake. Correlations were consistent in diabetic and non-diabetic patients.

Conclusions: The correlations observed in this study indicate that patients poorly responding to one dose or mode of albuminuria lowering intervention also respond poorly to other doses or modes of intervention in the RAS. Whether other drugs targeting pathways beyond the RAS improve individual response variability requires further study.

Acute Kidney Injury Serum Ureaplates Hepatic Transcription of Cytochrome P450 3A4 and 3A5

Katie Lane,1 John Dixon,1 Ekram Nabi,2 Barbara J. Philips,1 Iain Macphee,1 Mark E. Dockrell,2 1Critical Care, St. George’s Univ of London, United Kingdom; 2South West Thames Inst for Renal Research, United Kingdom; 3Renal Medicine, St. George’s Univ of London, United Kingdom.

Background: Hepatic drug metabolism by cytochrome P450 3A (CYP3A) is reduced in end stage kidney disease (ESKD) and acute kidney injury (AKI). The underlying mechanisms are uncertain. Previously we reported suppression of CYP3A4 mRNA transcription when human hepatocytes ( HepG2) were exposed to serum from ESKD patients compared to healthy adults. CYP3A4 and 5 protein concentrations were unchanged. We now investigate whether serum from patients with AKI elicits similar results.

Methods: Serum was collected from critically ill adults with varying AKI severity. Sera from 1KDGIO 0 (n=15) and KDIGO 3 (n=16) AKI patients were applied individually to HepG2s for 24 h, when cells were lysed. CYP3A4 and 3A5 gene expression was examined by RT-qPCR. CYP3A4 and CYP3A5 protein expression was examined by Western blotting. The sera were also applied to HepG2 in a pooled fashion, alongside pooled sera from adults with ESKD prior to hemodialysis (n=10) and healthy adults (n=6), to allow comparison with previous data.

Results: AKI serum exposure doubled CYP3A4 gene expression compared to No AKI serum (p=0.005 significant and p=0.003 pooled). AKI serum CYP3A5 mRNA increased approx. 25% compared to No AKI serum (p=0.11 individual and p=0.0098 pooled).

Comparison of Pooled Serum (10%) Effects on HepG2 CYP3A4 and CYP3A5

750A 750A
Results: Indoxyl sulfate caused a concentration-dependent decrease in Huh7 CYP3A4 expression with an IC50 value of 179.8 ± 20.1 μM. In CKD rats, indoxyl uremic toxins: indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD animals and similar to control animals. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD (P<0.05); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased AST-120 had indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD animals and similar to control animals. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD (P<0.05); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased hepatic CYP2C11 mRNA expression that was not recovered by AST-120.

Conclusions: Uremic concentrations of indoxyl sulfate decreased CYP3A4 mRNA expression in Huh7 cells. AST-120 given to rats with CKD reduced indoxyl sulfate, p-cresyl sulfate and hippuric acid levels similar to control levels. Hepatic CYP3A2 mRNA expression was decreased in CKD and partially recovered by AST-120. AST-120 did not affect the downregulation of CYP2C11 in rats with CKD. Therefore, gut-derived uremic toxins may partially mediate the downregulation of hepatic CYP3A in CKD.

SA-PO555

The Effect of AST-120 on Hepatic and Intestinal Drug Transporter Expression in Chronic Kidney Disease

Andrew S. Kucey, 1 Thomas Velenosi, 1 Alvin Tieu, 1 Stephanie E. Nevison, 1 Brad Urquhart. 1,2 ’Dept of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada; 1Lawson Health Research Inst, London, ON, Canada.

Background: Chronic kidney disease (CKD) is the progressive decline in renal function over time. There is a marked reduction in both renal and non-renal drug clearance in CKD. AST-120 is an oral absorbent that promotes the elimination of gut-derived toxins that accumulate in CKD due to impaired clearance. It is hypothesized that there will be a reduction in the expression of drug transporters in CKD conditions. AST-120 will help recover drug transporter expression in CKD by decreasing uremic toxins that accumulate in CKD.

Methods: In vivo: CKD was induced in Wistar rats by treatment with adenine (0.7%) in standard rodent chow for 7 weeks. Treatment groups received AST-120 in the final 3 weeks to decrease the concentration of uremic toxins. Expression of hepatic and intestinal transporters were determined by real-time PCR. In vitro: Using the human hepatoma cell line Huh7, specific uremic toxins (e.g. indoxyl sulfate, p-cresyl sulfate, CMPF) will be tested to see if they directly impair rosuvastatin transport. Rosuvastatin uptake will be measured with ultra-performance liquid chromatography coupled to mass spectrometry.

Results: Preliminary results have shown that OATP2 expression is decreased by 25% in CKD rat livers compared to control. Treatment with AST-120 causes a significant reduction in the plasma concentration of the uremic toxins indoxyl sulfate and p-cresyl sulfate. AST-120 treatment restores OATP2 expression to control levels.

Conclusions: Decreased hepatic OATP2 expression in CKD will result in reduced clearance of substrate drugs. This could lead to toxicity if a lowered dose is not administered. On average a CKD patient will be co-prescribed 10 different drugs. Clarifying the impact of CKD on drug transporter expression and activity will help guide dosing in this patient population.

SA-PO554

Patient Characteristics and Genetics Contribute to Kidney Function After Cisplatin Therapy

Cara A. Chang, 1 Nickie L. Johnston, 1 Madeleine Gomez, 1 Lucas Ellison, 1 Lauren Alekxunes, 2 Steven R. Kleeberger, 1 Cindy L. O’Bryant, 1 Melanie S. Joy. 1 ’Skaggs Schools of Pharmacy and Medicine, Univ of Colorado, Aurora, CO; 2’Ernest Mario School of Pharmacy, Rutgers Univ, NJ; 1NIHHS.

Background: It is known that kidney function can decline after a single dose of cisplatin necessitating alternate chemotherapy regimens. The current study explored the contribution of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to cisplatin kidney disposition on changes to renal function.

Methods: Blood (5mL) was obtained from patients (n=206) who received cisplatin. Genotyping assessments included candidate SNPs in kidney uptake and efflux transporters (SLC22A4, ABCB2, SLC47A1) and metabolism pathways (GSTA1, GSTP1, GGT1). Genotyping was performed using QuantStudio multiplex assays and coded [0( wt/ wt), 1( wt/var), or 2( var/var)]. Glomerular filtration rate (GFR, mL/min/1.73m2) and changes from baseline to 6 months after the time of cisplatin were calculated. Univariate and multivariate analyses were performed using patient characteristics and genotyping results.

Results: Patient demographics (mean±sd) included: age 55±14 y, weight 80±12 kg, BSA 1.9±0.3, Caucasian 90%, gender (50%M/50%F), and cisplatin dose (65±23 mg/m2). Specific patient characteristics that significantly (p<0.05) contributed to a beneficial effect on GFR were non-Caucasian race, baseline GFR, and non-fractonated cisplatin dosing. Genetic variant in GSTP1/GST pi-1 variant (rs1695) and wildtypes in SLC22A4/OCR2 (rs2279463 and rs3127573) significantly (p<0.05) contributed to a beneficial effect on GFR. Variables retained in the final model (R² 25.23%, P <0.0001) were: Change in GFR: 38.083 - 0.1714 (weight) – 0.3685 (baseline GFR) + 5.893 (GSTP1; rs1695).

Conclusions: The results from this study demonstrate the combined role of patient characteristics and genetic variants in drug disposition genes on changes to GFR secondary to cisplatin. Appropriate risk stratification based on patient characteristics and genetics may be used to simplify precision medicine to reduce the risk of kidney injury from cisplatin and potentially other nephrotoxins.

Funding: NIDDK Support
in LN patients. Pharmacokinetics of CTX and 4-hydroxycyclophosphamide (4OHCTX) were obtained from 22 patients randomly enrolled from 77 LN patients and applied to explore the mechanism.

Results: GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX treatment in these 77 LN patients. LN patients with a GSTA1*4 mutation (CT heterozygous) had a risk of none-response (P = 0.005).

Data suggest that FGF23 may directly suppress osteoblast maturation and mineralization, even when removed from the uremic milieu. We thus hypothesized that treatment response due to less exposure to activated 4OHCTX. A pharmacogenomic approach using the GSTA1 SNP may be useful for predicting clinical efficacy to CTX therapy in LN patients, and facilitating individualized therapy.

Pharmacokinetics data indicated that patients with a GSTA1*4 heterozygous variant had a lower exposure to 4OHCTX compared to wild-type patients (12.8(9.8, 19.5) μg/ml, P = 0.038), but not CTX. And clinical efficacy was significantly related to higher exposure to 4OHCTX, (P = 0.038).

Conclusions: LN patients with GSTA1*4 heterozygous genotypes had poor CTX treatment response due to less exposure to activated 4OHCTX. A pharmacogenomic approach using the GSTA1 SNP may be useful for predicting clinical efficacy to CTX therapy in LN patients, and facilitating individualized therapy.

Effect of Growth Factors on Bone Mineralization in Health and CKD

Nadine Khouzam,1 Renata C. Pereira,1 Isidro B. Salusky,2 Richard E. Bowen,2 Katherine Wesseling-Perry,1 1Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; 2Orthopedics, David Geffen School of Medicine at UCLA, Los Angeles, CA.

Background: Children with chronic kidney disease (CKD) develop unexplained resistance to PTH and GH. Moreover, bone expression of FGF23 is very high in CKD. Data suggest that FGF23 may directly suppress osteoblast maturation and mineralization in mice (Weng JBMR 2009); however, it is not known whether excess expression of this hormone has direct effects on bone cells in CKD. We have previously demonstrated that primary osteoblasts isolated from patients with CKD have altered proliferation, differentiation and mineralization characteristics, suggesting that CKD results in intrinsic changes to osteoblast biology, independent of circulating mineral ion and hormone concentrations.

Methods: To evaluate the interaction between CKD and 1,25D therapy on osteoblast maturation and mineralization, primary human osteoblasts from 3 healthy controls, 3 pediatric dialysis patients with low bone turnover (adynamic bone) and 3 pediatric patients with high bone turnover (2HPT) were cultured under pro-mineralizing conditions consisting of 10μM β-glycerolphosphate and 100 μg/ml ascorbic acid in the presence of 1,25D at 1, 2.5, and 4 weeks of growth under mineralizing conditions, cells were washed with PBS, fixed with 10% formalin, and stained with 2% Alizarin Red S. The amount of mineral content was assessed by measuring absorption of acetic acid-extracted Alizarin Red S dye (at 405 nm) normalized by live cell concentration (as assessed by absorption at 570 nm) of methanol-extracted Crystal Violet staining obtained from parallel cultures.

Results: Diminished mineralization is present in CKD; as previously demonstrated in pediatric patients. Further studies are required to assess whether PTH, IGF1 and FGF23 have an effect on mineralization of human osteoblasts.

Conclusions: Children with chronic kidney disease develop unexplained resistance to PTH and GH. Moreover, bone expression of FGF23 is very high in CKD. Data suggest that FGF23 may directly suppress osteoblast maturation and mineralization in mice (Weng JBMR 2009); however, it is not known whether excess expression of this hormone has direct effects on bone cells in CKD. We have previously demonstrated that primary osteoblasts isolated from patients with CKD have altered proliferation, differentiation and mineralization characteristics, suggesting that CKD results in intrinsic changes to osteoblast biology, independent of circulating mineral ion and hormone concentrations.

Methods: To evaluate the interaction between CKD and 1,25D therapy on osteoblast maturation and mineralization, primary human osteoblasts from 3 healthy controls, 3 pediatric dialysis patients with low bone turnover (adynamic bone) and 3 pediatric patients with high bone turnover (2HPT) were cultured under pro-mineralizing conditions consisting of 10μM β-glycerolphosphate and 100 μg/ml ascorbic acid in the presence of 1,25D at 1, 2.5, and 4 weeks of growth under mineralizing conditions, cells were washed with PBS, fixed with 10% formalin, and stained with 2% Alizarin Red S. The amount of mineral content was assessed by measuring absorption of acetic acid-extracted Alizarin Red S dye (at 405 nm) normalized by live cell concentration (as assessed by absorption at 570 nm) of methanol-extracted Crystal Violet staining obtained from parallel cultures.

Conclusions: Diminished mineralization is present in CKD; as previously demonstrated in pediatric patients. Further studies are required to assess whether PTH, IGF1 and FGF23 have an effect on mineralization of human osteoblasts.

CKD Induces Intrinsic Alterations in Osteoblast Response to 1,25D

Renata C. Pereira,1 Nadine Khouzam,1 Richard E. Bowen,2 Isidro B. Salusky,2 Katherine Wesseling-Perry,1 1Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; 2Orthopedics, David Geffen School of Medicine at UCLA, Los Angeles, CA.

Background: Skeletal mineralization defects are common in pediatric CKD patients. In vivo 1,25(OH)2 vitamin D (1,25D), the only currently approved therapy for the treatment of 2HPT in children, fails to normalize skeletal mineralization in these patients. We have recently demonstrated that primary osteoblasts obtained from patients with CKD have altered proliferation, differentiation and mineralization characteristics, suggesting that CKD results in intrinsic changes to osteoblast biology, independent of circulating mineral ion and hormone concentrations.

Results: Diminished mineralization is present in CKD; as previously demonstrated in pediatric patients. Further studies are required to assess whether PTH, IGF1 and FGF23 have an effect on mineralization of human osteoblasts.

Conclusions: Children with chronic kidney disease develop unexplained resistance to PTH and GH. Moreover, bone expression of FGF23 is very high in CKD. Data suggest that FGF23 may directly suppress osteoblast maturation and mineralization in mice (Weng JBMR 2009); however, it is not known whether excess expression of this hormone has direct effects on bone cells in CKD. We have previously demonstrated that primary osteoblasts isolated from patients with CKD have defects in maturation and mineralization, even when removed from the uremic milieu. We thus hypothesized that CKD-mediated alterations in osteoblast maturation may contribute to a blunted response to growth factors in pediatric CKD.

Methods: Human osteoblasts isolated from 3 patients with CKD and 3 normal controls were grown to confluence and induced to mineralize. Cells were treated twice weekly with fresh media and 100 nm of PTH, 200ng/ml of IGF1 or 10ng/ml of FGF23 for 0, 2 and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.
Fourier Transform Infrared Spectroscopy Crystallinity Indices in Bone from Patients with ADPKD Renata C. Pereira, 1 Berenice Y. Gitomer, 1 Isidro B. Salusky, 1 Diana George, 2 Jason W. Stoneback, 2 Karen B. King, 3 Myles S. Wolf, 2 Michael Chonko, 2 1Pediatrics, UCLA, Los Angeles, CA; 2Medicine, University of Colorado, Aurora, CO; 3Orthopaedics, Univ of Colorado, Aurora, CO; 4Nephrology, Northwestern Univ, Chicago, IL.

Background: We have previously shown that patients with autosomal dominant polycystic kidney disease (ADPKD) and normal kidney function have a low bone turnover state. This is coupled with increased expression of fibroblast growth factor 23, dentin matrix protein 1 and osteopontin in bone compared to healthy controls. To further characterize the bone defect in ADPKD fourier transform infrared (FTIR) spectroscopy was undertaken.

Methods: With an average eGFR 111 ml/min/1.73m2 and normal parathyroid hormone levels underwent standard tetracycline double labeling prior to transilac crest bone biopsy. FTIR imaging was performed on bone sections from 6 ADPKD patients and 6 age and sex matched healthy historical controls.

Results: The mean eGFR of ADPKD patients were 29±4 yrs and 115 ml/min/1.73m2, respectively. The sex distribution was 5 males and 1 female. Crystallinity a measure of the size of mineral crystals and the degree of order within the crystals was obtained by FTIR and differed significantly between ADPKD and control samples. The differences were more pronounced in the cortices (1.22 vs. 1.19; p = 0.03) than in the trabeculae (1.19 vs. 1.17; p=0.48). There were no significant differences in heterogeneity of crystallinity, mineral/matrix, carbonate/mineral, collagen maturity (cross links) or acid phosphate substitution between ADPKD and historical control samples.

Conclusions: We describe for the first time a significant difference in the chemical composition of cortical bone measured by FTIR in patients with ADPKD when compared to historical control bone samples. Bone crystallinity has been associated with bone strength and stiffness, it is thus intriguing to hypothesize that the observed changes may impact bone quality and expression of bone proteins in ADPKD. Future studies that also assess bone strength and stiffness will be required to more fully investigate bone quality in ADPKD.

Funding: NIDDK Support

Late Onset Avascular Osteonecrosis in Renal Transplant Recipients Spyridon Arampatzis, Anita Maurer, Vasileios Devetzis, Uyen Huynh-do, Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital Bern, Inselpital, Bern, Switzerland.

Background: Avascular osteonecrosis (AO) after renal transplantation (RT) is a debilitating skeletal complication. In most studies patients with AO presented within the first 24 months after RT. In order to determine the prevalence and therapeutic outcome of late onset AO (24 months after RT) we conducted a single-center retrospective study based on radiological/histological confirmed cases.

Methods: We conducted a single-center retrospective study among our RTR with a clinical diagnosis of AO over the past two decades. We evaluated 70 cases with a AO. In 46 patients AO was radiological/histological confirmed and all relevant clinical, radiological and laboratory data were extracted and analyzed.

Results: The average follow-up time was 14 (±8) years after the first RT. The prevalence of AO was 5.4%. Overall, 41 patients showed AO of the femoral head, 23 bilateral AO of the femoral head 5 of the knee and 5 of other locations, while 43 patients were symptomatic at the time of diagnosis. The mean age at the time of onset (379 ± 124 months) of AO after RT. On average, AO was diagnosed 90 months after RT (SD±78). Furthermore, RTR with late onset were younger at the time of diagnosis. In our cohort 71% presented late onset (³24 months) AO after RT. AO of the femoral head was diagnosed in 34% of patients AO was radiological/histological confirmed and all relevant clinical, radiological and laboratory data were extracted and analyzed.

Conclusions: Late onset avascular necrosis represent a corticosteroid related complication, with a particularly high prevalence among young RTR and is associated with their first RT (48%) compared to the group of early onset (15%; p=0.038). Overall, 34% of patients AO was younger at the time of first RT (39 ± 18 years, HD duration; 14.3 ± 6.8 years ) were treated by total parathyroidectomy with immediate autotransplantation (parathyroidectomy) and received iliac bone biopsies before and at 1 week (n=4) and at 4 weeks (n=10) after parathyroidectomy. Adipocyte volume per marrow volume (Fa/Va/V), adipocyte number per marrow volume (N/Fa/Ma/V/mm3), and mean adipocyte volume (Fa/Va/V) (x 103 mm3/n) were obtained in the area away from bone surface. If there are so many artifacts in bone marrow, the bone samples were excluded from this research.

Funding: Private Foundation Support
mass and osteopenia cellularly with marrow adiposity, compromising dynamic parameters. MSCs differentiation is competitively balanced; mechanisms that promote one cell fate actively suppress mechanisms that include the alternative.

SA-PO564
High Marrow Adiposity Is Associated with Low Turnover Bone Disease in Peritonal Dialysis Patients

Evelyne C. Barreto, 1 Rodrigo Azvedo de Oliveira, 1 Mariel Jose Hernandez, 2 Ana Clara Simões Florindo Almeida, 1 Luciene dos Reis, 2 Aluizio B. Carvalho, 3 Vanda Jorgetti, 4 Rosa M.A. Moyses, 2, 4 Pontificia Univ Católica do Paraná; 1Univ de São Paulo; 2Univ Federal de São Paulo; 1Univ Novo de Julho, UNINOVE; 1Univ Federal do Rio Grande do Norte; 1Univ de Caracas.

Background: Marrow adiposity has been implicated in the pathogenesis of bone disorders, such as osteoporosis and bone fragility. We sought to investigate the relationship between marrow adiposity and renal osteodystrophy in peritoneal dialysis patients.

Methods: We analyzed transilic bone biopsy specimens from 41 peritoneal dialysis patients (age:50.3±10.2 yrs) by quantitative histomorphometry to assess bone and marrow adipocyte parameters. Selected biochemical parameters, such as serum markers of bone turnover and sclerosin, were measured.

Results: Adipocyte area (Ad.Ar), perimeter (Ad.Pm) and percentage of adipocyte volume per marrow volume (Ad.V/Ma.V) correlated positively with age. Diabetic patients had higher marrow adiposity than non diabetic patients (Ad.V/Ma.V: 50.14±39.12%, P=0.009; Ad.Ar:619.06±0.6 vs 51.05.05 mm², P=0.02). Ad.V/Ma.V demonstrated inverse association with bone specific alkaline phosphatase (r=−0.32;P=0.04) and direct relationship with sclerostin (r=0.38; P=0.01). No association was found between marrow adiposity and dynamic bone histomorphometric parameters. Interestingly, patients with Ad.V/Ma.V >41% (median) presented higher percentage of low turnover bone disease (P=0.04) as well as significantly lower bone specific alkaline phosphatase (39.5±23.7 vs 65.3±25.9 U/L; P=0.006) and higher sclerostin (2.3±0.97 vs 1.6±0.97 ng/mL; P=0.02) levels than patients below the median.

Conclusions: Increased marrow adiposity seems to be associated to lower osteoblast activity and to lower turnover bone disease in peritoneal dialysis patients. The higher marrow fat in diabetic and aged patients might expose them to an increased risk for fracture. Further studies are needed to understand the possible contribution of marrow adiposity to the pathogenesis of renal osteodystrophy.

SA-PO565
Role of Wnt10b Signaling in Cinacalcet-Induced Bone Anabolic Effects

Chung-Mei Zheng, 1 2 3 Ying-Ho Hsu, 1 4 Yuh-Feng Lin, 1 2 3 Jia-Fwu Shyu, 1 2 3 Kuo-cheng Lu, 2 3 4 5 Graduate Inst of Clinical Medicine, Taipei Medical Univ, Taipei City, Taiwan; 2Dept of Nephrology, Shuang Ho Hospital, New Taipei City, Taiwan; 3Biology and Anatomy, National Defense Medical Center, Taipei City, Taiwan; 4Dept of Medicine, Cardinal-Tien Hospital, New Taipei City, Taiwan.

Background: Chronic kidney disease-mineral bone disorders (CKD-MBD) is important for osteoporosis and bone fractures in CKD patients. Since calcium receptor plays an important role in osteostatic differentiation, we assume that calcimimetic agents (cinacalcet) might have a role in bone remodeling.

Methods: Bone marrow mononuclear cells isolated from rat femur and tibia were induced into osteoclasts by M-CSF and RANKL treatments. Osteoclasts were treated with different doses of cinacalcet. untreated osteoclasts used as control. The release of clastokines (i-PTH) levels decrease from 903.6 ± 503.0 to 212.7 ± 98.1 pg/ml after the treatment with cinacalcet HCL and received bone biopsies before and at 1 year after the treatment (Group II). Osteocyte number in micro-petrosis area (N.Ot/Mp.V; N/mm²) was not changed in both mictropetrosis area (100.1 ± 68.2 to 99.6 ± 76.1 N/mm²) and in the other area (from 240.1 ± 63.9 to 279.6 ± 88.6 N/mm²) after the treatment (Group II).

Conclusions: Cinacalcet HCL did not reduce osteocyte number in both micro-petrosis area and in the other area, suggesting that this agent improves bone quality by maintaining osteocytic pericellular/canalicul system. Parathyroidectomy reduces osteocyte number in only the micro-petrosis area.

Trabecular Bone Score in Kidney Transplant Recipients

Kyla Lynn Naylor, 1 Lisa M. Lia, 1 Didier Hans, 3 Amit X. Garg, 1,4, 5 David N. Rush, 2 William Leslie. 2

Western Univ; 1Univ of Manitoba; 2Lassanne Univ Hospital; 3London Health Sciences Centre; 4Inst for Clinical Evaluative Sciences.

Background: Kidney transplant recipients have altered bone mineral metabolism and are at a higher risk of fracture compared to the general population. There is conflicting evidence regarding the ability of bone mineral density (BMD) to accurately predict fracture. Trabecular bone score (TBS) is a texture measure derived from dual energy x-ray absorptiometry (DXA) lumbar spine images which provides information independent of BMD. We assessed TBS in kidney transplant recipients.

Methods: We included 327 kidney transplant recipients from Manitoba, Canada, who received a post-transplant DXA (median 106 days post-transplant). We matched each kidney transplant recipient (mean age 45 years, 39% men) to three controls from the general population (matched on age, sex, and date of DXA). Lumbar spine (L-1-L-4) DXA images were used to derive TBS. Non-traumatic incident fracture (excluding hand, foot, and craniofacial) were assessed during a mean follow-up of 6.6 years. We used logistic regression to determine predictors of TBS and hazard ratios per standard deviation decrease in TBS to express the gradient of risk for fracture prediction using Cox proportional hazards regression.

Results: Compared to the general population, kidney transplant recipients had a significantly lower lumbar spine TBS (1.41 ± 0.13 versus 1.37 ± 0.13, P=0.001). Multiple logistic regression revealed reduced TBS (lowest versus highest tertile) in kidney transplant recipients compared to the general population (adjusted odds ratio, 2.13 95% confidence interval [CI] 1.47-3.07). TBS predicted fractures in kidney transplant recipients independent of the Fracture Risk Assessment (FRAX) score and spine BMD (adjusted hazard ratio per standard deviation decrease in TBS 1.57, 95% CI 1.07-2.9).

Conclusions: Kidney transplant recipients had abnormal bone texture as assessed by TBS. Lumbar spine TBS was able to predict incident fractures in kidney transplant recipients and may provide novel insights into skeletal fragility in this unique population.

754A
hypocalcemic hyperparathyroidism (n=4, 7%) showed either low or normal bone turnover. Hypophosphatemia was present in 11%. Vitamin D stores were sufficient in 52% (median HydroxyvitaminD 32 ng/ml). Spearman correlation revealed significant correlations between bone formation rate and biomarkers of bone formation & resorption (direct: bAP: r0.36, p=0.01; TRAP: r0.40, p<0.01; NTX: r0.38, p<0.01) and inflammation (inverse: Il6: r-0.51, p<0.001), but not with mineral metabolism hormones (PTH, FGF23, sclerostin).

Conclusions: Low bone turnover disease is the most prevalent bone disease in renal transplant recipients 1 year after successful renal transplantation. Additional studies are required to clarify underlying pathophysiological mechanisms. PTH, FGF23 and sclerostin do not correlate with histomorphometric parameters and circulating biomarkers of bone turnover.

SA-PO569
Sclerostin Bone Expression and Blood Levels in Patients with Chronic Kidney Disease Stages 2-5

Background: Sclerostin (Scl) produced by osteocytes (ocy) was found to be increased in blood in early stages of CKD patients (pts) with renal osteodystrophy (ROD). The aim of this study was to establish when blood scl levels and bone expression are increased and how they progress with worsening CKD.

Methods: Fifty pts underwent anterior iliac crest biopsies and blood was drawn at time of biopsy. Kidney function was determined by creatinine clearance using MDRD calculation. There were: 11 CKD-2, 16 CKD-3, 9 CKD-4 5 pts, and 14 healthy age-matched controls. Scl concentrations in blood were determined by ELISA and scl expression in bone was determined in undecalcified bone sections by counting number of ocy exhibiting positive scl immunostaining. Measurements were done separately in cortical and cancellous bone. Bone sections were also evaluated by histomorphometry for turnover, mineralization and volume.

Results: Blood scl levels were significantly greater in CKD compared to controls with no differences between stages (P=0.01).

Bone scl expression was significantly higher in cortical bone of CKD 2-5 pts compared to controls (P<0.01). Scl expression was significantly greater in cortical than in cancellous bone in CKD. In cancellous bone scl expression was higher in CKD, this reached significance in CKD-3 (Figure 1).

Conclusions: Scl expression in cortical and cancellous bone correlated with serum scl (rho=0.30, 0.40, rsp; P<0.05). Serum scl correlated negatively with bone formation, activation frequency and osteoblast number (rho=-0.33, -0.38, -0.43, rps; P<0.05). Scl in bone correlated negatively with trabecular thickness (rho=-0.51; P<0.05), osteoblast and osteoclast surface, and erosion depth (rho=-0.50, -0.52, 0.55; rps; P<0.01).

Conclusions: These findings ascribe a potential role to scl in the pathogenesis and management of ROD.

SA-PO570
Single Timepoint and Longitudinal Serum Sclerostin Levels as Mortality Predictors in Prevalent Dialysis Patients
Lotte Lins,1 Camiel L.M. de Roij van Zuijdewijn,1 Marc G. Vervloet,2 Peter J. Blankestijn,1 Marie H. Krzesinski,1 Xavier Warling,1 Martial Moonen,1 Nicole Simone Smelten,1 Hans Potell,1 Jean-Marie H. Krzesinski,1 Etienne Cavalier,1 Université de Liège, Belgium; 1Université de Liége, Belgium; 2Université de Liége, Belgium.

Background: Longitudinal serum sclerostin (sScl) levels, a 22kDa-sized glycoprotein inhibiting bone formation, are positively or negatively associated with mortality. Its concentration may change over time. Therefore, we investigated whether longitudinal sScl levels predict mortality better than a single measurement.

Methods: A post-hoc analysis on data from the CONTRAST study was performed, a RCT comparing online postdilution hemodiafiltration to hemodialysis in prevalent dialysis patients. sScl was measured in a subset of patients. Patients were eligible for analysis if a baseline (T0) and a 6 months (T6) sScl value were available. Hazard ratios (HRs) were calculated within quartiles for sScl level at T0, T6 and for Delta sScl. All-cause mortality was assessed as an end point. As the interaction between dialysis modality and Delta sScl was non-significant (p=0.1), pooled estimates are reported. To correct for multiple testing, a two-sided p-value <0.01 was considered statistically significant.

Results: Out of 714 patients, 341 were available for analysis. Baseline characteristics between the groups did not differ. Median sScl at T0, T6 and Delta sScl were 136.3 pmol/L (interquartile range [IQR] 98.7-186.1), 134.0 pmol/L (IQR 100.4-183.0) and 0 pmol/L (IQR -25 to 15), respectively. sScl values at baseline and T6 were negatively associated with mortality (adjusted HRs highest versus lowest quartile 0.49 [95% CI 0.30-0.81] and 0.48 [95% CI 0.29-0.82], respectively). However, we found no association between Delta sScl and mortality.

Conclusions: A single timepoint sScl is inversely associated with mortality in our cohort of dialysis patients. sScl change over a six month period does not predict mortality.

SA-PO571
Interleukin-1 Inhibition, Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD), and Physical Function
Kristen L. Nowak,1 Adriana Hung,2 Talat Alp Ikizler,3 Heather Farmer,1 Nataliee Salas,2 Rafia I. Chaudhry,3 Andrew N. Hoofnagle,4 Gerard John Smits,1 Michel Chonchol,4 Université de Colorado Denver; 1VA Tennessee Valley Healthcare System; 2VA Tennessee Valley Healthcare System; 3VA Tennessee Valley Healthcare System; 4Univ of Washington.

Background: In chronic kidney disease (CKD), physical function is associated with an increased risk of mortality. Interleukin-1 (IL-1) has been identified as an important player in the pathogenesis of CKD-MBD, and thus, the effect of IL-1 inhibition on physical function in CKD patients is of great interest.

Methods: In a two-site, double-blind trial, 42 patients with stage 3-4 CKD were randomized to receive either the IL-1 trap rilonacept (160 mg/week) or placebo for 12 weeks. The following CKD-MBD markers were assessed in serum before and after the intervention: calcium, phosphorus, 25-hydroxyvitamin D (25(OH)D), iPTH and FGF23. A battery of tests was also administered in a sub-group (n=22) to assess multiple domains of physical function (endurance, locomotion, dexterity, balance, strength, and fatigue).

Results: Participants were 63±11 years of age, 24% female, 29% Hispanic, mean eGFR 38±13 ml/min/1.73m2, and mean high sensitivity C-reactive protein (hsCRP) 4.7±4.2 mg/L. Rilonacept effectively reduced systemic inflammation, as evidenced by reduced hsCRP levels (p<0.01). There was no change in serum calcium, phosphorus, 25(OH)D, iPTH, or FGF23 levels (p>0.05) with IL-1 inhibition. Similarly, rilonacept did not alter locomotion, dexterity, balance, strength, or fatigue (p>0.02). However, endurance (400m walk time) tended to be reduced in the rilonacept (-29 sec) as compared to placebo (-6 sec; p=0.059).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: 12 weeks of IL-1 inhibition did not improve circulating markers of CKD-MBD or physical function (although it tended to improve endurance). These results support that inflammation does not directly mediate CKD-MBD or select domains of physical function.

Serum Metabolomic Profiling and CKD-MBD: A New Tool for Bone Turnover Evaluation Aline Lourenço Baptista,1 Kallyanda Padilha,2 Pamela Araujo Malagrinho,2 Gabriela Venturini,2 Ana Carolina de Mattos Zeri,1 Janaina Silva Martins,4 Rodrigo Azevedo de Oliveira,4 Geusa Dutra,1 Luciene dos Reis,3 Vanda Jorgetti,1 Alexandre Costa Pereira,2 Rosa M.A. Moyses,1,2 *Neurology, USP; 2Molecular Cardiology, INCOR, USP; 3LNBio, CNPEM; 4UEM; 5UFRN; 6CEPID.

Background: Bone biopsy still is the gold standard to assess bone turnover in CKD patients and serum biomarkers are not able to replace histomorphometry. Recently, metabolomics has emerged as a new technique that could potentially improve disease diagnosis and the understanding of pathophysiology. However, as this approach has never been tested in the CKD-MBD scenario we investigated whether a serum metabolomic profile could help us to better predict bone turnover in CKD patients.

Methods: Serum and bone histomorphometry data from hemodialysis (HD, n=51) and peritoneal dialysis patients (PD, n=40) were analyzed. They were classified as high (HT), 49.4%) or low turnover (LT). Metabolomic analysis was done through MRI spectroscopy, followed by identification and quantification of metabolites and PLS-DA. As HD had a completely different metabolome of PD group, we analyzed them separately. In addition, we selected the main metabolites found in each group and searched for the metabolomic pathways involved.

Results: The difference between LT and HT was explained by 12 metabolites in HD and 8 in PD (p = 0.03 and 0.01, respectively). ROC curve analysis showed that parahormone and alkaline phosphatase were the best predictors for HT, whereas glyceroi and glucose were the best predictors for LT in HD and PD, respectively. The main canonical pathways involved were glycerine degradation, tyrosine biosynthesis IV and phenylalanine degradation I in HD and creatine-phosphate biosynthesis, pyruvate fermentation to lactate and AMPK signaling in PD group.

Conclusions: In this preliminary analysis, we identified new metabolites that might be used as biomarkers of bone turnover. Moreover, the differences in metabolome between the two dialysis modalities and the different metabolic pathways suggest that the pathophysiological mechanisms involved in the modulation of bone turnover in these patients might be different.

Deletion of the Gene Encoding the Transient Receptor Potential Canonical Type 1 (TRPC1) Channel Produces Hyperparathyroidism, Low Calcitonin (CaT), Hypercalcemia, but Hypocalcuria and Enhanced Bone Mass: Evidence for the Role of TRPC1 in Regulating Intracellular Ca (Ca2+i) in Target Cells Bonnie Eby,1 Alexander Lau,2 Lindsay J. Barron,1 Marybeth Humphrey,1 Leonidas Tsiokas,2 Kai Lau.1,3 *Medicine, Univ of Oklahoma, Oklahoma City, OK; 2Cell Biology, Univ of Oklahoma, Oklahoma City, OK; 3Medicine, VA Medical Center, Oklahoma City, OK.

Background: We recently showed that TRPC1 deficiency impairs store-operated Ca entry (SOCE), reduces [Ca 2+i], stimulates PTH and causes hypercalcemia. We here selected the main metabolites found in each group and searched for the metabolic pathways involved.

Methods: Serum and bone histomorphometry data from hemodialysis (HD, n=51) and peritoneal dialysis patients (PD, n=40) were analyzed. They were classified as high (HT), 49.4%) or low turnover (LT). Metabolomic analysis was done through MRI spectroscopy, followed by identification and quantification of metabolites and PLS-DA. As HD had a completely different metabolome of PD group, we analyzed them separately. In addition, we selected the main metabolites found in each group and searched for the metabolomic pathways involved.

Results: The difference between LT and HT was explained by 12 metabolites in HD and 8 in PD (p = 0.03 and 0.01, respectively). ROC curve analysis showed that parahormone and alkaline phosphatase were the best predictors for HT, whereas glyceroi and glucose were the best predictors for LT in HD and PD, respectively. The main canonical pathways involved were glycerine degradation, tyrosine biosynthesis IV and phenylalanine degradation I in HD and creatine-phosphate biosynthesis, pyruvate fermentation to lactate and AMPK signaling in PD group.

Conclusions: In this preliminary analysis, we identified new metabolites that might be used as biomarkers of bone turnover. Moreover, the differences in metabolome between the two dialysis modalities and the different metabolic pathways suggest that the pathophysiological mechanisms involved in the modulation of bone turnover in these patients might be different.

Role of the Sodium/Calcium Exchanger NCX1 in Osteoclasts Giuseppe Albanò,1,2,3 Candice Stoudmann,1,2 Willi Hofstetter,2 Olivier Bonny,2,3 Daniel G. Fuster.1,3,4 *Div of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; 2Inst of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; 3Dept of Clinical Research, University Hospital Bern, Bern, Switzerland; 4NCCR Kidney.CH, Univ of Zürich, Zürich, Switzerland.

Background: Previous studies demonstrated that inhibition or siRNA-mediated knock-down of sodium/calcium exchanger 1 (NCX1) in osteoclasts decreases bone resorption in vitro, indicating a critical role of NCX1 in osteoclast-mediated bone resorption.

Methods: To test the role of NCX1 in osteoclasts in vivo, we generated mice with osteoclast-specific deletion of NCX1 (NCX1flox/flox). For this purpose, with a floxed exon 11 of NCX1 we crossed mice expressing Cre-recombinase under the influence of the osteoclast specific c窦phin K promoter.

Results: Osteoclasts differentiated from NCX1flox/flox mice displayed an 80-90 % reduction of NCX1 protein compared to wild-type mice. NCX1 expression was unaltered in extraosseous tissues in NCX1flox/flox mice. NCX2 and NCX3 were present at low levels in wild-type osteoclasts and not upregulated in NCX1flox/flox osteoclasts. In vitro RANKL stimulation of bone marrow cells isolated from wild-type and NCX1flox/flox mice yielded no differences in osteoclast development and resorptive activity. In addition, at 3 months of age, structural parameters of bone, quantified by high-resolution microcomputed tomography, were not different in NCX1flox/flox mice compared to wild-type littermates. To stimulate osteoclast-mediated bone resorption, we performed surgical ovariectomy (OVX) in 12 week old female mice, but OVX-induced bone loss over 12 weeks was similar in WT and NCX1flox/flox mice.

Interestingly, however, at 6 months of age, female NCX1flox/flox mice had significantly higher bone volume whereas male NCX1flox/flox mice displayed reduced bone volume compared to wild-type mice.

Conclusions: Our data indicate that genetically induced deficiency of NCX1 in osteoclast-precursors and mature osteoclasts does not affect osteoclast differentiation and bone resorption in vitro. However, NCX1flox/flox mice display an age- and sex-specific phenotype. Additional studies are needed to unveil the underlying mechanisms.

SA-PO576

Background: The arteriovenous-fistula (AVF) of the distal radius often remain patent after transplantation. Distal radius is the typical site for peripheral DXA measurements in renal transplant recipients (RTR). Since no data exist concerning the impact of a previously created AVF on peripheral bone characteristics in RTR we evaluated the effect of AVF on bone mineral density (BMD) as mirrored by contralateral differences between forearms and explored the demetsocrit correlation of distal radius with the tibia as an alternative peripheral measurement site.

Methods: This cross sectional study included 40 renal transplant recipients (RTR) and 40 chronic kidney disease (CKD) patients matched for age, gender and BMI. In addition to relevant demographic, biochemical and clinical aspects we assessed bone characteristics of both forearms, femoral neck and tibia by DXA.

Results: The CKD patients without any AVF, displayed no significant discrepancies concerning BMD in both forearms. In RTR BMD was significantly lower in the AVF forearm compared to the contralateral non AVF forearm. This observation was evident at all measured subregions of the AVF radius sides, i.e. at the 1/3 radius (0.710±0.103 vs. 0.727±0.104, p=0.003), ultradistal radius (0.424±0.085 vs. 0.444±0.080, p=0.007) and total radius (0.571±0.090 vs. 0.589±0.090, p=0.001) as well. This significant side-to-side difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7.0% at the ultradistal radius, respectively. The BMD intersite analysis between radius and distal site revealed a strong and highly significant correlation (r= 0.7346-0.875) between corresponding peripheral sites.

Conclusions: In conclusion, a previously placed AVF in RTR exerts a negative impact on the ipsilateral radius resulting in side-to-side BMD differences. A strong densitometric association exist between peripheral sites and thus DXA measurements at the tibia can be considered as a valuable alternative site to radius. Longitudinal studies are needed in order to replicated these findings by incorporating methods with higher bone density definition.

Cortical Bone Analysis in Pre-Dialysis Patients: A Comparison with a Dialysis Population Catarina Carvalho,1 Juliana Magalhães,2 Ricardo Neto,1 Luciano Pereira,1 Teresa Adragão,2 João M. Frazao.1 *Nephrology and Infectiology Research and Development Group, INEB, Porto, Portugal; 2Nephrology, Hospital Santa Cruz, Lisboa, Portugal.

Background: ROD presents early in CKD pts. Bone biopsy is the gold-standard diagnostic tool. Cortical bone assesses 80% of human bone and is the major determinant of bone strength.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 756A
Methods: We evaluated cortical bone histomorphometry in 13 CKD stage 3 and 4 pts, (9 male, age 65.3±10.4, eGFR 23.8±3.3 ml/min/m², who underwent trans-diaphyseal bone biopsy and compared them to 13 dialysis pts (9 male, 11 on HD, age 52.1±10.2, 55.3±17.6 mo in RRT).

Results: Biochemical values and external cortical bone parameters of both groups shown in table

Dialysis pts compared to the pre-dialysis population showed more deranged cortical bone, with decreased cortical thickness, increased osteonal formation rate and decreased apposition rate. In this pre-dialysis population, external cortical porosity positively correlated with both trabecular bone volume and osteoid volume (respectively, r=0.70 and 0.76, p=0.016 and p=0.006). External cortical ostereal BFR correlated negatively with PTH effects. These findings were not observed in internal cortical suggesting that this is more stable to PTH effects.

Conclusions: In pre-dialysis pts, our findings support that PTH has a modulating effect on both trabecular and cortical bone. As renal disease progresses cortical thinning is more pronounced, eventually contributing to the higher fracture rate. Understanding cortical abnormalities may have implications in the treatment of CKD-MBD.

SA-PO579
Chronic Hypoponatremia Is a Novel Risk Factor for Hip Fracture in Chronic Kidney Disease-Mineral Bone Disease
Sagar U. Nipwekar,1 Andrew S. Allegretti, Julia Beth Wenger, Juan Carlos Ayus,2 Ravi R. Thadhani,1 Ishir Bhan.1
1Massachusetts General Hospital; 2Renal Consultants of Houston.

Background: Risk factors that make skeleton more fragile in chronic kidney disease (CKD) are uncertain. Considering recently reported direct effects of sodium depletion on bone health, we investigated chronic persistent hypoponatremia (CPH) as a novel risk factor for hip fractures caused by CKD-mineral bone disease (CKD-MBD).

Methods: Cases for this multi-center case-control study were elderly (>65 years) patients with CKD (eGFR <60 ml/min) with a new hip fracture. Controls (CKD patients with no hip fracture) were matched to cases on age, sex, race and comparative health.

Results: We analyzed 1,236 cases and 4,515 controls. Mean age of all patients was 84 ± 9 years, 87% were whites, and 39% were females. Serum calcium, phosphate, parathyroid hormone and 25-hydroxy vitamin D levels were similar between cases and controls. Prevalence of CPH (21.2 vs. 9.9%, P<0.001), CPH180 (15.5 vs. 6.5%, P<0.001) and H1 (52.7 vs. 41.1%, P<0.001) were higher in cases compared to controls. In analyses adjusted for falls, tobacco-use, osteoporosis, eGFR, body mass index, heart failure and medications, CPH90 and CPH180 were associated with increased risk of hip fracture but H1 was not.

Conclusions: CPH is a risk factor for hip fractures caused by CKD-MBD. Mechanistic studies are needed to investigate the effects of CPH on bone turnover, mineralization and volume in CKD.

Follicle Stimulating Hormone Is Associated with Low Bone Mineral Density in Women in Hemodialysis

Background: CKD-BMD associated to sexual hormonal status have not been well evaluated. Aim: Assess the association between female hormones (FSH and estradiol) and bone mineral density (BMD) in women in hemodialysis (HD).

Methods: Cross-sectional study in 46 women (20-60 years), at least 3 months in HD in a tertiary care setting between Jan-Jul 2014. Patients or with steroid medication were excluded. Physical examination and blood markers of sexual hormonal and mineral-bone status were done. A bone densitometry of lumbar spine and non-dominant femur was performed. The results were classified as normal, osteopenia and osteoporosis.

Results: 5 had osteoporosis and 5 had osteopenia in the lumbar spine. In the femur, 2 had osteopenia and 18 had osteopenia. Comparisons are shown in Table. BMD in lumbar spine was associated to FSH (R 2 0.27; P<0.001), FSH (OR -0.52 [-0.02 - -0.008]; P=0.001), on the other hand BMD in femur (R 2 0.30; P<0.001), FSH (OR -0.34 [-0.01 - -0.001]; P<0.02), and CRP were significantly associated (OR -0.32 [-0.02 - -0.001]; P<0.03)

Conclusions: This study highlights utility of BMD to predict fracture in CKD, underscores the burden of DM on outcomes, and reveals independent higher mortality after hip fracture in end stage kidney disease.
Background: Recent studies found the incidence of hip fractures has increased greatly in patients on dialysis. Most of the increase occurred in patients with characteristics typical of bone frailty, where oversuppression of intact parathyroid hormone (iPTH) could be harmful. Since recent studies have not addressed clinical risk factors, we studied time-varying risk factors for hip fractures in patients on dialysis.

Methods: 142,407 prevalent patients of Fresenius Medical Care had hip fractures identified by ICD-9 codes. Four cohorts were constructed: observation periods 2001-2003, 2004-2006, 2007-2009, 2010-2012. For each, the prior year was used to measure exposure. Models for risk adjustment were created: Case Mix CM-adjusted: age, gender, race, dialysis vintage, and diabetic status, CM+Lab adjusted and CM+Lab+Med adjusted.

Results: There were 16 (13.56%) fractures in 118 hemodialysis patients. Patients with fractures were significantly older and more osteoporosis. All BMD parameters at hip region (including femoral neck, femoral shaft, and total hip) were notably lower in fracture group than in non-fracture group (0.74: (0.65-0.87) vs 0.82: (0.74-0.96); 0.88: (0.77-1.01) vs 0.99: (0.86-1.14); 0.80: (0.66-0.88) vs 0.88: (0.78-1.00)). There was no difference in clinical characteristics or blood biochemistry levels between the two groups.

Conclusions: Among hemodialysis patients, age and BMD at hip are associated with fracture. FRAX performs better than BMD and OSTA at identifying patients with fractures (P < 0.05). But FRAX2 performed better than BMD and OSTA at identifying patients with fractures (P < 0.05). The best cutoff values were 0.91, 3, 7.2%, and 3.4%.

Background: Restless legs syndrome (RLS) is a movement sleep disorder that is common among patients on hemodialysis (HD) and is associated with cardiovascular morbidity and mortality. The physiopathology of this syndrome is not completely understood, and CKD-MBD may be implicated. We aimed to evaluate the prevalence of RLS in patients on hemodialysis, testing the relationship with CKD-MBD markers.

Conclusions: In conclusion, we found that lower time-averaged iPTH and calcium were associated with a greater risk for hip fracture in dialysis patients.

The Discriminative Ability of Three Fracture Risk Assessment Tools in Hemodialysis Patients Ying Qian, An jin Chang, Xiaonong Chen, Nan Chen. Dept of Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: The present study aimed to explore factors associated with fractures among hemodialysis patients, and assess the ability of the World Health Organization’s fracture risk assessment tool (FRAX) compared with bone mineral density (BMD) and OSTa to discriminate fracture status.

Methods: We enrolled 118 hemodialysis patients in this cross-sectional study. Parameters including serum calcium, phosphate, intact parathyroid hormone, 25 hydroxy vitamin D, alkaline phosphatase were analyzed. Clinical characteristics were also collected. BMD values were at the lumbar spine and hip region. OSTa and FRAX scores were calculated using formula or through the FRAX website. Factors associated with fractures were examined. Discriminative ability of BMD, OSTa and FRAX (non-BMD model and BMD model) in fracture status was assessed with receiver operator characteristic (ROC) analysis.

Results: There were 16 (13.56%) fractures in 118 hemodialysis patients. Patients with fractures were significantly older and more osteoporosis. All BMD parameters at hip region (including femoral neck, femoral shaft, and total hip) were notably lower in fracture group than in non-fracture group (0.74: (0.65-0.87) vs 0.82: (0.74-0.96); 0.88: (0.77-1.01) vs 0.99: (0.86-1.14); 0.80: (0.66-0.88) vs 0.88: (0.78-1.00)). There was no difference in clinical characteristics or blood biochemistry levels between the two groups.

Conclusions: Among hemodialysis patients, age and BMD at hip are associated with fracture. FRAX performs better than BMD and OSTa in discriminating fracture status, suggesting its usefulness of fracture risk prediction in hemodialysis patients.

SA-PO583
Teriparatide for Low Bone Mass in Hemodialysis Patients Rikako Hiramatani, Yoshihumi Ubara, Junichi Hosho, Kennrei Takaichi. Nephrology Center, Toranomon Hospital, Tokyo, Japan.

Background: Fracture rates in dialysis patients are extremely higher than general population. Recently the prevalence of low turnover has greatly increased in dialysis population. Teriparatide would be also beneficial for low turnover dialysis patients with low bone mass. However, there have been only a few reports describing the use of teriparatide in dialysis patients.

Methods: Design This was a prospective, single-center, observational study. Hemodialysis patients with low iPTH (iPTH<60 pg/ml) were the target population. BMD determined by lumbar spine (LS) and femoral neck (FN) T-score<-2.5 with DXA were eligible and subcutaneous recombinant human PTH1-34 (20 µg teriparatide; Forteo) was injected 3 times per week at the end of each hemodialysis sessions. We analyzed the following parameters, including serum Ca, P, albumin, ALP, iPTH and bone metabolic markers including i1NP, BAP, OC, and TRACP-5b at baseline and following teriparatide. BMD at LS and FN were measured at baseline, 6, 18 months after treatment. Pharmacokinetics After the 24th administration of teriparatide, we measured the serum teriparatide acetate concentrations.

Results: Five patients (median age: 72 years old,median hemodialysis periods; 24 months) were included. After teriparatide injection, BMD of LS as well as FN at 6 months significantly increased from 0.67±0.18 to 0.86±0.19 g/cm2 and from 0.44±0.08 to 0.48±0.07 g/cm2, respectively. Corrected Ca levels significantly decreased at 3 and 6 months with increases in endogenous iPTH in response to lowering of serum Ca. As for bone metabolic markers, percent changes of serum BAP and serum i1NP levels significantly increased at 3 and 6 months. Conversely, serum TRACP-5b decreased after injection. Throughout this study, there were no fractures. Pharmacokinetics result is shown in Figure 1. There was a peak at 30 minutes at 157.2 pg/ml, and then it rapidly decreased to undetectable level at 240 minutes.

Conclusions: In conclusion, treatment with teriparatide, the dose was 20 µg 3 times/week, which is smaller than suggested dose for non dialysis patients, led to increase of BMD at LS and FN. Our data on pharmacokinetic of teriparatide suggested that we can use this agent in normal dose in dialysis patients.

SA-PO584
Restless Leg Syndrome in Hemodialysis Patients: Possible Relationship with Mineral and Bone Metabolism Precil Diego Miranda de Menezes Neves,1 Ramaiane Aparecida Bridi,1 Rosa M.A. Moyes,2 Rosilene M. Elias,1,2 Nephrology Div, Univ of Sao Paulo, Sao Paulo, Brazil; 1Nephrology Div, Univ Nove de Julho - UNINOVE, Sao Paulo, Brazil.

Background: Restless legs syndrome (RLS) is a movement sleep disorder that is common among patients on hemodialysis (HD) and is associated with cardiovascular morbidity and mortality. The physiopathology of this syndrome is not completely understood, and CKD-MBD may be implicated. We aimed to evaluate the prevalence of RLS in patients on hemodialysis, testing the relationship with CKD-MBD markers.

Conclusions: In conclusion, treatment with teriparatide, the dose was 20 µg 3 times/week, which is smaller than suggested dose for non dialysis patients, led to increase of BMD at LS and FN. Our data on pharmacokinetic of teriparatide suggested that we can use this agent in normal dose in dialysis patients.
Methods: Prevalence and severity of RLS were assessed using the International RLS Study criteria (IRLS) in 1665 patients.

Results: Of the 101 patients (53.5% women) included, RLS was observed in 29 patients (28.7%), with mild, moderate, severe and very severe presentation in 1, 12, 3 and 3 patients, respectively. RLS was more frequent among women (62% vs 38%, p=0.04), and was associated with normal fasting glucose (OR=0.80, 95% CI 0.57-1.14, P=0.22). The expression of Nrf2 and HO-1, increased by P load, but the expression of Runx2-induced calcification was decreased gradually within incubation time after H2O2 or SFN + H2O2, pretreated.

Conclusions: The calcification in RASMCs is associated with the overexpression of endogenous ROS. Overexpression of Runx2 induced by endogenous ROS, but not exogenous ROS, may be inhibited or attenuated by the activated Nrf2/ HO-1 pathway.

SA-PO587
Matrix Vesicles from Calculating Vascular Smooth Muscle Cells (VSMC) Have Different MicroRNA (miRNA) Expression from Non-Calculating VSMC. Neal X Cheng,1 Sarath Chandra Janga,1 Kalishia O’Neill,2 Manjunath Shetty,3 and Chad A. Wang2,3,1

Methods: We added P of 1, 1.5, or 2.0 mM in the culture media (DMEM) of hVSMC with normal fasting or high glucose (HG) (100 or 450 mg/dl), although hVSMC are usually with normal fasting glucose at Day 7 and 14. At Day 7, the mRNA expression of Sox9, a chondrogenic differentiation marker, increased by P load and was higher with normal fasting glucose. The SOX9 mRNA expression at Day 7 correlated significantly with the content of calcification related to VSMC. The content of calcification was decreased significantly with the SOX9 mRNA expression at Day 7. At Day 1, the content of CPP increased by P load, and was higher with normal fasting glucose. The SOX9 mRNA expression at Day 7 correlated significantly with the content of CPP at Day 1. At Day 1, the mRNA expression of osteopontin (OPN), a calcification inhibitor, decreased by P load and was less with normal fasting glucose. The content of calcification was decreased significantly with the mRNA expression of OPN at Day 1.

Results: Regardless of P load amount, the degree of calcification was severer with normal fasting glucose at Day 7 and 14. At Day 7, the mRNA expression of Sox9, a chondrogenic differentiation marker, increased by P load and was higher with normal fasting glucose. The content of calcification was decreased significantly with the SOX9 mRNA expression at Day 7. At Day 1, the content of CPP increased by P load, and was higher with normal fasting glucose. The SOX9 mRNA expression at Day 7 correlated significantly with the content of CPP at Day 1. At Day 1, the mRNA expression of osteopontin (OPN), a calcification inhibitor, decreased by P load and was less with normal fasting glucose. The content of calcification was decreased significantly with the mRNA expression of OPN at Day 1.

Conclusions: In conclusion, P load with normal fasting glucose reduced OPN expression and induced the formation of CPP, followed by the chondrogenic differentiation and calcification in hVSMC.

SA-PO589

VCAM - 1 and TNF Alpha Induce Vascular Calcification In Vitro
Kevin Willy, Ralf Schindler, Daniel Zickler. Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin.

Background: VCAM, TNF alpha and soluble TNF alpha receptor 1 (sTNFR1) are elevated in patients with chronic kidney disease (CKD). In previous clinical trials with high cut-off dialysis plasma levels of these molecules and in vitro vascular calcification were lowered. Here we assessed the role of sTNFR 1 and VCAM on in vitro calcification.

Methods: In human vascular smooth muscle cells (VSMCs) vascular calcification was induced by osteogenic medium (OM). VCAM, TNF-α and sTNFR1 were added. Calcification was quantified by alkaline phosphatase staining and alizarin red staining. Calcification was then normalized to WST-8.

Results: VCAM enhances vascular calcification in vitro in a dose-dependent manner (p<0.001). TNF-α -induced calcification was effectively inhibited by sTNFR1 (50% reduction of the initial level; p<0.001). sTNFR1 alone does not promote vascular calcification.

Conclusions: VCAM and TNF alpha promote vascular calcification in vitro. Their elimination with high cut-off dialysis or their pharmacological blockade may be advantageous in regard to vascular calcification in CKD.

SA-PO590

The Tripeptide Collagen Analog (GPO)10 Affects Calcifications of Vascular Smooth Muscle Cells in a Concentration Dependent Manner
Uwe Querfeld, Nadja Kretzschmar, Christian Freise. Pediatric Nephrology, Charité, Berlin, Germany; Center for Cardiovascular Research, Charité, Berlin, Germany.

Background: Extensive remodeling of the extracellular matrix and the trans-differentiation of vascular smooth muscle cells (VSMC) contribute to the pathogenesis of vascular calcifications in patients with chronic kidney disease (CKD). Matrix metalloproteinases (MMPs) are proteolytic enzymes that impact on both of these processes and, thus, represent potential therapeutic targets. We have previously shown that the synthetic collagen analog (Gly-Pro-Hyp)10 -(GPO)10 –impacts the substrate binding and the enzymatic activity/stability of the gelatinases MMP-2 and -9 in a concentration dependent manner [1]. Aim of this study was therefore to investigate potential regulatory functions of (GPO)10 in an in-vitro model of atherosclerotic VSMC calcification.

Methods: Calciums of murine VSMC were induced by a calcification medium (CM) containing elevated concentrations of calcium and phosphorus with or without the presence of (GPO)10 -concentrations. VSMC calcifications were quantified by measuring calcium depositions and ALP-release in the cultures. Effects on MMP-activities were determined by specific substrate assays.

Results: CM-treated VSMC exhibit strong calcifications compared to control. Low (GPO)10 -concentrations (50-70 nM) massively enhanced calcifications of VSMC and were accompanied by elevated gelatinase activities in VSMC supernatants. In contrast, higher concentrations of (GPO)10 (680 nM) blocked CM-induced calcifications of VSMC and reduced gelatinolytic activities in culture supernatants.

Protective Effects of Epigallocatechin Gallate (EGCG) on Vascular Calcification In Vitro and In Vivo
Uwe Querfeld, Karoline Websky, Christian Freise, Kerstin Sommer, Ursula Schulz, Veronika Bobb. Pediatric Nephrology, Charité, Berlin, Germany; Center for Cardiovascular Research, Charité, Berlin, Germany.

Background: Vascular calcifications are common in patients with chronic kidney disease (CKD). Our preliminary studies indicate that inhibition of matrix metalloproteinases (MMP)-2 and -9 suppresses the development of arterial calcification in uremic rats. Epigallocatechin gallate (EGCG), a polyphenol ingredient of green tea, has strong antiinflammatory properties and inhibitory effects on MMPs. We therefore investigated potential protective effects of EGCG on calcification of vascular smooth muscle cells (VSMC) in vitro and in an animal model of uremia-associated arteriosclerosis in vivo.

Methods: In vitro, calcifications of murine VSMCs were induced by a high phosphate (HP)-medium and cells were treated with different EGCG-concentrations (20-100µg/ml). VSMC calcifications were quantified using the ortho-cresolphthalein-methode and proteolytic activities of MMP-2 and -9 in VSMC supernatants were determined by gelatin zymographies. C57BL/6 mice were 5/6-nephrectomized and arterial calcifications were induced by calcitriol (1µg/kg body weight) and a HP-diet (2% phosphate). One cohort (n=10) was additionally administrated 0.02% EGCG in drinking water. Animals were sacrificed after 2 weeks of treatment and aortic calcifications were quantified after von Kossa-staining.

Results: In-vitro, EGCG provoked a dose-dependent decrease of HP-induced calcification (up to 85%) of VSMCs and of proteolytic MMP-2 and -9 activities. In vivo, all calcitriol-treated mice had severe arterial calcifications, involving 50% of the arterial wall after only 2 weeks of treatment. EGCG had no significant inhibitory effect on the development of vascular calcifications.

Conclusions: In this “negative experimental trial”, EGCG had no beneficial effect in the chosen animal model, which (considering the rapid development of calcifications) may have been too aggressive, thus overriding potential protective effects of EGCG. Encouraged by the positive in vitro results, the effects of EGCG and other polyphenols should nonetheless be further investigated in other animal models of uremia-associated arteriosclerosis.

induced arterial dilatation in situ. Cell lineage tracing was performed in Rosa-ttd mice bred to obtain aortic smooth muscle cell lineage. Mice harboring Rosa-ttd express tomato red cells in rearing Cav2 recombinase.

Results: Circulating activin and Dkk1 levels were increased while aklotho levels were decreased by CKD. In diseased kidneys, activin was expressed in myofibroblasts, and activin signaling through Smad 3 was increased. An ActRIIA ligand trap, RAP-011, inhibited renal pSmad 3, ColA1 expression, urinary protein levels, and circulating free activin levels in adenine-preloaded rats, indicating that activin signaling is increased in CKD kidneys.

Conclusions: Reduced VSMC differentiation and function. The ActRIIA ligand trap increased VSMC differentiation and inhibited osteoblastic transition and atherosclerotic calcification. In the circulation, the ActRIIA ligand trap decreased Dkk1 levels. CKD induced expression of tomato red in cells of the adventia after two weeks of femoral artery injury in Tek-Cre/Rosa-ttd mice compared to Tek-Cre/Rosa-ttd mice with normal kidney function.

Transient Azotemic Episode Exacerbates Vascular Calcification in Adenine-Induced Uremic Rats

Daisuke Mori,1 Isaio Matsui,1 Akhiro Shimomura,2 Yasuo Kusunoki,1 Sayoko Yonemoto,1 Masamitsu Senda,1 Yusuke Sakaguchi,1 Takayuki Hanno,1 Yoshitaka Isaka,2 Hiromi Rakugi.1

Background: Urea, the final metabolite of amino acids in the body, can carbamylate proteins at lysine residues, and thereby modifies characteristics of proteins irreversibly. Several studies have revealed that functions of proteins are impaired by carbamylation. In diseased kidneys, although AKI is not a perpetual condition, it is well-known that AKI follows a subsequent phase of cardiovascular diseases through yet-unknown mechanisms.

Methods: We evaluated the effects of transiently elevated serum urea on vascular calcification (VC). Male Sprague-Dawley rats at age 9 weeks were divided randomly into two groups: cellulose-preload + adenine diet (group C+A) and urea-preload + adenine diet (group U+A). Urea-preloaded group received 10% urea diet from 9 to 13 weeks of age. Controls were served as a control for urea. After one week of urea-washout period, all rats received 0.75% adenine-containing diet up to 19 weeks of age.

Results: Serum urea levels were 15.87 ± 2.96 mg/dl in cellulose-preloaded group and 39.20 ± 3.74 mg/dl in urea-preloaded group at the end of the preoad period. Serum urea levels in serum urea + preload group were normalized to 14.73 ± 1.28 mg/dl during the washout period. At age 19 weeks, rats in group U+A developed severe VC in comparison with the rats in group C+A. Serum creatinine, urea nitrogen, calcium, phosphorus, magnesium, albumin, and body weight were not different between the two groups at age 19 weeks. Western blot analysis of the aorta revealed that dietary preload of urea increased carbamylated protein.

Conclusions: Predialysis urea exacerbates VC in adenine-induced uremic rats. Protein carbamylation might link urea-preload to VC.

SNF472 Inhibits Cardiovascular Calcification in Uremic Rats

Joan Perello,1,2 Carolina Salcedo,1 Ellen Neven,2 Geert J. Behets,3 Pieter H. Joubert,1 Patrick SNF472 Inhibits Cardiovascular Calcification in Uremic Rats

1Sf472, an intravenous (i.v.) formulation of phytate, has been shown in vitro to inhibit CARIIA ligand trap signaling through Smad 3. This was confirmed in vivo using a rat adenine model of uremia. Further studies are required to determine the long-term effects of SNF472 on renal function and cardiovascular disease.

Methods: SNF472, an intravenous (i.v.) formulation of phytate, has been shown in vitro to inhibit CARIIA ligand trap signaling through Smad 3. This was confirmed in vivo using a rat adenine model of uremia. Further studies are required to determine the long-term effects of SNF472 on renal function and cardiovascular disease.

Conclusions: SNF472, an intravenous (i.v.) formulation of phytate, has been shown in vitro to inhibit CARIIA ligand trap signaling through Smad 3. This was confirmed in vivo using a rat adenine model of uremia. Further studies are required to determine the long-term effects of SNF472 on renal function and cardiovascular disease.
Deoxycholic Acid (DCA), a Metabolite of Bile Acid Cycles, and Coronary Vascular Calcifications in Chronic Kidney Disease (CKD)

Makoto Miyazaki,1 Shinobu Miyazaki-anzai,2 Audrey L. Keenan,1 Kristen L. Nowak,3 Jessica B. Kendrick,3 Geoffrey A. Block,3 Michel Chonchol.1 1Univ of Colorado Denver; 2Denver Nephrology.

Background: Our group has previously shown that DCA, a metabolite of circulating cholic acid, induces vascular mineralization and osteogenic differentiation in animal models and that circulating levels of DCA are elevated in patients with CKD. We investigated whether increased DCA serum levels are associated with an increase risk for higher coronary artery calcification (CAC) volumes and lower lumbar bone mineral density (BMD) in CKD patients.

Methods: We used stored baseline serum samples in 112 patients with moderate to advanced CKD (eGFR 20-45 mL/min/1.73m²) who participated in a randomized-controlled study to examine the effects of phosphate binders on vascular calcification. Circulating DCA levels were assayed using liquid-chromatography-tandem mass spectrometry (LC-MS/MS). CAC volume was obtained using GE-Imatron C150 scanner and lumbar BMD was determined using abdominal computed tomography scans with a calibrated phantom of known density. Linear regression models were used to examine the cross-sectional association between DCA with CAC volume and lumbar BMD.

Results: Participant characteristics were as follows: mean age, 68±11 years; 50% women; 10% black; mean eGFR, 32±8 mL/min/1.73m²; and median DCA 5.84 (Q29-112) ng/mL. After adjusting for demographics, co-existing illness, body mass index, eGFR and circulating markers of CKD-MBD including serum calcium, phosphorus, vitamin D, parathyroid hormone and fibroblast growth factor 23, an increase serum DCA level > 58 ng/mL positively associate with CAC volume (B = 4.94±3.28; p = 0.03) and negatively associated with BMD (B = -20.35± 9.56; p = 0.03).

Conclusions: Higher serum levels of DCA in patients with stage III and IV CKD is independently associated with higher CAC volume and lower lumbar BMD. Larger cohort studies are needed to confirm these findings.

Fibroblast Growth Factor 23 and Fetuin-A Levels in Pre-Dialysis Stage 4-5 Chronic Kidney Disease Patients with Aortic Calcification: A Case Control Study

Vijayakumar Theophilius-Sunder,1 Anna T. Valsal, Vinoi George David, Santosh Varughese, Tamilarasi Veerasamy. Dept of Nephrology, Christian Medical College, Vellore, Tamil Nadu, India.

Background: Vascular calcification (VC) contributes to the increased cardiovascular mortality seen in CKD. However, not everyone with advanced CKD develops VC, indicating that circulating levels of factors that modulate VC may play a role in determining individual susceptibility towards VC. We aimed to examine the hypothesis by measuring the levels of FGF-23 and Fetuin-A in a group of pre-dialysis CKD stage 4-5 patients who had documented abdominal aortic calcification (AAC) and an age, gender and eGFR matched group of patients who did not have AAC.

Methods: Out of a pre-existing cohort of 710 patients with CKD Stage 4-5, 28 patients with AAC (Group 1, cases) were compared with an equal number of age, gender and eGFR matched patients without AAC (Group 2, controls) with respect to their demographic and biochemical parameters, including FGF-23 and Fetuin-A. AAC was assessed by lateral abdominal X ray, while Fetuin-A and intact FGF-23 were estimated by ELISA in serum.

Results: Groups 1 and 2 were matched for age (mean 57.7 ± 57.6 years, respectively; p = 0.938), gender (84.6% males in both groups) and eGFR (median eGFR 14.5 ± 13.1 respectively, p = 0.826), and were not significantly different with respect to risk factors for AAC such as presence and duration of diabetes, hypertension, smoking, and obesity. Levels of calcium, phosphorus, PTH, 25 (OH) vitamin D, serum cholesterol, triglycerides, HDL and LDL were also comparable between the two groups. However, median FGF-23 levels were significantly higher in Group 1 [25.2, (Q1= 14, Q3=34.2)] compared to Group 2 [12.1 (Q1 = 6, Q3 = 14.1), p = 0.001]. Median Fetuin-A levels were also significantly higher in Group 1 [5.5 (Q1=4.4, Q3=6.5)] compared to Group 2 [4.1 (Q1 = 3.6, Q3 = 5.7, p = 0.034).

Conclusions: Pre-dialysis patients with Stage 4-5 CKD with AAC, had higher FGF-23 and Fetuin-A levels compared to age, gender and eGFR matched patients who did not have AAC. The nature and mechanism of this association between elevated FGF23 and Fetuin-A levels compared to age, gender and eGFR matched patients who did not have AAC.

Lack of Association Between Serum Osteoprotegerin, Osteopontin and Fetuin-A Levels and the Longitudinal Changes in Arterial Stiffness in CKD Patients Undergoing Renin-Angiotensin System Blockade

Cecile Lynso,1 Marie Frimodt-Moller,2 Marianne Rix,3 Audhild Lyngsoe,1 Mette Bjerve.3 1Dept of Nephrology, Herlev Hospital, Herlev, Denmark; 2Dept of Nephrology, Rigshospitalet, Copenhagen, Denmark; 3The Medical Research Laboratory, Dept of Clinical Medicine, Aarhus Univ, Aarhus, Denmark.

Background: Osteoprotein (OPG), osteopontin (OPN) and fetuin-A, have been suggested to participate in the accelerated development of arteriosclerosis seen in patients with chronic kidney disease (CKD). We have previously shown that measures of vascular stiffness were significantly reduced after 24 weeks of treatment with renin-angiotensin System (RAS) blocking agents. The aim of this longitudinal post hoc study was to investigate whether serum levels of OPG, OPN and fetuin-A were associated with these same changes in markers of arterial stiffness found in CKD patients treated with RAS blocking agents.

Methods: Serum OPG, OPN and fetuin-A levels were measured in 57 patients with CKD stage 3-5, mean eGFR 29 mL/min, as a post hoc analysis of data acquired during a 24-week placebo controlled trial in which patients were randomized to treatment with enalapril monotherapy with either enalapril or candesartan followed by 8 weeks of dual blockade. Serum levels were obtained upon study entry and after 16 and 24 weeks of RAS blocking therapy and compared to aortic pulse-wave velocity and augmentation index.

Results: Except for a significant correlation between OPN and central pulse pressure (p < 0.05), serum levels of OPG, OPN and fetuin-A did not correlate to markers of vascular stiffness. There were no significant changes in serum levels of OPG, OPN and fetuin-A when monotherapy with enalapril or candesartan was compared to dual blockade.

Conclusions: The present results do not corroborate the use of OPG, OPN and fetuin-A as surrogate markers for vascular stiffness in patients with CKD.

SA-PO601

Hyperuricemia Is Significantly Associated with Coronary Artery Calcification and Vascular Stiffness in Asymptomatic Subjects Undergoing General Health Examination

Arne Høj Nielsen,1 Allan Flyvbjerg,3 Mette Bjerre.3

Background: Recent studies suggest that hyperuricemia may be associated with increased adverse cardiovascular events even in healthy subjects. Quantity of coronary artery calcium (CAC) correlates with atherosclerotic plaque burden and increased cardiovascular events. This study aimed to determine the relationship between serum uric acid level (sUA) and coronary artery calcification score (CACS) as well as other traditional cardiovascular risk factors in asymptomatic subjects.

Methods: We consecutively enrolled 4,703 asymptomatic subjects who under-pBPM and coronary CT angiography as part of a general health examination. A high B-PWV was defined as having increased arterial stiffness. Hyperuricemia was defined as serum sUA greater than 497.5 μmol/L (75th percentile). The subjects were stratified into four groups according to sUA.

Results: Mean age of enrolled subject was 52.8 ± 9.4 years, 61 % of the study participants were male. Eight four percent of the study participants showed CACS greater than 100. The adjusted odds ratio (OR, 95% confidence interval) for the presence of high B-PWV in the second to fourth sUA quartile vs. first sUA quartile was 1.45 (1.137-1.840, P = 0.003), 1.42 (1.081-1.866; P = 0.012), 1.66 (1.246-2.218, P = 0.001), respectively, after adjusting for age, gender, diabetes, hypertension, smoking, body mass index (BMI), eGFR, serum total and low density lipoprotein cholesterol (eGFR), fasting blood sugar (FBS) and calculated LDL. Moreover, subjects with CACS greater than 100 also showed that fourth quartile of sUA was associated with high B-PWV compared with the first quartile of sUA [OR 2.4, (1.65-3.47, P = 0.001)]. Multivariate linear regression analysis demonstrated that old age, male, smoking, diabetes, BMI, FBS, eGFR and sUA were significantly associated with mean B-PWV and low transformed CACS.

Conclusions: Our results show that sUA is an independent risk factor for increased vascular stiffness and coronary atherosclerosis in asymptomatic adults undergoing health examination.
SA-PO603

Total Body multislice Computered Tomography as a Gold Standard of Vascular Calcification
Nadia Martin Alemany,1 Xoana Barros,2 Jordi Calabia,1 Juan Baños,3 1Nephrology, Univ Hospital Dr Josep Trueta, Girona, Spain; 2Radiology, Inst de Diagnostico para la Imatge (IDIG), Girona, Spain.

Background: Vascular calcification (VC) is a marker of cardiovascular risk in CKD patients. Imbalance of calcium-phosphate parameters and secondary hyperparathyroidism (sHP) has been proposed as indicators of VC. Traditionally VC has been evaluated with Kaupilla, Adragao and coronary Agatston scores but they are limited to restricted body areas and may underestimate total VC. We proposed a new method to assess VC in CKD patients with mild sHP based on total body multislice computered tomography (MSCT) without contrast.

Methods: Multicenter transversal study which included incident dialysis patients with mild sHP (PTH >150pg/dl) after signed informed consent. Kaupilla and Adragao scores were determined on abdominal and pelvic/hand X-ray, respectively. Total body area calcification (cm2) was measured by MSCT. Patients with a total calcified area of >150 cm2 were considered calcified. Sensibility and specificity of Kaupilla and Adragao scores were calculated considering total calcified body area > 150 cm2 as reference.

Results: We enrolled 22 patients (13 hemodialysis / 9 peritoneal dialysis), 45% diabetics, 62±15 years old. Mean±SD were: phosphorus 4.6±1.5mg/dl, calcium 9.2±1.04mg/dl and parathyroid hormone 278±132pg/dl. They presented mean Kaupilla score of 6.9±6.9, Adragao score of 2.3±3.7 and total calcified area of 112±61.96 cm2. 77% patients were calcified, considering positive if overall calcified area >150cm2. Diabetics and those with previous cardiovascular events had higher total body calcified area, whereas gender and type of dialysis didn’t demonstrate any influence on calcification. Sensibility of Kaupilla and Adragao scores were 70% and 30% respectively, whereas specificity of both of them was 100%.

Conclusions: It is possible to evaluate the overall body calcified area in patients with ESRD by multislice computered tomography, which could be considered as a potential gold standard of global vascular calcification in those patients.

SA-PO604

Comparison of Mineral Metabolic Markers and Therapy in Chronic Hemodialysis Patients with Different Degree of Abdominal Aortic Calcification Score
Manja Antoni,1 Saskia Lampreht,1 Zeljka Veceric Haler,2 Jakob Gubensek,2 Andrej Drozg.1 1Dept of Nephrology and Dialysis, General Hospital, Celje, Slovenia; 2Dept of Nephrology, Univ Medical Centre, Ljubljana, Slovenia.

Background: The correlations of vascular calcifications with different markers of CKD-MBD and also their therapy are not always consistent across the studies and cross-sectional associations are favoured over long-term analyses. We therefore aimed to evaluate laboratory markers and therapy load over a longer period in chronic hemodialysis patients with different severity of abdominal aortic calcification (AAC).

Methods: In hemodialysis patients AAC was determined by lateral lumbar radiography and quantified by Kaupilla score. Patients were divided in two groups according to median AAC score of the whole group. Mean active vitamin D and cinacalcet intake for last 4 years and calcium carbonate for last 10 years (or whole dialysis vintage for those on dialysis for shorter time) and mean mineral metabolism markers (Ca, P, iPTH, Ca×P product and alkaline phosphatase (AF) for last 4 years) were compared between the groups.

Results: With high AAC score were significantly older (72±5 vs. 59±15 years, p=0.003) and more often diabetic (15% vs. 2%, p=0.04) compared to 19 patients with low score, where there was no difference in dialysis vintage (6.4±4.8 vs. 5.3±4.2 years, p=0.44) or presence of cardiovascular disease. We found no difference in mean calcium carbonate dose (4.1±1.6 vs. 4.4±1.9 g/day, p=0.59) or mean cinacalcet dose (21.2±20 vs. 12±17 mg/day, p=0.18), but significantly higher mean calcium-equivalent dose of active vitamin D (1.7±0.8 vs. 0.9±0.8mg/wk, p=0.03). There was no significant difference in Ca, Ca×P product, iPTH or AF, but P was significantly higher (1.6±0.2 vs. 1.4±0.3 mmol/L, p=0.03) in group with high AAC score.

Conclusions: In patients with higher AAC score higher mean active vitamin D dose and higher phosphate levels over a long period of time were found in addition to older age and more diabetes. We find this retrospective analysis important because treatment and laboratory values were evaluated over a prolonged period.

SA-PO605

Influence of the Bone Mineral Disorder on Vascular Calcification Occurrence and Progression in Hemodialysis Patients
Sole Henrique Castro,1 Pasqual Barretti,1 Janaina Silva Martins,2 Rogerio Carvalho Oliveira.1 1Medical Clin, Faculdade de Medecina de Botucatu, Botucatu, Sao Paulo, Brazil; 2Medical Clin, Univ Estadual de Maringa, Maringa, Parana, Brazil.

Background: Cardiovascular disease is the main cause of death in hemodialysis patients; vascular calcification (VC) is common among them. The main objective of this study was to evaluate the influence of bone mineral disorders in VC and its progression in a prospective cohort of patients. Secondly, we intend to identify clinical, laboratory and medical predictors of the presence and progression of VC.

Methods: Adult patients undergoing HD for >90 days were included. At the beginning of and after 12 months Kaupilla and Adragao methods were used to determine the VC score.

SA-PO606

Low Bone Mineral Density of Lower Extremities Associates with Coroneary Calcification Score in End-Stage Renal Disease Patients
Zhiming Cheg1, Abdul Rashid Tony Qureshi,1 Bengt Lindholm,1 Hannah Olauosin,2 Peter F. Barry,1 Lars Wennberg,2 Jonaz Ripszewed,2 Peter Stenvinkel,1 1Renal Medicine & Baxter Novum, Karolinska Inst, Stockholm, Sweden; 2Transplantation Surgery, Karolinska Inst, Stockholm, Sweden; 3Radiology, Karolinska Inst, Stockholm, Sweden.

Background: Kidney transplantation (RTx) corrects many abnormalities in uremia but mineral and bone disorders and cardiovascular disease often persevere. We investigated associations between low bone mineral density (BMD) and coronary artery calcification (CAC) in hemodialysis patients (pts) with end stage renal disease (ESRD) undergoing living donor RTx.

Methods: In 40 pts (aged 44 ± 13 years; 60% male) undergoing living donor RTx, BMD measurements were made before (n=19), close to (n=40) and after (n=13) RTx and CAC measurements (n=34) were also made close to RTx. BMD was assessed by dual-energy X-ray absorptiometry (DXA) and CAC by computed tomography. We investigated the associations between BMD and CAC (measured at the same time). Logistic regression models were adjusted for age, gender and diabetes.

Results: Altogether 32% (13/43) pts had CAC Agatston score ≥100. CAC associated with SBP (OR=0.46, p<0.01) and diabetes (OR=0.57, p<0.001). At baseline, there were significant associations between CAC and BMD of upper extremities (rho = -0.49, p<0.01), BMD of lower extremities (rho = -0.66, p<0.001) and BMD of femoral neck (rho = -0.58, p<0.001). In multivariate analysis adjusted for age, gender and diabetes, BMD of lower extremities remained as significantly lower in pts with CAC scores ≥ 100 (p< 0.05). No significant differences were seen between values of BMD obtained -2.0 [-4.4, -1.1] years before Rtx (n=19) as compared to BMD obtained close to Rtx at -0.1 [-0.7, 0.6] years (n=40) or 2.1 [1.1, 3.3] years after (n=13) Rtx. Sex-stratified analyses also showed no significant differences in BMD before, close to and after RTx.

Conclusions: BMD of lower extremities is associated with CAC in ESRD pts undergoing living donor RTx. No significant changes in BMD were found when comparing values before, close to and after RTx. Further studies are required to elucidate the mechanism(s) linking BMD to CAC score in ESRD pts.

**Association of Metabolic Syndrome with Aortic Arch Calcification and Outcome in Non-Diabetic Peritoneal Dialysis Patients**

**Methods:** We enrolled 277 non-diabetic PD patients into this study. Posterior-anterior chest X-ray were assessed for the aortic arch calcification (AoAC). Frequency of different components and their constellation as MetS were determined according to the modified Adult Treatment Panel III criteria. Using multinomial logistic regression, the factors determining baseline AoAC were analyzed. We used Kaplan Meier analysis to assess the impact of MetS on both mortality and technique failure.

**Results:** Mean age was 48.4 ± 13 years and 43.1% (n=118) had metabolic syndrome. 179 patients were classified as no visible calcification (AoAC grade 0), 51 patients as mild calcification (AoAC grade 1), and 47 patients as moderate to severe calcification (AoAC grade 2-3). The adjusted odds ratio for AoAC grade 1 was 3.03 (95% CI: 1.34-6.84) and for AoAC grade 2-3 was 6.25 (95% CI: 2.26-17.27) among patients with MetS as compared to those without MetS. Multivariate linear regression analysis showed that the presence of MetS (P <0.001) was independent risk factor for higher inflammation, as denoted by high sensitivity C-reactive protein. Over a mean of 45.9 months of follow-up, 34 patients died. Kaplan Meier analysis demonstrated that the incidence of mortality and technique failure does not differ in patients with and without MetS.

**Conclusions:** MetS was independently associated with the presence and severity of AoAC but cannot predict mortality or technique failure in non-diabetic PD patients. Nevertheless, non-diabetic PD Patients with MetS warrant more aggressive risk factor management to reduce the risk of VC.

**SA-PO609**

**Increased Peripheral Arterial Calcification in Patients Receiving Warfarin**

**Methods:** A random sample from a computerized search of medical records yielded 430 patients with x-rays performed during or after warfarin therapy. Each was matched to a patient without warfarin exposure based on age and diabetes. Patients with warfarin exposure <1 month, history of ESRD, or serum creatinine > 2.0 were excluded. X-rays were reviewed visually for arterial calcification.

**Results:** Mean age was 66.9 ± 8.0, 41% were males, and 34% had diabetes. The indication for warfarin was atrial fibrillation in 45% and venous thrombosis or embolism in 44%, and mean duration of warfarin was 4.8 yrs (range: 1 month to 38 yrs). 68% were on warfarin at the time of the x-ray and the remainder had been off warfarin for a mean of 2.4 yrs (range: 1 day to 25 yrs). Serum calcium was slightly lower (9.04 +/- 0.03 vs. 9.17 +/- 0.02, p<0.0005) in the warfarin patient but serum creatinine and phosphorus did not differ. Prevalence of arterial calcification was 44% greater in warfarin patients (30.2% vs. 20.9%, p<0.0023) but not on x-rays performed prior to warfarin (26.4% vs. 22.4%, n=116), indicating that the increase was due specifically to the warfarin and not to underlying disease or other patient characteristics. The increase in calcification was seen only after >5 yrs of warfarin and only in the ankle and foot. It was similar in men and women and greatest (2.4-fold) in patients under age 60 (15% vs. 6.3%, p=0.04).

**Conclusions:** Warfarin use is associated with lower extremity arterial calcification in both men and women independent of age, diabetes, and other patient characteristics.

**SA-PO610**

**Matrix GlA Protein and Vascular Calcification in Patients with End Stage Renal Disease**

**Background:** Vascular calcification (VC) is a common and severe consequence of end-stage renal disease (ESRD). Matrix GlA protein (MGAP) is a calcification inhibitor expressed by the vasculature that counteracts the development of VC.

**Methods:** In 84 ESRD patients undergoing LD-Tx at Karolinska University Hospital, biopsies from the inferior epigastric artery were obtained during surgery. Vascular calcification was assessed by von Kossa staining both by manual scoring (0-3) and by semi-automated analysis (%). Total uncarboxylated MGP (uc-MGP) and diphospho-uncarboxylated MGP (dp-uc-MGP) were measured in plasma. Tissue MGP expression was quantified in arterial biopsies by TaqMan rPCR. DNA methylation of the MGP gene was assessed in peripheral blood from 12 ESRD patients and 12 healthy controls.

**Results:** 50 patients (59.5%) had low VC scores (0 and 1) and 34 (40.5%) patients had high VC scores (2 and 3). Plasma levels of dp-ucMGP were higher in patients with high VC scores compared to patients with low VC scores (2214 [1413-2995] vs. 1701 [1275-2233] pmol/L, p<0.05) and also associated with calcification (%)(Fig 1A). In addition, MGP expression was associated with arterial expression of MGP (Fig 1B: β [95%CI]: 0.04 [0.02 to 0.06] p<0.0001). uc-MGP levels were not associated with measures of DNA methylation of the MGP gene was significantly lower in patients with ESRD compared to healthy controls (adjusted p<0.01).

**Figure 1**

![Image](https://via.placeholder.com/150)

**Figure 1. The association between calcification % (as assessed by semi-automated analysis) and A) plasma dp-ucMGP levels, and B) tissue MGP expression.**

**Conclusions:** Tissue and plasma levels of dp-ucMGP were higher in patients with VC versus those without, possibly indicating a compensatory up-regulation of MGP to prevent further progression. The observation that the methylation of the MGP gene was lower in ESRD than in controls suggests that the altered expression could be due to epigenetic regulation.

**Funding:** Government Support - Non-U.S.

**SA-PO611**

**A Nationally Representative Case Control Study of Calciphylaxis Risk Factors**

**Background:** Prior studies evaluating calciphylaxis risk factors suffer from sample size limitations and none examine whether characteristics at dialysis initiation predict calciphylaxis risk.

**Methods:** Data for this matched case control study were derived from hemodialysis (HD) population at the Fresenius Medical Care North America (FMCNA). Cases were identified from FMCNA calciphylaxis prospective database. Controls (HD patients without calciphylaxis) were matched to cases on age, sex, and race. Data on variables at HD initiation were abstracted. Variables for multivariable logistic regression analyses were identified using stepwise selection.

**Results:** We analyzed 1,025 calciphylaxis cases (52% biopsy-confirmed) and 2,050 controls. Body mass index, diabetes mellitus (DM), serum parathyroid hormone (PTH) level, use of warfarin and phosphate binders were higher whereas serum calcium and active vitamin D use were lower at HD initiation in cases compared to controls.
No significant differences were noted for serum phosphorous, diacylate calcium, use of statins and cinacalcet. In DM subgroup, insulin injection use was more common in males. In multivariable analyses, obesity (OR: 2.55, 95% CI: 1.82-3.59), DM (OR: 2.63, 95% CI: 1.83-3.69), use of warfarin (OR: 3.60, 95% CI: 2.40-5.41) and insulin injections (OR: 1.29, 95% CI: 1.07-1.89) were associated with higher risk. Similar results were noted in analyses restricted to biopsy-confirmed cases.

Conclusions: Obese, diabetic HD patients treated with insulin injections or warfarin are at high risk for calciphylaxis.

SA-PO612 Calciphylaxis Quality Improvement Project and Case Series Rohan V. Mehta, Jean Luc Franck, Jason Cobb. Renal Div, Emory Univ, Atlanta, GA.

Background: Calciphylaxis (Calcific Uremic Arteriopathy) is a serious condition characterized by extended length of stays and multiple hospital admissions. The treatment of calciphylaxis can become a burden on the healthcare system especially with the demand on hospital systems to become more efficient. The lengths of stay & 30-day readmission rates are becoming a measure of hospital quality. We developed a multidisciplinary team including nephrologists, hospitalists, dermatologists, hospital administration, nurses, wound care staff, social workers, dieticians, and palliative care. The purpose of the team is to improve the quality of care of our calciphylaxis patients. In development of this quality improvement project we began by examining our baseline patient population. We are reporting our baseline data as a case-series.

Methods: Retrospective chart review of calciphylaxis patients from 2001-2014 in our single center hospital which includes academic and community physicians. Baseline data reported included age, calcium, phosphorus, PTH, albumin, hemoglobin, creatinine, BUN, and the use of warfarin. Treatment options, the length of stay, and number of admissions were reported.

Results: In 20 reported patients, 19 were African-American. Average age was 61 years old. Average calcium levels of 8.8 mg/dl and phosphorus of 5.5 mg/dl. The average PTH was 573, albumin 2.75 gm/dl, hemoglobin of 10.4 gm/dl, BUN of 42, and creatinine 6.5 mg/dl. 13 patients received hyperbaric oxygen treatment, 9 patients received sodium thiosulfate infusions and, 6 patients received cinacalcet. 11 patients were using warfarin for medical conditions including atrial fibrillation and deep venous thrombosis. The average length of stay was 45 days and 3 admissions per patient.

Conclusions: We reported one of the largest single center and predominant African-American calciphylaxis case series. In comparison to other reported calciphylaxis series our average PTH was lower and a high percentage of our patients were using warfarin at time of diagnosis. Future tasks include testing if the multidisciplinary quality improvement team interventions can improve our patient quality of care and hospital goals such as reductions in length of stay and 30-day readmission rates.

SA-PO614 The German Calciphylaxis Registry Vincent Brandenburg, Jürgen Floege, Joanna Korbiul, Markus Ketteler. 1Cardiology, RWTH Aachen Univ Hospital, Aachen, Germany; 2Nephrology, RWTH Aachen Univ Hospital, Aachen, Germany; 3Nephrology, Klinikum Coburg, Coburg, Germany.

Background: Calciphylaxis (CUA) is a rare disease and for patients a devastating condition associated with high morbidity and mortality. CUA is characterised by painful, ischemic, partly necrotic skin ulcerations. Pathomorphologically, media calcification of cutaneous arterioles and extracellular matrix remodelling are the hallmarks of CUA. Epidemiology and risk factors are incompletely understood. Referring patients to specialized units is limited due to high disease burden.

Methods: Therefore, we established an internet-based observational registry in 2006 (www.calciphylaxie.de) to allow online notification for pts with CUA. The registry includes a comprehensive data base with 71 parameters concerning patient and laboratory data, clinical background and presentation as well as therapeutic strategies. The diagnosis of CUA is made on clinical and/or histological grounds by the referring physician.

Results: Until Feb 2015 n=253 patients with CUA have been recorded (~30 pts/year at constant rate) with a median delay of 28 days after onset: 99% Caucasians, 60% females; 76% HD and 10% PD patients; median age 66 (IQR 59-76) years. Co-medication at the time of diagnosis: 75% ESA, 51% vitamin K antagonists (VKA). Skin biopsy was done in 45%, prior PEx in 12%; major skin lesion in 80% at the legs. Median lab data upon diagnosis of CUA: AK Phos 113 U/L (IQR 86-167); PT 173 mg/L (IQR 73-390); total calcium 2.20 mmol/L (IQR 2.04-2.36); phosphorus 1.62 mmol/L (IQR 1.28-2.00). Among the most frequently recorded therapeutic procedures were: surgical necrosectomy (plus antibiotics), intensifying dialysis modality, reduction of calcium supply, i.v. sodium-thiosulfate application. Survival was analyzed in a subgroup of 91 pts. Median survival time was 516 days after online notification.

Conclusions: CUA is a rare disease among ESRD pts with high mortality. Therapeutic strategies vary significantly among centers; EBM guidelines are absent. VKA usage appears to be a risk factor for CUA in ESRD pts. The German CUA registry is a valuable tool to collect data and may become a basis for a European registry (EuCalNet).

SA-PO615 Evaluation of the Effects of Sodium Thiosulfate Treatment on Calciphylaxis Pain Guillermo Ortiz, Joshua Wibecan, Julia Beth Wenger, Ravi I. Thadhani, Sagar U. Nigwekar. Nephrology Div, Massachusetts General Hospital, Boston, MA.

Background: Intravenous sodium thiosulfate (STS) is commonly prescribed to treat calciphylaxis, a highly fatal disease that presents with excruciating painful skin lesions. Anecdotal reports suggest that STS may improve calciphylaxis associated pain (CAP) within 2 weeks of initiation; however, systematic evaluation of effects of STS on CAP is lacking.

Methods: This observational study included 22 patients with biopsy-confirmed calciphylaxis who were hospitalized at our center for ≥ 2 weeks during 2012-2014 for newly diagnosed calciphylaxis and were treated with STS. Medical records were reviewed to abstract clinical data including CAP severity (0-10 scale) and analgesic use. CAP scores at baseline, 1-week, and 2-week time-points were noted and classified into mild (1-3), moderate (4-6), or severe (7-10) CAP.
moderate (4-6), and severe (7-10) categories. Responders were patients who reported ≥30% improvement in CAP severity score from baseline during the first 2 weeks of treatment. Predictors of response and association between CAP response during the first 2 weeks of STS treatment and 6-month outcomes (skin lesion status, mortality) were examined in univariate logistic regression analyses.

Results: Median age was 60 years (Range: 52-67). 59% were males, 95% were whites, 55% were on dialysis, 36% had chronic kidney disease not requiring dialysis, and 9% had normal kidney function. Median duration between lesion appearance and STS initiation was 12 weeks (Range: 6-19). There was a trend toward decrease in severe CAP from baseline to 2-weeks (figure 1) despite steady doses of opiate medications. No significant predictors of CAP response were observed and CAP improvement at 2-weeks did not predict 6-month outcomes.

Conclusions: A large prospective trial is needed to ascertain the effects of STS on CAP.

SA-PO616

Long-Term Impact of Strict Blood Pressure Control During CKD on Mortality Risk After ESRD

Evan Ku,1 Lawrence J. Appel,2 Jennifer J. Gassman,2 Miroslaw Smogorzewski,2 Mark J. Sarnak,3 David V. Glidden,1 Chi-yuan Hsu,1 UCSCF, 2AASK, 3Tufts.

Background: In extended follow-up of the Modification of Diet in Renal Disease (MDRD) study, we reported that strict BP control did not lower risk of ESRD but associated with lower mortality risk after ESRD (HR 0.72 [95% CI 0.58-0.89]) (Ku KI 2015). To further address this issue, we conducted parallel analyses in the African American Study of Kidney Disease (AASK) and post-hoc pooled analyses of AASK and MDRD.

Methods: AASK randomized 1094 persons with CKD attributed to hypertension to BP control targets (≤130/80 mmHg) vs usual care (≤140/90 mmHg). Median duration of follow-up was 6.2 years. We evaluated the effect of time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients with normal or mildly reduced kidney function using a Cox proportional hazards model as estimated by pooled logistic regression to assess the hazards of developing a 50% reduction in estimated glomerular filtration rate (eGFR) or end stage renal disease. In addition to adjusting for baseline comorbidities including age, gender, socioeconomic status, cardiovascular disease, and body mass index (BMI), we adjusted for time-varying covariates including systolic blood pressure (SBP), number of antihypertensive medications, use of mineralocorticoid antagonists, and eGFR.

Results: There were 219,701 patients that met inclusion criteria, with a median 4.9 years of follow-up. Median baseline eGFR was 72.6 mL/min/1.73m², median SBP was 146 mmHg, and median BMI was 32.8 kg/m²; 59% of patients were on RAS blockade at baseline, and 60% of patients were on it for at least half the duration of follow-up. Taking into account time-updated exposure, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93, p<0.01).

Conclusions: This study, conducted in a large real-world cohort of patients with detailed and time-updated data about blood pressure treatment, provides important evidence that RAS blockade may protect against deterioration in renal function among obese, hypertensive, non-diabetic patients.

Obesity, Renin-Angiotensin System Blockade, and Chronic Kidney Disease: A Population-Based Cohort Study

Background: Obesity substantially increases the risk of the development and progression of chronic kidney disease. Adipose tissue expresses all of the components of the renin-angiotensin system (RAS), which is an important contributing factor to the high prevalence of hypertension in obese patients, and drives renal hyperfiltration and subsequent glomerular injury.

Methods: We performed a retrospective cohort study using the Health Improvement Network, a primary care database with comprehensive demographic, laboratory, and pharmacy data. We analyzed data from patients in the United Kingdom. We calculated the effect of time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients with normal or mildly reduced kidney function using a Cox proportional hazards model as estimated by pooled logistic regression to assess the hazards of developing a 50% reduction in estimated glomerular filtration rate (eGFR) or end stage renal disease. In addition to adjusting for baseline comorbidities including age, gender, socioeconomic status, cardiovascular disease, and body mass index (BMI), we adjusted for time-varying covariates including systolic blood pressure (SBP), number of antihypertensive medications, use of mineralocorticoid antagonists, and eGFR.

Results: There were 219,701 patients that met inclusion criteria, with a median 4.9 years of follow-up. Median baseline eGFR was 72.6 mL/min/1.73m², median SBP was 146 mmHg, and median BMI was 32.8 kg/m²; 59% of patients were on RAS blockade at baseline, and 60% of patients were on it for at least half the duration of follow-up. Taking into account time-updated exposure, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93, p<0.01).

Conclusions: This study, conducted in a large real-world cohort of patients with detailed and time-updated data about blood pressure treatment, provides important evidence that RAS blockade may protect against deterioration in renal function among obese, hypertensive, non-diabetic patients.

Distribution and Prognostic Value of Central Blood Pressure in Chronic Kidney Disease

Yun Jung Oh,1 Su Mi Lee,2 Ji Yong Jung,3 So Mi Kim,4 Chung Sik Lee.1 Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; 2Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; 3Dept of Internal Medicine, Gacheon Univ Gil Hospital, Incheon, Republic of Korea; 4Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.

Background: Central blood pressure (CBP) has been shown to be a better predictor for cardiovascular events and target organ damages than brachial blood pressure. However, little is known about comparative values of CBP and brachial BP in chronic kidney disease (CKD) population. We investigated the distribution of CBP and evaluated the comparative value of CBP and brachial BP for the prediction of renal progression in both CKD and non-CKD population.

Methods: We conducted this study using data from 868 subjects who underwent CBP measurement by the radial artery tonometric method between 2009 and 2013. Demographic and clinical characteristics were obtained from a review of the medical records at the time of CBP measurement. The outcome was renal progression defined as decline of estimated glomerular filtration rate greater than 30% of baseline during the follow-up.

Results: In overall, estimated central systolic BP (cSBP) was higher than brachial systolic BP (bSBP). The cSBP was significantly increased with age in non-CKD group, but such a correlation was not observed in CKD group. In CKD population, high cSBP group with greater than mean cSBP value (>130mmHg) had significantly increased probability of renal progression (P=0.016), while high bSBP (>140mmHg) group did not predict the outcome (P=0.370). In contrast, the predictor of renal progression was high bSBP but not cSBP in non-CKD population. In Cox analysis adjusted for covariates, high cSBP remained a predictor of renal progression in CKD population (HR 5.408; 95% CI 1.008-29.030; P=0.049), whereas high bSBP was not a significant predictor in non-CKD population (HR 2.891; 95% CI 0.786-10.650; P=0.110).

Conclusions: The CBP had different correlation with age and clinical significance according to presence or absence of CKD, and the high cSBP was strong independent predictor of kidney disease progression in CKD patients.

Clinical Characteristics and Outcomes Associated with Resistant Hypertension in a Large Cohort of U.S. Veterans
Miklos Zsolt Molnar,1 Adriana Hung,1 Jun Ling Lu,1 John J. Sim,1 Robert B. Canada,2 Elvira Gosmanova,2 Fridthjof Thomas,1 Kamyray Kalantar-Zadeh.3 1VA Medical Center, Memphis, TN; 2Univ of Tennessee Health Science Center, Memphis, TN; 3VA Medical Center, Nashville, TN; 4Kaiser Permanente, CA; 5Univ of California, Irvine, CA.

Background: The prevalence of true resistant hypertension (RH), the characteristics of patients with RH and its association with clinical outcomes is unclear.

Methods: From 2,398,778 patients with essential HTN, we identified 95,334 (4%) with RH, defined as: Failure to achieve BP<140/90 mmHg with >=3 antihypertensives (one being a thiazide diuretic) or success with >=4 drugs; excluding measurements when patient was <5, when interfering medications were prescribed and excluding those with confounding conditions (CKD, secondary HTN, sleep apnea, urinary obstruction, arterial, thyroid and parathyroid over-activity). We examined with mortality, incident CKD, ESRD, steeper slopes of eGFR, incident coronary heart disease (CHD) and stroke in Cox models and logistic regression models adjusted for demographic and socioeconomic factors, comorbidities, BP, and antihypertensives.

Results: The mean SBP,DBP in RH and non-RH patients were 148±22/81±14 vs. 137±19/78±12 mmHg. Compared to non-RH, patients with RH were older (64 ±11 vs. 60 ±13), more likely to be black (25 vs. 17%), and had a higher prevalence of DM and CVD.

The prevalence of true resistant hypertension (RH), the characteristics of patients with RH and its association with clinical outcomes is unclear. Therefore, methods were developed to identify patients with RH. This study aimed to assess the clinical characteristics and outcomes associated with RH.

Conclusions: RH is relatively infrequent (4%) among patients with essential HTN, and is associated with older age and a higher comorbidity burden. Patients with RH have a greater risk of incident CHD and stroke.

SA-PO620
Association of Components of Body Mass Index with Treatment-Resistant Hypertension in Men and Women with Chronic Kidney Disease
Toshiyuki Aoki,1 Yasushi Ohashi,1 Reibin Tai,1 Kiyoto Koibuchi,2 Kiyoto Koibuchi,2 Atsushi Aikawa,1 Ken Sakai,1 1Nephrology, Toho Univ School of Medicine, Ohta-ku, Tokyo, Japan; 2Nephrology, Saiseikai Eastern Hospital, Yokohama, Kanagawa, Japan.

Background: Treatment-resistant hypertension is a risk for cardiovascular disease and end-stage renal disease. However, the appropriate clinical management strategies remain unclear in patients with CKD. Our objective is to investigate the association of components of body mass index (BMI) with treatment-resistant hypertension in patients with CKD.

Methods: Body fluid composition was measured in 310 patients with CKD from 2005 to 2014, and BMI was separated into 3 components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW), and (c) extracellular water (ECW). Treatment-resistant hypertension was defined as an office BP of >130/80 mmHg, despite receiving >=3 antihypertensives including diuretics, or >=4 drugs usage. The main outcomes were adverse renal outcomes, as defined by a decline of 50% or more from baseline GFR or initiation of renal replacement therapy and cardiovascular events.

Results: The prevalence of treatment-resistant hypertension were 69 male patients (35.4%) and 19 females (16.5%). Patients with treatment-resistant hypertension were more likely to be diabetic, have a higher BMI, GFR, and proteinuria, and to be older especially in women. In the components of BMI, those in men and women tended to have higher ECW content and free water mass, respectively. Higher ECW contents in men and diabetes in relation to higher free water mass in men were independently caused treatment-resistant hypertension. Compared with patients with no treatment-resistant hypertension during a median 743-day follow-up, those with treatment-resistant hypertension had worse adverse renal outcomes (16.2 vs. 6.1 per 100 patient-years, P < 0.001) and cardiovascular events (5.0 vs. 1.6 per 100 patient-years, P < 0.001).

Conclusions: Treatment-resistant hypertension is associated with diabetes in relation to higher free water mass in men and higher ECW in men, which exhibits adverse renal outcomes and cardiovascular events. These findings emphasize the importance of adequate weight and volume status.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: 1. RDN leads to the temporary decrease of plasma reninase concentration in patients with HTN. 2. Lower plasma reninase concentrations seems to be a counteractive reaction to the antihypertensive effects of RDN.

A Non-Vascular Treatment for Resistant Hypertension Richard R. Heusser, Adam Gold. 1, 2
1Cardiology, St. Luke’s Medical Center, Phoenix, AZ; 2Verve Medical, Scottsdale, AZ.

Background: Systemic arterial hypertension remains the most common and important risk factor for cardiovascular and renal disease. A safe and effective medical device effecting a significant and immediate fall in arterial BP addresses an unmet clinical need. Early clinical experience with the Verve non-vascular device causes an immediate BP drop in patients with resistant hypertension.

Methods: In humans, there is a greater abundance of efferent compared with afferent nerve fibers and the afferent nerves are much less abundant in general and are much less abundant as one goes away from the aorta. In contrast to the widespread distribution of EFFERENT Sympathetic nerve fibers in the kidney, the majority of the AFFERENT Renal Sensory nerves are located in the renal pelvic area. With our first generation device, we treated patients with resistant hypertension. Four patients with resistant hypertension were treated. They had immediate blood pressure drop (Systolic Mean 44mmHg, Diastolic Mean 13mmHg), which was maintained for 3 months. Because of the possibility of calyceal damage noted in follow-up in our animal model, we have redesigned the probe and shortened the duration of therapy.

Results: In over two dozen animals, it appears that we get a similar histopathologic results with our first generation probe without late pelvic or calyceal damage. In our first clinical application of this helical probe, there also is an immediate blood pressure drop.

Conclusions: Unlike other renal derervation treatments, the Verve natural orifice approach appears to treat the afferent nerves and results in an immediate blood pressure drop. More patients will need to undergo treatment to confirm these encouraging results. We will present our first series of resistant hypertensive patients treated with the helical device.

SA-PO624

Background: Preeclampsia is a hypertensive disorder of pregnancy associated with high morbidity and mortality. Hallmarks of preeclampsia are endothelial damage and functional (e.g. proteinuria) and morphological renal aberrations. The only known remedy against this is the delivery of the placenta. Cell derived microparticles (MP) of different origins are elevated in preeclampsia but their mechanistic relevance is unknown. Preeclampsia is also associated with a pro-inflammatory condition but there are meager mechanistic insights into this as well.

Methods: To address these questions MP (endothelial or platelet derived) were injected into C57Bl/6 pregnant mice and the pregnancy outcome (embryonic survival and growth, placenta morphology) was studied. Morphology of the kidney was studied using PAS staining and electron microscopy. Proteinuria was studied as a measure of renal dysfunction. To address mechanistic questions, inflammasome activation by MP in placenta and trophoblast cells was studied using western blotting and immunohistochemistry. Human trophoblast derived cells and placentas from pregnancies complicated with preeclampsia were also studied for activation of inflammasome. NLRP3 and Casp-1 KO mice were used to rescue the mice from disease conditions and establish causality of the mechanism.

Results: MP caused preeclampsia associated with fetal loss and embryonic growth restriction in mice. This was associated with renal damage indicated by proteinuria, glomerular enlargement, thickness of glomerular basement membrane, and podocyte effacement in the kidney. Human and mouse placenta analysis indicated inflammasome activation seen by elevated expression of NLRP3, cleaved casp-1 and IL-1β. The pregnancy outcome and renal function was rescued in NLRP3 and Casp-1 KO mice.

Conclusions: The findings stress the importance of a close follow up to identify those women who need further care.

Mean follow up 172 days (+/-39.6) after delivery

Preeclampsia: Long-Term Effects on Pediatric Neurologic Disability
Alberto Tejedor Jorge, Clara Nicolas, Patricinio Rodriguez Benitez, Olga Arroyo, Maria Silva, Laura Matesanz, Carmela Mercurio, Manuel Sánchez Luna. Hospital General Univ Gregorio Marañon.

Background: Preeclampsia affects up to 10% of pregnancies worldwide and is one of the main causes of fetal morbidity and mortality. Although it has been linked to developmental delay, its long-term effects on neurodevelopment in children have yet to be sufficiently quantified. Our aim is to evaluate whether the preeclampsia’s severity and the therapeutic options used to manage it correlate to the degree of developmental delay in these infants.

Methods: This is an observational and descriptive study performed on a population of 96 women who were diagnosed with preeclampsia at Hospital General Universitario Gregorio Marañón between 2007 and 2014, and their 111 children. To evaluate the mother, we gathered data pertaining to her medical history, renal function markers, and medical management of the preeclampsia. To assess the children, we collected fetal growth measurements, acute fetal distress markers and main diagnoses at birth. We used the Pediatric Disability Inventory in its computerized adaptive test version (PEDI-CAT) to study neurologic development, and the TNO-ASL Preschool children Quality of Life (TAQPOL) to estimate health-related quality of life.

Results: Early-onset and more severe preeclampsias were associated with higher preterm birth and perinatal mortality rates. Preeclampsias with a greater impact on maternal organ function showed a clear correlation to higher periventricular-intraventricular hemorrhage rates in the newborn. In terms of neurologic development, PEDI-CAT percentiles were consistently lower in the Social/Cognitive domain than in other areas. Lower Social/Cognitive percentiles were associated to both lower maternal IgG levels and lower Social/Cognitive percentiles were consistently lower in the Social/Cognitive domain than in other areas. Hemorrhage rates in the newborn. In terms of neurologic development, PEDI-CAT percentiles were consistently lower in the Social/Cognitive domain than in other areas. Lower Social/Cognitive percentiles were associated to both lower maternal IgG levels and lower Social/Cognitive percentiles were consistently lower in the Social/Cognitive domain than in other areas.

Conclusions: Lower Social/Cognitive percentiles were associated to both lower maternal IgG levels and poor social/cognitive outcomes exists that warrants further research, as does the possible link between preeclampsia, immaturity, and autistic features.

SA-PO627
Do Hypertension Providers Inquire About Hypertension in Pregnancy? 
Andrea G. Kattah, Vesna D. Garovic. Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Background: Hypertensive pregnancy disorders are increasingly recognized as a risk factor for future hypertension and cardiovascular disease. However, knowledge of this risk may be inadequate among internal medicine providers.

Methods: We reviewed all new consults in a 2-month period in a hypertension subspeciality clinic. We determined the frequency with which providers documented a reproductive history, a history of hypertension in pregnancy and known cardiovascular risk factors. We also studied whether there were differences according to gender and level of training of the provider (consultants vs. residents/fellows) using the chi-square test.

Results: There were 102 consults for hypertension in the study period. The majority of consults were by consultants, 55/102 (53.9%), and 23/102 (22.6%) were by female providers. The most frequent questions were dietary issues, 29 (62%) 32 (58%) 0.72 for women and men respectively. Other questions included alcohol use, exercise, and family history of hypertension, 37 (79%) 36 (55%) 0.94 for men and women respectively. There was no significant difference between the two groups for illicit drug use, smoking, diabetes, dyslipidemia, renal disease, and hypertension in pregnancy.

Conclusions: Hypertension providers rarely document a reproductive history or a history of hypertension in pregnancy, irrespective of level of training. Female providers were more likely to document pregnancies.

SA-PO628
Accuracy of a Spot Urine Protein-to-Creatinine Ratio in Preeclampsia
Roshni Upadhyaya 1 Juliet Mushii, 2 Mary King, 2 Belinda Bun Jim, 1 Anjali Acharya.
1 Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; 2 Obstetrics, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY.

Background: Correlation between a 24 hour urinary protein excretion with a spot urine protein-to-creatinine (SP/Cr) ratio in patients with preeclampsia is unclear. Moreover, urinary creatinine excretion is greater in populations such as Africans and non-white Hispanics. We studied the correlation of the SP/Cr ratio with a 24 hour urine protein measurement in this minority population.

Methods: ICD-9 codes of 642.4, 642.5, 642.6, 642.7 representing mild pre-eclampsia to eclampsia were used for data collection. Only 110 women with both 24 urinary protein collection and (SP/Cr) were included in the analysis. Correlation between SP Cr and 24-hour protein excretion was assessed by Spearman correlation coefficient. The sensitivity and specificity of the SP/Cr ratio at various cut-offs for the prediction of significant proteinuria were estimated with a 95% confidence interval, using the 24-hour urine collection as gold standard. Receiver operating characteristic (ROC) curve analysis was used to determine the best discriminator values of the (SP/Cr) to predict proteinuria above 300 mg/24 hr. A value of 0.05 or less was significant.

Results: The median SP/Cr ratio was 0.30 (interquartile range (IQR) 0.3) while the median 24 hour urine protein was 316.5 mg (IQR 286.8). The overall Spearman correlation was 0.48 (P < 0.001), and 0.63 (P = 0.05), 0.59 (P = 0.1), and 0.45 (P = 0.001) for the 1st, 2nd, and 3rd trimesters respectively. At the cut-off value of 0.15 for SP/Cr, the sensitivity and specificity were 91.8% and 75.5% respectively. The cut-off SP/Cr ratio 0.25 was identified as the best threshold to detect a 24 hour protein excretion of 300 mg with a sensitivity and specificity of 75% and 59% respectively. The area under the curve (AUC) by the ROC curve analysis was found to be 0.69.

Conclusions: Even in a minority, inner city population we found significant correlation between the 24 hour protein excretion and the SP/Cr ratio, especially in the 2nd and 3rd trimesters of preeclampsia. Our findings are in line with the literature despite a minority patient population.

SA-PO629
Thiazide Diuretics for Hypertension in Kidney Transplant Recipients Using Tacrolimus
Arthur David Moes, Dennis Alexander Hesselinck, Anton H. Van den Meiracker, Robert Zietse, Ewout J. Hoorn. Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

Background: Hypertension after kidney transplantation is common and associated with poorer graft and recipient outcomes. Recently, we and others showed that tacrolimus activates the thiazide-sensitive sodium chloride cotransporter to cause hypertension. This suggests that thiazide diuretics may be especially effective drugs in this context, but prospective data are lacking.

Methods: We conducted a non-inferiority crossover trial to compare chlorthalidone (CT, 12.5-25 mg) with amlopidine (AML, 5-10 mg). Patients were invited for ambulatory blood pressure measurement (ABPM) if office BP >140/90 mmHg. Other criteria included eGFR >30 ml/min, proteinuria < 1 g, and no use of glucocorticoids. The treatment periods were randomized, last 8 weeks (allowing dose titration after 2 weeks), and were separated by a 2-week wash-out. Background anti-hypertensive drugs were allowed except for diuretics.

Results: 71 patients underwent initial ABPM of whom 45 patients (63%) with average wake SBP>140 mmHg were enrolled (median 2.6 years after transplantation). 38 patients completed the study (5 patients stopped during CT mainly due to electrolyte disorders vs. 2 during AML, p=0.4). CT and AML both markedly reduced ABPM after 8 weeks (151/85 ± 119/81 to 129/9 mmHg vs. 151/84 ± 13/9 to 138/79 ± 147 mmHg). There was no statistical difference in blood pressure response between the two drugs (p=0.3 by 2-way ANOVA). Dose titration rates were similar (42% for CT vs. 37% for AML, p=0.8). CT decreased eGFR (53 ± 17 to 46 ± 15 ml/min), whereas amlopidine increased it (50 ± 16 to 53 ± 17 ml/min, P<0.001). The first post-CT eGFR returned to baseline (51 ± 17 ml/min). Treatment with CT resulted in less proteinuria (median 14 vs. 19 mg/mmol, p=0.03) and less edema (8 vs. 31%, p=0.02). Regression analysis showed that a higher aldosterone to renin ratio, lower baseline serum potassium, and higher baseline serum bicarbonate predicted a better anti-hypertensive response to CT.

Conclusions: Thiazide diuretics effectively lower blood pressure in kidney transplant recipients using tacrolimus. Thiazides were especially effective in patients with more aldosterone effect.

The Detrimental Effects of Beta-Blockers on Central Hemodynamic Parameters: A Propensity Score Analysis

Dominique Goupil,1  Dominique Dupuis,1  Stephan Troyanov,1  Francois Madore,1  Mohsen Agharazii,2

with decreased risk of development of dementia in comparison to treatment without CCBs. Results: In Model 1, the difference between peripheral and central systolic BP (DSBP) was 8.3 mmHg (OR 5.8, 11.6) with BB compared to 9.7 mmHg (7.1, 13.5) without (p<0.001), indicating that for any given peripheral BP, BB use resulted in higher central systolic BP. Pulse pressure amplification, augmentation index and augmented pressure were also less favorable with the use of BB. The different HR in Model 2 further increased the detrimental DSBP observed with BB to 7.9 (5.6, 11.0) vs. 10.6 (8.1, 14.3) without (p<0.001) and was associated with a higher central pulse pressure (46.5 ± 13.0 vs. 43.3 ± 11.3, p<0.001).

Conclusions: This study shows that the unfavorable central hemodynamic profile of BB has both a HR-dependent and a HR-independent component.

Funding: Government Support - Non-U.S.

SA-PO631
Risk of Development of Dementia During Treatment of Hypertension with Different Calcium Channel Blockers

Leonid Feldman,1  Shai Efrati,1  Ilia Beberashvili,2  Shlomo Vinker,2  Michal Shami,2

Background: Arterial hypertension (HTN) is proved to be a risk factor for development of dementia. Medical treatment of HTN may decrease the risk of dementia. Experimental study pointed to the possibility of difference between different calcium channel blockers (CCB) in their neuro-protective effect. The aim of our study was to evaluate the risk of dementia during treatment of HTN with one of three different CCBs.

Methods: This is a retrospective cohort study based on electronic database of Clalit Health Services, Central District. Study period was 11 years (2002-2012). Inclusion criteria: age 40-75, diagnosis of HTN without diagnosis of “Dementia” at the starting point, minimal duration of treatment >30 months with single specific CCB. New diagnosis of dementia was established according to appearance of its diagnostic code in the chronic diseases register or prescription of medication for its treatment – whatever occurred first. Results: 15,664 patients were included in the study: 3,884 were treated with amlodipine, 2,062 - with nifedipine, 609 - with lercanidipine and 9,109 never received CCBs. The mean age was 60.7 years, 52.9% were females and the mean baseline creatinine was 1.0 mg/dL. 13.4% of patients died during the study period. Dementia developed in 765 (4.9%) patients. Adjusted HR of dementia in patients treated with amlodipine, nifedipine and lercanidipine was 0.60 (p=0.001), 0.89 (NS) and 0.90 (NS).

Conclusions: Treatment of arterial hypertension with amlodipine may be associated with decreased risk of development of dementia in comparison to treatment without CCBs.

SA-PO632
The Association Between Antihypertensive Agents and Postural Blood Pressure Response Using Beat-to-Beat Data: Results from the Irish Longitudinal Study on Ageing

Mark N. Canney,1  Matthew D. O’Connell,1  Catriona M. Murphy,1  Mark Alan Little,1  Conall M. O’Seaghdha,2  Rose Anne M. Kenny,1

Background: Beat-to-beat blood pressure (BP) measurements provide a dynamic picture of BP behavior during postural change. Impaired BP stabilization after standing is associated with substantial morbidity and mortality. We aimed to define the relationship between class of antihypertensive drug and BP stabilization during an active stand.

Methods: Cross-sectional analysis from The Irish Longitudinal Study on Ageing, a nationally representative cohort study of 8175 adults ≥50 years. Beat-to-beat BP was recorded in participants undergoing an active stand test. We defined grade 1 hypertension according to European Society of Cardiology criteria (systolic BP [SBP] ≥140-159mmHg ≥ diastolic BP [DBP] 90-99mmHg). Orthostatic hypotension (OH) was defined as a drop in SBP ≥20mmHg ≥ DBP ≥10mmHg. Outcomes were sustained OH (OH throughout the test) and impaired BP stabilization (OH at each 10-second (s) interval during the test [total 110s]). Outcomes were assessed using logistic regression models adjusted for potential confounding variables.

Results: A total of 536 participants with self-report hypertension were receiving monotherapy with a renin-angiotensin-aldosterone-system inhibitor (317), betablocker (89), calcium channel blocker (89) or diuretic (41). Betablockers were associated with increased odds of sustained OH vs untreated grade 1 hypertension (OR 3.4, 95% CI 1.9-6.0). This was evident from 20s (OR 2.3, 95% CI 1.4-3.7) and remained statistically significant at 110s (OR 2.8, 95% CI 1.6-4.9). Multivariable adjustment did not attenuate the association. No significant association was detected among the other drug classes.

Conclusions: In older hypertensive adults betablocker monotherapy was associated with increased odds of increased odds of OH compared to subjects with untreated grade 1 hypertension. The effect was evident from 20s after standing and was sustained. This should inform decision-making regarding appropriate choice of antihypertensive agent in older adults.

Funding: NIDDK Support

SA-PO634
Effect of Vitamin D on 24 Hour Ambulatory Blood Pressure: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Ciaran Joseph McMullan,1  Lea Borgi,1  Gary C. Curhan,1  Naomi D.L. Fisher,1  John P. Forman.1

Background: Lower levels of 25-hydroxyvitamin D (25(OH)D) have been associated with an increased risk of hypertension in prospective cohort studies, suggesting that vitamin D might be a modifiable target for the prevention of hypertension. Vitamin D supplementation has also been shown to decrease clinic blood pressure (BP) in some studies.

Methods: We performed a randomized, double-blind, placebo-controlled trial of nonhypertensive participants with body mass index ≥25, and 25(OH)D<20ng/mL; subjects were randomized to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Mean 24 hour BP was measured using 24 hour ABPM at baseline and 8 weeks after starting the study. Results: By the end of the trial, 29 and 27 participants randomized to receive vitamin D and placebo, respectively, had adequate 24 hour ABPM at both baseline and at 8 weeks. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the intervention group and from 14.4 to 17.4 ng/mL in the placebo group. Vitamin D supplementation did not lower BP at 8 weeks; 24 hour systolic BP changed from 120±10 to 122±8 mmHg in the intervention group (p-value=0.29), and from 124±8 to 125±10mmHg in the placebo group (p-value=0.38), with a treatment effect p-value of 0.92.

Conclusions: In this randomized, double-blind, placebo-controlled trial of overweight/obese normotensive individuals, there was no improvement in mean 24 hour blood pressure after repletion of vitamin D. These findings are not consistent with vitamin D being a modifiable target for prevention of hypertension.

Effect of Uric Acid Lowering on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Ciaran Joseph McMullan,1  Lea Borgi,1  Gary C. Curhan,1  John P. Forman.1

Background: The relationship between serum uric acid on RAS activity in humans is unknown. We performed a randomized, double-blind, placebo-controlled trial analyzing the Modifiable Effectors of Renin System Activation Treatment Evaluation (MODERATE). Normotensive individuals with body mass index (BMI) ≥25 and uric acid level ≥ 5.0 mg/dL.

Funding: Government Support - Non-U.S.
Comparison of Office Orthostatic Blood Pressure and 24-Hour Ambulatory Blood Pressure Measurements in the Prediction of Autonomic Dysfunction

Background: Evaluation of orthostatic hypotension (OH) may involve office orthostatic blood pressure (BP<sub>OP</sub>) measurements, 24-hour ambulatory BP (ABP) and autonomic reflex screen (ARS). We investigated the predictive performance of BP<sub>OP</sub> and the variables of ABP, i.e., reversal of circadian pattern (RCP), postprandial hypotension (PPH) and noncompensatory heart rate variability (HRV), to predict autonomic dysfunction as measured by the AUC of the ROC curves.

Methods: Data from previously published study were analyzed. Ninety-four patients were included for analysis. BP<sub>OP</sub>, RCP, PPH, HRV were investigated for the presence or absence of autonomic dysfunction. Autonomic dysfunction was defined as a CASS SA-PO636

Effect of Vitamin D Supplementation on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Clarian Joseph McMullan, Lea Borgi,1 Gary C. Curhan,2 Naomi D.L. Fisher,1 John P. Forman.1 1Pediatric Nephrology and Cardiology, Fondazione IRCCS Ca' Granda Policlinico, Milan, Italy; 2Pediatric Cardiology, Policlinico A. Ahsan Ejaz, 2 Patrizia Salice.1

Background: Disruption of vitamin D signalling in rodents causes activation of the renin angiotensin system (RAS). In humans lower circulating 25(OH)D is associated with increased renal specific RAS activity (measured using renal plasma flow [RPF]; in addition, a small, open label, uncontrolled study found that vitamin D supplementation decreased renal specific RAS activity. However, the effect of vitamin D supplementation on the RAS in humans with vitamin D deficiency has never been examined in a rigorous manner.

Methods: We performed a randomized, double-blind, placebo-controlled trial of normotensive individuals with body mass index <25 and vitamin D deficiency (25(OH)D £20ng/mL). subjects were assigned to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Renal specific (assessed by RPF response to captopril in high sodium balance) and systemic RAS activity (plasma renin activity [PRA] and angiotensin II levels [AngII]) were measured at baseline and 8 weeks after starting the study.

Results: By the end of the trial, 43 and 41 participants allocated to receive vitamin D and placebo, completed the study with measurement of renal and systemic RAS activity. Mean vitamin D levels increased from 14.9 to 30.3 ng/mL in the ergocalciferol group and from 14.4 to 17.4 ng/mL in the placebo group. Renal specific D supplementation did not significantly change after vitamin D depletion: the RPF response to captopril was 33.9±56.1 mL/min at baseline and 35.7±87.7 mL/min at 8 weeks in the ergocalciferol group (p-value=0.26); and was 37.3±46.9 mL/min at baseline and 35.9±26.2 mL/min at 8 weeks in the placebo group (p-value=0.70), with a treatment effect p-value of 0.27. Similarly, vitamin D supplementation had no effect on PRA or AngII levels.

Conclusions: In contrast to animal experiments and observational studies, this randomized, double-blind, placebo-controlled trial found that lowering ionic acid had no effect on renal specific or systemic RAS activity.

Funding: NIDDK Support

SA-PO635

The diagnostic performance to predict autonomic dysfunction for HRV was superior to PPH. Both were superior to RCP. RCP was a better predictor of autonomic dysfunction than office BP<sub>OP</sub>.

Conclusions: Our data suggests that ABP is a reliable, simple and inexpensive predictor of autonomic dysfunction in routine clinical practice.

SA-PO637

Factors Predicting Long Term Renal Prognosis in Malignant Nephrosclerosis

Peng Xia, Jiaxin Lang, Yubing Wen, Mingxi Li, Hang Li, Xuewei Li, Limeng Chen. Nephrology, Peking Union Medical College Hospital, Beijing, China.

Background: This study investigated correlations between kidney pathology and Renin-Angiotensin System(RAS) activation, RAS inhibitor response and prognosis of malignant hypertensive nephrosclerosis(MHN) patients.

Methods: This retrospective cohort study included 82 essential MHN patients from Jan,2003 to Oct,2014 with renal biopsy followed up until May,2015. Pathology were evaluated by two pathologists independently. Localized renin expression and peritubular capillaritis(PTC) area were evaluated by IHC staining of renin and CD34. Renal replacement therapy, kidney transplant and death were defined as the primary end point.

Results: 87.8% of patients were male with mean age of 34.7±8.8 years. Clinical data showed highest blood pressure (BP) 226.6±25.7/152.2±22.0 mmHg, serum creatinine (Scr) 5.31±3.79 mg/dl, proteinuria 2.06±1.83 g/dl, eGFR 21.3±15.1 ml/min/1.73m<sup>2</sup>. Glomerular Sclerosis Index, tubular atrophy and interstitial fibrosis were 1.51±0.51, 63.7±18.3% and 64.0±18.3%. MHN patients has a lower PTC proportion (2.27±0.74%)<sub>(n=35)</sub>, 3.75±0.79%<sub>(n=17)</sub>, P<0.001) and a higher renin-positive juxtaglomerular apparatus ratio (35.1±17.8%<sub>(n=35)</sub>, 21.2±15.0%<sub>(n=17)</sub>, P<0.008) comparing with glomerular minimal lesion patients. Tubulointerstitial lesions correlated with Scr<sub>(r=-0.547,p<0.001)</sub>, eGFR<sub>(r=-0.574,p<0.001)</sub> and proteinuria<sub>(r=-0.447,p<0.001)</sub>. PTC area correlated with Scr<sub>(r=-0.675,p<0.001)</sub> and eGFR<sub>(r=0.648,p<0.001)</sub>. 90.4% patients received RAS inhibitors which was associated with improvements in BP (J Am Soc Nephrol 26: 2015) and kidney function (Kidney Int 87: 2013). However, the effect of vitamin D supplementation on the RAS in humans with vitamin D deficiency has never been examined in a rigorous manner.

Conclusion: MHN patients had localized activation of renin and less PTC area. RAS inhibitors benefited patients in BP control, eGFR improvements and long-term renal outcome.

Office Blood Pressure Monitoring: A Novel Tool for Evaluating Blood Pressure in Children (and Adults)

Gianluigi Ardissino,1 Paolo Marchetto,1 Francesca Tel,1 Sara Testa,1 Ilaria Possenti,1 Michela Perrone,1 Luciano Sangaletti,1 Amelia Ballarino,1 Stefani Rotondo,1 Silvia Ghiglia,1 Franco De Luca,1 Patrizia Salice.1 1Pediatric Nephrology and Cardiology, Fondazione IRCCS Ca' Granda Policlinico, Milan, Italy; 2Pediatric Cardiology, Policlinico Uni, Messina, Italy.

Background: Blood pressure measurement (BPM) is a common procedure in clinical practice but in children (C) obtaining reliable values can be challenging. Casual office BPM, the standard of care, is ill but accurate and ABPM may be difficult to perform or even misleading.

Methods: Office Blood Pressure Monitoring (OBPM) was developed at our Center in 2010 for evaluating BP in C with serial and automated BPM (³10 in at least 30 min)
with a standard oscillometric device. BP values are uploaded in a software to calculate the coefficient of variation (CV) after having excluded outlier values (<25 and >95th centiles of the recorded values).

Results: Since 2010 a total of 402 OBPMs have been performed but only the 282 in 110 C (59% Males) aged <18 yrs old (IQR 4.8-12.1) with a CV <10% for both syst and diast BP were considered for the analysis. The table compares BP as measured by OBPM with a single BPM (1st and 3rd) and with the mean of the 3 internal measurements (p<0.01 vs. others BPMs with student’s t test for paired data and c2).

Conclusions: OBPM provides significantly lower BP values, leading to a diagnosis of poor BP control in a smaller number of patients (10%). Given the lack of a gold standard, the present analysis doesn’t demonstrate that OBPM is more reliable than standard procedures however serial BPM have the potential of reducing measurement biases and white coat effect. We recommend the routine use of OBPM for measuring BP in C at risk of hypertension rather than relying upon few measurements.

SA-P0639
A Simple Prediction Score for Incident Hypertension in a Korean Population
Jong-Hwan Jung, Sung Kwang Park, Won Kim, Kyung Pyo Kang, Sik Lee.

Background: We aimed to develop a simple prediction model for incident hypertension that could help to prevent or delay the onset of hypertension for some patients who did not experience hypertension yet.

Methods: The Korean Genome and Epidemiology Study was used for the model development (n=3533) and validation (n=1698). Hypertension was defined when experiencing hypertension yet.

Results: That could help to prevent or delay the onset of hypertension for some patients who did not experience hypertension yet.

Conclusions: This prediction algorithm, weighted towards common modifiable variables, showed good performance characteristics in a Korean population.

SA-P0640
Hemodynamics and Cardiovascular Autonomic Efficiency During Blood Pressure Variations in Hemodialysis
Dan Sapoznikov, Rebecca Backenroth, Dvora Rubinger.

Background: Chronic hemodialysis (HD) is associated with hemodynamic instability and with reduced cardiovascular autonomic efficiency (Cae).

Methods: To define hemodynamic changes associated with intradialytic blood pressure variations, beat-to-beat systolic blood pressure (SBP) and interbeat interval (IBI) monitoring using Finometer device and Beatscope software was performed during HD sessions in 69 non-diabetic patients (Pts), age 56±15 y. Cardiac output (CO) and total peripheral resistance (TPR) were calculated using the Modelflow simulation method. Differences in variability indices during SBP periods, 10% above (high) or below (low) the mean SBP were considered representative of Cae.

Results: During low to high SBP periods, two patterns of changes were noted: increased CO and decreased TPR (18 Pts,TPR↓), and relatively stable CO with increased TPR (51 Pts, TPR↑). Low frequency (LF) range variability of SBP and IBI, CO and TPR (median and interquartile ranges) were:

![Table](https://example.com/table.png)

Conclusions: CT-Ps with intradialytic hypotension (56%) was significantly higher in TPR↑ than in TPR↓ (28%, p<0.036), while TPR changes were directly correlated with post dialysis SBP (r=0.45, p<0.001) and with sd IBI (r=0.35, p=0.001) in all Pts. There were no differences between groups in other variables.

Conclusions: 1.Cae resuming during HD may be associated with predominant CO and/or TPR variations; the latter are significantly correlated to sd IBI, a strong marker of autonomic activity. 2.Intradialytic hemodynamics may be different in hypotension-prone Pts. These observations are relevant to the pathogenesis of intradialytic hemodynamic instability and of postdialysis hypertension.

SA-P0641
Antihypertensive Medications and Blood Pressure Control in Chronic Kidney Disease: A Cross-Sectional Analysis from the German Chronic Kidney Disease (GCKD) Study

Background: We reported low rates of blood pressure (BP) control in a large German cohort of patients with chronic kidney disease (CKD). Here, we analyzed the antihypertensive drug therapy to assess the prevalence of resistant hypertension, and to determine associations with control of BP.

Methods: The German Chronic Kidney Disease (GCKD) study is a prospective observational cohort study which enrolled 5217 patients with CKD in Germany. Inclusion criteria were estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m2 or overt proteinuria. At enrollment, office BP was measured by trained study nurses, and antihypertensive drug therapy to assess the prevalence of resistant hypertension, and to determine associations with control of BP.

Conclusions: 1.Cae for resistant hypertension was present in 49.9% of CKD patients whose BP was uncontrolled hypertension, 49.9% met the definition of resistant hypertension (uncontrolled {140/90 mmHg and/or TPR variations; the latter are significantly correlated with sd IBI, a strong marker of autonomic activity. 2.Intradialytic hemodynamics may be different in hypotension-prone Pts. These observations are relevant to the pathogenesis of intradialytic hemodynamic instability and of postdialysis hypertension.

Conclusions: This prediction algorithm, weighted towards common modifiable variables, showed good performance characteristics in a Korean population.

Association Between Cystatin C Based eGFR, Ambulatory Blood Pressure Parameters, and In-Clinic versus Ambulatory Blood Pressure Agreement in Older Community-Living Adults

T佛山 Woodell, Jan M. Hughes-Austin, Tiffany Tran, Atul Malhotra, Joseph A. Abdelmalek, Dena E. Rifkin. UC San Diego.

Background: Although CKD IV-V has been associated with abnormal ambulatory blood pressure (ABPM) patterns, the associations with milder CKD have not been determined. We examined the relationship between mild chronic kidney disease (measured by cystatin C-based eGFR) and abnormal ABPM (including nocturnal dipping) in healthy older adults. Further, we assessed agreement between clinic and ambulatory blood pressure monitoring.

Methods: 334 older community-living adults had clinic BP and 24-hour ABPM measured. Serum cystatin C levels were used to calculate eGFRcys using the CKD-EPI equation. Multiple linear regression was performed to examine associations between eGFRcys < 60 ml/min/1.73m^2 (CKD stages) and ABPM parameters. Bland-Altman analysis was performed to evaluate agreement between clinic and ambulatory measurements.

Results: Average age was 72. Average eGFRcys was 78 ± 20, and 60 individuals with CKD stages. Compared to those without CKD, individuals with CKD stages were older, more likely to have clinic-based hypertension and less likely to be dippers. After multivariable analysis, the presence of CKD stages was significantly associated with lower mean ambulatory diastolic blood pressure (DBP) (-2 mm Hg, p = 0.048), but not with nocturnal dipping or other ABPM parameters. Analyses using creatinine-based eGFR yielded similar results. Cystatin c-based blood pressure (SBP) was significantly overestimated mean wake time ambulatory ABPM SBP; mean difference was 11 mmHg for those without CKD stages (95% limits of agreement -14 to 35 mmHg) and 14 mmHg for those with CKD stages (95% limits of agreement -13 to 41 mmHg); there was no statistically significant effect modification by CKD stage.

Conclusions: In older community-living adults, mild CKD as detected by cystatin C was associated with lower ambulatory DBP, but not with dipping status. This result is in contrast to findings with more advanced CKD in other studies and suggests that abnormal ABPM may only emerge at more advanced stages of CKD. The presence of CKD did not affect interpretation of clinic vs. ABPM pressures, although accuracy of clinic SBP was poor in this older cohort.

Serum MicroRNA Biomarkers for Obese Children with Hypertension

Scott Saint-Amour,1 Santosh Kumar Patnaik,2 Sudha Garimella.1 Pediatric Nephrology, Univ at Buffalo, Buffalo, NY; 2Cardiovascular Lab, RPCI, Buffalo, NY.

Background: Childhood obesity is a major health problem and 30% of obese children may develop hypertension. There is no clinical method to identify high risk obese children before they develop hypertension. MicroRNAs are non-coding RNAs that are implicated in pathways of inflammation and vascular injury. There has been no characterization of miRNA profiles of obese children with hypertension. This study aims to characterize miRNA profiles as a first step toward evaluating miRNAs as biomarkers for obesity-related hypertension.

Methods: 39 patients ages 3-21 were placed in four cohorts based on presence or absence of obesity and hypertension. Total serum RNA was isolated using miRCURY Biofluids kit Exiqon®, and examined for miRNAs by RT-PCR. Cq values were normalized by the global mean method. Rates of false discovery (FDR) arising from multiple testing were assessed using the Benjamini-Hochberg method.

Results: 69 of 179 examined miRNAs were detected in all samples. MiRNA measurements were globally reduced in sera of obese normotensive Vs. controls. Four miRNAs were identified as differentially expressed between these two groups at FDR < 0.1%, whereas no miRNA was identified as differentially expressed between controls and hypertensive obese. Tukey plots of miRNAs in the cohorts are shown.

Conclusions: Serum levels of four miRNAs appear to be reduced in patients with obesity alone, but not in those with obesity and hypertension. While it is possible that serum miRNA differences were because of variables such as serum lipid content and medications, our study suggests that serum miRNAs have utility in detecting hypertension risk in obese children. This should be validated in a larger study, and the biomarker value of the serum miRNAs correlated with ambulatory blood pressure monitoring data as well as left ventricular hypertrophy.

Funding: Pharmaceutical Company Support - Roswell Park Cancer Institute Support to Dr. Sai Yendamuri in the Cardiothoracic Lab at RPCI was used for this study.

Effect of Prenatal and Childhood Lead Exposure on Blood Pressure at 4 Years of Age Allison P. Sanders,1 Katherine Svensson,2 Chitra Amarasingirawana,2 Priyanka Basnet,1 Ivan Pantic,1 Adriana Mercado-Garcia,1 Lourdes Schnauss,3 Andrea A. Baccarelli,3 Martha M. Tellez-Rojo,4 Chris Gennings,5 Lisa M. Satlin,6 Robert O. Wright,1 1University of Medicine and Dentistry of New Jersey, 2Icahn School of Medicine at Mount Sinai, 3National Inst of Environmental Health Science, 4National Inst of Public Health, 5Harvard T.H. Chan School of Public Health.

Background: Prenatal lead (Pb) exposure occurs during a susceptible period of renal development and may program later life cardiovascular and renal disease.

Methods: Systolic and diastolic blood pressure (SBP and DBP) was obtained using an automated oscillometer from 397 children 4 years of age in the PROGRESS cohort located in Mexico City. Maternal blood samples were previously collected at the 2nd trimester (2T), 3rd trimester (3T), and at delivery and children’s blood samples were collected at birth (cord blood), 1 year, and 2 years of age. Blood lead levels (BLLs) were analyzed via inductively coupled plasma-mass spectrometry. We performed linear regression to examine the associations between longitudinal BLLs and children’s SBP, DBP, and pulse pressure (mSBP-mDBP) adjusting for child’s age, sex, body mass index, maternal education and environmental tobacco smoke.

Results: Maternal 2T BLLs ranged between 0.7 and 18.8 mg/dL, and 89 (22%) prenatal BLLs were above the CDC guideline level of 5 mg/dL. Increased 2T and 3T BLLs were associated with decreased pulse pressure (p<0.05) and modestly associated with increased DBP (p=0.1).

No significant associations were observed for childhood BLLs and BP. Stratification by sex showed that the effect of prenatal Pb (2T and 3T) on decreased pulse pressure was significant only among females.

Conclusions: Prenatal Pb exposure may contribute to subclinical changes in the developing kidney or cardiovascular system leading to elevated BP in childhood. Future studies will assess if the contributions of early life Pb exposure to BP outcomes persist at later life stages.

Figure 1. The effect of longitudinal lead exposure on childhood blood pressure at 4 yrs. Estimates (β) and 95% confidence intervals (βI) were adjusted for child’s age, sex, body mass index, as well as maternal education and environmental tobacco smoke.

Smoking, Microalbuminuria and Renal Function in Essential Never Treated Hypertensive Patients

Dimitrios Petras,1 Vanessa Tzamou,2 Athanasios Bramos,3 Panagiota E. Giannou,1 Stella-Maria Kyvelou,1 Eva Karpanou,1 Gregory Vissoulis,1 1Nephrology Dept, Hippokration Hospital, Athens, Greece; 21st Cardiology Clinic, Onassis Cardiac Surgery Center, Athens, Greece; 3Hypertensive Unit, 1st Cardiology Clinic, Univ of Athens, Hippokration Hospital, Athens, Greece; 4Microbiology Dept, Hippokration Hospital, Athens, Greece.

Background: The aim of the present study was to identify possible differences depending on patient’s individual smoking history with renal function and microalbuminuria in essential never treated hypertensive patients.

Methods: The study included 6100 consecutive patients with essential hypertension. In each patient the smoking status has been assessed by means of a standard questionnaire. Each patient had renal profile work up including microalbumin levels, albumin creatinine ratio in 24h urine collection (ACR) and 24h creatinine clearance.

Results: The study population was divided according to the smoking status in three groups: Smokers (n=2350), Ex-smokers (n=663) and Non-smokers (n=3121). Microalbumin aCR was significantly higher in smokers compared to ex-smokers and non-smokers [(26.3±24.3 vs 23.6±21.7 vs 22.0±20.0, p<0.0001), (31.5±30.2 vs 28.8±29.3 vs 27.4±27.2, p<0.0001), respectively]. There was no significant difference in creatinine clearance among the three groups of smokers (p=NS)

**Comparison of Salt Taste Thresholds and Salty Usage Behaviors Between Myanmar and Korean Adults**

Hyungjin Cho, 1  Fridtjof Thomas, 1

**Background:** Excessive oral salt intake can induce hypertension. According to previous studies, prevalence of hypertension is higher in Myanmar than Korea. We postulated that National Univ Hospital, Jeju, Republic of Korea.

**Methods:** This cross sectional study enrolled the patients who visited volunteer medical service clinic at Ansong in Korea and Hpleu and Bago in Myanmar in August 2014. We measured vital signs, height and weight of each patient and evaluate detection threshold, recognition threshold, salt preference, salt usage behavior score and spot urine sodium.

**Results:** Out of 131 patients who were enrolled and 64 of them were Myanmarese and 67 were Koreans. Blood pressure was significantly higher in Myanmar adults than Koreans. Detection threshold, recognition threshold, salt preference, spot urine sodium and salt usage behavior score was also higher in Myanmar than Koreans.

We calculated correlation coefficient between spot urine Na and other parameters that related to salt intake. salt usage behavior score and detection threshold significantly correlated with the spot Urinal.

**Conclusions:** All parameters related to salt intake, such as detection thresholds, the recognition thresholds, salt preference, salt usage behavior score and spot urine sodium concentration, of Myanmarese were significantly higher than those of Korean.

### SA-PO647

**Relationship Between Circadian Rhythm of Blood Pressure and Intrarenal Arteriolar Occlusion**

**Background:** Hypertension (HT) is a common complication in chronic kidney disease (CKD) patients. CKD patients often have circadian rhythm disorder of blood pressure (BP). However, the relationship between circadian BP pattern and intrarenal damage remains unclear.

**Methods:** Ninety patients with glomerulonephritis were included in this study. Patients with diabetes mellitus and prescription for antihypertensive agents were excluded. Clinic BP (CBP) and 24-h ambulatory BP (ABP) measurements were performed in all the study patients, and who were divided into the following four groups; normotension (NT), white coat hypertension (WHT), masked HT (MHT) and sustained HT (SHT). As renal histological assessments, we evaluated the percents of sclerotic glomeruli (SG) and interstitial fibrosis (IF), and classified the degrees of intimal thickening of intra-lobular arteries (ILA) and arteriolar hyalinosis (AH) into four grades (none, mild, moderate, severe) in each biopsy specimen.

**Results:** The prevalence of NT, WHT, MHT and SHT was 60.0%, 3.3%, 23.3% and 13.4%, respectively. In comparison of circadian BP pattern, all-day HT was most prevalent in the SHT group, and nocturnal HT was most prevalent in the MHT group. SG and IF were significantly severe in the SHT group compared to the NT group. As for intrarenal vascular lesions, the MHT and SHT groups had more severe AH compared to the NT and WHT groups, whereas ILA was comparable between all the four groups. Furthermore, we investigated the relationship between intrarenal vascular lesions and clinical characteristics. ILA was significantly correlated with age and renal function, whereas AH was significantly correlated with age, sex, smoking, total cholesterol, HT based on ABP (ABPHT) and HT based on CBP (CBPHT). In multivariate analysis, ILA was significantly correlated with only AH and was significantly correlated with age and sex.

**Conclusions:** Our findings suggest that intrarenal AH was markedly severe not only in the SHT group, but also in the MHT group. Careful ABP monitoring should be recommended in patients with glomerulonephritis.

### SA-PO648

**Association of Inpatient versus Outpatient Systolic Blood Pressure with All-Cause Mortality in Patients with Normal Estimated Glomerular Filtration Rate**

Ostas W. Okechukwu, 1  Miklos Zsolt Molnar, 1  Praveen Kumar Potukuchi, 1  Jun Ling Lu, 1  Fridtjof Thomas, 1  Kamary Kalantar-Zadeh, 1  Csaba P. Kovesdy, 1 2 1  Univ of Tennessee Health Science Center, Memphis, TN; 2 Unif of California, Irvine, CA; 2 VA Medical Center, Memphis, TN.

**Background:** Hypertension is associated with worse outcomes, and its treatment improves mortality and cardiovascular disease. Hospitalized patients undergo frequent BP measurements, and hence hospitalization is an opportunity to diagnose and treat hypertension. However, it is unclear if BP measured as inpatient is associated with outcomes.  

**Methods:** From 3,499,271 US veterans with normal eGFR, we identified 1,113,515 patients with inpatient and outpatient SBP recordings. We examined the association of baseline outpatient SBP, and baseline inpatient SBP (defined as the SBP obtained on the first day of the first hospitalization following cohort entry) with all-cause mortality in Cox proportional hazards analyses. Models included both in- and outpatient SBP and their interactions, and were adjusted for age, gender, race, eGFR, comorbidities, socioeconomic factors, and antihypertensives.

**Results:** Low SBP was associated with higher mortality in both settings, but much more so inpatients (Figure). Outpatient SBP ≥140-149 mmHg was associated with linearly higher mortality (hazard ratio (95%CI) for SBP ≥170 mmHg: 1.22 (1.16-1.29), p<0.001), but with less increase in mortality in the inpatient setting, which was only present for SBP ≥170 mmHg (HR (95%CI) for SBP ≥170 mmHg: 1.08 (1.02-1.14)).

**Conclusions:** SBP shows markedly different associations in the outpatient vs inpatient setting, with higher blood pressures in the inpatient setting conferring less mortality risk compared to the outpatient setting. Until randomized controlled clinical trials are done, caution is warranted when treating hypertension in hospitalized patients.

**Funding:** NIDDK Support, Veterans Administration Support

### SA-PO649

**Fibroblast Growth Factor 23 and Sodium-Volume Regulation: FGF23-Response to Sodium Restriction in Essential Hypertensive Subjects and to Long Term Extracellular Volume Reduction in Hemodialysis Patients**

**Background:** Dietary sodium load causes volume expansion and hypertension in mouse models of FGF23 and αKlotho deficiency. FGF23 also associates with ultrafiltration in cross-sectional analyses in hemodialysis (HD) patients (pts) further implicating this bone hormone in extracellular volume regulation.

**Methods:** 32 uncomplicated essential hypertensives were randomized to a 2-weeks high-sodium diet (200mmol/day) or to 2-weeks low sodium diet (10-20 mmol/day). After 1 week wash out, these treatments were crossed-over. At the end of each diet-period, pts underwent 24h urine sodium, 24h ABPM and serum intact FGF23 measurements. The FGF23 response to UF intensification was assessed in hypo-tension HD pts. FGF23 and normalized BP measurements were performed at baseline and after 6 months of UF intensification.

**Results:** In essential hypertensives, PRA and aldosterone (*P<0.01*) rose during low sodium. However, FGF23 remained unmodified [low sodium: median 36.2 pg/mL, inter-quartile range (IQR) 32.4-44.0; high sodium: 33.9 pg/mL, IQR: 29.5-41.0; P=0.18]. Changes in FGF23 were unrelated to systolic and diastolic ABP, heart rate, PRA and aldosterone changes. In hypertensive HD pts, baseline FGF23 was 4062 pg/ml (IQR: 1381-12571). BP during the longitudinal study fell from 144 to 139 mmHg (P=0.02) along with a parallel increase in dry BW.

**Conclusions:** Changes in sodium intake that potently activate the renin-aldosterone system do not alter FGF23 in essential hypertensives. Similarly, extracellular volume...
Association of Urinary Albumin Excretion and Salt-Sensitivity of Blood Pressure: Genetic Epidemiology Network of Salt Sensitivity (GenSalt) Study

Jing Chen,1,2 L. Lee Hamm,1 Chung-shiuian Chen,2 Kevin K. Wu,2 L. Gabriel Navar,3 Jiang He,2 1Medicine, Tulane School of Medicine, New Orleans, LA; 2Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Albuminuria is a marker of early kidney injury and associated with risk of hypertension, cardiovascular disease, end-stage renal disease, and premature death. However, it is unknown whether urinary albumin excretion is associated with salt- and potassium-sensitivity.

Methods: We investigated the association between urinary albumin excretion and salt- and potassium-sensitivity of blood pressure (BP) among GenSalt study participants.

Results: Urinary albumin-to-creatinine ratio (Acr, mg/g) was significantly reduced during low-sodium and potassium-supplementation interventions to 2.26 (1.11, 4.61) and 2.10 (1.46, 4.26), respectively, from a baseline ratio of 2.97 (1.20, 6.40) and increased during the high-sodium intervention to 3.23 (2.15, 5.73) with P for group difference<0.005. One standard deviation higher of baseline log-transformed ACR (2.23 mg/g) was significantly associated with 1.5 (95% CI 0.3, 2.7) mm Hg higher in mean arterial BP (P<0.01) from low-sodium to high-sodium intervention (salt-sensitivity) but not statistically significantly associated with potassium-sensitivity after adjusting for confounding factors.

Conclusions: These data indicate that urinary albumin excretion may be associated with BP salt-sensitivity.

Effects of Nephrectomy on Blood Pressure and Its Circadian Rhythm

Naro Ohushi,1 Sayaka Ishigaki,1 Shinsuke Isobe,1 Takayuki Tsuji,1 Akikito Kako,2 Hideo Yasuda,1 1Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; 2Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Japan.

Background: Intrarenal renin-angiotensin system (RAS) activation causes disturbance of sodium excretion from the kidney by increasing sodium reabsorption in the tubulus, with resultant blood pressure (BP) elevation and nocturnal hypertension. However, the effects of nephrectomy on BP and its circadian rhythm have not been clarified in the patients who have various renal functions.

Methods: We investigated 25 nephrectomized patients [17 men and 8 women, age: 61.3±14.7 years, chronic kidney disease stage 1 in 3 patients, stage 2 in 7, stage 3 in 5, stage 4 in 5 (nephrotic syndrome in 2 and peritoneal dialysis in 3), body weight (BW), circulating RAS [plasma renin activity (PRA) and plasma angiotensin II (AngII)] and 24-h ambulatory BP monitoring (ABPM) were examined before and after nephrectomy. We divided the daytime and nighttime for 24-h ABPM using sleep and waking times. Renal function [estimated glomerular filtration rate (eGFR)] was evaluated in non-dialysis patients.

Results: In non-dialysis patients, GBF after nephrectomy was significantly decreased compared with that before nephrectomy (67.8±23.1 ml/min/1.73m2 and after nephrectomy, 47.9±16.5 ml/min/1.73m2; p<0.01). There were no significant differences in the levels of BW, BP during daytime, nighttime and 24-h periods, and circulating RAS before and after nephrectomy. However, night-to-day (N/D) ratio of systolic BP (SBP) was significantly increased after nephrectomy compared with that before nephrectomy (before nephrectomy, 93.6±6.7% and after nephrectomy, 97.4±7.5%; p=0.032), and the patterns of circadian BP rhythm were also significantly changed before and after nephrectomy (p=0.021). Namely, dipper pattern decreased and non-dipper and riser patterns increased after nephrectomy. On the other hand, no significant findings were found in N/D ratio of SBP and the patterns of circadian BP rhythm in dialysis patients before and after nephrectomy.

Conclusions: Nephrectomy has effects on nocturnal hypertension due to the decrease of renal sodium filtration ability, but not absolute values of BP.

Association of Urinary Dopamine and Norepinephrine Excretion with Salt- and Potassium-Sensitivity of Blood Pressure

Ting Chen,1 2 Lee Hamm,1 Chung-shiuian Chen,2 Kevin K. Wu,1 L. Gabriel Navar,1 Jiang He,2 1Medicine, Tulane School of Medicine, New Orleans, LA; 2Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Dopamine and norepinephrine may play an important role in regulating sodium and potassium reabsorption in the proximal tubules. It is unknown, however, if urinary dopamine and norepinephrine excretion are associated with salt- and potassium-sensitivity of blood pressure (BP).

Methods: We investigated the association of urinary dopamine and norepinephrine with BP salt- and potassium-sensitivity among Genetic Epidemiology Network of Salt Sensitivity (GenSalt) study participants. The GenSalt dietary intervention consisted of a 7-day low sodium diet (51.3 mmol sodium/day), 7-day high-sodium diet (307.8 mmol sodium/day), and 7-day high-sodium diet with potassium supplementation (307.8 mmol sodium/day and 60 mmol potassium/day). Twenty-four hour urinary dopamine and norepinephrine were estimated at baseline and at the end of each intervention in 100 randomly selected GenSalt participants.

Results: Urinary dopamine (µg/24h) was significantly reduced (p=0.01) from baseline (191.5±142.3) during high-sodium (457.2±142.3) and high-sodium and potassium supplementation (149.5±139.7) interventions. Likewise, urinary norepinephrine (µg/24h) was significantly (p<0.001) reduced from baseline (38.6±24.3) during high-sodium (24.5±21.4) and high-sodium and potassium supplementation (24.6±24.1) interventions. In addition, one standard deviation higher in urinary dopamine concentration (124.2 µg/24h) was associated with 1.5 (-2.5, -0.6) mm Hg of mean arterial BP reduction from high-sodium to high-sodium plus potassium supplementation (p=0.001). One standard deviation higher in urinary norepinephrine concentration (24.3 µg/24h) was associated with 1.4 (0.2, 2.6) mm Hg mean arterial BP increase from low-sodium to high-sodium (p=0.02) and 2.2 (-3.1, -1.3) mm Hg mean arterial BP reduction from high-sodium to high-sodium plus potassium supplementation (p=0.001).

Conclusions: These data indicate that urinary excretion of dopamine and norepinephrine may play a role in BP salt- and potassium-sensitivity.

Uric Acid Levels Are Associated with Peripheral but Not Central Blood Pressure Variables in Normotensive Individuals

Pierre-Luc Lavoie,2 Stephan Troyanov,1 Francoise Madore,1 Remi Goupil,1 Nephrology, Hospital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

Background: Uric acid is increasing recognized as a risk factor for cardiovascular disease. Whether this could be explained by changes in peripheral or central blood pressure (BP) profiles remains controversial. The aim of this study was to assess the association of uric acid levels with peripheral and central hemodynamic parameters in untreated normotensive individuals.

Methods: Of 20,004 CARTAGENE participants, 8,420 were normotensive individuals not treated for hyperuricemia or hypertension with valid pulse wave analysis (46.9% male, 52.6 yr). The associations between uric acid levels and peripheral systolic BP (SBP), pulse pressure (PP) central systolic BP (cSBP), central PP (cPP), pulse pressure amplification (PPA), augmentation index (Alx) and increased pressure (AP) were tested with linear regression analysis.

Results: In univariate analyses, uric acid levels were significantly associated with all parameters. In contrast, in multivariate analyses, only SBP and cSBP remained independently associated with uric acid levels. As cSBP is usually highly dependent of SBP, it was further adjusted for peripheral BP, where it was not independently associated with uric acid levels (β coefficient -0.003, p=0.51).
Results: Mean age at 7th year was 78. Considering SBP or DBP separately, trajectory groups were primarily determined by baseline BP, and these were not independently associated with outcomes (all p<0.05). In contrast, three distinct groups were identified using joint SBP/DBP: (1) concordant increasing, (2) discordant (stable SBP and decreasing DBP), and (3) concordant decreasing. Compared with a concordant increasing, a concordant decreasing and discordant trajectory had increased risk of death. Concordant decreasing was associated with outcomes (all p>0.05). In contrast, three distinct groups were identified using joint SBP/DBP: (1) concordant increasing, (2) discordant (stable SBP and decreasing DBP), and (3) concordant decreasing. Compared with a concordant increasing, a concordant decreasing and discordant trajectory had increased risk of death. Concordant decreasing was also associated with increased risk for incident CVD and HF, compared with concordant increasing. Findings did not differ when we stratified by use of antihypertensives.

Among community-dwelling elders, distinct BP trajectories were identified integrating SBP and DBP. Decreasing BP is associated with higher risk for adverse outcomes. Funding: NIDDK Support, Other NIH Support - NHLBI

Serum Uric Acid and Vascular Stiffness in African Americans with Hypertension
Rajesh Mohandas,1 2 Xuering Wen,3 Jogiraju V. Tantravahi,1 2 Titte Srinivas,3 Richard J. Johnson,1 Mark S. Segal,1 2 Nephrology and Hypertension Section, North Florida/South Georgia Veterans Health System, Gainesville, FL; 3Div of Nephrology, Hypertension & Transplantation, Univ of Florida, Gainesville, FL; 4Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; 5Div of Renal Diseases and Hypertension, Univ of Colorado, Denver, CO.

Background: Elevated serum uric acid levels as well as vascular stiffness is associated with hypertension and cardiovascular (CV) disease. However, how uric acid affects vascular stiffness is not known. We examined the relationship between uric acid and vascular stiffness in a cohort of African American men and women with well-controlled hypertension.

Methods: 120 African-Americans with controlled hypertension were randomized in a double-blind, placebo controlled study to allopurinol (300mg/dl) or placebo for 4 weeks. Vascular stiffness was assessed by augmentation index at baseline and at 4 weeks after allopurinol therapy. Uric acid was characterized as low or high (>7 mg/dl in men and > 6 mg/dl in women).

Results: The mean age was 48.7 ± 8.73 years and majority of the participants were women (71%). Augmentation index was negatively correlated with uric acid at baseline (R= -0.24 ± p<0.009). The high uric group as compared to the low uric acid group, had a lower augmentation index (9.07 ± 5.52 vs. 11.22 ± 5.23 p=0.03) while the mean BP (119/75 vs 118/75), age (48.7 vs 48.6), and endothelial function as measured by endoPAT (22 vs. 22) were similar. With allopurinol therapy there was a drop in uric acid by 2.23 ± 1.4 mg/dl as compared to placebo ±0.15 ± 0.9 mg/dl but there were no significant changes in vascular stiffness or endothelial function.

Conclusions: In African Americans with hypertension uric acid is negatively associated with vascular stiffness and short-term therapy with allopurinol does not alter vascular stiffness. These changes are not explained by endothelial function. The mechanistic basis of how uric acid may be protective against vascular stiffness may explain the many conflicting studies on the contribution of uric acid to cardiovascular risk and merits further investigation.

The Impact of Renin-Angiotensin System Blockers on Renal Sodium Handling: An Analysis of CARTaGENE
Catherine Delmas-Frenette, Stephanie Troyanov, Joscée Bouchard, François Madore, Remi Goupil. Nephrology, Hospital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

Background: Renin-angiotensin system blockers (RASB) reduce the effects of angiotensin II, and subsequently aldosterone, leading to vasodilatation and natriuresis. The magnitude of the RASB-induced natriuresis compared to diuretics and other anti-hypertensive agents remains uncertain.

Methods: We identified patients treated for hypertension from the prospective CARTaGENE cohort, a random sample of the Quebec population aged 40 to 69, who had available urinary sodium levels. We compared the fractional excretion of sodium (FeNa) between patients on beta-blockers or calcium channel blockers without diuretics (Group 1), on RASB without diuretics (Group 2) and on diuretics (Group 3) with ANOVA and a general linear model adjusting for age, gender, estimated glomerular filtration rate (eGFR), diabetes and peripheral mean arterial pressure (pMAP).

Results: Of the 3828 individuals with treated self-declared hypertension, 155 had available urinary sodium levels. We compared the fractional excretion of sodium (FeNa) between patients on beta-blockers or calcium channel blockers without diuretics (Group 1), on RASB without diuretics (Group 2) and on diuretics (Group 3) with ANOVA and a general linear model adjusting for age, gender, estimated glomerular filtration rate (eGFR), diabetes and peripheral mean arterial pressure (pMAP).

Conclusions: After adjustment for important covariables, RASB therapy is associated with a natriuresis similar to diuretics and greater than other antihypertensive drugs in hypertensive patients. Whether the degree of natriuresis parallels the blood pressure response to these agents remains to be determined.

Urine Mitochondrial-DNA Copy Number Identifies Renal Injury in Severe Renovascular Disease

Background: We have previously demonstrated that mitochondrial injury contributes to renal dysfunction in swine renovascular disease (RVD), but its implications in human RVD remain unknown. Fragments of the mitochondrial genome released from dying cells are considered surrogate markers of mitochondrial injury. We hypothesized that RVD would be associated with increased urine mitochondrial DNA (mtdNA) copy numbers.

Methods: We prospectively measured urine copy numbers of the mtdNA genes COX3 and ND1 by quantitative real-time PCR in essential hypertensive (EH), moderate RVD, and severe RVD patients (based on ultrasound criteria and evident loss of functional renal mass) (Figure). In RVD patients, urinary COX3 and ND1 directly correlated with RVD (R²=0.18, p<0.02 and R²=0.37, p=0.001), proteinuria (R²=0.33, p<0.01 and R²=0.53, p<0.001), and serum aldosterone (R²=0.27, p=0.002 and R²=0.16, p<0.02) levels, and inversely with eGFR (R²=0.15, p=0.05 and R²=0.09, p=0.04, respectively).

Conclusions: We found progressive increments in urine mitochondrial injury markers with increased severity of RVD, implicating mitochondrial injury in kidney damage in human RVD. Mitochondria might represent a novel therapeutic target in RVD.

Association Between Urinary Big Angiotensin-25 and Microalbuminuria in Hypertensive Patients

Div of Circulatory and Body Fluid Regulation, Dept of Internal Medicine, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan; Dialysis Div, Univ of Miyazaki Hospital, Miyazaki, Japan; Dept of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan.

Background: In hypertensive patients, albuminuria is a predictive factor for cardiovascular events. Recently, a newly glycylated angiotensin-related peptide, Big angiotensin-25 (Bang-25), was isolated from human urine (Nagata et al. Biochem Biophys Res Commun 2013), and it was localized to podocytes in kidney tissue. Bang-25 may be involved in the renin-independent pathway for localized angiotensin II generation, and can contribute to dysfunction in organ disorders. Using cross-sectional data, we investigated the relationship between urinary Bang-25 and albuminuria in hypertensive patients.

Methods: We examined the data of 408 hypertensive patients (male 50.5%; mean age 70±10 years, BMI 25.3±7.5 kg/m², diabetes mellitus 36.6%, and eGFR 72±17 ml/min/1.73m²). We evaluated urinary albumin to creatinine ratio (ACR) and we measured urinary Bang-25 by specific AlphaLISA immunoassay. The association between urinary Bang-25/creatinine ratio and albuminuria was analyzed by a multivariate logistic regression.

Results: Thirty patients were excluded because of macroalbuminuria (ACR³300 mg/gCr). Of 378 patients, 96 had microalbuminuria (30≤ACR<300 mg/gCr). Patients were then divided by quartiles of Bang-25/creatinine ratio. Older patients, females, lower hemoglobin, lower uric acid, and higher HDL were more prominent in higher Bang-25/creatinine quartiles. At adjusting for age, sex, eGFR, and presence of diabetes, the odds ratios (95% confidence intervals) for microalbuminuria per quartile, calculated using multiple logistic regression, were as follows: Q1, reference; Q2, 0.72 (0.33-1.54); Q3, 0.99 (0.49-2.01); and Q4, 2.05 (1.01-4.14).

Conclusions: Higher urinary Bang-25/creatinine quartile was significantly associated with microalbuminuria in hypertensive patients. As Bang-25 is localized to podocytes, it may play some role in the development of albuminuria.

Independent Association of Vitamin D on Endothelial Function: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Nephrology, Brigham and Women's Hospital, Boston, MA; Endocrinology, Brigham and Women's Hospital, Boston, MA.

Background: In nonhypertensive individuals, lower levels of 25-hydroxyvitamin D (25(OH)D) have been associated with increased risk of cardiovascula...

Conclusions: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with vitamin D deficiency (body mass index [BMI] 25 and 25(OH)D<20ng/ml), we assigned subjects to receive either ergocalciferol (25,000 units) or matching placebo, once a week for 8 weeks. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 46 and 47 participants were allocated to receive ergocalciferol and placebo, respectively. Mean 25(OH)D levels increased from 14.9 to 30.3 in the vitamin D group and from 14.4 to 17.4 in the placebo. EDV did not change significantly with either vitamin D repletion (from 6.3±1.6% at baseline to 6.1±1.6% at 8 weeks; p-value=0.78) or placebo (7.9±4.7% to 6.8±4.7%; p=0.17). The treatment effect p-value (comparing the 8-week change with ergocalciferol to the change with placebo) was 0.35.

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after repletion of vitamin D in overweight/obese non-hypertensive individuals.

Secondary Hypertension, Primary Hyperaldosteronism, and Renal Cell Carcinoma
Nicole Piero, Krishnanath Gaitonde, Charuhas V. Thakar.

Cincinnati VA Medical Center; Univ of Cincinnati.

Background: Primary hyperaldosteronism (PH) is the most common cause of secondary hypertension. Renal cell carcinoma (RCC) can cause secondary hypertension, but as a renin-mediated process. We describe 5 cases referred for evaluation of PH (uncontrolled hypertension and hypokalemia), incidentally diagnosed with RCC, and the potential role of RCC as a renin-independent mechanism for hypertension.

Methods: At the initial renal visit, average blood pressure (BP) was 167/87 mmHg, with an average of 4 BP meds (nonaldosterone blockers). Average serum levels of potassium, sodium and bicarbonate were 3.1, 143 and 30 mmol/L respectively. Average plasma renin activity (PRA) was 0.12 ng/ml/hr, average serum aldosterone (sAldo) was 16.6 ng/dL, with a mean sAldo:PRA of 143.6. In 24-hour urine analysis, aldosterone ranged from 11.8 to 30.2 ng/dL and sodium ranged 82-226 mmol/24 hours. All patients required 1 or 2 aldosterone blocking agents to achieve an average BP of 134/75 mmHg. Upon imaging, 4/5 had adrenal adenomas and all 5 patients had incidental solid renal masses with radiological characteristics of RCC. To date, 3/5 have had renal masses treated with partial/total nephrectomy or cryotherapy; all have confirmed pathology of RCC. All those undergoing RCC treatment were had improved BP with 2/3 having reduced therapy. At presentation these 3 patients had an average BP of 159/87 mmHg and were on an average of 4.6 BP meds; between 5 and 9 months after RCC treatment BP was 133/75 mmHg on an average of 4 BP meds (no aldosterone blockers). Average serum levels of potassium, sodium and bicarbonate were 3.1, 143 and 30 mmol/L respectively. Average plasma renin activity (PRA) was 0.12 ng/ml/hr, average serum aldosterone (sAldo) was 16.6 ng/dL, with a mean sAldo:PRA of 143.6. In 24-hour urine analysis, aldosterone ranged from 11.8 to 30.2 ng/dL and sodium ranged 82-226 mmol/24 hours. All patients required 1 or 2 aldosterone blocking agents to achieve an average BP of 134/75 mmHg. Upon imaging, 4/5 had adrenal adenomas and all 5 patients had incidental solid renal masses with radiological characteristics of RCC. To date, 3/5 have had renal masses treated with partial/total nephrectomy or cryotherapy; all have confirmed pathology of RCC. All those undergoing RCC treatment were had improved BP with 2/3 having reduced therapy. At presentation these 3 patients had an average BP of 159/87 mmHg and were on an average of 4.6 BP meds; between 5 and 9 months after RCC treatment BP was 133/75 mmHg on an average of 4 BP meds, 2/3 able to eliminate aldosterone blockade. 2/3 patients treated for RCC had follow-up biochemical assessment. sAldo:PRA normalized in the patient with partial nephrectomy; whereas it remained elevated in patient treated with cryotherapy.

Conclusions: To our knowledge this is the first case series describing a possible renin-independent, aldosterone-mediated mechanism for secondary hypertension associated with RCC. Although such cases are rare, if this association is confirmed, these cases describe a physiological link between the two. Whether RCC leads to maladaptive steroid pathways leading to an aldosterone-like action in mediating hypertension requires detailed analysis of RCC tumors.

Effect of Uric Acid Lowering Agents on Endothelial Function: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Nephrology, Brigham and Women's Hospital, Boston, MA; Endocrinology, Brigham and Women's Hospital, Boston, MA.

Background: In nonhypertensive individuals, higher levels of serum uric acid have been associated with an increased risk of hypertension, and elevated serum uric acid has been associated with endothelial dysfunction in such individuals. However, the effect of lowering serum uric acid on endothelial dysfunction in nonhypertensive individuals has not been examined thoroughly.

Conclusions: Higher urinary Bang-25/creatinine quartile was significantly associated with microalbuminuria in hypertensive patients. As Bang-25 is localized to podocytes, it may play some role in the development of albuminuria.

Funding: NIDDK Support
Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with elevated serum uric acid (body mass index [BMI] ≥25 and serum uric acid ≥5 mg/dL), we assigned subjects to receive one of the following: allopurinol 300mg daily for 4 weeks followed by 600mg daily for 4 weeks; probenecid 500mg daily for 4 weeks, then 1000mg daily for 4 weeks, or matching placebo. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial artery ultrasound at baseline and 8 weeks post-randomization. Results: By the end of the trial, 43, 44, and 47 participants were allocated to receive probenecid, allopurinol and placebo, respectively. Mean serum uric acid levels decreased from 5.9 to 3.6 mg/dL in the probenecid group, from 5.6 to 2.9 mg/dL in the allopurinol group, and were unchanged in the placebo group (5.6 to 5.7 mg/dL). EDV did not change significantly with either probenecid (from 7.6±5.1% at baseline to 8.4±5.2% at 8 weeks; p-value=0.39), allopurinol (from 7.4±6.0% at baseline to 5.9±4.6% at 8 weeks; p-value=0.09) or placebo (6.8±3.8% at 7.1±4.9%; p=0.66). Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (as measured as EDV) after lowering serum uric acid in overweight/obese non-hypertensive individuals. Funding: NIDDK Support

SA-PO663
Azelnidipine Can Restore the Deceleration Capacity of Heart Rate Variability (DC) In CKD Patients with Preceding Treatment with ARB Michio Fukuda, 1 Toshiyuki Miura, 1 Yoshiaki Ogiyama, 1 Ryo Sato, 1 Daisuke Fuwa, 1 Hiroyuki Ito, 1 Tetsuehi Matsuoka, 1 Yukako Isobe-Sasaki, 1 Ken Kiyono, 2 Hiddo Jan Lambers Heerspink, 2 Dick de Vries, 2 Osaka Univ; 2Tokyo Univ.

Background: Recently, we have hypothesized that DC, novel measure of cardiac vagal modulation, is also attributable to sympathetic nerve activities. Azelnidipine was reported to decrease non-Gaussianity index of HRV (l25s), which can serve as a marker of sympathetic cardiac overdrive.

Methods: In 43 hypertensive patients with CKD under treatment with an angiotensin receptor blocker (ARB), we tested whether 8-week add-on administration of azelnidipine can increase DC. DC was calculated by Bauer’s signal processing technique of phase-rectified signal averaging. For reference, the power of high frequency (HF, 0.15–0.40 Hz) obtained from frequency measure of HRV was examined as a conventional indicator of vagal activity. Results: DC increased (6.17 ± 1.84 to 6.55 ± 1.85, p=0.002) and l25s decreased (0.56 ± 0.15 to 0.50 ± 0.12, p=0.001), while no significant changes were observed in other HR variability measures including HF (p=0.9). Change in DC correlated inversely with the change in l25s (r=0.38, p=0.01), but not with the change in HF (p=0.8). Conclusions: Our findings are consistent with the thesis that DC is not a simple measure of vagal activity but a product of complex interplay between sympathetic and vagal nerve activities.

SA-PO664
Elevated Levels of Podocyte Derived Urinary Microparticles in Angiotensin II Induced Hypertension Uta Erdbruegge, Christine Rudy, Sylvia Cechova, Rosa Chan, Joseph C. Gigliotti, Thu H. Le. Div of Nephrology and HTN, Univ of Virginia Health System, Charlottesville.

Background: Early and non-invasive biomarkers of kidney damage are needed to identify hypertensive patients at risk for kidney damage. Urinary microparticles (uMPs) have gained significant attention as potential novel biomarkers for kidney damage, and have already been identified in pre-albuminuric diabetic glomerular injury. These vesicles are less than 1 micron in size and carry markers of the parent cell. We hypothesized that podocyte-derived uMPs are elevated in angiotensin II-induced hypertension (HTN).

Methods: Wild-type mice were treated with AII (400ng/kg/min) via mini-osmotic pumps. Untreated WT mice served as controls. Blood pressure was measured with tail-cuff manometry. 24 hour urine were collected after 5 days of all treatment. Enumeration and phenotyping of MPs was done of podocyte culture supernatant and urine. UMP levels were normalized to urinary creatinine concentration. Podocalyxin (Pcal), podoplanin (Ppla) and annexin 5 (AV) were used as surface markers.

Results: Pcal and Ppla positive MPs as well as AV positive and negative MPs were detectable in supernatant from primary podocyte cultures. Compared to untreated controls (n=3), all treated mice (n=2) had an increase in systolic blood pressure (SBP) by 33 mmHg (p=0.02). Despite similar urinary albumin/creatinine ratios between groups, there was a trend of higher levels of total numbers of Pcal and Ppla positive MPs in hypertensive mice compared to untreated (see Figure 1). In addition, AV negative but Ppla and AV positive MPs were also numerically higher in hypertensive mice compared to AV positive uMPs.

Conclusions: In conclusion, podocyte derived urinary MPs are detectable in all HTN. These findings need to be confirmed in a larger group of animals. Urinary MPs can be potential marker for kidney end-organ damage in HTN.

Funding: Clinical Revenue Support

SA-PO665
Blood Pressure Lowering Effects of Sulodexide Depend on Albuminuria Severity Rik Hg Olof Engberink, 1 Hiddo Jan Lambers Heerspink, 2 Dick de Zeeuw, 2 Lizlert Vogt. 1 Nephrology, AMC, Amsterdam, Netherlands; 2 Clinical Pharmacy and Pharmacology, UMC, Groningen, Netherlands.

Background: Diabetic patients have a thinner endothelial surface layer (ESL), especially when macroalbuminuria is present. Sulodexide, a mixture of glycaminoglycans (GAGs), increases ESL thickness. Previous data indicate that the ESL is pivotal for BP regulation. In this study, we assessed whether the BP reducing effect of sulodexide is modified by albuminuria severity (a surrogate for the ESL) in type II diabetic patients.

Methods: In a post-hoc analysis of the randomized, double-blind, placebo-controlled Sun-MACRO trial, including type 2 diabetic patients with macroalbuminuria and maximal angiotensin II receptor blocker therapy, we studied the BP effects of sulodexide 200 mg/d. We stratified patients in baseline urinary albumin-creatinine ratio (UACR) tertiles. We used ANCOVA to study whether baseline UACR modified the 3-month SBP changes of sulodexide.

Results: Of 843 patients were available for analysis. Baseline BP was 138/73 mmHg. At 3 months, mean (SEM) SBP change was -0.9 (±0.9) and +1.7 (±0.9) mmHg in the sulodexide and placebo arm, respectively (p=0.037). The SBP reduction was most pronounced in the highest UACR tertile (-1.6 [-1.5 to 2.9] vs 2.9 [±1.6] mmHg; p=0.042). Treatment (p=0.015), baseline SBP (p=0.001), heart rate (p=0.007) and UACR (p=0.007) were associated with SBP change. We found an interaction between treatment and UACR (p=0.047), indicating that sulodexide and placebo differently affected SBP at various UACR levels. Age, eGFR, BMI, HbA1c and lipid profile (i.e., factors influencing ESL thickness) did not modify the treatment effect. The BP differences persisted during the first year of follow-up (p=0.047).

SA-PO666
Under-Diagnosis of Hypertension in a Large Cohort of Overweight/Obese Adolescents Brian William Sykes, Divya G. Moodalbail, Christopher J. LaRosa, Joshua Zaritsky. Nephrology, Nemours/A.I. duPont Hospital, Wilmington, DE.

Background: The obesity epidemic in children is strongly associated with increasing prevalence of childhood hypertension (HTN) along with heightened risk for cardiovascular morbidity and mortality in adulthood. Therefore we assessed the identification of HTN in overweight/obese adolescents cared for by a large healthcare system utilizing an EMR system.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

778A
Methods: We performed a retrospective study of patients (pts) in the Nemours Health Care System, aged 12-17 years, with a BMI >85%ile, and 3 documented BP values >120/80 in the outpatient setting, between 1/2010 and 12/2014. Pts with established diagnosis of htn (ICD-9 codes 401.XX – 405.XX), renal or heart disease were excluded.

Results: Of the 6604 distinct pts identified, only 253 (3.8%) received a diagnosis of htn during the study period, while 6,349 (96.2%) were undiagnosed. Pts who were undiagnosed had lower BMIs and BPs and were less likely to be African American or have Medicaid and were seen less by Nephrology, Cardiology or Weight management subspecialties compared with those diagnosed with htn (table). Additionally undiagnosed pts had fewer abnormal BPs and had a longer interval between their 1st and 3rd abnormal BP compared with those diagnosed with htn.

Conclusions: In this large cohort of overweight/obese adolescents with htn, the vast majority of pts were undiagnosed and not referred to subspecialists who manage BP monitoring and treatment. Thus it is crucial that future efforts focus on improving detection and early recognition of htn in order to reduce cardiovascular morbidity and mortality in this at-risk population.

SA-PO667 Multidisciplinary Selection of Angioplasty Indications in Atheromatous Renal Artery Stenosis Leads to an Improvement in Blood Pressure, Drug Sensitivity and Renal Function

Thomas Foumier,1 Florence Serei,2 Olivier Rouvière,2 Antoine Millon,3 Laurent Juillard,1 Gary L. Schwartz.1

Background: Angioplasty as treatment of atheromatous renal artery stenosis (ARAS) is controversial since 3 large randomised trials (CORAL, ASTRAL, STAR) failed to prove the superiority of percutaneous renal artery angioplasty and stenting (PTRAS) over medical treatment alone (MT). However, since population selection was questionable among other biases, the extrapolation of these results in clinical practice is uncertain.

Methods: ARAS cases were discussed during bi-monthly multidisciplinary meetings gathering nephrologists, radiologists and vascular surgeons from April 2013 to February 2015. For every patient, we compiled clinical, biological and radiological data. We then recorded blood pressure (BP), renal function and treatment evolution after a one-year follow-up.

Results: During 23 months, 52 cases were discussed. Mean age was 69 years. Two thirds of patients had at least 3 cardiovascular risk factors. Mean BP was 161/77 mmHg, despite the use of 2.5 ± 1.1 anti-hypertensive drugs. CKD-EPI was 55mL/min/1.73m². 31% of patients had a history of pulmonary edema. Collective decisions were PTRAS for 21 patients (40%), MT for 28 patients (54%) and surgery for 3 patients (6%). PTRAS and MT groups were initially comparable (blood pressure, renal function, treatment, comorbidities). In the PTRAS group, a significant improvement at 1 year was observed for clinic BP: -14.3/9.0 mmHg, P=0.0001 and 24h ABP: -9.0/4.8 mmHg, P=0.0001. The superiority of PTRAS over MT was also true for each racial subgroup: whites vs blacks: 22.5% vs 10.5% with the PTRAS strategy, and 41.1% for the other 2 strategies, P=0.08; in whites 63.5% with PTRAS strategy, 50.9% with A/R strategy, P=0.001 and 43.9% with TD strategy, P=0.001. This was also true for each racial subgroup: clinic BP: in whites: 50.3% with PTRAS strategy, 40.8% with A/R strategy (P=0.0004) and 31.7% with the TD strategy (P=0.0001); ABP: 61.3% with PTRAS strategy, 51.6% with A/R strategy (P=0.0001) and 43.9% with TD strategy (P=0.0001). It is uncertain which of these 3 strategies achieves the highest control rate with monotherapy in stage-I HTN.

Conclusions: Compared to TD and A/R, the PTRAS strategy for initial drug selection in stage-I HTN was associated with the highest control rate.

SA-PO669 Primary Hyperaldosteronism: An Inner City Hypertension Clinic Experience

Ewawola A. Ijadiulu, Srikanth Shrestha, Islamiyat J. Babs anirunasha, Jeffrey D. Wallach, Suladhanshi Jain. Nephrology, Harlem Hospital Center, New York, NY.

Background: Primary Hyperaldosteronism (PA) has historically been regarded as a rare disorder. Recent studies have shown a widely variable prevalence. We screened for PA in the Hypertension(HTN) Clinic at Harlem Hospital in patients with predominantly African-American and Hispanic ethnicities.

Methods: Retrospective observational study of patients seen at Harlem HTN Clinic between January 2008 to November 2013. The inclusion criteria were patients seen with completed aldosterone and renin levels. The exclusion criteria were patients on spironolactone prior to the laboratory studies or with incomplete data. Prevalence was measured as number of patients with both an Aldosterone/Renin ratio >20 and an Aldosterone level >15ng/dl as a ratio of total number of patients tested.

Results: A total of 268 patients who had plasma aldosterone and renin activity obtained was reviewed. Of these, 8 patients had incomplete data and were excluded. 220 of the remaining patients in the final cohort of patients were black, while 48 were Hispanic. Overall, 33/260, or 16.5% of the patients were found to have met biochemical criteria for PA. About half, 22/43 or 51% of the patients had CAT Scans showing adrenal adenomas. Additionally, one patient had bilateral enlarged adrenal glands consistent with adrenal hyperplasia, 10 had CAT scans with no evidence of an adrenal mass, while the remaining 10 patients had no abdominal imaging. In the 43 patients who met biochemical criteria for PA, 34 patients were black, 16 of which (47%) had CT evidence of adrenal adenoma while 1 patient had bilateral hyperplasia. Of the 9 Hispanic patients, 6 (67%) had CT evidence of adrenal adenoma. Overall, the prevalence of PA was 34/220 (15.4%) in African-American patients and 9/40 (22.5%) in Hispanic patients.

Conclusions: Our study suggests a higher than anticipated prevalence of PA in African-American and Hispanic patients in Harlem, NY, based on selective screening with plasma aldosterone and renin activity and adrenal scans were present by CT scan in at least 50% of cases, potentially treatable with surgery. Thus, adequate screening of patients for PA is essential, especially in minorities.

SA-PO670 HIV-2 and Chronic Kidney Diseases (French HIV-2 Cohort ANRS CO5)

Jerome Tourret,2 Aissatou Yale,1 Marine Naudin,1 Roland Tubiana,3,4 Philippe Genet,1 Diane Descamps,2,3,4 Francoise Brun-Vezinet,2 Catherine Fagard,1 Genevieve Cheze,2 Sophie Matheron,2,7 The French Anrs C05 cohort.1 INSERM U987, Univ Bordeaux, France; 2AP-HP Hôpital Bichat, France; 3AP-HP Hôpital Pitié Salpêtrière, France; 4UPMC, Univ Paris 06, France; 5INSERM UMR 1136, France; 6Hôpital Argetuel, France; 7Univ Paris Diderot, France.

Background: The link between HIV-2 and chronic kidney diseases (CKD) has not been studied. We describe the prevalence of CKD and their risk factors in people living with HIV-2.

Methods: All patients included in the HIV-2 French national cohort with 2 creatinine measurements at least 3 months apart were included. Glomerular filtration rate was estimated by MDRD formula and used to categorize CKD according to the NKF classification. Risk factors were determined by uni and multivariate analyses using a Cox model which included the main known risk factors for CKD and the main characteristics of HIV infection. A total of 1048 patients of which 917 had creatinine measurement. 69 patients were excluded because creatinine had not been measured at both points. Characteristics did not significantly differ from those of the total cohort: mean age (SD) was 50 (11) years, 62% of the patients were females, and 80.1% originated from sub-Saharan countries. On average, HIV-2 infection was diagnosed 12.8 (6.8) years before last creatinine measurement. Prevalence of CKD stage >2 was 39.8% and that of chronic kidney failure (stages >3) was 22.2%. In a multivariate analysis revealed that age (HR=1.06, p<0.01), HIV stage (HR=3.1, p<0.01 for CDC stage C), HIV-2 virus plasma viral load (HR=1.9 for each increment of log_{10}(copies/ml), p<0.10), and CD4 count (HR=3.12, p<10^(-1)/100 mm3) were risk factors for chronic
kidney failure. HIV stage A (HR=0.3, p<0.001) had a protective effect. Multivariate analysis revealed that age (HR=1.05, p=0.002) and CDC stage A (HR=0.35, p=0.01) were risk and protecting factors, respectively.

Conclusions: The prevalence of CKD in this very large cohort of people living with HIV-2 seems to be comparable to what is known in literature for people living with HIV-1. HIV-2 infection parameters determine most of the kidney risk. The role of ARV exposition remains to be taken into account.

SA-PO671

Effect of Nephropathy on the Frequency of Cardiac Dysautonomia in HIV Patients

Syed Rizwan Bokhari, 1 Syed Hunain Riaz, 2 Qurrat-ul-ain Abid, 2 Hafiz I. Ahmad, 1 Muhammad Zaman Khan Assir, 1 Fahima Ashfaq, 2 Kashif Saleem. 2 1Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; 2HIV Clinic, Jinnah Hospital, Lahore, Pakistan.

Background: Dysfunction of autonomic nervous system including Cardiac Dysautonomia (CD) is seen in a variety of conditions like diabetes mellitus, adrenal insufficiency and renal failure. CD is well documented in patients with renal dysfunction. CKD. Prevalence of renal dysfunction (HIV Nephropathy) is high in our population of HIV positive patients, but the effect of HIV nephropathy on the frequency of CD has not been previously studied. We conducted this study to determine the effect of HIV nephropathy on the frequency of CD.

Methods: This cross sectional study was conducted at HIV Clinic in collaboration with the Department of Nephrology Jinnah Hospital Lahore. A total of 47 HIV positive patients were enrolled; 13 (28%) with nephropathy and 34 (72%) without nephropathy. Patients underwent 5 tests for cardiac autonomic dysfunction including resting tachycardia, abnormal heart rate response to deep breathing, abnormal Valsalva ratio, abnormal 30:15 ratio and postural hypotension. Patients with 2 or more abnormal tests were considered positive for CD.

Results: Of 47 patients, 39(83%) were male, 5(11%) female and 3(6%) were transgender with median age of 31 years (range 19-56 years). The median CD4 count was 339 (range 39-797) and 96% (n=45) patients were on highly active anti-retroviral therapy (HAART). The median duration of HIV was 12 months (range 1-56) and median duration of HAART was 11 months (range 0-49). CD was seen in 42 (89%) patients. Seventeen (36.2%) patients had 2, 18 (38.3%) had 3, 6 (12.8%) had 4 and 1 (2%) had 5 abnormal tests. The frequency of CD was comparable among patients with and without nephropathy [92% (12 out of 13) vs 88% (30 out of 34), respectively; p value=1]. The presence of CD had no correlation with CD4 count, degree of renal impairment, treatment regimen and duration on HAART.

Conclusions: There was high frequency of CD in our population of HIV patients and it was independent of presence or absence of nephropathy, CD count and duration of anti-retroviral therapy.

SA-PO672

Glomerular Filtration Rate Estimation Equations Using Beta-Trace Protein and Beta-2 Microglobulin in Chronic Kidney Disease

Background: Beta-trace protein (BTP) and beta-2-microglobulin (B2M), like cystatin C (Cys), are novel serum filtration markers that have stronger associations with adverse outcomes than serum creatinine (Cr). However, comparisons of BTP and B2M to Cr and Cys as filtration markers are limited by the absence of rigorously developed GFR estimation equations. Methods: Using a pooled database of three populations with CKD (N=3551, mean measured GFR using iothalamate [mGFR] 48 ml/min/1.73m 2 ), we developed equations estimating GFR from multiple biomarkers. Models: Using a pooled database of three populations with CKD (N=3551, mean measured GFR using iothalamate [mGFR] 48 ml/min/1.73m 2 ), we developed equations estimating GFR using Cys, BTP or B2M. Equations were developed in 2/3 of the population and tested in the remaining 1/3. Results: The table shows the coefficients included in each equation and the performance of the equations in the validation dataset compared to established CKD-EPI Cr-Cys equations.

Conclusions: BTP and B2M are less influenced by age, sex and race than Cr or Cys but did not improve precision (IQRF) or errors (1-P30), even when averaged with Cr-Cys equation. CKD-EPI BTP and B2M equations provide tools for future study in their associations with mGFR and risk and adverse outcomes, but further study is required before clinical use.

SA-PO673

Estimation of Glomerular Filtration Rate

P.C. Pham, 1 Ruchika Bhusin, 1 Afshan Hafidharbardon, 1 Eileen C. McCann, 1 Solomon C. Huang, 1 Saman Sarani, 1 Anita Kamarzarian, 1 Goliz Jafari, 1 P.T. Pham. 2 Division of Nephrology and Hypertension, Olive View-UCLA Medical Center, Sylmar, CA, 3Kidney Transplant, UCLA Medical Center, Los Angeles, CA.

Background: Estimations of glomerular filtration rates (GFR) based on routine 24 hour urine collections have been replaced by relatively accurate equations derived from large epidemiological studies. Nonetheless, equations including Modification Diet in Renal disease-4 and 6 variables (MDRD-4, -6) and Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) are known to have wide variations in predicting GFR among patients with relatively good kidney function. As renal clearance of any solute is dependent on its presence in the plasma and not whole blood, we suspect that varying hemoglobin/ hematocrit (Hct) may play an important role in the actual clearance of solutes. We aim to determine if adding the plasma factor PF (1 - Hct/100) to MDRD-4, -6, or CKD-EPI equations can improve the accuracy of determining actual GFR.

Methods: This is a retrospective pilot study where the most recent 200 existing 24-hour urine collections obtained with creatinine concentrations as recorded by the Olive View-UCLA Medical laboratory are collected for analysis. Only 24-hour urine collections with concurrent measurements of complete blood count and chemistry 7 are included. To minimize poor 24 hour collections, only samples with urinary creatinine ranging between 15-25 mg/kg weight/day are used. PF is added as an inverse multiplication factor to MDRD-4 and 6-variables and CKD-EPI equations to assess for variations when correlated with actual 24 hour urine collections.
Results: 90 out 200 samples met inclusion criteria. Albeit small, when each of the aforementioned equation was adjusted for PF, R² variation improved. MDRD-4: unadjusted R²=0.836 to adjusted R²=0.853, MDRD-6, R²=0.811 to 0.813, CKD-epi, R²=0.746 to 0.747. Conclusions: Adding PF to MDRD-4, MDRD-6, and CKD-EPI equations reduced variations when correlated to 24 hour urine collections. Of interest, PF appears to improve MDRD (derived for CKD patients where anemia is prevalent) variations better than CKD-EPI. Large-scale reevaluation of eGFR estimates with consideration for PF is warranted.

SA-PO674
Interest of Cystatin C in the Evaluation of Glomerular Filtration Rate in Type 2 Cardio-Renal Syndrome Delphine Kervella,1,2,3 Sundrine Lemoine,2,3 Florence Lemoine,2,3, Denis Pouliquen,1,3 Laurence Dubourg,2,3 Fitsum Guebre
Background: In patients suffering from type 2 cardio-renal syndrome (CRS2), glomerular filtration rate (GFR) is overestimated with creatinine based formulae, leading to the misclassification of these patients in chronic kidney disease stages. As cystatin C is less dependent from muscle mass than creatinine, the aim of this study was to determine if estimation of GFR based on cystatin C offers a better evaluation of renal function than creatinine-based estimations in patients with CRS2.

Methods: GFR measured by Inulin clearance (measured GFR, mGFR) in 50 patients with CRS2 was compared to estimations of GFR (eGFR) with CKD EPI (Chronic Kidney Disease Epidemiology Collaboration) formulae based on creatinine (CKD EPI), cystatin (CKD EPIcyst) and cystatin and creatinine (CKD EPIcyst,cr) with the calculated absolute bias (eGFR-mGFR) and accuracy 30% for each formula.

Results: Mean mGFR is 26.5±11.5 mL/min/1.73 m². eGFR are 41.5±20, 35±14.5 mL/min/1.73 m² with CKD EPI, CKDEPICYST and CKD EPICYST-CREAT respectively.

Conclusions: Glomerular filtration rate is strongly overestimated with creatinine-based estimation in CRS2 patients as previously described. CKD EPI formula based on cystatin C offers a better evaluation of GFR in this population. The high prevalence of malnutrition in this population can explain these results.

SA-PO675
Cystatin C in Type 2 Cardio-Renal Syndrome
Delphine Kervella,1,2,3 Sundrine Lemoine,2,3 Florence Lemoine,2,3, Denis Pouliquen,1,3 Laurence Dubourg,2,3 Fitsum Guebre
Background: Serum creatinine is the most used endogenous marker to estimate glomerular filtration rate (GFR) in clinical practice. A handheld device (StatSensor®, Nova Biomedicals) allows to measure creatinine level in capillary blood. The aim of the study was to assess the accuracy of GFR values (eGFR) estimated from capillary blood creatinine level (cGFR), as compared with GFR values simultaneously measured by a gold standard method (mGFR) in patients with CKD.

Methods: The study included 79 adult patients (36 men, 43 women) who underwent renal function tests. The consent form contained information on the procedure and on the later use of the information for research. Inulin clearance was performed using a continuous infusion of inulin, and urine collections by periods of 30 min. Blood tests were done in the middle of each period of urine collection. Measurements of polyfructosan concentrations were performed using an enzymatic method. Inulin clearance was calculated in each period to obtain the average, and normalized to 1.73 m² body surface area. A drop of capillary blood was collected from a finger simultaneous to the first and the last blood sampling for inulin measurement. The drops were deposited on a test strip including enzyme reagents and inserted into the StatSensor® device. Reading was done at 30 sec. eGFR was calculated from CBCr with the CKD-EPI equation and the average of the 2 values was taken as eGFR. To assess the performance of CBCr-derived eGFR, the mean absolute bias (eGFR - mGFR) and the correlation coefficient (R²) were calculated.

Results: Mean age was 54.3±17 years, and mean BMI was 25.5±4.2 kg/m². Mean value of mGFR was 61.2±27 mL/min/1.73 m². Mean bias was -5.2 mL/min/1.73 m². On correlation analysis, there was no significant difference between the 2 methods (correlation coefficient 0.7,0.71).

Conclusions: Estimation of GFR using instant measurement of capillary blood creatinine level and CKD-EPI formula provides consistent results as compared with a gold standard method for GFR measurement, and could be used for screening and self-assessment purposes.

SA-PO676
Renal Function Estimated with Different Formulae and Mortality in the INCIPE Cohort: Results After 8 Years Follow-up Pietro Manuel Ferrara,1 Antonio Lupo,2 Giovanni Gambaro,1,3 Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy; Div of Nephrology, Univ of Verona, Verona, Italy.

Background: Chronic kidney disease is a known risk factor for adverse outcomes. Its presence and severity is usually ascertained with formulae to estimate renal function based on serum creatinine and/or cystatin C. We analyzed whether renal function estimated with different formulae has a differential association with mortality.

Methods: The INCIPE is a sample of the Italian population enrolled in 2006-07, with follow-up data available up to 2014. CKD stages were defined as GFR ≥90, 89-60, 59-45 and <45 mL/min based on the following formulae: Cockcroft-Gault (CG), Cockcroft-Gault normalized to body surface area (nCG), abbreviated MDRD (MDRD), 6-variables MDRD (MDRD-6), CKD-EPI calculated with serum creatinine (EPI-Cr), with serum cystatin C (EPI-Cys), and with both serum creatinine and cystatin C (EPI-CrCys). CKD stage was then included in a Cox proportional hazards model together with age, body mass index, sex, high blood pressure, diabetes, dyslipidemia, previous cardiovascular disease, smoking status and albuminuria. Harrell’s c statistics with 95% confidence intervals (CI) were then calculated and compared for each formula.

Results: The final sample included 2,916 participants, all caucasians, 47.4% males, with an average age at enrollment of 59.9±11.4 years. Participants contributed a total of 22,514 person-years of follow-up (median follow-up 7.9 years) during which 198 death events occurred. Overall, the models were highly predictive of mortality.

The GFR-Cys model performed significantly better than MDRD-6 (difference in c-statistics of 0.008, 95% CI 0.001, 0.015; p=0.034), whereas all the other models performed similarly.

Conclusions: Our study suggests that CKD defined with the CKD-EPI cystatin C formula shows a better prediction of mortality after accounting for a large number of potential risk factors.

SA-PO677
Do the BIS Equations Better Predict Death in Older Women? Muna T. Canales,1,2 Terri L. Blackwell,3 Areef Ishani,1,2 Brent C. Taylor,4 Allyson Hart,2 Rebecca Blyth,2 Kristine E. Ensrud,4,5 Malcom-Randall FAMC; Univ of Florida; Minneapolis VA Health Care System; Univ of Minnesota; Hennepin County Medical Center, Minneapolis, MN.

Background: KDIGO 2012 guidelines recommend use of the CKD-EPI equations to estimate GFR except when there are alternate equations that may perform better in certain populations such as older adults. The BIS equations were specifically developed in an aged population, but their performance when compared to the CKD-EPI equations to predict mortality in older adults is unclear.

Methods: We conducted a prospective study of 1289 community-dwelling elderly women (≥72 years old) enrolled in the Study of Osteoporotic Fractures (SOF) who had both serum cystatin-C (cysC) and creatinineSCR measured at Year 10(1992-1994). We used Cox proportional hazards regression and net reclassification improvement(NRI) to compare the ability of the BIS2 (cysC & SCR-based), CKD-EPI_Cys, BIS1 (SCR-based), and CKD-EPI_Cys, expressed as 4 eGFR categories (27, 60-74, 45-59, <45) to predict death. For NRI analyses, reference equations were CKD-EPI_cys, for BIS2 and CKD-EPI_cys for BIS1.

Conclusions: Our study suggests that CKD defined with the CKD-EPI cystatin C formula shows a better prediction of mortality after accounting for a large number of potential risk factors.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

781A
Results: The mean age was 79.5±4.6 years; 89% were white. Mean BMI was 27.5 kg/m². Mean follow-up time was 9.4 years. % eGFR<60 was: CKD-EPIcr 33%, BIS2 48%, CKD-EPI, 24% and BIS1 49%. When compared to eGFR<75 and after adjustment for age, race, BMI, HTN & DM, eGFR<45 by BIS2 was associated with a 2.1-fold greater risk of death (95% CI 1.5-3.0) vs 1.9-fold for eGFR <45 by CKD-EPIcr, (95% CI 1.5-2.5); BIS1 eGFR<45 was associated with a 1.6-fold greater risk of death (95% CI 1.1-2.1) vs 1.8-fold for eGFR <45 by CKD-EPI, (95% CI 1.2-4.4; p trend <0.001 across categories for each equation). In category-based NRI analyses neither of the BIS definitions materially changed discrimination of mortality risk when compared to CKD-EPI equations.

Conclusions: In this cohort of older community-dwelling women, the BIS equations identified a greater proportion of participants as having CKD. With respect to mortality risk prediction, the BIS equations did not perform better than current CKD-EPI equations recommended by KDIGO 2012.

SA-PO678

Canine Chronic Kidney Disease: New Protein Biomarkers and Treatment with Human Umbilical Cord Mesenchymal Stem Cells

Background: There are few strategies to prevent the progression of renal disease in humans or animals. In canine chronic kidney disease (cCKD), as in human CKD, proteinuria correlates with CKD progression, although there are no established urinary biomarkers. cCKD has become more common, dogs routinely being euthanized upon reaching the advanced stages. Mesenchymal stem cells (MSCs) have proven renoprotective in rodent CKD models. Here, we aim to characterize the roles that urinary excretion of albumin (Alb), Tamm-Horsfall protein (THP), vitamin D-binding protein (VDBP) and retinol-binding protein (RBP) play in cCKD and to determine whether human umbilical cord MSC (huMSC) administration slows its progression.

Methods: We performed Western blotting for urinary exosomal expression of Alb, THP, VDBP and RBP in cCKD stage 1-4 dogs (n=10/stage) and control dogs (n=10). We evaluated huMSC phenotypes with flow cytometry and immunocytochemistry. We randomized CKD stage 3 dogs to receive i.v.-injected placebo (n=5) or 10⁶ huMSC/kg (n=6).

Results: BIS has been analysed by immunonephelometry with N-Latex bTP Assay on a BN ProSpec ® System, Siemens, Germany. Analysis was done in 570 participants of the study.

Conclusions: Our findings broaden perspectives for CKD treatment. Supported by FAPESP.

SA-PO679

Validation of the Urine Total Protein-To-Creatinine Ratio-Based Chronic Kidney Disease Risk Classification: A Secondary Analysis

Background: The most recent Japanese chronic kidney disease (CKD) guideline states that patients without diabetes should be classified using the total urine protein-to-creatinine ratio (PCR) instead of the urine albumin-to-creatinine ratio (ACR); however, validation of the PCR is still required. This study was conducted to validate the PCR-based CKD risk classification compared with the ACR-based classification and to explore more accurate methods for classification, focusing on relatively early CKD patients.

Methods: We conducted a secondary analysis using two previous datasets with diabetic or cardiovascular patients who were classified into CKD stages A1-A2 and G1-G3b. We assessed the CKD stage and risk classification of each patient according to the estimated glomerular filtration rate and the ACR- or PCR-based classification method. Then, various candidate PCR values were utilized as the cut-off values between stages A1 and A2. Cohen’s kappa statistics were calculated to evaluate the agreement between each classification method.

Results: In total, 860 patients (131 from the diabetic clinic and 729 from the cardiovascular clinic) were enrolled. Using the cut-off value recommended in the current guideline (PCR 0.15 g/gCr), the misclassification rates in these populations were 26.0% and 16.6%, respectively; the misclassifications were primarily caused by underestimation. Cohen’s statistics achieved 0.56 (95% confidence interval, 0.45-0.69) and 0.72 (0.67-0.76), respectively. Using PCR values of 0.08-0.10 g/gCr as the cut-off value improved the misclassification rates and kappa values.

Conclusions: Current PCR-based CKD classification method leads to underestimation of risk classification in outpatient setting.

SA-PO680

Beta-Trace Protein as Renal Marker in Older Adults – Results from the Berlin Initiative Study

Background: It has been shown that GFR estimation based on β-Trace Protein (BTP), a relatively novel biomarker, is reliable and might serve as an alternative in kidney transplant recipients. Whether BTP-based eGFR equations can be applied in older adults is not known.

Methods: BTP has been analysed by immunonephelometry with N-Latex® BT Assay on a BN ProSpec System. Siemens, Germany. Analysis was done in 570 participants of the Berlin Initiative Study (mean age: 78.5 yrs) who underwent iohexol clearance measurement (mean mgFR: 60.3 mL/min/1.73m²). The following 3 currently available eGFR equations were used: Pöge (BTP): GFR = 47.17 ×BTP -1.86 , Pöge (BTP/Crea): GFR = 974.31 × BTP -1.758 × creatinine-0.204 and White (BTP/Crea): GFR = 167.8 × BTP -0.758 × creatinine-0.204 × (0.871 if female). Comparison of BTP estimating equations with mgFR was done for determination of bias (mgFR-eGFR), precision (SD) and accuracy (P10, P30).

Results: The boxplot includes median and eGFR range calculated with the 3 GFR-equations. Mean eGFR was 100.3 for Pöge (BTP), 62.7 for Pöge (BTP/Crea) and 86.2 mL/min/1.73m² for White (BTP/Crea).

Chronic Kidney Disease: Long Term Prevalence Trends and Influence of Modifiable Risk Factors
Stein I. Hallan, Marius Alter Øvrehus, Solfird Romundstad, Dena E. Rikf, Arnulf Langhammer, Joachim H. Ix.
UCSD, La Jolla, CA; Faculty of Medicine, NTNU, Trondheim, Norway.

Background: Prevalence of chronic kidney disease (CKD) is high worldwide, and it has been increasing in the US. However, less strict treatment goals for hypertension have recently been suggested despite increasing prevalence of obesity and diabetes. We aimed to determine whether CKD prevalence is increasing in Norway, evaluating the influence of changing prevalence of CKD risk factors on CKD prevalence, and compared findings to corresponding US data.

Methods: We included general population based participants from the Nord-Trøndelag Health Studies (HUNT), Norway: 65237 from HUNT2 (1994-96) and and 50586 from HUNT3 (2006-08). eGFR and u-ACR based on fresh blood and 3 urine samples were used to diagnose CKD. Thorough quality-control and comparisons of methods over time excluded analytical drift. We used attendance weights used to avoid responder bias.

Results: Total CKD prevalence remained stable in Norway 1996-2007 (11.3%-11.1%, p=0.42) but increased in subjects >75 years (36.6%-39.3%, p=0.014). eGFR <60 ml/min/1.73m2 increased (4.5%-4.8%, p=0.033) while albuminuria >30mg/g decreased (7.9%-7.4%, p=0.034). The most important contributors were a strong blood pressure decline during this 10 years period, more physical activity and lower cholesterol; without these improvements 2.8, 0.7 and 0.6 percentage-point higher CKD prevalence would have been expected, respectively. In contrast, the prevalence of diabetes and obesity increased moderately, but diabetics received more intensive preventive therapy, and the proportion of diabetic patients with CKD decreased substantially (33.4%-28.6%, p=0.002). In contrast, published US data indicate a stronger increase in obesity and diabetes, and physical activity was low and not improving. Access to effective care was also suboptimal for a substantial group of the population.

Conclusions: In contrast to the US where CKD prevalence has been increasing, it remained stable over a 10 year period in Norway, likely due to substantial improvements in blood pressure, lipids and physical activity despite modestly increasing diabetes and obesity. Funding: NIDDK Support

Natural Progression of Chronic Kidney Disease in Optimally Managed Patients on the Maximum Conservative Management Pathway
Suzanne H. Forbes, Kieran McCafferty, Muhammad M. Yaqoob, Nephrology, Royal London Hospital.

Background: The natural progression of advanced chronic kidney disease (CKD)/end-stage renal disease (ESRD) managed in a specialist palliative care nephrology clinic setting is unknown.

Methods: We conducted an observational study of all patients with advanced CKD undergoing predialysis counselling between 2009-2014 in a single UK center. All patients who opted for conservative management were followed up prospectively in a specialist conservative care clinic and their clinical phenotype and renal outcomes recorded. Change in eGFR was noted in those patients whose eGFR was<10, with 2 or more serum creatinine estimations taken more than 2 months apart.

Results: We prospectively studied 354 patients with median length of follow-up 452 days (165-769). Median eGFR at referral was 8ml/min (7-9). Demographics are shown.

| Age | 78 (73-84) |
| Gender | M - 62% F - 38% |
| Diabetes | Yes - 62% No - 38% |
| Ethnicity | Caucasian - 39% South Asian - 37% Black - 14% Other - 10% |
| Cause of CKD | Diabetes - 38% Renovascular (including hypertension) - 24% Urological - 9% GN - 5% Other - 4% Unknown - 20% |
| Previous Modality | Nephrolgy/Low Clearance Clinic - 92% Failing Transplant - 2% Unknown to Service - 6% |
| Death (n) | 209 |
| Cause of Death (n) | Cardiac - 16 (8) Sepsis - 13 (6) Stroke - 2 (1) Unknown - 38 (18) Other - 12 (6) |
| Age at Death | 80 (75 - 85) |
| Time to Death (days) | 276 (185 - 555) |

Galectin-3, Possible Useful Biomarker in Predicting Chronic Kidney Disease in Hepatitis C Positive Patients
Hany Refaat, Haitham Ezzat, Amir Mohab, Nephrology Dept, Ain Shams Univ, Cairo, Egypt.

Background: Galectin-3, a profibrotic mediator, is involved in mechanisms of tubulointerstitial fibrosis and CKD progression. Data regarding its predictive value of CKD development in Hepatitis C patients is scarce.

Methods: In this cohort study, we measured the level of Galectin-3 in the sera of 80 Hepatitis C positive patients. Patients levels were stratified into two groups: Forty hepatitis C positive patients with normal kidney function (Group I), and 40 hepatitis C positive patients with CKD (Group II). Galectin-3 concentration was also measured in 10 healthy individuals, as a control group (Group III). Other laboratory investigations were done which included hemoglobin level, serum creatinine, eGFR by MDRD equation, ALT, AST, INR, serum albumin, serum hirulbin and CRP titre. We correlated galectin-3 concentrations with demographic and biochemical parameters in all groups.

Results: 30 females (33.3%) and 60 males (66.7%) were included in the study with mean age 47.6±5.3 years. Plasma levels of Galectin-3 were highest in group II (22.1 ±5 ng/ml) when compared to group I (15 ±2.4 ng/ml) and group III (9.7 ±2.5 ng/ml) (p<0.001). Also CRP titre was highest in group II (10.1 ±1.5 mg/L), when compared to group I and III (2.5±0.9 mg/L and 2.3 ±1.1 mg/L respectively) (p<0.001). There was positive correlation between Galectin-3 level and CRP titre in both group I and II (p<0.001). Moreover, in group II, Galectin-3 level was positively correlated with serum creatinine (p<0.001), while inversely correlated with eGFR (p=0.001). There was no correlation between serum Galectin-3 level, and INR, ALT, AST and serum albumin in both group I and II.

Conclusions: In hepatitis C positive patients, galectin-3 concentrations increased with progressive renal impairment. Galectin-3 levels were not correlated with liver functions, suggesting the predictive value of galectin-3 for CKD development in hepatitis C positive patients.

Table 1 shows bias, precision and accuracy for all 3 equations compared to mGFR.

Fall in eGFR in ml/min/year was 3.9 (1.8-8). Neither baseline eGFR (p=0.13) nor presence of diabetes (p=0.72) affected this rate of decline. Time to death from eGFR 10ml/min was 276 days.

Conclusions: In this first longitudinal study of conservatively treated patients with advanced CKD, variable rate of decline of eGFR ranging between 1.8-8ml/year led to death of 55% of the cohort within the median follow up period of 15 months. Reassuringly the majority of patients died at their preferred place of terminal care (home/hospice) and were registered as deaths due to ESRD. Over 50% of patient’s eGFR decline was less than 4 ml/min per year which could translate into a life expectancy of >1 year without dialysis in these exceedingly frail individuals. Prospective study is ongoing to determine the quality of life of these patients treated conservatively.

Estimating County-Level Prevalence of Chronic Kidney Disease (CKD) in the United States
Jennifer L. Bragg,1 Daniel Dharmarajan,1 Jennifer L. Bragg-Gresham,1 Hal Morgenstern,1 Yi Li,1 Neil R. Powe,1 Delphine S. Tuot,1 Deborah Rolla,1 Sharon Saydah,1 Rajiv Saran.1
1Univ of Michigan, Ann Arbor, MI; 2Univ of California, San Francisco, CA; 3Centers for Disease Control and Prevention, Atlanta, GA.

Background: The prevalence of adult CKD in the US, estimated from 2005-2012 national survey data, is about 13%; however, those surveys are not designed to estimate rates for small regions. Applying a Bayesian multi-level model (BMLM), we estimated adult CKD prevalence in US counties using national and state surveys.

Methods: Data on self-reported CKD and risk-factors were obtained from (i) the National Health and Nutrition Examination Survey (NHANES 2005-2012; n=20,831), and (ii) the Behavior Risk Factor Surveillance System (BRFSS 2011; n=506,467); NHANES also provided CKD laboratory data. CKD was defined as estimated glomerular filtration rate 15-60 ml/min/m\(^2\) or urinary albumin-to-creatinine ratio >30mg/g. As BRFSS does not include laboratory data, CKD for each person in the BRFSS was multiply imputed using a logistic regression model trained on NHANES data. A BMLM that effectively combines information from neighboring counties was then fit to each imputed dataset to produce 10 sets of county-level estimates of CKD prevalence. These estimates were combined to obtain a final prevalence estimate for each county.

Results: Estimated county-level prevalence of CKD ranged from 12.3 to 27.8% (median: 18.8%) in 2011 (see map).

The standard deviation of these estimates ranged from 0.8 to 7%, and the coefficient of variation ranged from 5 to 32% of the estimate, suggesting good statistical precision.

Conclusions: We believe this is the first attempt to estimate CKD prevalence in U.S. counties. Our approach yields estimates with improved statistical precision for small counties, and is being used to study geographic variation in CKD burden across the U.S.

Overall CKD Prevalence in the U.S. Has Stabilized in Recent Years
Daniel P. Murphy,1 Charles E. McCulloch,1 Feng Lin,1 Tanushree Banerjee,1 Jennifer L. Bragg-Gresham,1 Mark Eberhardt,1 Meda E. Pavkov,1 Rajiv Saran,2 Neil R. Powe,1 Chi-yuan Hsu.1
1UCSF [Drs. CY Hsu and NR Powe are Co-Senior Authors]; 2Univ of Michigan; 3CDC.

Background: ESRD incidence rates in the U.S. have stabilized recently. We sought to better understand trends in CKD prevalence in the U.S. between 2003 and 2004.

Methods: We examined data on adults from the National Health and Nutrition Examination Surveys from 1988 through 2012. We determined prevalence of stage 3-4 CKD (CKD-EPI equation eGFR 15-59 ml/min/1.73m\(^2\)) overall and by age, sex, race, and diabetes strata. We examined crude prevalence and adjusted prevalence for age, sex, race, and diabetes mellitus (diagnosed and undiagnosed). Restricted cubic splines were used to model trends. The years 2003-4 (last years with published literature) were compared to 2011-12 (most recent years of available data).

Results: Consistent with the published literature, we saw a rise in CKD prevalence from the late 1990s to the early 2000s. But since around 2003-4, adjusted and unadjusted prevalence of CKD have stabilized (Figure). This temporal trend was observed across age (p for interaction=0.11), sex (p=0.61) and racial-ethnic subgroups (p=0.07; although the trend in non-Hispanic blacks appeared to differ); and did not differ by diabetes status (p=0.17). There was no difference in overall stage 3-4 CKD prevalence comparing 2003-4 and 2011-12 (p=0.25). Similar results were seen with an expanded definition of CKD to include persons with higher eGFRs but albuminuria or used the MDRD equation.

Conclusions: Over the last decade in the U.S., there has been stabilization in the overall prevalence of stage 3-4 CKD, with a possible exception in blacks. This is contrast to what has been reported by prior studies analyzing older data but consistent with the observed stabilization of overall ESRD incidence. Efforts should be continued to implement reno-protective measures, especially in blacks.

Global Prevalence of Chronic Kidney Disease Categories 3-5 – A Systematic Review
Tazeen H. Jafar1, Priscley Nkouibert Assam,1,2 Fahad Javid Siddiqui,1 Shreyasee S. Pradhan,1 Edwin S.Y. Chan.2 1Duke-NUS Graduate Medical School, Singapore; 2Singapore Clinical Research Inst.

Background: Chronic kidney disease (CKD) has become a leading contributor to the global burden of disease. We performed a systematic review of published studies to estimate the global prevalence of CKD categories 3-5 defined by estimated glomerular filtration rate (eGFR) less than 60 ml/min/m\(^2\).

Methods: PubMed, EMBASE and Scopus were searched for studies published in English from 2003 to 2013 reporting prevalence of CKD categories 3-5 in the general population. Studies were included if they (1) sampled from the general adult population, (2) assessed CKD using CKD-EPI or MDRD Study equations; (3) not on renal replacement therapy.

Results: A total of 13,081 studies were considered, of which 566 studies from 54 countries assessed prevalence of CKD, and 284 studies were in unsellected general population. The global prevalence of CKD accounting for clustering among all adults aged 20 years or older are shown in table below

Prevalence of Chronic Kidney Disease with Diabetes and Glomerulonephritis in China

Lixia Zhang, Jinwei Wang, Ming Hui Zhao. Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.

Background: Diabetes is the leading cause of end stage kidney disease worldwide, while glomerulonephritis is thought to be the predominant cause in developing countries. However, the surging prevalence of diabetes in developing countries such as China may have substantial impact on the spectrum of chronic kidney disease.

Methods: A national in-patient database involving 19.5 million patient-records was used. Diagnoses of chronic kidney disease with diabetes (DM-CKD) as well as with glomerulonephritis (GN-CKD) were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. Furthermore, a general population-based, national representative sample of 47 204 participants was used. Identification of DM-CKD and GN-CKD was based on laboratory tests and the questionnaire inquiring about medical history. Then the prevalence of DM-CKD and GN-CKD was compared among both hospitalized population and general population.

Results: Among 19.5 million hospitalized patients, 1.19% and 0.79% were identified as DM-CKD and with GN-CKD, respectively. Compared with GN-CKD, DM-CKD was associated with 7.2% (95% confidence interval [CI] 6.4-8.0%), 5.4% (95%CI 4.7-6.0%) and 59% (95%CI 46-73%) increase of costs, length-of-stay and in-hospital mortality, respectively. For general population, the prevalence of the GN-CKD is also exceeded by that of DM-CKD at 0.84% (95%CI 0.68-1.00%) and 1.23% (95% CI 1.06-1.41%), respectively. The estimated number of DM-CKD patients in China was 20.1 million.

Conclusions: Our study indicates that DM-CKD surpassed GN-CKD in both hospitalized population and general population, which marked a transition of kidney disease spectrum in China. Furthermore, DM-CKD is associated with substantial increased hospitalized population and general population, which marked a transition of kidney disease spectrum in China. Furthermore, DM-CKD is associated with substantial increased hospitalized population and general population.

Prevalence of Chronic Kidney Disease with Diabetes and Impaired Renal Function on the U.S.-Mexico Border: Role of Acculturation

Jonathan Michael Starkley, Kristina Vatcheva, Susan P. Fisher-Hoch, Joseph B. McCormick. Inst for Translational Sciences, Univ of Texas Medical Branch, Galveston, TX; Univ of Texas School of Public Health, Houston, TX.

Background: Mexican-Americans are the dominant Hispanic group in the US and face significant health disparities, including end-stage renal disease, diabetes and obesity. We characterize the quantity and associations of chronic kidney disease (CKD) in Cameron County, TX where almost 90% of the population is Hispanic and is predominantly zero or first generation Mexican-American.

Methods: The Cameron County Hispanic Cohort (CCHC) is a random sample of the Hispanic population on the southernmost point along the US-Mexico border. 1,777 participants with baseline serum creatinine measurements from 2003-2014 are included in this cross-sectional study. The glomerular filtration rate (eGFR) is estimated from serum creatinine and CKD is defined as eGFR < 60 ml/min/1.73 m². The weighted prevalence of CKD is estimated. A multivariate model of factors associated with CKD outcome.

Results: The prevalence of CKD is 6.0% in the CCHC and estimates the prevalence in Cameron County, TX. Stratified by gender, the prevalence in men and women is 6.9% and 4.0%, respectively. Multivariate analysis reveals significant associations of country of birth (OR 2.14, 95% CI [1.02, 4.46]) for those born in the US), hypertiglyceridemia (OR 2.72, 95% CI [1.41, 5.239]) and granulocyte count (OR 1.345, 95% CI [1.083, 1.708]) with CKD status after adjusting for age, gender, diabetes status, cardiovascular disease history, hypertension, smoking history, obesity, LDL and statin use.

Conclusions: The prevalence of CKD in the CCHC is higher than previous national estimates in Hispanics or Mexican-Americans. The data suggest that acculturation, triglycerides and inflammation are associated with CKD in Hispanics living on the US-Mexico border. More research is needed in Mexican-Americans to investigate CKD in this growing minority population.

Validation of the Kidney Failure Risk Equation in Manitoba

Paul Komenda,1,2 Claudio Rigatto,1,2 Allison Dart,1,4 Joe A. Bueti,1 Randy Wald,1 Navdeep Tangri,1,2,3 Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; 1Nephrology, Seven Oaks Hospital, Winnipeg, MB, Canada; 2Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 3Nephrology, Health Science Centre, Winnipeg, MB, Canada.

Background: Patients with chronic kidney disease (CKD) are at risk for progression to kidney failure. We previously developed the Kidney Failure Risk Equation (KFRE) to predict the progression of CKD to kidney failure in patients referred to nephrologists. This study aims to validate the KFRE in an unselected population in Manitoba, and to determine risk thresholds for clinical decision-making.

Methods: We included patients from the Diagnostic Services of Manitoba database with an eGFR < 60 ml/min/1.73 m² and a urinary albumin creatinine ratio measured between October 1, 2006 – March 31, 2007. Five year kidney failure risk was predicted using the 4-variable KFRE and compared with treated kidney failure events from the Manitoba Renal Program database. Sensitivity and specificity for KFRE thresholds (3% and 10% over 5 years) were then compared to eGFR thresholds (30 and 45 ml/min/1.73m²).

Results: 1,512 patients were included and 151 developed kidney failure over the 5-year follow-up period. The 4-variable KFRE more accurately predicted kidney failure when compared to eGFR alone (AUROCs 0.90 [95% confidence interval (CI) 0.88-0.92] for KFRE vs. 0.78 [95% CI 0.74-0.83] for eGFR). At a risk threshold of 3% over 5 years, the KFRE had a sensitivity of 97% and a specificity of 62%.

Conclusions: The KFRE is highly accurate at predicting 5-year risk of kidney failure in a population based sample of Manitobans with CKD Stages 3 to 5. Integration of the 4-variable KFRE into laboratory information systems should be considered.

A Risk Prediction Model of End-Stage Renal Disease in Type 1 Diabetes Using Urine MCP-1 as an Alternative Biomarker of ACR

Masayuki Yamamouchi, Monika A. Niewczas, Natalia Z. Nowak, Andrzej S. Krolewski. Genetics & Epidemiology, Joslin Diabetes Center, Boston, MA.

Background: There is a great need to develop risk prediction models to recruit patients at high risk of end-stage renal disease (ESRD) for clinical trials in patients with type 1 diabetes. We developed two models to predict progression of CKD 3 and 4 to ESRD in 5 years in patients with type 1 diabetes: “ACR model” that consists of patient’s age, eGFR, HbA1c and ACR, and “Urine MCP-1 model” that consists of the same markers but replacing ACR with urine MCP-1.

Methods: We identified 285 patients with type 1 diabetes and impaired renal function (eGFR < 60 ml/min/1.73 m²) from Joslin Proteinuria Cohort that was followed for 7 to 18 years to ascertain ESRD. We focused on the events within 5 years from enrollment. For the ACR model, the Cox model identified four baseline variables: age, eGFR, ACR, and HbA1c for the final model. For the urine MCP-1 model, urine MCP-1, age, eGFR and HbA1c were identified by the Cox model. Assigned point scores corresponded to each coefficient.

Results: 5-year risk of ESRD in the study group was 40.5%. In the ACR model, the variable with highest magnitude was eGFR<30, 4 points; followed by ACR<300, 2 points, HbA1c<7.5, 1 point; and age<45 years, 1 point, while in the urine MCP-1 model, the variable with highest magnitude was eGFR<30, 2 points; followed by urine MCP-1>545, 1 point; HbA1c<7.5, 1 point; and age<45 years, 1 point. The model with urine MCP-1 performed almost equal to the model with ACR (C statistic of 0.702 (0.556-0.831) vs. 0.719 (0.574-0.845)). Although the number of patients who developed ESRD in the high risk group in the urine MCP-1 model is smaller than in the ACR model, the incident rate of ESRD in the high risk group in the urine MCP-1 model was much higher than in the ACR model (291/1000 vs. 196/1000, p<0.001).

Conclusions: Using the risk score with urine MCP-1, we can identify a subgroup of patients at very high risk of ESRD.
SA-PO691
A Reliable Formula to Estimate 24-h Urine Sodium Excretion from Morning Fasting Urine in Patients with Chronic Kidney Disease
Se Yun Kim, Ho Jun Chinn, Sejoong Kim, Dong Ki Kim, Suhggwong Kim, Jung Hwan Park, Sung Joon Shim, Bum Soon Choi, Chun Soo Lim, Sang Ho Lee. Kyung Hee Univ Hospital, Seoul, Korea; Seoul National Univ Bundang Hospital, Seong-Nam, Korea; Seoul National Univ Hospital, Seoul, Korea; Konkuk Univ Hospital, Seoul, Korea; Dongsugkuk Univ Ilsan Hospital, Goyang, Korea; Seoul St. Mary’s Hospital, Seoul, Korea; Seoul National Univ Barnave Medical Center, Seoul, Korea.

Background: Estimated 24 hour urine sodium excretion based on spot urine has been proposed to replace 24 hour urine collection in epidemiologic studies. However, estimated sodium excretion has not been verified whether it is useful in patients with chronic kidney disease (CKD) as well as in interventional study. The aim is to evaluate the estimated sodium excretion in prospective low salt diet education study (ESPECIAL) cohort.

Methods: New formula was developed from baseline data of 228 CKD patients of ESPECIAL cohort using a multivariable linear regression and compared with previous three formulas from healthy population (Kawasaki, INTERSALT, Tanaka) and one from CKD patients (Nerbas) for the prediction of 24 hour sodium excretion after ARB treatment and low salt diet education.

Results: Among previous reported formulas, the estimation by Tanaka’s formula showed the smallest bias (estimated 144.3±46.5 vs. measured 154.1±69.6 mEq/day), but weak correlation (r=0.34). We developed new formula with improved bias (estimated 154.0±39.7 mEq/day) and correlation (r=0.56). New formula also showed the best correlation (r=0.57) with smallest bias (estimated ±3 mEq/day) even after ARB treatment, which did not show significant change of measured sodium excretion (156.3±70.6 mEq/day). Intensive low salt diet education elicited the significant decrease of measured sodium excretion (121.2±59.4 mEq/day). Although new formula also showed best correlation, any formula did not predict the amount of the decrease of measured sodium excretion.

Conclusions: We developed more reliable formula for estimating urine sodium excretion for CKD patients. However, our data suggests estimated sodium excretion could be applied for epidemiological study rather than low salt intervention study.

SA-PO692
Evaluation of Glycated Albumin for Glycemic Monitoring in Diabetic Nephropathy
Yang Fei, Ying Fan, Yunhe Liu, Niansong Wang. Dept of Nephrology and Rheumatology, Shanghai Jiaotong Univ Affiliated the Sixth Hospital, Shanghai, China.

Background: Glycated albumin(GA) has been now widely used for the evaluation of blood glucose in diabetic nephropathy(DN) patients. However, the effect of proteinuria on GA should be taken into account, especially in patients with advanced DN.

Methods: A total of 621 diabetic nephropathy patients from year 2009 to 2014 were enrolled in the study. According to the 24h urinary protein(UP) output, subjects were divided into 3 groups defined as (1) microalbuminuria: UP=30-300mg/24h, (2) moderate albuminuria: UP=300-1000mg/24h, (3) macroalbuminuria: UP>1000mg/24h.

In all DN patients, the related factors of GA were fasting blood glucose(FBG), body mass index (BMI), 24 h UP. The multivariate regression equation was GA = 0.254FBG + 0.341BMI - 1.306UP (R2=0.375). There was no correlation between GA and 24h UP in patients with micro or moderate albuminuria. However, GA was found to be much lower and negatively correlated with 24h UP in DN patients with macroalbuminuria. Therefore, adjusted GA (adjGA) was applied for those subjects, taking 24h UP, serum albumin (SA) and the ratio of normal albumin metabolism days to total albumin metabolism days into account. adjGA= mGA×(1+3.75×UP/SA). As a result, GA value was increased after adjustment in DN macroalbuminuria group. The adjGA was also found only correlated with FBG and PBG, and had no relation with 24h UP and SA.

Conclusions: In diabetic nephropathy patients, blood glucose, serum albumin and 24h urinary protein output may serve as important factors for the evaluation of GA on glycemic level. GA tended to be underestimated in DN patients with macroalbuminuria. The adjGA may be a better way to objectively evaluate glycemic status in patients with advanced DN.
Discussions About CKD Between African Americans with High CKD Risks

Methods: As part of a baseline assessment for a randomized controlled trial, we characterized CKD awareness and perceived risk of CKD among AA patients with an eGFR<60 ml/min/1.73m2 and 60% had albuminuria alone. The majority (n=37, 71%) of patients were not aware of their CKD. Among these, 27% (n=10) considered themselves unlikely to develop CKD and 19% (n=7) were not concerned about developing CKD. CKD awareness was greater among patients with an eGFR<60 (vs. eGFR≥60) (adjusted percentages [95% CI]: 50% [19-81%] vs 35% [9-61%]). Conversely, patients with diabetes reported less CKD awareness than those without diabetes (AP [95% CI]: 53% [reference] and 10% [2-38%], respectively, p<0.0006). Perceived risk of CKD did not vary by patient characteristics.

Conclusions: Among AA patients with uncontrolled hypertension and CKD, awareness of CKD was low, with some patients unconcerned about developing CKD in the future. Strategies to improve recognition of CKD risks among AAs at high CKD risk are needed.

Discussions About CKD Between African Americans with High CKD Risks and Their Primary Care Physicians

Methods: As part of a randomized controlled trial of African American (AA) patients with uncontrolled hypertension, we analyzed audio-recorded encounters between patients and their PCPs using the Roter Interaction Analysis System to characterize the occurrence of CKD discussions. Among 124 patients, the mean age was 58 years, 69% were female, 48% had diabetes, 35% had CKD (mean eGFR 83). The average visit length was 22 minutes. Patients and PCPs discussed CKD in 47% of visits and discussions more frequently occurred among patients with CKD (vs. without CKD) (66% vs. 36% respectively, p=0.002). Discussions were less common [Odds Ratio (95% CI) in visits of patients ≥ age 60 (vs. <60) (0.3 (0.1-0.8)], uncontrolled HTN (vs. controlled HTN): (0.75 [0.4-1.3]), male sex (vs. female): (0.6 [0.4-1.0]), and less common when visits were more (vs. less) patient-centered ([2.4 (1.0-5.8)] or when diabetes was (vs. was not) discussed [3.7 (1.5-9.4)]. Patient gender, comorbidity, and visit length did not predict discussions. Among patients with CKD (n=44), CKD discussions were also less common among patients ≥ age 60 ([1.0 (0.2-3.9)] or with higher eGFR [0.96 (0.92-1.0)].

Conclusions: AA patients at high risk of CKD and their PCPs discussed CKD in fewer than half of routine primary care visits. Efforts to improve the occurrence of CKD discussions during routine primary care encounters are needed.

Primary Care Utilization Is Associated with Reduced Mortality Among Older Adults With CKD

Background: Routine primary care visits provide opportunities to identify and manage patients’ CKD risk factors and to provide preventative care. It is unclear how primary care utilization impacts clinical outcomes among older adults with CKD.

Methods: We quantified the association between primary care utilization and ESRD incidence or mortality among older US adults with CKD (in 2005-2006) using Medicare claims. We assessed (in 2006) patients’ primary care utilization (no visit at least one), other care utilization (nephrology care [no visit at least one], the total number of annual evaluation and management (E & M) visits with any type of provider), and patients’ comorbid conditions and sociodemographics. We used standard and cause-specific (accounting for competing risk of death) Cox proportional hazard models overall and stratified by age (65-74, 75-84, or ≥85 years) to estimate hazard ratios (HRs) for ESRD or mortality.

Results: Among 106,765 patients, most (79%) had at least one primary care visit in 2006, and 21% had at least one nephrology visit. The median number of ambulatory & E&M visits was 10. Compared to patients with no primary care visits, patients with at least one visit were younger (78 vs. 80 mean years, p<0.001), less likely African American (10 vs. 14%, p<0.001), and had a greater prevalence of diabetes (46 vs. 42%, p<0.001), hypertension (88 vs. 78%, p<0.001), or coronary artery disease (74 vs. 72%, p<0.001). Overall, we report 24.26 patients developed ESRD and 45.059 died. Primary care utilization was not associated with ESRD incidence. However, compared to patients with no primary care visits, patients with at least one visit had a lower risk of death [HR (95%CI): 0.73 (0.72-0.75)] overall and in age stratified models.

Conclusions: Primary care utilization was not associated with lower ESRD risk, but it was associated with a lower risk of death among older adults with CKD. Efforts to improve the engagement of primary care providers in the care of patients with CKD represent an important strategy to improve the health of this high risk population.

SA-PO698

Routine Use of Health Care Among High-Risk African Americans at Risk of CKD

Background: Engagement in routine health care (RHC) is a key strategy to decrease health inequities among African Americans (AAs) at high risk of developing CKD or CKD complications. We examined demographic, attitudinal and socio-cultural factors associated with RHC among high-risk AAs at risk of CKD incidence or progression.

Methods: We quantified the prevalence of RHC (physical exam ~1 year prior) use among AA Jackson Heart Study (JHS) baseline participants (from 2000-2004) with hypertension (HTN) or diabetes. We identified demographic, attitudinal (e.g., perceived discrimination, anger and hostility, stress, trust in health providers) and educational (i.e., CKD awareness) factors independently associated with RHC use. Those missing demographic or attitudinal data were excluded.

Results: Of 5301 JHS participants, 1152 met inclusion criteria. Most (n=999, 79%) reported RHC use. Rates of RHC were similar in those with and without CKD (22% vs. 23%). Participants not using RHC (vs. using) were more likely to be < 55 years of age (44 vs. 38%), not married (43% vs. 36%), male (45 vs. 38%), uncontrolled hypertension (HTN) (9% vs. 5%), and had a lower degree of trust in their health provider (80% vs. 95%), more frequently reported difficulty obtaining health services (17% vs. 8%), and less frequently reported provider satisfaction (91% vs. 98%), all p<0.05. In multivariable models, not using RHC was associated with age <55 OR 1.75 (95% CI 1.25-2.5), male sex (OR 1.55 [1.2-2.16]), Hispanic ethnicity (OR 1.63 [1.122-2.34]), no HTN (OR 2.14 [1.34-3.41]), lower provider trust (OR 3.27 [1.61-6.65]) and less anger and hostility (OR 1.55 [1.1-2.1]).

Conclusions: Among high-risk AAs in the JHS, younger participants and males were less likely to use RHC. Those with low trust were also less likely to use RHC. Efforts to address health risks among high-risk AAs should target those using less RHC and consider attitudinal barriers to RHC.

SA-PO699

Development of a Question Prompt Sheet for Patients with Chronic Kidney Disease

Background: Patients with chronic kidney disease (CKD) commonly have unmet information needs. Greater patient participation in healthcare discussions can address these needs, and is associated with improved health outcomes. A question prompt sheet (QPS), a list of questions to prompt discussion, has been shown to increase patient participation in other chronic disease discussions; however, no QPS has been developed for CKD patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

787A
Methods: We conducted a 2-phase cross-sectional study involving semi-structured telephone interviews with an initial 67-item QPS targeted to patients with moderate CKD. Patients with an estimated glomerular filtration rate <60ml/min/1.73m2, on dialysis, or with a transplant were recruited from a single VA nephrology clinic. Phase 1 interviews included 17 open-ended questions assessing patients’ CKD information needs. Responses were quality coded into an initial 67-item QPS. Phase 2 participants reviewed pre-nailed QPS to rate the importance of asking each question on a 5-point Likert scale, provide open-ended feedback, and rate their willingness to use a CKD-QPS. Question item responses were refined and reduce QPS questions.

A total of 76 participants completed interviews (phase 1: n=32, phase 2: n=44). Most were male (96%), non-Hispanic white (68%), and mean age was 66 years. Patients desired more information about CKD, particularly regarding self-care techniques, dialysis/transplant, and CKD complications. The final QPS tool included 37-questions divided into 10 CKD subtopics (e.g., CKD definitions, causes, impact, monitoring, labs, self-care, treatment, dialysis, transplant, managing comorbid conditions). Most patients (91%) reported being ‘completely’ or ‘very’ willing to use a CKD-QPS in future doctor visits.

Conclusions: CKD patients have unmet information needs and wish to use a CKD-QPS. Further research is needed to assess whether our CKD-QPS effectively addresses patients’ information needs, enhances doctor-patient communication, and improves health outcomes.

Medication Burden and Safety in Veterans with Chronic Kidney Disease

Swati Lederer,1,2 Michael J. Fischer,1 Zhiping Huo,2 Katie Suda,2 Kevin Stroup.2 1Jesse Brown VAMC and Univ of Illinois Hospital, Chicago, IL; 2Hines VA Hospital, Hines, IL.

Background: Veterans are at exceptionally high risk for chronic kidney disease (CKD) and other chronic health conditions. Pharmacologic treatments are a core aspect of CKD disease management. We characterized medication burden and safety and their relationship to CKD severity among elderly Veterans.

Methods: Using national VA databases, we included all female and a random 10% sample of male VA healthcare users who were <65 years old. We characterized the average number of medications, frequency of contraindicated medications, and occurrence of drug-drug interactions. CKD was defined by estimated glomerular filtration rate (eGFR) in 2008 and classified according to conventional eGFR-based severity groups. A non-CKD comparison was used (eGFR >=60 ml/min/1.73m2). Medications were identified in calendar year 2009 from VA utilization data and Medicare Part D claims.

Results: Among a final cohort of 96,317 Veterans, 47% had CKD (mean age=79.8, male 81%, non-black=93%, hypertension=90%, diabetes=33%). Mean medications increased with CKD severity: 8.5(eGFR =>60), 9.6 (eGFR 30-59), 11.7 (eGFR<15-29), 12.5 (eGFR <15). After adjusting for demographic characteristics, CKD stage 3, 4, and 5 took 1.3, 1.3, and 3.6 more medications, respectively, compared to the non-CKD group (p-value<0.0001). Contraindicated medications were often prescribed to patients with an eGFR<30ml/min/1.73m2 and included bisphosphonates (5%) and nonsteroidal anti-inflammatory drugs (4%). Concerning drug-drug interactions with an eGFR<60ml/min/1.73m2 included: sedatives/opioids (3.8%), ace inhibitor-angiotensin receptor blocker (1.6%), statins-diltiazem or verapamil (5.1%).

Conclusions: Greater severity of CKD was independently associated with an increasing number of medications among elderly Veterans. Medications that were contraindicated in CKD and concerning drug-drug interactions were commonly prescribed. Increased awareness and interventions are needed to improve medication management and safety in Veterans with CKD.

Illicit Drug Use and Chronic Kidney Disease in an Urban Population

Teresa Kimberly Novick,1 Anika Alvarez,2 Ying Liu,1 Alan B. Zonderman,2 Deidra C. Crews.1 1Johns Hopkins Univ, Baltimore, MD; 2National Inst on Aging, NIH, Baltimore, MD.

Background: Opioid and cocaine use have been associated with risk of ESRD in retrospective studies, however, the association of illicit drug use with chronic kidney disease (CKD) has not been well-examined in prospective studies. Our objective was to determine the association of illicit drug use with reduced kidney function, albuminuria and rapid kidney function decline (KFD) among a cohort of urban-dwelling adults.

Methods: Our study included 2,286 Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study participants who are community-dwelling African American and white adults from 12 neighborhoods in Baltimore MD. We used logistic regression to examine whether opioid or cocaine use (defined as ≥ 5 lifetime uses of either drug) was associated with baseline reduced eGFR (<60 ml/min/1.73m2) by CKD-EPI), baseline albuminuria (albumin-to-creatinine ratio >30mg/g) or rapid KFD (eGFR decline of >5% per year over a median of 4.7 years of follow up).

Results: Participants’ mean age was 48 years, 57% were African American, 15% reported opioid use, and 22% reported cocaine use. Those reporting illicit drug use (opiod or cocaine) were more likely to be male, African American, living in poverty and/or uninsured, and tobacco use, problem drinking, and hepatitis C. The association of illicit drug use was not significant with any of the outcomes (P<0.01 for all variables). Our adjusted models included those variables above, and age, diabetes and hypertension. A total of 5.3% of illicit drug users had reduced eGFR compared to 5.0% of non-users (NS). A total of 5.9% of illicit drug users died during follow-up compared to 3.8% of non-users (P=0.03).

Conclusions: Illicit drug use was associated with prevalent reduced eGFR and albuminuria, but not rapid KFD. Illicit drug use may be an important risk factor for CKD in urban populations.

A Tailored, Interactive Mobile Health Communication Application for Patients with Chronic Kidney Disease: Development and Feasibility Assessment

Yali Cao,1 Nephrology, China-Japan Friendship Hospital, Beijing, China.

Background: Chronic kidney disease (CKD) is an increasingly common chronic condition whose prognosis can be improved by patient involvement and self-management. Patient involvement can be fostered by web-based Interactive Mobile Health Communication Applications (IMHCAs) combining health information with decision support, social support and/or behavior change support. Tailoring content and tone of IMHCAs to the individual patient’s needs might improve their effectiveness.

Methods: A tailored, IMHCAs was developed by collaborative profession (nephrologist, nurse, research fellow, web developer). The effectiveness and usage of the tailored IMHCAs were tested against the control arm without access to this IMHA in a small-scale single-blinded randomized trial. The content covers information on CKD, its complications and sequelae, and its treatment options including health behavior and dietary guidance. In the intervention group the content is delivered in dialogue format, tailored to relevant patient characteristics (the stage of CKD and the Etiology). Eighty patients (forty patients at each arm) with stage 3-5 CKD were enrolled in the study. The data were collected directly after the first visit, and at 3-month follow-up.

Results: There were no difference between the two groups as to the age, gender, CKD stage and blood pressure. Three months after system use, participants using the tailored system displayed significantly more knowledge(P=0.001), better blood pressure compliance rate (P=0.02) and improved dietary behavior, mainly regarding low protein and enough calories (P=0.003).

Conclusions: This is the first tailored IMHCAs in China. Our data demonstrated that implementation of IMHCAs into standard practice is feasible. Suggested developments will augment reported strengths to inform ongoing testing in the wider China network of units.

Evaluation of Clinical Pharmacy Services in the Management of Kidney Disease

Calantha K. Yong,1 Chai L. Low. Pharmacy, Veterans Affairs San Diego Healthcare System, San Diego, CA.

Background: Chronic kidney disease (CKD) and end stage renal disease (ESRD) place a significant burden on healthcare systems and is the focus of national health initiatives. Management of CKD requires a multidisciplinary approach to maximize outcomes. Studies support the impact of clinical pharmacists (CP) in medication management, but studies demonstrating the significance of a CP as part of a multidisciplinary approach to management of AKI and CKD/ESRD are lacking. This study evaluates the effectiveness of pharmacy services in the setting of a multidisciplinary approach to the management of AKI and CKD/ESRD.

Methods: Interventions by a CP in the inpatient setting were collected from 12/1/2010 to 11/1/2011 as part of Nephrol Consults. Interventions were categorized as: drug interaction, dose/frequency adjustment, untreated diagnosis, adverse reactions, duplication of therapy, and other. Cost avoidance from these interventions were calculated. Outpatient pharmacy patient encounters were monitored from 1/1/2008 to 12/31/2014 as patient visits or interventions in hemodialysis (HD), peritoneal dialysis (PD), erythropoietin stimulating agent (ESA) clinic, and renal access clinic. CPs were involved in the management of anemia, hyperparathyroidism, renal bone disease, transplant, dialysis related infections, pharmacokinetic drug monitoring, medication reconciliation and patient counseling.

Results: Most of the 440 interventional interventions were dose adjustments for renal function and medication therapy for untreated diagnoses during AKI. Inpatient interventions by a CP resulted in $706,911 in cost avoidance. HD and PD encounters by a CP increased from 241 in 2008 to over 1,400 since 2011. Patient visits in the ESA/anaemia clinic increased from 185 in 2008 to near 300 in 2014. Encounters in the renal access clinic increased from 19 in 2008 to near 300 in 2014.

Conclusions: The expansion of pharmacy services in nephrology at Veterans Affairs San Diego Healthcare System has resulted in the improvement in the quality of care provided to patients with AKI, CKD or ESRD with significant cost avoidance. Clinical pharmacists play a significant role in the multidisciplinary approach to the management of CKD/ESRD.
SA-PO704
Views and Practice Patterns of Dialysis Medical Directors Towards End-of-Life Decision Making for Patients with End-Stage Renal Disease

Enrica Fung,1 Nathan Samuel Slesnick,2 Manjula Kurella Tamura,1,3 Brigitte Schiller.1 1Stanford Univ, Palo Alto, CA; 2Satellite Healthcare, San Jose, CA; 3Geriatric Research and Education Clinical Center, Veterans Affairs, Palo Alto, CA.

Background: Nephrologists frequently engage in end-of-life decision making for patients with end-stage renal disease (ESRD). Patients with ESRD report infrequent end-of-life discussions and nephrology trainees report feeling unprepared for end-of-life decision making, but the views of dialysis medical directors have not been studied. Our objective is to understand dialysis medical directors’ views and practice patterns on end-of-life decision making for patients with ESRD.

Methods: We administered questionnaires to dialysis medical directors during medical director meetings of three different dialysis organizations in 2013. Survey questions corresponded to recommendations from the Renal Physicians Association clinical practice guidelines on initiation and withdrawal of dialysis.

Results: There were 121 medical director respondents from 28 states. The majority of respondents felt “very prepared” (66%) or “somewhat prepared” (29%) to participate in end-of-life decisions and most (80%) endorsed a model of shared decision-making. If asked to do so, 70% of the respondents provided prognostic information “often” or “nearly always”. For patients with a poor prognosis, 36% of respondents would offer a time-limited trial of dialysis “often” or “nearly always”, while 56% of respondents would suggest withdrawal from dialysis “often” or “nearly always” for those with a poor prognosis currently receiving dialysis therapy. Patient resistance and fear of taking away hope were the most commonly cited barriers to end-of-life discussions.

Conclusions: Views and reported practice patterns of medical directors are consistent with clinical practice guidelines for end-of-life decision making for patients with ESRD but inconsistent with patient perceptions.

Funding: NIDDK Support

SA-PO705
Emergency Department Utilization Among United States ESRD Patients

Brendan P. Lovasik, Rebecca H. Zhang, Taylor A. Melanson, Stephen O. Pastan, Rachel E. Patzer. Emory Univ, Atlanta, GA.

Background: Single center studies suggest that ESRD patients have a high rate of emergency department (ED) utilization, with 0.9-2.4 ED visits/patient-year. Prior studies show that ESRD is a stronger risk factor for ED use than heart failure, lung disease, or cancer. However, ED utilization among a national ESRD patient population has not been examined.

Methods: We examined a cohort of 788,182 incident adult ESRD patients in the United States Renal Data System from 2005-2011. ED utilization was identified using CPT codes 99281-5 (Severity Levels 1-5) and 99291 (Critical Care) by American College of Emergency Physicians guidelines. ED and hospital admission, diagnosis, and procedures were obtained from the USRDS and Medicare Physician/Supplier and Inpatient databases for Medicare Part A/B claims.

Results: In the first year of ESRD diagnosis, 1,143,372 ED visits were observed for 480,176 unique ESRD patients. 77% of ESRD patients used the ED within the first year ED visits/patient-year. The national range was 1 to 172 ED visits per year with median 2 visits (interquartile range 1-4 visits) and 95th percentile 8 visits.

Conclusions: The top 5% of patients accounted for 80.4% of ED visits, and 7 patients utilized the ED over 100 times in their first ESRD year. Nearly half (46.0%) of ED visits were coded as a Severity Level 5, with 9.6% coded as Critical Care emergencies. 15.4% of ESRD patients over 100 times in their first ESRD year. Nearly half (46.0%) of ED visits were coded as a severity level 5, with 9.6% coded as critical care emergencies. 15.4% of ESRD patients over 100 times in their first ESRD year.

Funding: NIDDK Support

SA-PO706
Impact of Evidence-Based Clinical Care on Major Adverse Clinical Events in Patients with Clinically Significant Proteinuria: A Population-Based Retrospective Cohort Study

Julius Oluolu Oke,1 Bilal Qarni,2 Timothy Olusegun Olamirewa,2 Aminu K. Bello.1 1Univ of Alberta; 2Univ of Ilorin, Nigeria.

Background: Proteinuria is an important prognostic marker for cardiovascular (CV) and renal events. Most studies of quality of care (QoC) in chronic kidney disease (CKD) have focused on other markers for risk stratification and outcomes. We hypothesized that in proteinuric CKD, markers of good quality care will be associated with lower risk of adverse clinical outcomes (all-cause mortality, all-cause hospitalization, CV and renal outcomes).

Methods: We used a population-based cohort of patients with significant proteinuria (albumin:creatinine ratio (ACR) ≥60 mg/mmol, protein:creatinine ratio (PCR) ≥100 mg/mmol or protein + 3+ on dipstick) to evaluate current patterns of evidence-based care and association with outcomes. Markers of good quality care were defined as nephrology referral, relevant laboratory testing and appropriate medication use (ACEI/ARBs; statins).

Results: The cohort was followed from their index date until March 2009 for outcomes of all-cause mortality, hospitalization, CV and renal events. The associations between quality of care markers and outcomes were estimated using Cox proportional hazards models.

Results: Of the 71, 660 with at least 1 or 2 proteinuria measurements, 16,204 (22.6%) had significant proteinuria. At follow-up, receipt of good quality care (1) timely referral, (2) JHbA1c testing, (3) use of ACEI/ARBs, and (4) use of statins) was associated with reduced risk of mortality: 0.67 (0.59-0.75), 0.52 (0.46-0.59), 0.68 (0.60-0.74), and 0.63 (0.57-0.69), and all-cause hospitalization: 0.85 (0.80-0.93) 0.65 (0.59-0.72) 0.93 (0.87-0.99) and 0.82 (0.77-0.88) respectively. There were no statistically significant associations with the risk of CV and renal events.

Conclusions: This study examined the link between evidence-based treatment and clinical outcomes in an especially high-risk population with CKD. Good quality care impacts mortality risk and all-cause hospitalization, and reduced risk of hospitalization. The impact of QoC on renal and cardiovascular events is less clear. The findings would justify future interventions to increase uptake of such treatments in patients with proteinuric CKD.

SA-PO707
APOL1 Risk Alleles and Risks of Cardiovascular Disease in Children with Focal Segmental Glomerulosclerosis (FGS)

Robert Woroniecki,1 Derek Ng,2 Sophie Limou,2 Cheryl Ann Winkler,3 Kimberly J. Reidy,4 Mark Mitsnefes,5 Craig S. Wong,6 Bradley Warady,7 Susan L. Furth,8 Jeffrey B. Kopp,9 Frederick J. Kaskel.1 1Stony Brook Children's Hospital, Stony Brook, NY; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, NY; 3NCI, NIH, FNL, Frederick, MD; 4Einstein/Children's Hospital at Montefiore, Bronx, NY; 5Cincinnati Children's Hospital, Cincinnati, OH; 6Univ of New Mexico, Albuquerque, NM; 7Children's Mercy Hospital, Kansas City, MO; 8Univ of Pennsylvania, Philadelphia, PA; 9NIDDK, NIH, Bethesda, MD.

Background: APOL1 renal risk alleles are a major cause of glomerular disease in African Americans (AA). It is controversial as to whether individuals with high risk (HR) APOL1 genotypes (2 risk alleles) are at risk for atherosclerotic heart disease, and association with left ventricular hypertrophy (LVH) has not been explored. It is unclear whether children with focal segmental glomerulosclerosis (FSGS) and HR APOL1 are at increased cardiovascular risk.

Methods: Self-identified AA children with FSGS in CKD study cohort were genotyped for APOL1 renal risk variants: G1 (rs73858531, S342G) and G2 (rs71785313, Y388S-389 deletion), and compared to non-AA children with FSGS, none with HR.

Results: Of the 71 children with FSGS, 36 were non-AA, and 25 were AA with HR. APOL1 compared to non-AA, children with HR APOL1 developed FSGS at a later age, 11.5 (IQR: 9.5, 12.5) vs 6 (IQR: 2.5, 11) years, p=0.005. There were no differences in GFR, hemoglobin, iPTH, calcium-phosphate product, or CRP. HR APOL1 subjects had a higher prevalence of uncontrolled hypertension (52% vs 28%, p=0.06) and a lower prevalence of nephrotic range proteinuria (13% vs 43%, p=0.02). Subjects with HR APOL1 had higher left ventricular mass index (41 [28, 53] vs 30 [27, 33] g/m2.7, p=0.01) and a higher prevalence of LVH (53% vs 12%, p<0.009) compared to non-AA children with FSGS.

Conclusions: Children with FSGS and HR APOL1 have later onset kidney disease and are at higher risk for cardiovascular disease than non-AA.

Trends in Burden of Out-of-Pocket Expenses in United States Adults with Kidney Disease from 2002-2011

Mukono O. Ozieh,1 Kine Gebreziabiher Bishu,2 Clara E. Dismuke,3 Leonard Egede.2 1Univ of Alberta; 2Satellite Healthcare, San Jose, CA; 3Geriatric Research and Education Clinical Center, Veterans Affairs, Palo Alto, CA.

Background: High out-of-pocket (OOP) burden negatively impacts health care access and outcomes. Studies examining high OOP burden in the general population exists however no studies have examined OOP healthcare burden in people with kidney disease (KD). This study examined trends in high OOP healthcare in people with KD while concurrently evaluating the impact of insurance status and income category on high OOP burden.

Methods: We analyzed 2,966 adults aged 18-64 years with kidney disease using the Medical Expenditure Panel Survey-MEPS. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and; 161

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

789A
SA-PO709 Health Disparities and Increased Risk of Developing End Stage Renal Disease in Patients With Chronic Kidney Disease Alejandro Ferrer, Ritika Sharma, Candace D. Grant, Ronak Patel, Monika Wadhwani, Vladimir Liberman, Shanza Mujeeb, Sairah Sharif, Shayan Shirazian, Nobuyuki (Bill) Liberman, Shanza Mujeeb, Sairah Sharif, Shayan Shirazian, Nobuyuki (Bill) Liberman, Shanza Mujeeb, Sairah Sharif, Shayan Shirazian, Nobuyuki (Bill) Liberman.

Background: Health disparities occur in groups of people that experience suboptimal care based on their social, economic, and/or environmental disadvantage. Identifying how these disparities affect the risk of chronic kidney disease (CKD) progression to end stage renal disease (ESRD) can hopefully lead to a reduction in these health inequities and improve clinical outcomes for all CKD patients. We examined health disparities and the risk of ESRD using patient-specific and community-specific variables.

Methods: We studied a cross-section of 623 patients with stage 3 and 4 CKD and estimated their 2- and 5-year risk of ESRD using the method of Tangri et al. (JAMA 2011; 305:1553–1559). The U.S. Census Bureau Community Survey was used to obtain patient zip code-specific data including percent foreign born, percent below the poverty level, median household income, and percentage graduating high school. We did a multivariable generalized linear analysis on the outcome variables of the 2 and 5 year risk of ESRD.

Results: Lower household income was associated with a higher risk of ESRD at 2 and 5 years (p<0.05). There was a trend towards a higher risk of ESRD amongst patients from zip codes with higher poverty rates and lower education levels. Being single, including by divorce and separation but not by being widowed, was associated with a significantly higher risk of ESRD. We also found that patients on Medicaid and patients with private insurance or self pay had a significantly higher risk of ESRD compared to those on Medicare.

Conclusions: Our findings suggest that there are substantial health disparities related to CKD and the risk of ESRD. Some of these disparities are patient-specific but others appear to be related to variables associated with the community where they reside. This suggests that evaluation of patient-specific as well as community-specific variables might help to better individualize CKD care and improve our ability to identify and treat the patient at increased risk of developing ESRD.

SA-PO710 Impact of Timely AV Fistula Placement on Resource Utilization After Initiation of Dialysis Edwin J Anand, 1 Kabir Jalal, 1 Laura L. Argauer, 2 Brian M. Murray, 1 Pradeep Arora, 3 Roco C. Venuto. 1 Medicine, SUNY at Buffalo, Buffalo, NY; 2Computer Task Group, Buffalo, NY; 3Epidemiology, SUNY at Buffalo, Buffalo, NY.

Background: Maintenance dialysis is ideally initiated in the outpatient setting with a permanent access. This requires advance planning and of care between nephrologists, and access surgeons. The costs associated with ‘crash’ initiation of dialysis is anticipated to be high. In this observational study, we studied the hospitalization rates and costs of care in the 12 months following dialysis initiation between patients who started dialysis in an ideal manner versus sub-optimally.

Methods: Claims and laboratory data from a large, regional insurance company covering half a million patients between January 2001 and May 2014 were reviewed. 32,121 patients were identified to have CKD (at least one eGFR <60 ml/min/1.73 m^3). Of these, 422 patients developed ESRD during the observed period. We defined a ‘crash’ if after the first instance of dialysis was in an inpatient setting, provided they had at least one eGFR value indicative of CKD before their first dialysis. Univariate and multivariate analyses were performed to analyze the effect of ‘crash’ on hospitalization and costs for 12 months following initial dialysis.

Results: 422 patients were started on dialysis in the above period. 257 patients (61%) had a crash start of dialysis. 86 patients (20%) had a fistula prior to dialysis. Compared to patients who did not crash, patients who crashed were older (p<0.0001), had a higher hospitalization rate in the one year period (p=0.0089). Multivariate analysis confirmed that patients who crashed had a significantly higher hospitalization rate in the one year period following dialysis (p=0.0067). Patients with a fistula in place prior to dialysis experienced fewer hospitalizations (p=0.0377). Cost in the first year was also higher in patients who had a ‘crash’ without a fistula (p=0.0181). The cost advantage of having a fistula decreased with increasing age (0.0402).

Conclusions: Dialysis ‘crash’ results in increased morbidity and resource utilization. Coordination of care and timely access creation should reduce hospitalization and costs.
Conclusions: Our study showed effectiveness of targeted interactive workshops to improve the recognition of CKD and its complications. Intelectualizing the taught concepts by residents did not translate to improved patient care. Declining retention of core concepts at 12-week testing indicates the need for ongoing reinforcement sessions. Continued education including online resources utilization is warranted as opposed to annual core-lectures provided by most training programs.

Evaluating Progress of Healthy People 2020 Chronic Kidney Disease Objectives: Are We There Yet? Aseel Ryskulova,1 Lawrence Agodoa,2 Paul W. Eggers,3 Kevin C. Abbott.2 1NCHS, CDC, 2NIDDK, NIH.

Background: Chronic Kidney Disease (CKD) is a significant public health problem in the U.S. and a major source of disability, poor quality of life, and premature death for those afflicted. CKD and End-Stage Renal Disease (ESRD), the final stage of the CKD, exact a high economic price. In 2012 ESRD costs exceeded $49 billion dollars including 34 billion (about 20%) of total Medicare expenditures. An estimated 11.5% of adults ages 20 or older had physiological evidence of CKD determined from data collected through the 2001-06 National Health and Nutrition Examination Survey (NHANES). Each year in the United States, more than 115,000 people are diagnosed with ESRD.

Methods: Reflecting the importance of CKD, 24 CKD objectives area were included in the Healthy People 2020 (HP2020) national health goals to reduce new cases of CKD and related complications, disability, death, and economic costs. CKD objectives are focused on improving cardiovascular care in patients with CKD; increasing the proportion of patients with CKD and diabetes who received recommended treatment and evaluation; reducing death rate and percentage of U.S. population with CKD; and increasing CKD awareness in persons with impaired renal function. All CKD objectives are measurable, having at least one data point from national data systems including the NHANES, National Death Index, and U.S. Renal Data System.

Results: In 2015, 14 objectives had met their target (n=9) or showed improvement (n=5). Six objectives showed little or no significant change. Two objectives: increase the proportion of persons with diabetes and CKD who received recommended medical treatment with angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, and increase the proportion of patients receiving a kidney transplant within 3 years of ESRD, moved away from the target. The remaining 2 objectives were not evaluated as they were informational with no target set. Disparities persisted by sex, race/ethnicity, and SES status.

Conclusions: The presentation will cover the most recent national and state data for selected CKD objectives and provide an overview of the HP2020 and data search using the HP2020 website.
