Results: Glomerular Gd-IgA1 deposition was detected in all cases of IgAN (n=17/17) and IgAV-N (n=6/6), and in patients with immune-complex-mediated membranulonephritis, including lupus nephritis (n=9/9), membranoproliferative glomerulonephritis (n=3/4), and membranous nephropathy (n=1/1). However, Gd-IgA1 was negative in patients with non-immune related glomerular diseases with IgA deposition, including idiopathic nephrotic syndrome (n=6/6), oligomanganeo nephropenia (n=2/2), Alport syndrome (n=1/1), dense deposit disease (n=1/1), and crescentic glomerulonephritis (n=1/1). Both IgA and Gd-IgA1 were negative in patients with idiopathic nephrotic syndrome (n=5/5), membranoproliferative glomerulonephritis, membranous nephropathy, oligomangeanephropenia, Alport syndrome, C3 glomerulonephritis, poststreptococcal acute glomerulonephritis, and hemolytic uremic syndrome (n=1/1 each).

Conclusions: Gd-IgA1 positivity in patients with IgAN and IgAV-N was consistent with previous report. Present study, Gd-IgA1 was also positive in patients with IgA-positive immune-complex-mediated membranulonephritis. KM55 may have the potential to distinguish incidental IgA deposition in pediatric cases. We speculate that Gd-IgA1 may be involved in the pathogenesis of these immune-related diseases, or KM55 may recognize IgA-related immune-complex nonspecifically.

PO1846
Urinary Exosomal MicroRNAs Are Potential Diagnostic and Prognostic Biomarkers in IgA Nephropathy Patients
Kyung hwan Jeong, Jin sug Kim, Hyeon Seok Hwang, Ji Yoon Kong, Shinyeong Kang, Ri Ra, Yang guin Kim, Ju young Moon, Sangho Lee. Division of Nephrology, Department of Internal Medicine, College of Medicine, Kyung Hee University, Seoul, Republic of Korea.

Background: Micro-RNAs (miRNAs) are small non-coding RNA molecules which regulate disease pathophysiology by modulating target gene expression. miRNAs are derived from tissues and biofluids such as serum, saliva, and urine. Recently, emerging evidence suggests urinary exosomal miRNAs as non-invasive biomarkers of various kidney diseases. However, few studies investigated clinical relevance of miRNA in IgA nephropathy (IgAN). In this study, we evaluated urinary exosomal miRNA expression and analyzed its clinical significance in patients with IgAN.

Methods: Urine samples were collected from 93 patients with biopsy-proven IgAN and 14 normal controls. We identified miRNA differential expression of renal tissue between IgAN and normal subjects in the gene expression omnibus dataset, and selected 884 glomerular and 67 tubulointerstitial genes through meta-analysis. We then used the miRtarBase, TargetScan, microRNA database to predict potential miRNA targets. Finally, 11 urinary exosomal miRNAs were selected. We observed urinary exosomal expression of miRNAs and analyzed their diagnostic and prognostic accuracy for IgAN.

Results: The expression of miR-16-5p, miR-26b-3p, miR-29a-3p, miR-29c-3p, miR-126-3p, miR-199a-3p, miR-615-3p, and miR-29a-3p were significantly upregulated in IgAN patients as compared with normal controls. miR-16-5p, miR-26b-3p, miR-29a-3p, miR-29c-3p, miR-126-3p, miR-199a-3p, and miR-29a-3p have good diagnostic accuracy for IgAN (area under curve of the receiver operating characteristic curve > 0.8). Baseline renal function significantly correlated with miR-16-5p, miR-29a-3p, miR-199a-3p, miR-199b-5p, miR-335-3p, and miR-615-3p. During follow-up period, 43 (46.2%) IgAN patients experienced adverse renal outcomes defined as a greater than 25% reduction in estimated glomerular filtration rate (eGFR), decline in eGFR category from the value determined at the time of renal biopsy, or start renal replacement therapy. miR-16-5p, miR-29a-3p, miR-199a-3p, and miR-335-3p were independently associated with increased risk of adverse renal outcomes.

Conclusions: Urinary exosomal miRNAs might be potential non-invasive biomarkers for diagnosis and prediction of disease progression of IgAN. Further studies are needed to clarify our results and ascertain the underlying mechanisms.

PO1847
Urinary Sediments Could Differentiate the Endocapillary Proliferative Lupus Nephritis and Endocapillary Proliferative IgA Nephropathy
Mo Yuan, Ying Tan. Institute of Nephrology, Peking University, Beijing, China.

Background: The role of manual urine sediment examination in the diagnosis and prognostication of endocapillary proliferative glomerulonephritis remains to be elucidated. This study aims to investigate the differences of urinary sediment findings between lupus nephritis and IgA nephropathy with endocapillary proliferative glomerulonephritis and further evaluated associations of leukocyturia with disease activity, pathological features and prognosis.

Methods: The urinary sediment of 126 patients, including 92 patients with lupus nephritis and 34 patients with IgA nephropathy with a renal biopsy-proven endocapillary proliferative glomerulonephritis were examined in the morning before renal biopsy according to a standardized method. The urinary elements investigated including various cells, casts and crystals. The associations of the level of leukocyturia and disease activity, pathological features and prognosis were further analyzed.

Results: In the patients with endocapillary proliferative glomerulonephritis, normal to mild leukocyturia (≤12/HFP), and moderate to severe leukocyturia (>12/HFP) were found in 52(41.27%) and 74 (58.73%) patients, respectively. The proportion of moderate to severe leukocyturia, the frequency of urinary white blood cells casts and waxy casts were significantly higher in endocapillary proliferative lupus nephritis patients compared with endocapillary proliferative IgA nephropathy patients (P<0.001, P=0.020, P=0.010, respectively). In the proliferative lupus nephritis group, the levels of leukocyturia was significantly correlated with serum creatinine (r=0.288, P=0.005), eGFR (r=0.284, P=0.006), serum C3 (r=0.275, P=0.009), SLEDAI scores (r=0.333, P=0.001) and leukocyturic leukocyte infiltration (r=0.285, P=0.002). A multivariate analysis showed that leukocyturia was identified as an independent risk factor for renal outcome in proliferative lupus nephritis (HR: 1.456, 95% CI: 1.083-1.957, P=0.013) but not in IgA nephropathy (HR: 1.069, 95% CI: 0.494-2.312, P=0.866).

Conclusions: Urinary sediments of the endocapillary proliferative lupus nephritis and endocapillary proliferative IgA nephropathy differed in many aspects. Leukocyturia could reflect the disease activity and prognosis of endocapillary proliferative glomerulonephritis, especially in lupus nephritis.
A Single-Center Retrospective Study of Thrombotic Microangiopathy

Background: Thrombotic microangiopathies (TMAs) are a rare group of clotting disorders of various origin, including infectious, idiopathic, autoimmune or drug-induced. This group shares common clinical manifestations that include low red blood cell and platelet counts. Although the disease is rare but treatable if clinician is aware about its manifestations. To increase the awareness and understand the disease better we conducted a retrospective study to characterize and assess TMAs in our institution.

Methods: An observational retrospective study of patients with a diagnosis of TMA at Westchester Medical Center in the past 5 years was conducted. Data was collected from electronic medical records. Demographic, clinical and therapeutic variables were extracted, tabulated and analyzed.

Results: A total of 43 patients with a diagnosis of TMA were identified and included in the study. The cohort had a mean age of 39.9 years, 20 were male and 23 as females. As shown in Table 1. Thrombotic thrombocytopenia purpura (TTP) (n=14, 32%), systemic lupus erythematosus (SLE) (n=5, 11.6%), and hemolytic uremic syndrome (HUS) (n=5, 11.6%) are the most common etiologies. Other identifiable etiologies were atypical HUS (9%), use of calcineurin inhibitors (9%), acute myeloid leukemia (4.6%). About 6.9% cases didn’t have any identifiable cause (6.9%). Patients with TTP had a mean age of 48 years, mean platelet count of 17k/mm3, and most were female (71%). Fifty-seven percent had hematuria, 21% proteinuria and 85% had schistocytes in the blood smear.

C3 Inhibition with Pegcetacoplan Targets the Underlying Disease Process of C3 Glomerulopathy (C3G) and Improves Proteinuria

Bradley P. Dixon,1 Latry A. Greenbaum,2 Liwei Huang,3 Sandeep K. Rajan,4 Derrick Robinson,5 Marvin R. Garovoy,6 Wyatt Gilmore,7 Natasha Picazio,8 Nick Robertson,9 Temiyayo Ajayi,10 Carl Di casoli,10 Pascal Deschatelles,10 Cedric G. Francois,11 Hetal S. Kocinsky,12 Federico Grossi,13 *University of Colorado School of Medicine, Aurora, CO; 2Emory University, Atlanta, GA; 3Tidelwater Kidney Specialists, Inc., Chesapeake, VA; 4University of Tennessee Health Science Center, Memphis, TN; 5Eastern Nephrology Associates, Wilmington, NC; 6Ex-Equals, LLC, Sausalito, CA; 7Apellis Pharmaceuticals, Inc, Waltham, MA.

Background: C3G is a rare renal disease in which C3 overactivation leads to the accumulation of C3 breakdown products in the glomeruli. Progression to end-stage renal disease occurs in up to 50% of patients (pts) within 10 years of diagnosis; no therapies target the underlying pathophysiology of C3 activation. The study aims to assess whether pegcetacoplan (APL-2; Apellis Pharmaceuticals, Waltham, MA), a C3 inhibitor, targets C3G complement dysregulation and reduces proteinuria.

Methods: This phase 2 open-label study was designed to evaluate preliminary efficacy and safety of pegcetacoplan in pts with complement-mediated glomerulopathies. Pts with C3G who were ≥16 years old, with proteinuria >750 mg protein/g creatinine, and eGFR ≥30 mL/min/1.73 m² were eligible for inclusion. Pegcetacoplan was administered as 360 mg daily subcutaneous infusions with transition to 1080 mg twice weekly from Week 24. The primary endpoint was change in proteinuria from baseline to Week 48, measured by 24-hour urine protein-to-creatinine ratios (uPCR). Serum C3, albumin, and creatinine as well as safety were also evaluated.

Results: Eight C3G pts were enrolled in the study. Three pts were excluded from efficacy analyses for self-reported non-compliance or interrupted study drug administration. Data showed a greater than 65% reduction in 24-hour uPCR from baseline to Week 48. Serum albumin and C3 increased, and serum creatinine was stable (Table). No serious or severe adverse events were reported and no TEAEs led to discontinuation.

Conclusions: These data suggest that pegcetacoplan targets the underlying pathophysiology of C3G, resulting in proteinuria reduction with stable renal function. Further studies are warranted to investigate the therapeutic potential of pegcetacoplan in the treatment of C3G.

C3 Glomerulonephritis Associated with Monoclonal Gammapathy: A Retrospective Case Series Study from a Single Institute in China

Xin Zhang, Yu Xiaojuan, Dan Y. Li, Su-xia Wang, Fu Dezhou, Ming Hui Zhao. Peking University First Hospital, Beijing, China.

Background: To analyze the demographic and clinicopathological features and renal outcomes of Chinese patients with C3GN in the setting of monoclonal gammopathy.

Methods: Patients with renal biopsy-proven C3GN and monoclonal gammopathy, with measurable serum and/or urine monoclonal Ig from 2006 to 2018 in Peking University First Hospital were included, clinical data, renal pathology type, treatment and prognosis were collected.

Results: Nineteen patients were enrolled, accounting for contemporaneous 26.7% of C3GN patients. The mean age was 55 years old, and average eGFR at biopsy 48.42mL/min/1.73m². The IgG was the most common isotype of monoclonal Ig on immunofixation. Eleven patients had nephrotic range proteinuria and hypalbuminemia. Kidney biopsies revealed a relative prominent MPGN pattern. Two patients had concurrent TMA-like renal injuries. The median renal survival was 24 months. Median renal survival was 12, 12, and 34 months, respectively in patients receiving conservative therapy, immunosuppressant therapy, and clone-targeted chemotherapy, without statistical significance. Plasma exchange therapy only improved one patient’s renal outcome.

Conclusions: The clinicopathological features of Chinese patients with C3GN combined with monoclonal gammapathy are consistent with the previously reported population. Renal prognosis of these patients is poor, and immunosuppressant therapies show no advantage over supportive therapy in renal prognosis, while the benefit of clone-targeted chemotherapy is still requiring investigation.

Funding: Government Support - Non-U.S.
Hemodialysis was initiated for uremic symptoms. Complement function test was consistent with ongoing complement dysregulation at C3 convertase level and C5 convertase level without the presence of autoantibodies towards complement proteins. 2 months after her kidney biopsy, she developed worsening anemia and thrombocytopenia, elevated lactate dehydrogenase and undetectable haptoglobin. Direct coombs test was negative, peripheral smear showed schistocytes. ADAMS13 level was 65%, consistent with diagnosis of atypical hemolytic uremic syndrome. Patient was started on Eculizumab therapy with stabilization of hemoglobin and platelets but remains dialysis dependant.

Discussion: In our growing understanding of alternative complement pathway, it is thought that dysregulation at fluid state is associated with C3GN, while solid state dysregulation is associated with widespread endothelial injury leading to aHUS. Our patient developed both pathologies, suggests further research is needed in understanding the details of complement system.

PO1856
Acute Renal Failure from Thrombotic Microangiopathy: Is IgA Vasculitis to Blame?
Dipal Patel, Yale University School of Medicine, New Haven, CT.

Introduction: Thrombotic microangiopathy (TMA) has been associated with several cases of IgA nephropathy. In most cases the clinical significance of the TMA is uncertain. We describe a case of acute renal failure in a patient with systemic IgA vasculitis, who was found to have severe renal-limited TMA treated with eculizumab for the possibility of underlying complement dysregulation.

Case Description: A 34 year old male presented with abdominal pain and bloody bowel movements, and found to have extensive duodenitis. Infectious testing of stools was negative, though he later tested positive for H. pylori. While hospitalized he developed acute kidney failure, with creatinine rising from 1.5 to 11.7 within four days. Urine sediment demonstrated granular casts consistent with acute tubular injury, though he also had white cell casts for which acute interstitial nephritis was considered. Blood counts were normal on admission, but he developed anemia and thrombocytopenia with mildly positive markers of hemolysis (haptoglobin 25, LDH 269, no schistocytes). Serum complements were profoundly low (C3 33, C4 9). A kidney biopsy revealed severe TMA. Given the rapidity of progression to renal failure requiring dialysis, he was started on eculizumab for a presumed atypical hemolytic uremic syndrome (aHUS). Since he did not have evidence of active hemolysis, he was not started on plasmapheresis. Kidney biopsy demonstrated proliferation and expansion of the mesangium with IgA deposition. Endoscopy was later performed with biopsy consistent with systemic IgA vasculitis, for which he was started on steroids. Abdominal symptoms improved and he was discharged home. He continues on eculizumab with normalization in complements, but without improvement in renal function.

Discussion: There have been case reports of complement factor dysregulation resulting in both IgA vasculitides and TMA. Given the extent and acuteness of renal failure in this case, we treated our patient with eculizumab for presumed aHUS.

PO1857
Proliferative Glomerulonephritis with Monoclonal IgG Deposits (PGNMID): A Report of Two Cases Managed with Renin-Angiotensin system (RAAS) Inhibition Alone
Marianna Vynnyk, Maria V. DeVita, Jordan L. Rosenstock. Lenox Hill Hospital, New York, NY.

Introduction: PGNMID is a relatively rare disorder with monoclonal immunoglobulins (Ig) deposition in glomeruli that resembles immune complex glomerulonephritis (GN), after exclusion of other related disorders such as amyloidosis and cryoglobulinemia. The pathogenesis and management of PGNMID remains uncertain, especially if no systemic clonal disorder is found, which is frequently the case. Some groups have recommended anti-plasma cell or anti-B cell therapy in most if not all cases, even if a clone is not identified. We present two cases of PGNMID that were managed with RAAS blockade alone and whose renal disease remained stable over 6 and 10 years of follow up.

Case Description: Two cases were identified who had prolonged follow up with PGNMID managed with no immunosuppressive treatment. Charts were reviewed retrospectively and data collected from time of biopsy until most recent follow up. Case 1 is a 25 year old obese black woman with recent onset of hypertension who presented with serum creatinine (sCr) 1.4mg/dl. Urinalysis (UA) showed 1+ protein and no blood. 24hr urine protein was 296mg. Renal biopsy (done as she had positive antiphospholipid antibodies) revealed PGNMID (IgG kappa) with diffuse mesangial proliferation and focal sclerosing GN with focal fibrous crescents. There was no evidence of thrombotic microangiopathy. Serum and urinalysis (UA) were negative for monoclonal protein. Bone marrow biopsy was unremarkable. The patient was treated with angiotensin-receptor blocker (ARB) without immunosuppressive therapy. Six years later the most recent sCr was 1.5mg/dl and urine protein-creatinine ratio (PCR) was 1100mg/g. Case 2 is a 41 year old white woman who presented with sCr 0.6mg/dl. UA had 3+ protein and no blood. 24hr urine protein was 2.3g. Renal biopsy showed PGNMID (IgG kappa) with mesangial and endocapillary proliferation. Serum and urine IF were negative for monoclonal proteins. Bone marrow biopsy was not done. The patient was treated with an angiotensin-converting enzyme inhibitor (ACEI) alone. After ten years of follow up, her sCr was 0.7mg/dl, and urine PCR was 0.2mg/g.

Discussion: We report 2 cases of PGNMID with stable renal function and proteinuria after 6 and 10 years of RAAS therapy alone. This suggests that not all patients with PGNMID may require immunosuppression.
PO1860
An Atypical Case of Fibrillary Glomerulonephritis
Jessica M. Greco,1 Ashish Thakker,2 Clarissa A. Cassol,1 Anjali A. Satskar,2 Salem Almuaai,3 Arkana Laboratories, Little Rock, AR; 2The Ohio State University Wexner Medical Center, Columbus, OH; 3Veterans Health Administration, Columbus, OH.

Introduction: Fibrillary glomerulonephritis (FGN) is a rare primary glomerular disease that can be associated with multiple disease associations such as hepatitis C, malignancy, and dysproteinemia. Despite these known associations, little is known about the interaction between FGN and other comorbidities. We present a case of FGN that presented years after successful treatment of hepatitis C infection (HCV).

Case Description: The patient is a 49-year-old Filipino female, hypertensive, with a history of HCV infection. Case series reported elevated blood pressure and nephrotic-range proteinuria. Initial adjustment of her anti-hypertensive regimen controlled her blood pressure. Subsequently, she developed resistant hypertension and increasing proteinuria. Creatinine increased to 2.1 mg/dl from a baseline of 1 mg/dl. In 12 months, a second renal biopsy was done showing widespread podocyte foot process effacement and mesangial fibrillary deposits measuring 10-30 nm. At this time, proteinuria increased to 7596.05 grams from 1622.08 grams with a creatinine clearance of 39.80 ml/min/1.73 m². After discussing with the patient, she was given Rituximab as four weekly doses of 375 mg/m², followed by a prednisone taper. At 6 months, proteinuria decreased to 2756.55 grams with a creatinine clearance of 39.80 ml/min/1.73 m². Further discussion with the patient is recommended.

Discussion: In general, FGN prognosis is poor and majority of patients progress to ESRD. Treatment options are currently limited and conclusions regarding immunosuppressive therapy cannot be drawn from limited published data. Rituximab may offer benefit particularly in patients with relatively normal baseline renal function.

PO1861
Fibrillary Glomerulonephritis Treated with Rituximab: A Case Report
Serah Kae L. Laquindanum, Eladio Miguel M. Penaranda, Makati Medical Center, Makati City, Philippines.

Introduction: Fibrillary Glomerulonephritis (FGN) is a rare primary glomerular disease first described by Rosenmann and Eliaikim in 1977 present in 0.5 to 1% of native kidney biopsies defined by haphazardly arranged fibrils 10 to 30 nm in thickness deposited in the mesangium, glomerular basement membranes or both. Initially, FGN was considered to be idiopathic. However, approximately one-third have a history of malignancy, monoclonal gammopathy, autoimmune disease, hepatitis C infection or an IgM glomerular deposition disease. Prognosis is generally poor with 50% of patients developing ESRD within 6 years of presentation. The most common form of treatment is steroids with or without a second agent usually Cyclophosphamide or Rituximab. To date, there is no convincingly effective treatment but published case series reports clinical response referred to as “nonprogression” defined by stable renal function in those treated with Rituximab.

Case Description: Our patient is a 49-year-old Filipino female, hypertensive, diagnosed case of Immune Complex-Mediated Glomerulonephritis presenting with elevated blood pressure and nephrotic-range proteinuria. Initial adjustment of her anti-hypertensive regimen controlled her blood pressure. Subsequently, she developed resistant hypertension and increasing proteinuria. Creatinine increased to 2.1 mg/dl from a baseline of 1 mg/dl. In 12 months, a second renal biopsy was done showing widespread podocyte foot process effacement and mesangial fibrillary deposits measuring 10-30 nm. At this time, proteinuria increased to 7596.05 grams from 1622.08 grams with a creatinine clearance of 39.80 ml/min/1.73 m². After discussing with the patient, she was given Rituximab as four weekly doses of 375 mg/m² intravenously. After five months, there was significant reduction in proteinuria at 1734.32 grams with stable creatinine clearance of 31.99 ml/min/1.73 m².

Discussion: In general, FGN prognosis is poor and majority of patients progress to ESRD. Treatment options are currently limited and conclusions regarding immunosuppressive therapy cannot be drawn from limited published data. Rituximab may offer benefit particularly in patients with relatively normal baseline renal function.
Renal Biopsy. Cryoglobulinemic Glomerulonephritis

**PO1863**

Clinico-Biological Characteristics and Treatment of Hepatitis B Virus-Related Mixed Cryoglobulinemia: Current Clinical Evidence

**Introduction:** Hepatitis B virus (HBV)-related mixed cryoglobulinemia (MC) was considered to be a rare disease, presented as mild clinical symptoms just like purpura to severe organ damage such as glomerulonephritis. We aimed to clarify the clinico-biological characteristics and treatment of HBV-related MC.

**Methods:** We reported a case of HBV-related MC, enrolled 41 HBV-related MC cases from literature, and summarized demographic, clinical, laboratory, treatment, and outcome data of the 42 HBV-related MC cases. Meanwhile, the Asian and European group, patients in remission and refractory were compared. Kidney involvement, death and time to death were included for survival analysis.

**Results:** Of the 42 HBV-related MC, Mean age was 53±14 years, and 47.6% patients were male. Extrahospital clinical manifestations mainly included cutaneous lesions, kidney involvement, peripheral neuropathy, articular involvement, which accounted for 78.6%, 54.8%, 35.7%, 19.0%, respectively. 87.1% (27/31) patients had low serum C4, and 92.6% (25/27) patients' rheumatoid factors (RF) were positive. Renal pathology showed membranous proliferative glomerulonephritis, the capillary lumen disclosed hyaline thrombi and electron microscope found microtubular substructure. 36 (85.7%) patients received antiviral therapy. Corticosteroids were used in 22 (52.4%) patients, immunosuppressive agents were given to 13 (31.0%) patients, and plasma exchange (PE) were used in 9 (21.4%) patients. At the end of follow-up, 52.4% (22/42) patients were in remission, 47.6% (20/42) patients had refractory disease, and 11.9% (5/42) patients died.

**Conclusions:** Extrahospital clinical manifestations of HBV-related MC were varied. Anti-HBV treatment, corticosteroids, immunosuppressive agents and PE were useful for some patients. The patients with kidney involvement may be related to poor prognosis.

**PO1864**

Membranoproliferative Glomerulonephritis (MPGN) Associated with Epstein Barr Virus (EBV)

**Introduction:** Immune complex-mediated MPGN has been commonly associated with viral infections including Hepatitis B, C, HIV and Hantavirus. We present a rare case of EBV associated MPGN successfully treated conservatively.

**Case Description:** A 19-year old female, previously healthy, presented with fatigue, sore throat and periorbital swelling for 3 weeks. Vitals were stable on presentation. Her EBV IgM and IgG serologies were positive while CMV was negative. UA showed proteinuria (>300mg/dl) and microscopic hematuria. Albumin was 2.9 g/dl. Spot urine protein to creatinine ratio was 2.6 g/g. Urine sediment was bland. SCr was 0.72 mg/dl. Extensive serological work up was negative. Renal biopsy showed mesangial hypercellularity, double contours of capillary loops with intramembranous, subendothelial and subepithelial immune type electron dense deposits. Immunofluorescence revealed segmental globular to coarsely granular staining in the glomerular capillary walls for IgG (3+), IgA (1+), IgM (3+), kappa (2+), lambda (3+), C3 (1-2+), C1q (3+), and C4 (1+). Mesangial regions showed segmental granular staining for IgG (1+), kappa (1+), lambda (1+) and C4 (1+). She was treated with furosemide 20mg daily as needed for swelling and lisonopril 5mg daily. Her symptoms resolved within 2 weeks of initiating treatment. She self-discontinued her medications after 4 months. On 6 month follow up, she remained asymptomatic and urine protein was undetectable.

**Discussion:** Infectious Mononucleosis (IM) is caused by EBV. EBV primarily infects human B cells via the CD21 receptor and may infect renal tissue since the CD21 molecule has been detected in proximal tubular cells of kidneys. Further, acute EBV infection may cause immune-mediated response with deposition of immune complexes and subsequent glomerulopathy. Renal involvement is reported with 3-16% cases of acute IM. Common renal lesions include acute tubulointerstitial nephritis, membranoproliferative, minimal change disease and vasculitic lesions. MPGN is a rare presentation of EBV and should be considered in patients with IM and proteinuria. Previous case reports have suggested that nephrotic syndrome in patients with an acute EBV infection is usually self-limiting. Our case report also suggests that MPGN associated with EBV may have a relatively benign course.

**PO1865**

Infection-Related Glomerulonephritis Mimicking Lupus Nephritis

**Introduction:** Differentiating infection vs auto-immune related GN is crucial in order to avoid inadvertent immunosuppressive therapy that can be harmless and even lead to fatal consequences. This case illustrates the dilemma of medical management in lupus like GN.

**Case Description:** A 66 year old man with mitral valve prolapse, was found to have elevated creatinine of 3.59 mg/dl from a baseline of 1 mg/dl. He complained of leg rash and dark urine. His rash was symmetric and non blanchable petechiae. Urine sediment showed 20 dysmorphic RBC per high power field and RBC casts. Urine protein/creatinine ratio was 1.35 g/g. Serum creatinine peaked at 10.4 mg/dl. Hemodialysis was begun. Further testing was significant for pancytopenia, low complements (C3 was 40 mg/dl, C4 10 mg/dl) and positive MPO-ANCA. Kidney biopsy was performed (Fig 1). On light microscopy 2 glomeruli were globally sclerotic. One glomerulus showed crescentic and necrotizing lesion. There was diffuse ATN. Some tubules showed red blood cell casts. Interstitial inflammation was mild. Direct IF showed a full house pattern with bright IgG, IgM, kappa, lambda, C3, C5 and mild to moderate IgA staining. EM identified few mesangial and subendothelial deposits with a single subepithelial hump. During his hospitalization, streptococcus bacteremia was documented. Echo showed mitral valve vegetation. In setting of bacterial endocarditis, the Biopsy is consistent with infection related glomerulonephritis (IRGN).

**Discussion:** Crescents as well as ANCA positivity have been described in IRGN. However a full-house immunostaining pattern is not typical of IRGN and has never been reported in IRGN. Instead, this is typical of lupus-like GN. The patient didn’t have positive ANA, however he developed pancytopenia and hypocomplementemia which can be manifestations of both SLI even at an old age as well as infection. The dilemma is that auto-immune mediated GN warrants immunosuppressive therapy which is contraindicated in IRGN. Our patient received penicillin and underwent mitral valve replacement His kidney function gradually improved and dialysis was discontinued after 4 months.

**PO1866**

Hypocomplementemic Urticarial Vasculitis: Interstitial Nephritis with New Microtubular Deposits and Successful Response to Rituximab

**Introduction:** HUV is caused by antibodies to C1q complement and has many features of systemic lupus and cryoglobulinemia. Different patterns of GN often occur such as the mesangial GN, MPGN or membranous GN but interstitial nephritis has never been described.

**Case Description:** A 57 year old female in 2007 developed recurrent hives, anasarca, angioedema, leucocytoclastic vasculitis on skin biopsy & 5 g proteinuria with RBC casts. C1q complement was 2 mg/dl, C3 20 mg/dl, C4 6 mg/dl & C1q antibody was 35 mg/mL (NL<10). All other serology and cryos were negative. Serum creatinine was 0.6mg/dl.
Her 1st renal biopsy showed mesangial proliferative GN with +3 IF for IgG, IgA, C1q & EM deposits. On clinical grounds, subendocardial infarction was the initial location of the initial inflammation. Parallel microtubular structures, 25 nm wide with hollow cores, were present in interstitial capillaries and hilar arterioles but not in the glomeruli. Tubular basement membranes & peritubular capillaries were +3 positive for IgG & C1q with ground glass staining of proximal tubules & cytoplasmic vacuolization. C3 was 4 mg/dL, C1q antibody > 100 mg/mL. A 2nd renal biopsy showed diffuse endocapillary proliferation with membranous GN similar to lupus Class IV & V and interstitial inflammation. IF was +3 for IgG, IgA, C1q and kappa and lambda in the same locations as biopsy 1. Tubular basement membranes & peritubular capillaries had 25 nm hollow microtubule structures as before. Rituximab was initiated at 375 mg/m^2 for 4 doses. It induced a complete renal remission after 3 months with a serum creatinine of 0.6 mg/dL & urine total protein of 210 mg.

**Discussion:** We conclude: In addition to glomerulonephritis HUV can cause interstitial nephritis with +1F for IgG & C1q. HUV causes unique microtubular structures in the interstitium but not the glomeruli. Rituximab rapidly induces clinical renal remission in HUV.

**PO1867**

Unusual Aggregation of Different Glomerulopathies in a Family Resolved by Genetic Testing

*Vahahan S, Keskinyan, Reeti Kumar, Rasheed A. Gbadegesin. Duke University, Durham, NC.*

**Introduction:** Glomerulonephritis (GN) is a major cause of chronic kidney disease (CKD) in children. The conventional approach to diagnosis of GN includes clinical evaluation and in most cases kidney biopsy to make a definitive diagnosis. However, in many instances, clinical presentations of different GNs can lead to uncertainty in diagnosis and management even after renal biopsy. In this report we identify a family with clinical diagnoses of post infectious glomerulonephritis (PIGN) and IgA nephropathy in a parent and two children. Renal biopsies were inconclusive and we were only able to map biopsies in each of the family members after genetic testing and reverse phenotyping.

**Case Description:** A previously healthy 7 year old male presented to the emergency department with hematuria, fever, and sore throat. Apart from being obese, his physical examination was unremarkable. Laboratory evaluation was remarkable for microscopic hematuria and non-nephrotic range proteinuria. C3/C4 complements, ASO, anti-DNase B, anti-dsDNA, ANCA, and anti-GBM titers were all normal. A presumptive diagnosis of PIGN was made. However, he had persistent hematuria and proteinuria over the next 10 months. Further history at follow up revealed a history of IgA nephropathy in his mother and CKD of unclear etiology in his maternal grandfather. Renal biopsy was initially reported to be consistent with IgA nephropathy. However, because of the family history we carried out genetic testing and identified a rare hemizygous variant [c.3437G>A (p.Gly1146Glu)] in the gene COL4A. Staining was performed on family members and genetic testing in him was negative for the COL4A5 variant found in his brother and mother.

**Discussion:** This case highlights the utility of genetic testing and reverse phenotyping in resolving clinical diagnosis in families with unusual combinations of different glomerulopathies. We propose that clustering of different glomerular disease phenotypes in a family should be an indication for genetic testing.

**PO1868**

Unusual Case of Histiocytic Glomerulopathy in the Setting of Sarcoma- toid Malignancy

*Faris Al faris, Majd Al-Ahmad, Llewellyn A. Foulke, Mauricio Monroy, Kelly H. Beers. Albany Medical Center, Albany, NY.*

**Introduction:** We present a case of histiocytic glomerulopathy and pauci-immune ANCA negative glomerulonephritis (GN) in the setting of sarcomatoid malignancy.

**Case Description:** An 83-year-old female presented to our hospital for evaluation of mid-abdominal tenderness on palpation. Aortic angiography revealed occlusion of the celiac artery. She later developed acute kidney injury (AKI) with creatinine rising to 1.5mg/dl from baseline of 1.2mg/dl. Work up reveled bland urine sediment and 24-hour creatinine ratio was 8.7 with RBC casts. C1q was 4 mg/dL, C3 38 mg/dL, C4 4 mg/dL & C1q antibody > 100 mg/mL. A 2nd renal biopsy showed diffuse endocapillary proliferation with membranous GN similar to lupus Class IV & V and interstitial inflammation. IF was +3 for IgG, IgA, C1q and kappa and lambda in the same locations as biopsy 1. Tubular basement membranes & peritubular capillaries had 25 nm hollow microtubule structures as before. Rituximab was initiated at 375 mg/m^2 for 4 doses. It induced a complete renal remission after 3 months with a serum creatinine of 0.6 mg/dL & urine total protein of 210 mg.

**Discussion:** We conclude: In addition to glomerulonephritis HUV can cause interstitial nephritis with +1F for IgG & C1q. HUV causes unique microtubular structures in the interstitium but not the glomeruli. Rituximab rapidly induces clinical renal remission in HUV.

**PO1869**

Bilateral Renal Infarctions: A Perplexing Presentation of Polyarteritis Nodosa

*Alissa Lee, Matthew Fay. Louisana State University Health Sciences Center, Baton Rouge, LA.*

**Introduction:** Classic polyarteritis nodosa (c-PAN) is an autoimmune necrotizing vasculitis with predilection for medium-sized vessels. Although c-PAN can be associated with renal involvement, acute renal failure or extensive renal infarctions are exceedingly uncommon. We report a rare case of c-PAN manifested by bilateral renal infarctions on initial clinical presentation.

**Case Description:** A 40 year old man with no known medical issues presented to the emergency department with encephalopathy in the setting of one month of reported myalgia, fevers, chills, night sweats, and unintentional ten lb. weight loss. Upon physical examination, his vitals were 95.1°F, 101 beats/min, 145/101 mmHg, with no evidence of trauma or skin abnormalities. His lab results were notable for Cr 1.83 mg/dL, AST 1357 U/L, ALT 136 U/L, Hbg 12.6 g/dL, WBC 2.4 x10^3/L, and UA with hematuria and proteinuria. An extensive workup was completed, and his HIV, Hepatitis B and C, ANCA, Cardiolipin Ab, DRVVT, and ANA results were negative. TEE was normal. His ESR was 116 mm/hr, and he had transient worsening of his Cr (2.96 mg/dL) and Hbg (6.7 g/dL). CT/CTA revealed bilateral renal infarctions with perinephric and retroperitoneal hematomas, right renal artery aneurysm, thrombosis of one of three left renal arteries, and splenic hematoma, while MRI demonstrated a small parietal hematoma and thoracic intrathoracic epidural hemorrhage. He was initiated on monthly cyclophosphamide and prednisone. One month later, he had symptomatic resolution and a Cr of 1.89 mg/dL.

**Discussion:** Given his fulfillment of five American College of Rheumatology (ACR) criteria, he was diagnosed with c-PAN as a constellation of clinical findings can be used, and biopsy results are not always necessary, especially given the risk of hemorrhage. Although it is a rare condition, it is important to remain cognizant and consider c-PAN in the differential due to its significant implications and the importance of timely treatment.

**PO1870**

Clinical Predictors of Response to Rituximab in the Nephrotic Syndrome Study Network (NEPTUNE) Cohort

*Daniella Levy Erez, 1,2 Kevin E. Meyers, 1,2 Jarcy Zee, 1 Abigail R. Smith, 3 Division of Nephrology, Children’s Hospital of Philadelphia, Philadelphia, PA; 1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Arbor Research Collaborative for Health, Ann Arbor, MI.*

**Background:** Rituximab, an anti CD20 monoclonal antibody, is one of the alternative medications offered to children and adults with Nephrotic syndrome. Despite the growing knowledge regarding this medication, there are still concerns regarding long-term safety that need to be considered prior to initiation of therapy. Given these risks there is a need to identify characteristics of patients who will respond best to rituximab therapy.

**Methods:** We identified all patients who received rituximab within NEPTUNE, a prospective study of adults and children with glomerular disease enrolled at the time of first biopsy or at initial presentation. Remission was defined as UPCR<0.3 mg/mg.

Validating a Computable Phenotype for Nephrotic Syndrome in Children and Adults Using PCORNet Data

Andrea L. Oliverio,1 Dorota Marchel,1 Cheryl L. Tran,4 Isabelle Ayoub,2 Salem Almamari,2 Jessica M. Greco,3 Michelle Denburg,3 Debbie S.吉son,2 Laura H. Mariani.1 1University of Michigan Medical School, Ann Arbor, MI; 2The Ohio State University Wexner Medical Center, Columbus, OH; 3The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Mayo Clinic Minnesota, Rochester, MN.

Background: Primary nephrotic syndromes (pNS) are rare diseases which can be a barrier to adequate sample size for observational patient-oriented research. A computable phenotype may be powerful in identifying patients with these diseases for research while leveraging data from millions of patients in the PCORNet Common Data Model (CDM).

Methods: A comprehensive algorithm of ICD-9 and ICD-10 codes indicative of pNS was developed based on prior work in the University of Michigan Health System. Cases of pNS were defined as subjects that were seen for at least one encounter with more than 1 NS code, and did not have codes for diabetes mellitus, systemic lupus erythematosus, or amyloidosis. Non-cases were individuals not meeting case criteria who were seen in the same calendar year and within 2 years of age of a case. The algorithm was executed against the PCORNet CDM at 3 institutions from Jan 1, 2009 to Jan 1, 2018, where a random selection of 50 cases and 50 non-cases were reviewed by a nephrologist, for a total of 150 cases and 150 non-cases reviewed. The classification accuracy (sensitivity, specificity, positive and negative predictive value, F1 score) of the computable phenotype was determined.

Results: The algorithm identified a total of 2,708 patients with NS from 4,305,092 distinct patients in the CDM at all sites. For all sites, the sensitivity, specificity, PPV, and NPV of the algorithm were 99.1%, 81.0%, 76.7%, and 99.3%, respectively. The accuracy of the algorithm was 88.8% with an F1 score of 86.5%. The most common cause of false positive classification was secondary FSGS (735), followed by class V lupus nephritis (935).

Conclusions: While prior computable phenotypes for glomerular diseases have used ICD and SNOMed codes, this computable phenotype had good classification in identifying both children and adults with pNS utilizing only ICD-9 and ICD-10 codes, which are universally available. This may facilitate future screening and enrollment for research, however further refinements to the algorithm or addition of natural language processing may help better distinguish primary and secondary FSGS.

Fractional Excretion of Total Protein in Nephrotic Syndrome
Hideaki Kuno, Go Kanzaki, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Kentaro Koike, Nobuo Tsuobi, Takashii Yokoo. The jikei university school of medicine, Minato-ku, Japan.

Background: Lower estimated glomerular filtration rate (eGFR) and higher proteinuria are the most sensitive predictor of the development of progressive renal insufficiency in various glomerular diseases. Fractional excretion of total protein (FETP) calculated by dividing the total protein clearance (Cp) by creatinine clearance (CCr) is tightly associated with both proteinuria and GFR. However, few studies have analyzed in glomerular diseases the FETP to evaluate their relationship with renal function and histologic lesions. This study aimed to evaluate the relationship between FETP and the clinical features and histologic lesions and to assess whether FETP predicts outcome in nephrotic syndrome (NS).

Methods: Subjects who exhibited NS with a histological diagnosis were retrospectively analyzed at the Jikei University School of Medicine Hospital, Tokyo, Japan, during biopsy performed between 2002 and 2018. We analyzed 24-h urinary protein excretion, FETP, and other clinicopathological findings at kidney biopsy. The FETP was determined by the standard clearance technique based on 24-h urine collection: FETP = (urinary total protein / serum total protein) / (urinary creatinine / serum creatinine) × 100.

Results: A total of 113 subjects with NS were identified (Age 53.7 ± 17.3 [mean ± SD] years old; Male 71.7%, eGFR 57.6 ± 27.2 mL/min/1.73m²; urinary protein excretion 7.02 ± 3.67 g/day; minimal change nephrotic syndrome [n = 41]; focal segmental glomerulosclerosis [n = 10]; membranous nephropathy [n = 36]; diabetic nephropathy [n = 26]). FETP was significantly associated with eGFR (r = 0.65, P < 0.01), urinary protein excretion (r = 0.58, P < 0.01), interstitial fibrosis and tubular atrophy (r = 0.24, P < 0.05), and glomerulosclerosis (r = 0.24, P < 0.05). Interestingly, patients with diabetic nephropathy showed the highest level of FETP with the poor renal outcome, while membranous nephropathy revealed the lowest level of FETP.

Conclusions: These results suggest that FETP would be a useful marker combining the two predictors of the decline of renal function in NS showing increased glomerular protein permeability and decreased glomerular filtration function.

PO1876

Prediction of Morphological Lesions Using Various Glomerular Filtration Rate Equations in Patients with Primary Glomerulonephritis

Background: Glomerular filtration rate (GFR) is generally accepted best overall index of kidney function. However, it remains controversial to use GFR as a marker of morphological lesions. Aim. To assess GFR equations as a predictor of chronic morphological lesions in patients with glomerulonephritis (GN).

Methods: 100 patients [48 female, age Me 39 (27; 54) years] with biopsy proven primary GN were included in the study (9%–minimal change disease, 28%–focal segmental glomerulosclerosis, 26%–membranous nephropathy, 37%–IAa-nephropathy). Serum creatinine was measured by enzymatic, serum cystatin C - immunoturbidimetric methods. GFR was estimated using creatinine clearance (CCr), MDRD, CKD-EPICr, CKD-EPICysC, CKD-EPICrCysC, full age spectrum equations. Glomerulosclerosis (GS) was assessed quantitatively, tubulo-interstitial fibrosis (TIF), tubular atrophy (TA) - semi-quantitatively (0-lesions absent; 1-mild focal lesions; 2-moderate lesions; 3-diffuse lesions). All patients were separated continuously in two groups according to the degree of each morphological lesion: “mild” (GS<25% or TIF/TA<1), “severe” (GS>25% or TIF/TA≥2-3).

Results: Independently of estimating equation, GFR positively correlated (r=0.001) with GS, TIF, TA and was higher in patients with “mild” GS, TIF and TA (r=0.001). Based on the results of ROC-analysis patients were separated (p=0.001) in two groups using all equations according to the degree of morphological lesions (“mild” or “severe” GS, TIF and TA). Using comparison of AUC we found the significant difference between CCr and CKD-EPICr, CKD-EPICysC, CKD-EPICrCysC between MDRD and CKD-EPICr, CKD-EPICysC equations in prediction of TIF, between CKD-EPICrCysC and FASsCr - in prediction of GS and no difference for all equations in prediction of TA (Fig.1).

Conclusions: Independently of estimating equation, GFR is a good marker of morphological lesions in patients with primary GN. Our data shows that CKD-EPI equations, especially CKD-EPICrCysC, provide the highest diagnostic value in prediction GS and TIF.

PO1877
Fluid Overload and Markers of Cardiovascular Damage in Severe Nephrotic Syndrome
Aleksandra Rymarz, Anna Matyjek, Stanislaw Niemczyk, Military Institute of Medicine, Warsaw, Poland, Warsaw, Poland.

Background: The purpose of the study was to evaluate the dimension of body water compartments and markers of cardiovascular damage in patients with severe nephrotic syndrome (SNS) defined as nephrotic range proteinuria and hypalbuminaemia ≥2.5 g/dL.

Methods: 40 patients with SNS and eGFR >30 ml/min/1.73m² formed the study group (SNSG) and 40 healthy volunteers without SNS matched according to age, sex, height, body mass, kidney function formed the control group (CG). Body water compartments were assessed using Body Composition Monitor, Fresenius Medical Care. For statistical analysis Spearman’s correlation coefficients, chi² or Mann-Whitney U tests were used (Statistica v.13.1).

Results: SNSG included 28 males and 12 females, the mean daily proteinuria was 10.5±5.0 g. The groups are described in the table. In SNSG significantly higher increases in TBW, NT-proBNP and extracellular water(ECW) were observed in comparison to CG. Total body water (TBW) did not differ between the groups. Overhydration (OH) was higher in SNSG than in CG. Significant, positive correlation was observed between OH and NT-proBNP (R=0.56, p=0.0001) as well as hsTnT (R=0.60, p=0.0001). We did not observed any significant correlation between ECW and NT-proBNP or hsTnT.

Conclusions: In SNSG fluid retention was associated with the increase in ECW and the decrease in ICW whereas TBW was the same in both groups. Such constellation can indicate interstitial or intracellular hydration which was not described so far. OH, which is a derivative of ECW, correlated with markers of cardiovascular damage and can be important for patients with resistant SNS and influence their prognosis.

PO1878
Glomerular Filtration Barrier Dysfunction in an RNA Virus-Induced Glomerulopathy: Reassembles Findings of Common Nephrotic Syndromes
Christian Nussbaumer1, Alisa Stütz2, Stefan Häggle3, Claudia Speer4, Florian Kähkle5, Christoph Eckert1, Christian Morath1, Jochen Reiser1, Martin G. Zeier1, Ellen Krauthämer1, Heidelberg University Hospital, Heidelberg, Germany; 2Rush University Medical Center, Chicago, IL.

Background: Virally induced kidney dysfunction is highlighted by the alarming incidence of SARS-CoV-2 associated acute renal disease including nephrotic syndrome (NS). Plasma levels of soluble urokinase plasminogen activator receptor (suPAR) are elevated in COVID patients and provide prognostic insights. SuPAR is also involved in proteinuric kidney diseases such as focal segmental glomerulosclerosis in which podocytes effacement injury is a common feature. Hantavirus-induced hemorrhagic fever with renal syndrome (HFRS) represents another RNA virus-induced disease with acute kidney injury and NS. The exact pathophysiology of podocyte injury is, however, unclear. We hypothesized that hantavirus infection results in podocyte injury and a dysfuctional glomerular filtration barrier (GFB), similar to findings in common NS.

Methods: Renal biopsy specimens were analyzed by light and electron microscopy. Urinary neprhin and serum suPAR were measured over time in 26 patients with HFRS and 18 healthy controls.

Results: Hantavirus patients showed significantly increased urinary neprhin, immunoglobulin G (IgG), α1-microglobulin (α1-MG) and serum suPAR concentrations compared to healthy controls. Furthermore, neprhin and IgG levels were significantly higher in patients with severe than with mild proteinuria. Differences in α1-MG levels, however, disappeared after normalization to urinary creatinine. Urinary neprhin levels as a marker for podocyte damage correlated strongly with biomarkers of non-selective glomerular proteinuria. Interestingly, suPAR correlated significantly with urinary neprhin, IgG and albumin levels, suggesting suPAR as a potential pathophysiological mediator in GFB dysfunction in response to RNA virus infection. The main finding in microscopy analyses was a focal foot process effacement. Podocyte injury and kidney dysfunction recovered autonomously in all patients.

Conclusions: Hantavirus infection causes a podocyte injury leading to GFB dysfunction. A better understanding of transient virally induced proteinuria syndromes and their often self-limiting disease character may generate new therapeutic approaches for NS.

PO1879
Nephrotic Syndrome from the Age of 65 Years: Epidemiological, Clinical, and Renal Biopsy Data
Luana R. Soares1, Jose Mariano S. Pantoja2, Lecticia Jorge3, Viktoria Woronik1, Cristiane B. Dias4, Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: This study aims to evaluate epidemiological, clinical, and renal biopsy data of patients aged 65 or over with nephrotic syndrome, admitted in a University Hospital.

Methods: Retrospective cohort study of renal biopsies performed from 2012 to 2017, considering the age 65 years or over, with diagnosis of nephrotic syndrome, under follow-up at the Nephrology Department of the Hospital das Clinicas of the University of Sao Paulo.

Results: In this period 103 renal biopsies were performed in patients aged 65 or over, 45 (43.68%) of them were indicated by the diagnosis of nephrotic syndrome. These 45 patients had mean age of 70.00±5.24 years old, 60% male, laboratory data at diagnosis were median serum creatinine of 2.02±1.53 mg/dl, hemoglobin of 11.3±4.1 g/dl, serum albumin of 2.23±0.83 g/dl and proteinuria of 6.9±4.64 g/day. Only minor complications of renal biopsy were observed and occurred in 6.6% of cases. The most frequent histological lesion was Membranous Nephropathy in 13 cases (28.88%), followed by Renal Amyloidosis AL in 9 cases (20%), Focal Segmental Glomerulosclerosis (FSGS) in 8 (17.77%) highlighting that 4 patients had the Collapsing Form, Minimal Change Disease (MCD) occurred in 7 cases (15.55%) and the remaining 8 had other glomerular diseases. In Table 1 has the comparison between patients data according the glomerular disease. [Table]

Conclusions: Renal biopsies were described as median [25,75 percentile] or n[%]. Membranous Nephropathy was the most common histological lesion followed by Amyloidosis AL in aged 65 or over. Highlights the Collapsing glomerulopathy founded in 8.8% of the patients none of them associated with HIV or other disease. Minimal Change Disease was the only case of nephrotic syndrome with acute tubular necrosis in this population, while FSGS had less vascular lesions at renal biopsy.

Clinical Characteristics, Treatment Patterns, and Outcomes of Children and Adults with Biopsy-Proven Minimal Change Disease from the Cure Glomerulonephropathy Network Study (CureGN)
Dhriti P. Chen1, Margaret Helmut2, Rasheed A. Gbadegesin3, Amy K. Mottl4, Debbie S. Gipson4, Katherine Twombley5. The Cure Glomerulonephropathy Network Study (CureGN) University of North Carolina, Chapel Hill, NC; 5Research Collaborative for Health, Ann Arbor, MT; 4Duke University Hospital, Durham, NC; 3University of Michigan Mott Children’s Hospital, Ann Arbor, MI; 1Medical University of South Carolina, Charleston, SC.

Background: The age of Minimal Change Disease (MCD) onset spans all ages. We analyzed the CureGN multi-center observational cohort study to elucidate differences in natural history and treatment patterns by age of MCD onset.

Methods: 567 participants enrolled within 5 years from kidney biopsy were available. Continuous variables were described as median [25,75 percentile] or n[%]. Univariate comparisons were performed using chi-square tests and Wilcoxon rank-sum tests for categorical and continuous variables, respectively. eGFR was winsorized to 120 ml/min in repeated measures models used to assess eGFR over time.

Results: Comparisons by age group are shown in the Table. There were modest differences in the racial/ethnic composition and weight. Severity of proteinuria was similar at disease onset [6.1 vs 6.5, p-value=0.5] but higher in adults at biopsy (6.6 vs. 3.4, p-value=0.001). At biopsy, eGFR was higher in children than adults (127.7 vs 88.6, p-value=0.001), and were more likely to have received immunosuppression prior to biopsy (58% vs. 18%, p-value=0.001). Compared to children, adults were more likely to report a history of HTN (29% vs 43%, p-value=0.001). Children were more likely to have frequently relapsing/stereoid dependent disease than adults (51% vs. 29%, p-value<0.001), and higher steroid resistant disease than adults (17% vs. 12%, p-value<0.001). Over a median of 29.1 months follow up, ESKD occurred in 13 (2%) participants in adults and in 1 (0.5%) children. Suicide and major complications were observed in 4 (1%) children.

Conclusions: Significant sociodemographic and clinical differences exist between adult-onset versus pediatric onset MCD at the time of biopsy. These differences are most notable in differences in treatment and biopsy practices relative to symptom onset.

PO1881
Clinical Characteristics of Acute Glomerulonephritis with Presentation of Nephrotic Syndrome at Onset in Children
Huipeng Ge, Qiongjing Yuan, Xiangcheng Xiao. Xiayia Hospital Central South University, Changsha, China.

Background: Acute glomerulonephritis (AGN) is a common disease in children, which placed a huge burden on developing countries. Prognosis of it may not always be good. However, the clinical characteristics of AGN with nephrotic syndrome (NS) at onset have not yet fully clarified.

Methods: 113 cases were analyzed retrospectively. Clinical data, pathological results and prognosis between AGN with NS (AGN-NS) and AGN without NS (AGN-no-NS) were compared.

Results: 20 (17.7%) of 113 patients were AGN-NS. The patients with AGN-NS were more likely to have hypertension (55.0% vs. 25.8%) and acute kidney injury (AKI) (50% vs. 17.2%). The AKI was significantly related to the manifestation of AGN-NS in children (OR=3.812, P=0.040). Compared with the AGN-no-NS, the immunosuppressive treatments were more common in AGN-NS. A severer pathological grade was significantly related to the lower C3 fraction, estimated glomerular filtration rate (eGFR) and AKI, but not the performance of AGN-NS. There was no difference in prognosis between two groups.

Conclusions: The AKI was significantly associated with AGN-NS. The prognosis of AGN-NS and AGN-no-NS in our study was almost good. Given the fact that AGN-NS patients more likely to use the immunosuppressive therapy, the long-term outcome of AGN-NS is worth a further research.

Steroid Treatment for the First Episode of Childhood Nephrotic Syndrome: Comparison of the 8- and 12-Week Regimen Using an Individual Patient Data Meta-Analysis
Anne M. Schiervens,1,3 Lynne Teeninga,1,3 Eiske Dorrestein,1,3 Nicholas Webb,1,3 Michel F. Schreuder,1,3 Radboudumc, Nijmegen, Netherlands; 2Erasmus MC, Rotterdam, Netherlands; 3Royal Manchester Children's Hospital, Manchester, UK; 4Health Innovation Manchester, Manchester, UK; 5Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.

Background: Steroids are the cornerstone of the treatment of childhood nephrotic syndrome. The optimal duration for the first episode remains a matter of debate. The aim of this study is to determine whether the 8 weeks ISKDC regimen (prednisolone 4 weeks/6 mg/kg body weight daily, 4 weeks 40 mg/kg on alternate days) is equally effective as the 12 weeks APN regimen (prednisolone 6 weeks 60 mg/kg daily, 6 weeks 40 mg/kg on alternate days).

Methods: An individual patient data (IPD) meta-analysis of randomized controlled trials reporting on prednisolone treatment for a first episode of childhood nephrotic syndrome was conducted. European trials investigating the ISKDC and/or APN steroid regimen were selected. Statistical models were adjusted for relevant covariates.

Results: Four trials included European patient cohorts treated according to the ISKDC and/or APN steroid regimen. IPD of two trials were available (PREDNOS, UK, 2019, n=109 and Nephrotic Syndrome trial, the Netherlands, 2013, n=62). Baseline characteristics did not significantly differ between the two treatment groups, with the exception of ethnicity. A significant difference was found in the time to first relapse after cessation of steroid treatment between the 8 and 12 weeks treatment group (p=0.04). The incidence of frequent relapsing nephrotic syndrome (FRNS) was similar in the two groups (p=0.75). Interestingly, a significant difference was found in the incidence of steroid dependent nephrotic syndrome (44% [8 weeks] vs 24% [12 weeks], p=0.01). Overall, relapse rate ratios were 51% higher in the 8 weeks group compared to the 12 weeks group (p=0.01). Finally, children below 4 years of age seem to have a significantly lower survival time to time to first relapse and time to FRNS compared to children of 4 years and older (p=0.02 and p=0.003).

Conclusions: The results of this IPD meta-analysis suggest that the 8 weeks regimen for a first episode of nephrotic syndrome is not equally effective as the 12 weeks steroid regimen. Although less steroids for the first episode would be beneficial in terms of steroid toxicity in the short term, these results suggest patients treated with a 12 week steroid regimen may have a less complicated disease course.

PO1884
Targeted B-Cell Depletion with Rituximab in Adult Relapsing Minimal Change Disease

Background: Case series suggest use of rituximab is effective in treating adults with relapsing Minimal Change Disease (MCD). We previously reported rituximab to increase time in remission, however, the majority of patients did have further relapses. We thus studied the efficacy of retreatment with rituximab on B cell repletion for 2 years to prevent relapse.

Methods: Adult patients with recurrent MCD relapses were identified and treated with rituximab and monitored for lymphocyte depletion (total B-lymphocyte <100) with pre-empptive re-dosing after reconstitution was observed.

Results: 16 patients (8 female, 8 male) started B cell targeted maintenance rituximab for up to 2 years. At start of the maintenance period, 14/16 were on immunosuppression, tacrolimus (7) steroids (3), or both (4), stopped at a mean of 6.4 months (range 2–16 months). 15/16 patients re-dosed after reconstitution was observed. 1/16 received 6 monthly rituximab, without waiting for lymphocyte reconstitution, due to a history of rapidly relapsing disease. 3/16 achieved lymphocyte depletion post rituximab. 3/16 relapsed during the 2 year treatment period, 1/3 was B cell deplete at relapse, 2/3 were B cell replete at relapse having been deplete on their previous blood test. As of May 2020, 10/16, have completed 2 years treatment, with a mean follow up post treatment of 6.6 months (range 1 to 13). Of these 3/10 have subsequently relapsed at mean time of

Belimumab for the Treatment of Frequently Relapsing Nephrotic Syndrome: The BELNEPH Study

Background: A pathogenic role of B cells in pediatric idiopathic nephrotic syndrome (INS) has been suggested by the therapeutic efficacy of B-cell depletion, which however can impair immune memory. Belimumab treatment affects B-cell survival and differentiation but preserves the established immune memory. Its efficacy has been proven in other immune-mediated diseases, such as systemic lupus erythematosus and membranous nephropathy.

Methods: In this open-label, prospective, single-arm study, 5 children with frequently-relapsing INS who were on alternate-day prednisone only were enrolled. Belimumab was administered at 10 mg/kg i.v. on day 0, 14, 28 and then every 4 weeks for up to 12 months. Concomitant prednisone treatment was gradually tapered up to reach the lowest possible dose. Safety, efficacy and laboratory blood and urine parameters were monitored for the duration of the study.

Results: Four patients completed the primary endpoint (6 months) and 2 patients completed the study. Infusions were well tolerated. One patient experienced a pulmonary infection which required hospitalization on 2.3 months after the first infusion. Four patients experienced a first relapse within 6 months (1.9, 2.5, 2.6, 3.3 months after starting treatment) and 1 patient 8.1 months from first infusion. Three patients discontinued the study due to the frequency of relapses (2) after 5.2, 9.2, 9.6 months, respectively, and were started on another corticosteroid-sparing agent. The study was discontinued due to apparent lack of efficacy. CD20 B cells decreased during the follow-up, with a nadir at 6 months (8.6% of lymphocytes vs 19.1% at baseline, p=0.01). naïve B cells started to significantly decrease after 1 month (7.7% vs 12.4% at baseline, p=0.05) and continued to decline during the follow-up. In contrast, no significant impact was observed on memory B cells, which became the most represented B cell subset already at month 1 (43.5% of B cells vs 27.3% at baseline, p=0.01), with an initial shift toward a switched subset (57.4% and 59.0% of memory B cells at 3 and 6 months, respectively, vs 48.3% at baseline, p=0.01). Serum IgG, IgA and IgM levels were not significantly modified.

Conclusions: In this first-in-human study, treatment with belimumab resulted in a marked reduction in urinary PCR (26-54%), which correlated with the degree of glomerular hyposialylation. Baseline plasma ManNAc levels in nephrotic subjects with normal eGFR were similar to those in subjects with normal renal function, but baseline plasma free NeuAc levels were elevated in nephrotic subjects with lower eGFR. This is consistent with NeuAc having high glomerular permeability and little tubular reabsorption. Plasma ManNAc levels peaked 2-4 h after dosing and returned to baseline after ~12 h. Plasma free NeuAc levels peaked ~10 h after dosing, remained elevated beyond 48 h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. These findings suggest that no adverse effect related to the increased free NeuAc levels was observed. Further studies are needed. These data support twice daily dosing, with reduced doses for subjects with low eGFR.

Conclusions: Oral ManNAc was safe and well tolerated in glomerular disease subjects. ManNAc supplementation showed a trend towards proteinuria reduction, possibly linked to the degree of glomerular hyposialylation. A phase 2 study is planned to include assessment of longer-term pharmacokinetics, efficacy and safety.

PO1887 Phase 1 Study of N-Acetylmannosamine (ManNAc) for Glomerular Disease

Background: ManNAc is an uncharged monosaccharide and precursor of N-acetylmannosamine acid (NeuAc, sialic acid). It provides anionic charges to proteins, including those constituting the glomerular filtration barrier. Glomerular hyposialylation is common in nephrotic diseases and may contribute to podocyte foot process effacement and increased protein permeability. ManNAc showed benefit in nephrotic mouse models.

Methods: We performed a phase 1 study to evaluate the safety, tolerability, and pharmacokinetics of single and multiple doses of ManNAc in nephrotic subjects (NCT02639260). Seven subjects were enrolled, with 6 focal segmental glomerulosclerosis and 1 with membranous nephropathy. Urine protein/creatinine ratio was 1.3 to 9.9 g/g.

Results: One subject received a single dose of 6 g ManNAc.

Results: ManNAc administration was well-tolerated. There were no serious adverse events among 6 subjects (5 of 6) that received ManNAc twice daily. A marked reduction in urine PCR (26-54%), which correlated with the degree of glomerular hyposialylation. Baseline plasma ManNAc levels in nephrotic subjects with normal eGFR were similar to those in subjects with normal renal function, but baseline plasma free NeuAc levels were elevated in nephrotic subjects with lower eGFR. This is consistent with NeuAc having high glomerular permeability and little tubular reabsorption. Plasma ManNAc levels peaked 2-4 h after dosing and returned to baseline after ~12 h. Plasma free NeuAc levels peaked ~10 h after dosing, remained elevated beyond 48 h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. These findings suggest that no adverse effect related to the increased free NeuAc levels was observed. Further studies are needed. These data support twice daily dosing, with reduced doses for subjects with low eGFR.

Conclusions: Oral ManNAc was safe and well tolerated in glomerular disease subjects. ManNAc supplementation showed a trend towards proteinuria reduction, possibly linked to the degree of glomerular hyposialylation. A phase 2 study is planned to include assessment of longer-term pharmacokinetics, efficacy and safety.

PO1888 Efficacy and Safety of ACE Inhibitor and ARB Therapies in Primary FSGS Treatment: A Systematic Review and Meta-Analysis
Kirk N. Campbell,1 Natali Pennese,2 Andrea Zaffalon,2 Barbara Magalhaes,2 Marina Faiella,2 Dawn J. Caster,1 Jai Radhakrishnan,1 Vladimir Tesar,4 Howard Trachtman.6 1Mt Sinai School of Medicine, New York, NY; 2LatticePoint Consulting, Geneva, Switzerland; 3University of Louisville School of Medicine, Louisville, KY; 4Columbia University Medical Center, New York, NY; 5Charles University, General University Hospital, Prague, Czechia; 6NYU School of Medicine, NYU Langone Medical Center, New York, NY.

Background: Use of ACEi and/or ARB (RASi) as conservative management to control proteinuria in primary and genetic focal segmental glomerulosclerosis (FSGS) follows guideline recommendations based on other proteinuria-related kidney diseases. There is lack of consensus about the efficacy and safety of RASi therapies in primary and genetic FSGS, thus this systematic review aims to assess the benefits and risks of RASi therapies on renal outcomes in these patients.

Methods: English-language studies were searched in MEDLINE, Embase and Cochrane Central Register of Controlled Trials, from inception to April 2019. Cohort studies assessing efficacy (response to treatment and indicators of renal function) and safety outcomes in primary and genetic FSGS were selected. Study results were summarized as Ratio of Means (ROM) between baseline and follow-up measurements, or as Hazard Ratio (HR) using random effects models.

Results: We selected 30 studies of which only 5 were controlled trials. Only 8 assessed RASi as monotherapy while the rest studied them in combination with other drugs, mainly immunosuppressants (IS). On average, a 32% reduction on proteinuria (ROM=0.68; 95% CI: 0.47-0.98) and no change on CrCl (ROM=1.00; 95% CI: 0.77-1.16) from baseline to variable follow-up periods was observed in patients treated with RASi therapy alone. A reduction of 72% in proteinuria was observed when RASi were combined with other drugs, mainly IS (ROM=6.24, 95% CI: 0.88-6.55). Published data did not allow to evaluate the eGFR ROM between follow-up and baseline and the
effect on the risk of reaching ESRD or RASI therapy alone. Only one controlled study reported adverse effects of RASI as monotherapy. Overall, the available evidence exhibits considerable heterogeneity in cohort baseline characteristics and study design.

**Conclusions:** This review supports the tendency to observe a reduction of proteinuria in patients treated with RASI, and demonstrates the lack of strong evidence to quantify their effect on eGFR and their long-term impact on renal survival. The current lack of properly controlled studies in primary FSGS stresses the need for longer and better designed clinical trials to better understand the effect of RASI.

**Efficacy and Safety of Immunosuppressive Therapy in Primary FSGS: A Systematic Review and Meta-Analysis**

Dawn J. Caster,1 Barbara Magalhães,2 Natali Pennese,3 Andrea Zaffalon,2 Marima Faella,2 Kirk N. Campbell,1 Jai Radhakrishnan,3 Vladimir Tesar,4 Howard Trachtman,5 Eunice H. Lui,1 University of Louisville School of Medicine, Louisville, KY; 2LatticePoint Consulting, Geneva, Switzerland; 3Columbia School of Medicine, New York, NY; 4Columbia University Medical Center, New York, NY; 5Howard University College of Medicine, Washington, DC. *Commercial Support - Retrophin, Inc.*

**Background:** Few studies directly compared the presentation and treatment response of nephrotic syndrome (NS) concerning the racial and ethnic differences of different countries.

**Methods:** NEPTUNE is a prospective cohort study of NS across 23 North American centers. Nephrotic Syndrome Registry (N-KDR) is a Japanese retrospective cohort in Nagoya area. Nephrotic FSGS/MCD adults who received immunosuppressive therapy (IST) were included. Demographics and laboratory data of the patients were compared. Time to complete remission (CR: UPCR<0.3) from the start of IST were evaluated (14 studies, ROM=0.34, 95% CI 0.25-0.46). Pooled studies showed a lower CR at the end of the follow-up compared to baseline (ROM=0.77; 95% CI 0.71-0.83). In contrast, eGFR measurements suggested no change from baseline to follow-up (16 studies, ROM=0.92; 95% CI 0.84-1.01). IS therapy had uncertain effect on reducing the risk of reaching ESRD (HR=0.79; 95% CI 0.45-1.37) and its impact on long-term renal survival was not clearly demonstrated.

**Conclusions:** This systematic literature review supports that patients treated with IS have on average, a reduction in proteinuria between baseline and varying follow-up periods. Reported changes from baseline to follow-up in CrCl and eGFR are contrasting within studies but not across studies. Due to lack of properly controlled studies, it is hard to attribute how much of these outcome are due to IS treatment effect, stressing the low certainty evidence currently available in the literature and the need for better designed studies to reliably assess the effect of IS on primary FSGS patients.

**The Epidemiological Comparison Between North American and Japanese FSGS/Minimal Change Disease Patients:**

Tatsuya Kominami,1 Shota Hayama,1 Laura H. Mariani.1 University of Michigan, Ann Arbor, MI; 2Nagoya University Graduate School of Medicine, Nagoya, Japan.

**Background:** Few studies directly compared the presentation and treatment response of nephrotic syndrome (NS) concerning the racial and ethnic differences of different countries.

**Methods:** NEPTUNE is a prospective cohort study of NS across 23 North American centers. Nephrotic Syndrome Registry (N-KDR) is a Japanese retrospective cohort in Nagoya area. Nephrotic FSGS/MCD adults who received immunosuppressive therapy (IST) were included. Demographics and laboratory data of the patients were compared. Time to complete remission (CR: UPCR<0.3) from the start of IST were evaluated (14 studies, ROM=0.34, 95% CI 0.25-0.46). Pooled studies showed a lower CR at the end of the follow-up compared to baseline (ROM=0.77; 95% CI 0.71-0.83). In contrast, eGFR measurements suggested no change from baseline to follow-up (16 studies, ROM=0.92; 95% CI 0.84-1.01). IS therapy had uncertain effect on reducing the risk of reaching ESRD (HR=0.79; 95% CI 0.45-1.37) and its impact on long-term renal survival was not clearly demonstrated.

**Conclusions:** This systematic literature review supports that patients treated with IS have on average, a reduction in proteinuria between baseline and varying follow-up periods. Reported changes from baseline to follow-up in CrCl and eGFR are contrasting within studies but not across studies. Due to lack of properly controlled studies, it is hard to attribute how much of these outcome are due to IS treatment effect, stressing the low certainty evidence currently available in the literature and the need for better designed studies to reliably assess the effect of IS on primary FSGS patients.

**POI891**

**Long-Term Renal Outcomes in Focal Segmental Glomerulosclerosis:**

Benjamin M. Forster, Robert Nee, Stephen W. Olson. Walter Reed National Military Medical Center, Bethesda, MD.

**Background:** Focal Segmental Glomerulosclerosis (FSGS) is a glomerular disease defined by pathomagnorphic histopathology but is caused by multiple mechanisms of disease, not all of which have been fully elucidated. Therefore, the reported renal prognosis, treatment strategies, and treatment response has varied significantly in previous small case series. We sought to analyze long term renal survival and associated risk factors in the largest cohort over the longest period of follow up described to date.

**Methods:** We performed a retrospective cohort study on all previous and current active duty military with biopsy proven FSGS. Potential cases were identified through review of the military electronic medical record for International Classification of Diseases 9 and 10 codes (581.1, 582.1, and N04) and then confirmed by comprehensive chart review. Extensive data collection was performed and then analyzed using STATA 16.

**Results:** We identified 348 patients with biopsy proven FSGS with a mean follow up of 9.5 years. The majority were black, male, and under 40 years old. Progression to end stage kidney disease (ESKD) was 14%, 25%, and 35% at 5 years, 10 years, and 15 years after diagnosis, respectively. More patients with nephrotic range proteinuria progressed to ESKD (20%, 31%, and 49% at 5, 10, and 15 year follow up, respectively) compared to non-nephrotic range proteinuria (13%, 20%, and 31% at 5, 10, and 15 year follow up, respectively), and no significant proteinuria (6%, 14%, and 23% at 5, 10, and 15 year follow up, respectively). p=0.04. Overall progression to stage 3 chronic kidney disease (CKD3) was 32%, 40% and 50% at 5, 10 and 15 years after diagnosis, respectively. Full report of renal outcomes from initial treatment was associated with a substantial reduction in progression to ESKD (2%, 4%, and 7% at 5, 10, and 15 year follow up, respectively) compared to partial remission (12%, 21%, and 30%) and no remission (27%, 45%, 63%), p<0.001.

**Conclusions:** We present the largest cohort of biopsy proven FSGS cases over the longest follow up period to date. Approximately one third of all FSGS patients develop ESKD and one half developed CKD3 within 15 years. Proteinuria significantly increased the risk of progression to ESKD. Achieving a full or partial remission after initial treatment significantly decreased the risk of progression to ESKD.

**POI892**

**Cellular Senescence Is Associated with Faster Progression of Renal Disease in Adults with Focal Segmental Glomerulosclerosis:**

Enric Fernéola,1,2 Michaela Saijo,3 Daniela Picciotto,1 Francesca Viazzini,1 Elisa Russo,3 Leda Cipriani,3 AnnaLina Carta,1 Francesca Costiglioli,2 Gabriele Gaggero,2 Pasquale Esposito,1 Giacomo Garibotto,2 Laura Poggii,3 Division of Nephropathy, Dialysis and Transplantation, Department of Internal Medicine, University of Genova and IRCCS Ospedale Policlinico San Martino, Genova, Italy; 4Division of Pathology IRCCS Ospedale Policlinico San Martino, Genova, Italy.

**Background:** A current hypothesis is that an acceleration of cellular senescence, a state of irreversible cell cycle arrest mediated by cyclin-dependent kinase inhibitors, is not only an impaired renal repair but also an indicator of impaired renal repair and of disease progression. Senescent cells are involved in impaired renal repair and in the progression of renal diseases. The functional role of the senescent changes observed in patients with glomerular diseases are unknown and if senescence is really associated with more disease progression is still not understood.

**Methods:** The hypothesis that cell senescence represents a proximate mechanism by which kidney is damaged could be examined among both African American and white patients and was evaluated by Cox proportional hazard model and selected using a backward stepwise method.

**Results:** Eighty-eight eight NEPTUNE and 302 N-KDR cases were eligible. The median of follow-up was 35 and 47 months in NEPTUNE and N-KDR, respectively. In NEPTUNE, 20.7% were African Americans and 26.1% were Hispanic. NEPTUNE had higher proportion of FSGS (55.7 vs. 16.2%, p=0.001). N-KDR cases were older (55 vs. 43 years, p=0.001) and showed more rapid NS onset (0.8 vs. 1.5 months, p=0.004). NEPTUNE cases demonstrated lower level of UPCR (4.20 vs. 8.00, p=0.001) and hypoalbuminemia (2.6 vs. 1.8 mg/dL, p=0.001). In both cohorts, >85% started on steroid monotherapy.

In NEPTUNE, only 1% of patients changed within first 28 days as compared to 10% of N-KDR patients. N-KDR cases showed higher proportion of CR in overall sample (85.7 vs. 42.5%, p<0.001) and in African American (67.4 vs. 42.2%, p=0.015) and in CKD4 (9 vs. 87.2%, p=0.113). Multivariate analysis showed associations of FSGS (HR=0.65, 95%CI: 0.52-0.81), hypertension (HR=0.64, 95%CI: 0.45-0.90), serum albumin (HR=0.62, 95%CI: 0.45-0.85) and eGFR (HR=1.24, 95%CI: 1.17-1.32, for 10 ml/min/1.73m² with time to CR. There were significant interactions between the cohort and hypertension (p=0.008), and between cohort and eGFR (p=0.001).

**Conclusions:** Adult nephrotic FSGS/MCD in the North American cohort showed diverse ethnic background and less severe NS. Japanese patients had a higher rate of response to the IST. FSGS, hypertension, higher albumin, and lower eGFR were considered as shared predictors of renal treatment response between both cohorts.

Clinicopathological Characterization of Focal and Segmental Glomerulosclerosis in a Dominican Republic Sample
Eliana Dina-Batlle,1 Limber I. Rojas,2 Mirtha C. Almanzar, Hector A. Pantaleon,1 José J. Sánchez.2 1Hospital Metropolitano de Santiago, Santiago, Dominican Republic; 2Hospital General de la Plaza de la Salud, Santo Domingo, Dominican Republic; 3Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

Background: There are limited recent epidemiological and clinicopathological behavior reports on FSGS in the Caribbean population. The aim is to identify clinical characteristic, epidemiological trend and treatment response of patients with diagnosed FSGS and their different variants in a Dominican Republic sample

Methods: Cross-sectional study of performed transcutaneous native kidney biopsy taken in an interval date from years 2018-2019 of two separate nephrology consult from Dominican Republic. Diagnosed FSGS biopsy reports available and biochemical laboratory parameters (creatinine, BUN, 24h Proteinuria, cholesterol, triglycerides, hematuria) within the date of biopsy were analyzed. Histopathological analysis of foot process effacement (FPE) degree reported and nephrotic syndrome (NS) presentation was correlated to primary or secondary cause of FSGS. Also, description of FSGS variants and response to the different treatments implemented at the time of data collection, overlapping comorbidities and serology were taken in notice

Results: 49 biopsies were analyzed with FSGS. NOS variant was the most common (72%), tip lesion (6%) and collapsing (6%), with no reported perihilar or cellular variants and 3% reported as unsampled biopsy of FSGS. Biopsy with diffuse FPE (>80%) 24 presented with nephrotic syndrome and 8 did not (p=0.010). Remission in biopsy with described diffuse foot process effacement (DFPE) with unidentified cause 32% had complete remission (CR) (serum albumin >3.5 g/dl or <300 mg/24h protein), 16% had partial remission (PR) (≥50% reduction basal proteinuria, subnephrotic proteinuria), and 20% did not remit at a 6 month period (p=0.921). Steroids and calcineurin inhibitors treatment were significantly associated with CR in FSGS with DFPE with unidentified cause (p=0.029, p=0.014 respectively)

Conclusions: Biopsies analyzed in a 2 year period presented NOS as the most common variant while perihilar or cellular variants were not reported. In the sample studied the degree of FPE was associated to NS presentation. The use of steroids and calcineurin inhibitors in suitable patients is significantly associated with remission of disease. The FSGS biopsy, clinical manifestations of patients and history represent the best tools for correct diagnosis and treatment

POI1894
Differentiating Focal and Segmental Glomerulosclerosis
Afonso Santos,1 Anna Lima,1 Ana Gaspar,1 Ana C. Brás,1 Pedro Pereira Campos,2 Rita Theias Manso,3 Karina Soto.1 1Nephrology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal; 2Pathology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal.

Background: FSGS is a histological pattern of kidney injury associated to broad causes and pathogenesis. FSGS can be primary, genetic or secondary to other conditions. Differentiating these subclasses is crucial for management and prognosis, but there is no gold standard for disease grouping. The purpose of this study is to compare the different diagnostic approaches in a series of patients with FSGS classification based on clinical and histological criteria comparing outcomes

Methods: In a retrospective analysis of 359 kidney biopsies we identified patients with histological diagnosis of primary and secondary FSGS were identified based on clinical and histological data. Genetic FSGS was considered if they present at least one of the following:a) nephrotic syndrome (NS) resistant to corticosteroids;b)NS with normal serum albumin;c)NS with focal foot process effacement or d)non-nephrotic proteinuria with diffuse foot process effacement. Each group was divided in immunosuppression treatment (IST) or only supportive treatment (ST) groups. Renal and survival outcomes were assessed

Results: Among 66 FSGS patients, 63% were males, 71% non-black, 74% had HTN, 26% diabetes; median eGFR 26.5 mL/min/1.73m2 (IQR: 15.3-48.8), 24-h proteinuria 4.4 g (IQR 2.5-7.6). Globally, 38% (n=25) progressed to ESKD and mean time to RRT was longer in IST group (p=0.067). According to the applied criteria 52% (n=34) were classified as having secondary FSGS, 23% (n=15) primary and 25% (n=17) as genetic FSGS. Among primary FSGS patients 40% received IST. In ST group 25% progressed to ESKD in a median time to RRT of 24 months (SD±21.7) vs 13% in 66mos (SD±3.3) in IST group. Among secondary FSGS, 17.6% received IST. Of them, 50% developed ESKD in 31.7mo (IQR SD±28.8) vs ST group with 46% progression to ESKD in 12mo (SD±28.7). From the genetic group 59% were in IST group and 30% progressed to ESKD in 12mo (SD±27.1) vs ST group with 29% ESKD in 42mo (SD±27.1).

Conclusions: FSGS etiology is not straightforward in most patients. Since IST can be inappropriate and potentially harmful in some FSGS subclasses, it is crucial to identify patients that are likely to benefit from such therapies, in order to obtain better outcomes. Most of genetic forms of FSGS do not respond to IST and have a rapid progression to ESKD. Therefore, in a suspicion of a genetic cause a genetic screening should be performed for appropriate management.

The Dual Endothelin/Angiotensin II Receptor (ET, R/AT, R) Antagonist Sparsentan Slows Renal Disease, Improves Lifespan, and Attenuates Hearing Loss in Alport Mice: Comparison with Losartan and Atrasantan

Dominic E. Cosgrove,1 Brianna M. Dufek,1 Duane C. Delimont,1 Daniel T. Meehan,1 Gina C. Samuelson,1 Jared Hartsook,2 Grady Phillips,2 Ruth Gill,1 James Hasson,2 Celia P. Jenkinskin,3 Radko Komers,3 Michael Anne Gratton,1 1Boys Town National Research Hospital, Omaha, NE; 2Washington University, St. Louis, MO; 3Retropin, Inc., San Diego, CA.

Background: In Alport syndrome (AS), ET, R activation is important in renal and inner ear pathologies. Previously, sparsentan (SP) was shown to prevent increases in proteinuria, glomerulosclerosis, and glomerular basement membrane dysmorphology in AS mice. Here we compare the effect of SP, the AT, R antagonist losartan (LS), and the ET, R antagonist atrasantan (ATR) on lifespan and proteinuria, and of SP and LS on hearing loss and inner ear pathology.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (V), 60 or 120 mg/kg of SP (SP06, SP120), LS (20 mg/kg; 3-4 W) or LS (10 mg/kg females or 10 mg/kg males) in the drinking water. Two studies were conducted: early intervention for hearing from 3.8-7.5 W (V, SP120 and LS), and for lifespan with treatment from 3 W (V) or from 3 W (SP60, SP, LS or ATR). Urinary protein/creatinine ratio (UP/C) was assessed weekly. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8-8.75 W. The cochleae were fixed and were preserved and strait pathologically determined by electron microscopy.

Results: SP120 significantly (P<0.05) increased median lifespan compared to any other group (Figure 1). At 8 W, only SP120 significantly (P<0.05) attenuated the increase in UP/C compared to V (UP/C mg/mg meanSD 42±18 AT, 42±18 LS, 42±18 SP60; 20±3 SP120). UP/C at 11 W in SP120 mice was significantly attenuated (P<0.05) vs. LS mice. SP120 significantly improved post-noise ABR thresholds at 16 kHz vs. V mice (P<0.05). LS had no effect. Dysmorphology of the stria vascularis was noted in LS but not SP120 treated mice.

Conclusions: SP120 in AS mice extended lifespan beyond that of mice treated with SP60, LS, or ATR and attenuated noise-induced hearing loss compared to LS. Sparsentan may therefore offer a novel, dual-therapeutic approach in AS by reducing both renal injury and hearing loss.

Long-Term Outcomes of Tacrolimus Treatment for Idiopathic Membranous Nephropathy

Aikaterini K. Nikolopoulou,1 Sarah Gleeson,1 Rakesh Duttani,1 Marie B. Condon,1 Tom Cairns,1 Jeremy B. Levy,1 Liz Lightstone,2 Stephen P. McAdoo,1 Frederick W. Tam,3 Charles D. Pusey,3 Megan Griffith,3 1Imperial College Healthcare NHS Trust, London, United Kingdom; 2Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Tacrolimus (TAC) is effective for the treatment of membranous nephropathy (MN).

Methods: Retrospective study of longterm outcomes of 111 patients (pts) with MN treated with TAC from January 2000 to June 2018.

Results: Demographics: Table 1. Treatment: 91/111 TAC monotherapy, 20/111 dual therapy with mycophenolate + TAC. All pretreated with ACEI/ARB. Median follow up (FU) 68 months (IQR 33-115). 93/111 pts (84%) reached Partial Remission (PCR) reduction by 50% and <300 mg/mmol at 5.1 months (median, IQR 2-11). 76/111 (69%) also reached Complete Remission (PCR reduction by 90%) at 15.2 months (9.3-24). 18/111 (16%) did not respond to initial treatment with TAC. 3/18 progressed to ESRD rapidly, 9/18 were treated with Rituximab (RTX), 4/18 with cyclophosphamide (CYP) and steroids. Only 4 achieved remission, all in the RTX group. 2 lost to FU. 48/83 (51%) of pts that achieved remission relapsed after 22 months (14-34) (Figure 1) following withdrawal of immunosuppression. 28/48 were retreated with TAC and all achieved remission, 15/48 treated with RTX, remission in 11/15. 3/48 treated with CYP and steroids (2/3 remission, 1 lost to FU). No treatment in 2. 11/28 cases retreated with tacrolimus had a second relapse. At 3 months on TAC there was a reduction of eGFR from baseline (median, IQR 78 ml/min (48-99)) (Figure 2). Renal function stabilised thereafter during the follow up period to 10 years. 10/9% pts reached ESRD and 5/10 within 12 months from diagnosis;these pts had a lower baseline eGFR 48ml/min (23-61).

Conclusions: TAC can be an effective treatment for MN with a relatively rapid response. Lack of response to TAC and low eGFR at presentation are associated with non-response to alternative immunosuppression and ESRD. Relapse is common, necessitating repeat immunosuppression. Most pts maintain eGFR in the longterm.

Etiology, Histology, and Prognosis of Primary and Secondary Membranous Nephropathy in Young Patients Under 50 Years Old: A 35-Year, Two-Center Experience

Yasuhiro Oda, Masayuki Yamanouchi, Tatsuya Suwabe, Junichi Hoshino, Yoshifumi Ubara. Toranomon Hospital Kajigaya, Kawasaki, Japan.

Background: Membranous nephropathy (MN) is often diagnosed in older age group; its mean age of onset is 50-60 years old. Although retrospective analyses on young patients with primary MN have been published, most clinicopathologic characteristics of primary MN and secondary MN combined in young patients have not been reported.

Methods: All patients diagnosed with MN in the age under 50 years old by a kidney biopsy performed between January 1985 and December 2019 at Toranomon Hospital and Toranomon Hospital Kajigaya were retrospectively analyzed. All patients with glomerular membranous changes presumed to be due to subepithelial deposits were included except for cases with classic membranoproliferative glomerulonephritis.

Results: 37 patients met the criteria. 19 of them (51%) had nephrotic syndrome, 17 (46%) had hypertensive protein-excretion less than 3.5 g/24 hours, and one (3%) had no proteinuria. To evaluate renal biopsy specimens, light microscopy was performed in all cases, fluorescence microscopy in 36 cases and electron microscopy (EM) in 28 cases. 14 patients (38%) were diagnosed with primary MN, 22 patients (59%) with secondary MN, and one patient (3%) with de novo MN post-transplantation. Secondary MN were due to lupus erythematosus (27%), mixed connective tissue disease (14%), Sjögren’s syndrome (3%), hepatitis B (11%), bicusculine use (3%), and graft versus host disease (GVHD) after peripheral blood stem cell transplantation (3%). Mean and median follow-up period was 14.9 and 12.0 years, respectively. At the end of follow-up, only two patients out of the 37 patients reached end-stage renal disease, and 33 patients (89%) observed serum creatinine level lower than 1.5 mg/dL. 21 patients achieved complete remission (CR). Among 27 cases who underwent EM, cases with subendothelial deposits had smaller CR rate (3/11 cases) than those without subendothelial deposits (12/16 cases), which was statistically significant (z = 6.01, p < 0.001). The CR rates of cases with mesangial deposits (12/21 cases) and those without mesangial deposits (3/6) was not significantly different (z = 0.096, p = 0.76).

Conclusions: The prognosis of renal function was fairly good in patients with MN in the age under 50 years old. Cases with coexisting subepithelial deposits showed lower CR rate than the rest.

PO1900

A Target Antigen-Based Approach to the Classification of Membranous Nephropathy

Shane A. Bobat,1 Shahzrad Tehranian,1 Sanjeev Sethi,1 Mariam P. Alexander,1 Samih H. Nasr,1 Julie A. Vrana,1 Samar M. Said,1 Callen D. Giesen,1 John C. Lieske,1 Fernando C. Fervenza,1 An S. De Vries,1 1Mayo Clinic Minnesota, Rochester, MN; 2AZ Sint-Jan Brugge-Oostende AV, Brugge, Belgium.

Background: Primary membranous nephropathy (MN) is caused by circulating auto-antibodies against podocyte surface antigens, identified as M-type-phospholipase–A2-receptor (PLA2R) in 70-80% and thrombospondin-type-1-domain-containing-7A (THSD7A) in 2-5% of patients. Secondary MN occurs in the context of malignancy, autoimmune disease, infection, paraproteinemia or medication. Some patients with PLA2R-associated MN have a current or previously diagnosed associated condition, but it remains unclear whether it is causally related or coincidental. A few THSD7A-associated MN cases have a strong etiologic link with active malignancy, while in others malignancy appears coincidental. Exostosin 1/exostosin 2 (EXST1/EXST2) are recently discovered target antigens in patients with MN, the majority of whom have autoimmune disease. These recent findings blur the traditional distinction between primary and secondary membranous nephropathy.

Methods: To describe the phenotypes of PLA2R-, THSD7A- and EXST1/EXST2-associated MN, 201 adult patients with biopsy-proven MN were classified using serology, immunostaining and mass spectrometry. Clinical, biochemical and follow-up data were assessed.

Results: Among 27 cases who underwent EM, cases with subendothelial deposits had smaller CR rate (3/11 cases) than those without subendothelial deposits (12/16 cases), which was statistically significant (z = 6.01, p < 0.001). The CR rates of cases with mesangial deposits (12/21 cases) and those without mesangial deposits (3/6) was not significantly different (z = 0.096, p = 0.76).

Conclusions: The prognosis of renal function was fairly good in patients with MN in the age under 50 years old. Cases with coexisting subepithelial deposits showed lower CR rate than the rest.
PLA2R-associated MN (n=16) occurred predominantly in middle-aged women: 12 with primary MN and 4 with recurrent MN. Only 1 case of recurred MN-associated MN was identified, with a concomitant malignancy. EXT1/EXT2-associated MN (n=8) was identified in younger females and was strongly linked with active autoimmunity. The majority of patients who were negative for all three target antigens (n=23, 18%) presented with associated disease, mainly malignancy and autoimmunity.

Conclusions: In conclusion, the historical primary-secondary dichotomy has substantial limitations when applied to MN. We propose a terminology combining the target antigen involved in pathogenesis and the associated clinical diseases in order to classify MN and guide clinical decision making.

Noninvasive Diagnosis of Primary Membranous Nephropathy Using Anti-Phospholipase A2 Receptor (PLA2R) Antibodies: A Validation Study
Shane A. Bobart,1 Shahzad Tehrani,1 Cristina Andrades Gómez,2 Sanjeev Sethi,1 Callen D. Giesens,1 John C. Lieske,1 An S. De Vries,3 Fernando C. Fervenza,1 1Mayo Clinic Minnesota, Rochester, MN; 2Hospital Universitario Virgen del Rocio, Sevilla, Spain; 3A2-Sint-Jan Brugge-Oostende AV, Brugge, Belgium

Background: Kidney biopsy is the current gold standard to diagnose membranous nephropathy (MN). Approxi mately 70-80% of patients with primary MN have circulating anti-PLA2R antibodies without tissue confirmation, both on histology and immunofluorescence. We designed a protocol to evaluate the usefulness of enzyme-linked immunosorbent assay (ELISA) for the detection of anti-PLA2R antibodies in MN patients.

Methods: We analyzed 128 positive sera from Mayo Clinic and Mayo Clinic Florida patients with MN, with 33 sera having previously reported.

Results: A total of 1522 anti-PLA2R antibody tests were ordered in 1112 unique patients, yielding 128 positive results. We excluded previously reported patients (n=33), renal transplant recipients (n=5), no biopsy available (n=18), and pediatric cases (n=2). In all 70 remaining patients, the primary biopsy diagnosis was MN. Associated disease was identified in 28 cases (autoimmunity = 10, malignancy = 6, NSAID = 4, Hepatitis = 3, monoclonal protein = 5). Of the 42 patients with negative work up for secondary causes, 32 (76%) had preserved renal function. One patient had fibrin thrombi and neutrophils in the capillary loops, and one patient had 1 glomerulus with focal glomerular basement membrane duplication. Thirty-six patients had final diagnosis of MN or MCD. Among the 10 patients with eGFR <60 mL/min/1.73m2, additional findings that altered the treatment plan included acute interstitial nephritis (n=1) and superimposed diabetic nephropathy (n=1).

Conclusion: The study extends our previous observations that in patients with preserved renal function and no evidence of secondary causes or diabetes, a positive PLA2R test by ELISA and IFA confirms the diagnosis of MN.

PO1902
Association Between Anti-Complement Factor H Antibodies and Renal Outcome in Primary Membranous Nephropathy
Yu Kagaya, Norutomi Hayashi, Keiji Fujimoto, Hiroki Adachi, Kengo Furuchi, Hitoshi Yokoyama. Department of Nephrology, School of Medicine, Kanazawa Medical University, Uchinada, Japan.

Background: The complement factor H (CFH) regulates activation of the alternative complement pathway. Autoantibodies against CFH have been involved in progressive renal dysfunction in a case with primary membranous nephropathy (MN) (Ronco P. et al. N Engl J Med 2018;378:279-81). However, the prevalence and the roles of anti-CFH antibodies in the clinical outcome of MN remains unclear.

Methods: We investigated retrospectively 36 Japanese patients with primary MN (23 males, 13 females; age 64.5 [59-72] years old) and 18 healthy normal controls (8 males, 10 females, age 31 [27-38] years old). Serum anti-CFH antibody titers were measured by enzyme-linked immunosorbent assay (Vidia VestaC, Czech Republic) to evaluate the association between anti-CFH antibody titers and the clinical outcome of MN patients.

Results: Anti-CFH antibody titers were significantly higher in MN patients as compared with normal controls [4.69 (3.60-6.38) IU/mL vs. 0.0 (0.0-0.0) IU/mL, p <0.001]. Twenty-eight patients were classified into the anti-CFH antibody positive group. The other 8 patients were classified into negative group. According to the Kaplan-Meier method, no significant difference was observed in the complete or incomplete remission rate of proteinuria, the incidence of renal dysfunction by the 30% reduction in estimated glomerular filtration rate (eGFR) and 50% elevation of serum creatinine (s-Cr) levels between the anti-CFH antibody positive group and the negative group of MN patients, however. In MN patients, anti-CFH antibody titer was selected an independent unfavorable predictor of renal dysfunction in Cox proportional hazards analysis adjusted by age, gender, sCr levels, proteinuria (g/gCr), anti-CFH antibody titer and immunosuppressive therapy (adjusted hazard ratio (HR) 1.344, 95% confidence intervals (CI) 1.038 to 1.741, p=0.025 for 30% reduction of eGFR, adjusted HR 1.930, 95% CI 1.180 to 3.363, p=0.020 for 50% elevation of sCr).

Conclusions: These data suggested that anti-CFH antibodies may be involved in the deterioration of renal function in primary membranous nephropathy.

PO1903
Concurrent Anti-Glomerular Basement Membrane Nephritis and Membranous Nephropathy

Background: Anti-GBM nephritis is an uncommon entity with a rapidly progressive course. The concurrence of anti-GBM nephritis with membranous nephropathy (MN) is rare and poorly understood. We report a single center case series of this dual glomerulopathy with emphasis on presenting features, course, and outcome.

Methods: A total of 12 cases of combined anti-GBM nephritis and MN were identified from the archives of the Columbia Renal Pathology Laboratory over the past 18 years. Presenting clinical, histopathologic and laboratory data with follow up were obtained by chart review.

Results: The cohort of 12 cases included 7 men and 5 women with age range 18-81 years. The most common presenting feature was AKI (mean creatinine 9.3 mg/dL), with one patient having pulmonary symptoms. Positive anti-GBM serology was available at presentation for 11 cases, 5 with titters >100 au/mL, and all were ANCA negative. Of those tested the majority were PLA2R negative. Patients were predominantly Caucasian (N = 9). All patients required hemodialysis (HD) at presentation, and two patients, a 28-year-old woman and an 81-year-old woman had renal recovery with the later having a stable creatinine of 2.0 mg/dL 11 months later. Treatment regimens included the following: cyclophosphamide, plasmapheresis, and prednisone (N=9); cyclophosphamide and prednisone (N=1); prednisone and plasmapheresis (N=1) and rituximab alone (N=1).

Conclusions: Concurrent anti-GBM and MN is a rare entity presenting with severe AKI and renal failure. Renal recovery is uncommon. High percentage of crescents are consistent with poor outcomes. Treatment and course are dominated by anti-GBM nephritis. The MN component is predominately PLA2R negative, and further studies into pathogenesis are needed.

PO1904
Recurrent Membranous Post Transplantation: Histopathology, Treatment, and Outcomes
Sarah Gleeson,1 Akikateru K. Nikolopoulou,1,2 Megan Griffith,1,2 Marina Loucaidou,1 Michelle Willcombe,1 Candice A. Roufosse,1 1Imperial NHS Healthcare Trust, London, United Kingdom; 2Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Membranous nephropathy(MN) recurs in 30-45% of transplants. Reported recurrence rates are higher in centres that perform surveillance biopsies. Optimal treatment is unknown. We examined recurrent MN in our cohort in terms of their histopathology, treatment and outcomes.

Methods: Patients with MN as the cause of their ESRF who were later transplanted were identified from an in-house database. Further data was collected from the electronic health record.

Results: 36 patients with a diagnosis of MN were transplanted. Mean follow up was 6.4 ± 4.2 years. 41.6% had a rejection episode (mean time from transplant 0.42±1.5 years). Overall there was 22% graft loss (mean time 6.5±2.7 years). Two patients died, both on HD, one 16 years later from unknown cause and one 3 months after presentation from sepsis. Analysis of the 12 renal biopsies showed combined linear and granular staining of GBMs for IgG, with crescents involving 23-100% of glomeruli, and fibrinoid necrosis involving 15-100%. The two patients who recovered renal function had no crescents (82% crescents, and 25%, respectively) and less fibrinoid necrosis (15% and 31%) compared to the subgroup without recovery respectively, on kidney biopsy.

Conclusions: Combined anti-GBM and MN is a rare entity presenting with severe AKI and renal failure. Recurrent membranous nephropathy is rare. The most common presenting feature was AKI (mean creatinine 9.3 mg/dL), with one patient having pulmonary symptoms. Positive anti-GBM serology was available at presentation for 11 cases, 5 with titters >100 au/mL, and all were ANCA negative. Of those tested the majority were PLA2R negative. Patients were predominantly Caucasian (N = 9). All patients required hemodialysis (HD) at presentation, and two patients, a 28-year-old woman and an 81-year-old woman had renal recovery with the later having a stable creatinine of 2.0 mg/dL 11 months later. Treatment regimens included the following: cyclophosphamide, plasmapheresis, and prednisone (N=9); cyclophosphamide and prednisone (N=1); prednisone and plasmapheresis (N=1) and rituximab alone (N=1).

Conclusions: Combined anti-GBM and MN is a rare entity presenting with severe AKI and renal failure. Renal recovery is uncommon. High percentage of crescents are consistent with poor outcomes. Treatment and course are dominated by anti-GBM nephritis. The MN component is predominately PLA2R negative, and further studies into pathogenesis are needed.
Secondary Polycythemia Associated with Membranous Nephropathy
Ramakrishna Thotakura,1 Sunan Siddamreddy,2 Sruhti Kanur,4 Aditya Kadiyala,1 University of Arkansas for Medical Sciences, Little Rock, AR;3 Baptist Health, Little Rock, AR;1 University of Maryland Medical System Corporation, Baltimore, MD; Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR.

Introduction: Polycythemia has been recognized as a common occurrence in certain renal diseases such as cystic diseases of the kidney, renal cancer, tuberous sclerosis and hydrenephrosis. However, polycythemia in association with membranous nephropathy has rarely been reported. Here we report a case of secondary polycythemia from membranous nephropathy. Although the mechanism of this phenomenon is unclear, decreased effective circulating volume leading to hypoxemia and thereby polycythemia seems to be the most likely explanation

Case Description: 37-year old white male with Hypertension, OSA using CPAP, tobacco use was admitted with 40-lb weight gain and anaarca. 24-hour urine collection revealed 17-gram protein excretion with serum albumin of 1.1 and marked hyperlipidemia. Kidney biopsy revealed membranous nephropathy. Staining for PLA2R and THSD7a were negative within the glomerular deposits. Evaluation for secondary causes of membranous nephropathy was negative for ANA, RPR/lyphilis antibodies, Hepatitis, HIV, ANCA, Anti-GBM Ab and normal C3,C4 levels. CT of torso was negative for overt malignancy or hepatosplenomegaly. Patient’s hemoglobin ranged between 16.5- 18.5 g/dl (ht 52-60%). Serum erythropoietin level was 12.3 IU/L (Normal 5-30IU/L) with corresponding hemoglobin of 18.2 g/dl. JAK2 exon12, V617F mutations were negative. Hematology evaluation concluded that primary polycythemia is unlikely. Patient received 2 doses of 1 Gm Rituximab given 2 weeks apart. Patient was placed on Apixaban for prophylactic anticoagulation. Follow up labs to evaluate response to therapy are currently pending. It is yet to be seen if polycythemia resolves with remission of membranous nephropathy.

Discussion: Polycythemia is seldom seen in patients with membranous nephropathy. We postulated that hypoxia induced by decreased renal perfusion is the main trigger for polycythemia. However, it is puzzling as to why more patients with membranous nephropathy are not polycythemic. This leads us to believe that there might be some unique processes leading to polycythemia in membranous nephropathy, as in this patient, which will need further evaluation. This patient is on Apixaban for prophylactic anticoagulation in setting of severe hypoalbuminemia. Hence, prophylactic anticoagulation should strongly be considered in these patients.
PO1910
Glomerular Tip Lesion FSGS: A Rare Case of Nephrotic Syndrome in African Americans
Andrew A. Moses, Syed A. Husain, Woon Ahn. Columbia University Irving Medical Center, New York, NY.

Introduction: Nephrotic syndrome caused by focal segmental glomerular sclerosis (FSGS) in African Americans is known to have a poor prognosis and frequent treatment failure. Tip variant FSGS connotes good prognosis, usually responsive to calcineurin inhibitor (CNI) and steroid. We present a case of CNI resistant tip lesion FSGS requiring plasma exchange (PLEX) and rituximab.

Case Description: A 25-year-old African-American male, initially presenting to outpatient clinic for edema associated with proteinuria. He had a past medical history of seizure disorder controlled with zonisamide. He trialed hydrochlorothiazide and furosemide without success. His urine showed nephrotic range proteinuria with 6g/g creatinine on spot urine. Outpatient workup was unrevealing, and was managed with enalapril and torsemide. He eventually had worsening edema and shortness of breath, prompting ED visit. Biopsy was performed which showed FSGS, tip variant. He was discharged on cyclosporine and increased diuretic. Cyclosporin caused gastrointestinal upset, and so patient switched to tacrolimus. He again had increasing swelling, and represented to hospital. He was found to have acute kidney injury, and 10g/g creatinine despite therapeutic tacrolimus levels. Patient trialed stress dose steroids but serum creatinine rose to 4.44. He started PLEX for 10 treatments, and then transitioned to rituximab. During treatment with PLEX patient creatinine quickly downtrended, and after second dose of rituximab as an outpatient he was back to baseline. He lost 30 kg with resolution of his edema. Patient then tapered off steroids, and will continue on rituximab.

Discussion: Glomerular tip lesion is more common in European Americans and associated with a favorable outcome compared to other subtypes of FSGS. Resistance to one immunosuppressive treatment is not always associated with resistance to other treatment modalities. PLEX and rituximab should be considered in glomerular tip lesion in African Americans.

PO1911
Utility of Immunofluorescent Intensity of IgG3 and Phospholipase A2 Receptor-to-IgG4 Ratio to Presume the Prediction of Patients with Membranous Nephropathy
Takatsugu Iwashita, Kaori Takayanagi, Maiko Yamasaki, Mai Aoyagi, Taisuke Shimizu, Hajime Hasegawa. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background: Membranous nephropathy (MN) is likely to show the long-term course and is a frequent glomerulonephritis in the elderly. For this reason, effective use of immunosuppressive drugs in a short period of time is desirable. In this study, we aimed to investigate the factors that could predict treatment responsiveness, using the treatment outcome in a short period of time, and retrospectively analyzed patients with MN in our hospital.

Methods: We included 66 patients who underwent renal biopsy and were diagnosed with MN in our hospital between April 2009 and December 2017. The percentage reduction in proteinuria one month after initiation of steroids, immunosuppressants, and ARBs was set to the endpoint. Intensity of immunofluorescent staining (IF) was scored according to the criteria of Japanese Society of Nephrology. Hematuria was quantified by 7-grade scoring of RBC numbers in high powered microscopic field.

Results: The intensity of IF (IgG subclass, PLA2R, THSD7A) was numerically evaluated and used for the analysis. The mean age of the patients included in the analysis was 66.4±11.7 years and baseline eGFR 63.9±18.7 ml/min, baseline urine protein was 7.05±5.45 g/gCr. Multiple parameters in high responder (HR, n=39) that resulted in less than 50% of urine protein after one month and low responder (LR, n=27) that remained proteinuria more than 50% were compared. Baseline urine protein and scored baseline hematuria were both higher in HR group (urine protein: 6.95 in HR vs 3.86 g/gCr in LR, p=0.003; hematuria: 1.0 in HR vs 0.0 in LR, p=0.036), but there was no difference in baseline eGFR (70.5 in HR vs 60.4 ml/min in LR, p=0.087). The mean dose of prednisone was also not different between the two groups (18.6 in HR vs 14.0 mg/day in LR, p=0.451). In IF, significant differences were observed between the two groups in the scored staining intensity of IgG3 and the staining intensity ratio of PLA2R to IgG4 (PLA2R-to-IgG4 intensity ratio:PGIR) were both lower in HR group (IgG3: 0.0 in HR vs 0.9 in HR vs 0.5 in LR, p=0.049; PGIR: 0.55 in HR vs 1.00 in LR, p=0.029).

Conclusions: From the result of the present examination, staining intensity of IgG3 and intensity ratio of PLA2R to IgG4 might be helpful to predict better therapeutic responsiveness in addition to the baseline proteinuria and hematuria.

PO1912
Graves Disease and Nephrotic Syndrome
Sajid Mahmood, Alaleh Mazhari, Nicholas Emanueu, David J. Leechey. Loyola University Health System, Maywood, IL.

Introduction: Disorders of the thyroid and kidney may co-exist. Isolated case reports of Graves’ disease associated with various glomerular diseases, including membranous nephropathy, membranoproliferative GN, fibrillary GN, and minimal change disease have been published. A patient with membranous nephropathy and Graves’ disease who had improvement but not resolution of proteinuria after treatment with radioactive iodine has been described (Sasaki et al. CEN Case Rep. 2014; 3(1): 90-93). We report a case of nephrotic syndrome associated with Graves’ disease which completely resolved after treatment of the thyroid disease with radioiodine.

Case Description: A 33-year-old healthy female was seen for a routine life insurance evaluation. BP was normal, and she had trace-1+ lower extremity edema. Urinalysis showed 3+ protein, 1 red blood cell and 1 white blood cell per high power field. Urinary albumin/creatinine ratio was 4010 mg/g. Serum albumin was 2.7 g/dl. Renal function was normal. Tests for hepatitis B and C, HIV, RPR, ANA, C3, C4, cryoglobulins, immunofixation, and free light chains were normal. Renal biopsy was performed but the patient missed the biopsy date. Subsequently she returned to clinic complaining of neck swelling. Exam revealed tachycardia, palpable goiter, 1+ pedal edema, no tremor. She reported heat intolerance, occasional diarrhea, insomnia, diaphoresis, and weight loss for the past month. A thyroid panel showed TSH <0.01 UU/ml(0.40-4.60 UU/ml), free T3 =2000 pg/dl (230-420), and free T4 10.6 ng/dl (0.8-1.7). TSH receptor and thyroid peroxidase antibodies were present. The patient was treated with methimazole and tapering steroids. She refused thyroid surgery and ultimately underwent two sessions of radioactive iodine treatment. After this treatment, nephrotic syndrome went into complete remission (Figure).

Discussion: Although relatively uncommon, Graves’ disease needs to be considered as a reversible cause of nephrotic syndrome.
PO1913

Treatment of Systemic Lupus Erythematosus with or Without Nephritis with the Immunoproteasome Inhibitor KZR-616: Initial Results of the MISSION Study

Mary K. Farmer,1 Samir V. Parikh,2 Richard Furie,1 Christopher Kirk,1 Ken Harvey,3 Darrin Bomba.1 Kezar Life Sciences, Inc, South San Francisco, CA; 3Northwell Health, Great Neck, NY.

Background: Immunoproteasome inhibition demonstrated therapeutic potential in preclinical models of systemic lupus erythematosus (SLE) and lupus nephritis (LN). KZR-616 is a first-in-class selective immunoproteasome inhibitor, which has been safe and well tolerated in early clinical trials. One hundred subjects across 2 healthy volunteer studies, with dosing of KZR-616 up to 75mg SC, achieved target levels of immunoproteasome inhibition at doses ≥30mg. Here we report safety, tolerability and exploratory efficacy data from the Phase 1b portion of MISSION (KZR-616-002; NCT: NCT03393013), a clinical trial in which KZR-616 was administered to patients with active SLE with or without LN.

Methods: In this open-label dose-escalation study, SLE patients (per SLICC classification criteria) with SLEDAl4 despite stable background therapy received KZR-616 at doses of 45mg (Cohort 1), 60mg (Cohort 2), or 60mg following a step-up dose (Cohorts 2a, 2b, 2c) SC weekly through Week 13 (W13) with 12 weeks of follow-up.

Results: To date, 39 patients with SLE, including 2 patients with active proliferative LN, have enrolled in MISSION. The majority of TEAEs have been mild or moderate with injection site reactions the most common TEAE. Tolerability has improved with an initial step-up dosing regime, subsequent doses and the introduction of a lyophilized formulation. To date, no patients have discontinued from cohorts after implementation of these protocol modifications. Multiple measures of disease activity improved from Baseline to W13 and persisted through W25; no patients worsened over 13 weeks. KZR-616 administration resulted in improvements in multiple serologic markers as well as reduced expression of inflammatory gene expression modules. Both patients with biopsy-proven active proliferative LN had reductions in proteinuria.

Conclusions: KZR-616 has been safe and tolerated at a target dose of 60 mg weekly. Step-up dosing, use of select pre-medications, and/or introduction of a lyophilized preparation have increased its tolerability. The administration of KZR-616 resulted in improvement across multiple disease activity measures as well as serologic markers, including improvement in proteinuria in patients with active proliferative LN. MISSION is an on-going study now focused on patients with LN.

PO1914

Rituximab as Maintenance Therapy in Lupus Nephritis

Anushya Jeyabalan, Jillian Rosenthal, Reza Zonozi, Noah Huizenga, Karen A. Libberte, John Niles. Massachusetts General Hospital, Boston, MA.

Background: Rituximab (RTX) has been shown to be effective in refractory lupus nephritis (LN) in some studies. Minimal literature exists on using RTX as maintenance therapy for LN.

Methods: We performed a retrospective review of 21 patients (pts) with biopsy-proven LN who received RTX. We analyzed clinical data at baseline (pre-RTX) and up to 36 months (mo) of follow-up.

Results: Of 21 pts, 7 received RTX as part of first-line treatment, 7 for refractory LN and 7 for relapsing LN. All continued RTX (1gm q4-6 mo) as maintenance therapy. 15/21 (71%) pts were on RTX monotherapy (excluding prednisone and plaquenil) at 12 mo, 14/16 (88%) at 24 mo, and 11/13 (85%) at 36 mo. 17/19 (89%) had continuous B cell depletion at 12 mo, 13/14 (93%) at 24 mo, and 11/12 (92%) at 36 mo. At 12 mo, 16/21 (76%) achieved complete or partial remission. Median UPCR (g/g) decreased from 2.95 at baseline to 0.61 at 12 mo, 0.42 at 24 mo and 0.21 at 36 mo. 16/21 (76%) pts were on prednisone ≤5mg/day at 12 mo, 13/16 (81%) at 24 mo, and 10/13 (77%) at 36 mo. Over 36 mo, 2 pts had LN relapses while on RTX alone, and later progressed to ESRD. 2 pts developed hypogammaglobulinemia.

Conclusions: RTX monotherapy appears promising as maintenance therapy in LN. Given favorable renal outcomes and steroid-sparing effect, larger studies studying this effect may be warranted.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
23.2 to 9.04, respectively. The doses of prednisolone (mg/day) decreased in both groups. The IgG level decreased from 1377 to 1204 (mg/dL) in N group and from 1009 to 865 in R group. In 18 patients with urinary protein of 0.2 to 0.4 g/CR or more, proteinuria significantly decreased from 0.54 to 0.20 to 0.23 (g/gCr) and DNA antibody improved from 67 to 34 to 35.1 (U/mL) at 3 and 6 months after BCl therapy.

**Conclusions:** BCl may improve SLE activities and also renal function in patients with renal insufficiency as effectively as in those with normal renal function, although hypogammaglobulinemia comparably develops in both groups.

A Multicenter Double-Blinded Preclinical Randomized Controlled Trial (pRCT) on Jak1/2 Inhibition in Lupus Nephritis

Yutian Lei,1 Bettina Sehnert,4 Reinhard E. Voll,1 Conxita Jacobs Cachá,4 María Jose Soler,1 María Dolores Sanchez-Nino,1 Alberto Ortiz,1 Roman D. Bülow,2 Peter Boor,2 Hans J. Anders.1 Division of Nephrology, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; 1Institute of Pathology and Department of Nephrology, RWTH University of Aachen, Aachen, Germany; 1JIS-Fundacion Jimenez Diaz, School of Medicine, Universidad Autonoma de Madrid, Fundacion Renal Iñigo Alvarez de Toledo-IRSN and REDINREN, Madrid, Spain; 2Nephrology Department, Hospital Universitari Vall d’Hebron, Universitat Autònoma de Barcelona, Nephrology Research Group, Vall d’Hebron Research Institute (VHIR) and REDINREN, Barcelona, Spain; 3Division of Nephropathy, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; 2Department of Rheumatology and Clinical Immunology, Medical Center-University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany.

**Background:** We conducted the first multicenter double-blinded pRCT in the field of nephrology and tested the Jak1/2 inhibitor baricitinib in experimental lupus nephritis.

**Methods:** We conducted a pRCT at two Spanish and two German academic sites. One site included MRL/lpr mice from their own breeding colony and the other sites purchased MRL/lpr mice from the Jackson Lab. Eligibility criteria included female and 13-14 weeks old. Mice were randomized at a 1:1 ratio and orally dosed with 20 mg/kg/day of baricitinib or vehicle for 4 weeks. Samples were assembled for blinded analyses, including histology, which was assessed by an independent pathology institute. The primary endpoint was proteinuria.

**Results:** A total of 55 mice were randomly assigned to the vehicle (n=28) and baricitinib group (n=27). Baricitinib-treated mice showed a trend towards decreased proteinuria, but this did not reach statistical significance (p=0.104). In contrast, plasma total IgG and lymphadenopathy score were significantly improved in the baricitinib group. In the vehicle group, at the initiation of treatment, self-breed mice had less proteinuria, but this did not reach statistical significance (p=0.104). In contrast, plasma total IgG and lymphadenopathy score were significantly improved in the baricitinib group.

**Conclusions:** In a pRCT, targeting Jak1/2 with baricitinib for 4 weeks had no significant effect on the primary end-point proteinuria in MRL/lpr mice, whereas total plasma IgG and lymphadenopathy score significantly improved. Mice of different origins had different lupus phenotypes and increased the variability. Placebo controlled multicenter trials are feasible in animal models of lupus, however, standard deviations may increase due to multiple factors, which requires higher numbers of animals.

Management of Lupus Nephritis (LN) with Voclosporin: An Update from a Pooled Analysis of 534 Patients

Brad H. Rovin,1 Samir V. Parikh,1 Robert B. Huizinga,2 Neil Solomons,2 Simrat Randhawa.2 The Ohio State University Wexner Medical Center, Columbus, OH; 1Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

**Background:** Voclosporin (VCS) is a novel calcineurin inhibitor (CNI) with a favorable metabolic profile and a consistent, predictable dose response potentially eliminating the need for therapeutic drug monitoring. VCS significantly improved renal response (RR) in patients with LN in two pivotal trials. Compared to MMF (target dose 2g/day) and prednisone (ramp taper), the addition of VCS 23.7 mg BID increased renal response by 25% in the Phase 2 AURA-LV (OR: 3.21; 95% CI: 1.68, 6.13; p < 0.001) and 18% in the Phase 3 AURORA (OR: 2.65; 95% CI: 1.64, 4.27; p < 0.001) studies at one year. To provide more information on VCS treatment effect we analyzed an integrated data set from AURA-LV and AURORA.

**Methods:** The two pivotal trials were of similar design, conducted in comparable patient populations and defined similar key outcome measures. The integrated data set included an intent to treat (ITT) population of 266 control and 268 VCS 23.7 mg/BID patients. Here we report key integrated data of interest including renal response defined as: UPCR ≤ 0.5 mg/gCr ● eGFR ≥ 60 mL/min or no decline ≥ 20% from baseline ● ≤10 mg prednisone 8 weeks prior to endpoint measurement ● No rescue medications

**Results:** RR at one year was 43.7% for VCS vs 23.3% for control (OR 2.76, 95% CI: 1.88, 4.05; p < 0.0001), and at 6 months (VCS 31.7%; control 20.3%); [OR: 2.01; 95% CI: 1.34, 3.01; p = 0.0008]. In addition, 1-year RR for Hispanic patients was 37.9% in VCS group and 21.5% in control. No difference was observed in glomerular sclerosis at 1 year. The largest estimated eGFR change from baseline for VCS vs control-treated patients occurred early, at week 4, (−5.6 mL/min, p < 0.0001) which decreased to −3.7 mL/min in week 52 (p = 0.0012). Mean change from baseline of eGFR in the VCS arm at week 52 was −1.0 mL/min (p<ns). Finally, serious adverse events were similar between groups (20.5% VCS vs 18.8% control).

**Conclusions:** This integrated analysis provides further support to the efficacy of VCS seen in both AURA-LV and AURORA including in Hispanic patients, a high-risk LN patient population. Furthermore, VCS’ expected impact on mean eGFR as a CNI was mild over the course of one year.

Clinical Outcomes in Lupus Nephritis by Renal Response Status: A Retrospective Analysis of the Hopkins Lupus Cohort
Michelle Petri,1 Qinggong Fu,2 Yulia Green,3 Anuradha Madan,4 Daniel W. Goldman,1 Selin Cooper-Blenkinsopp,5 Johns Hopkins University School of Medicine, Baltimore, MD; 2GlaxoSmithKline, Upper Providence, PA; 3GlaxoSmithKline, Uxbridge, United Kingdom; 4GlaxoSmithKline, Collegeville, PA; 5GlaxoSmithKline, Stevenage, United Kingdom.

Background: A retrospective analysis of the Hopkins Lupus Cohort (a prospective, longitudinal study of patient pts) with systemic lupus erythematosus reported that renal response (complete/partial/none) at 24 months post-diagnosis of lupus nephritis (LN) predicts long-term renal survival.1 Here, we compare long-term renal survival and chronic renal insufficiency-free survival in pts with and without a renal response (RR) to standard LN therapy, as defined by primary endpoint in the Phase 3 BLISS-LN study (GSK Study BEL114054; NCT01693359).

Methods: This retrospective analysis (GSK Study 213039) of the Hopkins Lupus Cohort included pts with biopsy-proven class III, IV, or V LN. Endpoints were: long-term renal survival (no end-stage renal disease [ESRD] and/or mortality) and long-term chronic renal insufficiency-free survival by RR status at 24 months post-biopsy, both assessed by Kaplan–Meier plots with log-rank test and Cox proportional hazards regression.

Results: Out of 62 patients with biopsy-proven lupus nephritis, 53 (85.5%) were female. Whites, Hispanics, and Native Americans comprised 35.5, 30.6, and 16.1% of the cohort, respectively while 56% of the participants identified ethnically as Hispanic. Mean biopsy age, serum creatinine, and spot urine Protein/Creatinine were 34.5 (SD 15.3) years, 1.34 (SD 0.83) mg/dl, and 4.2 (SD 4.9) g/g, respectively. Class IV (48.4%) and III (16.1%) were the most prevalent lupus classes. Median (IQR) follow-up was 474.5 (1170) days. On multivariate analysis, higher age at biopsy was associated with decreased risk of doubling of serum creatinine (Figure 1). A higher spot urine Protein/Creatinine and C4 level at the time of biopsy were associated with increased risk of doubling of serum Cr.

Conclusions: Previous studies have shown that biochemical markers at the time of kidney biopsy are a poor prognostic marker of renal outcomes in lupus nephritis. In this study, demographic, biochemical, and histological markers failed to predict doubling of serum creatinine. The age and the level of proteinuria at the time of kidney biopsy were associated with doubling of serum creatinine.

PO1920
Predictors of Doubling of Serum Creatinine at the Time of Biopsy in a Lupus Nephritis Cohort
Jaime (James) A. Vondenberg, Saeed K. Shaffi, University of New Mexico, Albuquerque, NM.

Background: Lupus nephritis is associated with significant morbidity and it is imperative to study the factors associated with renal survival. We study the determinants of doubling of serum creatinine in a predominantly Hispanic cohort.

Methods: We identified patients with biopsy-proven lupus nephritis from the biopsy registry that comprises of biopsies performed between 2002-2016. Demographic, clinical, and biochemical variables were obtained from the registry and electronic medical records. We studied the factors associated with the doubling of creatinine by performing univariate and multivariate Cox proportional hazard analysis. All significant associations (p < 0.05) were studied in a multivariate Cox regression model. Patients were censored upon death or the last follow-up.

Results: Out of 62 patients with biopsy-proven lupus nephritis, 53 (85.5%) were female. Whites, Hispanics, and Native Americans comprised 35.5, 30.6, and 16.1% of the cohort, respectively while 56% of the participants identified ethnically as Hispanic. Mean biopsy age, serum creatinine, and spot urine Protein/Creatinine were 34.5 (SD 15.3) years, 1.34 (SD 0.83) mg/dl, and 4.2 (SD 4.9) g/g, respectively. Class IV (48.4%) and III (16.1%) were the most prevalent lupus classes. Median (IQR) follow-up was 474.5 (1170) days. On multivariate analysis, higher age at biopsy was associated with decreased risk of doubling of serum creatinine (Figure 1). A higher spot urine Protein/Creatinine and C4 level at the time of biopsy were associated with increased risk of doubling of serum Cr.

Conclusions: Previous studies have shown that biochemical markers at the time of kidney biopsy are a poor prognostic marker of renal outcomes in lupus nephritis. In this study, demographic, biochemical, and histological markers failed to predict doubling of serum creatinine. The age and the level of proteinuria at the time of kidney biopsy were associated with doubling of serum creatinine.

Lupus-Related Renal Disease Increases Inpatient Mortality: Analysis of the National Inpatient Sample
Ehizogbe Edigbe,1 Precious Eseaton,2 Augustine Manadan,3 University of Benin Teaching Hospital, Benin City, Nigeria; 2John H Stroger Hospital of Cook County, Chicago, IL; 3Rush University Medical Center, Chicago, IL.

Background: The aim of this study is to analyze the difference in outcomes of Systemic Lupus Erythematosus (SLE) with and without lupus-related renal disease. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Databases. NIS is the largest inpatient admission database in the USA. The NIS was searched for adult SLE hospitalizations with and without lupus-related renal disease as principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There were over 71 million discharges included in the combined 2016 and 2017 NIS database. 355,740 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE: 51,875 (14.6%) and 303,865 (85.4%) of these hospitalizations were for SLE with and without lupus-related renal disease respectively. 7,060 adult SLE hospitalizations (2%) resulted in inpatient mortality. 1,110 (2.14%) of the deaths occurred in SLE with lupus-related renal disease vs 5950 (1.96%) without lupus-related renal disease (P=0.228). The adjusted odds ratio (AOR) for inpatient mortality for SLE with lupus-related renal disease compared to those without lupus-related renal disease was 1.38 (95% CI 1.17-1.61, P<0.0001). SLE with lupus-related renal disease hospitalizations had a mean increase in adjusted LOS of 1.14 days (95% CI 1.05-1.24, P=0.0001) compared to SLE without lupus-related renal disease. SLE hospitalizations for SLE with lupus-related renal disease had an increase in adjusted total hospital charges of $15,910 (95% CI 13,085-18,736, P<0.0001) compared to SLE without lupus-related renal disease.

Conclusions: Hospitalizations for SLE with lupus-related renal disease have increased inpatient mortality, LOS, and total hospital charges compared to those without lupus-related renal disease. SLE patients with lupus-related renal disease require a multidisciplinary approach involving the rheumatologist and nephrologist to optimize outcomes.
PO1922

Analysis of Characteristics and Risk Factors of Sepsis in Patients with Lupus Nephritis

Zhenjian Xu,1 Meisheng Liang,2 Anping Xu,1 Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China; 1The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, China.

Background: Patients with lupus nephritis are at high risk of infection due to intrinsic immune dysregulation and treatment with glucocorticoids and immunosuppressants. Infection is a common complication in patients with lupus nephritis and is a major determinant of in-hospital mortality. Sepsis are the most frequent causes of infection-related mortality. In this research, we study the clinical characteristics and related risk factors of sepsis in patients with lupus nephritis according to a retrospective analysis.

Methods: A retrospective study was carried out for 322 hospitalized patients with lupus nephritis in Sun Yat-Sen Memorial Hospital from 2010 to 2019. The infected group consisted of 140 patients (The infected patients were subdivided into septic group and non-septic group according the sepsis criteria) while the non-infected group consisted of 182 patients without infection. Baseline data including sex, age, disease duration, hospitalization duration, associated organ involvement, use of glucocorticoid and immunosuppressants.

Results: Compared to the non-infected group, longer hospitalization duration (4 vs. 3.6 [IQR: 2.8–6.0] days), p<0.05), higher systolic blood pressure (143 ± 22 vs. 135 ± 20, P<0.05), higher diastolic blood pressure (87 ± 10 vs. 78 ± 9, P<0.05), higher percentage of methotrexate treatment (55.7% vs. 44.6%, P<0.05), cyclophosphamide(22.9% vs. 14.3%, P<0.05), and calcineurin inhibitors(18.6% vs. 10.4%, P<0.05), and higher dose of oral corticosteroid (15 vs. 10mg, P<0.05) can be seen in the infected group. Compared to the non-septic group, higher proportion of patients with GI bleeding(8.5% vs. 0.0%, P<0.05), and higher severity of infection scores(26.0 ± 10.3 vs. 10.0 ± 6.3, P<0.05), higher proportion of puse therapy (65.7% vs. 26.3%, P<0.05) and higher severity of infection scores(26.0 ± 10.3 vs. 10.0 ± 6.3, P<0.05), while higher level of serum creatinine(134.0 ± 88.0 [IQR: 0.0–38.0], P<0.05), C reactive protein(43.8 ± 12.3, P<0.05), and erythrocyte sedimentation rate(60.0 ± 45.5 mm/h, P<0.05) can be seen in the sepctic group. Multivariable Logistic regression analysis revealed that male and pulse methylprednisolone treatment within 1 month were independent risk factors of sepsis in patients with lupus nephritis (P<0.05).

Conclusions: Male and pulse methylprednisolone treatment within 1 month were independently associated with sepsis in patients with lupus nephritis.

PO1923

An Evaluation of Costs Associated with Overall and Renal-Specific Organ Damage in Patients with Systemic Lupus Erythematosus in the United States

Christopher F. Bell,1 Juliana Meyers,2 Mayank A. Jherera,1 Benjamin Wu,3 Joan Von Feldt,3 GlassoSmithKline, Research Triangle, NC; 2RTI Health Solutions, Research Triangle Park, NC; 3GlassoSmithKline, Philadelphia, PA.

Background: Systemic lupus erythematosus (SLE) is a chronic, multisystem, inflammatory, autoimmune disease affecting multiple organ systems, and characterized by fluctuating disease activity (flares). The combination of flares and SLE treatment toxicity increases the risk of organ damage (OD), including renal OD. Despite the high prevalence of OD and the associated poor disease prognosis, real-world studies on the economic impact of OD, especially renal OD, in SLE are limited.

Methods: This retrospective analysis (GSK Study 208380) used the IQVIA PharMetrics Plus Database to identify patients with SLE and OD during 01/01/09–06/30/18. Patients with OD were identified using International Classification of Diseases (ICD)-9/10 codes derived from the Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index.1 Inclusion criteria: i) age ≥18 years; ii) continuous enrollment 12 months both pre and post index (index: date of first observed OD medical claim); iii) inpatient (IP) or ≥3 outpatient (OP) claims separated by ≥30 days for SLE (ICD-9: 710.0 or ICD-10: M30.X); iv) 64 [IQR: 45–84] ml/min/1.73 m². The lupus cohort predominantly consisted of females and class IV lupus nephritis. Many patients of Hispanic ethnicity identified as White with respect to race. At the time of lupus nephritis diagnosis, antibody status, serum creatinine, and urine spot protein/creatinine ratio were similar among ethnicities. Hispanics were more likely to be non-infected and use ibuprofen. The most common maintenance therapy was follow by MMF, and the most common maintenance therapy was MMF.

Results: A total of 8952 patients met OD criteria and 486 (5.4%) had renal-specific OD medical claim); 30 days for SLE (ICD-9: 710.0 or ICD-10: M30.X); 64 [IQR: 45–84] ml/min/1.73 m². The lupus cohort predominantly consisted of females and class IV lupus nephritis. Many patients of Hispanic ethnicity identified as White with respect to race. At the time of lupus nephritis diagnosis, antibody status, serum creatinine, and urine spot protein/creatinine ratio were similar among ethnicities. Hispanics were more likely to be non-infected and use ibuprofen. The most common maintenance therapy was follow by MMF, and the most common maintenance therapy was MMF.

Conclusions: In patients with SLE and OD, annual costs increased after OD diagnosis. A similar increase in annual costs was observed for patients with renal-specific OD at index. Glidman DD and Urowitz MB. Lupus. 1999;8:632–7.

PO1924

Characteristics of Lupus Nephritis in a Cross-Sectional Study of Hispanic and Native American Patients in New Mexico

Jaime (James) A. Vondenberg, Saeed K. Shaffi. University of New Mexico, Albuquerque, NM.

Background: In patients with lupus, nephritis develops in ~50% of patients, and is associated with significant morbidity. Therefore, it is important to characterize the demographic and biochemical variables associated with lupus nephritis. In this cross-sectional study comprised of many Hispanics and Native Americans, we investigate the demographic and biochemical variables at the time of lupus nephritis diagnosis.

Methods: We identified 62 patients with lupus nephritis from the University of New Mexico kidney biopsy registry that contains biopsies from 2002-2016. Demographics, comorbidities, outcomes, therapies, and laboratory data typically followed in lupus patients (complements, spot urine protein/creatinine (Pcr/Cr) ratio, urine RBCs, serologies, etc) were collected from the registry and medical charts.

Results: 62 patients were included, 53 females and 9 males. White, Hispanic, and Native American races accounted for 35.5%, 30.6%, and 16.1% of the cohort, while 56.6% of patients identified ethnically as Hispanic. 3 patients had no labs. Overall mean age at the time of renal biopsy was 34.5 (SD 15.3) years old. Laboratory data among ethnicities is shown in Figure 1. Class IV was the most common classification in the whole cohort (48.5%), for Hispanics (56.7%), and Non-Hispanics (30%). Antibody status was similar among all ethnicities: ANA positive (95%; 80% titer ≥ 1:80), anti-dsDNA positive (73%), anti-Smith positive (56%), and SS-A positive (56%). The most common comorbidities were hypertension (n=46) and depression (n=16). For induction therapy, 11 patients received low dose cyclophosphamide (CYC) (41%), and Non-Hispanics received mycophenolate mofetil (MMF) (35%). For maintenance therapy, both Hispanics (37%) and Non-Hispanics (35%) most often received MMF. 7 patients progressed to ESKD, by ethnicity: 5 Hispanic and 2 Unavailable (1 African American). Male and pulse methylprednisolone treatment within 1 month were independent risk factors of sepsis in patients with lupus nephritis (P<0.05).

Conclusions: In patients with SLE and OD, annual costs increased after OD

Conclusion: We demonstrated the utility of CI and assessing interstitial regions in predicting renal prognosis. The 2016 classification can predict the clinical outcomes more precisely than the 2003 classification.

Resolution of Immune Deposits in the Glomeruli of Patients with Lupus Nephritis (LN)
Ana Malvar,1 Valeria G. Albertson,2 Karina Fayolle,2 Rocío A. Jones,2 Pedro J. Davilla Terreros,2 Bruno J. Lococo,2 Brad H. Rovin,1 1The Ohio State University, Columbus, OH; 2Hospital Fernandez, Buenos Aires, Argentina.

Background: Patients with proliferative LN have severe glomerular immune injury that resolves over time with treatment. The extent of resolution has been assessed by the fractional charge index (FCI) which patients who have had a repeat kidney biopsy during maintenance immunosuppression, and many patients do achieve an AI=0, so-called histologic remission. The fate of glomerular immune complexes in treated LN patients has not yet been characterized. This study examined the immunofluorescence (IF) patterns in biopsies obtained during LN therapy.

Methods: A cohort of Hispanic LN patients (n=89) was studied. All patients had biopsy-proven (Bx1) proliferative (Class III, IVaV) LN, and were treated with corticosteroids plus cyclophosphamide or MMF for 6 months and then switched to MMF for maintenance therapy. After a median of 42 (range 30-52) months patients had a second protocol biopsy (Bx2) to determine if they had achieved histologic remission (AI=0) or had persistent histologic activity (AI>1). Kidney biopsies were evaluated by standard IF microscopy (IgG, IgA, IgM, C3, C1q), and semi-quantitatively graded on a scale of 0-3 (not present-bright).

Results: cyclophosphamide (48%). These patients had a median serum creatinine of 0.7 mg/dL (0.5-2.2) and proteinuria of 0.2 g/dL (0-8.0). The 26 patients who had persistent histologic activity at Bx2 had a median AI of 2 (1-6), serum creatinine of 0.75 mg/dL (0.6-1.1), and proteinuria of 0.2 g/dL (0.1-0.9) and about half had been treated with MMF. No residual IF was present in 30% of patients with an AI of 0, but was present in all patients who had an AI>1. IF for IgG became negative in 46% of patients with an AI=0 between Bx1 and Bx2, but in only 7.7% of patients with AI1 (P=0.0005). Similarly, IF for C3 became negative in 84% of patients with AI=0, compared to 31% of patients with AI>1 (P=0.0001). After a median of 23 months (11-39) 7 patients who had been in histologic remission suffered an LN flare. None of these patients had complete resolution of IF on Bx2. In contrast, no patient with an AI=0 and an absence of IF on Bx3 had an LN flare during a follow-up of 44 months (19-105).

Conclusions: About one third of patients with LN can achieve histologic and immunologic kidney remission. These patients appear to have an outstanding long-term kidney prognosis.

Vasculopathy Associated with Lupus Nephritis (Severity and Outcomes)
Marcial Torres, Muhammad Alqudsi, Juan Carlos Q. Velez, Muner Mohanned. Ochsner Clinic Foundation, Ochsner Health System, New Orleans, LA.

Background: Lupus nephritis (LN) is common in patients with systemic lupus erythematosus. Classification, prognosis, and treatment considerations of LN relyas mainly on kidney biopsy features. Although few observational studies showed LN with vasculopathy has more severe course, literature reviews are scarce and mostly from Asian populations. The goal of the study was to shed more light on severity and response to Immunosuppression (IS) therapy in this subgroup of LN.

Methods: This is a single center retrospective chart review of LN patients from 2010-2019. Inclusion criteria were adult patients with native kidney biopsy proven LN documented in chart. Patients with systemic thrombotic microangiopathy (TMA) or possible secondary cause of renal TMA (other than SLE) were excluded. Two groups were identified for comparison, LN without vasculopathy (WOV) and LN with vasculopathy (WV). Vasculopathy was defined from kidney biopsy as vascular sclerosis (at least grade 3A). Patients with LN-WV induction IS regimen was MMF in 52%, and CYC in 23%. At baseline, mean baseline serum Cr, Alb, and UPCR remained similar (p = 0.59, 0.49, and 0.64 for 6 months, and 0.34, 0.41, 0.53 for 12 months). No difference was found in ESRD events: 7 (18%) in LN-WOV and 8 (15%) in LN-WV, p = 0.86.

Conclusions: In our cohort, both groups of LN-WO and LN-WV showed no statistical difference in the severity of presentation, nor in response to IS therapy assessed at 6 and 12 months follow-up of Cr, Alb, and UPCR, and ESRD. Hence, LN-WV was not associated with ominous outcomes or more resistance to IS.

Urine Epidermal Growth Factor Levels Are Associated with Kidney Prognosis in Lupus Nephritis
Juan M. Mejía,1 John P. Shapiro,2 Xiaolan Zhang,3 Cristinocruz,1 Grant R. Zimmerman,1 Rossa A. Méndez,1 Samir V. Parikh,2 Haikady N. Nagaraja,3 Luis E. Morales-Buenrostro,1 Brad H. Rovin.1 1Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; 2The Ohio State University Wexner Medical Center Dorothy M Davis Heart and Lung Research Institute, Columbus, OH; 3Department of Biotistics, School of Public Health, The Ohio State University, Columbus, OH.

Background: Epidermal growth factor is a protein specifically synthesized in the kidneys. EGF urine levels have been associated with progressive chronic kidney disease. This study evaluated the role of urine epidermal growth factor (uEGF) as a biomarker of chronic kidney damage in lupus nephritis (LN).

Methods: Through a proteomic approach we identified uEGF as a biomarker of interest in an LN discovery cohort. The expression of uEGF was characterized in two large multiethnic LN cohorts, and the association between uEGF at flare and long-term outcomes assessed in a subset of 120 patients. The expression of uEGF over time was observed in two longitudinal LN cohorts in which serial urine samples were collected.

Results: The proteomic analysis showed lower uEGF in patients with active LN than in normal controls. The peptide sequence was consistent with the proEGF isoform, and this was confirmed by immunoblotting. These findings were verified by ELISA. Patients with active LN had a significantly lower levels of uEGF than patients with active non-renal lupus, patients with inactive lupus, and kidney donors. Urine EGF was inversely correlated with the kidney biopsy chronicity index (r=−0.67, p<0.001). Multivariate survival analysis showed that uEGF at flare was associated with the time to doubling of serum creatinine (HR 0.88, 95% CI 0.77-0.99, p=0.045). In patients who progressed to doubling of serum creatinine (Figure 1A) and end-stage kidney disease (Figure 1B), uEGF was lower at flare and then decreased over the 12 months following flare. A uEGF cutoff of 44 months identified all patients who progressed to end-stage kidney disease.

Conclusions: Urine EGF levels correlate with histologic kidney damage. Low uEGF levels at flare and decreasing uEGF levels over time are associated with adverse long-term kidney outcomes.

Idiopathic Hypokalemia in Lupus Nephritis: A Previously Unrecognized Entity
Emmanuel A. Adomako,1 Saira Bilal,3 Yu-Lun Liu,1 Ayesha M. Malik,2 Kamalnathan K. Sambandam.1 1University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2Aga Khan University, Karachi, Pakistan; 3George Washington University Medical Faculty Associates, Washington, DC.

Background: The lupus nephritis (LN) population at Parkland Hospital is among the largest in the country. During the course of usual care in this population, we encountered a phenomenon of unexplained hypokalemia that has never been previously described. Here we begin to phenotype this cohort by comparing it to a group of LN controls as well as LN with distal renal tubular acidosis (RTA).

Methods: From our population of 403 LN patients followed in the Parkland Hospital and Immunology System, we identified a cohort of 20 patients with idiopathic hypokalemia (HK). This cohort is compared to 90 LN controls (control) and 10 LN patients with distal RTA (RTA). In contrasting the three groups, the Chi-squared test or Fisher’s exact test were used for categorical data and the one-way ANOVA or Kruskal-Wallis test was used for continuous measures. For paired comparisons of continuous variables between the groups, the student’s t-test was employed.

Results: The HK cases had lower mean serum potassium compared to control and RTA (3.24 vs 4.06 to 3.75 mmol/L, respectively; P= 0.001). The mean serum bicarbonate was normal in HK and control but lower in RTA (25.83 vs 25.20 vs 19.28 mmol/L, respectively; P= 0.001). The urine pH was abnormally high only in the RTA group (6.13 vs 6.22 vs 19.28 mmol/L, respectively; P= 0.001). There were differences in serologic markers of autoimmunity. Compared with control, both HK and RTA were more likely to be seropositive for anti-RNP (P= 0.002 and 0.15, respectively). In contrast, compared to controls, only HK expressed a higher rate of anti-RNP seropositivity (P= 0.002) and only control-RTA had a higher rate of anti-SSB positivity (P= 0.044).

Conclusions: A syndrome of idiopathic hypokalemia was revealed in 20/403 (5%) of patients within our lupus nephritis population and is distinct from the RTA that is
known to rarely occur in lupus. This phenomenon has not been previously described. We speculate that this hypoplastic holokemia is the result of a novel target of autoimmunity in lupus affecting renal tubular transport.

Outcomes of Lupus-Related Glomerular and Tubulointerstitial Disease: Analysis of the National Inpatient Sample

Ehzokie Edgin,1 Precious Eseaton.2 John H Stronger Hospital of Cook County, Chicago, IL; University of Benin Teaching Hospital, Benin City, Nigeria.

Background: The study aims to compare the differences in outcomes of hospitalizations for Systemic Lupus Erythematosus (SLE) with glomerular and tubulointerstitial related renal disease. The outcomes compared were inpatient mortality, hospital length of stay (LOS), and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient hospitalization database in the United States (U.S). The NIS was searched for adult SLE hospitalizations with lupus-related glomerular and tubulointerstitial disease as principal or secondary diagnosis using ICD-10 codes. The analysis was done using STATA. Multivariate logistic and linear regression analysis was used accordingly to adjust for confounders for the outcomes.

Results: There were combined 71 million discharges included in the 2016 and 2017 NIS database. 51,875 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE with lupus-related renal disease. 51,525 (99.3%) and 350 (0.7%) of these hospitalizations were for SLE with lupus-related glomerular and tubulointerstitial disease respectively. The mean age for SLE with lupus-related glomerular disease was 40.6 vs 44.2 years for lupus-related tubulointerstitial disease (P<0.004), 7,060 adult SLE hospitalizations resulted in inpatient mortality, 1,110 (2.14%) of the deaths occurred in SLE with lupus-related glomerular disease. The number of deaths for lupus-related tubulointerstitial disease was less than 10, hence it was omitted during the analysis by STATA. SLE with lupus-related glomerular disease had similar LOS (6.4 ± 6.7 days, p=0.865) and total hospital charges ($79,718 vs $83,006, p=0.961) compared to those with tubulointerstitial disease.

Conclusions: SLE with glomerular disease makes up the vast majority of SLE with lupus-related renal hospitalizations. Almost all the in-hospital deaths of SLE patients with lupus-related renal disease occurred in SLE with glomerular disease. LOS and total hospital charges were similar between hospitalizations for SLE with lupus-related glomerular and tubulointerstitial diseases.

PO1931
Lupus Podocytopathy Systematic Review

Ivan L. Claudio-Gonzalez, Ajai S. Rajabalani, Jose E. Navarrete, Jason Cobb. Emory University Woodruff Health Sciences Center, Atlanta, GA.

Background: Patients with lupus, can present with a renal lesion distinct from the ones described by the ISN/RPS classification of lupus nephritis called lupus podocytopathy. Lupus podocytopathy has been described as minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in patients with SLE with or without mesangial involvement but without proliferative or membranous lupus nephritis features. We have gathered the available data on lupus podocytopathy and analyzed it to provide a comprehensive report in this review.

Methods: We searched electronic databases including pubmed and google scholar, using keywords related to lupus podocytopathy and synonyms and treatment from inception to December 2019. Articles retrieved were screened for relevance, including reference list of retrieved. We included cohort studies, case series, and retrospective studies. Individual case reports were excluded.

Results: The search identified 8 studies, of which 6 were included with a total of 107 patients. The patients were predominantly female (88%). The average age was 35 years. Studies done outside of China had predominantly African-American patients 72.5%. The average serum creatinine was 2.06 mg/dL. The average proteinuria was 6.5 g/day. Four studies reported monotherapy corticosteroids, and three studies reported varied treatments. The average follow up was 3.7 years. Complete remission was reported to be 67% from 3 studies. Four studies reported relapse rate of patients, and it accounted to 72.5% of patients.

Conclusions: Our study is the first systematic review of lupus podocytopathy. The strength of this study is the merger of data from known studies in lupus podocytopathy which is a rare but important disease entity in lupus patients with renal disease. The treatment and possible prognosis of lupus podocytopathy patients are different from proliferative and membranous lupus nephritis, and physicians should be aware of this process. Patients can be spared from unwarranted immunosuppressive medications and their side effects. Greater collaborations and biopsies are needed to learn more about this interesting disease process.

PO1932
Extended Follow-Up of Patients Recruited to a Randomized, Controlled Trial of Rituximab vs Azathioprine, After Rituximab Remission Induction for Patients with Relapsing ANCA-Associated Vasculitis

Rona M. Smith,1,2 David R. Jayne,1,2 Peter A. Merkel.1 University of Cambridge, Cambridge, United Kingdom; 2Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 3University of Pennsylvania, Philadelphia, PA.

Background: RTX is an effective remission induction therapy in AAV. However, the effect of RTX is not sustained, and relapse rates are high, especially in patients with a history of relapse. The RITAZAREM trial was an international, open-label, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy, after induction of remission with RTX, of repeat dose RTX or AZA as relapse prevention strategy.

Methods: Patients with relapsing AAV received induction therapy with RTX and glucocorticoids (GC). If remission was achieved by month 4, patients were randomized 1:1 to receive RTX (1000 mg every 4 months for 5 doses) or AZA (2 mg/kg/day) as maintenance therapy for 24 months. Patients continued to be followed until at least 36 months after enrolment, with a primary outcome of time to disease relapse. The final patient reached month 36 in the trial in November 2019.

Results: 190 patients were enrolled and 170 randomized at month 4 (85 to RTX; 85 to AZA): median age = 59 years (range 19-89); prior disease duration = 5.3 years (0.4-38.5); 123/170 (72%) with anti-PR3 ANCA, 47/170 (28%) with anti-MPO ANCA; 161 (94%) enrolled after a severe relapse, 66/170 (39%) after a non-severe relapse; GC induction regimen: 48/170 (28%) higher-dose, 122/170 (72%) lower-dose; 114 (67%) patients had prior renal involvement. We previously presented the results demonstrating the superiority of rituximab over azathioprine during the maintenance treatment period. Results of the follow up phase of the study after discontinuation of maintenance therapy will be presented at the 2020 meeting.

Conclusions: The results of the extended phase of RITAZAREM will examine the long-term impact of B cell depletion in patients with AAV on sustaining remission beyond the treatment period, clinical or biomarker factors associated with risk of relapse, and post-treatment safety of prolonged use of rituximab, including a focus on hypomunoglobulinemia.

Funding: Other NIH Support - The VCRG is funded through collaboration between NCAVC and the National Institute of Arthritis and Musculoskeletal and Skin Diseases, and has received funding from the National Center for Research Resources (U54 RR019497), Commercial Support - Genentech/Roche

PO1933
Renal Disease During Maintenance Treatment in ANCA-Associated Vasculitis (AAV) Remains a Problem and Glucocorticoid Use Is High

Peter A. Rutherford, Dieter K. Goette. Vifor Pharma Ltd, Glatthurg, Switzerland.

Background: AAV is a relapsing remitting long term condition and patients are at risk of organ damage from active AAV and therapy in particular glucocorticoids (GC). The remission maintenance phase of AAV is critical for good long term renal outcomes. This retrospective study examined the pattern of renal disease during the maintenance phase in AAV patients managed in routine clinical practice.

Methods: 1478 AAV patients managed by 493 EU physicians (61% Nephrologists) who completed induction therapy for organ/life threatening AAV and initiated therapy between 2014-16 were studied. Data were collected from when maintenance was determined to begin by the physician and then after 6, 12, 18 and 36 months.

Results: 49% had GPA; mean age 54.2 years and 56% male. 49% had incident AAV and 51% were studied from relapse. 70% received cyclophosphamide/GC and 36% received rituximab/GC with 28% plasma exchange. Physicians defined time of start of maintenance as mean of 5.7 months from diagnosis. Over 36 months from maintenance start 38% patients had relapse (26% 1, 8% 2, 3% 3 and 1% 4). Only 22% had no morbidity at diagnosis, hypertension and renal impairment were common. eGFR CKD stage changed over time - stage 5 (8% to 11%), stage 4 (12% to 8%), stage 3 (43 to 37%) and stage2/3 (38 to 46%) – mean at 36 months of 53.3 ml/min. Hypertension and renal impairment were frequent comorbidities and renal related AEs were often reported. Many patients stayed on GCs and renal impairment and hypertension as well as active/chronic vasculitis activity were more frequent in patients remaining on GCs throughout maintenance. Renal function worsened in 24% patients and 46% were still receiving steroids vs 35% and 37% of those with improved or unchanged renal function (p<0.05)
PO1934
Cost-Effectiveness of Maintenance Therapy with Azathioprine vs. Rituximab (Tailored vs. Fixed-Schedule) in Adults with Generalized ANCA Vasculitis in Colombia
Kateir Contreras, Viviana Orozco Ortiz, Eduardo J. Puche Carrascal, Paola Garcia, Camilo A. Gonzalez, Patricia Rodriguez, Diego Rosselli. Hospital Universitario San Ignacio, Bogota, Colombia.

Background: Azathioprine has been the drug of choice for maintenance therapy in patients with generalized ANCA vasculitis. However, recent studies show that rituximab, a high-cost biological agent, which can be administered in two different schedules, might be more effective, so it is now necessary to know the cost-effectiveness. Our goal was to compare the cost-effectiveness of the 3 maintenance schemes: standard therapy with azathioprine; fixed-dose rituximab and rituximab tailored according to CD19 lymphocyte level and ANCA titres, from the perspective of the Colombian healthcare system.

Methods: We designed a 5-year annual cycle Markov model with the following stages: remission, minor relapse, major relapse and death. Transition probabilities were obtained from a systematic review of the literature (Scopus and Pubmed). Following national guidelines for economic studies, costs, in 2018, USD = 2.956 Colombian pesos (COP), were estimated based on national drug registries, and official tariff manuals for professional services. Main outcome was quality-adjusted life years (QALY), using lupus nephropathy as a proxy; values were obtained from Tufts CEA Registry and validated by local expert panel through a modified Delphi technique. Cost-effectiveness threshold was three-times per capita GDP (USD 17253). Discount rate was 5%. Univariate and probabilistic sensitivity analyses were performed.

Results: Overall discounted 5-years costs were USD 1536 for azathioprine; USD 4750 for tailored rituximab and USD 6162 for fixed rituximab. QALY gains were 2.94, 3.63 and 3.64, respectively. Both tailored and fixed rituximab were cost-effective (cost per QALY gained: USD 4.919 and USD 6.865 respectively), but tailored dosing was preferable due to its lower cost. Sensitivity analyses did not modify these results significantly.

Conclusions: To our knowledge this is the first economic evaluation that compare azathioprine with tailored and fixed rituximab regimens as a vasculitis maintenance treatment in adults with ANCA generalized. Due to its lower effectiveness azathioprine should not be the first line of treatment. Tailored rituximab should be a better option than fixed schedule due to its lower cost with similar effectiveness.

PO1935
Use of Subcutaneous IgG to Treat Hypogammaglobulinemia in ANCA-Associated Vasculitis
Sam Kant, Antoine Azar, Eric J. Gapud, Duvuru Geetha. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Intravenous immunoglobulin (IVIG) has been used to treat ANCA vasculitis (AAV) patients with recurrent infections as a result of hypogammaglobulinemia. Subcutaneous immunoglobulin (SCIG) has a better safety and tolerability profile. We characterized the clinical features, treatment and outcomes of AAV patients treated with SCIG).

Methods: We conducted a retrospective chart analysis of 187 patients in our AAV database to identify patients with recurrent infections and hypogammaglobulinemia subsequently treated with SCIG. Patient demographics, clinical characteristics, treatment and immunological parameters were assessed.

Results: Of the 187 patients identified with AAV, 6 were treated with SCIG. All were Caucasian, PR3 positive and majority (n=4) were females. All patients had pulmonary involvement, and regimens of cyclophosphamide (CYC) and/or rituximab (RTX) were employed for induction and remission. Ig levels (IgG, IgM, IgA) were reduced in all patients. CD19/CD20 B cells were depleted, and CD3/4/8 and NK cells were preserved in all patients. The majority of patients (n=4) experienced recurrent URRs, 3 had shingles in addition to other infections(table 1). All patients had no discernible IgG antibody response to pneumococcal vaccine. Mean duration between first rituximab administration and initiation of SCIG was 6.4 years. Four patients continued to receive RTX every 6 to 12 months while 2 patients remained in remission off RTX for over 2 yrs. IgG levels normalized and none of the patients had recurrence of infections after initiation of SCIG

PO1936
Glucocorticoid Maintenance Therapy and Severe Infectious Complications in ANCA-Associated Vasculitis
Clausdus Speer1, Christian Nussbag,1 Florian KÖBBLE, Christian Morath,1 Martin G. ZIEER, Raoul Bergner,2 Matthias Schauer.1 University of Heidelberg, Heidelberg, Germany; 2Clinical Center Ludwigshafen, Ludwigshafen, Germany.

Background: Although treatment and outcomes in anti-neutrophil cytoplasmic autoantibody associated vasculitis (AAV) have been improved over the last decades, intensified immunosuppressive burden is concurrently associated with life-threatening adverse effects which are the main cause of death during the first year after disease onset. Our study evaluates the impact of cyclophosphamide (CYC) induction dose and glucocorticoid maintenance dose and duration on patient outcomes with an emphasis on infectious complications.

Methods: A total of 130 AAV patients from two different German Vasculitis Centers diagnosed between 2004 and 2019 treated with CYC for induction therapy and glucocorticoids a mycophenolate mofetil or azathioprine for maintenance therapy were included in this study. We evaluated the impact of CYC dose for induction therapy and glucocorticoid dose and treatment duration for maintenance therapy on time to relapse, kidney function, infectious complications, irreversible physical damage and mortality. Patients were separated into four groups: <3g versus ≥3g cumulative CYC dose and <7.5mg after 6 months versus ≥7.5mg glucocorticoids after 6 months.

Results: The baseline demographic and disease characteristics were comparable between groups. Cumulative CYC dose had no impact on relapse rate, kidney function, infectious complications or mortality. Patients receiving ≥7.5mg glucocorticoids after 6 months had an increased rate of infectious episodes per patient (0.6 vs. 1.7; p<0.001). Urinary tract infection (p=0.007), pneumonia (p=0.003) as well as opportunistic pneumonia (p=0.022) and sepsis (p=0.008) appeared more frequently. Especially pneumonia during the first 24 months after disease onset (hazard ratio, 3.0 [95% confidence interval (CI), 1.5 – 6.1]) led to more death by infections (p=0.034). Patients ≥65 years with ≥7.5mg glucocorticoids after 6 months were at particular risk for infectious complications. Glucocorticoid maintenance therapy had no impact on relapse rate or kidney function after the last follow-up.

Conclusions: An extended glucocorticoid maintenance therapy may induce severe infectious complications leading to an increased frequency of death by infection, has no effect on time to relapse and should therefore be critically revised throughout the aftercare of AAV patients.

PO1937
Country Differences Exist in the Treatment of ANCA-Associated Vasculitis (AAV), but High-Dose and Prolonged Glucocorticoid Use Is Observed Across Europe
Peter A. Rutherford, Dieter K. Goette. Vifor Pharma Ltd, Glatthurg, Switzerland.

Background: European AAV guidelines recommend remission induction therapy with combination of high dose glucocorticoids (GC) and rituximab (RTX) or cyclophosphamide (CYC) and maintenance therapy with either RTX or azathioprine (AZA). This retrospective study examined the pattern of prescribing, including the use of GCs, across Europe in AAV patients managed in routine clinical practice.

Methods: 1478 AAV patients managed by 493 rheumatology centers in France, Germany, Italy, Spain and UK who completed induction therapy for organ or life threatening AAV(49%
Validation of a Clinical-Pathologic Renal Risk Score in ANCA-Associated Glomerulonephritis: The US Experience

Sam Kang,1 Silke R. Brix,2 Francesca Costigliolo,1 Paride Fenaroli,1 Avi Z. Rosenberg,1 Duvuru Geetha,1 Johns Hopkins University School of Medicine, Baltimore, MD; 3Manchester Royal Infirmary, Manchester, United Kingdom

Background: The prognostication of renal disease in the setting of ANCA-associated vasculitis (AAV) continues to pose a significant clinical challenge given lack of validated clinical and pathologic correlates. A risk score has been developed by a German consortium (Brix et al Kidney International 2018), to stratify risk of AAV-related renal disease progression to ESKD. We applied this risk score in our cohort of AAV patients to ascertain its reproducibility.

Methods: A single center retrospective cohort study was performed reviewing 148 renal biopsies of patients with AAV GN. Data for score calculation was available of 119 patients with a median follow up of 58 months (IQR 28 – 97 months). Three parameters were used in the risk prediction score: (1) # of normal glomeruli (N0 >25%, N1 10-25%, N2 <10%), (2) tubular atrophy and interstitial fibrosis (T0 <25%, T1 >25%) and (3) eGFR at the time of diagnosis (G0 >15, G1 <15). A weighted assignment of points to each parameter was as follows: N1 [4], N2 [6], T1 [2], G1[3], and the resulting aggregate risk score used to classify predicted ESRD risk was low (0), intermediate (2 to 7), or high (8 to 11 points).

Results: In the cohort of 148 patients, median age was 62 years and mean eGFR at diagnosis was 27.7. Seventy-six were MPO, 57 were PR3 positive and 15 were ANCA negative. With regards to risk stratification, 34 were in low risk category, 59 in the medium risk category and 26 patients in the high-risk category. Overall, 23 patients (15.3%) progressed to ESKD with 2 (5.9%), 11 (18.6%), 10 (58.8%) in low, medium and high risk groups, respectively. A Kaplan-Meier survival curve (Figure1) demonstrates worsening of renal survival across the risk groups (p=0.0035).

Conclusions: This AAV renal risk score was able to reliably predict risk for progression to ESKD. A further analysis revalidating cut-offs and risk score points would likely refine the score improving its prediction accuracy.

AAV prescribing (**p<0.05 vs respective highest/lowest country)

PO1938

Clinical Features and Outcomes of Anti-Neutrophil Cytoplasmic Autoantibody-Associated Vasculitis in Chinese Elderly and Very Elderly Patients

Ting Meng, Departments of Nephrology, Xiangya Hospital Central South University, Xiangya Hospital Central South University, Changsha, China.

Background: Anti-neutrophil cytoplasmic autoantibody-associated vasculitis (AAV) is predominantly a disease of the elderly, and the incidence increases with age. However, there are few data focusing on the clinical features in elderly-onset AAV, especially in very elderly-onset AAV in China. The aim of this study was to explore whether elderly-onset AAV shows any specific clinical features and outcomes in Chinese patients.

Methods: We performed a retrospective study in Xiangya Hospital, a mixed tertiary medical center in south China. A total of 177 patients presenting with AAV were included between January 1, 2010 and December 31, 2017. Patients were divided into younger group (age<65 years) and older group (age65-74 years) which was sub-divided into elderly group (age 65-74 years) and very elderly group (age 75 years).

Results: We found patients in the very elderly group had more chest and cardiovascular involvement (P<0.033 and P=0.017). Older AAV patients had less renal involvement and lower serum C4 level (P = 0.003 and P = 0.001). Very elderly AAV patients had lower platelet counts. Patients in the younger group had a higher level of BVAS among three groups (P<0.05 younger group vs. very elderly group; P<0.05 younger group vs. elderly group). There were no significantly difference in the proportion of ISRD patients among the three groups (P = 0.473). Patients in the very elderly group had the poorest patient survival (P = 0.002).

Conclusions: Older AAV patients had less renal involvement, lower serum C4 level and BVAS. The very elderly group got the most chest and cardiovascular involvement and had lower platelet counts. Older age is associated with higher mortality in AAV patients.

PO1940
Validation of the Renal Risk Score for ANCA-Associated Glomerulonephritis in a National Irish Cohort
Jennifer Scott,1 Silke R. Brix,2 Laura M. Slattery,3 Michelle Clíncie,3 Mark A. Little.1 Trinity Health Kidney Centre, Trinity College Dublin, Ireland 1Trinity Health Kidney Centre, Dublin, Ireland; 2The University of Manchester, Manchester, United Kingdom.

Background: Histopathological examination is currently the gold standard for diagnosis of ANCA-associated glomerulonephritis (AAV GN). However, the commonly used Berden score is inconsistent at predicting renal outcomes across different cohorts. Furthermore, treatment related morbidity remains a major problem. Brix et al. recently published a clinic-pathological score to predict End-Stage Kidney Disease (ESKD), using 3 parameters to stratify patients into 3 risk groups. Parameters include: percentage normal glomeruli (N0 ≥25% = 0 points, N1 10 to 25% – 4, N2 <10% = 6), percentage tubular atrophy and interstitial fibrosis (T0 ≥25% = 0, T1 ≥25% = 2), and estimated glomerular filtration rate at the time of diagnosis (G0 >15 ml/min/1.73 m2 = 0, G1 ≥15 ml/min/1.73 m2 = 3). The ultimate aim is to use this to personalise treatment, enabling the optimal balance of toxic immunosuppression for every patient.

Methods: The Rare Kidney Disease (RDkD) registry is an Irish national longitudinal, multi-centre, cohort study which includes 567 AAV patients, to date, diagnosed using the European Medicines Agency Algorithm (1990-2019). Patients with Granulomatosis with polyangiitis (Wegener’s), Polymyalgia Rheumatica and positive PR3 or MPO serology were included in our validation of the renal risk score.

Results: 248 patients, of whom 43 (17.3%) developed ESKD and 35 (14.1%) died, over a median follow up of 32 months (interquartile range, IQR 5-95 months), were identified. Outcome data and histology were available for 205 patients. Forty-five patients were in the lowest risk group (group 1) - (2.4%) of which developed ESKD. Eight (6.8%) of the 93 patients in the middle risk group (group 2) reached ESKD. Sixty-seven patients were in the highest risk group (group 3) and 28 (41.8%) of them required permanent renal replacement therapy. Kaplan-Meier survival analysis demonstrated a difference in renal outcome between the 3 risk groups (p < 0.0001).

Conclusions: The proposed renal risk score accurately predicts ESKD in patients with AAV GN, in our national Irish cohort. The next step is to further refine the predictive cut-off values for the 3 clinic-pathologic parameters using a regression tree analysis.

PO1941
Hypocomplementemia Is Associated with More Severe Renal Disease and Worse Renal Outcomes in Patients with ANCA-Associated Vasculitis: A Retrospective Cohort Study
Aglaia Chalkia,1 Konstantinos Thomas,2 Panagiota E. Giannou,1 Zoe Alexakou,2 Athanasia Kapota,3 Christina Tsalapaki,3 Dimitrios Vassilopoulos,2 Dimitrios I. Petras.1 1Nephrology Department Hippokration General Hospital, Athens, Greece; 2Joint Rheumatology Program, NPIA or Mamic Kardiotissia (NπΠ), with biopsy proven AAV GN and positive PR3 or MPO serology were included in our validation of the renal risk score.

Background: The complement system has been recently proposed to play an important role in the pathogenesis of ANCA associated vasculitis (AAV). Real life data assessing its predictive role in renal outcomes are limited. In this study, we evaluated the value of serum and kidney deposited C3 in predicting renal outcomes in patients with AAV.

Methods: In this retrospective study, patients with AAV were categorized according to their baseline serum C3 levels as hypo- or normocomplementemic and to those with positive or negative kidney biopsy immunofluorescence (IF) for C3. Clinical, serologic, treatment and histopathologic characteristics, as well as prognosis between the 2 groups were compared.

Results: Forty-seven patients (51% men) were enrolled with a mean age at diagnosis of 65 years and were followed up for a median period of 56 months. At baseline, 23% (11/47) of the patients were hypocomplementemic (C3 <75 mg/dL). These patients were older (74 vs. 65 years, p=0.013), had higher creatinine levels (4.9 vs. 2.2 mg/dL, p<0.006), were more often hemodialysis dependent (64% vs. 19%, p<0.009) and progressed more often to ESRD (55% vs .11%, p=0.01) compared to normocomplementemic patients (n=36). On univariate analysis, serum C3 at diagnosis (HR=16.8, 95% CI: 1.354-206.62, p=0.028) and low serum C3 (HR=2.492, 95% CI: 0.537-11.567, p=0.044) were independent predictors for ESRD. Among 25 patients with kidney biopsy data, those with positive IF staining for C3 (56%, n=14) had more often a mixed histological pattern (72% vs. 27%, p=0.033), low serum C3 levels (42% vs. 18%, p=0.001) and serious infections during follow-up (57% vs. 18%, p=0.047) compared to those with negative (n=11) IF staining.

Conclusions: The subgroup of patients with AAV and low C3 levels at diagnosis (23%) have more severe renal disease and outcomes (ESRD) compared to patients with normal C3 levels. This should be taken into account in therapeutic and monitoring strategies.

PO1942
Clinical Features and Treatment Outcomes of Patients with Paucl-Immune Vasculitis with and Without a Medical History of Autoimmune Disease
Sophia Lionaki,1 Smaragdi Marinaki,1 Sofia Fragioudaki,1 Emmanouel Kalaitzakis,1 Petros Kalogeropoulos,1 Georgios Liapis,2 Athanasia Tzioufas,1 Ioannis Boletis.1 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece.

Background: A proportion of patients with pauc-immune vasculitis (PIV) report a past medical history (PMH) of other autoimmune disorder prior to the diagnosis of vasculitis. The purpose of this study was to identify the differences, if any, between patients with PIV with or without a PMH of other autoimmune disease prior to the onset of vasculitis.

Methods: Among 304 patients with biopsy proven PIV at any site, detailed information regarding their PMH was available in 235 patients (77.3%). Of these, 60 (25.5%) reported a PMH of other autoimmune disorder including Sjogren syndrome, Crohn’s disease, autoimmune thyroiditis, psoriasis, rheumatoid arthritis, and scleroderma.

Results: The clinical characteristics and outcomes of the two groups are displayed in [table 1].

Conclusions: Patients with a PMH of other autoimmune disorder prior to the diagnosis of PIV were predominantly P/MPO-ANCA positive, had less impaired kidney function at presentation and a lower probability of relapse after achieving remission, compared to patients without a PMH of autoimmunity.

PO1943
Low Serum C3 at Diagnosis of Paucl-Immune Glomerulonephritis Is Associated with More Advanced Kidney Impairment and Worst Renal Prognosis
Sophia Lionaki,1 Smaragdi Marinaki,1 Sofia Fragioudaki,1 Emmanouel Kalaitzakis,1 Sofia Fragioudaki,1 Petros Kalogeropoulos,1 Georgios Liapis,2 Athanasia Tzioufas,1 Ioannis Boletis.1 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece.

Background: Recent evidence supports the notion that complement activation plays a critical role in pauci-immune (PI) vasculitis pathogenesis. The aim of this study was to investigate if the clinical, serological and laboratory characteristics and treatment outcomes of patients with PI glomerulonephritis (GN) with low serum complement levels at diagnosis differ from those of patients with complement values within the normal range.

Methods: In a retrospective design we studied patients with biopsy proven PIGN with available serum complement measurements at diagnosis, or during a relapse, prior to initiation of immunosuppressive therapy. All patients were tested for anti-neutrophil cytoplasmic antibodies (ANCA) at presentation. Fisher’s exact tests and Wilcoxon rank sum tests were used to compare the characteristics by serum C3.

Results: Of 96 patients included in the study, 22 (23.9%) had low serum C3 at diagnosis. Comparison of clinical, serological and laboratory characteristics and outcomes between the two groups is shown in [table 1].

Conclusions: Almost one quarter of patients with biopsy proven PIGN had low serum C3 at diagnosis in this cohort. These patients had more advanced renal impairment, required acute dialysis more frequently and were more likely to end up in end-stage kidney disease compared to patients with serum C3 within the normal range.
PO1944

**Serum and Urinary Metabolites Discriminate Disease Activity in ANCA-Associated Glomerulonephritis**  
**Sam Kant, Anne Le, Nabeel Attarwala, Duvuru Geetha. Johns Hopkins University School of Medicine, Baltimore, MD.**

**Background:** Relapse of disease and treatment related morbidity due to lack of a reliable biomarker for disease activity continue to be a significant issue in patients with ANCA associated vasculitides (AAV). Renal biopsy is currently gold standard for reliable detection of active disease. Metabolomics have been used to successfully discern disease activity in a number of autoimmune diseases. We sought to investigate the use of serum and urinary metabolomics to discriminate disease activity in AAV associated GN.

**Methods:** Ten patients with AAV renal disease having serum and urine supernatant sample collections during active and remission phases of disease. Active renal disease was defined by presence of hematuria >5 RBC/hpf, urinary RBC casts or an increase in serum creatinine >30% or < in eGFR by 25% or biopsy proven GN. The samples were then extracted and targeted metabolomics data acquisition using a Thermo Scientific Q Exactive plus Orbitrap Mass Spectrometer Plus with a Vanquish UPLC at our metabolomics facility.

**Results:** The mean age in this cohort was 61 years, with 6 patients each being male and Caucasian. Nine patients had biopsy proven renal disease, with clinical diagnosis in one. Mean BVAS and mean GFR was 17 and 28 respectively. Intensities of urinary citrate and iso-citrate are significantly higher in the remission group compared to the active group (Fig 1A). Similar trend of higher citrate and iso-citrate intensities present in serum of patients in remission versus active disease (Fig 1B). There was a disproportionately high intensity difference in citrate and iso-citrate levels in serum and urine samples compared to other metabolites of the TCA cycle implying involvement of additional metabolic pathways.

**Conclusions:** This study indicates that serum and urinary citrate and iso-citrate may be utilized to monitor disease activity in AAV and emerge as an alternative to kidney biopsy.

PO1945

**Renal Involvement in Granulomatosis with Polyangiitis Does Not Increase Inpatient Mortality Compared with No Renal Involvement**  
**Phizhog Edgin,1 Precious Eseason,2 Augustine Manadan.1,2 John H Strger Hospital of Cook County, Chicago, IL; 1University of Benin Teaching Hospital, Benin City, Nigeria; 2Rush University Medical Center, Chicago, IL.**

**Background:** The aim of this study was to analyze the difference in outcomes of Granulomatosis with polyangiitis (GPA) with and without renal involvement. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

**Methods:** Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the United States. The NIS was used for adult GPA hospitalizations with and without renal involvement as the principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

**Results:** There were 71 million discharges included in the combined 2016 and 2017 NIS database. 23,670 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for GPA. 8,265 (34.92%) and 15,405 (65.08%) of these hospitalizations were for GPA with renal and without renal involvement respectively. Inpatient mortality occurred in 1.0% (GPA) patients (5.1%) compared to 0.9% (5.1%) who had deaths occurred in GPA with renal involvement vs 585 (3.8%) without renal involvement (p=0.0287). The adjusted odds ratio (AOR) of inpatient mortality for GPA with renal compared to without renal involvement was 1.14 (95% CI 0.84-1.56, p=0.406). GPA with renal involvement hospitalizations had a mean increase in adjusted mean LOS of 1.36 days (95% CI 0.82-1.91, p<0.0001) compared to GPA without renal involvement. GPA with renal involvement hospitalizations had an increase in adjusted total hospital charges of $18,723 compared to GPA without renal involvement (95% CI 9,595-27,852, p<0.0001).

**Conclusions:** There was no statistically significant difference in inpatient mortality for hospitalizations of GPA with and without renal involvement. However, LOS and total hospital charges in GPA with renal involvement were higher than those without renal involvement. Hence GPA with renal involvement has a greater burden to the healthcare system compared to without renal involvement.

PO1946

**Immunological Indexes Both in Renal and Serum Were Associated with Inflammatory and Patient Outcome in Chinese Patients with Myeloperoxidase-ANCA-Associated Glomerulonephritis**  
**Wei Lin, Zhong Yong. Department of Nephrology, Xiangya Hospital, Central South University, China, Changsha, China.**

**Background:** Rapidly progressive glomerulonephritis (RPGN) caused by antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are typically characterized by few or no immune deposits in glomerular which was defined as pauci-immune glomerulonephritis (GN). Immune complex (IC) deposits in glomerulus and acute tubular necrosis (ATN) has also been reported in AAV with ANCA. Patients with AAV in China are positive for anti-myeloperoxidase (MPO), which more frequently had renal involvement and developed RPGN. Therefore, it is necessary to assess serum immunological indexes and the IC deposits in renal in MPO-ANCA-associated GN.

**Methods:** To determine clinical and immunological characteristics of AAV in Chinese patients. Clinical and immunological indexes were measured on admission. Immunological indexes (anti-MPO, anti-PR3, anti-GM, anti-GBM, anti-citrullinated protein antibody (AICA-Ab)) were detected. The diagnosis was retrospectively analyzed.

**Results:** Patients with low sC3 (<790 ml/L) and low sC4 (<100 ml/L) at diagnosis showed poorer renal survival compared to patients with normal value (p=0.003, 0.011). Moreover, among patients of low sC3 at diagnosis, the cases with persistent low sC3 showed obviously worse renal survival than those whose sC3 recovered to normal after treatment (p<0.001). There are 41%(40/97) patients showed positive IF findings (a≥2 on a 0 to 4+ scale) for at least one Ig or complement component. In our study, the patients with IC deposits showed higher level of serum creatinine (p=0.01) and lower platelet counts (p=0.009), sC3 level (p=0.031) than patients with pauci-IC deposition at diagnosis. We also found IgG deposits related to worse renal outcome than the negative cases (p=0.047). What’s more, complement C1q deposits displayed significant poorer patient survival than the cases without C1q deposits (p=0.001).

**Conclusions:** Patients with a persistent low sC3 showed poorer renal prognosis than the patients whose sC3 level return to normal after a period of treatment, which was confirmed that both initial and continuously low sC3 can act as predictive indicators for renal outcome. IgG and complement C1q deposits associated with poorer renal and patient outcome, which can help to judge the prognosis of MPO-ANCA-associated GN to some extent.

PO1947

**Rituximab vs. Cyclophosphamide in the Treatment of Anti-GBM Crescentic Glomerulonephritis: An Observational Study**  
**Ajay Jarval, Sanjay Vikrant. Indira Gandhi Medical College, Shimla, India.**

**Background:** Anti glomerular basement membrane (GBM) crescentic glomerulonephritis (CsGN) is a rare disease affecting kidneys and/or lungs. At present most of the evidence for its treatment is with use of plasmapheresis (PP), high dose steroids (HDS) and cyclophosphamide (CYC). The use of Rituximab (Rtx) in addition to PP and HDS is only anecdotal. Herein, we are describing our experience with the use of both regimens.

**Methods:** A retrospective analysis of all the patients with anti GBM CsGN admitted in our hospital from September 2018 to November 2019 was done. Anti GBM CsGN was diagnosed on the basis of 50% crescents on kidney biopsy and immunofluorescence showed IgG deposition along GBM and/or by the presence of anti GBM antibodies. Rsults: 11 patients were admitted with anti GBM CsGN, during this period (15 months). Kidney biopsy was done in 10 patients and in one anti GBM GN was diagnosed on the basis of raised anti GBM antibody titres. There were 8 females and 3 males (age range 37-72 years). The mean serum creatinine was 8.69mg/dl. Out of 11 patients 2 refused for treatment and 2 were lost to follow up. 3 out of 7 patients had diffuse alveolar hemorrhage (DAH) and in all it succeeded renal involvement (one had diagnosis of usual interstitial pneumonia for 1 year). 4 out of 11 patients had concomitant urinary tract infection, 5 out of 7 (71.42%) were ANCA positive, 2 out 11 had type 2 diabetes mellitus, 5 out of 11 were oligoanuric and 7/11 (63.6%) were dialysis requiring at presentation. PP was given on alternate days. Both the patients who refused for treatment died on follow up. Among remaining 7 patients 5 had received PP+HDS + CYC and 2 had received PP+HDS+Rtx. In CYC group 4 all (4 were dialysis dependent and 3 were oligoanuric) out of 5 patients died whereas in Rtx group both the patients survived (one was dialysis dependent and oligoanuric).
Conclusions: In our study most of the patients presented late to the hospital due to vague symptoms at the onset (mean 30 days) and few had co-existing UTI (this delayed the treatment). 63.6% were dialysis requiring at presentation and DAH was the most common cause of in-hospital death. Two out the three survivors achieved normal eGFR (one in CYC and one in RTx arm) whereas third one had no progressive decline in eGFR (RTx). The use of RTx along with HDS and PP showed favourable outcomes in our study.

PO1948
Impact of Race on Hospitalization Outcomes for Goodpasture Syndrome in the United States

Juan A. Medrano,1 Charat Thongprayoon,2 Michael A. Mao,3 Boonchomphon Boonporn,4 Wisit Kaewpun,5 Wisit Cheungpasitporn.1 Division of Nephrology, Department of Internal Medicine, University of Mississippi Medical Center, Jackson, MS; Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 1Phramongkutklao College of Medicine, Bangkok, Thailand; 2Department of Medicine, Mayo Clinic, Jacksonville, FL; 3Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA.

Background: Goodpasture’s syndrome is a rare and life-threatening autoimmune disease. While Goodpasture’s syndrome is well described in Caucasian and Asian populations, its prevalence and outcomes among African Americans and Hispanic populations are unclear. We conducted this study to assess the impacts of race on hospital outcomes among patients with Goodpasture’s syndrome.

Methods: The National Inpatient Sample database was used to identify hospitalized patients with a principal diagnosis of Goodpasture’s syndrome from 2003-2014. Goodpasture’s syndrome patients were grouped based on their race. The differences in hospital treatments and outcomes between Caucasian, African American, and Hispanic Goodpasture’s syndrome patients were assessed using logistic regression analysis.

Results: 964 patients were hospitalized with a primarily diagnosis of Goodpasture’s syndrome. Of these, 786 were included in the analysis: 622 (65%) were Caucasian, 73 (8%) were African American, and 91 (9%) were Hispanic. The need for mechanical ventilation, non-invasive ventilation support, and renal replacement therapy in African Americans and Hispanics were comparable to Caucasians. There was no significant difference in organ failure, sepsis, and in-hospital mortality between African Americans and Caucasians. In contrast, Hispanics had higher in-hospital mortality than Caucasians but similar risk of organ failure and sepsis.

Conclusions: African American and Hispanic populations account for 8% and 9% of hospitalizations for Goodpasture’s syndrome, respectively. While there is no significant difference in in-hospital mortality between African Americans and Caucasians, Hispanics with Goodpasture’s syndrome carry a higher in-hospital mortality compared to Caucasians.

PO1949
Overlap Syndrome of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis and IgG4-Related Disease: Distinct Clinicopathologic Clues for Precise Diagnosis

Peifen Liang,1 Qiongqiong Yang,1 Wenfang Chen,2 Shuling Yue,3 Qianqian Han,4 1Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; 2Department of Pathology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3Guangzhou KingMed Center for Clinical Laboratory Co., Ltd, Guangzhou, China.

Background: Both antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and IgG4-related disease (IgG4-RD) are multi-system inflammatory disorders. The coexistence of both diseases present the possibility of a new overlap syndrome which leads to different treatment and outcome. In this study, the symptomatic and pathological concurrence of AAV and IgG4-RD is investigated to explore the possibility and clinicopathologic clues to the diagnosis of this overlapped syndrome.

Methods: A case of a 67-year-old man in our hospital who exhibited the characteristics of both AAV and IgG4-RD was presented. The treatment response and outcome of the case were followed up for the next 15 months. Then, a systematic literature review of the overlap syndrome of AAV and IgG4-RD was performed on PUBMED database from 1976 until January 2020.

Results: Mild hematuria with rapid progressive renal failure of the patient was observed while renal biopsy revealed pauci-immune crescentic glomerulonephritis, especially with IgG4-related tubulointerstitial nephritis. Glucocorticoids combined with cyclophosphamide therapy led to partial remission. Literature review of 52 cases met both AAV and IgG4-RD criteria as overlap syndrome and four common clinicopathologic features were identified. First, atypical clinical and laboratory manifestations were characteristics of this entity. Second, positive MPO-ANCA are more common. Third, tissue symptoms showed overlapping histological patterns when kidneys were involved. Fourth, the combination of glucocorticoids and immunosuppressive therapy was often required and led to a remission within 3 months.

Conclusions: AAV may overlap with IgG4-RD while presenting atypical manifestations. Four common clinicopathologic characteristics could be used as specific clues to the diagnosis of overlap syndrome.

PO1950
Anti-IL-5 Therapy in Eosinophilic Granulomatosis with Polyangiitis (EGPA): An 18-Month Follow-Up Study of a Steroid-Sparing Therapeutic Approach

Allyson C. Fegan,1 Pasupathy Sivasothy, Robin B. Gore,1 Caroline M. Owen,1 Rachel B. Jones,1 Rona M. Smith,1 Lisa C. Willcocks,1 Stella M. Burns,1 David R. Jayne.2 Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 1University of Cambridge, Cambridge, United Kingdom.

Background: EGPA is a small vessel vasculitis with protein renal manifestations including necrotizing glomerulonephritis, eosinophilic interstitial nephritis and obstructive uropathy. In the randomized, placebo-controlled MIRRA trial for relapsing and refractory EGPA, adjuvant therapy with 300mg anti-IL-5 mAB Mepolizumab (MEPO), accrued lesions in remission, reduced steroid exposure and reduced relapse rates.

Methods: The aim of our study was to analyze the outcome for EGPA patients who received 100mg s/c of MEPO monthly for 18 months and beyond. This retrospective, descriptive study analyzed 13 patients with EGPA, who received 100mg s/c of MEPO therapy monthly. Time points of assessment included MEPO commencement [M0] and ≥ 18 months [>M18].

Results: This study demonstrates that anti-IL-5 therapy serves as a favorable model for steroid minimization in EGPA, with an overall 50% reduction in steroid dosage. Additional reduction in conventional immunosuppressants was also observed in 3 patients. ANCA positive serology normalized in all four patients. Well tolerated, it demonstrated considerable clinical benefit, with 12 patients [92.3%] continuing anti-IL-5 therapy beyond 18 months. Renal function was preserved. One patient had MEPO switched to Rituximab to treat both EGPA and new onset rheumatoid arthritis. Three patients were switched to alternative anti-IL5 therapies, benralizumab (x2) and Reslizumab (x1).

Conclusions: The relapsing nature of EGPA places a potential dependency of therapy on steroids, underscoring the importance of targeted pathway specific biologics to minimize steroid exposure, prevent tissue damage and ensure early response to therapy. This is a 50% reduction in steroid dosage in this study, with preserved renal function.

PO1951
Pauic-Immune Lupus Nephritis: A Case Report

Bharath Suraveyara, Anvita Anne, Varun Kumar Bandi. Dr. Pinnanenii Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disease with multisystem involvement, and Lupus nephritis (LN) typically shows immune deposits on biopsy. Pauic-immune LN is a rare entity.

Case Description: A 35 year old female presented with pedal edema, reduced urine output & yellowish discoloration of eyes since 20 days. No vomiting, dysnea, joint pains, rashes, or hematuria. She had similar episodes in 2011 and 2013 & was given blood transfusion and oral steroids. She is a hypertensive for 10 years and diabetic for 2 years. She had 2 normal vaginal deliveries with no obstetric complications. On examination she had pancytopenia and generalized edema, blood pressure of 170/90mmHg. Rest of the examination was normal. She had severe anemia, renal failure, positive ANA, dsDNA and direct Coomb’s test, with normal complements. There was no evidence of acute hemolysis. SLE was consistent with Auto immune hemolytic anemia (AIHA) and probable lupus nephritis (LN) was diagnosed. Steroid pulse was started with stabilization of renal function and mebipoglobin. Renal biopsy showed necrotising crescentic glomerulonephritis with no endocapillary proliferation. Immunofluorescence did not show any immune deposits. A diagnosis of pauci immune LN was made, and was started on cyclophosphamide. She had partial renal recovery with creatinine of 1.5 mg/dl, no hematuria, no hemolysis.
PO1952

Pulmonary Renal Connection: A Case of ANCA Vasculitis and Atypical Anti-GBM Antibody Associated with Vaping

Josephine Abraham, Lahir Al-Rabadi, Monica P. Revelo Penafiel, Martin C. Gregory. University Of Utah University of Utah Hospital, Salt Lake City, UT.

Introduction: The use of e cigarettes and vaping is linked to the development of lung injury (EVAlI). We present a case of ANCA (antineutrophil cytoplasmic antibody) vasculitis with atypical Anti GBM (glomerular basement membrane) antibody in a patient with EVAlI.

Case Description: A 17 year old male with a history of vaping presented with acute respiratory failure requiring mechanical ventilation. CT chest revealed diffuse bilateral consolidation. Evaluation for infection was negative. Nephropathy was consulted for acute renal failure. Urine analysis was notable for hematuria and proteinuria. Urine microscopy identified dysmorphic erythrocytes. Renal biopsy showed pauci immune crescentic glomerulonephritis (panel A). ANCA with MPO (myeloperoxidase) specificity and Anti GBM antibody were positive. He was treated with methylprednisolone, therapeutic plasma exchange and oral cyclophosphamide initially and subsequently Rituximab. Four months later his creatinine was 1.2 mg/dL, improved from a peak level of 7.5mg/dL with plasma exchange and oral cyclophosphamide initially and subsequently Rituximab. Four

Discussion: Anti GBM disease had been associated with alveolar injury from exposure to hydrocarbons or smoking. The presence of the erythrocyte casts and positive anti GBM antibody in patients with vaping associated lung injury raises the possibility of pulmonary and renal injury from a common mechanism. While the pathogenesis of vaping associated renal injury is unclear, examination of the urinary sediment should be performed in all patients presenting with vaping associated lung injury and hematuria.

PO1953

Sabotaged: Hydralazine-Induced ANCA Glomerulonephritis

Larissa Krueger comes, Estilida Sula Karrecri, Krishna A. Agarwal, Ruth Schulman, Jeffrey H. William, Stewart H. Lecker, Isaac E. Stillman. Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: While usually well known to cause SLE-like syndrome, hydralazine (HZ) can also be involved in a different clinical scenario with ANCA vasculitis.

Case Description: 77yo woman with hypertension and COPD presents with 2 days of hemoptysis and hematuria, requiring urgent intubation. CT scan reveals multifocal infiltrates and bronchoscopy shows diffuse alveolar hemorrhage. Labs showed Hb of 6.8 and Cr of 1.9. Dysmorphic RBCs were seen in the urine sediment and proteinuria at 1.2g/g. Given concern for anti-GBM, she received 1g of methylprednisolone and plasma exchange. ANA 1:1280 with MPO-ANCA levels >8.0 U, along with positive anti-histone and SCL-70 antibodies, but with negative anti-GBM and ds-DNA. Kidney biopsy showed pauci-immune crescentic GN with trace staining for IgA, IgM, C3, kappa and lambda. As she had been on HZ, the diagnosis of HZ-induced ANCA-associated vasculitis was made. Offending agent was held and cyclophosphamide was started. After 2 months, kidney function returned to baseline, with resolution of proteinuria and hematuria.

Discussion: In patients with HAV, unusually high titers of MPO are present and can be used to differentiate drug-associated and spontaneous cases. A minority of patients can also present with other positive antibodies, such as ds-DNA, anti-histone, or Scl-70. As HZ can also cause SLE-like pattern of injury, it can be difficult to obtain a diagnosis based on serologies alone; biopsy is essential for diagnosis and prognosis. The treatment of HAV involves not only removing the inciting agent, but also further immunosuppression, as HZ is thought to lead to increased expression of MPO and PR3 breaking neutrophil tolerance and leading to auto-antibody formation. When choosing a treatment strategy, guidelines for spontaneous ANCA should be followed; in this particular case, as she had severe lung involvement, cyclophosphamide was chosen.

Rare Case of Silicosis-Induced Pauci-Immune Glomerulonephritis

Sandheep Venkataraman, Matthew Ray, James F. Dylewski. University of Colorado, Denver, CO.

Introduction: Silica exposure is most often associated with pulmonary disease but there have been case reports of RPGN associated with it too. The majority of these patients were MPO positive. T-cell dysregulation and endothelial damage from PMNL free radical generation is a proposed mechanism for this disease. Duration and intensity of silica exposure are known risk factors. In addition to pulmonary-renal symptoms, these patients may have systemic manifestations of lupus, rheumatoid arthritis, scleroderma, or dermatomyositis. More research is needed to further understand the management of these patients. This patient represents a rare case of silica-induced ANCA vasculitis. He was treated with 3 days of IV methylprednisolone, followed by a rapid prednisone taper. He also received IV Rituximab 1 gm on days 0 and 14, plus IV cyclophosphamide 500 mg every 2 weeks for 6 doses starting on day 0. The patient responded well with Cr improving to 1.0 and decreased proteinuria. Unfortunately he relapsed 3 months after last rituximab dose.

Discussion: Silica exposure is most often associated with pulmonary disease but there have been case reports of RPGN associated with it too. The majority of these patients were MPO positive. T-cell dysregulation and endothelial damage from PMNL free radical generation is a proposed mechanism for this disease. Duration and intensity of silica exposure are known risk factors. In addition to pulmonary-renal symptoms, these patients may have systemic manifestations of lupus, rheumatoid arthritis, scleroderma, or dermatomyositis. More research is needed to further understand the management of these patients. This patient represents a rare case of silica-induced ANCA vasculitis. He also received IV Rituximab 1 gm on days 0 and 14, plus IV cyclophosphamide 500 mg every 2 weeks for 6 doses starting on day 0. The patient responded well with Cr improving to 1.0 and decreased proteinuria. Unfortunately he relapsed 3 months after last rituximab dose.

ANCA-Negative Small-Vessel Vasculitis with IgG4-Positive Plasma Cell Infiltration: A Case Report and Literature Review

Huipeng Ge, Cuifang Li, Qiongjing Yuan. Xiangya Hospital Central South University, Changsha, China.

Introduction: Although the histopathology was critically important for differential diagnosis between AAV and IgG4-RD, overlapping morphologies and clinical manifestations put the clinicians in a dilemma of diagnosis sometimes. Here, we described a case of ANCA negative PICGN with IgG4-positive plasma cell infiltration.

Case Description: A 60-year-old male patient presented with cough for 3 months and progressive renal impairment for 8 days. He had elevated serum IgG4 level with absence of anti-neutrophil cytoplasmic antibodies (ANCA). Lung CT as shown in Figure 1. Renal biopsy showed severe tubulointerstitial nephritis (TIN) with extensive infiltration of IgG4-positive plasma cells, suggesting a diagnosis of IgG4-related kidney disease(Figure 2). However, the identification of necrotizing glomerulonephritis and crescents forming and the absence of storiiform fibrosis and obliteratorive phlebitis led to a diagnosis of ANCA negative renal small-vessel vasculitis. The condition was improved by using corticosteroids and cyclophosphamide at beginning.

Discussion: ANCA negative cannot exclude the diagnosis of AAV. The elevated serum IgG4 and/or abundant IgG4-positive cell infiltration can act as one of the manifestations in AAV. ANCA-negative pauci-immune crescentic glomerulonephritis (PICG) might represent an independent disease entity from ANCA positive PICG. Besides, IgG4-related disease (IgG4-RD) is an exclusive diagnosis and needs to be differentiated from vasculitis and other diseases. It is suggested that ANCA-negative PICG with elevated serum IgG4 and/or abundant IgG4-positive cell need to be further studied.

Figure 1. Lung CT in different periods.

Figure 2. Histological findings of the kidney.

Adalimumab-Associated Pauci-Immune Glomerulonephritis: Coincidence or Causation Effect?

Nirav N. Patel, Emma Spangler, Pavan Annamalai. Johnston Memorial Hospital, Abingdon, VA.

Introduction: Adalimumab is a TNF-blocker used in the treatment of hidradenitis suppurativa (HS). Infections, lupus-like syndrome, and lymphoma are known safety concerns with TNF-blockers. We report a rare case of adalimumab associated pauci-immune crescentic GN (PICGN) in a patient with HS.

Case Description: A 19-yr-old male with a history of HS on adalimumab for 6 months was seen on 4/1/20 with a fever of 103°F, cough & epistaxis for 2 weeks. CT sinuses showed polyps and sinusitis. He was treated with antibiotics for sinusitis. CT chest, nasal PCR for COVID-19, blood, and urine cultures were negative. By hospital day 8, he remained febrile and developed AKI [Creatinine (Cr) 9.9 mg/dl; baseline of 0.8 mg/dl]. Physical exam showed chronic scarred skin lesions on the chest and axilla with no signs of infection or rash. Hematuria and microalbuminuria were noted. Ultrasound showed renalomegalgy. Inflammatory markers were high (CRP 254 mg/L, Ferritin 1059 ng/mL), PR3-ANCA antibody was positive 530 IU/mL. A renal biopsy confirmed PICGN (Fig 1). Bone marrow biopsy showed no evidence of hemophagocytosis. The patient was treated with pulse doses of steroids and rituximab and plasma exchange (peak cr 6.4 mg/dl). On a 3-week follow up creatinine improved to 1.8 mg/dl suggesting a favorable outcome. The patient never required dialysis.

Discussion: AKI, microscopic hematuria, and proteinuria can be seen in a febrile illness. However, epistaxis and renomegaly prompted us to check for ANCA serology. To our knowledge, this is the first case of adalimumab associated PICGN in a patient with HS. Interestingly, our patient is much younger compared to previously reported cases (mean 51.4 years). It is possible that adalimumab may be unrelated to the vasculitis; however, due to a strong temporal association, it was felt to be the culprit agent. Nephrologists must be aware of the renal side effects of this class of drugs.
A Case of C-ANCA Associated Retroperitoneal Fibrosis and Periaortitis

Vinay Srinivasan. Darling Downs Health Service, QLD Australia. Darling Downs Hospital and Health Service, Toowoomba, QLD, Australia.

Introduction: Granulomatosis with Polyangiitis (GPA) is a type of small vessel vasculitis that has prevalence rate of 25-150 cases per million population, and a incidental rate of 0.4 cases per 100,000 population per year. Clinical features of the disease involve the respiratory and renal systems. However, large vessels such as the Aorta and retroperitoneal tissue are rarely involved.

Case Description: We present the case of a middle-aged male who presented with an obstructive nephropathy in which abdominal CT revealed a soft tissue mass encompassing the Aorta and Inferior Vena Cava causing obstruction of the Left ureter. Despite ureteric stenting, serum creatinine failed to improve. Further urinanalysis demonstrated an active urinary sediment; hemoproteinuria. Serum c-ANCA and PR-3 antigen titers were positive. Renal biopsy was performed and confirmed pauci-immune vasculitis. The patient was induced with pulsed intravenous methylprednisolone and cyclophosphamide and as part of his maintenance treatment received plasmapheresis and oral cyclophosphamide. On follow up, partial remission has been achieved with his serum creatinine remaining between baseline level and proteinuria reduced, though erythrocytes are still evident. Repeat abdominal imaging has revealed a reduction in the size of the soft tissue mass with treatment.

Discussion: Biopsy proven vasculitis has been shown in patients with retroperitoneal fibrosis. Few case reports and series have described this association, inferring a pathogenic role of ANCA in the development of retroperitoneal fibrosis. Moreover it has been suggested that retro peritoneal fibrosis may be an early clinical manifestation of ANCA associated vasculitis. Consequently, ANCA associated vasculitis should be considered in the differential diagnosis of any patient who has Retroperitoneal fibrosis and an active urinary sediment.
A Case of Lupus Podocytopathy (LP) with Focal Segmental Glomerulosclerosis (FSGS): Is It Time to Add LP to the Next Revision of the Classification of Lupus Nephritis?

Introduction: Lupus podocytopathy is not included in the commonly used International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification of Lupus Nephritis (LN). It has been reported in literature for the last 20 years. LP can have pathologic transition with variable outcomes. We describe a case of LP with FSGS in a young male patient with subsequent relapse.

Case Description: 25 year old male with past history of lupus without nephritis and chronic immune-mediated thrombocytopenia presented with generalized fatigue. Physical exam revealed diffuse rash and vital signs were within normal limits. Relevant laboratory findings included platelet count of 21000/microliter, acute kidney injury with creatinine (Cr) of 1.6 mg/dl (baseline Cr of 0.8 to 1.1 mg/dl), spot urine protein creatinine ratio of 4.3 g, 24 hour urine protein of 4.1 g, low C3 and C4, hemoglobin of 9.6 g/dl and WBC count of 3.6/microliter. Serology was positive for ANA, dsDNA and SAA indicating active lupus flare. Left kidney biopsy showed mild mesangial expansion, no endocapillary proliferation and subtotal (>80%) podocyte foot process effacement. No subendothelial or subepithelial deposits were seen. He was treated with pulse dose steroids followed by oral steroids and serum Cr came back to baseline. Subsequently he was treated with mycophenolate mofetil 2 g/day. At 2 weeks, proteinuria came down to 1.8 g/day and by 12 weeks he achieved remission. However at 6 months, he had urine protein of 8.5 g in 24 hours with increase in Cr to 2.4 from 1.6, suggesting relapse.

Discussion: The presence of minimal or no capillary wall immune deposits with or without mesangial proliferation and effacement of podocyte foot processes in the setting of nephrotic range proteinuria is collectively termed as LP. LP must be considered in patients with lupus presenting with NS (Nephrotic Syndrome). It is cardinal that we consider adding this distinct entity in the classification of lupus nephritis.

Minimal Change Disease in Systemic Lupus Erythematosus: An Infrequent Variant

Ehsun Naecm, Paul S. Kellerman, Saima Mansuri. Beaumont Health, Royal Oak, MI.

Introduction: Lupus Nephritis (LN) is thought to complicate the disease course of almost half of all patients diagnosed with Systemic Lupus Erythematosus (SLE). While nephrotic syndrome (NS) in these patients is usually due to type IV/V Lupus Nephritis (LN), it may in rare instances occur secondary to minimal change disease (MCD), a phenomenon known as Lupus Podocytopathy (LP). We report a case of a young female with LP with concomitant Acute Tubular Necrosis (ATN).

Case Description: 40 year old female, known case of SLE (not on maintenance immunosuppression) and Hypertension presented with bright red blood per rectum and dyspnea for 2 weeks. Review of systems was pertinent for generalized swelling and facial rash. On initial assessment, she was hypertensive and physical exam revealed facial swelling, discoid rashes and 2+ lower Extremity edema bilaterally. Workup revealed Normocytic Anemia, Acute Kidney injury, Hyperkalemia and Metabolic Acidosis. Urine studies showed nephrotic-range proteinuria and hematuria but were negative for casts. Free K/L ratio was high at 2.32 and C3 levels low at 42 mg/dl. Ultrasound guided kidney biopsy showed mild thickening of GBM and dilated tubules with diminished brush borders in the absence of crescentic changes. Electron Microscopy noted diffuse fusion of foot processes, along with rare intramembranous deposits. Immunofluorescence revealed a full house staining pattern within the Mesangium and the patient was diagnosed with Lupus Podocytopathy with concurrent LN Type 1. Substantial reduction in proteinuria was seen with a brief course of Prednisone.

Discussion: Our patient with SLE presented with NS and AKI, features typical of membranous/proliferative LN. Interestingly, her biopsy findings provided little evidence of endocapillary proliferation or sub-epithelial IC deposits and were more consistent with MCD. The suggestive of Lupus podocytopathy: LP is rare to the extent that it does not form part of the official WHO classification for LN and has only been described a handful of times in prior literature, mostly in the form of case reports. However, given its prognostic implications, LP remains an important consideration in the evaluation of NS in SLE patients. While patients with Type IV/V LN require aggressive immunosuppressive therapy, patients with LP frequently respond well to steroids alone and have a much slower progression of disease.

Oliginacut Protects Renal Function and Podocytes in In Vivo and In Vitro Models of Podocytopathies

Emmanuel S. Buyu, 1 Ehtesham Arif, 2 Suzana Marusic, 1 Deepak Nihalani, 2 Cynternet, Cambridge, MA; 1 Medical University of South Carolina, Charleston, SC, 1 Hooke Laboratories, Lawrence, MA.

Background: The nitric oxide (NO) receptor soluble guanylate cyclase (sGC) is a signal-transduction enzyme producing the secondary messenger cGMP. Impaired NO-sGC-cGMP signaling is associated with renal dysfunction. sGC stimulators, such as olinciguat, which enhance NO-mediated cGMP signaling, improve renal function in animal models of cardiac injury.

Methods: We studied the renoprotective effects of olinciguat, a clinical-stage sGC stimulator, by studying in vitro and in vivo models of glomerular injury.

Results: In an acute focal segmental glomerulosclerosis (FSGS) model of glomerular injury induced by nephrotoxic serum (NTS), treatment with olinciguat attenuated proteinuria and kidney pathology when compared to vehicle-treated mice. Additionally, olinciguat treatment prevented NTS-induced mislocalization of the slit diaphragm proteins synaptopodin and nephrin. Ultrastructural analysis by transmission electron microscopy revealed that podocyte foot process morphology was preserved in mice treated with olinciguat. To further assess the protective effect of sGC stimulation on podocytes, human podocytes injured by exposure to proline-sulfate (PS) were treated with olinciguat. Olinacutin stimulation restored PS-induced damage of podocyte actin cytoskeleton organization and the localization of podocyte cell membrane proteins. In the genetic MRL/MpFas−/− mouse model of systemic lupus erythematosus (SLE), disease progression, assessed by interstitial inflammation and albuminuria, was significantly reduced in mice treated with the positive control cyclophosphamide or with olinciguat than in vehicle-treated mice. Fewer kidney lesions (interstitial infiltrates, tubular atrophy, tubular epithelium vacuolation, tubular and interstitial lesions, and glomerular lesions) were observed in mice treated with cyclophosphamide or olinciguat than in vehicle-treated mice. In contrast to cyclophosphamide, olinciguat treatment did not result in leukopenia, reduction in spleen weight, or lower anti-dsDNA antibody in serum, suggesting that olinciguat did not impact the auto-immune aspect of SLE.

Conclusion: In summary, olinciguat, an orally bioavailable sGC stimulator, exhibits significant renoprotective effects in nonclinical models and warrants further evaluation for the treatment of FSGS, other podocytopathies, or nephropathies associated with diseases such as sickle cell disease.

Oliginacut in a Rat FSGS Model

Yossi Danon, Hari Raghu, Tingting Ge, Liron Walsh, John F. Reilly. Goldfinc Bio Inc. Cambridge, MA.

Background: Activation of Rac-related C3 botulinum toxin substrate 1 (Rac1) plays a key role in podocyte injury and dysfunction in focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). In diseased podocytes, Rac1 activation is mediated by calcium influx through the transient receptor potential canonical 5 (TRPC5) ion channel. GFB-887 is a sub-type selective, small molecule inhibitor of TRPC5 that reduces albuminuria in deoxycorticosterone acetate (DOCA)-salt and ZSD rat models of FSGS and DN, respectively. Here, we aimed to develop a urinary biomarker to assess podocyte Rac1 activity in kidney disease and in response to GFB-887 treatment.

Methods: Using a sandwich ELISA, we measured Rac1 concentrations in sera of male rats treated with GFB-887 in a rat FSGS model following treatment with GFB-887, and in urine from healthy volunteers, FSGS, DN and Alport patients.

Results: Rac1 was detected in extracellular vesicles (EV) isolated from podocyte culture supernatant and rat and human urine. GFB-887 treatment lowered urinary Rac1 concentrations in normal and DOCA-salt rats, and the decreased Rac1 was associated with decreased albuminuria in the DOCA-salt rats. Urinary Rac1 concentrations were markedly elevated in FSGS and DN but not in Alport patients.

Conclusion: The TRPC5 inhibitor, GFB-887, targets the TRPC5-Rac1 pathway and suppresses urinary Rac1 associated with its therapeutic action in a rat model of FSGS. Urinary Rac1 concentrations are markedly higher in FSGS and DN compared to healthy subjects, but not elevated in Alport. GFB-887 is efficacious in rodent models of FSGS and DN, but not in Alport, suggesting that elevated urinary Rac1 is predictive of response. Together, these data support the potential for clinical utilization of urinary Rac1 as a pharmacodynamic and predictive biomarker for GFB-887 treatment in FSGS and DN. GFB-887 is currently being studied in TRACTION™, a Phase 2 clinical trial in FSGS and DN which baseline and on-treatment urinary Rac1 measurements will support further development of the biomarker.

PO1966

A Novel In Vivo Approach to Capture the Podocyte Foot Process Proteome

Lori L. O'Brien, Gary F. Gerlach. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Podocytes are an extraordinary cell of the kidney filtration system with their tentacle-like foot processes flowing out from each cell body and interdigitating with neighboring processes. Proper kidney function relies on these cells and the complex architecture created by the interdigitating processes. They are the most critical component of the glomerular filter. Podocytes are injured and their integrity is compromised in the majority of kidney diseases leading to progressive proteinuria. However, we know little about the full complement of proteins localized to the foot process and how they change with disease.

Methods: We have developed a novel genetic mouse model capable of generating a spatially restricted, real-time, in vivo proteome. Recently, proximity labeling techniques have been developed to provide snapshots of spatially localized proteomes. The BioID method utilizes a promiscuous bacterial biotin ligase flexibly linked to a target protein of interest to biotinylate proteins within the vicinity. We have adapted this approach to identify the podocyte foot process proteome. Using podocin as a handle, we have modified the Nphs2 (podocin) locus to link the mutated, promiscuous BirA biotin ligase to podocin (Nphs2^{BioID}). A flexible, 13x linker allows for a generous proximity around podocin, thereby capturing the broad proteome of the podocyte foot process.

Results: We have obtained viable Nphs2^{BioID}{+/-} animals. Utilizing immunostaining, we have confirmed the proper expression and localization of the podocin-BioID. The HA-tagged BirA ligase appended to podocin coloculated with podocin and other foot process proteins. To test it's functionality, we injected biotin dialy for 7 days. This produced an increase of biotinylated proteins in Nphs2^{BioID}{+/-} podocytes versus wild type biotin injected controls or un.injected Nphs2^{+/-} mice. We have affinity purified the biotinylated proteins from glomerular isolations and are currently performing proteomic analyses.

Conclusions: We have generated the first of it's kind in vivo mouse model to specifically identify the spatially localized proteome of the podocyte foot process. Our proteomics results will provide unprecedented insights into the make-up of this highly specialized and critical structure.

Soluble RARRES1 Induces Apoptosis of Podocytes to Promote Progression of Kidney Disease

Anqun Chen,1,2 Ye Feng,2 Yu Li,2 Chengguo Wei,2 Tianjun Guan,1 Kyung Lee,1 John C. H.2 1Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China; 2Division of Nephrology, Department of Medicine, Icahn School of Medicine at Mount Sinai, NY, NY.

Background: Podocyte loss is a major event leading to the progression of focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). Here, we found that retinoic acid receptor responder protein 1 (RARRES1) contributes to the podocyte loss in FSGS and DN.

Methods: We determined the role of RARRES1 in human and mouse with FSGS and DN. We investigated the mechanisms of RARRES1 in cultured human podocytes.

Results: The expression of RARRES1 increased in the glomeruli of patients with FSGS and DN and correlated with the eGFR. Single-cell RNA-sequencing of the kidney showed that RARRES1 expressed highly in podocytes. Immunostaining confirmed that podocyte expression of RARRES1 increased in patients with DN and FSGS as compared to MCD. RARRES1 expression was strongly induced by TNF-α in cultured human podocytes. RNA-sequencing of podocytes with RARRES1 overexpression revealed genes enriched in apoptosis. RARRES1 was cleaved into a soluble RARRES1 and the cleavage site was mapped at the aa70. Overexpression of wild RARRES1 or adding soluble RARRES1 in cultured human podocytes induced apoptosis, while overexpression of RARRES1 cleavage mutant lost the apoptotic effect. Further, we showed that soluble RARRES1 underwent endocytosis to interact with intracellular RIO1K1, leading to the activation of p53 and apoptosis in podocytes. In vivo, podocyte-specific overexpression of RARRES1 resulted in marked glomerular injury and albuminuria in mice, while the overexpression of RARRES1 cleavage mutant had no renal phenotype. Finally, knockdown of RARRES1 in podocytes ameliorated kidney injury in mice with adriamycin-induced nephropathy.

Conclusions: We demonstrate a new role and mechanism of RARRES1 in regulation of podocyte apoptosis in glomerular disease, as summarized in the Figure: TNF-α induces expression of RARRES1, which is cleaved, then undergoes endocytosis to interact with intracellular RIO1K1, leading to the activation of p53 and apoptosis. High RARRES1 expression promotes the progression of FSGS and DKD.

The Glomerulus-on-a-Chip as a System to Unravel Novel Membrane Attack Complex (MAC)-Independent Role of Complement in Membranous Nephropathy

Stefano Da Sacco,1 Astigik Petrosyan,2 Susan Hartzell,1 Valentina Villani,1 Chalmi Dedina,1 Andrea Angeletti,3 Joaquin Manrique,4 Roger E. De Filippo,1 Laura P.,1 Paolo Cravedi,1 Infante’s Hospital of Los Angeles, Los Angeles, CA; 2Complejo Hospitalario de Navarra, Pamplona, Spain; 3Università di Bologna, Bologna, Italy; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide due to the deposition of anti-podocyte-antibodies against in the glomerular subepithelial space. While complement deposition is thought to play a crucial pathogenic role, the exact effector mechanism of complement in MN is unclear due to the lack of in vitro and in vivo systems that recapitulate human disease. We have developed a novel glomerulus-on-a-chip system (GOAC) using human primary podocytes and human glomerular endothelial cells (GEC) in combination with OrganoPlates and assessed the functional response to human MN serum and the role of MAC deposition and C3a/C3aR1 signaling in MN pathogenesis.

Methods: GOAC chips were cultured with serum from anti-PLA2R + MN patients or healthy individuals. Functional response was assessed by albumin permeability assay to evaluate selective-permeability. Role of MAC and C3a/C3aR1 signaling pathway in glomerular filtration barrier damage was assessed by immunofluorescence and functional analysis while mechanisms of action were explored by PCR arrays, Western Blotting and immunostaining. Results were confirmed in vitro using podocytes on which C3aR1 was silenced and in vivo using a C3aR1 KO mice model.

Results: Following exposure to sera from MN patients, we have confirmed deposition of human IgG on podocytes and formation of MAC complex, accompanied by albumin leakage. GOAC supplemented with C3aR1 antagonists as well as GOAC using podocytes in which C3aR1 was silenced were able to prevent glomerular filtration damage on the GOAC kidney as confirmed by rescue of permeability efficiency, while inhibition of MAC formation by protein S (an inhibitor of MAC formation) did not significantly reduce GOAC permeability.

Conclusions: We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying renal regenerative and disease mechanisms in proteinuric diseases. Using this model, we showed that C3a/C3R signaling plays a dominant role in complement-mediated MN pathogenesis.

Dach1 Is Essential for Maintaining Normal Podocytes

Keiko Tanaka, Taiji Matusaka. Department of Basic Medicine, Tokai University School of Medicine, Isehara, Japan.

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We, therefore, aimed to elucidate the function of Dach1 in normal podocytes in vivo.

Methods: Podocyte-specific Dach1-knockout (KO) mice were generated by mating Dach1^{Cre} mice with Nphs2{loxP}-{loxP} or Nphs2^{CreERT2} mice. Podocyte injury was evaluated by urinary analysis (SDS-PAGE) and histology. In addition, we analyzed primary cultured podocytes of Dach1 overexpressing knock-in transgenic (KI) mice (n=9), in which Dach1 is expressed under the control of Rosa26 promoter.

Results: Although the efficiency of Cre-mediated recombination was not high, all of the congenital Dach1/KO mice (n=20, more than 4 weeks old) presented abnormal albuminuria. Seven out of the 11 (63%) mice histologically analyzed showed focal segmental glomerulosclerosis. Injured podocytes lacked Dach1 staining, whereas intact podocytes retained Dach1. When Dach1 KO was induced in adult mice, the mice showed abnormal albuminuria within two weeks. Immunostaining revealed that podocytes lacking Dach1 causes leakage of albumin, while retaining WT1 protein. Since endogenous Dach1

608
expression in podocytes is very high with transgenic expression of Dach1 driven by the Rosa26 promoter, we analyzed primary cultured podocytes, in which endogenous Dach1 was downregulated. Dach1 mRNA was 3.8-fold higher (p=0.0007) in Dach1-KI podocytes than in control podocytes. We previously found that Dpp4 is one of the candidate target genes of Dach1 by knockdown experiments. Dpp4 mRNA in Dach1-KI podocytes was found to be increased (1.5-fold, p=0.0022).

**Conclusions:** These results indicate that Dach1 is important in maintaining normal podocyte integrity, and Dach1 gene deficiency induces podocyte injury.

**Dysregulated Dynene-Mediated Vesicle Trafficking Is a New Mechanism of FSGS**

Hua Sun,1,2 Martin R. Pollak,1,3 Beth Israel Deaconess Medical Center, Boston, MA; 1Boston Children’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA.

**Background:** Focal segmental glomerulosclerosis (FSGS) is a deteriorating kidney disease with poor prognosis. The lack of understanding of its mechanism has hindered the development of treatment. Mutations in INCA2 cause FSGS characterized by a podocytopathy with misfolded slit diaphragm (SD) protein critical for the integrity of the glomerular filtration barrier (GFB). This feature has been found in FSGS of other etiologies, making INCA2 related podocytopathy a good model to dissect the disturbed vesicle trafficking in podocytopathies prone to FSGS. By yeast two hybridization screening we identified the interaction of INCA2 with Dynl1, a dynen component. We hypothesize that INCA2 regulates dynen mediated vesicle trafficking, which shuts endocytosed protein to proteolytic system. This interaction could be disrupted by pathogenic mutations in INCA2, suggesting dysregulation of dynen mediated trafficking is an underlying mechanism of FSGS.

**Methods:** The INCA2-Dynl1 interaction was confirmed by yeast mating and CO-IP. The dysregulated dynen mediated trafficking of nephrin was investigated in cultured podocytes by fluorescent based and surface biotinylation based assays, and time-lapse imaging in vitro; and was also demonstrated in the purinomycin aminoglycoside induced nephropathy (PAN) of INCA2 transgenic mice with knockin (KI) of R218Q, a pathogenic mutant that disrupts INCA2-Dynl1 interaction.

**Results:** 1. We demonstrated that INCA2 limited dynen mediated retrograde trafficking of nephrin by binding to and sequestering Dynl1, a component essential for the integrity of dynen. 2. R218Q KI podocytes illustrated an impaired recycling of nephrin with enhanced recruitment of dynen components, which could be rescued by targeting dynen transport pathway using Cilobrevin D (Dynex inhibitor), dominant negative Dynactin 1, siRNA for Dynl1 or overexpression of wildtype INCA2 (to sequester Dynl1). 3. PAR-218Q KI mice was characterized by increased recruitment of Dynl1 to nephrin, correlated to increased ubiquitination and decreased surface nephrin, suggesting an enhanced dynen trafficking pathway underlies the impaired functional trafficking of nephrin, disintegration of SD and malfunction of the GFB.

**Conclusions:** Recognition of the dysregulated dynen mediated trafficking of SD protein has enlightened a new understanding and therapeutic targets for INCA2 related podocytopathy and FSGS.

**Podocyte Cell Cycle Activation During CKD Progression**

Laura Perm,1,2 Camille H. Nicolas Frank,3 Roger E. De Filippis,2 Kevin V. Lembey,1,2 Children’s Hospital of Los Angeles, Los Angeles, CA, 1University of Southern California, Los Angeles, CA.

**Background:** Podocytes, quiescent cells, seem not capable of regeneration to compensate for their loss during CKD progression. Their only adaptive response to loss is through hypertrophy, allowing the remaining podocytes to effectively cover the filtration surface. This adaptive response is associated with signs of cell cycle activation, but podocytes do not divide successfully: they detach from the basal membrane and are lost in urine. How the cell cycle phases modulate this “mitotic catastrophe” is not known. To study the cell cycle in CKD, we used an Alport Syndrome (AS) mouse model characterized by podocyte loss, combined with the Fucci technology which allow the identification of the cell cycle phases using fluorescent reporters: red for G1/S, green for S/G2/M.

**Methods:** We established a mouse model where Fucci proteins are under the control of NPHS2 gene (podocytes specific) and crossed these mice with AS mice to generate AS-POD-Fucci mice. Using flow cytometry, we isolated and evaluated podocytes in different cell cycle phases in WT (males and female) and AS-POD mice. Protein expression of NPHS2 in G1 and G0 podocytes. In vitro studies were performed in primary podocytes damaged with purinomycin.

**Results:** In WT mice (males and females), as expected, 98.1% of podocytes were quiescent (G0). In AS mice, podocyte number in G0 decrease over time: at 2months (mild proteinuria) 89% are in G0, at 6months (end-stage kidney disease) 59% are in G0 while the percentage of podocytes in G1 increased from 7.6% at 2 months to 33% at 6 months. Podocytes were isolated in different cellular states (hypertrophy) along disease progression. In 6months AS WT Hf females (mild proteinuria), only 15% of podocytes are in G1. PAN damage induced podocytes to switch from G0 to G1 phase, and rapamycin (a cell cycle regulator) rescue damage by maintaining cells in G0. Proteomics data showed important differences of cell cycle regulators (cyclins and CKDs, mTor, integrin signaling) between G0 and G1 of WT and AS mice.

**Conclusions:** We demonstrated that podocytes enter their cell cycle (in male and female) to increase of cells in G1 (associated with proteinuria) as the disease worsens. Regulating cell cycle may be pivotal in developing novel therapies to prevent podocyte loss.

**Funding:** Private Foundation Support

**RNA Sequencing and ATAC-Seq Reveal Gene Profiles in Injured Podocytes in Mice, and Podocyte-Specific Hypoxia Inducible Factor 2 α Deletion Protects from Adriamycin-Induced Podocyte Injury**

Xinrnan Liu1,2, H. William Worton3,4, Ernie Tamborero,5,6, Ryo Tokuno,5,6, Ko Hayashida,1,2 Northwestern University Feinberg School of Medicine, Chicago, IL; 1Ann and Robert H Lurie Children’s Hospital of Chicago, Chicago, IL.

**Background:** Roles for hypoxia-inducible factor (HIF) in kidney diseases have been controversial. Upregulating HIF expression is beneficial in protecting kidney from acute injury, while we and others showed that HIF aggravates chronic fibrosis. In podocytes, deletion of VEGFR caused progressive glomerular damage, prevented by overexpression of hypoxia inducible factor 2α. Here, using podocyte-specific HIF-2α deletion mice, we tested effects of HIF-2α deletion on gene profiles in injured podocytes.

**Methods:** HIF-1α1/2-/- or HIF-2α1/2-/- mice were crossed with either NPHS1-/- or Pkd2-/- mice. HIF-2α1/2-/- mice were further crossed with ZiEG mice that express GFP only in cells where Cre is active. At 8 weeks old, the mice were given Adriamycin (12 mg/kg) i.v. two weeks later, urine and blood were harvested. Creatinine and albumin levels in urine and serum, and blood urea urine levels in serum were measured with ELISA kits. Podocytes were isolated from HIF-2α1/2-/- /ZiEG mice by flow sorting and RNAseq and ChIP-seq were performed.

**Results:** HIF-2α-/-; NPHS2-Cre showed preservation of foot processes and kidney functions, and significantly less proteinuria compared to the WT littermates after being subjected to Adriamycin, while HIF-1α-/-; NPHS2-Cre mice developed a similar degree of podocyte injury to that of WT. HIF-1 α or 2α; NPHS1-Cre; ZiEG mice showed little GFP expression in podocytes, suggesting that weak penetrance of NPHS1-Cre led to minimal functional effects. This group was therefore not further evaluated. Podocytes isolated from HIF-2α1/2-/-; NPHS2-Cre; ZiEG were used for RNAseq and ATACseq. In RNAseq, Ndufa12 (ubiquinol cytochrome oxidase subunit A12) was most significantly upregulated in podocytes subjected to ADR, while Slc22a30 [solute carrier family 22, member 30], Slc7a13 [solute carrier family 7, (cationic amino acid transporter, y+ system) member 13] and Pfp [PFEP, alpha-2-macroglobulin like] were most significantly downregulated. Correlation with ATAC-seq results were being processed.
PO1974

Shroom3-FYN Regulates Podomecas via LKB1-AMPK Signaling
Khadija Banu, John M. Basgen, Qisheng Lin, Arun Cumpelik, Lewis Kaufman, Marina Planoutene, Barbara T. Murphy, John C. He, Madhav C. Menon. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Previously, we showed Shroom3–FYN interaction regulated podocyte cytoskeleton via FYN activation. Intriguingly, global shroom3 knockdown mice (CAGS-TG/Shr3 Kd) displayed reduction in glomerular volume-V glom, podocyte & endothelial fraction of V glom without podocytopenia [1a].

Methods: To examine mechanism of podomecas regulation by Shr3, we used Shr3 & FYN Kd human podocytes (hPodo) to study cell protein content & growth regulatory pathways; performed unilateral nephrectomy examining V glom hypertrophy in remnant kidneys

Results: At day-7, CAGS-TG mice showed restricted V glom hypertrophy with reduced expansion of PodoV glom vs NTGs [1b]. We observed reduced hPodo volume (FSC), Protein:DNA ratios (n=5; P<0.01) & inhibited ribosomal biogenesis (18S RNA) in vitro & in vivo suggesting reduced protein synthesis and FYN to be downstream of Shr3 in regulating hPodo size. Notably, we observed increased AMPK activation, increased p-EF2 & autophagy (high p-ULK1 and LC3II levels) downstream of AMPK, in vitro/in vivo by immunoblot (IB) & immunofluorescence (IF)[1c] suggesting negative regulation of protein synthesis. Next, we examined LKB1 localization (AMPK-kinase) by IB after subcellular fractionation & IF in Shr3/FYN Kd hPodo identifying increased LKB1/Cytosolic:Nuclear ratio, explaining AMPK activation due to increased cytosolic pool of active LKB1 [1d]. Finally, we used an AMPK inhibitor, Compound C in CAGS-TG mice and observed reversal of podomecas changes-V glom & V podo fractions, induction of podocytopenia with AMPK-inhibition [1e]

Conclusions: Here, we show Shroom3-FYN interaction regulating podomecas via AMPK-signaling in podocytes. The protective morphometric effects have implications to disease models with podocyte/ nephrin loss requiring obligate V glom/Podocyte hypertrophy

The Role of Opioid Receptor Signaling in Podocytes and Renal Damage in Dahl Salt-Sensitive Rats
Daria Golosova, 1 Oleg Patalyn, 1 Vladislav Levenchenko, 1 Christine A. Klemens, 1 Ashraf El-Meanawy, 2 Alexander Starchenko, 1 Medical College of Wisconsin Department of Physiology, Milwaukee, WI; 2 Medical College of Wisconsin Department of Medicine, Milwaukee, WI.

Background: The rise in opioid use underscores the urgent need to better understand the direct and indirect effects of opioids on renal function, especially in patients with chronic kidney disease (CKD) or hypertension. The extensive use of opioids is strongly correlated with poor cardiovascular outcomes. We hypothesize that stimulation of opioid receptors (ORs) elevates intracellular calcium level in podocytes leading to kidney damage and progression of hypertension.

Methods: Freshly isolated glomeruli from Dahl salt-sensitive (SS) rats, human kidneys and immortalized human podocytes were used to elucidate the contribution of specific ORs to podocyte calcium flux. Calcium response in the podocytes was analyzed via ratiometric confocal fluorescent microscopy. For chronic studies Dahl SS rats were on a 0.4% (LS) or 8% (HS) NaCl diet for 14 days with or without a daily intravenous bolus infusion of BRL52375, a potent and selective kappa/OR agonist.

Results: Stimulation of kappa-ORs, but not mu-ORs or delta-ORs, mediated calcium influx in podocytes through activation of TRPC6 channels in rat and human kidney. The effect of BRL52375 was completely abolished when we used the 0 mM calcium media or when SAR7334 (a TRPC6 channel inhibitor) was applied. Triggering the kappa/OR/ TRPC6 pathway induced podocyte cell shape changes via actin cytoskeleton remodeling. In vivo studies revealed that SS rats chronically treated with BRL52375 exhibited augmented blood pressure (MAP was 179 ± 15 mmHg vs. 151 ± 11 mmHg), nephritemia, albuminuria, and elevation in podocyte calcium in BRL52375 treated Dahl SS rats.

Conclusions: Stimulation of kappa/OR modulates calcium influx in podocyte via TRPC6 channels. The opiate-induced increase in the calcium flux in podocytes is expected to contribute to podocytopathy, proteinuria, kidney injury and progression of salt-induced hypertension. These findings are important to advance our knowledge of the pathogenesis of the development of CKD and hypertension in the context of pain management.

Knockout of the Neonatal Fc Receptor (FcRn) Alters Lysosomal Function in Podocytes
Judith Blaine, 1 Madeline D. Ng, 1 Pantipa Tonsawan, 2 Linda Lewis, 1 James F. Dylewski. 1 University of Colorado Denver School of Medicine, Aurora, CO; 2 Khon Kaen University, Khon Kaen, Thailand.

Background: FcRn is a trafficking protein that diverts monomeric IgG from the lysosome but sorts multimeric IgG and immune complexes (ICs) to the lysosome for processing. FcRn is required in dendritic cells to traffic ICs to the lysosome for proteolytic processing and presentation on MHC II. Podocytes express FcRn and previous work has proposed that podocytes can act as antigen presenting cells. Here we show how cultured podocytes are weak antigen presenting cells (APCs) and that knockout (KO) of FcRn in podocytes does not alter podocyte response to an immune stimulus but does result in significant downregulation of lysosomal function.

Methods: Cultured wild type (WT) and FcRn KO podocytes were treated with interferon gamma (IFNγ) to simulate proinflammatory conditions. MHC II and costimulatory marker expression was assessed by flow cytometry. Antigen presentation was evaluated by examining T cell response when WT or FcRn KO podocytes were treated with ICs and used as APCs. Lysosomal size and cellular location in WT and FcRn KO podocytes were examined using confocal microscopy. WT or FcRn KO podocytes were treated with ICs and colocalization of lysosomes and ICs was quantitated. RNA-seq was used to examine lysosomal pathways.

Results: Both WT and FcRn KO podocytes upregulated MHC II after treatment with IFNγ but there was no difference in expression levels between WT and KO. There was no change in CD80 expression between WT and KO after treatment with IFNγ. CD86 and ICOSL expression levels in WT and FcRn KO were minimal at baseline and after treatment with IFNγ. When used as APCs, WT podocytes induced a very modest amount of IL-2 production by T cells (a marker of T cell activation) whereas KO podocytes induced none. After treatment with ICs, lysosomes in WT podocytes were significantly larger and were also clustered around the nucleus, indicative of lysosomal activation. In contrast, after IC treatment lysosomes in the KO were smaller and more peripherally located. Treatment with ICs also resulted in significantly greater colocalization between lysosomes and ICs in WT versus FcRn KO podocytes, demonstrating that ICs were not directed to the lysosome in the KO. RNA-seq showed significant downregulation of lysosomal pathways in KO podocytes compared to WT after treatment with ICs.

Conclusions: FcRn KO in podocytes alters lysosomal trafficking and function.

Apolipoprotein M as a Biomarker of Glomerular Lipotoxicity in Nephrotic Syndrome
Yelena R. Drexler, Judith T. Molina David, Sandra M. Merscher, Alessia Fornoni. University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.

Background: Dysregulation of intrarenal metabolic pathways involved in cholesterol efflux is implicated in lipid-induced podocyte injury in glomerular diseases. Among several genes that are involved in cholesterol efflux, we recently reported a significant downregulation of glomerular apolipoprotein M (APOM) expression in patients with FSGS. HDL-associated APOM facilitates reverse cholesterol transport and is the carrier enzyme responsible for S1P degradation, cause a familial form of FSGS. We hypothesize that glomerular APOM deficiency is a surrogate biomarker for lipid-induced kidney injury in NS.

Methods: Patients with FSGS, MN, and MCD enrolled in NEPTUNE, a multi-center, longitudinal cohort study of children and adults with NS, who were >1 g/g at baseline were selected for analysis. RNA expression data were obtained from the

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

610
glomerular compartment isolated from kidney biopsies and compared with living kidney donors to assess APOM levels by ELISA using matched samples. Linear regression analysis was used to correlate glomerular APOM expression with plasma and urinary levels of APOM and to correlate glomerular APOM expression and plasma and urinary APOM levels with eGFR at baseline.

Results: Among 84 patients, 68% were male, mean age was 40 years, mean baseline eGFR was 80.6 mL/min/1.73m², and mean uPCR was 4.9 g/g. Glomerular APOM expression was decreased in patients with NS compared to healthy controls (p < 0.001), irrespective of histologic diagnosis. APOM expression was positively correlated with plasma and urinary APOM levels in the NS cohort (R² = 0.089, p = 0.003) and in the FSGS subgroup (R² = 0.189, p = 0.0218). Decreased APOM expression (p = 0.005) and decreased plasma APOM (p = 0.031) were associated with a lower eGFR at baseline. After adjustment for age, sex, and race, each unit decrease in APOM expression was associated with a 9.83 mL/min/1.73m² (95% CI, 3.72 to 15.93, p = 0.002) lower eGFR at baseline.

Conclusions: Glomerular APOM deficiency and decreased plasma APOM levels were associated with decreased kidney function at baseline in the NS cohort. These findings identify APOM as a potential biomarker of lipid-induced kidney injury in NS.

The Sensitivity of Podocytes to ATP in Vivo is Distinctly Lower than the Sensitivity of Glomerular Endothelial and Proximal Tubular Cells

Julia Bing,1 Bernhard Scherner,1 Thomas Benzinger,2 Matthias Hackl,1 1Department of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 2CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.

Background: ATP signaling is involved in a plethora of pathways, involving damage signaling. Cell culture models as well as experiments on isolated glomeruli indicate that podocytes respond to ATP with a calcium transient. To date a direct effect of ATP on podocytes in vivo has not been described.

Methods: In this study mice expressing GCaMP3 in podocytes (Pod:cre), proximal tubular cells (Pax8:cre) or endothelial cells (Tie2:cre) underwent multiphoton imaging of the kidney. Mice were anesthetized, an arterial catheter was placed into the right carotid artery or the aorta and the left kidney was exteriorized. The vasculature was labelled with a 70-kDa dextrane. Different doses of ATP were injected as a bolus via the catheter and dose-dependent calcium transients were monitored.

Results: Our data indicates that even doses of 5 mg/kg ATP did not induce calcium transients in podocytes. In contrast, proximal tubular cells as well as a cortical arteriole responded with a calcium transient, while robust activation of calcium signaling was induced in endothelial and proximal tubular cells with 0.5 mg/kg ATP. Further increasing the ATP dose by injection via an abdominal aortic catheter resulted in a calcium transient in podocytes.

Conclusions: In contrast to endothelial cells and proximal tubular cells, podocytes show a low sensitivity to ATP-mediated calcium signaling. We therefore hypothesize, that the low sensitivity ATP of podocytes is a protection mechanism to avoid calcium signals from filtered ATP.

Cytomegalovirus Viremia-Associated Collapsing FSGS in an Immunosuppressed Systemic Lupus Erythematosus Patient

Emily Daniel, Dominick Sappokio, Andrew S. Bornhack, Hilda E. Fernandez, Columbia University Irving Medical Center, New York, NY.

Introduction: Maintaining a broad differential in evaluating AKI in SLE patients with a history of lupus nephritis (LN) is important. We describe a patient with SLE and AKI progressing to dialysis dependence due to collapsing FSGS in the setting of CMV infection.

Case Description: A 23 yo African American F with a history of LN class IV + V (maintained on MMF 1g BID) and APLS presented with one week history of nausea, vomiting and diarrhea. Admission labs were notable for a Cr of 10.5 mg/dl (baseline Cr 0.7), pancytopenia, with albumin of 1.7 mg/dl. Spot urine protein to creatinine ratio was >27 g/g. Serologies showed low C3 and C4, positive ANA, LDI 1437 and negative HIV test. Patient became anuric and required hemodialysis. Stress dose steroids were administered for presumed RPGN from LN. Renal biopsy on hospital day 8 demonstrated collapsing FSGS with 100% podocyte foot process effacement without significant IFTA and 4/9 globally sclerotic glomeruli. Testing revealed CMV viremia with viral load of >700,000 IU/mL. MMF was held. Ganciclovir was initiated with a subsequent decrease in viral load of 99.6%. 24 hours later, EGFP, cleaved-caspase 3 (cCasp3) and TUNEL staining were performed on glomeruli. In vivo imaging of the kidney. Mice were anaesthetized, an arterial catheter was placed into the right carotid artery or the aorta and the left kidney was exteriorized. The vasculature was labelled with a 70-kDa dextrane. Different doses of ATP were injected as a bolus via the catheter and dose-dependent calcium transients were monitored.

Results: Our data indicates that even doses of 5 mg/kg ATP did not induce calcium transients in podocytes. In contrast, proximal tubular cells as well as a cortical arteriole responded with a calcium transient, while robust activation of calcium signaling was induced in endothelial and proximal tubular cells with 0.5 mg/kg ATP. Further increasing the ATP dose by injection via an abdominal aortic catheter resulted in a calcium transient in podocytes.

Conclusions: In contrast to endothelial cells and proximal tubular cells, podocytes show a low sensitivity to ATP-mediated calcium signaling. We therefore hypothesize, that the low sensitivity ATP of podocytes is a protection mechanism to avoid calcium signals from filtered ATP.

Transcriptional Reprogramming by WT1 Mediates a Repair Response During Podocyte Injury in Mice and Human Kidney Organoids

Sandrine S. Etou,1 Youngsook L. Jung,2 Tomoya Miyoshi,3 Ken Hiratsuka,4 Ryuji Morizane,5 Peter Park,3 Jordan A. Kreidberg,1 1Boston Children’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Massachusetts General Hospital, Boston, MA.

Background: We previously identified WT1 as one of the most upstream transcription factors regulating gene expression in podocytes, binding nearly all genes known to be crucial for maintenance of the glomerular filtration barrier. Here, we focus on understanding WT1 transcriptional mechanism in response to injury.

Methods: We used Adria-37Cin (A37C)-induced podocyte injury as a model for human Focal Segmental Glomerulosclerosis in mice and human kidney organoids, and a conditional WT1 inactivated mouse model to decipher the transcriptional mechanism through which WT1 regulates podocyte gene expression during injury, using transcriptomic approaches.

Results: After injury, we observed a transient increased expression of podocyte genes in mice and human kidney organoids. Transcriptomics analyses of podocytes isolated from mTmG-Nphs2cre mice during the course of injury revealed a transient increase in the expression of crucial podocyte genes, including Nphs2. Sympo and many others, reflecting a reparative response during the early stages of injury. ChIP-seq analyses demonstrated that WT1 binds nearly 50% of known genes in podocytes, and the vast majority of genes whose expression changes during the response to injury. We identified de novo binding of WT1 that were only bound during the course of injury, and the expression of novel WT1 target genes. It appears that WT1 increases gene expression during injury through both the acquisition of novel binding sites, and increasing its binding intensity at sites previously occupied by WT1. Finally, motifs predicted to be overrepresented in other podocyte specific transcription factors were highly enriched at sites where WT1 binding increased after injury. Since the DNA binding transcription factors is modulated by chromatin accessibility, we used FACS-isolated podocytes to study epigenetic reprogramming. Both Adria-37Cinduced podocyte injury or inducible podocyte specific inactivation of WT1 resulted in the conversion of active to repressive histone marks at WT1-bound sites.

Conclusions: These results demonstrate that target gene binding of WT1 is highly dynamic in response to injury. WT1 directs the epigenetic regulation of gene expression, maintaining active chromatin marks at bound genes, that change to repression marks in the absence of WT1.

Atypical Cyscple 3-Dependent Death Process in Podocytes

Kazuyoshi Yamamoto,1 Masahiro Okabe,1 Takashi Yokoo,1 Taiji Matussuka,2 1The Jikei University School of Medicine, Tokyo, Japan; 2Tokai University School of Medicine, Isehara, Japan.

Background: Apoptosis of podocytes has been widely reported in many in vitro studies, but apotosis has rarely been documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo using a Cyscple 3-dependent CKD mouse model. Primarily, Cyscple 3 (C3) induced tubulocystic disease (CKD25) and EGFP expression plasmid and treated with a hCd25-targeting immunotoxin, LMB2 (1nM). 24 hours later, EGFP, cleaved-caspase 3 (cCasp3) and TUNEL staining were performed on in vivo experiments, podocyte injury was induced by injecting LMB2 into NEP25 mice, which express hCd25 in podocytes. In some experiments, NEP25 mice carrying another transgene expressing EGFP in podocytes were used. Results: In in vitro studies, administration of LMB2 caused leakage of co-introduced EGFP in 56.8±13.6% of hCd25-targeted cells, incorporation of propidium iodide in 13.6±2.5%, activation of caspase 3 in 19.6±2.5% and TUNEL staining in 4.5±1.3%. However, LDH activity in the culture medium did not significantly increase. These phenomena were not observed in cells without hCd25 or without LMB2. Acte-DEVD-CHO (10µM), a caspase-3 inhibitor, attenuated the leakage of EGFP by 38.2%, while inhibitors for caspase-1, necroptosis or apoptosis did not. These indicate that LMB2 induced typical caspase-3-dependent apoptosis in podocytes in vitro. In in vivo studies, injection of LMB2 (25ng/g BW) frequently induced leakage of EGFP from podocytes. In separate six NEP25 mice, 7 days after injection of LMB2 (1.25g/kg BW), 41.8±5.1% of glomeruli were found to contain cCasp3-positive cells, but no TUNEL-positive cell was observed. In primary sediments contained podocytin-positive podocytes (2.5±3.3%). Among these, 39.1±3% were stained for cCasp3 and 21.7±5.5% were stained for TUNEL. EM analysis showed no apoptotic body, but occasionally rupture of plasma membrane of podocytes. To evaluate the effect of glomerular filtration, NEP25 mice were similarly injected with LMB2 and subjected to ULO 1 day before sacrifice. Detaching podocyte cell bodies were frequently observed in the contralateral kidney by SEM analysis, but never in the obstructed kidney.

Conclusions: These collectively indicate that podocytes dying dependently on caspase 3 are quickly lost by detachment or plasma membrane rupture before completing full apoptotic processes. Glomerular filtration facilitates detachment of dying podocytes.

Systematic In Silico Exploration of the Kidney Rho-GTPase System Regulation in CKD

Background: It has become evident that dysregulation of the Rho-GTPase system would result in rearrangement of the actin cytoskeleton in the podocyte with resulting foot process effacement, a hallmark for glomerular diseases. To build further understanding how the dysregulation in disease states affects the kidney system occurs in CKD, we performed a systematic mining of kidney transcriptomics data to generate a full-viewport picture and insights on complex interplay between the members of the large family of Rho-GTPases and their regulatory proteins, the Guanine Nucleotide Exchange Factors (GEFs) and the GTPase-activating proteins (GAPs).

Methods: A comprehensive list of 143 genes was compiled including the members of the three gene families according to HUGO Gene Nomenclature Committee (HGNIC). Publicly available human transcriptomics data from healthy and CKD kidneys (microarray and RNA-seq, bulk-tissue and single-cell) were used for interrogation of gene expression patterns, including presence of detectable expression, its abundance, cell type specificity, modulation in disease, and co-expression structure. WGCNA and Cytoscape were used to correspondingly generate and visualize the gene co-expression network.

Results: All but one (142/143) genes were detectable in the human kidney, with 121 having robust levels >1TPM. The majority of genes were broadly expressed across the different tissues outside the kidney, however expression of several GEF and GAP members showed specific kidney enrichment. A number of GEFs and GAPs were modulated in CKD patient kidneys as compared to controls, predominantly with tendency for upregulation and negative correlation with renal function, reflecting first time activation in potentially pathophysiological or compensatory disease mechanisms. Hierarchical clustering of pairwise correlation values and WGCNA module analyses identified clusters of closely expressed genes that may implicate functional similarities.

Conclusions: To our knowledge, this is the first systematic evaluation of the Rho-GTPases, GEFs and GAPs kidney expression in the CKD context. Elucidation of the molecular interplay provides systems-level understanding and mechanistic insights that can lead to new biological hypotheses and therapeutic targets.

Bag3 as a Potential Mechanoprotector in Podocytes
Ingo Plagmann, Markus M. Rinschen, Jan C. Degenhardt, David Unnerjós-Jess, Sybille Kohler, Bernhard Schermer, Thomas Benzing, Department II of Internal Medicine and Center for Molecular Medicine, University of Cologne, Cologne, Germany; Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; The Scripps Research Institute, La Jolla, CA; The University of Edinburgh Centre for Discovery Brain Sciences, Edinburgh, United Kingdom.

Background: Podocyte loss is a hallmark of glomerular diseases leading to glomerulosclerosis and progression of kidney disease. Sitting on the outside of the glomerular tuft podocytes have to withstand extensive mechanical stress due to perfusion and filtration. Hyperfiltration and hyperperfusion e.g. in disease states cause podocyte detachment when overwheming their mechanoprotective capacity, which start a vicious cycle of mounting strain on the remaining podocytes. Bag3 is an important mechanoprotector in many mechanical strained tissues and by inducing chaperone-assisted autophagy (CASA) maintains the proteinostasis of e.g. Filamin and Synaptopodin – indispensable for podocyte biology. Additionally Bag3 insufficiency renders susceptibility to diabetic nephropathy in a mouse model. These findings point toward Bag3 as a candidate for mechanical stress protection in podocytes.

Methods: Using immunofluorescence, super-resolution-microscopy and mass-spectrometry we examined glomeruli and podocytes for Bag3/CASA expression and characterized the CASA-complex composition in podocytes by immunoprecipitation. The influence of mechanical clues was examined by stiff matrices and cyclic stretch. The role of Bag3 in vivo was being evaluated in different mouse lines (Bag3.F209L mutation, a renal knockdown, fusion-protein).

Results: In the glomerulus the Bag3 and the entire CASA-complex is enriched in podocytes in mass-spectrometry. Bag3 staining localizes to the slit diaphragm protein nephrin in superresolution microscopy. Importantly the co-chaperone Bag3 shows interaction with the essential actin cytoskeleton regulators rhoA, Arp2 and Dynamin2 in co-immunoprecipitation. The expression of Bag3 and the CASA-complex in podocytes is regulated by mechanical clues. Knockdown of the Bag3 homologue starvin in drosophila nephrocytes displays a mild filtration disturbance. The dominant-negative Bag3.F209L mutant causes a mild proteinuria in a whole-body overexpression model.

Conclusions: The data further emphasize the role of Bag3 and chaperone-assisted-selective-autophagy in podocyte mechanoprotection and maintenance of podocyte cytoskeleton architecture. Currently undergoing characterization of podocyte specific Bag3/QCT lines and the in vivo disease models will further help to understand the role of Bag3 at the kidney filtration barrier.

Knockout of the Neonatal Fc Receptor in Podocytes Ameliorates Nephritis by Reducing Glomerular Apoptosis
Judith Blaine, James F. Dylewski, Linda Lewis, Pantipa Tonsaworn, University of Colorado, Aurora, CO; Khon Kaen University, Khon Kaen, Thailand.

Background: There are few targeted treatments for immune mediated kidney diseases which can result in progressive renal failure. Podocytes express the neonatal Fc receptor (FcRn), a traffickin receptor that transports immunoglobulin-G (IgG) to the lysosome. In dendritic cells FcRn mediated trafficking of Igs to the lysosom is required for antigen processing and presentation on MHC II. We have found that podocyte specific knockout (KO) of FcRn ameliorates nephrotoxic serum nephritis (NPS) but that this protection occurs via a non-immune mediated mechanism. Here we show that KO of FcRn in podocytes results in a significant reduction in apoptosis both in vitro and in vivo after an immune challenge.

Methods: Wild type (WT) and FcRn KO podocytes were cultured in the presence or absence of Igs. The intrinsic and extrinsic apoptotic pathways were assayed by Western blot and ELISA. RNA-seq was performed to evaluate changes in apoptotic pathways. NTS nephritis was induced in control and podocyte specific FcRn KO (podFcRn KO) mice. Glomerulosclerosis and crescent formation were quantitated on PAS sections. Flow cytometry was used to measure renal CD4+, CD8+ or FoxP3+ T cells. Glomerular apoptosis was assessed using the TUNEL assay.

Results: In vitro, after treatment with Igs, FeRn KO podocytes expressed significantly less caspase-3 and caspase-9 (intrinsic pathway caspases) and caspase-3 activity was significantly decreased in KO podocytes compared to WT. There was no difference in caspase-8 expression (a marker of extrinsic apoptosis) between WT and KO podocytes. RNA-seq analysis demonstrated significant downregulation of intrinsic apoptotic pathways in FcRn KO podocytes compared to WT. In vivo, after induction of nephrotoxic serum nephritis, there was no change in renal CD4+, CD8+ or FoxP3+ T cells in WT mice, however in KO mice significantly less glomerulosclerosis and crescent formation. Podocyte-specific KO of FeRn also resulted in a significant reduction in the number of apoptotic cells within the glomerulus.

Conclusions: KO of FcRn reduces apoptosis via the intrinsic pathway in cultured podocytes after an immune challenge and ameliorates immune-mediated nephritis in vivo by reducing glomerular apoptosis.

The African APOL1 E150 SNP and Cell Surface Expression Are Required for Kidney Risk-Variant (G1/G2)-Mediated Cytotoxicity in Podocytes

Background: Apolipoprotein L1 (APOL1) variants G1 and G2 protect against trypanosome infection, but homozygosity greatly increases the risk of chronic kidney diseases, purportedly by acting as surface cation channels in kidney podocytes. “Wild type” APOL1-G0 exhibits various single nucleotide polymorphisms (SNPs), most commonly haplotype E150K, M228I and R255K (“KIK”), where the Reference Sequence is “EMR”), whereas G1 and G2 are only found in a single African haplotype background (“EIK”), also seen in some G0 Africans. Lannon et al (Kidney Int. 96: 1303) recently documented that differential cytotoxicity of APOL1-G1 and G2 variants versus G0 in HEK-293 cells depended on the haplotype. However, HEK-293 cells are unusually sensitive to APOL1, and podocytes are a more relevant cell type. Furthermore, only the small fraction of APOL1 that is transported to the cell surface (from its major expression site in the ER) is responsible for cytotoxicity and cell surface levels were not shown in that study. Since APOL1 residue 150 can differ in G0 Africans, we focused on comparing the cytotoxicities of E150 vs K150 SNPs in podocytes expressing equal surface levels of APOL1.

Methods: We generated podocytes stably expressing APOL1 G0, G1 or G2 under a doxycycline-inducible promoter and compared the effect of the African E150 (EIK) vs K150 (KIK) SNPs on cytotoxicity (by the Cyto-Tox Glo assay). Surface and total APOL1 were measured by FACS and Western blotting at increasing doxycycline levels. Brefeldin A was used to prevent APOL1 transport to the cell surface.

Results: Cell surface APOL1 levels increased in a doxycycline dose-dependent manner, but only the E150 G1 and G2 variants caused toxicity to podocytes as compared to E150 G0 at equal surface expression levels; K150 G0, G1 and G2 were not toxic. E150 G1 and G2 cytotoxicity was dose-dependent and required exit of APOL1 from the ER.

Conclusions: Using a physiologically relevant podocyte cell line, we confirmed that the African haplotype (EIK) is required for APOL1-G1 and G2 to exert cytotoxicity. Non-natural KIK versions were not toxic. Additionally, APOL1 G0 was not toxic in either the KIK or EIK background. Furthermore, African (E150) G1 and G2 cytotoxicity required ER exit, supporting the surface cation channel hypothesis. Our data thus suggest two potential therapeutic avenues for APOL1 nephropathies.

Glomerular Heterogeneity and Modulation of miR-93: The Role of Extracellular Vesicles

Laura Perin,1,2 Charmi Dedhia,3 Paola Aguilar,4 Roger E. De Filippo,5 Sargin Sedrakyan.5 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2University of Southern California, Los Angeles, CA.

Background: Modulation of miRNA in podocytes and glomerular endothelial cells (GEC) has been associated with development of renal diseases. miR-93 is a potent regulator of pathways responsible for glomerular damage, like VEGF, TGFβ and Mek2. We have evidence that miR-93 is altered in the glomeruli of mice with X-linked Alport syndrome (AS), carrying the Col4a5 mutation, and in glomeruli of AS patients. Here, we investigated the role of miR-93 in mesangial cells, podocytes and GEC from WT and AS mice. We also used extracellular vesicles (eEVs) derived from human amniotic fluid stem cells (hAFCs) to assess their disease modifying activity in vitro and in vivo by regulation of miR-93.

Methods: miR-93 expression was evaluated by qRT-PCR in mesangial cells, podocytes and GEC sorted from glomeruli of male and female WT (C57BL6/J), and AS (kidney disease) mice, the result of a nuclear transcriptomics with single cell sequencing. miR-93 expression was evaluated in vitro and EV therapeutic effect was evaluated in vivo by RNA-seq and survival.

Results: miR-93 expression is different between male and female mice along disease progression. In AS males miR-93 level was significantly lower in GEC, but not in podocytes or mesangial cells vs WT cells. miR-93 expression was downregulated also in AS patients. Expression of WT in paracrine aminoacidoside damaged podocytes, and expression of fibroenectin and VEGF in damaged GEC was restored by miR-93 hEV cargo transfer. In vivo, hEVs showed therapeutic effect by ameliorating the level of proteinuria, sclerosis and death at 42 days. It was found that the signalling mechanism of which has so far remained elusive. Our previous works suggest a role for miR-93 in the regulation of disease pathways and podocyte loss.

Conclusions: Gender-specific variation in miR-93 expression in glomerular cells might indicate important differences in response to injury in progressive disease. hEVs demonstrate great potential to restore lost miR-93 expression and its targets, thus presenting a targeted approach for treatment of CKD.

GDC-0879 Rescues Lipid Peroxidation and Podocyte Dysfunction in Coenzyme Q-Deficient Kidney Disease

Eriene-Heidi Siddhom,1,2 Choai Kim,1,2 Maria Alinovia,3 May Theng Tang,4 Julian R. Avila-Pacheco,5 Andrew J. Watts,1,2 Katherine A. Vernon,1,2 Jamie L. Marshall,1,2 Astrid Weins,1,2 Jillian Shaw,1,2 Anna Greka,1,2 Harvard Medical School, Boston, MA; 3Washington University, St. Louis, MO; 4Brigham and Women’s Hospital, Boston, MA; 5Columbia University Irving Medical Center, New York, NY.

Background: Mutations affecting mitochondrial coenzyme Q (CoQ) biosynthesis lead to kidney failure due to selective loss of essential cells of the kidney filter called podocytes. Curiously, neighboring tubular epithelial cells are spared early in disease, despite their higher mitochondrial content. We therefore sought to illuminate new, cell-specific roles for CoQ, independent of its role in the electron transport chain (ETC).

Methods: Here we use CoQ deficiency caused by a monogenic disorder due to PDS2 mutations as a model system with which to investigate the cell-specific mechanisms of disease. The resolution afforded by single nucleus RNA sequencing revealed podocyte-specific disease pathways in homozygous kld/kld (kidney disease) mice, the result of a spontaneous missense mutation in Pds2 (V117M, Pds2K447C). We combine single nucleus transcriptomics with in vitro metabolomics and transcriptomics analyses to better understand the metabolic perturbations within this disease.

Results: Single nucleus RNA sequencing from kidneys of Pds2K447C mice, characterized by nephric syndrome and CoQ deficiency in all cells, identified a podocyte-specific perturbation of the Braf/Mapk pathway. Treatment with GDC-0879, a Braf/Mapk-targeting compound ameliorated kidney disease in Pds2K447C mice. In vitro, mechanistic studies revealed that depleted podocytes revealed a previously unknown perturbation in PUF A metabolism leading to lipid peroxidation. Ablation PUF A metabolism was confirmed in vivo, where the abundance of Gpx4, an enzyme that protects cells from lipid peroxidation, was elevated in disease and restored after treatment with GDC-0879. We demonstrate broader human disease relevance of these findings by uncovering patterns of Gpx4 and Braf/Mapk pathway gene expression in tissue from patients with several different kidney diseases.

Conclusions: Our studies reveal ETC-independent roles for CoQ in podocyte injury and point to Braf/Mapk as a conserved, podocyte-specific pathway for the treatment of kidney diseases.

Noncanonical PAR-1 Signalling Leads to Profibrotic Effects in Podocytes in Response to Steroid-Resistant Nephrotic Syndrome Diabetic Plasma

Musleeha Chesar, Jack P. Tuffin, Carl J. May, Gavin I. Welsh, Moin Saleem. Bristol Renal University of Bristol, Bristol, United Kingdom.

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to the presence of an unknown “circulating factor”, the identity of which has so far remained elusive. Our previous works suggest a role for protease-activated receptor-1 (PAR-1) involving an unknown circulating protease leading to increased podocyte motility. We have now further elaborated the signalling pathways downstream of PAR-1, which suggests pro-fibrotic activation in podocytes.

Methods: Conditionally immortalised human podocytes (ciPods) were treated with PAR-1 agonist peptide or post-transplant SRNS relapse plasma and paired-remission plasma with or without PAR-1 antagonists, BW 5117 and FR17113 was effective in inhibiting effects of relapse plasma, suggesting a non-canonical activation of PAR-1 in SRNS. The phosphorylation of VASP, JNK and TRPC6 was effective in inhibiting effects of relapse plasma, suggesting a non-canonical activation of PAR-1 in SRNS. The phosphorylation of VASP, JNK and TRPC6 was effective in inhibiting effects of relapse plasma, suggesting a non-canonical activation of PAR-1 in SRNS. The phosphorylation of VASP, JNK and TRPC6 was effective in inhibiting effects of relapse plasma, suggesting a non-canonical activation of PAR-1 in SRNS.

Conclusions: We propose that the SRNS circulating factor acts as a pro-fibrotic effector that can activate PAR-1 leading to increased podocyte injury. A greater understanding of these signalling pathways will lead to the identification of novel therapeutic targets for this disease.

TRPC6 Is a Key Mediator of a PAR-1 Activation Pathway in Podocytes That Is Responsible for FSGS

Carl J. May, Musleeha Chesar, Gavin I. Welsh, Moin Saleem. University of Bristol, Bristol, United Kingdom.

Background: There is good evidence for the role of a circulating factor in the post-transplant recurrence of idiopathic nephrotic syndrome (FSGS). We have previously presented our work hypothesising the role of circulating plasma proteases. An active form of the protease activated receptor, PAR-1 expressed in the podocytes of SV129 mice (PAR-1Sve,1) led to proteinuria, sclerosis and death at 42 days. It was found that the signalling

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

613
response to PAR-1 agonist treatment of podocytes in vitro was also present in the kidney and in vivo, as seen in the podocyte dysmorphisms. Changes in the podocyte tropomyosin isoforms after injury might be linked to changing podocyte shape and the FPE phenomenon.

Methods: To test our hypothesis, we used RT-PCR and RNAseq (Illumina and Pacbio) to identify the whole array of Tpm isoforms that are enriched in podocyte and in injured human nephropathy glomeruli. Using different mouse models for podocyte injury (i.e., Cd2ap KO, Lamb2 KO, Co4a3s K0 & AdrNephropathy (AdrN)), we identified a change in Tpm isoforms in the glomeruli isolated from these mice.

Results: RNAseq results from WT glomeruli show a different pattern of Tpm cytoskeletal components than the injured glomeruli, with the most significant changes occurring in Tpm 1.7 & Tpm 3.4. Pacbio data also showed an interesting novel Tpm-related gene product only in injured glomeruli. We isolated RNA from WT and AdrN glomeruli and compared them to primary podocytes treated from podocyte-specific translating-ribosome-affinity-purification ("TRAP") mice. This system allowed us to purify podocyte mRNA for RNAseq, away from that in other glomerular cell types. Comparing the isolated RNA from WT-TRAP & AdrN-TRAP mice, we are able to identify the podocyte-specific Tpm isoforms that are associated with injury.

Conclusions: This study suggests roles for tropomyosin isoform changes in regulating podocyte shape in health and injury conditions.

IRE1α Is Essential for Podocyte Proteostasis and Mitochondrial Health
José R. Navarro-Betancourt,1 Joan Papillon,1 Julie Guilemette,1 Takao Iwawaki,2 Andrey V. Cybulsky,1 McGill University, Montreal, QC, Canada; 2Kanazawa Medical University, Kahoku-gun, Japan.

Background: Glomerular epithelial cell (GEC)/podocyte proteostasis is disrupted in glomerular diseases. To maintain proteostasis, the endoplasmic reticulum (ER) orchestrates the unfolded protein response (UPR), which includes upregulation of chaperones and clearance of misfolded proteins via autophagy. Inositol requiring enzyme-1 alpha (IRE1alpha) and PERK are the sensors of the UPR, which eliminates misfolded proteins when ER is stressed. This study characterizes the mechanisms by which IRE1α regulates proteostasis in GECs.

Methods: Mice with podocyte-specific deletion of IRE1α (IRE1α KO) were produced by breeding IRE1α flox/flox mice with mice expressing podocin-Cre recombinase. Nephropathy was induced with a single injection of adriamycin (ADR). GECs were cultured from glomeruli of IRE1α flox/flox and IRE1α KO mice and were treated by deletion of Cre recombinase. Cellular oxygen consumption rate (OCR) was quantified using the Seahorse mitochondrial stress test. Mitochondria were visualized using MitoTracker Red CMXRos or MitoTracker Green FM.

Results: Podocyte-specific IRE1α KO mice had greater ADR-induced albuminuria compared to control littermates. ADR increased expression of ER chaperones in glomeruli of control mice, but this upregulation was impaired in IRE1α KO mice. Autophagy induction was blunted in ADR-treated IRE1α KO animals, evidenced by reduced LC3-I and II and increased p62 levels, compared to treated controls. Electron microscopy showed prominent swelling of the ER and mitochondrial injury in podocytes of ADR-treated IRE1α KO mice. In cultured GECs incubated with tunicamycin (TM), deletion of IRE1α or chemical inhibition of the IRE1α RNase with 4μC attenuated upregulation of ER chaperones and LC3 lipidation compared to control. LC3 transcription and total LC3 protein levels were also reduced in TM-treated IRE1α KO GECs. Compared to control, IRE1α KO GECs showed decreased maximal and ATP-linked OCR. Mitochondrial membrane potential was lower in IRE1α KO GECs. IRE1α KO mice and IRE1α KO glomeruli were smaller, while total mitochondrial mass was similar in both groups. Inhibition of IRE1α signaling increased ER stress-induced apoptosis.

Conclusions: Stress-induced chaperone production, autophagy and mitochondrial damage are compromised by IRE1α deletion. IRE1α deletion is cytoprotective in glomerular disease associated with podocyte injury and ER stress.

Studying the Pathogenesis of Congenital Nephrotic Syndrome Using NPHS2 Mutant Kidney Organoids
Aude Dorison,1 Sara E. Howden,1,2 Thomas A. Forbes,1,2 Irene Ghobrial,1,2 Melissa H. Little,1,2 Kidney Development, Disease and Regeneration, Murdoch Children’s Research Institute, Melbourne, VIC, Australia; 1Department of Anatomy, Neuroscience, The University of Melbourne, VIC, Australia; 2Department of Nephrology, Royal Children’s Hospital, Melbourne, VIC, Australia; 2Department of Paediatrics, The University of Melbourne, Melbourne, VIC.

Background: Nephrotic syndrome (NS) is one of the most common forms of renal disease in children. NPHS2 mutations are the most common cause of congenital NS with misense NPHS2 mutations reported to result in misfolding and mis Trafficking of the encoded slit-diaphragm protein, Podocin. Studies have overexpressed mutated protein in podocytes and mouse podocytes to identify how the disease is caused. This is the first in vivo model to identify how mutations in the endogenous NPHS2 locus as well as a control wild type (WT) line. These include the sequence variants c.274G>T, c.535C>T and c.530G>A leading to the protein changes G92C, P118L and R168H respectively. Control and mutant lines were used to generate...

kidney organoids containing all nephron segments. Podocin localisation was assessed by electron microscope analysis and tubular injury was assessed by tissue injury. We also found that the previously reported knockdown of OASIS CKO mice was protected from LPS-mediated tubular injury. DNA damage was assessed by Comet assay. However, this difference was not statistically significant.

Results: We discovered that in addition to K+ and Na+, the APOL1 channel is permeable to Ca2+. The RRVs led to an influx of Ca2+ and Na+, which increased the plasma membrane, where they localized prior to cation flux. Reduction of Ca2+ and Na+ in the media inhibited RRV-mediated cell death. We also found that the previously reported high Ca2+ channels were a consequence of perforated podocytes. Our data suggests that targeting RRV channel activity represents a promising avenue for drug development.

PO1997
Cloning of an IgG Autoantibody Specific for Phospholipase A2 Receptor (PLA2R) Using IgG-Producing Cells from a Patient with Membranous Nephropathy
Zhi qiang Huang,1 Rodney G. King,1 Barbara Knopova,1 Colin Reily,1 Qi Bian,1 Stacy D. Hall,1 David J. Salant,2 Laurence H. Beck,2 Bruce A. Julian,1 Jan Novak.1
1University of alabama at birmingham, Birmingham, AL; 2Boston University Medical Center, Boston, MA.

Background: Primary membranous nephropathy (MN) is a common autoimmune kidney disease, in which 70% of patients exhibit circulating autoantibodies to one or more conformational epitopes in PLA2R. Anti-B cell therapies have proved effective to decrease autoantibody production and limit further development of the membranous subepithelial immune deposits of PLA2R and IgG. However, better characterization of anti-PLA2R autoantibodies is needed.

Methods: We used Epstein-Barr virus (EBV)-immortalized B cells isolated from peripheral blood from an anti-PLA2R seropositive MN patient to develop a protocol for the cloning and expression of recombinant IgG (rIgG) specific for PLA2R. A C-terminally His-tagged fragment consisting of the first 5 domains of human PLA2R was expressed in Escherichia coli and affinity purified by incubation with biotin labeled reagents (recombinant PLA2R or IgG-specific antibody) and streptavidin-conjugated magnetic beads. A FITC-conjugated N-terminal PLA2R peptide was used to isolate B cells with antigen-specific B-cell receptor (membrane IgG) by FACS. Variable regions of IgG heavy (VH) and light (VL) chains were cloned through a single-cell isolate B cells with antigen-specific reactive with non-reduced PLA2R. This subpopulation was next stained with FITC-conjugated PLA2R peptide and the corresponding VH and VL of IgG were cloned using our single-cell workflow. We expressed the cloned VH and VL as rIgG in Expi293 system. ELISA confirmed that the rIgG bound PLA2R.

Conclusions: This is the first report of cloning a PLA2R-specific IgG autoantibody from a patient with MN. These approaches can be used for further characterization of the molecular mechanisms of autoimmunity and epitope spreading in MN.

Pharmacologic Blockade of the Natriuretic Peptide Clearance Receptor Ameliorates Glomerular Disease in an Animal Model of FSGS
Liliana Yang1,2, Yaping Tan1,2,3,4, Rachel Buckley1, Robert F. Spurny1,2
1Duke University, Durham, NC, 2Duke VA Medical Center, Durham, NC.

Background: Glomerular podocytes play a key role in glomerular disease processes. Accumulating evidence suggests that cGMP signaling has podocyte protective effects in kidney diseases (J Am Soc Nephrol 28: 260, 2017). cGMP is produced by nitric oxide and by natriuretic peptides (NPs). NPs are the predominant source of cGMP generation in podocytes. NPs stimulate cGMP production by binding to NP receptors (NPRs). NPRA and NPRB stimulate cGMP generation. In contrast, NPRC binds and degrades NPs. Podocytes express all three NPRs (NPRA, NPRB, and NPRC). We hypothesized that blockade of NPRC would enhance local NP levels, promote cGMP signaling in podocytes and attenuate glomerular injury.

Results: We blocked clearance of NPs by NPRC using the pharmacologic agent ANP (4-23), which specifically binds NPRC without binding NPRA or NPRB. For the experiments, we used a mouse transgenic (TG) model of focal segmental glomerulosclerosis (FSGS) created in our laboratory (J Clin Invest 125:1913, 2015). These TG mice express a constitutively active Gaα15 subunit specifically in podocytes. In these animals, treatment with a single dose of the podocyte toxin puromycin aminonucleoside (PAN) causes robust albuminuria in TG mice, but only mild disease in non-TG animals.

Results: PAN induced heavy proteinuria in vehicle-treated TG mice at day 14 (1426±37 ng/mg creatinine) vs. 127±25 [vehicle] vs. 127±25 (6.7±1.0 ng/mg creatinine) compared to mice treated with vehicle (4.9±1.0 ng/mg creatinine), but this difference was not statistically significant.
Conclusions: These data suggest that: 1. Pharmacologic blockade NPRC may be a useful strategy for treating proteinuric kidney disease; and 2. Treatment outcomes might be improved by optimizing blockade of the NPRC to more effectively inhibit clearance of NPs from the circulation.

PO1999
Mitochondrial Damage in FSGS due to ANLN Mutation
Brandon M. Lane,1,2 Guanghong Wu,3 Megan Chryst-Stangl,1 Gentzon Hall,1,2 Rasheed A. Gbadegesin,1,2 Department of Pediatrics, Duke University School of Medicine, Durham, NC; 3Duke Molecular Physiology Institute, Durham, NC; 1Department of Medicine, Duke University School of Medicine, Durham, NC.

Background: We previously identified ANLN R431C as a cause of focal segmental glomerulosclerosis (FSGS). In addition to defects in actin bundling, targeted evaluation of this variant in cultured human podocytes identified disruption of AKT/mTOR signaling as a cause of ER stress and reduced podocyte viability. Creation of the orthologous R431C point mutation in mice confirmed the increased podocyte ER stress and identified mitochondrial damage as another possible feature of disease. To gain an unbiased view of the molecular mechanisms driving ANLN R431C induced disease, we used transcriptomic analysis and automated live cell imaging to interrogate cultured human podocytes.

Methods: Conditionally immortalized human podocytes overexpressing wildtype ANLN or the R431C variant were evaluated by mRNA-Seq and smRNA-Seq analysis to identify differentially expressed genes and microRNAs, as well as the molecular pathways involved. Potential therapeutic strategies were examined by evaluating cultured podocyte cellular and organelle-specific viability using automated live cell imaging.

Results: The top differentially expressed genes encode molecules that interact with previously identified pathological mechanisms including F-actin bundling (SYNPO2L) and AKT/mTOR signaling (CAVIN3, KIT). KIT SYNO2L podocytes displayed increased susceptibility to mitochondrial damage that could be rescued by treatment with AKT/mTOR pathway inhibitors. Additionally, compounds targeting improved mitochondrial viability through increased bioenergetic function (AP39), reduced oxidative stress (MitoQ, MitoTEMPO) and prevention of pore opening (Olesoxime) could all rescue the increased susceptibility to apoptosis in ANLN R431C podocytes.

Conclusions: Unbiased transcriptomic analysis confirmed that ANLN R431C disrupts AKT/mTOR signaling and actin cytoskeletal dynamics, resulting in increased ER stress and mitochondrial damage that reduce podocyte viability. Targeting various aspects of mitochondrial regulation may present viable alternative treatment strategies for FSGS due to defects in ANLN gene.

Prothrombin Modulates Podocyte Health and Function During Glomerular Proteinuria
Amanda P. Waller,1 Katelyn Wolfgang,1 Tasha K. Wilkie,1 Sagar Bhayana,1 Kyle Kyer,2 William E. Smoyer,2 Bryce A. Kerlin,1,2 Abigail Werner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 1The Ohio State University College of Medicine, Columbus, OH.

Background: Ongoing podocyte injury is a known critical determinant of glomerular disease progression. Recent research suggests thrombin exerts beneficial effects in vitro podocyte injury, however, pharmacologic manipulation may cause both on- and off-target effects. Thus, the purpose of this study was to directly examine the effects of thrombin on glomerular proteinuria by manipulating its yzogen precursor, prothrombin (PT). We hypothesized that circulating PT would directly modulate both podocyte function and in situ survival in a rat model of nephritic syndrome.

Methods: Purumycin amninosulfonic acid (PAS)-induced proteinuria was treated with: 1) PT antiserum oligonucleotide to induce hypoprothrombinaemia (LoPT), 2) Serial i.v. PT infusions to sustain hyperprothrombinaemia (HiPT), or 3) sham (PAN only) controls (Con; n=12/group). Ongoing podocyte injury was a known critical determinant of glomerular disease progression. Recent research suggests thrombin exerts beneficial effects in vitro podocyte injury, however, pharmacologic manipulation may cause both on- and off-target effects. Thus, the purpose of this study was to directly examine the effects of thrombin on glomerular proteinuria by manipulating its yzogen precursor, prothrombin (PT). We hypothesized that circulating PT would directly modulate both podocyte function and in situ survival in a rat model of nephritic syndrome.

Results: Circulating plasma PT levels (Figure A) modulated podocyte function (B) such that it was significantly decreased in LoPT and increased in HiPT, compared to Con. LoPT also decreased in situ podocyte death (C), while HiPT increased in situ podocyte death, and resulted in fewer podocytes per glomerulus (D).

Conclusions: In conclusion, prothrombin modulates podocyte function (proteinauria) and survival (death and numbers) in the PAN model of glomerular proteinuria. Future studies should work to determine the prothrombinase mechanism that enables thrombin formation and signaling in the glomerulus and evaluate its potential as a novel therapeutic target to slow glomerular disease progression toward chronic kidney disease.

PO2001
Exosomal Long Non-Coding RNA-G21515 as a Potential Predictive Biomarker for Segmental Sclerosis Change in IgA Nephropathy
Tianqian Han,1 Jiajia Li, Xiaona Wei, Peifen Liang, Qiongqion Yang, Sun Tat-Sen University Sun Tat-Sen Memorial Hospital, Guangzhou, China.

Background: Segmental sclerosis (S) is an independent pathological predictor for renal progression in IgAN patients, and is closely related to proteinuria. However, there is less invasive biomarker for pathological S change. We investigate the difference in expression profiles of exosomal long non-coding RNAs (lncRNAs) in plasma from IgAN patients compared with their healthy first-degree relatives, then explore the possible lncRNA associated with S.

Methods: To isolate exosomes from the plasma of both IgAN patients and their healthy first-degree relatives, High-throughput RNA sequencing and real-time quantitative polymerase chain reaction (qRT-PCR) was used to validate lncRNA expression profiles. Target lncRNAs were selected by bioinformatics analysis. The relationship between target lncRNA and S was analyzed by Spearman correlation. ROC curve evaluated the area under curve (AUC) of the target lncRNA for diagnosis S and its predictive sensitivity and specificity.

Results: 18 pairs of IgAN patients and their healthy first-degree relatives were enrolled in this study. The mean age was 29.71±6.06 years and urinary protein was 1.00±0.62±1.00 g/24h in these IgAN patients. lncRNA-G21515 was significantly down-regulated in IgAN patients. The predicted target genes of lncRNA-G21515 are FCGRs, which encode family of Fc gamma receptors (FcrRs). S was observed in 12 IgAN patients (66.7%) and was positively correlated with lncRNA-G21515 relative expression (r=0.545, P=0.019), but had no correlation with proteinuria, blood pressure, mesangial hypercellularity(M), endocapillary proliferation(E), tubulointerstitial fibrosis (T) and crescent(C). The relative expression (fold change) of lncRNA-G21515 was higher in S1 group than in S0 group (11.26(7.92,20.38) vs 7.04(3.93,11.00), P=0.025). The AUC of lncRNA-G21515 to predict S change was 0.81(95% confidence interval, 0.62~1.00) with a sensitivity of 83.3% and a specificity of 83.3% when a cutoff value of 9.58 was used for lncRNA-G21515 relative expression (Fold change). In addition, patients with higher lncRNA-G21515 relative expression had more severe podocyte injury.

Conclusions: Exosomal lncRNA-G21515 was down-regulated in IgAN patients, but positively correlated with S change. Exosomal lncRNA-G21515 may be a potential independent predictor for S lesion in IgAN patients.

PO2002
Analysis of the Relationship Between Proteasome and Autophagy in Podocytes Using Podocyte-Specific Proteasome Impairment Mice
Shinichir Makino,1 Hiroyuki Yamada,1 Ika N. Kadariswantiningsih,1 Maulana A. Emplia,1 Motoko Yanagita,1 Katshikori Asanuma,1 Chiu Daigaku Daigaku Ikuken Yaku,1,2 Katsuhiko Asanuma,1,2 Chiba Daigaku Daigaku Ikuken Yaku,1,2 Chiba, Japan; 1Chiba Daigaku Daigaku Ikuken Yaku,1,2 Chiba, Japan; 1Chiba Daigaku Daigaku Ikuken Yaku,1,2 Chiba, Japan.

Background: Ubiquitin-proteasome system and autophagy-lysosome system are major intracellular protein degradation mechanism. The relationship of these systems in podocyte has not well been understood.

Methods: In this study, we generated podocyte-specific proteasome impaired mice (Rplt3pKO) by deletion of Rplt3, which is essential for construction of 26S proteasome, using Cre-loxP system. Albuminuria and number of sclerotic glomeruli increased in the Rplt3pKO mice compared with Rplt3control mice. Oxidative stress and podocytes apoptosis were related to podocyte injury. To evaluated autophagic activity, LC3 dots

in podocytes were evaluated after administration of chloroquine, inhibitor of autophagic flux. In cell culture experiments, cultured podocytes were treated with bortezomib (BTZ), proteasome inhibitor, which lead to podocyte apoptosis. The expression of LC3 was evaluated in podocytes after administration of bortezomib in the presence of 6E4/peptatinA, inhibitor of autophagic flux.

Results: In vivo, after administration of chloroquine, LC3 dots decreased in podocytes of Rpt3pdKO mice compared with RptCtrol mice. In vitro, the expression of LC3 decreased and the accumulation of p62 increased in cultured podocytes after treatment of BTZ in the presence of 6E4/peptatinA. These results indicated autophagic activity was stimulated in both proteasome inhibition and pULLK, which is a downstream of mTOR signal, was phosphorylated in podocytes with proteasome impairment, suggested that suppression of autophagic activity was associated with mTOR activation. Pre-treatment of rapamycin, inhibitor of mTOR, ameliorated podocyte apoptosis induced by BTZ in vivo and in vitro, the number of sclerotic glomeruli decreased in Rpt3pdKO mice with rapamycin administration compared with in RptCtrol pdKO mice without rapamycin administration.

Conclusions: Impairment of proteasome suppressed autophagic activity associated with mTOR activation in podocytes. Activation of autophagy have the protective effect on podocyte injury due to proteasome impairment.

Functionally Resolving WT1 Variants of Uncertain Significance in Nephrotic Syndrome
Jennifer Lai Yee,1 Xiaoyan Jia,1 V. Vega-Warner,1 Matt G. Sampson,2 Jacob O. Kitzman,1,3 1University of Michigan, Ann Arbor, MI; 2Boston Children’s Hospital, Boston, MA.

Background: Patients with Mendelian forms of nephrotic syndrome (NS) are likely to progress to end stage kidney disease. Because of the increased availability and promise to guide clinical decision, genetic screening among affected patients is proliferating. However, accurate attribution of pathogenicity to rare variants found during genetic screening remains challenging. WT1 is the second most common gene causing Mendelian NS. Therefore, this project aims to develop a model system to test the transcriptional activity of WT1 variants, as a first step towards high-throughput functional analysis to comprehensively classify variants in this key NS gene.

Methods: Wild-type and several bona fide pathogenic WT1 variants were tested for transcriptional activity in a standard dual-luciferase assay. Several cell lines including HeLa, HEK293, and HK2, were co-transfected with variant or wild-type WT1 and an NPHS1 promoter luciferase vector. Furthermore, potential WT1 target genes specific to HEK293 cells were identified by analyzing differential gene expression in RNA-seq data of WT1 over-expressing HEK293 cells, in order to identify additional WT1-responsive promoters for use as WT1 activity reporters.

Results: Overexpression of wild-type WT1 in HeLa cells and HEK cells increased expression of luciferase under the NPHS1 promoter by ~2-fold relative to truncated WT1. The luciferase activity of bona fide pathogenic WT1 variants was also significantly lower than the wild-type WT1 and bona fide benign WT1 variants (P<0.05). Overexpression of wild-type WT1 in HEK293 resulted in upregulation (log2 fold change=0.4, adjusted p<0.05) of IGFIIR, EGFR, TGFβ2. These candidates are being developed as WT1 responsive reporters.

Conclusions: Previous reports suggested NPHS1 promoter reporters as a model system to investigate mutant WT1 function. However, the transcriptional effect of WT1 was subsequently not cell specific. Future work to establish a robust WT1 reporter is ongoing using cloned IGFIIR, EGFR, TGFβ2 promoters.

Sources of Variability in Podocyte Foot Process Width Measurements and Approaches to Mitigation
Molly Geraghty,1 Morgan P. Thompson,1 Donal Gorman,1 Hui Chen,1 Kondala R. Atkuri,2 Stephen Berasi,2 J. B. Copley,2 Joel M. Henderson,1 1Boston Medical Center, Boston, MA; 2Pfizer Inc, New York, NY.

Background: Podocyte foot process (FP) morphology is used in the research setting to quantify podocyte injury and has the potential to be leveraged for diagnostic use. However, the pre-analytical and analyzable variables on these measurements are not well understood. We sought to identify these sources of variability and develop a robust method for podocyte foot process width (FPW) measurement within various kidney diseases.

Methods: We examined the impact of operator bias and sample size on FPW measurement in electron micrographs from nephrotic (NS) and non-nephrotic (N) cases, including primary focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD), and other glomerular lesions effecting the podocyte. FPW was measured for each individual FP between the midpoints of flanking filtration slits and the geometric mean was reported by image. We found that identification of filtration slits was subjective, but interoperator variability was mitigated through use of standardized morphologic criteria, operator training, adjudication of ambiguous features, and a mapping process that eliminated duplicate measurements in adjacent images. These methods reduced interoperator variability in FPW, averaged by image, from 12% to 7%.

Results: Preliminary analysis suggests that, in addition to the expected larger FPW mean in MCD cases vs. Nx cases, there is also larger FPW variability in MCD cases. Related analysis shows ~125 FPW measurements within each of 2 glomeruli (~250 total) in a MCD vs. the same precision as ~100 FPW measurements in each of 10 glomeruli (~1,000 total) in a MCD case. We also found that intraglomerular variability among 3

Glomerular Transcriptomic Analysis of Glucocorticoid- and Pioglitazone-Treated Nephrotic Syndrome
Sagar Bhavana, Shipra Agrawal, Melinda A. Chanley, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratan, James Fitch, Bryce A. Kerlin, William E. Smoyer. Nationwide Children’s Hospital, Columbus, OH.

Background: Nephrotic Syndrome (NS) is among the most common glomerular diseases in children. Glucocorticoids (GC) are the primary treatment for NS, but 15-20% of children have or develop steroid resistant NS, creating an unmet need for novel therapeutics. Thiazolidinediones (TZDs) such as pioglitazone (Pio) have been shown to slow diabetic nephropathy progression, and to reduce proteinuria in animal models of NS. Since both GC and Pio act via binding to nuclear receptors we hypothesized that the reported similar degrees of proteinuria reduction by GC and Pio are driven via common molecular pathways.

Methods: We performed transcriptome analyses on glomeruli isolated from GC- and Pio-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Principal component analyses revealed distinct transcriptional profiles between controls vs. PAN-treated rats, with 319 and 126 differentially up- and down-regulated genes in PAN respectively, which were largely reversed by both GC and Pio. Ingenuity pathway analyses (IPA) combined with drug-target interaction network analyses and gene set enrichment analyses identified 29 glomerular genes that were commonly regulated by GC, Pio, and their respective nuclear receptors (NRE1 and PPARy). Gene ontology annotation revealed these 29 genes to be involved in: ECM modification, plasma membrane dynamics, DNA damage/repair, transcription factor binding, lipid metabolism, and cytoskeletal organization. Gene segregation into their cells of origin using reported gene sets for cell transcriptional revealed most dysregulation and restoration of gene expression within podocytes, with moderate changes within mesangial cells and minimal changes within endothelial cells. IPA-based disease and toxicity algorithms developed from these cell-specific data also revealed enhanced cytoskeletal organization and improved cell viability after both GC and Pio vs. PAN.

Conclusions: GC and Pio treatment reduced proteinuria similarly in NS, but by inducing alterations in both distinct and overlapping glomerular gene-sets. Notably, informatics analyses of overlapping genes identified ECM proteins, as potential novel targets for future therapies for NS, distinct from current immunosuppressive approaches.

Novel Podocyte Protective Compounds Identified Using Ultra-Miniaturized High-Content Screening (HCS) Assays
Manuel Noben,1 Danish Qavi,1 Shreyaa Khanna,1 Ha Won Lee,1 Mehmet M. Altintas,1 Jochen Reiser,1 Susanne Heyen-Genel,1 Vineet Gupta,2 1Rush University Medical Center, Chicago, IL; 2Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Background: Podocytes are specialized epithelial cells which are part of the filtration barrier in the kidney. Podocyte dysfunction is part of kidney pathology hallmarkled by proteinuria. Using a high-content imaging based assay, we have shown that podocytes can be used to identify novel therapeutic compounds.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates. After 10-14 days of differentiation, cells were exposed to puromycin amionucleoside (PAN, podocyte injury inducing agent), with compounds from the screening library or newly identified targets, or DMSO as control, for 48 hours. After, cells were fixed with 4% paraformaldehyde and permeabilized with 0.1% Triton X-100. Cells were labeled with cytoplasmic stain HCS CellMask Green, and actin fibers were detected by using labeled phallolid. Cell images were taken with using Opera High-content Screening (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. We utilized commercial libraries containing >50k unique compounds to identify podocyte protective hits.

Results: Using PAN as a podocyte damaging agent, we noticed marked reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes. Screening of a library of chemical compounds identified >25 hits which had favorable profiles.

Conclusions: Using our optimized podocyte high-throughput screening assay in 1536-well plates, we have identified a number of highly novel compounds. Further mechanistic studies provide new insights about podocyte pathways that can be therapeutically targeted.

The Role of FNBP1L in Podocytes
Qiaoli Tang, Lu Ren, Hui Song, Zhang Sipan, Zheng Tang, Shaolin Shi. Jinglin Hospital National Clinical Research Center of Kidney Diseases, Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China.

Background: Podocytes exhibit a complex cellular morphology characterized by the formation of foot processes. The normal structure of podocytes depends on their unique podocyte-specific, actin microfilament component. Nucleation of actin monomers is the rate limiting step in actin polymerization. There are two distinct nucleators for actin nucleus in podocytes, Arp2/3 complex and formin, which mediate branch and linear actin filament formations, respectively. Our previous study identified hundreds of genes expressed in every single podocyte, which were potential podocyte essential genes. Of them, FNBP1L is known to be involved in Arp2/3 complex and formin activities in nucleus, supporting FNBP1L's essentiality for podocytes. Here, we test this hypothesis.

Methods: Cultured podocytes were used for this study. FNBP1L was knocked down by siRNA, and immunostaining, immunoblotting, qPCR, wound healing assay, co-immunoprecipitation were performed to test FNBP1L essentiality and mechanism.

Results: FNBP1L was specifically expressed in podocytes in glomeruli, and its expression was decreased in purinycin aminonucleosides-treated in podocytes. When FNBP1L was knocked down, we found that the expression of WT1, SYNPO and CD2AP were decreased; that the migratory capability was impaired; that F-actin stress fibers were reduced and disorganized; and that focal adhesion number was decreased while their size increased as shown by p-FAK staining. Mechanistically, FNBP1L regulated Arp2/3 complex and IN2 (a formin) actin nucleus activities. Co-IP and IF showed that FNBP1L colocalized and interacted with CDC42 and N-WASP to facilitate interaction of N-WASP with Arp2/3 complex, thereby increasing the activity of Arp2/3 complex in actin nucleus in podocytes coloaded with INF2 and affected its localization in cytoplasm and its actin nucleus. Consistently, the reduction of FNBP1L impaired the interaction between N-WASP and Arp2/3 complex and mis-localized INF2 in the cytoplasm.

Conclusions: FNBP1L may regulate branched and linear actin filament productions. This was supported by regulation Arp2/3 complex and INF2 actin nucleus activities in podocytes, thereby maintaining podocyte normal structure and function. Reduction of FNBP1L expression is involved in podocyte injury and targeting FNBP1L may represent a novel therapeutic approach for podocytepathies.

Role of AT1e in Radiation-Induced Nephrotoxicity
Anis Ahmad1, Cameron Bader1, Saba Ansari1, Jumana Affaghani1, Sandra M. Merscher1, Alessia Fornoni2, Youssef Zeidani1, Robert B. Levy1, Brian Marples1. 1Radiation Oncology, Department of Radiation Oncology, University of Miami, Miller School of Medicine, Miami, FL; 2Department of Radiation Oncology, Anatomy, Cell Biology, and Physiology, American University of Beirut School of Medicine, Beirut, Lebanon; 3Peggy and Harold Katz Family Drug Discovery Center and Division of Nephrology, Department of Medicine, University of Miami, Miami, FL; 4Department of Emergency Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY; 5Department of Microbiology and Immunology, Miller School of Medicine, University of Miami, Miami, FL.

Background: Argininylation increases actin polymerization and supports cellular morphology. However, the effect of radiation therapy (RT) on argininylation is not known. This study investigated the impact of RT on arginyltansferease 1 (ATE1) and its role in podocyte morphology and kidney function.

Methods: Human podocytes were irradiated with 4 Gy, and preceeded by rituximab mAb (100 μg/ml) or IgG (100 μg/ml) treatment, 30 min before RT. Additionally, 8-8-week-old C57BL/6 male and female mice were subjected to either (i) 1x14 Gy bilateral kidney-only RT (ii) lethal-dose total body irradiation (TBI 10.5 Gy) and rescued by strain-donor hematopoietic stem cell transplantation (HSCT) or (iii) untreated (sham-RT control). Functional, histopathological, and biochemical changes were studied at baseline and 10 weeks post RT

Results: In podocytes, RT (4 Gy) produced time-dependent downregulation of ezrin (30%) and AT1e (50%) and a significant increase in apoptosis at 4h (p<0.001). Rituximab pretreatment protected from ezrin relocalization and AT1e downregulation and podocyte apoptosis. In C57BL/6 mice, RT significantly decreased glomerular surface area and increased mesangial expansion scores in 14Gy and TBI animals compared to controls (p<0.01). Similarly, both RT schedules resulted in significant increases in renal fibrosis (p<0.01), serum BUN (p<0.01), and serum creatinine levels (p<0.01). Western blot analysis showed downregulation of ATE1 in the kidney cortex: 67.7±9.6% (14Gy); 69.3±13.3% (TBI) compared to control. Similarly, IHC data showed a decrease in ATE1 expression in glomeruli after 14Gy (50%) and TBI (70%) compared to control. Podocyte numbers of ezrin microtubular structures associated with podocyte infolding, coining a podocyte infolding glomerulopathy (PIG). Here, we test this hypothesis.

PO2010

Podocyte Infolding Glomerulopathy: New Disease or Pattern of Injury?
Sri Vibhavari Guntupalli, Suzanne G. Martin. St. Vincent Hospital, Worcester, MA.

Introduction: Occasional podocyte infolding is reported in membranous nephropathy, but global and diffuse infolding is rare. Whether this is a new disease entity or a pattern of podocyte injury may influence therapy.

Case Description: 52 year-old-male with hypertension developed lower extremity edema, pleuritic chest pain and dyspnea. CT chest showed bilateral pulmonary emboli. Creatinine was 0.92 mg/dl, cholesterol 239 mg/dl, albumin 3.2 g/dl, urine protein:Cr ratio 32.647 mg/gCr. Renal biopsy showed immune complex deposition in a membranous pattern, and subepithelial deposits with targeted microvascular substructures, suggesting a podocyte infolding glomerulopathy (PIG) [Fig.1 Electron microscopy showing PIG]. Immune deposits were dominantly reactive for IgG4, and also for other IgG subclasses, C3, IgM, and kappa and lambda light chains. Deposits were reactive for PLAZR. Serum PLAZR antibody and other serologies were negative. He was anticoagulated and treated for 6 months with the modified Ponticelli protocol. Creatinine remains normal, but hypoalbuminemia and proteinuria (190mg – 1.2g) persist 8 months after starting treatment.

Discussion: In 1985, Dales and Wallace [1] described massive deposits of spherular organelles in the subepithelial space of glomerular capillary walls in a patient with membranous nephropathy. In 2008, Jh et al [2] studied 25 Japanese patients with microspheres and microtubular structures associated with podocyte infolding, coming the term “podocyte infolding glomerulopathy.” Rare cases are reported in India, Latin America and Europe. It is unknown whether PIG is a subtype of membranous nephropathy or a distinct glomerular lesion. Identification of PIG associated with vesicoureteral reflux, myeloma, and autoimmune diseases, and the absence of immune complexes in many biopsies, suggest a distinct type of podocyte injury. Ultimately, the pathophysiology of PIG is not yet understood. Response to therapy and prognosis are not well-described. This patient was treated with the modified Ponticelli protocol, given findings of membranous nephropathy, with a reduction in proteinuria but not full remission. This may represent a partial response to therapy or may imply that podocyte infolding glomerulopathy is a separate disease entity not responsive to immunosuppression.

Podocyte Infolding Glomerulopathy: New Disease or Pattern of Injury?
Sri Vibhavari Guntupalli, Suzanne G. Martin. St. Vincent Hospital, Worcester, MA.

Introduction: Occasional podocyte infolding is reported in membranous nephropathy, but global and diffuse infolding is rare. Whether this is a new disease entity or a pattern of podocyte injury may influence therapy.

Case Description: 52 year-old-male with hypertension developed lower extremity edema, pleuritic chest pain and dyspnea. CT chest showed bilateral pulmonary emboli. Creatinine was 0.92 mg/dl, cholesterol 239 mg/dl, albumin 3.2 g/dl, urine protein:Cr ratio 32.647 mg/gCr. Renal biopsy showed immune complex deposition in a membranous pattern, and subepithelial deposits with targeted microvascular substructures, suggesting a podocyte infolding glomerulopathy (PIG) [Fig.1 Electron microscopy showing PIG]. Immune deposits were dominantly reactive for IgG4, and also for other IgG subclasses, C3, IgM, and kappa and lambda light chains. Deposits were reactive for PLAZR. Serum PLAZR antibody and other serologies were negative. He was anticoagulated and treated for 6 months with the modified Ponticelli protocol. Creatinine remains normal, but hypoalbuminemia and proteinuria (190mg – 1.2g) persist 8 months after starting treatment.

Discussion: In 1985, Dales and Wallace [1] described massive deposits of spherular organelles in the subepithelial space of glomerular capillary walls in a patient with membranous nephropathy. In 2008, Jh et al [2] studied 25 Japanese patients with microspheres and microtubular structures associated with podocyte infolding, coming the term “podocyte infolding glomerulopathy.” Rare cases are reported in India, Latin America and Europe. It is unknown whether PIG is a subtype of membranous nephropathy or a distinct glomerular lesion. Identification of PIG associated with vesicoureteral reflux, myeloma, and autoimmune diseases, and the absence of immune complexes in many biopsies, suggest a distinct type of podocyte injury. Ultimately, the pathophysiology of PIG is not yet understood. Response to therapy and prognosis are not well-described. This patient was treated with the modified Ponticelli protocol, given findings of membranous nephropathy, with a reduction in proteinuria but not full remission. This may represent a partial response to therapy or may imply that podocyte infolding glomerulopathy is a separate disease entity not responsive to immunosuppression.

Podocyte-Derived Testican 2 Promotes In Vitro Glomerular Angiogenesis

Donghai Wen,1 Debby Ngo,2 Benjamin D. Humphreys,2 Martin R. Pollak,3 Robert Gerzsenyi,1 James G. Wilson,1 Eugene P. Rhee,1 Massachusetts General Hospital, Boston, MA; 2Washington University in Saint Louis, Saint Louis, MO; 3Beth Israel Deaconess Medical Center, Boston, MA.

Background: In addition to their fundamental role in clearance, the kidneys release select molecules into the circulation, but whether any of these anabolic functions provides insight on kidney function is unknown.

Methods: Using aptamer-based proteomics, we characterized arterial (A) to renal venous (V) gradients for >1,300 proteins in 22 human individuals who underwent invasive sampling. To localize testican-2, immunohistochemistry, immunofluorescence, immunogold electron microscopy and single cell RNA sequencing in human kidney tissue were used. Functional effects of testican-2 were tested on cultured primary human glomerular endothelial cells (HGEC).

Results: Although most of the proteins that changed significantly decreased from A to V, consistent with renal clearance, several were found to increase, the most significant of which was testican-2 (V/A = 1.40, P = 1.5 x 10^9). Imaging and single cell RNA sequencing demonstrated testican-2 expression in human podocytes. Testican-2 promoted angiogenesis and migration in cultured HGEC, but not proliferation. Further, testican-2 upregulated MMP-2/9 activity in the culture media of HGEC.

Conclusions: Testican-2 is a circulating protein that is synthesized in the human podocyte. Podocyte-testican2 promotes angiogenesis in cultured HGEC, which may be mediated by upregulating MMP-2/9 activity and increased endothelial cell migration.

PO2012
Mitochondrial Quality Control Mechanisms in Renal Cortical Mitochondria During the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Nishikawa,1 Masatoshi Takenaka,1,2 Masato Katagiri,1,2,3 Kitasato University, Sagamihara, Japan; 1University of Nebraska Medical Center, Omaha, NE; 2International University of Health & Welfare, Minatoku, Tokyo, Japan; 3Seikai, Tochigi, Japan.

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria. Because accumulation of damaged mitochondria can contribute to renal dysfunction, we aimed to determine if oxidative stress in DM triggers 1) mitochondrial fission or fusion, 2) increased fatty acid metabolism, and/or 3) mitophagy as quality control mechanisms.

Methods: Rats receiving i.p. injection of streptozotocin (STZ, 65 mg/kg) or vehicle (3) mitophagy as quality control mechanisms.

Results: During the normoalbuminuric stage of DM, renal cortical mitochondria undergo increased fatty metabolism, as well as enhanced fission and mitophagy that are blunted by TLM in association with its antioxidant effect and, thus, are likely quality control mechanisms triggered by oxidative damage.

PO2013
Indoxyl Sulfate Modulates Expression of Myosin Heavy Chain Isoforms and induces Sarcopenic Phenotype in Mouse

Takashi Higashihara, Hiroshi Nishi, Koji Takemura, Masaomi Nangaku. Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan.

Background: In patients with chronic kidney disease, sarcopenia is frequently associated with decreased renal function and correlates with increased morbidity and mortality. However, the molecular mechanism to underlie uremic sarcopenia is not fully elucidated yet. We hypothesized that the accumulation of uremic toxin might have a direct negative effect on skeletal muscle, and investigated the mechanism of indoxyl sulfate (IS) induced toxicity on mouse skeletal muscle.

Methods: We conducted the in vivo experiments using C57BL/6 mice. After unilateral nephrectomy, vehicle (PBS) or high dose IS was intraperitoneally administered daily for 1 week, and evaluated exercise tolerance (treadmill fatigue test and four limbs grip test), skeletal muscle wet weight, cross-sectional area, and protein levels of myosin heavy chain protein.

Results: IS reduced exercise tolerance and was associated with increased muscle weight and decreased cross-sectional area.

Conclusions: IS induces direct sarcopenic effect on mouse skeletal muscle and predominantly decreases on fast-twitch muscle fibres. In the future, we will further investigate the molecular mechanism of uremic toxin induced sarcopenia.

PO2014
Lnc-Gm43360 Regulates TCMK-1 Senescence by the miR-141/Sirt1 Pathway

Jie Li, Hongli Jiang, Lei Chen. The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China.

Background: Aging is a complex process, which will lead to the gradual decline of physiological functions of all organ systems. The kidney, which is a metabolically active organ, is extremely susceptible to aging, but the mechanism of kidney aging is not clear. Long-chain non-coding RNA (lncRNA) is an non-coding RNA consisting of 200 nucleotides, which play an important role in kidney fibrosis and diabetic nephropathy, but there is no study on kidney senescence.

Methods: Detection of Lnc-Gm43360 expression by qRT-PCR. Transfection with Lnc-Gm43360 siRNA and overexpressed plasmid to measure the miR-141 and Sirt1 expression by qRT-PCR, and the p53, p21 and p16 expression by western blot, and SA-β-gal expression. Transfection with miR-141 mimic and inhibitor to measure Sirt1 expression by qRT-PCR, and p53, p21 and p16 expression by western blot, and SA-β-gal expression.

Results: Lnc-Gm43360 expression in 24-month-mouse lower than 3-month-mouse kidney tissue. The reduction of Lnc-Gm43360 expression significantly increases miR-141 expression, decrease Sirt1 expression on both the mRNA and protein level, and induces the SA-β-gal expression. Lnc-Gm43360 negatively regulates miR-141 expression and positively regulates Sirt1 expression at both the mRNA and protein level. The function of Lnc-Gm43360 in regulating Sirt1 expression depends on modulating miR-141 expression.

Conclusions: Lnc-Gm43360 can induce TCMK-1 senescence by miR-141/Sirt1 pathway.

PO2015
Modifed Lipoproteins Modulate Renal Lymphatic Vessel Vasodynamics via NKCC1 on Lymphatic Endothelial Cells

Jianyong Zhong, Jing Liu, Elaine L. Shelton, Eric J. Delprie, Haichun Yang, Valentina Kon. Vanderbilt University Medical Center, Nashville, TN.

Background: In addition to its pivotal role in chloride transporting epithelia, the sodium-potassium–chloride cotransporter 1 (NKCC1) is increasingly recognized as a key modulator of vascular tone. We previously documented NKCC1 expression in renal lymphatic endothelial cells (LECs) of rats and cultured human LECs. Ex vivo we showed that blocking NKCC1 by furosemide caused a dose-dependent dilatation in renal lymphatic vessels, decreased amplitude, and decreased frequency of spontaneous contractions. Since lymphatic vessels clear interstitial lipids and kidney injury increases lipid peroxidation products including isoleucylglutamides (IsoGLu) which modify lipoproteins (apoA1), we examined whether apoA1 modified with IsoGLu (apoA1-IsoGLu) modulates renal lymphatic vessel contractility via NKCC1.

Methods: Paroxysmic nephropathy (PAN) was induced in Sprague Dawley rats, while non-injected rats served as controls (Cont). Renal lymphatic vessels were isolated and mounted in a perfusion chamber to assess vasoreactivity. The effects of apoA1 or IsoGLu-apoA1 on the NKCC1 signaling pathway were assessed in LECs.

Results: PAN rats had significantly higher renal lymph flow which contained significantly more isoGLU vs Cont. Ex vivo studies showed renal collecting lymphatic vessels from PAN were more dilated than Cont. Immunostaining revealed NKCC1 expression on LECs that was more prominent in PAN renal lymphatic vessels vs Cont.

Progranulin Deficiency Exacerbates High-Fat Diet-Induced Inflammation in Kidney
Maki Murakoshi, Tomohito Gohda, Yusuke Suzuki. Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.

Background: Progranulin (PGRN) has been reported to bind to tumor necrosis factor (TNF) receptor (TNFR) and inhibit TNFα signals. Conversely, PGRN is a ‘bad’ adipokine that can contribute to insulin resistance in some metabolic diseases. We evaluated the effect of augmentation of TNFα signals by PGRN deficiency on the progression of kidney injury in high-fat diet-induced obesity model mice.

Methods: Eight-week-old PGRN knockout (KO) mice and their wild-type (WT) mice were fed a standard diet or high-fat diet (HFD) for 12 weeks. Mouse proximal tubule (mProx24) cells knocked down with PGRN siRNA were treated with TNFα stimulation.

Results: The body weight and albuminuria were significantly increased in WT-HFD group compared with WT-standard diet (SD) group. The body weight of KO-HFD group was significantly decreased compared with WT-HFD group. However, albuminuria and the expression of renal inflammatory markers including TNFα in KO-HFD group were increased than those in WT-HFD group. On the other hand, the WT-HFD mice showed vacuolization in the proximal tubule, but KO-HFD mice did not. Immunohistochemical analysis showed that vacuolar membranes were clearly positive for a lysosomal marker, LAMP-1, suggesting impairment in lysosomal function. The expression of megalin which plays a critical role in the reabsorption of protein in proximal tubules was found to be decreased in KO mice compared with WT mice, and also reduced in mProx stimulated with TNFα.

Conclusions: PGRN deficient exacerbated renal inflammation caused by high-fat diet, while the results also showed improvement in tubular vacuolation. Anti-inflammatory treatment with PGRN for kidney diseases should be considered based on the opposing function of PGRN.

Diet Has a Stronger Impact on the Gut Microbiota Than Kidney Function in Rats with Moderate CKD
Annabel Biruete,1 Tzu-Wen L. Cross,2 Stephen R. Lindemann,3 Kelly Swanson,3 Neal X. Chen,3 Sharon M. Moc,1 Indiana University School of Medicine, Indianapolis, IN; 1Purdue University, West Lafayette, IN; 2University of Illinois at Urbana-Champaign, Urbana, IL.

Background: Diet and CKD have been shown to alter the gut microbiota. However, whether diet or kidney function plays a stronger role in the gut microbiota in moderate CKD is not well established. We assessed the effects of two diets on the gut microbiota in rats with moderate CKD.

Methods: Cy5+/ rats (CKD) and normal littermates (NL) consumed an autoclaved grain-based diet containing 0.7% phosphorus (0.3% phytate-bound) and 3.5% crude fiber from birth. At 17-wk-old, half of the animals were maintained on the same diet (Grain) and the other half switched to a semi-purified casein-based diet containing 0.7% phosphorus (0% phytate-bound, 0.6% phosphate additives) and 5% non-fermentable cellulose (Casein) until 26-wk-old (n=10 rats/group). DNA was extracted fromecal and fecal samples collected at euthanasia, the V4 region of the 16s rRNA gene was sequenced via Illumina MiSeq, and data were analyzed using QIIME2 and LEfSe.

Results: Intestinal microbial a-diversity, or diversity within a sample, was significantly greater in rats fed the grain diet compared to casein diet regardless of kidney function. Diet and kidney function both had significant impacts on microbial β-diversity (diversity between samples), but diet explained a larger portion of the observed variability (27%) than kidney function (11.5%). Consumption of the grain-based diet increased many genera with short-chain fatty acid (SCFA) producing capacity, including Bifidobacterium, Ruminococcus, Roseburia, and Prevotella than the casein diet. Whereas the casein diet drove greater Bacteroides abundance that can metabolize tryptophan to indoles, which may exacerbate the formation of uramic toxins. Notably, the casein diet led to a greater abundance of Bilophila in NL rats and greater Allipotri in CKD. Both of these taxa have been shown to be more fibrotic compared to the other two groups. The sequencing of 16s rRNA gene was completed and is currently being used to assess the composition and diversity of gut microbiota in each group.

Conclusions: Supplementation with fiber or probiotics may reduce kidney injury after ischemia. Additional studies to identify specific changes in metabolites driving this protection are needed.

Effect of High Fiber or Probiotics-Enriched Diets on Kidney Injury in Mice Model of Bilateral Ischemia Reperfusion
Shirin Pourafshar, Nabin Poudel, Nataliya Skrypnyk, Junlan Yao, Mark D. Okusa. University of Virginia Health System, Charlottesville, VA.

Background: Changes in dietary intake have a significant effect on the incidence and development of chronic kidney disease (CKD). The progressive decline in kidney function during CKD can lead to increased systemic chronic inflammation and worsening of kidney injury. Fibers and probiotics are used by gastrointestinal bacteria to produce metabolites with anti-inflammatory activities. The objective of our study was to investigate the role of fiber and probiotics in ameliorating kidney injury using bilateral ischemia reperfusion (IR) surgery as a CKD model in mice.

Methods: Thirty-six 57BL/6j wild type, male mice were purchased from the Jackson Laboratory (Bar Harbor, ME, USA). After co-housing for a week, they were then isolated and randomly assigned to a diet: normal chow (C); control), high fiber (HF; modified AIN-93G with increased Hi-Maize Corn), and probiotics (P; AIN-93G with added Bifidobacteria spp.). After 14 days, mice underwent sham surgery (5 per group) or IR surgery (7 per group) and then resumed assigned diet for 28 days. Blood and fecal samples were collected both before surgery and after surgery. Mice were euthanized after 42 days to collect kidneys, small intestine, colon, fecal, and blood samples. Measurements of plasma creatinine, markers of kidney injury, and tissue staining were performed. Fecal samples were further processed to assess diversity of gut microbiota. Two-way ANOVA with Tukey’s multiple comparisons was used for statistical analysis.

Results: On each diet, the IR increased serum creatinine compared to sham (P<0.05). In the HF group, the IR increased serum creatinine compared to sham (P<0.05). However, NGAL and KIM1 were lower in HF and P compared to C, respectively (p<0.005). The histology sections in control group appeared to be more fibrotic compared to the other two groups. The sequencing of 16s rRNA gene was completed and is currently being used to assess the composition and diversity of gut microbiota in each group.

Conclusions: Supplementation with fiber or probiotics may reduce kidney injury after ischemia. Additional studies to identify specific changes in metabolites driving this protection are needed.

Dietary Fat Intake and Mortality Across Kidney Function in a Nationally Representative Cohort

Yoko Narasaki, Amy S. You, Tsuyoshi Miyagi, Yoshihazu Miyasato, Hiroshi Kimura, John Sy, Anna Jin, Csaba P. Kovesdy, Danh V. Nguyen, Kamyr Kalantar-Zadeh, Connie Rhoe. University of California Irvine, Irvine, CA; The University of Tennessee Health Science Center, Memphis, TN.

Background: In the general population, lower dietary intake of saturated fatty acids (SFA) and higher intake of polyunsaturated fatty acids (PUFA) are associated with greater survival. However, the optimal amount and type of dietary fat intake in patients with kidney disease is unknown. We assessed the relationship between dietary fat intake and mortality in a cohort of US adults with and without kidney disease.

Methods: We examined the association between dietary intake of fat subtypes (SFA, PUFA, monounsaturated fatty acids [MUFA]) ascertained by 24-hour dietary recall with mortality in continuous NHANES adult participants (1999-2014) stratified by absence vs. presence of kidney dysfunction (eGFRs ≤60 vs. >60ml/min/1.72m², respectively). Dietary fat intake was estimated as a proportion (%) of total energy intake, and associations with all-cause mortality were estimated using adjusted Cox models.

Results: Among 37,155 participants who met eligibility criteria, 7% (N=2,677) had kidney dysfunction. In participants with normal kidney function, those with the highest tertile of SFA intake had higher death risk (ref: lowest tertile) (HRs [95%CI] 1.09 [1.04,1.15]), whereas those with the highest tertile of PUFA intake had better survival (HR [95%CI] 0.82 [0.76, 0.90]). In participants with kidney dysfunction, those in the second and third highest tertiles of SFA intake had significantly higher mortality risk and trended towards higher mortality, respectively: HRs (95%CI)s 1.21 (1.04, 1.41) and 1.33 (0.97, 1.82), respectively; however, PUFA was not associated with survival. In participants with and without kidney dysfunction, MUFA intake was not associated with mortality.

Conclusions: Higher dietary SFA intake was associated with a higher mortality in US adults with and without kidney dysfunction, whereas higher PUFA intake was associated with greater survival in those with preserved kidney function only. Further studies are needed to elucidate mechanisms behind the association of dietary fat intake with mortality.

Predictors of Healthy Behavior Engagement in CKD

Sarah J. Schrauben, Jesse Y. Hsu, Julie A. Wright Nunes, Ana C. Ricardo, Michael J. Fischer, Raquel C. Greer, Cheryl A. Anderson, Madhumita J. Mohanty, Sankar D. Navaneethan, Jing Chen, Amanda H. Anderson, Laura M. Dember, Harold I. Feldman. University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; University of Illinois at Chicago College of Medicine, Chicago, IL; Johns Hopkins University, Baltimore, MD; Baylor College of Medicine, Houston, TX; Tulane University School of Medicine, New Orleans, LA; Tulane University, New Orleans, LA; University of Michigan, Ann Arbor, MI; University of California San Diego School of Medicine, San Diego, CA; Wayne State University School of Medicine, Detroit, MI.

Background: Guidelines for chronic kidney disease (CKD) management recommend healthy behaviors to mitigate disease progression, but behavior engagement is low. Identifying predictors of behavior engagement could inform strategies to increase healthy behaviors.

Methods: Using data from the Chronic Renal Insufficiency Cohort Study, potential predictors of behavior engagement included demographics, clinical and psychosocial factors, and behaviors at baseline. We dichotomized behaviors (recommended vs. not): smoking (no vs. current), body mass index (BMI <18.5 or ≥30 kg/m²), physical activity (>150 vs <150 minutes/week), diet (score of ≥2 vs 0-1), and hemoglobin A1c (<7 vs ≥7) if diabetes. Relationships between predictors and behaviors at 2 years were estimated by multivariable adjusted logistic regression models.

Results: Among 5,209 participants at baseline, mean age was 60 years, mean eGFR was 48 ml/min/m², and 51% had diabetes. In multivariable analyses, baseline behaviors were most strongly associated with behaviors at 2 years (Table). Higher SF-12 physical component scores, which relate to better physical function and pain control, associated with recommended behaviors at 2 years. In models that did not adjust for baseline behaviors, no smoking was associated with older age, female sex, and non-White race, but the other behavior associations were not notably changed.

Conclusions: Interventions to increase healthy behavior engagement should be implemented and tested to evaluate whether they improve physical function and pain control, and possibly mitigate CKD progression.

Impact of Participation in Food Assistance Programs Among NHANES Dialysis Patients from 2001-2016

Hannah Chen, Lea Borgi. Brigham and Women’s Hospital, Boston, MA.

Background: Food insecurity and malnutrition are recognized risk factors for poor outcomes and mortality among end-stage renal disease (ESRD) patients on dialysis. However, little is known about the effect(s) of participation in food assistance programs such as Supplemental Nutrition Assistance Program (SNAP) on outcomes among dialysis patients.

Methods: This study is a cross-sectional analysis of dialysis patients in the National Health and Nutrition Examination Survey (NHANES) cohorts from 2001-2016. Food assistance program participation was self-reported as part of the NHANES interview. Differences in baseline characteristics were determined through null hypothesis testing. Logistic and linear regressions were used to examine the association between food assistance program participation and outcomes including hospitalizations and albumin as

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

621
a marker of nutrition status. The analyses were adjusted for demographics, BMI, diabetes, hypertension, and hyperlipidemia.

Results: A total of 1,565 dialysis patients were analyzed across all NHANES cohorts. Dialysis patients receiving food assistance were more likely to receive less calories and protein while on dialysis. Food assistance participation was significantly more likely to report lower food security and less likely to report full food security. Specifically, they reported more concerns regarding food running out, food not lasting, and not being able to afford balanced meals. Approximately 30% of dialysis patients report food insecurity but do not participate in food assistance programs. When adjusted to be representative of the noninstitutionalized U.S. population, there was a non-significant trend towards increased hospitalization among dialysis patients on food assistance programs (OR 1.73 [95% CI 0.42-7.12]). There was a non-significant negative correlation between food assistance program participation and serum creatinine.

Conclusions: Food assistance programs are not widely used among dialysis patients, even when patients report food insecurity. Food assistance program participation among dialysis patients did not significantly impact hospitalizations and serum albumin.

PO2023
Tanushree Banerjee,1 Deidra C. Crews,1 Charles E. McCulloch,1 Nilka Rios Burrows,2 Karen R. Siegel,1 Rajiv Saran,3 Yuto Han,3 Neil R. Powe.1
1University of California San Francisco, San Francisco, CA; 2Johns Hopkins University, Baltimore, MD; 3Centers for Disease Control and Prevention, Atlanta, GA; 4University of Michigan, Ann Arbor, MI.

Background: Food insecurity has been associated with CKD and its progression. Trends in food insecurity among adults with CKD have not been well characterized in the US population, particularly across racial/ethnic groups.

Methods: Data from NHANES from 2003-2016 were used to estimate the prevalence of food insecurity among individuals with CKD (defined by albuminuria or eGFR 15-59 mL/min/1.73 m²), overall and by racial/ethnic group. We included individuals aged 20 years and with a household income ≤ 400% of the federal poverty level (n=3180). Food insecurity was defined as ≥ 3 yes responses on the 18-item questionnaire. Racial/ethnic groups were defined as non-Hispanic white (NHW) and non-NHW. Survey years were collapsed into time periods 2003-2006, 2007-2010, and 2011-2016. Prevalence rates for all groups were defined as non-Hispanic white (NHW) and non-NHW. Survey years were collapsed into time periods 2003-2006, 2007-2010, and 2011-2016. Prevalence rates were estimated after standardization to the 2010 age population distribution from the US Census. Log binomial regression model was used to estimate adjusted risk ratios (RR) for the association of food insecurity and racial/ethnic groups.

Results: Overall prevalence of food insecurity in adults with CKD was 19.9%. During the period, the age-standardized prevalence rate of food insecurity increased from 5.7% to 32.8% among NHW and from 23.2% to 35.8% among non-NHW (p-trend=0.001). After adjusting for age, sex, education level of post-secondary education (p<0.05). These patients also reported significantly higher daily sugar intake. Dialysis patients receiving food assistance were significantly more likely to report lower food security and less likely to report full food security. Specifically, they reported more concerns regarding food running out, food not lasting, and not being able to afford balanced meals. Approximately 30% of dialysis patients report food insecurity but do not participate in food assistance programs. When adjusted to be representative of the noninstitutionalized U.S. population, there was a non-significant trend towards increased hospitalization among dialysis patients on food assistance programs (OR 1.73 [95% CI 0.42-7.12]). There was a non-significant negative correlation between food assistance program participation and serum creatinine.

Conclusions: Food assistance programs are not widely used among dialysis patients, even when patients report food insecurity. Food assistance program participation among dialysis patients did not significantly impact hospitalizations and serum albumin.

PO2024
Approach to Nutritional Protein Intake in Hemodialysis Patients with Hyperphosphatemia: Associations with Mortality in the DOPPS
Sugaru Yamamoto1, Brian Bieber,2 Hirota Komaiba,3 Hiroki Kitabayashi,3 Takanoobu Nomura,4 Alex Cases,3 Christian Combe,5 Ronald L. Pisoni,6 Bruce M. Robinson,7 Masafumi Fukagawa.8 Arbor Research Collaborative for Health, Ann Arbor, MI; 2Research Institute for Contemporary Medical Science, Tokyo, Japan; 3Kyorin University Co., Ltd., Tokyo, Japan; 4Tokai University School of Medicine, Isehara, Japan; 5Universitat de Barcelona, Barcelona, Spain; 6Université de Bordeaux, Bordeaux, France.

Background: Pts undergoing hemodialysis (HD) have poorer nutritional status than the general population, and worse nutritional status is associated with poor outcomes. Hyperphosphatemia is common in HD pts due to abnormal mineral and bone metabolism. Nephrologists manage hyperphosphatemia by prescribing phosphate binders and/or promoting dietary protein restriction; the latter may, however, adversely affect nutritional status. We address the hypothesis that, even in the presence of hyperphosphatemia, liberalizing dietary protein leads to better outcomes.

Methods: The analysis includes 11,628 HD pts in 12 countries in DOPPS phase 4 (2009-2011), from 254 facilities where the medical director reported facility practices. The primary exposure variable was response to the following question: “For pts with s. albumin 3.0 g/dl. and phosphate 6.0 mg/dl, do you typically recommend to (A) increase or (B) not change/decrease dietary protein intake?” The primary outcome was all-cause mortality, analyzed by Cox regression. Linear regression was used to model associations between the exposure and intermediate nutrition markers. Models were adjusted for country, case-mix, and lab values.

Results: In the case scenario, 91% of medical directors in N. America recommended to increase protein intake compared to 58% in Europe (range=16-83% in 7 countries) and 56% in Japan. Advice to increase dietary protein intake was associated with 0.33 mg/dl higher s. creatinine levels (95% CI: 0.08-0.57) while clinically meaningful associations were not observed for s. albumin and phosphorus. Advice to increase dietary protein intake was weakly associated with lower mortality-HR (95% CI)=0.89 (0.77-1.03). The association with survival was stronger in pts with age ≥ 70 yrs and for those without diabetes (p=0.08 and 0.20 for interaction).

Conclusions: In this large international cohort study, the medical director’s protein intake recommendation increased in dietary protein intake for HD pts with low albumin and high phosphorus levels was most common in N. America and associated with higher s. creatinine levels and potentially lower all-cause mortality. Further research into the possible benefits of protein intake liberalization for HD pts, even in the presence of hyperphosphatemia, is warranted.

PO2025
Dietary Acid Load Is Associated with the Risk of Mortality and Kidney Replacement Therapy in Diabetic CKD Patients but Not in Non-Diabetics
Alisson D. Machado,1 Dirce Marchioni,1 Paulo lotus,1 Isabela M. Bensencor,2 Silvia I. Titan,3,4 Department of Nephrology, Hospital das Clinicas, Faculdade of Medicine, University of São Paulo, São Paulo, Brazil; 2Department of Nutrition, School of Public Health, University of São Paulo, São Paulo, Brazil; 3Clinical Research Center, University Hospital, University of São Paulo, São Paulo, Brazil; 4Tufts Medical Center, Boston, MA.

Background: Dietary acid load (DAL) may be related to CKD progression but results are still conflicting. In addition, no studies have evaluated the association of DAL with mortality in CKD. The aim of this study was to evaluate two estimates of DAL, PRAL (potential renal acid load) and NEAP (net-endogenous acid production), in relation to events of mortality and kidney replacement therapy (KRT) in CKD.

Methods: Baseline clinical and dietary data (food frequency questionnaire) from the PROGREDIR Cohort (n=454), a CKD cohort based on Sao Paulo, Brazil, composed predominantly of older people with CKD G3 and G4 was used in this analysis. PRAL and NEAP were computed using previously validated formulas, and those with missing values were excluded (n=11). Events of death (n=190) and KRT (n=62) were ascertained after a median follow-up time of 6 years. Uni and multivariable Cox proportional hazards and Coxnet M. Risk models were computed.

Results: Mean age was 68 ± 12, mean eGFR was 38 ± 15 mL/min/1.73m², 63% were male and 56% were diabetic. Mean intake of PRAL and NEAP was 4.1 ± 18.5 and 51.9 ± 17.4 mEq/d, respectively. Initially, neither PRAL nor NEAP were associated with mortality or KRT. However, after stratification for diabetes, both estimates were positively related to the risk of KRT and death in diabetics only, even after adjustments (Table). Competing risk analysis were consistent with the Cox findings. By entering interaction terms between diabetes and DAL estimates, which were significant, both PRAL and NEAP showed an inverse association with the risk of clinical events.

Conclusions: Our results suggest the existence of a relevant interaction between PRAL/NEAP and diabetes: whereas DAL estimates were associated with mortality and KRT in diabetics, this association was not observed in non-diabetes.

Higher Estimation of Dietary Phosphorus Content with More Plant-Based Protein in Hemodialysis Patients Across Race/Ethnicity Using 3-Day Food Records with Interviews

Amanda R. Tortorici,1 Connie Rhee,1 Amy S. You,1 Elani Streja,1 Keith C. Norris,2 Kamyar Kalantar-Zadeh,1 *University of California Irvine, Orange, CA; 1University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Dietary phosphorus (P) restrictions are commonly recommended based on the estimated phosphorus (P) content of foods, not accounting for P type or its absorbability. Whereas plant-based diets have important benefits, they are traditionally not recommended to dialysis patients given perceived higher P content in plant vs animal-based proteins, although P is less absorbable in plant foods. We examined dietary differences across race/ethnicity in a group of hemodialysis (HD) patients from several dialysis centers in Southern California.

Methods: We performed a cross-sectional study of HD patients at four Southern California facilities. Patients were randomized to one of two smoking intervention groups: a standard intervention or one focusing on dietary changes. Dietary data was collected using a 3-day food record. Results were analyzed by race/ethnicity to identify differences in estimated P content and P type across groups.

Results: There were 102 patients in each group, with an average age of 63 years. The majority of patients were white (72%) and male (60%). The mean estimated P content was significantly lower in the standard group compared to the dietary intervention group (1927 ± 1127 vs. 2383 ± 1369 mg/day, p < 0.001). There were no significant differences in estimated P type across groups (26% vs. 27% animal-based P, p = 0.72).

Conclusions: Dietary interventions focusing on dietary changes can significantly reduce estimated dietary P content in HD patients, with no significant effect on estimated P type.

Benefits of Home-Delivered, Low-Sodium Meals in Hemodialysis Patients

Luis M. Perez, Hsin-Yu Fang, Brett Burrows, Alexis King, Sadia anjum Ashrafi, Kenneth R. Wilund. Renal and Cardiovascular Research Laboratory University of Illinois at Urbana-Champaign, Urbana, IL.

Background: Patients undergoing maintenance hemodialysis (HD) therapy are routinely counseled to reduce dietary sodium intake to reduce sodium retention, volume overload (VO), and hypertension. Unfortunately, low-sodium trials in HD are sparse and mostly indicate that dietary education and behavioral counseling alone are ineffective in reducing sodium intake. The purpose of this study is to determine if 4-weeks of a low-sodium home delivered meals intervention will reduce interdialytic weight gain (IDWG) and subsequent VO and hypertension in patients undergoing HD when compared to 4-weeks of a usual diet.

Mediterranean Diet and the Risk of CKD: A Systematic Review and Meta-Analysis

Panupong Hansrivit1, Sharad Oli,2 Resha Khanal,1 Nasroolah Ghahramani,1 Chane Li,3 Morancy Shang,3 Saleh, Kingsley Morancy,1 Mirza,1 Morancy Shang,4 UPM-P, Paris; Harrisburg, PA; 2Pou州 State College of Medicine, Hershey, PA; 3Mayo Clinic Minnesota, Rochester, MN; 4University of Mississippi Medical Center, Jackson, MS; 5Maimonides Medical Center, Brooklyn, NY.

Background: Mediterranean diet has been shown to be associated with lower risk for cardiovascular disease. However, its association with chronic kidney disease (CKD) remains inconclusive as the results were not consistent among population-based studies. Thus, this study aims to assess the association between Mediterranean diet adherence and CKD prevention.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched from database inception to March 2020 without language restrictions. We included studies describing the risk for CKD in community-dwelling subjects > 18 years of age. The study criteria were set based on the definition of the CKD per the National Kidney Foundation. The results were stratified by median dietary adherence as assessed by standardized food frequency questionnaires. Meta-analysis and meta-regression analysis were used to evaluate the risk of CKD and the association between clinical factors and incidence of CKD, respectively.

Results: Of 168 citations, a total of ten (n = 19,151) and five studies (n = 9,099) were included in the systematic review and meta-analysis, respectively. Only studies adopting Mediterranean Diet Scale (MDS) were included in the meta-analysis. The mean score was 4.0 ± 0.1 points. The mean age was 53.1 ± 8.2 years. The mean eGFR was 77.3 ± 29.6 mL/min/1.73m². The average total daily energy intake was 1,999 ± 258.0 kilocalories per day. Up to 50.4% were male, 7.1% were black, and 14.9% had a history of diabetes mellitus. With the mean follow-up duration of 11.5 ± 9.5 years, the pooled adjusted odds ratio (OR) for CKD was 0.897 (95% CI, 0.865-0.930; F 26.5%). By excluding kidney transplant patients, the adjusted OR for CKD was 0.901 (95% CI, 0.868-0.935; I² 9.4%). Both findings remained significant on sensitivity analysis. No publication bias was detected. The incidence of CKD was 0.028 events per person-year (95% CI, 0.012-0.044). From meta-regression analysis, male sex was associated with higher incidence of CKD in an adjusted model. There was no significant association between age, black race, eGFR, and total daily energy intake vs. CKD incidence.

Conclusions: Adherence to Mediterranean diet by a 1-point increment of MDS was associated with 10% lower risk of CKD. However, this only applies to healthy patients, the pooled adjusted OR for CKD was 0.901 (95% CI, 0.868-0.935; I² 9.4%).

PO2027

Attitudes Toward Plant-Based Eating (PBE), Self-Reported Habits, and Relationship to BMI and Blood Pressure in a Population of Inner-City CKD/ESKD Patients

Ahmad Saleh, Kingsley Cрукshank, Takisha Morancy, Iqra Nadeem, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: The benefits of a PBE dietary pattern are well described, yet there is a lack of research on the attitudes of CKD/ESKD patients regarding PBE as well as their self-reported habits.

Methods: A face-to-face survey was conducted in a random convenience sample patients from CKD clinic (15), Transplant clinic (12), and the Dialysis Unit (4). Pts were asked to answer questions assessing their attitudes and understanding of PBE using a 7-point Likert scale, and to rate their daily vegetable intake. There was no difference noted in answers among the clinics so all data were analyzed together. All comparisons are by t-test unless noted.

Results: Mean age was 54.7 ± 1.7 yrs. There were 16 (53%) men and 14 (47%) women with 25 Black (81%), 12 people (40%) had an income < $20k, with 10 (33%) between $20k and $30k, and 10 (33%) were employed. 64.5% (20) were interested in learning more about PBE; 35% had never heard of it. 22% (7) reported consuming animal protein 2-3x/week, and 77.9 ± 5.2, p<0.05), and higher systolic and diastolic BP (144.3 ± 8.2 vs. 133.9 ± 10.7, p<0.05) than those who did not eat plant-based foods had a higher BMI than those who consumed plants. From meta-regression analysis, male sex was associated with higher incidence of CKD in an adjusted model. There was no significant association between age, black race, eGFR, and total daily energy intake vs. CKD incidence.

Conclusions: Adherence to Mediterranean diet by a 1-point increment of MDS was associated with 10% lower risk of CKD. However, this only applies to healthy patients, the pooled adjusted OR for CKD was 0.901 (95% CI, 0.868-0.935; I² 9.4%). Both findings remained significant on sensitivity analysis. No publication bias was detected. The incidence of CKD was 0.028 events per person-year (95% CI, 0.012-0.044). From meta-regression analysis, male sex was associated with higher incidence of CKD in an adjusted model. There was no significant association between age, black race, eGFR, and total daily energy intake vs. CKD incidence.

Conclusions: Adherence to Mediterranean diet by a 1-point increment of MDS was associated with 10% lower risk of CKD. However, this only applies to healthy patients, the pooled adjusted OR for CKD was 0.901 (95% CI, 0.868-0.935; I² 9.4%).

Underline represents presenting author.

263
Methods: We recruited 20 subjects (55±12 years, BMI 40.7±16.6 kg/m², 45% male, 65% >70 DM, 50% CVD) from a HD clinic in central IL. Participants followed a usual-control diet for the first 4-weeks. PurFoods, LLC prepared and shipped 3 low-sodium kidney meals (<700 mg sodium, potassium, and phosphorus each) per day to patients in the following 4-weeks. We collected monthly IDWG, bioelectrical impedance, standardized blood pressure, 3 days (HD, non-HD, and weekend day) of dietary recalls, and blood at baseline (0M), after a usual diet (1M), and post-intervention meals (2M).

Results: Home-meal delivery significantly reduced both dietary sodium intake, IDWG, BP, and VO in HD patients. It will be important determine if these changes can be sustained long-term with additional counseling and in larger sample sizes. The long-term benefits and cost-effectiveness of this approach also needs to be evaluated.

Performance of GLIM for Nutritional Assessment of Hemodialysis Patients: Comparison with Subjective Global Assessment (SGA) and Malnutrition-Inflammation Score (MIS)

Carla M. Avesani,1 Alice Sabattino,4 Alessandro Guerra,2 Juan J. Carrero,3 Giovanni maria Rossi,1 Peter Stenvinkel,1 Enrico Fiaccadori,2 Bengt Lindholm,1 Karolinska institutet Department of Clinical Sciences Intervention and Technology, Huddinge, Sweden; 2Università degli Studi di Genova, Genova, Italy; 3Karolinska Institutet, Stockholm, Sweden; 4Parma University Hospital, Parma, Italy.

Background: There is a need for methods to identify and monitor malnutrition in maintenance hemodialysis (MDH) patients (pts). We assessed GLIM (Global Leadership Initiative on Malnutrition) evaluated agreement and survival prediction of GLIM vs. SGA and MIS in MDH pts.

Methods: We investigated two cohorts, MHD Italy (121 adult pts from Italy; 67±16y, 65% men, BMI 25±5 kg/m² and MHD Brazil (169 elderly (age>60 y) pts from Brazil; 71±7y, 66% men, BMI 25±4 kg/m²), followed for 40 (27; 46) and 17 (12; 31) months (median and 25% 65%; 70%). Respectively, GLIM comprises: 1. Screening and 2. Confirming malnutrition by phenotypic and etiologic criteria. For 1., presence of >1 criteria from protein energy intake ≤ 5 and 8 was considered inadequate.}

Conclusions: Malnutrition was present in 38.8% by GLIM, 25.6% by SGA and 29.7% by MIS. There was a low agreement between SGA and MIS (κ = 0.43), and between SGA and MIS (κ = 0.38). The long-term benefits and cost-effectiveness of this approach also needs to be evaluated.

PO2031
Dietary Fiber Intake, Cardiovascular Risk Factors, and Kidney Function: A Mediation Analysis

Background: Higher fiber intake may be associated with higher eGFR but the mechanisms underlying this association are poorly understood. Considering that higher fiber intake is linked to improved cardiovascular (CV) risk factors, we hypothesize that the effect of fiber intake on eGFR could be mediated by these CV factors.

Methods: CARTaGENE is a population survey of healthy adults. We used multiple linear regression to study the association between dietary fiber and eGFR while adjusting for confounding factors, including age, sex, diabetes, hypertension, dyslipidemia, body mass index [BMI], smoking, prior CV disease, physical activity and caloric intake. We assessed whether CV risk factors lie in the causal pathway between fiber intake and eGFR through mediation analyses.

Results: We included 9,854 of the CARTaGENE participants with a completed food questionnaire (mean age: 53 years, 56% males). The main comorbidities were hypertension (25%), diabetes (6%) and cardiovascular disease (7%). The median daily fiber intake was 17.2g (IQR 10.7-23.7) and the mean eGFR was 87.3 ± 14.6 mL/min/1.73 m². After adjustment for the above factors, fiber intake was associated with higher eGFR and serum HDL levels, and lower BMI, glycated hemoglobin and triglyceride levels (Table). Other risk factors were found to be non-significant. The mediation analysis demonstrated that only 10% of the effect of fiber intake on eGFR was mediated through BMI and triglyceride levels.

Conclusions: Higher dietary fiber intake is associated with higher eGFR and better control of certain cardiovascular risk factors. While the association between fiber intake and kidney function may be marginally mediated by healthy weight and triglyceride levels, further studies are needed to understand the mechanisms underlying this association.

Association between dietary fiber intake and clinical variables.
Protein Supplements and Proteinuria: A Case-Control Study in Military Candidates

Sofia H. Marques,1,2 Alberto Freitas,3 Hospital Militar Polo Porto, Porto, Portugal; 1Hospital de Braga, Braga, Portugal; 3Faculty of Medicine of the University of Porto, Porto, Portugal.

Background: Man has long wanted to improve both image and physical performance using supplements some of which include proteins. Low protein diets are recommended by guidelines to attenuate the progression of chronic kidney disease. In healthy individuals, however, protein intake does not seem a risk factor. This study addressed whether protein supplements could cause proteinuria in a healthy population.

Methods: We performed a case-control study at the Military Hospital of Oporto including 1541 military candidates who had urinalysis in 2017. Among them, 102 (6.6%) had proteinuria (dipstick test ++/+ and these) were compared to a random sample of 106 non-proteinuric candidates. Telephone interviews collected data on comorbidities, exercise, smoke, alcohol habits, drugs, supplements, height and weight. Protein supplements were accessed as risk factors for proteinuria using the Pearson Qui-square test.

Results: Answers were obtained from 49 cases and 52 controls. Of these 101 candidates, 88 were males, had a median age of 19 and mean body mass index of 24.1±2.4kg/m2. Most (97%) exercised for a mean weekly time of 6±3.7h: 40% practiced only resistance training; the rest both resistance and strength. Half used supplements at some point in time and 32 were current users. All used protein powder, mainly whey protein. Additional supplements (mostly amino acids) were used by 13. The weekly powder dose ranged from 3 to 14 scoops (20-30g/scoop). No significant association was found between the use of protein supplements and proteinuria (p=0.51). Similarly, no difference was found in creatinine, urea or other laboratory parameters. Supplements were significantly used more by those who practiced strength, as compared with resistance-training subjects.

Conclusions: One third of Portuguese military candidates used protein supplements. Increased use was noted in strength training most likely due to peer pressure. Proteinuria was found in 6.6%, similar to screenings in other healthy populations. No relation was found between protein supplements and proteinuria which could mean that the kidneys of healthy individuals are capable of dealing with a higher metabolic strain after increasing protein loads. However we acknowledge that proteinuria as a marker of disease has limitations and that the cumulative exposure and lifetime impact of protein supplements was not considered and may be relevant.

Continuous Intraluminal Amino Acid Infusion from the Start of Dialysis Is Better to Avoid Catabolism Under the High-Volume Pre-Dilution Online Hemodiafiltration

Motoko PO2034
Matsuda Kato,1 Yukie Kitajima,1 Kenichi Kokubo,1 Toru Hyodo,2 Department of Clinical Engineering, Eijin Clinic, Hirotsuka, Japan; 1Tokyo University of Technology School of Health Sciences, Setagaya, Japan; 2Allied Health Science, Kitasato University, Sagamihara, Japan; 3Dialysis Center, Eijin Clinic, Hirotsuka, Japan.

Background: Amino acid infusion during dialysis is useful for improving nutritional status (Clin Nephrol 3:234,1975). Usually, amino acid is infused 60 to 90 minutes before the end of dialysis, but it is reported that continuous administration from the start of dialysis is better (Kidney Int 21: 500, 1982). Moreover, these effects are unclear in the high-volume pre-dilution on-line HDF (HVPO-HDF). The optimal administration method of amino acid infusion under the HVPO-HDF was analyzed.

Methods: The subjects were 10 patients receiving HVPO-HDF (7 males, 4 diabetics, mean age: 77.2±5.5 years). We compared the pre- and post-dialysis plasma amino acids levels and the total amino acids amount in the waste fluid when the amino acid infusion was performed from the start of dialysis (Group A) and from 1 hour before the end of dialysis (Group B). The treatment time is 4 hours. The mean blood flow rate was 200 mL/min. The replacement fluid flow rate was 600 mL/min. The replacement fluid volume was 90 mL/min and total replacement fluid volume was 400 mL/min.

Results: In pre-dialysis plasma levels of total amino acid (TAA), Group A and Group B showed the same level (2477 ± 267 mmol/mL and 2622±319 mmol/mL, respectively). In the essential amino acid (EAA) and non-essential amino acid (NEAA), similar results were obtained (827±145 mmol/mL and 847±99 mmol/mL of EAA, 1644±216 mmol/mL and 1120±193 mmol/mL of NEAA, respectively). Moreover, the losses of amino acids were also almost equal (900±81 mg/dL and 880±1204 mg of TAA, 880±5712 mg of EAA and 454±6453 mg of EAA, 402±644 mg and 434±862 mg of NEAA, respectively). In Group A, post-dialysis plasma levels of amino acids were significantly lower than in Group B (2066±636 mmol/mL of TAA, 946±193 mmol/mL and 220±439 mmol/mL of EAA, 1120±193 mmol/mL and 1577±260 mmol/mL of NEAA, respectively, p < 0.01).

Conclusions: We analyzed 175,392 US veterans who received care between 2004 and 2006, with available serum LDL and albuminuria (UCAR) data. All UCAR measurements until the end of follow-up (2014) were used to ascertain UCAR slopes using mixed effects modeling. The relationships between LDL and faster UCAR slope (a 0.1 mg/dL/year) stratified by baseline albuminuria stage (A1-A3) were estimated using logistic models adjusted for baseline demographics, comorbidities, prescription of statins and non-statins, BMI, albumin, HDL, triglycerides, eGFR, and UCAR.

Results: Assessment of abnormal serum albuminuria (UCAR) was considered as a marker of kidney disease progression. Prior studies showed abnormal albuminuria levels may predict the progression of renal function decline; however, associations of low-density lipoprotein cholesterol (LDL) with UCAR change is unclear. Therefore, we sought to investigate the association of LDL and UCAR slope across albuminuria stages. We analyzed 175,392 US veterans who received care between 2004 and 2006, with available serum LDL and albuminuria (UCAR) data. All UCAR measurements until the end of follow-up (2014) were used to ascertain UCAR slopes using mixed effects modeling. The relationships between LDL and faster UCAR slope (a 0.1 mg/dL/year) stratified by baseline albuminuria stage (A1-A3) were estimated using logistic models adjusted for baseline demographics, comorbidities, prescription of statins and non-statins, BMI, albumin, HDL, triglycerides, eGFR, and UCAR.

Results: Cohort mean age was 65±11 and included 3% females, 14% African-Americans, and 87% diabetics. The median [IQR] of serum LDL level and eGFR were 97 [75,119] mg/dL and 73 [58,88] mL/min/1.73m2. To further study the relationship with LDL by age, we performed age-stratified analysis and found similar results. The odds ratio of faster UACR slope for serum LDL levels of 5.0 mg/dL in the age group of 20-39 years was 1.67 (95% CI: 1.14, 2.43), and 1.67 for serum LDL levels of 5.0 mg/dL in the age group of 40-49 years, and 1.86 for serum LDL levels of 5.0 mg/dL in the age group of 50-59 years. The odds ratio of faster UACR slope for serum LDL levels of 5.0 mg/dL was 1.64 (95% CI: 1.14, 2.37) in the age group of 60-69 years, and 1.83 for serum LDL levels of 5.0 mg/dL in the age group of 70-79 years. The odds ratio of faster UACR slope for serum LDL levels of 5.0 mg/dL was 1.69 (95% CI: 1.15, 2.48) in the age group of 80 years or older. These findings suggest a strong association between LDL and faster progression of albuminuria.
yet attenuated relationship was observed among A2 patients. Odds of faster UACR slope was higher only in patients with LDL ≤160 mg/dL and with index UACR>300 mg/g. For A3 patients, there was no association between LDL level and UACR slope.

Conclusions: Among patients with baseline UACR <300 mg/g, both low and very high LDL were associated with higher odds of having fast UACR change. Yet, among those with higher albuminuria, the relationship with LDL and UACR change was null. More studies are needed to delve into the mechanism between LDL and CKD progression in order to further manage patients kidney health.

PO2037
Lipidomic Markers for Cognitive Impairment in Maintenance Hemodialysis Patients
Ke Zheng, Yujun Qian, Xuemei Li. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Cognitive impairment (CI) was relatively common in maintenance hemodialysis patients. The pathophysiology of CI in this particular population was not well understood. Whether the classic lipid components that affect cognitive outcome in general population have similar effect in dialysis patients is not clear. In this study, we tried to get a better understanding of the pathogenesis CI in hemodialysis patients by lipidomic analysis and find potential lipid markers to predict cognitive decline.

Methods: From July 2013 to July 2019, we followed up the cognitive evaluation results of the hemodialysis patients in our dialysis center. The cognitive function was evaluated by the MMSE and MoCA at baseline and follow-up period. Plasma and hemocytes of enrolled patients were collected at baseline. Lipidomic analyses were performed on an Exion LC-system coupled with a QTRAP 6500 PLUS system (Sciex). Principal component analysis and orthogonal project to late structures discriminant performed on an Exion LC-system coupled with a QTRAP 6500 PLUS system (Sciex).

Results: At the baseline, plasma from 21 patients and hemocytes from 65 patients were collected for lipidomic analyses. 539 lipids were detected in plasma and 237 lipids were detected in hemocytes. In individuals with plasma lipid files data, 10/21 suffered MMSE scores decrement and 16/21 showed MoCA decrement. In patients with hemocytes lipids files date, 29/65 of them suffered MMSE scores decrement and 43/65 showed MoCA decrement. Compared with retained MMSE scores group, decreased MMSE scores group presented higher level of plasma PA 32:1, PA 38:5, CE-17:1, and lower level of plasma DAG 40:6(18:0/22:6), PE 36:4(18:1/18:3). There was no significant difference in erythrocytes lipids between the two groups. Compared with retained MoCA scores group, decreased MoCA scores group presented higher level of plasma LacCer d18:1/18:0, LPE 18:2, G3M d18:1/20:1, PE 36:3(18:1/18:2), LPE 18:1, lower level of plasma PI 38:5(18:0/20:5), and higher level of erythrocytes GM3 d18:0/20:0 (Fold change >1.5 or <1/1.5, P value <0.05).

Conclusions: The pathogenesis of CI in dialysis patients may closely relate with vascular injury. Lipid analysis may contribute to a new approach to predict the risk of cognitive decline in hemodialysis patients.

PO2038
The Combination of Malnutrition Inflammation and Limitations in Functional Status Is Associated with a Very High Risk of Mortality in Hemodialysis Patients: Results from the DOPPS
Marcelo Lopes,1 Eiichiro Kanda,2 Brian Bieber,1 Kazukihito Tsuuryu,2 Hideki Hirakata,1 Angelo Karaboyas,1 Stefan H. Jacobsson,1 Indranil Dasgupta,1 Bruce M. Robinson,1 Roberto Pecos-Filho,1 DOPPS ‘Arbor Research Collaborative for Health, Ann Arbor, MI; 2Kawasaki I Daigaaku, Kurashiki, Japan; 3Nara-ken, Nara, Japan; 4Fukao Renal Clinic, Fukaoa, Japan; 5Karolinska Institute, Stockholm, Sweden; 6University of Warwick Warwick Medical School, Coventry, United Kingdom.

Background: The malnutrition-inflammation-complex (MIC) is a risk factor for mortality and lower quality of life in hemodialysis (HD) patients. The identification of MIC and its risk factors, which include the limited ability to perform functional status (FS), is key to improve the patient experience on HD. Our study investigates the association of MIC and FS combinations with mortality in HD patients.

Methods: We analyzed data from a cohort of 5465 HD patients from Australia, France, Germany, Italy, Japan, New Zealand, Spain, Sweden, and United Kingdom, enrolled in the Dialysis Outcomes and Practice Patterns Study phases 4 (2009-2011) and 5 (2012-2015). MIC syndrome was defined as low serum albumin (<3.8 g/dL) and high serum C-reactive protein (>3mg/L in Japan; >10mg/L elsewhere). Poor functional status was defined as the sum of scores from the self-reported limitations in the Katz Index of Independence in Activities of Daily Living (0 to 5) and the Lawton-Brody Instrumental Activities of Daily Living Scale (score ranges from 0 to 8) less than 11. We investigated the association between combinations of MIC (+/-) and FS (low/high) with death, using Cox proportional hazards models adjusted for possible confounders including patient demographics, comorbidity history, catheter use, serum creatinine, phosphorus levels, WBC count, hemoglobin level, and time on dialysis therapy.

Results: The prevalence of different combinations were: MIC-/ High FS 57%, MIC-/ Low FS 24%, MIC+/High FS 9%, and MIC+/Low FS 10%. Patients with MIC+/high FS were younger, better nourished, and had lower prevalence of comorbidities. Compared to the reference group, the hazard ratios [HR (95% CI)] for all-cause mortality were 1.56 (1.24-1.98) for MIC-/ low FS, 1.75 (1.32-2.32) for MIC+/ high FS, and 2.97 (2.31-3.82) for MIC+/ low FS groups. The adjusted HRs for infection-related mortality were 1.57 (0.91, 2.71) for MIC-/low FS, 1.67 (0.84, 3.31) for MIC+/high FS, and 5.45 (3.15, 9.45) for MIC-/low FS groups.

Conclusions: The combination of MIC and low FS is a strong predictor of mortality, and infectious mortality in particular, in HD patients. Identification of patients with MIC and FS.

PO2039
High-Amlose Resistant Starch (RS) Cookies Supplementation Does Not Decrease Trimethylamine N-Oxide (TMAO) Plasma Level in Hemodialysis (HD) Patients
Denise Mafra,1 Julie ann Kemp,1 Henrique F. Santos,1 Hugo E. de Jesus,1 Marta Escalghado,1 Bruna Pavia,1 Bengt Lindholm,2 Peter Bergman,2 Peter Stenvinkel.1 1 Federal University Fluminense, Rio de Janeiro, Brazil; 2Karolinska Institute, Stockholm, Sweden.

Background: TMAO is generated from dietary nutrients by the gut bacteriome and it is associated with cardiovascular mortality in HD patients. Thus, to reduce its generation, nutritional strategies have been proposed. The aim of this study was to analyze the TMAO levels and potential changes in TMAO-associated bacterial taxa in HD patients after RS supplementation.

Methods: This is a randomized, double-blind, placebo-controlled trial with HD patients that were allocated to RS or placebo group to receive alternately 9 cookies/d (dialysis days) and 1 sachet/d (non-dialysis days) containing 16g/d of RS (H6-Maize 260, Ingredion®) or manioc flour as the placebo, during 4 weeks. Plasma TMAO, choline, and betaine levels were measured with LC-MS/MS. Fecal bacteriome composition was evaluated by high-throughput sequencing of 16S ribosomal RNA gene V1–V3 region, followed by a search for TMAO-associated bacterial taxa.

Results: Thirty-one participants finished the study, 15 in RS group (53.3 %); 56.0±7.5 yrs; 50.0±3.6 months on HD and BMI 26.1±5.0 kg/m^2 and 16 in the placebo group (31.2%); 53.5±11.4 yrs; 44.3±2.6 months on HD and BMI 26.6±5.2 kg/m^2. After four weeks of supplementation no significant changes in TMAO, choline and betaine plasma levels were observed (Table 1). Notably, after the RS supplementation, TMA-producing bacterial taxa such as Ruminococcus torques group [0.026 (0.023 - 0.04) vs. 0.017 (0.017 - 0.02), p=0.061] and Streptococcus had decreased the relative abundance, while Prevotellaceae family and Enterococcus increased their relative abundance in placebo group. However, the differences did not reach statistical significance. Additionally, the relative abundance of TMA-producing bacterial taxa was low in both groups.

Conclusions: RS supplementation did not influence TMAO plasma levels nor fecal taxa potentially linked to TMAO in HD patients, suggesting that RS did not modify the composition of gut bacteriome that convert its precursors into TMAO.

Public Health Effects of Sterilized, Used Hemodialyzers for Water Purification in Rural Ghana

Johanna B.B.,1 Goosen G. Raimann,1,2 Philip K. Nurh,1 Seth Johnson,1,3 Linda L. Donald,1 Harrison K. Matti,1 Maria E. Ferris,1 Mathieu Lamolle,1 Hongbin Zhang,1 Friedrich K. Port,1 Nathan W. Levin.1 Easy water for everyone, Accra, Ghana; 2Department of Field Epidemiology and Applied Biostatistics, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; 3Health Service, Ada, Ghana; 3Arbor Research Collaborative for Health, Ann Arbor, MI; 4Graduate School of Public Health and Health Policy, New York City, NY; 5Renal Research Institute, New York, NY; 6University of North Carolina System, Chapel Hill, NC; 7Water for Everyone, Geneva, Switzerland.

Background: Contamination of contaminated water is a risk factor for infectious diarrhea and according to estimates of the World Health Organization the most often reported cause of death in children and the elderly. Our organization “Easy Water for Everyone (EWfE)” uses a membrane filtration device with repurposed hemodialyzers and we hereby present our remarkable public health effects (Raimann for EWfE, SciRep 2020). Here we report the impact our project had on the incidence of diarrhea in two villages in rural Ghana.

Methods: This prospective study was conducted with approval from Ghana Health Service and involved the quantification of self-reported diarrhea 4 months before and after implementation of a membrane filtration device in a school and a primary healthcare center. Using a mixed-effects generalized linear model, the odds of developing diarrhea in presence of the membrane device were estimated. In addition to this, we also tested the association of age on the estimate, and conducted a subset analyses in those younger than 15 years. Analyses were conducted in R version 4.0 and odds ratios (OR) reported as OR (95%CI).

Results: We studied 927 villagers (55% female, 43% <15 yrs and 33% >50yrs) and the incidence rate of diarrhea was 0.30 per subject month per village-month before and 0.26 after implementation of the device. We found a statistically significant association between the device and incidence of diarrhea [OR 0.79 (0.67 to 0.95)] with significantly higher odds of diarrhea in the younger [OR 1.32 (1.07 to 1.63)] and the elderly [OR 1.45 (1.06 to 1.99)].

Conclusions: Our study supports provision of clean drinking water as means to prevent diarrhea and its possible adverse sequelae such as acute kidney injury (AKI). Additionally, we conclude the youngest and the eldest in the population are at highest risk of diarrhea.

Development and Validation of a Multifrequency Bioimpedance Spectroscopy Equation to Predict Appendicular Skeletal Muscle Mass in Hemodialysis Patients

Ting-yun Lin. Taipei Tzu Chi Hospital, Taipei, Taiwan.

Background: Sarcopenia is prevalent and associated with poor outcomes in patients with chronic kidney disease (CKD). Although bioimpedance analysis is accepted by major consensus statements as an alternative for muscle mass assessment, it can be affected by hydration status in CKD patients. The Body Composition Monitor (BCM), a multifrequency bioimpedance spectroscopy device, has been widely used to assess body composition and dry weight in hemodialysis patients because it can distinguish normally hydrated lean tissues from overly hydrated tissues. Therefore, our study aimed to develop and validate an equation for obtaining appendicular skeletal muscle mass (ASM) from BCM using dual-energy X-ray absorptiometry (DXA) as the reference among hemodialysis patients.

Methods: A total of 322 consecutive body composition measurements with BCM and DXA in 263 hemodialysis patients were randomly divided at a ratio of 2:1 into development and validation groups. Stepwise multiple regression modeling was applied to develop the ASM prediction equation. Tests for agreement included mean differences and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using ROC and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using ROC and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using ROC and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using ROC and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using ROC and Bland-Altman plots.

Results: BCM yielded the following equation: ASM (kg) = −1.838 + 0.395 × total body water (L) + 0.105 × body weight (kg) + 1.231 × male sex − 0.026 × age (years) (R² = 0.914, standard error of estimate = 1.35 kg). In the validation group, Bland-Altman reliability analysis showed no significant bias of 0.098 kg and limits of agreement of 2.440 kg. Using the AWGS criteria, the model was found to have a sensitivity of 94.1%, a specificity of 98.8%, a positive predictive value of 84.2%, and a negative predictive value of 99.6% for the diagnosis of sarcopenia. Low ASM predicted by the BCM equation was associated with significantly worse overall survival among CKD patients but not hemodialysis patients.

Conclusions: The new BCM equation provides a feasible and valid option for assessing ASM in hemodialysis patients. Its utility in clinical practice requires further research.

Indoxyl Sulfate Reduces the Inducibility of NLRP3 Inflammasome in Hemodialysis Patients

Li-chun Hu,1,2 Chang Min-Yu,1,2 Yi-che Lee,1 Hsi-Hao Wang,1 Ching-fang Wu,3 Shih-Yuan Hung.1,3 I-Shou University, School of Medicine, Kaoshing City, Taiwan; 2Department of General Medicine, Yanchao, Taiwan; 3E-Da Hospital, Division of Nephrology, Department of Internal Medicine, Yanchao, Taiwan.

Background: The NLRP3 inflammasome is a cellular component of innate immunity responsible for the maturation of interleukin-1β (IL-1β). Studies have shown that the basal activity of the NLRP3 inflammasome is increased in the immune cells of hemodialysis (HD) patients, but the inducibility of the NLRP3 inflammasome upon canonical stimulation has not been studied.

Methods: Peripheral blood mononuclear cells (PBMCs) isolated from 13 HD patients and 18 volunteers without a history of chronic kidney disease (CKD) were treated with a combination of lipopolysaccharide (LPS) and nigericin to induce NLRP3 inflammasome activation. Likewise, THP-1 monocyte cell-derived macrophages, with or without indoxyl sulfate (IS) pretreatment, underwent the canonical NLRP3 inflammasome stimulus as well. The activity of the inflammasome was determined by immunoblot analysis.

Results: Despite the high plasma levels of IL-1β in HD patients, caspase-1 and IL-1β in the PBMCs of HD patients remained predominantly immature and were not stimulated in response to the canonical stimulus. Further investigations showed that while IS treatment alone facilitated the secretion of IL-1β from THP-1-derived macrophages, IS pretreatment reduced the inducibility of NLRP3 inflammasome in response to LPS and nigericin, characterized by the low mature rate of caspase-1. The PBMCs derived from HD patients and the macrophages exposed to IS both had low expression levels of NLRP3 inflammasome components, suggesting insufficient supplies of inflammasome machinery.

Conclusions: The low stimulation response of the NLRP3 inflammasome attributed to indoxyl sulfate probably constitutes a breach of the immune defense system, which may explain the high infection risk in HD patients.

Prevalence and Risk Factors of High-Altitude Hyperuricemia in the Bai Ethnic Group

Chenni Gao, Xiaonong Chen. Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital Department of Nephrology, Shanghai, China.

Background: The Bai ethnic group is one of the 55 minorities in the People’s Republic of China. Hyperuricemia is not rare among this ethnic partly due to the chronic exposure to high altitude. However, the prevalence of hyperuricemia in the Bai ethnic group remains unclear.

Methods: We collected retrospectively the demographic characteristics and laboratory measurements of 1393 Bai ethnic adults undergoing annual medical examination during Jan 2019 to Dec 2019 in the People’s Hospital of Jiuanzuan County (average altitude 2300m), Yunnan Province. We investigated the prevalence of hyperuricemia as well as its clinical features and risk factors.

Results: Of the 1393 participants enrolled in the study, the prevalence of hyperuricemia was 24.8%, and the prevalence was significantly higher in male gender (33.2% in men vs. 11.0% in women, P<0.001). The prevalence of hyperuricemia increased from 19.2% among participants aged 30-40 years to 30.1% among participants aged 50 years and older. Also, the prevalence elevated from 17.2% among participants with normal body mass index (BMI) to 35.5% among those who were overweight/obese. Interestingly, we found a positive correlation between hemoglobin level (HB) and serum uric acid (P=2.19, P<0.01). Logistic regression analysis revealed main risk factors for hyperuricemia in the Bai ethnic group included age, sex, BMI, systolic blood pressure (SBP) and Hb.

Conclusions: Hyperuricemia is common in the Bai ethnic group. Besides traditional risk factors such as age, sex and BMI, polycythemia secondary to chronic exposure to high altitude may also contribute to the hyperuricemia.

Fig 1 Prevalence of hyperuricemia and serum uric acid level in different age group (Left: Prevalence of hyperuricemia, Right: serum uric acid level). *P<0.001
Changes in the Gut Microbiota After a Controlled Feeding Study in Individuals with CKD and Healthy Controls

Annabel Birute,1 Gretchen Wiese,2 Tzu-Wen L. Cross,2 Riya Thakkar,2 Stephen R. Lindemann,2 Elizabeth Stremske,2 Ranjani N. Moorthi,1 Kelly Swanson,1 Sharon M. Moe,1 Kathleen M. Hill Gallant.1,2 Indiana University School of Medicine, Indianapolis, IN; 3Purdue University, West Lafayette, IN; 4University of Illinois System, Urbana, IL

Background: Diet has been shown to alter the gut microbiota composition and function. However, controlled diet studies assessing the gut microbiota in CKD patients are limited. We assessed the differences in the gut microbiota composition before and after a week of controlled meals in patients with moderate-to-advanced CKD and healthy adults.

Methods: In a secondary analysis, we studied patients with CKD (n = 7, GFR 29-55mL/min/1.73m2) vs. controls (n = 7) matched for sex, age, and race. Participants ate a diet controlled for macronutrients (protein 0.8g/kg/d), fiber (25g/d), P (1500mg/d), Ca (1400mg/d), K (3500mg/d), and Na (2400mg/d) for 1 week. Fecal samples were obtained before and after the dietary intervention. Fecal DNA was extracted and used to amplify the V4 region of the 16S rRNA gene. Sequencing was performed via Illumina MiSeq platform and analyzed using QIME2 and LEfSe.

Results: Fecal microbial diversity did not differ between patients with CKD or matched controls and was not affected due to the dietary intervention. At baseline, control individuals had a relative higher abundance of Bifidobacteria and an unclassified genus within Coriobacteriaceae, while CKD patients had a higher relative abundance of Lachnospiraceae. After receiving a week of controlled meals, CKD patients had a higher relative abundance of Anaerotruncus and Clostridium, while controls had a higher relative abundance of Parabacteroides and Sutterella. Comparing data before and after dietary treatment within groups, CKD individuals had a lower relative abundance of Lachnospiraceae and higher Bacteroides and Holdemansia. Meanwhile, healthy controls had a lower relative abundance of Anaeroanaerobias and Clostridium, while controls had a higher relative abundance of Parabacteroides and Sutterella. Changes in the Gut Microbiota After a Controlled Feeding Study in Individuals with CKD and Healthy Controls

Mitochondrial Dysfunction and Uremic Toxins from Gut Microbiota in CKD Patients: Is There a Link?

Denise Mafra,1 Bruna Paiva,1 Dreily V. Reis,1 Karla thais R. Teixeira,1 Lais G. Moreira,1 Estelina S. Capistrano,1 Ludmilla F. Cardozo,1 Lia S. Nakao,1 Jessyca S. Brito,1 1Federal University Fluminense, Rio de Janeiro, Brazil; 2Universidade Federal do Paraná, Curitiba, Brazil

Background: Dysbiosis in patients with chronic kidney disease (CKD) is associated with increased production of uremic toxins, such as indoxyl sulfate (IS), p-cresyl sulfate (p-CS) and indole-3-acetic acid (IAA), which are linked to oxidative stress and may be related to mitochondrial dysfunction with alterations in peroxisome proliferator activated gamma receptor coactivator 1 alpha (PGC-1α), mitochondrial transcription factor (TFAM). The aim of this study was to verify possible associations between metabolites produced by gut microbiota and genes related to mitochondrial function (PGC-1α, NRF-1, TFAM) in CKD patients.

Methods: This was a cross-sectional, observational study, involving 46 patients with CKD: 20 patients on hemodialysis (HD) (12 men, 44.2 ± 8.9 years) and 26 non-dialysis patients (8 men, 57.6 ± 6.2 years, GFR 25.0 ± 13.0ml/min), selected by non-probabilistic sampling of convenience. Plasma levels of IS, p-CS and IAA were assessed by high-performance liquid chromatography (HPLC). The analysis of the gene expression of PGC1-α, NRF-1 and TFAM were performed by real time Polymerase Chain Reaction (RT-PCR) in peripheral blood mononuclear cells (PBMCs). For statistical analysis, software R, version 3.5.0 (R Core Team, Vienna, Austria) was used and the results were expressed as mean ± standard deviation, with a significance level of p < 0.05.

Results: As expected, the levels of uremic toxins were higher in HD patients than in non-dialysis patients [IS: 31.1 ± 14.3 mg/L vs 2.9 ± 1.7 mg/L (p < 0.001); p-CS: 53.4 ± 34.6 mg/L vs 14.6 ± 10.8 mg/L (p < 0.001); IAA: 2560.1 ± 1379.6 ug/L vs 1050.4 ± 984.8 ug/L]. There was no significant difference in the mitochondrial parameters between matched patients with IS and PGC1α between the groups of patients. In the HD group was observed a positive linear correlation between TFAM and NRF1 (r = 0.978, p < 0.001); as well as between PGC1α and NRF1 (r = 0.8, p = 0.006). However, in both groups there was no correlation between mitochondrial genes and uremic toxins.

Conclusions: The uremic toxins levels were significantly higher in HD patients; however, we did not find any correlations with the parameters of mitochondrial function analyzed.

Dysbiosis of Gut Microbiota in Adult Idiopathic Membranous Nephropathy with Nephrotic Syndrome

Jun Zhang, Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Gut bacterial microbiota is altered in patients with chronic kidney disease (CKD) and those on dialysis. However, it is not yet clear what bacterial composition changes occur in patients with idiopathic nephrotic syndrome. We present in this report the changes in gut bacterial microbiota in idiopathic nephrotic syndrome patients with membranous nephropathy.

Methods: A total of 158 individuals were recruited for this study. Of these, 80 were CKD–3–5 stage patients without nephrotic syndrome, 48 patients had idiopathic nephrotic syndrome and pathological diagnosis of membranous nephropathy, and 30 were age- and sex-matched healthy controls. The gut microbiome composition was analyzed using a 16S ribosomal RNA gene-based sequencing protocol. The results indicated that the nephrotic syndrome (NS) patients had a significantly different alpha and beta diversity compared with the CKD–3–5 group and healthy controls (p < 0.01). At the phylum level, the NS patients showed increased Fusobacteria and Proteobacteria but reduced Firmicutes when compared with the healthy controls. At the genus level, Megamonas, Megasphaera, Akkermansia, and the butyrate-producing bacteria Lachnospiraceae, Roseburia, and Fusobacterium were more abundant in the controls (LDA score > 3) than the CKD–3–5 and NS patients. Compared with the healthy controls, we found that Parabacteroides was increased in CKD–3–5 and NS patients. In addition, Oscillibacter and Ruminococcus were more abundant in CKD patients than in the other two groups (LDA score > 3). At the genus level, ten bacterial taxa were more prevalent in the healthy controls. Providencia and Myroides were more prevalent in NS patients.

Conclusions: Our findings highlight that, NS patients had a significantly different alpha and beta diversity and decreased gut microbiota-derived short-chain fatty acids, such as butyrate. However, large-scale prospective studies should be performed to identify the cause and effect factors of these changes in the microbiota in NS patients.

Funding: Government Support - Non-U.S.

The Alter of Gut Microbiota in Dialysis Patients and Its Influence on the Prognosis for ESRD Patients

Zan Zhang, Dan Luo, Huaixia Xiong, Hui-qun Li, Department of Nephrology, the Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Previous studies have found that alteration in gut microbiota occurred in end-stage renal disease (ESRD) patients with or without dialysis, and are associated with complications such as inflammation and cardiovascular events. However, it has not been clarified whether gut microbiota are influenced by dialysis intervention in ESRD patients.

Methods: The fscal samples of 73 ESRD patients were collected, including 33 pre-dialysis ESRD patients, 19 peritoneal dialysis (PD) patients, and 21 hemodialysis (HD) patients; 19 healthy fecal samples were also collected as control in this study. The 16S rRNA sequencing and the bioinformatics was used to analyze the the composition and function of gut microbiota. The clinical outcomes of the patients were tracked from April 2017 to the end of May 2020.

Results: Compared with the pre-dialysis patients, Bacteroides decreased significantly in HD patients. At the genus level, a total of 14 genera showed differences between patients before and after dialysis. Pre-dialysis patients have a increased abundance of Parabacteroides, Prevotella, and Oscillibacter, and the decreased abundance of Lachnospiraceae, Klebsiella, Akkermansia and Roseburia. HD could repair the abnormal changes of these flora in pre-dialysis patients. We could not found any bacteria difference between PD and pre-dialysis patients in phylum and genus level. The PICRUSt analysis showed that PD and HD could change the signal transduction and metabolic pathways of ESRD patients. It was found that Bacteroides and SMB53 were associated with the occurrence of cardiovascular events. Blautia, Faecalibacterium, and Veillonella were associated with peritonitis in PD patients.

Conclusions: Our results suggested that compared with healthy control, the composition and function of gut microbiota of pre-dialysis patients were changed, HD could restore the relative abundance of beneficial bacteria and reduced some potential pathogen bacteria. Some gut microbiota were associated with prognosis in all of ESRD patients and peritonitis in PD patients.
Effect of Intradialytic Oral Nutritional Supplementation with and Without Exercise on the Skeletal Muscle Quantity and Quality of Adult Hemodialysis Patients

Geovana Martín-Alemayhu,1 L. M. Perez-Navarro,1 Angeles Espinosa-Cuevas,2 Gloria G. Garcia Villalobos,1 Elba O. Medina,1 Miguel Angel Reyes Caldeñas,1 Rafael Velázquez-Oritz1 (Hospital General de México, Dr. Eduardo Liceaga. Ciudad de México, Mexico; 2National Institute of Medical Science and Nutrition Salvador Zubira, Ciudad de México, Mexico.)

Background: The muscle mass (MM) is one of the major tissues affected by the chronic kidney disease. Patients undergoing chronic hemodialysis (HD) have low of MM due to many factors. Intradialytic oral nutritional supplementation (ONS) and exercise (EX) have been shown to improve the amount and quality of MM and physical function (PF). We evaluate the effect of the ONS with and without exercise during the HD sessions for 6 months in the quality and quantity of MM in adult HD patients.

Methods: Patients were randomized in two different groups: 1) ONS and 2) EX + ONS. Patient’s realized 30 minutes of aerobic EX using static bicycles and 30 minutes of resistance EX using Theraband Bands. Quantity and quality of MM were measured with anthropometrics and computed tomography (CT). PF was measured by short physical performance battery (SPPB), six-minute walk test (6 MWT) and handgrip strength (HGS). According to the data distribution Student t test or Mann-Whitney test were used to analyze the data.

Results: Twenty-three patients complete the study. Both groups improved their weight (ONS: baseline, 53.5 ± 4.9kg; final, 54.3 ± 4.9kg; p = 0.020 and ONS + EX: baseline, 57.2 ± 9.2kg; final: 59.9 ± 9.2kg; p = 0.001) and the AMC (ONS: baseline, 227 ± 20mm; final; 241 ± 19mm; p = 0.040 and ONS + EX: baseline, 235 ± 27mm; final: 250 ± 31; p = 0.047).

In the ONS group we observed decreases in the 6MWT; baseline: 417 ± 53.9m; final: 405 ± 52m; p = 0.016 and improvements in the SPPB; baseline:10.8 ± 1.3, final: 11.2 ± 1.4, p = 0.005) with no change in the intramuscular lipid infiltration (baseline: 53.5 ± 5.8% LIT; final: 53.5 ± 4.9% LIT). The EX group had improvements in the 6MWT: HGS and in the SPPB (baseline: 383 ± 58m, final: 425 ± 44m; p = 0.000; baseline: 22.6 ± 8.8kg, final: 24.8 ± 8kg, p = 0.000 and baseline: 10.2 ± 1.1, final: 10.8 ± 1.4, p = 0.801, respectively) with decreases in the intramuscular lipid infiltration (baseline: 53.1 ± 4.5% LIT; final: 50.0 ± 3.8% LIT).

Conclusions: Exercise training for 6 months improves the MM composition of HD patients measured by CT and this was reflected with the improvements in the PF tests and no changes were observed in MM composition in the ONS group.

Muscle Mitochondrial Function and Physical Performance Are Associated with Branched-Chain Amino Acid Levels in Patients with CKD

Jorge Gamboa1, Berfu Korucu,1 Dunpeng Peng,1 Baback Roshanravan,2 Talat Alp Ilkizler1, Vanderbilt University Medical Center, Nashville, TN; 2University of California Davis, Davis, CA.

Background: Muscle mitochondrial function and physical performance are impaired in patients with chronic kidney disease (CKD). Previous studies suggest that decreased branched-chain amino acids (BCAA) levels are associated with muscle catabolism in patients with CKD. We hypothesized that BCAA is lower in patients with CKD and associated with mitochondrial function and physical performance, critical components of protein-energy wasting observed in patients with CKD.

Methods: In a cross-sectional study, we evaluated 63 participants [20 with CKD stage 3-5, 20 with CKD stage 5 on maintenance hemodialysis (MHD), and 20 controls with no history of CKD]. Mitochondrial function was evaluated using 31P magnetic resonance spectroscopy to evaluate the phosphocreatine (PCr) recovery after exercise. A longer PCR recovery results in a greater time constant tau (τ), which indicates worsening mitochondrial function. Physical performance was measured using the six-minute walk test. BCAA levels were measured in plasma samples using nuclear magnetic resonance. Linear regression analysis was used to evaluate association and adjusting by age, race, sex, and body mass index (BMI).

Results: Groups were similar in terms of gender, BMI, and history of diabetes and hypertension. Patients on MHD were younger than patients with CKD stage 3-4 (p<0.05, r=0.67 and p<0.05, r=-0.54, respectively). The EX group had improvements in the 6MWT: HGS and in the SPPB (baseline: 383 ± 58m, final: 425 ± 44m; p = 0.000; baseline: 22.6 ± 8.8kg, final: 24.8 ± 8kg, p = 0.000 and baseline: 10.2 ± 1.1, final: 10.8 ± 1.4, p = 0.801, respectively) with decreases in the intramuscular lipid infiltration (baseline: 53.5 ± 4.9% LIT; final: 50.0 ± 3.8% LIT).

Conclusions: Exercise training for 6 months improves the MM composition of HD patients measured by CT and this was reflected with the improvements in the PF tests and no changes were observed in MM composition in the ONS group.

Funding: Private Foundation Support
Gut Dysbiosis and Mortality in Hemodialysis Patients

Ting-yun Lin. Taipei Tzu Chi Hospital, Taipei, Taiwan.

Background: Persistent inflammation plays a pathogenic role in CKD-associated protein-energy wasting, cardiovascular disease, and mortality. Gut dysbiosis, characterized by decreased microbial diversity, promotes inflammation. The gut microbiota is markedly altered in patients with ESKD. Therefore, we aimed to determine the relationship between gut dysbiosis and mortality in an ESKD cohort.

Methods: In an observational study, we examined the associations between microbial diversity and mortality in ESKD patients undergoing maintenance hemodialysis (n=109) using Cox proportional hazards models. The gut microbiota was assessed by 16S rRNA sequencing. Microbial diversity was calculated using the Simpson index. Participants were stratified into higher- (above the median) and lower-diversity (below the median) groups and were followed up for a median of 2.1 years. Next, in a matched case-control study, we compared the microbial composition between nonsurvivors and survivors.

Results: Kaplan-Meier analyses revealed a significant association between higher diversity and a lower risk of death (P=0.015). After adjustment for patient characteristics and comorbidities, the risk of death among patients with higher diversity was 74% lower than that among patients with lower diversity (hazard ratio, 0.26; 95% CI, 0.07 to 0.95). Nonsurvivors and survivors were matched 1:4 for age and sex. We observed significantly lower values of microbial diversity and higher levels of proinflammatory cytokines (IL-1β) among nonsurvivors (n=14) than survivors (n=56). Notably, the relative abundance of Succinivibrio and Anaerostipes, two short-chain fatty acid-producing bacteria, was reduced in nonsurvivors compared with survivors.

Conclusions: A unique gut microbial composition is associated with an increased risk of mortality in patients with ESKD and may be used to identify subjects with a poor prognosis. Our findings need to be validated in a larger independent cohort.

Insulin Resistance and Pancreatic Beta-Cell Function in Calcium Kidney Stone Formers

Olive W. Tang,1 Kevin Mitchell,2 Jie Tang,1 Johns Hopkins Medicine, Baltimore, MD; 2Alpert Medical School of Brown University, Providence, RI.

Background: Diabetes mellitus is common among individuals with kidney stones; however, the risk factors associated with glucose dysregulation in this population is unclear.

Methods: We characterized the independent associations between vitamin D, urinary measures of dietary intake (sodium, magnesium), and urinary ammonia and citrate with homeostasis model assessment of β-cell (HOMA-B) and insulin resistance (HOMA-IR) in prevalent calcium kidney stone formers without diabetes mellitus recruited from Lifespan Kidney Stone Clinic (N = 96). We used linear regression with adjustment for demographics, body mass index, hypertension, hyperlipidemia, parathyroid hormone, and serum uric acid.

Results: The study population had a mean age of 53 years, 48% were male, and 83% were Caucasian. The mean 25-hydroxy-vitamin D (25D) was 50 ng/ml, 1,25-dihydroxyvitamin D (1,25D) was 55 pg/ml. 24-hour urine sodium was 145 mmol, urine ammonia was 30 meq, urine citrate was 590 mg, and urine magnesium was 102 mg. Mean HOMA-B was 172.1, and mean HOMA-IR was 5.4. Urine sodium was negatively associated with HOMA-B, but not HOMA-IR. Urine ammonia was positively associated with HOMA-IR, but not HOMA-B. Urine citrate was positively associated with both HOMA-B and HOMA-IR (Table).

Conclusions: In our cohort of calcium kidney stone formers, high salt intake and low urine citrate were associated with worse beta-cell function. High urine ammonia and citrate were associated with increased insulin resistance.

Time to Hyperkalemia Recurrence in 1 Year Among 103,155 US Veterans

Jui-Ting Hsiaung,1 Rubeen K. Israni,2 Cachet Wenziger,1 Nipun Atreja,2 Connie Ha,1 Deborah A. Anzalone,2 Kamnyar Kalantar-Zadeh,3 Elani Streja,1

1Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2AstraZeneca, Wilmington, DE.

Background: Elevated serum potassium (sK) is commonly asymptomatic, but in a subset of patients, hyperkalemia (HK) is associated with worse outcomes and frequent recurrence. Whether the initial HK event was captured during a hospitalization may be associated with time to recurrence. Further characterizing time to recurrence in inpatient (INPT) and outpatient (OPT) settings may improve HK monitoring and treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Among 3,958,837 US veterans that had a sK between 2004-2006, there were 589,019 that had an index sK ≥5.0 mEq/L during this period where we could ascertain INPT/OPT status. We then identified patients who had a recurrent HK event 7-365 days after the index HK and had at least one normal sK ≤5.0 mEq/L in between events. We examined time to recurrence in 30-day intervals according to whether the index sK was INPT or OPT. Patients who’s INPT/OPT status at HK recurrence could not be ascertained were excluded.

Results: HK recurrence over one year occurred in 103,155/589,019 (17.5%) patients, or 17,215/51,262 (34%) and 85,940/53,757 (16%) of patients with index INPT and OPT events, respectively. The 103,155 patients with HK recurrence had a mean patient age of 68±11 years, consisted of 98% males, 14% African Americans, 56% diabetics, and 60% with estimated glomerular filtration rate <60 mL/min/1.73 m². In patients with HK recurrence, 50% (n=51,675) developed this event 6 months after the initial HK (table). Among patients who had an OPT index HK, 56% developed recurrence 6 months after index HK event. However, 51% of the patients who had an INPT index HK event developed recurrence within 60 days of the index HK.

Conclusions: A significant proportion of VA patients with HK developed another HK event within one year. Hospitalized patients with HK developed recurrence faster than patients in the OPT setting despite requiring 7 days between HK events and normalization of sK between events. This could be due to the fact that hospitalized patients are usually sicker or they were monitored more closely by the healthcare providers, therefore it is easier to catch HK recurrence in INPTs than OPTs.

Workplace Outreach Program Facilitates Referral into Physician Care and Diagnosis of CKD
Olga A. Jakoubova, Carmen H. Tong, Charles M. Rowland, Andre Arelanno, Lance A. Bare, Maren S. Fragala, James J. Devlin, Charles E. Birse. Quest Diagnostics Nichols Institute, San Juan Capistrano, CA

Background: Chronic kidney disease (CKD) is often unrecognized and undertreated. Timely diagnosis can improve disease management and slow CKD progression. We asked whether a workplace outreach program facilitates CKD diagnosis and improves management of CKD.

Methods: An annual workplace health assessment that included eGFR testing was offered to employees. Those with confirmed CKD by repeat eGFR <60 mL/min/1.73 m² or by albumin to creatinine ratio test were eligible to participate in a CKD outreach program. A study coordinator made up to 3 phone calls in an effort to contact each eligible employee, to provide an explanation of CKD risk and to offer a physician consultation to discuss test results and referral into care. Those who accepted the phone call (participation group) were compared to those who were not reached by phone (control group). Using logistic regression models that adjusted for prevalent CKD, we analyzed claims data to estimate the effect of outreach participation on nephrologist visits, physician visits, and new CKD diagnoses 5 months after the outreach. Changes in eGFR levels were evaluated at the following annual health assessment.

Results: Of the 398 eligible employees, 156 participated in the outreach program; the remaining 242 served as the control group. CKD risk factor profiles at baseline were similar between participants and controls. Participants had 3-fold greater odds of visiting nephrologists, 60% greater odds of visiting physicians and 80% greater odds of being diagnosed with CKD, compared with the controls. Participants had 40% lower odds of an annual eGFR decline >5 mL/min/1.73 m² compared with controls (Table). One participant initiated kidney dialysis, compared with none in the control group.

Conclusions: A workforce CKD outreach program facilitates diagnosis of CKD and improves disease management including referral to a nephrologist.

Effect of Exercise on Quality of Life and Functional Capacity in Patients with CKD

Vijay Kumar Bandi1, Hanceesha Kolli1, Sreelakshmi Nimmagadda1, Sandhya Komatla1,2

1Dh Pinnamaneni Siddhartha Institute of Medical Sciences & RF; Gannavaram, India; 2Kommareddy Venkata Sadashiva Rao Siddhartha College of Pharmaceutical Sciences, Vijayawada, India.

Background: Chronic kidney disease patients have lower activity levels when compared to normal population, compounded by sedentary lifestyle and is associated with increased mortality, which might reduce with exercise

Methods: Patients with chronic kidney disease were evaluated for 12 weeks of supervised exercise program. The subjects were divided into 2 groups: Group I (CKD stage 3-5) and Group II (CKD on maintenance hemodialysis). Serum hemoglobin (Hb), calcium (Ca), phosphorous (Pi), and albumin (Alb) were done at baseline and at 12 weeks. Symptom burden was assessed using Functional Assessment of Chronic Illness Therapy-Symptom Burden (FACT-SB) and Leicester Uremic Symptom (LUS) Scale. Quality of life using SF-36 questionnaire, functional capacity using Duke Activity Status Index, Physical Fatigue Scale (FACIT-F) and Leicester Uremic Symptom Scale, Quality of life Symptom burden was assessed using Functional Assessment of Chronic Illness Therapy-Overall Well being (FACT-G), Functional Assessment of Chronic Illness Therapy-Physical Well being (FACT-P), Functional Assessment of Chronic Illness Therapy-Spiritual Well being (FACT-S) and Leicester Uremic Symptom Scale, Quality of life

Results: At baseline, SF-36 and FACIT-F scores were similar. At baseline, FACIT-F significantly correlated positively with physical activity (r = 0.35, p<0.05). The impact of renal transplantation on body composition and muscle quality has not been established. Low muscle mass relative to fat mass (relative sarcopenia) has been associated with mortality and disability but has not been examined following transplantation.

Methods: DXA measures of fat mass index (FMI) and appendicular lean mass index (ALMI: representing muscle mass), CT measures of muscle density (low density Z-scores were lower vs. controls (all p<0.001). Transplant recipients received glucocorticoids throughout. The prevalence of obesity increased from 18 to 45%. Although ALMI increased following transplantation (p<0.001) and was comparable to controls from 6 months onward, gains were outpaced by increases in FMI, resulting in persistent ALMIFMI deficits (mean Z-score -0.31 at 24 months, p=0.02 vs controls). Fat gains were disproportionately_visitual distribution (p<0.05). Muscle strength improved but remained low compared with controls independent of ALMI (p<0.05). Exercise increased in the early months following transplantation (p<0.05) but remained lower than controls (p<0.02).

Conclusions: The two-year interval following renal transplantation was characterized by gains in muscle mass and strength that were outpaced by gains in fat mass resulting in persistent relative sarcopenia.

Changes in Body Composition, Muscle Strength, and Fat Distribution Following Renal Transplantation

Susan Ziolekowski1, Simin Goral2, Jin Long3, Joshua F. Baker4, Justine Shults5, Babette Zemel6, Peter P. Reese7, Francis P. Wilson8, Mary B. Leonard9, Susan Lavender2,1 Stanford University School of Medicine, Stanford, CA; 2University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3The Children's Hospital of Philadelphia, Philadelphia, PA; 4Lucile Packard Children's Hospital at Stanford General Pediatrics, Palo Alto, CA; 5Yale University School of Medicine, New Haven, CT; 6University of Pennsylvania, Philadelphia, PA.

Background: The impact of renal transplantation on body composition and muscle quality has not been established. Low muscle mass relative to fat mass (relative sarcopenia) has been associated with mortality and disability but has not been examined following transplantation.

Methods: DXA measures of fat mass index (FMI) and appendicular lean mass index (ALMI: representing muscle mass), CT measures of muscle density (low density Z-scores were lower vs. controls (all p<0.001). Transplant recipients received glucocorticoids throughout. The prevalence of obesity increased from 18 to 45%. Although ALMI increased following transplantation (p<0.001) and was comparable to controls from 6 months onward, gains were outpaced by increases in FMI, resulting in persistent ALMIFMI deficits (mean Z-score -0.31 at 24 months, p=0.02 vs controls). Fat gains were disproportionately_visitual distribution (p<0.05). Muscle strength improved but remained low compared with controls independent of ALMI (p<0.05). Exercise increased in the early months following transplantation (p<0.05) but remained lower than controls (p<0.02).

Conclusions: The two-year interval following renal transplantation was characterized by gains in muscle mass and strength that were outpaced by gains in fat mass resulting in persistent relative sarcopenia.

Results: We included 36 participants with CKD (mean eGFR=38) and 19 controls. Mean age was 61±13 years, 51% male, and 25% had diabetes. Diabetes and CKD were independently associated with lower ATPmax (-0.12 m/s, p<0.01 and -0.19 m/s, p<0.01, respectively). Accelerometry counts per minute (r=58, p<0.01) was more strongly correlated with ATPmax than HAP scores (r=46, p<0.01) with no interaction by CKD status (p=9). Accelerometry counts explained 43% of the difference in ATPmax between CKD and controls and HAP scores 15% after adjustment.

Conclusions: Objective PA was more strongly associated with ATPmax and explained more of the differences in ATPmax between CKD and controls than self-reported PA. Further studies should demonstrate if exercise interventions can improve muscle ATPmax in CKD.

Metabolic Acidosis and Muscle Metabolic Health Are Important Determinants of Fatigue in Persons with CKD
Tae Youn Kim,1 Se Ri Bae,1 Jorge Gamboa,2 Chensao R. Vargas,1 Sophia Liu,2 Kishang V. Patel,1 Ian H. de Boer,1 Bryan R. Kestenbaum,2 Baback Roshanravan.1 University of California Davis, Davis, CA; 2University of Washington, Seattle, WA.

Background: Chronic kidney disease (CKD) is associated with a high prevalence of physical frailty, reduced physical function and fatigue, contributing to increased morbidity, mortality risk, and poor quality of life. Impaired muscle mitochondrial oxidative capacity (ATPmax) underlies poor physical endurance in persons with CKD. Metabolic acidosis may mediate effects of CKD on ATPmax. Little is known about the relevance of metabolic acidosis and ATPmax on patient-reported fatigue in CKD.

Methods: We performed a cross-sectional analysis of 58 participants (39 CKD and 19 non-CKD) from the CKD Muscle Mitochondrial ENergetics and Dysfunction (MEND). Muscle metabolic health of the tibialis anterior leg muscle was measured from the time course of phosphocreatine after exercise using 31P Magnetic Resonance Spectroscopy. Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) scale. Metabolic acidosis (MA) was determined from serum bicarbonate (< 22 mmol/L). Linear regression was used to test associations adjusting for age, sex, body mass index (BMI), and diabetes.

Results: The cohort included 48% female and 29% diabetes with a mean age of 61±12 years and a mean BMI of 28.5±1. The mean eGFR was 39±7.5 ml/min per 1.73m² in CKD and 98±15 in non-CKD. The mean ATPmax was 0.67±0.185 mM/sec and mean FACT-F score was 49±11.5. CKD was associated with increased fatigue (mean difference: 7.6, 95% CI [1.8, 13.5], p=.025) compared to non-CKD after adjustment. Of those with CKD each 1 SD (standard deviation) greater ATPmax was associated with a 5.4-point (95% CI [1.03, 9.7]), p=.017) reduction in fatigue after adjustment. Further adjustment for MA attenuated the estimated association by 38% (3.3 points, 95% CI [-1.1, 7.7], p=.134). Of those with CKD, participants with MA (n=15) had a 10. points greater fatigue (95% CI [1.8,18.1], p=.018) after adjustment compared to those without MA (n=21).

Conclusions: ATPmax is directly associated with fatigue. MA might play an important role in the association of muscle metabolic health with fatigue in CKD. Further research is needed to examine the impact of treating MA on improvement in muscle metabolic health, fatigue and quality of life in CKD.

Blood Pressure in Young Adults with CKD and Associations with Cardiovascular Events and CKD Progression
Alexander J. Kula,1,2 Nisha Bansal,2 David K. Prince,1 Joseph T. Flynn.1,2 Seattle Children’s Hospital, Seattle, WA; 2University of Washington, Seattle, WA.

Background: Young adults (age 18-40yrs) with CKD are a poorly studied subset of CKD patients. Blood-pressure management for young adults with CKD relies on extrapolating findings from studies conducted in older adults or children. Our objective was to perform an observational study exclusively in young adults with CKD to test the association between BP and adverse outcomes.

Methods: Participants aged 21-40yrs of age enrolled in the Chronic Renal Insufficiency Cohort Study were included (n=317). Exposures included baseline systolic blood pressure (SBP) and diastolic blood pressure (DBP), and time to first cardiovascular event (CVD event) during follow-up (2013-2018). Outcomes of interest were cardiovascular disease and kidney disease progression, defined as ≥50% eGFR decline or ESRD. Cox proportional-hazards regression models were used to test the association between BP and adverse outcomes. Covariate adjustment was made for age, sex, race/ethnicity, marital status, education, smoking, and body mass index.

Results: Of the 317 participants, 48% were female, 29% had diabetes, and mean age was 28±3yrs. Of those with CKD, 30.7% had CKD stage 3, 14% had CKD stage 4, and 5.5% had CKD stage 5. Median SBP was 120 (IQR: 110-130) mmHg and median DBP was 70 (IQR: 60-75) mmHg. In adjusted models, a baseline SBP ≥130 was significantly associated with CVD events (HR: 3.32, 95% CI: 1.34-7.8) and CKD progression (HR: 1.63, 95%CI: 1.02-2.59) compared with SBP<120. Every 10 mmHg in SBP was significantly associated with CKD progression (HR: 1.13, 95%CI: 1.02-1.26) in adjusted models.

Conclusions: There is a graded association of higher SBP with greater risk of CV events and CKD progression in young adults with CKD. Among those with SBP≥130, 5.8% per year had a CV event and risk was 3-fold higher compared with SBP<120; and 20.7% per year had CKD progression and risk was nearly 2-fold higher. These data suggest that higher SBP is an important risk factor for adverse outcomes in young adults with CKD.

Angiotensin Converting Enzyme Inhibitor and Angiotensin Receptor Blocker Use Among Hypertensive US Adults by Albuminuria Status, 2013-2018
Chii-D. Chu,1 Neil R. Powe,1 Charles E. McCulloch,2 Tanushree Banerjee,1 Deidra C. Crews,2 Rajiv Saran,2 Jennifer L. Bragg-Gresham,1 Hal Morgenstern,2 Meda E. Pavkov,1 Sharon Saydah,2 Delphine S. Tuot,1 CDC CKD Surveillance Team 1University of California San Francisco, San Francisco, CA; 2University of Michigan, Ann Arbor, MI; ‘Centers for Disease Control and Prevention, Atlanta, GA; ‘Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Since 2003, U.S. hypertension (HTN) guidelines have recommended angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy for uric acid/creatinine ratio (UACR) ≥300 mg/g. Our objective was to assess the prevalence of ACEi/ARB use for UACR ≥300 mg/g among adults with HTN. We identified veterans receiving a statin but not a TG-lowering agent from the VA Corporate Data Warehouse, a database of the VA electronic health record, and to examine the association between UACR and ACEi/ARB use.

Methods: We studied adults with HTN in the National Health and Nutrition Examination Surveys 2013-2018. Respondents were classified as having HTN if they had systolic blood pressure ≥140 mmHg or diastolic blood pressure ≥90 mmHg, currently using anti-hypertensive medications, or reported being told by a clinician they had HTN. ACEi/ARB use was assessed by review of medication containers by study staff. Modified Poisson regression was used to estimate crude and adjusted prevalence ratios (PR) for the association between ACEi/ARB use and UACR; adjustment was for sex, race/ethnicity, diabetes, systolic blood pressure (continuous), chronic kidney disease stage, and having a reported routine site for healthcare.

Results: Among 7,377 adults with HTN, 83.4% had UACR 0-29 mg/g, 13.5% had UACR ≥300-299 mg/g, and 3.2% had UACR ≥300 mg/g. ACEi/ARB use was 43%, 54%, and 48% in UACR categories 0-29, 30-299, and ≥300 mg/g, respectively. This represents approximately 1.5 million adults with UACR ≥300 mg/g who are not receiving ACEi/ARB therapy. Adjusted ACEi/ARB use was minimally associated with UACR ≥300 mg/g (PR = 1.09, 95% CI 1.03-1.17 for UACR 30-299 mg/g; PR = 0.96; 95% CI 0.83-1.10 for UACR ≥300 mg/g; reference = UACR <30 mg/g).

Conclusions: Nationally representative data indicate a large gap in guideline-concordant ACEi/ARB use among adults with HTN and UACR ≥300 mg/g. Improving uptake of ACEi/ARB therapy presents a substantial opportunity for prevention of cardiovascular disease and kidney disease progression for adults with HTN.

Increased Residual Cardiovascular Risk in US Veterans with Moderately Elevated Baseline Triglycerides, Well-Controlled LDL Cholesterol Levels on Statins, and Decreased Renal Function
Sarah Leatherman,1 Ryan E. Ferguson,1 Cynthia Hau,1 Craig B. Granowitz,2 Kelly M. Harrington,1 Sephy Philip,2 Peter P. Toth,2 Deepak L. Bhatt,3 William E. Boden.1 1VA Boston Healthcare System, Boston, MA; 2Amarin Corp, Bridgewater, NJ; 3Brigham and Women’s Hospital, Boston, MA; 4CGH Medical Center, Sterling, IL.

Background: Recent studies have suggested a causal role for elevated triglycerides (TG) in incident cardiovascular (CV) events. Using a large cohort of U.S. veterans with statin-controlled LDL-C levels (40-100mg/dL), we explored whether increased residual CV risk existed in patients with elevated baseline TG levels versus those with normal TG levels in the subset who had reduced eGFR (<60 ml/min).

Methods: We identified veterans receiving a statin but not a TG-lowering agent from the VA Corporate Data Warehouse, a database of the VA electronic health record, and to examine the association between UACR and ACEi/ARB use.

Results: Among 7,377 adults with HTN, 83.4% had UACR 0-29 mg/g, 13.5% had UACR ≥300-299 mg/g, and 3.2% had UACR ≥300 mg/g. ACEi/ARB use was 43%, 54%, and 48% in UACR categories 0-29, 30-299, and ≥300 mg/g, respectively. This represents approximately 1.5 million adults with UACR ≥300 mg/g who are not receiving ACEi/ARB therapy. Adjusted ACEi/ARB use was minimally associated with UACR ≥300 mg/g (PR = 1.09, 95% CI 1.03-1.17 for UACR 30-299 mg/g; PR = 0.96; 95% CI 0.83-1.10 for UACR ≥300 mg/g; reference = UACR <30 mg/g).

Conclusions: Nationally representative data indicate a large gap in guideline-concordant ACEi/ARB use among adults with HTN and UACR ≥300 mg/g. Improving uptake of ACEi/ARB therapy presents a substantial opportunity for prevention of cardiovascular disease and kidney disease progression for adults with HTN.

from 2010-2015. We compared CV event rates (nonfatal MI, stroke, unstable angina, or coronary revascularization) between the elevated TG (150-499 mg/dL) and normal TG (<150 mg/dL) groups. We calculated crude event rates, rate ratios, and 95% CI for both groups, and adjusted event rate ratios for age, sex, baseline blood pressure, glomerular filtration rate, and weight.

Results: We included 152,266 veterans (predominantly male and white) in the analysis cohort of whom 43,670 (29%) had elevated TG levels. These subjects were younger and had higher BMIs. Table 1 details the crude and adjusted CV event rates. The overall crude and adjusted CV event rate ratios were 1.28 (95% CI 1.23,1.33) and 1.12 (95% CI 1.07, 1.16), respectively.

Conclusions: In this large cohort of veterans, those with elevated TG levels and moderately decreased renal function showed a significant increase in CV events despite well-controlled LDL-C on statins compared to veterans whose baseline TG was in a normal range.

Deep Learning Analysis of Derived Cardiac Function Metrics for the Detection of CKD and Subsequent Outcome Prediction in Community-Dwelling Individuals

Niall Cosgrafe,1 John D. O’Connor,1 George S. Mellotte,1 Brenda Griffin,2 Conall M. O'Seaghdha,2 Scott Reule,6 Robert N. Foley,1 Silvin P. Knight,1 Mark A. Little,1,2 Donal J. Sexton1,2,3 University of Dublin Trinity College, Dublin, Ireland; 2Trinity Health Kidney Center, St James’s Hospital & Tallaght University Hospital, Dublin, Ireland; 3Beaumont Hospital, Dublin, Ireland; 4Nephrology and Renal Office, Health Service Executive of Ireland, Dublin, Ireland; 5United States Renal Data System Coordinating Centre, Minneapolis, MN; 6Minneapolis VA Health Care System, Minneapolis, MN

Background: Whether subtle abnormalities in cardiac function exist in community dwelling individuals and can be used toagnostically discern those with reduced kidney function and incident adverse outcomes over follow up is unknown.

Methods: The Irish Longitudinal Study on Ageing (TILDA) is a prospective nationally representative cohort study based on random sampling of the community-dwelling general population aged ≥50 years in Ireland. Wave 1 was performed between June 2009-June 2011. Participants underwent a detailed health assessment including blood tests, and an active stand test using the Finometer, which measures continuous blood pressure and heart rate for 10 mins while supine at rest, then throughout the standing test and for 2 mins thereafter. Cardiac function metrics are derived: left ventricular ejection time (LVET), cardiac output, and total peripheral resistance. CKD-EPI equation was used for eGFR. We analysed repeated measures data at 10 second intervals over the entire observation period using sequential neural networks with the categorical outcomes of coincident CKD, and incident mortality. Follow up was approximately 10 yrs. Python v 3.77 and TensorFlow v2.0.0 were used for the analysis.

Results: N=4388 TILDA participants were included, N=2013 were male, mean age was 62 (8) yrs, 647 had CKD. 178 died over follow up. Figure 1. A demonstrates profiles coincident CKD, AUC = 0.81(resampled model: which included an input variable weight at time x was estimated based on propensity score to either be—or not be—anaemia at time t. Weighted survival probability and weighted hazard ratio were estimated.

Risk of Mortality, ESKD, and Hospitalization Among Medicare Beneficiaries with Pulmonary Hypertension and CKD

Sankar D. Navaneethan,1,3 Carl P. Walther,1 L. Parker Gregg,2 Wolfgang C. Winkelmayer,1 Vijay Nambi,1,3 Jingbo Niu.1 Baylor College of Medicine, Houston, TX; 1University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2Michael E DeBakey VA Medical Center, Houston, TX

Background: Pulmonary hypertension (PH) is highly prevalent among patients with non-dialysis dependent CKD (~20%). We studied the risks of mortality, ESKD, cardiovascular (CV) and non-CV hospitalizations among those diagnosed with both PH and CKD.

Methods: Patients with PH (based on 2 claims within 2 years) were identified from a Medicare 5% sample (1995-2016). For each PH patient we randomly selected 5 participants diagnosed with the same CKD stage as the PH patient but without a PH diagnosis. We used Cox proportional hazards models to assess the association between PH and mortality, adjusting for age, sex, race, and comorbidities. We considered death as a competing event in Fine-Gray models to assess the association between PH and ESKD.

Results: We studied 41,478 patients with PH and CKD and 207,390 CKD stage-matched patients without diagnosed PH. Over 59% of the study population were >80 years, 12% were African American, 47% had diagnosed diabetes and 46% had COPD. The presence of diagnosed PH (vs. no PH diagnosis) was associated with increased risk of mortality, ESKD, and CV and non-CV hospitalizations at 1-, 3-, and 5-year follow-up (Table 1). Diabetes modified these associations with higher risk of all outcomes noted among those without diabetes.

Conclusions: Among older Medicare beneficiaries diagnosed with CKD, the presence of PH increased risk of mortality, ESKD, and hospitalization. Mechanistic understanding of these associations, especially the increased risk of ESKD, requires additional study.

Funding: NIDDK Support

Table 1. Associations of PH with mortality, ESKD, and cardiovascular and non-CV hospitalization in those with PH and CKD

PO2070
A Marginal Structural Model to Estimate Causal Effect of Time-Dependent Anemia Status on Renal and Cardiovascular Outcomes Among Community-Dwelling Japanese Subjects at Beginning of Impaired Renal Function

Satoshi Onozawa,1 Tomomi Kimura,1 Masatasta Morita,1 Osamu Yamamoto,1 Tadao Akizawa,2 Astellas Pharma, Inc., Tokyo, Japan; 2Astellas Pharma, Inc., Northbrook, IL, 3Showa University School of Medicine, Tokyo, Japan

Background: We investigated whether anemia increases the risk of renal and cardiovascular (CV) outcomes considering the changes of anemia status over time, using a marginal structural model.

Methods: We retrospectively analyzed data from a Japanese database (IMDC) consists of annual health checkup data linked to medical and pharmacy claims for over 3 million of beneficiaries. Subjects with consequent eGFR values of ≥60 and then <60 mL/min/1.73 m 2 within 2 years and during the period between 2008 and 2019 were included. The first date where the eGFR value became <60 was defined as the index date. Patients without serum creatinine (Scr) record within 38 months from the index date were excluded. Anemia status (yes/no) was defined by the age-specific hemoglobin value according to the Japanese guidelines. Renal outcomes (composite of ≥30% eGFR decline over 3 years, eGFR <15 mL/min/1.73m2, SCR doubling, initiation of chronic dialysis and kidney transplantation), CV outcomes (myocardial infarction, stroke, unstable angina and heart failure) and mortality was assessed. In order to incorporate dynamic change of anemia status and covariates during the follow-up, a time-dependent standardized inverse probability weight at time x was estimated based on propensity score to either be— or not be—anemia at time x. Weighted survival probability and weighted hazard ratio were estimated.

Results: 32,870 subjects were enrolled in the study cohort (median age 52, 73% male) and 4.2% of subjects had anemia at the baseline. Anemia treatment was rarely provided even in the anemia group (3.9%). During the average of 4.1-year of follow-up period, 210 renal outcomes and 1039 CV outcomes occurred. In 91% of the cases with the renal outcomes, eGFR decline occurred first. The weighted hazard ratios (95% confidence intervals) for renal outcomes, CV outcomes and mortality were 2.6 (1.7-3.8), 1.6 (1.2-2.2), and 2.8 (1.8-4.3), respectively.
PO2077
Estimation of Sodium Consumption by Novel Formulas Derived from 12-Hour Urine Collection
Pitchaporn Sonuch, Surasak Kantachavesiri. Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: 24-hour urine sodium excretion is the gold standard for estimating sodium intake. Several equations have been used to estimate 24-hour urine sodium excretion from spot urine samples. However, a validated formula for predicting 24-hour urine sodium excretion from 12-hour urine collection has not been established. This study aims to establish novel equations for predicting 24-hour urine sodium excretion from 12-hour urine collection and to also validate spot urine equations for predicting 24-hour urine sodium excretion.

Methods: 299 adults were recruited from hospital personnel. Participants were asked to perform a 12-hour daytime, nighttime, and a random spot urine collection in 1 day. Pearson correlation was used to compare measured 24-hour sodium excretion to the estimated values from three different methods. A multivariate linear regression analysis was performed to create novel equations. Bland-Altman method was used to estimate bias and agreement between the equations.

Results: The mean 24-hour urine sodium excretion was 4,055±1,712 mg/day (male 4,307±1,694 and female 3,882±1,710 mg/day, P<0.007). The 24-hour urine sodium excretion in non-healthcare workers was higher than in healthcare workers (4,442±1,865 and 3,617±1,406 mg/day respectively, P<0.001). Estimated urine sodium excretion from 3 different equations using spot urine samples showed moderate correlation with actual 24-hour urine sodium excretion (r=0.54, P<0.001 for Kawasaki; r=0.57, P<0.001 for Tanaka; r=0.66, P<0.001 for INTERSALT). Novel equations for predicting 24-hour urine sodium excretion was then developed using variables derived from 12-hour daytime urine collection, 12-hour nighttime urine collection, and random spot urine samples which showed strong correlation with actual measured values; r=0.88, P<0.001; r=0.83, P<0.001; r=0.67, P<0.001 respectively. Bland-Altman plots indicated good agreement between predicted values and actual 24-hour urine sodium excretion using the new equations, with biases for 12-hour daytime urine collection of -0.28 mmol/day (95%CI: -5.09 to 4.53), for 12-hour nighttime urine collection of 0.85 mmol/day (95%CI: -4.86 to 6.56), and for random spot urine sample of 0.90 mmol/day (95%CI: -6.66 to 8.45).

Conclusions: The correlation of spot urine equations from 12-hour urine collection and 12-hour nighttime urine collection can accurately predict 24-hour urine sodium excretion.

Cardiac Structure and Function and Long-Term Risk of ESKD in African Americans: The Atherosclerosis Risk in Communities (ARIC) Study
Manabu Hishida,1,2 Junichi Ishigami,1 Lena Mathews,1 Morgan Grams,3 Josef Coren,3 Scott D. Solomon,3 Kunihiro Matsushita,1 Welch Center Johns Hopkins University, Baltimore, MD; 2Nagoya Daigaku Daigakukan Igakuei Kenkyuka Igakubu, Nagoya, Japan; 3Brigham and Women's Hospital, Boston, MA.

Background: Cardiovascular disease and end-stage kidney disease (ESKD) disproportionately affect African Americans. Whether cardiac structure and function is associated with the risk of ESKD in this population is not well-characterized.

Methods: In 1,929 African American ARIC participants who underwent echocardiography between 1993-1995 (mean age 58.5 [SD 5.6] years, 36% male), we explored the association of left ventricular mass index (LVMi), fraction shortening (FS), left atrial diameter (LAD), and LV end-diastolic diameter (LVEDD) with the subsequent risk of ESKD using Kaplan-Meier method and multivariable Cox models.

Results: During a median follow-up of 22.3 years, 82 participants developed ESKD (incidence rate 3.0 per 1,000 person-years). The cumulative incidence of ESKD was highest in the top quartile (bottom quartile for FS) of all echo parameters (Figure). Although the risk separation was most evident for LVMi. The association of LVMi with ESKD remained significant even after accounting for potential confounders like blood pressure and clinical history of cardiovascular disease (HR, 2.46 [1.3-5.38] in the top vs. bottom quartile). FS, LAD, or LVEDD were not independently associated with ESKD.

Conclusions: Among African Americans, higher LVMi was robustly and independently associated with the risk of ESKD. Our findings support the importance of LVMi or its pathophysiology in CKD progression in African Americans.

PO2074
Myeloperoxidase and the Risk of Atrial Fibrillation in the Chronic Renal Insufficiency Cohort (CRIC) Study
Katherine Curtis,1,2 Simon Correa,1,2 Sushrut S. Waikar,3 Finninn R. McCausland,1,2 Brigham and Women's Hospital, Boston, MA; 3Harvard Medical School, Boston, MA; 4Hospital Universitario Principe de Asturias, Alcala de Henares, Spain; 5Boston Medical Center, Boston, MA.

Background: Myeloperoxidase (MPO) catalyzes the formation of reactive oxygen intermediates and is associated with adverse CV outcomes and progression of chronic kidney disease (CKD). We wished to determine the association of MPO with hospitalization for atrial fibrillation (AFib) in patients with baseline CKD.

Methods: We evaluated 3,872 participants with MPO measured at baseline in the CRIC Study, a large prospective multicenter cohort of non-dialysis dependent CKD. The association of MPO with hospitalization for atrial fibrillation (AFib) was evaluated through adjusted Cox proportional hazard models in all study participants, and separately in subjects with and without AFib at baseline. Models were adjusted for age, sex, race, DM, SSB, coronary artery disease, CHF, cGFR (CKD-EPI), proteinuria, ACEi- ARB, beta-blocker and diuretic use.

Results: Median sMg was 2.0 mEq/L (25th-75th percentile 1.9 to 2.1 mEq/L). Higher sMg at baseline was associated with lower SBP (2.63 mmHg; 95% CI 0.25 to 4.05, per 1 mEq/L) and lower DBP (-2.75 mmHg; 95% CI -4.16 to -1.34, per 1 mEq/L) (Fig 1A, 1B). Higher sMg was associated with a lower risk of AHA-defined HTN at baseline (aOR 0.25, 95% CI 0.12-0.55, per 1 mEq/L), a lower risk of sub optimally controlled BP (aOR 0.22, 95% CI 0.10-0.53, per 1 mEq/L) but not with a higher risk of CRIC-defined HTN (aOR 0.77, 95% CI 0.50-1.20, per 1 mEq/L). In time-to-event analyses, higher baseline sMg was associated with a numerically lower risk of incident CRIC-defined HTN (aHR 0.68, 95% CI 0.40-1.13, per 1 mEq/L).

Conclusions: Higher sMg is associated with lower SBP, lower DBP and a nominally lower risk of incident HTN. Monitoring and optimal control of sMg should be considered in patients with CKD for improved BP control.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Mean age was 57.5 years, 55.2% were male and 40.4% were black. In the overall population, MPO was associated with a 15% higher risk of AFib hospitalization (aHR 1.15, 95% CI 1.05-1.27, per 1 SD log transformed MPO). The association of MPO with future AFib hospitalization was predominantly noted in those with a prior history of AFib (n=650; P-interaction<0.001), such that there was a 16% higher risk in those with baseline AFib (aHR 1.16, 95% CI 1.01-1.34, per 1 SD log transformed MPO) (Fig 1A), while there was no significant association for those without baseline AFib (aHR 1.11, 95% CI 0.97-1.28, per 1 SD log transformed MPO) (Fig 1B).

Conclusions: In patients with CKD, higher MPO was associated with an increased risk of hospitalization due to AFib, which appeared to be restricted to those with a prior AFib diagnosis. Whether therapies targeting MPO activity and oxidative stress in this population reduce AFib hospitalizations remains to be tested.

PO2075
The Association Between Pre-Donation Hypertension and Early Post-Donation Systolic Blood Pressure Among Older Living Kidney Donors
Fawaz Al Ammary, Abimereki Muzzaalic, Daniel C. Brennan, Dorry L. Segev, Allan Massie. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: One mechanism underlying predonation hypertension in older (age≥50) living kidney donors is a reduced number of nephrons. The 50% nephron mass reduction associated with donor nephrectomy may exacerbate predonation, controlled hypertension. In light of evolving hypertension guidelines, we aimed to study systolic blood pressure (BP) trajectory in older donors with- vs. without hypertension.

Methods: We conducted a national registry study of 11,969 older living kidney donors from 2010-2018. We modeled the association between predonation hypertension and postdonation systolic BP using a mixed linear model with donor-level random intercept adjusting for age, sex, race, predonation systolic BP, BMI, and year of donation. We modeled odds of having 6-month postdonation systolic BP >130 mmHg and >140 mmHg using multivariable logistic regression.

Results: 1,161 of 11,969 older donors (9.7%) had hypertension. Median (IQR) predonation systolic BP was 130 mmHg (122-140) among donors with hypertension vs. 124 mmHg (115-132) among those without (p<0.001). After adjustment for baseline characteristics including predonation systolic BP, hypertension was associated with a 2.43 mmHg increase in postdonation systolic BP (p<0.001). Hypertension was associated with 39% higher odds of having 6-month postdonation systolic BP >130 mmHg (aOR 1.39, 95% CI 1.07-1.82, p<0.001) and 50% higher odds of having 6-month postdonation systolic BP >140 mmHg (aOR 1.50, 95% CI 1.18-1.90, p<0.001).

Conclusions: Predonation hypertension was associated with higher risk of uncontrolled 6-month postdonation systolic BP among older donors, even after adjusting for predonation systolic BP. Our findings call for programs to monitor postdonation systolic BP in donors with hypertension to ensure adequate BP control following nephrectomy.

PO2076
Temporal Trends of the Burden of CKD Among Hospitalized Aortic Stenosis Patients in the Province of Quebec, Canada
Nada Khelifi,1 Denis Hamel,2 Sonia Jean,2 Claudia Blais,2,3 Fabrice Mac-Way,1 1CHU de Quebec Research Center, Faculty of Medicine, Université Laval, Québec, QC, Canada; 2Institut national de santé publique du Québec, Québec, QC, Canada; 3Faculty of Medicine, Université Laval, Québec, QC, Canada.

Background: Aortic stenosis (AS) is associated with valvular calcifications which are highly prevalent in chronic kidney disease (CKD). The aim of this study was to describe the temporal trends of comorbid CKD status in patients hospitalized for AS and evaluate the impact of these two conditions on 1-year mortality in the province of Quebec, between 2000 and 2017.

Methods: Using the Quebec Integrated Chronic Disease Surveillance System, we identified patients ≥20 years with incident AS using ICD-9 and ICD-10 codes, in the hospital discharge database. We then combined hospital discharges and physician billing claims databases to identify patients with comorbid CKD status in the two years prior to the AS diagnosis. Three subgroups of CKD status were considered: 1) non-CKD, 2) pre-dialysis and 3) dialysis. To allow comparison over time, direct adjustment using age distribution of the 2016-2017 AS population was used for proportion, 1-year all-cause and cardiovascular mortality.

Results: We included 108,780 patients with incident AS (Women: 51.8%; mean age (aSD): 76.4 ±11.7; non-CKD: 74.2% (n=80,768); pre-dialysis: 24.6% (n=26,809); dialysis: 1.1% (n=1,203). During the study period, the age-adjusted proportion of AS patients with non-CKD comorbid status decreased by 14% (80.7% [95% CI 77.6-84.0] to 69.6% [95% CI 67.2-71.9]). Inversely, the age-adjusted proportion of AS patients with pre-dialysis and dialysis comorbid status increased by 58% (18.5% [95% CI 16.9-20.2] to 29.3% [95% CI 27.8-30.9]) and 46% (0.7% [95% CI 0.5-1.1] to 1.1% [95% CI 0.8-1.4]), respectively. Age-adjusted 1-year all-cause and cardiovascular mortality decreased over time but remained higher in patients with comorbid CKD. In 2015-2016, age-adjusted relative risk (RR) of 1-year all-cause mortality was significantly higher in pre-dialysis (RR=1.56 [95% CI 1.44, 1.69]) and dialysis (RR=2.04 [95% CI 1.62-2.61]) compared to non-CKD patients. Age-adjusted RR of 1-year cardiovascular mortality was also significantly higher in pre-dialysis (RR=1.83 [95% CI 1.66-2.03]) and dialysis (RR=2.28 [95% CI 1.68-3.09]) compared to non-CKD patients.

Conclusions: Proportion of patients with incident AS and comorbid CKD increased from 2000 to 2017. One-year all-cause and cardiovascular mortality improved over time but remained higher in AS patients with comorbid CKD.
**PO2078**

**Pediatric vs. Adult Ambulatory Blood Pressure Monitoring (ABPM)**

**Criteria for the Diagnosis of Hypertension (HTN) and Detection of Left Ventricular Hypertrophy (LVH) in Adolescents**

Kamal Merchant,1 Paras P. Shah,2 Parulina Singer,2 Laura J. Castellanos,1 Christine B. Sethna,1,2 Cohen Children’s Medical Center, Queens, NY; Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

**Background:** Normative values for clinic blood pressure (BP) measurements in adolescents were recently updated to align with adult HTN guidelines (CPG 2017). However, the most widely accepted pediatric normative values used to diagnose HTN by ABPM criteria have not been updated. The objective of this study was to compare pediatric ABPM criteria (pHTN) vs. adult ABPM criteria (aHTN) for the diagnosis of HTN and detection of LVH in adolescents.

**Methods:** ABPM and ECHO reports from adolescents age 13-21 years performed from 2015-2019 at a single center were analyzed. The concordance of HTN diagnosis based on pHTN (AHA 2014) was compared to aHTN from ACC/AHA 2017 (overall BP ≥125/75 mmHg, wake BP ≥120/80 mmHg, sleep BP ≥110/70 mmHg) using Cohen’s kappa statistic. Logistic regression adjusted for body mass index (BMI) z-score and receiver operating curves (ROC) were used to compare the ability of pHTN vs. aHTN to detect LVH (left ventricular mass index [LVMI] >95th percentile reference values and LVMI >51 gm/m²).

**Results:** Of 306 adolescents (15.9±1.6 years, 73.5% male), 140 (45.8%) had HTN based on pHTN compared to 228 (74.5%) based on aHTN. There was poor agreement in the diagnosis of HTN between pHTN and aHTN (kappa 0.39, N=137, kappa 0.41). 1.0% (N=3) had HTN by pHTN only while 29.7% (N=91) had HTN by aHTN only. Although a higher prevalence of LVH was captured by aHTN only, 9 (5.6%) adolescents who had LVH >95th percentile did not have HTN either by criteria. In logistic regression, adjusted for BMI z-score, there were no significant differences between pHTN and aHTN in the detection of LVH >95th percentile (OR 1.24, CI: 0.66-2.31, p=0.51) or >51 gm/m² (OR 1.06, CI: 0.47-2.40, p=0.89). ROCs for pHTN were not significant for detecting LVH >95th percentile (0.50, p=0.91) or >51 gm/m² (0.55, p=0.45). However, the ROC for aHTN was significant for detecting LVH >95th percentile (0.59, p=0.045) but not >51 gm/m² (0.63, p=0.07).

**Conclusion:** There is good concordance of HTN and aHTN for the diagnosis of HTN in adolescents. aHTN appears to better predict LVH than pHTN, although neither criteria diagnosed all patients who had LVH. A consideration to align the ABPM criteria for the diagnosis of HTN in adolescents with adult guidelines is warranted.

**PO2079**

**Effect of Psychiatric Diagnosis and Selective Serotonin Reuptake Inhibitors (SSRIs)/Serotonin Norepinephrine Reuptake Inhibitors (SNRIs) Use on BP Using 24-Hour Ambulatory Blood Pressure Monitoring (ABPM)**

**Background:** Hypertension (HTN) and psychiatric disorders frequently co-exist. Psychiatric conditions and their treatment by SSRIs/SNRIs affect serotonin & norepinephrine and may cause variation in blood pressure (BP). There is limited data to assess this variation by using ABPM.

**Methods:** Subjects who underwent psychiatric evaluation & ABPM within six months of each other between 1/2012 to 12/2017 were identified. Demographics, comorbidities, medications, ABPM, lab data were retrospectively collected. Subjects were divided into group-subjects with no psychiatric diagnosis & no psychiatric medication (Group 1), subjects with psychiatric diagnosis & on SSRIs/SNRIs (Group 2) and subjects with psychiatric diagnosis & on no medications (Group 3). BP systolic & diastolic levels (daytime, nighttime) were compared between groups controlling for age, sex, race, HTN, DM and smoking. Single and multivariable linear regression models were used to analyze group differences.

**Results:** Of 475 subjects met inclusion criteria-Group 1=135, Group2=232, and Group3=108. First, Group 1 was compared with Group 2 for daytime systolic & diastolic, nighttime systolic & diastolic BP. In multivariable analysis adjusted for age, sex, race, HTN, DM, and smoking, subjects in Group 2 had higher nighttime systolic BP (122.7±11.0 vs 117.5±11.0, p<0.0001) and nighttime diastolic BP (62.2±6.3 vs 56.2±6.2, p<0.0001). There was no difference in the prevalence of early signs of kidney dysfunction over weight and obese adolescents by examining routine labs including creatinine for hyperfiltration and albuminuria.

**Conclusions:** Obesity is a potentially modifiable risk factor for the development and progression of kidney disease in children. The aims of this study were to assess this variation by using ABPM.

**PO2080**

**Obesity-Related Renal Damage in Adolescent Women: Body Surface Area Matters**

Dana Bielopolski,1 Neha Singh,1 Caroline S. Jiang,1 Robert B. Macarthur,1 Kimberly S. Vasquez,1 Dena S. Motfah,2 Rhonda Kost,3 Jonathan N. Tobin,2,3 The Rockefeller University, New York, NY; Clinical Directors Network Inc., New York, NY.

**Background:** Obesity is a potentially modifiable risk factor for the development and progression of kidney disease in children. The aims of this study were to assess this variation by using ABPM.

**Methods:** De-identified electronic health record (EHR) data were extracted for female adolescents aged 12-21 years, who received health care services from 1/1/2011 to 12/31/2015 in NYC from 12 academic health centers and community health centers that are part of PCORnet NYC Clinical Data Research Network (NYC-CDRN). Data were analyzed using SAS (v 3.25) on 60,549 unique subjects. Patient characteristics and outcomes by subgroups were examined using standard statistical software. BMI groups were coded according to NHANES as underweight, normal weight, overweight or obese. Multiple linear regression analyses will control for covariates.

**Results:** Mean creatinine values were similar between normal weight, overweight and obese BMI groups, yet after calculating eGFR and adjusting for BSA, significant and alarming differences appeared. Obese adolescent women had significantly higher eGFR, estimated by CKD-EPI and the Schwartz formula according to age, compared to normal weight subjects. Only subjects in the obese group (BMI>30) exhibited hyperfiltration (eGFR=135 ml/min).

**Conclusion:** Obesity adolescent women present with significant alteration in kidney function that without intervention will lead to ESRD, and adverse outcomes associated with the deleterious effects of adiposity. Awareness should be raised to consider body size when estimating GFR in adolescents.

**Urinary Magnesium Predicts Risk of Cardiovascular Disease in Pre-Dialysis CKD Patients**

Qiongjing Yuan,1 Hui Xu,1 Jinwei Wang,1 on behalf of the C-STRIDE study group.1 Guangzhou Hospital Central South University, Changhai, China; 2 Peking University First Hospital, Beijing, China.

**Background:** 24h Urinary magnesium concentration (24h U Mg), an indicator of intestinal magnesium absorption, may provide a better insight in the connection of CKD progression.

**Methods:** We examined 3179 participants aged 18 to 74 years pre-dialysis patients in the Chinese Cohort Study of Chronic Kidney Disease (C-STRIDE) study. We performed a time-to-event analysis of the data using Kaplan-Meier Survival model, Cox proportional hazard and competing risks Fine and Gray sub-distribution hazard models.

**Results:** During the median follow-up of 4.19 (IQR 3.42-5.09) years, lower incidence rate of ESRD events was observed with increases in 24h U Mg (Figure 1). Higher incidence rate of CVD events was seen with increase in 24 h U Mg (Figure 2). After adjustment for demographic and traditional ESRD risk factors, 24h U Mg was strongly associated with risk of CVD (HR of 1.509 [95% CI 1.031-2.208] Table 1).

**Conclusions:** 24h U Mg risk variants display a modest association with CVD in pre-dialysis CKD patients.

**Funding:** Government Support - Non-U.S.

Left Atrial Strain Measurements Are Associated with Cardiovascular Outcomes in Patients with ESRD
Ruth F. Dubin,1 Amrita S. Ayer,2 Catherine L. Donovan,1 Lauren Nelson,3 Sanjiv Shah.1 1University of California San Francisco, San Francisco, CA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 3Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Left atrial (LA) strain is a marker of diastolic dysfunction, heart failure and atrial fibrillation that has been validated in populations without chronic kidney disease. There are few studies of LA strain in patients with end-stage renal disease (ESRD), among whom cardiovascular (CV) mortality is high and there are no accepted methods of CV risk stratification. We sought to examine associations of LA reservoir strain with CV hospitalization and mortality in a cohort of patients with ESRD on dialysis, and to investigate prognostic utility of strain measurements for CV outcomes.

Methods: 190 ambulatory participants with ESRD on dialysis in the Cardiac Endothelial Function and Arterial Stiffness in ESRD (CERES) study underwent 2D echocardiography at one study visit. The composite outcome, CV hospitalization or death, was adjudicated over a median of 2 years. Hospitalizations related to missing dialysis were not counted as events. LA and left ventricular (LV) structure and function were captured by a single technician, and de-identified images were read by a single reader using GE Echopac software. Associations of LA reservoir strain with the composite outcome were analyzed with cox survival analyses, adjusting for age, gender, comorbidities, and systolic blood pressure.

Results: Mean age was 56 years, 1/3 were women, and the median time since dialysis initiation was 3.5 years. 45% were diabetic and 14% had a history of heart failure. Participants were relatively euvoletic, based on well-controlled blood pressure and weight. Mean (SD) LA volume index was 40ml/m² (±6.9), mean LA reservoir strain was 24% (±9.1%). There were 61 events: 40 hospitalizations and 21 deaths. In the adjusted model, HR (95%CI) per SD LA volume index was 1.4(1.0, 1.9); LA reservoir strain was 1.5(1.1, 2.1); LA reservoir strain and LV global longitudinal strain had a c-statistic(95%CI) of 0.72(0.63, 0.81) for the composite outcome.

Conclusions: Our results suggest that LA strain is independently associated with CV hospitalizations and death among patients with ESRD on dialysis. Strain measurements have the potential to contribute to CV risk stratification in this population. Larger studies are necessary to validate our findings.

PO2084
Under Diagnosis of Pediatric Hypertension
Anoosh Moin, Craig B. Langman. Ann and Robert H Lurie Children’s Hospital of Chicago, Chicago, IL.

Background: Pediatric hypertension is associated with target organ damage in children and cardiovascular morbidity in adults. Therefore, prompt diagnosis and treatment are critical. Application of clinical practice guidelines is inconsistent.

Methods: Using electronic health record data (from 8 community centers), we evaluated the proportion of children (3-18 years) with elevated blood pressures (≥90th percentile) who were appropriately diagnosed as either hypertension or elevated blood pressure over 1 year (2016-17), and provided guideline directed follow-up, by age, sex, race/ethnicity and weight.

Results: The sample included 6233 children with elevated blood pressure, 15% were appropriately diagnosed. These children were more likely to be older, white, and obese. 55 children met criteria for hypertension with 23 being appropriately diagnosed, there was no difference by patient characteristics. Of children with blood pressure ≥95th percentile, 13% had follow-up within 1 month; they were more likely to be older, female, of Hispanic ethnicity or ‘other’ race. Children of blood pressure ≥90th percentile, 41% had follow-up within 6 months, and were more likely to be older, of either white, Hispanic, Asian race or Hispanic ethnicity.

Conclusions: We found persistent underdiagnosis of pediatric hypertension and elevated blood pressure as well as disparities in the diagnosis of elevated blood pressure and guideline-directed follow-up among diverse children in a community setting. New strategies are needed to improve compliance with guidelines.

Associations of Blood Pressure Variability with Cardiovascular Events, Death, and ESKD in Patients with CKD

L. Parker Gregg,1,2 Susan Hedaya,1 Hui Yang,1,2 Peter N. Van Buren,1,2 Sankar D. Navaneethan,3,4 Salim S. Virani,1,2 Wolfgang C. Winkelmayer,5 Carlos A. Alvarez,1,2 University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 3VA North Texas Health Care System, Dallas, TX; 4Baylor College of Medicine, Houston, TX; 5Michael E DeBakey VA Medical Center, Houston, TX; 6Texas Tech University Health Sciences Center School of Pharmacy, Dallas, TX, US, Dallas, TX.

Background: Visit-to-visit blood pressure variability (BPV) is associated with cardiovascular (CV) events in individuals with chronic kidney disease (CKD) stages 3-5. We examined the associations of BPV with CV events, death, and end-stage kidney disease (ESKD) among veterans with CKD stages 1-5 and hypertension, and if treatment with a thiazide or loop diuretic modified these associations.

Methods: In a matched cohort study, patients seen between 2010-2016 with non-dialysis CKD and hypertension on single-agent therapy with a non-diuretic were propensity matched 1:1 for initiation of a loop or thiazide diuretic vs. other antihypertensive class as their second agent. BPV, defined as the coefficient of variation of outpatient systolic blood pressure over 6 months after prescription of the second antihypertensive, was divided into quintiles. Cox proportional hazards regression measured associations of BPV with time to CV events (first among myocardial infarction [MI], hospitalization for heart failure, or ischemic stroke), each component of the primary outcome, all-cause death, and ESKD.

Results: We included 31,394 new users of diuretics and 31,394 patients initiating other agents. Over a median (IQR) follow up time of 393 (244-752) days, there were 7,326 CV events, 16,376 deaths, and 2,029 ESKD events. Higher BPV was associated with composite CV events (Figure). Diuretic exposure attenuated these associations at the fourth and fifth quintiles of BPV (interaction P=0.03 at the 4th and .04 at the 5th quintile). BPV was also associated with MI, heart failure, stroke, and death, but not with ESKD (Figure). Diuretic treatment did not modify these associations.

Conclusions: BPV was associated with CV events and all-cause death but not ESKD in patients with CKD and hypertension. Diuretic use attenuated the association of BPV with CV events at the highest quintiles of BPV. Future studies should test whether diuretics improve CV outcomes in those with high BPV.

abnormalities. Left ventricular mass index (LVMI), relative wall thickness (RWT) and ejection fraction were normal. Left ventricle was dilated in 1 patient. On beta-2 nanograms/mL, complement C3, C4, C1q, proteinaemia, use of steroids and antihypertensive do not differ significantly between the patients with and without BP abnormalities.

**Conclusions:** Masked HTN and blunted nocturnal dipping is common in adolescents with SLF and can be missed if ABPM is not applied in clinical practice. Additional studies between the patients with and without BP abnormalities.

ABPM has been shown to correlate with target organ damage and provides a more reliable assessment of blood pressure (BP) control compared to clinic BP. Exercise stress testing (EST) is not recommend by the AAP for the evaluation of hypertension although anecdotal, it is used frequently by pediatric cardiologists. Despite this, reports in adults show an association between exaggerated exercise systolic blood pressure (EESP) and cardiovascular mortality and morbidity, masked hypertension, and target organ damage. We report 2 pediatric patients with hypertension and evidence of target organ damage, but with a discrepancy between their ABPM and EST BP results.

**Case Description:** See table below.

**Discussion:** We describe 2 adolescent cases of hypertension diagnosed by clinic BP and target organ damage but not confirmed by ABPM. Both patients had EST done as part of their evaluation because they were first seen by cardiologists at the study center who frequently employ EST as part of evaluation for hypertension. The cut-off value of 180mmHg for EESP was employed in this report as a previous study had identified 181mmHg as the threshold for CVE and ACM. We also examined the interactions of diuretic use with the treatment on CVE and ACM. We also examined the interactions of diuretic use with the treatment on CVE and ACM. We also examined the interactions of diuretic use with the treatment on CVE and ACM.

**Results:** There were 90 and 21 patients in groups A and B, respectively. At baseline, demographics were similar in both groups (Table 1). At endpoint, Group A had more patients at targeted blood pressure (BP) (55.6% vs 33.3% at 140/90 mmHg; 21.1% vs 19% at 130/80 mmHg), and larger reduction in both brachial and central BP parameters (Table 2). The mean (SD) of number of office visits were 3.1(1.0) and 2.9(1.1), in Groups A and B, respectively. In Group A, mean aorta compliance was increased 23.3% and 1.7% in the subgroups that met and did not meet target BP, respectively. Mean number of medications at baseline/endpoint were 1.7/2.6 and 1/2.0 in groups A and B, respectively. At endpoint, Group B had negligible change in distribution of drug classes, while Group A had significant increased use of calcium channel blockers (dihydropyridines) and beta-blockers.

**Conclusions:** Impedance cardiology is a simple, noninvasive method for evaluating underlying hemodynamic drivers of HTN. Hypertension management is more effective when guided by hemodynamic state.

The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on Incident Strokes in the SPS3 Trial

Robert E. Boucher,1 Guo Wei,1,2 Olesya Ilkun,3 Srinivasan Beddhu,1,3 1Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; 2Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 3Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** In persons with low baseline diastolic blood pressure (DBP) and previous stroke, intensive systolic blood pressure (SBP) lowering might decrease cerebral perfusion increase risk for recurrent stroke.

**Methods:** SPS3 was a 2x2 factorial RCT that examined the effects of intensities versus standard (<130 vs. 130-149 mmHg) SBP control and combination versus aspirin alone antplatelet therapy on stroke outcome in 3020 participants. We examined whether the effects of intensive SBP lowering on stroke were modified by baseline DBP using spline regression models.

**Results:** Mean baseline age was 63±11 yrs, 63% male and 15% black. Mean baseline SBP was 143±19 mmHg and DBP was 78±11 mmHg. There were 267 strokes over 10725 person-years of follow-up. In spline regression models, those with lower baseline SBP were at higher risk for stroke (Fig1, panel A) but stroke incidence was lower in intensive vs. standard SBP arm all three baseline DBP tertiles (Fig1, panel B). In a spline regression model, there was no evidence that intensive SBP lowering increased the risk of stroke in those with low baseline DBP (Fig 2). Repeating the analysis with a cardiovascular composite (MI, CHF, stroke, or cardiovascular death) table similar results.

**Conclusions:** While observational analysis suggested higher risk of recurrent stroke with low baseline SBP, intensive SBP lowering did not increase recurrent stroke risk in those with low baseline DBP and previous stroke.

The Influence of Baseline Diastolic Blood Pressure on the Effects of Blood Pressure Lowering on Death and ESKD Outcome

Olesya Ilkun,1 Guo Wei,1,2 Robert E. Boucher,1 Srinivasan Beddhu,1,3 1Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; 2Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 3Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.

**Background:** Intensive systolic blood pressure (SBP) lowering decreased the risk of death in SPRINT. However, there are concerns in those with low baseline diastolic blood pressure (DBP) that intensive SBP lowering might adversely affect kidney perfusion and increase the risk for death/ESKD.

**Methods:** The African-American Study of Kidney Disease and Hypertension (AASK) trial examined the effects of two different BP goals (mean arterial pressure (MAP) = 92 vs 102-109) in African American men and women (N=1094) with kidney disease but no diabetes. We investigated whether the effects of BP intervention on the risk of death/ESKD was modified by baseline DBP.

**Results:** Mean baseline age was 55±11 yrs and DBP 95±14 mmHg. There were 264 death/ESKD events over 4714 years of follow-up. Compared to usual BP control, low BP goal resulted in lower levels of follow-up SBP, MAP and DBP across baseline DBP tertiles (Fig 1). Despite the lower follow-up MAP and DBP values, there was no evidence that low BP goal increased the risk of death/ESKD in those with low baseline SBP (Fig 2). Interaction of baseline DBP and BP intervention for death/ESKD was not significant (p =0.22).

**Conclusions:** The effect of BP lowering on the risk of death/ESKD was not modified by low baseline DBP. Hence, low baseline DBP by itself should not be an impediment for intensive BP lowering in CKD.

Figure 1. Mean follow-up SBP, DBP and MAP by BP arm in baseline DBP tertiles.
Early GFR Decline with Intensive BP Lowering and the Risk of Death and ESKD: Mediation Analysis of AASK Study
Srinivasan Beddhu,1,2 Jincheng Shen,1 Glenn M. Chertow,1 Paul K. Whelton,4 Guo Wei,1,2 Robert E. Boucher,1 Alfred K. Cheung,1,2 Tom Greene,1 1Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; 2Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT; 3Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 4Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; 5Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Intensive BP lowering appears to have a largely beneficial direct effect and a small deleterious indirect effect on death/ESKD in CKD.

Methods: AASK Study (N = 1094) was a RCT of low vs. usual mean arterial pressure (92 vs. 102 to 107 mmHg) on kidney outcomes. Using the change in measured iothalamate GFR from baseline to the average of months 3 and 6 (early GFR change), we examined the acute effect of the intervention on subsequent death/ESKD in a mediation analysis. We partitioned the total effect of BP intervention on death/ESKD that was mediated through early GFR change (indirect effect) and independent of early GFR change (direct effect). We also used SIMEX method to access the impact of measurement error in early GFR change on the findings.

Results: We included 976 AASK participants with GFR measurements at baseline, 3 and 6 months. Mean baseline GFR was 55±11 ml/min/1.73m². There were 223 deaths, 293 ESKD events and 445 death/ESKD events during an average of 7.2±3.3 years of follow-up. BP separation was maintained through the trial (Fig 1, panel A) with an early decline in GFR in the lower BP group but GFRs in the two arms that were similar at the end of the trial (Fig 1, panel B). After adjustment for covariates listed in the footnote to Fig 2, we observed a borderline significant beneficial total effect of the BP intervention on death/ESKD and a slightly stronger direct effect (Fig 2). The HR for the indirect effect was slightly > 1, consistent with the possibility of a small adverse effect of early GFR change.

Conclusions: Intensive BP lowering appears to have a largely beneficial direct effect and a small deleterious indirect effect on death/ESKD in CKD.

Funding: NIDDK Support, Other NH2 Support - NHLBI, Veterans Affairs Support
Methods: We performed a retrospective study on 214 patients with CKD and arterial hypertension admitted between January and June 2019 to the Unit of Nephrology and Dialysis of Policlinico G. Martino in Messina, Italy. 72 patients were diagnosed with RH, defined as blood pressure >140/90 mmHg despite use of three different classes of antihypertensive medications (one of which must be a diuretic) at the maximum tolerated doses.

Results: MHR appeared inversely related to eGFR (p = -0.163; P = 0.0172). MHR was significantly higher among RH patients compared to non-RH ones (12.39 [IQR 10.67 - 16.05] versus 7.30 [5.49 - 9.06] (Figure 1); P < 0.0001). Moreover, MHR was significantly different according to the number of anti-hypertensive drugs per patient in the whole study cohort (F = 46.723; P = 0.001) as well as in the non-RH group (F = 14.19; P = 0.001). Lastly, MHR values differed according to gender, being higher among males (9.41 [6.75 - 12.07] versus 8.02 [5.94 - 10.57]; P = 0.0463).

Conclusions: MHR may be a reliable biomarker due to the connection between HDL and monocytes. HDL prevents and reverses monocyte recruitment and activation into the arterial wall and impairs endothelial adhesion molecule expression. Our study suggests that MHR can reflect inflammatory status and OS in CKD patients with RH, in order to implement appropriate treatment strategies.

PO2098

Primary Aldosteronism in CKD

Heather Wachtel,1 Jae Ermer,1 Angela C. Davio,2 Yuta Tczuka,3 Gregory L. Hunderman,2 Adina Turcu,1 Anand Vaidya,4 Debbie L. Cohen,1 1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Ottawa Hospital, Ottawa, ON, Canada; 3University of Michigan, Ann Arbor, MI; 4Brigham and Women’s Hospital Department of Medicine, Boston, MA.

Background: Primary aldosteronism (PA) is a common cause of secondary hyperaldosteronism, with unilateral causes of PA being potentially cured with an adrenal resection. Treatment of PA in CKD is often avoided for concerns of safety and efficacy.

Methods: We conducted a retrospective cohort study of patients with PA and CKD (eGFR <60 ml/min/1.73m²) at 3 institutions (2009-2019). eGFR was calculated using the CKD-EPI equation. Statistical comparison utilized the student’s t-test, Chi-square test, and Wilcoxon rank-sum test.

Results: Of 250 patients included, mean age was 56.6 years (±10.5), and 64% were female. Median plasma aldosterone concentration was 29.0 ng/dl [IQR:20.3-47.4]; median plasma renin activity was 0.2 ng/ml/hr [IQR:0.1-0.6] and aldosterone-renin ratio was 119 (ng/dl)/(ng/ml/hr) [IQR:63.5-240.0]. Median eGFR on initial evaluation was 49.0 ml/min/1.73m² [IQR:40.3-58.2]. Adrenal vein sampling (AVS) was performed in all patients; unilateral PA was diagnosed in 67.6% (n=169). Adrenalectomy was performed in 163 subjects. Surgical pathology demonstrated adrenocortical adenomas in 66.9%, nodular hyperplasia in 4.9%, and nodular hyperplasia with a dominant nodule in 10.4%. The median tumor size was 1.2 cm [IQR:1.0-1.8]. No differences were detected in baseline MAP, number of anti-hypertensive medications (AHM), serum creatinine, or potassium levels between adrenalectomy patients and those medically managed. Adrenalectomy patients had significantly lower AHM requirements at 1 month (4.5 ± 4.5 AHM vs 7.3 ± 4.5 AHM, 22% vs. 35%, p=0.002) and 1 year (2.6 ± 2.3 AHM vs 4.8 ± 4.3 AHM, 40% vs. 58%, p=0.002) postoperatively.

Conclusions: Patients with CKD and unilateral PA experience significant and durable decrease in AHM requirement and demonstrate stabilization of eGFR after adrenalectomy when compared to medically managed patients. AVS was successful despite reduced eGFR. This study demonstrates that patients with CKD and suspected PA should undergo evaluation to determine whether they have surgically curable disease, as there is a clear benefit in medication reduction and stabilization of eGFR at 12 months.

PO2099

Bilateral Nephrectomy in a Patient with Refractory Hypertension Prior to Development of ESKD

Anna M. Zemek1, Alexander Hilepas2, Martin Herl1, Waileed Ali3, Benjamin A. Roddy1, George L. Bakris,3 1Department of Medicine, Division of Nephrology, Rush University Medical Center, Chicago, IL; 2Department of Medicine, Rush University Medical Center, Chicago, IL; 3Department of Medicine, Comprehensive Hypertension Center, University of Chicago Medicine, Chicago, IL; 4Department Transplant Surgery, Rush University Medical Center, Chicago, IL.

Introduction: Renal denervation (RDN) reduces increased sympathetic activation in refractory HTN (rHTN) while preserving kidney function, and trials in both the US and Europe demonstrate a 7-12 mmHg placebo subtracted reduction in systolic BP. Bilateral nephrectomy (BLN), originally performed in ESKD patients in the 1970s for rHTN is an effective treatment, but is reserved for ESKD pts. We present a case of life threatening rHTN in a pt with Stage 3b CKD that was unresponsive to open surgical renal denervation (OS RDN) but responded extremely well to BLN.

Case Description: A 43 y/o white woman with stage 3b CKD (eGFR 38 ml/min/1.73m²) presented with a resting SBP between 180-240 mmHg on maximal doses of 8 different antihypertensive medications including spironolactone and minoxidil. She required frequent hospitalizations for symptomatic HTN with IV CCBs and beta blockers. Workup included an evaluation of all secondary causes including drug screening, urine metanephrines, renal MRI, and renin/aldo ratio. In an effort to avoid BLN, she initially underwent bilateral OS RDN by severing all neural tissue entering the kidney. Renal vein renin levels were 9.1, 7.8 ng/ml/hr pre OS RDN and 0.7, 1.4 ng/ml/hr post. Despite an initial drop in BP to 140/70 mmHg on only 2 medications, within 4 wks of OS RDN, her BP rose to 240/120 on 4 medications and she was symptomatic. At this point, BLN was performed as the only remaining option. Understanding of the need for RRT following BLN, the patient consented to proceed. Follow up BPs have been in the 130/80 mmHg range and no more than a 12.5mg bid alone.

Discussion: Neither OS RDN nor pre-ESKD BLN for rHTN have been previously reported. Advancements in endovascular RDN are becoming more effective, but still only lower systolic BP by 7-12 mmHg placebo subtracted. Our case failed to respond to OS RDN, where we were guaranteed completed resection of the nerves and surrounding connective tissue, and suggests the effects of any form of RDN may be limited. BLN for rHTN in pts on RRT was started in the 1970s. Almost 50 yrs later, despite enormous improvements in medications, there is still a role for this procedure, and it emphasizes how little we still know about the etiology of HTN. Requiring this in a patient pre-ESKD was extreme but we felt a life-saving requirement. She will be referred for transplantation.
PO2100
Rostral Ventrolateral Medullary Compression: A Rare but a Cardinal Cause of Refractory Hypertension (RfHTN)

Mrunalini Sarkar, Susanne B. Nicholas. University of California Los Angeles, Los Angeles, CA.

Introduction: RfHTN is defined as uncontrolled HTN with BP >140/90 mmHg despite 5 different classes of maximally tolerated antihypertensive agents, including a diuretic and a mineralocorticoid receptor antagonist. RfHTN may be underdiagnosed.

Case Description: A 43-year-old female with a history of mitral valve prolapse, iron deficiency anemia, mild asthma and migraines presented for management of uncontrolled severe HTN. Her HTN became increasingly resistant following use of pheniramine and febrifuramine for two years and a recent hysterectomy, with persistently elevated blood pressure (BP) up to 250/100 mmHg. Her medications included: hyalurazine, lopressor, procardia, demadex, accupril, diovan, catapres and aldactone. On physical exam, her BP was 230/136 mmHg with regular pulse of 96 beats/min and no papilledema or bruits. Renal function and aldosterone levels were normal. Renal ultrasound/doppler, captopril scan, and angiograms showed no renal artery stenosis or coarctation of the aorta, and 24-hour urine metanephrines were normal. Her echocardiogram showed concentric left ventricular hypertrophy with ejection fraction of 60%. Minoxidil was initiated and procardia and lopressor were maintained, with no effect on BP. A high-resolution brain MRI with spectroscopy showed a venous angioma in the right superior temporal lobe and CT angiogram showed irregularity of the basilar artery with outpouching at the left posterior communicating artery and right anterior choroidal artery. She was diagnosed with neurogenic arterial HTN from neurovascular compression (NVC) of the rostral posterior communicating artery and right anterior choroidal artery. She was diagnosed with a cervical ICA dissection, CKD stage 3, heart failure, and severe aortic stenosis. The patient continues to have RfHTN despite maximal medical therapy and has now developed complications including a cervical ICA dissection, CKD stage 3, heart failure, and severe aortic stenosis.

Discussion: NVC is related to neurogenic HTN when occurring in the RVL medulla. This case highlights that brain MRI be performed in patients with intractable resistant HTN when all other secondary causes are ruled out.

PO2102
Percutaneous Angioplasty of Renal Artery Stenosis Most Beneficial in Patients with AKI Requiring Acute Hemodialysis

Nabil H. Abu amer,1 Lesya Kukuy,1 Uri Rimon,1 Eliezer J. Holtzman,2 Pazit Beckerman,2 Dganit Dinour,2 Sheba Medical Center at Tel Hashomer, Tel Hashomer, Israel; 2Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: Treatment of atherosclerotic renal artery stenosis (RAS) is still controversial and several protocols have shown that percutaneous transluminal renal angioplasty with stenting (PTRAS) is not superior to medical treatment, and the procedure is commonly reserved for malignant hypertension, flash pulmonary edema or deterioration of kidney function. The benefit of endovascular intervention among acute kidney injury (AKI) patients requiring hemodialysis secondary to severe RAS has not been studied. We studied the effects of PTRAS in patients with atherosclerotic RAS, specifically those who presented with AKI indicated for hemodialysis.

Methods: 109 PTRAS were performed in 92 patients with RAS from 2003 to 2019 in a tertiary hospital. Eleven patients presented with AKI secondary to high grade RAS and underwent PTRAS after starting acute hemodialysis. Data collected included demographic parameters, medical background, indication for intervention, technical procedure parameters and complications and long term data including dialysis treatment and mortality. Patients were categorized as responders or non-responders based on improvement in kidney function and discontinuation of dialysis.

Results: A total of 109 procedures were performed in 92 patients with severe renal artery stenosis. Eleven patients (12%) underwent PTRAS for severe high grade stenosis causing renal hyperperfusion and hemodialysis-dependent AKI. After PTRAS, 8 of 11 patients (73%) improved kidney function and discontinued dialysis. The average time on dialysis was 17 days (range 3-35 days) to PTRAS and 22 days (range 3-42 days) to recovery of kidney function, which occurred 6.5 days (range 1-24 days) after PTRAS. Two of the 8 patients later required long term hemodialysis. Only two cases were reported with mild complications.

Conclusions: In patients with hemodialysis dependent AKI, PTRAS should be considered as a rescue treatment as kidney function may recover even after prolonged time on dialysis.

PO2103
Outcomes of Cardiac Surgery in CKD Stage 3 vs. Stage 4 and 5

Aimen Lianat,1 Elias Basil,1 Jonathan J. Taliercio,1 Ali Mehdi,1 Remy Daou,2 Susana Arriagin,1 Victoria Konig,1 Jesse D. Schold,1 Serge C. Harb,1 Per Wierup,1 Sevag Demirjan,1 Georges Nakhoul,1 Cleveland Clinic, Cleveland, OH; 2Universite Saint-Joseph, Beirut, Lebanon.

Background: Pre-operative kidney dysfunction is associated with worse outcomes following cardiac surgery. However, few studies have assessed the outcomes of advanced Stage 4 and 5 Chronic Kidney Disease (CKD) patients.

Methods: Using our Electronic CKD registry, we compared the outcomes of 988 patients with CKD stages 3 vs. 4 and 5 undergoing Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery. We compared length of stay (LOS), ICU days, days on pressors, and days intubated as continuous values and as proportion above the 50th percentile using Kruskal-Wallis and Chi-square tests. We estimated Fine and Gray’s competing risks cumulative incidence function of days to post-operative AKI requiring dialysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
dialysis (AKI-D) with mortality as a competing risk during hospitalization. We also compared the proportion developing AKI-D with Chi-square test.

**Results:** Among 988 total patients with cardiac surgery, 115 (12%) had CKD stage 4/5 and 873 (88%) had CKD stage 3. Average age was 71.2 ± 9.5 and 590 (59.7%) were male. Patients with CKD 4/5 had a higher proportion of diabetes (60% vs. 37%). Compared to CKD 3 patients, CKD 4/5 patients required longer intubation (33% more than 2 days compared to 20%, p=0.003), more pressors (47% more than 3 days vs. 32%, p=0.003), longer ICU LOS (median of 5 days vs. 4 days, p=0.001), longer post-operative LOS (median 12 days vs. 9, p=0.001), 24 patients (20.9%) with CKD 4/5 developed post-operative AKI-D vs. 42 (4.8%) in the CKD 3 group (p < 0.001). The cumulative incidence of End-Stage-Kidney Disease (ESKD) with death as a competing risk at 15 days was 5% (95% CI: 4, 8) in CKD 3 group vs. 24% (15, 33) in CKD 4/5 group (p < 0.001). (Table 1)

**Conclusions:** Advanced CKD stages 4/5 is associated with worse outcomes following cardiac surgery including prolonged ICU stay, intubation duration, days on pressors, development of AKI-D and ESKD.

**Cardiovascular Events and Mortality in Adults with Kidney Failure after Major Noncardiac Surgery**

Tyrone Harrison,1 Paul E. Ronksley,1 James Wick,1 Shannon M. Ruzycki,1 Matthew T. James,1 Deirdre Mccaughhey,1 Kelly B. Zarnke,1 Brenda Hemmelgarn.2,1 University of Calgary Cammung School of Medicine, Calgary, AB, Canada; 1University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada.

**Background:** People with kidney failure have a high incidence of major surgery. Despite this surgical exposure, there is a paucity of literature investigating postoperative CV events and death. We aimed to determine the risk of these outcomes based on surgery type.

**Methods:** This retrospective cohort study used administrative health data from Alberta, Canada from April 2005 to February 2017. Adults (≥18 years) with kidney failure (receipt of chronic dialysis or two outpatient eGFR measures <15 mL/min/1.73m²) admitted to hospital for a surgical procedure were included. Surgery type, categorized using ICD-10 codes from hospitalization data, was examined for association with acute myocardial infarction (AMI) and death within 30 days of surgery using multivariable logistic regression. We adjusted for demographics, comorbidities, preoperative laboratory measures, procedure urgency, and kidney disease specific variables.

**Results:** 3398 people with kidney failure had a major surgery (1905 hemodialysis; 590 peritoneal dialysis; 903 non-dialysis). Most of the cohort was male (61.0%), the median age was 61.5 years (IQR 50.0, 72.7), and over half of the procedures were urgent (56.9%). 198 people (5.8%) had an AMI or died within 30 days of major surgery. Compared to CKD 3 patients, CKD 4/5 patients required longer intubation (33% more than 2 days compared to 20%, P=0.003), more pressors (47% more than 3 days vs. 32%, P=0.003), longer ICU LOS (median of 5 days vs. 4 days, P=0.001), longer post-operative LOS (median 12 days vs. 9, P=0.001), 24 patients (20.9%) with CKD 4/5 developed post-operative AKI-D vs. 42 (4.8%) in the CKD 3 group (p < 0.001). The cumulative incidence of ESKD with death as a competing risk at 15 days was 5% (95% CI: 4, 8) in CKD 3 group vs. 24% (15, 33) in CKD 4/5 group (p < 0.001). (Table 1)

**Conclusions:** Advanced CKD stages 4/5 is associated with worse outcomes following cardiac surgery including prolonged ICU stay, intubation duration, days on pressors, development of AKI-D and ESKD.

**PO2105**

**Race Differences in Cardiovascular Events After Percutaneous Coronary Intervention-Induced AKI**

Joseph Lunvera,1 Robert M. Clare,2 Karen Chisswell,2 Julia J. Scialla,2 Patrick H. Pun,2,1 Kevin L. Thomas,3,1 Monique Starks,2,1 Clarissa J. Diamantidis.1 1Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3University of Virginia School of Medicine, Charlottesville, VA.

**Background:** AKI portends a higher risk of subsequent cardiovascular disease (CVD). Although racial differences in AKI incidence have been found, it is unclear if the risk of CVD events following AKI also varies by race.

**Methods:** We quantified racial differences in the association of AKI with CVD events 1-year following percutaneous coronary intervention (PCI), using the Duke Databank for Cardiovascular Disease (DDCD). The DDCD captured all patients who underwent PCI at Duke between January 1, 2003 and December 31, 2013 with a combination of structured (forms) and electronic health record (EHR) data. Patients were followed prospectively for CVD events. AKI was defined as a ≥1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. The primary outcome was a CVD composite including all-cause death, myocardial infarction, stroke, and revascularization. Cox models from date of AKI to outcome were adjusted for demographics, baseline cardiac comorbidities, medication use (RAAS inhibitors and NSAIDS), indication and urgency of PCI, and BP at PCI and number of stents placed.

**Results:** Among 9432 patients (median age 63y; 33% women; 75% white, 20% black), 865 (9%) developed AKI. Among 6699 patients with follow-up, the cumulative incidence of CVD at 1-year was 21%. After adjustment, AKI vs no AKI was associated with 1.84 greater hazards for the composite CVD outcome [95% confidence interval (CI) 1.62 to 2.01]. Compared to whites, other race (HR 0.79, 95% CI 0.63 to 0.99) but not black race (HR 1.07, 95% CI 0.95 to 1.20) was associated with lower risk of subsequent CVD. There was no interaction between race and AKI (p-interaction 0.216). Results were similar with individual components of the outcome.

**Conclusions:** AKI vs. no AKI following PCI is associated with greater risk for CVD events, regardless of race. Efforts to offset long-term consequences of AKI should target all patients undergoing PCI.

**Funding:** Private Foundation Support
PO2106
Frailty Is Associated with Higher Risk of Cardiovascular Events and Death in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study
Mary Hannan,1 Ana C. Ricardo,1 Julia Brown,1 Eunice Carmona,1 Zahraa Hajiri,2 Natalie Meza,1 Jinsong Chen,1 Mildy R. Saunders,2 James P. Lash,1 1Department of Medicine and 2Department of Urology, University of Illinois at Chicago College of Medicine, Chicago, IL; 2UCHicago Medicine, Chicago, IL.

Background: Frailty is common in individuals with chronic kidney disease (CKD). In the general population, frailty is associated with increased risk of cardiovascular events and mortality, but this association has not been fully examined in the CKD population. The objective of this study is to evaluate frailty status as a predictor of cardiovascular events and death in individuals with CKD.

Methods: Among 2,537 CRIC Study participants, frailty status was assessed using five criteria (slow gait speed, muscle weakness, low physical activity, exhaustion, and unintentional weight loss). Frailty was defined as meeting ≥3 criteria, pre-frailty as meeting 1-2 criteria, and non-frailty as meeting zero criteria. Cox proportional hazards models were used to evaluate associations with atherothrombotic events, incident heart failure, and death.

Results: Baseline age was 57.5 years, 45.5% were female, mean eGFR was 46.9mL/min/1.73m², and median urine protein was 0.13 mg/day. Frailty was present in 21% of the participants and 66% were pre-frail. During a median follow-up of 12.5 years, there were 349 atherothrombotic events, 398 incident heart failure events, and 398 deaths. In multivariable analyses, frail individuals had a higher risk of each outcome compared to non-frail individuals. Pre-frail individuals had a higher risk of atherothrombotic events compared to non-frail individuals (Table).

Conclusions: In adults with CKD, frailty is associated with increased risk for cardiovascular events and death. Future studies are needed to evaluate the impact of interventions to reduce frailty in individuals with CKD.

PO2107
CKD Predicts Stroke Severity, Disability, and Early Recurrence in a Population-Based Cohort Study

Background: Chronic kidney disease (CKD) is associated with cerebrovascular disease and related mortality, and with under-utilisation of acute and preventive treatments, but any impact on initial event severity and recurrence risk is unclear. We aimed to determine whether CKD is associated with worse initial stroke severity and disability, and whether CKD is independently predictive of recurrent stroke and other vascular events.

Methods: In a population-based study of all TIA/stroke (Oxford Vascular Study), we studied initial stroke severity and disability using the National Institutes of Health Stroke Scale (NIHSS) and modified Rankin scale (mRS), respectively, in relation to CKD in all patients presenting with TIA and stroke from April 1, 2002 to March 31, 2017. Associations between CKD and event severity, and between CKD and risk of recurrent vascular events (stroke, myocardial infarction, and sudden cardiac death) were examined using ordinal and Cox regression models, respectively, adjusted for age, sex, and known vascular risk factors, and stratified by TOAST subtype.

Results: Among 3178 patients with TIA (n=1167), ischaemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. CKD was independently associated with greater risk of ischaemic stroke compared to TIA (adjusted OR=1.31, 95%CI=1.11-1.56; p=0.002) and with greater initial NIHSS (adjusted OR=1.28, 1.04-1.46; p=0.018), driven mainly by those with an estimated glomerular filtration rate (eGFR) < 30 mL/min/1.73m² (adjusted OR=2.59, 1.44-4.66; p=0.001) for ischaemic stroke; adjusted OR=4.06, 2.04-8.06; p=0.001 for initial NIHSS). Among patients with ischaemic stroke, CKD was also associated with higher one-month mRS scores (adjusted OR=1.40, 1.13-1.74; p=0.002), driven by those with an eGFR < 30 mL/min/1.73m² (Adjusted OR=6.51, 3.04-13.97; p=0.001). Risk of early (<90 days) recurrent stroke was increased with CKD (adjusted HR=1.60, 1.15-2.21; p=0.005) as was the risk of longer-term (0-15 year) composite vascular outcomes (adjusted HR=1.14, 1.05-1.40; p=0.01).

Conclusions: The consistent independent impact of CKD on initial event severity, early disability and recurrence risk suggests that there may be processes intrinsic to CKD leading to uniformly worse outcomes. Further research should determine whether there are CKD-specific treatments that may improve stroke outcomes.

PO2108
Control of Blood Pressure in Elderly Patients with Heart Failure and Risk of Mortality
Antonios Dourou,1,2 Alice Schneider,1 Natalie Ebert,1 Martin K. Kuhlmann,2 Nina Mielke,1 Markus van der Giet,1 Elke Schuefner,1 1Charite Universitätsmedizin Berlin, Berlin, Germany; 2Vivantes-Netzwerk für Gesundheit GmbH, Berlin, Germany; 2McGill University, Montreal, QC, Canada.

Background: Blood pressure (BP) targets in elderly patients with heart failure (HF) are unclear and guidelines are based on expert consensus and extrapolation from populations without HF. Thus, our population-based prospective cohort study assessed if BP control <140/90 mmHg is associated with a decreased risk of mortality in elderly HF patients.

Methods: We included participants of the Berlin Initiative Study, all ≥70 yrs, with HF and treated with antihypertensive drugs at baseline (2009-2011). Demographics, lifestyle factors, medication, and comorbidities were obtained in face-to-face interviews and linked with administrative healthcare data. BP status was defined as normalized BP (systolic BP <140 and diastolic BP <90 mmHg) or non-normalized BP (systolic BP ≥140 or diastolic BP ≥90 mmHg) and updated every 2 yrs, so that each patient could contribute person-time to both exposure categories during follow-up. Time-dependent Cox proportional hazards models estimated adjusted hazard ratios (HRs) with 95% confidence intervals (CIs) of cardiovascular death and all-cause mortality associated with normalized BP compared with non-normalized BP in HF patients. Analyses were repeated in non-HF patients.

Results: There were 544 HF patients treated with antihypertensive drugs (mean age 82.4 yrs; 45.4% female). During a median follow-up of 7.5 yrs and compared with non-normalized BP, normalized BP was associated with an increased risk of cardiovascular death (HR, 1.79; 95% CI, 1.23-2.61) and all-cause mortality (HR, 1.48; 95% CI, 1.15-1.90). No increased risks of cardiovascular death (HR, 1.23; 95% CI, 0.87-1.74) or all-cause mortality (HR, 1.19; CI 0.95-1.49) associated with normalized BP were observed among 1079 non-HF patients.

Conclusions: BP <140/90 mmHg was not associated with a decreased risk of mortality in elderly HF patients. The increased risk requires further confirmation.

Renal Outcomes of Sacubitril-Valsartan vs. ACE Inhibitors and Angiotensin Receptor Blockers in Heart Failure: A Systematic Review and Meta-Analysis

Background: Chronic kidney disease is an important comorbidity in heart failure patients through elevation in blood pressure and activation of the RAAS. Angiotensin converting enzyme inhibitors and angiotensin receptor blockers have been linked to beneficial effects on clinical outcomes of HF patients with CKD; however, they have been found to increase the risks for renal impairment. Clinical trials on the angiotensin receptor neprilysin inhibitor, sacubitril-valsartan, have found that it causes kidney dysfunction less frequently. This study determined the effect of sacubitril-valsartan on renal outcomes among HF patients compared to ACEi and ARBs alone.

Methods: A comprehensive literature search was done through electronic databases and readings until November 2019. This analysis incorporated randomized controlled trials in which indicators of renal function of patients on sacubitril-valsartan were compared to those of patients on reference drugs—estimated glomerular filtration rate, serum creatinine, and increase in serum potassium.

Results: Four RCTs were included with a total of 14,377 subjects for analysis. Two of the studies used an ACEi (enalapril), while the remaining 2 used an ARB (valsartan). Compared with ACEi and ARBs, there was a nonsignificant difference between decline in GFR (RR 0.75, 95% CI 0.55 to 1.02; participants = 14777; studies = 4; 12%, p ≥ 0.53), but a significant difference between rise in serum potassium level (RR 0.90, 95% CI 0.84 to 0.96; participants = 14334; studies = 4; 12% 66%), and elevation of serum creatinine level (RR 0.86, 95% CI 0.78 to 0.95; participants = 1470; studies = 3; 12% 72%).

Conclusions: In HF patients, sacubitril-valsartan shows possible reduction of risks for renal impairment, and definite reduction of risks for both increasing serum creatinine and hyperkalemia, as compared to ACEi and ARBs.

The Accuracy of Current Ankle-Brachial Index and Toe-Brachial Index Diagnostic Criteria for Peripheral Artery Disease Among Patients with CKD
Jing Chen,1 Hua He,2 Charlton C. Starke,2 Yajun Guo,3 Siyi Geng,2 Chunjian Chen,2 Erin Mahone,2 Jodie R. Laurent,2 Christina L. Wiggins,2 Praktiti Mehta,2 Paige R. Pielert,2 Vecchi Batuman,1 L. Lee Hamm,1 Jiang He.2
1Tulane University School of Medicine, New Orleans, LA; 2Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Ankle-brachial index (ABI) less than or equal to 0.9 and toe-brachial index (TBI) less than or equal to 0.7 are used as diagnostic criteria for peripheral artery disease (PAD). The sensitivity and specificity of the ABI and TBI diagnostic criteria have not been evaluated in patients with chronic kidney disease (CKD).

Methods: We performed ABI, TBI, and doppler ultrasound among 100 patients with CKD using standard methods. Color doppler ultrasound, which has a high level of diagnostic performance with a sensitivity of 93% and a specificity of 95% for diagnosing PAD, was used as the reference standard. Doppler ultrasound diagnostic criteria were determined by multiple ultrasound features including reduction in luminal diameter, monophasic waveform, peak systolic velocity ratio (PSV ratio) > 2.0, and presence of stenosis greater than or equal to 50% based on doppler ultrasound imaging was used to diagnose PAD. Sensitivity, specificity, positive predictive value, and negative predictive value were estimated. The areas under the curve (AUCs) for ABI and TBI were calculated.

Results: Participants with PAD were older, and more likely to be male and have a history of cardiovascular disease. The average estimated glomerular filtration rate and proteinuria were similar among participants with and without PAD. The sensitivity, specificity, positive predictive value, and negative predictive value were 15.6%, 88.3%, 20.8%, and 84.2% for ABI and 44.8%, 93.3%, 54.2%, and 99.5% for TBI, respectively. AUCs for ABI and TBI were 0.71 and 0.73, respectively.

Conclusions: These data indicate that current ABI and TBI diagnostic criteria have suboptimal accuracy in diagnosing PAD in CKD. New ABI and TBI diagnostic criteria with a higher sensitivity and specificity need to be developed.

PO2111
Efficacy and Safety of Roxadustat in Patients with Non-Dialysis-Dependent CKD, Anemia, and Heart Failure
Daniel W. Coyne,1 Steven Fishbane,2 Pablo E. Pergola,3 Lynda Szczez,4 Tyson T. Lee,4 Dustin J. Little,4 Kin-Hung P. Yu,4 Washington University School of Medicine in Saint Louis, Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2Northwell Health, Great Neck, NY; 3Renal Associates PA, San Antonio, TX; 4FibroGen Inc, San Francisco, CA; AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Patients with heart failure (HF) represent an important clinical subgroup of patients with CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, roxadustat-alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent (DD) CKD were assessed in the subgroup of patients with a history of NYHA Class III or IV HF at baseline. Endpoints were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy, time to first blood/RBC transfusion during the treatment period, and mean monthly IV iron use during weeks 28–52. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 25% (991/3980) of patients had HF (roxadustat=499; epoetin alfa=492). Baseline characteristics were generally similar. Mean (SD) Hb levels (g/dL) at baseline were 9.59 (1.30) in the roxadustat group and 9.65 (1.29) in the epoetin alfa group. Patients achieved significantly larger least-squares mean (LSM) [SEM] CFB in Hb levels (g/dL) with roxadustat vs. epoetin alfa (1.24 [0.04] vs. 0.94 [0.04]), corresponding to a LSM difference of 0.29 (95% CI: 0.18, 0.40) (p<0.0001). The hazard ratio for first blood/RBC transfusion during the treatment period in the roxadustat and epoetin alfa groups was 0.76 (95% CI: 0.54, 1.08), p=0.1274. Mean (SD) monthly IV iron (mg) use was lower in roxadustat- vs. epoetin alfa-treated patients: 55.8 (288.8) vs. 68.6 (142.7) (p<0.0001). TEAE rates were comparable between treatment groups and similar to those in the overall DD-CKD study population.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing Hb levels and reducing mean monthly IV iron use in DD-CKD patients with HF. The safety and tolerability profile was similar to the overall population and consistent with that observed in this patient subgroup.

Roxadustat Lowers Low-Density Lipoprotein Cholesterol in Patients with Anemia of CKD
Simon D. Rogier1, Mohamed A. El-Shalawy2, Carol A. Pollock2, Rosa H. Jimenez3, Robert Leon3, Maksym Pola3, Kin-Hung P. Yu4, Renal Research, Gosford, NSW, Australia; 2The University of Sydney, Sydney, NSW, Australia; 3FibroGen Inc, San Francisco, CA; 4AstraZeneca, Warsaw, Poland; 5University of Southern California Keck School of Medicine, Los Angeles, CA.

Background: Roxadustat is an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor with positive safety and efficacy results in phase 3 studies in patients with anemia in CKD. The HIF pathway affects cholesterol metabolism; at high altitude, total and low-density lipoprotein cholesterol (LDL-C) decrease in healthy individuals. Roxadustat reduced LDL-C in phase 2 studies. We evaluated the effect of roxadustat on LDL-C in patients with anemia in non-dialysis-dependent (NDD) and dialysis-dependent (DD) CKD.

Methods: Data were pooled from three pivotal phase 3 studies in patients with NDD-CKD and three pivotal phase 3 studies in patients with DD-CKD, including the incident dialysis (ID; on dialysis <4 mo at randomization) population. Mean changes from baseline (CFB) in LDL-C (regardless of statin use) averaged over weeks 12–28 were analyzed using a mixed model of repeated measures and reported least-squares mean (LSM) treatment differences.

Results: In patients with NDD-CKD, there was a 17.2% reduction in LDL-C averaged over Weeks 12–28 in the roxadustat group (n=1948) and a 14.2% increase in the placebo group (n=1430). The LSM treatment difference was statistically significant (p<0.0001). In the patients with DD-ID group, there was a 18.5% reduction in the roxadustat group (n=1650) and a 1.7% reduction in the epoetin alfa group (n=1741). The LSM treatment difference was statistically significant (p<0.0001). In patients with DD-DD-CKD, there was a 21.5% reduction in the roxadustat group (n=680) and a 4.6% reduction in the epoetin alfa group (n=691). The LSM treatment difference was statistically significant (p<0.0001).
Conclusions: Treatment with roxadustat vs. placebo or epoetin alfa lowered LDL-C in patients with NDD-CKD and DD-CKD, respectively.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis, which can affect blood pressure (BP). We assessed the effect of roxadustat on BP in dialysis-dependent (DD) and non–dialysis-dependent (NDD) patients with anemia of CKD.

Methods: Pooled data from three, phase 3, randomized, placebo-controlled trials in NDD patients (n=4270), and three pivotal phase 3 randomized, active-controlled trials in DD patients (n=3880), including incident-dialysis-dependent (ID-DD; on dialysis for ≤ 90 days) patients and NDD patients (data censored after dialysis initiation) were included. Mean change from baseline (CFB) in mean arterial pressure (MAP) averaged over Weeks 20–28 (NDD-NDD, SDD) and over weeks 10–12 (ID-DD); time to first exacerbation of hypertension (SBP ≥ 170 mmHg or DBP ≥ 110 mmHg and an increase from baseline ≥ 20 mmHg [SBP] or ≥ 15 mmHg [DBP]); and adjudicated hypertensive emergency were analyzed.

Results: In NDD-NDD, the least squares mean (LSM) difference between roxadustat and placebo in MAP (mmHg) was 0.67 (0.30) [95% CI: 0.09, 1.25]. Values for ID-DD and SDD patients were −0.35 (0.66) [95% CI: −1.65, 0.95] and −0.06 (0.42) [95% CI: −0.88, 0.76]. Hazard ratios (95% CI) for HTN exacerbation in NDD-NDD, ID-DD, and DD patients were 1.12 (0.95, 1.32), 1.02 (0.84, 1.25), and 1.06 (0.93, 1.21). Follow-up adjusted incidence rates [events/100 patient-exposure year] of adjudicated hypertensive emergency were significantly reduced among patients with eGFR≥60 compared to placebo (0.85 vs placebo, 95% CI 0.76–0.96; p<0.009) in peripheral arterial disease (PAD) patients following lower extremity revascularization (LER). This analysis examines the prespecified subgroup of VOYAGER PAD patients with CKD.

Conclusions: Pooled analyses of phase 3 data across a continuum of patients with CKD and anemia showed that roxadustat did not have any clinically meaningful effect on BP, HTN exacerbation, or hypertensive emergency vs. placebo in NDD-PAD and NDD-CKD patients and epoetin alfa in DD-CKD patients.

Rivaroxaban Reduces Major Cardiovascular and Limb Events in Patients with CKD and Peripheral Artery Disease with Recent Lower Extremity Revascularization: Insights from VOYAGER PAD

Judith Hsia,1,2 Mark R. Nehler,1,2 Sonia Anand,1 Manesh R. Patel,4 William R. Hiatt,3 Sebastian Debus,3 Connie Hess,3 Warren H. Capell,1 Elizabeth Diao,1 Scott D. Berkowitz,2 Eva Muelhholzer,1 Lloyd P. Haskell,1 Rupert M. Baurersachs,3 Marc P. Bonaca,1,2 CPC Clinical Research, Aurora, CO; 1University of Colorado Denver School of Medicine, Aurora, CO; 1McMaster University, Hamilton, ON, Canada; 2Duke University, Durham, NC; 1University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; 1Bayer Corp, Whippany, NJ; 1Janssen Global Services LLC, Raritan, NJ; 2Bayer AG, Leverkusen, Germany; 3Klinikum Darmstadt, Darmstadt, Germany; 4Universityklinikum Hamburg-Eppendorf Universitats Herzzentrum Hamburg GmbH, Hamburg, Germany.

Background: In the VOYAGER PAD trial, rivaroxaban reduced cardiovascular (CV) and limb ischemic events (HR 0.85 vs placebo, 95% CI 0.76–0.96; p<0.009) in peripheral arterial disease (PAD) patients following lower extremity revascularization (LER). This analysis examines the prespecified subgroup of VOYAGER PAD patients with CKD.

Methods: VOYAGER PAD (NCT02504216) randomized 6564 PAD patients following LER to rivaroxaban 2.5 mg twice daily or placebo on a background of aspirin 100 mg daily. The primary endpoint was a composite of acute limb ischemia, major amputation for vascular cause, myocardial infarction, ischemic stroke or CV death. Intention-to-treat analyses utilized Kaplan Meier estimates and Cox proportional-hazards models.

Results: Mean baseline eGFR was 57±23 mL/min/1.73m² with 79, 20, 1 and <1% of patients with CKD stage ≤ 2, 3, 4 and 5, respectively. During 28-month median follow-up, rates of major CV and limb events were higher among patients with more severe CKD (placebo group event rate: 7.4/100 patient-years for eGFR ≤ 60, 10.0 for eGFR 30–60 and 9.8 for eGFR 15–30). Rivaroxaban reduced primary endpoint events with no heterogeneity by eGFR above or below 60 (most CV death stage 3) (Figure). Acute limb ischemia and major amputation were significantly reduced among patients with eGFR≤60 (HR 0.77, 95% CI 0.63, 0.94) and ≤60 (HR 0.55, 95% CI 0.36–0.86). Major bleeding was infrequent with no heterogeneity by CKD category.

Conclusions: Rivaroxaban reduced CV and limb events in patients with CKD, PAD following LER, a particularly high-risk population.

No Adverse Effects of Veverimer on Volume Status or Blood Pressure in Patients with CKD and Metabolic Acidosis

Donald F. Wesson,1 Vandana S. Mathur,2 Navdeep Tantri,3 Yuri Stasiev,4 Dawn Parsons1, Elizabeth Li1, Gerrit Klarenbeek,5 David A. Bushinsky,1,2 Baylor Scott & White Health and Wellness Center, Dallas, TX; 3Mathur Consulting, Woodside, CA; 4University of Manitoba, Winnipeg, MB, Canada; 5Tricida, Inc., South San Francisco, CA; 2PharmaStat LLC, Fremont, CA; 3University of Rochester Medical Center, Rochester, NY.

Background: Current American Heart Association guidelines recommend sodium bicarbonate (NaHCO₃) for treatment of metabolic acidosis in dialysis patients. Veverimer would not increase BP, weight or induce volume overload. In Phase 3 randomized, blinded placebo-controlled trials in acidic patients (pts) with CKD (baseline mean eGFR 29 mL/min/1.73 m²), veverimer significantly increased serum bicarbonate (L/S mean ± 4.7 μEq/L at Week 52) with safety profile similar to placebo (Wesson et al. Lancet, 2019).

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.
Methods: We analyzed parameters related to volume status in these Phase 3 trials. In these studies, 97% and 31% of pts had HTN and CHF, respectively and 193 pts were treated with veverimer or placebo for up to 52 weeks. Treatment with veverimer (v placebo) had no effect on weight, BP, urine Na/creatinine ratio, volume-related adverse events, or increased use of diuretics or antihypertensives (Table). Conclusion: Veverimer, a novel non-absorbed HCl binder, effectively treats metabolic acidosis in CKD without adversely affecting BP or volume status.

Optimal Medical Therapy Attainment by Dialysis Status in the ISCHEMIA-CKD Trial

Roy O. Mathew,1 David J. Maron,2 Rebecca Anthopolos,3 Jerome L. Fleg,4 Sean O’Brien,5 Frank W. Rockhold,6 Carlo Brugioni,7 Marek Roik,2 Tomasz Mazurek,6 Marcin Demkow,2 Robert Malecki,8 Upendra Kaul,11 Marius Miglinas,9 Ron Wald,4 David M. Charytan,5 Mandeeep S. Sidhu,4 Judith Hochman,7 Sripal Bangalore,1 ISCHEMIA-CKD Research 1 Vilniaus Universiteto ligonines Santariskiu klinikos, Vilnius, Lithuania; 2Department of Internal Medicine, Infant Jesus Teaching Hospital, Medical University of Warsaw, Warsaw, Poland; 3National Institute of Cardiology - II Cardiology Clinic, Mazovian, Poland; 4St Michael’s Hospital, Toronto, ON, Canada; 5Albany Medical College, Albany, NY; 6National Heart Lung and Blood Institute, Bethesda, MD; 7New York University School of Medicine, New York, NY; 8Stanford University Department of Medicine, Stanford, CA; 9Duke Clinical Research Institute, Durham, NC; 10Warszawski Uniwersytet Medyczny, Warszawa, Poland; 11Batra Hospital and Medical Research Centre, New Delhi, India; 12Mediterranea Cardiocentro, Naples, Italy; 13William Jennings Bryan Dorn VA Medical Center Mental Health Department, Columbia, SC.

Background: The efficacy of an aggressive multiple risk factor intervention approach – optimal medical therapy (OMT) – to reduce major adverse cardiovascular events in patients with CKD has not been tested. Objective: to examine OMT goal attainment in patients with CKD on dialysis (CKD-D) and non-dialysis CKD (CKD-ND) in the ISCHEMIA-CKD trial.

Methods: OMT was recommended to all participants in ISCHEMIA-CKD. Longitudinal trajectories of individual OMT components (smoking cessation, systolic blood pressure (SBP) >140 mmHg, low density lipoprotein (LDL) cholesterol <70 mg/dl, high-intensity statin use, and aspirin use) were modeled over study follow-up. Covariate-adjusted percentage point difference in each OMT goal achieved at 24 months between CKD-D patients and CKD-ND patients at baseline. CKD-D were younger (61 v 67 yrs, p<0.001) and less often diabetic (53% v 62%, p=0.023) CKD-D patients were 7.9% (0.7%, 14.8%) more likely than CKD-ND to attain the SBP goal at 24 months (Figure). CKD-D patients were 22.7% (-33.3%, -11.4%) less likely to receive high-intensity statins. There was a steady and similar increase in proportional achievement of OMT during follow up.

Conclusions: OMT improved over time in advanced CKD-ND and CKD-D. CKD-D achieved the SBP goal more than CKD-ND, yet CKD-D were less likely to be treated with high-intensity statin. Future studies should explore systemic and patient-related barriers to attainment of OMT in this high-risk cohort.

PO2118

Cardiovascular Determinants of Physical Function in Patients with ESKD on Hemodialysis

Sherna F. Adewunla,1 Gaurav S. Gulsin,1 Roseanne Billany,2 Daniel S. March,3,7 Robin Young,1 Alysha Careless,1 Clare L. Tomlinson,1 Gerry P. Mccann,4,5 James Burton,1 Matthew Graham-Brown,1 University of Leicester and NIHR Leicester Cardiovascular Biomedical Research Centre, Leicester, United Kingdom; 2John Walls Renal Unit, University Hospitals Leicester NHS Trust, Leicester, United Kingdom; 3University of Glasgow Robertson Centre for Biostatistics, Glasgow, United Kingdom; 4NIHR Leicester Biomedical Research Centre, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.

Background: Patients with end-stage kidney disease (ESKD) are often sedentary and decreased functional capacity associates with mortality. The relationship between physical function and cardiovascular disease (CVD) has not been fully explored. Understanding the relationships between prognostically relevant measures of CVD and physical function and capacity may offer insight into whether exercise interventions could target specific elements of CVD.

Methods: 130 patients on haemodialysis underwent cardiovascular phenotyping with cardiac MRI (left ventricular (LV) structure and function, pulse wave velocity and native T1 mapping) and cardiac biomarker assessment. Participants completed the incremental shuttle walk test (ISWT) and sit-to-stand 60 (STS60) as field-tests of physical function and capacity. Separate linear regression analyses identified CV determinants of physical function measures. Multivariate models were adjusted for age, gender, BMI and diabetes.

Results: Mean age was 57±15 years, 73% were male and median dialysis vintage was 1.3 years (0.5, 3.4). In multivariate models, NT pro-BNP and global native T1 were independent determinants of ISWT and STS60 performance. LV ejection fraction was also an independent determinant of ISWT distance. However, age, gender and diabetes had the strongest relationship with physical function. Cardiovascular markers that were significant in multivariate models are shown in Table 1. Conclusion: Markers of CV health could be targeted in exercise interventions to improve outcomes in patients with ESKD. NT pro-BNP, global native T1 and LV ejection fraction were independent CV determinants of physical function. The influence of age and diabetes on performance had the strongest relationship. Improving strategies for prevention and management of diabetes may ameliorate deconditioning in these patients.

The Relationship of Cardiovascular Morbidity with Death and End-Stage Kidney Failure in Patients with Diabetes and CKD Receiving Specialist Renal Care

Ken-Soon Tan1,2 and Stephen P. McDonald.3,4 CKD.QLD The University of Queensland Faculty of Medicine, Herston, QLD, Australia; Griffth University School of Medicine, Gold Coast, QLD, Australia; Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; The University of Adelaide Adelaide Medical School, Adelaide, SA, Australia.

Background: Patients with diabetes (DM) and CKD have worse cardiovascular, renal and mortality outcomes than those with neither and either condition alone. However, relationships between these 3 outcomes remain unclear, especially in patients receiving specialist renal care. Aims: To examine the relationship of major adverse cardiovascular event (MACE), end stage kidney failure (ESKF) and death using competing risk analysis.

Methods: CKD.QLD is a large Australian registry of patients with CKD not on RRT receiving specialist renal care. Patients with DM enrolled between 1/1/2011 and 31/12/2016 inclusive were studied. Follow-up was censored by death, ESKF, MACE post enrolment, movement of patient interstate/overseas, loss to follow-up or censor date of 31/12/2017, whichever occurred first. Competing risk analysis was performed with MACE, ESKF and death in turn as the primary outcome whilst the other 2 were competing risks. Covariates examined were age, gender, ethnicity, incident status, access to services, biopsy, smoking, diabetes treatment, Hba1c, MACE prior to enrolment, eGFR, proteinuria, Hb, RAAS blocker and lipid lowering therapy.

Results: 2355 patients underwent 6615 patient-years follow-up (pyru), mean 2.8y. The first event was MACE in 571 patients (24.2%), ESKF in 299 patients (12.6%) and death in 268 patients (11.3%), giving respective event rates of 86, 45 and 41 per 1000 pyru. 1137 patients (48.3%) experienced no event. Table 1 summarises the results of the best fit multivariable model with each primary outcomes. p < 0.05 was deemed significant.

The first event was MACE in 571 patients (24.2%), ESKF in 299 patients (12.6%) and death in turn as the primary outcome whilst the other 2 were competing risks. Covariates examined were age, gender, ethnicity, incident status, access to services, biopsy, smoking, diabetes treatment, Hba1c, MACE prior to enrolment, eGFR, proteinuria, Hb, RAAS blocker and lipid lowering therapy.

Introduction: Laboratory data provide clues to the etiology of resistant hypertension. We present one such case where in a prescriptive diagnosis of Liddle’s syndrome was made, and appropriate therapy initiated. Yet the hypertension failed to be controlled despite multiple antihypertensive regimens.

Case Description: A 26-year-old African American male was evaluated 8 years ago for a history of resistant hypertension. He was compliant with five blood pressure medications yet his systolic blood pressures were greater than 180mmHg. He denied smoking or consuming licorice products. No family history of early deaths, hypertension, or strokes. He reported having early onset of puberty at around age 12, being taller than his peers and now being short as an adult. He was a thin individual with no abdominal striae. Investigations revealed hypokalemia with mild metabolic alkalosis along with low renin and aldosterone. His kidney ultrasound was normal as were his renal functions and free metanephrines. 24-hour urine cortisol was not elevated. A presumptive diagnosis of Liddle’s syndrome was made and amiloride was added to his anti-hypertensive regimen, with little effect on BP control. Over the subsequent years, he was admitted repeatedly for hypertension emergencies. This led to changes in his regimen along with a trial of Aldactone with no benefit. During one such episode, he complained of retrosternal pain. A CT was done to rule out a dissecting aneurysm, but it revealed a 5cm adrenal mass. Work up revealed high deoxycorticosterone, 11 deoxycortisol, dehydroepiandrosterone sulphate and testosterone which was suggestive of 11-hydroxylase deficiency causing congenital adrenal hyperplasia (CAH). He was started on dexamethasone 2 mg daily and his blood pressure control began showing improvement.

Discussion: CAH due to 11-hydroxylase deficiency is commonly seen in South Asians. It presents with features suggestive of mineralocorticoid excess. The differential diagnoses are Liddle’s syndrome, Crhousos syndrome, syndrome of apparent mineralocorticoid excess and Geller syndrome. This patient was wrongly diagnosed which led to repeated hospitalizations with inadequate therapy. Liddle’s syndrome responds well to amiloride without the need for additional medications. The fact that he was on multiple medications in addition to amiloride should be a clue to the misdiagnosis.

The Combined Prognostic Significance of Red Blood Cell Distribution Width and Vascular Calcification in Patients with ESKD

Du won Kim, Dongryul Kim, Yeonhee Lee, Seok Joon Shin, Hye Eun Yoon. Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea.

Background: Red blood cell distribution width (RDW) is a simple parameter that reflects the degree of red blood cell volume variability. Recent evidence has shown that increased RDW is associated with adverse clinical outcomes in end-stage kidney disease (ESKD) patients. Vascular calcification (VC) is another major independent risk factor for mortality among ESKD patients. This study investigated the combined prognostic effect of RDW and VC in ESKD patients starting dialysis.

Methods: We conducted a retrospective observational cohort study of 582 ESKD patients treated at a single center from January 2006 to July 2017. VC was assessed by the aortic calcification index (ACI) using abdominal computed tomography. Patients were divided into four groups based on the median ACI (17.12) and serum RDW value (14.3) as low ACI-low RDW, low ACI-high RDW, high ACI-low RDW, or high ACI-high RDW. The association between RDW and VC on the composite of cardiovascular events (CVEs) and death was investigated.

Results: During a median follow-up of 3.1 years (range, 1.5-5.5 years), 165 (28.3%) CVEs and 126 deaths (21.4%) occurred. The Cox regression analyses showed that the patients with low ACI-high RDW (adjusted hazard ratio, 1.934; 95% confidence interval, 1.185-3.157; P = 0.008) and high ACI-low RDW (adjusted hazard ratio, 1.921; 95% confidence interval, 1.171-3.152; P = 0.001) had a greater risk of the composite endpoint than patients with low ACI-low RDW. Patients with high ACI-high RDW had the greatest risk (adjusted hazard ratio, 2.367; 95% confidence interval, 1.465-3.824; P <0.001). The interaction between ACI and RDW on CVEs and mortality was statistically significant (p = 0.002).

Conclusions: In ESKD patients starting dialysis, the combined effect of VC and high RDW was associated with a higher risk of CVEs and death. Also, high serum RDW amplified the risk associated with VC.

A Case of Disappearing Hypertension: Difficulties of Managing Hypertension in a Breast Cancer Survivor

Xiao Ling, Shubba Ananthakrishnan. University of California Davis Department of Internal Medicine, Sacramento, CA.

Introduction: Treating hypertension in breast cancer survivors often hold unique difficulties. These patients may have undergone sentinel lymph node biopsy (SNB) or axillary lymph node dissection (ALND), and are often advised to avoid blood pressure medications in addition to amiloride should be a clue to the misdiagnosis.
using her lower extremities since her mastectomy. Blood pressure measured with her right upper extremity was 116/68.

**Discussion:** Often patient after mastectomy with SNB or ALND avoids taking blood pressure on affected limb regardless of lymphedema in order to prevent lymphedema. Despite this, the evidence for this is sparse with most recent studies reporting blood pressure measurement in ipsilateral affected arm as not being risk factor for lymphedema.

PO2124

**Effect of Dietary Salt Reduction on Blood Pressure in Kidney Transplant Patients: A Randomised Controlled Trial**

Louise E. Ross,1 Rebecca Suckling,1 Mark E. Dockrell,1 Thomas Bailey,2 Pauline A. Swift.1 Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; 2University of Warwick, Coventry, United Kingdom.

**Background:** Cardiovascular morbidity and mortality are increased in kidney transplant patients. High blood pressure (BP) contributes significantly to this risk and is associated with shortened allograft survival. Dietary salt reduction is widely recommended as a strategy to lower BP in the general population and in chronic kidney disease. Due to a lack of evidence there is currently no consensus on dietary salt restriction in kidney transplant patients.

**Methods:** Sixty stable kidney transplant patients, a 6-months post-transplantation, with BP ≥120/80 mmHg, and sodium intake ≥80 mmol/24hrs, were randomised in this parallel-designed study to receive either a regular-salt diet (target 150 mmol/24hr) or a low-salt diet (target 80 mmol/24hr) for 8-weeks. The primary outcome measure was systolic and diastolic BP. Secondary outcome measures included 24-hour ambulatory BP (ABP) and proteinuria. Dietary salt intake was assessed by 48-hour urinary sodium excretion.

**Results:** At baseline, patients (72% men) were 56±11 years with estimated glomerular filtration rate (eGFR) 53±18 mL/min/1.73m². Mean urinary sodium was 128±42 mmol/24hr, mean systolic BP was 132±12 mmHg, and mean diastolic BP was 77±10 mmHg. At the end of the intervention period sodium excretion was significantly lower in the low-salt group compared with the regular-salt group (96±37 vs. 132±51 mmol/24hr; adjusted mean difference, -36 [95% CI, -59 to -14] mmol/24hr; p=0.002). We found no difference in systolic BP (adjusted mean difference, -2 [95% CI, -12 to 9] mmHg; P=0.750), diastolic BP (adjusted mean difference, 0 [95% CI, -4 to 4] mmHg; P=0.887), 24-hour systolic ABP (adjusted mean difference, -3 [95% CI, -9 to 2] mmHg; P=0.213) or 24-hour diastolic ABP (adjusted mean difference, -2 [95% CI, -5 to 1] mmHg; P=0.267). There was no significant effect on proteinuria, eGFR, serum osmolality, uric acid, renin concentration, or aldosterone.

**Conclusions:** In this study baseline urinary sodium was lower than expected and baseline BP was well-controlled. Reducing dietary salt by 2g/day did not have a significant effect on office blood pressure readings.

PO2125

**Left Atrial Reservoir Strain Is an Independent Predictor of End-Stage Renal Impairment in Patients with CKD**

Gary Gan,1 Krishna K. Kadappu,2 Aditya Bhat,1 Fernando Fernandez,1 Kenneth H. Gu,1 Suzanne Eshoo,1 Brian J. Nankivell,1,3 Liza Thomas,1,2 Blacktown & Mount Druitt Hospital, Blacktown, NSW, Australia; 1University of New South Wales, Sydney, NSW, Australia; 2Campbelltown Hospital, Campbelltown, NSW, Australia; 3University of Sydney, Sydney, NSW, Australia; 4Westmead Hospital, Westmead, NSW, Australia; 5The University of Sydney, Sydney, NSW, Australia.

**Background:** Left atrial (LA) enlargement is common in patients with chronic kidney disease (CKD) and is a predictor of adverse cardiovascular events. Our study sought to evaluate the value of LA reservoir strain (LAS), a novel echocardiographic measure of LA function, as a prognostic marker of adverse renal outcomes.

**Methods:** Patients with stable Stage 3 and 4 CKD without prior cardiac history were prospectively recruited and underwent transthoracic and stress echocardiography. Patients with normal left ventricular (LV) function, without significant valvular disease and without ischaemia on stress testing were included and followed for up to 5 years for development of end stage renal disease (ESRD) and/or doubling of serum creatinine.

**Results:** 280 patients (65.8±12.2yrs, 63% male) were recruited and followed for a mean period of 3.9±2.7years. 56 patients developed the composite endpoint. On log rank tests, impaired LAs (Figure 1), older age, lower eGFR, anaemia, diabetes mellitus, greater urinary albumin/creatinine, greater number of antihypertensive agents, higher indexed LV mass and larger LA volumes were significant predictors of the composite outcome (p<0.01 for all). On Multi-variable Cox proportional hazards regression analysis, impaired LAs in addition to eGFR, number of antihypertensive agents and urinary albumin/creatinine (p<0.01 for all) were independent predictors of ESRD and/or doubling of serum creatinine. Impaired LAs was associated with a 2.5-fold higher risk of the composite outcome.

**Conclusions:** LAs is an independent predictor for development of ESRD and/or doubling of serum creatine and thus has the potential to be a ‘biomarker’ for identification of high-risk patients, enabling early initiation of therapy.

The Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction to Promote Atherogenesis by Regulating Heme Oxygenase 1 Expression

Hadevski Negoro,1,2 1Harvard Medical School, Boston, MA; 2The Graduate School of Project Design, Tokyo, Japan, Japan.

Background: The circadian clock is a molecular structure that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic prothrombogenic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. We also confirmed that HO-1 levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Weight Gain Is a Risk Factor for the Progression of Coronary Artery Calcification in CKD: From the KNOW-CKD Study

Ji Hye Kim, Young Youl Hyun. Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea.

Background: In chronic kidney disease (CKD), patients with high body mass index or weight gain have better survival. However, their cardiovascular risk is uncertain. The aim of this study was to investigate the relationship between weight changes and the progression of coronary artery calcification (CAC) in CKD.

Methods: This study analyzed 839 participants (Mean age 52.5±12.03, Males 41.12%) from the KNOW-CKD cohort. Changes in weight between baseline and 4 year follow-up period were categorized in tertiles: first tertile (T1) (-31.3kg to -1.1kg), second tertile (T2) (-1kg to 0.9kg) and third tertile (T3) (1kg to 30kg). The coronary artery calcium score (CACS) was assessed using cardiac computed tomography at baseline and 4 years after enrollment. The CAC progression was defined as increase of CACS after 4 years.

Results: The study participants’ baseline median CACS was 0.0 (median) [0 (25th quartile)- 34.5(75th quartile)] and 387 (46.13%) participants had baseline CACS above 0. After 4 years, numbers of patients in each tertile was 247 (29.4%) in T1, 258 (30.8%) in T2 and 334 (39.8%) in T3. Median difference in CACS between baseline and follow-up was 2 [0 -69.3] in T1, 0 [0-47.2] in T2 and 6.4 [0-64.7] in T3. (p=0.088) Multivariate analysis showed that preventing excessive weight gain might help prevent cardiovascular complications in CKD.

Conclusions: Third tertile group, which gained between 1 to 30kg after 4 years, was significantly and independently associated with CAC progression compared to weight stable second tertile group in Korean predialysis CKD patients. These results suggest that preventing excessive weight gain might help prevent cardiovascular complications in CKD.

Macrophase Neutrophil Gelatinase-Associated Lipocalin Has a Critical Role in Aldosterone-Induced Renal Fibrosis via the CCL5/IL4 Pathway

Benjamin Bonnard, Marie Gent, Jaime Ibarral, Amaya Fernandez-Celis, Natalia Lopez-Andres, Frederic Jaissie, INSERM U1138, PARIS, France; INSERM Clinical Investigation Centre 1433, Nancy, France; Universidad Publica de Navarra, Pamplona, Spain.

Background: Neutrophil Gelatinase-Associated Lipocalin (NGAL) (or lipocalin 2) is a matrix metalloproteinase inhibitor in the cardiovascular system. NGAL is also described as an acute renal lesion biomarker and NGAL serum concentration is associated with the severity of renal damages patients with a chronic kidney disease (CKD). Lipocalin2 (Lcn2) gene infection in a CKD mouse model protects from proteinuria and renal lesions. We hypothesized that NGAL produced from macrophages promotes expression of chemotacticant molecules involved in renal lesions induced by mineralocorticoid excess.

Methods: The role of Lcn2 was analyzed using full Lcn2 knock out mice (NGAL KO) challenged with uni-Nephrectomy, Aldosterone 200 mg/kg/day. Salt 1% (NAS model) during 6 weeks. Assessment of CCL5/IL4 in kidney fibrosis were studied using macrophage administration (50 mg/kg in chow diet) or by injections of anti-IL4 antibody (600 mg/kg week).

Results: NAS induced a significant increase in the expression (relative values, meansSEM, compared to 1 in the control samples, p<0.05) of extracellular matrix proteins such as collagen I (2.35±0.33), a-SMA (2.04±0.44) and fibronectin (3.38±0.42) in the kidney of WT mice associated with interstitial kidney fibrosis (6.49±0.70). This is fully prevented by Lcn2 deletion. Expression of macrophages markers F4/80, CD80, CD86 and CCL5  was increased (5.11±0.46, 4.84±0.19 and 5.22±0.45 respectively) in WT NAS mice and partly prevented in Lcn2 KO mice. Macrophages isolated from Lcn2 KO or WT mice were co-treated with aldosterone (10µM) and NaCl (40mM). In WT macrophages, expression of CCL5 (2.81±0.30) and the CCL5 chemokine (2.48±0.32) was increased. The increase of CCL5 was blunted in Lcn2 KO macrophages. Similarly to Lcn2 inactivation, CCL5 receptor blockade improved renal fibrosis and reduced high levels of Th2 CD4+ cell markers induced by NAS. Neutralization of IL4, a Th2 cytokine, in NAS mice injected with anti-IL4 antibody blunted kidney fibrosis and overexpression of profibrotic proteins such as collagen I, a-SMA and fibronectin.

Conclusions: NGAL produced by macrophages plays a critical role in renal interstitial fibrosis through the CCL5/IL4 pathway in mice exposed to mineralocorticoid excess.

PO2130
Water Intake and Blood Pressure in Children: Results from the SPA Project

Gianluigi Ardissino, Michela Perrone, Silvia A. Ghiglia, Patrizia Salicci, Francesca Tel, Valentina Capone, Maria Cristina Mancuso, Sandra Piantanida, Silvia Di michele. SPA Project 'Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; 'Pediatric Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; 'Pediatric Department, Vittore Buzzi Children's Hospital, University of Milano, Milano, Italy; 'Polo Materno Infantile - Ospedale F. del Ponte, Varese, Italy; 'UOC Pediatría Ospedale di Pescara, Pescara, Italy.

Background: Sodium (Na) intake is involved in the development of hypertension (HTP); to reduce Na is important in the treatment of HTP, but the increase in renal Na excretion might also be a potential preventive and/or therapeutic opportunity. The SPA Project studied blood pressure (BP) in relation to water (H2O) and Na intake with the working hypothesis that increased water intake can improve renal Na handling.

Methods: 339 healthy, non-overweight children (166 girls, 5 years old (IQR: 3.5-6.2) were characterized for: BP (using standardized multiple office BP measurement), Na and water intake (by means of urinary Na and creatinine from 4 samples taken in 4 different days). After categorizing subjects as low/high Na and low/high water intake (based on median value), BP was compared.

Results: Among children with higher Na intake, those introducing more water, showed a significantly (p<0.001) lower BP (both systolic and diastolic) compared to those who drink less (figure). This difference was not observed among children with lower Na intake.

Conclusions: Our findings support the hypothesis that an increased water intake, reduces BP, perhaps by increasing renal excretion. We speculate that this simple, highly acceptable, inexpensive and harmless measure might play a role in preventing and minimizing the epidemics of HPT and related morbidities.

PO2131
Altered Tryptophan Catabolism via the Kynurenine Pathway Associates with CKD-Accelerated Atherosclerosis

Vetalk K. Cheefoor, Nancy F. Roese, Lixia Zeng, Jaeman Byun, Anna V. Mathew. University of Michigan Medical School, Ann Arbor, MI.

Background: Non-traditional risk factors like inflammation and oxidative stress play an essential role in the increased cardiovascular disease risk prevalent in chronic kidney disease (CKD). Tryptophan catabolism by the kynurenine pathway (KP) is linked to atherosclerosis and renal function in both clinical studies and experimental models. However, the role of KP in the pathogenesis of CKD accelerated atherosclerosis is unknown.

Methods: 9-week old 5/6 nephrectomized (CKD) and sham-operated (CON) LDLr−/− mice were placed on a high-fat/high-cholesterol diet (HFD) for 16 weeks. KP metabolites were measured using targeted mass spectrometry in the plasma, urine and tissues. Expression and activity of Indolamine 2,3 dioxygenase (IDO1) - first step of the KP were quantified by immunoblotting, immunohistochemistry, and kynurenine to tryptophan ratio (KTR) in aortic tissue in both groups.

Results: CKD mice demonstrate increased KP metabolites compared to sham-operated mice (CON) both at baseline and after exposure to HFD for 16 weeks. Exposure to HFD for 16 weeks increases most KP metabolites in both CON and CKD mice, except for levels of tryptophan and 3-hydroxy antranilic acid that decrease with HFD exposure. 3-hydroxy kynurenine and kynurenine acid increase with HFD exposure in CKD mice, whereas these levels tended to decrease in controls. Hepatic tissue in the CKD mice fed HFD reveals no changes in KP metabolites except increased quinolinic acid, whereas the splenic tissue and renal tissue reveals low tryptophan levels and higher KTR, kynurenine acid, and antranilic acid. These changes in the HFD fed CKD mice are likely due to a combination of increased synthesis in specific tissues and reduced clearance. IDO expression and activity were also increased in atherosclerotic lesions of CKD mice on HFD for 16 weeks compared to control mice with intact renal function.

Conclusions: In summary, KP metabolites are altered both in the circulation, tissues, and arterial wall of the CKD atherosclerosis model implicating KP in the pathogenesis of atherosclerosis in CKD.

Male Sex Hormones Drive an Increase in Renal Necrosis in Spontaneously Hypertensive Rats (SHR)

Mahmoud Abdelbarry, Ellen E. Gillis, Michael W. Brands, Jennifer C. Sullivan. Augusta University Medical Center, Augusta, GA.

Background: We recently published that maturation in male SHR increases necrosis which contributes to the development of hypertension. Maturation in male SHR is associated with both increases in sex hormones and blood pressure (BP). Testosterone has been shown to induce renal tubular cell necrosis in vitro. This study tested the hypothesis that male sex hormones drive maturation-induced increases in renal necrosis in male SHR.

Methods: At 4 wks of age, male SHR were randomly assigned to one of three groups: sham, gonadectomy (ORX), or treatment with the BP lowering drugs hydrochlorothiazide (HCTZ; 55mg/kg/day) and reserpine (Res; 4.5 mg/kg/day) in drinking water to prevent age-related increases in BP (n=6). At 8 wks of age, telemeters were implanted in a subset of rats (n=3-4/group). Rats were allowed 1 wk of recovery, then BP was continuously recorded. All rats were euthanized at 13 wks of age. Renal necrosis was quantified using FACs analysis of 7AAD+ cells. Data are expressed as mean ± standard error. Kidneys were isolated from additional untreated 5 and 15 wk old male SHR (pre- and post-maturation) and processed for Western blot analysis of key proteins mediating necrosis, receptor-interacting protein kinase 3 (RIP-3) and high mobility group box 1 (HMGB-1).

Results: H2O was significantly lower in ORX and HCTZ/Res-treated SHR compared to sham (mean arterial BP (mmHg): Sham = 139±2, HCTZ/Res = 117±3; ORX = 126±2; p<0.002). As expected, renal necrosis was greatest in sham control (renal necrosis

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
expressed as % total gated kidney cells: Sham = 46±3.0%. ORX significantly decreased renal CD81 and increased NCC in Hypertensive nephropathy compared to normal nephroi, with no evident altered vs. sham despite having the lowest BP (ORX = 4.4±0.9; HCTZ/Res = 3.5±0.3; p<0.003). To begin to gain insight into the mechanisms mediates maturation-induced increases in nephrosis, RIP3 and HMGB1 protein expression were measured in 5 and 15 wk old normal blood pressure, decreased kidney function, as well as decreased KLF2 expression of glomerular endothelial cells was similar compared to control. 5/6 nephrectomy in rats resulted in increased blood pressure, decreased kidney function, as well as decreased KLF2 expression of glomerular endothelial cells.

**Conclusions:** We established that renal afferent pathways combine very likely "classical" neural signal transduction to the central nervous system and a substance P (SP) dependent mechanism to control sympathetic activity. SP content ofafferent sensory neurons is known to mediate neurogenic inflammation upon release. We tested the hypothesis that alterations in SP dependent mechanisms of renal innervation contribute to experimental nephropathy.

**Methods:** Nephritis was induced by OX-7 antibodies in rats, six days later instrumented for recording of blood pressure (BP), heart rate (HR), drug administration; intrarenal administration (IRA) of the TRPV1 agonist capsaicin to stimulate afferent renal nerve pathways containing SP and implantation of electrodes for renal sympathetic nerve activity (RSNA). The presence of the SP receptor NK-1 on renal immune cells was assessed by FACS.

**Results:** IRA: capsaicin decreased RSNA from 62.4±5.1 mV*sec to 21.6±1.5 mV*sec (p<0.003) in controls, a response impaired in nephritis. Suppressed RSNA in nephritic rats and enhanced SP was revealed transiently after systemic administration of a neurokinin 1 (NK1-R) blocker. NK-1 receptors occurred mainly on CD11+ dendritic cells (DCs). An enhanced frequency of CD11c+CD11c+ cell, NK-1 receptor+ macrophages and DCs were assessed in nephritis. Administration of the NK-1 antagonist aprepitant during nephritis reduced CD11c+CD11c+ cell, macrophage infiltration, renal expression of chemokines and markers of sclerosis.

**Conclusions:** Hence, SP promoted renal inflammation by weakening sympatheticnhibitory mechanisms while at the same time substance SP released intrarenally from afferent nerve fibers aggravated immunological processes i.e. by the recruitment of DCs.

**Funding:** Government Support - Non-U.S.

**Renoprotective Effect of KLF2 on Glomerular Endothelial Dysfunction in Hypertensive Nephropathy**

Eunjin Baek,1 Mi-yeon Yu,1 Ji Eun Kim,1 Kyung Doy Yoo,3 Jong moo Joong,2 Park,1 Dong Jun Park,1 Yon Su Kim,2 Seung Hee Yang1 Gyeyongsang National University Changwon Hospital, Changwon, Gyeyongsanga-do, Republic of Korea; Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; Kore University Guro Hospital, Seoul, Republic of Korea; Ulsan University Hospital, Ulsan, Republic of Korea; Seoul National University College of Medicine, Seoul, Republic of Korea; Hanyang University Guri Hospital, Guri, Republic of Korea.

**Background:** KLF2 plays a role in maintaining normal vascular integrity by proinflammatory, anti-thrombotic, anti-angiogenic effects in endothelial cells. Endothelial dysfunction is associated with hypertension, and is a predictor of atherosclerosis development and cardiovascular death. Also, it is commonly observed in chronic kidney disease (CKD). The association between glomerular endothelial cell damage in diabetic nephropathy of KLF2 has been studied, but not in hypertensive nephropathy. Here, we present a role of KLF2 in hypertensive nephropathy.

**Methods:** Human primary glomerular endothelial cells were harvested and cultured under various duration, pressure condition by a rotational force device for mimic hypertensive nephropathy. We established the appropriate culture environment by confirming the pressure and survival rate applied to endothelial cells according to rotational force and observing adhesion of cells and cell death. We established the appropriate culture environment by confirming the pressure and survival rate applied to endothelial cells according to rotational force and observing adhesion of cells and cell death.

**Results:** The survival rate of human primary glomerular endothelial cells was maintained at a pressure of up to 4mHg and decreased from above. After the application of 4mHg pressure for 48hr in human primary glomerular endothelial cells, expression of KLF2 mRNA was decreased, while eSMA mRNA was increased and KLF4 mRNA was similar compared to control. 5/6 nephrectomy in rats resulted in increased blood pressure, decreased kidney function, as well as decreased KLF2 expression of glomerular endothelial cells.

**Conclusions:** Hence, SP promoted renal inflammation by weakening sympatheticnhibitory mechanisms while at the same time substance SP released intrarenally from afferent nerve fibers aggravated immunological processes i.e. by the recruitment of DCs.

**Funding:** Government Support - Non-U.S.
Substance P: Differential Influences on Action Potential Production in Afferent Neurons of the Kidney? Kristina Rodionova,1 Tilmann Ditting,1,2 Christian Ott,2,3 Roland E. Schmieder,4 Mario Schiffer,2 Kerstin U. Amann,1 Roland Veelken,1,2,3 Friedländer-Alexander- Universität Erlangen-Nürnberg, Erlangen, Germany; 2Paracelsus Medizinische Privatuniversität, Nürnberg, Germany.

Background: Afferent nerve fibers of the kidney play a role in controlling sympathetic activity in hypertension and cardiovascular diseases. Proinflammatory substances influence the action potential production of these neurons. Therefore, we tested the hypothesis that proinflammatory substance P(SP) released from afferent nerves inhibits the action potential production in neurons with renal afferents.

Methods: Cultured dorsal root ganglion neurons (DRG Th11-L2) of rats with renal afferents were investigated in current clamp mode to assess action potential generation during both current injections and TRPV1 stimulation with proteins (pH 6) with and without exposure to SP (0.5 μm) or CGRP (0.5 μm). Neuronal classification as tonic (high AP generation under stimulation) and phasic (AP ≤ 5 upon stimulation). Additional experiments were performed in voltage clamp mode to fully assess electrophysiological properties of the neurons.

Results: Renal neurons were stimulated with current injection (14.4±1.5 APs/600ms, mean±SE) and protons (9.6±1.9 APs/60 of stimulation with pH6). The co-injection of renal NKA and SP decreased the number of action potentials in tonic neurons (15.2±2.1 APs/600ms vs. 10.1±1.6 APs/600ms, p≤0.05, mean±SE), however superfusion of renal neurons with both protons (pH 6) and SP increased (9.6±1.9 APs/60 vs. 16.9±2.3 APs/60, p≤0.05, mean±SE). Addition of SP did not affect phasic neurons. Co-stimulation with CGRPP was without significant effect under any circumstances.

Conclusions: Neuronal SP influences action potential production in renal neurons in a very complex way: Both inhibition and specific increases in action potential via a TRPV1-dependent mechanism in acid-sensitive renal afferents could be demonstrated. Afferent nerve fibers are like respond very specific in different conditions while influencing sympathic nerve activity and putatively renal physiology or pathology (proinflammatory actions of SP).

The Intrarenal RAS Upregulates SGLT2 Expression and SGLT2 Inhibitors Attenuate Angiotensin II Induced Hypertensive Kidney Injury in Mice

Kana N. Miyata,1 Chao-Sheng Lo,1 Shuiling Zhao,1 Junzheng Peng,1 Matthias Kretzler,2 Janos G. Filep,1 Julie R. Ingelfinger,1 Shao-Ling Zhang,1 John S. Chan.1 1Centre Hospitalier de l’Universite de Montreal Centre de Recherche, Montreal, QC, Canada; 2University of Michigan, Ann Arbor, MI; 3Hospital Massonneuve-Rosemont, Montreal, QC, Canada; 4Massachusetts General Hospital, Boston, MA.

Background: Clinical trials have shown that SGLT2 inhibitors (SGLT2i) improve both cardiac and renal outcome in several diseases. However, the mechanisms underlying regulation of SGLT2 gene expression remain unclear. Here, we studied whether the intrarenal-angiotensin-system (RAS) modulates SGLT2 expression and SGLT2i efficacy.

Methods: We analyzed the association between RAS-related genes and SGLT2 gene expression in the tubulointerstitial compartment of the kidneys of adult non-diabetic patients in the Nephrotic Syndrome Study Network (NEPTUNE). We compared SGLT2 expression in transgenic mice overexpressing angiotensinogen (Agt) in their renal proximal tubular cells (RPTCs/Agt-Tg) vs RAS blockers, and wild-type (WT) mice. We administered angiotensin II (AgtII, 1000 ng/kg/min subcutaneously) in WT mice a canagliflozin (Can), 15mg/kg/day in drinking water for 4 weeks.

Results: In human kidney samples (N=183 patients), SGLT2 mRNA was significantly correlated with Agt (r=0.55, p<0.001), Renin (r=0.46, p<0.001), ACE (r=0.47, p<0.001), and ATIR (r=-0.28, p<0.001), but not with AT2R. SGLT2-immunopositive staining was higher in RPTCs of Agt-Tg mice than in WT mice and this was attenuated by losartan treatment. Ang II infusion in WT mice significantly increased blood pressure, which was not reversed by Cana co-treatment. Ang II caused glomerulosclerosis, tubulointerstitial fibrosis, and albuminuria, which were all attenuated by Cana. Fractional glucose excretion was significantly higher in Ang II+ Canal than WT+Cana. In vitro, Ang II dose-dependently stimulated SGLT2 mRNA in HK2 cells, and these were inhibited by losartan.

Conclusions: Our data demonstrate that the intrarenal RAS upregulates SGLT2 expression and show that SGLT2i ameliorate AngII-induced kidney injury independent of blood pressure.

Loss of Soluble (Pro)renin Receptor Attenuates DOCA-Salt Hypertension

Nirupama Ramkumar, Deborah Stuart, Caitlin S. Peterson, William Wheatley, Donald E. Kohan. University of Utah Health, Salt Lake City, UT.

Background: Cleavage of the extra-cellular domain of the (pro)renin receptor (PRR) yields a soluble fragment (sPRR), which may be involved in mediating hypertension. We recently developed a mouse model with mutation in the cleavage site of the PRR using CRISPR/Cas9 such that sPRR is not generated and showed that absence of sPRR attenuated angiotensin-II induced hypertension and kidney damage. In this study, we examined if sPRR alters blood pressure (BP) in angiotensin-II independent hypertension induced by deoxycorticosterone acetate (DOCA)-salt treatment.

Methods: Mutant sPRR mice and littermate controls were treated with DOCA (50 mg/kg) and high Na+ diet for 3 weeks. BP was monitored by radio-telemetry and metabolic balance studies performed on Day 17-18 of DOCA-salt treatment. Only male mice were studied as the PRR gene is on the X-chromosome.

Results: Compared to control male sPRR mice, final body weight and blood pressure was lower in mutant sPRR mice (final body weight 24.9 ± 2.5 vs control 28.0 ± 2.5 g; systolic BP 110 ± 5 vs control 121 ± 6 mm Hg). Percentage decrease in body weight was similar between sPRR and control mice (4.1 ± 0.8% vs control 3.1 ± 1.6%). In the renal cortex, sPRR mice had lower BUN, creatinine, and albuminuria compared to controls (Table 1). Mutant sPRR mice had lower fractional glucose excretion than controls (0.6 ± 0.1% vs control 1.2 ± 0.2%). No differences in renal histology were noted between control and mutant sPRR mice.

Conclusions: Loss of sPRR attenuates DOCA-salt mediated hypertension. The mechanisms by which sPRR might regulate BP and water/Na+ homeostasis in DOCA-salt hypertension are currently being investigated.

**Effect of Dietary Magnesium Supplementation on Tubulointerstitial Damages in Angiotensin II-Induced Hypertensive Rats**

Koari Takayanagi,1,2 Taikazu Shimizu,1 Tatagusaki Iwashita,2 Hiroaki Hará,2 Akira Kurosawa,2 Masaaki Terao,2 Hajime Hasegawa.1 Ishikawa Kinikai Kawagoe Ekimae Clinic, Kawagoe, Japan; 2Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University; Kawagoe, Japan.

**Background:** Recently, it has been epidemiologically suggested that Mg deficiency promotes progressive renal damage, and conversely, it has been reported that Mg load to Cyclopodrine A-induced renal damage models attenuates renal impairment. This study aimed to investigate the ameliorating effect of high Mg diet on the renal impairment by use of hypertensive nephrosclerosis model.

**Methods:** Eight-week-old SD rats were subjected to continuous infusion of Ang II by subcutaneously placed osmotic minipumps for 2 weeks (435 ng/kg/min) and then housed for 6 weeks. The food for animals was normal Mg diet (NMD): 4% NaCl+0.05% Mg or high Mg diet (HMD): 4% NaCl+0.5% Mg. PicroSirius Red staining was used to assess fibrosis, and immunostaining of Claudin-16, which is known to be down-regulated in the renal interstitial damage, was also performed.

**Results:** No significant difference in mean blood pressure was seen between two groups (NMD: 97.8±6.7 mmHg vs HMD: 94.2±9.0 mmHg, n=4), and serum Mg was elevated in HMD group (NMD: 1.6±0.19 mg/dL vs HMD: 2.4±0.09 mg/dL, n=4). Analysis of PicroSirius Red staining positive area by semi-quantification showed that positive area in outer medullary region was significantly reduced in HMD group (NMD: 1.6±0.10±1.5% vs HMD: 1.1±0.10%, n=4). Positive area of claudin-16 immunostaining in HMD was greater than NMD (NMD: 1.5±0.13% vs HMD: 1.7±0.01%, 15%, n=4).

**Conclusions:** Hypertensive nephrosclerosis is one of the major causes of end-stage renal failure, and its suppression is important. It was confirmed that the outermedullary fibrosis was inhibited by high Mg diet, while there was no change in the blood pressure, indicating that anti-fibrotic effect of high Mg diet seemed to be an independent mechanism from the blood pressure. We report the fact that claudin-16 expression is reduced and Mg excretion is increased in the interstitial fibrosis model (Shimizu, Magnesium Res 2018). These results suggest that high Mg diet has an inhibitory effect on fibrogenesis through suppressing the increased Mg-excretion.

**Pharmacological Sympathetic Denervation of the Kidney with Angiotensin II Receptor Blockade?**

Kristina Domondon,1,2 Dominique Ditting,1 Karl F. Hilgiers,1 Christian Ott,1 Roland E. Schneiders,1 Mario Schiffer,1 Kerstin U. Amann,1 Roland Veelken.1,2 Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; 2Paracelsus Medizinische Privatuniversität, Nuremberg, Germany.

**Background:** A putative interaction between angiotensin II (Ang II) and the renal sympathetic nervous system has been described. We tested the hypothesis that the angiotensin II receptor inhibitor candesartan mimicks a functional renal sympathetic denervation.

**Methods:** Measurement of arterial blood pressure (MAP), heart rate (HR), renal sympathetic nerve activity (RSNA), glomerular filtration (GFR), renal plasma flow (RPF), urine volume and urinary sodium. To assess neural control of volume homeostasis, 21 days after the induction of congestive heart failure (CHF) via myocardial infarction rats underwent volume expansion (0.9% NaCl, 10% body weight) to decrease RSNA. CHF rat and controls with or without renal denervation (DNX) or pretreated with the angiotensin II type 1 receptor antagonist candesartan (0.5 ug iv) were studied.

**Results:** CHF rats excreted only 68±5% of the volume load in 90 min. CHF rats pretreated with candesartan or after DNX excreted from 92% to 103% like controls. Decrease of RSNA induced by volume expansion were impaired in CHF rats but unaffected by candesartan point to an intrarenal drug effect. GFR and RPF were not significantly different in controls or CHF rendering more hemodynamic effects on sodium and water excretion unlikely. 0.5 mg candesartan did not inhibit the pressor response to i.v. Ang II as compared to higher blood pressure lowering doses.

**Conclusions:** The prominent function of increased RSNA – retaining salt and water - could no longer be observed after renal ANG II receptor blockade in CHF rats mimicking renal nerve ablation. Since inhibitors of the renin-angiotensin system are nowadays standard treatment of patients with CHF and hypertension, the role of efficient sympathetic denervation in these patients needs further meticulous scrutiny.

**Extracellular Volume, Peripheral Resistance, and Cardiac Index May Be Altered in Early CKD**

E. Parker Gregg,1,2 Peter N. Van Buren,1,2 Subhash Banerjee,1,2 Susan Hedaya.1,2

1University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2VA North Texas Health Care System, Dallas, TX.

**Background:** It is unknown if extracellular volume (ECV), cardiac index (CI), and peripheral resistance are altered in early stages of chronic kidney disease (CKD) before significant decline in glomerular filtration rate (GFR) or if these can be identified by routine laboratory measures.

**Methods:** A total of 21 participants, including 13 with CKD stages 1-3 and 8 non-CKD controls, were prospectively recruited from outpatient clinics. CKD stage 3 was defined as an estimated GFR (eGFR) of 30-59 ml/min/1.73 m² and stage 1-2 as an albuminuria-to-creatinine ratio >30 mg/g and eGFR ≥60. ECV was measured using bioimpedance spectroscopy and normalized to total body weight. CI and total peripheral resistance index (TPRI) were measured using non-invasive cardiac output monitoring. Measurements were compared using Fisher exact tests, Student’s t tests, and Pearson correlations.

**Results:** Participants with CKD had a mean (SD) age of 65.4 (12.9) years vs 59.5 (13.5) years for controls, P=0.36. Mean eGFR in the CKD group was 47.0 (17.9) mL/min/1.73 m². In the CKD group there were 8 (61.5%) with diabetes, vs 3 (7.7%) controls, P=0.39. Mean systolic blood pressure was 159.2 (22.3) in the CKD group vs 143.1 (26.2) in the control group, P=0.17. Edema was present in 9 (69.2%) of the CKD group vs. 2 (25.0%) controls, P=0.08. Mean (SD) ECV/weight was marginally higher in the CKD group vs controls (74.2±7.6 mmHg vs HMD: 94.2±7.6 mmHg, P=0.06). The CKD group had higher b-type natriuretic peptide (BNP), 182.8 (236.0) vs 33.5 (35.4) pg/mL, P=0.04, lower CI, 2.4 (0.4) vs 3.0 (0.5), P=0.04, and higher TPRI, 3800.4 (645.7) vs 2980.8 (265.3) dyn.s.cm⁻⁵, P=0.001. Log-transformed BNP correlated with CI, r=-0.77, P=0.002, and TPRI, r=-0.50, P=0.04 (Table). ECV/weight did not correlate strongly with CI, r=0.27, P=0.29, and TPRI, r=0.25, P=0.42.

**Conclusions:** In this hypothesis-generating study, patients with CKD had higher TPRI and lower CI than non-CKD controls. CI and TPRI correlated with BNP but not systolic blood pressure. BNP, an easily measured and universally available test, may be used as a correlate for CI and TPRI in patients with early stage CKD. These findings need to be confirmed in larger cohorts.

Inhibition of Mineralocorticoid Receptor Ameliorates Salt-Sensitive Hypertension After Ischemic-Reperfusion Injury in Rats

Takumi Kamisato,1 Shigehiro Doi,1 Ayumu Nakashima,1 Takao Masaki.1
1Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; 2Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.

Background: The transition from acute kidney injury (AKI) to chronic kidney disease (CKD) is a major pathway for progression to end-stage kidney disease. Although AKI is reported to be associated with the clinical progression of chronic kidney disease, the mechanism by which AKI induces hypertension remains elusive. Previous studies have demonstrated that salt-sensitive hypertension occurs in rats after ischemic reperfusion injury. We used an acute model of AKI, and then nephrons play an important role in the development of salt-sensitive hypertension. Herein, we investigated the role of the mineralocorticoid receptor (MR) in the progression of IRI-induced salt-sensitive hypertension in rats.

Methods: Seven days after right nephrectomy, IRI was induced by clamping of the left kidney for 45 min in 6-week-old male Sprague-Dawley rats. Rats were sacrificed at 7 days after IRI, and expression of MR examined. IRI rats were also given drinking water with 1% sodium chloride (IRI/NaCl), or were implanted with an osmotic mini-pump to infuse aldosterone (IRI/Aldo). Exsudates (3 mg/kg/day; a non-steroidal MR antagonist [MRA]), or vehicle were administrated in IRI/NaCl and IRI/Aldo rats for 6 weeks. Blood pressure and urinary protein level were measured weekly during the study period. Protein expression in renal tissues was examined by immunoblotting and immunohistochemistry.

Results: MR expression was increased at 7 days after IRI. Further, blood pressure and urinary protein excretion increased in IRI/NaCl and IRI/Aldo rats over the 6-week observation period, whereas these effects were negated by MRA administration. Similarly, MRA ameliorated the expression of the β-epithelial sodium channel (ENaC), γ-ENaC, and fibrotic markers, but not α-ENaC or NaCl cotransporter channel in both IRI/NaCl and IRI/Aldo rats.

Conclusions: Upregulation of MR, β-ENaC, and γ-ENaC may play a pivotal role in the development of salt-sensitive hypertension in rats after IRI.

Funding: Government Support - Non-U.S.
OR=1.20, 95% CI=0.99-1.45; p=0.07). Similarly, although patients with CKD had a lower prevalence of small vessel disease (8.8 vs 13.6%; p=0.01), undetermined (26.1 vs 39.4%; p=0.001), and other aetiology (1.0 vs 3.6%; p=0.001) subtypes, these associations were also lost after adjustment (Adjusted OR=0.81, 0.67-0.97; p=0.03).

Conclusions: There were no independent positive associations between CKD and specific TOAST subtypes which suggests that renal-specific risk factors are unlikely to play an important role in the aetiology of particular subtypes. Future studies of stroke and CKD should report subtype-specific analyses to gain further insights into potential mechanisms.
as well as circulating plasma ACE2 activity. Its efficacy was documented by reduced BP and ACR in Ren TgMK, a hypertensive model due to RAS activation. Thus, this novel ACE2 variant with extended half-life offers potential for treatment of kidney disease and hypertension.

### PO2158

**Title:** Fibroblast Growth Factor 23 Induces Ventricular Arrhythmias and Prolongs QTc Interval in Mice In Vivo Mediated Through FGF Receptor 4

**Authors:** Julian Vallejo, Derek Wang, Jonah M. Graves, Christian Faul, Michael J. Wacker.

**Institution:** Department of Biomedical Sciences, School of Medicine, University of Missouri-Kansas City, Kansas City, MO; Division of Nephrology, Department of Medicine, The University of Alabama at Birmingham, Birmingham, AL.

**Background:** Sudden cardiac death and arrhythmias are leading causes of mortality in those with compromised renal function, such as in chronic kidney disease (CKD). Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone released by osteocytes, which becomes markedly elevated in CKD. Previously, we found that FGF23 increases intracellular Ca²⁺ in cardiomyocytes and alters contractility in mouse ventricles ex vivo via stimulation of FGF receptor 4 (FGFR4). Since FGF23 could disrupt Ca²⁺ homeostasis, we hypothesized that FGF23 at pathological levels would alter depolarization/repolarization of the heart and induce arrhythmias in vivo via a mechanism involving FGFR4.

**Methods:** To assess our hypothesis, CD-1 male mice (3 months old) were anesthetized and electrocardiogram (ECG) needle electrodes were inserted into the limbs. The jugular vein was cannulated for infusion of vehicle or FGF23 (9ng/ml total blood volume) with and without pretreatment with an FGFR4-specific blocking antibody (anti-FGFR4; U3 Pharma). Lead II ECG and arrhythmias were monitored at baseline and then for 30 minutes post injection.

**Results:** FGF23 induced premature ventricular contractions (PVCs) in 5 out of 11 mice (P=0.038 vs vehicle) with an average maximal rate of PVCs in these mice of 10.2 ± 5.2 PVC/minute (P=0.01 vs vehicle). Vehicle (n=9) and FGF23 anti-FGFR4 treated (n=8) mice did not exhibit PVCs. Treatment with Isoproterenol (0.1mg/kg) after FGF23 further augmented arrhythmias to a maximal rate of 28.0 ± 21.1 PVC/minute (P<0.05 vs vehicle) and 2 out of 8 mice displayed ventricular tachycardia. Upon examination of ECG intervals, FGF23 prolonged QTc within 30 minutes (P<0.05, n=8) compared to vehicle treatment (n=9), whereas no effect was found for PR interval or QRS duration. FGFR4 blockade abrogated the QTc prolonging effects of FGF23 (n=8).

**Conclusions:** We conclude that FGF23/FGFR4 signaling in the heart may contribute to ventricular arrhythmogenesis and repolarization disturbances commonly observed in patients with CKD and may be an important therapeutic target to reduce cardiac mortality in CKD.

### PO2159

**Title:** Use of Immune Checkpoint Inhibitors in ESKD

**Authors:** Rirmi Wanchoe, Jia Hwei Ng, Jamie S. Hirsch, Rushang Parikh, Yurin Khanin, Kenzar D. Jhaeveri. Northwell Health, Great Neck, NY.

**Background:** Use of immune checkpoint inhibitors (ICI) in ESKD patients is limited. We describe our single-center experience of ICI use in ESKD patients and summarize the current literature.

**Methods:** Using an analytics database, we identified all patients with a minimum of one IESKD diagnosis code who received ICI therapy at our health system. Charts were reviewed manually to confirm that patients were on HD or PD during the ICI therapy. Clinical details such as demographics, comorbidities, cancer type, immune-related adverse events (irAEs), cancer disease status, and patient survival were reviewed. Further literature search was performed for all published cases of ICI use in ESKD patients and was summarized as part of the methods.

**Results:** In total, 8 patients with ESKD were initiated on ICI. A variety of malignancies were identified. Four patients received pembrolizumab, two received nivolumab, one received both ipilimumab and nivolumab, and the last received PD-1 inhibition alone. Eight patients were receiving proton pump inhibitors. The mean duration on dialysis (dialysis vintage) prior to ICI therapy was 15.8 months (range: 3-60 months). Two patients had an immunotherapy-related adverse event. In both cases, the physicians discontinued the offending ICI agent and started the patients on systemic steroid therapy. Both patients subsequently survived from this event. The remaining patients tolerated the ICIs well, without significant complication or side effect. No dose adjustments were required. In regards to cancer status, the cancer did not progress in 3 patients but progressed in the remaining five. 4 patients died. Literature review revealed total of 26 patients mostly receiving HD (92%). Interestingly, 27% of these patients were on dialysis as a result of a rejected kidney transplant due to ICI therapy, and then continued to receive ICI. Over 80% of the patients had either partial or complete response to treatment. Aside from the kidney transplant rejection preceding death, a minimal number of patients had a grade 2, 3, or 4 adverse immunotherapy related event (15%).

**Conclusions:** Based on our series and previously published literature review, the rate of adverse events appear similar to non-ESKD patients (15-25%). ESKD may not be a contraindication to the use of ICI therapy.

### PO2160

**Title:** AKI as a Risk Factor for Mortality in Oncological Patients Receiving Immunotherapy

**Authors:** Clara García-Carro, Mónica Bolufer, Roxana Bury, Eva Muñoz, Enriqueta Clara Bury, Alejandro Gabaldon, María Jose Cearreas, Daniel Serrón, Maria Jose Soler.

**Institution:** 1Hospital Vall d’Hebron, Nephrology Department, Barcelona, Spain; 2Hospital Vall d’Hebron, Oncology Department, Barcelona, Spain; 3Hospital Vall d’Hebron, Pathology Department, Barcelona, Spain.

**Background:** Checkpoint inhibitors (CIPI) are used to treat cancer by promoting immune-mediated elimination of tumor. CPI-association AKI (CPI-AKI) is an adverse effect and its incidence is 13-29%. The effect of CPI-AKI on patient survival is unknown. Our main goal was to evaluate if CPI-AKI is a risk factor for mortality in patients with cancer under immunotherapy.

**Methods:** We evaluated data of all patients under CPI at our centre between March 2018-May 2019 and followed-up until April 2020. We divided them into 2 groups according the development of CPI-AKI. Kaplan-Meier and Cox survival analysis comparing patients who developed CPI-AKI with those who did not were performed.

**Results:** 821 patients received CPI during the study period. Mean age was 62.03 years and 59.2% men. Malignancies: lung 30.3%, urogenital 20.5%, melanoma 10.8%. CPI treatment: 54.34% patients received anti-PD1, 28% anti-PDLL1, 1.16% antiCTLA4, 4.4% other drug. 11.7% two CPI. Mean baseline creatinine was 0.85±0.30 mg/dl. 125 patients (15.2%) developed CPI-AKI. 790 patients completed follow up and were included in the survival analysis, including all with CPI-AKI. Mean time of follow up 13.2months. 50.8% patients had died at the end of follow up, mean time after starting CPI 8.60 months. There were no differences in age/gender or basal creatinine between patients who died and those who survived. In patients who developed CPI-AKI, mortality was 70.40% vs 47.27% as compared with non-CPI-AKI (p<0.0001). Cox survival analysis including age/ gender, malignancy and type of CPI identified CPI-AKI as a risk factor for mortality (HR 1.597, 95%CI 1.258-2.028, p<0.001) as well as malignance (melanoma HR 1.897, 95% CI 1.290-2.793, lung HR 1.272, 95% CI 1.010-1.602 and urogenital HR 1.543, 95% CI 1.178-2.041, p<0.001) and CPI (PD1 HR 2.160, 95% CI 1.458-3.205, PDL1 HR 1.887, 95% CI 1.523-2.384 and 2 drugs HR 2.049, 95% CI 1.279-3.279, p=0.005).

**Conclusions:** In a study including more than 800 patients with advanced cancer receiving immunotherapy, CPI-AKI incidence was 15.2%. More than 50% of patients died during a mean follow up of 13 months. CPI-AKI development was a risk factor for mortality in our series. As far as we know, this is the first time that the association between AKI and mortality in patients receiving immunotherapy is described.

### PO2161

**Title:** A Single-Center Cohort Study of Nephrotoxicity due to Immune Checkpoint Inhibitors

**Authors:** Craig T. Irwin, Jennifer Panic, Fahad A. Lodhi, Joshua T. Lee, Sabri E. Elkhidir, Connie M. Folz, Soumya Pulipati, Adam M. Bissonnette, Zefi Fatima, Rebecca Blonsky, Chady A. Leon, Siddhartha Kattamanchi. Marshfield Clinic Health System, Marshfield, WI.

**Background:** Previous studies and case reports have demonstrated an increased risk of nephrotoxicity in patients receiving immune checkpoint inhibitors (CIPIs) compared to clinical trials. The primary objective of this study was to contribute to the existing data regarding the frequency, causes of, and risk factors for CPI-induced AKI.

**Methods:** This was a retrospective cohort study of patients receiving at least one dose of a CPI at a health system in Central Wisconsin from 2013 to 2019. Baseline serum creatinine, defined as the average of all values obtained within 6 months of the CPI start date, was compared to the baseline creatinine measured during CPI therapy and through 60 days after the last CPI dose. Patients developing an AKI of at least three day duration were further assessed to determine the likely cause of AKI, with the incidence of potentially CPI-induced AKI being our primary outcome.

**Results:** Of a total of 936 patients, 7 at least one dose of a CPI at MCHS during the study period. After applying exclusion criteria, a total of 910 patients were included in the analysis. A total of 8.4% of patients (76 of 910) were on dual CPI therapy (ipilimumab...
and nivolumab). The incidence of AKI of any duration was 36.6% (333 of 910 patients), with 2.6% (24 of 910 AKI (defined as 3 days or longer or not re-measured) occurring in 31.0% of patients (282 of 910). The incidence of presumed CPI-induced AKI was 3.2% (29/910).

A total of 25.2% (71/282) of sustained AKI patients had at least one concurrent immune-related adverse effect (irAE), compared to 55.2% (16/29) of presumed CPI-induced AKI. CPI-induced AKI occurred on average 88.2 days (standard deviation 80.6) after starting the CPI, with several AKI events occurring within 60 days after stopping the CPI.

Conclusions: AKI secondary to CPI is a common side effect of CPI. In our population, it occurred at an incidence of 3.2% and sometimes occurred even after the last dose of CPI. The etiology of AKI in almost all cases of biopsy-proven CPI-induced AKI is acute interstitial nephritis. The risk appears to be increased if a patient has already received concurrent bevacizumab. 164 patients (26%) experienced AKI in the first 12 months after initiation of CPI use; 51% of these patients were male, and 90% were White. In the first year of follow-up, 62% experienced hyponatremia, 27% had hypokalemia, 26% had hyperkalemia, 49% had hypophosphatemia and 9% had hypocalcemia. Grade 3 or 4 hyponatremia was seen in 136 patients (6%) and occurred 164 days (SD 100) after checkpoint inhibitor initiation; only 9 cases of grade 3 or 4 hyponatremia were due to endocrinopathies. CTLA4 inhibitors were associated with a higher risk of grade 3 or 4 hyponatremia and hypophosphatemia. Patients with gastrointestinal malignancies experienced the highest risk of grade 3 or 4 electrolyte abnormalities.

Conclusions: Electrolyte abnormalities are common in cancer patients receiving immune checkpoint inhibitors. Endocrinopathies leading to severe hyponatremia are rare (<0.5%).

PO2163

AKI and Immune-Related Adverse Events (irAEs) in Patients with Genitourinary Cancers Receiving Immune Checkpoint Inhibitors (ICIs)

Harish Shanthanu Seethapathy, Nilasha Rusibamayila, Donald F. Chute, Meghan Lee, Jan A. Stroehblm, Nilasha Rusibamayila, Donald F. Chute, Kerry Reynolds, Meghan E. Sise. Massachusetts General Hospital, Boston, MA; Northwell Health, Great Neck, NY.

Background: Hyponatremia due to endocrinopathies such as adrenal insufficiency and hypothyroidism has been reported in patients receiving immune checkpoint inhibitors. Other electrolyte abnormalities such as hypercalcemia and hypokalemia have also been associated with the use of these agents. We study the incidence and predictors of electrolyte abnormalities in cancer patients receiving immune checkpoint inhibitors.

Methods: Patients who received immune checkpoint inhibitors at Massachusetts General Hospital Cancer Center between 2011 and 2018 were included. Incidence of electrolyte abnormalities were determined in the first 12 months after drug initiation and graded for severity by using Common Terminology for Cancer Adverse Events criteria. The predictors of severe electrolyte abnormalities were determined using a multivariable logistic regression model.

Results: We analyzed 2438 patients started on checkpoint inhibitors in our cancer center. Average age was 64 (SD 13) years, 58% were male and 90% were White. In the first 12 months following treatment, 62% experienced hyponatremia, 27% had hypokalemia, 26% had hyperkalemia, 49% had hypophosphatemia and 9% had hypocalcemia. Grade 3 or 4 hyponatremia was seen in 136 patients (6%) and occurred 164 days (SD 100) after checkpoint inhibitor initiation; only 9 cases of grade 3 or 4 hyponatremia were due to endocrinopathies. CTLA4 inhibitors were associated with a higher risk of grade 3 or 4 hyponatremia and hypophosphatemia. Patients with gastrointestinal malignancies experienced the highest risk of grade 3 or 4 electrolyte abnormalities.

Conclusions: Electrolyte abnormalities are common in cancer patients receiving immune checkpoint inhibitors. Endocrinopathies leading to severe hyponatremia are rare (<0.5%).

ImmuneCheckpointInhibitor–Associated Glomerular Disease: A Systematic Review and Meta-Analysis
AbhiJit Kitchlu,1 Kenar D. Shaveri,2 Shikha Wadhwani,2 Priya Deshpande,3 Ziv Harari,4 Teruko Kishibe,4 Kammi J. Henriksen,4 Rimda Wanchoo,4 1University Health Network, Toronto, ON, Canada; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3iCaib School of Medicine at Mount Sinai, New York, NY; 4St. Michael’s Hospital, Toronto, ON, Canada; 5University of Minnesota, Minneapolis, MN.

Background: Immune checkpoint inhibitors (ICI) are increasingly used to treat several cancers. Kidney immune-related adverse events (IRAE) are now well-recognized, with purported incidence of 2-5%. The majority of initial data related to kidney IRAE has focused on acute interstitial nephritis (AIN). Recently various glomerular diseases have been reported; however, there is minimal data on the types and relative frequencies of glomerular diseases associated with ICI, their treatment, and outcomes.

Methods: We performed a systematic review and meta-analysis of all biopsy-proven published cases/series of glomerular pathology associated with ICI therapy. We searched the MEDLINE, EMBASE and Cochrane Central databases from inception to February 2020. We abstracted patient-level data, including demographics, cancer and ICI therapy details, and characteristics of kidney injury. We performed exploratory univariate logistic regressions for predictors of end stage kidney disease (ESKD) or death.

Results: After screening, 27 manuscripts with 45 cases of biopsy-confirmed ICI-associated glomerular disease were identified. Several types of lesions were observed, with the most frequent being pauci-immune glomerulonephritis and renal vasculitis (27%), minimal change disease (MCD) (20%), and C3 glomerulonephritis (11%). Concomitant AIN was reported among 41% of cases. The majority of patients had ICI discontinued (88%), and nearly all received corticosteroids (98%). Complete or partial remission of proteinuria was achieved in 45% and 38%, respectively. Most patients had full (31%) or partial (42%) recovery from AIN although 19% required dialysis and approximately one-third of patients died. In exploratory univariate logistic regression for predictors of end stage kidney disease (ESKD) or death, glomerular lesion, ICI class, and RCC, BMI, and line of therapy remained significant in multivariate analysis.[OD1]. Overall survival (OS) was 12.2 months in absence of AKI vs 10.7 months with AKI (p=0.0125). Statin use (p=0.007) and RCC diagnosis (p=0.012) were significantly associated with RirAE with a trend to higher rates in combination immunotherapy (p=0.064). These three variables were also significant in multivariate analysis. OS was not different in the RCC group (10.8 months) vs no RCC group (11.8 months).

Conclusions: Patients undergoing ICI therapy can develop AKI as well as RirAE. However, outcomes are worse for AKI. Survival for pts who develop RirAE does not appear to differ from patients without RirAE. AKI and RirAE share an independent risk factor in RCC. However, statin use and combination ICI therapy appear to be unique risk factors for RirAE. Further studies are needed to verify the findings regarding statin use, a drug with widespread use.

PO2166

Statin Use, Renal Cell Carcinoma, and Combination Immunotherapy: Risk of Checkpoint Inhibitor-Induced Nephritis: A Single-Center Database Study
Jason Prosek,1 Dwight Owen, Mariam Husain, Lai Wei, Gabrielle A. Lopez, Songdua Zhao.1 The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Immune checkpoint inhibitors (ICI) are associated with improved cancer outcomes, however immune related adverse events (irAE) develop and are poorly understood. Renal irAE (RirAE) are less common but may jeopardize effective cancer therapy, and no reliable risk factors for RirAE have been identified. Concomitant medications have been shown to play a role in response to ICI but the impact on toxicity is unknown. We report risk factors and clinical outcomes of patients who develop RirAE.

Methods: We queried a patient database with advanced cancer treated with ICI between 2010 and 2017 at Ohio State Univ for pts who developed AKI (defined as a doubling of creatinine after initiation of ICI). irAEs were reviewed by nephrologist and oncologist. Overall survival (OS) was calculated from date of initiation of ICI to death from any cause or date of last follow-up. Associations between irAE incidence and categorical outcomes were studied using chi-square or Fisher’s exact test. The Wilcoxon test was used for continuous outcomes. Survival outcomes were studied using log-rank test or cox regression model.

Results: Of 1,091 pts treated with ICI, 160 (14.7%) developed AKI of any cause and 30 (2.74%) developed RirAE. PPI use (p=0.032), renal cell carcinoma (RCC) diagnosis (p=0.009) and line of therapy (p=0.033) were all associated with development of AKI, and RCC, BMI, and line of therapy remained significant in multivariate analysis.[OD1]. Overall survival (OS) was 12.2 months in absence of AKI vs 10.7 months with AKI (p=0.0125). Statin use (p=0.007) and RCC diagnosis (p=0.012) were significantly associated with RirAE with a trend to higher rates in combination immunotherapy (p=0.064). These three variables were also significant in multivariate analysis. OS was not different in the RCC group (10.8 months) vs no RCC group (11.8 months).

Conclusions: Patients undergoing ICI therapy can develop AKI as well as RirAE. However, outcomes are worse for AKI. Survival for pts who develop RirAE does not appear to differ from patients without RirAE. AKI and RirAE share an independent risk factor in RCC. However, statin use and combination ICI therapy appear to be unique risk factors for RirAE. Further studies are needed to verify the finding regarding statin use, a drug with widespread use.

A Potential Mechanism of Distal Renal Tubular Acidosis in Patients Treated with Immune Checkpoint Inhibitors
Sandra Herrmann,1 Mariam P. Alexander,1 Michael F. Romero,1 Ladan Zand,2 1Mayo Foundation for Medical Education and Research, Rochester, MN; 2University of Minnesota, Minneapolis, MN.

Background: The main cause of acute kidney injury in patients on immune checkpoint inhibitors(ICIs) is acute interstitial nephritis(AIN). However, as their use continues to increase, we observe other renal manifestations being described. Distal renal tubular acidosis(dRTA) has been described, but the mechanism is not clear to date. We hypothesized that an alteration of H+-ATPase in collecting duct is affected.

Methods: We present two patients with AIN and dRTA secondary to ICI: Patient#1 with metastatic adenocarcinoma of lung and patient#2 with metastatic melanoma, both treated with anti-PD1-antibodies(pembrolizumab/infucinib). They had prominent electrolyte abnormalities consistent with dRTA(Figure 1A). Kidney biopsy was performed in each patient which showed diffuse AIN with negative routine immunofluorescence(IF) staining. Both patients had received PPI in addition to ICI therapy and had improvement in their kidney function following steroid therapy and with discontinuation of the drugs. In order to investigate the potential mechanism for developing dRTA, the kidney biopsy frozen sections from patients#1 and #2 were further stained by indirect IF for acid-base transporters in α-IC(c4 and B1)subunits of the vacuolar H+-ATPase(V-ATPase) and the AE1. In order to quantify the staining, data were normalized to a T0 allograft biopsy as control.

Results: α-IC cell markers were decreased in both patients compared to the control as shown in Figure 1B. Quantification of AE1, B1-V-ATPase and A4-V-ATPase were all reduced compared to control biopsy, however, staining for other markers of α-IC(c-kid) were not reduced. This suggests a more targeted reduction in α-IC in patients with AIN secondary to ICI with and without dRTA in the future will be useful.

Conclusions: The reduction in staining for V-ATPase subunit could be related to damage from AIN, however, an immune-mediated process that reduces the expression of V-ATPase in α-IC is likely. Comparing staining of V-ATPase in α-IC in patients with AIN secondary to ICI with and without dRTA in the future will be useful.

Clinical Features of AKI in Patients Receiving Tisagenlecleucel (CAR-T Therapy)
Meghan Lee,1 Ian A. Stroehbahn,2 Harish Shanthanu Seethapathy,3 Nifasha Rusibamalya,2 Keagan S. Casey,2 Shrutti Gupta,2 David E. Leaf,1 Matthew Frigaard,2 Meghan E. Sise.1 Massachusetts General Hospital, Boston, MA;2 Brigham and Women’s Hospital, Boston, MA.
Background: CAR-T therapy uses genetically engineered T cells to target tumor antigens. It is associated with cytokine release syndrome (CRS), neurotoxicity, and, in severe cases, AKI. Prior series demonstrated 20% incidence of AKI after axicabtagene ciloleucel (Yescarta), a CD28 costimulatory domain CAR-T. Tisagenlecleucel (Kymriah) is a 41BB CAR-T that targets CD19 on B cells but has delayed toxicities, slower expansion kinetics, longer persistence, and is associated with lower rates of severe CRS. We determined incidence and clinical features of AKI in patients receiving tisagenlecleucel.
Methods: We performed a retrospective review of adults with diffuse large B cell lymphoma treated with tisagenlecleucel at our institution between Jan 2019–Apr 2020. Baseline demographics, laboratory data, and clinical outcomes were obtained from electronic health records. The primary outcome, AKI, was defined as a ≥1.5-fold rise in creatinine from pre-CAR-T baseline and staged using KDIGO criteria.
Results: Overall, 37 patients received tisagenlecleucel: average age was 60 (SD 18), 65% male, 86% white. CRS occurred in 51% (no severe CRS); neurotoxicity occurred in 24%. Thirteen (35%) required steroids, 8 (22%) received tocilizumab, and 8 (22%) received anakinra to treat CRS/neurotoxicity. AKI occurred in 2 (5%) patients; both had stage 3 AKI. One had acute tubular necrosis due to septic shock starting post-infusion day 1. The other had AKI with new-onset nphrictic range proteinuria (5-6g/g) concurrent with a hemophagocytic lymphohistiocytosis-like syndrome beginning day +8. The patient was also receiving amphotericin and acyclovir. Both patients with AKI died (days 4 and 28, respectively). Among patients without AKI, the 30-day mortality was 8.6%. Clinically significant electrolyte disorders were also common (Table).
Conclusions: Compared to prior reports, we found lower rates of CRS and AKI in patients receiving tisagenlecleucel. We report a case of new-onset nephrotic-range proteinuria and AKI following CAR-T.

PO2169
Dabrafenib-Induced Acute Interstitial Nephritis (AIN) and AKI in Patients with Cancer
Meghan Lee, Harish Shanthanu Seethapathy, Orhan Efe, Ian A. Stroehbahn, Nifasha Rusibamalya, Ivy Rosales, Robert B. Colvin, Donald F. Chute, Meghan E. Sise. Massachusetts General Hospital, Boston, MA.
Background: BRAF inhibitors (vemurafenib, dabrafenib, encorafenib) commonly used to treat BRAFmutant cancers have been associated with AKI. Cases of acute and chronic tubular injury and AIN have been reported with dabrafenib. We aimed to define the incidence and clinical features of AKI in patients on dabrafenib.
Methods: We conducted a retrospective cohort of patients receiving dabrafenib from 2010-2018 in a large healthcare system. Baseline comorbidities and medication use were determined by chart review. The primary outcome was AKI (≥1.5-fold increase in baseline creatinine) within 12 months. AKI etiology was reviewed by 2 nephrologists. Multivariable modeling was used to determine predictors of AKI.
Results: Overall, 199 patients were included; mean age was 59 (SD 16) years, 56% were male, and 94% were white. 96% received trametinib (a MEK inhibitor) concurrently. Mean baseline creatinine was 0.9 (SD 0.2) mg/dL (20.10%) had baseline CKD (eGFR<60 mL/min/1.73m²), and 42 patients (21%) experienced AKI at a mean of 141 (SD 116) days after starting dabrafenib. In multivariable modeling, only baseline liver disease predicted AKI. Etiology and stage of AKI are shown in Fig 1A; clear alternative causes for AKI were found in 32 of 42 cases. Ten patients (5% of total cohort, 24% of AKI) experienced AKI attributed to dabrafenib-induced cytokine release syndrome (CRS); all experienced fever, chills, gastrointestinal distress (nausea, vomiting, diarrhea) +/- rash and transaminisits within 4-6 weeks of starting dabrafenib. The majority improved with intravenous hydration and discontinuation of the drug. One patient with persistent AKI underwent kidney biopsy demonstrating granulomatous AIN (Fig 1B); he was treated with intravenous solumedrol and a prednisone taper for two weeks with full resolution of AKI.
Conclusions: AKI is common in patients on dabrafenib (21%). A febrile systemic response or CRS after dabrafenib may explain up to 24% of AKI; we report another case of AIN after dabrafenib.

PO2170
Temporal Trends of Palliative Care Use Among Hospitalized Patients with Metastatic Renal Cell Carcinoma
Si Li, Yichen Wang, Min Zoua, Qiyu O. Wang, Nasha Elavia, Nishant Sharma, Bojana Milecik, The Wright Center for Graduate Medical Education, Scranton, PA; Cook County Health and Hospitals system, Chicago, IL; Beth Israel Deaconess Medical Center, Boston, MA.
Background: Patients with metastatic renal cell carcinoma have a poor prognosis and they may suffer from hypercalcemia, venous thromboembolism, anorexia-cachexia syndrome. Little is known about the trends in the utilization of palliative care in this patient population.
Methods: We conducted a retrospective cohort study using data from 2004 to 2014, which were extracted from the National Inpatient Sample. ICD-9-CM was used to identify all diagnosis variables. We compared the baseline demographics. We assessed the annual trend over time in palliative care utilization rates. Statistical analysis was performed using STATA 16.0. We considered a two-tailed P value of <0.05 as statistically significant.
Results: We identified 181,199 hospitalizations with metastatic renal cell carcinoma from 2004 through 2014, of which 16,390 (9.0%) involved palliative care services. Inpatient palliative care utilization increased from 2.8% in 2004 to 16.3% in 2014 (p<0.001). Compared with patients discharged from non-teaching hospitals, we noticed a significantly higher rate of palliative care utilization in patients discharged from teaching hospitals (aOR 1.46; 95% CI 1.29 to 1.65). There were higher odds of receiving palliative care in patients with private insurance (aOR 1.26; 95% CI 1.11 to 1.42). We also observed lower odds of receiving palliative care in Hispanic patients (aOR 0.83; 95% CI 0.70 to 0.98, p=0.03).
Conclusions: The rate of inpatient palliative care use in metastatic renal cell carcinoma patients sharply increased between 2004 and 2014. Our findings demonstrated improving adherence to the National comprehensive cancer network (NCCN) guidelines, which is highly encouraging. Patients from teaching hospitals and using private insurance and were more likely to receive palliative care.

PO2171
AKI Secondary to Multiple Myeloma: Complications of Treatment with High Cut-Off Filters
Background: Acute kidney injury is a frequent complication of MM that can affect 18 to 56% of patients and more than 10% end up needing dialysis. One of the drawbacks associated with the technique is attributed to the albumin loss. The other complications are related with the dialysis technique itself, especially infections.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We have performed 28 treatments of hemodialysis with High cut off filters (HD-HCO). The HD-HCO protocol includes daily dialysis session of 6 hours during the first 6 days to subsequently switch to dialysis every other day until free light chains levels below 500 mg / L, or until the recovery of renal function allows the independence of dialysis. All these patients have a chemotherapy regimen based on Bortezomib (250 mg of the drug is given 3 times a week) and Dexamethasone (28) treatments of hemodialysis (a retrospective analysis of the 28 treatments that are performed with HD-HCO after 8 years of experience (July 2011 to May 2019) to demonstrate the presence of the same complications as the conventional HD.

Results: Loss of albumin is one of the main drawbacks of the technique. Our patients have had changes in albumin levels due to the fact that our protocol includes the infusion of 2 vials of 20% albumin of 50 ml. at the end of each HD-HCO session. Another concern is intradialytic complications. We have reviewed this topic and our results show that patients in HD-HCO do not present a greater number of complications than those who dialyze with HD-C. The total number of sessions was 291. 21 patients developed hypotension (7%). The number of sessions in which the patient presented fever was 6 (2%), coagulation of the circuit occurred in 23 sessions (7.7%). The catheter dysfunction (when it does not allow to reach 250 ml/min of blood flow) in 26 sessions (8.7%) and only 13 times the replacement of the catheter (4.26%) was necessary, consequently, in those who required a greater number of dialysis sessions. In only 1 case (patient who required 27 sessions) to place a permanent Tesio catheter was necessary. Figure 1

Conclusions: Our findings indicate that the HD-HCO has the same safety profile as the conventional HD. There is no serious infectious complications in our patients despite the fact that all of them are immunosuppressed patients (AKI secondary to Multiple Myeloma in patients treated with chemotherapy).

PO2172
Acute Myeloid Leukemia Worsens Sepsis-Induced AKI
Takayuki Tsuji, Tsuji, Tetsu, Yamashita, Xuzhen Hu, Peter S. Yuen, Robert A. Star. Renal Diagnostics and Therapeutics Unit National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: Patients with hematologic malignancies are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. Sepsis is the main cause of AKI in ICU patients with hematologic malignancies. However, the contributions that host or cancer cells make to systemic inflammation during sepsis-induced AKI is not known.

Methods: We created a mouse xenograft model of acute myelogenous leukemia (AML) associated sepsis AKI. Human leukemia HL-60 cells were injected into the tail vein of 6 week-old male NOD/SCID/IL-2Rγ-/- (NSG) mice. After engraftment 2 weeks later, coelomic ligation and puncture (CLP) was performed to induce sepsis (n=8-12 per group). Tumor engraftment in the bone marrow (BM) and blood tumor burden were measured by flow cytometry of human CD33 and human CD45 double positive cells. Multiple organ damage, and both mouse and human systemic cytokines were evaluated at 24 h after CLP or sham surgery.

Results: AML infused sepsis-induced AKI. Both BUN and LDH were significantly higher in AML+CLP than CLP alone (AML+CLP vs vehicle+CLP, BUN 74.5±25.4 vs 42.7±25.3 mg/dL, LDH 3,969±1,720 vs 1,863±661 mg/dL, p<0.05). CLP dramatically increased the percentage of circulating leukemia cells (pre CLP vs post CLP, 2.2±1.3 % vs 20.6±13.3 %, p<0.05). Tumor burden in either BM or blood did not correlate with AKI severity. Systemic mouse IL-6 in AML+CLP at 24 hours after CLP was significantly higher than CLP alone (45.9±2.4 vs 15.1±2.4 ng/mL, p<0.05). Systemic human IL-6 in AML+CLP was higher, but not significantly, than vehicle+CLP. There was no correlation between human cytokines and severity of AKI, although human cytokines (IL-6 and TNFa) significantly correlated with tumor burden in both BM and blood at 24 hours after CLP.

Conclusions: We established a clinically relevant mouse xenograft model of human leukemia associated sepsis AKI. Leukemia intensifies sepsis-induced AKI, and sepsis increased the numbers of circulating AML cells. Systemic cytokines derived from the human leukemias correlates with tumor burden, but not with the severity of cytokines-induced AKI. Whereas malignant cells do not produce circulating cytokines that directly drive the systemic immune response to subsequent sepsis-induced AKI, cell-cell interactions in the BM niche may impact systemic inflammation indirectly, possibly through mouse IL-6.

PO2173
Acute Acquired Fanconi Syndrome (FS) in Multiple Myeloma (MM) After Autologous Hematopoietic Stem Cell Transplantation (HCT): A Case Series
Janina Paula T. Sy-Go, Nelson Leung, Mayo Clinic Minnesota, Rochester, MN.

Background: Proximal tubular dysfunction can occur in patients with MM. The main clinical presentation is electrolyte abnormalities indicative of FS. The objective of the study was to describe and identify the rate and clinical predictors of developing acute acquired FS in adult patients with MM after autologous HCT.

Methods: We identified 2515 adult MM patients who underwent autologous HCT at 28 treating centers. Conventional dialysis (CM) from December 31, 2018. 45 without research authorization were excluded. 13 patients were identified after searching for “Fanconi,” “Fanconii,” and “Fanconi’s” in the EMR. 6 patients did not have FS. 4 patients were diagnosed with FS prior to HCT. The remaining 3 patients (0.12% of cohort) were clinically diagnosed to have FS based on features suggestive of FS- hypokalemia, hypophosphatemia, hypouricemia, proximal renal tubular acidosis, and normoglycemia.

PO2174
Hyponatremia Is Common After Indwelling Catheter Drainage of Malignant Ascites
Shruti Gupta,1 Maria Clarissa Tio,2 Emily D. Gutowski,2 Michael S. Stecker,3 Ashish Verma,2 Shveta S. Motwani,2 David B. Mount2,1 Gearoid M. McMahon,4 Sushrut S. Waikar1,4 Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Dana-Farber/Children's Hospital Cancer Center, Boston, MA; 4Boston Medical Center, Boston, MA.

Background: Indwelling peritoneal catheters (IPCs) are frequently used to drain tense, symptomatic, malignancy-related ascites. Large-volume drainage may lead to hyponatremia due to massive salt depletion. To date, no studies have examined the epidemiology of hyponatremia after IPC placement.

Methods: We retrospectively reviewed the charts of 461 patients who had IPCs placed between 2006 and 2016 at a tertiary care hospital. Among the 309 patients with labs available pre- and post-catheter, we studied the incidence of hyponatremia and its risk factors. We also examined the management of hyponatremia and its association with mortality.

Results: The overall incidence of hyponatremia post-IPC placement was 85%, of whom 8% had severe hyponatremia with a serum sodium (sNa) <120 meq/L. The mean decline in sNa pre- versus post-catheter was 5 mEq/L (+/- 5.1) and fell by a 10 meq/L among 52 patients (16.8%). Patients with hyponatremia prior to catheter placement had an 8-fold (95% CI, 2.9-21.7) higher adjusted odds of having persistent hyponatremia post-catheter (Table 1). Patients with hepatitis pancreatic-biliary malignancies and lower BMI also had a higher adjusted odds of hyponatremia. Hyponatremia was either unrecognized or untreated in 61% of patients. Patients who had sNa ≤120 meq/L had shorter median survival compared with those with a post-IPC sNa <120 meq/L (8 versus 17 days, log-rank p value = 0.03 (Figure 1)).

Conclusions: Though IPC placement is often a palliative measure, severe hyponatremia is common, and severe hyponatremia may be associated with shorter survival. These patients may warrant closer monitoring post-catheter placement.

Seleznio-Associated Hyponatremia: Single-Center Real-World Data
Omar Mamlok,1 Kenar D. Jhaveri,2 Jaya Kala.3 1University of Texas MD Anderson Cancer Center, Houston, TX; 2Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 3University of Texas John P and Katherine G McGovern Medical School, Houston, TX.

Background: Introduction: Hyponatremia is a commonly reported side effect in recent clinical trials evaluating the efficacy and safety of selinexor in treatment of refractory multiple myeloma (MM). With incidence ranging 7-47%, the hyponatremia was reported to be generally asymptomatic, transient, and highly responsive to medication dose reduction and sodium. The etiology for hyponatremia is not yet completely understood and speculated to be multifactorial, hypovolemia, diarrhea, poor solute intake, or pseudo-hyponatremia from high M protein level.

Methods: We retrospectively reviewed the medical records of all relapsed MM patients at our cancer institute. The study was approved by the institutional review board. We reviewed data relevant to hyponatremia in patients' clinical presentation, medication history, comorbid conditions, physical examination, and laboratory review.

Results: Hyponatremia was seen in 13/17 patients within 5 weeks of therapy, 8 of whom required hospitalized. Three of these hospitalized patients had grade 3 hyponatremia (serum sodium 120 to ≤130 meq/l) with severe symptoms including fall and altered mental status. Both groups of patients received antiepileptics, anti-depressants and diuretics that included thiazides. Cancer related pain was observed in both groups but the hyponatremic group was on higher dose selinexor and more likely to have more gastrointestinal side effects, sepsis, hypotension. Nephropathy was consulted on only 4 out of 13 patients. These patients with selinexor and selinexor side effects (hypovolemia, nausea and possible unidentified factor) may contribute to hyponatremia. It is possibly dose dependent, more likely to occur with patients who had gastrointestinal side effects, sepsis and hypotension. We recommend discontinuation of medications associated with hyponatremia prior to starting/during selinexor therapy, obtaining basic hyponatremia investigations, and early referral to nephrology to prevent potential serious symptoms.

PO2176
Antiemetic Drugs and the Risk of Cisplatin-Induced AKI
Roman A. Shingarey,1 Andrea Knezevic,1 Sheron Latcha,1 Melanie S. Joy,2 Lauren Aleksunes,3 Edgar A. Jaime,1 1Memorial Sloan Kettering Cancer Center, New York, NY; 2University of Colorado, Denver, CO; 3Rutgers, Rutgers The State University of New Jersey, New Brunswick, NJ.

Background: Cisplatin (CIS) is an effective first line therapy for a variety of cancers. Acute kidney injury (AKI) is a common side effect of CIS seen in up to 30% of patients (Latcha et al CAJAN, 2016). AKI results from the selective uptake and accumulation of CIS in proximal tubules. CIS is a highly emetogenic and fluid loss can also contribute to AKI. This retrospective study evaluated whether anti-emetics modify the risk of AKI.

Methods: The medical records of acute adult cancer patients who received CIS between Jan 1, 2010 and Dec 31, 2016 (n=6,889) were reviewed. The association between use of anti-emetics and development of AKI (50% increase in serum creatinine (sCr)) was evaluated. Inclusion criteria were adults, baseline sCr, CIS dose and administration of anti-emetics. Fisher’s exact test was used for univariable associations between categorical values and logistic regression analyzed multivariable associations with AKI at p<0.05.

Results: Of ~8700 patients, 6889 met search criteria. A total of 3,381 (56.3%) patients received antiemetics. AKI developed after cisplatin in 1,666 (24.2 %) patients. Of those with AKI (n=1666), patients who received any antiemetic represented 52.6% (n=877), while patients with no documented antieumetic use represented 47.4% (n=789). Of patients without AKI (n=5223), patients who received any antiemetic represented 57.5% (n=3004), while patients who did not have documented antiemetic use represented 42.5% (n=2219). (P<0.001). Patients who received antieumetics also received a higher cumulative dose of CIS (360 vs 330 mg/m², P<0.001). By univariate analysis older age, male gender, black race, and cumulative CIS dose were associated with higher risk for AKI (OR=0.001). After adjusting for these variables, use of any antieumetic was protective for AKI (OR 0.84, 95% CI: 0.75, 0.94; P<0.001).

Conclusions: Our study confirms the high rate of AKI in patients receiving CIS. While anti-emetic use appears to be associated with a lower rate of AKI, additional analyses will be needed to determine risk or benefit profiles of specific agents and/or class of agents given recent data demonstrating inhibition of kidney transporters with certain anti-emetics. Dissecting out other important covariates such as requirements for anti-emetics based on higher cumulative CIS will be necessary in prospective randomized controlled studies.

PO2177
Acute Kidney Disease After Microvascular Radical Cystectomy for Bladder Cancer Is Associated with CKD
Shengnan Ge, Ying Tang, Junzhe Chen, Sha Fu, Qiyuan Huang, Wenzuan Yu, Anping Xu. Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Guangzhou, China.

Background: Acute kidney disease (AKD) proposed in 2012 by KDIGO is getting more and more attention for its vital role in acute kidney injury (AKI) to chronic kidney disease (CKD) transition. However, no study has explored the incidence, risk factors of AKD and its impact on new-onset CKD after microvascular radical cystectomy (RC).

Methods: The medical records of 308 patients at our hospital between January 2014 and May 2019 were reviewed. We excluded 29 patients from the study due to missing sCr preoperatively or postoperatively. AKD was diagnosed as a ≥25% decrease in eGFR or >50% increase in sCr between 7-90 days after surgery. AKI alone was defined by the 2012 KDIGO classification but failed to meet AKD criteria after 7 days. No kidney disease (NKD) was defined if patients didn’t meet either criteria. Logistic regression model was used to explore risk factors of AKD, while its significance for CKD was assessed using Kaplan-Meier analysis and Cox model.

Results: We evaluated 279 bladder cancer patients, including 168 for Robotic-assisted Laparoscopic RC and 111 for Laparoscopic RC. The incidence of AKD was 14.7% whereas AKI alone was 13.6%. Risk factors for AKD included chemotherapy (odds ratio [OR]=3.245, P=0.024), robotic RC (OR=2.437, P=0.029) and operation time (OR=1.005, P=0.012). Of 150 patients without CKD history, CKD developed in 62.5% of patients with AKD,33.3% with AKI alone and 30.6% with NKD during the 30 months follow up (p=0.013). K-M analysis showed AKD patients had the highest CKD incidence(Fig.1). Cox model also identified AKD (HR=2.224, P=0.012) but not AKI alone, was independent risk factor predicting CKD, along with age.

Conclusions: The incidence of AKD was higher than AKI alone after microvascular RC. The high incidence of AKD may be related to the microvascular RC and resulted in higher risk of new-onset CKD compared with No-AKD. This persistent or repetitive injury is significantly associated with CKD.Hence, interventions for AKD are needed to improve outcomes.

PO2178
Comparative Analysis of Characteristics and Survival Outcomes of Clear Cell and Sarcomatoid Subtypes of Renal Cell Carcinoma: Results from the SEER Database 2000-2017
Dona Attia,1 Tapas Ranjan Behera,2 Sara A. Attia.1 Taussig Cancer Institute, Cleveland, OH; 2Northeastern University, Boston, MA; 3Cleveland Clinic, Cleveland, OH.

Background: Renal cell carcinoma (RCC) accounts for more than 90% of kidney cancers. Clear cell RCC (ccRCC) is the commonest type, while sarcomatoid RCC (sRCC) is rare and constitutes 5% of all RCCs. sRCC is known for aggressive clinical course and poor prognosis. In this study, we sought to compare the epidemiological features and survival trends of ccRCC with sRCC, using SEER dataset 2000-2017.

Methods: The Surveillance, Epidemiology and End Results (SEER) database was used to identify all adult patients (a18 years) diagnosed with ccRCC and sRCC between 2000 and 2017. Variables included age, sex, ethnicity, laterality, staging, histological grade, and nephrectomy. Overall survival was estimated using the Kaplan-Meier method, and compared using the Log-Rank test. Multivariable covariate-adjust Cox models were used for adjusted survival analyses. Results: A retrospective cohort study of 20248 patients (19398 ccRCC, 850 sRCC) with overall survival rate of 38% (40% ccRCC and 16.2% sRCC). Although the two subtypes share similar demographic characteristics, including mean age (66.3±13.7 for ccRCC vs 62.9±12 for sRCC), the female-ratio (1.71 vs 2.31), and being caucasian race more affected (79% vs 82%), sRCC had a significantly worse prognosis in univariate analysis with median overall survival of 7 months vs 30 months for ccRCC. Caucasian male patients were more affected in both types. But neither sex nor race significantly affected survival in sRCC (P 0.814, 0.794 respectively), however, black americans have worse outcomes in ccRCC (HR 1.123[1.083-1.163], P < 0.001). On multivariate
regression analysis, advanced stage, high histological grade, and older age 65+years (HR 1.002, 95%CI [1.000–1.004], P = 0.0001) were associated with worse outcomes. Patients with cancer-related death had significantly shorter survival time in both RCCs (P =< 0.001). Nephrectomy was associated with better survival outcomes (HR 0.486 [0.459-0.514], P =< 0.001).

Conclusions: sRCC had worse prognosis. Advanced stage, high histological grade, and older age are the most important predictors of survival in both subtypes of RCC. Although caucasian male patients were more affected in sRCC, gender and ethnicity have no impact on survival. Nephrectomy imparts better survival benefits in both subtypes.

PO2179
Acid-Base Biomarkers and Cancer Mortality
Ashish Verma,1 Sonu Subudhi,2 Ankit B. Patel,1 Maria Clarissa Tio,1 Sushrut S. Waikar,1 1Brigham and Women’s Hospital, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 1Boston University Medical Campus, Boston, MA.

Background: Acidosis in the tumor microenvironment is associated with cancer progression in animal models. We explored the association of serum bicarbonate and anion gap – measures of acid-base balance – with cancer mortality in community-dwelling adults.

Methods: We conducted a prospective cohort study using the National Health and Nutrition Examination Survey (NHANES), a nationally representative cross-sectional survey of the US non-institutionalized population. Anion gap (mEq/L) was calculated as serum sodium (mEq/L) – (serum chloride (mEq/L) + serum bicarbonate (mEq/L)). We used weighted Cox proportional hazards models to assess the associations between serum bicarbonate and anion gap with cancer-specific mortality, as recorded by the National Death Index. Multivariable models were adjusted for demographics data, BMI, smoking status, diabetes, systolic blood pressure, cardiovascular disease history, ACEi/ARB, diuretics, HIV drugs, metformin, serum albumin, total cholesterol, total protein, total caloric intake, hemoglobin, cancer diagnosis, eGFR and urine albumin to creatinine ratio.

Results: This study included total 39,137 participants [mean (SD) age, 46.83(19.25) years, 20,162(51.5%) females, 18,119 (46.3%) white]. During 4,433,277 person-years of follow up, 964 (2.46%) participants died secondary to cancer. A history of cancer at the time of enrollment was reported in 3186 (8.8%). Table 1 shows the associations between serum bicarbonate and anion gap in tertiles with cancer-related mortality. In analyses restricted to those with a history of cancer, results were 78% increased risk for cancer mortality in highest tertile compared to lowest tertile [HR 1.78; 95% CI (1.11,2.87)].

Conclusions: Increased anion gap may be a risk factor for cancer mortality. The reasons driving this association deserve further examination.

Risk of cancer mortality according to bicarbonate and anion gap as tertiles (method – weighted survey cox regression)

PO2180
In-Hospital and 1-Year Mortality Among Patients with AKI and Haematological Malignancies
Indro P. Efebera,1 Teresa Chua,2 Hugo Ferreira,2 Ana M. Paiva,2 José M. Costa,2 1Hospital Amato Lusitano, Castelo Branco, Portugal; 2Instituto Portugues de Oncologia do Porto Francisco Gentil EPE, Porto, Portugal.

Background: Patients with haematological malignancies (HM) are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. The aim of this study was to identify the prognostic factors for in-hospital mortality and one-year mortality in this population.

Methods: We conducted a single centre, retrospective, observational cohort study of 101 in-hospital patients with AKI and HM between 1 January 2015 and 31 December 2019. We recorded essential demographic, clinical and laboratory data at baseline, 1 and 12 months. We classified AKI according to the KDIGO definition. Cox proportional hazard model was applied to investigate the one-year mortality, and logistic regression analysis was used to assess the in-hospital mortality.

Results: The study population included 64 males and 37 females, with a mean age of 58.7 ± 16.8 years. Multiple myeloma was present in 30.7% (n=31) of the patients, followed by non-Hodgkin lymphoma (LNH) in 27.7% (n=28). 51.5% (n=52) were admitted to intensive care unit (ICU). 60.4% (n=61) needed renal support therapy (RST). Basal GFR, one-month GFR and one-year GFR were, respectively, 65.7 ± 28.9 mL/min/1.73m², 57.1 ± 28.5 mL/min/1.73m² and 54.9 ± 28.1 mL/min/1.73m². Mean length of in-hospital stay was 16 days (IQR 1-88). In-hospital death was 52.5% and after one year only 26 patients were alive. In multivariate analysis, the independent predictors for in-hospital mortality were invasive mechanical ventilation (IMV) (OR 49.53; 95% CI 19.17 – 267.57; p<0.001) and sepsis (OR 5.09; 95% CI 1.18 – 21.89; p=0.029). The C-statistic was 0.93 (95% CI: 0.87 – 0.98), indicating that the equation had a great discriminatory power. The independent predictors for one-year mortality were LNH (HR 2.78; 95% CI 1.53 – 5.05; p<0.001), cancer progression (HR 2.91; 95% CI 1.156 – 5.41; p<0.001) and IMV (HR 5.79; 95% CI:3.30 – 10.15; p<0.001). Elevated levels of albumin at the time of AKI conferred a better prognosis (HR 0.63; 95% CI:0.42 – 0.95; p=0.07).

Conclusions: Our model showed that HM patients with AKI are at high risk of sepsis and IMV, and resulting in elevated in-hospital death. Elevated levels of albumin at the time of AKI correlated with a better one-year survival, while LNH, cancer progression and IMV were risk factors for death.

PO2181
Renal Recovery from AKI After Hematopoietic Stem Cell Transplant: A Systematic Review and Meta-Analysis
Karthik Kovuru,1 Swetha Rani Kanduri,1 Wisit Cheungpasitporn,2 Charat Thongprayoon,2 Juan A. Medaura,1 Kianoush Kashani,2 1University of Mississippi Medical Center, Jackson, MS; 2Mayo Clinic Rochester, Rochester, MN.

Background: Patients with the recovery of renal function after an episode of acute kidney injury (AKI) have better outcomes compared to those without recovery. The current systematic review is conducted to assess the rates of kidney function recovery among patients with AKI or severe AKI requiring RRT within 100 days after hematopoietic stem cell transplant (HSCT).

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systematically searched from database inception through August 2019 to identify studies reporting the rates of recovery from AKI after HSCT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 458 patients from 8 cohort studies with AKI after HSCT were enrolled. Overall, the pooled estimated rates of AKI recovery among patients with AKI and severe AKI requiring RRT within 100 days were 58% (95% CI: 37%-78%) and 10% (95% CI: 2%-4%), respectively. Among patients with AKI recovery, the pooled estimated rates of complete and partial AKI recovery were 60% (95% CI: 39%-78%) and 29% (95% CI: 10%-61%), respectively. There was no clear correlation between study year and the rate of AKI recovery (p = 0.26).

Conclusions: The rate of recovery from AKI after HSCT depends on the severity of AKI. While recovery is common, complete recovery is reported in about two-thirds of all AKI patients. The rate of recovery among those with AKI requiring RRT is substantially lower.

Table 2. Forest plots of the involved studies assessing renal recovery rates from AKI after HSCT

PO2182
Renal Outcomes After Autologous Stem Cell Transplantation for AL Amyloidosis
Naresh Bummag, Michael Ozga, Isabelle Ayoub, Salem Almaani, Nidhi Sharma, Yvonne A. Efereba, Samir V. Parikh. The Ohio State University, Columbus, OH.

Background: Renal involvement in AL Amyloidosis is common and results in end-stage kidney disease (ESKD) in 30% of cases within 3 years of diagnosis. Newer therapeutic regimens directed at the plasma cell clone including high-dose melphalan with autologous stem cell transplantation (ASCT) are associated with improved survival but effect on renal outcome is not well established. We evaluated renal outcomes for patients who underwent ASCT and achieved a complete (CR) or very good partial (VGPR) hematologic response.
Methods: We performed a retrospective analysis of 50 AL Amyloidosis patients who underwent ASCT. Patients with renal involvement who achieved a hematologic response were included. Renal response was defined prior to transplant, according to consensus guidelines, as partial response (PR, > 30% decrease in proteinuria) or stable disease (SD, ≤ 30% proteinuria reduction). Primary endpoints were progression free survival (PFS) and overall survival (OS). PFS and OS were defined as the time from transplant to day of progression or death, respectively. Kaplan-Meier survival function estimated the PFS and OS. The log-rank test tested the equality of survivor functions between different groups of patients.

Results: Following ASCT, 16 patients (32%) achieved hematological VPGF/CR after ASCT. All had renal involvement. Baseline and 1-year post-transplant proteinuria and serum creatinine (SC) levels are shown in the Table. In the group of pts achieving VPGF/CR as hematological response PFS and OS were similar for patients having PR and SD as renal response respectively (p=0.89 and p=0.44, respectively). No patients required hemodialysis. Median follow up for PFS was 4.1 years and for OS was 5.6 years (PR) and 11.9 years (SD).

Conclusions: Hematological response is important in AL amyloidosis and survival improves similarly with VPGF and CR. In patients with renal involvement, this study shows similar outcomes to patients who achieved a PR or SD as renal response prior to ASCT. However, our study has a small sample size and we would recommend a larger study.

High-Dose Methotrexate (HDMTX) and Nephrotoxicity: Effect on Subsequent Dosing

Background: HDMTX is an important part of various chemotherapeutic protocols due to its central nervous system penetration. A key complication of HDMTX is nephrotoxicity as this leads to delayed MTX excretion and further morbidity. Nephrotoxicity in a previous cycle of HDMTX leads to an increased risk of future toxicity. Our aim was to establish how nephrotoxicity affected clinical decision making with regards to future dosing.

Methods: A retrospective review of the electronic medical record was performed to identify patients who developed nephrotoxicity post HDMTX from 1/1/02 to 12/31/18. We stratified the effect of nephrotoxicity by grade of AKI, according to the acute kidney injury network criteria, on resumption of MTX. In those who received a subsequent dose, we assessed whether a dose reduction have an impact on rate of Nephrotoxicity. Analysis was performed in Minitab.

Results: We identified 670 episodes of nephrotoxicity which equated to an overall incidence rate of 19% of total cycles. The majority were AKI grade 1 (79.7%). Higher grade AKI were significantly less likely to receive a future dose (p<0.001), with 71.3% of AKI N1, 59.2% of AKI N2, and 21.2% of AKI N3. Other factors associate with future dosing with no significant reduction in incidence with reduction in MTX dose. Given the retrospective nature of the data and the many complexities to dosing in future dosing with no significant reduction in incidence with reduction in MTX dose.

Conclusions: Nephrotoxicity had an important impact on subsequent dosing, especially with higher grade AKI. Previous AKI infers a higher rate of nephrotoxicity in future dosing with no significant reduction in incidence with reduction in MTX dose. Given the retrospective nature of the data and the many complexities to dosing calculation, this should be further explored with a prospective study.

P20184

Nephrology and Hematology Referral Trends in CKD Patients with Monoclonal Gamopathy and Factors Associated with Deferring Kidney Biopsy

Nattawat Kloomjitt,1 Ladan Zand.1 2 Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 1 Division of Nephrology and Hypertension, Department of Medicine, University of Minnesota, Minneapolis, MN.

Background: Many patients with CKD are managed by their primary care providers (PCP). The presence of monoclonal gamopathy (MG) in the setting of CKD raises the possibility of monoclonal gamopathy of renal significance (MGRS) which would require a nephrology or hematology referral. However, rate and factors that affect specialty referral in population remains unknown. Moreover, factors for deferring a kidney biopsy are also unknown.

Methods: We retrospectively identified adult CKD patients with MG at our center from 2017-2018. Baseline characteristics and laboratories studies were compared between nephrology/hematology referral group (RG) vs. no referral group (NRG). We also assessed the rate of kidney biopsy and the reasons for not pursuing a biopsy in the referral group.

Results: We identified 596 CKD patients with MG. Of these, 416 (69.8%) were seen by nephrology/hematology (RG) and 180 (30.2%) were not referred to either. Of the 180, 32% were followed by their PCP (n=57), 30% by cardiologist (n=54), and 19% by neurologist (n=35). Demographics were similar between the two groups. Patients in the NRG were more likely to have coronary artery disease, dementia, acute or metastatic cancer. In multivariate analysis, 24-hr urinary protein (OR: 1.36 (1.01, 2.09)), abnormal FLC (OR 2.46 (1.29, 4.93)), and serum creatinine (OR 2.38 (1.37, 4.59)) were strong independent predictors for referral. Of 416 patients in RG, 62 (15%) patients underwent a kidney biopsy and 26 had an MGRS lesion. There were no differences in the comorbidities between the patients that were biopsied vs. those that were not. The main reason for deferring biopsy was lack of awareness of CKD or MG (42.40%) and low suspicion for MGRS (130, 37%). In 62 patients, biopsy was not pursued as it was unlikely to change management (majority had amyloidosis). Other reasons included watchful waiting and patient's frailty.

Conclusions: Up to 30% of CKD patients with MG are not referred to a specialist. Co-morbidities lower the rate of referral whereas impaired kidney function and higher M-spike & FLC increase referral. However, once patients are referred, the comorbidities had no impact on who underwent biopsy. Most common reason for not pursuing a biopsy was lack of awareness that patient had CKD or MG.

P20185

Efficacy of Early Use of Double Filter-Based Extracorporeal Treatment Combined with Chemotherapy in Acute Myeloma Kidney Disease

Fulvia Zappulo,1 Gabriele Donati,1 Elisa Maietti,1 Anna Scervino,1 Giorgia Comai,1 Olga Baraldi,1 Lorenzo Gasperoni,1 Lucia Pantani,1 Elena Zamagni,1 Gaetano La Manna.1 1Nephrology Dialysis and Renal Transplantation Unit, S.Orsola University Hospital, Bologna, Italy; 2Biomedical and Neurormotor Sciences of University of Bologna, Bologna, Italy; 3Hematology and Oncology Unit, L. & A. Seràgnoli, S.Orsola University Hospital, Bologna, Italy, Bologna, Italy.

Background: Before the introduction of modern chemotherrapy, less than 25% of patients with AKI and Multiple Myeloma (MM) who required dialysis recovered sufficient renal function to no longer be on dialysis, with an overall survival of less than 1 year. Although impaired renal function has been a marker of poor prognosis there are may other factors involved in determining patient survival. We aimed to investigate the factors related to renal recovery and to an higher survival rate in MM patients.

Methods: A monocentric retrospective study was carried out enrolling 23 patients with biopsy-proven acute myeloma kidney and sFLC levels >1000 mg/l. Patients received Bortezomib-based chemotherapy and extracorporeal treatment for sFLC removal. For each session 2 dialyzers of the same kind were used and the dialytic dose was only related to the sFLC removal. The dialyzers had high absorptive properties: PMMA (poly(methylmethacrylate), Filtreytor BK-F 2.1 m2 cut-off 20 kDa); PEGA (poly ester polymer alloy; FDX or FYD 210-GW 2.1 m2, cut-off undisclosed).

Results: The factors that have been found to be significantly and independently associated with higher survival rate were: baseline serum albumin, reduction of sFLC at day 12 and day 30, reduction of sFLC at day 30 above 50%, number of session and dialysis independence.

Conclusions: Our analysis highlights the importance of the early treatment for removal of sFLC in AKI for MM. In fact the variable associated with higher survival rate are the reduction of sFLC at day 12 and day 30 and number of session. These results indicate that the early removal of sFLC can guarantee a better outcome. Baseline serum albumin is also associated with survival rate and it demonstrates that it still carries a prognostic value in the population with AKI. This finding suggests the importance of albumin-sparing extracorporeal treatments. In fact alternative techniques, as HD-HCO, have been proposed for sFLC removal but they present high costs and albumin leakage.
PO2186
Daratumumab for Management of Bortezomib-Resistant Monoclonal Gammapathy of Renal Significance
Salem Almaani, Samir V. Parikh, Naresh Bumma, Nidhi Sharma, Yvonne A. Efereba, Isabelle Ayoub. The Ohio State University Wexner Medical Center; Columbus, OH.

Background: The management of monoclonal gammapathy of renal significance (MGRS) is challenging. In our center, MGRS patients are initially treated with a bortezomib-based regimen. Patients who do not respond have very limited therapeutic options. Daratumumab is an anti-CD38 monoclonal antibody that is being increasingly used in patients with multiple myeloma with a favorable adverse effect profile, and represents a potential therapeutic option for patients with MGRS.

Methods: Retrospective review of the use of daratumumab in management of patients with bortezomib-resistant MGRS.

Results: Five patients were treated with daratumumab after receiving a variety of immunomodulatory therapies (Table 1). All received bortezomib with no response. One patient had a dramatic improvement in proteinuria with a stable renal function. One patient had resolution of glomerular monoclonal protein deposits but had persistent proteinuria due to significant damage to the glomerular basement membrane. One patient suffered from an acute kidney injury due to acute tubular necrosis (noted on biopsy) and became dialysis dependent. Two patients were started on daratumumab recently and had limited follow up, however both demonstrated a reduction in proteinuria. Daratumumab was well-tolerated and no patients required hospitalization due to adverse effects.

Conclusions: Our experience in using daratumumab for management of bortezomib-resistant MGRS suggests good tolerability and short-term response rates.

PO2187
Diffuse Background Monoclonal Light Chain Staining in Kidney Biopsies, Without Electron Dense Deposits: Is It Relevant?

YO Salem, J Am Soc Nephrol 31: 2020

Center, Columbus, OH

Background: The management of diffuse background monoclonal light chain staining is challenging in renal biopsy. Large experience indicates that diffuse background monoclonal light chain staining in the biopsy report, but by itself, should not be classified as MGRS. It does warrant a thorough hematologic work-up and may help to unmask previously unsuspected underlying active myeloma which many patients. But it is important to note that there is a subset of patients that do not have active myeloma despite the strong background staining. Care must be taken to avoid inadvertent immediate clone-directed therapy in these patients, but periodic monitoring with hematologic and renal parameters to watch for possible malignant transformation is important.

PO2188
Immune Checkpoint Inhibitor-Induced p-ANCA Multigranulat Vasculitis
Marelle Montanez,1,2 Jamie Lin,2 Omar Mamlouk,1,2 Alia Abudayyeh,2 William F. Glass.1 1University of Texas Health Science Center at Houston, Houston, TX; 2University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Use of immune checkpoint inhibitors (ICIs) has led to improved mortality in melanoma, lung cancer, and lymphoma. ICIs augment immunologic reaction against tumor cells via blockade of cytotoxic T-lymphocyte antigen-4 (CTLA-4), programmed cell death-protein 1 (PD-1), or programmed death-ligand 1 (PD-L1). Renal complications from ICi use are uncommon but can involve development of glomerular diseases and interstitial nephritis. Below we present a case of p-ANCA vasculitis in a patient on ICI therapy.

Case Description: A 52-year-old female with adenocarcinoma of the right lung (T2N2) s/p right lower lobectomy, cisplatin/vinorelbine, radiation therapy, and durvalumab was hospitalized for evaluation of new onset oral blisters, fevers, hemoptysis, skin lesions, and acute kidney injury. Her creatinine rose to 3.2 mg/dl (baseline of 0.5 mg/dl). Urimysis revealed >180 RBCs and 17 WBCs per high power field with a urine to protein ratio of creatinine (UPCR) of 2.63 g/g. ANCA titers were positive for PR-3 antibody of 4.6 units. Patient underwent renal biopsy, which revealed evidence of renal vasculitis involving all glomeruli and crescents in 4 out of 20 glomeruli. There was no evidence of endocarditis with vegetation seen on echocardiogram; however, with negative blood cultures the etiology was attributed to autoimmune (vasculitis) rather than infection. The patient was aggressively treated for ANCA vasculitis with pulse steroids, plasmapheresis, and rituximab (1g given 2 weeks apart). She had a dramatic improvement in her skin lesions, hemoptysis, cardiac and renal function. Two months following her last rituximab infusion, she has not had further hematuria, her UPCR remains < 0.5 g/day, and creatinine is stable at 1.2 mg/dl. PET/CT continues to demonstrate clinical remission of her underlying cancer.

Discussion: With the dramatic cancer responses seen in patients receiving immune checkpoint therapy, there has also increased understanding associated toxicities. Although reports of ANCA positive vasculitis from ICi has been reported; this case is unique due to the multigranulat involvement of her vasculitis including the heart valves. Aggressive treatment with steroids, plasmapheresis, and rituximab has proven effective without hindering her tumor response.

PO2189
IgA Nephropathy in the Setting of Dual Immune Checkpoint Inhibitor Use
Lorenz Leuprecht,1 Steven Salvatore,1 Victoria Gutgarts,2,3 Ilya Glezerman.2,1
1Weill Cornell Medicine, New York, NY; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Acute kidney injury (AKI) is a recognized side effect of immune checkpoint inhibitors (ICPI), with acute tubulointerstitial nephritis (AIN) as the foremost common pathologic finding. Risk of AKI is higher with use of proton pump inhibitors (PPIs) and dual ICPI use. Glomerular disease with ICPI is infrequently found on kidney biopsy. We report a case of concomitant IgA nephropathy and AIN associated with dual ICPI blockade.

Case Description: A 62-year-old male with metastatic sarcoma recently initiated on ipilimumab and nivolumab presented with dark colored urine for 2 days. He was recently hospitalized for neutropenic fevers with a negative infectious work-up. Admission blood pressure was 181/94 and he was afebrile. Physical exam was notable for new bilateral lower extremity edema, and no rash present. His creatinine was 2.2mg/dl (0.6-1.3), with a baseline creatinine of 0.8mg/dl. He started a PPI one month ago and denied NSAID use. Laboratory findings showed eosinophilia 7.7% (0.0-4.9) and urine eosinophils. His urinalysis had >50 RBCs and 5 WBCs per high power field and 24-hour urine protein was 5085mg. His serum complement levels were normal. Kidney biopsy showed moderate AIN and an exudative and mesangial glomerulonephritis with dominant IgA deposits. The patient was started on prednisone 60mg daily and PPI was stopped. No additional doses of immunotherapy were administered. His serum creatinine improved to 1.6mg/dl after 1 week, with plan for outpatient steroid taper. At 10mg prednisone daily, his creatinine increased to 4.5mg/dl prompting pulse steroids due to concern for ongoing interstitial inflammation versus worsening IgA nephropathy. One week later creatinine improved to 2.7mg/dl, though he developed several steroid related side effects. Due to inability to tolerate higher doses of steroids, mycophenolate was added to his treatment regimen while undergoing steroid taper.

Discussion: This case underscores the importance of considering acute glomerulonephritis as a cause for AKI in patients recently started on ICPI therapy. Risk of AKI in this patient was higher given use of PPI and dual ICPI therapy. This case is unique as the renal biopsy showed both AIN and IgA nephropathy. These findings had important implications for the treatment plan since the patient was unable to successfully stop prednisone and required a second immunosuppressive agent.
PO2190
Hypercalcemia Associated with Immune Checkpoint Inhibitors
Eshetu L. Obol, Isabelle Ayoub. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Immune checkpoint inhibitors revolutionized treatment of many cancers with marked improvement in prognosis. They target CTLA-4, PD-1/PD-L1 pathways. However immune related adverse events complicate their use. Here we present the case of AKI due to hypercalcemia as a result of immune checkpoint inhibitors.

Case Description: A 68-year-old man with metastatic renal cell carcinoma underwent right nephrectomy followed by immunotherapy with ipilimumab and nivolumab. Two weeks after his second cycle of immunotherapy, he presented with inflammatory arthritis and pruritis. Workup was significant for sCa 12.8 mg/dl and Scr 3.6 mg/dl. Hypercalcemia was suspected to be malignancy related from bone metastasis or humoral stimulation. He received fluids, calcitonin and Zoledronic acid. Further investigations showed a suppressed iPTH-6.3 pg/ml, normal PTrP, low TSH 0.04 uU/ml, free T4 1.91, normal 25-OH vitamin D, 1,25dihydroxy vitamin D 7.6 pg/ml and normal androgens. No monoclonal proteins were detected in serum. CRP and interleukin 6 were elevated to 80 mg/dl and 176 pg/ml respectively. PET scan showed diffuse hypermetabolic lymph nodes in mediastinum, neck, and abdomen. Transbronchial needle aspiration was negative for malignancy. Inflammatory arthritis, pruritis, hyperthyroidism, nonmalignant diffuse lymphadenopathy, and 1.25 dihydroxvitamin D induced hypercalcemia are suggested of immune related adverse effects rather than disease progression. Patient was started on prednisone 1mg/kg/d. Hypercalcemia, AKI, pruritis and inflammatory arthritis resolved.

Repeat 1.25 dihydroxvitamin D and CRP levels were back to normal.

Discussion: Hypercalcemia related to checkpoint inhibitors was previously described in setting of increased PTrP. Our patient had hypercalcemia directly related to immunotherapy likely through increased alpha hydroxylase.

PO2191
Double Trouble with Pembrolizumab: Immune Checkpoint Inhibitor-Induced Type I Renal Tubular Acidosis and Secondary Adrenal Insufficiency
Dayvan M. Adbor, Hafsa Tariq, Arash Rashidi. University Hospitals, Cleveland, OH.

Introduction: Pembrolizumab is a novel immune checkpoint inhibitor (ICI) that targets programmed cell death protein (PD-1) signaling. Checkpoint inhibitor associated nephrotoxicity is an immune-mediated process that can manifest with a variety of clinical presentations. Here, we report a unique case of Pembrolizumab induced distal renal tubular acidosis (RTA) and secondary adrenal insufficiency (AI) which was successfully treated with steroids.

Case Description: A 72-year-old male with a history of stage IIC malignant melanoma, who had recently completed 3 cycles of therapy with Pembrolizumab was admitted with generalized fatigue, weakness, and anorexia. Initial work up was notable for severe hypernatremia, and a non-anion gap metabolic acidosis (NAGMA). (Na: 120 mmol/L, Cl: 89 mmol/L, K: 3.8 mmol/L, HCO3: 20 mmol/L and Creatinine 6.7 mg/dL). Urine anion gap was positive at 8meq/L, urine osmolar gap was low at 57 mosm/kg and urine pH was 6.0. Subsequent laboratory work up was notable for AM cortisol of 1.0 ug/dL, serum ACTH 1.4 pg/mL and DHEA 12 ng/dl. Other pituitary hormones including LH, TSH, FSH, prolactin and insulin were normal. Histopathology revealed grade II chronic active T-cell mediated rejection (TCMR). With GIS. After a multidisciplinary discussion, he underwent transplant nephrectomy.

Discussion: Recent studies have shown that acute interstitial nephritis is the most common type of Pembrolizumab associated nephrotoxicity. We report a novel case of Pembrolizumab toxicity, where distal RTA concurrently manifests with secondary AI. Rapid resolution of both these conditions upon initiation of steroids suggests that they are both immune mediated adverse effects associated with Pembrolizumab.

PO2193
Immune Checkpoint Inhibitor Therapy-Related Graft Intolerance Syndrome in a Failed Kidney Transplant Recipient on Hemodialysis
Christina Irene Mejia, Adam M. Frank, Pooja Singh, Anju Yadav. Thomas Jefferson University, Philadelphia, PA.

Introduction: Immune checkpoint blockers (ICBs) are monoclonal antibodies against inhibitory receptors on T-cells resulting in anti-cancer activity. The use of ICBs among kidney transplant (KT) recipients and cancer is controversial, as ICBs can lead to immune tolerance and is associated with a higher risk of rejection in functioning allografts. In failed allografts, the effects of ICBs are unknown. We present a unique case of a patient with a failed KT on maintenance hemodialysis (HD) who developed graft intolerance syndrome (GIS) after ICPI therapy for metastatic renal cell carcinoma (RCC).

Case Description: Our patient is a 66-year-old male with a history of diabetes, RCC and left nephrectomy in 1996. He developed end-stage kidney disease and had a deceased donor KT in 2012. His graft failed 6 years post KT, due to biopsy-proven recurrent diabetic nephrosclerosis. He was started on HD in 2018 and immunosuppression was tapered off. In 2019, he was diagnosed with renal and urethelial cell cancer in the right native kidney and underwent nephrectomy. Ten months later, distant metastasis was detected, and he was started on Nivolumab and Ipilimumab. Twenty-eight days after his 1st cycle of immunotherapy, he had good oncological response, but developed gross hematuria, pain over his allograft, malaise, and anemia consistent with GIS. Urine culture and cystoscopy were normal. A computed tomography scan of the abdomen revealed an enlarged allograft with patchy enhancement and perinephric stranding consistent with GIS. After a multidisciplinary discussion, he underwent transplant nephrectomy.

Discussion: Although acute graft rejection from ICPI therapy has been documented, this is the first known report of GIS developing with ICPI therapy in a failed allograft. GIS typically occurs within 6-12 months of graft failure. Meanwhile, in functioning allografts, GIS is usually related to allograft rejection or acute cellular rejection. In our case, GIS developed after ICPI initiation. The temporal relation of GIS to ICPI initiation in our patient suggests the potential role of the latter as a trigger for GIS. As ICPI use becomes more prevalent in cancer management, we need to be aware of the potential complications with its use among KT recipients even with failed allografts, which requires multidisciplinary management.

PO2194
Crescentic Glomerulonephritis and Phospholipid A2 Receptor-Positive Membranous Nephropathy in a Lung Cancer Patient on an Immune Checkpoint Inhibitor
Matthew Abramson,1 Surya V. Seshan,2 Insarra Jaffer Sathick.1,2 Memorial Sloan Kettering Cancer Center, New York, NY; Weill Cornell Medicine, New York, NY.

Introduction: Acute kidney injury (AKI) occurs in 3% of patients on immune checkpoint inhibitors (ICPI), usually due to interstitial nephritis, yet the array of ICPI-mediated AKI is not fully understood, with rare reports due to Crescentic Glomerulonephritis (cGN). To date there is no known case of PLA2R-positive Membranous Nephropathy (MN) associated with ICPI. Here we report the first case of ANCA-negative cGN with PLA2R MN, which developed after initiation of ICPI, with response to rituximab (RTX).

Case Description: Nephropathy was confirmed for AKI and hematuria in a 67-year-old male smoker with lung adenocarcinoma. He started on pembrolizumab and pemetrexed 8 months ago, last dose 3 weeks prior to consult. He developed thrust irrigation from local irradiation, and pantophobia was initiated. No NSAIDs, herbal medications or iodinated contrast exposure. Prior to treatment, baseline Creatinine (Cr) was 1.1 mg/dl, and urinalysis was negative for proteinuria. NIH SLE criteria was 11/12, and no edema was present. Cr was elevated at 3.7 mg/dL. UA showed +3 protein, >50 RBC, 10-25 WBC, and no pathologic casts. Renal sonogram was normal. Protein:creatinine ratio (UPC) was 1.52g/l. Complements were normal. Serology workup was negative. PET-CT showed diffuse cGN.[Glomeruli: necrosis (2/38), cellular crescents (10/38), and fibrocellular crescents (18/38)]. Protein:creatinine ratio (UPC) was 1.52g/l. Complements were normal. Serology workup was negative. PET-CT showed diffuse cGN.[Glomeruli: necrosis (2/38), cellular crescents (10/38), and fibrocellular crescents (18/38)].
PO2195
Diffuse Large B-Cell Lymphoma Presenting with Light Chain Cast Nephropathy: A Case Report
Shen-Li Cho,1 Hao-Yu Wu,1 Tai-Chung Huang,1 Tzong-Shinn Chu,1 Taomin Huang,1,2 Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 2Department of Epidemiology and Preventive Medicine, National Taiwan University College of Public Health, Taipei, Taiwan.

Introduction: Light chain cast nephropathy is caused by filtration of excessive amounts of free light chains into the renal tubules, leading to acute kidney injury (AKI). The most associated cell lineage is multiple myeloma (MM). Non-associated cases of cast nephropathy associated with diffuse large B-cell lymphoma (DLBCL) were reported.

Case Description: A 55-year-old previously healthy man presented with foamy urine for 3 months and exercise intolerance. Physical exam showed pale conjunctiva, multiple neck masses, and no edema. His serum creatine (Scr) was 7.6 and 15.2 mg/dL initially and on admission 4 weeks later, whereas baseline Scr had been normal one year ago. His hemoglobin level was 7.9 g/dL, and white blood cell count was 8750/mumL without esophagitis. No active urine sediments were found. A UPCR was 7250 mg/g, and a UPCR 300 mg/mumL. Ultrasound showed decreased kidney sizes (R 9.0, 4.7 cm). Immuno-electrophoresis detected monoclonal λ light chain in both his serum and urine, and a serum λ free light chain level was 8830 μg/mL, with a k-to-λ ratio of 0.0024. Following a diagnosis of DLBCL (Lugano stage IV) by neck mass biopsy, a renal biopsy disclosed diffuse aggregation of amorphous eosinophilic proteinaceous casts in the tubules, with a normal glomerular compartment and mild arteriosclerosis, findings consistent with IgG-λ light chain cast nephropathy. He was treated with 4 courses of R-CHOP, hemodialysis, and a short course of plasmapheresis, thereby spiking his creatinine to 2830 μg/mL after 4 months. His complete response for DLBCL was achieved 6 months later but he remained on hemodialysis.

Discussion: This is, in the literature, the first adult DBLCL patient presenting with proteinuria and renal deterioration proven to be light chain cast nephropathy. Standard lymphoma treatments were given, and based on limited evidence, plasmapheresis was given to reduce the light chain load (Median serum free light chain level was 6590 mg/mL in MM patients as reported by Bridoux in JAMA 2017). Decreasing plasma light chain concentration leading to improvement in AKI has been reported for MM. However, this case remained dialysis-dependent despite a decline in light chain levels. To conclude, we provide a unique case of DLBCL with cast nephropathy. Clinicians could take this entity into consideration and treatment may be tailored for better outcomes.

PO2196
A Case of Mixed Cryoglobulinemia Type II with Monoclonal Gammopathy in a Patient with Chronic Hepatitis B
Hui Zhan Tan, Chandramouli Nagarajan, Alwin Hwai Liang Loh, Ricce Koniman, Jason Choo Chon Jun. Singapore General Hospital, Singapore, Singapore.

Introduction: Non-Hepatitis C related mixed cryoglobulinemia Type II (MCT2) is rare. Causes include lymphoproliferative disorders, chronic infections like Hepatitis B and autoimmunity.

Case Description: A 68-year-old Chinese male presented with livedo reticularis and autoimmunity. He was a chronic hepatitis B carrier with chronic hepatitis B infection. His liver function tests were within normal limits and HBsAg was positive. He was treated with interferon therapy for hepatitis B 15 years ago. The patient presented with headache, fatigue, arthralgia, myalgia, rash, and Raynaud's phenomenon. He was diagnosed with MCT2 by a minor criterion of non-HCV-related mixed cryoglobulinemia (MCT2). He was treated with oral prednisolone 10 mg/day for 4 months. After 4 months, his clinical symptoms and laboratory parameters improved. The patient was maintained on chemotherapy and hemodialysis, and he died 8 months after renal biopsy.

Discussion: A 54-year-old Chinese man presented with a 4-year history of multiple myeloma, proteinuria and hematuria. He had Monoclonal IgAλ, plus free λ spike in both serum and urine. He was treated with chemotherapy. His serum creatinine was normal until 11 months before admission, and he was on hemodialysis for 3 months before admission. Renal biopsy showed diffuse amyloid casts in the tubular lumen, and he had no obvious amyloid deposits in other kidney compartments and no sign of extra-renal amyloidosis. The amyloid fibrils formed around mononuclear cells which were IgM kappa positive. The patient was treated with chemotherapy and hemodialysis, and he died 8 months after renal biopsy.

Case 2: A 58-year-old Chinese man presented with a one-and-a-half-year history of proteinuria and slowly rising serum creatinine. He had Monoclonal IgDλ spike in both serum and urine. Amyloid casts were observed in the tubular lumens and in the centre of some casts were mononuclear cells. There were no amyloid deposits in other kidney compartment and no sign of systemic amyloidosis. The patient also had fine granular deposits along the tubular basement membrane with linear staining along tubular basement membrane suggestive of IgA to IgM amyloid. He was treated with chemotherapy and achieved very good partial remission (VGPR). After twenty-seven months of follow-up, the patient still had no sign of systemic amyloidosis.

Discussion: These 2 cases of MCT2 with cast nephropathy have different pathologic characteristics from the usual myeloma casts and tubular epithelial cells may play important roles in the pathogenesis.

PO2197
Myeloma Cast Nephropathy with Diffuse Amyloid Casts: Two Case Reports and Literature Review
Zhihao Yong,1,3 Yu Xiaojuan,1 Su-xia Wang,1,2 Ming Hui Zhao.1,3 Renal Division, Department of Medicine, Peking University First Hospital; Institute of Nephrology, Peking University; Renal Pathology Center, Institute of Nephrology, Peking University; Key laboratory of Renal Disease, Ministry of Health of China; Key Laboratory of CKD Prevention and Treatment, Ministry of Education of China; Beijing, China; Laboratory of Electron Microscopy, Pathological Centre, Peking University First Hospital, Beijing, China; 3Peking-Tsinghua Center for Life Sciences, Beijing, China.

Introduction: Multiple myeloma (MM) is a plasma cell derived hematologic malignant disease. The malignant proliferating plasma cells can secrete massive monoclonal immunoglobulins which can cause various pathologic types of renal injury. Myeloma cast nephropathy (MCN) is the most common pathologic lesion with the worst renal prognosis. Rarely, the free light chains in the protein casts can form amyloid fibrils. Here, we report two rare cases of myeloma cast nephropathy with diffuse amyloid casts.

Case Description: Case 1: A 54-year-old Chinese man presented with a 4-year history of multiple myeloma, proteinuria and hematuria. He had Monoclonal IgAλ, plus free λ spike in both serum and urine. He was treated with chemotherapy. His serum creatinine was normal until 11 months before admission, and he was on hemodialysis for 3 months before admission. Renal biopsy showed diffuse amyloid casts in the tubular lumen, and he had no obvious amyloid deposits in other kidney compartments and no sign of extra-renal amyloidosis. The amyloid fibrils formed around mononuclear cells which were IgM kappa positive. The patient was treated with chemotherapy and hemodialysis, and he died 8 months after renal biopsy.

Case 2: A 58-year-old Chinese man presented with a one-and-a-half-year history of proteinuria and slowly rising serum creatinine. He had Monoclonal IgDλ spike in both serum and urine. Amyloid casts were observed in the tubular lumens and in the centre of some casts were mononuclear cells. There were no amyloid deposits in other kidney compartment and no sign of systemic amyloidosis. The patient also had fine granular deposits along the tubular basement membrane with linear staining along tubular basement membrane suggestive of IgA to IgM amyloid. He was treated with chemotherapy and achieved very good partial remission (VGPR). After twenty-seven months of follow-up, the patient still had no sign of systemic amyloidosis.

Discussion: These 2 cases of MYC with diffuse amyloid casts have different pathologic characteristics from the usual myeloma casts and tubular epithelial cells may play important roles in the pathogenesis.

PO2198
Masked Light Chain Proximal Tubulopathy (LCTP) and Focal Segmental Glomerulosclerosis (FSGS) in Multiple Myeloma (MM)
Matthew Abramson,1 Surya V. Seshan,2 Carlos D. Flombaum,1,3 Memorial Sloan Kettering Cancer Center, New York, NY; Weill Cornell Medicine, New York, NY.

Introduction: Patients with MM often do not have a myeloma-defining disease, and delayed recognition/treatment of a monoclonal gamopathy of renal significance (MGRS) may confer worse renal outcome. Here we report 3 patients with “masked” LCTP (one also had FSGS) and a 4th patient with both FSGS and LCTP. None had crystalline deposits. All 4 patients had a history of untreated, smoldering MM and the initial kidney biopsy interpretation in 3 of the cases reported no evidence of MGRS. Treatment of the underlying MM resulted in improvement of renal parameters in all, suggesting MM as the etiology for the renal disease.

Case Description: 75 y/o, worsening renal function (WRF), albuminuria and monoclonal proteinuria (MP). Biopsy: FSGS. Initial immunofluorescence (IF) was negative. Re-examination after prostate digestion 6 months later: LCTP. Therapy for MM resulted in decreasing freem light chains (FLCs), decreasing renal function, and decreased albuminuria and MP 72 y/o, WRF and albuminuria. Biopsy: FSGS and LCTP attributed to MM. Therapy for MM resulted in decrease in FLCs, stabilization of renal function and decreased albuminuria. 75 y/o, WRF and heavy MP. Biopsy: diabetic nephropathy with interstitial inflammation. IF was negative. Following autologous stem cell transplant for progression to symptomatic MM, there was a striking improvement in FLCs, renal function and MP 73 y/o, WRF, heavy MP and Fanconi’s syndrome. Biopsy: mild glomerulomegaly and focal sparse lysocytic infiltrates. Initial IF was negative. Re-examination after prostate digestion 6 months later: LCTP. Therapy for MM resulted in decreasing FLCs, improvement of renal function and improvement in renal markers. The patient remained asymptomatic.

Discussion: FSGS has been rarely linked to MM. In view of the connection between treatment of the MM and improvement of the renal parameters, FSGS must be considered as an additional MM-related MGRS. The presence of monoclonal light chains (LCs) in the tubular epithelial cells (TECs) should raise the possibility of this diagnosis. Because monoclonal LCs deposits in TECs may not be detectable by standard IF techniques (“masked” LCTPs), paraffin IF after prostate digestion should always be performed in the setting of the underlying lymphoproliferative disease causing monoclonal gamopathy of renal significance (MGRS). Early treatment of MCT2 is not established, although immunosuppression consisting of corticosteroids with Rituximab or cyclophosphamide is required in severe renal involvement. We demonstrated a favourable outcome with Bortezomib-based clone directed therapy after achieving a non-sustained response with Rituximab/prednisolone. Long-term monitoring of the underlying low grade non-Hodgkin’s lymphoma (NHL) is necessary.
kidney biopsies of patients with monoclonal gammopathies. In addition, detailed EM examination of the tubules is essential to identify the lysosomal abnormalities typical of LCPT.

PO2199

CKD After 225Ac-PSMA617 Therapy in Patients with Advanced Metastatic Prostate Cancer: A Report of Two Cases

Karyne Pelletier, Gabrielle Côté, Abhijat Kitchlu. University Health Network, University of Toronto, Toronto, ON, Canada.

Introduction: A promising therapeutic efficacy has been demonstrated with targeted radionuclide therapy (TRNT) using 225Ac-PSMA617 in patients with advanced metastatic castration-resistant prostate cancer (mCRPC). However, these novel agents may be associated with significant toxicity. As seen in animal models, the multiple alpha particles generated in the decay chain of 225Ac may accumulate in the renal tubular cells, resulting in nephropathy. We report our experience with 225Ac-PSMA617 therapy in 2 patients with advanced mCRPC who developed kidney injury.

Case Description: Patient 1: a 68-year-old man with widely metastatic mCRPC despite multiple lines of therapy and secondary chronic hydropnephrosis with bilateral nephrostomy tubes. He received 3 rounds of 225Ac-PSMA617 in 2-month intervals. Baseline serum creatinine was 1.6 mg/dL (GFR 44 mL/min/1.73m²) and it increased up to 3.3 mg/dL (GFR 18 mL/min/1.73m²) after 225Ac-PSMA617 therapy. A kidney biopsy was obtained and revealed severe interstitial fibrosis with ongoing tubular injury and interstitial inflammation. A trial of corticosteroids therapy was attempted with no improvement in kidney function. 225Ac-PSMA617 therapy was discontinued because of related kidney failure. Patient 2 is a 67-year-old man with mCRPC with progression on multiple prior therapies. He first initiated Lu177-PSMA and one year later was combined with 225Ac-PSMA617 in 2-month intervals. He received 5 rounds of 225Ac-PSMA617 in total, the last round being complicated with grade 3 proteinuria leading to cessation of treatment. Baseline serum creatinine at initiation of TRNT was 1.0 mg/dL (GFR 82 mL/min/1.73m²). He subsequently developed progressive CKD and serum creatinine was 1.7 mg/dL (GFR 40 mL/min/1.73m²) on last follow-up.

Discussion: We report 2 cases of progressive kidney disease in the setting of 225Ac-PSMA617 therapy for patients with advanced mCRPC. One underwent kidney biopsy showing tubulointerstitial injury, consistent with 225Ac-PSMA617-related tubular accumulation of toxic nuclides seen in animal models. This kidney injury was not responsive to corticosteroids therapy. Our case studies emphasized the need for careful assessment and monitoring of kidney function in patients receiving these novel agents.

PO2200

Successful Management of Chronic Ifosfamide Nephrotoxicity with Immunosuppression: A Case Series

Sankalp Malhotra,1 Jason Prosek.2,3 The Ohio State University, Department of Internal Medicine, Columbus, OH; 1The Ohio State University, Division of Nephrology, Columbus, OH.

Introduction: Ifosfamide is an alkylating chemotherapeutic agent that causes both acute and chronic kidney injury. Ifosfamide-induced chronic tubulointerstitial nephropathy was re-evaluated after exposure, therapy delaying diagnosis, and treatment. Here, we describe three cases of chronic ifosfamide nephrotoxicity, wherein the time-course and outcomes suggest that earlier recognition and initiation of immunosuppression may benefit these patients.

Case Description: Three adult patients with distinct malignancies, status-post at least 3 cycles of ifosfamide chemotherapy, presented to our onco-nephrology clinic for worsening renal function. On average, the patients were referred to our clinic ~8 months after their last dose of ifosfamide. In this period, their serum creatinine (SCr) had risen to a peak of ~2.5mg/dL from ~1mg/dL. The patients reported occasional frothy urin but were otherwise asymptomatic. Urine analysis and microscopy was significant for mild glucosuria/proteinuria, sterile pyuria, and granular casts, with urine protein/creatinine ratio of ~1.2. Autoimmune serologies, complement levels, protein electrophoresis, and renal ultrasound were unremarkable. Kidney biopsies, performed 10 months after the last ifosfamide cycle, demonstrated tubulointerstitial nephritis with moderately advanced interstitial fibrosis. Cytologic atypia of the tubular epithelium was consistent with karyomegaly interstitial nephritis (KIN), previously documented in cases of ifosfamide toxicity. In these cases, prednisone therapy led to improvement and plateau of SCr ~2.1. Curiously, multiple attempts to wean corticosteroids led to worsening SCr and active urinary sediment. In 2 patients, addition of mycophenolate mofetil enabled dose reduction but not cessation of corticosteroids. In all cases, SCr remained stable at ~2.1 after 1 year of follow-up.

Discussion: These cases illustrate the latent presentation and challenging management of chronic tubulointerstitial nephritis secondary to ifosfamide. On average, prednisone was started ~10 months after the last ifosfamide dose, when significant interstitial fibrosis had already developed. Subsequent therapy and ongoing inflammation may have also contributed to the failure to stop corticosteroids. Overall, early surveillance, prompt recognition, and long-term immunosuppression is likely important in these patients to stabilize and maintain renal function.

PO2201

Hyperphosphatemia in the Setting of Fibroblast Growth Factor Inhibitor Inhibitors

Shahraz Zonoobi,1 Bader Kfouri,2 Abdullah Sassine Geara,1,2 Pennsylvania Hospital, Philadelphia, PA; 1Hospital of the University of Pennsylvania, Philadelphia, PA.

Introduction: Fibroblast growth factor (FGF)-23 is a phosphaturic hormone which works by reducing apical membrane expression of sodium-phosphate co-transporters in the proximal renal tubule and thus decreasing phosphate re-absorption. Fibroblast growth factor receptors (FGFR) are ubiquitously expressed in different tissues and become activated in various types of cancer. TAS-120 is one of several pan-FGFR inhibitors currently in clinical trials for use in patients with cholangiocarcinoma. Hyperphosphatemia is seen in more than 70% of patients on this therapy.

Case Description: A 44-year-old female with metastatic intrahepatic cholangiocarcinoma with progressive disease despite conventional therapy was started on TAS-120. Fifteen days into treatment she developed pain in knees and hips and was noted to be hyperphosphatemic to 7 mg/dL. She was initiated on sevelamer but given persistent hyperphosphatemia to 6.4 mg/dL, acetazolamide, calcitomin and phytodiolinates were added. Despite this, phosphorus remained elevated at 5.8 mg/dL; addition of alendronate 35mg weekly alongside dose reduction of TAS-120 led to sustained improvement in serum phosphorus levels. A 49-year-old male with a history of cholangiocarcinoma was started on TAS-120. Four days into treatment he developed calf pain and was noted to be hyperphosphatemic to 7.3 mg/dL. The medication was briefly stopped and he was initiated on sevelamer with improvement in phosphorus to 2.7 mg/dL. Resumption of TAS-120 led to recurrent hyperphosphatemia for which acetazolamide was initiated. Three months after initiation of TAS-120 he had ongoing hyperphosphatemia; following dose reduction of TAS-120 and starting phytodiolinates, probencid and calcitomin, serum phosphorus levels remained within normal limits.

Discussion: FGFR-induced hyperphosphatemia has a similar clinical presentation as hyperphosphatemic familial tumoral calcinosus (HFTC) with debilitating joint pain and tissue calcification. The current management of hyperphosphatemia relies mainly on dietary modification and gastrointestinal phosphate binding that were insufficient for our patients. The hyperphosphatemia and calciphylaxis pain was successfully treated with phosphaturic medications (acetazolamide, calcitomin) and alendronate. Phytodiolinates (vitamin K) interfere with matrix Gla protein, a tissue inhibitor of calcification.
PO204
Should We Give the Green Light to Green Top Tube? Reverse Pseudohyperkalemia in Leukemia Patient
Ming-Jen Chan, Chung Gong Memorial Hospital, Taoyuan, Taiwan.

Introduction: Here we described a 69-year-old woman presented with hyperleukocytosis with reverse pseudohyperkalemia. This is also the first case of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytic leukemia.

Case Description: The 69-year-old woman was rushed to our emergency department due to progression of dyspnea for one week. Upon lab examination, hyperleukocytosis (> 500000/uL) with blasts that suggestive of acute leukemia. Notably, marked hyperkalemia (11.6 mEq/L) with normal renal function was noted but there is no typical electrocardiogram change. High LDH (3393 U/L) and low haptoglobin (< 8.8 mg/dL) also noted. After clarification, the blood tube that had result of hyperkalemia is sodium heparin (green top) tube. We restated potassium by using serum separate tube with 5 minutes of 5000 revolutions per minute, revealing serum potassium level 3.8 mEq/L. Reverse pseudohyperkalemia was impressed. She received leukapheresis and chemotherapy for leukostasis. The bone marrow biopsy later confirmed Philadelphia chromosome positive acute lymphoblastocytic leukemia. Reverse pseudohyperkalemia resolved after leukocyte return to normal level.

Discussion: Pseudohyperkalemia is suspected when the measured potassium is high but the patient does not manifest signs of hyperkalemia, such as abnormal electrocardiogram. Pseudohyperkalemia is falsely elevation of serum potassium levels without elevation of plasma potassium levels, commonly occurred in patients with hematological disease. Heparin anticogulated plasma samples provide more accurate measurement of the true potassium level in these patients and sodium heparin (green top) tube is widely used. However, in reverse pseudohyperkalemia, serum potassium is within normal range, and plasma potassium falsely elevated, such as in our patients. The heparin in the plasma collection tube causes damage to the cell membrane during processing and centrifugation in the context of fragile cells of hematologic malignancy. Reverse pseudohyperkalemia had been reported in chronic lymphocytic leukemia patient. To our knowledge, this is the first case report of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytic leukemia patient. This case reminds us that potassium obtained using heparin tube is not panacea to get accurate level, and reverse pseudohyperkalemia is a must-known phenomenon for clinicians.

PO2203
Attack of the Clones: Leukemia and Myeloma
Sara Wong, Shreyas Patel, Elizabeth A. Alaimo, Shanaz Azad, Pankaj Jain, Tauseef A. Sargurkar. Francisca Health Inc, Mishavaka, IN.

Introduction: Chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) are both neoplastic diseases that are monoclonal tumors of differentiated B-cells that rarely occur simultaneously. There is disagreement and conflicting evidence as to whether these seemingly distinct disorders may arise from identical clones. In some cases MM may be diagnosed up to 15 years after the established diagnosis of CLL. We describe a rare case of a patient with renal failure and nephrotic range proteinuria where both CLL and MM were diagnosed concomitantly from a single renal biopsy.

Case Description: 59 y/o Indian male with COPD, DM-type 2, HTN, recent pseudomonas aeruginosa pneumonia presented with bilateral temporal headaches and fevers. Work-up revealed creatinine: 1.7mg/dL, UPCR: 6.6 g/g, free kappa/lambda ratio of 0.25 and mildly depressed C3 and C4. Renal biopsy showed diffuse proliferative and crescentic glomerulonephritis with IgG lambda light chain restriction, CD-20 positive subepithelial hump-shaped deposits and abundant glomerular neutrophils suggesting crescentic glomerulonephritis. At the same time, we also found focal lymphocyte infiltration, light chain amyloidosis. At the same time, we also found focal lymphocyte infiltration, which are confirmed of nodal marginal zone B-cell lymphoma and three different types of cast nephropathy present simultaneously in patient with multiple myeloma.

Discussion: CLL is a common hematologic malignancy that has many systemic complications. Autopsies have shown that 90% of CLL patients have renal infiltration; however there is seldom renal impairment. This is a rare case of renal CLL infiltration causing type-I cryoglobulinemia with IgG lambda monoclonal gammapathy of renal significance. Early diagnosis with renal bone marrow biopsy and subsequent treatment with immunosuppressive therapy is crucial.

PO2206
Breast Cancer-Associated Podocytopathy

Introduction: Podocytopathies such as FSGS have not been classically associated with solid malignancy. Here we present a case of a female with a diagnosis of FSGS and its association bilateral lobular carcinoma in situ of the breast.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

673
Case Description: A 52 year old Sri Lankan female with history of DM2 (with no prior proteinuria) was referred for sudden onset of proteinuria. The patient first reported profound foamy urine in October 2017 with workup significant for sub-nephrotic proteinuria of 2 g of normal serum creatinine and albumin. A kidney sonogram was unremarkable. Further workup was negative for infectious, autoimmune, vasculitis and anti-glomerular basement membrane (GBM) antibodies. The patient was started on Lisinopril 10mg, however proteinuria worsened to 12.6 gms thereby switch to losartan (100mg daily) with slight improvement in proteinuria. A kidney biopsy was performed which showed focal global glomerulosclerosis secondary to adaptive changes with minimal fibrosis with no diabetic nephropathy related changes seen. Light microscopy showed globally sclerosis (9%) and IFTA (5-10%). Immunofluorescence microscopy showed no evidence of primary podocyte disease, immune complex-mediated disease or para-protein deposition disease. The patient was managed conservatively on anti-proteinuriac agent. Almost a year after the diagnosis of FSGS, patient was diagnosed with bilateral lobular carcinoma in situ (breast) with atypical lobular hyperplasia. She underwent lobectomy and started on anastrozole. Following cancer surgery and initiation of hormonal therapy, she noticed resolution of her fatigue, urine foamy and proteinuria (repeat U/P/Cr <23 mg (Figure 1)).

Discussion: Our case demonstrates a potential link of the diagnosis of lobular ductal cancer of the breast with a diagnosis of FSGS. Interestingly, the FSGS diagnosis preceded the diagnosis of the breast cancer. While the proteinuria came into partial remission with conservative management, a dramatic resolution of FSGS was noted post-surgery and hormonal therapy for the breast cancer.

PO2207
Snapshot of AKI Profile in Patients in Oncology Settings: A Single-Center Experience
Girish Pratap Murthy,1,2 Praveen Kumar Koppula,1 Rajasekara C. Madarasa.3 RENOWN Clinical Services, Hyderabad, Telangana, INDIA.1 Basavatarama Indo-American Cancer Institute and Research Centre, Hyderabad, India; 2RENOW Clinical Services, Hyderabad, India.

Introduction: Acute kidney injury (AKI) may result from the cancer itself, treatment of cancer or associated complications. In cancer patients with AKI complete recovery of renal function was seen in 82% and chronic dialysis was needed in 6% of patients. Overall severity of illness, age, and functional status have more of an impact on prognosis than underlying malignancy, and the presence of cancer may not be an absolute exclusion criterion for withholding RRT. Hospital mortality approaches 80% in cancer patients with AKI. Cancer associated AKI (CA-AKI) is very prevalent with reported incidence of 12% to 49%. We tried to look into incidence, etiology and outcome of AKI in a tertiary cancer hospital.

Case Description: For two consecutive months all patients admitted in ICU at Basavatarama Cancer Hospital were observed for development of AKI with K/DOQI criterion. We found 45 patients who developed AKI out of 83 total ICU admissions (54.21%). Chronic kidney disease was present in 17 patients (37.77%), diabetic kidney disease being the commonest (64.70%), amongst whom either it was sepsis (77.8%) and septic shock was present in majority of these patients (66.7%). Other causes of AKI were hypercalcemia (4.4%), chemotherapy associated (44.4%), obstructive nephropathy (8.9%), metabolic acidosis was predominant finding (75.6%) and oliguria being least common (26%). Hematological malignancies were frequently associated with AKI (33.3%) followed by gastrointestinal tract tumors (24.4%). Urological malignancies were least associated with AKI (6.6%). Large number of patients required renal replacement therapy (RRT) (48.9%). SLED was commonest modality (n=15; 68.18%) of RRT followed by CRRT/CVVHD (N=8; 34.78%). Regional citrate anticoagulation was commonest anticoagulation used (62.5%). 46% patients recovered their renal functions but creatinine did not reach baseline for 11% of patients. 29% patients with AKI died and a 14% of patients lost to follow up. CRRT was associated with better survival (n=4; 50%) followed by SLED (n=4; 26.66%).

Discussion: Incidence of AKI was higher among patients in oncological ICU with half of them required RRT. Commonest etiology of AKI was sepsis where shock state was observed in majority of patients. Although SLED was used more frequently, outcomes were better with CRRT/CVVHD.
Discussion: Narsoplimab is a human monoclonal antibody that inhibits mannann-binding lectin associated serine protease-2 (MASP-2) which is an essential enzyme in the complement system leading pathway. It is designed to prevent endothelial injury without interfering with other complement pathway roles. Data from phase 2 study showed an improvement in patient survival and TMA blood markers (LDH, haptoglobin, and platelet count). It might improve renal function as well as its inhibition to lectin activation pathway can ameliorates proteinuria induced kidney injury. However she did not improve in her platelet count, LDH and C5b9 levels. Further studies are ongoing (Phase 3 trials in IgA nephropathy and HSC-TMA) to evaluate such renal benefits.

PO2210
The Histopathologic Spectrum of Kidney Biopsies in Patients with Thymoma, Myasthenia Gravis, or Both: A Report of 24 Cases from a Single Institution
Akira Takahashi, Takamasa Miyauchi, Narihito Tatsumoto, Michifumi Yamashita. Cedars-Sinai Medical Center, Los Angeles, CA.

Introduction: Nephropathy in patients (Pts) with thymic diseases such as thymoma and myasthenia gravis (MG) is rare and has been the subject of case reports. Previously, 93 cases have been reported from multiple institutions, and of these, common diseases are minimal change disease (MCD; 45.2%), membranoproliferative GN (MPGN; 19.4%), and primary focal segmental glomerulosclerosis (FSGS; 9.7%). Here we characterize the spectrum of kidney biopsy findings in 24 cases from a single institution.

Case Description: Total 40,268 renal biopsy cases from 2005 through 2019 at Cedars-Sinai Medical Center were reviewed. 24 cases (0.0596%) of Pts have history of thymoma and/or MG. Main pathological diagnoses are following: MCD (10 cases; 41.7%), Tubulointerstitial nephritis (TIN; 3 cases; 12.5%), Immune complex-mediated glomerulonephritis (ICGN; 2 cases; 8.3%); Diabetic glomerulosclerosis (2 cases; 8.3%); acute tubular necrosis/interstitial nephritis (ATIN) with myoglobin casts (2 cases; 8.3%); AT/ATIN (1 case; 4.2%); IgA nephropathy (1 case; 4.2%); MN (1 case; 4.2%); secondary FSGS (1 case; 4.2%); and Monoclonal Ig deposition disease (1 case; 4.2%).

Discussion: Consistent with previous reports, MCD is the most common renal lesion in Pts with thymic diseases. However, we experienced only one case of MN and no primary FSGS, the 2nd and 3rd common diseases in the reports. We, instead, observed kidney diseases that haven’t been reported before: TIN, and AT/ATIN with myoglobin casts. Of TIN cases, 1 showed granulomatous interstitial inflammation without infection; and 1 case showed acute tubulitis with immune complex deposits both in mesangium and along tubular basement membranes. In addition, 40% of MCD cases showed an atypical feature: IC deposits in mesangial area. The possible mechanisms of thymic disease-associated nephropathy include T cell dysregulation, IC formation containing tumour antigen, and effects of tumor-releasing lymphokines. In conclusion, this is the largest and unique case series of nephropathy in Pts with thymic disease from a single institution.

PO2211
Erdheim-Chester Disease: A Rare Cause of Bilateral Renal Artery Stenosis and AKI
Ng Ng,1,2 Saw Yu Mon,1,3 Rachael O’Rourke,4,5 Nigel Mott,3 Touroa Tabers,6,7 Kirk Morris,6,8 Pedro H. Gois,9,10 Kitchen Health Service, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 2Faculty of Medicine and Institute for Molecular Bioscience, University of Queensland, Brisbane, QLD, Australia; 3Medical Imaging, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 4Medical Imaging, Prince Charles Hospital, Brisbane, QLD, Australia; 5Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; 6Pathology Queensland, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; 7Department of Cancer Services, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia.

Introduction: Erdheim-Chester disease (ECD) is a rare, non-Langerhans cell histiocytosis affecting multiple organ systems. We report a case of ECD with bone involvement affecting multiple organ systems. We report a case of ECD with bone

Discussion: The disease affects renal arteries in 18-27% cases and should be considered as a cause of renal artery stenosis in older patients with multisystem anomalies. Renal artery stenting in this subset can improve hypertension and renal outcomes. The disease has characteristic radiological findings and the diagnosis is frequently reliant on imaging. Histological examination is often not sufficient to confirm the diagnosis. ECD diagnosis is essential for treatment of the underlying disease process.

PO2212
Renal Involvement as Initial Presentation of Mantle Cell Lymphoma: A Case Series
Ibrahim El Halabi,1 Natasha Riguai Soler,1 Elvira O. Gostanova,2 Swati Mehta, Andrea R. Lightle,1 Tony H. Salmond,1 Mauricio Monroy,1,2 Albany Medical College, Albany, NY; 2Albany Stratton VA Medical Center, Albany, NY.

Introduction: Mantle cell lymphoma (MCL) rarely affects kidneys. We present 2 cases with different spectrum of kidney involvement in MCL.

Case Description: The 1st case was a 63-yr old male with incidental finding of Serum creatinine (SCr) of 10mg/dL. Chronic lymphocytic leukemia was diagnosed 2 weeks prior via peripheral blood analysis & Bow flow cytometry (FC) done due to constitutional symptoms and headaches for which he was using daily ibuprofen for several months. On exam he had elevated blood pressure but no signs of volume overload. Initial supportive treatment did not improve kidney function and hemodialysis was initiated due to worsening azotemia and persistent nausea and vomiting suspicious for uremia. Renal biopsy showed diffuse acute on chronic interstitial nephritis with perivascular lymphoid aggregates of monoclonal CD 20+ B-cells positive for CD5 and Cyclin-D1 consistent with MCL. No significant immunostaining was found. Bone marrow biopsy confirmed renal biopsy findings and diagnosis of MCL. Until last follow up, the patient refused chemotherapy and remained on maintenance dependent. The 2nd case was a 73-yr old male with incidental finding of SCr of 1.9mg/dL in association with glomerular hematuria and grade A3 proteinuria. He had no constitutional symptoms and had normal physical exam except for presence of diffuse lymph node (LN) enlargement. Renal biopsy was obtained and showed MPGN-pattern with 25% crescents on light microscopy, presence of all immunoglobulin classes with k-light chain (KLC) predominance in glomeruli and lymphoid infiltration with KLC in the interstitium on immunostaining. MCL was confirmed with FC and excisional LN biopsy. Prednisone/Rituximab/Bendamustine therapy led to improvement in kidney function and proteinuria.

Discussion: MCL can cause different kidney involvement from direct tumor infiltration to MCL-associated glomerulonephritis. Therefore, correct diagnosis with renal biopsy and prospective registries are needed to generate data about differences in outcomes in MCL with various kidney involvement.

PO2213
Cystatin C Measurement Improves Renal Function Estimation with Selpercatinib Use
Victoria Gutgarts,1,2 Dazhi Liu,1 Lauren A. Kaplanis,1 Alexander Drilon,1,2 Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medicine, New York, NY.

Introduction: Selpercatinib (LOXO-292) is a selective RET inhibitor that is approved for the treatment of RET-dependent lung and thyroid cancers. In the LIBRETTO-001 trial of selpercatinib, a treatment-emergent increase in serum creatinine was noted in ~18% of patients. Cystatin C is mainly excreted by glomerular filtration and is partly secreted via tubular secretion as MATE, as compared to creatinine. As MATE is not expressed in high abundance in the kidney, selpercatinib, can reduce cystatin C clearance leading to an incorrect diagnosis of drug related kidney injury. Cystatin C is an alternative marker that is freely filtered, completely reabsorbed and not affected by renal function and proteinuria. It is therefore not affected by transporter inhibitors and may be a better marker of kidney injury in patients receiving Selpercatinib. We present a patient on Selpercatinib with significant difference in kidney function by creatinine and cystatin C.

Case Description: 58-year-old male with metastatic RET fusion-positive lung cancer who progressed on cabozantinib started selpercatinib. His pre-treatment creatinine was 0.8mg/dl and increased to 1.8mg/dl one year of therapy with no change from baseline and with no significant proteinuria. Renal sonogram showed right side hydronephrosis which prompted placement of ureteral stent. Creatinine did not improve with persistent hydronephrosis prompting conversion to a nephroureterostomy tube one year later. Creatinine remained elevated at 1.9mg/dl despite resolving hydronephrosis. Cystatin C levels were measured and showed significant discrepancy with serum creatinine as shown in Table below. This finding highlighted that although the patient did have chronic kidney disease, the extent was less than estimated by solely creatinine.

Discussion: This case highlights the benefit of checking both creatinine and cystatin C in patients on selpercatinib. Despite urological intervention, the persistence in elevated
PO2214

ALECT 2 and Hepatocellular Carcinoma: An Intriguing Association

Janame J. Kotkey, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: Amyloidosis derived from leucocyte chemotactic factor 2 (ALECT2) is the third most common type of renal amyloidosis in the United States. The incidence of ALECT2 is highest among Hispanics and there is a predilection for involvement of the kidney and liver with sparing of the heart. We report a case of hepatocellular carcinoma (HCC) in a patient with ALECT2.

Case Description: A 69-year-old Hispanic man with chronic kidney disease secondary to ALECT2 and monoclonal gammapathy of undetermined significance was admitted for constipation and distended abdomen. Creatinine on admission was 5mg/dl and he was initiated on dialysis. Imaging revealed cirrhosis, ascites and two liver masses involving the portal vein. Alpha fetoprotein was 7123ng/mL and he was diagnosed with multifocal HCC. Evaluation for hepatitis, autoimmune disease and other etiologies for chronic liver disease was negative and cirrhosis was presumed to be secondary to ALECT2. Based on the Barcelona Clinic Liver Cancer staging, he was given a stage D. His functional status precluded any liver directed therapies or systemic chemotherapy and he failed to meet the Milan criteria for liver transplantation. Following a discussion of the prognosis he was transitioned to palliative care.

Discussion: ALECT2 is a recently described form of systemic amyloidosis that has quickly emerged as a common and possibly underdiagnosed cause of systemic amyloidosis particularly in patients of Hispanic ancestry. ALECT2 can involve various organs but usually spares the heart and brain. ALECT2 in association with HCC has not been reported to date. Interestingly in one study, expression of LECT2 in human kidney and liver with sparing of the heart. We report a case of hepatocellular carcinoma (HCC) in a patient with ALECT2.

PO2216

Eculizumab for Treatment and Prevention of Recurrent Gemcitabine-Induced Atypical Hemolytic Uremic Syndrome After Gemcitabine Rechallenge: A Case Report

Orhan Efe,1 John Niles,2 Reza Zonoz.1 1Massachusetts General Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA.

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare side effect of gemcitabine. Here, we report a case of gemcitabine-induced aHUS successfully treated with eculizumab, with subsequent use of eculizumab to prevent recurrence of aHUS after reinitiating gemcitabine.

Case Description: A 29-year-old male with intrahepatic cholangiocarcinoma on gemcitabine and cisplatin was admitted with AKI. On presentation, he was newly hypertensive to 162/108 mmHg and edematous. His labs were notable for a serum creatinine (Scr) of 1.19 mg/dL (baseline 0.6 mg/dL), hemoglobin 8.8 g/dL (baseline of 12.6 g/dL) with reticulocytosis, platelet count 190 K/uL, LDH 635 U/L, haptoglobin <10 mg/dL, schistocytes on blood smear, and a normal ADAMS13 level. Urine studies revealed hematuria, proteinuria, and granular casts. Gemcitabine and cisplatin were discontinued, yet his SCR continued to rise to 2.12 mg/dL, LDH to 1222 U/L and platelet count fell to 77 K/uL. Eculizumab was initiated and his creatinine improved to 1.14 mg/dL, and his LDH, platelet count, and haptoglobin normalized. Eculizumab was stopped after 2 months without subsequent recurrence. He was reinitiated on dose-reduced gemcitabine and cisplatin due to progression of his cancer despite multiple alternative chemotherapy regimens. Eculizumab was reinitiated concurrently with gemcitabine and continued bweekly. His blood pressure, Scr, haptoglobin, LDH and platelet count remained stable. Unfortunately, he died due to cancer progression 3 months later. Figure 1 summarizes his treatment and laboratory course.

Discussion: We report a case of successfully utilizing eculizumab to prevent recurrence of gemcitabine-induced aHUS after gemcitabine reinitiation, which has not been previously reported to our knowledge. There are scarce reports of gemcitabine reinitiation without eculizumab, most of which resulted in recurrent renal toxicity. There may be utility in the use of eculizumab in patients who need to reinitiate gemcitabine. Larger studies evaluating this approach are warranted.

PO2217

A Case of Lupus Nephritis Improved by Molecular Targeted Drug Therapy for Multiple Intrapulmonary Metastasis of ROS-1 Gene-Positive Lung Cancer

Miho Karube, Hiroko Uchida, Yoshinori Komagata, Shinya Kaname. Division of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan.

Introduction: Systemic lupus erythematosus is a multisystemic disease associated with genetic, environmental and epigenetic factors. The effect of tyrosine kinase inhibitors has only been reported in SLE model mice for imatinib. Here we report a case in which lupus nephritis was improved by a molecular targeted drug for multiple intrapulmonary metastases of ROS-1 gene-positive lung cancer.

Case Description: Thirty-one-year-old woman, who was diagnosed with SLE at the age of 14 years, had been treated with immunosuppressive agents including corticosteroids, cyclophosphamide and mycophenolate mofetil, with frequent relapses. At the age of 30 years, she was admitted to our hospital due to development of systemic erythema, which was diagnosed as drug-induced eruption with increased SLE activities. She was treated with prednisolone (PSL) 50 mg/day and remission was achieved for
SLE, however, during the systemic screening, lung adenocarcinoma was accidentally detected, and thoracoscopic right middle lobeectomy was performed. Seven months after surgery, she had an exacerbation of erythema on the face and bilateral arms, arthralgia and urinary proteins, with elevated anti-ds-DNA antibodies and decreased serum complement levels. The dose of PSL was increased, but the symptoms did not improve, when multiple intrapulmonary metastases were detected, indicating recurrence of lung adenocarcinoma. The previous lung specimens revealed a high expression of PD-L1 and positive ROS-1 fusion gene, thus tyrosine kinase inhibitor (crizotinib) was selected as the anti-cancer therapy instead of anti-PD-L1 antibodies. Interestingly, urine protein and erythema/arthralgia and size of lung tumor reduced.

**Discussion:** Crizotinib is a molecular targeting agent with non-receptor-type tyrosine kinase inhibitor action that competitively binds to the ATP binding site of EML4-ALK tyrosine kinase, resulting in signal transduction inhibition. In this case, the molecular targeting drug induced improvement of lupus nephritis along with regression of lung cancer, suggesting that tyrosine kinase inhibitors may be effective for lupus nephritis.

**PO2218**

**Paraneoplastic Minimal Change Disease Associated with High-Grade Neuroendocrine Tumour**

Mohankumar Doraiswamy, Jessamyn S. Carter, Sethu M. Madhavan, Jason Prosek. The Ohio State University Wexner Medical Center; Columbus, OH.

**Introduction:** Minimal Change Disease (MCD) is usually associated with Lymphoma. Leukemia and solid tumors like Lung Cancer, Renal Cell Carcinoma and Thymoma but data on incidence of paraneoplastic glomerular disease are lacking. To our knowledge, only two cases of neuroendocrine tumor (NET) presenting with Paraneoplastic MCD related to neuroendocrine tumor (NET) were reported. Here we report a 47-year-old patient with duodenal NET with nephrotic syndrome and renal biopsy was suggestive of minimal change disease.

**Case Description:** A 47-year-old man with history of well-differentiated metastatic NET (not on therapy) and HTN admitted for dyspnea and anasarca for two weeks. His labs were significant for creatinine of 3.9 mg/dL, proteinuria of 4.3 g/day and Na 118 mmol/L. IV diuretics with albumin infusion initiated, which improved his kidney function. Serologies and proteinuria workup - negative. Renal biopsy performed for nephrotic syndrome, showed prominent podocyte foot process effacement with mild acute tubular necrosis, and mild glomerular sclerosis. Diagnosed with paraneoplastic MCD from metastatic NET and treatment with steroids initiated. Chemotherapy not started because of the overall decline in his clinical status and increased tumor burden. One week after steroids, his proteinuria was 42 g/day, and steroid doses were increased. Three weeks later, proteinuria decreased to 6 g/day and his symptoms improving. Unfortunately, he suffered further kidney injury because of hypotension and hemodialysis initiated one month later.

**Discussion:** The most common paraneoplastic glomerular disease is membranous glomerulopathy in tumor burden, but MCD should be kept on the differential as well. Like membranous nephropathy, remission of MCD been reported on ablation of the tumor, suggesting a paraneoplastic process, though the precise mechanisms are not fully understood. In our case, since the patient did not qualify for chemotherapy because of increased tumor burden, steroids were initiated which helped in part to reduce symptoms. The etiology of glomerulopathy in cancer does not appear to be related to tumor burden, metastatic spread or the site or extent of invasion, but to the secretion of substances from the tumor cells. Kidney biopsy should be performed early, as prompt diagnosis is important to ensure patients do not receive ineffective and potentially harmful treatments.

**PO2219**

**Management of IgA Nephropathy and Concomitant Breast Cancer**

Victoria Gutierrez, 1, 2 Steven Savatora, 1, 2 Roman A. Shingara, 1, 2 Memorial Sloan Kettering Cancer Center, New York, NY; 3 Weill Cornell Medicine, New York, NY.

**Introduction:** Immunoglobulin A nephropathy (IgAN) is the most common glomerulonephritis worldwide. Although treatment guidelines have been established, there is little known about the management of IgAN in the setting of solid malignancy. Herein we describe two cases of IgAN and breast cancer diagnosed at our center.

**Case Description:** Case 1: 42-year-old female with newly diagnosed breast cancer 3 months prior presenting to our renal clinic for acute kidney injury (AKI). She had a 1.6g pulse of MP followed by prednisone tapered over 5 months. She completed 3 cycles of ddAC. Creatinine improved to 0.9mg/dL and proteinuria reduced from 7g to 0.5g.

**Discussion:** These cases highlight the complexity in management of IgAN while patients are undergoing treatment for a concurrent malignancy. Temporal relationship of IgAN and malignancy is unclear, but suggests potential value of cancer screening of patients with newly diagnosed IgA nephropathy.

**PO2220**

**Sezary Syndrome with Renal Involvement**

Sheikh B. Khalid, 1, 2, 3 J. Charles Jennette, 4 Monica L. Reynolds, 4 Obijulu Kanu, 4 Vikas Singh. 5 University of North Carolina at Chapel Hill, Chapel Hill, NC; 6Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan.

**Introduction:** Sezary Syndrome is a cutaneous T-cell lymphoma that presents with erythroderma, lymphadenopathy, and circulating malignant T cells. While involvement of the spleen, liver, bone marrow and lung are well documented, kidney involvement is rare. We present a case of acute kidney injury (AKI) due to biopsy-proven T cell lymphoma invasion of the kidneys.

**Case Description:** A 69-year-old female with a history of cutaneous T-cell lymphoma was admitted to the oncology service with AKI. Serum creatinine (sCr) 3.3mg/dL (baseline 0.6mg/dL), urine protein-to-creatinine ratio 2.5g/g, urine sediment bland and renal ultrasound unremarkable. A PET scan, performed to evaluate systemic disease burden, revealed diffuse kidney enlargement with high FDG uptake throughout the renal parenchyma. A kidney biopsy was performed Light microscopy showed diffuse interstitial infiltration by atypical small lymphoid cells and prominent focal apoptosis with apoptotic bodies and focal interstitial hemorrhage. The lymphoid cells had the same immunophenotype as the cutaneous T cell lymphoma. The patient had slight segmental wrinkling of capillaries and glomerular basement membranes, and segmental podocyte swelling. She also had leptomeningeal involvement. Treatment included dexamethasone, systemic and intrafleural doxorubicin, methotrexate, and cytarabine. SCr returned to baseline, however, her course was complicated by severe mucositis, neutropenic fever, gastrointestinal hemorrhage and refractory shock. The patient was stabilized and opted to return home with hospice.

**Discussion:** AKI caused by kidney involvement in Sezary syndrome has only been reported via case reports. The mechanism of AKI is thought to be tubular compression by the lymphomatous infiltrates inhibiting tubule function and peritubular capillary blood flow. Our patient’s biopsy supports this mechanism. Her AKI resolved with urgent corticosteroids and chemotherapy. Further reporting is needed on the prevalence of this condition and nephrologists should consider renal lymphomatous invasion when evaluating AKI in those with cutaneous T-cell lymphoma.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**

Underline represents presenting author.
Discussion: Even in EBV recipient-positive patients, there is still a risk to develop PTLD and hence consider prophylactic PTLD which resolved spontaneously when withdrawing Belatacept. This suggests that overly aggressive immune suppression, rather than induction of dysregulated proliferation, was the culprit. The fact that the patient did not show an acute increase in EBV RNA, and EBV by ISH on core biopsy of the spleen was negative, suggests that pre-transplant serosering based on EBV seropositivity may not be sufficient to predict risk for developing PTLD. The patient had complete resolution of AMS and B symptoms with discontinuation of Belatacept, with no subsequent recurrence of PTLD after switching to sirolimus/mycophenolate.

PO2224
Longitudinal Assessment of Unilateral Ureteral Obstruction Kidney Injury by Relaxometry and Spin-Lock exchange MRI
Feng Wang, Tadashi Otuka, Keiko Takahashi, Raymond C. Harris, Takamune Takahashi. Vanderbilt University Medical Center, Nashville, TN.

Background: Non-invasive imaging technique allows longitudinal and repetitive assessment of renal disease progression. In this study, we assessed the utility of a new MRI technique, quantitative relaxometry and Spin-lock exchange MRI, in detecting renal pathology in unilateral ureteral obstructed (UUO) kidneys, focusing on destructive tubular injury (dilation) and renal fibrosis, the pathological changes commonly observed in progressive kidney disease.

Methods: BALB/c mice (n=6-8) were imaged before and after (day 5, 10 and 15) UUO surgery at 7T magnet. Spin-lock images were acquired in a transverse plane using a fast spin echo sequence preceded by a preparatory spin-lock cluster. The dispersion of R2 with locking frequency was fit to Chopra model. The fits provided regional values of transverse relaxation rates R2obs, R1obs at infinite spin-lock frequency (R1∞), and an exchange rate-weighted parameter S1. Since cortex and outer stripe of outer medulla (OSOM) were clearly identified with T1-weighted image, even with UUO kidneys, these regions were selected for analysis. Paraffin tissue sections were stained using picrosirius red or anti-collagen I antibody. Histological scores for tubular dilation and fibrosis, based on conventional image and positive fibrotic areas in sections, were computationally measured and the correlation between MRI parameters and histological scores were assessed.

Results: In histology, evident tubular enlargement was observed at UO day 5, while tubulointerstitial fibrosis was mild at this stage. Both histological changes became more evident with progression and fibrosis showed larger increases from day 5 to day 15 (tubular dilation ~25% increase, fibrosis ~3 fold increase). Relaxation rates R2obs, R1obs and S1 were progressively dropped (25-50%) in UUO kidneys. Interestingly, R1obs showed the highest sensitivity to tubular dilation, while S1 showed the highest correlation with renal fibrosis.

Conclusions: Relaxation parameters showed high detectability to tubular dilation and overall changes in UUO progression. S1 best detected fibrotic changes. This would be because it depends mainly on the average exchange rate between water and collagen fibres, which is shifted relative to water as amides to collagen triple helices and collagen accumulations. These new MRI parameters could be used for the assessment of kidney disease progression.

PO2225
Kidney-Specific Landscape of Aging Mitochondrial DNA Mutations by Duplex Sequencing
Mariya T. Sweetwine, Monica Y. Sanchez-Contreras, Kristine A. Tsantis, Jeremy A. Whitson, Matthew D. Campbell, David J. Marcinek, Peter S. Rabinevitch, Scott R. Kennedy. University of Washington School of Medicine, Seattle, WA.

Background: Accumulation of mutations in the mitochondrial genome (mtDNA) is a potential mechanism of aging in the mitochondrial rich kidney, where mtDNA damage also increases with diabetes, CKD and AKI. Accurately detecting low level somatic mtDNA mutations within the cellular complexity of the kidney was previously confounded by variable levels of mtDNA heteroplasmy. Using ultra-sensitive Duplex Sequencing (DS), a modified next-gen sequencing (NGS) technique, we decreased the error rate relative to conventional NGS by >105, allowing us to accurately characterize mtDNA mutation patterns unique to the aging kidney relative to other organs.

Methods: We compared mtDNA mutations in kidneys from cohorts of aged (26- m.o.) and young (5-m.o.) NIA C57Bl/6 mice to multiple organs with high mitochondrial content (heart, eye, liver, skeletal muscle and brain). In both ages, kidney carried the highest burden of mtDNA point mutations. Mutation spectrum analysis showed that mtDNA point mutations in the kidney increased significantly with age and were primarily G>C/T mutations, indicative of oxidative damage, the second most common type. Aged kidneys were further separated into glomeruli or tubule-rich whole cortex fractions to determine regional mutation burden.

Results: Glemorula had ~25% fewer total mtDNA mutations (p= 0.002) and specifically ~80% fewer oxidative lesions (G>C/T, A-G>C/G, G= 0.02). Furthermore, differential accumulation of mtDNA mutation between kidney fractions does not appear to be randomly distributed across the genome but is instead gene-specific as demonstrated by differential accumulation of reduced mutations in glomeruli of mtRNA gene mtRib1 but not mtRib2, and of Complex IV gene mt-Co2, but not mt-Co1 or 3. Finally, we sequenced kidneys from aged mice treated systemically for 8 weeks with SS-31, a mitochondrial therapeutic peptide that reduces oxidative stress in the kidney, and found that mutations stemming from oxidation, but not polymerease error, were significantly reduced.

Conclusions: These data suggest that renal mtDNA mutation is cell specific and that even in aged, accumulation of some mutations is tractable with therapeutic intervention.

Integrated Analysis of the DNA Methyome, Transcriptome, and Proteome in Human Glomerular and Tubulointerstitial Compartments
Samir V. Parikh,1 Kimberly S. Collins,1 Ricardo Melo Ferreira,1 Yinghua Cheng,1 Daria Barwinska,1 Michael J. Ferkowicz,2 Ken Dunn,1 Katherine J. Kelly,1 Timothy A. Sutton,1 John P. Shapiro,1 Brad H. Rovin,7 Pierre C. Dagher,1 Tarek M. El-Achkar,1 Michael T. Eadon,1 Indiana University School of Medicine, Indianapolis, IN; 2The Ohio State University Wexner Medical Center, Columbus, OH.

Background: The interplay between the human DNA methylome, transcriptome, and proteome in the kidney glomerulus and tubulointerstitium is incompletely understood. Promoter sequence methylation is often thought to contribute to gene and protein expression regulation. We hypothesized that promoter sequence methylation would explain differential protein expression between the glomerulus and tubulointerstitium.

Methods: Nine reference nephrectomies underwent laser microdissection of the glomeruli and tubulointerstitium. DNA methylation sequencing, RNA sequencing, and mass spectrometry quantification of peptides was completed for both compartments in the samples. Datasets were dimensionally reduced to match expressed proteins (N = 4600). Regions of hypermethylation in promoter sequences, introns, and exons were assessed and compared to corresponding protein and mRNA expression.

Results: At least three patterns of hypermethylation were observed across the methylome: promoter sequence, intrinsic, and exonic methylation. In many cases, promoter sequence or exonic methylation of the tubulointerstitium correlated with a higher glomerular to tubulointerstitial protein and mRNA expression ratio. Likewise, increased tubulointerstitial protein or mRNA expression was associated with glomerular hypermethylation of promoter or exonic regions. For example, Uromodulin (UMOD) protein and mRNA expression were higher in the tubulointerstitium than the glomerulus. The strongest regions of uromodulin hypermethylation were observed in exons 9 and 10 of the glomerular compartment, although hypermethylation was also observed in the promoter sequence and two intrinsic regions of the tubulointerstitium. In contrast, regions of hypermethylation of Apolipoprotein L1 (APOL1) were exclusively confined to the tubulointerstitium, distributed in all three patterns.

Conclusions: Promoter sequence methylation alone does not explain differential expression patterns between the glomerular and tubulointerstitial compartments. Hypermethylation of exonic regions also contributes to expression regulation.

Single-Cell Transcriptomics of the Peripheral Blood Revealed Inflammation and Infection Were Associated with IgAN
Changwei Wu, Guisen Li, Li Wang. Renal Department and Nephrology Institute, Sichuan Provincial People’s Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.

Background: Immunoglobulin A nephropathy (IgAN) is the most common primary glomerular disease worldwide. Due to the diverse clinical manifestations and the complex pathological features, IgAN patients have different response to therapy, and the optimal treatment for IgAN remains controversial. Our study investigated the pathogenesis of IgAN by single-cell transcriptome sequencing.

Methods: Single-cell transcriptome sequencing was performed on peripheral blood monocytes derived from 3 IgAN patients and 1 healthy control, and differential gene expression profiles of peripheral blood single-cell were established. Functional analysis was performed to explore the pathogenesis of IgAN. Meanwhile, RT-PCR was used to validate the differential expression of mRNA and miRNA.

Results: According to quality control and cell selection, we characterized 21739 cells using unbiased single-cell RNA sequencing. 3 IgAN patients included 7847, 5389 and 6609 cells, respectively, and the healthy control included 1894 cells. We used unsupervised clustering to cluster cell clusters. In addition, cells were divided into 14 cell groups, including B lymphocytes and T lymphocytes, based on cell markers (Figure 1). Functional analysis revealed that differential genes were extensively enriched in inflammation / infection-related pathways in each cell type (Figure 2), and the EBV infection pathway focused on antigen presentation (Figure 3). RT-PCR of B lymphocytes demonstrated that SPI1, MXD1 and S100A9 mRNA levels were higher in IgAN patients than controls (Figure 4), which showed the results of single-cell transcriptome sequencing was available.

Conclusions: Differential gene expression profiles of IgAN in peripheral blood single cells were successfully established, and it demonstrated that the inflammation/ infection pathway was associated with IgAN.

Background: Renal NF-E2-related factor 2 (Nrf2) is known to be increased in the presence of oxidative stress. Administration of an Nrf2 activator has also been reported to lessen the degree of renal damage. However, biomarkers for detection of Nrf2 activation in the kidney are largely unknown. Urinary exosomes, a subset of extracellular vesicles released by renal epithelial cells, contain RNA molecules that are expected to be biomarkers for renal disease. Thus we analyzed urinary extrosomal RNAs after administration of bardoxolone methyl (BARD), an Nrf2 activator, in rats.

Methods: Male Sprague-Dawley rats were randomly divided into two groups; the BARD group, intraperitoneally receiving 10 mg/kg BARD, and the control group, receiving only vehicle (100% DMSO). The urine was obtained for 6 hours just after administration, and exosomes were isolated from the urine. At 6 hours after administration, rats were sacrificed and the kidneys were removed. Thereafter RNAs were extracted from the kidneys and urinary exosomes. The RNAs (27,012 mRNAs and 1,218 miRNAs) were analyzed with microarrays.

Results: BARD altered expression of 98 renal mRNAs and 357 urinary extrosomal mRNAs with more than 2.0-fold relative to the control. BARD also changed expression of 15 renal miRNAs and 3 urinary extrosomal miRNAs. The correlation coefficients between renal and urinary extrosomal mRNAs as well as miRNAs were both less than 0.1. mRNAs were commonly changed in both the kidney and urinary exosomes were 13. Among them, 8 genes are known to be targets of Nrf2 including Akr1b8, Actc19, Bsh51, Ep101, Hmox1, Pir, Slc4a11 and Ugdh. Of 8 genes, Akr1b8 and Pir were increased more than 10-fold in the kidney and more than 4.0-fold in urinary exosomes. For miRNA, only mro-mir-877 was changed in both the kidney and urinary exosomes.

Conclusions: The correlation coefficients between renal and extrosomal exosomal RNAs were less than 0.1, suggesting that specific RNAs were selectively loaded into exosomes. In addition, Akr1b8 and Pir expression was dramatically increased in both kidney and urinary exosomes. Therefore, they could be potential biomarkers to detect their renal expression changes by renal Nrf2 activation.

Urinary Excretion of Extracellular Vesicles in 24 Hours: Time Point Collection and Normalization Strategy
Luca Mosافت, Sabrina La saliva, Ulu Erdreugger. University of Virginia Health System, Charlottesville, VA.

Background: Urinary extracellular vesicles (uEVs) are an ideal source of biomarkers for kidney diseases. Despite the interest generated, little is known about collection time and normalization approach. The majority of the studies on uEVs focus on spot urine collection based on the assumption that it accurately reflects the renal function. However, the practice to collect spot urine does not allow for calculating and standardizing the uEV excretion rate and then assessing the renal function. Moreover, no research has been carried out yet to show the difference between spot urine and 24h collections. The aim of this study is to compare uEVs excreted in all 24 hour urine void as single spot and compare it with 24 hour collection.

Methods: Each single spot void urine was collected and 20% of the volume was used to create the 24 hours collection. uEVs were enriched by differential centrifugation. Transmission electron microscopy (TEM), western blot (WB), nanoparticle tracking analysis (NTA), tunable resistive pulse sensing (TRPS), imaging flow cytometry (iFC) and miRNA (miR16 and miR200b) quantitation by qPCR were used to quantify uEVs markers variation during the 24 hour. Creatinine, urinary osmolality and particle concentration (NTA, TRPS) were used to normalize the analytes.

Results: TEM showed a heterogeneous population of uEVs and WB confirmed the presence of EVs marker (TSG101, ALIX and CD9). RNA was extracted by a column-based method (miRNA extraction kit Qiagen) and cel-39 miRNA was spiked in each sample. A multiparametric detection of nephron markers podocalyxin (PODXL1), aquaporin-2 (AQP2) and uEv pan tetraspanins (CD9 + DC63 + CD81) was performed in imaging flow cytometry and imaging flow cytometry. Whereas the uEV composition of did not change across the 24 hours analysis, the quantity of uEVs and related markers (miRNA and proteins) fluctuated during the day depending on the hydration and excretion rate. Creatinine, urinary osmolality and particle count normalization failed to normalize “outliers".

Conclusions: In conclusion, this study represents the very first report which compares single void urine versus 24 hour uEV analysis. We concluded that the 24 hour collection is the preferred choice for a robust and rigorous assessment of uEVs and its associated markers.

PO2230

Ultra-Fast Clearing Protocol for 3D Optical Renal Pathology
David Unmersiö-Jesu, Linus Butt, Martin Höhne, Anna Wittasp, Lucas Kuehne, Peter Hoyer, Jaakko Patrakkia, Paul T. Brinkkoeetter, Annika Wernerson, Bernhard Schermer, Thomas Benzing, Lena Scott, Hjalmar Brismar, Hans Blom. Karolinska Universitetssjukhuset i Huddinge, Huddinge, Sweden; Department of Internal Medicine and Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany; Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; Pediatric Nephrology, Pediatrics II, University of Duisburg-Essen, Essen, Germany; Science for Life Laboratory, Dept. of Women’s and Children’s Health, Karolinska Institutet, Solna, Sweden, Solna, Sweden; Science for Life Laboratory, Dept. of Applied Physics, Royal Institute of Technology, Solna, Sweden.

Background: Kidney pathology involves three separate microscopy workflows. Histology, typically carried out on paraffin-embedded sections, used to optically visualize large-scale renal morphology. Immunofluorescence, used for mapping presence of specific molecular variations, carried out on paraffin-embedded or fresh-frozen thin sections. To visualize renal ultrastructures, electron microscopy is applied, with elaborate preparation protocols on ultra-thin sections.

Methods: We have modified published protocols in order to simplify and speed up the workflow of routine optical kidney imaging. The presented protocol yields a slight swelling of a cleared sample, and increase effective resolution enough for 3-D confocal visualization of filtration barrier structures. The duration of the protocol is only 5 hours from harvesting the tissue until full image acquisition.

Results: Our simple and fast protocol can resolve footprint processes in mouse and human tissue using standard lab equipment and conventional 3-D confocal microscopy. Importantly, the protocol can be used to visualize various large-scale histopathological features as well as immune deposits in human patient material too. Compared to others, our tissue protocol is simpler and faster, and allow better 3-D in situ imaging capabilities.

Conclusions: We conclude that our simple and fast protocol, allow researchers and pathologists to use a single preparation and microscopy technique, to visualize both renal ultrastructure, histology and protein expression. Our protocol has the potential of, not just to complement, but also merging workflows used today while adding accessing to in situ depth information on all scales.

Expression of Immunoglobulin G in Human Proximal Tubule Epithelial Cell and Its Role in Epithelial Mesenchymal Transformation

Zhending Deng, Song Wang, Yue Wang. Peking University Third Hospital, Beijing, China.

**Background:** Our previous studies showed that human mesangial cells and podocytes can synthesize and secrete IgA and IgG respectively, participating in cell viability and adhesion. Proximal tubular epithelial cells (PTECs) mediate transcytosis of IgG through neonatal Fc receptor (FcRn). Whether PTECs express IgG has not been reported. The aim of this study was to explore whether PTECs express immunoglobulins.

**Methods:** Kidney cortical tissues were obtained far from the tumor of patients undergoing nephrectomy as a result of renal carcinoma. Immunohistochemical (IHC) staining was used to assay the IgG expression in PTECs. Single PTECs were sorted by FACS from the cell suspension of the cortices. 10xGenomics and nested PCR combined with Sanger sequencing were used to detect the transcripts and repertoires of IgG in single PTECs. An immortalized PTEC cell line (HK-2) was used to detect IgG protein expression and potential roles in tubular epithelial mesenchymal transformation.

**Results:** IHC showed positive staining of IgG but not other IgGs in PTECs of kidney cortex. High throughput single cell RNA sequencing by 10xGenomics only detected IgG transcripts in few PTECs without V(D)J rearrangements. Nested PCR amplified IgG transcripts in 82% (91/111) manually picked single PTECs. Sanger sequencing showed that PTEC-derived IgG γ variable region displayed classic V, D, J rearrangements but predominant VH1-24/DH2-15/HJ4 sequence, biased VH1 usage and less diversity than B cells derived IgG. Western blot and immunofluorescence staining demonstrated IgG immunoreactivity (including IgG4, Igκ and Igλ in HK-2, RP215, which specifically recognizes non-B cell-derived IgG, can identify the IgG γ in HK-2. The IgG γ was upregulated by TGF-β1 and accompanied by the up-regulation of α-smooth muscle actin and the down-regulation of E-cadherin. In addition, the transcripts of recombination activating gene 1/2 (RAG1/2, essential for V(D)J rearrangement) and activation-induced cytidine deaminase (AID, essential for class switch recombination) were detected in HK-2.

**Conclusions:** Our study suggests that PTECs can express IgG in a similar way as B cells. TGF-β1 can upregulate the expression of IgG in PTECs. PTEC-derived IgG may be involved in tubular epithelial mesenchymal transformation and interstitial fibrosis.

Long-Term Mitochondrial Protection Reduces Proteinuria in Obese Aged Mice

Marilyta T. Sweetwene, Rene Coig, Ruby Sue M. Mangalindan, John Morton, Jeremy A. Whitson, Peter S. Rabinovitch, Warren C. Ladiges. University of Washington School of Medicine, Seattle, WA.

Background: In humans, obesity is associated with higher rates of kidney disease, which is compounded by aging. As an energetically demanding tissue, it has been proposed that preventing mitochondrial dysfunction is one key to reducing renal decline. Previously, we showed that an 8-week systemic treatment of aged 24-month-old (m.o.) mice with a mitochondrial targeted protective tetrapeptide, SS-31, significantly reduced the burden of age-induced glomerulosclerosis by 26-m.o. and preserved podocyte integrity.

Methods: To determine if SS-31 aging protection also applied with a comorbidity of obesity, 18-m.o. male NIA C57Bl/6j mice were fed regular chow (RC) or a high fat, high sucrose diet (HFHS) for 10 months and treated with SS-31 injected 5x/wk (3 mg/kg) or saline vehicle (n= 20/group).

Results: Mice were weighed weekly. RC mice averaged 33g with no change from age or treatment. HFHS mice gained weight in the first month but by 5 mo. of diet, SS-31+HFHS mice weighed significantly less relative to HFHS untreated mice (40.4g vs. 45.9g p= 0.047). Spot urine was collected monthly for albumin/creatinine ratio (ACR, μg/mg). At 18-m.o. baseline, ACR averaged 48μg/mg. In RC mice, ACR increased modestly, and not significantly, with age although SS-31 RC mice had lower ACR at endpoint (28-m.o. control 125.9 vs. SS-31 60.0). HFHS untreated mice displayed more renal disease than RC mice (ACR: RC = 32.6 vs. HFHS = 243.2, p = 0.003), climbing significantly to an average of 519.8 μg/mg at 28-m.o. ACR increased in SS-31 HFHS mice but leveled off by 23-m.o. (5 mo. treat.), averaging 146.1 μg/mg with no significant increase by 28-m.o. By 9 mo. of treatment, ACR was significantly lower in HFHS/SS-31 treated mice than in the control group. Pre- and post-treatment quantification of podocyte by pS75 nuclear stain and PAS counter stain (n=4-7) showed that HFHS mice, regardless of treatment, had a 30% decrease in podocyte density relative to RC mice. Control HFHS mice tended to higher tuft volume (glomerular hypertrophy) than in SS-31 HFHS mice. However, results were not significant due to low sample size.

Conclusions: Combined with improved ACR our results suggest that podocyte integrity, if not number, may be preserved in mice fed a Western diet by SS-31 intervention and that long-term mitochondrial protection is a potential therapeutic target to preserve renal function that extends to aging.

Bacterial and Fungal Communities Entombed Within Calcium Oxalate, Struvite, and Brushite Human Kidney Stones

Elena M. Wilson,1,2 Jessica J. Saw,1,2 Mayandi Sivaguru,1 Dirk Lange,1 Yiran Deng,1,2 Robert A. Sanford,1,2 Christopher J. Fields,1 Melissa Cregger,1,4 William J. Bruce,1,3 Annette Merkel,1,4 John C. Lieske,1 Amy E. Krambeck,1,2 Marcelino E. Rivera,1 Tim Large,1 Nicholas L. Chia,1 Michael F. Romero,1 Joseph R. Weber,1,2 Bruce W. Fouke,1,2 Carl R. Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign, Urbana, IL; University of Rochester School of Medicine, Rochester, MN; Oak Ridge National Laboratory, Oak Ridge, TN; Mayo Clinic Minnesota, Rochester, MN; Indiana University School of Medicine, Indianapolis, IN; Jackson Bell Research Centre, Vancouver, BC, Canada; Roy J. Carver Biotechnology Center, University of Illinois at Urbana-Champaign, Urbana, IL; China University of Geosciences, Wuhan, China.

Background: Mechanisms of human kidney stone formation are poorly understood. More than 70% of stones are composed of calcium phosphate and/or oxalate. Recent studies have shown that kidney stone formation follows a continuum of complex biogeochemical transitions and is strongly influenced by the presence of human host and microbial organic matter.

Methods: Kidney stones, removed via percutaneous nephrolithotomy, were prepared as 25 μm thick doubly polished petrographic thin sections and analyzed using brightfield, confocal and super-resolution autofluorescence microscopy. DNA was extracted from 18 calcium oxalate stones, 1 struvite stone, and 1 brushite stone for Fluidigm™ PCR amplification. Pair-end sequencing of bacterial 16S rRNA gene sequences and fungal internal transcribed spacer (ITS) regions was completed using Illumina® MiSeq. Reads were correlated with patient metadata and analyzed using DADA2, phyloseq v1.22.3 and R software.

Results: A 153-amplicon sequence variant (ASV) fungal community, dominated by A. niger (92% of total reads), was present in 11 of 20 total sequenced stones and correlated with higher patient urine calcium excretion (335 ± 131 vs 175 ± 108 mg/day, p=0.01). Petrography of 30 stones documented entombed coccoidal and rod-shaped bacterial cells in the struvite stone and well-preserved fungal borings and hyphae in one calcium oxalate stone. Bacterial and fungal bacterial sequences were most closely affiliated with Actinobacter and Curtobacterium. The brushite stone microbiome contained Capnocytophaga and Humibacter and the struvite stone microbiome included Pseudomonas and Staphylococcus.

Conclusions: This presentation firsts the evidence of a low-diversity fungal and bacterial microbiome community entombed and preserved within calcium oxalate struvite, and brushite human kidney stones. The macromolecules secreted by the fungal and bacterial communities may play crucial roles in human kidney stone growth, dissolution and recrystallization, similar to processes that have been documented in natural geologic stone growth.

Targeting of Factor D in Cfh-/- Mice Does Not Relieve C3 Glomerulopathy due to the Action of C3(H2O)

Yuzhou Zhang,1 Adam C. Keenan,1 Dao-Fu Dai,1 Kristofer S. May,1 Gabriella R. Pitcher,1 Ronald P. Taylor,1 Richard J. Smith.1 Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; Department of Pathology, University of Iowa, Iowa City, IA; University of Virginia School of Medicine, Charlottesville, VA.

Background: C3 glomerulopathy (C3G) is an ultra-rare kidney disease defined by underlying complement dysregulation and characterized by complement C3 deposition on the glomerular basement membrane (GBM). Dysregulation of the alternative pathway (AP) is fundamental to disease expression, although terminal pathway dysregulation is also common. Treatment of C3G with ecilizumab is unsuccessful in the majority of patients, consistent with the fact that C3G can lead to the terminal complement cascade while leaving upstream complement dysregulation untouched. Of up-stream targets, factor D (FD) is appealing because it circulates in the plasma at low concentrations and has a single function, to cleave its substrate, factor B, to generate C3 convertases of the alternative complement pathway. Mice with a targeted deletion of factor H (FH; Cfh-/- mice) develop features of C3 glomerulopathy (C3G).

Methods: To assess the impact of FD inhibition, we studied Cfh-/-;Cfd-/- mice. After crossing the Cfd-/- and Cfh-/- mice, Cfh-/-;Cfd-/-;Cfd-/- progeny were backcrossed to C57BL/6 for 10 generations. Littermates of Cfh-/-, Cfd-/-;Cfd-/-, and wildtype were used for assessing complement dysregulation and renal pathology.

Results: The C3G phenotype in the Cfh-/- mouse is not rescued by removing FD. Instead, Cfh-/-;Cfd-/- mice develop a subtype of C3G and nephrogenic diabetes insipidus. We used serum from the Cfh-/-;Cfd-/-;Cfd-/- mouse to show that residual AP function is present in Cfh-/- mice. In addition, and FH and FI are not required for CFD to induce C3 deposition in vivo due to the action of C3(H2O). Therefore, uncontrolled tick-over leads to slow activation of the AP in the Cfh-/-;Cfd-/- mouse. While a tiny amount of FD suffices to activate complement, a minimal threshold of FH is needed to prevent tissue deposition of C3 in the absence of FD.

Conclusions: These findings suggest that efforts to block AP activity by targeting FD may lead to unanticipated outcomes in subgroups of C3G patients. Sustained complete and persistent FD blockade may be difficult to maintain, and due to the action of CFD, may not completely suppress complement activation; substantial breakthrough through complement activation may then occur as even minuscule amounts of free FD become available.

A Mutation in Complement Factor B Causing Massive Fluid-Phase Dysregulation of the Alternative Complement Pathway Can Result in Atypical Hemolytic Uremic Syndrome

Yuzhou Zhang,1 Robin A. Kremsdorf,2 John Sperati,1 Kammi J. Henriksen,1 Mari Mori,1,5 Rene X. Goodfellow,1 Gabriella R. Pitcher,1 Nicolo Ghiringhelli Borsa,1 Ronald P. Taylor,1 Carla M. Nester,1 Richard J. Smith.1 Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; Department of Pediatrics, Warren Alpert Medical School of Brown University, Providence, RI; Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD; Department of Pathology, University of Chicago, Chicago, IL; Division of Genetic and Genomic Medicine, Nationwide Children’s Hospital, Columbus, OH; Department of Pediatrics, College of Medicine, The Ohio State University, Columbus, OH; University of Virginia School of Medicine, Charlottesville, VA.

Introduction: Atypical hemolytic uremic syndrome (aHUS) is an ultra-rare disease characterized by microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury. Pathogenesis is driven most frequently by dysregulated cell-surface control of the alternative pathway (AP) of complement secondary to inherited and/or acquired factors.

Case Description: We present two unrelated aHUS patients (a 5-year-old female and a 55-year-old female) who presented with the classic signs of thrombotic microangiopathy associated with renal failure with the additional finding of an un dctectable C3 level. Circulating levels of C5 and properdin were also low, consistent with over-activity of both the alternative and the terminal pathways of complement. Genetic testing identified a heterozygous novel variant in the complement factor B gene (CFB c.1101 C>A, p.Ser367Arg). Functional studies demonstrated strong fluid-phase C3 cleavage when membrane-bound C3b was mixed. Cell-surface C3 deposition was strongly positive when patient serum was supplemented with C3. In vitro control of C3 conversion activity could be restored with increased concentrations of factor H.

Discussion: CFB p.Ser367Arg is a gain-of-function pathogenic variant that leads to dysregulation of the AP in the fluid-phase and increased C3b deposition on cell surfaces. This report highlights the complexities of complement-mediated diseases like aHUS and illustrates the importance of functional studies to characterize variants of unknown significance and to gain insight into the disease phenotype.

Efficacy of Low-Intensity Pulsed Ultrasound on CKD-Associated Cachexia and Muscle Wasting Prevention in a Mouse Model
Shing-Hwa Liu,1 Kuan-Yu Hung,1,4 Chih-Kang Chang,1,2 Institute of Toxicology, National Taiwan University, Taipei, Taiwan; 1Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; 2Supersite Senior Office, National Taiwan University Hospital Hein-Chu Branch, Hsinchu, Taiwan; 3Department of Internal Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

Background: Low-intensity pulsed ultrasound (LIPUS), a therapeutic ultrasound, is recognized to elevate the bone fracture repair process and help in some soft tissue healing. Here, we tested the prevention of chronic kidney disease (CKD)-associated cachexia and sarcopenia by LIPUS in a renal ischemia/reperfusion injury (IRI) mouse model.

Methods: Adult C57BL/6J male mice were used. A model of unilateral IRI with nephrectomy of the contralateral kidney with or without LIPUS treatment (3 MHz, 0.1 W/cm², 20 minutes/day) 5 days before and 14 days after surgery was performed. The CKD-related cachexia/muscle wasting in mice was evaluated. Mice were euthanized 14 days after IRI.

Results: LIPUS treatment significantly alleviated the decrease in the serum albumin/globulin (A/G) ratio and the increases in the serum levels of blood urea nitrogen (BUN), creatinine, cystatin C, and fibroblast growth factor (FGF)-23, and the renal pathological changes and fibrosis in CKD mice (p<0.05, n=8; for A/G ratio and FGF-23). The development of epithelial-mesenchymal transition and the induction of senescence-related molecular signals and decreased protein expressions of α-Klotho and endogenous antioxidant enzymes in the kidneys of CKD mice were significantly alleviated by LIPUS treatment (p<0.05, n=4). LIPUS treatment could also significantly reverse the decreased muscle mass, grip strength, and cross-section areas (CSA) of muscle fibers (p<0.05, n=8; for soleus muscle weight, hindlimb grip strength), and the increased muscular protein expressions of atrosogen, Atrogxin1 and MuRF1, and phosphorylated AMP-activated protein kinase (AMPK), and the decreased muscular protein expressions of phosphorylated Akt, peroxisome proliferator-activated receptor-γ coactivator 1-α (PGC-1α), and mitochondrially encoded cytochrome c oxidase I (MT-CO1) in CKD mice (p<0.05, n=8). In mice treated with LIPUS, albumin/globulin (A/G) ratio and the increases in the serum levels of blood urea nitrogen (BUN), creatinine, cystatin C, and fibroblast growth factor (FGF)-23, and the renal pathological changes and fibrosis in CKD mice (p<0.05, n=8; for A/G ratio and FGF-23). The development of epithelial-mesenchymal transition and the induction of senescence-related molecular signals and decreased protein expressions of α-Klotho and endogenous antioxidant enzymes in the kidneys of CKD mice were significantly alleviated by LIPUS treatment (p<0.05, n=4). LIPUS treatment could also significantly reverse the decreased muscle mass, grip strength, and cross-section areas (CSA) of muscle fibers (p<0.05, n=8; for soleus muscle weight, hindlimb grip strength), and the increased muscular protein expressions of atrosogen, Atrogxin1 and MuRF1, and phosphorylated AMP-activated protein kinase (AMPK), and the decreased muscular protein expressions of phosphorylated Akt, peroxisome proliferator-activated receptor-γ coactivator 1-α (PGC-1α), and mitochondrially encoded cytochrome c oxidase I (MT-CO1) in CKD mice (p<0.05, n=8).

Conclusions: LIPUS treatment showed the benefits for renal and muscular protection in a CKD mouse model via inhibition of renal fibrosis, restoration of antioxidant enzymes, and attenuation renal senescence/aging, and muscle mass loss via prevention of muscular mitochondrial dysfunction, AMPK activation, and Akt downregulation. LIPUS treatment may be potentially applied to an alternative non-invasive therapeutic intervention on CKD-associated cachexia/muscle wasting therapy.

PO2240

Mechanisms of Suppressed Autophagic Flux in the Kidney Caused by Sham Surgery and Unilateral Nephrectomy
Carolyn N. Brown,1 Carolyn Pokhrel, Chris Edelstein. Unvo Colorado, Aurora, CO.

Background: Compensatory renal hypertrophy resulting from loss of nephron mass has been implicated in promoting further nephron damage. Unilateral nephrectomy (UNX) is a model of compensatory hypertrophy in the remaining kidney. We previously reported that in the remaining mouse kidney that both sham surgery (SS) and UNX vs. normal kidney (N) resulted in increased mTORC1/2, decreased lysosomal function, suppressed autophagic flux. P62/SQSTM1, a marker of autophagic flux, a decrease usually indicating increased autophagic flux. P62/SQSTM1, is an autophagy receptor that links cargo proteins with the autophagosome membrane. p62 is destroyed by the lysosome and is a marker of autophagic flux, a decrease usually indicating increased autophagic flux. The aim of the study was to measure p62 and other potential mechanisms of suppressed autophagy caused by SS and UNX.

Methods: C57BL/6 mice. p62 and ERK was measured by quantitative immunoblot analysis. Cytokines were measured by Mesoscale. Mice were treated with the MEK1/2 inhibitor Trametinib (T) (1 mg/kg for 3 days) that is a potent ERK1/2 inhibitor.

Results: There was an increase in p62 in SS and UNX kidneys. p62/GAPDH (densitometry units) was 0.6 in N, 1.0 in SS (P<0.05 vs N) and 1.0 in UNX kidneys (P<0.05 vs N). p62 is known to modulate pro-inflammatory cytokines. In the serum, there were increases (fold) in IL-1β (50), IL-4 (10), IL-6 (100), IL-8 (5), IL-12 (5), GMCSF (2), IL-10 (2), TNFα (0) in SS and UNX vs N. Pro-inflammatory cytokines can activate ERK1/2, a known autophagy suppressor. There was a large increase in ERK1/2 in SS and UNX kidneys. Phospho/total ERK (densitometry units) was 0.2 in N, 1.4 in SS (P<0.001 vs N) and 2.0 in UNX kidneys (P<0.001 vs N). Trametinib blocked the increase in pERK in sham surgery and UNX kidneys and resulted in a significant decrease in p62. Phospho/total ERK (densitometry units) was 1.0 in N, 0 in SS+T (P<0.001 vs N) and 0 in UNX+T kidneys (P<0.001 vs N). p62/GAPDH (densitometry units) was 1.6 in N, 0.4 in SS+T (P<0.05 vs N) and 0.4 in UNX+T kidneys (P<0.05 vs N).

Conclusions: The mechanism of suppressed autophagy with SS and UNX may be related to an intense systemic inflammatory response and an ERK-mediated increase in p62. It is important that researchers are aware that changes in ERK1/2, systemic pro-inflammatory cytokines and autophagy can be caused by sham surgery as well as the kidney injury/disease itself.

PO2241

Differential Role of NAD+ Deficiency in Acute and Chronic Kidney Disease
Anna Faienza,1,2 Elena Katsyuba,1 Thomas Verissimo,1 Carolyn Heckenheimer,1 David Legouis,1,2 Sophie M. De Seigneur,1,2 Universite de Geneve, Geneva, Switzerland; Hopitaux Universitaires de Geneve, Geneve, Switzerland; Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland.

Background: Nicotinamide adenine dinucleotide (NAD+) is a ubiquitous coenzyme involved in electron transport and a co-substrate for many dehydrogenase. NAD+ deficiency has been shown in acute kidney injury (AKI), but few is known about chronic kidney disease (CKD).

Methods: We studied the expression of key NAD+ biosynthesis enzymes in kidney biopsies from allograft patients during reperfusion, mimicking AKI, and in patients with CKD at different stages. We used ischemia-reperfusion injury (IRI) and ex vivo injection to model AKI, unilateral ureteral obstruction (UO) and tubulointerstitial fibrosis induced by proteinuria (POD-ATTAC) to investigate CKD in mice. Then we assessed the effect of a potent NAD+ replenishment therapy, the nicotinamide riboside (NR), in both AKI and CKD models.

Results: RNA-sequence analysis of human kidney allograft biopsies during reperfusion showed that the NAD+ de novo synthesis is impaired in the immediate post-transplantation period. This decrease in de novo NAD+ synthesis was confirmed in two mouse models of IRI where NR supplementation prevented plasma urea and creatinine elevation and tubular injury. In biopsies from CKD patients, the NAD+ de novo synthesis was impaired according to CKD stage, with better preservation of the salvage pathway (Figure 1). Similar alterations in gene expression were observed in UO and POD-ATTAC mouse models. NR supplementation did not prevent CKD progression in contrast to its efficacy in AKI.

Conclusions: Impairment of NAD+ synthesis seems to be a hallmark of AKI and CKD. An oral NR supplementation showed protective effects on AKI but had no effect on CKD mouse models. This study shows the dual role of NAD+ deficiency in AKI and CKD and the potential of NAD+ replenishment therapies as a preventive strategy for human AKI.

Plasminogen Activator Inhibitor 1 (PAI-1) Induction During Kidney Injury Promotes Epithelial Dysfunction via TGF-β1 Receptor Signaling and Klotho Downregulation
Cody C. Gifford,1 Fei Lian,1,2 Jiaqi Tang,1 Angelica Costello,1 Roei Goldschmeding,2 Rohan Samarakoon,1 Paul J. Higgins,1 Albany Medical College, Albany, NY; 2Albany Medical Center, Albany, NY; 2Department of Pathology, University Medical Center Utrecht, Utrecht, Netherlands.

Background: Persistent PAI-1 induction is evident in several nephropathies in mice and humans. Although PAI-1 is an established CKD promoting factor, the precise role of PAI-1 in disease progression is unclear and, surprisingly, this fibrogenic response appears to be mediated by αvβ3-independent mechanisms. Expression of the anti-aging gene klotho is lost during renal injury, predisposing to CKD, and recombinant klotho administration in mice suppresses progressive fibrosis. Whether kidney tubular PAI-1 induction promotes maladaptive repair and orchestrates klotho downregulation is currently unknown.

Funding: Veterans Affairs Support, Other U.S. Government Support
Methods: To mimic sustained renal epithelial PAI-1 expression during renal injury, we stably expressed PAI-1 via lentiviral transduction in HK2 human kidney epithelial cells (CMV-PAI-1); western blotting confirmed PAI-1 overexpression relative to vector controls (CMV-Con). Double-transgenic cells engineered to express both PAI-1 and klotho were used to assess pathological interplay between PAI-1 and klotho in renal fibrosis.

Results: PAI-1 expressing HK-2 cells robustly upregulated pro-fibrotic factor expression/secretion (fibronectin and collagen-1) and exhibited deredifferentiation (loss of E-cadherin and increased vimentin expression), G2/M growth arrest and susceptibility to apoptosis, evident by increases in p73, p21 and p53 expression, caspase3 cleavage and annexin V positivity compared to the CMV-Con population. PAI-1-transductants had increased TGF-β receptor 1/2 levels and SMAD2/3 activation relative to vector controls. TGF-β1 receptor-1 kinase inhibition with SB431542 attenuated the PAI-1-driven fibrotic phenotype, independent of TGF-β-signaling pathway. Interestingly, sustained PAI-1 expression also downregulated klotho protein levels compared to controls. Rescue of klotho expression in CMV-PAI-1 cells attenuated fibrogenesis and reversed the proliferative arrest.

Conclusions: Persistent PAI-1 expression promotes a fibrotic maladaptive repair orchestrated, in part, via TGF-β1-receptor1/2 hyperactivity and klotho loss. Our studies identify not only a novel role for PAI-1 in renal tubular dysfunction but also in klotho deregulation in renal fibrosis.

PO2243
Percutaneous Renal Biopsy Using an 18-Gauge Automated Needle Is Not Optimal

George Sousaniach, William L. Whittier, Roger A. Rodby, Vasili Peev, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

Background: As percutaneous renal biopsies (PRB) are increasingly performed with a 14, 16 and 18-gauge automated needles.

Methods: PRB of 592 native (N) and 1023 transplant (T) kidneys was performed by a nephrologist or a supervised nephrology fellow at Rush University Medical Center from 1/2002 to 12/2019 using real-time ultrasound guidance. Baseline clinical and laboratory data, biopsy sample data (number of cores, total glomeruli per biopsy (glomeruli on light and immunofluorescence + electron microscopy) and total glomerular per core and overall data (hematoma on renal US 1-hr post-PRB and complications requiring a transfusion or procedure post-PRB) were collected prospectively. PRB with N14g(n=337) vs N16g (n=255) and T16g (n=892) vs T18g (n=131) needles were compared. A P value of <0.05 was significant.

Results: PRB with an 18g needle yielded the lowest number of total glomeruli per biopsy (N14g vs N16g: 33±13 vs 29±12, P<0.01 and T16g vs T18g: 34±16 vs 21±11, P<0.001 and N16g vs T18g, P>0.001). PRBs with 18g needle were also less likely to have ≥20 total glomeruli per biopsy (N14g vs N16g: 85% vs 82%, P>0.4 and T16g vs T18g: 83% vs 46%, P<0.001). The number of cores per biopsy was: N14g:2.3±0.7, N16g: 2.2±0.6, T16g:2.8±0.7 and T18g: 2.2±0.6. Adjusting for the number of cores obtained, the total glomeruli per core was significantly less with 18g needle (N14g vs N16g: 15±8 vs 14±7, P<0.1 and T16g vs T18g: 15±6 vs 10±2, P=0.001 and N16g vs T18g, P<0.001). A hematoma by routine screening US 1-hr post-PRB was significantly higher for native (14g-35% vs 16g-29%, P=0.2), and transplant biopsies (16g-10% vs 18g-9%, P=0.9) irrespective of needle size. The complication rate for native (14g-8.8% vs 16g-7.1%, P>0.5), and transplant biopsies (16g-4.6% vs 18g-1.3%, P<0.02) as well as the transfusion rate for native (14g-7.7% vs 16g-5.8%, P=0.4), and transplant biopsies (16g-3.8% vs 18g-0.8%, P=0.1) were not significantly different irrespective of needle size.

Conclusions: The use of the smaller, 18g biopsy needle compromises the adequacy and thus, quality of the PRB while not enhancing safety.

PO2244
Deep Neural Network Facilitated Immunofluorescence Assessment of Glomerular Diseases: A Preliminary Report

Peichen Lv.1 Yibo Wen.1 Xuesong Zhao.1 Hua Zheng.1 Xuemei Li.2 Fei Ren.2 Limeng Chen.1 1Nephrology Division, Peking Union Medical College Hospital, Beijing, China; 2Institute of Computing Technology, Chinese Academy of Sciences, Beijing, China.

Background: Immunofluorescence (IF) tests of renal tissue are important in diagnosing glomerular diseases. Deep neural network were used to facilitate analysis of pathologic images recently, but not in IF assessment. We proposed a novel Convolutional Residual Dense Network (CR-DenseNet) to facilitate IF assessment of glomerular diseases.

Methods: A dataset with 614 IF images of glomeruli, including IgA Nephropathy, IgAN (n=319), Idiopathic Membranous Nephropathy, IMN (n=211) and Secondary Membranous Nephropathy, SMN (n=84) from Peking Union Medical College Hospital, PUMCH were used for training of CR-DenseNet. Additional 78 IF images from PUMCH (35 IgAN, 15 IMN and 28 SMN) and 98 IF images (36 IgAN, 34 IMN and 28 SMN) from other 3 hospitals were used for validation and human tests. These images were annotated by two nephropathologists independently. Convolutional residual dense blocks were introduced. Each of them consisted of a dense block with a convolutional skip connection connection. The number of filters in each dense block is 128, followed by a 1 × 1 convolution layer. In the output layer, the number of filters is the number of classes (2). The accuracy and F1 score were 80.0% to 84.6% and 0.762 to 0.880, respectively.

Conclusions: Our data showed that CR-DenseNet model were useful in IF assessment of typical glomerular diseases.

IgA Staining Patterns Differentiate Between IgA Nephropathy and IgA-Dominant Infection-Associated Glomerulonephritis

Sergey V. Brodsky, Clarissa A. Cassol, Anjali A. Satoskar, Tibor Nadasy.
The Ohio State University Medical Center, The Ohio State University Wexner Medical Center, Columbus, OH.

**Background:** Differential diagnosis of primary IgA nephropathy (IgAN) and IgA-dominant infection-related glomerulonephritis, particularly Staphylococcus infection-associated glomerulonephritis (SAGN), on a kidney biopsy can be challenging because of similar morphologic findings by light microscopy, immunofluorescence and electron microscopy. Clinical management approach however, is very different. Immunosuppressive therapy is contraindicated in SAGN because it can lead to sepsis and even death. Antibiotics constitute the first line of therapy. In contrast to that, primary IgAN is treated either with conservative management or with immunosuppression. There are no specific biomarkers to distinguish between these two diseases.

**Methods:** Kidney biopsies from patients with IgAN or SAGN were analyzed. Immunofluorescence with an antibody to IgA was performed on sections of frozen and paraffin embedded tissue.

**Results:** In total, 75 biopsies (45 with IgAN and 30 with SAGN) were evaluated. All 75 biopsies showed distinct granular staining for IgA in the non-sclerotic glomeruli (Figure 1). Globally sclerosed glomeruli were identified in 47 biopsies (29 with IgAN and 18 with SAGN). Among the 29 biopsies of IgAN, 20 (69%) had positive granular staining for IgA in the globally sclerosed glomeruli and 9 (31%) cases did not. Among the 18 kidney biopsies with SAGN, only one case (5.6%) showed positive staining for IgA in globally sclerosed glomeruli, whereas the remaining 17 (94.4%) did not (Table 1). The sensitivity of positive IgA staining in globally sclerosed glomeruli for kidney biopsies with IgAN was 68.97%, specificity was 94.44%.

**Conclusions:** Evaluation of IgA staining in sclerosed glomeruli can help to differentiate between primary IgAN and SAGN in the right clinical context, and aid in patient management in most cases.

The Spectrum of Biopsy-Proven Glomerular Diseases in Mexico: Experience at a Tertiary Hospital

Octavio R. Garcia-Flores, Belen Martinez-Vazquez, Virgilia Soto, Bernardo Moguel. Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

**Background:** Glomerular diseases are still one of the leading causes of end-stage renal disease. The diagnosis of these diseases relies on the interpretation of the renal biopsy.

**Methods:** This investigation was performed in a tertiary hospital. We assessed the main demographic, clinical and histological data of individuals who underwent native kidney biopsies in one tertiary hospital in Mexico. From January 2011-December 2019, totally 1,541 patients first received renal biopsy. After excluding alloagraft biopsies, inadequate sampling, and failed interpretation, there are still 853 cases with a clear diagnosis.

**Results:** We evaluated 853 renal biopsies: female 65.3%, elderly (>60 years) 16.4%. The most frequent biopsy-proven diseases were secondary (59.1%) and primary (28.7%) glomerulonephritids (GN), tubulointerstitial nephritis (TIN) was observed in 2.5% and vascular diseases in 1.5%, hereditary disease in 1.2%. Among primary GN the most frequent diagnosis were focal segmental glomerulosclerosis (FSGS) (17.2%), membranous GN (MGN) (5.7%) and IgA nephropathy (IgAN) (4.8%). Among secondary GN, lupus nephritis (LN) represented 38.9%, diabetic nephropathy 8.1% and pacious immune crescentic GN 4.9%. The most common diseases in patients with nephrotic proteinuria were LN 14.8%, FSGS 5.8%, MGN 4.1%. Ultrasound needle guidance was used in 97.8%. The frequency of serious complications was approximately 2.5%.

**Conclusions:** This report provides representative population-based data on native biopsy-proven renal diseases in Mexico. FSGS and LN are the most frequent primary and secondary GN respectively. FSGS and MGN were the most common diseases in patients with nephrotic proteinuria.

**PO2249**

Clinical Context and Outcomes of Kidney Biopsy in Pregnant Women: An Institutional Review

Indiana University School of Medicine, Indianapolis, IN.

**Background:** Kidney biopsy is an excellent method of gaining insight to causes of renal decline but is not without risk, particularly in pregnant patients. While we await the era of biomarkers which enhance our ability to diagnose diseases of pregnancy, biopsy remains the most inclusive way of reaching a diagnosis. Clinical manifestations warranting biopsy include gross deterioration in renal function, de novo development of nephrotic syndrome, or suspicion for glomerulonephritis. A recent metanalysis found that the risk of complications during pregnancy was 7% and should be limited to patients in whom the diagnosis would warrant urgent therapy. We sought to explore indications for biopsy and histopathology in patients evaluated at our institution.

**Methods:** Our surgical pathology database was searched for renal biopsy specimens interpreted from 2008 to mid-2020. Patients were either pregnant at the time of biopsy or within 3 months postpartum. Indiana University IRB approved the study. A chart review was completed to obtain lab data at the time of biopsy and post procedure.

**Results:** We identified biopsy specimens from 38 women who were pregnant during the specified time period. Histopathologic diagnoses included lupus nephritis (n=4), FSGS (8), diabetic kidney disease (3), allergic interstitial nephritis (1), IgA (10) and minimal change disease (3). Chart information was available for 19 women including 15 Caucasian and 4 African American patients, with a mean age of 28.6 years. Eight specimens were obtained during pregnancy and 11 during the postpartum period. Proteinuria was present in 17 patients with a mean value of 3.5g/d. Hematruia was also present in 14 of the patients. Mean serum creatinine was 2.6mg/dL.

**Conclusions:** Renal biopsy is a procedure with high risk and morbidity for pregnant women. At our institution, biopsy was performed for either worsening renal function or proteinuria. Our population showed diverse diagnoses which justified need for biopsy, including requiring urgent intervention. Our study highlights the need of judicious biopsy in pregnant women. Further studies can be done to determine long term kidney outcomes in pregnant women.

Prevalence and Risk Factors Associated with Nephroclerosis in Renal Parenchyma Specimens of Patients Undergoing Partial or Radical Nephrectomy

Juan D. Salcedo Betancourt,1 Kenny A. Goodrich,2 Olekssii Iakymenko,2 Jhoo B. Rozas,1 Ragi Phillips,1 Gabriel Contreras,1 Alessia Fornoni,1 Laura Barisoni,2 Jorge A. Florindez,3 David B. Thomas,1 Jair Munoz Mendoza.1

1University of Miami School of Medicine, Miami, FL; 2Duke University School of Medicine, Durham, NC; 3IIM Health Financial Services, PLLC, Charlotte, NC.

**Background:** Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We evaluated the prevalence of histological signatures and nephroclerosis and its association with clinical factors in patients undergoing nephrectomy for any cause at our institution.
Methods: Two nephropathologists evaluated the status of the renal parenchyma in 811 nephrectomy specimens. They assessed and either partial or radical nephrectomies between 2013 and 2017. Age-adjusted global glomerulosclerosis (GS), interstitial fibrosis (IF), tubular atrophy (TA), and arteriosclerosis (AS) were evaluated by light microscopy. Nephrosclerosis was defined as the presence of a 2 histologic variables. Clinical, demographic, and pathological data were collected by chart review. Logistic regression analysis was used to evaluate the association between clinical parameters and nephrosclerosis.

Results: The mean age was 60 ± 14 years. 38% were female, 44% were Hispanics, 59% had hypertension, 22% had diabetes mellitus, and 24% had a smoking history. The pre-nephrectomy eGFR was 73 ± 27 ml/min/1.73m² and 31% had an eGFR < 60 ml/min/1.73m². The prevalence of age-adjusted GS was 82%, any TA was 80%, more than 5% IF was 78% and any AS was 95%. The prevalence of nephrosclerosis was 88%. Lower pre-nephrectomy eGFR (adjusted odds ratio [OR] per 10 units decrease in eGFR, 0.04, 95% CI, 0.32-1.23) and age (adjusted OR per 10 years increase, 0.04, 95% CI, 1.04-2.39) were significantly associated with nephrosclerosis. Gender, history of hypertension, diabetes, and smoking were not associated with nephrosclerosis (p>0.05 for all).

Conclusions: Nephrosclerosis is highly prevalent in renal parenchyma of patients undergoing nephrectomy. Lower pre-nephrectomy eGFR and older age were independently associated with significantly greater odds of nephrosclerosis. Future studies should evaluate the association between nephrosclerosis and post-nephrectomy eGFR.

PO2250

Evaluation of Preexisting Renal Disease in Nephrectomies

Juan D. Salcedo Betancourt,1 Oleksii Iakymenko,2 Kenny A. Goodrich,3 Jhioan B. Rozas,4 Ragi Philips,4 Alessia Fornoni,1 Gabriel Contreras,5 Dipen Patel,6 Laura Barisoni,7 David B. Thomas,3 Jair Munoz Mendoza,1 1University of Miami School of Medicine, Miami, FL; 2Duke University School of Medicine, Durham, NC; 3IYM Health Financial Management, Orlando, FL; 4Intelligent Optical Systems, Inc., Torrance, CA

Background: Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We aimed to determine the prevalence of pre-existing renal diseases in all patients who underwent nephrectomy for any cause in our center.

Methods: The surgical pathology protocol for nephrectomies was modified with a) additional sampling of non-tumoral renal parenchyma, b) Hematoxylin and eosin, Periodic acid-Schiff, trichrome and silver stains, and c) addition of the expanded checklist for reporting nephrectomy from the Renal Pathology Society recommendations. All samples were reviewed by 2 trained pathologists (NP). A total of 831 nephrectomies (449 nephrectomies for malignancy, 382 nephrectomies for non-malignancy) were included in the study. Reasons for nephrectomy were malignancy in 645 (79%) of patients, of which 528 (82%) had renal cell carcinoma, 100 (16%) urothelial carcinoma, and 168 (21%) benign lesions (42 oncocytomas, 34 pyelonephritis, 13 trauma, and 31 nephrolithiasis). Clinical, demographic, and pathological data were collected by chart review.

Results: The mean age was 60 ± 14 years. 62% were male and 44% Hispanics, 59% had hypertension, 22% had diabetes mellitus, and 24% had a history of smoking. Baseline eGFR was 73 ± 27 ml/min/1.73m² and 31% had an eGFR < 60 ml/min/1.73m². Only 41 patients (5%) had a documented pre-operative consult to nephrology. 296 (36%) patients had at least one renal disease diagnosis and only 62 (8%) had a single diagnosis. 371 (45%) clinical diagnoses were reported including focal segmental glomerulosclerosis (FSGS) (157), mostly NOS variant (88%), diabetic glomerulosclerosis (57), interstitial nephritis (66), arteriopneumocerosis (39), pyelonephritis (36), acute tubular injury (10), chronic scarring glomerulonephritis (41), amyloidosis (1) and atheroembolic renal disease (31).

Conclusions: Pre-existing renal disease are frequently identified in nephrectomy specimens. FSGS was the most common diagnosis. A collaborative effort involving nephrologists, urologists and pathologists is warranted to improve the care of patients undergoing surgical nephrectomy.

PO2251

Kidney Filtration Markers in Human Saliva: Accuracy and Reproducibility of Novel Salivary Cystatin C Measurements

Konstantina Kalantar-Zadeh,1 Manal Beshay,2 Connie Rhee,1 Trong D. Nguyen,2 Maria Ortega,2 Michael Shlipak,3 Danh V. Nguyen,4 1University of California Irvine, Orange, CA; 2Intelligent Optical Systems, Inc., Torrance, CA; 3University of California San Francisco, San Francisco, CA

Background: Invasive phlebotomy followed by laborious blood specimen processing is the only reliable approach to assess routinely measured kidney filtration markers including cystatin C (CysC). Non-invasive testing of these markers is urgently needed particularly during the COVID-19 pandemic to enhance social-distancing.

Methods: We developed novel Enhanced Enzyme and Immunoassay-based Lateral Flow (ELF) assays to measure concentrations of CysC in human saliva. Highly selective binding reagents were screened for optimum specificity, followed by applying sample treatment steps to mitigate sample to sample variability using healthy donor saliva samples spiked with known levels of the filtration markers. Standard calibration curves (SCCs) for each marker was developed with nonlinear 4-parameter logistic curve fitting to triplicate measurements at each spiked concentration level. Accuracy/fit of the SCC was assessed using the coefficient of determination (R²). Intra-assay reproducibility was assessed using coefficient of variation (CV) and studies of inter-assay reproducibility over time (over ~8 days) examined reproducibility of whole experimental protocol.

Results: SCC fitted to relative optical intensities (ratio of test to control lines vs. spiked CysC 0-14 ng/ml) was excellent (R²=0.991) and provided accurate estimates of spiked true CysC levels (R²=0.994). Assessment of intra-assay variation showed that repeatability is very good with CV <10% throughout the dynamic range of measurements. Assessment of inter-assay variation (measurements over 8 days) showed that reproducibility is acceptable with CV <13% throughout most of the dynamic range. Preliminary assessment of long-term reproducibility (stability) out to 258 days indicated similar performance. [figure]

Conclusions: We demonstrated feasibility of CysC measurements in human saliva samples with acceptable ELF assay characteristics including accuracy, repeatability, reproducibility, and long-term stability. Validation studies are ongoing to optimize the saliva testing framework for kidney function markers.

**Comparison of Creatinine-Based Estimated Glomerular Filtration Rate Equations with DTPA GFR in Healthy Adults**

Varun Kumar Bandi, Spoorthi Ramineni. Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Vijayawada, India.

**Measurement of Glomerular filtration rate (GFR) is a reliable technique but is expensive and cumbersome for routine use. GFR is routinely estimated (eGFR) with serum creatinine. These equations are not widely validated in Indian population.**

**Methods:** The cross-sectional study was done on live kidney donors. DTPA was used to measure GFR, 24 hour creatinine clearance (CCi) was measured and creatinine based eGFR was calculated using Cockcroft-Gault (CG), Modification of Diet in Renal Disease-variable (MDRD-4), Modification of Diet in Renal Disease-6 variable (MDRD-6), and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations.

**Results:** 88 subjects were included, of whom 29.5% were male, with a mean age of 46.8 yrs, and BMI of 25.7 kg/m2. Mean GFR (a standard deviation) obtained by CKD-EPI, MDRD-4, MDRD-6, CG, CCi, and DTPA GFR were 98.8 ±15.2, 98.2 ±17.9, 106.1 ±220.2, 83.3 ±38.7, 89.3 ±22.5 and 93.6 ±41.1 respectively. The mean absolute difference in GFR and percentage variation between calculated and measured GFR for CKD-EPI, MDRD-4, MDRD-6, CG, CCi were 14.7 ±16.5%, 16.2 ±17.9%, 19.8 ±22.2%, 33.2 ±36.5%, and 23.6 ±25.7% respectively. Percentage of values within 20% of DTPA GFR in each equations were CKD-EPI - 69.32%, MDRD-4 – 70.45%, MDRD-6 - 54.55%, CG - 38.64%, and CCi- 45.45%. There was no significant co-relation between the measured GFRs and eGFR using any of the above equations.

**Conclusions:** All the equations used (CKD-EPI, MDRD4, MDRD6, CG) and CCi did not correlate significantly with the measured GFR. Among the equations, CKD-EPI had the least variation with about 69% confirming within 20% of DTPA GFR, and about 86% and 97% confirming within 30% and 50% of DTPA GFR.

**Table 1: Percentage of eGFR estimations occurring within 20%, 30%, and 50% variation of DTPA GFR values**

**Fecal Calprotectin Correlates with Serum Albumin in Patients with CKD**

Yura Chag, Eun Sil Koh, Jongho Son, Sungjin Chung. The Catholic University of Korea, Seoul, Republic of Korea.

**Background:** Persistent inflammation, a characteristic feature in chronic kidney disease, contributes to decreased serum albumin levels and plays a central role in the Malnutrition, Inflammation and Atherosclerosis (MIA) syndrome, which is associated with poor clinical outcomes. Altered bowel habit is also a highly frequent status among patients with chronic kidney disease potentially due to their low fiber and fluid intake, medications, multiple comorbidities and dysbiosis of the gut microbiota. In this study, we have explored whether measurement of fecal calprotectin, a commonly used marker for increased neutrophil infiltration and local inflammation in gastrointestinal diseases, could reflect a state of low serum albumin in patients with chronic kidney disease.

**Methods:** Clinical and biochemical data including stool samples for calprotectin were collected from 579 cases of patients with no history of inflammatory bowel disease. Fecal calprotectin was significantly correlated with serum albumin (r = -0.010). Patients with higher tertile of fecal calprotectin were older and likely to have lower hemoglobin. Multivariable linear regression analysis showed that fecal calprotectin was significantly correlated with serum albumin (β = -17.702, P = 0.010). Patients with higher tertile of fecal calprotectin were older and likely to have lower hemoglobin.

**Conclusions:** These observations that serum albumin were significantly correlated with fecal calprotectin in patients with chronic kidney disease, suggest that the bowel inflammatory response may be another contributing factor.

**PO2255**

**A Case of Sevelamer-Induced Colon Perforation**

Venkata R. Manchala, Rajendra Mandalapu, Soumya P. Thumma, Nithin Karakala. University of Arkansas for Medical Sciences, Little Rock, AR.

**Introduction:** Sevelamer is an anion exchange resin used to treat hyperphosphatemia in patients with chronic kidney disease. It does not cause hypercalcemia or vascular calcification. Common adverse effects include nausea, vomiting, diarrhea, dyspepsia and constipation. Case reports of sevelamer associated bowel perforation have been reported in the literature 2. Here we report a case of sevelamer induced colon perforation.

**Case Description:** 61 year old Caucasian male with history of ESRD from diabetic nephropathy on automated peritoneal dialysis presented to the emergency department with abdominal pain. Physical exam was notable for epigastric tenderness. Labs were unremarkable except for hyperglycemia of 427 mg/dL. CT scan abdomen showed scattered yellow eosinophilic, acellular crystalline material with “fish scale” morphology within the lumen suggestive of sevelamer resin. Patient was on sevelamer 800mg TID for several years. Patient improved with appropriate medical management. Sevelamer was discontinued prior to discharge.

**Discussion:** Sevelamer is composed of a non-absorbable hydrogel with ammonia on the hydrochloride (Renagel) or the carbonate (Renvela). In the acid milieu of stomach, it binds phosphate in the intestine3. The exact pathogenesis of intestinal perforation remains unclear. It is hypothesized that presence of sevelamer crystals in the gastrointestinal tract was associated with mucosal abnormalities including inflammation, ischemia and necrosis. This combination of characteristic sevelamer crystals (typically seen as bright pink linear acellular linear formations with a rusty yellow background and irregularly spaced fish-scales) on pathology along with the supporting clinical history clinches the diagnosis. It is important for clinicians to be aware of this rare but a serious potential complication of bowel perforation associated with sevelamer.

**PO2256**

**Case of Pulmonary-Renal Syndrome Involving Goodpasture Disease and Granulomatosis with Polyangiitis**

Shatabhad Khan. AU-UGA Internal Medicine, Athens, GA.

**Introduction:** Wegner’s granulomatosis and Goodpasture’s disease are two rare causes of pulmonary-renal syndromes syndromes. Both have similar presentation and different treatment. It is crucial for any nephrologist to be aware of each condition. WG is a systemic vasculitis that affects the respiratory and renal systems and associated with C-ANCA (PR3) antibodies. Goodpasture’s disease is an autoimmune condition that is characterized by rapidly progressive glomerulonephritis (RPGN) and severe alveolar hemorrhage. It most often relates to anti-glomerular basement membrane antibodies against the glomerular basement membranes. It is suggested that 5% of all ANCA+ patients are also positive for anti-GBM and of all the anti-GBM about 1/3rd also have ANCA but that does not always correlate with active clinical disease. This leads to a significantly poor prognosis and worse renal outcomes than either disease process alone.

**Case Description:** We present a 59-year-old female with initial complaint of weakness, lethargy and sinus congestion. She had a history of untreated hypertension. She was noted to be hypoxic and had rales and ronchi bilaterally. Labs revealed WBC of 35, Hg 5.6, hct 15.5 and platelets 594. She had a history of radiation for lung cancer. She was noted to have profound hypochromic anemia. She had a history of chronic obstructive pulmonary disease. She was started on a course of immune suppressive therapy. She was noted to have significant improvement in her anemia. She eventually was started on plasmapheresis. She was noted to have very high levels of anti-glomerular basement membrane antibodies. Subsequently a CT angiogram was obtained. During renal arteriography, the right renal artery developed dissection with minimal catheter manipulation suggestive of significant underlying abnormality. The procedure was aborted given risk for further complications including rupture of the right main renal artery. She was noted to have poor perfusion in the right kidney. She was noted to have significant improvement in her anemia. She was noted to be clinically improved and had significant improvement in her anemia. She was noted to be clinically improved and had significant improvement in her anemia.

**Discussion:** This case illustrates that both WG and GP can occur in the same patient. Such patients can present with CAP that rapidly deteriorates. Early recognition of the pulmonary involvement is crucial for appropriate treatment by plasmapheresis and immunosuppressant. Although these patients with severe glomerular involvement will be lifelong dependent on dialysis, their 1- and 2-year survival can be significantly improved with appropriate therapy and follow up.
beading noted, consistent with a diagnosis of FMD. The patient’s creatinine remained stable during her hospital stay, and she was initiated on losartan prior to discharge.

Discussion: Fibromuscular dysplasia can be diagnosed by histopathology or angiography. It may manifest as a systemic vascular disease involving multiple vascular beds, mimicking systemic vasculitis. Since treatment of FAN and FMD is vastly different, it is important to consider both differentials and have definitive diagnosis prior to initiation of therapy.

PO2258
Asymptomatic Sporuous Hyperuricemia Related to Waldenstrom Macroglobulinemia
Pankuj Goyal, 1 Prakash S. Gudsoorkar, 1 Charuhas V. Thakar, 1,2 University of Cincinnati Academic Health Center, Cincinnati, OH; 1Cincinnati VA Medical Center, Cincinnati, OH.

Introduction: Increased IgM has been shown to result in underestimation of uric acid levels and pseudo-hypouricemia; however, there are no reported cases of hyperuricemia in the setting of paraproteinemia. We present a case of Waldenstrom’s Macroglobulinemia (WM) resulting in marked elevation of uric acid level in the absence of tumor lysis syndrome (TLS).

Case Description: A 73-year-old man with history of WM was incidentally noticed to have very high uric acid level of 37.2 mg/dL. He had no history of crystal arthropathy or chronic kidney disease. He was started on Acalabrutinib because of high serum viscosity and elevated IgM level. After 30 days of treatment, his serum viscosity and uric acid levels improved significantly, however, the treatment had to be discontinued due to development of potential drug related adverse events. After discontinuation of Acalabrutinib, his serum viscosity and uric acid level gradually increased back to the previous level. Laboratory parameters were not suggestive of TLS and potassium, calcium and phosphorus were all normal. 24-hour uric acid excretion was noticed to be low normal (314 mg/24 hours).

He was treated with allopurinol and monitored in clinic with serial uric acid checks. He continued to remain asymptomatic despite of having a uric acid level consistently above 35 mg/dL. He was not treated with Rasburicase due to lack of symptoms and potential false elevation of uric acid in the setting of paraproteinemia.

Discussion: Paraproteins often cause factitious biochemical measurements by forming opaque precipitates with the test reagents and interfering with various automated assay methodologies. These interferences may be difficult to anticipate as they are intermittent and patient specific. Ultrafiltration of paraproteins, dilution or deproteinization of the samples can sometimes help correct these measuring errors. WM and other paraproteinemias may cause true hyperuricemia in the setting of TLS. However, the absence of other coagulopathies, anemia should raise suspicion of factitious results. An observant clinician should be aware of these findings in order to avoid unwarranted testing and treatment. Also, a very high level of uric acid in the absence of symptoms may point towards a possibility of undiagnosed paraproteinemia.

PO2259
Is the Well-Recognized Intravascular Tamm-Horsfall Protein Polyp a Misnomer? A Case Report from a Patient with Obstructive Uropathy and Hematuria
Lives Su, Kyle Meissner, Amal Musa, Vikas D. Reddy, Jade M. Teakell, William E. Glass. University of Texas Health Science Center at Houston, Houston, TX.

Introduction: Tamm-Horsfall protein (THP), a renal epithelial glycoprotein, was originally identified from normal urine and can be the predominant constituent of urine in cases of renal proteinuria. The phenomenon of THP polyp formation in obstructive uropathy first appears in the literature about 1978. The polyps are described in these reports as being located in veins or sometimes lymphatics. Our case is the first to confirm the location of a THP polyp by immunohistochemical (IHC) analysis.

Case Description: A 64-year-old Caucasian male presented with bilateral flank pain and persistent gross hematuria. On admission, he had mildly elevated BUN (26.0 mg/dL) and serum creatinine (1.9 mg/dL). Urine analysis showed red blood cells > 182 /hpf with negative leukocyte esterase and negative nitrates. He developed azotemia during the hospitalization with the highest creatinine of 7.4 mg/dL on day 3 of admission. Renal ultrasound indicated mild-moderate hydronephrosis with a collapsed bladder. Renal biopsy was performed given lack of proper explanation for his presentation. Biopsy showed Periodic acid-Schiff (PAS) positive THP with polyhedral use. Her physical examination was unremarkable. Her admission labs were notable for a Cr 2.25mg/dL, potassium 3.1mmol/L, bicarbonate 15mmol/L, phosphorus 2.2mg/dL, uric acid 1.3 mg/dL, urinalysis specific gravity 1.011, pH 6.5, glucose 500 mg/dL, small blood, protein 30 mg/dL, negative leukocyte esterase, nitrite negative, 2 RBC, 4 WBC, negative urine culture, and spot protein/creatinine ratio 1.1. Further workup revealed urine electrolytes: Cr 39mg/dL, sodium 77mmol/L, potassium 20mmol/L and phosphorus 22.9mg/dL. Fe/Ps was 61% suggesting renal wasting. Serologic workup was negative forANA, ANCA, ncl c3, c4 and spep. Renal sonogram showed normal renal masses with two nonobstructing calculi in each kidney. Renal biopsy revealed focal degenerative changes in the tubules with flattening of the epithelium consistent with mild ATN. The interstitium had diffuse inflammation with mononuclear cells and frequent cosinophils consistent with ATN. EM showed tubuloreticular inclusions. He was started on postop Rx which was tapered over 8 weeks. Creatinine downtrended to 1.1mg/dL.

Discussion: Vodolzumab reported AIN and mild ATN has not thus far been reported. Here we report the first case which seemed to have a cumulative dose response. Whether this patient has a mild proximal RTA due to this medication remains to be elucidated, as the phosphorus wasting could have been due to her primary hyperparathyroidism. Clinicians should be made aware of such reported associations so that both a timely renal biopsy and therapy could be instituted without delay.

PO2260
Vedolizumab-Induced Acute Interstitial Nephritis and Acute Tubular Necrosis
Abdulrahman Muzib, Rushang Parikh, Vanesa Bijol, Nupur N. Uppal, Mala Sachdeva. Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Great Neck, NY.

Introduction: Vedolizumab is a humanized monoclonal antibody used in the treatment of ulcerative colitis. To date there has been no reported case of vedolizumab associated acute interstitial nephritis (AIN) and acute tubular necrosis (ATN). We report the first such case.

Case Description: A 58 year old female with history of ulcerative colitis on vedolizumab for one year, primary hyperparathyroidism and calcium oxalate nephrothiasis presents due to acute kidney injury. Patient received her last dose of vedolizumab two months prior. She had been receiving 300mg IV every eight weeks, making her last dose her seventh dose. Her pre-medication creatinine (Cr) was 0.9mg/dL. Approximately one week prior to admission she was found to have a Cr of 2.0mg/dL. She continued to receive her IV and oral infusion. Her physical exam was unremarkable. Her admission labs were notable for a Cr 2.25mg/dL, potassium 3.1mmol/L, bicarbonate 15mmol/L, phosphorus 2.2mg/dL, uric acid 1.3 mg/dL, urinalysis specific gravity 1.011, pH 6.5, glucose 500 mg/dL, small blood, protein 30 mg/dL, negative leukocyte esterase, nitrite negative, 2 RBC, 4 WBC, negative urine culture, and spot protein/creatinine ratio 1.1. Further workup revealed urine electrolytes: Cr 39mg/dL, sodium 77mmol/L, potassium 20mmol/L and phosphorus 22.9mg/dL. Fe/Ps was 61% suggesting renal wasting. Serologic workup was negative forANA, ANCA, ncl c3, c4 and spep. Renal sonogram showed normal renal masses with two nonobstructing calculi in each kidney. Renal biopsy revealed focal degenerative changes in the tubules with flattening of the epithelium consistent with mild ATN. The interstitium had diffuse inflammation with mononuclear cells and frequent cosinophils consistent with ATN. EM showed tubuloreticular inclusions. She was started on postop Rx which was tapered over 8 weeks. Creatinine downtrended to 1.1mg/dL.

Discussion: Vedolizumab reported AIN and mild ATN has not thus far been reported. Here we report the first case which seemed to have a cumulative dose response. Whether this patient has a mild proximal RTA due to this medication remains to be elucidated, as the phosphorus wasting could have been due to her primary hyperparathyroidism. Clinicians should be made aware of such reported associations so that both a timely renal biopsy and therapy could be instituted without delay.

PO2261
An Unusual Case of Granulomatous Interstitial Nephritis (GIN)
Charis E. Whitney, Ronald L. Mars, University of Florida Health Science Center-Jacksonville, Jacksonville, FL.

Introduction: A 28 Y/O man was admitted with stage 5 CKD. He was entirely asymptomatic with a negative PMH except for recent HTN & proteinuria. Entire proteinuria w/u was negative. PE was unremarkable. Kidney biopsy showed advanced glomerulosclerosis with chronic non-casing GIN. Etiology was uncertain except for history of BCG vaccination. BCG induced GIN was proposed. He was given a trial of ACE-I's, but ultimately required long term hemodialysis (HD).

Case Description: A 28 Y/O Hispanic male with 1 yr PMH of untreated HTN & proteinuria presented with BUN 88, Cr 7.85. 1 day after foot surgery Cr increased to 8.14 A/H NPO. He was discharged a day later on diazoxide. 1 year ago he was diagnosed with HTN & proteinuria. He had never received f/u or treatment. PMH was negative. FIH was significant for a cousin with ESRD s/p kidney transplant & an uncle with diabetes. Full proteinuria w/u was (-). Renal US revealed normal size kidneys & increased cortical echogenicity c/w medical renal disease. ACE-I's were added. We continued to improve, with BUN & Cr improving but no renal function & was then started on HD. Kidney biopsy revealed acute tubular injury with regeneration changes, acute & chronic interstitial nephritis with a few granulomas, 75% global glomerulosclerosis, mild tubular atrophy & interstitial fibrosis. GMS & AFB stains were negative for fungus & mycobacteria. No electron dense deposits (EDD's) were seen on electron microscopy. Further discussion with patient revealed he received BCG vaccine when 2 weeks old.

Discussion: Bacillus Calmette-Guérin (BCG) vaccine is a live but attenuated strain of Mycobacterium bovis used to protect against TB in many countries with a high prevalence of TB. BCG has been implicated in the development of granulomatous disease in multiple organs, but rarely in the kidneys. Our patient received an intra-dermal BCG injection 2 wks after birth & had no sequelae or side effects. The historical (-) PMH, absence of infections or infectious process, (-) serologic w/u, (+) history of environmental exposures made the incidental discovery of asymptomatic stage 5 CKD with proteinuria all the more surprising. The unexpected finding of GIN raised the consideration for stimulated immunity & granuloma formation from latent BCG vaccine. While literature documents granuloma formation in other organs, its occurrence in kidneys & potential contribution to progressive CKD seems less common, but should not to be overlooked.

PO2262
An Unusual Case of AKI
Malar Khadrain, Cynthia Miracle, Haiyan Zhang. University of California San Diego, La Jolla, CA.

Introduction: New-onset nephritic syndrome often requires kidney biopsy for diagnosis. Pathology is at times insufficient.

Case Description: An 81-year-old Hispanic female with HTN, CKD stage III presented with rash, fever, peripheral eosinophilia, AKI and diagnosed with DRESS
ALECT2 amyloidosis after steroids for allergic symptoms. This potential interplay between have triggered amyloidogenesis. A prior case report describes a patient who developed suspicion for preceding immune dysregulation, in the form of DRESS/steroids, that may patients who often have mixed clinical pictures. Circumstances leading to this case raise the recognition of disproportionate proteinuria was essential to question the diagnosis AIN and ALECT2 amyloidosis superimposed on a background of hypertensive changes; by ALECT2 amyloidosis and be associated with clinical sequelae. Cardiac involvement in ALECT2 amyloid prevalence populations. Complications related to systemic disease transplantation and should be considered in older patients, especially from higher spectrometry revealed ALECT2 as the amyloidogenic protein. Autopsy revealed massive amyloid deposition in the native kidneys, adrenals, spleen, marrow biopsy did not show a plasma cell dyscrasia. Kidney biopsy noted amyloidosis (Congo red positive deposits in glomeruli, vessels, interstitium) with 56% global glomerulosclerosis and >60% severe IFTA. Mild interstitial inflammation with occasional eosinophils suggested resolving AIN. Severe findings of hypertensive sequelae noted. Immunofluorescence was 2+ for IgG and kappa. Electron microscopy showed 10nm fibrils and severe podocyte foot process effacement. Mass spectrometry diagnosed ALECT2 amyloidosis.

Discussion: Our case is unusual in having three simultaneous pathologies, namely AIN and ALECT2 amyloidosis superimposed on a background of hypertensive changes; the recognition of disproportionate proteinuria was essential to question the diagnosis and avoid early closure on AIN. Concurrent renal pathologies are a common finding in patients with ALECT2 amyloidosis, underscoring the utility of kidney biopsy in these patients who often have mixed clinical pictures. Circumstances leading to this case raise suspicion for preceding immune dysregulation, in the form of DRESS/steroids, that may have triggered amyloidogenesis. A prior case report describes a patient who developed ALECT2 amyloid after steroids for allergic symptoms. This potential interplay between genetic and environmental factors requires further investigation.

PO2263

ALECT2 Amyloidosis with Cardiac Involvement Complicating Renal Transplantation

Introduction: ALECT2 amyloidosis may be associated with slowly progressive renal failure that is clinically unsuspected at the time of transplantation. While this is typically not clinically significant, we report a case with extensive systemic ALECT2 amyloidosis that also involved the myocardium, contributing to perioperative death post renal transplantation.

Case Description: A 72-year-old Hispanic woman presented for renal transplantation due to ESRD from hypertension. She was bradycardic on admission. Cardiac workup prior to transplantation had not identified an infiltrative process. Post-transplant hypertensive bradycardic arrests lead to multiorgan failure, anoxic brain injury and death. Autopsy revealed massive amyloid deposition in the native kidneys, adrenals, spleen, and less extensive infiltration of liver and myocardium. Cardiac intramural vasculature from venales to capillaries, arterioles and arteries showed amyloid deposition. Mass spectrometry revealed ALECT2 as the amyloidogenic protein.

Discussion: ALECT2 is a systemic amyloidosis that typically involves kidneys, adrenals, spleen and liver. It may be clinically unsuspected at the time of renal transplantation and should be considered in older patients, especially from higher ALECT2 amyloid prevalence populations. Complications related to systemic disease may add to morbidity or mortality post-transplantation. Cardiac involvement in ALECT2 amyloidosis has not been previously identified as a significant clinical or autopsy finding, but our case demonstrates that the cardiovascular system may indeed rarely be involved by ALECT2 amyloidosis and be associated with clinical sequelae.

PO2264

Cell-Based C5b9-ELISA to Identify Patients with Atypical Hemolytic Uremic Syndrome

Martin Reinhardt, Hermann G. Haller, Yulia Kiyana. Medizinische Hochschule Hannover Zentrum Innere Medizin, Hannover, Germany.

Background: Discrimination between different diseases in patients suffering from thrombotic microangiopathies is often challenging. Measuring C5b9 deposit on endothelial cells using confocal microscopy have been shown to be convenient in diagnostic and therapy monitoring of Atypical hemolytic uremic syndrome (aHUS) but methods are complex and costly.

Methods: We developed a cell-based C5b9-ELISA to measure C5b9-deposits on activated endothelial cells. Patients with suspected aHUS and other thrombotic microangiopathies were identified in early disease stage. Serum was drawn and tested versus healthy controls. After confirmation of the diagnosis aHUS therapy efficiency was monitored using the assay.

Results: In patients with the clinical diagnosis of aHUS we were able to show up to six-fold higher C5b9-depositions in contrast to normalized human serum (NHS) (p-value < 0.0001). In comparison to healthy controls, patients suffering from either Shiga-Toxin-HUS or Thrombotic Thrombocytopenic Purpura (TTP) we could demonstrate a two- to three-fold higher deposit (p-value=0.0103 and below). After onset of eculizumab treatment, the amount of C5b9-deposits becomes lower than in healthy controls, proving the efficiency of the therapy. One-Way-ANOVA shows significant differences between aHUS-groups and controls, but not between aHUS patients using Tukeys-multiple comparisons test.

Conclusions: We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring C5b9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.

ELISA-results with 95 % CI. A: C5b9-deposits in different patients. B: C5b9-deposits before and after two doses of eculizumab in patient 2 compared to healthy control 1.

PO2265

Chronic Neurological Impairment in Patients with Thrombotic Thrombocytopenic Purpura: Preliminary Findings in a Comprehensive MRI Protocol

Jeff Hamilton, Michael T. Jurkiewicz, Jonathan D. Thiessen, Shih-Han S. Huang. Western University, London, ON, Canada.

Background: Thrombotic thrombocytopenic purpura (TTP) is a life-threatening blood disorder characterized by insufficient activity in ADAMTS13 (a disintegrin and metalloproteinase with thrombospondin type 1 motif, member 13). This protein prevents blood clotting, so in TTP there is spontaneous clotting throughout the microvasculature. Treatment includes plasma exchange therapy and immunosuppressants to improve fever, thrombocytopenia, and kidney failure. However, neurological changes, such as seizures and confusion, persist. There is limited research on TTP on the brain but it is known that TTP presents similar pathology to stroke. This study aims to better understand the long-term impact of TTP on the brain using a comprehensive magnetic resonance imaging (MRI) protocol and cognitive testing.

Methods: 13 patients (5 male, mean age 44.5) in hematological remission were recruited. Participants had a 65-minute MRI scan (Siemens mMR Biograph 3T) based on best-practice guidelines for imaging stroke. The protocol included five qualitative acquisitions and three quantitative acquisitions. Participants also completed a 40-minute cognitive test (Cambridge Brain Sciences) to assess cognitive impairment.

Results: Table 1 summarizes the findings across qualitative acquisitions. The most salient findings were the white matter hyperintensities seen in the T2 FLAIR in Image 1. 12 participants completed the cognitive testing and there is evidence of cognitive impairment.
PO226 Persistent Coagulation Abnormalities in ESRD After 1 Year of Follow-Up
Emily Rontekoe, Vinod K. Bansal, Fakihma Siddiqui, Debra Hoppensteadt, Jawed Fareed. Loyola University Medical Center, Maywood, IL

Background: Common to end-stage renal disease (ESRD), coagulation abnormalities can lead to severe bleeding events or excessive thrombosis formation and engender increased morbidity and mortality in this population. Repeated heparin administration to ESRD patients during maintenance hemodialysis may also contribute to changes in the coagulation system. Thus, profiling coagulation parameters in ESRD patients over 1-year may provide insight to long-term coagulation dysfunction in this population.

Methods: Blood samples were collected at baseline and 1-year from ESRD patients undergoing maintenance hemodialysis (n=95) 48-hours post-dialysis. Plasma samples were analyzed using clot-based methods including activated partial thromboplastin time (aPTT), prothrombin time (PT), and thrombin time (TT). Chromogenic assays measured heparin levels by anti-Xa and anti-IIa methods. Patients were categorized by heparin administration during dialysis (n=44) and compared via statistical method and percent change.

Results: In the clotting and chromogenic assays, all parameters were elevated in the baseline and 1-year ESRD cohorts compared to controls, as shown on Figure 1. Only anti-IIa levels demonstrated a significant difference in ESRD patients after 1-year (p=0.0001). Heparin administration varied in aPTT, TT, and anti-Xa (p=0.05).

Conclusions: These results suggest ESRD patients on dialysis exhibit a long-term, hypo-coagulable state as shown by prolonged aPTT and TT. Elevated parameters maintained over 1-year suggests persistent dysregulation of clotting factors in ESRD patients. Circulating levels of heparin, as evidenced by anti-Xa and anti-IIa assays may be due to impaired clearance of heparin components via dialysis.

PO2267 Using Skin Biopsies to Measure Target Occupancy of a Renal Anti-fibrotic Monoclonal Antibody (mAb) in a Phase 1 Clinical Study
Rossan Boweed,1 Geoffrey I. Johnston,1 Linghong Huang, James Z. Song,2 Tim S. Schmidt,2 Allison L. Bigley,1 Graham Oggi,4 Eric Wong,1 Elizabeth S. Thomson,1 Jane Y. Chan,3 Anastasia Raivskas,1 Timothy S. Johnson,1 UCB Pharma, Slough, United Kingdom; 2Prisys Biotechnology, Shanghai, China; 3OracleBio, Chapelhill, United Kingdom; 4University of Oxford, Oxford, United Kingdom; 5Veramed, London, United Kingdom.

Background: Defining the optimal dose of drug required to bind to its mechanistic target (target occupancy, TO) and affect a measurable distal event (target engagement, TE) in damaged kidney is a challenge in the development of anti-fibrotic therapies for chronic kidney disease (CKD). We aimed to identify an accessible surrogate human tissue to predict TO in the kidney, prior to application in a Phase 1 study.

Methods: We developed a 'biopsy-on-biopsy' approach in skin: a 3mm biopsy initiated at the first month of 2020 was done. Adequacy was defined by the number of glomeruli for native renal biopsy (Bx) samples in our laboratory over time.

Results: From 2004 to 2018, there was a significant change in adequate biopsies. Deep nephrologists decreased from 29.7% to 28.5% to 14.2% to 12.7% in 2018. The needle gauge significantly changed from 27G to 22G to 18G to 16G in 2018. The needle gauge significantly changed from 27G to 22G to 18G to 16G in 2018.

Conclusions: Inadequate Tissue for Renal Biopsy Analysis Has Significantly Increased Since the Switch to Interventional Radiology (IR)
Patrick D. Walken,1 Vanessa Moreno,2 Caleb Nissen,3 'Arkana Laboratories, Little Rock, AR; 1University of Arkansas for Medical Sciences, Little Rock, AR

Background: The aim of this study was to determine the incidence of inadequate native renal biopsy (Bx) samples in our laboratory over time.

Methods: A retrospective study of native kidney biopsy adequacy from 2004 through the first month of 2020 was done. Adequacy was defined by the number of glomeruli for light microscopy (LM) as follows: 1. Ideal ≥20; 2 Adequate 10-19; Limited 4-9; Miss 0-3. An in-depth study of kidney biopsies received in 2004 and April-August of 2018 was conducted. Comparisons were made with 29.3 mL/min/1.73m². At the end of follow-up, eGFR was 39.6 ± 20.9 mL/min/1.73m². The mean miss rate changed from 2% in 2004 to 7% in 2009 through 2018. The needle gauge significantly changed from 27G to 22G to 18G to 16G in 2018.

Results: Inadequate Biopsy Analysis Has Significantly Increased Since the Switch to Interventional Radiology (IR)
Patrick D. Walken,1 Vanessa Moreno,2 Caleb Nissen,3 'Arkana Laboratories, Little Rock, AR; 1University of Arkansas for Medical Sciences, Little Rock, AR

Background: The aim of this study was to determine the incidence of inadequate native renal biopsy (Bx) samples in our laboratory over time.
important diagnostic tool. The change to IR as primary operators has significantly reduced tissue adequacy. An extraordinary educational outreach to IR is needed.

4 weeks to 10 weeks gestation. In addition, 8 early menophaeric kidney from 10 weeks to 21 weeks of gestation were identified from our surgical pathology and autopsy cases for comparison with menophaeric specimens. Beside routine hematoxylin and eosin staining, the sections were stained for Periodic Acid Schiff (PAS) to detect proximal tubules (PT) brush borders and glomerular basement membranes (GBM). Furthermore, menophaeric and metanphreric sections were immunohistochemically stained for CD133 for progenitor cells, GATA3 for mesangial cells and distal tubules, P504S for proximal tubules, and kidney injury molecule-1 (KIM-1) for PT injury.

**Results:** CD133 was positive in mesophaeric glomerular and tubular structures at 4 weeks but this expression disappeared in the menophaeric from 5 weeks to 10 weeks, implying gradual maturation. GATA3 staining was positive in Wolffian duct, mesangial cells of primordial glomeruli (at 7 weeks the GBM was PAS+) and distal tubules, but not in PT. PT were positively stained for P504S. PT of mesophaeric kidneys revealed brush borders on PAS stained sections from 7 to 10 weeks suggestive of reabsorption capacity. The PT of mesophaeric at 7 weeks stained positively for KIM-1, suggestive of acute tubular injury during apoptosis processes. The menophaeric showed expression of markers in respective renal compartments, similar to those in mesophaeric.

**Conclusions:** Human mesophaeric can have GATA3+ mesangial cells in the glomeruli. Although structures are simplified (no loop of Henle and collecting ducts), the human mesophaeric nephrons include primitive glomeruli, PT showing brush borders and distal tubules, having morphological features similar to those of advanced metanphric stages with excretory function. They have react to injury, at least during 7 to 10 weeks of gestation based on identification of brush borders and KIM-1 expression in PT.

**PO2272**

### Monogenic Causes of Nephrolithiasis or Nephrocalcinosis in Korean Children

Jeong yeon Kim,1 Beomhee Lee,2 Heeyeon Cho,1 Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea.

**Background:** Nephrolithiasis (NL) or nephrocalcinosis (NC) can be the early manifestation of hereditary nephropathy in children and early detection of hereditary nephropathy gives us chance to provide therapeutic and preventative intervention. In this study, we present genetic characteristics of NL/NC in pediatric patients who were treated in tertiary medical center in Korea.

**Methods:** The medical records of pediatric patients (age of 0-18 year) who had NL/NC and underwent genetic test under suspicion of hereditary nephropathy from March of 2013 to January of 2020 in Samsung Medical Center, Korea were reviewed. When specific disease was suspected, the sanger sequencing was done. The whole exome sequencing was performed when suspected mutations were not detected in sanger sequencing or when the disease could not be specified. DNA was extracted from whole blood or saliva. The novel mutations were evaluated by clinical findings and bioinformatics analysis such as in silico prediction.

**Results:** Total 20 patients underwent genetic test and two of them were sibling. The median age at the time of NC/NL detection was 4.8 years and male was predominant (M/F=2:3). Genetic diagnosis was done at the median age of 5.5 years. Three patients had family history of NC/NC (15%). Total 13 pathogenic gene mutations were detected in 16 patients (80%): 5 genes (SCL3A1, GRIK1, CLCN5, OCLR1, CLCNKB) were known to cause monogenic forms of NL/NC and 8 genes (PA2X, PKD1, HNF1B, SLC36A2, SLC34A1, SLC34A2, SLC34A3, SLC33A1) were newly detected in this study. Three pathogenic autosomal recessive mutations were detected in 3 individuals; BUB1B (n=1), GRIK1 (n=1), VPS33B (n=1). We also detected pathogenic mutations in 6 autosomal dominant genes in 7 individuals; CLCNKB (n=1), SLC3A1 (n=1), PA2X (n=1), HNF1B (n=2), SLC11A (n=1), PKD1 (n=1), SLC36A2 (n=1). Two X-linked recessive genes were detected in 5 individuals; CLCN5 (n=4), OCLR1 (n=1). In one patient, X-linked dominant gene was detected; PHEx. Eight of 16 detected mutations (50%) were novel mutation that have not been previously reported in database of human disease causing mutation.

**Conclusions:** In conclusion, NL/NC can be the clue to detect monogenic cause of hereditary nephropathy in children. Further large population study is needed to evaluate NL/NC as indicator for genetic analysis to detect monogenic hereditary nephropathy in children.

**PO2273**

### Trans IL-6 Signaling Does Not Distinguish Between Pediatric Patients with and Without Scarring After Febrile Urinary Tract Infection

Sudipti Gupta, Sara E. Lautenbiser, John D. Spencer, Brian Becknell, Christina B. Ching, Nationwide Children’s Hospital, Columbus, OH.

**Background:** The inflammatory response generated in response to infection is believed to be largely responsible for the development of renal scarring after UTI. IL-6 is a cytokine known to be induced during UTI with a putative role in mediating renal fibrosis known as trans signaling. We hypothesized there would be differences in markers of trans IL-6 signaling between patients with a history of febrile urinary tract infection (UTI) who had subsequent renal scarring as compared to those with a history of febrile UTI who did not develop renal scarring.

**Methods:** Urine samples were collected on consenting/assenting pediatric patients with a history of febrile (≥38°C) UTI (urine culture ≥50K uropathogen) with documented presence or absence of renal scarring on imaging. Patients were not actively infected at time of sample collection. Enzyme-linked immunosorbent assays were performed on samples for markers of trans IL-6 signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble
Bacterial suspension was inoculated with a catheter transurethrally. To assess the colony-clearing UPEC UTIs resistant to experimental UTI.

David Human Neutrophil Peptide 1-3 Protects the Urinary Tract from PO2275 Febrile and Afebrile Urinary Tract Infection

Results: 50 urines from patients with a history of febrile UTI were collected: 23 with and 27 without scarring. The groups were not significantly different in age or gender. Urine IL-6 levels (pg/mL) in patients with and without scarring were not significantly different between those with and without scarring. While IL-6 values significantly correlated with sgp130 values (p=0.0004) in those without scarring, the values did not correlate in those with scarring (p<0.05). Ratios of IL-6/sgp130 and sIL-6R/sgp130 were not different between groups.

Conclusions: This study found that expression of trans IL-6 signaling in those with renal scarring compared to those without due to a lack of correlation of sgp130 with IL-6 in those with scarring. The absolute values and ratios of these markers of trans IL-6-signaling, however, are not significantly different between individuals with a history of febrile UTI with and without renal scarring in the non-acute setting.

PO2274

Markers of Trans IL-6 Signaling Are Not Differentially Induced During Febrile and Afebrile Urinary Tract Infection

Sudipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. Nationwide Children’s Hospital, Columbus, OH.

Background: Febrile urinary tract infections (UTIs) are generally thought to be evidence of tissue inflammation such as pyelonephritis as compared to afebrile UTIs which are thought to be more localized to the bladder. As such, generally the concern for renal damage is more in those with febrile UTI and thought to be a result of the inflammatory response generated. IL-6 is a known mediator of inflammation, particularly through its trans signaling pathway. We hypothesized there would be differences in markers of trans IL-6 signaling in the urine of children with febrile compared to afebrile UTI.

Methods: Pediatric patients with signs of active UTI were consented/assented for participation in this study. Urine was collected at time of evaluation for active UTI in the urology or nephrology office or at hospitalization and were divided into those with a fever (axillary temperature ≥38°C) compared to those without (<38°C). Patients were included in the analysis if they had a positive urine culture (>50K CFU of a uropathogen) and for those without a fever if they had symptoms of dysuria, urgency, frequency, or new or worsening urinary incontinence. Those with fever were termed afebrile UTI and those without a fever were termed febrile UTI.

Results: 17 patients with febrile UTI and 23 patients with afebrile UTI were included. Two of the patients with febrile UTI were male while all of the afebrile UTI patients were female (p=0.1258). The groups did not differ significantly based on age (p=0.6218). While we found that those with a febrile UTI had a higher IL-6 in their urine at the time of collection (p=0.0479), there was no significant difference in expression of sIL-6R or sgp130. Ratios of these markers also were not significantly different.

Conclusions: Markers of trans IL-6 signaling, either as absolute values or ratios, are not different between individuals at the time of febrile or afebrile UTI.

Human Neutrophil Peptide 1-3 Protects the Urinary Tract from Uropathogenic Escherichia coli Infection in Humanized Mouse Model

Jorge J. Canas, Jenaya Hooks, Sam W. Arregui, Andrew L. Schawderer, David S. Hains. Division of Pediatric Nephrology, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN.

Background: Urinary tract infection (UTI) susceptibility is defined by heritable genetic differences associated with the innate immune system development and efficiency. DNA copy number variations in the alpha-defensin DEF A1A3. species as a causative organism (OR 6.222; 95% CI 2.396-15.46; P<0.001), previous antibiotic exposure to patients (OR 2.418; 95% CI 1.071-5.461, P=0.04), and stayed longer in hospital than the ESBL-negative study group (7.0 days vs. 4.5 days, <0.001).

Methods: We generated female mice with a Rnase6<sup>EGFP<sup> knock-in allele, human RNASE6 transgenic, or controls on a C57BL/6J genetic background. We identified cellular sources of RNase 6 along with the consequences of its gain and loss of function during experimental urinary tract infection (UTI).

Results: Rnase6<sup>EGFP<sup> mice were female (p=0.1258). The groups did not differ significantly based on age (p=0.6218). While we found that those with a febrile UTI had a higher IL-6 in their urine at the time of collection (p=0.0479), there was no significant difference in expression of sIL-6R or sgp130. Ratios of these markers also were not significantly different.

Conclusions: Markers of trans IL-6 signaling, either as absolute values or ratios, are not different between individuals at the time of febrile or afebrile UTI.

Risk Factors for Urinary Tract Infection Caused by Extended-Spectrum Beta-Lactamase Gram-Negative Bacteria in Infants

Yi Hong Ahn, Hyun Kim, Jyunyeong Lee, Seonhee Lim, Hee Gyang Kang, Yu-Jeong Han, Ji Hyeon Kim, Jyunyeong Lee, Seonhee Lim, Hee Gyang Kang. 1Seoul National University Children's Hospital, Seoul, Republic of Korea; 2Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 3Inha University Hospital, Incheon, Republic of Korea.

Background: Community-acquired extended-spectrum beta-lactamase (ESBL)-producing bacterial infections are an evolving public health problem. Urinary tract infections (UTIs) due to ESBL-producing bacteria are increasing even in infants rarely exposed to antibiotics. We aimed to identify risk factors for UTI caused by ESBL-positive bacteria in infants.

Methods: We retrospectively analyzed the medical records of hospitalized infants with the first episode of UTI from 2018 to 2019. Data includes demographic characteristics, birth history, previous use of antibiotics, febrile event, urinalysis results, and urine isolated organisms. Multivariate regression analysis was used to quantify independent risks associated with ESBL-positive UTI.

Results: UTIs were diagnosed in 266 patients at a median age of 3.6 (interquartile range 1.2-5.4) months of age. Two (0.4%) patients were diagnosed with UTI caused by ESBL-producing bacteria. When we divided patients according to ESBL status, there was no difference in gender, age, birth history, milk type, and use of postpartum care centers. Maternal use of antibiotics during pregnancy (odds ratio [OR] 3.817, 95% confidence interval [CI] 1.812-8.040, P<0.001), previous antibiotic exposure to patients was higher in the ESBL-positive group than in the ESBL-negative group (32.3% vs. 10.3%, P<0.001, and 22.6% vs. 12.3%, P=0.044, respectively). Klebsiella species was more frequently identified in the ESBL-positive group than in the ESBL-negative group (19.4% vs. 4.9%, P=0.002). In multivariate analysis, maternal use of antibiotic during pregnancy (odds ratio [OR] 3.817, 95% confidence interval [CI] 1.812-8.040, P<0.001), previous antibiotic exposure to patients (OR 2.418; 95% CI 1.071-5.461, P=0.04), and Klebsiella species as a causative organism (OR 6.222; 95% CI 2.396-16.158, P=0.001) were associated with ESBL positivity. A comparison of clinical courses of patients, the ESBL-positive group showed severe leukocytosis (WBC 16,795 /μL vs. WBC 14,620 /μL, P<0.04), and stayed longer in hospital than the ESBL-negative group (7.0 days vs. 4.5 days, P=0.001).

Conclusions: In this study, the high rate of ESBL positivity was detected in infants with UTI. Antibiotics exposure on both parents and infants was associated with UTI caused by ESBL-producing bacteria. Identification of underlying risk factors could improve treatment and preventive strategies.
PO2278

Urinary Sodium to Potassium Molar Ratio in Pediatric Stone Patients
Vimal Master sankar rai, University of Illinois College of Medicine at Peoria, Peoria, IL.

Background: The incidence of pediatric stone disease is on the rise. Dietary elements including high salt intake and reduced water consumption remain the major risk factors for stone formation. Urine stone profile in pediatric literature remains limited. The purpose of this study is to get data on 24 hr urinary mineral excretion in pediatric stone formers with particular emphasis on these two research questions 1. How does urinary sodium/potassium (Na/K) molar ratio in pediatric stone patients compare to the national average intake data in USA? 2. How does risk factors of stone formation such as hypercalciuria correlates with dietary risk factors in pediatric stone formers?

Methods: This retrospective cohort study included all Pediatric stone patients who attended outpatient Nephrology clinic from 03/1/2014 to 10/1/2018. Children with known metabolic/genetic causes for stone disease, incomplete 24 hr urinary collection or on medications that affect mineral excretions were excluded from the study.

Results: 150 patient charts were screened and 89 included in the study. Average age of the study population was 12.7 years with 58% females and 42% males. Mean Na/K molar ratio in pediatric stone patient was 3.7, statistically significantly higher than the national average of 2.5 using one sample T test (P < 0.001). Urinary calcium excretion showed a strong linear correlation with sodium excretion (r = 0.545, P < 0.001). Multiple regression model using urinary calcium excretion as the dependent variable showed correlation with Urinary sodium excretion (P = 0.004), urinary volume (P < 0.0001) and uric acid (P = 0.001)

Conclusions: 24 hr urinary sodium potassium molar ratio is significantly higher in stone formers indicating a higher salt and lower potassium consumption when compared to national average intake. Water intake, salt consumption and alteration of urinary Ph remains the main dietary modality to alter calcium excretion and hence reduce risk of stone formation.

PO2279

Keratin 5+ Urothelial Cells Are Developmental and Tissue Repair Progenitors in the Bladder
Ashley R. Jackson, Birong Li, Brian Becknell. Center for Clinical and Translational Research, Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; Division of Pediatric Nephrology, Nationwide Children’s Hospital, Columbus, OH.

Background: Urothelium is nearly quiescent during homeostasis, but injury engages a robust regenerative capacity. Several progenitor cell candidates have been implicated, but prevailing models demonstrate conflicting roles discrete urothelial subpopulations. We recently demonstrated that Keratin 5 (K5)-expressing UCs are temporally restricted renal urothelial progenitors. It is unclear whether similar temporal restrictions are imposed on bladder K5-UCs, and whether an investigation into the temporality of the K5-UC progenitor may clarify bladder progenitor models. The objective of this study was to determine temporal progenitor-progeny relationships responsible for bladder urothelium generation and regeneration.

Methods: Using Ker5+;CreERT2;Rosa26 mice, K5-UCs were inducibly and permanently labeled with tdTomato (tdT). Tamoxifen (TMX) was administered at postnatal day (P) 1, 7, 14, P14, P21 or P41. Mice were sacrificed (SAC) at P42 or subjected to a single round of urothelial injury (cyclophosphamide) and euthanized 2 weeks later. Immunofluorescence microscopy was used to visualize and quantify tdT, K5, (uroplakin), Upk and K20 expression.

Results: Fate mapping analysis found that 22% (TMX0;SAC0) and 23.5% (TMX0; SAC0) of neonatal tdT+ UCs differentiated into adult Upk+ UCs (tdT-;Upk+ mostly intermediate cells) by P42 compared to 9% (TMX0;SAC0) or 2.25% (TMX0;SAC0) of juvenile tdT+ UCs, and 0% adult (TMX0;SAC0) (P<0.01, ANOVA). Following urothelial injury, 63% (TMX0;Cyc-); 54.33% (TMX0;Cyc-); and 69% (TMX0;Cyc-;Cyc0) of umbrella cells expressed tdT2 (tdT2;K5+;Upk20). Adult (TMX0;Cyc+;Cyc0) tdT+ UCs rarely formed umbrella cells.

Conclusions: K5-UCs form intermediate and superficial cells, but the capacity for K5-UCs to form these derivatives is lost over time. In response to acute adult bladder urothelial injury, neonatal and juvenile tdT+ UCs regenerate umbrella cells, while adult tdT+ UCs do not. These studies establish that bladder K5-UCs are context dependent progenitors - responsive to temporal and pathologic cues. Our findings support an intermediate cell acute injury progenitor model, and show that intermediate cells formed by neonatal and juvenile K5-UCs repair acutely injured bladder urothelium.

PO2280

Perinatal Cystatin C as Biomarker of Nephron Endowment
Beatrice L. Crippa, Stefano Ghirardello, Valentina Capone, Gianluigi Ardissino. 1NICU, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy.

Background: Nephron endowment has a wide individual variability and plays a crucial role in drug toxicity, outcome of kidney diseases and pathogenesis of arterial hypertension (AH), but nephrons count is technically impossible in vivo. During acute dehydrations, subject with reduced nephron mass (unilateral renal agenesis or renal hypoplasia) exhibit increased levels of biomarkers of renal function compared to healthy subjects. We hypothesized that healthy newborns with reduced nephron endowment will have high levels of cystatin c (Cys-c) during perinatal dehydration. The aim of the study was to compare Cys-c level during physiological perinatal dehydration in healthy term infants with hypertensive fathers (HF) and normotensive fathers (NF).

Methods: Healthy, Caucasian, born at term neonates were enrolled: infants with fathers on antihypertensive therapy were compared to infants with normotensive fathers > 40 yo. Enrolled infants underwent Cys-c capillary determination at time of expanded newborn screening.

Results: We enrolled 40 infants with HF and 80 infants with NF. Basic characteristics were not different between the two groups except for the number of hypertensive grandfathers, that was higher among infants with HF. Cys-c levels was determined at a median of 62.5 hours of life (IQR 55-71) without any difference between groups. Cys-c was significantly higher in infants with HF (1.6 ± 0.3 mg/L vs 1.4 ± 0.3 mg/L, p = 0.01). Linear regression analysis corrected for confounders (type of feeding, delivery mode, weight loss velocity) confirmed that paternal hypertension was the only variable significantly associated with high Cys-c level (mean difference 0.2 mg/L, IC 95% 0.1-0.3 in, p = 0.01).

Conclusions: Our results support the key role of nephron endowment in the pathogenesis of AH and suggest the possibility of identifying at-risk subjects at birth. This opportunity opens up specific and targeted preventive health measures very early in life.

PO2281

Elevated Urinary Neutrophil Gelatinase-Associated Lipocalin Predicts Postoperative AKI
Cara L. Slagle, Hailey W. Gavigan, James A. Rowe, Brenda Poindexter, Kelli A. Kralilman, Alexandra Schmerger, Chunyan Liu, Shelley Ehrlich, Meera Kotagal, Stuart Goldstein. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Post-operative acute kidney injury (AKI) in neonates remains understudied despite occurring frequently. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as a novel predictive biomarker for AKI, yet clinical utilization lags behind in neonatology.

Methods: Infants undergoing a general surgical procedure, excluding gastric tube placement alone, were prospectively enrolled. uNGAL samples were obtained prior to surgery and over post-operative days (POD) 0-3 at six time points. AKI was defined by the 2014 neonatal modified Kidney Diseases: Improving Global Outcomes (KDIGO) definition. Samples were processed using The NGAL Test® (BioPorto, Denmark). Generalized additive mixed effect model (GAMM) was utilized to study the longitudinal trajectory of log transformed uNGAL values. The ability to predict AKI was assessed using receiver operating characteristic curves (AUC-ROC).

Conclusions: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

693
**Results:** A total of 141 neonates underwent 192 surgical procedures. AKI occurred in 90% of infants. AKI was more likely to have undergone an emergent procedure (63% vs. 31%, p=0.001) and had higher uNGAL levels (Table 1). Pre-op uNGAL did not differ between AKI and no AKI patients (26ng/ml vs 59ng/ml, p=0.12). uNGAL levels were higher at all post-op time points even when controlled for pre-operational AKI (p ≤ 0.001 to 0.0536). The AUC-ROC for predictability of post-operative AKI using uNGAL at 24 hours was 0.8 (95% CI: 0.71,0.88).

**Conclusions:** Post-op uNGAL predicts AKI. In patients undergoing emergent procedures, careful monitoring of renal function should be performed and uNGAL offers clinicians a guideline to avoid further FO. uNGAL trends could allow clinicians to better understand renal injury in real time and adjust treatment plans and/or avoid or restart nephrotoxic medications.

**Funding:** NIDDK Support, Private Foundation Support

Abbreviations: Renal Angina Index (RAI)

**Results:** The optimal cutoff for creatinine-based DayAKI was found to be stage 3; the optimal cutoff for RAI was stage 3; and the optimal cutoff for uNGAL was 0.79 (95% CI: 0.70, 0.87) and 0.79 (95% CI: 0.69, 0.82) respectively, although each scoring measure differed in sensitivity and specificity. The modified RAI had an optimal cutoff of ≥ 10 and the highest AUC (0.79; 95% CI 0.72, 0.85) with a high sensitivity and moderate specificity for prediction of CRRT requirements (table 1).

**Conclusions:** As a more accurate tool for discriminating patients in need of CRRT, a modified RAI has numerous potential implications. Identifying patients who ultimately require CRRT at an earlier timepoint may influence timing of CRRT initiation in an attempt to improve nephrotoxic exposure further. Furthermore, the diagnostic capabilities of the modified RAI may be further refined by the addition of urinary biomarkers. These findings should be validated in a larger cohort.

| Modification of the Renal Angina Index for Identifying Need for Renal Replacement Therapy in Pediatric Shiga Toxin-Producing Escherichia coli-Associated Hemolytic-Uremic Syndrome (STECK-HUS): A Single Center’s 12-Year Experience

Neha D. Pottanatt, Sarah P. Andreoli, Chiuee Miller, Myda Khalid. Indiana University Riley Hospital for Children, Indianapolis, IN.

**Background:** Half to 2/3 of children with STEC-HUS require renal replacement therapy. The modality is chosen based on a center’s individual experience and its association with complications.

**Methods:** We performed a retrospective cohort analysis using electronic medical records and chart review of 80 patients with STEC-HUS identified through billing data from July 1, 2008 to May 30, 2020. Cases of Streptococcal pneumoniae associated HUS and atypical HUS were excluded.

**Results:** Dialysis was required in 47 patients (59%). Except for one patient, acute PD was chosen as the initial modality. 43 patients (91%) received PD successfully immediately after the catheter was placed. Four patients required a modality change to either hemodialysis (HD) or continuous renal replacement therapy (CRRT). Leaking of dialysate around the catheter exit site was noted in only 5 patients, out of which only one underwent a catheter revision and resumed PD successfully, two were switched to HD, and two patients had renal recovery allowing for cessation of dialysis. Peritonitis occurred in a single patient but did not lead to a change in modality. In two patients, PD was unsuccessful due to severe intestinal ischemia/collitis, and these patients were switched to CRRT. A central venous catheter (CVC) was often placed at the time of the PD catheter (40 patients). 46 patients had thrombocytopenia (<100,000/mm3) prior to PD catheter and/or CVC placement. Despite having a mean preoperative platelet count of 42,100/mm3, only 6 patients received a platelet transfusion. Furthermore, 15 patients with preoperative platelets between 15,000 – 35,000/mm3 did not have a bleeding event and did not receive a transfusion.

**Conclusions:** During a time when HD and CRRT have become the more preferred modalities for acute dialysis in children in the US, acute PD is safe and successful in STEC-HUS. We describe a low complication rate, despite immediate use of the PD catheter, indicating that acute PD can be performed before the exit site heals. Platelet transfusions in STEC-HUS patients confer greater odds of AKI and those with AKI had worse long-term outcomes. Attention to kidney function should be paid to neonates with PD catheter and CVC placement.

**PO2285**

**Post-Operative Fluid Overload Is Associated with AKI and Elevated Urinary Neutrophil Gelatinase-Associated Lipocalin Values**

Cara L. Slagle, Hailey W. Givigan, James A. Rowe, Brenda Poidexter, Kelli A. Krrallman, Alexandra Schmeger, Meera Kotagal, Shelby Ehrlich, Chunyan Liu, Stuart Goldstein. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

**Background:** Positive fluid accumulation (FO) in neonates is associated with increased morbidity and mortality and may represent underlying acute kidney injury (AKI). AKI is defined by changes in serum creatinine (sCr) and urine output (UOP). FO can be unreliable in the setting of FO. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as an alternative biomarker in assessing AKI in patients with FO.

**Methods:** Infants undergoing a general surgical procedure, excluding gastric tube placement alone, were prospectively enrolled. uNGAL values were obtained pre-op and on post-op days (0-3) at six time points. FO was defined as 10% weight increase from pre-op weight during PODs 0-5. Percent FO was calculated using post-op net fluid balance=[pre-op weight] + [weight gain during PODs 0-5] - [pre-op weight]. The AUC was calculated by Bland-Altman analysis using median and IQR data. The uNGAL threshold for FO was determined as the 90th percentile of uNGAL values and did not receive a transfusion.

**Conclusions:** Positive fluid accumulation in neonates is associated with increased morbidity and mortality and may represent underlying acute kidney injury (AKI). AKI is defined by changes in serum creatinine (sCr) and urine output (UOP). FO can be unreliable in the setting of FO. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as an alternative biomarker in assessing AKI in patients with FO.

**Methods:** Infants undergoing a general surgical procedure, excluding gastric tube placement alone, were prospectively enrolled. uNGAL values were obtained pre-op and on post-op days (0-3) at six time points. **Use of B-Type Natriuretic Peptide as a Quantitative Marker of Fluid Overload in Neonatal Renal Replacement Therapy**

Nourreddin D. Nourbakhsh,1,2 Nadine M. Benador,1,2 Comprehensive Kidney Care Center, Rady Children’s Hospital, San Diego 1Rady Children’s Hospital, San Diego, San Diego, CA; 2University of California San Diego, La Jolla, CA.

**Introduction:** Neonatal renal replacement therapy (RRT) remains one of the most challenging dialysis scenarios in Pediatric Nephrology. Evaluation of dry weight can be particularly difficult as fluid overload may be mistaken for adequate nutritional weight gain. Physical exam is insensitive in assessing hypervolemia until significant fluid overload develops. Non-invasive BP measurements are often difficult to obtain as upper extremities are typically used for IV access and the patient’s lack of cooperation alters measurement. B-type natriuretic peptide (BNP) has long been used in the evaluation of heart failure and has even been reported to be a marker of fluid overload in adult hemodialysis patients. In this study, we evaluate the role of BNP as a quantitative marker of fluid overload in a neonate with ESRD.

**Case Description:** A 3 week old child with bilateral renal agenesis required emergent RRT. Following the failure of peritoneal dialysis in this 2.19 kg child, RRT modality was converted to hemodialysis (HD). Despite daily 3 hr HD treatments with ultrafiltration (UF) goals guided by weight, physical exam findings and blood pressure, patient developed bilateral pulmonary edema and an enlarged cardiac silhouette at 3 weeks of age. BNP was converted to HDVHD, but upon transition to HD, she again developed fluid overload and required placement back on CVVHDF. Thereafter, BNP was utilized as a quantitative marker of fluid overload in this patient with RRT.

**Discussion:** Providing successful dialysis in infants is more problematic than in older patients. To assess fluid overload in children on dialysis, traditional tools include clinical assessment, serial weights and measuring blood pressure. In this infant, measurement of serial BNP levels allowed for an objective assessment of volume status, which was helpful in maintaining dry weight and lead to successful dialysis.

**Comparison of Nafamostat Mesylate and Regional Citrate Anticoagulation for Anticoagulation in Pediatric CRRT**

Mai J. Miyaji,1,2 Kelli A. Kraliman,1 Kentaro Ide,1 Stuart Golstein,1 1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2National Center for Child Health and Development, Kokuritsu Kenkyu Kaisatsu Hojin Kokuritsu Seiiku Iryo Kenkyu Center, Setagaya-ku, Japan.

**Background:** Regional Citrate Anticoagulation (RCA) is the preferred anticoagulant for CRRT in the US and children. Nafamostat Mesylate (NM), a synthetic serine protease, has been widely used for CRRT anticoagulation in Japan and Korea. While NM is considered safe and effective, there is a paucity of evidence in pediatric literature. We describe the safety and efficacy of NM compared to RCA for pediatric CRRT.

**Methods:** Using one children’s hospital in Japan and one in the US, medical records of patients <21 years who received CRRT between 2017-2019 were reviewed. Patients receiving CRRT concurrently with ECMO were excluded. Basic demographics, CRRT characteristics, and outcomes were analyzed between the RCA and NM groups. Filter life (FL), defined as the number of hours a single CRRT filter was in use, was in, was the primary efficacy outcome of efficacy. For Kaplan Meier analysis, circuits were censored for elective filter discontinuation. Safety is assessed by anticoagulation complications.

**Results:** 28 pts (100 filters) received RCA and 36 pts (90 filters) received NM. Baseline Table 1. There was no difference in median FL (42.6h in RCA vs 42h in NM, p=0.17). Kaplan-Meier curves of time to spontaneous filter failure shown in Figure 1. The mortality and bleeding rate did not differ between the groups.

**Conclusions:** NM provides similar efficacy compared to RCA for FL. No significant difference in safety was observed between the two groups.

**Renal Replacement Therapy and Mortality Rates for Children with Posterior Urethral Valves and Prune Belly Syndrome**

Emily J. Stonestock,1 Yuri V. Sebastião,1 Brian Becknell,1,2 Christina B. Ching,1,2 Daryl J. McLeod,1,3 Nationwide Children’s Hospital, Columbus, OH; 1Center For Clinical and Translational Research, The Research Institute at Nationwide Children’s Hospital, Columbus, OH; 3Center for Surgical Outcomes Research, The Research Institute at Nationwide Children’s Hospital, Columbus, OH.

**Background:** Posterior Urethral Valves (PUV) and Prune Belly Syndrome (PBS) cause congenital obstructive uropathy and dysplasia in infants. Resulting chronic kidney disease and pulmonary hypoplasia may lead to renal replacement therapy (RRT), mechanical ventilation and death.

**Methods:** This retrospective cohort study queried The Pediatric Health Information System (PHIS) database to identify patients with PUV or PBS who were born at one of four cbo’s PHS hospitals by 3 months of age between 1/1/2006 and 9/20/2016. Ethnicity, race and insurance were investigated as predictor variables for time to RRT or in-hospital mortality. Prematurity and mechanical ventilation were evaluated as predictors of in-hospital mortality.

**Results:** 1673 PUV and 236 PBS patients met inclusion criteria. There was no difference in time to RRT or mortality based on ethnicity, race, or insurance. 212 patients (11.1%) required RRT by 2 years of age. There was no difference in RRT requirement between the PUV and PBS groups. 130 patients (6.8%) died during the initial admission:

Preterm Birth in Mice Results in Differential Gene Expression and Premature Cessation of Nephrogenesis

Aleksandra Cwiek, Kimberly Deronde, Masako Suzuki, Kimberly J. Reidy, Jennifer R. Charlton, Albert Einstein College of Medicine, Department of Genetics, New York, NY; Children’s Hospital at Montefiore, Department of Pediatrics, Division of Nephrology, New York, NY; University of Virginia, Department of Pediatrics, Division of Nephrology, Charlottesville, VA.

Background: Neonates born preterm are at risk of developing chronic kidney disease (CKD). In humans, nephron development is completed by 36 weeks’ gestation and the successful formation of nephrons is dependent on self-renewing niches of cells which reside directly under the kidney capsule in the nephrogenic zone (NZ). Little is known about the fate of these progenitor cells or the other compartments of the kidney following premature birth. The objective of this study was to characterize the effect of premature birth on kidney development in murine model of prematurity. We hypothesize that preterm mice will have a shorter period of postnatal nephrogenesis and gene expression profiles will reflect premature differentiation.

Methods: Timed pregnant CD-1 dams were stratified into 2 cohorts. The preterm group was comprised of 59 pups born by Cesarean section at 18 days post-conception (dpc) and the term group contained 79 pups delivered vaginally at 20 dpc. The mice were euthanized on 20-27 dpc. The presence of the nephrogenic zone was determined on histological sections. Genome-wide expression profiles of 20 dpc mice kidneys were evaluated with RNA-seq in both preterm and term groups (n=3 per group).

Results: At 25-27 dpc, kidney to body weight ratios were significantly lower in preterm cohort. In the kidney, the cap mesenchyme was not detectable in the preterm mice a full day (25 dpc) prior to its cessation in the term mice (24 dpc). The expression profiles of 20 dpc kidneys in the preterm group showed distinct alterations compared to the term group. The differentially expressed genes were enriched in a fat-soluble vitamin (including vitamin A and D) metabolic process related pathways.

Conclusions: In a mouse model of prematurity, there is an early differential expression of genes that may be important in nephrogenesis. The shortened window of nephrogenesis may result in a lower nephron number and future risk for CKD in neonates born preterm.

Gestational Age (GA) Affects Urine Biomarkers by Postnatal Age but Most Converge by 34 Weeks Post-Menstrual Age (PMA)

David J. Askenazi, Brian A. Halloran, Robert Schmicker, Patrick J. Heagerty, Sandra Jial, Stuart Goldstein, Sangeeta R. Hingorani, PENUT Investigators, The University of Alabama at Birmingham School of Medicine, Birmingham, AL; University of Washington, Seattle, WA; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Urine biomarkers may improve our understanding of kidney development and disease in premature neonates. We evaluate how 1-week differences in GA impact 11 biomarkers by postnatal age and PMA.

Methods: Neonates were grouped by GA. Urine was collected on postnatal days 1, 3, 5, 7, 9, 14, 28; on PMA of 30 and 34 weeks; and discharge in 750 neonates without stage 2/3 AKI. Neutrophil-gelatinase associated lipocalin (NGAL), Clusterin, kidney injury molecule 1 (KIM-1), alpha glutathione-S-Transferase (a-GST), albumin, beta-2-microglobulin (B2M), cystatin c, epithelial growth factor (EGF), osteopontin (OPN), uromodulin (UMOD), were evaluated by electrochemiluminescence; creatinine by mass spectrometer. Biomarkers are displayed as 7-day rolling mean (day X ± 3 days) on log10 scale. GEE models with mother as a clustering variable were used to determine the association between day, GA, and day*GA for each biomarker. T-tests evaluated differences in 34-week (± 3 day) PMA values.

Results: Figure: Left side plot biomarkers by postnatal age; right side plot biomarkers by PMA. When exploring the values by postnatal age, the most premature neonates have higher NGAL, clusterin, KIM-1, a-GST, albumin, B2M, Cystatin C, OPN, and lower EGF, UROMOD, and Creatinine (p<0.05; * in Figure) after adjusting for day. The association of biomarker and time is significantly modified by GA for a-GST, Albumin, B2M, Creatinine and Cystatin C (interaction term p<0.05; ** in Figure) over the first 30 postnatal days. Only B2M and OPN differ by GA at 34 weeks PMA (p<0.05, *** in Figure).

Conclusions: Urine biomarkers differ and are modified by GA during first 30 postnatal days. Most biomarkers converge and are not significantly different by 34 weeks PMA.

PO2291
The Association Between Infantile Pulmonary Hypertension, Sildenafil, and AKI During Hospitalization
Emily E. Zangla, Emily L. Joyce. University Hospitals, Rainbow Babies and Children’s Hospital, Department of Nephrology, Cleveland, OH.

Background: Pulmonary hypertension (pHTN) is a nidus for poor organ perfusion, and is an understudied potential risk factor for acute kidney injury (AKI) in infants. Neither the association between pHTN and AKI, nor treatment with phosphodiesterase-5 inhibitors (i.e. sildenafil) on renal recovery have been elucidated. We sought to describe AKI in a cohort of hospitalized infants with pHTN.

Methods: A retrospective chart review was performed on 18 infants (less than 1 year of age) during the initial hospitalization for diagnosis of pHTN over one year at a single institution. Adapted neonatal KDIGO criteria was utilized to determine presence of AKI during the hospitalization for each patient.

Results: Out of 18 infants with pHTN, 50% developed AKI during hospitalization. Those who developed AKI were older at the age of diagnosis of pHTN (p = 0.04) and more likely to be treated with sildenafil (p = 0.02). Within the cohort, 7 (39%) were treated with sildenafil. On univariate analysis, treatment with sildenafil was associated with increased odds of developing AKI (OR 6.7, 95% CI 0.81-55.0). Of those treated with sildenafil who developed AKI, 80% (4/5) developed AKI before initiation of treatment and 20% (1/5) developed AKI after initiation of treatment.

Conclusions: AKI is prevalent in infants diagnosed with pHTN. The increased odds of developing AKI in patients treated with sildenafil is likely a reflection of severity of illness, as most patients developed AKI prior to initiation of treatment. Further research is needed to evaluate the association between pHTN and AKI, as well as determine the role of sildenafil treatment in preventing AKI or promoting renal recovery.

Baby NINJA (Nephrotoxic Injury Negated by Just-in-Time Action) Transfusion Rates
Hailey W. Gavigan, Cara L. Slagle, Kelli A. Krallman, Brenda Poindexter, David K. Hooper, Stuart Goldstein. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: Acute kidney injury (AKI) is associated with poor outcomes in neonates. Nephrotoxic medication (NTM) exposure is a common cause of AKI. Nephrotoxic Injury Negated by Just-in-time Action (NINJA) identifies patients with high NTM burden and recommends daily creatinine (Cr) screening. In neonates, concern for iatrogenic anemia decreases AKI screening. We monitored transfusion rates in our project modeled off the neonatal NINJA adaptation, Baby NINJA.

Methods: Critically ill neonates with high NTM exposure initially received modified Cr monitoring (only with routine labs) before transitioning to standard daily Cr monitoring. Patients transfused 3 days into & up to 7 days after Baby NINJA exposure periods counted as an associated transfusion. Statistical process control methods were used to detect changes from baseline. X² and Poisson regression analyses were used to compare metrics between SCr monitoring eras.

Results: Figure 1 shows an increase in transfusions 15 weeks before an increase in Cr compliance. A decrease in transfusions was sustained through the standard Cr era where the highest rate of Cr compliance was seen. The rate of NINJA-associated transfusions was unchanged. Table 1 shows that Cr compliance increased during each era, transfusions decreased between modified & standard Cr eras, NINJA-associated transfusions remained stable, and transfusion rate changes were independent of NINJA-associated transfusions.

Conclusions: There was no association between transfusion rates and daily Cr testing with Baby NINJA implementation; therefore, critically ill neonates with high risk NTM exposure can safely be screened for NTM associated AKI.

PO2293
Elimination of Intravenous Phthalate Exposure Abrogates Most Neonatal Hypertension in Premature Infants
Katherine Farnbach, Ryan Forbush, Sandra Iragorri, Randall Jenkins. 1Oregon Health and Science University; Portland, OR, 2Boise State University, Boise, ID.

Background: The incidence of hypertension in premature infants in a neonatal intensive care unit (NICU) was noted to transiently drop during a 2-year period when the IV fluid (IVF) temporally changed to a phthalate-free IVF. The objective of the study is to quantify the effect of varying periods of IVF phthalate exposure on incidence of hypertension in premature infants.

Methods: A chart review was performed of all hypertensive premature infants born at one NICU during the last 6 years including a 3-year baseline period, a 20-month phthalate-free IVF period, and a 10-month period when the original phthalate-containing IVF returned to use. Patients born during 4-month transitions between periods were excluded. Incidence of hypertension for each period were compared for significant difference using Chi-Square analysis.

Results: Incidence of hypertension decreased from 9.7 cases per year (baseline) to 1.2 cases per year when IVF was phthalate-free, rising back to 12.0 cases per year when phthalate-containing IVF returned to use. Most cases met criteria for the pulmonary category of hypertension – for these infants the incidence of hypertension dropped from 7.3 to 1.2, then increased to 10.8 cases per year when evaluated for the same periods of varying phthalate exposure.

Conclusions: Serendipitous removal of IVF containing phthalates resulted in near elimination of hypertension in one NICU – an effect reversing entirely after the same brand of phthalate-containing IVF returned to clinical use. These results suggest that phthalate exposure from IVF plays a major role in neonatal hypertension, especially for those infants in the pulmonary category.
Children with a History of Low Birth Weight (LBW) Show Greater Reduction in Kidney Function Than Previously Described Using the Updated Schwartz Equation

Kaye E. Brathwaite,1 Rebecca Levy,1 Harini Sarathy,2 Ilir Agalli1,2 Tanya S. Johns,1 Kimberly J. Reidy,1,2 Frederick J. Kaskel,1,2 Michiel L. Melamed,1,2 Children’s Hospital of Philadelphia, Philadelphia, PA; 1University Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY; 1University of California San Francisco, San Francisco, CA.

Background: There is a higher risk of reduced kidney function in adults born with LBW (birthweight<2500g). A study using the Counahan-Barrat (CB) eGFR estimation showed a modest risk increase in adolescents with LBW. However the CB equation is based on histology are available; genetic analyses are not yet included. Efforts to improve the equation for CB equation is limited. A study using the Counahan-Barrat (CB) eGFR estimation showed a greater association of LBW and reduced kidney function OR 1.51 (95% CI 1.16-1.97) compared to the CB equation, OR 1.44 (95% CI 1.06-1.96). In an adjusted analysis, the odds of reduced kidney function in adolescents with LBW remained significant OR 1.46 (95% CI 1.1-1.97) using Schwartz but not the CB equation.

Conclusions: A higher prevalence of reduced kidney function was seen in children born with LBW utilizing updated Schwartz compared to the CB equation. The higher risk was sustained in adjusted analyses. These findings may support development of guidelines for CKD screening during long term follow up in the pediatric population with LBW.

PO2295

FCGG Renal Biopsy Network: First Epidemiological Report on Pediatric Renal Disease

Noel Knops,1 Johen M. De Meester,1 Amélie Dendooven,2 Wim Laurens,1 Ben Sprangers,1 Elena N. Levchenko,1 AZ Nikolaas, Sint-Niklaas, Belgium; 1Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; 1Universitair Ziekenhuis Gent, Gent, Belgium.

Background: In 2016, a regional renal biopsy network was founded as a collaboration between renal pathologists and nephrologists in order to standardize diagnosis and therapy. Uniform renal biopsy request and renal biopsy report forms were introduced, together with a new comprehensive list of renal pathology diagnoses for coding purposes. The study aim was to define options for pediatric eGFR reporting that optimize accuracy and minimize the impact of missing concurrent height in routine lab work.

Methods: We performed a cross sectional analysis of children aged 12-15 from the National Health and Nutrition Examination Survey from 1999-2016. Reduced kidney function was defined as eGFR <90mL/min/1.73m. Participant characteristics were described as weighted sample means and proportions. We constructed logistic regression models adjusted for important sociodemographic factors to evaluate the association of LBW with reduced kidney function.

Results: A total of 6345 individuals were analyzed, representing 13,760,132 adolescents of whom 8% had a history of LBW. Of those born with LBW, the mean age was 13.6 years, 49% were males, 49% were white, 25% were black, 19% were Mexican-American, and 7% were other race. All higher percentage of children with LBW was seen in worse poverty groups. Mean eGFRs in those born LBW were 103 and 107mL/min/1.73m using the updated Schwartz and CB equation, respectively. The prevalence of reduced kidney function in those born LBW was greater using the updated Schwartz equation compared to the CB equation, 30% vs 21.4%. The Schwartz equation showed a greater association of LBW and reduced kidney function OR 1.51 (95% CI 1.16-1.97) compared to the CB equation, OR 1.44 (95% CI 1.06-1.96). In an adjusted analysis, the odds of reduced kidney function in adolescents with LBW remained significant OR 1.46 (95% CI 1.1-1.97) using Schwartz but not the CB equation.

Conclusions: A higher prevalence of reduced kidney function was seen in children born with LBW utilizing updated Schwartz compared to the CB equation. The higher risk was sustained in adjusted analyses. These findings may support development of guidelines for CKD screening during long term follow up in the pediatric population with LBW.

PO2296

Facts Related to Significant Albuminuria or Low Glomerular Filtration Rate in Adolescents from a Population with a High Prevalence of CKD of Unknown Origin

Jose M. Arceola Guerra,1 Cesar M. Gutierrez, Izel Ovalle, Mariana J. Macias,2 Andrina L. Garcia Diaz.1,2 Centro Hospitalario do Estado de Mexico, Mexico.

Background: Chronic kidney disease (CKD) of unknown origin has been recognized as the leading cause of kidney disease in young adults in some underdeveloped countries. In Aguascalientes Mexico we report a high prevalence of treated CKD (1997 ppm), with more than half (54%) of unknown cause. The peak of prevalence is between 20 - 30 years (45%), being in that group 73% CKD of unknown origin. For this reason, a CKD screening study was designed in high school students in the state. The aim of this report is to describe the findings of a pilot study obtained in the first three schools.

Methods: Cross-sectional study of high school students. Determination of albumin/creatinine ratio was performed in isolated urine sample and standardized serum creatinine to calculate eGFR with Schwartz formula, an abnormal albumin/creatinine ratio>30 mg/ gr and GFR<75 ml/min were defined as CKD. Students and parents were questioned about potentially risk factors. For the multivariate analysis, only students with complete questionnaires were included.

Results: During March 2020, three high schools in the municipality of Calvillo (Aguascalientes) were visited, accepting entry to the study 187 students out of 260 (72%). The average age was 13.3 years (IQR 12-14) with a predominance of males (n = 109, 58.2%). 33 students with ph CKD were detected (17.6%), 32 of which were due to the presence of abnormal albumin/creatinine ratio. Only two patients had low GFR, one with 43 ml/min and the other with 75 ml /min. Four patients presented macroalbuminuria, the rest microalbuminuria. In the multivariate analysis, next variables remained significant: economic income less than 4,000 Mx$, (OR 4.4, 95% CI, 1.3 - 14.7), frequent NSAID intake (OR 3.5, 95% CI 1.16 - 13, P=0.02), a son or brother affected by diabetes (OR 4.3, 95% CI 1.2 - 14.5, P < 0.01), use of clay dishes by parents and grandparents (OR 4.3 95% CI 1.4 - 12.9, P < 0.01), and BMI <17 kg / m2 (OR 5.8, 95% CI, 1.8 - 18.7, <0.01).

PO2298
Measurement of GFR and Vasoactive Substances in Children with Sickle Cell Anemia
Oluwadamilola Ejike,1 George J. Schwartz,2 Susan Legan,3 Amy M. Becker,4 Raymond P. Quigley,5 Baylor Medical Center, San Antonio, TX; 2University of Rochester Medical Center, Rochester, NY; 3University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 4Driscoll Children’s Hospital, Corpus Christi, TX.

Background: Patients with sickle cell anemia (SCA) have a high risk of developing renal disease. Sickle cell nephropathy is thought to begin in childhood with higher than normal glomerular filtration rates (GFRs) known as hyperfiltration that can lead to proteinuria, sclerosis of the glomeruli, decreased GFR, and eventual renal failure. This model of sickle cell nephropathy has not been validated in clinical studies. This study measured directly the GFRs of patients with sickle cell anemia and age matched control patients. In addition, urinary vasoactive substances were measured to correlate with the GFR.

Methods: Subjects: SCA:32 and Control:13 The GFR of the sickle cell group was 148 ± 36 ml/min/1.73 m2 (Mean and SD) and the control group was 130 ± 17 ml/min/1.73 m2. The p-value (unpaired t-test) is 0.03 and thus is statistically significant. However, the SCA group had 21/32 with a GFR >130 while the control group had only 3/13 (p=0.019). Thus, there were more patients in the SCA group with hyperfiltration. There was no difference in urinary cGMP or PGE2. However, PGF2α was higher in the control group. Surprisingly, the urinary angiotensinogen (factored for urinary creatinine) was lower in the SCA group than in the controls (see table).

Cell Angiotensinogen / urine creatinine
HbSS urine angiotensinogen/creatinine was significantly lower than control (p=0.005).

PO2299
Food Insecurity During COVID-19 in Children with ESKD: The Second Wave?
Melvin Chan, Amy C. Wilson, Neha D. Pottanat, Michelle C. Starr. Indiana University School of Medicine, Indianapolis, IN.

Background: Food insecurity (FI) affects 1 in 6 children in the US and has increased three-fold during the COVID pandemic. Children with end-stage kidney disease (ESKD) may be at even higher risk of FI due to complex care needs, medication burden and dietary restrictions. A pre-COVID study assessing FI in pediatric hemodialysis (HD) patients described 70% prevalence. No data exists describing the effects of the COVID pandemic on FI in pediatric HD patients.

Methods: We assessed FI among families of patients age 0-18 years with ESKD on chronic HD at a single academic pediatric center. Families were screened for FI by using the Hunger Vital sign, a validated 2 question tool. We assessed impact of COVID on FI in pediatric HD patients.

Results: A total of 14 families were enrolled. 12 of 14 (86%) of children with ESKD were FI, and all 12 (100%) reported that COVID had worsened their FI status. The intraincreal remi-angiotensin system appears to play a role in this hyperfiltration. Further studies are needed to continue to understand this phenomenon.

HbSS urine angiotensinogen/creatinine was significantly lower than control (p=0.005).

PO2300
Incidence of Hypercalcemia with Calcitriol Compared with Paricalcitol in Pediatric Patients Receiving Hemodialysis
Rohan Dwivedi, Jennifer L. Morris, Jessica Geer, Poyyappakam Srivaths, Sarah J. Swiftz. Texas Children’s Hospital, Houston, TX.

Background: At our institution, both calcitriol and paricalcitol are available for use. Paricalcitol is generally used when adverse effects of calcitriol are observed or during times of calcitriol shortage. There are limited data on the efficacy and safety of vitamin D analogs in pediatric (ped) hemodialysis (HD) patients (pts) to support preference of either agent. This study evaluated the incidence of hypercalcemia in ped HD pts receiving calcitriol compared to paricalcitol.

Methods: Single-center, retrospective review of ped pts on HD treated between January 2012 – December 2018 who received in-center doses of calcitriol or paricalcitol. Pts were excluded if they received in-center doses of both paricalcitol and calcitriol or if they had incomplete data. Pts were not excluded from either group if they had an active prescription for oral calcitriol for home. Data were collected for 6-months from the date of the first in-center calcitriol or paricalcitol dose. The primary objective was to evaluate the incidence of hypercalcemia in those receiving calcitriol compared to paricalcitol. Secondary objectives included the incidence of hyperphosphatemia, high calcium-phosphorus product, and hyperparathyroidism (PTH). Data were evaluated using descriptive statistics, Mann-Whitney-U and Fisher’s Exact test.

Results: 34 pts met the criteria for the study (calcitriol group=15; paricalcitol group=19). The groups had no statistically significant differences at baseline. Patients in the paricalcitol group received an average weekly dose of 14 ± 7 mcg, equivalent to 4.67 ± 2.33 mcg of calcitriol compared to 2.36 ± 1.51 mcg in the calcitriol group (p=0.002). There were no differences between the time averaged serum calcium, phosphorus, calcium-phosphorus product, and iPTH between the two groups. Between the paricalcitol and calcitriol groups the incidence of hypercalcemia events per patient (EPP), based on age-related normal calcium was 1.11 and 0.53 (p=0.23), hyperphosphatemia EPP was 3.4 and 2.67 (p=0.20) and high iPTH EPP was 2.63 and 2.2 (p=0.38).

Conclusions: The incidence of hypercalcemia in patients receiving paricalcitol compared to calcitriol was high but did not reach statistical significance. There is no clear advantage seen with the use of paricalcitol when compared to the calcitriol group in ped's population.
Background: Biomarkers of tubular injury, repair, and inflammation may improve the ability to identify children at high risk of rapid kidney function decline and help elucidate the pathophysiology of CKD progression. In this study, we investigated whether the urinary biomarkers EGF, KIM1, MCP1, YKL40, and alpha-microglobulin are prognostic of CKD progression in children.

Methods: In the prospective CKiD study, children aged 6 months to 16 years old with an eGFR of 30-90 were enrolled and eGFR was assessed annually. We measured urine biomarkers collected 5 months after study enrollment. Urine biomarkers were indexed to urine creatinine. The primary outcome was CKD progression, defined as a composite of a fall in eGFR of >50% and need for dialysis or transplantation.

Results: Of the 375 children included, median age was 12 years [IQR, 8-15], 227 (61%) were male, and baseline eGFR was 44 [IQR, 35-56]. Overall, 187 children (50%) reached the primary outcome over a median follow-up time of 6.2 years [IQR, 3.0-10.3]. All biomarker levels were higher in children with CKD progression, except for EGF which was lower in those with CKD progression (p for all <0.05). After adjustment for confounders, children with urine EGF concentrations in the highest quartile [KIM1 aHR; 2.6 (95% CI: 1.6-4.1), MCP1 aHR; 2.8 (95% CI: 1.7-4.7)] compared to those in the lowest quartile [EGF aHR; 0.20 (95% CI: 0.11-0.39)] (Table). Children with urine KIM1 and MCP1 in the highest quartile were at a significantly higher risk of CKD progression which was lower in those with CKD progression (p for all <0.05). After adjustment for confounders, children with urine EGF concentrations in the highest quartile were at a significantly lower risk of CKD progression compared to those with EGF in the lowest quarter [EGF aHR; 0.20 (95% CI: 0.11-0.39)] (Table). Children with urine KIM1 and MCP1 in the highest quartile were at a significantly higher risk of CKD progression compared to those in the lowest quartile [KIM1 aHR; 2.6 (95% CI: 1.6-4.1), MCP1 aHR; 2.8 (95% CI: 1.7-4.7)].

Conclusions: Low urine EGF and elevated urine KIM1 and MCP1 concentrations are independently associated with CKD progression in children.

PO2303

Effect of Cholecalciferol Supplementation on FGF-23 in Children with CKD

Stephen M. Chu, Meredith A. Atkinson. Johns Hopkins University, Baltimore, MD.

Background: Cholecalciferol increases total vitamin D levels in children with chronic kidney disease (CKD), but by increasing serum phosphate levels may also increase levels of fibroblast growth factor 23 (FGF23), which is associated with adverse outcomes in both adults and children with CKD. Our objective was to quantify changes in FGF23, α-klotho and vitamin D binding protein (VDBP) in children participating in a vitamin D supplementation trial.

Methods: We utilized stored serum samples from a 4-week pilot randomized controlled trial of supplementation with 4000 (high dose) vs. 400 (DRI) IU per day of cholecalciferol in children with mild-to-moderate CKD. Intact and C-terminal FGF23, soluble α-klotho, and VDBP were measured using commercially-available ELISAs in the Johns Hopkins Institute for Clinical and Translational Research Core Laboratory. Statistical analyses conducted using Stata 14.

Results: Thirty-four children were included in the analysis; 17 received the intervention dose of 4000 IU/day and 17 received the control dose of 400 IU/day. The mean (SD) age of the cohort was 10.9 (5.8) years, 26.5% female, 23.5% black, 58.8% white, and 17.7% other race. Mean (SD) GFR at baseline was 60 (17.6) ml/min/1.73m². Median (IQR) baseline total vitamin D level was 29 (20, 34) ng/ml in the control arm and 32 (23, 39) in the intervention arm. Total vitamin D level did not change significantly after 4 weeks of supplementation in the control arm, but was increased to 38.5 (31, 50) in the intervention arm (p<0.001). The table compares baseline and 4-week FGF23, α-klotho, and VDBP levels in the control and intervention arms, and no significant differences were noted between the groups who received DRI vs. high dose cholecalciferol.

Conclusions: Cholecalciferol supplementation of 4000 IU/day in children with CKD was not associated with significant differences in FGF23, α-klotho, or VDBP levels compared to children who received only the DRI.

B=baseline
W=4 week

PO2304

Improving Metabolic Acidosis in Patients with CKD

Background: Pediatric chronic kidney disease (CKD) is characterized by multiple metabolic derangements including metabolic acidosis. Untreated acidosis is associated with bone disease, increased mortality, and CKD progression1-2. Current guidelines

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
recommend bicarbonate supplementation for CKD patients with serum bicarbonate < 22mmol/L. Review of our nephrology division’s clinical practice in the past year found that 36% of patients with CKD stage 3-5 were acidotic, although only 25% of these received an intervention to address the acidosis. Our aim is to increase the percentage of interventions for acidosis in this population from 25% to 50% by June 30, 2020.

Methods: Monthly reports were generated for patients with CKD stage 3-5 and acidosis in the nephrology clinic. Our outcome measure is the percentage of acidic patients. Process measures include the percentage of acidosis recognition, appropriate intervention, and patients on bicarbonate treatment. The balancing measure is patients with alkalosis (bicarbonate > 28mmol/L) while on supplementation. A multidisciplinary team identified multiple root causes and baseline data identified that lack of provider recognition of mild acidosis (bicarbonate 20-22) was the primary driver why treatment was not initiated. Countermeasures were developed to address this gap.

Results: Using PDSA cycles, we have implemented 2 countermeasures. Initially, we utilized provider directed feedback to notify those who had patients with untreated acidosis in the past month. Then, an education session was completed in March 2020. Our goal of increasing interventions for acidosis to 50% was exceeded by March 2020 (75%). There was also a decrease in the number of acidic patients, increase in provider recognition and bicarbonate treatment, with no increase in patients with alkalosis (Figure 1).

Conclusions: Utilizing provider directed feedback along with educational sessions have effectively increased the percentage of CKD stage 3-5 patients who are appropriately treated for acidosis. Further interventions are ongoing.

PO2305
Factors Influencing Duration of Dialysis in Children with Shiga Toxin-Producing Escherichia coli-Associated Hemolytic Uremic Syndrome (STEC-HUS) at a Single Center
Myida Khalid, Neha D. Pottanat, Chloe Miller, Sharon P. Andreoli. Indiana University School of Medicine, Indianapolis, IN.

Background: More than half the children with STEC-HUS require renal replacement therapy. Several factors influence the duration of dialysis.

Methods: We performed a retrospective cohort analysis using electronic medical records and chart review of 67 patients with STEC-HUS identified through billing data from July 1st 2008 to August 30th 2015. Cases of atypical hemolytic uremic syndrome (HUS), Streptococcal pneumoniae associated HUS were excluded.

Results: The mean age at presentation with STEC-HUS was 4.9yrs (range 0.99-17.16yrs). 44 (66%) were females compared to 23 (34%) males. Data on intravenous fluids (IVF) administration prior to diagnosis of HUS was available in 54 subjects of which 39 (72%) received IVF anytime during four days prior to presentation, and 15 (28%) did not. Of the patients receiving IVF, 22 (56%) required dialysis for an average duration of 11.4d whereas in subjects without IVF, 7 (47%) required dialysis for an average duration of 14.7d, 9 of 55 subjects received NSAIDS during the illness, and six of the nine required dialysis. For these 6 subjects, the average duration of dialysis was 17d compared to 10.3d in subjects without NSAID exposure. We also evaluated patients for antibiotic exposure before and after the diagnosis of HUS. In 30 (53%) subjects without any antibiotic exposure the average duration on dialysis was 9.8d. For 11 (19%) subjects receiving antibiotics before the diagnosis of HUS average duration of dialysis was 13.6d. Dialysis duration in the 12 (21%) subjects receiving antibiotics after the diagnosis of HUS was 13.3d.

Conclusions: To our knowledge our study is first to evaluate the impact of NSAIDS on the severity of HUS, and demonstrates that the use of NSAIDS in STEC-HUS increases the duration of dialysis significantly. Confirming previous literature, the use of antibiotics results in prolongation of dialysis regardless of the timing of administration. We also note that IVF administration in the first 4 days prior to the diagnosis of HUS may result in a shorter time on dialysis.

PO2306
Determining the Optimal Dose of Cholecalciferol Supplementation for Children with CKD (C, Trial): An Open-Label Multicentre Randomized Controlled Trial
Arpna A. Iyengar,1 Nivedita Kamath,1 Hamsa V; Susan Uthup; Jayoti Sharma,2 Jayoti S. Singhal,1 Sudha Ekambarami,3 Mandy Wan,4 Rukshana Shroff.1 St John’s Medical College Hospital, Bangalore, India; 2Mehta Hospitals, Chennai, India; ‘Government medical College Hospital, Trivandrum, India; 3KEM Hospital, Pune, Pune, India; ‘Great Ormond Hospital for Children, London, United Kingdom.

Background: The optimal treatment regimen for correcting 25-hydroxyvitamin D (25OHD) deficiency in children with CKD has not been established. We studied oral cholecalciferol treatment regimens that achieve and maintain 25OHD levels above 30ng/ml in children with CKD stages 2-4.

Methods: We performed an open label, multicentre randomized controlled trial in children with 25OHD <30ng/ml, randomized 1:1:1 to oral cholecalciferol as 3000IU daily, 25,000IU weekly or 100,000IU monthly for 3months intensive phase therapy. A maximin of 3 courses of intensive phase treatment were allowed if 25OHD was <30ng/ml. Patients achieving normal 25OHD entered maintenance phase with 1000IU cholecalciferol daily for 9 months. Primary outcome was achieving 25OHD levels a30 ng/ml at end of intensive phase therapy.

Results: Of the 150 children screened, 90 were 25OHD deficient and randomised to daily(n=30), weekly(n=29) or monthly(n=31) treatment arms. Age, gender, renal disease, eGFR and baseline 25OHD were comparable between treatment arms. At end of the intensive phase 68.8% achieved 25OHD >30mg/ml with comparable levels between arms(median 44.3 39.4 and 39.3 ng/ml p=0.24) on daily, weekly, monthly regimens respectively. The time taken to achieve 25OHD ≥30 ng/ml was comparable between treatment arms (p=0.28) with 7.7% not achieving normal 25OHD after 3 courses. Irrespective of treatment arm, median 25OHD were lower in children with glomerular disease than non-glomerular disease [25.8 vs 41.8ng/ml; p=0.007]. There was no significant difference in 25OHD between treatment arms at end of intensive phase therapy (p=0.24) or maintenance phase therapy (p=0.05). There was no hypercalcemia or hypercalciuria.

Conclusions: Intensive phase therapy with oral cholecalciferol as daily, weekly or monthly regimens achieved similar 25OHD levels without toxicity. Children with glomerular disease require higher doses of cholecalciferol compared to non-glomerular disease.

PO2307
ESRD Risk in Type 1 vs. Type 2 Childhood-Onset Diabetes Mellitus
Oren Plencecum,1,2 Gilad Twig,1 Tomer Erlich,1 Lital Keinan Boker,1 Karl Skorecki,1 Ronit Calderon-margalit,1 Asaf Vivante,1 ,2 Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; 2Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel; 3Rambam Health Care Campus, Haifa, Israel; 4Israel Defense Forces, Tel Aviv, Israel; 5University of Haifa School of Public Health, Haifa, Israel; 6Hebrew University of Jerusalem, Braun School of Public Health and Community Medicine, Jerusalem, Israel.

Background: Diabetic kidney disease (DKD) is becoming increasingly common among children. We aimed to estimate the risk of end-stage renal disease (ESRD) and mortality among adolescents with type 1 diabetes mellitus (T1DM) or type 2 diabetes mellitus (T2DM) and normal renal function compared to non-diabetics. We hypothesized that childhood onset T1DM vs T2DM would be associated with a different risk profile for developing ESRD and its complications.

Methods: A nationwide, population-based, retrospective cohort study, including 1,500,522 adolescents examined for military service between 1967-1997, which were classified according to the presence and type of diabetes. Data were linked to the Israeli ESRD registry. Cox proportional-hazards models were used to estimate the hazard ratio (HR) for ESRD.

Results: At study enrolment, 1,183 adolescents had T1DM and 196 had T2DM. ESRD developed in 2,386 non-diabetic individuals (0.2%) compared to 72 individuals (6.1%) with T1DM, and 8 individuals (4.1%) with T2DM. Participants with T1DM were younger at ESRD onset than participants with T2DM (median age: 36.0 vs. 40.5 years, P<0.05). In a multivariate model adjusted for age, sex, paternal origin, enrollment year, BMI, and blood pressure, T1DM and T2DM were associated with HR of 36.4 (95% CI,
PO2309
Clinical Relevance of Fluid Volume Status Assessment by Bioimpedance Spectroscopy in Children on Maintenance Dialysis
Jeesu Min,1 Peong Gang Park,1 Ji hyun Kim,2 Yo Han Ahn,2 II-Soo Ha,1 Hee Gyung Kang,1,2 Seoul National University Children's Hospital, Seoul, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea; 1Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Bioimpedance spectroscopy (BIS) has been used as a noninvasive method to evaluate body fluid volume status in dialysis patients. However, reports in pediatric dialysis patients about the effectiveness of this method are rare. We asked if there is a correlation in the results of BIS and clinical characteristics, and if there is a subsequent change of cardiovascular characteristics in patients whose dialysis prescription was modified based on BIS.

Methods: Medical records of children on maintenance dialysis who were evaluated by multifrequency BIS between January 2016 and December 2019 were reviewed. Their first result of BIS was assessed and fluid overload status was correlated with hypertension, number of oral antihypertensive medications and echocardiography results. In patients with fluid overload, change of dialysis prescription and clinical characteristics over time were reviewed.

Results: Among the 47 patients (male/female 28:19, hemodialysis/peritoneal dialysis 17:30) with a median age of 13.5 years, 13 children were overhydrated with the proportional overhydration relative to extracellular water more than 15%. Majority of children (76.9%) with fluid overload were taking two or more oral antihypertensive medications, while less than half of those without fluid overload were. 11 out of 13 overhydrated children changed their dialysis prescription to reduce their target body weights. Subsequent BIS in overhydrated children revealed a significantly decreased amount of fluid overload (initial: median 22.9%, follow-up: median 13.4%). However, their mean blood pressure (initial: 89.8 mmHg, follow-up: 84 mmHg) and the number of antihypertensive medications (initial: median 2 (0-4), follow-up: median 2 (0-3)) did not significantly change. Also, none of the children initially overhydrated had their left ventricle hypertrophy changed.

Conclusions: While BIS might be a useful and noninvasive method to assess fluid status, implementation of this tool did not lead to clinically meaningful improvement of cardiovascular characteristics in the children on maintenance dialysis. Long-term follow-up of a larger population and correlation with a more objective clinical indicator of fluid overload such as serum brain natriuretic peptide would be necessary to verify the clinical effectiveness of BIS in pediatric dialysis patients.

PO2310
Variants of SLC34A1, SLC34A3, and AGXT in an Infant with Nephrocalcinosis and Hypercalcemia
Marjiah L. Wright, John D. Mahan, Tahagod Mohamed. Nationwide Children's Hospital, Columbus, OH.

Introduction: Idiopathic infantile hypercalcemia (IIH) is a rare genetic disorder that can lead to neonatal nephrocalcinosis. It is typically caused by loss of function mutations in CYP24A1 or less commonly in SLC34A1. SLC34A1 encodes the NaPi-IIa transporter which aids in phosphate reabsorption in the renal proximal tubules. Defects in AGXT are responsible for primary hyperoxaluria type 1 (PH1). Defects in either AGXT or SLC34A1 can lead to infantile nephrocalcinosis and subsequent renal damage.

Case Description: A term male infant had bilateral hydropneumothorax on prenatal ultrasound. Postnatal labs showed hypercalcemia, hypophosphatemia, high 1,25 dihydroxyvitamin D3 and acute kidney injury. The patient was treated with fluids, furosemide, and calcitonin without significant change in serum calcium. Pamidronate was given which decreased serum calcium and worsened hypophosphatemia. Phosphate supplementation was initiated. Whole exome sequencing revealed two variants in SLC34A1, one of which was pathogenic, and a variant in SLC34A3 of unknown significance. Incidentally, this patient was compound heterozygous for three variants in AGXT: one pathogenic and two benign. After these results, patient was found to have generalized aminoaciduria and mild hyperoxaluria for age. Serum calcium decreased with maintenance of adequate plasma phosphate levels.

Discussion: Compound heterozygous mutations of SLC34A1 can cause IIH type II, and the variant in SLC34A3 could be contributing to this patient's clinical phenotype in a unique triallelic pattern. The pathologic AGXT gene variants could cause this patient to develop PH1. The combined effects of IIH and PH1 could significantly impact the clinical course of this patient. Mutations in both AGXT and SLC34A1 have not been previously described in the literature. During acute severe hypercalcemia, it might be necessary to use pamidronate to lower serum calcium to levels that are safe for the administration of phosphate supplements.
PO2311
Dent Disease Phenotype Caused by Immunodysregulation Polyendocrinopathy Enteropathy X-Linked Syndrome: Due to Anti-Tubular Basement Membrane Antibody Disease
Raja Dandamudi, Keith A. Hruska. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Introduction: Immunodysregulation, polyendocrinopathy, enteropathy, X-linked (IPEX) syndrome is caused by a de novo heterozygous c.1376A>T (p.K459M) mutation in the Cullin 3 gene (FOXL3). The transcription factor affecting the function of circulating regulatory T cells. Previously described renal manifestations were immune complex deposition in a membranous- pattern and interstitial nephritis. Here we report novel renal manifestations of IPEX syndrome.

Case Description: 5-year-old male presented at the end of the first month of life, with type 1 diabetes mellitus, hypothyroidism, and chronic diarrhea and diagnosed by IPEX syndrome by c.434C>T, p.Ala145Val mutations in the FOXL3 gene. He underwent stem cell transplant at 6 months of age from a fully matched unrelated donor. Post stem cell transplant he had improved chimerism with low but relatively stable donor T cells. He remained relatively stable until 4 years of age when he presented with the clinical picture of Dent’s disease: nephrocalcinosis, tubular proteinuria, Fanconi syndrome (proximal RTA, phosphaturia, calcium, glycosuria and aminoaciduria) and renal insufficiency. No disease-causing mutations in CLCN5 gene or the OCRL1 gene were identified on genetic testing. Renal biopsy demonstrated non-sclerotic glomeruli with no capillary loop spike formation, no crescent formation, no endocapillary proliferation, or segmental necrosis. Immunoﬂuorescence showed tubular basement membranes stain with IgG, C3, kappa and lambda. Glomerular basement membranes were negative. Tubular basement membranes show extensive small electron dense deposits without substructure.

Discussion: In this case report we presented child with confirmed IPEX syndrome with nephrotic-range tubular proteinuria, proximal RTA, phosphaturia, calciuria, medullary nephrocalcinosis, and renal insufficiency, in addition to the classical triad of enteropathy, dermatitis and polyendocrinopathy. Our report is the first to document the anti-tubular basement disease clinically manifesting as the Dent’s disease phenotype in association with IPEX syndrome.

PO2312
Severe Hyperkalemia in a 4-Month-Old Female due to Cullin-3 Mutation
Grace C. Yu,1 Faris Q. Hashim,2 Christian Hanna.1 Mayo Clinic Minnesota, Rochester, MN; 2Baylor Scott and White Central Texas, Temple, TX.

Introduction: Pseudohypokalemicosthenia (PHA) type II, also known as familial hyperkalemic hypertension, is a rare autosomal-dominant disorder that causes renal tubular acidosis (RTA) type 4, characterized by late-onset hypertension, hyperkalemia, renal acidosis, and growth retardation. We present a case of a female infant with PHA type II who presented with asymptomatic severe hyperkalemia due to Cullin-3 Mutation. Treatment with thiazide diuretics resulted in rapid correction of her hyperkalemia.

Case Description: A 4-month-old female presented with unexplained hyperkalemia due to Cullin-3 Mutation. Treatment with thiazide diuretics resulted in rapid correction of her hyperkalemia.

Discussion: Our case highlights that KIN can develop in children after chemotherapy. Diagnosis requires high index of suspicion and thorough pathological examination of kidney biopsy specimen. A trial of corticosteroid therapy may be considered.

PO2313
A Rare Pediatric Case of Karyomegalic Tubulointerstitial Nephritis
Carlos C. Bercerril romero,1,2 Sasha R. Kapil,1,2 April Rahrig,1,2 Carrie L. Phillips,1,2 David S. Hains,1,2 Jodi L. Skiles,1,2 Sushil Gupta,1,2 1Indiana University School of Medicine, Indianapolis, IN; 2Indiana University Health, Indianapolis, IN.

Introduction: Karyomegalic tubulointerstitial nephritis (KIN) is a rare type of interstitial nephritis that often progresses to chronic kidney disease. The pathogenesis is unclear but speculated to result from disruptions to tubular epithelial cell division by genetic predisposition or external insults. Only 6 pediatric cases have been reported and perhaps this condition is underdiagnosed.

Case Description: A 2-year-old male with history of refractory AML received a matched unrelated donor stem-cell transplant following busulfan, fludarabine, and single fraction total body irradiation. His post-transplant course was complicated by engraftment syndrome, hyperacide gastric versus host disease (GVHD), thrombotic microangiopathy, and acute kidney injury. He required ICU stay, treatment with eculizumab and two weeks of renal replacement therapy. His kidney function improved but serum creatinine stayed higher than baseline (picture). Four months post-transplant, he was treated with cefepime, acyclovir, ibuprofen for enterococcus bacteremia and pericardial effusion. Seven months post-transplant, while off all immunosuppression, he developed eosinophilia, renal tubular dysfunction with increased serum creatinine. Eosinophilia resolved spontaneously. Bone marrow was negative for leukemia and infectious workup was negative. Eight months post-transplant, he developed GVHD, diagnosed with skin biopsy. He also had persistent high serum creatinine with normal urine analysis. Ultrasound showed echogenic kidneys. Kidney biopsy was performed because of unexplained high serum creatinine. Specimen tissue showed tubulointerstitial nephritis with widespread karyomegaly in medullary tubules. Glomeruli were unaffected. Some cortical tubules showed ultrastructural myelinosomes. His renal function improved with steroids.

Discussion: Our case highlights that KIN can develop in children after chemotherapy. Diagnosis requires high index of suspicion and thorough pathological examination of kidney biopsy specimen. A trial of corticosteroid therapy may be considered.

PO2314
Rescue Therapy with Eculizumab for Catastrophic Antiphospholipid Syndrome in Juvenile Systemic Lupus Erythematosus
Patricia A. Arrovo Parejo Draver, Malek Al Barbandi, Marissa J. Defreitas,2 Matthew P. Katsoulis, Jayanthi Chandran, Carolyn L. Abitbol, Wacharee Secherunvong. University of Miami School of Medicine, Miami, FL.

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is a life-threatening condition, and is associated with acute multiorgan failure, small vessels thromboembolism, and elevated markers of antiphospholipid syndrome (APL). Early recognition and prompt treatment can improve the outcome. We present a case of juvenile systemic lupus erythematosus (SLE), who presented with CAPS, refractory to conventional treatment, but rescue with Eculizumab.

Case Description: The patient is a 10yo female, previously diagnosis with systemic lupus erythematosus (SLE) without renal involvement and treated with hydroxychloroquine and low dose steroid, who presented with acute kidney injury and hypertensive crisis. On exam, her weight was 31.3 kg, height 133 cm. Her BP was 185/127 mmHg and pulse 118/ min. Initial investigation showed hemoglobin of 7.2 g/dl, platelet count of 182/12, BUN 99 mg/dl, Cr 7.86 mg/dl, haptoglobin < 10 mg/dl. Urine protein to creatinine ratio was 5 mg/mg. Serum complements were low and had positive serology for Anti-DSDNA, lupus anticoagulant, Anti-β2 glycoprotein, and anticardiolipin. The presumptive diagnosis was CAPS associated with SLE and thrombotic microangiopathy (TMA) which was confirmed by kidney biopsy. She underwent Methylprednisone, therapeutic plasma exchange (TPE), renal replacement therapy and Nicardipine infusion. After 7 sessions of TPE, Methylprednisone, Rituximab, and Mycophenolate Mofetil, her renal function improved and was taken off hemodialysis. Blood pressure was still uncontrolled. She had evidence of on-going hemolysis with undetectable haptoglobin and elevated LDH. Repeat TPE did not control her BP or hemolysis, thus Eculizumab was administered as
a rescue therapy for TMA associated with CAPS. After 2 weeks doses Eculizumab, her renal function, blood pressure and hemolytic markers were much improved. Currently, her serum creatinine was 1 mg/dL, without significant proteinuria. She remained on 3 antihypertensive medications with good BP control.

Discussion: This is a rare but challenging case of juvenile SLE, complicated with CAPS and TMA, who responded partially to conventional treatment. Eculizumab served as a rescue therapy with good result. Our case supports the use of Eculizumab for refractory CAPS in SLE.

PO2315

Hypertensive Crisis in an Infant: The Mass Effect
Jonathan S. Chawla,1 David Manning,2 Isa Ashoor.1,2 1Louisiana State University Health Sciences Center, New Orleans, LA; 2Children’s Hospital New Orleans, New Orleans, LA.

Introduction: It is unusual for congenital hydronephrosis to present with a hypertensive crisis. Recognition of this etiology and prompt urologic intervention to relieve the acute mass effect is critical to prevent further morbidity and mortality.

Case Description: A 3 month-old male with known, mild, right-sided hydronephrosis secondary to ureteropelvic junction obstruction (UPJO) presented to the ED with one week of poor feeding, emesis, and abdominal distension. His recent urine output had been normal. Right upper extremity blood pressure (BP) was recorded as 140/79 mmHg in the ED. Labs were unremarkable with a normal urinalysis and serum creatinine of 0.3 mg/dL. Abdominal ultrasound revealed massive pelvocaliectasis of the right kidney with the kidney parenchyma stretched and thinned over the massively dilated central collecting system. Findings were confirmed on abdominal CT which also revealed profound mass effect on abdominal organs and vessels, specifically compressing and displacing the aorta and inferior vena cava. He was admitted to the pediatric ICU for BP management, which was controlled with IV hydralazine. Pediatric urology placed a percutaneous nephrostomy tube and drained over one liter of urine from the right collecting system. At discharge, the patient was normotensive off medications. A right pyeloplasty was completed shortly following discharge.

Discussion: UPJO is the most common cause of antenatally detected hydronephrosis. The renal pelvis of infants exhibits increased compliance and can accommodate large urine volumes. Kidney function may be preserved or could undergo deterioration depending on UPJO severity. If missed prenatally, infants with UPJO may present with a palpable abdominal mass, urinary tract infection, hematuria, or failure to thrive. Kidney failure and hypertensive crises are rare presentations but are indications for prompt surgical intervention to prevent permanent damage and reduce blood pressure. Infants with preserved function can be monitored conservatively with serial Imaging.

PO2316

Missed Diagnosis: A Case of Asymptomatic Isolated Orthostatic Proteinuria from Nutcracker Phenomenon
Anna R. Gaddy, Ranjani N. Moorthi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: In children, proteinuria which exceeds 100 mg/m2 per day or 150 mg per day is considered abnormal. Isolated proteinuria is relatively common, but persistent proteinuria is abnormal and should be investigated. Persistent proteinuria can be further divided into orthostatic subtype if the recumbent Pr/Cr is ~0.2mg/mg but this rises to abnormal (~0.2mg/mg) after standing. One cause of orthostatic proteinuria is entrapment of the left renal vein, which is known as the Nutcracker Syndrome. Orthostatic proteinuria, isolated hematuria and pelvic congestion pain are the most common manifestations, however Nutcracker Syndrome is highly heterogeneous and frequently missed.

Case Description: We present an 18 year-old female with intermittent proteinuria, hematuria and occasional flank pain for nine years. The patient had proteinuria on dipstick at age eight. At age 15, she again was noted to have proteinuria on serial urinalyses with up to 500mg/dL protein. ANA, anti-dsDNA, C3, and C4 were normal. Renal ultrasound was performed with unremarkable kidneys and urinary bladder. For several years, proteinuria was mild and intermittently negative and no further workup was done. Split urine collection demonstrated minimal protein on first morning void but over 1g/g Pr/Cr by afternoon. We ordered renal ultrasound with Doppler, which demonstrated Doppler ultrasoundography showed the left renal vein had significantly increased flow velocity and appeared to be compressed between the AO and SMA.

Discussion: Differential for etiology of orthostatic proteinuria should include Nutcracker Syndrome as this diagnosis requires a high degree of suspicion. Nutcracker Syndrome can involve proteinuria as well as hematuria but also pelvic pain, back pain, and pelvic congestion symptoms.
Cyanotic Nephropathy (CN) in Pre-Fontan Congenital Cyanotic Heart Disease (CCHD) with Solitary Kidney

**PO2318**

**Introduction:** CN is a glomerulopathy seen in patients with CCHD. Chronic hypoxia leads to proteinuria and reduced GFR through tubular and glomerular injury.

**Case Description:** A 10 yo male with single kidney and pre-Fontan CCHD presented with hematuria and proteinuria on cardiac transplant evaluation. He had 6 months of symptomatic hypoxia requiring increased supplemental O2, but no other recent illness. Exam was notable for 3/6 pansystolic murmur, tachypnea with clear lung fields, hepatoplenomegaly, cyanotic nailbeds with marked clubbing, but no peripheral edema. 24 hour urine protein measured 4.1g (normal <0.2g), 38% was albumin. Serum albumin was 3.5 g/L (normal) and eGFR by Cystatin C was 72 ml/min/1.73m². Hemoglobin was elevated at 20.1 (normal 12.5-16.1 g/dL). C5, C4, ANA, dsDNA, ANCA were normal. Ultrasound showed solitary left kidney with nephromegaly (12.5cm, 1000g/renal). Randomized diastolic flow. MRI abdomen showed dilatation of the left renal vein and IVC. Renal biopsy showed marked glomerular enlargement, segmental mesangiolysis with erythrocytolyis, and irregular thickening of glomerular capillaries. EM showed widespread subendothelial widening and remodeling of basement membranes without immune deposits, consistent with CN (Figure 1).

**Discussion:** CN risk factors include duration of hypoxia, elevated hematocrit (>40%), and thrombocytopenia. All were present in our patient. Solitary kidney and elevated venous pressure may have contributed. After heart transplantation, renal function improved with most recent eGFR by Cystatin C 121 ml/min/1.73m². Treatment and prevention of CN depend on correction of cyanosis. CN has become less common as most children with CCHD undergo Fontan in early childhood. There are limited data about medical management but proposed treatments include renin angiotensin system blockade, beta blocking drugs, diuretics, ivabradine, digoxin, and hydralazine/isosorbide dinitrate.

Therapeutic plebotomy has been reported. To our knowledge this is the first report of CN in a patient with solitary kidney. Low renal mass and baseline glomerular hyperfiltration may increase the risk of CN progression in this subset of patients.

Lupus Vasculopathy Successfully Treated with Eculizumab and Rituximab in an 8-Year-Old Male

**PO2319**

**Introduction:** Lupus vasculopathy of the kidney is a rare form of vascular disease in patients with systemic lupus erythematosus characterized by non-inflammatory, necrotizing vessel wall changes. The pathogenesis may be related to immune-mediated vascular injury from accumulation of immunoglobulins and complement in the vascular wall. Lupus vasculopathy carries a poor renal prognosis, and no standardized treatment has been established.

**Case Description:** An 8-year-old previously healthy male presented to the emergency department with fever, fatigue, headache, diarrhea, nosebleeds, decreased urine output and lower extremity swelling. He was found to have hypertension, fluid overload, active urine sediment and severe acute kidney injury necessitating renal replacement therapy. He had thrombocytopenia and hemolytic anemia without presence of antiphospholipid antibodies or abnormal ADAMTS13 activity. He met criteria for systemic lupus erythematosus including hypocomplementemia, positive ANA and dsDNA antibodies. Renal biopsy showed class III lupus nephritis and multifocal arterial and arteriolar large intimal complex deposits with endothelial cell necrosis, consistent with a diagnosis of lupus vasculopathy. He received 6 sessions of plasmapheresis without improvement. Based on renal biopsy, he was treated with cyclophosphamide per Euro Lupus protocol. Eculizumab was started for treatment of lupus vasculopathy. His anemia, thrombocytopenia, and proteinuria improved after initiation of eculizumab, but he remained dialysis-dependent. Eculizumab was discontinued after 6 weeks of therapy, but he again developed thrombocytopenia, hemolytic anemia, worsening proteinuria and hypertension. These improved after restarting eculizumab. Due to ongoing evidence of lupus activity, rituximab was given after completion of cyclophosphamide. Hemodialysis was discontinued one month after his first rituximab dose with B-cell depletion. He remains on eculizumab therapy and has stable chronic kidney disease stage 2 despite B-cell repopulation.

**Discussion:** Prior case reports have documented effective treatment of lupus vasculopathy with rituximab. To our knowledge, no data exists on eculizumab for treatment of lupus vasculopathy. Given our patient’s clinical improvement with these therapies, we conclude that more research is needed to define their role in treatment of patients with lupus vasculopathy.

Managing Pediatric Renal Cell Carcinoma in Jehovah’s Witness Patient

**PO2321**

**Introduction:** Pediatric Renal Cell Carcinoma (pRCC) is rare in children and adolescents and only account for about 5% of pediatric renal neoplasms. The driver mutation of the majority of these tumors is due to cytogenetic translocations involving the MiT family of transcription factors. Surgical resection of the mass is the main treatment and depending on the advancement of the cancer, can result in a complete nephrectomy. Due to complexity of surgery and the risk of blood loss, treatment can be complicated by a patient’s religion that decline blood product transfusions, such as Jehovah’s Witness. This case describes an already rare cancer requiring a unique medical management due to a family’s religious belief.

**Case Description:** A previously healthy 14-year-old male presented complaining of left flank pain. Patient was hemodynamically stable to the 120s, and initial vital signs were 133/81 that self resolved. Due to persistent pain with unknown etiology imaging was obtained and MRI revealed 8 cm solid mass in the left kidney with a dilated and thrombosed left renal vein. The mass could not be differentiated between Wilms Tumor or pRCC, and a complete nephrectomy was decided to be the best course of treatment. Due to family’s religious background of Jehovah’s Witness a multi-disciplinary approach was considered to reduce the need for blood transfusions. Patient received daily erythropoietin injections and iron supplementation about three weeks prior to nephrectomy to stimulate red blood cell production post-operatively. Additionally, on the day of his procedure, interventional radiology (IR) first emobilized the left renal artery leading to tumor followed immediately by a left radical nephrectomy. Patient tolerated the procedure well with minimal blood loss and only had mild anemia. He required no post-operative blood transfusion. There was mild increase in creatinine level 6 weeks after kidney status-post nephrectomy that has since improved. Pathology report came back and confirmed clear cell renal cell carcinoma. Cytogenetic screen showed a translocation of...
the transcription factor E3 (TFE3) gene. Patient did well post-operatively with no signs of cancer on recent imaging and did not require any chemotherapy.

Discussion: This case adds to the field of pediatric renal cell carcinoma and highlights a treatment approach that incorporates religious backgrounds into medical management.

PO2322

IgG4-Related Disease: Nephropathy and Bone Marrow Failure in a 2-Year-Old Child

Eduardo La Porta,1,2 Isabella Pisani,1 Maura Faraci,1 Francesco P. Pilato,3 Luca Lanino,4 Daniela Verzola,4 Giacomo Garibotto,4 Angela R. Sementa,4 Letizia Gnetti,4 Enrico E. Verrina,4 Istituto Giannina Gaslini, Genova, Italy; Istituto Clinico Ligure di Alta Specialita, Rapallo, Italy; Ospedale Universitario, Parma, Italy; Ospedale Policlinico San Martino, Genova, Italy.

Introduction: IgG4 related disease (IgG4 RD) is a systemic immune-mediated disorder that can potentially affect every organ. It is characterized by fibro-inflammatory tissue damage, IgG4 positive plasma cells, and often by elevated serum IgG4. Renal involvement can include tubulointerstitial nephritis (TIN), membranous glomerulopathy (MGP), and retroperitoneal fibrosis. The disease is more frequent over 50 years of age and only a few cases of IgG4 RD are reported in children.

Case Description: A 2-year-old child was diagnosed with a trilineal bone marrow failure. Bone marrow biopsy showed poor and dyshomogeneous cellularity and lymphoplasmacytic infiltrate organized in follicular structures. Hematologic DNA analyses were negative. IgG subclass analysis showed elevated serum levels of IgG4 subclass (353 mg/dL). Kidney failure was also found (creatinine 1.3 mg/dL, microhematuria, proteinuria, and granular casts). A renal biopsy was performed. Light microscopy showed tubulointerstitial inflammatory infiltrate, thickening of the glomerular basement membranes, and subepithelial deposits. IF showed subepithelial glomerular IgG deposits with granular pattern and tubular wall deposits; C3 glomerular deposits and focal tubular deposits. A diagnosis of MGP associated with TIN was made. IHC staining for IgG4 demonstrated plasma cells with overlapping positivity for IgG and IgG4. After the diagnosis of IgG4 RD, a therapy with steroids was started, without clinical response.

Discussion: IgG4 RDK in adults with simultaneous TIN and MGP has been reported in a few cases. This is the first documented case of IgG4 RDK with simultaneous TIN and MGP in a pediatric patient. IgG4 RD is an emerging systemic disease and it should be taken into account in the differential diagnosis in systemic autoimmune diseases, also in pediatrics.

PO2324

Proteinuria and Dipping on 24-Hour Ambulatory Blood Pressure Monitoring in Children

Christine Y.Bahkhoum,1,2 Kimmy T. Vuong,1,2 Caitlin E. Carter,1,2 Pranav S. Gaminella,1 Joachim H. Ix,1,2 Rady Children’s Hospital San Diego, San Diego, CA;1 University of California San Diego, La Jolla, CA.

Background: Absence of nocturnal blood pressure dipping is associated with adverse cardiovascular outcomes in adults. Risk factors for non-dipping in adults include obesity and proteinuria. In children, risk factors for non-dipping have not been well established.

Methods: We identified consecutive patients aged 5 to 19 years who underwent 24-hour ambulatory blood pressure monitoring (ABPM) at Rady Children’s Hospital from August 2018 to January 2019 and had a spot urine protein to creatinine ratio (PCR) measurement within one year of their ABPM. Dipping was defined as a 10% reduction in systolic and diastolic blood pressure from day to night. Multivariable logistic and linear regression models evaluated the association of proteinuria with dipping, employing backwards selection models to retain important confounders.

Results: Seventy-seven children had ABPM and urine PCR assessments during the study period, among whom 27 (35.1%) were non-dippers. Non-dippers had a higher left ventricular mass index as compared to dippers (mean difference 6.9 g/m², 95% CI 1.6 to 12.2). Doubling of urine PCR was associated with 38% higher odds of non-dipping in the multivariable model (Table). Doubling of urine PCR was also associated with a lower diastolic dipping percent by 1.33 (95% CI 0.31 to 2.34), after adjusting for age, body mass index, and estimated glomerular filtration rate.

Conclusions: Proteinuria is significantly associated with non-dipping in children. Pediatric patients with non-dipping should be evaluated with urine PCR, and conversely, those with proteinuria may benefit from a 24-hour ABPM.

Is a Single Static Cut Point Useful to Define Ambulatory Hypertension in Youth? The SHIP AHYO Study

Ghilam Hamdani,1 Michael A. Ferguson,4 Marc Lande,4 Kevin E. Meyers,3 Mark Mitschefske,1 Joshua A. Samuels,1 Joseph T. Flynn,5 Elaine M. Urbina,1 The SHIP AHYO Investigators; 1Schneider Children's Medical Center of Israel, Petah Tikva, Israel; 2University of Rochester Medical Center, Rochester, NY; 3Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 4Seattle Children's Hospital, Seattle, WA; 5The Children's Hospital of Philadelphia, Philadelphia, PA; 6Boston Children's Hospital, Boston, MA; 7University of Texas Health Science Center at Houston, Houston, TX.

Background: Ambulatory blood pressure monitoring (ABPM) is increasingly utilized for the diagnosis of hypertension (HTN). While adult guidelines use absolute blood pressure (BP) cut points to define ambulatory HTN, current pediatric guidelines utilize for the diagnosis of HTN based on a sex- and height-specific 95th percentile derived from limited pediatric normative data, in which many tall adolescents have a threshold for HTN higher than adult cut-points.

Methods: We compared absolute ABP values with sex- and height-specific ABP percentiles and predictors of left ventricular hypertrophy (LVH) in youth. We measured casual BP, ABPM, anthropometrics, and echo for LV mass index (LVMI) in 357 adolescents (mean age 15.5 ±1.7 years, 63% white, 59% male). ABPM was performed with Ontrak device (Spacelabs Inc., Snoqualmie, WA). ABP index was defined as mean ABP above and below height-specific 95% percentile. LVH was defined as LVMI ≥38.6 g/m².7 (pediatric cut-point). Logistic regression was used to assess different ABP measures as predictors of LVH. Sensitivity and specificity of different ABP cut points as predictors of LVH were calculated.

Results: Seventy participants (19.6%) had LVH. Systolic 24-hour, wake and sleep mean BPs and indexes were all significantly associated with LVH. The C-statistics for absolute 24-hour (AUC 0.642 vs. 0.612, p=0.042) and wake (AUC 0.628 vs. 0.590, p=0.03) SBP predicted LVH better than SBP indexes of the same time periods. Absolute SBP cut points also had better balanced sensitivities and specificities in predicting LVH (24-hour SBP 120: 66% and 61%; wake SBP 125: 63% and 59%; sleep 110: 61% and 61%). There was no significant association between diastolic BP measures and LVH.

Conclusions: A single static cut-point using absolute ambulatory SBP is non-inferior to sex-and height-based SBP percentile in predicting LVH in youth. The cut-points for 24-hour and wake ABPM are lower than those for adults but may be used to define ambulatory HTN in this population.

Association of Environmental Tobacco Exposure with Blood Pressure in US Children
Rebecca Levy,1 Kaye E. Brathwaite,1 Harini Sarathy,1 Kimberly J. Reidy,1 Frederick J. Kessel,2 Michal L. Melamed,1 Albert Einstein College of Medicine, Bronx, NY; 1University of California San Francisco, San Francisco, CA.

Background: Hypertension is a leading cause of cardiovascular and kidney disease in adults, and there is evidence that pathologic sequelae begin in childhood and young adulthood. Nicotine and other tobacco compounds have a variety of toxic effects, but to date their associations with chronic hypertension is unclear, especially in pediatric populations.

Methods: We examined the association between tobacco exposure and high blood pressure (HBP) in children who participated the National Health And Nutrition Examination Survey (NHANES) during 2008-2016. Children were classified as having tobacco exposure if they had blood cotinine levels >0.05ng/dL or reported living with a smoker or smoking themselves. High blood pressure was classified according to the 2017 AAP Clinical Practice Guidelines. Analysis was conducted by logistic regression with adjustment for baseline demographics, income and other possible confounders. Subgroup and sensitivity analyses were conducted.

Results: There was a positive association of high blood pressure with tobacco exposure in the study population. After adjustment for demographics, the odds of having high blood pressure was 1.39 (95% Confidence Interval (CI) 1.04, 1.87) for any tobacco exposure compared to no smoking exposure. The association was similar across participant subgroups. The association remained significant by sensitivity analysis using cotinine exposure as a continuous variable. Separately, the odds of having high blood pressure for passive smokers was 1.35 (CI 0.983, 1.85) while the odds for active smokers was 1.71 (CI 1.14, 2.54) compared to participants with no tobacco exposure.

Conclusions: Tobacco exposure is associated with high blood pressure in US children and adolescents.

Hypertension and CKD at 7 Years After Surgical Repair of Congenital Heart Disease in Children
Jason H. Greenberg,1 Michael Zappitelli,2 Heather Thiessen Philbrook,3 Yaqi Jia, Prasad Devarajan,4 Chirag R. Parikh.3 TRIBE-AKI Consortium, Yale University, New Haven, CT; 3Hospital for Sick Children, Toronto, ON, Canada; 1Johns Hopkins University, Baltimore, MD; 4Cincinnati Children’s Hospital Medical Center Division of Child and Adolescent Psychiatry, Cincinnati, OH.

Background: We previously determined that children who require surgery for congenital heart disease (CHD) are at an increased risk for hypertension and CKD 5 years after cardiac surgery. This study assessed the long-term risk of hypertension and CKD after cardiac surgery and if these outcomes are sustained.

Methods: We prospectively enrolled children from 1 month to 18 years old, undergoing cardiopulmonary bypass at three centers. Children who survived their surgical procedure, and had a combined procedure, and 7 were not defined. Hypertension, microalbuminuria, and eGFR<90, and eGFR<60 was 15%, 8%, 9%, and 1%, respectively, at the 5-year visit.

Results: Of 131 children with a follow-up visit 5 years after cardiac surgery, 88 (67%) children participated in the 7-year follow-up visit. The median age of the cohort at the 7-year visit. Compared to the five-year visit, hypertension was sustained in the majority of children. Although CKD was not sustained, there was an increased incidence of new children with GFR<90 at the 7-year visit. The risk factors for sustained hypertension and kidney disease should be further studied in children with congenital heart disease.

PO2327
Evaluating the Role of the Kidneys in Posterior Reversible Encephalopathy Syndrome in Pediatric Patients
Shruti Shah, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Kidney disease is a known risk factor for posterior reversible encephalopathy syndrome (PRES), but the specific markers of kidney function that are relevant to PRES are undescibed. The objective was to investigate the associations of various markers of kidney function with PRES.

Methods: In a case-control study of high-risk children, we recorded most-recent blood urea nitrogen (BUN), documentation of acute kidney injury (AKI), serum creatinine, serum albumin, and hemoglobin level and calculated the estimated glomerular filtration rate (eGFR). PRES cases were confirmed clinically and radiologically. We applied multivariable regression models to estimate the associations of the exposures with PRES. We utilized directed acyclic graphs to inform the following model adjustments: 1) history of kidney disease and nephrotoxic medication exposure for the kidney function models; 2) history of kidney disease, eGFR, and albumin treatment for the serum albumin model; and 3) age, sex, history of kidney disease, eGFR, fluid overload, and nephrotoxic medication exposure for the hemoglobin model.

Results: The mean age of the study population was 9.5 years (±4.9) and 51% were female. Of that population, 29% had a history of kidney disease, 67% had exposure to nephrotoxic medications, and 29% had AKI prior to the onset of PRES. BUN [adjusted OR (aOR) 1.03 per 1 mg/dl increase, 95% CI 0.99-1.07, p=0.09] and AKI (aOR 3.78, 0.68-21.13, p=0.13) were modestly associated with PRES. eGFR (aOR 1.0 per 1 ml/min increase, 0.98-1.02, p=0.02) and albumin (aOR 1.7 per 1 g/dl increase, 0.73-3.93, p=0.50) and hemoglobin (aOR 1.12 per 1 g/dl increase, 0.81-1.56, p=0.48) were not associated with PRES.

Conclusions: In a case-control study of children at high risk for PRES, we determined that among several markers of kidney function, BUN and AKI were modestly associated with PRES. Further prospective studies with larger sample sizes and higher power are necessary to fully evaluate the role of kidney function in the development of PRES.

PO2328
Effect of Hypertension on Childhood-Onset Systemic Lupus Erythematosus in a Tertiary Medical Center in Korea
Jeong yeon Kim, Hee Yeon Cho. Department of Pediatrics, Samsung Medical Center; Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background: Hypertension (HTN) is prevalent in childhood-onset systemic lupus erythematosus (cSLE) and affected either by disease activity itself, cSLE medication or both. The purpose of this study is to evaluate the prevalence, clinical characteristics and long-term clinical effect of HTN in Korean cSLE patients treated in tertiary medical center in Korea.

Methods: The medical records of cSLE patients, diagnosed by 2019 SLE European League against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria, who visited Samsung Medical Center from January 2009 to May 2019 were reviewed retrospectively. The disease activity was evaluated by Modified Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and renal activity (renal SLEDAI) was measured by scores from SLEDAl-AKR. The long-term damage was evaluated by The Pediatric Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (Ped-SDI). The sex-, age- and height-blood pressure standards recommended by AAP 2017 guideline was used to define HTN. Left ventricular hypertrophy (LHV) was defined by sex, age specific left ventricular mass index (LVMi) ≥ 95th percentile.

Results: Total 32 patients were enrolled in this study. The median follow-up duration was 7.3 year and female was predominant. Median age at SLE and HTN diagnosis were 14.2 and 14.3 year, respectively. Initial renal involvement was detected in 12.5%. The hypertensive LN was detected in 84.4% (n=28) and 37.5% of them was class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=11) and stage 2 HTN was prevalent (n=9). The median dose of steroids, converted to prednisolone, at diagnosis was 20 mg, 10.5 mg, 2.3 mg, and 0.6 mg in stage 1, 2, 3, and 4, respectively. The prevalence of HTN, including 2 transient HTN, was 34.4% (n=28) and 37.5% of them was class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=11) and stage 2 HTN was prevalent (n=9). The median dose of steroids, converted to prednisolone, at diagnosis was 20 mg, 10.5 mg, 2.3 mg, and 0.6 mg in stage 1, 2, 3, and 4, respectively. The prevalence of HTN, including 2 transient HTN, was 34.4% (n=28) and 37.5% of them was class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=28) and 37.5% of them was class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=28) and 37.5% of them was class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=28) and 37.5% of them was class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=28) and 37.5% of them was class IV (n=12).

Conclusions: In conclusion, HTN in cSLE is associated with BMI and renal activity at SLE diagnosis. Also, HTN affect long term damage accumulation in cSLE.
PO2329
Hemodialfiltration Maintains a Sustained Improvement in BP Compared with Conventional Hemodialysis in Children: The HDF, Heart and Height (3H) Study
Francesca De Zan,1 Colette J. Smith,1 Aysun Bayazit,2 Karolis Azukaitis,3 Sevcan A. Bakkaloglu,1 Fabio Pagliolonga,3 Mohan Shenoy,1 Manish Sinha,1 Branka B. Spasojevic,5 Claus Peter Schmieder,10 Franz S. Schaefer,10 Enrico Vidal,11 Rukshana Shroff,12 University Hospital of Padova, Padova, Italy; 1UCL Institute of Global Health, London, United Kingdom; 2Cukurova Hospital, London, United Kingdom; 9University Children’s Hospital, Belgrade, Serbia; 7Royal Manchester Children’s Hospital, London, United Kingdom; 4Clinic of Pediatrics, Vilnius University, Vilnius, Lithuania; 3Gazi University Hospital, Ankara, Turkey; 10Division of Pediatrics, Department of Medicine, University of Barcelona, Barcelona, Spain; 11Division of Pediatrics, Department of Medicine, University of Udine, Udine, Italy; 12Great Ormond Street Hospital for Children NHS Foundation Trust, and University College London Institute of Child Health, London, United Kingdom.

Background: Hypertension is prevalent in children on dialysis and associated with left ventricular hypertrophy, cardiovascular disease, and mortality. We studied the blood pressure (BP) trends as well as risk factors associated with the evolution of BP over 1-year in children on conventional hemodialysis (HD) vs hemodiafiltration (HDF).

Methods: This is a post-hoc analysis of the “3H - HDF-Hearts-Height” dataset, a multicenter, non-randomized, parallel-arm observational study. Mean arterial pressure (MAP) derived from 24-hour ambulatory BP monitoring was calculated and hypertension defined as 24-hour MAP standard deviation score (SDS) ≥95th percentile.

Results: 78 children on HD and 55 on HDF who were followed-up for 1-year and had three ABPM measures were included. MAP-SDS was under-estimated by pre-dialysis systolic BP-SDS (mean difference -0.6; 95% LoA -4.9 to 3.8). At baseline 82% on HD and 44% on HDF were hypertensive, with uncontrolled hypertension (BP-SDS >95th centile on medications) in 88% vs 25% respectively; p<0.001. At 12-months children on HDF had lower MAP-SDS compared to those on HD in all age groups (p<0.001). Over the one-year follow-up, the HD group had a mean MAP-SDS increase of +0.98 (95%CI 0.77 to 1.20; p<0.0001), whereas the HDF group had a non-significant increase of +0.15 (95% CI -0.10 to 0.40; p=0.23). Significant and independent predictors of MAP-SDS were dialysis modality (β=0.83 [95%CI 0.51 to 1.15] SDS for HD vs HDF, p<0.0001) and higher IDWG (β=0.13 [95%CI 0.06 to 0.19] p<0.0003).

Conclusions: Children on HD had a significant and sustained increase in BP over the 1-year study period compared to an attenuated and non-significant increase in HDF. Volume overload with higher IDWG0, but not anti-hypertensive medications, was associated with a higher MAP-SDS in both groups of the mechanisms of being misfolded protein/HLA class II complexes that are aberrantly transported to the cell surface inducing immune responses (Jim, Arase et al. PNAS 2014). Therefore, we investigated the relationship between each HLA allele and nephrin, based on the hypothesis that nephrin protein/HLA class II complexes might be involved in the development of SSNS.

Methods: Nephrin lacking the transmembrane domain (Nephmis) was used as a model of misfolded protein that is not expressed on the cell surface. We co-transfected Nephrin and HLA-DR to HEK293T cells and assessed the expression patterns by flow cytometry and immunoprecipitation.

Results: Nephrin was detected on the cell surface in the presence of HLA-DR, which was more intense in the risk alleles than in the protective allele (DRB1*07:01-DRBI*08:02-DRB1*13:02). While Nephrin was not detected in the absence of HLA-DR. [Discussion] Podocytes are sometimes considered as hematopoietic professional antigen presenting cells because they present antigens on the cell surface via HLA class II and stimulate immune signaling. We showed that the risk HLA DR allele tended to present Nephrin stronger than the protective allele, suggesting that an immune response could be more easily induced in the risk alleles than in the protective allele. Although there are a variety of possible mechanisms by which HLA-DR could be associated with SSNS, the binding of specific molecules, such as nephrin or Nephmis, and their presentation may provide new insights into the pathogenesis of SSNS.

Conclusions: Our results suggest that nephrin protein/HLA class II complexes can be involved in the pathogenesis of childhood SSNS.

PO2331
Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Previously Treated with Eculizumab: 26-Week and 1-Year Data
Larry A. Greenbaum,1 Noaya Fujita,2 Brigitte V. Adams,3 Alvaro Madrid Arias,3 Masayo Ogawa,2 Stephan Ortitz,3 Marc Vallec2,1 Kazuki Tanaka,2 1Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA; 2Aichi Shoni Hoken Iryo Sogo Center, Obu, Japan; 3Alexion Pharmaceuticals Inc, Boston, MA; 4Queen Fabiola Children’s University Hospital, Brussels, Belgium; 5Children’s Nephrology and Renal Transplantation Service, Children’s Maternity Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain.

Background: The complement C5 inhibitor eculizumab improves outcomes of atypical hemolytic uremic syndrome (aHUS) but must be administered every 2–3 weeks. Ravulizumab, engineered from eculizumab for a longer half-life, is efficacious and safe in adult aHUS with 8-week dosing intervals. This analysis was in eculizumab-treated children with aHUS.

Methods: ALXN1210-aHUS-312 (NCT03131219) is a phase 3, single-arm trial in complement inhibitor-naïve children (Cohort 1; reported separately) and children who were receiving treatment with eculizumab without thrombotic microangiopathy (TMA; Cohort 2; reported here). This analysis assessed TMA activity, and the pharmacodynamic measure serum free C5 levels after patients switched from eculizumab to ravulizumab treatment. Patients received loading doses then maintenance treatment with ravulizumab every 4 or 8 weeks, dependent on weight, for 26 weeks. An extension phase is ongoing; here we report data on efficacy through 1 year and safety from all available follow up (median 50.2 weeks).

Results: Ten patients (mean [SD] age 11 [5.0] years) were enrolled into Cohort 2; all completed the 26-week initial evaluation period and entered the extension. Mean eGFR, hematologic outcomes (platelet, lactate dehydrogenase and hemoglobin normalization), and fatigue measures remained stable during both trial periods. At 1-year, the mean (SD) changes from baseline were: eGFR, -3.9 (8.3) mL/min/1.73m²; platelets, -17.8 (54.6) x10^9/L; LDH, -1.0 (17.9) U/L; hemoglobin, +4.5 (7.1) g/L. All patients were in the same eGFR category at 1 year as recorded at baseline (eGFR mL/min/1.73m² ≥90, n=6; 60–89, n=1; 49–59, n=1). No patients required dialysis. Despite the increased dosing interval, serum free C5 levels were maintained below the threshold of 0.5 mg/mL. All patients experienced adverse events (AEs) but none discontinued the trial. No meningococcal infections occurred. One patient experienced serious AEs due to a respiratory tract infection.

Conclusions: Continued efficacy, no additional safety concerns and the benefit of reduced dosing frequency was demonstrated in pediatric patients with aHUS who were stable on eculizumab and switched to ravulizumab.

PO2332
Typical Hemolytic Uremic Syndrome in Children: A Single-Center Experience
Siddharth A. Shah, University of Louisville, Prospect, KY.

Background: Typical hemolytic-uremic syndrome (HUS) associated with diarrhea can be a fatal disease in children. Diarrhea and blood-stained stools are early symptoms. Oliguria and renal failure can occur anywhere from 3-7 days after onset of diarrhea. hemolytic anemia (Hemolytic anemia (iv) fluids in the initial timeline of disease presentation may decrease the need for dialysis. Oligo-amuria at admission and leukocytosis is associated with poor outcomes during hospitalization. After recovery, there is a risk of long-term renal complications such as hypertension, proteinuria, and chronic kidney disease (CKD).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We performed a retrospective analysis of 43 children admitted with diarrhea associated with HUS at our center in the last ten years. The ‘late presentation’ defined as serum creatinine >1 mg/dl, oliguria, or anuria at admission. The primary outcome was the presence of long-term renal sequelae. It included proteinuria, hypertension, or chronic kidney disease (CKD) (eGFR <75 ml/min/1.73m²) after one year of disease-onset. The Chi-square and correlation analysis performed on the SPSS platform.

Results: Overall, 32/43 presented late in the disease course, 30/43 required dialysis (median: 8 d), and 8/43 had a recent history of NSAID use. The administration of dextrose and saline containing iv fluids in the early presentation was associated with the decreased requirement of dialysis (p=0.045), but the effect was not significant with NSAID use (p=0.064). Peak white blood cell count (Wbc) had a strong correlation with days of hospitalization (p=0.001). 10/43 children were lost to follow up. 13/33 children showed renal sequelae (includes 3 with CKD and 1 with ESRD who required kidney transplant) after one year. The count >20000 cells/mm3 (at p=0.001) and duration of dialysis-14 days (at p=0.002) were associated significantly with the primary outcome. 6/43 children were un-immunized. There was no mortality.

Conclusions: High peak WBC count may be a useful prognostic marker to evaluate the risk of long-term renal complications. These children need monitoring periodically after discharge and recovery. Early diagnosis and iv fluids before the onset of renal failure may help to prevent dialysis-related morbidity at the time of admission. More awareness is needed to discourage the use of NSAIDs following initial symptoms of HUS.

PO2333
Targeting Bloody Diarrhea to Fight Shiga Toxin-Producing Escherichia coli-Hemolytic Uremic Syndrome in Children: The Experience of the ItaKid HUS Network
Gianluigi Ardissino,1 Rosaria Colombo,2 Laura Daprai,3 Valentina Capone,1 Antonella Dodaro,1 Sara Testa,1 Fabio Pagliarola,1 Chiara Vagnati,2 Carla Mancuso,1 Francesco Tel,1 Ilaria Pagliarola,1 Giovanni Montini,1 Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy; 2Microbiology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy; 3Pediatric Department, Vittore Buzzi Children’s Hospital, Università degli Studi di Milano, Milano, Italy.

Background: Bloody diarrhea (BD) is often the first distinctive sign of hemolytic uremic syndrome (eHUS), the leading cause of acute kidney injury in infants, caused by shiga toxin (Stx)-producing Escherichia coli (STEC) infection. The few days prior the development of the renal complication, when bloody diarrhea is the only symptom, represent a window for better understanding, preventing or mitigating HUS. The present study aims at identifying patients at risk for HUS early and at evaluating the rate of BDs associated with STEC infection.

Methods: This multicenter case series study was performed between 2010 and 2019 in Pediatric emergency departments and clinics belonging to a network of 63 pediatric hospitals in Northern Italy (referral population: 12 million general population; 2.3 million children). 4767 screened samples, 214 (4.5%) turned out to be positive for Stx genes (1 and 2) using a Reverse Dot blot assays (Genotype EHEC - Arnika) until 2018 and Real Time PCR (RIDA Gene-Relab) thereafter. Stx-positive cases were further investigated for E.coli serogroups. Children positive for Stx genes were monitored for hemoglobinuria, blood tests to rule in or out the diagnosis of STEC-HUS were done if urine dipstick turned positive for hemoglobinuria.

Results: Out of the 4767 screened samples, 214 (4.5%) turned out to be positive for either Stx1 (n: 62; 29.0%) or Stx2 (n: 97; 45.3%) or both (n: 55; 25.7%). 34 patients out of the 214 (15.9%) developed eHUS (0.71% of BDs). Patients infected with STEC producing Stx2 alone were at higher risk for eHUS compared with Stx1+2 (23.7% vs. 12.7%) while Stx1 alone was only exceptionally associated with eHUS (1.1%). The most frequent serogroup found in patients with Stx+BD was the O157 while in patients with eHUS the O26 was the most (36.5% of cases), followed by O157 (20%).

Conclusions: STEC is all but a rare cause of BD in children thus the screening for Stx positive BD is recommended. We also suggest to monitor patients carrying Stx2 closely with urine dipstick for hemoglobinuria every 12 hours for the early detection of eHUS together with providing them with generous fluid infusion.

PO2334
Hemoglobinuria for the Early Identification of STEC-HUS in High-Risk Children
Valentina Capone,1 Gianluigi Ardissino, Maria Cristina Mancuso, Giovanni Montini. Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy.

Background: Shigatoxin-producing Escherichia coli – associated hemolytic uremic syndrome (STEC-HUS) represents one of the main causes of acute kidney injury in children and can be associated with several extrarenal complications. Its management is entirely based on supportive care, which includes generous fluid infusions, since delayed treatment has been described to have a worse outcome, compared to early recognition and overhydrated patients. The present study aims at validating urine dipstick/urinalysis for hemoglobinuria as a early test to screen patients at high risk for the development of STEC-HUS (children with bloody diarrhea secondary to Shigatoxin – Stx – 2 or 1+2) for the early diagnosis of the disease.

Methods: Since 2010, a network 63 pediatric units (the ItaKid-HUS Network) has been developed in Northern Italy, with the aim of the early identification and management of STEC infections and STEC-HUS. Once a patient with bloody diarrhea (BD) is identified as Stx positive, he/she is rehydrated as appropriate and followed up with urine dipstick/urinalysis for hemoglobinuria until HUS develops or diarrhea resolves. We here reviewed all the urine dipstick/urinalysis results from pediatric patients with Stx positivity either with BD only (Group 1) or with ongoing HUS (Group 2) from 2010 to 2019. Results: A total of 100 children were eligible for the study. In Group 1, 22/63 patients had or developed hemoglobinuria while the remaining 41/63 were and remained negative. In 15/22 positive cases, blood tests ruled in a ongoing HUS, while in the remaining 7 the diagnosis was excluded. Among the 41 negative patients no one developed HUS. As expected 37 children in Group 2 (already ongoing HUS) all had hemoglobinuria at admission.

Conclusions: Hemoglobinuria shows a sensitivity of 100% (95% CI 93-100%) and a specificity of 85% (95% CI 74-93%), with positive predictive value of 68% and negative predictive value of 100% in diagnosing ongoing HUS. Thus, urine dipstick or urinalysis for the detection of hemoglobinuria can be proposed as an easy, fast, inexpensive and repeatable test to screen patients at high risk for the development of STEC-HUS and to start supportive treatment as soon as possible.

PO2335
Hemoglobinuria for the Early Identification of Atypical Hemolytic Uremic Syndrome Relapse: Data from the ItalKid-HUS Network
Gianluigi Ardissino, Marta Brambilla, Fabio Pagliarola, Sara Testa, Valentina Capone, Antonio Vergori, Donata C. Cresseri, Giovanni Montini. Ospedale Maggiore Policlinico, Milano, Italy.

Background: Atypical hemolytic uremic syndrome (aHUS) is at risk of relapse any time, thus patients require lifelong monitoring. We suggested that patients could be monitored for relapses, with hemoglobinuria (twice weekly and during intercurrent diseases) based on the hypothesis that a thrombotic microangiopathy involving the glomerulus, cannot take place without hematuria. However this assumption has not been validated.

Methods: The aim of the study is to analyze our experience with the mentioned approach in patients with aHUS who have never been treated (group 1), on treatment (group 2) and who have discontinued C5 inhibition (group 3). The records of all aHUS patients managed or referred to our Center from January 2009 to March 2020 were included and the analysis for the presence of hemoglobinuria was restricted to the period following primary remission with the aim of validating this biomarker as a reliable one for the early identification of relapses. Patients with persistent hemoglobinuria, although in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥1+. Patients reporting positive urine dipstick were addressed to laboratory investigations to rule in or out, the diagnosis of aHUS relapse.

Results: 84 patients with aHUS (50% females) were included with 1517 determinations of hemoglobinuria during a cumulative observation period of 261 patient-years (Figure). Hemoglobinuria for the early diagnosis of ongoing aHUS relapse shows a sensitivity of 100% and a specificity of 87.4% with a PPV of 10.5% and NPV of 100%.

Conclusions: Hemoglobinuria is a very sensitive and acceptably specific marker of aHUS relapse. This finding and its validation may have an important positive impact both on patient’s quality of life and on the outcome of disease via an early diagnosis of relapses.

Extensive Complement Analysis in a C3 Glomerulopathy Cohort of Dutch Children with Benign Outcome

Kiao L. Wijnema,1 Marloes Michels,2 Roel Kervurs,2 Joanna Van Wijk,2 Antonia Bouta,2 Valentina Gracchi,2 Flore Horuz-Engels,3 Mandy G. Keijzer-Veen,4 Eiske Dorrestijn,5 Elena Volokhina,1 Lambertus P. Van den heuvel,1 Niels Van De Kar,1 on behalf of the COMBAT consortium 1Amalia Children’s Hospital, Radboudumc, Nijmegen, Netherlands; 2Emma Children’s Hospital: Amsterdam University Medical Center, Amsterdam, Netherlands; 3Beatrice Children’s Hospital, University of Groningen, Groningen, Netherlands; 4Sophia Children’s Hospital, Erasmus Medical Center, Rotterdam, Netherlands; 5University Hospitals Leuven, Leuven, Belgium; 6Wilhelmina Children’s Hospital, University Medical Center Utrecht, Utrecht, Netherlands; 7Maastricht University Medical Center, Maastricht, Netherlands.

Background: C3 glomerulopathy (C3G) is a rare renal disorder driven by dysregulation of the complement alternative pathway (AP) and characterized by predominant C3 depositions in the glomerulus. C3G can be subdivided in dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). Patient cohort studies including clinical features offer important data in rare renal diseases. Moreover, biomarkers are increasingly used to select patients for clinical trials with novel complement-targeted therapies. This retrospective study describes complement biomarker profiles and outcome of 29 Dutch children.

Methods: Patients with a C3G diagnosis from 5 Dutch university medical centers (1992-2014) were included. Clinical, genetic, and laboratory findings were retrieved from patient files. Specialized biochemical assays were used to detect complement-directed autoantibodies and complement biomarkers.

Results: A total of 29 patients with DDD (n=19) and C3GN (n=10) were included. Median (IQR) follow-up was 51 months (26-90). Patients presented with proteinuria and hematuria (>90%) and low serum C3 levels (84%). Ten patients (35%; 8 DDD, 3 C3GN) presented with an impaired glomerular filtration rate (GFR). DDD patients presented at younger age and with a lower GFR (P<0.05). C3 nephritic factors were found in 19 patients (74% of the patients). 3 patients carried rare genetic variants in AP genes. Elevated levels of the complement activation markers C3d, C3bBbP, and C5b-9, combined with lowered C3 and C5 levels, indicated AP activation in the acute phase. Taking longitudinal data into account, a linear mixed model showed that C3GN patients had higher C5b-9 and lowered C3 levels than DDD patients (P<0.05). During follow-up, 13 (45%) patients experienced a relapse. No significant differences in clinical or laboratory features were observed between patients with and without a relapse and persistent renal sequelae. At last follow-up, only 4 patients (14%; all C3GN) had a GFR below 60 ml/min/1.73m².

Conclusions: We present the extensive description of clinical, genetic, and biochemical complement features of a large pediatric C3G cohort. In most patients AP abnormalities were found. Overall, the outcome of the patients we described was relatively benign.

PO2337

Comparison of Clinicopathological Findings Between Childhood IgA Nephropathy and IgA Vasculitis Nephritis Using Oxford Classification

Yuko Shimada,1 Koichi Nakashiki,1 Hironobu Mukaiyama,1 Yu Tanaka,1 Takuzo Wada,1 Kandai Nozu,2 Ryojiyo Tanaka,1 Kazumoto Iijima,3 Noriaki Yoshikawa,4 Noriaki Watanuma,1 Kenjiro Yamagata,4 Takatsuki General Hospital, Kobe, Japan; 2Pediatrics, Graduate School of Medicine, Kobe University, Kobe, Japan; 3Pediatrics, Graduate School of Medicine, Kobe University, Kobe, Japan; 4Clinical Research Center, Takatsuki General Hospital, Kobe, Japan.

Background: IgA nephropathy (IgAN) and IgA vasculitis nephritis (IgAVN) are nephritis with a common pathological feature of significant mesangial IgA deposition, but it remains controversial whether they are the same disease.

Methods: We compared clinical and pathological findings between patients with IgAN and 100 patients with IgAVN who underwent renal biopsy from April 2000 to April 2019 to clarify the differences.

Results: Clinical findings showed significant differences in onset age (IgAVN vs IgAN 10.7 years vs 12.7 years, p<0.001), episode of gross hematuria (8.0 vs 24.3%, p<0.0007), duration from onset to renal biopsy (1.7 vs 6.6 months, p<0.0001), and amount of proteinuria (1.8 vs 0.5 g/gCr, p<0.0001). Pathological findings by Oxford classification showed significant differences in the frequency of M1 (94.0 vs 59.2%, p<0.0001), S1 (21.0 vs 37.2%, p<0.0004), T present (28.0 vs 46.1%, p=0.004), C present (72.0 vs 58.1%, p=0.02) and G present (8.0 vs 19.1%, p=0.01), but no difference in that of E1 (52.8 vs 42.2%, p=0.0004), T present (28.0 vs 46.1%, p=0.004). Electron microscopic findings showed significant difference in the frequency of glomerular basement membrane (0.7 vs 0.05%, p<0.0001). Degree of proteinuria is positively correlated with the frequency of M1 and equal or greater severity of S1 (r=0.38, p<0.01). Electron microscopic features of IgAN are similar to those of IgAVN.

Conclusions: IgAVN has higher frequency of M1 lesion regardless of degree of proteinuria, a frequent proteinuria of chronic lesions such as T, S, and G, and a higher frequency of acute lesions such as M and C compared with IgAN. Although IgAVN had some pathological similarities to that of IgAN, there seems to be differences which cannot be explained by the timing of renal biopsy.

Evaluating Nephrotic Syndrome Response to Rituximab in Children

Anna E. Williams, Katherine Twombley, Annabelle N. Chua, Raheel A. Gbadeboyan. Duke University, Durham, NC; Medical University of South Carolina, Charleston, SC.

Background: Nephrotic syndrome (NS) is the most common cause of glomerular disease in the pediatric population. In children, 80% of cases are steroid sensitive (SSNS) & 20% are steroid resistant (SRNS). Rituximab (RTX) has been identified as a steroid-sparing therapy with minimal nephrotic side effects. The determinants of clinical response to rituximab is not completely known.

Methods: A retrospective review of patients aged 0-21 years with idiopathic NS who received at least 2 doses of RTX therapy over 6 years. Data collected included gender, race, ethnicity, age at diagnosis, steroid response, number of RTX doses, CD20 levels post therapy & outcomes. Outcome was defined as complete remission, CR (urine protein to creatinine ratio mg/mg: UPCR ≥ 0.2), partial remission, PR (UPCR 0.3-1.9) & no response, NR (UPCR ≥ 2). Data were compared by Fisher’s exact & Wilcoxon Rank Sum tests.

Results: 48 patients met the inclusion criteria for the study comprising of 23 (48%) with SSNS & 25 (52%) with SRNS. There was no difference in race or age of onset between the patients with SSNS & SRNS. 18/2962 (6%) of patients who had CD20 lymphocyte levels measured following treatment achieved therapeutic end point of CD20 lymphocyte depletion. There was no difference in the proportion of patients who achieved this therapeutic end point between the patients with SSNS & SRNS (46% vs 72%). Overall, 72% of patients achieved partial or complete remission. The remission rate was significantly higher in the SSNS group compared with the SRNS group (87% vs 58%, p=0.001); however, there was no difference in remission rate between patients who achieved the therapeutic end point of CD20 lymphocyte depletion & those who did not in the entire cohort (56% vs 55%, p=1.0) as well as in subgroup of patients with SSNS & SRNS.

Conclusions: Children with both SSNS & SRNS achieved the desired therapeutic effect of CD20 lymphocyte depletion following treatment with RTX; however, disease remission rate was higher in children with SSNS. This data suggests that RTX can be administered at any phase of the disease (relapse or remission) without jeopardizing clinical response.
PO2343
Caregiver Perspectives of Pre-Transplant Evaluation for Children

Background: Pre-transplant evaluation is mandated by Centers for Medicare and Medicaid Services, but there is institutional variation in implementation. The family experience of this process also is incompletely understood. Current literature largely focuses on adult transplant recipients. Our interview study aims to fill the knowledge gap about family experience of the evaluation for children.

Methods: Interviews took place 07/2019 - 02/2020 with caregivers of children referred for kidney transplant at our center 07/2017 - 12/2018. The interview guide included closed- and open-ended questions; responses were audio-recorded and then transcribed for coding of themes. Respondents also completed a brief electronic questionnaire.

Results: Our team interviewed 19 children; demographics in Fig. 1. Prominent themes included (1) the pre-transplant evaluation is overwhelming and emotional, (2) prior experiences and background knowledge are influential and (3) frustration with communication among teams was common. Fig. 2 highlights representative quotations from caregivers.

Conclusions: These findings are relevant to nephrologists to optimize delivery of information about transplant and other complex topics. The data highlight the importance of (1) acknowledging the scope of content and continually reevaluating accessibility of delivery (2) recognizing the influence of prior experiences and tailoring elements accordingly for increased family-centeredness and (3) making concerted efforts to define roles and set expectations, especially when multiple teams are involved in care.

PO2345
Vaccination Status in Pediatric Kidney Transplants: An Integrated Pediatric Transplant Research Database Study
Jaya S. Parulekar, Eric J. McGrath, Amrish Jain. 1Wayne State University School of Medicine, Detroit, MI; 2Division of Pediatric Nephrology, Children’s Hospital of Michigan, Detroit, MI; 3Division of Pediatric Infectious Disease, Children’s Hospital of Michigan, Detroit, MI.

Background: The American Society of Transplant recommends candidates be immunized before transplantation. However, there is limited data on pre/post-transplant vaccination status for children with kidney transplants. Our study evaluates vaccination rates & an approach to increasing vaccination in our kidney transplant program.

Methods: Pediatric kidney transplant recipients at Children’s Hospital of Michigan from 2013-2019 were included. Official immunization records were obtained from the State of Michigan’s Michigan Care Improvement Registry. During the pre-transplant period, age-based catch-up or accelerated immunization was performed at primary care provider’s or at the in-house immunization center. Demographic, clinical & serology data were entered into an integrated database created through RedCap and analyzed with SPSS Version 26.

Results: Included were 58 children with mean age at transplant of 11.9±5.7 yrs, 66% Male, 52% African-American, 31% Caucasian, 76% deceased donor transplants & 10% re-transplants. Median duration of follow-up was 3 years. Pre-transplant vaccination rates of ≥95% were achieved for all vaccines, except PCV13 (69%), PCV23 (62%) & HPV4/9 (86%). Pre-transplant serology for HepA, HepB and Varicella showed immunogenicity of 95%, 93%, 88% respectively. Catch-up & accelerated immunization increased the vaccination rate to 100% from 53% (Varicella); 57% (HepA); 73% (MCV); 72% (MMR).

Post-transplant vaccination series was ≥95% complete for all vaccines except PCV23 (43%); HPV4/9 (37%); MCV (30%).

PO2344
Treatment-Related Anxiety in Children After Kidney Transplant
Michelle N. Keyser, Elizabeth G. Ingulli, Euyhyun Lee, Paul Riviere. 1University of California San Diego, La Jolla, CA; 2Rady Children’s Hospital, UC San Diego, San Diego, CA.

Background: An increasing number of children experience anxiety and pediatric kidney transplant recipients are particularly susceptible to mental health conditions given the impact of their complex chronic medical histories on their quality of life. We performed a retrospective study to assess the impact of anxiety on health-related quality of life (HRQoL) in pediatric kidney transplant recipients in order to design targeted interventions to improve HRQoL after transplant.

Methods: We retrospectively analyzed scores from the disease-specific Pediatric Quality of Life (PedsQL) 3.0 ESRD and Transplant Modules in pediatric ESRD and transplant patients ages 2-18 years between 2014 and 2019 at Rady Children’s Hospital. We used a linear mixed-effects model with a random intercept and ANOVA with Tukey post hoc tests to analyze the effect of variables of interest on HRQoL in various groups.

Results: 180 modules were completed by pediatric patients who received dialysis and/or transplantation. Transplant recipients had significantly better total HRQOL scores compared to dialysis patients (p < 0.001). Treatment-related Anxiety was the lowest (worst) scoring domain among kidney transplant patients (p = 0.01), especially among patients ages 5-7 years old (p = 0.009). Patients 13-18 years old had the lowest scores in the Transplant domain, which measures social isolation related to a patient’s transplant (p = 0.008). Variables such as age at diagnosis, time on dialysis, diagnosis category, and time to transplant were not significant predictors of HRQoL.

Conclusions: These data suggest that children with kidney transplants have better HRQoL compared to children on dialysis. However, transplant recipients experience high rates of anxiety and social isolation. This may simply reflect the psychosocial stress surrounding medical care, but we may also be capturing more nuanced psychological issues in this population that requires further evaluation. Since transplant patients typically have frequent access to medical care, we have established a multi-disciplinary model in our clinic in part based on these data that utilizes psychologists to address acute and chronic psychological concerns simultaneous with their medical visits. This model may improve the HRQoL of transplant patients without increasing the overall burden of medical care and may have broader applicability to the general population of children with anxiety.
PO2346
Decreased CD28 Expression in Memory CD4+ T Cells in Children Awaiting Kidney Transplant Is Associated with Increased Expression of Senescence Markers

Charlotte Dumeton,1 Roshan P. George,2,1 Mandy L. Ford,1 Pamela D. Winterberg,2 Emory University, Atlanta, GA;1 Children’s Healthcare of Atlanta Egleston Hospital, Atlanta, GA.

Background: Despite improved patient and graft outcomes with CD28-CD80/86 costimulation blockade, increased early acute rejection has hindered the widespread use of this strategy (Cytocare) for kidney transplant. Our group has previously reported lower pre-transplant frequencies of CD28+ effector helper T cells (CD4+CD28+CCR7-) with decreased functional capacity in adults that were subsequently free from early rejection on belatacept. We aimed to determine if a similar T cell phenotype is detectable in children awaiting kidney transplant.

Methods: We analyzed existing flow cytometry data of unstimulated blood cells collected from children on dialysis (n=30) or healthy children (n=18) and examined expression of markers of costimulation (CD28), senescence (CD57, PD1), activation (CD38) and cytotoxicity (Perforin, Granzyme B) on memory CD4+ T cells.

Results: None of the children had CD28-CD4+ T cells frequencies as low as those we have previously observed in adults that were rejection-free on belatacept. However, 8 children on dialysis (27%) had CD28-CD4+ T cells frequencies below the minimum value observed in healthy children (Fig1A-B). Patients with this “stable-like” T cell phenotype had higher frequency of CD4+TEM cells bearing senescence markers (CD57+ Fig1C) and cytolytic effectors (Granzyme B, Perforin, Fig 1D) but decreased activation markers (CD38+ Fig 1E).

Conclusions: Despite their young age and limited antigen experience, a subset of children on dialysis accumulate CD4+ T EM cells that have lost CD28 expression and bear markers suggestive of impaired function, a phenotype reminiscent of adults with decreased risk for early rejection on belatacept. The functional capacity of these cell populations in children needs further study.

PO2347
Predicting Allograft Survival in Young Pediatric Kidney Transplant Recipients
Florian Manca Barayre,1 Jerome Harambat,1 Amelia Le Page,4 Stephen D. Marks,2 Chanel Prestidge,6 Matthew P. Sypek,7 Stephen P. McDonald,1 Rachel E. Patzer,1 Julien Hogan,1,2 Emory University School of Medicine, Atlanta, GA;2 Robert-Debré Hospital, APHP, Paris, France;3 Bordeaux University Hospital, Bordeaux, France;4 Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia;5 Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom;6 Starship Children’s Health, Newmarket, New Zealand;7 Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia.

Background: Kidney transplantation (kTx) presents specific challenges in young pediatric recipients. There are no predictive model of renal allograft loss in young pediatric recipients to inform donor selection. We aimed to develop and validate a predictive model of graft loss in an international cohort of young kTx recipients.

Methods: We included first-time kTX recipients under 5 years of age in the USA, Australia, New Zealand, UK and France between 2005 and 2018. A multivariate Cox regression was used to develop a predictive model of graft loss or death on the US cohort. Model discrimination (C-statistics) and calibration were assessed internally and externally on the non-US cohort.

Results: 2543 kTx in children <5 years old were included. 10-year overall graft survival rate was 80.0% [95% CI = 77.7% – 82.2%]. Given the interaction between some predictors and recipient’s age, we developed two models stratified on recipient age (cut-off: 36 months) including donorrecipient body surface area ratio, ischemia time, donor weight and immunological matching. Immunological matching was a stronger predictor among older recipients, while morphological variables were stronger predictors in younger recipients. C-statistics on the training cohort were 0.63 (95% CI = 0.57 – 0.68) and 0.65 (95% CI = 0.59 – 0.71) and the models were well calibrated. Figure 1 presents the discrimination of the models at different time horizons and the calibration at 10 years on the validation cohort.

Conclusions: We confirm the overall good renal allograft survival in children transplanted under the age of 5. We developed and validated predictive models of graft loss or death based on pre-transplant factors in this population that may be used to inform donor selection.
PO2348
Safety and Efficacy of Low-Dose Rabbit Antithymocyte Globulin in Pediatric Renal Transplant Recipients
Vaka K. Sigurjonsdottir,1,2 Paul C. Grimm,1 Abanti Chaudhuri,1 1Landspítali, Reykjavik, Iceland; 2Stanford University, Stanford, CA.

Background: Currently there is no consensus among pediatric kidney transplant centers regarding the use and regimen for immunosuppressive induction therapy. The safety and effectiveness of reduced Rabbit Antithymocyte Globulin (ATG) ≤ 3.5 mg/kg cumulative dosing as induction therapy in low risk pediatric kidney transplant recipients is unknown.

Methods: Pediatric renal transplant recipients transplanted 1/1/2013-5/1/2018 were considered for inclusion. Recipients of deceased or living donor organs and with least 12-month follow-up were included. “High risk” was defined by a repeat transplant, preformed donor specific antibodies (DSAs), peak panel-reactive antibodies >20%, or African-American race. Maintenance immunosuppression protocol was tacrolimus and mycophenolate mofetil, steroid free unless high risk. Outcomes were de novo DSA (dnDSA formation), graft survival, biopsy proved rejection (BFR) and EBV/CMV BK viremia infection during the first 12 months. DSAs were routinely screened at 3.6 and 12 months. Protocol biopsies were done at 6 and 12 months and graded with Banff criteria. Subcortical/borderline findings were included with or without treatment. Additional DSA testing and/or biopsies were done if there was a clinical concern.

Results: A total of 181 patients met inclusion criteria. Age of patients was 11 years (11 mo-21 y), median, range), 21% received a living donor transplant and 49% were female. Graft survival and dnDSA formation did not differ significantly between the three treatment groups. Graft loss at 12 months was a rare event with 99.5% graft survival and patient survival was 100%. Patients outcomes based on groups is shown in the table.

Conclusions: Reduced ATG dosing (≤ 3.5 mg/kg) when compared with higher dosing (≥3.5 mg/kg) is safe and effective. Reduced ATG dose was associated with lower rates of BK viremia and BK nephropathy without increasing risk of dnDSA or BFR.

PO2349
Pediatric-Specific Models Improve Prediction of Kidney Transplant Survival for Children Under 5 Years Old
Florian Manca Barayva,1 Larry A. Greenbaum,1 Rouba Garro,1 Pamela D. Winterberg,1 Rachel E. Patzer,1 Julien Hogan,1,2 Emory Transplant Center 1Emory University, Atlanta, GA; 2Rôbert-Debré Hospital, APHP, Paris, France.

Background: The kidney allocation system directs high-quality kidneys to pediatric recipients, but the kidney donor profile index (KDPI) used to quantify donor quality may not accurately predict graft survival in small pediatric recipients. We aimed to determine if a pediatric-specific KDPI could improve the prediction of graft longevity for young recipients.

Methods: We evaluated first-time kidney transplantations in pediatric recipients between 1/2005 and 8/2018 in the U.S. (SRTR) and used a Cox model to assess KDPI accuracy for combined primary outcome of death or graft loss in young recipients. We developed an adapted KDPI score for recipients <5 years old of deceased (SP-KDPI) or living (SP-LKDPI) adult donor transplants using multivariate cox regression and scaled these models to allow comparison between living and deceased donors. Models’ accuracies were validated internally by cross-validation.

Results: KDPI C-statistic was 0.52 (95% CI = 0.50 – 0.54) in recipients less than 5 years old. Ethnicity, age, body surface area, gender, cold ischemia time and number of HLA-B mismatches, were significant predictors for deceased donors (SP-KDPI model) while race, age, HLA-B mismatch and donor/reipient body surface area ratio were used in the living donor model (SP-LKDPI). C-statistics were 0.64 (95% CI = 0.57 – 0.70) for SP-KDPI and 0.65 (95% CI = 0.58 – 0.73) for SP-LKDPI. Figure 1 shows allograft survival by donor type and SP-(L)KDPI stratum. The SP-LKDPI model identified 16.8% of living donors with predicted graft survival superior to any deceased donor (denoted as SP-LKDPI = 0).

Conclusions: Our adaptation of the KDPI demonstrated a higher accuracy to predict graft loss in young recipients of deceased donors. Furthermore, our SP-LKDPI model may allow direct comparison of living versus deceased donors offered to the youngest recipients.
**PO2352**

**Variability in Surveillance Monitoring and Management of Donor-Specific Antibodies Among Pediatric Transplant Programs Participating in the Improving Renal Outcomes Collaborative (IROC)**

Lyndsay Harshman,1 Hiren P. Patel,2 Gina-Marie Barletta,3 David K. Hooper,4 Rouba Garo,5 6 7 8

1The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA; 2Nationwide Children’s Hospital, Columbus, OH; 3Phoenix Children’s Hospital, Phoenix, AZ; 4Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 5Emory University, Atlanta, GA; 6Children’s Healthcare of Atlanta, Atlanta, GA.

**Background:** There have been few advancements in long-term outcome of pediatric kidney transplant (KT) recipients who develop rejection. Many centers perform surveillance monitoring for donor specific antibodies (DSA) to diagnose and treat subclinical rejection. Despite the existence of guidelines, there is variability in monitoring and management of DSA post-pediatric KT.

**Methods:** An IRB approved survey was distributed using REDCap among pediatric KT programs participating in IROC to evaluate practice patterns in monitoring and management of DSA post KT.

**Results:** Twenty-nine of 33 (88%) IROC centers completed the survey. Twenty-five of 29 (86%) centers perform surveillance DSA monitoring. Of those 25 centers, 20 (69%) check DSA twice or more in year one post KT. Nineteen (65%) check once in the second year and annually thereafter. Ten (35%) centers check DSA only by indication after year two post KT. Twenty-eight (97%) utilize MFI trend in interpreting DSA results and 10 (34%) centers use C1q complement fixing antibody assay to guide management. Management of patients with +DSA, stable creatinine and no evidence of antibody mediated rejection (AMR) on biopsy varies across centers from monitoring (58%) to intensification of baseline immunosuppression (65% to 69%). Very few centers reported giving IVIG alone (3/29, 10%) or IVIG and rituximab (3/29, 10%). Only 34% of centers (10/29) perform kidney biopsy if DSA develops with stable creatinine. When rituximab is used for treatment of DSA+, AMR, 11/29 (41%) centers use one dose and 18/29 (61%) use 2 doses with variable frequency. Of centers using CNI+IVIG as monotherapy for treatment of DSA+ AMR, 12/20 (60%) use 1 g/kg/dose and 6/20 (30%) use 2 g/kg/dose. The frequency of IVIG dosing is monthly in 16/20 (80%). The number of IVIG doses is variable ranging from 1 to 6.

**Conclusions:** There is significant variability in surveillance monitoring and management of DSA post-KT across pediatric centers. Large, multicenter studies should be considered to evaluate the ideal post-KT surveillance DSA monitoring strategy and to determine the effect of different treatment approaches on long-term outcomes in pediatric KT recipients.

**Assessment of Pediatric Nephrology Programs’ Readiness to Participate in Prospective Clinical Trials**

Shyamne Hetley,1 Noel Howard,1 H. William Schnaper,2 William E. Smoyer,3 Katherine M. Dell,4 Coleman Gross,5 Katherine Twombly,6 Tetyana L. Vasylyeva,1 Scott E. Wenderfer,1 7 Texas Tech University Health Sciences Center School of Medicine, Amarillo, TX; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 2Nationwide Children’s Hospital, Columbus, OH; 7Cleveland Clinic, Cleveland, OH, 51Relypsa Inc, Redwood City, CA; 5Medical University of South Carolina, Charleston, SC; 7Baylor College of Medicine, Houston, TX.

**Background:** Currently, there is a limited availability of effective, FDA-approved drugs for children with kidney disease in the United States; therefore, there is an increased need for clinical trials to evaluate drug effectiveness and safety for pediatric usage. Implementation and conduction of clinical trials is complex process, which requires a team approach, involves multiple inter-dependent steps, research infrastructure support, legal policies/procedures, equipment, and access to a regulatory oversight board. The conduct of clinical trials in small pediatric subspecialties (i.e. pediatric nephrology) may be hampered by provider clinical demands and small numbers of patients available for such studies. The goal of this survey was to assess the readiness to conduct clinical trials by pediatric nephrologists in institutions of different sizes. As such, it would give consideration to the sites for prospective trials and educate the programs about steps needed in clinical research.

**Methods:** The survey was designed and tested by a small group of pediatric nephrology experts. Qualtrics Online Survey Platform and Statistical analysis were used. The survey was distributed to members of ASPN (60 sites in 30 U.S states and 2 Canadian Provinces). Respondents were asked to complete the survey on behalf of the institution/practice, not their individual preferences. There was a total of 17 survey questions, which assessed the respondent’s institution’s participation/interest in conduction of clinical research. Availability of clinical research coordinator/IRB, and access to equipment for trial execution (dry ice, centrifuges, freezers).

**Results:** Currently, we have recorded 68 survey responses. Two of the responding institutions had no interest in conducting clinical trials (2.9%). Notably, more respondents practiced at Academic Centers/Universities (91%) than in private practices (8.3%). We noted no major differences in access to clinical trial resources between large and small institutions.

**Conclusions:** Clinical trials remain vital to finding better treatments and cures for pediatric patients with renal diseases. Overall, pediatric nephrology programs have good infrastructure and readiness to conduct clinical trials independently of the size of the institution.
PO2354

Telemedicine During the COVID-19 Pandemic: Parents’ Experience in a Pediatric Nephrology Clinic at the University of Florida

Background: In the setting of the COVID-19 pandemic, pediatric nephrology clinics at the University of Florida were switched to telemedicine. This transition occurred quickly without much education to either providers or families. There are some attempts to study the experience of providers, but there is no data regards to patients’ and parents’ experience with telemedicine.

Methods: We surveyed parents and patients (>18 years old) who had at least 1 telemedicine encounter via anonymous Qualtrics® survey sent to their email. Results were analyzed via qualitative analysis.

Results: Out of the 80 parents, 47.5% (38) completed the survey. 95% of the patients participated via Zoom and 5% used the telephone. 10.5% experienced technical issues. 100% reported that telemedicine had a positive impact on their family life. In response to the quality of time spent with physicians, 84% reported that telemedicine was similar to the clinic, and 10.5% reported it was better. In terms of receiving virtual medical care, 50% reported that they were very comfortable, 50% reported that they were comfortable but preferred some interim clinic visits. 71% rated telemedicine experience 5, 25% rated 4, and 5% rated 3 out of 5.

Conclusions: We observed that parents perceived the effect of telemedicine clinics as positive in respect to ease in the incorporation, quality of time spent by the physician, receiving virtual medical care, and the impact on the families. Though telemedicine seems to be effective in the current setting, it can only be served as additive to in-person clinic visits in the future, since 90% of families preferred a mixture of clinic and telemedicine visits in our setting. Larger studies are needed to further evaluate the utility and efficacy of telemedicine in a pediatric setting.

PO2355

Prevalence and Determinants of Sickle Cell Nephropathy in Children Living in a Low-Resource Setting

Ovindamola C. Adebayo,1,2 Dieumerci Betukumusu Kabasele,3 Agathe B. Nkoy,1 Pepe M. Ekulu,1 Veerle Labarque,2 Lambertus P. Van den heuvel,1,4 Elena N. Levchenko.1 Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium;1 Centre for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium;1 Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the);3 Department of Pediatric Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands.

Background: Clinical and genetic factors have been reported to influence the development of sickle cell nephropathy (SCN). However, data on the association between these factors and SCN remain limited in the pediatric population, especially in sub-Saharan Africa. Our study aimed to: (i) determine the prevalence of the reported markers of SCN, including albuminuria, glomerular hyperfiltration and reduced kidney function in a pediatric sickle cell anemia (SCA) population from the Democratic Republic of Congo (DRC); (ii) examine the association between these SCN markers and some clinical and genetic factors.

PO2356

Disparities in Kidney Failure Care for Children: A Global Survey

Rovenwa Lalji,1,2 Anna Francis,1,3 Germaine Wong,1,4 David W. Johnson.1,5 on behalf of the Pediatric GKHIA working group 1The University of Queensland Faculty of Medicine, Herston, QLD, Australia;2 Princess Alexander Hospital, Wooloongabba, QLD, Australia; 3The University of Sydney, Sydney, NSW, Australia; 4Westmead Institute for Medical Research, Westmead, NSW, Australia; 5Queensland Children’s Hospital, South Brisbane, QLD, Australia.

Background: Globally, the capacity to access and deliver kidney replacement therapies (KRT - dialysis and transplantation) to children has never previously been described. The present study reports current disparities in access to kidney care between children and adults worldwide based on the results of the 2018 International Society of Nephrology Global Kidney Health Atlas (GKHA) survey.

Methods: A mixed methods analysis of pediatric-specific data from the 2018 GKHA survey were used. Respondents were from countries categorized as low (LIC), lower-middle (LMIC), upper-middle (UMIC) or high income (HIC) according to 2018 World Bank income classification. Descriptive statistics were used for the population-based analysis of health expenditure across different world bank countries. Open text responses were thematically analyzed using HyperRESEARCH.

Results: Responses were received from 160 (88%) of 182 countries, including LIC (n=26, 16%), LMIC (n=36, 23%), UMIC (n=39, 24%) and HIC (n=59, 37%). Child access to end stage kidney disease care (ESKD) and KRT differed from adults in 29% and 23% of countries, respectively. Lower income countries were associated with graded increases in disparate access to ESKD (LIC 62%, LMIC 38%, UMIC 18%, HIC 19%) and KRT care (LIC 58%, UMIC 33%, UMIC 13%, HIC 9%). Five themes explained access disparities for children: inadequate resources for KRT; kidney failure care is expensive and incurs lifelong costs; priority and access based on a country’s economic status; a lack of child-specific resources; and longer travel distances for children.

Conclusions: There are significant disparities worldwide in care for children with kidney failure when compared with adults, particularly in low resource settings. Future policy and advocacy efforts are needed to promote universal, equitable kidney care for children globally.

Clinical and Biopsy Characteristics in a Pediatric Cohort of C3 Glomerulonephritis (C3G) and Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN)
Bradley P. Dixon,2 Amy Goodwin Davies,3 Hanieh Razzaghi,1 Sherin Meloni,1 Melissa E. Thomas,3 Joseph T. Flynn,4 Donna J. Claes,5 Mark Mitsnefes,5 Brian R. Storrier,5 Vikas R. Dhamidharka,1 Caroline A. Gluck,1 Joshua Zaritsky,1 Michael J. Somers,5 Mahmoud Kallash,5 William E. Smoyer,5 Susan L. Furth,5 Christopher B. Forrest,1 Benjamin L. Laskin,5 Michelle Denburg,3 ‘Renal Section, Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO; ‘Children’s Hospital Colorado, Aurora, CO; ‘The Children’s Hospital of Philadelphia, Philadelphia, PA; ‘Seattle Children’s Hospital, Seattle, WA; ‘Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; ‘Washington University in Saint Louis School of Medicine, Saint Louis, MO; ‘Nemours/Alfred I. DuPont Hospital for Children, Wilmington, DE; ‘Boston Children’s Hospital, Boston, MA; ‘ Nationwide Children’s Hospital, Columbus, OH.
Background: C3G and IC-MPGN are rare diseases. The ability to identify and phenotype children with C3G and IC-MPGN using electronic health records (EHR) would aid description of natural history and prognosticate therapeutic response.
Methods: Using a computable phenotype algorithm, a pediatric cohort of children with glomerular disorders was identified in PEDSnet, a national network of pediatric health systems with aggregated EHR data, and refined using MPGN-specific SNOMED-CT codes to identify C3G and IC-MPGN patients at 6 centers. Discrete data elements were captured from electronic health records, and additional clinical data were extracted by standardized chart review. Biopsy diagnosis was classified as C3G or IC-MPGN by applying an automated algorithm to immunofluorescence data.
Results: Of 285 identified patients, 173 were true cases of C3G or IC-MPGN (p = 0.005). There were no significant differences in light microscopic injury pattern or ultrastructure between C3G and IC-MPGN biopsies, but C3 intensity was higher in C3G compared to IC-MPGN (p = 0.006) (Table 3).
Conclusions: Patients with C3G and IC-MPGN can be identified and characterized by the use of a computable phenotype, allowing the creation of robust databases to define clinical predictors of treatment response. This may prove to be a vital asset for recruitment into clinical trials of complement-targeted agents likely beneficial to this patient population.

PO2358
Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Sickle to Complement Inhibitor Treatment: 26-Week and 1-Year Data
Gema Arieta,1 Bradley P. Dixon,2 Seong Heon Kim,3 Gaurav Kapur,3 Teri Jo Mauch,1,4 Stephanie Ortiz,1 Marc Vallee,1 Andrew E. Denker,5 Hee Gyung Kang2 Larry A. Greenbaum,3 ‘Hospital Vall d’Hebron, Barcelona, Spain; ‘University of Colorado School of Medicine, Aurora, CO; ‘Pusan National University Children’s Hospital, Seoul, Republic of Korea; ‘Children’s Hospital of Michigan, Detroit, MI; ‘University of Nebraska Medical Center, Omaha, NE; ‘Alexion Pharmaceuticals Inc, Boston, MA; ‘Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA; ‘Seoul National University College of Medicine, Seoul, Republic of Korea.
Background: Ravulizumab is a complement C5 inhibitor derived from eculizumab, with an increased half-life extending the maintenance dosing schedule from every 2–3 to every 4–8 weeks. We evaluated the efficacy and safety of ravulizumab to resolve active thrombotic microangiopathy (TMA) in children with atypical hemolytic uremic syndrome (aHUS) naïve to complement inhibitors.
Methods: ALXN1210-aHUS-312 (NCT03131219) is a phase 3, single-arm trial in children with TMA due to aHUS. Patients received ravulizumab every 4–8 weeks, depending on bodyweight. The primary endpoint was complete TMA response (platelet count and lactate dehydrogenase normalization and ≥ 25% improvement in serum creatinine from baseline at 2 visits ≥ 28 days apart) through 26 weeks. Key secondary endpoints included eGFR and dialysis requirement. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year and safety from all available follow-up (median 82.6 weeks).
Results: Eighteen patients (mean [SD] age 6.4 [4.5] years; 55.6% female) were enrolled; 14 (77.8%) achieved complete TMA response by 26 weeks, and 3 more patients (94.4%) by 50 weeks. Further improvements in TMA parameters occurred with long-term treatment (Table). Mean (SD) increase in eGFR from baseline was 19.2 (30.1) mL/min per 1.73 m2 at 26 weeks, and 25.4 (41.7) mL/min per 1.73 m2 at 50 weeks. Of 6 patients on dialysis at baseline, 5 (83.3%) discontinued dialysis by week 26, and the last patient by week 50. Complete free C5 inhibition was sustained throughout the trial. No unexpected adverse events, deaths, or meningococcal infections occurred.

A Pharmacologic “Stress Test” for Assessing Select Antioxidant Defenses in Patients with CKD

Richard A. Zager,1,2 Ali C. Johnson,1 Alvayo F. Guillem,3 Donald J. Keyser,3 Bhupinder Singh,1,4 Fred Hutchinson Cancer Research Center, Seattle, WA; 1University of Washington Department of Medicine, Seattle, WA, US, Department of Medicine, Irvine, CA; 2Renibus Therapeutics, Southlake, TX; 3University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA.

Background: Oxidative stress is a hallmark and mediator of CKD. Diminished antioxidant defenses are thought to be partly responsible. However, there is currently no way to prospectively screen for antioxidant enzymes in humans. RBT-6 (n=18) or protoporphyrin IX; SPP) induces mild, transient oxidative stress in animal models, triggering increased expression of select antioxidant proteins (eg, heme oxygenase 1 [HO-1], NADPH [H] dehydrogenase [quinoxine] 1, ferritin, p21). Hence, we tested the hypothesis that RBT-6 can also variably increase these proteins in humans and can thus serve as a pharmacologic “stress test” for gauging general responsiveness and antioxidant reserves.

Methods: A total of 18 healthy volunteers and 24 participants with stage 3 CKD (n=12; eGFR 30–59 ml/min per 1.73m²) or stage 4 CKD (n=12; eGFR 15–29 ml/min per 1.73m²) received a single dose of RBT-6 at 9, 27, or 90 mg administered intravenously. Plasma and/or urinary antioxidant proteins were measured at baseline and for up to 4 days post-dosing. Kidney safety was assessed by serial measurements of BUN, creatinine, eGFR, albuminuria, and urinary AKI biomarkers (kidney injury molecule 1, neutrophil gelatinase–associated lipocalin, cystatin C, and N-acetylglucosaminidase).

Results: Plasma HO-1, ferritin, p21, and urinary NQO1 were all elevated at baseline in CKD participants. Plasma HO-1 and urinary NQO1 levels each inversely correlated with eGFR (r=0.85 to 0.95). All four proteins manifested statistically significant dose- and time-dependent elevations after RBT-6 infusion. However, marked inter-subject differences were observed. p21 responses to high-dose RBT-6 and HO-1 responses to low-dose RBT-6 were significantly suppressed in participants with CKD versus healthy volunteers. RBT-6 was well tolerated by all participants, and no evidence of nephrotoxicity was observed.

Conclusions: RBT-6 can be safely administered and, after its infusion, the resulting changes in plasma HO-1, NQO1, ferritin, and p21 concentrations can provide information as to antioxidant gene responsiveness/reserves in subjects with and without kidney disease. Additionally, baseline values of these markers may also be indicative of oxidative stress at baseline, especially in patients in CKD.

PO2360

Prediction of Kidney Drug Clearance: A Comparison of Tubular Secretory Clearance and GFR

Yan Chen,1,2 Leila R. Zelnick,3,4 Andrew N. Hoofnagle,2,4 Catherine K. Yeung,2,5 Laura M. Shireman,1 Calder C. Brauchla,1 Ian H. de Boer,1,5 Jonathan Himmelfarb,1 Bryan R. Kestenbaum,2,3 1University of Washington Department of Epidemiology, Seattle, WA; 2Kidney Research Institute, Seattle, WA; 3University of Washington Department of Medicine, Seattle, WA; 4University of Washington Department of Laboratory Medicine, Seattle, WA; 5University of Washington Department of Pharmacy, Seattle, WA.

Background: Tubular secretion is the primary mechanism of kidney drug elimination. Few studies have empirically evaluated the role of tubular secretion on the kidney elimination of administered drugs.

Methods: We evaluated 54 participants with and without chronic kidney disease. We administered a single dose of iohexol, furosemide, and famciclovir at the start of the study visit. We used LC-MS/MS to measure furosemide, penciclovir (the active form of famciclovir), and secretory solutes in sequential timed plasma samples and timed urine collections. We compared iohexol GFR (iGFR) with the kidney clearances of secretory solutes in sequential timed plasma samples and timed urine collections.

Results: Kidney secretion was assessed directly, a profound decrease in renal clearance of IS was detected already after 1 week on adenine diet with only a small further decrease by the 3rd week. Tubular secretion was estimated by measuring renal clearance of the endogenous secretory solutes indoxyl sulfate (IS), hippuric acid (HA) and cinnamoylglycine (CMG) using liquid chromatography couple to mass spectrometry. GFR was estimated by transcutaneous measurements.

Conclusions: Mice on adenoine diet developed kidney disease, indicated by progressive GFR decline. Histological assessment showed normal glomeruli throughout the study and a moderate tubular damage at 1 week which progressed to severe at 3 weeks. However, the maximum urinary albumin-creatinine ratio was reached already at 1 week of treatment, as was Kim-1, an early tubular injury marker, suggesting extensive early tubular injury and functional damage preceding structural damage. Likewise, when tubular secretion was assessed directly, a profound decrease in renal clearance of IS was detected already after 1 week on adenoine diet with only a small further decrease by the 3rd week. Similar trends were observed for HA and CMG. In direct comparison, the decline in GFR versus tubular secretion over time revealed that at 1 week GFR was decreased by 30% whereas tubular secretion was decreased by >65%, suggesting earlier impact on the latter. Immunohistological analysis revealed a reduction in oat1 transporter expression, to an extent not fully accounting for the reduction in secretion. This suggests a component of oat1 inhibition and/or involvement of other transporters.

The Influence of Vitamin D Status and CKD on the CYP3A Metabolism Substrate Midazolam

Stacey M. Tuyet,1 Linda Prebheela,2 Michael F. Wenpe,1 Michel Choncol,2 Nirav A. Shah,3 Thomas D. Nolin,3,4 Melanie S. Joy,1,2 University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 2University of Colorado, Division of Renal Diseases and Hypertension, Aurora, CO; 3University of Pittsburgh, Department of Pharmacy & Therapeutics, Pittsburgh, PA; 4University of Pittsburgh, Department of Medicine Renal Electrolyte Division, Pittsburgh, PA.

Background: Patients with chronic kidney disease (CKD) have a high prevalence of vitamin D (ViD) deficiency. Given its widespread use and knowledge of CYP gene induction, there is a paucity of data on how the pharmacokinetics (PK) of CYP3A substrates may be impacted by ViD in CKD. This study sought to investigate the role of ViD status (deficient vs. replete state) on CYP3A metabolism in CKD and healthy control (HC) subjects using midazolam (MDZ) as a prototypical probe substrate.

Methods: CKD (n=19) and HC (n=6) subjects with ViD deficiency (25(OH)D < 30ng/mL) were enrolled in a 2 phase study. In Phase 1, subjects were given one dose of oral midazolam (MDZ, 5000 IU) and oral MDZ (2 mg). In Phase 2, subjects received D3, 5000 IU daily for up to 14 weeks to repletion (25(OH)D > 30ng/mL) and were again given one dose of oral D3, 5000 IU and MDZ 2 mg. Blood was serially collected for up to 48 hours at each phase. MDZ plasma concentrations were measured by LC-MS/MS. Population PK analysis was performed using Phoenix NLME (v.8.2, Certara®).

Results: A 2-compartment model with delayed absorption and a mixed ratio residual error model was fit to the observed MDZ plasma concentration data. Glomerular filtration rate (GFR) and study phase were included as covariates in the model. MDZ population parameter estimates (N=25) were: central volume of distribution (Vc/F) 95 L (26.8%), clearance (CL/F) 31.1 L/h (25.0%), peripheral volume of distribution (Vp/F) 213 L (39.5%), inter-compartmental clearance (Q/F) 36.5 L/h (24.3%), and absorption rate constant (k) 16.4 h^-1 (42%). Individual subject PK parameter estimates were determined from the 2-compartment PK model (Table).

Conclusions: ViD status did not significantly influence the PK of MDZ in either HC or CKD subjects. There was a trend in CL/F being slower in CKD compared to HC regardless of phase, which may be due to decreased renal elimination or reduced ability to induce. Regardless of phase, which may be due to decreased renal elimination or reduced ability to induce CYP3A secondary to renal impairment. Future analyses will explore the ability to induce P450 enzymes and drug transporters activity, resulting in the change of pharmacokinetics. This study investigated the effect of age and renal function on activity of CYP3A and various drug transporters in healthy Thai elderly and CKD patients using a validated microdose probe substrate cocktail.

PO2363

Effect of Kidney Disease and Vitamin D Repletion on Drug Transporter Activity

Morgan A. Casal,1 Linda Prebheela, Raymond E. West,1 Nirav A. Shah,2 Michel Choncol,3 Melanie S. Joy,1,2 Thomas D. Nolin,1,2 University of Pittsburgh School of Pharmacy, Pittsburgh, PA; 2University of Colorado School of Medicine, Aurora, CO; 3University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO.

Background: CKD patients exhibit altered nonrenal drug clearance, which is reflected in numerous drug metabolism and transport pathways. Vitamin D (ViD) deficiency is common in CKD, and ViD-mediated regulation has been implicated in decreased renal and nonrenal transporters. This study aimed to elucidate the impact of ViD status (deficiency vs repletion) on drug transporter activity in CKD patients and healthy controls (HC).

Methods: ViD deficient (25(OH)D < 30 ng/mL) subjects with CKD stage I-III (n=15), CKD stage IV-V (n=8) and HC (n=9) were enrolled. The phenotypic probe drugs fexofenadine (FEX) and olmesartan (OLM) were used to assess P-glycoprotein (P-gp), organic anion transporter (OAT) and organic anion-transporting polypeptide (OATP) function, and endogenous N-methylhistamine (NMH) was used to assess multidrug and toxin extrusion proteins 1 and 2K (MATE1/2K) activity. FEX 60 mg and OLM 10 mg were orally administered at baseline (ViD deficiency) and after 12 weeks of oral therapy with ViD. 5000 IU daily and confirmed repletion (25(OH)D < 30 ng/mL). Serial blood and urine samples were collected for 48 hours. FEX, OLM, and NMH concentrations in plasma and urine were determined by LC/MS/MS and noncompartmental pharmacokinetic (PK) parameters were calculated.

Results: CKD IV-V subjects had 77% higher FEX systemic exposure (AUC 0-last of Gr3 1.22 and 1.90 folds, D 1.65 and 4.43 folds, P 0.99 and 1.57 folds, R 1.43 and 1.83 folds, M 2.19 and 2.68 folds, D 1.65 and 4.43 folds, P 0.99 and 1.57 folds, R 1.43 and 1.83 folds, and A 2.28 and 4.22 folds). AUC 0-last of Gr3 exhibited a doubling of AUC 0-12 (1.12 and 1.59 folds, P 1.22 and 1.90 folds, R 1.12 and 1.59 folds, and A 2.28 and 4.22 folds). AUC 0-12 of Gr3 was significantly increased when compared to Gr2 in D, P and A (2.69 (p<0.001), 1.59 (p<0.001) and 1.92 (p<0.001) folds, respectively). Cmax were significantly increased only in P and A (1.70 (p<0.001) and 1.94 (p<0.001) folds, respectively).

Conclusions: Independent of ageing, CKD itself further reduces the activity of drug transporters, suggesting that this information has to be taken into account when drugs that pass through these transporters are prescribed to CKD patients.

Funding: Government Support - Non-U.S.

A Single Time Point Plasma Concentration of Mycophenolic Acid Predicts Enteric-Coated Mycophenolate Sodium Exposure in Thai Renal Transplant Recipients

Napatsanan Tananithipuwarat,1,2 Pajaree Chariyavilaskul,1,2 Nattavudh Townamchai,1,2 Supecha Wittayalertpanya,1,2 Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University 'Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; 2Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University, Bangkok, Thailand.

**Background:** Enteric-coated mycophenolate sodium (EC-MPS) is a salt form of mycophenolate widely used in renal transplantation. The area under the concentration-time curve (AUC) of an active form of EC-MPS, mycophenolic acid (MPA) of ≥30 μg/mL is highly associated with drug efficacy. However, this technique is impractical in clinical setting. Little is known regarding metabolites’ AUC. This study determined the relationships of a single time point of plasma MPA level and time to optimum MPA exposure. The full profile of active (7-O-MPA-glucuronide; MPAG) and inactive (acyl mycophenolic acid glucuronide; AcMPAG) metabolites, both free and total form are also measured and related to its AUC.

**Methods:** Twenty renal transplant recipients with EC-MPS were studied. On day 3 post transplantation, plasma samples were collected at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 6, 8, 10, and 12 hours post dose. Total and free form levels of MPA and metabolites were measured using a fully validated LC-MS/MS. Receiver operating curve (ROC) was calculated for each metabolite.

**Results:** The AUC of the MPA total form moderately correlated with a single time point plasma MPA concentration at Cmax (r2 = 0.50) with the concentration cut of 2.5 μg/mL (sensitivity 87%, specificity 80%, area ROC = 0.83). The AUC of the MPA free form poorly correlated with a single time point concentration. The AUCs of total and free forms of MPAG and AcMPAG highly correlated with a single time point concentration of C8 (r2 = 0.97) and C9 (r2 = 0.95) for MPAG and C8 (r2 = 0.59) and C9 (r2 = 0.81) for AcMPAG. High variability in metabolites concentrations were observed, suggesting inter-individual variability in drug metabolizing enzyme activity.

**Conclusions:** At the early stage post transplantation, in renal transplant recipients who received EC-MPS, a single time point of the total form plasma MPA concentration is best monitored at 4 hours post dose. The MPA level of ≥2.5 μg/mL at that time point predicts optimum AUC. Further studies required for the use of metabolites’ AUCs to assess drug efficacy and to evaluate a single time point concentration that predicts drug exposure.

Preclinical Characterization of MAU868, a Novel Neutralizing Antibody Targeting BK Virus

Atul Sathe,1 Mark Knapp,2 Lihong Zhao,2 Peter Kim,2 Andreas Hein,4 Meike Scharenberg,4 Jacob Shaull,2 Kelly A. Wong,2 Steven J. Kovacs,1 Elisabetta Traggiai,1 Amy Patick,1 Johanna R. Abend.1 1Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; 2Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; 3Amplyx Pharmaceuticals, Inc. San Diego, CA; 4Novartis Institutes for BioMedical Research Basel, Basel, Switzerland.

**Background:** Reactivation of BK virus (BKV) can cause significant kidney and bladder disease in immunocompromised patients. There are currently no effective BKV-specific therapies. MAU868 is a novel human monoclonal IgG1 that binds to the BKV major capsid protein VP1. Its binding affinity, antiviral activity, and resistance profile were investigated in vitro.

**Methods:** Binding affinity was determined using a solution equilibrium titration assay. Neutralization of BKV infection in primary renal proximal tubule epithelial (RPTE) cells was evaluated by quantitating Tag-expressing cells using an immunofluorescence-based assay. The area under the concentration-time curve (AUC) of an active form of EC-MPS, mycophenolic acid (MPA) of ≥30 to 60 μg/mL, 34.3% of RTR achieved this range with 56.7% above this therapeutic exposure. There were 52.2% of RTR within the therapeutic tacrolimus AUC-12hr target of 120-200 ng.hr/ml with 46.1% below this range with no age relationship. Reduced tacrolimus CL/BMI was noted in elderly compared to middle age.

**Conclusions:** Tacrolimus and mycophenolic acid pharmacokinetics demonstrates age-related differences with lower clearances or exposures in the elderly. Tacrolimus and mycophenolic acid immunosuppression may require age-adjusted individualization to achieve therapeutic exposure.

Pharmacokinetic Evaluation of Drug Interactions Between Vadadustat and HM-CoA Reductase Inhibitors (Statins)

Ajit B. Chavan,1 Rishikesh Sawant,1 Leontia Burke,2 Susan K. Paulson.1 Akebia Therapeutics Inc, Cambridge, MA; 2AGTC, Cambridge, MA.

**Background:** Cardiovascular disease is the most common cause of mortality in patients with chronic kidney disease (CKD). Vadadustat is an oral hyposulinemic-factor (HIF) prolyl hydroxylase inhibitor (HIF-PHI) in late-stage development for the treatment of anemia due to CKD. The prevalence of dyslipidemia in CKD is very high, and nearly 50% of patients have been prescribed statins to decrease cholesterol levels. The disposition of most statins is dependent on metabolic enzymes and transporters. This study evaluated the drug interaction potential for statins when co-administered with vadadustat.

**Methods:** In this 3-part study (NCT03801733), 108 healthy adults were enrolled for vadadustat-statin pharmacokinetic (PK) evaluation. Vadadustat (600 mg daily) was administered concomitantly with either rosvastatin (20 mg; n=34), pravastatin (40 mg; n=34), simvastatin (40 mg; n=34), or statin-free (n=34). Changes in lipids were calculated from the PK parameters area under the curve (AUC) and maximum concentration (Cmax).

**Results:** Vadadustat was generally well tolerated by healthy subjects when taken alone or with statins. Exposure (AUC and Cmax) to rosuvastatin, a BCRP and OATP1B1 substrate, increased 2- to 3-fold in the presence of vadadustat. No change in exposure to pravastatin (an OATP1B1 substrate) was observed. The AUC for atorvastatin (a BCRP and OATP1B1 substrate) increased 1.4-fold, although no change in Cmax was noted; for simvastatin (a BCRP and OATP1B1 substrate), the AUC increased 2-fold and Cmax increased 1.6-fold in the presence of vadadustat.

**Conclusions:** There were no clinically significant interactions with pravastatin or atorvastatin, suggesting that vadadustat has a low likelihood for OATP1B1-mediated drug interactions. Increases in exposures to rosuvastatin and simvastatin are possibly due to BCRP inhibition. In summary, these results provide information to aid in the management of concomitant administration of vadadustat with statins. Funded by: Akebia Therapeutics, Inc.

Impact of Renal Impairment and Dialysis on the Pharmacokinetics and Pharmacodynamics of Roxadustat

Dorien Groenendaal-van de Meent,1 Virginie Kerbusch,2 Rugider Kaspera,1 Maria Barroso,1 Piergiorgio Galletti,1 Gernot Klein,1 Martin den Adel.1 Astellas Pharma Europe B.V, Leiden, Netherlands; 2PharmAspire, Wijchen, Netherlands; 3APEX GmbH, Munich, Germany.

**Background:** Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor for the treatment of CKD anemia. The objective was to evaluate the pharmacokinetics (PK), metabolic profile, pharmacodynamics, and safety of roxadustat in patients (pts) with varying degrees of renal function (RF).

**Methods:** In this phase 1, open-label study (EudraCT: 2015-002565-28), 16 pts were enrolled in one of four RF groups: normal (NRF; eGFR >90 mL/min/1.73 m2), mild (eGFR 60-89 mL/min/1.73 m2); moderate (eGFR 30-59 mL/min/1.73 m2) and severe (eGFR 15-29 mL/min/1.73 m2) RF. Following a 2-week run-in period with roxadustat, a single dose of 100-mg oral roxadustat on Day 1. Two treatment periods (P1/P2), separated by a washout period, were used for HD/HDF treatment periods (P1/P2), separated by a washout period, were used for HD/HDF

**Results:** AUC and Cmax increased 3.5- to 4.3-fold across RF groups (P1/P2), separated by a washout period, were used for HD/HDF
PO2372
Pharmacological Inhibition of Vanin 1 Is Not Protective in Models of Acute and Chronic Kidney Disease

Background: Dysregulated oxidative stress handling is a hallmark of acute and chronic kidney diseases. The panthetinase Vanin-1 is highly expressed in tubular cells and is regarded as a key player in producing oxidative stress by inhibiting the replenishment of cellular anti-oxidative glutathione stores. The aim of this study was to elucidate whether pharmacological inhibition of Vanin-1 protects mice from acute or chronic kidney injury.

Methods: C57Bl6 mice undergoing ischemia reperfusion injury and Col4α3−/− (Alport syndrome) mice were treated orally for 1d and 3wk, respectively, with a potent and selective Vanin-1 inhibitor or placebo. In vitro oxidative stress insult was mimicked in human renal proximal tubular epithelial cells either chemically or by hypoxia/reoxygenation Kidney function was determined by serum and urinary creatinine as well as serum urea and urinary albumin. Furthermore, mRNA and protein expression, Vanin-1 activity, oxidative stress level and tubular apoptosis were monitored.

Results: Oxidative stress levels were elevated in all models. Treatment with the Vanin-1 inhibitor resulted in ample systemic compound exposure and full inhibition of Vanin-1 activity in kidney tissue in vivo. However, this did not translate to a relevant reduction of oxidative stress level. Moreover, kidney function (serum Crea, blood urea, albuminuria), fibrosis marker gene expression and tubular cell apoptosis were not improved in Vanin-1 inhibited mice.

Conclusions: Pharmacological inhibition of Vanin-1 is insufficient to protect kidneys from oxidative stress insults contributing to acute and chronic kidney injury. The biological relevance of pharmacological Vanin-1 inhibition for the treatment of kidney diseases remains to be proven.

PO2373
Evaluation of Veverimer Drug Interaction Potential for pH-Dependent Drugs
David Down Parsell,1 Robert Gutendorf,2 Yick Sen Wu,1 Lillian Tsoa,1 Angela Tabakman,1 Yari Sitasiv,1 Angela A. Lee,1 Kalpesh N. Byani,1 Gerrit Klaerner.1 1Tricida, Inc., South San Francisco, CA; 2Aclairo Pharmaceutical Development Group, Vienna, VA; 3Unaffiliated, Burlingame, CA.

Background: Veverimer, an orally administered, non-absorbed polymer that selectively binds and removes hydrochloric acid (HCl) from the gastrointestinal tract, is negative charge, with small size as a secondary determinant. Veverimer did not bind to any of the anionic probes and a panel of 16 drugs were used to define characteristics required for binding. Test drugs covered a broad range of size, charge, solubility and permeability characteristics across 14 drug classes. The magnitude and duration of veverimer’s effect on gastric pH was determined in fed and fasting healthy subjects via 24-h monitoring with an intragastric pH probe. Results from binding and gastric pH studies informed selection of drugs for human DDI studies.

Results: In vitro studies showed the most important determinant for binding to veverimer is negative charge, with small size as a secondary determinant. Veverimer did not bind any positively charged, neutral or zwitterionic drugs. Negatively charged drugs with pH-dependent solubility (warfarin, dabigatran) were limited to effects on absorption of other oral drugs via (1) direct binding (2) increases in gastric pH resulting from HCl binding.

Methods: Features important for binding to veverimer were determined in vitro. A set of anionic probes and a panel of 16 drugs were used to define characteristics required for binding. Test drugs covered a broad range of size, charge, solubility and permeability characteristics across 14 drug classes. The magnitude and duration of veverimer’s effect on gastric pH was determined in fed and fasting healthy subjects via 24-h monitoring with an intragastric pH probe. Results from binding and gastric pH studies informed selection of drugs for human DDI studies.

Conclusions: We observed: 1) no effect of veverimer on the bioavailability of drugs most susceptible to binding to the polymer; 2) modest, transient effects of veverimer on gastric pH; 3) no effect on bioavailability of drugs with pH-sensitive solubility. We conclude that there is a negligible risk of clinically significant veverimer DDIs.

PO2374
Action of Veverimer on Gastrointestinal Acid Binding Is Not Affected by Omeprazole
Robert Gutendorf,1 Yuri Stasiv,1 Elizabeth Li,1 Gerrit Klaerner,1 Vândana S. Mathur,1 Tricida, Inc., South San Francisco, CA; 2Aclairo Pharmaceutical Development Group, Vienna, VA; 3PharmaStat LLC, Fremont, CA; 4MathurConsulting, Woodside, CA.

Background: Veverimer, an orally administered, non-absorbed polymer that selectively binds and removes hydrochloric acid (HCl) from the gastrointestinal tract, has been shown to correct metabolic acidosis in patients with CKD. Unlike proton pump inhibitors (PPIs), which do not affect systemic acid-base status, the removal of HCl decreases the overall systemic acid-base neutrality.

Methods: Pharmacological inhibition of Vanin 1 is not protective in models of acute and chronic kidney disease. The panthetinase Vanin-1 is highly expressed in tubular cells and is regarded as a key player in producing oxidative stress by inhibiting the replenishment of cellular anti-oxidative glutathione stores. The aim of this study was to elucidate whether pharmacological inhibition of Vanin-1 protects mice from acute or chronic kidney injury.

Results: Oxidative stress levels were elevated in all models. Treatment with the Vanin-1 inhibitor resulted in ample systemic compound exposure and full inhibition of Vanin-1 activity in kidney tissue in vivo. However, this did not translate to a relevant reduction of oxidative stress level. Moreover, kidney function (serum Crea, blood urea, albuminuria), fibrosis marker gene expression and tubular cell apoptosis were not improved in Vanin-1 inhibited mice.

Conclusions: Pharmacological inhibition of Vanin-1 is insufficient to protect kidneys from oxidative stress insults contributing to acute and chronic kidney injury. The biological relevance of pharmacological Vanin-1 inhibition for the treatment of kidney diseases remains to be proven.

A Genotype-Guided Antihypertensive Therapy and CKD Care Precision Health Initiative
Judith Maddatu, Ranjani N. Moothri, Katherine M. Speich, Nehal Sheth, Michael T. Eadin. Indiana University School of Medicine, Indianapolis, IN.

Background: A precision health initiative was implemented, wherein pharmacogenomic predictors of antihypertensive response and genomic predictors of chronic kidney disease (CKD) were provided to clinicians caring for nephropathy patients.

Methods: This is a prospective cohort study of 580 individuals who presented to outpatient nephrology clinics. Subjects were genotyped for 60 antihypertensive response variants, 9 chronic kidney disease (CKD) predictors. Predictors included variants of CYP2D6 for metoprolol dosing and CYP2C9 for angiotensin receptor blocker dosing. Variants in APO1, UMOD, and SHROOM3 were markers of CKD risk prediction. Subjects were followed to ascertain utilization of the genetic information by nephrologists.

Results: The cohort was 46% female and 43% African-American. Actionable variants were found in 85% of subjects. These variants are known to affect metabolism of a drug or contribute to CKD progression. The prevalence of actionable genotypes was 66% for CYP2D6, and 36% for CYP2C9. In African American subjects, 23% of CKD patients had at least one actionable CKD risk variant. Clinicians adapted treatment for 43% of individuals with actionable genotypes. The primary nephrologist was surveyed for each subject. In the 143 subjects who completed follow-up, nephrologists reported a change in diagnosis in 44% of their patients and a change in management in 28.0% based on genotype. Clinicians discussed the genetic testing results with their patients in 83.9% of cases.

Conclusions: Nephrologists utilized a genetic testing panel of up to 60 variants in the routine care of their CKD patients. Pharmacogenomics predicts of disease response may prove to be very valuable the care of patients with chronic kidney disease.

KBP-5074, a Nonsteroidal Mineralocorticoid Receptor Antagonist, Reduces Urinary Albumin-to-Creatinine Ratio and the Risk of Hyperkalemia in a Rat Model of Chronic Kidney Disease
Frederic Jaissier,1 Liu Jinrong,1 Shuangshuang Chi,1 Ping Wang,1 Judy Tan,1 Vincent Benn,1 Y. Fred Yang,1 Jay Zhang.1 KBP Biosciences USA Inc, Princeton, NJ; 2KBP Biosciences Co Ltd, Jinan, China; 3Centre de Recherche des Cordeliers, Paris, France.

Background: KBP-5074 is a novel non-steroidal mineralocorticoid receptor antagonist (MRA) being developed for uncontrolled hypertension and advanced chronic kidney disease. The primary objective of this study was to evaluate KBP-5074 and eplerenone for renal protection against aldosterone-mediated renal disease in a uninephrectomized Sprague-Dawley (SD) rat model.

Methods: Uninephrectomized rats were maintained on a 6% high salt diet, and received aldosterone infusion for 27 days. Urinary albumin to creatinine ratio (UACR), urinary Na+/K+ ratio and serum K+ were assessed following 14 and 27 days of treatment. Blood samples were collected on days 1 and 26 to determine PK profiles. PK/PD analyses were performed on urinary Na+/K+ ratio, UACR, and serum K+.

Results: KBP-5074 (1, 3, and 10 mg/kg/day) significantly reduced UACR by 77%, 96%, and 99% respectively on day 14, and 59%, 86% and 99% respectively on day 26 in a dose dependent manner, while eplerenone (100 and 900 mg/kg/day) reduced UACR by 40% and 99% respectively on day 26. PK/PD analysis of Urinary Na+/K+ ratio indicated that KBP-5074 was approximately 18-fold more efficacious than eplerenone. Analysis of UACR and serum K+ indicated that the EC50 for serum K+ increase and UACR reduction was 538 nM and 22.0 nM respectively for KBP-5074, and 666 nM and 1071 nM respectively for eplerenone, resulting in a therapeutic index (TI) against hyperkalemia of 24.24 for KBP-5074 vs 0.62 for eplerenone. Thus, the TI against hyperkalemia of KBP-5074 is 39-fold superior to eplerenone suggesting that the non-steroidal MRA, KBP-5074 may present an extended therapeutic window as compared to the steroidal MRA eplerenone.

Conclusions: KBP-5074 demonstrated a significant effect on UACR reduction with less risk for hyperkalemia compared to eplerenone in a rat model of nephropathy.

721
from the gastrointestinal tract by veverimer leads to a net increase in blood bicarbonate. Veverimer was designed to bind HCl across a wide range of intraluminal pH, but the effect of veverimer on acid binding in the presence of PPIs has not been previously described.

**Methods:** To evaluate the effect of veverimer on gastric pH, we conducted a Phase 1, open-label, 2-stage study in which subjects (N=46) were randomized 1:1:1:1 to receive 1 of 4 single oral drug treatments (water fasted; water fed; veverimer fasted; veverimer fed) in the presence and absence of a steady-state level of omeprazole. Gastric pH was measured continuously for 22 hours (hrs) using a microelectrode pH probe positioned in the gastric fundus.

**Results:** Ingestion of veverimer caused a modest, transient increase in gastric pH that peaked within 1 hr post-dose. In the absence and presence of food, the median (distribution-free 95% CI) times to peak pH after veverimer administration was 0.25 (0.17, 1.00) and 0.71 (0.25, 1.17) hrs, respectively. Peak pH after veverimer administration was ~3 and ~1.5 pH units greater than that observed after water control in the fasted and fed states, respectively. The magnitudes of these increases were in the same range in the presence of omeprazole. Gastric pH returned to baseline after ~1.5 hrs under fasting conditions and after ~3 hrs under fed conditions. In the presence of omeprazole, the veverimer-induced gastric pH increase dissipated by 4 hrs post-dose or shortly after initiation of the subsequent meal.

**Conclusions:** The effect of veverimer on gastric pH is transient and similar in the presence or absence of omeprazole. The magnitude of the individual effects of food, veverimer, and omeprazole on gastric pH were similar (increase of 2–4 pH units). These findings are consistent with prior studies in patients with CKD in which the magnitude of efficacy of veverimer was unaffected by use of H2-receptor antagonists and PPIs (Wesson et al. Lancet, 2019).

**PO2376**

**Circulating Heparin and Its Relevance to Thrombin Generation Profile in ESRD Patients Undergoing Maintenance Hemodialysis**

Fakhra Siddiqui, Emily Bontekoe, Debra Hoppensteadt, Walter Jeske, Vinod K. Bansal, Jawed Fareed. Loyola University Medical Center, Maywood, IL.

**Background:** End stage renal disease (ESRD) is a complex pathophysiologic syndrome which results in vascular disorders and hemostatic disturbance. Despite the use of heparin during maintenance hemodialysis some of these patients exhibit hypercoagulable state. The purpose of this study was to characterize the thrombin generation (TG) profile in ESRD patients in relation to circulating heparin levels.

**Methods:** Citrated blood samples from 95 patients with ESRD undergoing maintenance hemodialysis were collected. NHP was prepared for referencing purposes.

**Individual samples were supplemented with heparinase. TG parameters such as peak thrombin, lag time and area under the curve (AUC) were compiled. Circulating heparin levels were determined using activated partial thromboplastin time (aPTT) and chromogenic anti-Xa and H2 assays. The ESRD cohort was stratified into heparinized and heparin naïve groups.**

**Results:** ESRD group showed decrease in peak thrombin (107.1 ± 163.5 M) and AUC (589.8 ± 815.7 nM*min) with increase in lag time (2.9 ± 2.2 min) compared to NHP. Heparinase supplementation increase the lag time (3.4 min, p value <0.0001), while decrease the peak thrombin (100.0 nM, p value 0.0245) and AUC (503.4 nM*min, p value <0.0001). Such parameters as aPTT (43.2 ± 31.1 sec), anti Xa (0.21 ± 0.14 U/mL) and anti-IIa (0.27 ± 0.15 U/mL) decreased with heparinase treatment. Heparin naïve group showed decreased peak thrombin and AUC values whereas the lag time was increased. Simultaneously aPTT, anti-Xa and anti-IIa levels were decreased in this group. Heparinized patients did not show any difference in peak thrombin, decrease in AUC values and an increase in lag time. However, the aPTT, anti-Xa and anti-IIa were decreased in this group.

**Conclusions:** These studies showed that heparinase treatment of plasma samples from ESRD patients resulted in the decrease in aPTT, anti-Xa and IIa levels suggesting the digestion of heparin. However, contrary to these results, TG parameters such as peak thrombin and AUC were decreased whereas lag time was increased suggesting that the depolymerized heparin fragments possess thrombin generation inhibitory properties.

**PO2377**

**Clinically Apparent AKI Secondary to Suspected Vancomycin Toxicity: A Cellular Kinetic Analysis**

Ryan P. Flood, Matthew Ray, Judith Blaine, Anip Bansal. University of Colorado Denver School of Medicine, Aurora, CO.

**Background:** The use of antimicrobial therapies for treatment of hospitalized patients is abundant. While the usage rate of antibiotics has remained stable over the last decade, however, with the emergence of methicillin-resistant staphylococcus aureus, vancomycin usage has increased during that same time period. Although vancomycin induced AKI or vancomycin associated nephrotoxicity (VAN) has been a topic of debate since its generalized use approximately 50 years ago, the proposed mechanism of VAN is an on-going focus of research. The current study aims to answer whether proximal tubular creatinine secretion, which can account for upwards of 20% of creatinine clearance, is impacted by vancomycin dosing, and whether vancomycin trough levels seen in clinical practice alter this relationship.

**Methods:** For the cellular kinetic analysis, we took immortalized human proximal tubule epithelial cells, and after allowing them to epithelialize on a semi-permeable membrane, evaluated creatinine secretion in the presence of varying concentrations of both CRCL and vancomycin, while measuring eliminated levels for up to 24 hours. For the patient analysis, IRB approval was obtained to evaluate the cases of possible VAN on the renal consult service.

**Results:** Creatinine secretion through the cellular epithelium was not affected by vancomycin at levels up to 4X therapeutic, the upper limit of those seen on a cohort of patients in the renal consult service at the university of Colorado. This is consistent with other pharmacokinetic data, indicating that vancomycin is able to inhibit transporters of creatinine, but at levels not seen in clinical practice. The patient cohort analysis identified thirteen patients who were deemed to have “possible VAN,” and in all of these the rise in Cr did happen temporally related to vancomycin, and there were many other factors potentially confounding their AKI.

**Conclusions:** Proximal tubule dysfunction from vancomycin inhibition of cellular transporters does not cause a decrease in creatinine elevation in conditions used clinically. The cases of clinically apparent vancomycin associated nephrotoxicity are multifactorial. Therefore the nephrotoxicity associated with vancomycin administration does not seem to be the sole cause of creatinine elevation in patients with AKI.

**PO2378**

**Systemic Absorption of Vancomycin from Sternal Slurry Contributing to Vancomycin Nephrotoxicity**

David V. Li, Thomas A. Golper. Vanderbilt University, Nashville, TN.

**Introduction:** Vancomycin has come a long way since its start as “Mississippi mud”. It has been a valuable and safe agent in general. Adverse reactions include flushing and anaphylactic injury. Clinicians are developing strategies to circumvent these problems. One strategy is the use of antibiotic slurry/paste applied to infected tissue. This has
traditionally not been associated with systemic vancomycin toxicity. We report here an incidence of vancomycin nephrotoxicity secondary to a sternal venacavum slurry that required dialysis.

**Case Description:** A 62-year-old 91 kg man with Marfan’s Syndrome and total aortic arch replacement presented with mediastinal abscess and recurrent sternal osteomyelitis. The infecting agent was a vancomycin-resistant enterococcus and a trans-thoracic echo revealed a circumferential fluid collection around the aortic arch. He underwent a “redo” sternotomy, exploration and drainage. Plasma creatinine concentration (P_c) on admission was 0.76 mg/dL, his known baseline. He received one dose of 1250 mg IV vancomycin prior to the operation. Intra-operatively 4 grams of vancomycin paste was applied to his sternum. That evening he received cefepime 2g IV and vancomycin 1250 mg IV (see figure), both scheduled to be repeated every 12 hours. P_c and vancomycin troughs are detailed in the figure. On POD2 serum vancomycin trough was 42 mg/L. Intravenous vancomycin was undetectable and P_c was 6.45mg/dL.

He was emergently dialyzed. After 5 rounds of dialysis, serum vancomycin concentration lowered to 8 mg/L and P_c to 2.77 mg/dL. Urine output improved to 1200 mL/day. He was discharged on POD14 on daptomycin and ceftriaxone. On POD21 at follow-up, serum vancomycin was undetectable and P_c was 1.08 mg/dL.

**Discussion:** There can be substantial unaccounted systemic absorption from vancomycin paste. The POD 4 AM serum level was 48 mg/dL and he was dialyzed 14 hours later under operating conditions such that the level should be reduced by at least one-third. The post dialysis level was 47 mg/dL, so by conservative estimation his predialysis level was about 70 mg/L, suggesting that there was a substantial contribution of vancomycin to the serum level in that 17-hour interval from sternal slurry.

**PO2379**

**Efficacy of the Recommended Ceftazidime/Avibactam Dose in Treating Carbapenem-Resistant Enterobacteriaceae in Critically Ill Patients Using Renal Replacement Therapies**

**Case Description:** We report a case of a 53-year old 50kg woman admitted for surgery for a 5 cm left carotid endarterectomy. Her medical history included ESRD, DM, HTN, atrial fibrillation, and peripheral vascular disease. She was hemodialysis dependent and was on IHD 3 times weekly. Her baseline renal function was GFR 15 mL/min. She was recently diagnosed with a transesophageal echocardiogram showing a 1.5 cm thick atrial myxoma,amenable to surgical resection. She had a history of chronic kidney disease stage 5 and significant azotemia (BUN 33). Both the cases were found to be arousable and GCS of 12/15, intact strength & sensation of both extremities, no ataxia, dysarthria, hemineglect or signs of proctor drift. In both cases, Gabapentin toxicity was suspected and the dosage of Gabapentin was reduced to 100 mg orally at night. There was a drastic improvement of confusion and other symptoms within 2 to 3 days post dosage adjustment in both patients. **Discussion:** Renal insufficiency predisposes patients to increased risk of gabapentin induced toxicity due to reduced clearance. Advanced age and other comorbidities may further accelerate the risk. The range of Gabapentin toxicity across the spectrum of renal insufficiency. The first case was a 48-year-old female with a history of ESRD (HD X 3 times/week), HCV, DM, HTN and spinabps accessed with new onset seizure, body stiffening with head and eye deviation, confusion, fall and hypertensive emergency while awaiting for dialysis. She had a second seizure while in the ED and was started on anti-seizure medication Levetiracetam. Home medications included Gabapentin (800 mg TID). Head CT was unremarkable. The second case was a 69-year-old female patient with a history of DM, peripheral vascular disease, coronary artery disease & atrial fibrillation who presented with non-healing heel ulcer. Home medications included Gabapentin (300 mg 3 times daily). The patient developed contrast-induced AKI due to a CT angiogram procedure on admission. Following the development of AKI, the patient became confused without evidence of significant azotemia (BUN 33). Both the cases were found to be arousal and GCS of 12/15, intact strength & sensation of both extremities, no ataxia, dysarthria, hemineglect or signs of proctor drift. In both cases, Gabapentin toxicity was suspected and the dosage of Gabapentin was reduced to 100 mg orally at night. There was a drastic improvement of confusion and other symptoms within 2 to 3 days post dosage adjustment in both patients. **Conclusion:** Gabapentin toxicity is one of a number of first-line medications for the treatment of pain. It has multiple well-known side effects but less recognized is edema. We describe a case of Gabapentin induced edema, which was misdiagnosed as CHF exacerbation, resulting in significant diuretic use and stage 3 AKI.

**PO2381**

**Gabapentin Toxicity in Existing and Developing Renal Failure**

**Case Description:** Gabapentin is a medication used to treat partial onset seizures, neuropathic pain caused by diabetic neuropathy, postherpetic neuralgia, & central neuropathic pain. This medication is nearly completely excreted by the kidneys. It is recommended as one of a number of first-line medications for the treatment of pain. **Conclusion:** Here we report two cases of potential Gabapentin toxicity across the spectrum of renal insufficiency. The first case was a 48-year-old female with a history of ESRD (HD X 3 times/week), HCV, DM, HTN and spinal abscess presented with new onset seizure, body stiffening with head and eye deviation, confusion, fall and hypertensive emergency while awaiting for dialysis. She had a second seizure while in the ED and was started on anti-seizure medication Levetiracetam. Home medications included Gabapentin (800 mg TID). Head CT was unremarkable. The second case was a 69-year-old female patient with a history of DM, peripheral vascular disease, coronary artery disease & atrial fibrillation who presented with non-healing heel ulcer. Home medications included Gabapentin (300 mg 3 times daily). The patient developed contrast-induced AKI due to a CT angiogram procedure on admission. Following the development of AKI, the patient became confused without evidence of significant azotemia (BUN 33). Both the cases were found to be arousal and GCS of 12/15, intact strength & sensation of both extremities, no ataxia, dysarthria, hemineglect or signs of proctor drift. In both cases, Gabapentin toxicity was suspected and the dosage of Gabapentin was reduced to 100 mg orally at night. There was a drastic improvement of confusion and other symptoms within 2 to 3 days post dosage adjustment in both patients. **Conclusion:** Renal insufficiency predisposes patients to increased risk of gabapentin induced toxicity due to reduced clearance. Advanced age and other comorbidities may further accelerate the risk. The range of Gabapentin toxicity across the spectrum of renal insufficiency is underrecognized. In this case report, a patient with AKI only was confused and the patient with ESRD had myoclonus and seizure in addition to confusion. There seems to be a graded increase in toxicity with the corresponding deterioration of renal function. Heightened awareness about medication toxicity developing in renal failure is important to prevent significant adverse effects.

Case Description: An 85-year-old male with a past medical history of stage 4 chronic kidney disease secondary to diabetic nephropathy (baseline serum creatinine 2.2 mg/dL). Type 2 Diabetes Mellitus, diabetic neuropathy, and hypertension, presented to clinic for worsening of serum creatinine. Pertinent home medications included bumetanide 3 mg BID, metolazone 2.5 mg daily and gabapentin 600 mg TID. Bumetanide and metolazone were up titrated for worsening bilateral lower extremity edema over last 3 months with 20-pound weight gain. Exam was notable for 2+ LE edema. His serum creatinine progressively increased from 2.4 to 4 mg/dL in the setting of aggressive diuresis. A recent TTE showed only grade 1 diastolic dysfunction. The presumed diagnosis was heart failure with preserved ejection fraction. Urine sediment was bland. After identification of gabapentin as potential culprit agent for his edema, both gabapentin as well as his diuretics were discontinued with a resultant significant drop in his weight and serum creatinine to 218 lbs and 2.7 mg/dL respectively over next one month and complete resolution of his edema.

Discussion: Incidence of gabapentin induced edema varies from 2% to 8% and has been correlated to dosage. Exact mechanism is unknown but possibly related to loss of venoarteriolar reflex leading to increased capillary hydrostatic pressure and hence increased net capillary fluid filtration into the interstitium. Gabapentin induced edema, just like calcium channel blockers induced edema, is not associated with salt and water retention and hence diuretics are ineffective. Physicians, especially nephrologists, should be mindful of uncommon side effect of this commonly prescribed medication as distinguishing this early can prevent a lot of unnecessary work up and potentially prevent harm to the patient.

Gomerular Changes in Transplant Glomerulopathy
Samir Husami, Dina Hammad, Jeffrey H. Miner, Tarek Alhamad, Hani Sulaiman. Washington University in Saint Louis Department of Medicine, Saint Louis, MO.

Background: Transplant glomerulopathy (TG) affects 20% of transplanted kidneys 5 years post transplantation. It carries an important significance due to its correlation with decreased graft survival. Repeated endothelial cell injury by chronic active antibody mediated rejection (CAMR) leads to glomerular basement membrane (GBM) reduplication and thickening, the hallmark finding of TG. Based on our previous molecular mapping of the GBM, we aim to define the composition of the thickened GBM in TG using super-resolution microscopy.

Methods: Two super-resolution microscopy techniques, STORM (Stochastic optical reconstruction microscopy) and Airyscan, were used to image confirmed TG and control biopsies. For STORM, fresh frozen, 200 μm sections were imaged. While for Airyscan, 1-3 microns, formalin fixed paraffin embedded (FFPE) sections were used. Samples were labeled with antibodies for Laminin α5, Integrin α8, Myosin IIA, Vimentin, Synaptopodin, Integrin β1, Fibronectin, and several collagen IV chains.

Results: STORM TG samples showed increased distance between Integrin β1 labeled membranes, indicating thickening of the GBM. Collagen α1α1α2(IV) did not change, while Collagen α1α2(IV) was increased at the GBM's endothelial aspect. There was an increase in Fibronectin, suggesting a role for the TGFβ pathway. Airyscan TG images showed Vimentin- and Integrin αII-positive areas inside the GBM, indicating cellular protrusions extending into the GBM. Since these markers stain mesangial as well as endothelial cells, this suggests differentiation of endothelial cells and transition to mesenchymal cells. We detected alternating Myosin IIA and Synaptopodin labeling in the form of “Sarcomere-like structures”.

Conclusions: Our data revealed increased Collagen α1α2(IV) secreted from the endothelial side, while Collagen α1α2(IV) was unchanged at the GBM's endothelial aspect. We hypothesized that Csa compared to Tac exerts more pronounced toxic side effects at the cellular level, with endoplasmic reticulum (ER)-stress and maladaptive unfolded protein response (UPR) as the most prominent landmarks.

PO2385
Calcineurin Inhibitor Cyclosporine A but Not Tacrolimus Induces Proapoptotic Endoplasmic Reticulum Stress in Kidney Epithelial Cells
Duygu E. Yilmaz,1 Karin M. Kirschner,1 Hasan Demirci,1 Sebastian Bachmann,1 Kerim Mutig,2 1Charite Universitatsmedizin Berlin, Berlin, Germany; 1LM. Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation.

Background: Current immunosuppressive strategies in solid organ transplantation rely on the calcineurin inhibitors (CNI), cyclosporine A (CsA) or tacrolimus (Tac). Their nephrotoxicity is a major limitation for long-term usage. We hypothesized that CsA compared to Tac exerts more pronounced toxic side effects at the cellular level, with endoplasmic reticulum (ER)-stress and maladaptive unfolded protein response (UPR) as the most prominent landmarks.

Methods: To test this hypothesis we treated human embryonic kidney (HEK293) cells with CsA (10 μM) or Tac (10 μM) for 6h. The established ER stress-inducing agent, thapsigargin, served as positive control. To study the molecular mechanisms of CNI-induced cell toxicity we studied genetically-modified HEK293 cells lacking the crucial UPR elements, PERK or ATF6. Abundances of the ER-stress sensor IRE1α, adaptive transcription factor XBP1, and proapoptotic transcription factor CHOP were evaluated as endpoints.

Results: Treatment of native HEK293 cells with CsA or Tac equally increased phosphorylation of the known calcineurin substrate, NFAT, verifying the treatment protocols. CsA increased levels of activating IRE1α phosphorylation (pIRE1α) and spliced XBP1 (sXBP1) products. In contrast, Tac enhanced ER stress-induced, thapsigargin, served as positive control. To study the molecular mechanisms of CNI-induced cell toxicity we studied genetically-modified HEK293 cells lacking the crucial UPR elements, PERK or ATF6. Abundances of the ER-stress sensor IRE1α, adaptive transcription factor XBP1, and proapoptotic transcription factor CHOP were evaluated as endpoints.

Conclusions: In summary, CsA but not Tac significantly increased the number of cleaved caspase 3-positive cells suggesting enhanced apoptosis rate. Treatment with the chemical chaperone, TUDCA, partially abolished the CsA-induced increases of CHOP but did not affect sXBP1, suggesting alleviation of ER-stress. Knockdown of CsA binding partners, cyclophilin A and B, by siRNA reduced their expression approximately by half and increased CHOP expression suggesting that suppression of cyclophilins may contribute to CsA-induced cellular toxicity. PERK- or ATF6 deficiency blunted the increases of CHOP and sXBP1 in response to CsA, suggesting an implication of these pathways in CsA-induced ER-stress and UPR.

Methods: Kidneys from MyD88 knock-out (KO) or MyD88 and Trif double knock-out (DKO) mice were harvested and stored in a cold preservation solution (UW) for 4 hours, and then transplanted into bi-nephrectomized syngeneic or allogeneic recipients. Graft survival, renal function, histology change, phenotype analysis, and expression of involved genes, were observed and/or determined. Primary RTECs isolated from B6 and BALB/c mouse kidneys were stimulated by lipopolysaccharide (LPS) and cytokines in supernatant were collected.

Results: C57BL/6 (B6) kidneys were more susceptible to IR injury following syngeneic transplant compared to BALB/c kidneys. Genetic ablation of MyD88 in B6 donors, but not BALB/c donors significantly reduced creatinine levels at post operation day (POD) 1-2, compared with wild-type (WT) kidneys. Moreover, compared with recipients of WT kidneys at POD 1-2, recipients of MyD88/Trif DKO kidney allografts showed improved graft function that was consistent with improved tissue integrity. Strikingly, MyD88/Trif DKO donor induced indefinite renal allograft survival and preserved intact renal allograft architecture at POD 100. In vitro study showed that levels of cytokines were increased by both B6 and BALB/c RTECs upon LPS (TLR4 agonist) stimulation, but BALB/c RTECs produced significantly higher levels of cytokines (including TNFα, IL-6, and IL-10) in a dose-dependent manner. Expression of Ki-1, a known biomarker for renal allograft rejection, were significantly increased by B6 RTECs co-cultured with that in BALB/c RTECs. These results suggest that kidney-intrinsic innate immunity, especially the TLR/MyD88 pathway, plays a critical role in the susceptibility to transplant IRI and DGF.

Conclusions: Kidney-intrinsic TLR/MyD88 signaling regulates the susceptibility of delayed graft function following kidney transplantation.

Immunosuppression by Cyclosporine A Affects Proximal Tubular Homeostasis via Endoplasmic Reticulum Stress

Suncica Popović," 1 Junda Hu,1,2 Hasan Demirci,1,2 Duygu E. Yilmaz,1 Carsten Dittmer,1,2 Yan Xu," 3 Martin N. Thomson,1 Kerim Mutig,1,2 Sebastian Bachmann,1,4 Charite Universitätsmedizin Berlin, Berlin, Germany; 3Pervuy Moskovsky gosudarstvennyj medicinskij universitet imeni I M Sechenova, Moskva, Russian Federation.

Results: Rats with CsA displayed a stimulated RAS and increased distal NaCl transporter activity along with decreased urine volume, GFR, FE, and COX-2 expression. Pathological changes in vasculature and glomeruli were inconspicuous, whereas early proximal tubular segments (S1, S2) revealed large lysosomal vacuoles with granular content, their abundance correlating with epithelial dedifferentiation, basement membrane thickening, and subepithelial collagen I accumulation. Protein endocytosis was diminished. Changes in UPR included enhanced pERF2α, pPERK, CHOP, and Bip levels. Parallel studies in cultured cells indicated sensitivity to chemical chaperones ameliorating proteostasis.

Conclusions: These results suggest a so far unrecognized role of proximal tubular homeostasis in long term CsA-induced nephropathy. Addressing UPR failure and restitution of proteostasis in proximal tubule may, therefore, have renoprotective potential.

Fibroblast culture from CABMR patients were cultured to purity and to mimic this condition fibroblasts were pre stimulated with IL-6 (20ng/ml), IL-17 (50ng/ml), IL-6 plus IL-17 for 24 hrs and culture supernatent were collected for IL-6 ELISA to see synergistic activation. Serum IL-6 levels of CABMR and Non-CABMR patients were measured by ELISA. mRNA expression of pro-fibrotic genes; COL1A1, FN1, ASMA1, and anti-fibrotic gene; MMP2/TIMP was analyzed by real-time PCR. Student’s t-test was used for statistical analysis in SPSS 17 software.

**Results:** IL-6 in sera of CABMR patients was significantly higher (p<0.001) than non-rejection patients. In comparison to IL-6 and IL-17 alone these cytokines synergistically induced IL-6 production from renal fibroblasts(Fig 1). Together IL-6+IL-17 significantly increased the expression of COL1A1, ASMA1, Fibronectin and CCL2(MCP1) and reduced expression of MMP2 gene against GAPDH gene compared to alone IL-6, IL-17 and untreated fibroblasts.

**Conclusions:** CBMR is perpetuated by inflammation amplifier or synergistic induction of IL-6 and IL-17 which results in chronic inflammation and Allograft rejection. Anti-IL-6 may attenuate the CABMR related injury.

B-Cell Maturation Phenotypes and Time Post-Transplant

Alcino Gama, Olivier Despy, Stephanie Beland, François Bouchard-Boivin, Sacha A. De Serres. CHU de Québec-Université Laval, Quebec, QC, Canada.

**Background:** Over the past decade, B cell participation in allograft response has been progressively elucidated. Beside the occurrence of DSA (donor-specific alloantibodies), different patterns of B cell phenotypes are also being related to graft outcome. Loss of naive B cells and appearance of memory B cells have been linked to chronic rejection and ultimately to graft loss. Here we show the impact of time post-transplant on phenotypic B cell changes, particularly regarding different distributions of naive B cells.

**Methods:** Single-center, observational cohort of 82 kidney transplant recipients (KT), adults and clinically stable. Blood samples were collected between January 2015 and November 2018. Peripheral blood mononuclear cells (PBMCs) were isolated and analyzed on flow cytometry. B cells (CD19+) were stained for CD38 and IgD and classified according to Bm classification (IgD+ vs CD38-).

**Results:** The median time post-transplant was 2.9 [0.9-9.89] years and the mean age was 54.13 years. 83% of the patients were males and mean eGFR was 49±17 ml/min. B cells absolute counts were lower in latter phases post-transplant (R -0.4, p<0.01). Among all B cell subtypes, Bm2 compartment (comprised mainly by naive B cells) had the most significant reduction in both absolute counts (R -0.62, p<0.01) and relative percentage (R -0.58, p<0.01) over time. On the opposite, mature B cells (both Bm5 and early Bm5 compartments) absolute counts did not differ over time (R -0.04 and 1.11 respectively, p>0.05) whereas the percentages of them were positively correlated with time post-transplant (R 0.40 and 0.56 respectively, p<0.01). Linear regression model showed that the absolute reduction in Bm2 cell compartment (i.e. naive B cells) was independent of age, sex, graft function and immunosuppression scheme.

**Conclusions:** Patients with longer time post-transplant have fewer circulating peripheral B cells. Phenotypic analysis of B cell subsets reveals that this reduction is due to an absolute decrease in naive B cells counts. Mature B cell absolute numbers, on the other hand, did not change significantly. Either exhaustion due to long-term immunosuppression or immunologic accommodation due to chronic allograft exposure could explain these observations.

PO2392

Donor Derived Cell-Free DNA in Renal Transplants, AlloSure vs. Prospera

Ali Khalil,1 Salman Khan,1 Erika Kalu,1 Muhammad Saim,1 Mark J. Lerman.1 Medical City Dallas Kidney Transplant, Medical City Dallas Hospital, Dallas, TX;2Dallas Nephrology Associates, Dallas, TX.

**Background:** The risk for allograft loss remains high due to rejection. Measuring donor cell free DNA has recently become an important noninvasive test for renal allograft injury and rejection. Two of the commercially available tests to measure dd-cfDNA, are Allosure(AS) and Prospera.

**Methods:** We measured dd-cfDNA in 44 post kidney transplants simultaneously using both tests. Patients were 3 to 50 months post kidney transplant and all samples were drawn for cause. Eleven of the 44 patients had allograft biopsies, see table. All patients had routine labs including trough CNI levels and in some cases DSA and/or BK PCR.

**Results:** 44 patients had side by side dd cf-DNA done using AS and Prospera for cause. There were 5 patients with either ACR 1a or 1b or AMR on biopsy. 6 patients had no rejection on biopsy. Please see image for statistical analysis.

**Conclusions:** There was no statistical difference between dd-cfDNA as measured by both commercial tests in all 44 patients, including 5 with ACR or AMR and 6 without rejection by biopsy. We acknowledge the number of patients who underwent biopsies were small. Prospera demonstrated larger measurements of dd-cfDNA in comparison to AS, but this was not statistically significant p>0.27. Side by side analysis showed AS had marginally better AUC but no significant differences between diagnostic test characteristics observed. AS had better specificity, PPV, and NPV, but this did not reach statistical significance.
Results: Of 208 biopsies done at a median of 5.8 months post-transplant, 108(52%) were done for allograft dysfunction; 74(36%) for surveillance (due to DSA) and 26(12%) for post-rejection treatment surveillance. There were significant discrepancies between Hx and MMDx; with MMDx(92; 44%) identifying a higher number of rejection cases vs Hx(79; 38%). While MMDx identified a higher number of antibody-mediated rejection cases(65; 31%) than Hx(43; 21%); the opposite was true for T-cell mediated rejection(TCMR; Hx:27(13%) vs MMDx: 13(6%)). AUC Curves for ccfDNA concentration and prediction of rejection were more robustly correlated with MMDx(AUC=0.830; p<0.001) than with Hx(AUC=0.75; p<0.001). The median ccfDNA level increased significantly for rejection treatment(median 0.94 to 0.29; p=0.015) vs non-responders(0.76 to 0.82; p=0.25)

Conclusions: In this single-center study, for the first time we describe the calibration of ddcfDNA with simultaneous assessment of kidney transplant biopsy with traditional histology and MMDx. We confirmed and expanded on the data from the DART study where a cut-off of 1% was highly sensitive and specific for ruling-in rejection. We report the correlation of ccfDNA with response to rejection therapy. We propose that the combination of tissue gene expression using the molecular microscope and blood-based ddcfDNA may add precision to traditional histology and could change future practice and treatment paradigms

PO2396
Elevated Donor-Derived Cell-Free DNA (dd-cfDNA) Attributed to Anti-Class II Type I Receptor Antibodies (ATIR-Ab) in Renal Re-Transplantation
Howard H. Coke,1 Matthew Van Norman,1 Aksha P.2 Aleksandra De Golovine,2 Angelina Edwards,2 University of Texas McGovern Medical School, University of Texas John P and Katherine G McGovern Medical School, Houston, TX;1 Memorial Hermann Texas Medical Center, Houston, TX.

Introduction: Complications of renal transplants include graft rejection and failure. Noninvasive ddcfDNA values greater than 1% detect renal allograft injury and rejection, prior to changes in creatinine. Although antibody-mediated rejection (AMR) typically involves donor specific antibodies (DSAs) to human leukocyte antigens (HLA), non-HLA antibodies may also impact allograft outcomes. This series of re-transplantation patients with graft injury from ATIR-Ab (<10 U/mL) shows improvement in ddcfDNA levels with initiation of an ARB, Losartan.

Case Description: Case #1: 23-year-old man with history of CKD IV due to hypoplastic kidneys. First transplant living unrelated donor failed due to renal vein thrombosis. Received a 2nd deceased donor transplant (DDRT) with thymoglobulin induction. Antibody assessment showed negative DSA but positive ATIR-Ab at 16 U/mL. Post-transplant allograft function was excellent with nadir creatinine of 0.8 mg/dL. Non-invasive allograft surveillance was initiated with initial ddcfDNA (ALLOSURE, CareDx, Brisbane, CA) elevated at 1.8%. Antibody assessment was negative for DSA but positive for ATIR-Ab at 28 U/mL. Losartan was initiated with a sustained decrease in ddcfDNA to <0.3% and stable creatinine levels. Case #2: 63-year-old woman with ESRD from hypertension. Prior living donor transplant failed due to chronic allograft nephropathy. Received 2nd DDRT with thymoglobulin induction given cPRA of 98%, with no DSA. Post-transplant allograft function was excellent with nadir creatinine of 0.8 mg/dL. Non-invasive allograft surveillance showed an acute rise in ddcfDNA to 3.9% on post-operative week 5. Despite stable creatinine, a renal biopsy showed C4d-negative, mild antibody mediated rejection with peritubular capillaritis (ptc 2) and glomerulitis (g1). Antibody assessment showed no DSA but positive ATIR at 16 U/mL. Following Losartan initiation, ddcfDNA decreased to <1%, with continued excellent graft function.

Discussion: ATIR-Ab may be more prevalent in the re-transplant population and is a causative factor for accelerated allograft injury, chronic fibrosis, and graft loss. Early detection of kidney injury via ddcfDNA, prompt assessment of ATIR-Ab, and initiation of ARB therapy may lead to preserved allograft function, particularly in high immunologic risk patients.

Donor-Derived Cell-Free DNA Identifies Patients with Antibody-Mediated Rejection and Strongly Correlates Histologically with Microvascular Inflammation

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
PO2400
Impact of Body Mass Index on Baseline Donor-Derived Cell-Free DNA in Kidney Transplant Recipients

Background: Donor derived cell free DNA (dd-cfDNA) is useful in predicting acute rejection in renal allografts. The technology uses next generation sequencing and does not require donor genotyping. dd-cfDNA is expressed as a percentage of the total (including self and non-self) circulating DNA fragments. Since self-portion of cell free DNA can vary according to body size, we aimed to test the hypothesis that expressed percent of baseline dd-cfDNA can vary by the recipient’s body mass index (BMI).

Methods: Our center has been doing for cause as well as surveillance (for high immunologic risk) dd-cfDNA in kidney transplant recipients (KTRs) using AlloSure (CareDx, Brisbane, CA). We identified patients who underwent kidney transplantation between September 2017 and June 2019 and had serial dd-cfDNA levels. A dd-cfDNA value ≥1% prompted allograft biopsy. KTR with biopsy evidence for rejection or other injuries were excluded from the analysis. Study subjects were divided into BMI (kg/m²) groups as follows: <25, 25-29.9, ≥30. Baseline dd-cfDNA values were compared between BMI groups.

Results: There were 88 (81 first-time and 7 repeat) KTRs during the study period who had dd-cfDNA measurements and available BMI. We excluded 16 first-time and 3 repeat KTRs from the analysis due to biopsy evidence of rejection. The remaining 69 patients had 227 dd-cfDNA levels available for analysis. Patients were divided based on BMI categories with stratification of baseline dd-cfDNA values as shown in table 1. There were no significant differences in baseline dd-cfDNA values for BMI groups <25 vs. 25-29.9 (0.63 ± 0.63% vs. 0.41 ± 0.27%, p=0.16) and BMI groups 25-29.9 vs. ≥30 (0.41 ± 0.27% vs. 0.33 ± 0.16%, p=0.22). However, there was a trend towards significantly higher baseline dd-cfDNA values in BMI group <25 vs. ≥30 (0.63 ± 0.63% vs. 0.33 ± 0.16%, p=0.06).

Conclusions: Our study showed a trend towards significant differences in dd-cfDNA values between extremes of BMI groups. These differences could become significant with larger study subjects. Our findings point towards the need for normalization of dd-cfDNA values with respect to body size for reporting purposes.

Protocol-Based Donor-Derived Cell-Free DNA Surveillance in Kidney Transplant Recipients: A Single-Center Experience
Pichpouch Naisaisorarakorn, Het Patel, Martha Pavlakis, Amitul Aala, Nikiil Agrawal. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Kidney biopsy is invasive and has limited utility when used as a surveillance test post-transplant. Donor-derived cell-free DNA (dd-cfDNA) surveillance testing has never been studied in comparison with other routinely performed surveillance tests.

Methods: Our transplant center implemented the dd-cfDNA (AlloSure) surveillance protocol (1,2,3,4,6 months and then quarterly post-op) in kidney transplant recipients starting July 2018, in addition to our existing protocol measurements of serum Cr, proteinuria and DSA. We retrospectively reviewed all kidney allograft recipients transplanted between July 2018- April 2020. Data collection was done at measurement of dd-cfDNA surveillance and included: dd-cfDNA (positive if ≥1% dd-cfDNA), elevated Cr (≥0.3 mg/dL from baseline), proteinuria (≥0.3 mg/dL from baseline), DSA (if available).

Results: 366 screening dd-cfDNA test results were reviewed from 84 patients. There were 123/366 positive dd-cfDNA tests in 8/84 patients. 5 of the 8 patients underwent a kidney biopsy which showed: 4 rejections (2 humoral, 2 cellular) (for 1 patient who had cellular rejection, dd-cfDNA test was the only surveillance test that was positive) and 1 ATN (dd-cfDNA test was borderline positive at 1.0%). The 3 remaining patients did not undergo a biopsy and repeat dd-cfDNA testing improved without intervention. In the 353/366 negative dd-cfDNA tests in 76 patients: 8 patients underwent a biopsy: 2 patients who had increased Cr showed borderline acute cellular rejection, 3 had recurrent disease (MPGN, DM, IgAN) and 3 showed ATN/Vascular disease/IFTA. In the 2 patients with borderline acute cellular rejection dd-cfDNA was <0.7%.

Conclusions: We found that the addition of surveillance dd-cfDNA testing to current surveillance testing algorithm was able to identify rejection in 1 patient, when others surveillance tests were negative. A negative result may obviate the need for biopsy, including protocol biopsies in centers who perform them.

PO2402
Successful Transplantation Outcomes Using Deceased Donors with AKI
Amy L. Harshman, Luke Preiszewski, Meghan Muldoon, Giselle Guerra. Miami Transplant Institute, Miami, FL.

Background: Kidneys from deceased donors with acute kidney injury (AKI) are discarded at a higher rate than those without AKI, exacerbating the organ shortage. This paper reviews outcomes of kidneys from deceased donors with AKI over a four-year period at a single transplant center.

Methods: We analyzed 1119 consecutive deceased donor kidney adult recipients transplanted from 2016 through 2019 at our center. Donors were classified using AKIN criteria for AKI based on increase of terminal serum creatinine (Scr) over initial Scr. Death-censored graft survival and eGFR (MDRD) were compared.

Results: 911 recipients received kidneys from donors with no AKI (Stage 0). 208 (18.6%) received kidneys from donors with AKI: 45 (4.02%) had Stage 1 AKI, 59 (5.27%) had Stage 2 AKI, and 104 (9.29%) had Stage 3 AKI. There were no significant differences between the AKI and non-AKI groups in recipient age, gender, ethnicity, or Estimated Post-Transplant Survival score. Using a Cox Proportional Hazards Model, death-censored graft survival at 1 year was not distinguishable between recipients whose donor had any stage of AKI versus donors without AKI (HR 1.09, p=0.854) nor among AKI stages (Figure 1). Mean eGFR by MDRD formula for recipients alive and with followup at 1 year was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors, which was of no statistical significance (p=0.4384). The rate of delayed graft dysfunction was significantly higher in recipients from AKI donors (62.0%) versus non-AKI donors (31.5%), (p<0.0001).

Conclusions: Recipients of AKI donors did not yield inferior outcomes to those of non-AKI donors at 1 year. Increased DGF can be anticipated, but does not appear to have any lasting impact on graft survival or renal function. As such, transplant centers should consider expanding the use of these kidneys for any waitlisted candidate.

PO2403
Combined Impact of Presensitization and Delayed Graft Function on Allograft Outcome in Deceased Donor Kidney Transplantation: Nationwide Cohort Study
Byung ha Chung,1 Haubi Lee,1 Yohan Park,1 Tae Hyun Ban,2 Sang Heon Song,2 Jaeceok Yang,1 Curie Ahn,1 Chul Woo Yang.1 Korean Organ Transplantation Registry Study group; 1Seoul Saint Mary’s Hospital, Seocho-gu, Seoul, Republic of Korea; 2Eunpyeong St. Mary’s Hospital, Seoul, Republic of Korea; 3Pusan National University Hospital, Busan, Republic of Korea; 4Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

Background: Pre-sensitization to HLA has detrimental effect on allograft rejection, worse allograft function and survival. Delayed graft function (DGF) is associated with poor allograft outcome by ischemia-reperfusion injury. We undertook analysis to determine combined association of pre-sensitization to HLA and DGF on allograft outcome in deceased donor kidney transplantation (DDKT) and whether there is a synergistic effect.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

729
Methods: In our prospective cohort study, between May 2014 and June 2019, 137 patients with deceased donor kidney transplants were assigned into 2 groups: pre-sensitized and non-pre-sensitized. Each group was divided into 2 subgroups according to DGF. Pre-sensitization was defined as the presence of donor specific antibodies (DSA) or the presence of panel-reactive antibody (PRA), combination with crossmatch positive. DGF was defined as the need for dialysis before discharge. We compared the clinical outcomes including allograft rejection, the change of allograft function, infectious and cardiovascular complication and allograft survival.

Results: Pre-sensitization group were 137 (10.0%) patients and others (n=1233, 90.0%) were assigned to non-pre-sensitized group. Pre-sensitization-non-DGF subgroup was 21 (15.3%) and pre-sensitization-non-DGF group was 116 (84.7%). Pre-sensitization-DGF subgroup was 133 (9.7%) and non-pre-sensitization-non-DGF group was 1100 (80.3%). In both pre-sensitization and non-pre-sensitization groups, allograft function using eGFR by CKD-EPI equation (mL/min/1.73m²) was lower in DGF subgroup than non-DGF subgroup. In contrast, allograft rejection rate showed no significant difference between DGF and non-DGF subgroup within non-pre-sensitization group (15.0% vs 12.9%, p<0.493). There was no significant difference between DGF and non-DGF subgroups in both groups in regard to allograft survival and patient survival.

Conclusions: DGF combined with pre-sensitization had much worse effect on allograft outcome in terms of allograft rejection. Therefore, we suggest more careful monitoring or surveillance for allograft rejection when DGF occurred in DDKT with pre-sensitization to HLA.

PO2404
The Clinical Significance of Preformed C1q-Binding Donor-Specific HLA Antibodies in Kidney Transplantation
Sun Lee,1 Byung Ha Chung,2 Chul Woo Yang,2 Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Catholic University of Korea, Seoul, Republic of Korea.

Background: The anti-human leukocyte antigen (HLA) antibodies are well known for risk factor of rejection or allograft loss in kidney transplantation (KT). De novo complement component 1q-binding donor-specific anti-HLA antibodies (C1q-binding DSAs) are already reported to be associated with an increased risk of acute allograft rejection in KT. This study investigated the clinical significance of identification of preformed C1q-binding DSAs for predicting graft outcomes in KT.

Methods: From December 2016 to December 2018, 323 recipients underwent KT at Seoul St. Mary’s Hospital. If the results of panel reactive antibodies (PRA) were positive in the pre-transplant examination, DSAs and C1q-binding DSAs were performed using Luminex Single Antigen Bead Assay (SAB) at the same time. Graft outcomes in terms of Chronic Kidney Disease-Epidemiology Collaboration estimated Glomerular Filtration Rate, biopsy proven acute rejection and graft survival were compared between recipients with preformed C1q-binding DSAs and recipients without preformed C1q-binding DSAs.

Results: Eighty-two of 323 recipients (25.4%) were evaluated DSAs and C1q-binding DSAs before transplantation. Among them, 40 recipients (48.8%) had preformed DSAs and 8 recipients (9.9%) had preformed C1q-binding DSAs. The higher MFI values of DSAs had higher prevalence of C1q-binding DSAs (9263.9 ± 3670.3 vs. 5955.3 ± 5245.5; p = 0.050). There was a strong correlation between the presence of DSAs against Class II and C1q-binding DSAs (p = 0.007; CI 95% OR 9.333). Five of 21 patients (23.8%) with positive at least one of complement-dependent cytotoxicity (CDC) or flow cytometry crossmatch (FCXM) had preformed C1q-binding DSAs. There was a significant difference between positivity of crossmatch and preformed C1q-binding DSAs (p = 0.024; CI 95%, OR 6.042). Four of 8 recipients (50%) in C1q-binding DSAs(+) group were confirmed acute antibody mediated rejection. C1q-binding DSAs(+) group had higher incidence of acute antibody mediated rejection than C1q-binding DSAs(-) group (p=0.048; CI 95%, OR 4.286).

Conclusions: The identification of preformed C1q-binding DSAs may be important in predicting acute antibody mediated rejection. Therefore, the surveillance such as protocol allograft biopsy is required for early detection of acute antibody mediated rejection after transplantation in patients with preformed C1q-binding DSAs.

PO2405
Potential Combined Use of Kidney Donor Profile Index (KDPI) and Estimated Post-Transplant Survival (EPTS) Scales to Predict eGFR Decline in Deceased Donor Kidney
Pablo Magrini,1 Sergio Hernandez-Estrada,1 Odette Del Carmen Diaz Avendano,1 Christian P. Flores,2 Benjamin Gomez-Navarro,3 Maria Guadalupe R. Ramirez,1 Jose H. Cano,1 Maria Concepcion Oseguera-Vizcaino,1 Daniel F. Ovando-Morga,1 Mayra M. Matias Carmona,1 Renal Transplant Unit, National Medical Center “20 de Noviembre”, Mexico City, Mexico; Renal Transplant Unit, Hospital Civil de Guadalajara Fray Antonio Alcalá, Guadalajara, Mexico; 3Centro Medico Nacional de Occidente, Guadalajara, Mexico.

Background: The use of the sum of EPTS and KDPI scales to predict the decline of eGFR in patients who received a deceased donor transplant. Assess the reproducibility of the Organ Assignment System of the USA in our country.

Methods: 128 deceased-donor kidney transplant recipients at two National Mexican Hospitals between 2015 – 2017, retrospective, observational cohort study over 36 months following transplant. We include age, gender, primary renal disease, sensitization events, peak panel-reactive antibody, cold ischemia time, dialysis type and vintage, KDPI and EPTS, DGF, PTDM, Acute rejection, eGFR and cause of graft failure P. outcome: Relationship between a decrease >30% eGFR and the different combined scores of the KDPI and EPTS scales.

Results: The sum of the scores of the EPTS and KDPI scales >81% had a sens. 76% and a spec. 84% to predict a >30% decline in eGFR. AUC 80.8% [95% [CI] 0.022 to 0.005; p < 0.001). Multivariable Cox proportional hazard model: the sum of EPTS and KDPI scores >81% was associated with a 9.9-fold increase in losing more than 30% eGFR over the 36-months follow-up ([adjHR] 9.9; 95% [CI] 1.85 to 53.6, p = 0.007). Acute rejection was associated with a 3.1-fold increase in losing more than 30% eGFR ([adjHR] 3.1; 95% [CI] 1.15 to 8.72, p = 0.02).

Conclusions: Observing the donor and the recipient as a sum can be a new tool that helps us to predict the decline eGFR in Deceased Donor Kidneys transplants.

PO2406
Vasopressin Use After Deceased Donor Kidney Transplant (DDKT): Patient Characteristics, Graft Function, and Clinical Outcomes
Muhammad Y. Jan, William Goggins, Muhammad S. Yaqub, Tim E. Taber, Dennis P. Mishler, Sharon M. Moe, Ranjani N. Moothri, Michael T. Eadon, Jeanne Chen, Asif A. Sharifuddin. Indiana University School of Medicine, Indianapolis, IN.

Background: Vasopressin (AVP) is used for maintenance of volume status and hemodynamics due to its vasopressor activity with less arrhythmogenic and ischemic potential. It has catecholamine sparing effect. AVP has been shown to improve rates of deceased organ donation. We studied AVP use post DDKT for improving hemodynamics with resultant effect on graft function and clinical course.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

730
Methods: A retrospective chart review was done on patients ≥18 years of age who required AVP post operatively after a DDKT over 5 years (2012-2017). Recipient, donor characteristics, intraoperative parameters, hospital/ICU stay, graft failure, patient survival, and hyponatremia during first 48 hours were reviewed.

Results: A total of 43 patients fulfilled inclusion criteria. Refer to Table for summary. Total of 5 patients (11.6%) required dialysis, 3 of whom received donation of kidney after cardiac death. There were 3 deaths during the first 12 months (6.9%). Mean cold and warm ischemia time were 32.5±12.9 hours and 39.2±10.2 minutes, respectively. Mean time to start AVP was 6.8 hours postoperatively and mean duration of AVP use was 43.2 days with a median of 30 hours. 72.1% of patient also required dopamine. Mean hospital stay was 14.5 days and length of ICU stay was 5.4 days. Mean creatinine at day 7 was 4.0 ± 4.2 mg/dl. There was no incidence of hyponatremia during the first 48 hours. Graft survival was 72% at median follow up time of 7.2 years.

Conclusions: Patient requiring AVP post DDKT have unique characteristics - fewer anti-HTN medications and longer time on dialysis prior to transplant. A longer than median hospital length of stay was noted. To our knowledge this is the first study reviewing AVP use post DDKT. Future studies are needed to compare characteristics and outcomes with patients’ who did not require AVP post DDKT.

PO2407

Differences in Urinary Inflammatory Profiles in Donor-Recipient Pairs

Elizabeth Spiwak, Corina Nailescu, Andrew L. Schwaderer. Riley Hospital for Children at Indiana University Health, Indianapolis, IN.

Background: Renal transplant is the most common type of transplant performed in the US. Immunosuppressants are used in transplant recipients to prevent rejection. Kidney transplant recipients are at a higher risk for infection in the pre- and post-transplant state. Urine inflammatory profiles may lend insight to this balance between infection and rejection. Since donor and recipient urine is generated by genetically identical kidneys, it represents an ideal biosample for paired analysis.

Methods: Urine samples were obtained from stable children ≥2 months post-transplant along with their donors (n=6) and another 8 recipient-donorrecipient pairs (adult and children) that were collected for longitudinal samples; of which a pretransplant sample has been obtained. Using the V_PLEX Human CytoKine Panel (Mesoscale Discovery, Rockville MD) urine inflammatory mediators were quantified. The paired T-test or Wilcoxon test for parametric and nonparametric data respectively.

Results: Interleukin (IL)-7, IL-15, Monocyte chemotactic protein-1 (MCP-1) and Granulocyte-macrophage colony-stimulating factor (GM-CSF) were higher in the pediatric post-transplant recipients compared to their donors P values of 0.017, 0.037, 0.046 and 0.031 respectively. IL-9 was higher in recipient urine in pre-transplant patients (p=0.004) compared to donors.

Conclusions: Transplant patients have an elevated urine inflammatory mediator profile. Pretransplant patients have elevated IL-9 compared to their donors. Reasons for this altered inflammatory profile include immunologic, hemodynamic or physiologic changes intrinsic to the transplant procedure versus medications used to manage transplant patients.

PO2408

LIMS1 Gene Mismatching and Risk of Rejection in Kidney Transplant Recipients

Yasar Calisik,1 Safak Mirioglu,2 Halil Yazici,2 Ahmet B. Dirim,2 Erol Demir,2 Ozgur A. Oto,2 John C. Edwards,1 Rosemary Ousph,1 Aydin Turkmen,2 Krista L. Lentine,1 Saint Louis University, Saint Louis, MO; 2Istanbul University, Istanbul, Turkey.

Background: Recent advances in precision medicine have provided new insights into the pathogenesis of kidney transplant (KTx) rejection such as the potential role of genetic risk variants in LIM Zinc Finger Domain Containing 1 (LIMS1). We aimed to evaluate the relationship between donor and recipient LIMS1 genotype matching status and allograft rejection and survival.

Methods: We genotyped 41 prevalent living KTx recipient [24 (59%) males; mean age 34±13 years] and donor [15 (37%) males; mean age 47±13 years] pairs for LIMS1 rs893403 variant by Sanger sequencing in order to assess their impact on rejection and graft failure. The recipients homozygous for LIMS1 rs893403 GG genotype which tags a common 1.5-kb deletion (CNVR915.1) received a transplant from a nonhomozygous donor were defined as risk mismatched. CNVR915.1 deletion is confirmed by PCR in recipients with rs893043-AG and GG genotypes. Rejections were defined as T-cell mediated (TCMR) or antibody mediated rejection (ABMR) defined by Banff 2013 criteria. Outcomes were abstracted by review of medical records.

Results: There were no differences between recipients with risk LIMS1 mismatching (n=5) and recipients without risk LIMS1 mismatching (n=36) regarding demographic factors, duration of dialysis, pretransplant PRA, HLA mismatching, immunosuppressive protocols and follow up time. After a median post-KTx follow up of 10.5 (IQR 8.7-12.6) years recipients with risk LIMS1 mismatching had significantly higher risk of allograft rejection (60%; median 1 month) compared to recipients without risk LIMS1 mismatching (13.9%; median 72 months) (HR=4.32, 95CI% 1.46-12.76, p=0.015). TCMR was higher in recipients with risk LIMS1 mismatching (40%) compared to recipients without risk LIMS1 mismatching (11.1%) (p=0.087). There were no significant differences found between patients with and without risk LIMS1 mismatching regarding risk of post-KTx DSA, ABMR and allograft failure. The mean eGFR levels at last follow up were also similar among recipients with and without risk LIMS1 mismatching.

Conclusions: Genomic mismatching at LIMS1 gene appears to impact risk of TCMR. LIMS1 may be a potential minor histocompatibility antigen and pre-transplant genetic testing may have clinical implications for the prediction and clinical management of KTx rejection.

Figure 1. Catheterized urine samples from recipients at time of transplant have higher levels of IL-9 than their donors
PO2409
Monitoring of Gene Expression in Tacrolimus-Treated De Novo Renal Allograft Recipients Facilitates Individualized Immunosuppression: Results of the IMAGEN Study
Claudia Sommerer,1 Merce Brunet,2 Klemens Budde,3 Olga Millan,2 Lluis Guirado,4 Petra Glander,4 Stefan Meuer,4 Martin G. Zeier,4 Thomas Giese.4
1Nephrology, University Hospital Heidelberg, Heidelberg, Germany; 4Renal Transplant Unit, School of Medicine, Uchinada, Ishikawa, Japan.

Background: The expression of nuclear factor of activated T-cells (NFAT)-regulated genes in the peripheral blood has been suggested as a potentially useful immune monitoring tool to individualize tacrolimus (Tac) therapy. The aim of the present study was to characterize the possibility and clinical utility of monitoring of residual NFAT-regulated gene expression in renal allograft recipients in a multicenter approach.

Methods: The IMAGEN study enrolled 64 de novo renal transplant recipients from three European centers. All patients were treated with Tac, mycophenolic acid, and corticosteroids. NFAT-regulated gene expression (NFAT-RGE; II-2, IFN-g, GM-CSF) was evaluated by quantitative real-time PCR in whole blood samples at day 7, month 1, 2, 3, and 6 after transplantation.

Results: Altogether, 60 patients could be evaluated. Tac concentrations (C0 and C1.5) correlated inversely with gene expression (p<0.001). NFAT-RGE showed a high interindividual variability (1 to 61%). RGE increased in the first two months from 16±9% to 34±21%. Patients (n=20) with high residual gene expression (NFAT-RGE≥30%) were at the increased risk of acute rejection in the following months (35% vs 5%, p=0.002), whereas patients (n=40) with low residual gene expression (NFAT-RGE<30%) showed a higher incidence of viral complications, especially cytomegalovirus and BK virus replication (52.5% vs 10%, p=0.001).

Conclusions: NFAT-RGE was confirmed as a potential non-invasive early predictive pharmacodynamic marker in the immediate post-transplant period for the risk of acute rejection and infectious complications in Tac-treated renal allograft recipients. Monitoring of NFAT-RGE may provide additional useful information for physicians to achieve individualized treatment adjustments based on the immunomodulatory effect of Tac, thus preventing serious clinical events. The method of NFAT-RGE measurements can be applied in trials with multicenter approach.

PO2410
The Role and Inducers of Nonclassical HLA-G in Renal Transplanted Allografts
Sho Kimano, Keiji Fujimoto, Hiroki Adachi, Kengo Furuchi, Hitoshi Yokoyama. Department of Nephrology, Kanazawa Medical University School of Medicine, Uchinada, Ishikawa, Japan., Kahoku, Japan.

Background: Non-classical class I molecule HLA-G has a high potential to modulate immune response. However, the mechanism of HLA-G induction was still unknown. In this study, the expression of HLA-G on proximal tubular epithelial cells (pTECs) and the inducer of HLA-G were investigated.

Methods: Our subjects comprised 40 adult Japanese subjects whose allograft had survived for at least 1 year (35 patients from a living donor, 5 patients from a deceased donor). They were evaluated for HLA-G1/5 expression using an immunofluorescence method. We investigated inducer of HLA-G using primary cultured human pTECs treated with cytokines and immunosuppressants.

Results: In renal biopsy tissues, 2 to 4 weeks or 1 year following the transplantation, HLA-G expression was noted in the perinuclear region or on the basement membrane with cytokines and immunosuppressants. In total cohort, 611 recipients (61.7%) and 379 recipients (38.3%) underwent living-donor KT and deceased-donor KT, respectively. Recipients were classified as no DSA (990 recipients, 91.8%), only DQ (18 recipients, 1.8%), non-DQ (57 recipients, 6.3%), and DQ + non-DQ (6 recipients, 0.7%). The overall incidence of acute rejection and acute antibody-mediated rejection (AMR) were 20.3% and 7.5%. Only DQ, non-DQ, and DQ + non-DQ group had significantly higher the incidence of acute AMR compared to no DSA group (p < 0.05, respectively). There was no significant difference in the incidence of acute AMR between sensitized groups. There was no difference in the rate of death-censored graft loss between groups. In univariate Cox regression analysis, all of 3 groups with DSA were associated with high risk of acute AMR (Only DQ: HR 5.01; CI 95%, p<0.002, non-DQ: HR 6.005; CI 95%, p < 0.001, DQ + non-DQ: HR 7.748; CI 95%, p = 0.005, respectively). HLA-DQ DSA and other DSAs (HLA-A, HLA-B, HLA-C, HLA-DR) had a tendency to interact with acute AMR, although no statistical significance (p = 0.05).

Conclusions: Preformed HLA-DQ DSA may be necessary to improve graft outcomes.

PO2411
The Clinical Impact of Preformed HLA-DQ Donor-Specific Antibodies on Graft Outcomes in Kidney Transplantation
Sua Lee,1 Chul Woo Yang,2 Byung ha Chung.3 1Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Catholic University of Korea, Seoul, Republic of Korea.

Background: Preformed HLA-DQ donor-specific antibody (DSA) has been identified as a risk factor for graft rejection and loss in kidney transplantation (KT). Recently, the impact of preformed HLA-DQ DSA has been discussed. This study aimed to investigate the clinical impact of preformed HLA-DQ DSA on graft outcomes.

Methods: We evaluated 990 recipients who underwent kidney transplantation at Seoul St. Mary’s Hospital from January 2010 to July 2019. According to the result of DSA using luminex single antigen bead assay, recipients were classified as no DSA, only DQ, non-DQ, and DQ + non-DQ. Primary outcomes were the incidence of biopsy-proven acute rejection and the rate of death-censored graft loss.

Results: In total cohort, 611 recipients (61.7%) and 379 recipients (38.3%) underwent living-donor KT and deceased-donor KT, respectively. Recipients were classified as no DSA (990 recipients, 91.8%), only DQ (18 recipients, 1.8%), non-DQ (57 recipients, 6.3%), and DQ + non-DQ (6 recipients, 0.7%). The overall incidence of acute rejection and acute antibody-mediated rejection (AMR) were 20.3% and 7.5%. Only DQ, non-DQ, and DQ + non-DQ group had significantly higher the incidence of acute AMR compared to no DSA group (p<0.05, respectively). There was no significant difference in the incidence of acute AMR between sensitized groups. There was no difference in the rate of death-censored graft loss between groups. In univariate Cox regression analysis, all of 3 groups with DSA were associated with high risk of acute AMR (Only DQ: HR 5.01; CI 95%, p < 0.002, non-DQ: HR 6.005; CI 95%, p < 0.001, DQ + non-DQ: HR 7.748; CI 95%, p = 0.005, respectively). HLA-DQ DSA and other DSAs (HLA-A, HLA-B, HLA-C, HLA-DR) had a tendency to interact with acute AMR, although no statistical significance (p = 0.05).

Conclusions: Preformed HLA-DQ DSA is associated with the development of acute rejection, especially acute AMR. Therefore, the identification of preformed HLA-DQ DSA may be necessary to improve graft outcomes.

PO2412
Outcomes of High Kidney Donor Profile Index Kidneys at a Large Center

Background: Kidneys from donors with high Kidney Donor Profile Index (KDPI) are often discarded due to concerns about outcomes. Despite decreased survival, the survival benefit of receiving a transplant and avoiding time on dialysis is beneficial, especially for selected patients.

Methods: We increased use of high KDPI (KDPI>85) deceased donor kidneys (DDKT) over several years. We performed a single-center analysis of 1119 consecutive adult DDKT from 2016-2019. Our endpoints were Kaplan-Meier death-censored

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
PO2413
Could Individually Measured Creatinine Clearances Decrease the Discard Rate of High Kidney Donor Profile Index (86-100) Deceased Donor Kidneys?

Adnan A. Khan, Robert W. Steiner, Hannah L. Turner, Charles K. Wainaina, Ashley S. Hahn. University of California San Diego, La Jolla, CA.

Background: The Kidney Donor Profile Index (KDPI) guides center acceptance and allocation of deceased donor kidneys (DDKs). It uses donor factors such as serum creatinine (sCr), diabetes mellitus and hypertension to predict organ quality and corresponding longevity. Due to this higher KDPI kidneys are often discarded. KDPI offers "only moderate predictability" of long-term transplant function with a c statistic of 0.6.

Methods: As an unexplored, but direct measure of deceased donor kidney quality, we determined pre-recovery creatinine clearances (CrCls) in 260 deceased donor candidates (1/2015 -12/2018) using ICU urine collections (Uccols) and pre- and post-recovery serum creatinine (sCr) values. We used CrCl > 80 ml/min as the threshold of interest, as that defines acceptable kidney function for living kidney donor candidates. Donor creatinine production rates were calculated to assess the veracity of CrCls. Organ match sequence was reviewed for all denials and UNOS denial codes and corresponding reasons for denial were reviewed.

Results: Of the 134 kidneys available from 67 high KDPI donors, 32/67 donors had both kidneys transplanted, 7/67 donors had one kidney transplanted and 28/67 donors were not transplanted. Reviewing the 35/67 donors in whom either one or both kidneys were not transplanted; 10 of them had CrCl > 80. This amounts to about 28.6 % (10/35) of the non-transplanted donors with high KDPI, having a CrCl >80 ml/min. In the high KDPI group 28/67 candidates (~42%) had measured CrCl>80 ml/min. In the KDPI 21-85 group, 97/155 (63%) of donors had CrCl >80 ml/min; while 42/50 (84%) in the KDPI 0-20 group had measured CrCls > 80 ml/min. Lower CrCls did not correlate with higher KDPIWs within each subgroup. Donor creatinine production rates were 17.9 ± 9.1 mg/kg/day, within population expectations. UNOS denial codes for high KDPI organ offers were mostly 830 - donor age or quality or 837 - organ specific donor issue.

Conclusions: Our data suggests that about 28.6% of the non-transplanted high KDPI donors had CrCl>80 and these kidneys could have been potentially used and not discarded. Direct measurement of CrCl in deceased kidney donors is not difficult and deserves further study, as it may improve estimates of donor kidney quality and reduce inappropriate discards in a heterogeneous group.

Glomerular Blood Flow in Living Donor Kidney Transplant Recipients

Gio Kanazaki, Takaya Sasaki, Kotaro Haruhara, Rina Oba, Yusuke Okabayashi, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Nobuo Taibo, Takashi Yokoo. The Jikei University School of Medicine, Minato-ku, Japan.

Background: Renal graft hemodynamics may be a valuable predictor of graft survival and long-term outcomes. Although several studies have reported that renal blood flow was correlated with graft function and decreased remarkably during acute rejection episode, the glomerular hemodynamic changes during kidney transplantation are lacking because there is no method of measuring nephron number in vivo. In this study, we calculate glomerular blood flow (GBF) by estimating the nephron number and investigate changes in GBF after kidney transplantation and their clinicopathological relationship.

Methods: We performed a retrospective analysis of 42 patients who underwent living donor kidney transplantation. The number of glomeruli (Ngлом) was calculated as the cortical volume of both kidneys as assessed on computed tomography times the 1-hour posttransplant renal biopsy-determined glomerular density. Effective renal plasma flow (ERPF) was assessed as 99mTc-MAG3 clearance. GBF was calculated as follows: GBF (nl/min) = ERPF/Nglomer(-1-hematocrit/100) x10^6. We analyzed the GBF before and during a 1-month observation period after transplantation. The GBF ratio as a marker of change in GBF was calculated as follows: (GBF one-month post-transplantation) / (GBF before transplantation in donors).

Results: Prior to transplantation, the GBF in donors was 559 ± 257.3 nl/min, whereas the GBF in recipients on day 2 post-transplantation was decreased to 502.6 ± 317.4 nl/min. After successful transplantation, the GBF one-month post-transplantation has settled down to 491 ± 299.1 nl/min, while the eGFR progressively rose (48.7 ± 18.4 ml/min/1.73m2) together with the hematocrit (31.1 ± 3.9 %). The GBF at one month was positively associated with eGFR at one month (p<0.05). Of note, the GBF ratio was correlated with the eGFR and urinary protein excretion at one month and urinary protein excretion at 1 year but was not correlated with eGFR at 1 yr.

Conclusions: We first reported the GBF in kidney transplant recipients before and after kidney transplantation. Our findings suggest that abnormal change in GBF may be considered predictive indices for short-term allograft outcomes.
PO2416
Outcomes of Delayed Graft Function: A Systematic Review and Meta-Analysis
Vanessa Sandra,1 Navin Sanichar,1 Emily Daniel,1 Miah T. Li,1 Kristen L. King,1 Jacob Stevens,2 Syed A. Husain,1 Tracy J. Mayne,2 Sumit Mayne,1 Columbia University, New York, NY; 2Angion Biomedica, San Francisco, CA.

Background: Delayed Graft Function (DGF) is a frequent complication of kidney transplantation, but its impact on long and short-term outcomes remain uncertain.

Methods: We conducted a literature search for studies investigating the association of DGF on subsequent outcomes from 2007-2020. Outcomes were abstracted and used to create cumulative forest plots with pooled odds ratios, stratifying our analysis between center-studies and registry-studies and follow-up time where possible. The outcomes analyzed were graft failure (GF), acute rejection (AR), patient survival, and renal function.

Results: Of the 1464 articles reviewed, 27 were included. In single-center-studies, DGF patients experienced higher GF at 1 year (OR 2.45, 95% CI 1.79-4.29, p<0.001), 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.001), increased AR 1-year post-transplant (OR 1.48, 95% CI 1.79-4.28, p=0.001), and decreased 1-year patient survival (OR 0.46, 95% CI 0.28-0.73, p<0.001). Registry-studies showed a similar significant association with GF at 1 year (OR 2.76, 95% CI 1.79-4.28, p=0.001) and 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.046), with AR within 1 year (OR 1.48, 95% CI 1.45-8.67, p=0.005) and 3-years (OR 0.54, 95% CI 0.41-0.72, p=0.001), and 1-year survival (OR 0.45, 95% CI 0.26, 0.77, p<0.001). Qualitative analysis showed that DGF had significant effect on eGFR and creatinine levels, though studies conflict on timeframe. Few studies investigated outcomes stratifying DGF severity or KDPI.

Conclusions: DGF was associated with increased risk of GF, AR, and mortality, although effects were largest within 1 year post-transplant. Our analysis indicated a need for a standardized method to measure DGF severity and further studies on DGF outcomes on varying KDPI. These results should inform the selection process, treatment, and monitoring of transplanted kidneys at high risk for DGF.

PO2417
Duration of Delayed Graft Function Predicts Kidney Allograft Function and Survival
Sanjana Kapoor, Nawras Alshoubaki, Chethan M. Puttarajappa, Sundaram Hariharani. University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: The current study evaluated the duration of DGF as a measure of severity of ischemic injury to kidney transplant outcome.

Methods: This single center study evaluated DD kidney transplant recipients with DGF between Jan 2014 and Dec 2019. DGF was defined as the need for dialysis within 7 days post-transplant & were divided into three groups according to post transplant dialysis duration. Group I: dialysis ≤7 days, Group II: dialysis 8-14 days and Group III: dialysis >14 days. All primary & repeat adult kidney recipients of DD transplants were included. We excluded multiorgan recipients and pediatric en-bloc kidneys. We calculated eGFR over time using CKD EPI formula. Statistical analysis was performed to identify differences in variables, Linear Mixed Model for eGFR over time. Log-rank test was used to evaluate differences in graft & patient survival & composite end point (graft loss, patient loss & GFR, 20ml/min) for all 3 subgroups.

Results: A total of 132 DD KT recipients with DGF were identified: Group I: n=84 (64%), Group II: n=24 (18%) & Group III: n=24 (18%). The recipient/donor demographics and Donor (KDPI) & Transplant variables were similar across groups. Figure 1 (left) shows significantly lower eGFR values over time using linear mixed model among patients who needed dialysis for >14 days (Gr III vs II, p<0.006). Table 1 shows the incidence of Isolated Graft Loss, Patient death and combination of graft loss & patient death among 3 groups. Figure 1 (right) shows significantly lower composite end point (combination of patient loss, graft loss and impending graft loss) for patients who needed dialysis for >14 days (P<0.0002).

Conclusions: In conclusion, we found a strong association between prolonged DGF>14 days with lower GFR values and survival outcomes. No differences in eGFR and survival rates were noted among patients with DGF patients <7 days vs 7-14 days.

PO2418
Design of the Graft Improvement Following Transplant (GIFT) Trial, a Phase 3 Study of ANG-3777 in Kidney Transplantation Patients with Delayed Graft Function
Flavio Vincenzi1, Tracy J. Mayne,2 Deb Gouveia,1 John F. Neylan.1 University of California San Francisco, San Francisco, CA; 2Angion Biomedica, San Francisco, CA.

Background: Patients after kidney transplantation can experience acute kidney injury (AKI) resulting in delayed graft function (DGF). The Food and Drug Administration has prioritized the development of new treatments for DGF. A Phase 2 trial demonstrated that treatment with ANG-3777, a hepatocyte growth factor (HGF) mimetic, improved renal function up to 12-months in patients with signs of DGF.

Methods: Objective: To describe the GIFT trial (Study 001-15), designed to evaluate the efficacy and safety of ANG-3777 in renal transplantation patients with signs of DGF.

Results: GIFT is a Phase 3, multicenter, prospective, randomized, placebo-controlled, study enrolling patients who have undergone a kidney transplantation with a deceased donor kidney who exhibit signs of DGF (producing a mean of <500cc urine per hour over 8 hours in the first 24-hours post-transplantation). Patients are randomized 1:1 to ANG-3777 (2 mg/kg) or placebo administered intravenously once daily for 3 consecutive days starting within 30 hours after transplantation. The primary endpoint is estimated glomerular filtration rate (eGFR) at 12 months. Secondary endpoints include proportion of subjects with eGFR > 30 ml/min/1.73m² at days 30, 90, 180 and 360; proportion of subjects whose graft function is slow, delayed or primary non-function; length of hospitalization, duration of dialysis through day 30. A study schematic is shown in Figure 1. Adverse events are being assessed throughout the study.

Conclusions: No pharmacologic intervention has been demonstrated in a rigorous trial to be effective preventing or improving the outcome of DGF. The GIFT study will generate data that are critical to advancing the treatment of DGF.
Clinical Outcomes of Kidney Transplant Recipients Living Away from Their Home Country

Background: Many people leave their home country looking for better job opportunities and among those are kidney transplant recipients. However, taking care of such recipients might be challenging especially when information regarding induction immunosuppression, donor HLA typing, donor-specific antibodies, crossmatch and/or infections are not available. The aim of this study was to compare clinical outcomes of kidney recipients transplanted in their home country with kidney recipients transplanted locally.

Methods: In this retrospective cohort, we included all adult recipients transplanted between 2005 and 2016 and followed at our transplant clinics within their first year of transplant. Patients were categorized into two groups; local group including recipients transplanted at our center and abroad group including recipients transplanted in their home country.

Results: There were 111 patients in local group and 110 patients in abroad group. The mean age at transplant in local and abroad groups were 48 and 42 year-old, respectively. 63% of recipients in local group were from the Middle East, while 53% of patients transplanted abroad were from South Asia. Deceased donation was higher in local group (41% vs. 3%; p=0.0001). There was no difference in recipient sex, native kidney disease, primary immunosuppression, drug disruption or incomplete medical record. Kidney recipients transplanted abroad are at increased risk of acute cellular rejection; however, patient and graft survival rates remained excellent.

Conclusions: Transition of care between countries carries its risks as it may be related to drug disruption or incomplete medical record. Kidney recipients transplanted abroad are at increased risk of acute cellular rejection; however, patient and graft survival rates remain excellent.

Factors Associated with the Use of Hypothermic Machine Perfusion in Kidney Transplant Recipients

Nadir Goulamhoussen,1 Lawrence Slapcoff,2 Dana Baran,3 Isabelle Houde,4 Anne Boucher,5 Martin Albert,1 Pierre Marsolais,6 Heloise Cardinal,7 Josec Bouchard,1 1Hôpital du Sacre-Coeur de Montreal, Montreal, QC, Canada; 2McGill University, Montreal, QC, Canada; 3Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 4CHU Québec, Quebec, QC, Canada; 5Centre Hospitalier de l’Université de Montreal, Montreal, QC, Canada.

Background: Delayed graft function (DGF) is associated with an increased risk of graft loss. The use of cold hypothermic machine perfusion (HMP) has been shown to reduce the incidence of DGF in kidney transplant recipients (KTRs), especially when extended-criteria donors (ECDs) are used. However, there is a paucity of data on the determinants of HMP use in real-life setting.

Methods: We aimed to determine the factors associated with the use of HMP in a cohort of donors and KTRs. We collected data on consecutive brain-dead donors admitted to a multi-organ procurement organization and their KTRs between June 2013 and December 2018 in 5 adult transplant centers in Canada. There is no standardized protocol for the use of HMP in the province of Quebec. The use of HMP is left at the discretion of the surgeon recovering organs. However, a HMP device was available for every organ recovered at the center where the surgeons practiced, suggesting that surgeon preference/training plays an important role in determining the use of HMP. The presence of ECD did not influence the use of HMP. The reasons underlying the differences in practice between centers should be explored in further studies.

Clinical and Immunologic Predictors of Post-Transplant Outcomes

Bogdan Obrina1, Maria Butia,2 Ramasamy Bakhtavatsalami,2 Kelly D. Smith,2 Iris C. De Castro,2 Christopher D. Blosser2, Lena Sibulevsky2,2 Catherine Kling,2 Gener Ismaiel,1 Bogdan M. Sorohan,1 Nicolaie Leca,1 1Fundeni Clinical Institute, Bucharest, Romania; 2University of Washington, Seattle, WA.

Background: Microvascular inflammation (Mi) is the main histological lesion for ABMR. Mi may occur separate from other ABMR criteria, early in the injury process, and may not be captured by the current Banff criteria. Donor-derived cell-free DNA (dd-cfDNA) has the potential to identify early allograft injury and supplement the current diagnostic criteria for rejection.

Methods: We included all patients (n=54) who underwent a kidney transplant biopsy for suspicion of rejection at our center from 9/17-12/19. Determinants of a biopsy were renal dysfunction, elevated dd-cfDNA, or presence of DSAs.

Results: Dd-cfDNA correlated strongly with the presence of ABMR, Class II DSA-2500, and histological lesions of ABMR. The strongest association was with Mi lesions (OR 192.95; 95% CI, 18.6, 1984, p<0.001). Of the 18 patients with Mi, 2 died not meet the criteria for ABMR and had a dd-cfDNA level of 0.32% and 1.9%. All patients with Mi that met the criteria for ABMR had a dd-cfDNA over 1%. There was no association with renal function or histological lesions of tubulitis or interstitial inflammation (Fig 2).

Conclusions: Dd-cfDNA has the potential to identify early allograft injury and allow for early and less aggressive interventions that can potentially benefit long-term outcomes of kidney transplant recipients.

Point-of-Care Creatinine Self-Testing in Renal Transplant Patients: An Assessment of Accuracy, Precision, and Patient Experience

Fabiana Fernandes da Costa,1 Michelle Willicombe,1,2 Kate Bramham,3 Clare B. Kelly.1 Imperial College NHS TRUST, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3Department of Women and Children's Health, King's College London, London, United Kingdom.

Background: During the Covid-19 pandemic it has become increasingly important to provide virtual care for patients with CKD. Point-of-Care testing of capillary creatinine (POC-Cr) is now available and has demonstrated validity, ease of use, improved efficiency and cost-efficiency. We aimed to determine patients’ desire to self-monitoring of POC-Cr and their characteristics.

Methods: Renal transplant patients were shown how to perform self-POC-Cr testing with a NovoBio StatSensor®Xpreshed device, then undertook a test independently and answered survey questions about their attitude to self-testing of POC-Cr.

Results: All patients (N=189; Median age 52 years (IQR 40, 64); 44 (23%) English as a second language; 128 (68%) male; Median eGFR 49 nls/min/1.73m2 (IQR 34,64) successfully performed a POC-Cr test and 110/120 (91%) of patients who completed the survey reported they would like to self-monitor POC-Cr. Most patients wished to reduce their clinic attendance and the majority were willing to have telephone consultations. Characteristics of the cohort are described in Table 1.

Conclusions: All transplant patients successfully performed a POC-Cr test with written instructions and a demonstration. Most patients would like to self-monitor POC-Cr and reduce clinic attendance. Limitations include the single-centre design, number of participants and language barrier. Virtual care including patient self-monitoring using POC-Cr should be explored.

Characteristics of patients who would and would not like to self-monitor POC-Cr at home

Short-Term Variability in Graft Function Is Associated with Long-Term Mortality but Not Allograft Survival in Kidney Transplant Recipients

Reini Lyv, Didier A. Mandelbrot, Arjang Djamali, Brad C. Astor. University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.

Background: It is critical to identify kidney transplant recipients (KTR) at highest risk of graft failure and death to focus on monitoring and interventions to improve long-term outcomes. Variability in native kidney function is associated with the risk of mortality and hospitalization in chronic kidney disease, but it remains uncertain whether such associations exist in KTR. We examined the hypothesis that short-term graft function variability is associated with long-term outcomes in KTR.

Methods: Using the Wisconsin Allotransplant Recipient Database (WisARD), we identified 2919 KTRs who had a functioning allograft at least 2 years after transplantation and at least 3 outpatient estimated glomerular filtration rate (eGFR) measurements from 1 to 2 years post-transplant. Graft function variability was defined for each patient as the coefficients of variation based on a linear regression of eGFR from 1 to 2 years.

Results: Patients with greater variability were more likely to be female, have more comorbidities, and have more prior hospitalization events, and have. Compared to the lowest quartile, the highest quartile of eGFR variability was associated with a higher risk of total graft loss (adjusted HR 1.51, 95% CI: 1.11-2.06) and a higher risk of death (adjusted HR 1.85, 95% CI: 1.23-2.76), but not with a higher risk of graft failure (subHR 1.08, 95% CI: 0.64-1.83 in competing risk analysis), independent of eGFR and slope of eGFR. The associations remained consistent across strata of acute rejection, diabetes, peripheral arterial disease, baseline eGFR, history of cardiovascular disease, baseline hospitalization, and with all variability indicators and modeling approaches.

Conclusions: Short-term eGFR variability is associated with long-term death but not graft failure. Variability in eGFR provides independent prognostic information on transplantation outcomes and may be an indicator to differentiate the risk of death and graft failure.

PO2424

Defining a Minimal Clinically Meaningful Difference (MCMD) in Estimated Glomerular Filtration Rate (eGFR) for Kidney Transplantation

Tracy J. Mayne,3 Sumit Mohan,2 Jesse D. Schold,3 Matthew R. Weir,4 Bob Nordyke.2 Angion Biomedica, San Francisco, CA; 3Columbia University, New York, NY; 4Cleveland Clinic, Cleveland, OH; 5University of Maryland School of Medicine, Baltimore, MD.

Background: eGFR is an established measure of renal function & predicts clinical outcomes. A MCMD for eGFR has never been clearly defined.

Methods: Data source: United Network for Organ Sharing (OPTN) database Study population: Adults (≥18 years of age); received deceased donor kidney 01/01/2013 to 12/31/2018; multi-organ & non-incident transplants were excluded. Analysis: Cox proportional hazards regression Primary outcome: Death-censored graft survival starting 12-months post-transplantation. Predictors: Recipient (gender, age, race, diabetes, body mass index, panel reactive antibodies); Donor (age, diabetes, hypertension, proteinuria); Transplantation (cold ischemia time, pump, DR locus mismatch, delayed graft function); 12-month eGFR (CKD-EPI). Analyses: eGFR was stratified by bands of 5, 7 or 10 mL/ min/1.73m2. Regressions compared each band to the next sequential band. A weighted mean hazard ratio was calculated using OPTN population eGFR distribution.

Results: The relationship between 12-month eGFR & graft failure is non-linear: HR=3 to 4 at eGFR <15 mL/min/1.73m2; HR=1.1 at eGFRs ≥ 55. Mean HR=1.47 for 10 mL/min/1.73m2 bands; 1.30 at 7 mL; 1.19 at 5 mL.

Conclusions: Controlling for multiple factors, 12-month eGFR is a strong predictor of death-censored graft survival. Mean HR (1.19) is consistent with an effect size considered significant, clinically meaningful, & supporting of regulatory approval (eg, angiotensin receptor blockers; statins). This supports 5 mL/min/1.73m2 as the eGFR MCMD in kidney transplantation. DISCLAIMER. The interpretation & reporting of these data are the responsibility of the authors & in no way should be seen as an official policy or interpretation by the OPTN or the US Government.
PO2425
Composite Events Associated with Increased Expected Post-Transplant Survival Scores
Yasmeen Suphamai,1 Nakul N. Datta,2 Piyavadee Homkrila1,3 Suphramai Bunnapradist,2 Erik L. Lum,1,3 1University of California Los Angeles, Los Angeles, CA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Kidney transplant candidates on the waiting list are assigned an expected post transplant survival (EPTS) score. This score is used to determine allocation of kidneys in the kidney allocation system (KAS). The outcomes of candidates with an EPTS > 95% at the time of listing is limited.

Methods: UCLA kidney Transplant Program data of waiting list with EPTS > 80% from January 2015 – December 2018 were included. Median follow up time of waiting list was 885 days. The outcomes included kidney transplant rate, 3 year death censored graft survival and patient survival in candidates with EPTS a 95% compared with EPTS < 95%.

Results: A total of 124 patients were identified with an EPTS score > 95% at the time of listing during the study period. Of these patients 23 received a kidney transplant during the specified time frame (transplant rate of 16.9%). Recipients of kidney transplant had a longer dialysis vintage (2368.6 days vs. 9881 days, P=0.0001) and were more sensitized at the time of listing (34.3% vs. 11.8%, p=0.018). Compared to a group with an EPTS between 80-94% at time of listing (n=170) there were no differences in mortality (4.35% vs. 4.55%, p=0.969), graft failure (14.3% vs. 6.4%, p=0.254), or 3 year death censored graft survival (70.0% vs. 84.5%, p=0.517). The EPTS > 95% was older group, had a longer dialysis vintage, had a higher proportion of candidates with diabetes as a cause of ESRD, and was less likely to undergo transplantation. Candidates with an EPTS >95% who did not receive a transplant had a mortality rate of 7.9% and waitlist removal rate 16.9%.

Conclusions: Kidney transplantation in candidates with an EPTS > 95% provides comparable outcomes to candidates with an EPTS between 80-94%, which was superior to remaining on dialysis. Despite this benefit, the transplantation rate of this group was low and a quarter of those not transplanted either died or are removed from the waitlist. Strategies are needed to improve transplantation rates in this population.

PO2426
Transition of Renal Transplant Care from Pediatrics to Adolescence and Young Adulthood: Retrospective Study Comparing Serum Creatinine-Based GFR Estimating Equations
Dandamudi R,1 Hmiel S,2 Bommarc VR,3 Lum WP1,2
1University of California Los Angeles; 2University of California Los Angeles David Geffen School of Medicine; 3Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Background: The evaluation of graft function is vital in the management of pediatric kidney transplant (pKTx) recipients. Measured GFR (mGFR) using exogenous markers, is very accurate, but not suitable for daily use. Estimated glomerular filtration rate (eGFR) using Serum creatinine (Scr) is the easiest way and equations are categorized as either pediatric or adult specific. None of the equations were formally compared in adolescents and young adults with renal transplants. The aim of study was to assess the performance of creatinine-based formulas in a cohort of pKTx in pediatric, adolescents and young adult age groups.

Methods: This retrospective study was conducted at our hospital from January 2000 to March 2019 from 125 pKTx recipients. We compared 415 mGFR values to 5 different Scr-based eGFR formulae (original Schwartz(OS), BS, Pottel, Modification of Diet in Renal Disease (MDRD), CKD-EPI), and average of BS and CKD EPI. Baseline on the age at which the GFR was measured we divided the cohort in to 3 categories (children <12 ys, Adolescents 12-17 yrs and young adults >18-21 yrs. We used Bland-Altman analysis to evaluate the bias, precision and accuracy between eGFR and mGFR.

Results: Pottel and BS performed well across pediatric and adolescent age groups with high 30% accuracy(figure). MDRD and CKD EPI performance improved in young adults ~18 years. Average of BS and CKD EPI outperformed other equations in young adults and provides an overall unbiased estimate of GFR.

PO2427
A Comparison of the Associations of Urine Markers with the Rate of Decline in Kidney Allograft Function
Yoshitsugu Obu,1,2 Naotsubu Ichimaru,3 Yoshitaka Isaka,1 Takayuki Hamano,1-3 The CANDLE-KIT Trial Investigators ‘Ohi Clinic, Osaka, Japan; ‘The University of Tennessee Health Science Center College of Medicine, Memphis, TN; ‘Osaka Daigaku Daigakusen Igukuei Kenkyusha Igakubu, Suita, Japan; ‘Ippin Zaidan Hoin Sumitomo Byoin, Osaka, Japan; ‘Nagoya Shitsuru Daigaku Daigakusen Iguku Kenkyusha Igakubu, Nagoya, Japan.

Background: Various urine markers are proposed to predict renal outcomes. However, there are few head-to-head comparison studies comparing their clinical relevance among kidney transplant recipients (KTRs).

Methods: In a prospective clinical trial, we enrolled 153 KTRs with anemia and ≥1-year history of transplantation across 23 facilities and followed them for 2 years. The annual change in eGFR was estimated based on mixed effects model. We then selected 102 patients who had baseline urine data on total protein, beta-2-microglobulin (β2M), N-acetyl-beta-D-glucosaminidase (NAG), and L-type fatty acid binding protein (L-FABP). Total protein, NAG, and L-FABP were standardized according to urine creatinine concentration. We then compared the associations of the quintiles of each urine marker with annual decline in eGFR using univariate and multivariable linear regression models.

Results: Patients were 51±12 years-old and 54% were male. The median (IQR) of proteinuria was 5 (9, 12) mg/L, and the baseline eGFR levels were 31 ± 9 mL/ min per 1.73 m². The annual eGFR change was -1.6±2.0 mL/min per 1.73 m²/year. The median (IQR) urine levels of total protein, β2M, NAG, and L-FABP at baseline were 0.3 (0.1-1.1) g/g Cr, 1535 (238-4780) μg/L, 0.06 (0.04-0.12) IU/L, and 16.7 (4.2-42.1) μg/g Cr, respectively. The higher levels of L-FABP and total protein were significantly associated with more rapid annual eGFR decline (P for trend <0.001 for both; Figure) while there was no significant association for β2M or NAG. R² was 0.10 (P=0.03) and 0.18 (P<0.001) for L-FABP and total protein, respectively. After adjustment for age, gender, mean arterial blood pressure, and baseline eGFR, the association remained significant for total protein but not for L-FABP (Figure).

Conclusions: Among urine markers of total protein, L-FABP, NAG, and β2M, total protein appears to have greatest predictive value for eGFR decline among KTRs.

PO2428
Chronic Graft vs. Host Disease in Pancreas After Kidney Transplant Recipient: An Unrecognized Entity
Prince Singh,1 Aleksandra Kukla. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Graft-versus-host disease (GVHD), a common complication after allogeneic bone marrow transplantation is rarely seen after solid organ transplants (SOT). Reports of acute GVHD (maculopapular rash, diarrhea and cholestatic liver disease) described after SOT invariably happened in the early post-transplant period (days to months). In contrast, reports of SOT recipients with clinical features more consistent with chronic GVHD (cGVHD) (resembling autoimmune disease with chronic inflammation/fibrosis) are lacking. We present a case of cGVHD in pancreas after kidney transplant (KP) patient diagnosed at 42 months post transplant.

Case Description: A 43 year old man received a HLA 5/6 mismatch, CMV mismatch (donor positive, recipient negative) deceased donor pancreas transplant two years after receiving a HLA 5/6 mismatch living unrelated kidney transplant. Anti-thymocyte globulin (ATG) was used to manage the acute rejection. The patient had a history of chronic hypertension and smoking. The patient developed acute renal failure 48 months post transplantation and was eventually put on non-cyclosporine immunosuppression. The patient was found to be sensitized for a new panel-reactive antibody (PRA) as per the laboratory protocol 2 years after transplantation. The patient had 15% PRA at that time. The patient was found to have chronic allograft dysfunction (CRAD) 2 years after transplantation. The patient had a creatinine of 1.3 mg/dL with a transplant vintage of 8 (5, 12) years, and the baseline eGFR levels were 31±9 mL/min per 1.73 m². The annual eGFR change was -1.6±2.0 mL/min per 1.73 m²/year. The median (IQR) urine levels of total protein, β2M, NAG, and L-FABP at baseline were 0.3 (0.1-1.1) g/g Cr, 1535 (238-4780) μg/L, 0.06 (0.04-0.12) IU/L, and 16.7 (4.2-42.1) μg/g Cr, respectively. The higher levels of L-FABP and total protein were significantly associated with more rapid annual eGFR decline (P for trend <0.001 for both; Figure) while there was no significant association for β2M or NAG. R² was 0.10 (P=0.03) and 0.18 (P<0.001) for L-FABP and total protein, respectively. After adjustment for age, gender, mean arterial blood pressure, and baseline eGFR, the association remained significant for total protein but not for L-FABP (Figure).

Conclusions: Among urine markers of total protein, L-FABP, NAG, and β2M, total protein appears to have greatest predictive value for eGFR decline among KTRs.

globulin induction was given along with a maintenance immunosuppression - tacrolimus, mycophenolate mofetil and prednisone. Post-transplant course was complicated by multiple opportunistic infections (Figure 1) leading to immunosuppression reduction. At 42 months post transplant, he developed dry eyes, arthralgia, anorexia, elevated alkaline phosphatase, dyspnea on exertion, lichen simplex chronicus dermatitis, and severe pancytopenia. GVHD was suspected which lead to peripheral blood chromatin testing revealing 90% pancreas donor-derived DNA in CD3-positive fraction of T cells. Patient passed away.

Discussion: The infections may have represented the immune dysfunction associated with GVHD. De-escalation of immunosuppression could have led to an unopposed activation of donor cytotoxic T-lymphocytes resulting in worsening GVHD. Donor-derived T lymphocytes received during pancreas transplant may have targeted the bone marrow, causing severe pancytopenia, hence compounding the dysregulated immune state. Transplant professionals should be aware of the possibility of the rare but challenging diagnosis of GVHD in PAK recipients and hence identify it appropriately.

PO2430
Association of the Rate of Kidney Transplant Function Decline with the Risk of Death After Graft Loss
Everly Ramos, Laura Binari, Peter E. Thorne, Gunet S. Kochar, Saed Shaur, Thomas G. Stewart, Heather L. Prigmore, Rachel C. Forbes, Khaled Abdel-Kader, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

Background: Patients with failed kidney transplants are at increased risk of death after graft loss compared to transplant-naive counterparts. We hypothesized that in this high risk population, a faster decline in eGFR in the 2yr prior to graft loss is associated with death after graft loss.

Methods: We retrospectively reviewed all patients with death censored graft loss of eGFR from 1995-2018 at a single center. We collected demographic, clinical and transplant characteristics at time of transplant and graft loss. Rate of eGFR decline was expressed as eGFR slope, calculated from all SCR values obtained within 2yr prior to graft loss. Cox proportional hazards regression was used to determine the association between rate of eGFR decline and death while adjusting for age, gender, race, cause of ESKD, cause of graft loss, dialysis access at graft loss, and nephrectomy after graft loss.

Results: 333 patients with DCGL were included. Baseline characteristics were: median age 45y (IQR 35.57), 59% male, 43% black; 19% DM as cause of ESKD. CAN (65%) and acute rejection (29%) were the top causes of graft loss at a median time from transplant of 4.9y (IQR 2.5,7.9). Rate of eGFR decline (in ml/min/1.73m²) was -14.49 ± 13.24 (means±SD) and -11.73 (-18.72,-6.19) (median, IQR). At time of DCGL, 46% had a history of acute rejection and 54% had a permanent dialysis access. Of the 251 patients without missing data, 97 (40%) died and 68 (27%) underwent a nephrectomy after graft loss. Median time from graft loss to death was 3.1y (IQR 1.47,7.3). In multivariable analysis, there was a 0.6% increase in risk in death for every 1 ml/min/1.73m² increase in rate of eGFR decline though not statistically significant (HR 1.006, 95% CI 1.00-1.01). Exploratory analysis with non-linear modeling of eGFR slope showed that the risk of
death increases up to a rate of decline of 10 ml/min/1.73m²/y. DM as cause of ESKD was associated with an almost 2-fold increase in risk of death after graft loss compared to non-DM (HR 1.95, 95% CI 1.27-2.96).

Conclusions: In this single-center cohort of kidney transplant recipients with DCGL, a faster rate of eGFR decline in the 2y prior to graft loss was not associated with a higher risk of death after graft loss after adjustment for important clinical variables.

PO2432
Renal Recovery After Liver Transplantation Alone in Patients with Liver Cirrhosis and Severe CKD with Normal Kidney Size
Suivan Jung. Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.

Background: Most guidelines recommend simultaneous liver-kidney transplantation (SLKT) in patients with liver cirrhosis (LC) and severe chronic kidney disease (CKD) over liver transplantation alone (LTA). CKD, however, is not irreversible. This study evaluates the reversibility of kidney disease after LTA based on kidney size.

Methods: In this single-center retrospective study, we classified 90 patients with LC and severe CKD into 3 groups: normal kidney-LTA (NK-LTA, n=39), small kidney [both <9cm]-LTA (SK-LTA, n=46), and small kidney-SLKT (SK-SLKT, n=11). Baseline characteristics and renal recovery and survival outcomes were compared among 3 groups.

Results: The NK-LTA group had a lower percentage of hepatocellular carcinoma, a higher pre-LT eGFR, and a shorter duration of eGFR at >60 ml/min and pre-LT dialysis. This group, however, was older, received livers from a higher percentage of deceased donors and had a higher Child-Pugh score. Renal recovery, defined as no hemodialysis (HD) after LT, was found in 79% of those in the NK-LTA group, which was higher than 75% of those in the SK-LTA group. Renal survival, defined as patient survival without progression to HD or kidney transplant was found in 56% of patients in the NK-LTA group, which was higher than 2.5% of those of the SK-LTA group.

Conclusions: Patients with LC and severe CKD with normal kidney size may experience reversible kidney disease after LTA. Therefore, kidney after liver transplantation is recommended over SLKT for these patients.

PO2433
Immediate Allograft Function After Liver Transplant (LT) Modifies the Effect of Pre-LT Renal Dysfunction (RD) on Post-LT Survival
Hani Wadei, Shennen Mao, Martin L. Mai, Naheel Aslam, Kristopher Croome. Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Background: Pre-LT RD is associated with higher post-LT mortality. It is unclear if immediate liver allograft function modifies this risk.

Methods: We retrospectively reviewed data on 2,856 primary LT performed in our center from 1998 to 2018. Pre-LT RD was defined as Cr≥1.5 mg/dl or on dialysis at LT. Immediate liver allograft function was defined using the validated early allograft dysfunction (EAD) criteria (bilirubina10 mg/dl, INR ≥1.6 or ALT/AST ≥2000IU/mL on POD 7). Pre-LT RD was present in 591(21%), of these 429 patients had Cr≥1.5 and 165 were on dialysis. EAD developed in 784(27%). The cohort was divided into 4 groups according to pre-LT RD and EAD. Group 1 (n=1,617): No RD and no EAD, Group 2 (n=643): No RD but had EAD, Group 3 (n=451): had RD and no EAD, Group 4 (n=140): had both RD and EAD. The unadjusted and adjusted post-LT survival was compared between the 4 groups.

Results: Results are presented in Figure 1. Group 1 had the best outcome with 1.3 and 5 year survival of 95%, 89% and 82%, respectively, and group 4 had the worst outcome with 1.3 and 5 year survival of 79%, 70% and 60%, respectively, P<0.0001. Group 2 and 3 had intermediate and comparable (P=0.5 between group 2&3) outcomes. Survival was better in group 2&3 compared to those in group 4 (P<0.001) but was worse than group 1 (P=0.02). After adjusting for recipient age, female gender, DM, MELD score, cause of ESLD and DRI, group 4 had the highest risk of death (aHR 2.33, CI 1.69-3.21, P<0.001). Patients in group 2 (aHR 1.16, CI 0.95-1.41, P=0.3) and group 3 (aHR 1.23; CI 0.96-1.58, P =0.09) had comparable adjusted risk of death to group 1 patients.

Conclusions: LT recipients with pre-LT RD who enjoy immediate liver allograft function have comparable adjusted survival to those with normal renal function at LT. Our results indicate that livers at higher risk of EAD should be avoided in LT recipients with RD.

PO2434
Sex and Equity in Pediatric Kidney Transplantation

Background: Mortality in pediatric kidney failure (ESRD) is higher in girls than in boys, in contrast to the general population. In a recent report, correcting for access to transplantation partiallyameliorated this risk, prompting an examination of equity in pediatric kidney transplantation.

Methods: USRDS files were used to examine incidence of pediatric ESRD (ages 18) and initial Rx modalities from 2000-15. UNOS data were used to evaluate pediatric kidney recipients between 2000-2019. Logistic regression was used to calculate an odds ratio (OR) for receiving a living donor kidney (LD). Hazard ratios (HR) of death, graft failure and death-censored graft failure (dGF) were obtained in Cox models stratified for LD/deceased-donor (DD). Models were adjusted for age, sex, and year of transplant and reported with 95% CI.

Results: Among 17,366 incident pediatric ESRD patients in USRDS, 42.8% were female. Mean and median age did not differ. Initial kidney treatment was transplantation in 17.9% of girls and 23.8% of boys, with more hemodialysis in girls (46.0 vs 40.5%, P<0.001). Among 16,811 UNOS recipients, 41.0% were female. Changes in allocation policy were associated with a shift from parental donors to deceased-donors, which was more marked in female recipients (figure), 42.8% of boys and 39.7% of girls received LD (P<0.001); adjusted OR of receiving LD was 0.91 (0.85, 0.98, P=0.007) for girls. Compared to boys, girls had inferior outcomes with DD, with HRs: death 1.51 [1.30, 1.76], graft failure 1.31 [1.21, 1.46], and dGF 1.30 [1.20,1.40, P<0.001 for all]. LD outcomes did not differ by sex.

Conclusions: Female children have fewer early transplants and higher odds of receiving DD kidney transplants that are associated with inferior outcomes than their male counterparts. Attention to sex-specific disparities may improve ESRD outcomes in girls.

PO2435
Outcomes of Emergency Department Visits of Children After Kidney Transplantation

Christian Hanna,1 Ashish Shah,2 Mark G. Roback,3 Priya S. Verghese,3 Ronald A. Furnival,1 *Mayo Clinic Minnesota, Rochester, MN; 2Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 3University of Minnesota, Minneapolis, MN; 4University of Colorado, Denver, CO; 5Northwestern University - Chicago, Chicago, IL

Background: Systematic data evaluating the postoperative Emergency Department (ED) care and outcomes of Pediatric Kidney Transplant (PKTx) recipients is limited. Our study objective is to identify the risk factors, disposition, and outcomes of PKTx recipients presenting to the ED.

Methods: We retrospectively reviewed the medical records of PKTx patients (<18 years of age) who presented to our University Children’s Hospital ED from 04/01/2011 to 06/30/2015. Data pertaining to patient demographics, chief complaint, evaluation, interventions, results, length of stay (LOS) and disposition were abstracted. Multiple logistic regression analysis was used to study the associations between admission, the presence of bacteremia, and multiple risk factors.

Results: During the study period, 60 of the 85 PKTx recipients (71%) presented to the ED for acute care (total of 210 visits, range 1-20; mean 3.5 per recipient). The majority (148/210, 70%) of the visits occurred in the first year following transplant. Fever (44%) and gastrointestinal complaints (27%) were the most frequent presentations. Mean ED LOS was 3.5 hours (range 0.22-10.8 hours). Most (109/210, 52%) visits resulted in hospital admission, for a mean inpatient LOS of 4 days (range 1-55 days). After adjusting for age and sex, the following risk factors were significantly predictive of hospital admission: shorter time since transplant (p=0.003), presence of fever (p=0.001), higher heart rate (p<0.001), higher white blood cell count (p=0.004), and presence of Systemic Inflammatory Response Status (SIRS) (p<0.001). Age adjusted systolic and diastolic blood pressure, type of transplant (deceased vs living donor), underlying primary kidney disease, the presence of a central line, or the number of immunosuppressant drugs were not predictive of hospital admission. Multivariate analysis of all significant risk factors found that shorter time since transplant and presence of SIRS were the only factors significantly associated with hospital admission (p<0.05). Only presence of SIRS was significantly associated with positive blood cultures (p=0.03).

Conclusions: Nearly-three-quarters of all PKTx recipients presented to ED most frequently in the first postoperative year, with over half requiring hospital admission. Shorter time since transplant and presence of SIRS were significantly predictive of hospital admission.

PO2436
The First Increase in Live Kidney Donation in the United States in 15 Years

Fawza Al Ammary, Allan Massie, Deidra C. Crews, Dorry L. Segev, Abimereki Muzzaale. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: After more than a decade of decline, the first sustained increase in live kidney donation was observed in the US from 2017 to 2019. Understanding these trends in donation may provide opportunities to effectively sustain or even enhance this recent increase in donors.

Methods: We conducted a national registry study of 35,900 donors (70.3% white, 14.5% Hispanic, 9.3% black, 4.4% Asian) to understand the increase in 2017-2019 vs. 2014-2016 using Poisson regression stratified by donor-recipient relationship (biologically related, unrelated, and kidney paired donors).

Results: Among biologically related donors aged ≥35, 35-49, and ≥50 years, the number of donors did not change across race/ethnicity but increased by 38% and 29% for Hispanic and black ≥50. Among unrelated donors <35, 35-49, and ≥50, white donors increased by 18%, 14%, and 27%; Hispanic donors <35 did not change but increased by 22% and 35% for 35-49 and ≥50; black donors <35 declined by 23% and did not change for 35-49 and ≥50; Asian donors did not change. Among kidney paired donors <35, 35-49, and ≥50, white donors increased by 42%, 50%, and 68%; Hispanic donors <35 and 35-49 increased by 36% and 55% and did not change for ≥50; black donors did not change; Asian donors <35 did not change but increased by 107% and 82% for 35-49 and ≥50.

Conclusions: The increase in live kidney donation was driven predominantly by unrelated and paired white donors. Donation among unrelated black individuals should be promoted.

Demographic Variability of Kidney Function in Live Donors: A Single-Centre Analysis
Tina Thomson, Andreas Kousios, Rawya Charif, Honeylet Orr, Harvinder K. Duklu, Marina Loucaidou. Imperial College London Department of Medicine, London, United Kingdom.

Background: Live donation is encouraged as better outcomes in transplant recipients. Donor assessment requires thorough evaluation but kidney function varies with demographics. We compare mGFR with the performance of eGFR formulas and creatinine clearances.

Methods: Analysis of 997 live donors between February 1995 and October 2019. Using pre-donation measured GFR(Te EDTA-GFR) as the gold standard, we compared the performance of CKD-MDRD(CKD – EPI(ml/min/1.73m2),24-hour creatinine clearance(Cr Cl) and Creatinine clearance by Cockcroft Gault(2CrCl(C/G)(ml/min)) between age, ethnicity, and gender. We also calculated the relative bias(mGFR-eGFR/mGFR), root mean square error and the accuracy(P30(eGFR between +30 and mGFR) of different eGFR equations.

Results: 422/423.32% males donors. 616(62%) Caucasian, 228(23%) South Asian. 114(11%) Afro Caribbean and 39(4%) of other ethnic groups(Arabic, oriental and mixed ethnicity). Mean mGFR was 100.08(SD 10.87). Mean mGFR for males and females were 105.77 ± 96.27, respectively(p=0.05). 63(6%) donors were >65 years. Mean mGFR comparing young and >65 years old donors were 103.44 ± 82.27, respectively(p=0.0028). As predicted, there is a linear decline in mGFR with increasing age. Cr Cl-C G has a tendency towards underestimating function in healthy living donors over 65 years old. GFR calculated by CKD-EPI formula was comparable to mGFR amongst all age groups, genders and ethnically diverse living donors. CKD-EPI performed better in terms of least bias and highest accuracy compared to MDRD for all donor subgroups(Table1).

Conclusions: mGFR declines with age and healthy older donors have significantly lower mGFR compared to younger donors. Cr Cl-C G overestimates kidney function and should be used with caution. eGFR by CKD EPI comes closest to compared to mGFR in all groups. It could be reliably used as first screening tool for assessing function of living donors pre donation, irrespective of age, gender or ethnicity.

Demographics & Comparative performances

Assessment of Kidney Function at 3 and 6 Months in Kidney Donors with Cardio-Metabolic Risk Factors
Jesus D. Lima Lacor, Rafael Valdez-Ortiz, L. M. Perez-Navarro, Ana G. Ortiga, Ernesto C. Lopez, Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

Background: Cardio-metabolic risk factors (CRFs) in kidney donors contribute to further deterioration of kidney function after donation, increase their post-donation cardiovascular risk. Objective: To assess the renal function of kidney donors with CRFs at 3 and 6 months after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center “Dr. Antonio Fraga Mouret” during the period from 2015 to 2019. Descriptive statistics were made. ANOVA with a 95% CI and a different eGFR equations

Results: 153 donors were admitted, 34% without social security, 59% women, with a mean age of 42.7 ± 10.7 years. The clinical and biochemical characteristics at hospital admission were: mean SBP / DBP was 106 ± 6 / 72.9 ± 5.4, BMI, 26.3 ± 3.2, proteinuria 124.6 ± 13.4, hemocrit 44.6 ± 4.9, albumin 4.1 ± 0.4, K 9.4 ± 0.6, Uric acid 5.4 ± 1.2, Total cholesterol 185.6 ± 34, triglycerides 156.5 ± 91.7, fasting glucose 91.6 ± 15.2, Creatinine 0.78 ± 0.14. The mean bleeding during surgery was 263.6 ± 447 mL, creatinine after surgery was 1.21 ± 1.8, upon release from hospital it was 1.13 ± 0.27. 72% of donors presented acute kidney injury (AKI) after surgery, with an average of 1.56 ± 1.8 days with AKI, 30% of donors released from hospital with AKI. More than 25% of kidney donors had 2, 3 and 4 CRFs. Figure 1 presents the comparison between groups (AKI vs No AKI) of creatinines at baseline, 3 months and 6 months.

Conclusions: A higher presence of CRFs is associated with higher AKI events after kidney donation. AKI patients during renal donation show a further deterioration of renal function at 3 and 6 months of follow-up. Timely interventions prior to donation could improve the evolution of this group of patients.
considered as HCV positive. The outcome of kidneys from HCVAb positive but NAT negative donors are unknown.

Methods: A national-registry-based retrospective cohort study was conducted using the SRTR data set. We identified all HCV negative recipients between April 1st, 2015 and March 2nd, 2018, who received kidney transplant from HCV Ab positive and NAT negative (D-HCVAb(+)/NAT(-); n=116) and HCV Ab negative and NAT positive (D-HCVAb(-)/NAT(+); n=25,574) donor kidneys. We then compared recipients’ estimated glomerular filtration rate(eGFR) at 6 months in matched cohorts, using combined exact matching (based on KDPI) and propensity score matching. We created two separate matched cohorts to examine differences in outcomes based on how HCV positive status is defined: for the first cohort, we used the allocation KDPI (where HCV is considered positive in D-HCVAb(+)/NAT(-)patients), while for the second cohort we used a modified KDPI, where the HCV component of KDPI was considered negative in D-HCVAb(+)/NAT(-)patients.

Results: The mean±SD age of the allocation KDPI matched cohort at baseline was 59±10 years, 69% were male, 61% and 30% of the patients were white and African American, respectively. The baseline characteristics of the recipients were well-balanced in both matched cohorts. Recipients’ eGFR at 6 months after transplantation was significantly higher in the D-HCVAb(+)/NAT(-) group compared to the D-HCVAb(-)/NAT(-) group (61.1±17.9 versus 55.6±18.8 mL/min/1.73m², p<0.011) in the allocation KDPI matched cohort, while it was similar (61.8±19.5 vs. 62.1±20.1 mL/min/1.73m², p=0.9) in the modified KDPI matched cohort.

Conclusions: Recipients who received HCVAb positive, but NAT negative donor kidneys did not experience worse 6-month eGFR than correctly matched D-HCVAb(-)/NAT(-) recipients. HCVAb positive, but NAT negative donor kidneys should not be allocated as HCV positive kidneys.

PO2443
Transplantation of Kidneys from Hepatitis C-Infected Donors to Hepatitis C-Negative Recipients: A Single-Center Experience

Background: Direct-acting antivirals (DAA) for Hepatitis (Hep) C have a 96-100% sustained viral remission (SVR) rate. This makes transplant of Hep C nucleic acid amplification testing (NAT)+ kidneys and treatment post-transplant feasible. We performed a prospective IRB approved trial at our center to validate the use and challenges of this approach.

Methods: Informed consent from eligible patients was obtained. Patients with chronic liver disease, dual organ transplants, HIV and active Hep B infection were excluded. Post-transplant, viral load was tested on day 3-5 and 7-10 and weekly thereafter until viremia was confirmed. All pts. were treated by hepatologist based genotype and insurance company preference. Standard of care immunosuppression protocols was used.

Results: 51 pts. got Hep C NAT+ kidney. The median age of the recipients was 58 years (range 29-72) and the mean wait time was 802 days (range 68-3073). Mean KDPI was 58.8 (range 27-94) with a median donor age of 38 years (range 21-56). Out of 16 implant biopsies, 13/16 (81%) had <5 %of sclerotic glomeruli, 14/16 (88%) had minimal interstitial fibrosis, and 15/16 (94%) had no arteriolar sclerosis. There was a 100 % transmission rate of Hep C. As of now, 46/51 (90%) have completed a 12-week course of DAA, and 45/46 (98%) have become RNA negative with 34/46 (74%) achieving SVR.

Conclusions: Transplantation of HepC NAT+ kidneys to Hep C negative recipients followed by treatment with DAA is a feasible option as a standard of care outside trials. Recipients should be monitored for Hep C related complications.

PO2444
Transplantation of Kidneys from Hepatitis C-Infected Donors to Hepatitis C-Negative Recipients: 1-Year Renal Allograft Outcomes
Miklos Z. Molnar,1,2 Ambreen Azhāt,1,2 Makoto Tsujita,1,2 Manish Talwar,1,2 Vasanthi Balaraman,1,2 Abdulshah Bhatta,1,2 Csaba P. Kovessy,2 Sathesh P. Nair,1,2 James D. Eason,1,2 Methodist Transplant Epidemiology Research Group 1Methodist University Hospital, Memphis, TN; 2The University of Tennessee Health Science Center, Memphis, TN.

Background: Transplant centers in United States are increasingly willing to transplant kidneys from HCV infected donors to hepatitis C negative recipients. Long-term renal outcome data of a non-prophylactic HCV treatment approach outside clinical trials is missing.

Methods: We examined 65 HCV negative recipients who received a HCV infected kidney transplant (HCV+) and 59 HCV negative recipients who received a HCV non-infected kidney transplant (HCV-) during 2018 in a single transplant center. We compared estimated glomerular filtration rate (eGFR), cumulative results of per-cause and surveillance protocol biopsies, development of de novo donor specific antibodies (DSAs), co-infection rates and patient and graft outcomes up to 1 year post-transplant between HCV+ versus HCV- groups.

Results: The mean±SD age of recipients was 52±11 years, 43% were female, 19% and 80% of recipients were Caucasian and African-American, respectively. Baseline characteristics were similar between the HCV+ and HCV- groups. The delayed graft function rate, estimated GFRs at post-transplant 3, 6, 9 and 12 months, cumulative rejection rate, development of de novo DSAs and co-infection rates were not statistically significantly different between the HCV+ and HCV- groups (Table).

Conclusions: Recipients of HCV-viremic kidneys have similar renal allograft function, incidence of rejection in the first year after transplantation compared to those who received HCV-non-viremic kidneys.

Renal graft and patient outcome of all kidney transplant recipients

Human Herpesvirus 8-Associated Kaposi Sarcoma Developing in a Kidney Allograft from a Hepatitis C-Positive Donor
Maria T. Story,1 M. Lee Sanders,1 Sreedevi koppisetti Jenigiri,1 Amani Bashir,1 Jude Longo,1 Elliot Grodstein,2 Christie P. Thomas,1 Daniel Katz,1 ’The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA; 2Donald and Barbara Zacker School of Medicine at Hofstra/Northwell, Hempstead, NY; 3Iowa City VA Medical Center, Iowa City, IA.

Introduction: Kaposi Sarcoma (KS) is an endothelial malignancy caused by the oncogenic virus Human Herpesvirus-8 (HHV-8) and transmission during kidney transplantation can occur. We describe two cases of donor-to-recipient transmission of HHV-8, with one recipient developing KS in the kidney allograft causing acute kidney injury (AKI).

Case Description: Donor: The donor died from complications of IV drug use and had known hepatitis C (HCV) at the time of organ donation. Recipient 1: 64-year-old male with ESRD, induction with basiliximab. He tested positive for HCV on post-transplant day 2 and was treated with sofosbuvir/velpatasvir for 12 weeks. Two months post-transplant, he developed encephalopathy and was found to have HHV-8 viremia during his workup. Immunosuppression was decreased, HHV-8 PCR levels were monitored and eventually were undetectable. He did not develop KS. Recipient 2: 71-year-old male with ESRD, induction with anti-thymocyte globulin. He was treated pre-emptively for HCV with glecaprevir/pibrentsvir. Five months post-transplant he was admitted for rising creatinine. Initial allograft biopsy was of poor quality but was suggestive of Banff IA

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
rejection; IV methylprednisone and anti-thymocyte globulin were administered. Repeat biopsy at 1 year of transplant revealed increased interstitial inflammation and tubulitis. A biopsy from a control kidney revealed metastatic KS. Immunosuppression was discontinued and he underwent allograft nephrectomy. He died at home 2 months later. Retrospective testing of samples prior to transplantation revealed the donor was HHV-8 PCR positive at the time of death and both recipients were HHV-8 antibody and PCR negative.

Discussion: We describe donor-to-recipient transmission of HHV-8 during kidney transplantation. HHV-8 associated post-transplant KS is well described but rare in the US. Post-transplant KS typically presents with classic skin lesions and kidney allograft involvement. This is the only case reported in the literature. Future interest is needed into this population to determine if post-transplant HHV-8 PCR monitoring or adjustments in immunosuppression are needed for kidney transplant recipients of HHV-8 increased risk groups.

PO2445

John Cunningham Virus (JCV) in Renal Allograft Recipients (RAR)

Bushra Z. Saleem, Sonitka Pur, Zahidul H. Mondal. Rutgers The State University of New Jersey, New Brunswick, NJ.

Introduction: Both JCV and BK virus belong to Polyoma virus (PV) family and can lead to opportunistic infection in RAR. BK nephritis in RAR is well described in literature (incidence 1-10%) in contrast to JCV nephropathy (JCVN) which is a rare entity. Here we describe two cases of JCV in RARs.

Case Description: Case 1: 44-year-old woman with PMH of HTN and ESRD received her first renal transplant in 2009 followed by antibody mediated rejection (AMR) resulting in graft dysfunction. She received a preemptive second renal transplant in 12/2015 followed by multiple RA biopsies within first few months due to elevated serum creatinine (s.cr). The biopsies showed borderline CMRs, acute AMRs and eventually chronic active AMR. Treatment regimen included steroids, rituximab, IVIG and plasmapheresis. Despite repeated treatments, her s.cr remained elevated leading to another biopsy in 6/2016 showing viral cytopathic changes suspicious for PVN. SV40 stain was negative as was serum BK titer. Immunosuppression (IS) was reduced and a biopsy was repeated in 8/2016 that stained positive for SV40. Given repeatedly negative serum BK, serum JCV titer was sent, which was positive and peaked at 350659 copies/ml on 9/2016. Titer improved to 66153 after 2 doses of Cidofovir however, later deteriorated to 33420. She had no neurological involvement. Despite Cidofovir, her renal function deteriorated rapidly requiring bilateral RAL nephrectomies with pathologic showing JCVN. IS was discontinued following which JCV titer became undetectable. Case 2: 59-year-old man with PMH of HTN and ESRD who received renal transplant in 4/2013 followed by baseline s.cr of 1.6 mg/dl. He was on Myfortic, Sirolimus and Prednisone for IS. He presented with rising s.cr in 9/2019 (2.1mg/dl). He underwent RA biopsy in 11/2019 showing viral cytopathic changes, positive SV40 consistent with PVN. BK by PCR resulted negative x 2 but JCV titer returned at 3896 copies/ml. Myfortic was discontinued. Repeat JCV titer trended down to 2630 in 3/2020. Further follow up was delayed due to COVID-19 pandemic.

Discussion: The diagnosis of JCVN is challenging and easy to miss. Index of suspicion should be high with positive viral cytopathic changes (+/- SV40 stain) on allograft biopsy and negative serum BK. Currently there is no definitive therapy for JCVN. Early diagnosis and reduction in IS are critical. Cidofovir may be of utility.

PO2446

Disseminated Adenovirus Treated with Brincidofovir in a Kidney Transplant Recipient

Tiffany Truong, Thanh Cao, Santhi Voora, Thin Thaw Min. University of Southern California, Los Angeles, CA.

Introduction: Adenovirus is a common viral infection, with which immunocompromised patients have an increased risk of disseminated disease. It is less frequently described in solid-organ transplant recipients and the optimal therapy for disseminated disease is unknown. We present a case of disseminated adenovirus in a kidney transplant recipient who was treated successfully with brincidofovir.

Case Description: A 56 year old female with ESRD of unknown etiology received her second kidney transplant from a deceased donor 2 years ago with thymoglobulin in immunosuppression. She presented one day of gross hematuria and right flank pain, as well as 2 weeks of malaise and 5 days of fever, cough, sore throat, nausea and vomiting. She had acute kidney injury with creatinine of 1.75 mg/dl from a baseline of 0.8 mg/dl. She was found to have adenovirus in urine (420,000 IU/ml) and serum. Other infectious etiologies were ruled out. Initial treatment consisted of reduced immunosuppression with discontinuation of mycophenolate mofetil and tacrolimus and increased prednisone from 5mg to 10mg daily due to leukopenia. Given disseminated symptoms, adjunctive treatment was also initiated with cidofovir 1mg/kg IV q48h alternating with IVIG 500mg/kg q48h. She received 4 doses of cidofovir and IVIG, with resolution of hematoma and adenovirus level in urine. Although she received hydration before and after cidofovir, creatinine rose to 2.04 mg/dl. With 2 additional cidofovir doses, she continued to have adenovirus level in urine. Although she received hydration before and after cidofovir, creatinine rose to 2.04 mg/dl. With 2 additional cidofovir doses, she continued to have adenovirus level in urine. Although she received hydration before and after cidofovir, creatinine rose to 2.04 mg/dl.

Discussion: The most commonly used adjunctive treatment to reduced immunosuppression in management of adenovirus infection is cidofovir. However, cidofovir is nephrotoxic and rarely cleared. This may limit its use, particularly in kidney transplant patients. Brincidofovir is less nephrotoxic due to decreased accumulation in proximal tubules, and may be better tolerated in kidney transplant recipients. We report a case of well tolerated brincidofovir treatment of disseminated adenovirus infection in a kidney transplant recipient who demonstrated clearance of infection and improvement in kidney function.

PO2447

Early Ganciclovir-Resistant Cytomegalovirus Infection in a Kidney Transplant Recipient: Could We Avoid It?

Introduction: Although uncommon, ganciclovir-resistant cytomegalovirus (GR-CMV) can lead to a therapeutic challenge given drug nephrotoxicity. Here we report a case of GR-CMV infection during early post-kidney transplant (KT).

Case Description: A 41-year-old woman with ESRD received the second KT in February 2019 with rATG induction. She also received rituximab one dose for pre-KT donor specific HLA antibodies. Maintenance immunosuppression are tacrolimus, mycophenolate sodium (MPS), and prednisone. Serum creatinine slowly trended down to the baseline of 1.3mg/dl at 3 month post-KT. CMV IgG serostatus was D+/R-. She received a 6-month CMV prophylaxis with a renally-adjusted dose of valganciclovir 450 mg twice weekly for 1 month, which was increased to 450 mg twice daily for 5 more months. 4 months after the CMV prophylaxis was completed, she developed asymptomatic CMV viremia with a titer up to peak of 47,643 IU/ml. Valganciclovir 900 mg twice daily was started and MPS was decreased. CMV PCR slowly decreased to 440 IU/ml after 1 month of therapy. Despite continuation of valganciclovir, CMV PCR became rapidly increased to 3,349 IU/ml [Figure]. A CMV genetic resistance test revealed a UL97, but not UL54 resistance. Flow cytometry was started and CMV PCR was decreased. Allograft function has been at the baseline.

Discussion: Our patient has several risk factors for GR-CMV including high-risk CMV serostatus, prolonged exposure to low-dose oral valganciclovir prophylaxis, and intensified immunosuppression including rituximab. Given current treatment for GR-CMV remains limited with drug toxicity, adequate dose of CMV prophylaxis is critical to avoid GR-CMV. Pattern of CMV PCR after initiation of therapy should also raise a suspicion for GR-CMV and genetic CMV resistance testing is paramount in early diagnosis. Novel preventive and therapeutic options may mitigate the risk of GR-CMV and drug-induced renal allograft toxicity.
Discussion: By inciting an inflammatory response due to direct cytotoxic endothelial cell damage, CMV infection may cause a procoagulant state. This can lead to potentially life-threatening end-organ infarction such as splenic infarction. To our knowledge, this is the first reported case of CMV infection in a KT recipient presenting with splenic infarction. A high index of suspicion for this association is warranted for early recognition and treatment of these potentially reversible conditions.

PO2449

BK Polyomavirus Nephropathy After Kidney Transplantation from HCV-Infected Donor to HCV-Uninfected Recipient

Faisal Abdulameer,1 Hisham N. Abu Farsak,1 Barry M. Wall,1,2 Miklos Z. Molnar,1 The University of Tennessee Health Science Center; Memphis, TN;2 VA Medical Center, Memphis, TN.

Introduction: BK polyomavirus (BKPyV) is an important cause of renal allograft dysfunction. We previously published the potential association of an increased risk of BKPyV DNAemia/nephropathy in kidney transplant recipients receiving Hepatitis C (HCV) infected donor transplantation. Here, we report severe BKPyV DNAemia/nephropathy in a recipient who received HCV infected donor transplantation, which was temporally associated with initial HCV treatment failure. This case report demonstrates the clustering of BKPyV DNAemia/nephropathy and severe BKPyV DNAemia/nephropathy, supporting the previous finding that transplantation from HCV-infected donors to uninfected recipients may be a risk factor of BKPyV DNAemia/nephropathy.

Case Description: A 62-year-old HCV negative African American male received a cadaveric kidney transplant from an HCV infected donor in January 2019, with immediate graft function. Laboratory results 4 weeks later indicated HCV PCR of 9,310,000 IU/mL, serum creatinine 1.62 mg/dL, and BKPyV DNAemia was negative. He received ganciclovir and peginterferon (March 2019) for a total of 12 wk. At completion of treatment, HCV PCR was negative. Evaluation 4 weeks later revealed HCV PCR level of 482,446 IU/mL, indicating initial treatment failure. While waiting for insurance approval for coverage of secondary direct acting antiviral (DAAs) regimen, he developed acute kidney injury 6 wk after HCV viremia, with serum creatinine peaking at 3.3 mg/dL along with a rapidly rising BKPyV DNAemia to >3,000,000 copies/mL. His immunosuppressive regimen was decreased. Allograft biopsy showed BKPyV nephropathy and proliferative glomerulonephritis (GN) with monoclonal IgG deposits. He was started on cidofovir, levofloxacin and intravenous immunoglobulin, followed by a course of sofosbuvir/velpatasvir/voxilaprevir and ribavirin for a total of 12 wk, achieving SVR at 12 wk. His BKPyV DNAemia slowly responded with 1,257,789 copies/mL at 6 wk of DAA treatment and 7,378 copies/mL at 12 wk. Serum creatinine gradually improved to 2.04 mg/dL. His 1 year protocol biopsy still showed tubulointerstitial inflammation, rare positive SMA staining, proliferative GN with improving monoclonal IgG deposits, indicating Banff borderline acute cellular rejection. His immunosuppressive regimen was intensified and graft function has remained stable.

Discussion: Our case report with close proximity of HCV treatment failure and severe BKPyV DNAemia/nephropathy supports the previous finding that transplantation from HCV infected donor kidneys to uninfected recipients may be a risk factor of BKPyV DNAemia/nephropathy.

PO2450

Cytomegalovirus-Associated Collapsing Glomerulopathy in a Renal Transplant Recipient

Chirag Lavani, Alexander J. Gallan. Division of Nephrology Medical College of Wisconsin, Milwaukee, WI.

Introduction: Cytomegalovirus (CMV) is a cosmopolitan virus that has long been recognized as a common cause of disease in transplant recipients. It can cause a variety of complications leading to impairment of renal allograft function. There are several possible manifestations of CMV nephropathy including interstitial nephritis, positive staining for CMV inclusions in glomerular cells, and collapsing focal segmental glomerulosclerosis. CMV nephropathy is an uncommon complication of CMV viremia following renal transplant but should be considered in the differential diagnosis of patients with CMV viremia and AKI.

Case Description: A 73 year old Caucasian male with history of ERUS due to collapsing glomerulopathy (CG) is a glomerular disease presenting with nephrotic syndrome and acute kidney injury (AKI), and showing collapse and sclerosis of glomerular capillaries with hypertrophic and injured podocytes on kidney biopsy. CG is most often seen in association with HIV infection and APOL1 nephropathy; however, CG can be associated with non-HIV viral infections. We describe a case of CMV-associated CG in a renal transplant patient.

Case Description: A 73 year old Caucasian male with history of ERUS due to collapsing glomerulopathy (CG) is a glomerular disease presenting with nephrotic syndrome and acute kidney injury (AKI), and showing collapse and sclerosis of glomerular capillaries with hypertrophic and injured podocytes on kidney biopsy. CG is most often seen in association with HIV infection and APOL1 nephropathy; however, CG can be associated with non-HIV viral infections. We describe a case of CMV-associated CG in a renal transplant patient.

Early Increase in Urinary Exosomal BK Virus MicroRNA as a Predictive Marker of BK Virus Nephropathy: A Prospective Kidney Transplantation Cohort

Won-Hye Cho,1 Su Woong Jung,1 Ju young Moon,1 Yang gyun Kim,2 Kyung hwan Jeong,3 Sangho Lee.1 Kyung Hee University Hospital at Gangdong Department of Orthopedic Surgery, Seoul, Republic of Korea; 2Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.

Background: Urinary exosomal bkv-miR-B1-5p was associated with BK virus (BKV) nephropathy (BKVN) in a cross-sectional study. However, its time-dependent post-transplantation changes and predictive value for BKVN have not been investigated.

Methods: We carried out a multicenter prospective cohort from which 83 kidney transplant recipients (KRTs) in South Korea (biopsy-proven BKVN [n=10], presumptive BKVN [n=12], and non-BKVN patients [n=61]) were selected for the measurement of urinary exosomal bkv-miR-B1-5p levels at 0.5, 3, 6, and 12 months posttransplantation.

Results: At 2 weeks posttransplant, urinary exosomal bkv-miR-B1-5p levels showed an increasing trend (non-BKVN < presumptive BKVN < biopsy-proven BKVN), while plasma BKV DNA levels were undetectable in all groups. Thereafter, both urinary exosomal bkv-miR-B1-5p and plasma BKV DNA levels peaked at 3 months posttransplantation and then decreased. Multivariable-adjusted Cox regression showed that urinary exosomal bkv-miR-B1-5p makes its predictive ability for biopsy-proven BKVN superior to that of plasma BKV DNA at 2 weeks posttransplantation.

Conclusions: Our results suggest that urinary exosomal bkv-miR-B1-5p can be used to identify the KRTs at high risk for BKVN at earlier time than plasma BKV DNA loads, enabling earlier intervention.

Discussion: BKVN is rarely described as having crescentic glomerular lesions, and if present, only one glomerulus per biopsy was affected. There are no reported cases of rapidly progressive glomerulonephritis in BKVN. In our case, we found crescent formation more frequently in 33% of glomeruli. Additionally, viral cytopathic changes uncommonly affect glomeruli, typically only involving parietal epithelial cells when present. We demonstrated viral infection of both parietal and visceral epithelial cells. Our case highlights a pattern of kidney injury not commonly seen in BKVN and supports that crescent formation can be caused by viral infection of the parietal epithelial cells.

Discussion: BKVN is rarely described as having crescentic glomerular lesions, and if present, only one glomerulus per biopsy was affected. There are no reported cases of rapidly progressive glomerulonephritis in BKVN. In our case, we found crescent formation more frequently in 33% of glomeruli. PO2453

Polyomavirus Nephropathy with Crescent Formation

Laura Binari, Meghan E. Kapp, Heidi M. Schaefer, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Polyomavirus reactivation in an immunosuppressed transplant patient may cause polyomavirus nephropathy (PVN). Classically seen as a pleomorphic tubulointerstitial inflammatory reaction to the virally infected tubular epithelial cells, there are few reports of glomerular viral tropism. We present unique histopathological findings of PVN including crescent formation with ultrastructural and immunohistochemical evidence of viral infection of glomerular epithelial cells in a kidney transplant recipient with acute kidney injury.

Case Description: A 52 y/o man s/p DDKT with well-controlled HIV presented with 2 weeks of worsening cough. He was diagnosed with multifocal pneumonia and disseminated CMV and VZV infection. His serum creatinine (SCR) and BK virus PCR were elevated to 3mg/dl (baseline 1.4-2.0 mg/dl) and 3.8M copy/mL respectively. He received ganciclovir and his immunosuppression was reduced. His pneumonia improved, but his BK PCR increased to 13.6M copy/mL and SCR remained elevated at 2.4 mg/dl. A renal biopsy showed a diffuse plasma cell-rich pleomorphic interstitial inflammatory infiltrate, tubulitis, and acute tubular injury. Viral cytopathic effect was evident and SV40 immunostain was positive in 60-70% tubular profiles, as well as parietal and visceral epithelial cells. EM revealed viral particles measuring 30 nm in diameter in tubular epithelial cells and a parietal epithelial cell. In addition, 7 of 21 total glomeruli had crescent formation with no GBM breaks or fibrinoid necrosis. There was no evidence of concomitant cellular or antibody-mediated rejection or CMV infection. These findings were indicative of PVN, with the rare finding of frequent crescents with glomerular epithelial cell infection.

Discussion: PVN is rarely described as having crescentic glomerular lesions, and if present, only one glomerulus per biopsy was affected. There are no reported cases of rapidly progressive glomerulonephritis in PVN. In our case, we found crescent formation more frequently in 33% of glomeruli. Additionally, viral cytopathic changes uncommonly affect glomeruli, typically only involving parietal epithelial cells when present. We demonstrated viral infection of both parietal and visceral epithelial cells. Our case highlights a pattern of kidney injury not commonly seen in PVN and supports that crescent formation can be caused by viral infection of the parietal epithelial cells.
PO2455
A First-in-Human Study of MAU868, a Novel Neutralizing Antibody Against BK Virus
Steven J. Kovacs,1 Johanna R. Abend,1 Xiaoying Xu,2 Sachin Desai,2 Amanda Nguyen,2 Laura M. Sterling,1 Michael R. Hodges,1 Peter Pertel,1 Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; Celerion Inc, Lincoln, NE; Amplyx Pharmaceuticals, Inc, San Diego, CA.

Background: Reactivation of BK virus (BKV) infection can cause significant kidney and bladder disease in immunocompromised patients. BKV nephropathy is a leading cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the BKV major capsid protein (VP1) with potent in vitro neutralizing activity against the 4 major BKV genotypes (IC50 ranging from 0.009 to 0.093 μg/mL).

Methods: MAU868 was administered i.v. (1, 3, 10, 30, and 100 mg/kg) or s.c. (3 mg/kg) to healthy adults in a randomized, placebo-controlled, blinded, single ascending dose design. Each i.v. cohort was 5 subjects (4 MAU868:1 placebo); the s.c. cohort was 8 subjects (6 MAU868:2 placebo). Subjects were observed for 24 h and followed for 106 d with routine safety monitoring and PK assessments. Ex vivo neutralizing activity of serum was measured before and 4 w after dosing. The range of doses included and exceeded the predicted clinically efficacious dose.

Results: 33 subjects completed the study. Adverse events were mild and infrequent; those occurring in more than 1 subject included nasopharyngeal pain (3, 9.1%), and injection site hemorrhage (ecchymosis after s.c. injection; 2, 6.1%). There were no infusion reactions. No subject discontinued the study due to an adverse event or developed anti-drug antibodies. MAU868 PK was typical of a human IgG with a half-life of 23 to 30 d. AUC and Cmax were dose-proportional, ranging from 9880 to 106000 μg·hr/mL and 24.7 to 2740 μg/mL (ie, no evidence of FcRn saturation). Day 29 plasma MAU868 concentrations, adjusted for extravascular distribution to estimate parenchymal exposure, were approximately 7- to 751-fold higher than the highest in vitro EC50 (0.093 μg/mL). Maximum ex vivo neutralizing activity of serum was achieved for doses >10 mg/kg. Bioavailability after s.c. injection was 57.6%.

Conclusions: MAU868 was safe and well tolerated with PK typical for a human IgG. The ex vivo neutralizing activity suggests where the therapeutic range may be for the treatment or prevention of BKV disease. These results warrant further clinical investigation of MAU868 in patients with or at risk for BKV disease.

PO2456
Induction with Alemtuzumab and Thymoglobulin in Kidney Transplant and the Risks of Leukopenia, Cytomegalovirus Infection, and BK Virus Nephropathy
Ali M. Zebi, Aria Ghahramani, Mujahed M. Dauleh, Nastrollah Ghahramani. Penn State College of Medicine, Hershey, PA.

Background: Induction immunosuppressive therapy at the time of kidney transplantation reduces the risk of allograft rejection and improves graft outcomes. We compared the association between induction with thymoglobulin and alemtuzumab on the risks of leucopenia, CMV infection, and BKV virus nephropathy.

Methods: We used TriNetX, a global federated research network that provides access to statistics on the electronic medical record (EMR). The Penn State Health TriNetX searchable database allows the analysis of approximately 1.7 million Penn State Health patient observations dating back to 1997. We analyzed the EMR of 1070 adult transplant recipients with routine safety monitoring and PK assessments. We compared the association between induction with thymoglobulin and alemtuzumab on the risks of leucopenia, CMV infection, and BKV virus nephropathy.

Results: Study cohorts included 220 patients (mean age: 57 ± 15) in the thymoglobulin group, and 160 patients (mean age: 54 ± 19) in the alemtuzumab group. Leukopenia occurred in 50 patients in the thymoglobulin group and in 70 patients in the alemtuzumab group (RR: 0.52; CI: 0.39 to 0.76; p<0.0001). CMV infection occurred in 80 patients in the thymoglobulin group and in 20 patients in the alemtuzumab induction group (RR: 1.45; CI: 0.89 to 2.39; p = 0.14). BKV virus nephropathy occurred in 20 patients in the thymoglobulin group and in 20 patients in the alemtuzumab induction group (RR: 0.72; CI: 0.41 to 1.31; p = 0.29).

Conclusions: Induction therapy with thymoglobulin is associated with a lower risk of leukopenia compared with alemtuzumab induction. The risks of CMV infection and BKV virus nephropathy are not statistically different in the two induction therapies.

PO2457
Effects of Early Conversion to mTOR Inhibitors on Viral Infections in Renal Transplant Recipients: Eight-Year Single-Center Experience
Waleed Hassan,1 Hisham Mostafa,2 ‘The University of Tennessee Health Science Center College of Medicine, Memphis, TN; ‘Minia Nephrology and Urology University Hospital, Minia, Egypt.

Background: Mammalian target of rapamycin inhibitors (mTORis) may decrease cytomegalovirus (CMV) and BK infection in renal transplant recipient. long-term effect of rejection rate deserves follow up.

Methods: This is a retrospective analysis of all patients who underwent living unrelated donor kidney transplantation at Nasr city Insurance and Nile Badrawy Hospitals from 2011 to 2018, panel reactive antibody zero and no donor specific antibody. Uni- and multi-variant analysis were done to compare between mTORis based regimen and cyclosporin inhibitors (CNI)-based regimen.

Results: We identified 1458 patients who underwent living unrelated kidney transplant with intermediate risk for CMV. All patients received Induction with anti-thymocyte globulin then were maintained on mycophenolate mofetil (MMF)+CNI-prednisone for at least 6 months. They were classified into two groups: * Group I: 658 patients on mTORis (sirolimus or everolimus), who were shifted from CNI to mTOR-I due to different causes. Group II: 800 patients on CNI (cyclosporin or tacrolimus). The overall incidence of CMV infection and BK infection (Table 1) were statistically significant lower in mTORis group compared to CNI group with no statistical differences in incidence of rejection in the first 36 month but late higher rate of BPAR (Table 2).

Conclusions: mTORis/MMF is associated with low incidence of CMV and BK infection with no significant difference in rejection rate in the first 36 months. However, further regimen modification is required to reduce late rejections.

PO2458
The Utility of Procalcitonin in the Management of Kidney and Pancreas Transplant Recipients with Suspected Infection
Sarah Gilligan, Fuaad S. Shihab, Divya Raghavan, Laith Al-Rabadi, Josephine Abraham, Isaac E. Hall. University of Utah Health, Salt Lake City, UT.

Background: Procalcitonin is used to differentiate between bacterial and viral infections to guide judicious use of antibiotics. It has not, however, been well studied in renal and pancreas transplant recipients. These patients are frequently exposed to antibiotics and are at risk for developing resistant infections. Thus, there is a need for reliable markers of bacterial infection. The purpose of this study was to compare procalcitonin levels in patients with and without bacterial infection to determine whether procalcitonin is a reliable marker of bacterial infection in the transplant population.

Infection Rate at 1 Year of Deceased Donor Kidney Transplant in the Elderly

Wina Yousman, Nicole Low, Wei Xiang Wong, Venkatesh Kumar Ariyamuthu, Bekir Tanriver. The University of Arizona, Tucson, AZ.

Background: There is limited publications about infection incidence rate in deceased donor kidney transplant (DDKT) recipients older than 65. The objective of this study is to examine our center specific infection incidence rate within one year of DDKT.

Methods: Retrospective chart review of DDKT (N=176) from July 2016 to December 2019 at Banner Medical Center in Tucson, AZ. Primary outcome was the infection incidence rate among recipients older than 65 year-old, including Cytomegalovirus (CMV) viremia and BK viremia (screened by monthly plasma PCR testing), or urinary tract infection (UTI) (diagnosed with positive urine culture and urinary symptoms within first year of transplant). We also fitted a multivariable logistic regression for the outcomes variables adjusted for demographics, KDPI, CIT, EPTS, and cPRA.

Results: The characteristics of the study cohort was shown in Table 1. Out of 176 patients, 63 patients (35.8%) were older than 65 year-old. There was no significant difference in the incidence rate of total infection, CMV viremia, BK viremia, and UTI in the elderly versus non-elderly patient (0.3% vs 51.3% p=0.11, 20.6% vs 11.5% p=0.10, 15.9% vs 11.5% p=0.41, 32.3% vs 28.3%, p=0.59). The multivariable logistic regression analysis (adjusted for ethnicity, KDPI, EPTS, cPRA, and CMV mismatch) did not show increased odds of all types of infection among older recipients.

Conclusions: The infection rate of elderly versus non-elderly who received DDKT were similar.

Table 1: Baseline Characteristics and Outcomes of Elderly vs. Non-elderly

PO2460

Two Deaths of Acute Transplant Patients from Strongyloides Hyperinfection Syndrome (SHS): Can We Prevent Harm with Screening and Prophylaxis at the Time of Transplantation?

Background: A 59 year old Vietnamese man presented with non-specific abdominal pain 8 weeks after a deceased donor kidney transplant. He was thoroughly investigated and no cause for the pain identified. On day three of the admission he became febrile and hypoxic. He died with multi-organ failure. Within three months a patient of Congolese origin presented nine weeks post transplant with abdominal pain. He became febrile with gram positive bacteraemia and was admitted to the ICU with type 1 respiratory failure where he unfortunately died. Autopsy findings revealed SHS. These cases were patients at a transplant centre in a non-endemic area albeit with an ethnically diverse population. A survey of other UK transplant centres showed that none did pre-transplant screening for strongyloides infection.

Methods: As a result of these cases we implemented and evaluated a program to screen for and prophylactically treat Strongyloides infection: Live donor patients were screened with Strongyloides serology in advance of transplantation. All recipients of deceased donor transplants were screened on admission for their transplant unless they had never travelled to an endemic area. At induction recipients received a weight adjusted dose of Ivermectin pending serology results. If positive a second prophylactic dose was administered at day 14. Travel histories and demographic data were recorded.

Results: Between July 2019 and March 2020; 135 patients were transplanted at our unit. Of those 125 had strongyloides serology testing; eight were positive at time of transplant. In an additional patient reported as “borderline”, the further patient tested positive on a previous admission for a transplant which was cancelled; but was negative on the admission of the successful transplant. This indicates that at least 8% of our transplant listed patients are positive for strongyloides infection. By May 2020 there were no recorded deaths due to SHS, or morbidity associated with strongyloides infection in this group.

Conclusions: We have demonstrated that there is a significant level of sero-positivity within our pre-transplant population and that a relatively low-cost strategy may help prevent the potentially fatal Strongyloides Hyperinfection Syndrome.

PO2461

Infectious Complications and Malignancy After Kidney Transplant in the Elderly Population

Luz E. Liriano-Ward, Yorg Al Azzi, Cindy T. Pynadath, Maria Ajaimy, Pablo Lorette Campos, Purna Bindu Nandigam, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: Kidney transplantation improves quality of life and survival in all patients regardless of age. However, older patients are prone to development of side effects related to immunosuppressive medications including infections and malignancy. We aim to evaluate clinical outcomes in recipients >65 years of age.

Methods: We retrospectively reviewed all patients over the age of 18 who received an isolated renal transplant at our center from January 2013 to June 2017. We compared clinical outcomes including allograft and patient survival, as well as the development of infections and malignancy in patients > 65 compared to younger patients.

Results: Out of 624 patients analyzed, 148 (24%) were > 65 years of age. There was no difference in terms of gender, race, immunosuppressive or induction therapy between the two groups. Older patients were more likely to receive a deceased donor kidney transplant (92% vs. 81%, p=0.009). During a median 48 months (28, 70) of follow-up, as expected mortality was higher in older patients (16% vs. 6.5%, p=0.0001) but there was

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
no difference in terms of death-censored graft loss (10.8% to 9%, p=0.52) compared to younger patients.  Detailed analysis of infections revealed that there was no difference in terms of BKV and CMV viremia, pneumonia, bacteremia, influenza and c. diff between the two groups. However, older patients were more often with fungal and urinary tract infections and malignancy. The most common infection in the elderly was PJP pneumonia (4%), candidemia (3%), and cryptococcal infection (2%). The most common malignancy in the elderly was skin cancer (6%) followed by prostate (2%), lung (1%), and colon (1%).

**Conclusions:** Recipients older than 65 had similar graft survival compared to younger patients, but had a higher incidence of fungal and urinary tract infections and malignancies.

**Results:** The number of matched 7,462 subjects (total 22,386) were included to each study groups. During median 3.57 years of follow-up duration, the incidence rate for active-TB was 3.92/1,000, 4.38/1,000, and 0.67/1,000 person-years in the KT, dialysis, and general population groups, respectively. The KT group showed a significantly higher risk of active-TB than the general population group [adjusted HR 3.39 (1.88-6.12)] but a similar to the dialysis group [adjusted HR 0.98 (0.73-1.31)]. Active-TB was a significant risk factor for death [adjusted HR 2.24 (1.19-4.42)] or death-censored graft failure [adjusted HR 2.21 (1.36-3.58)] in the KT patients.

**Conclusions:** In Korea with moderate TB prevalence and active surveillance strategies, KT patients may not have to burden additional risk of active-TB when compared to dialysis patients. Still, clinical attention for active-TB complication should not be overlooked in end-stage kidney disease patients, particularly for KT patients as active-TB was associated with worse post-transplant prognosis.

**PO2464**

**Risk of Active Tuberculosis Infection in Kidney Transplantation Recipients: A Matched Comparative Nationwide Cohort Study**

Sehoon Park,1 Ji Eun Kim,2 Mi-yeon Yu,1 Yong Chul Kim,3 Dong Ki Kim,1 Kwon Wook Joo,1 Youn Su Kim,2 Kyungdo Han,3 Hajeong Lee,3 Armed Forces Capital Hospital, Seongnam, Gyeonggi-do, Republic of Korea; 3Seongil University, Dongjak-gu, Seoul, Republic of Korea; 4Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 5Hanyang University Guri Hospital, Gyeonggi-do, Republic of Korea; 6Kyungpook National University, Guro Hospital, Seoul, Republic of Korea.

**Background:** Although the risk of *mycobacterium tuberculosis* (TB) infection is high in both kidney transplantation (KT) recipients and dialysis patients, a large-scale evidence comparing the risk between the two groups in a nation with moderate or higher TB prevalence was rare.

**Methods:** We performed a nationwide retrospective cohort study based on the claims database of South Korea where moderate TB prevalence is reported. We included incident KT recipients from 2011 to 2015 and compared their active-TB risks with matched controls. The 1:1 matched general population group was matched for age, sex, and era, while the dialysis group was matched for age, sex, era, underlying hypertension, and diabetes. We excluded the matched pairs with age < 20 years old, a previous TB history, and those matched to a multi-organ transplantation case. The incident active-TB risk was assessed by the multivariable Cox regression analysis. Within KT group, associations between active-TB, as a time-dependent variable, and post-transplant death or death-censored graft failure was investigated.

**Results:** The incidence of complications >3- to 8-years post-KTx, according to 3xs Regimen and HCQ Use (7-12 mos).

**Conclusions:** HCQ is an inexpensive immunomodulatory agent that may be used safely in selected KT recipients as an alternative or adjunct to standard immunosuppression.

**PO2465**

**Hydroxychloroquine as an Alternative or Adjunctive Antimetabolite in Kidney Transplant Recipients: Analysis of Linked US Registry and Claims Data**

Krista L. Lentine,1 Tarek Alhamad,2 Huiling Xiao,1 Mark Schnitzler,1 Su-Hsin Chang,2 Yasar Caliskan,3 David Axelrod,3 Daniel C. Brennan.4 1Armed Forces Institute of Pathology, Washington, DC; 2Edward M. Kennedy Institute, Boston, MA; 3Saint Louis University, St Louis, MO; 4Washington University in Saint Louis, Saint Louis, MO; 5University of Iowa, Iowa City, IA; 6Johns Hopkins University, Baltimore, MD.

**Background:** Hydroxychloroquine (HCQ) is an antimalarial drug with immunomodulatory effects in patients with systemic lupus erythematosus (SLE) and scleroderma. The potential anti-viral effects of HCQ have raised attention in the context of the COVID-19 pandemic, although safety is controversial.

**Methods:** We examined a novel database linking national transplant registry identifiers for kidney transplant recipients (KTs) to records from a large U.S. pharmaceutical claims warehouse (2008–2017) and Medicare claims to study HCQ use among Medicare beneficiaries with kidney failure due to SLE or scleroderma (N=2,550). We compared 3 groups based on immunosuppressive regimen 7–12 mos. post-KTx: 1) Tac+HCQ+MPA+Pred; 2) Tac+HCQ+Pred; and 3) Tac+HCQ+MPA+Pred. Associations of regimen with graft failure, death and clinical cardiovascular complications captured in Medicare claims >1-to-3 yrs post-KTx were examined with multivariate Cox regression, adjusted for baseline factors in the registry.

**Results:** Among the study sample, 18.3% received Tac+HCQ+MPA+Pred; 7–12 mos. post-KTx, while 1.7% received Tac+HCQ+Pred. Use of HCQ containing regimens was more common in women (vs men), and Black and Hispanic (vs white) recipients; use of Tac+HCQ+MPA+Pred was more common in younger patients (vs older) patients (Table). The unadjusted incidence of adverse events did not differ across the 3 groups (Fig A); risks also did not differ with covariate adjustment (Fig B).

**Conclusions:** HCQ is an inexpensive immunomodulatory agent that may be used safely in selected KT recipients as an alternative or adjunct to standard immunosuppression.

748
globulin induction, and maintenance tacrolimus, mycophenolate, and prednisone. Two months later, he presented with diffuse violaceous papules (Figure 1A). Biopsy of a papule with Wartthin-Starry stain showed clusters of bacteria suggestive for BA (Figure 1B). Diagnosis was confirmed with a positive serum Bartonella polymerase chain reaction (PCR). He was treated with doxcycline with resolution of symptoms. BH and BQ Immunglobulin G (IgG) were equivocal. A few weeks later, IgG for BH was 1:256 (reference range <1:128). Echocardiogram, abdominal computed tomography, and kidney biopsy were unremarkable. Recipient Bartonella PCR and antibodies on the day of transplant were negative. Donor Bartonella PCR and BH IgG were negative. Donor BQ IgG was equivocal. The recipient had a cat 8 years prior to KT without recent exposure. Allograft function remains intact, and the rash completely resolved. Bartonella PCR 6 months on treatment was negative.

Discussion: Our patient developed signs of BA with positive seroconversion within the first 3 months of KT which is rare. BA should be considered in the differential diagnosis of fever and cutaneous angiomatous-like lesions in KT recipients, even in the absence of exposures. Combined serology and molecular testing (PCR) is useful in diagnosing BA as serology alone may be unreliable. Early empiric treatment should be considered in transplant recipients while waiting for confirmatory results.

Figure 1. (A) Violaceous papules on the trunk. (B) Wartthin-Starry stain showing bacteria (arrow).

National Trends in Kidney Transplantation Among Patients with ESKD from Plasma Cell Dyscrasias

Jia Huei Ng,1,2 Stephanie Izard,1 Kenar D. Jhaveri,1,2 Vinay Nair,1,2 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 1Northwell Health, Great Neck, NY.

Background: Due to relapses and kidney involvement, plasma cell dyscrasias have been a relative contraindication for kidney transplantation. With newer medications and improved prognosis of plasma cell dyscrasias, kidney transplantation in this population is becoming more common. We aimed to describe national trends in the proportion of kidney transplants among patients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Methods: We used data from the United Network for Organ Sharing1/ Organ Procurement and Transplantation Network (UNOS/OPTN) database. Patients 18 years or older, BMI >15 or <45 kg/m2 not having a preference for organ type, with plasma cell dyscrasia (PCD) were included. Survival of 26-47 months. Lack of response to first line therapy is considered the dominant prognostic factor. Early recognition and diagnosis remain crucial for improving outcome.

Results: A total of 160,966 patients received a first kidney transplant. Among these, 487 (0.3%) had ESKD and kidney transplants among patients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Table 1. National trends in kidney transplantation among patients who had end-stage kidney disease from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Conclusions: Despite improvement in treatment of plasma cell dyscrasias, national trends show only a small rise in the proportion of kidney transplantation for patients with ESKD from plasma cell dyscrasias. Additional analyses are needed to assess the outcomes of these kidney transplant recipients.

PO2470

A Retroperitoneal Cyst of Pancreatic Origin in a Renal Transplant Recipient: Expect the Unexpected

Muhammad Q. Saleem,1 Ambreen Chughtai,1 Imran Y. Gani,1 Muhammad I. Saeed,1 Rajan Kapoor,1 1Augusta University, Augusta, GA; 2FMM College of Medicine and Dentistry, Lahore, Pakistan.

Introduction: The immunosuppression required to maintain a renal allograft function puts the recipient at a higher risk of malignancy. We report a rare case that presented a diagnostic dilemma with a retroperitoneal hemorrhagic cystic tumor turned out to be an adenocarcinoma of pancreaticobiliary origin.

Case Description: A 57-year-old woman with PMH of ESRD x/p kidney transplant (D+/R-, E-), with chronic ChEI of 30-40% presented with paroxysms and numbness over the right side of her body with mild ataxia 2 years post transplant. Physical exam revealed only numbness over the right side of body. MRI with contrast revealed a left thalamic lesion with moderate vasogenic edema, and MR spectroscopy confirmed high grade neoplasm involving left thalamus. Stereotactic biopsy showed polymorphic CD-20 and EBV positive PTLD. EBV PCR were elevated. Further evaluation ruled out systemic PTLD. Myectomy was stopped and oral steroids started with mild improvement in symptoms. Choice of systemic chemotherapy was limited due to reduced ChEI and risk of graft failure. She received modified regimen with re-titrated high dose Methotrexate, Vincristine and Rituximab for 6 cycles with partial remission and then Tenozolomide for 7 cycles with complete remission.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV driven. PTLD is a monoclonal cell neoplasms. PCNs-PTLD has a higher incidence in renal SOT, occurs late and is usually monomorphic unlike our patient. Median time of occurrence is 4-5 years after transplant. Risk factors include age, intensity of immunosuppression, time to transplant and EBV status of donor and recipient. Common presenting features include neurological deficits, seizure, and raised intracranial pressure. MRI is the preferred imaging and shows multifocal, ill defined, ring enhancing lesions usually in supratentorial and lobar regions. Positive EBV PCR is highly suggestive but biopsy remains the gold standard for diagnosis. Treatment modalities include reduction of immunosuppression, rituximab, high dose methotrexate, cytarabine and cranial radiotherapy. Use of high dose methotrexate has shown improved outcomes with median survival of 26-47 months. Lack of response to first line therapy is considered the dominant prognostic factor. Early recognition and diagnosis remain crucial for improving outcome.

PO2471

Secondary Malignancy in Kidney Transplant Recipients: University of Southern California Experience

Alexandra K. Wong, Tiffany Truong, Poorva Vaidya, Gino In, Thin Thinh Maw, Keck Hospital of USC, Los Angeles, CA.

Background: Kidney transplant recipients (KTR) on immunosuppressive therapy are at higher risk of developing secondary malignancy (SM). Although previous studies have demonstrated this increased risk, much remains to be elucidated regarding the spectrum of SM and the contributing factors to morbidity and mortality.

Methods: We conducted a retrospective review of all KTR from April 2005 to December 2017 at our institution. We then selected only those patients with SM, and collected demographics, variables related to kidney transplant, malignancy, and outcomes.

Results: Among 1414 KTR, 84 patients (pts) had post-tx SM. Forty-five percent of pts were Hispanic, 35% Caucasian, 11% Asian and 6% African American. Twenty-four pts (28%), 11 pts (13%), and 51 pts (59%) developed cutaneous malignancy, hematological malignancy and solid organ malignancy (SOM) respectively. One patient developed both a secondary cutaneous and SOM, while another pt developed 2 different SOM. 46 (55%) pts were deceased by 1/1/20: 25 pts died from malignancy and 9 pts died from infection. Among those 46 pt, 37 pts (80%) had intact graft function at death. Eleven pts (13%) had malignancy prior to tx. The induction was ATG (36%) and basiliximab (41%). 20 pts had biopsy-proven acute rejection; of these 75% was prior to and 25% was post cancer diagnosis. 18 pts were switched to mTOR inhibitor from tacrolimus and celacipt was stopped in 22 pts.

Conclusions: We describe a wide range of SM among a diverse population of KTR, with nearly half of our patients being Hispanic. This highlights the need for further investigation of the impact of ethnicity on SM. Among our KTR, SM was the cause of death for 25 pts and infection was for 9 pts. Regardless of etiology, the majority of pts (80%) had intact graft function at death. Our findings illustrate the need for vigilant cancer screening and additional strategies to decrease cancer risk and death in KTR.

PO2472

Spectrum and Consistency of Cancer Outcomes in Randomized Trials in Kidney Transplant Recipients: A Systematic Review

Eric J. Ng,1 Allison Tun,1,2 Genevieve Wong,1,2 Jonathan C. Craig,1 1The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; 2Children’s Hospital at Westmead Centre for Kidney Research, Sydney, NSW, Australia; 3Flinders University College of Medicine and Public Health, Bedford Park, SA, Australia.

Background: Cancer is an important cause of morbidity and mortality in kidney transplant recipients. Despite being described as a critically important outcome by patients, caregivers and health professionals, inconsistency in how cancer outcomes are defined and reported in trials of kidney transplant recipients may limit decision-making. The aim of this study was to assess the spectrum and consistency of cancer outcomes in trials involving kidney transplant recipients.

Acute Rejection and Graft Failure in a Kidney Transplant Recipient with Malignant Melanoma and Treated with Pembrolizumab: A Case Report

Annalise M. Panthofer, Kurtis J. Swanson, Didier A. Mandelbrot, Neetika Garg, University of Wisconsin School of Medicine and Public Health, Madison, WI.

Introduction: Malignancy treatment with immunotherapy in renal transplant recipients is complicated by a high risk of rejection. Immune checkpoint inhibitors increase immune recognition and destruction of immune-evading cancer cells. This can lead to an overly robust immune response leading to allograft injury and failure. Here we present a case of graft failure due to rejection within a week of starting immunotherapy.

Case Description: 73-year-old female with a history of end-stage renal disease attributed to hypertensive nephrosclerosis underwent live unrelated kidney donor transplant and presented 6 months post-transplant with a right foot lesion and was diagnosed with stage IIIIC malignant melanoma. Her maintenance immunosuppression was decreased from tacrolimus/prednisone to prednisone monotherapy and the lesion was excised. 14 months later, disease surveillance via PET scan revealed metastatic disease. After carefully weighing the risks of mortality without treatment versus graft rejection, pembrolizumab, a programmed cell death one (PD-1) inhibitor, was initiated. 5 days after administration of the first dose, the patient presented emergently with acute kidney injury with Cr of 4.3 mg/dL, increased from baseline Cr of 0.9-1.0 mg/dL. Ultrasound of her graft demonstrated significant edema and graft thrombosis. Allograft biopsy was consistent with 95% cortical necrosis with thrombotic microangiopathy and grade III acute cellular and antibody mediated rejection. Transplant nephrectomy was performed on day 7 and HD was re-initiated.

Discussion: Immune checkpoint inhibitors have been shown to be effective treatments for certain malignancies (melanoma, renal cell carcinoma) namely; however, they can cause acute rejection and graft loss in transplant recipients. Though PD-1 inhibition has been a major scientific breakthrough in late-stage cancer treatment, its risk profile should be carefully considered in organ transplant recipients due to high risk of graft rejection. Prevention and management of rejection in a transplant recipient with an aggressive melanoma such as ours is not clear.

PO2474
Renal Transplant Recipients Suffer Significantly More Complications After Breast Cancer Surgery but Benefit from Treatment at Transplant Centers

Ankur P. Choubey,1 Afshin Parsikia,2 Maria Castaldi,2 Rifat Latifi,3 Jorge Ortiz,3
1The University of Toledo Medical Center, Toledo, OH; 2Westchester Medical Centers, New York, NY; 3Miami, Miami, FL

Background: Breast Carcinoma has the highest incidence of any cancer in adult females. The impact of kidney transplant (KT) on breast cancer surgery has not been examined. Our objective was to evaluate the influence of a previous KT on the short-term outcomes of mastectomy or lumpectomy.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. Population included adult females with kidney transplant and surgically treated for breast malignancy. Weighted multivariate regression models were employed to compare outcomes at transplant and non-transplant centers.

Results: 598 women met the inclusion criteria. There was a greater proportion of African-American (p<0.001), and Hispanic women (p=0.01) compared to the cohort. KT recipients had more comorbidities and higher Eluxhauser Comorbidity Index scores (p<0.001). We noted longer length of stay (p<0.001), higher expenditure (p<0.001), and complications (p<0.001). Specifically, rates of hematoma (p=0.041), acute renal failure (p=0.001), blood transfusion (p=0.001), fresh frozen plasma transfusion (p=0.001), cardiovascular (p=0.001), and other complications (p=0.012) were increased. There was no mortality among transplant recipients. Weighted multivariate analyses highlight that rates of complication (p<0.001), and length of stay (p<0.001) are lower at transplant centers.

Discussion: Cancer is one of the most important outcomes for patients post-transplantation, but cancer outcomes are very poorly defined and highly variable in KT recipients. A core outcome for cancer for all trials in kidney transplant recipients should be developed that is consistent and meaningful to patients and clinicians.

Funding: National Cancer Institute - U.S.

PO2475
Local Renal Graft Irradiation as Salvage Treatment for Renal Graft Rejection Secondary to Checkpoint Inhibitor: A Case Report

Edgar A. Acuna-Morn, Oscar A. Garcia Valencia, Javier Pagan, University of Miami, Miami, FL.

Introduction: Graft rejection after treatment for malignancies with checkpoint inhibitors targeting the CTLA-4 and the PD-L1 pathways has been a growing interest in recent years since the rates of graft rejection are high as 33.3% with a median time to rejection of 8 days. To the best of our knowledge, there are no prior case reports of a renal transplant patient with stage IV gastric adenocarcinoma treated with pembrolizumab (a PD-1 inhibitor) who developed graft rejection and required local irradiation.

Case Description: This is a 65-year-old male with history of ESRD secondary to IgA nephropathy, chronic Hepatitis B and related donor kidney transplant who was diagnosed with gastric malignancy with peritoneal carcinomatosis and outlet obstruction after 12 years of transplantation. Gastric adenocarcinoma was HER2 equivocal, FISH negative, MMR deficient, PD-L1 positive. Initial therapy included discontinuation of Tacrolimus, steroid monotherapy. Initial chemotherapy included 2 cycles of FLOT followed by ramucirumab. After finding disease progression at 6 months, he received a salvage chemotherapy with pembrolizumab. Two weeks after, presented to the ED with anuria AKI. A Mag-3 scan demonstrated good perfusion and a kidney biopsy showed cortex coagulative necrosis. High dose steroids and sirolimus were given with no response and required initiation of hemodialysis. In the following weeks, presented to the ED complaining of gross hematuria and clots. Cystoscopy with bladder biopsy was performed and showed no bladder injury and normal mucosa. The hematuria was found to be secondary to kidney graft rejection and he was started on high dose of steroids with mild improvement. Nephrectomy was not an option due to poor nutritional status and overall health condition. Palliative radiation therapy to the kidney was the only option for immunosuppression. He received local graft irradiation of 7.5 Gy in 5 fractions with resolution of hematuria.

Discussion: The case illustrates first, that the use of checkpoint inhibitors in patients with kidney transplant convey a high risk of severe irreversible allograft rejection and can occur after only one dose. Second, the viability of palliative radiation as a non-surgical option for acute kidney graft rejection causing symptomatic hematuria resistant to conventional immunosuppressant therapy.
A Rare Presentation of Disseminated Nocardia in a Kidney Transplant Recipient
Ruchi Haik, Saed Shawar, Heidi M. Schaefer, Vanderbilt University Medical Center, Nashville, TN.

Introduction: Nocardiosis is a very rare infection caused by the Nocardia asteroides bacterium. It most commonly involves the lungs but can spread to other areas of the body and is more likely to infect immunosuppressed patients. We report a case of a kidney transplant patient who presented with a tender lump of his right shoulder.

Case Description: Patient is a 58 year old African American man with a history of ESRD due to hypertension and reduced kidney mass status post right radical nephrectomy for renal cell carcinoma in 2001. He underwent deceased donor kidney transplant in May 2017 after being on dialysis for 13 years. He received alemtuzumab and methylprednisolone prednisone for induction followed by maintenance immunosuppression with Tacrolimus, mycophenolate mofetil and prednisone. In January 2020, he presented to the orthopedic clinic with a 10-day history of pain in a soft tissue mass of the right scapula and was diagnosed with a parascapular muscle tear. One week later he presented to an outside hospital with fevers and CT of chest showing pulmonary nodule with satellite lesions in the RUL concerning for malignancy. He was transferred to our hospital where PET CT scan showed multiple intensely FDG avid masses in the lungs, brain, cecum and soft tissue inferior to the right scapula concerning for malignancy. Core tissue biopsy from the right scapular region was negative for bacterial or acid-fast bacilli stain but showed gram positive beaded rods identified as Nocardia. He was initially treated with intravenous sulfamethoxazole/trimethoprim and intravenous meropenem and then based on susceptibility transitioned to intravenous ceftaroline and oral sulfamethoxazole/trimethoprim. A follow-up MRI two months from diagnosis showed marked improvement in all lesions and he was transitioned to oral doxycycline to complete at least 12 months of therapy.

Discussion: Nocardiosis can present in unusual fashion in transplant recipients and one should have a high suspicion in patients who present with fever and disseminated lesions on imaging with plan for biopsy and culture of tissue early. In most cases, Nocardia can be treated successfully with appropriate antibiotics.

Hypercalcemia Associated with Pneumocystis jirovecii Pneumonia in Renal Transplant Patients

Introduction: Pneumocystis jirovecii pneumonia (PJP) is a common complication following solid organ transplantation with an estimated incidence of 5-15%. Although previously reported, hypercalcemia is not classically a sign of PJP. In the past 6 months at our institution, there have been six cases of PJP presenting with varying degrees of hypercalcemia.

Case Description: All patients in the table below presented with signs and symptoms concerning for pneumonia and were diagnosed with PJP by DFA and/or PCR from induced sputum or bronchoscopy. Patient demographics, labs, and calcium trends are outlined in the table. All patients were treated with Bactrim and prednisone for PJP (some later converted to alternative therapy); patients 1 and 2 were also given intravenous fluids and calcitonin specifically for treatment of their hypercalcemia. Patient 6 was initially thought to have aspiration pneumonia but was hypercalcemic on presentation. Because of our experience with the previous patients, when we noted elevated 1,25 dihydroxyvitamin D (1,25(OH)2 VitD) and low PTH level, and his sputum was positive for PJP by DNA PCR.

Discussion: PJP occurs in 5–15% of KTRs without prophylaxis with significant morbidity and mortality. A timely diagnosis is challenging given its indolent presentation. Since hypercalcemia can occur in 20-30% of cases during early stages of PJP from increased production of 1,25(OH)2 VitD via 1-alpha-hydroxylase from alveolar macrophages, its presence should alert clinicians of its diagnosis. In 2019, 2 out of 5 PJP cases at our center had hypercalcemia at least 2 weeks prior to PJP diagnosis with high 1,25(OH)2 VitD and low PTH. In both cases, hypercalcemia resolved after treatment of PJP. These 2 cases illustrate hypercalcemia could be a prodromal feature in PJP. Early recognition with appropriate treatment would significantly reduce its morbidity and mortality.

Effect of UNOS Kidney Allocation System on Transplantation Rates for Veterans Waitlisted at Veterans Affairs Transplant Centers

Nidhi Aggarwal,1,2 Sankar D. Navaneethan,1 Jingbo Niu,1 Jenny S. Pan,1,2 Chandan Vangala,1,2 Ronald T. Cotton,1,2 Venkat Ramanathan,1,2 Michael E DeBakey VA Medical Center, Houston, TX; 3Baylor College of Medicine, Houston, TX.

Background: Impact of new Kidney Allocation System (KAS) on kidney transplantation (KT) rates for Veterans waitlisted at Veterans Affairs Transplant Centers (VATC) is unknown. This study compares effect of KAS on waitlisted patients at VATC and non-VATC.

Methods: UNOS data on adult patients waitlisted for KT during January 2009 to December 2016 were obtained. Logistic regression was used to assess association between center type (VATC vs. Non-VATC), time period (pre-KAS 2009-2014 vs. post-KAS 2015-2016) and outcomes (receiving KT or death on waitlist) within 2 years of waitlisting. Odds ratio (OR) was calculated adjusting for demographic factors, comorbidities, calculated Panel Reactive Antibodies (cPRA) and Estimated Post-Transplant Survival (EPST) score.

Results: During study period, a total of 263,410 patients were listed at non-VATC (75% pre-KAS; 25% post-KAS) and 3,150 at VATC (68% pre-KAS; 32% post-KAS). VATC patients were significantly older (58.3 vs. 51.7 years), diabetics (55.4% vs. 42.5%), had lower cPRA, higher EPST (53 vs.39%) and longer duration of dialysis (762 vs.727 days). Within 2 years of waitlisting, Veterans listed at VATC did not benefit from the new KAS like patients in non-VATC centers. Overall, independent of the era, Veterans tend to be transplant listed in this early waitlisting period. But waitlist was longer in VATC patients. (Results are shown in the table).

Conclusions: Benefit of new KAS did not extend to Veterans listed at VATC who are older, less immunogenic and have higher EPST score. Early benefit of KAS seen in non-VATC’s could be due to “bolus effect” from transplantation of younger, highly sensitized patients. However, risk of death is significantly lower in VATC waitlisted patients.

Outcomes of patients within 2 years of waitlisting for kidney transplantation

Lend Me Your Ear: An Unusual Presentation of a Transplant Complication

Meredith McAdams, Krti Yagnik, Swee-Ling Levea, Jeffrey Tessier, Reuben J. Arasaratnam, University of Texas Southwestern Medical School, Dallas, TX.

Introduction: Infections are a major complication in solid organ transplant (SOT) patients due to need for life-long immunosuppression. Incidence of fungal infections following solid organ transplant ranges from 5-20%. Cryptococcosis is an invasive fungal infection that can cause several types of infections including meningitis, pulmonary, cutaneous, and disseminated disease.

Case Description: A 66 y F with past medical history of ESRD s/p deceased donor kidney transplant 15 months ago, DM, HTN presented to renal transplant clinic with right ear pain for the past 4 weeks after being evaluated in the emergency room. Her exam was notable for painful ear and cheek lesions (Figures A and C). Fungal serologies were obtained and patient was sent to dermatology clinic for evaluation. Punch biopsies were taken from several lesions and cultures obtained. Serum cryptococcal antigen was positive with titer of 1-4096, fungal culture from lesion grew Cryptococcus neoformans. Skin biopsy showed cryptococci (Figure B). Patient was admitted to the hospital and further testing revealed positive CSF cryptococcal antigen, CT chest with nodular opacities, leading to a diagnosis of disseminated cryptococcal infection. She was treated with amphotericin B and fluconazole and eventually transitioned to oral fluconazole.

Discussion: Cryptococcal infection is the third most common invasive fungal infection in SOT patients and typically presents later in kidney transplant patients, 16-21 months, compared to other transplanted organs. Risk factors include type of immunosuppressive agent and comorbid conditions such as diabetes. The majority of transplant patients with cryptococcus present with CNS manifestations or disseminated disease, cutaneous involvement is less common. Our patient had risk factors including diabetes, older age, and use of induction immunosuppression. Initial presentation with skin lesions is atypical for cryptococcal infection. It is important to have a high suspicion for fungal infections in immunosuppressed patients even those with atypical presentations.

PO2481

Pegloticase for Uncontrolled Gout in Kidney Transplant Recipients:
Early Data Report of a Multicenter, Open-Label Efficacy and Safety Study

Abdul A Abdellatif,1 Lin Zhao,2 Paul M. Pelosso,2 Katya Cherny,2 Brad A. Marder,2 John D. Scandling,1 Kenneth G. Saag,3 Baylor College of Medicine, Division of Nephrology, Houston, TX; 2Horizon Therapeutics plc, Lake Forest, IL; 3Stanford School of Medicine, Division of Nephrology, Stanford, CA; 4University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background: Gout is common and more severe in US kidney transplant (KT) recipients, with prevalence >10x higher than in non-transplant patients. The management of gout can be challenging in KT patients due to decreased urate lowering therapy (ULT) clearance and drug-drug interactions. Recent reports suggest that pegloticase, a pegylated uricase approved for treating uncontrolled gout, has improved efficacy and safety when co-administered with immunosuppressive medications (IMM). We conducted the PROTECT trial (NCT04807720) to examine pegloticase use in KT recipients.

Methods: Patients with uncontrolled gout (sUA ≥7 mg/dL, intolerance of or contraindication to ULT, and a1 of the following: tophi, chronic gouty arthritis, a2 flares in past yr) and functioning KT graft (eGFR ≥15 mL/min/1.73m2) were included in this trial. Pegloticase (8 mg q2w for 24 wks) safety and efficacy are examined. Primary endpoint is 5% pegloticase responders during Month 6 (sUA <6 mg/dL for 80% of time).

Results: 7 patients were enrolled by Apr 30, 2020 (age: 52.0±11.2 yrs, KT 15.3±5.0 yrs ago, sUA: 10.0±1.4 mg/dL, gout duration: 5.9±4.3 yrs; all on stable doses of a2 IMM) and received 2-12 infusions. 1 patient discontinued. In the 1 completed and 5 ongoing studies, all central lab sUA levels were <1 mg/dL, indicating treatment response; no infusion reactions occurred. No notable eGFR changes were observed; 2 patients with baseline albuminuria of >300 mg/g showed >35% reduction in UACR by wk 14. 12 SAEs (stomach ulcer,cellulitis) unrelated to pegloticase were reported.

Conclusions: Early data of this ongoing clinical trial are promising and suggest pegloticase is safe and effective for treating uncontrolled gout in KT recipients. Additional efficacy and safety data are planned.

Serum uric acid (sUA) and kidney function parameters

PO2482

Minoxidil-Induced Chylous Asciates in a Renal Transplant Recipient

Vivek Pathak, Kovai Medical Center and Hospital, Coimbatore, India.

Introduction: Chylous ascites is generally associated with malignancies and surgical trauma and rarely secondary to administration of drugs (Halaz et al J Clin Med 2019;8:466). Calcium channel blockers related chylous ascites is more common is Asian ethnicity we could not find any published report of minoxidil causing chylous ascites.

Case Description: This patient is a 64 y old diabetic and hypertensive male who underwent kidney transplantation on 09.06.2009. He was HBsAg positive for last 9 years. He was taking multiple medications namely carvedilol, amiodarone, lasix minoxidil, prednisolone, MMF, Tacrolimus, insulin, metformin and linagliptin and Entecavir. He came in May 2019 with ascites. Investigation revealed normal kidney function and ultrasound guided ascitic fluid tapping was done and it was found to be chylous. He underwent abdominal paracentesis and about 12 lt of ascitic fluid was drained but he came back within 10 days with ascites again. Portal hypertension was ruled out by transjugular hepatic venous pressure gradient measurement and liver biopsy did not show any evidence of chronic liver disease. An upper GI endoscopy and duodenoscopy including duodenal biopsy were normal. Whole body PET scan did not show any active infection or disease. Meanwhile literature review suggested association of miopladine with chylous ascites and it was stopped but he continued to develop recurrent ascites. An abdominal CT lymphangiogram was done which did not show any lymphatic leak.
He also underwent diagnostic laparoscopy which also ruled out TB or any malignancy. This resulted in bilateral chylous ascites for 6 months then we decided to discontinue minoxidil as it is known to cause fluid accumulation including pleural and pericardial. He showed immediate improvement after stopping minoxidil and never developed ascites again. He was fine even 6 months later on follow up.

Discussion: Minoxidil causes vasodilation like calcium channel blockers though by a different mechanism so the mechanism of chylous ascites formation could be the same that it is also a lipophilic drug allowing it to pass rapidly into the lymphatic system and causes relaxation of smooth muscles of lymphatic vessels, interferes with lymphatic drainage and increases the hydrostatic pressure in lymph vessels and causing it to leak in the peritoneum. Minoxidil must be considered as a probable cause of atramatic drug induced chylous ascites.

PO2483
COVID-19 in Kidney Transplant Recipients: Experience from a Large Health System in Louisiana
Aldo E. Torres Ortiz, Joseph B. Walker, Juan Carlos Q. Velez, Jorge C. Garces. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Background: Infections are an important cause of morbidity and mortality among kidney transplant recipients. The novel Coronavirus Disease 2019 (COVID-19) has affected all kinds of populations world-wide. However, the role of immunosuppression in the outcomes of these patients is not well understood.

Methods: We conducted a retrospective study in kidney transplant recipients from a single health system that were diagnosed with COVID-19 based on a positive real-time reverse transcription polymerase chain reaction test for SARS-CoV-2 RNA between 11 March 2020 and 20 December 2020. We compared them with affectees who were not kidney transplant and without any kind of immunosuppressive medication (control). We examined the rates of hospitalization, intensive-care unit (ICU) admission, acute kidney injury (AKI) and mortality as outcome measures.

Results: A total of 8473 patients were diagnosed with COVID-19 within our Health System within the study period. Thirty-three (0.4%) were kidney transplant recipients. Sixteen of the 33 (48%) were admitted to the hospital (median age of 56, 68% males, 93% African American) vs 2201 admissions (25%) for the control group (median age 66, 48% males, 65% African-American), i.e., a significantly greater risk for hospitalization for transplant recipients (p < 0.002). Percentage of patients with hypertension in the transplant group was numerically higher (93% vs 80%, p = 0.06), as well as the number of ICU admissions (43% vs 28%, p = 0.055). AKI was more common in transplant patients (81% vs 33.8% p<0.0001). No difference in mortality was observed (31 vs 24%, p = 0.34).

Among transplant patients, those hospitalized were more likely to be on prednisone (75% vs 35%, p = 0.025) and had a post-transplant graft life of 7.9 years compared to 5.5 years for those not hospitalized, p<0.08.

Conclusions: Kidney transplant recipients affected with COVID-19 exhibited a greater incidence of hospitalization, AKI and a trend for more ICU admissions. Use of immunosuppression with prednisone was associated with greater risk for hospitalization.

PO2484
Recurrent Anemia due to Chronic Parvovirus B19 Infection in a Kidney Transplant Recipient: Can Everolimus Make a Difference?
Diana Rodriguez-Espinosa, Nuria Esforzado, Fritz Dickmann, Ignacio Revuelta. Hospital Clinic de Barcelona, Hospital Clinic de Barcelona, Barcelona, Spain.

Introduction: Parvovirus B19 (PB19) is a common infection among transplant recipients. Usually, it is asymptomatic, but some patients may suffer severe infections, often presenting with recurrent flares despite standard treatment. Relapses are usually managed by reducing immunosuppressive treatment (IST), potentially increasing graft rejection risk.

Case Description: 45-year-old woman with ESKD due to ADPKD, received a living-donor kidney transplant on May 2013. Maintenance IST consisted of mycophenolate mofetil (MMF), prednisone and tacrolimus. A month after transplantation, she presented with fever and anemia. A bone marrow aspirate revealed pure red blood cell aplasia (PRCA) which was attributed to PB19 after positive serum qualitative PCR. She was treated intravenous immunoglobulin (IVIG) at 2g/kg and MMF was stopped with good response. After 3 new relapses occurred (anemia and anemia with viral loads for PB19 over a million copies). A monthly prophylactic dose of IVIG was initiated to control the infection. In spite of this, episodes of anemia and a high PB19 viral load (over a half million copies) continued to happen at least 3 times per year. Finally, given the potential antiviral properties of mTOR inhibitors (mTORi), conversion from tacrolimus to everolimus was decided, Since November 2017 her maintenance IST consists of everolimus and prednisone alone, her last prophylactic IVIG was on December 2017, and since then she has been non-anemic with viral serum loads below 1000 copies, and without IVIG treatment.

Discussion: Incidence of symptomatic PB19 infection is highest during the 1st year after transplantation, like in the case presented. Standard therapy consists of IVIG. However, early KTR, often relapse after the IVIG effect wears off. In such cases, reduction of IST is needed to control the infection and avoid recurrences. There are multiple studies indicating that mTORi have antiviral properties although their effect on PB19 has not been specifically studied. In conclusion, conversion from tacrolimus to an mTORi, could be an interesting approach in difficult-to-manage cases similar to ours, moderating the reduction of IST and minimizing the risk of rejection. Further studies are needed to establish this approach as “treatment of choice” in relapsing PB19 infection.

PO2485
Adjusted Donor Age Score: Validity and Influence on Deceased Donor Offer Decisions
Christoph F. Mahler,1,2 Emma. Morganti,1 Dhirri Dosani,1 Anamika Adwaney,1 Rupert B. Bright,1 Damien Ashby,1 West London Renal and Transplant Centre 1Imperial College London, London, United Kingdom; 2Ruprecht Karls Universität Heidelberg, Heidelberg, Germany.

Background: Although a number of donor factors are known to affect outcome following deceased donor kidney transplantation, many units have no clear criteria for acceptance. Existing donor scoring systems, such as KDRI, perform poorly in the modern comorbid donor pool, and are difficult for patients to understand. Adjusted Donor Age (ADA) is a patient-friendly scoring system in which donor age is modified according to the presence or absence of a number of risk factors, as categorised by ADA decade (using cut-offs at 50, 60, 70 and 80 years) into quintiles (A – E) representing increasing donor risk (A – C: favourable, D: marginal, and E: unfavourable).

Methods: All deceased-donor kidney offers at a single centre were analysed over a 3 month period (beginning after the September change in UK organ allocation) during which ADA was optionally available to clinicians at the time of considering the offer. The effect of ADA on acceptance decisions and outcome in those transplanted were analysed.

Results: Out of 230 offers median(IQR) ADA was 67(56–76). Kidneys were transplanted in 24%, declined due to concern over donor risk in 44%, with recipient and other factors responsible for non-transplantation in 32%. In those identified as favourable by ADA (quintiles E – C, with exclusion factors), organs were rejected due to donor risk in 28/104 offers (27%), compared to 50/186 (27%) in the 2018 cohort. In those identified as unfavourable by ADA (quintile E) organs were transplanted in 0/38 offers (0%), compared to 10/66 (15%) in the 2018 cohort. At 1 month post-transplantation (N=55, from quintiles A – D only, since no organs from quintile E were accepted) one recipient remained dialysis dependent (from quintile D). In those with functioning transplants (N=54) recipient GFR was strongly correlated with ADA (R=0.52, p<0.001) and was seen to reduce across quintiles A – D (74, 55, 43 and 36 ml/min/1.73m2).

Conclusions: ADA is a patient-friendly score, calculated from donor age but adjusted for 12 potential risk factors, which can be used to guide acceptance decisions. At this early stage of familiarity, clinicians appear to be more persuaded by an unfavourable ADA quintile, than a favourable one. In this validation cohort, ADA strongly predicts early post-transplant outcome.

PO2486
Kidney Offer Calculator: The Risk of Accepting an Offer vs. Waiting for a Better Offer
Shan Shan Chen,1 Igor Litvinovich,2 Ashish Kataria,2 Yiliang Zhu,2 Christs Argyropoulos,2 Yue-Harn Ng,1 1University of Washington, Seattle, WA; 2University of New Mexico, Albuquerque, NM.

Background: Currently, no tools exist to facilitate patients with decisions to accept or refuse an offer. Using the scientific registry of transplant recipients database, we formulated a risk calculator for allograft failure and patient mortality risk (if offer accepted) vs. mortality risk if the patient refused.

Methods: Using a multi-state model approach, we created multiple competing risk models for: 1) first kidney offer or dying on wait-list without any offer; 2) if offer is refused, the probability of a) receiving a transplant vs. b) death and 3) if an offer is accepted, the probability of a) allograft failure vs. b) death. All models were adjusted for 12 potential risk factors, which can be used to guide acceptance decisions. At this early stage of familiarity, clinicians appear to be more persuaded by an unfavourable ADA quintile, than a favourable one.

Racial-Ethnic Disparities in Preemptive Kidney Transplantation Among Incident ESKD Adult Patients, 2006 to 2018

Navya Baranwal,1 Rebecca Thorsness,2 Shailender Swaminathan,1,3 Rachel E. Patzer,4 Rajnish Mehrotra,4 Amal Trivedi,5,6 *Brown University Warren Alpert Medical School, Providence, RI; 2Brown University School of Public Health, Providence, RI; 3Providence VA Medical Center, Providence, RI; 4Harborview Medical Center, Seattle, WA; 5Division of Transplantation, Department of Surgery, Emory University School of Medicine, Atlanta, GA.

Background: Preemptive kidney transplantation (PKT) is the preferred treatment for ESKD. Among kidney transplant recipients, black and Hispanics are less likely to receive PKT than whites, but less is known about disparities in PKT among the entire incident ESKD population. This is a critical gap in knowledge given the Advancing American Kidney Health goal of 80% of all new ESKD patients receiving transplant or home dialysis by 2025. This study assessed racial/ethnic disparities in initial treatment with PKT vs. dialysis among all incident kidney failure patients aged 19-74 from 2006 to 2018.

Methods: Treatment modality for incident ESKD patients was identified using the CMS Medical Evidence Report Form. Linear regression models estimated PKT rates for white, blacks, Hispanics and Asians, adjusting for clinical, geographic, socioeconomic, and access factors.

Results: Among 1,133,326 incident ESKD adult patients, the age/sex adjusted PKT rate declined from 3.0% in 2006 to 2.5% in 2018, with varied trends in each racial/ethnic group (white: 5.0% to 4.0%, black: 0.3% to 0.7%, Hispanic: 1.3% to 1.3%, and Asian: 2.4 to 2.9%) (Figure). In age-sex adjusted analyses, whites had 3.9, 3.2, and 1.7 percentage point higher rates of PKT compared to blacks, Hispanics, and Asians, respectively. These differences persisted after adjusting for clinical, geographic, SES, and pre-ESKD nephrology care (Table). Among patients aged 19-44, whites had 8.0, 6.3, and 3.3 higher rates of PKT, compared to blacks, Hispanics, and Asians.

Conclusions: Among incident ESKD adult patients, racial/ethnic disparities in receipt of PKT are substantial, persistent, and not explained by differences in observed clinical factors and socioeconomic status. Efforts to increase preemptive transplantation must address disparities in access to this preferred treatment for ESKD.

PO2488

Lower Prevalence of Kidney Transplant Waiting List Among Smaller Facilities in Non-Metropolitan Areas

Eric D. Weinhandl,7 H. E. Hamilton,1 Loren S. Dalrymple,1 *Fresenius Medical Care, Waltham, Anguilla; 2Chronic Disease Research Group, Minneapolis, MN.

Background: The Percentage of Patients Waitlisted (PPPW) measures the percentage of patients at a dialysis facility who are on the kidney or kidney-pancreas transplant waitlist. This measure joined the End Stage Renal Disease Quality Incentive Program in performance year 2020, with a weight of 4%. PPPW is adjusted for age, but not for other factors. Physical distance between residence and transplant center may influence PPPW. As an indirect test of this hypothesis, we assessed whether PPPW was associated with rural-urban commuting area (RUCA) levels.

Methods: We analyzed data in Dialysis Facility Compare (DFC), as of October 30, 2019. DFC included PPPW values that quantified waitlisting prevalence during 2018. According to ZIP code, we classified the location of each dialysis facility as metropolitan (RUCA values, 1-3), micropolitan (4-6), small town (7-9), or rural (10). We estimated weighted mean PPPW values in each location class, with the weight of each facility equal to the number of patients contributing to PPPW. We fit a linear regression model to test differences in PPPW values between the location classes.

Results: PPPW values were reported in 7086 (94%) of 7566 dialysis facilities, and RUCA values were identified in 6999 (99%) of 7086 facilities. The weighted mean PPPW value among all facilities was 17.5%. There were 5363 (77%) facilities in metropolitan areas, 954 (14%) in micropolitan areas, 550 (8%) in small towns, and 132 (2%) in rural areas. By location class, weighted mean PPPW values were 18.5% in metropolitan areas, 12.8% in micropolitan areas, 12.1% in small towns, and 10.8% in rural areas. Relative to the mean PPPW value in metropolitan areas, mean PPPW values were 5.8, 6.5, and 7.7 percentage points lower in micropolitan areas, small towns, and rural areas, respectively (P < 0.01 for each).

Conclusions: The PPPW measure takes significantly lower values in dialysis facilities located in micropolitan areas, small towns, and rural areas, relative to metropolitan areas. The physical distance between residence and transplant center may preclude many patients in non-metropolitan areas from completing the process of kidney transplant evaluation. New processes are needed to improve access to transplantation in outlying areas.

PO2489

Demonstrating Charitable Premium Assistance as a Mechanism for Overcoming the Cost Barrier to Transplant for Low-Income Patients in the United States

Michael Spiegel,1 Morenike Bello,1 Melanie Paris,1 Lisa Vo,2 Silas Norman,2 *American Kidney Fund, Rockville, MD; 2University of Michigan Transplant Center, Ann Arbor, MI.

Background: The optimal treatment for patients with end-stage renal disease (ESRD) is kidney transplantation. Adequate insurance coverage is one requirement for transplant eligibility. Many low-income ESRD patients cannot afford insurance coverage. Patients on dialysis are eligible for Medicare. Because Medicare covers only 80% of healthcare costs, most patients require supplemental insurance, often Medigap. Although Medigap
plans reduce out-of-pocket spending on healthcare services by almost 50%, spending on hospital visits more than doubles compared to Medicare premiums alone. For low-income patients who cannot afford such premiums, inadequate insurance coverage can become an insurmountable barrier to qualifying for a kidney transplant (KT). We evaluated a premium assistance program designed to help low-income ESRD patients maintain adequate insurance and the impact on KT access.

Methods: We performed a descriptive analysis of self-reported patient data collected from paper and digital applications submitted to American Kidney Fund’s (AKF) Health Insurance Premium Program (HIPPP) between November 15, 2018 and December 31, 2019.

Results: HIPP provided financial assistance grants to 1,357 (5.8% of all) kidney patients transplanted in the United States during the study period so they could maintain their health coverage in 2019. Of the 1,357 grants, 36% of grants issued helped patients pay premiums on a plan that recipients were more likely to be a 65 (24%), more likely to be African American (38% vs. 34%), and had lower median incomes ($23,622 vs. $27,168 respectively) compared to the overall transplant population.

Conclusions: KT candidates face financial barriers to transplantation. Premium assistance significantly reduced the barrier to transplant among KT candidates who rely on Medigap for ensuring adequate coverage.

PO2490

“Some Person Behind a Desk Is Going to Be Looking at My File”: Thematic Analysis of the Health Records of a National Sample of Patients with Advanced Kidney Disease Evaluated for Kidney Transplant

Catherine Butler,1 Aaron G. Wightman,1 Janelle S. Taylor,1 Claire Richards,1 Chun-fen Liu,1,2 Ann M. O’Hare.1,2 1University of Washington, Seattle, WA; 2VA Puget Sound Health Care System, Seattle, WA; 3Seattle Children’s Hospital, Seattle, WA; 4University of Toronto, ON, Canada.

Background: To be considered for kidney transplant, patients with advanced kidney disease must participate in a formal evaluation and selection process. Little is known about how this process unfolds in real-world clinical settings.

Methods: We conducted a thematic analysis of clinician documentation related to the kidney transplant evaluation in the VA-wide electronic medical records of patients who were referred to a transplant center among a random sample of 4,000 adults with advanced kidney disease between 2004 and 2014 who were followed through 2019.

Results: We identified 211 patients (5.2%) who were referred to a VA transplant center during follow-up. Four dominant themes emerged from qualitative analysis of clinician documentation in the electronic medical records of these patients: 1) far-reaching and intrusive and placed substantial demands on patients’ family members; 2) psychosocial valuation: the psychosocial transplant assessment could be subjective and invasive and placed substantial demands on patients’ family members; 3) surveillance over compliance: clinicians monitored patients’ adherence to a wide range of medical recommendations; 4) dispensemom and lack of transparency: patients had a strong desire to receive a transplant, but neither they nor their local clinicians had a clear understanding of what to expect from the evaluation process or the rationale for selection decisions, which left patients and their clinicians with little choice but to adhere to the transplant center’s recommendations.

Conclusions: To be considered for kidney transplant, patients had little choice but to engage in a lengthy, demanding, opaque evaluation process over which neither they nor their local clinicians had much control. These findings call for a more evidence-based, transparent, and individualized approach to the kidney transplant evaluation process.

PO2491

Implicit Bias in Recipient Selection

Youssef Swwidan,1 Christine Mayuga,1 Kenneth Chavin,2 Titte Srinivas,1 Aparna Padya.1 1University Hospitals Cleveland Medical Center Department of Medicine, Cleveland, OH; 2University Hospitals Cleveland Medical Center Department of Surgery, Cleveland, OH.

Background: The decision to place or exclude a candidate from the waitlist is not exclusively based on medical criteria. Scar literature exists regarding the intergroup dynamics within selection committees that influence decision making. This study attempts to clarify how the composition of selection committee meetings may affect listing outcome of kidney transplant candidates.

Methods: We performed a single-center retrospective study of kidney transplant selection committee attendance sheets and minutes from January 2012 to December 2015. We sought to determine if candidates who were evaluated by the same providers in attendance at selection committee are more likely to be listed for kidney transplant.

Results: 5205 (48.4%) of 6630 donor and recipient candidates presented during 91 selection meetings from 2012 to 2015 were listed. 8 nephrologists, 9 surgeons and 3 social workers comprised the clinicians that both evaluated potential candidates and attended recipient selection meetings. Table 1 describes the frequency with which clinicians who were in attendance at selection meetings had previously evaluated the candidates being discussed. Using a backward logistic regression, the presence of the nephrologist on the surgeon who had evaluated the patient was significantly associated with a greater likelihood of the candidate being listed (OR 4.443 and 3.952 respectively, p<0.001, see Table 2). White race was also associated with an increased propensity to list, OR 1.202, p = 0.006. Interestingly, the presence of both the nephrologist and surgeon who evaluated the patient, or the presence of both physicians and the social worker, were associated with reduced likelihood of listing (OR 0.267 for both, p<0.001; OR 0.715, p=0.001 for all three, see Table 2).

Conclusions: The composition of attendees at recipient selection meetings may influence listing outcomes of potential kidney transplant candidates.

PO2492

Predictors of Kidney Transplant Evaluation Non-Attendance

Christopher G. Ford,1 Eric Kruger,1 Yuridia Levy,1 Yiliang Zhu,1 Kellee Reynolds,2 Emilie J. Crockett,2 Mury Poo,2 M. Puttarajappa,2 Mark L. Unruh,1 Yue-Harn Ng,1 Larissa Myaskovsky.1 1University of New Mexico Health Sciences Center, Albuquerque, NM; 2University of Pittsburgh Medical Center, Pittsburgh, PA; 3University of Washington Medical Center, Seattle, WA.

Background: We examined which medical and socio-cultural factors predict kidney transplant evaluation (KTE) non-attendance, because missing a KTE appointment precludes access to transplantation, and having empty clinic slots impacts access to care for other patients.

Methods: We collected patient characteristics in an interview prior to KTE, covering demographics (e.g., income, education), medical factors (e.g., on dialysis, co-morbidities), cultural factors (e.g., medical mistrust), psychosocial characteristics (e.g., social support, health literacy), and knowledge (e.g., knowledge of KTE). We used latent class analysis (LCA) to determine if we could identify meaningful classes (groups of patients with patterns across variables) that were associated with KTE non-attendance.

Results: Our sample (N=1119) was 37% female, 76% non-Hispanic White, median age 59.4 years (IQR= 49.2-67.5), 25% had income below federal poverty line, 47% were < high school graduate, 48% were married, 44% had public insurance only, and 142 (13%) did not attend KTE appointment. LCA analyses indicated that a two-class solution consisting of a (1) high burden and (2) low burden group was optimal. Relative to the low burden group, the high burden group was less likely to be married, more likely to be on dialysis, less likely to have potential living donor, had higher kidney disease burden, more experiences of healthcare discrimination, higher medical mistrust, less social support, more depression, less knowledge about transplant, and more worry about kidney transplant harm. Belonging to the high burden group was associated with approximately twice greater odds of KTE non-attendance (OR=1.92, 95% CI 1.17-3.24).

Conclusions: Medical and socio-cultural factors predict KTE non-attendance. Transplant teams should consider targeting patients with characteristics indicating high burden for additional support (e.g., exploring motivation and barriers with patients, assisting with resources to attend appointment, and providing additional reminders or notifications). Given the association of clinic non-attendance with being on dialysis, a treatment with significant patient burden, future research should also focus on the benefits of referring patients for transplant evaluation prior to initiating dialysis.

Racial Disparities in Receipt of Medications for Secondary Prevention of Cardiovascular Disease in Kidney Transplant Recipients in the FA VORIT Trial

Mohammad Kazem Fallahzadeh Abourouhi,1 Elaine Ku,1 Chi D. Chu,2 Charles E. McCulloch,1 Delphine S. Tuot.1 1Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; 2Division of Nephrology, UCSF, San Francisco, CA.

Background: Cardiovascular disease (CVD) is the most common cause of death with a functioning graft in kidney transplant recipients. Black patients have been shown to have higher prevalence of cardiovascular (CV) risk factors and less intensive risk factor modification. We evaluated racial disparities in receipt of HMG-CoA reductase inhibitors (statins) and aspirin for secondary prevention of CVD in kidney transplant patients in the Folic Acid for Vascular Outcome Reduction in Transplantation Trial (FAVORIT) trial.

Methods: FAVORIT was a multicenter international trial of vitamin therapy to lower low density lipoprotein (LDL) CV outcomes in kidney transplant patients. We identified FAVORIT trial participants from US and Canada who had a self-reported

Patient Barriers to Kidney Transplantation on the Mexican American Border

Background: Hispanics are the largest minority group in the United States and are more likely to develop end-stage renal disease (ESRD) compared with non-Hispanic whites. However, Hispanics with ESRD are less likely to receive a deceased donor kidney transplant. We reviewed data from clinics on the Mexican American border to evaluate barriers to transplantation.

Methods: We gathered data from three dialysis clinics in Laredo, Texas, a city on the Mexican American border. It has a population of approximately 250,000 inhabitants of which 73% are white, 15% Hispanic, and 12% of other races. A number of patients were scheduled for living donor transplantation was evaluated. We also determined the number of patients that were referred but not listed and those that were not referred at all and investigated reasons for non-referral.

Results: A total of 285 patients were included in the analysis. 52 patients (18.2%) were waitlisted or denied for living donor transplantation. An additional 91 patients (31.9%) were referred but not yet waitlisted nor scheduled for living donor transplantation. A total of 140 (49.1%) were not referred. Of those not referred, the most common reasons included: deceased donor unacceptably heavy weight (4.2%), asynchronous donors, no organ offer and/or waitlisted (1.6%), peripheral vascular disease (1.0%). The most common reasons for referring patients were: patient's strong preference (1.4%), patient's advanced age (1.1%), and patient's health status (1.1%). In this analysis, 49% of the patients received a living donor transplant offer and 46% of those referred were waitlisted or scheduled for living donor transplantation. This is lower than previous studies showing a greater percentage of referred patients as waitlisted (up to 66% in some studies). Major barriers to referral included age, immigration status, and transportation limitations. The latter two barriers are likely more of a factor in a Mexican American border town than in other areas of the United States. Identifying these barriers highlight areas for improvement in access to renal transplantation for Hispanics.

The Strength of Weak Ties and Living Donor Offers: A Multi-Site Social Network Analysis of Hemodialysis Patients

Ayrum Gillespie,1 Jonathan Daw,2 Riley Brown,3 Jamie Cappiello,4 Edward L. Fink,5 Heather M. Gardiner,5 Crystal A. Gadegbeku,6 Peter P. Reese,7 Zoran Obradovic.8 1Temple University, Philadelphia, PA; 2Pennsylvania State University, University Park, PA; 3University of Pennsylvania, Philadelphia, PA.

Background: Increasing the rate of living donor kidney transplantation is crucial. Little is known about hemodialysis patients’ social networks and the members who offer to donate yet are never evaluated.

Methods: We administered a REDCap social network survey in an urban (Philadelphia) and suburban (North Brunswick) hemodialysis clinic. We asked participants to identify their strongest and weakest network members, who offered to donate, whose offers were accepted, and who got tested. We analyzed the associations between living donor offers and the size and strength of the connections in the networks. Strongly connected members are those connected to greater than 2/3 of the other network members.

Results: A total of 105 patients participated. Their mean age was 60 +/- 13 years. Half (54%) identified as male and 75% identified as black. Half were on the waiting list and unsure of receiving a kidney (50%). Half of the 527 network members identified, 133 offered to donate, 43 of these offers were accepted with 12 being evaluated for donation. Most (83%) network members were strongly interconnected within the participants network, however, a greater proportion of weakly interconnected network members offered a kidney donation compared to strongly connected members (31% vs. 19%, p = 0.02). Participants accepted a greater proportion of offers from weakly connected members than strongly connected members (56% vs 33%, p = 0.03). Although a greater proportion of strongly connected members were evaluated compared to weaker connected members this was not significantly different (36% vs. 17%, p = 0.16).

Conclusions: Weakly connected social network members tend to offer to be living donors more frequently than those of other degrees of connectedness. Unfortunately, most (89%) social network members who offer to donate never make it to the transplant center. Future interventions should focus on patients accepting living donor offers as well as identify methods to increase testing of interested donors especially those weakly connected in the network.

PO2496

Association of SNAP Benefit Use by Inner-City Kidney Transplant Recipients with Poorer Graft Function, Lower Fruit and Vegetable Intake, and Increased Psychosocial Stress

Elizabeth G. Kasparov, Kingsley Cruickshank, Ahmad Saleh, Soyeon Pak, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Longterm graft survival may be affected by factors other than biologic, including social determinants of health such as food scarcity and psychosocial stress.

Methods: A face-to-face survey was conducted in a random convenience sample of 31 pts in transplant clinic. The Stress and Social Support survey and the Perceived Stress Scale were used. Dietary intake was assessed using 24-hr recall and analyzed with ASA-24 software. All comparisons are by Chi square or t-test.

Results: There were 11 women(36%), 20 men(65%), 22 Black(71%). Mean age was 55.2±9.9 yrs, since transplant 63.9±14.1 mos. 24 (77%) reported income <$40K, with 12 (39%)<$20K. 12 (39%) received SNAP benefits (SNAP+). Income or employment rate did not differ for SNAP+ vs SNAP-. SNAP+ had significantly worse kidney function(creatinine 2.17±0.24 vs 1.44±0.11 mg/dl=0.014) and eGFR 37.9±3.8 vs 38.8±3.8 mg/dl (p=0.06, min-p=0.003). SNAP+ did not differ for race, gender, race, BMI, tacrolimus level or age. SNAP+ also were more likely to disagree with the statement “I feel I am in control of my health and it doesn’t control me” (33% vs 0%, p=0.017), to report never or almost never feeling confident about handling personal medical problems (16% vs 16%, p=0.018), and to be unable to control irritations in their lives(67% vs 16%, p=0.043, p=0.043). No difference in caloric or macronutrient intake existed, but SNAP+ ate less(<11.1±3 vs 16±1.8 gmp, p=0.023) and fewer servings of fruits/vegetables(1.5±0.28 vs 3.75±0.85, p=0.021). When asked about missed medication they did not report more missed doses.

Conclusions: In our patient population: 1. Pts receiving SNAP had worse kidney function than those who did not despite similar time since transplant, tacrolimus level, income, and employment status. 2. They ate less fiber and fewer servings of fruits/vegetables despite similar caloric intake, which should be investigated further as higher intake of fruit/vegetables is associated with delayed progression of kidney disease in non-transplant pts. 3...They also reported feeling less control over their health and less ability to handle daily stress. 4. These finding suggests that special attention should be paid to this population who have issues with social determinants that may affect kidney function.

Cardio-Metabolic Risk Factors in Kidney Donors at a Third-Level Hospital of Care in Mexico

Jesús D. Lima Lucero,1 Ana G. Ortega,2 Rafael Valdez-Ortiz,1 L. M. Perez-Navarro,3 Ernesto C. Lopez,1 1Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; 2Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

Background: Donor kidney transplantation is the treatment of choice for chronic terminal kidney disease. A high prevalence of cardio-metabolic risk factors (CRFs) in the general population implies challenges when choosing the best candidate for kidney donation. Knowing the frequency of CRFs will allow us to make timely interventions in order to reduce cardiovascular complications after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center “Dr. Antonio Fraga Mouret” during the period from 2015 to 2019. Descriptive statistics were made, with a 95% IC. CRFs were included; systolic hypertension (SBP) higher than 120mmHg, diastolic hypertension (DBP) higher than 80mmHg, anemia hemoglobin less than 13 g/dl in men and less than 12 g/dl in women; impaired fasting glucose> 110 mg/dl, body mass index (BMI)> 25. Results: 153 donors were included, 59% were women, 33% were siblings and 31% were the patient’s mother; 34% had no social security. The mean age was 42.7 ± 10.7 years; the mean BMI 26.3 ± 5.4, with a mean GFR 101.9 ± 13.4 (61-136) ml/min. 28% of donors smoked, 7% had SBP risk and 27% DBP risk, 60% had BMI> 25, 4% had anemia and 13% hypobulinemia; 10% with impaired fasting glucose. Figure 1 shows the prevalence of CRF. More than 25% of kidney donors had 2, 3 and 4 CRFs on admission to hospital for donation. 72% presented acute kidney injury (AKI) after surgery, none required renal replacement therapy. The highest AKI frequency was observed in subjects who had 1 to 4 CRFs with frequencies to 126-34%.

Conclusions: A BMI higher than 25 was the most prevalent CRFs; associated with AKI when more than 1 CRF was observed. Timely detection of CRFs will allow for timely interventions that will reduce post-donation cardiovascular risk and decrease the risk of AKI.

PO2499

The Effect of Anemia Correction with ESA and Cholecalciferol Supplementation on Post-Transplant Malignancy Among Kidney Transplant Recipients: A Prespecified Analysis of a Randomized Clinical Trial

Yoshitsu Ohishi,1,2 Naotsugu Ichimaru,1,4 Yoshitaka Isaka,1 Takayuki Hamano,1,3 The CANDID-KIT Trial Investigators 1The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2Obi Clinic, Osaka, Japan; 3Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan; 4Japan Zaidan Hoin Samitomo Byoin, Osaka, Japan; 5Nagoya Shiritsu Daigaku Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: Kidney transplant recipients (KTRs) are at increased risk of cancer, and post-transplant malignancy (PTM) is among the leading causes of death with functioning allograft. Aggressive anemia correction with ESA shows the rate of decline in kidney allograft function but may increase the incidence of PTM. Vitamin D is proposed to exert pleiotropic effects including anti-cancer properties and may prevent the development of post-transplant malignancy (PTM). Whether this association is due to inflammation, iron overload or combination of the two.

Methods: We enrolled 153 KTRs with anemia and >1 year history of transplantation across 23 facilities in Japan and conducted a multicenter, two-by-two factorial, open-label, randomized clinical trial. Patients were randomly assigned to either a high or low hemoglobin (Hb) target (>12.5 g vs <10.5 g/dL) and to either cholecalciferol 1000 IU/day or control. PTM was a prespecified secondary outcome.

Results: Patients were 51±12 years, among whom 54% were male. The median (IQR) of transplant vintage was 8 (5, 12) years. Their baseline eGFR, Hb, and serum 25(OH)D levels were 30.6±11.0 ml/min per 1.73 m², 10.7±1.2 g/dL, and 14.5±5.2 ng/mL, respectively. There was no between-group difference in the prevalence of prior malignancy in either arm. The mean Hb level was 11.4±.0.6 g/dL and 10.6±.0.6 g/dL in the high and low Hb target groups, respectively. The mean serum 25(OH)D level exceeded 30 ng/mL in the cholecalciferol group after Month 6 whereas it did not change in the control group throughout the study period. A total of 7 PTMs developed 2 years of the follow up; 2 lung cancers, 1 breast cancer, 1 gastric cancer, 1 testicular cancer, 1 renal cell carcinoma, and 1 myelodysplastic syndrome. There was no between-group difference in the incidence of PTM in the hemoglobin target arm (i.e., n=3 [4.1%] vs. [5.1%] in the high vs low Hb target groups, respectively; P=0.77). In the cholecalciferol arm, all 7 PTMs developed in the control group while none was observed in the cholecalciferol group (i.e., 9.1% vs 0%, respectively; P=0.007).

Conclusions: The incidence of PTM was not increased by aggressive anemia correction with ESA and was reduced by cholecalciferol supplementation among KTRs. Large clinical trials with a long-follow up period are needed to validate these findings. Registered at ClinicalTrials.gov (NCT01817699).

PO2500

Association Between Elevated Ferritin and Graft Survival During the First Year After Kidney Transplant

Benya Rozen-Zvi,1 Amir Schechter,1 Ruth Rahamimov,2 Anat Gafler,1 Zaidan Hojin Sumitomo Byoin, Osaka, Japan; 2Obi Clinic, Osaka, Japan; 3Obi Clinic, Osaka, Japan; 4Ippan Hospital of Care in Mexico.

Background: Both iron deficiency and iron overload are associated with adverse outcomes in patients with end stage kidney disease on chronic hemodialysis. In contrast, the effect of iron metabolism markers post transplantation have not been thoroughly evaluated. In this study we aimed to evaluate the association between serum ferritin and transferrin saturation during the first year post transplantation on patients and graft survival.

Methods: Retrospective cohort study, using the Rabin Medical Center (RMC) kidney transplant registry. We included adults (>18 years) patients transplanted between 1/1/2006 and 31/12/2017 that had at least one available iron, transferrin and ferrite value during the first year post transplantation. Ferritin and transferrin were logarithm transformed and serum ferritin was also analyzed as a dichotomous variable with 500 ng/ml as a cutoff value. Primary outcome was the composite of graft and patients’ survival. Secondary outcomes included death censored graft loss. Univariate and multivariate Cox models were used for the primary composite outcome of patients’ and graft survival.

Results: Seven hundred and twenty-six patients were included in the study, of whom 219 (30.2%) had serum ferritin above 500 mg/dL. Patients with high serum ferritin were older with more diabetes mellitus (DM) and heart disease and tended to have deceased donors, and post-transplantation delayed graft function. By univariate Cox analysis, ferritin level above 500 mg/ml was associated with increased risk of death and graft loss (Hazard Ratio (HR) 2.38, 95% Confidence Interval (CI) 1.69-3.35, p<0.001). By extensive multivariate model ferritin was still highly associated with increased rate of graft loss (HR 1.87, 95% CI 1.29-2.72, p=0.001). High ferritin was also associated with increased risk of the secondary outcome of death censored graft loss (HR 2.09, 95% CI 1.26-3.48, p=0.005). The results were similar when ferritin was evaluated as continuous variable. In contrast, transferrin saturation was not associated with overall death and censored death graft survival. High ferritin was associated with reduced graft survival. Further research is needed to evaluate whether this association is due to inflammation, iron overload or combination of the two.

PO2501

Iron Deficiency in Kidney Transplant Recipients: Impact on Cognitive Functioning

Joanna Sophia J. Vinkle,1 Aaltje L. Ziegens,2 Lisanne van Sonderen,2 Antonio W. Gomes Neto,2 Åne Buunk,3 Stefan P. Berger,1 Stephan J. Bakker,1 Michele F. Eisenga,1 Martin H. De Borst,1 1University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands; 2University Medical Center Groningen, Department of Neurology, Groningen, Netherlands.

Background: Cognitive function impairment is common in kidney transplant recipients (KTRs). Brain functioning requires energy, for which iron is essential at the level of oxygen delivery and mitochondrial function. Iron deficiency (ID) has been linked to compromised cognitive functioning in premenopausal women. We aimed to investigate whether ID could be a potentially modifiable risk factor for cognitive function impairment in KTRs.

Methods: In a prospective study among KTRs participating in the TransplantLines Biobank and Cohort study, we analyzed KTRs ≥1 yr post-transplant with data on iron status. All participants underwent neurocognitive testing to measure memory (Digit Span Backward, Symbol Digit Modalities Test, Trail Making Test-A) and executive functioning (Trail Making Test-B, Digit Span Backward). Attention and mental speed (Symbol Digit Modalities Test, Trail Making Test-A) and executive functioning (Trail Making Test-B, Digit Span Backward). ID was defined as ferritin <100 μg/L or ≥100 μg/L with transferrin saturation (TfS) ≥20%. We used multivariable linear regression analysis to assess associations between ID and neurocognitive outcomes. Analyses were adjusted for hemoglobin, CRP, age, sex, eGFR, BMI, smoking, alcohol intake, time since transplantation, dialysis duration, donor type, educational level and immunosuppressives.

Results: We included 398 KTRs (age 56±14 yrs, 62% male, eGFR 52±14 ml/min/1.73 m²). ID was present in 289 (73%). ID and iron neurocognitive scores are presented in the table. Conclusions: ID, low ferritin and low TfS are consistently associated with poor performance on neurocognitive tasks measuring verbal memory, executive functioning,
mental speed and attention in KTRs, independent of hemoglobin and other potential confounders. Future studies should address whether ID correction restores cognitive function.

PO2502

Anemia and Decreased Muscle Mass and Muscle Strength in Kidney Transplant Recipients

Joanna Sophia J. Bakker,1 Hanneke J. Wouters,2 Adrian Post,1 Suzanne P. Stam,1 Rianne M. Douwes,1 Antonino W. Gomes Neto,1 Stefan P. Berger,1 Stephan J. Bakker,1 Martin H. De Borst,1 Michele F. Eisenga.1 University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands; 2University Medical Center Groningen, Department of Hematology, Groningen, Netherlands.

Background: Anemia is highly prevalent in kidney transplant recipients (KTRs). It is known that anemia impairs quality of life, especially physical functioning. Although surmised, data about the latter in KTRs specifically are scarce. Hence, we aimed to investigate the association between anemia and muscle mass and muscle strength in KTRs.

Methods: In a prospective study among KTRs participating in the TransplantLines Biobank and Cohort study, we used KTRs >1 yr post-transplant with data on hemoglobin (Hb) levels and muscle mass. Muscle mass was assessed in two ways: by using 24-hour urinary creatinine excretion and with bioelectrical impedance analysis (BIA). Muscle strength was determined by means of hand grip strength using a dynamometer. The mean overall hand grip strength was calculated out of three attempts of both hands with 30 seconds recovery time in between. Anemia was defined as an Hb <12 g/dL for women and <13 g/dL for men, according to WHO definitions. We used multivariable linear regression analyses to assess associations between anemia and muscle mass and strength.

Results: We included 824 KTRs (age 56±13 years, 60% males, eGFR 52±18 mL/min/1.73 m², serum HB 13.5±1.8 g/dL). Anemia was present in 30% of KTRs. Hb levels were associated with creatinine excretion, independent of age, sex, eGFR, BMI, hs-CRP, smoking status, alcohol use and the use of RAAS-inhibitors, statins, calciuminhibitors, proliferation inhibitors or prednisolone (β<0.01). Similarly, the presence of anemia was independently associated with a lower creatinine excretion (st.β=-0.14, P<0.001). Similarly, the presence of anemia was independently associated with a lower creatinine excretion (st.β=-0.09, P=0.021). Hb levels (st.β=-0.20, P=0.001) were also independently associated with muscle mass, estimated using BIA resistance measurements. In line with muscle mass parameters, Hb (st.β=-0.18, P=0.001) and anemia (st.β=-0.01, P=0.005) were associated with handgrip strength independent of potential confounders as well.

Conclusions: Low hemoglobin levels and anemia are both strongly associated with lower muscle mass and muscle strength in KTRs, likely impairing physical functioning. Future research is needed to address whether correction of anemia improves physical performance in KTRs.

PO2503

Sevelamer-Associated Gastrointestinal Complications in Kidney Transplant Recipients

Mahmoud S. A. Alhazin,1 Stanley Kwong, Julie M. Yabu, Erik L. Lum, Elizabeth A. Kendrick. University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Introduction: Sevelamer (SV) is a resin based oral phosphate binder used commonly in chronic kidney disease (CKD) patients. Clinical trials performed for approval for clinical use showed mild to moderate gastrointestinal (GI) intolerance in a minority of patients. In general clinical use of SV in CKD patients, there have been case reports of more serious GI problems than were reported in original trials, including GI bleeding and colonic complications including colitis and perforation. The majority of patients receiving kidney transplants have required long term oral phosphate binders at the time they are transplanted, often using SV. Delayed graft function (DGF) early post transplant may require ongoing use of oral phosphate binders to control hyperphosphatemia.

Case Description: We report 3 cases of significant GI morbidity in association with SV occurring in transplant recipients within the first 2 weeks after kidney transplantation. In one patient, the post transplant course was complicated by sepsis due to perforated colonic diverticulum in the context of preexisting diverticulitis disease; surgical intervention showed SV crystals associated within the area of bowel perforation. Two patients had severe upper GI symptoms and abnormal findings on upper endoscopy, including severe esophagitis and esophageal ulceration. SV crystals were found in the biopsies of abnormal areas. Both patients had long-term use of SV prior to transplantation, whereas one patient was treated with SV for a short time only after transplantation. All had required more than one phosphate binder for long-term control of hyperphosphatemia; two required cinacalcet for management of secondary hyperparathyroidism.

Discussion: SV use may have more serious GI adverse effects in CKD patients than noted in the original clinical trials. Preexisting GI disease and/or abnormalities may increase the risk of adverse GI effects related to SV. Recent use of SV prior to kidney transplantation or use of SV for control of hyperphosphatemia in the context of DGF can be associated with GI morbidity in the early post transplant setting. Need for higher doses of phosphate binders and severity of hyperparathyroidism may be contributing factors to this risk.

PO2504

C-Terminal and Intact FGF-23 in Kidney Transplant Recipients and Their Associations with Kidney Transplant Loss and Mortality

Chang Chu,1 Shufei Zeng,1 Yingquan Xiong,1 Ahmed A. Hasan,2 Bernhard K. Krämer,2 Berthold Hochert.3 'Charité - Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany; 2Fifth Department of Medicine (Nephrology/Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Germany; Mannheim, Germany; Institute of Nutritional Science, University of Potsdam, Potsdam, Germany.

Background: Increased fibroblast growth factor 23 (FGF23) is a risk factor for mortality, cardiovascular disease, and progression of chronic kidney disease. Limited data exist comparing the association of either c-terminal FGF23 (cFGF23) or intact FGF23 (iFGF23) in kidney transplant recipients (KTRs) with graft loss and all-cause mortality.

Methods: We conducted a prospective observational cohort study in 562 stable kidney transplant recipients. Patients were followed for graft loss and all-cause mortality for a follow-up of 48 months.

Results: During a median follow-up of 48 months, 94 patients had adverse outcome (graft loss or death). Both cFGF23 and iFGF23 concentrations were significantly higher in patients who had adverse outcome than without adverse outcome (24.59 [11.43-87.83] vs. 10.67 [5.99-22.73] pg/mL; p<0.0001 and 82.24 [18.63-159.0] vs. 29.04 [15.23-60.65] pg/mL; p=0.002 for cFGF23 and iFGF23, respectively). cFGF23 and iFGF23 measurements correlated well (rho=0.54, p<0.0001). ROC analysis of cFGF23 and iFGF23 yielded AUC of 0.69 (p<0.0001) and 0.61 (p=0.02) for prediction of the composite endpoint, respectively. Cox regression analyses adjusted for confounding factors, showed that cFGF23 (HR for one unit increase of log transformed cFGF23: 1.35; 95% CI, 1.03-1.77; p=0.028) but not iFGF23 (HR for one unit increase of log transformed iFGF23: 1.03; 95% CI, 0.81-1.31; p=0.827) was associated with the composite endpoint (Figure 1).

Conclusions: Elevated cFGF23 levels at baseline are independently associated with an increased risk all-cause mortality or graft loss. iFGF23 measurements were not independently associated with the study endpoint. The iFGF23 ELISA might detect bioactive FGF23 fragments that are not detected by the iFGF23 ELISA.

Figure 1. Multivariable-adjusted Cox regression analyses of composite endpoint: graft loss or all-cause mortality. Model 1: adjusted for eGFR; Model 2: adjusted for eGFR, age, sex, time on dialysis, pre-donation smoking, donor age, donor sex, donor family history of cardiovascular disease, recipient race, recipient BMI, recipient age, recipient Systolic BP, recipient smoking status, recipient body mass index and preemptive. HR: Hazard Ratio; 95% CI: 95% Confidence Interval; p-value: p-value for the HR.

PO2505

The Time Is Now: Reducing Waiting Times in Minority Populations

Background: A significant limiting factor to transplantation resides on waiting time based on blood type. Historically candidates in blood groups B and O experience higher waiting times for kidney transplantation. Our center has worked to increase the rate of acceptance in kidney donors that would have previously been discarded to try to maximize the donor pool for these blood groups.

Methods: We retrospectively analyzed 1287 consecutive deceased donor kidney transplantations from 2015 to 2019. This cohort was chosen to ensure baseline was after allocation system changes, so the change is a result of change in practice at our center. Average waiting time to transplantation and renal transplantation rates were analyzed based on ABO stratification as well as ethnicity to compare longitudinal disparities.

Results: We observed a decrease in waiting time across all blood types (Figure 1) over the 5 year period of this study. There was a substantial benefit in blood type B recipients with a 6.4 year decrease in average waiting time from 2015 to 2019. Waiting time in
PO2506
Ethnic Disparities in Hospitalization After Deceased Donor Kidney Transplantation
Shahidul Islam,1,2 Sumit Mohan,3,4 William M. Brown,4 Stephen O. Pastan,3 Ayaj K. Israni,3,4 Robert S. Gaiston,3 Alejandro Mena-Gutierrez,3 Amber M. Reeves-Daniel,4 Bruce A. Julian,3 Barry L. Freedman,3 Jasmin Divers.1,2 Division of Health Services Research, Department of Foundations of Medicine, NYU Long Island School of Medicine, Mineola, NY, 1Winthrop Research Institute, NYU Long Island School of Medicine, Mineola, NY, 2Division of Nephrology, Department of Medicine, Columbia University College of Physicians & Surgeons, New York, NY, 3Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, NY, 4Renal Division, Division of Medicine, Emory University School of Medicine, Atlanta, GA.

Background: The cause of disparities in hospitalization after deceased donor kidney transplantation (DDKT) is unknown. In a prior study, we found that African American (AA) recipients were more likely than European American (EA) recipients to have hospitalizations after DDKT. Here we evaluate the contribution of two possible factors: (1) donor factors (mortality, preservation, and pre-morbid factors) and (2) recipient factors (medical comorbidities) to hospitalizations after DDKT.

Methods: We reviewed the records of 9,068 patients who received a DDKT from 2006-2015. Using logistic regression, we evaluated the contributions of donor and recipient factors to hospitalizations after DDKT, adjusting for transplant era (2001-2005, 2005-2010, after 2010), the kidney donor index risk (KDR), estimated post-transplant survival (EPS), donor- and recipient age, sex, recipient insurance, prior employment status, delayed graft function (DGF) and cold ischemia time.

Results: HRs were higher among recipients of kidneys from AA donors compared to EA donors (odds ratio 1.41, 95% CI 1.29-1.52) after adjusting for the donor mortality (KDR), estimated post-transplant survival (EPS), donor- and recipient age, sex, recipient insurance, prior employment status, delayed graft function (DGF) and cold ischemia time.

Conclusions: HRs for the DRPs have increased over time with higher rates among recipients of AA DD kidneys. Additional donor-level factors may contribute to the hospitalization rate after DD kidney transplantation.

A Randomized Trial of Vitamin D Supplementation on Skeletal Muscle in Patients Early Post Kidney Transplantation
Makoto Tsutui,1 Yoshitsugu Obi,2 Takayuki Hamano,3 1Masuko Kinen Byoin, Nagoya, Japan; 2The University of Tennessee Health Science Center, Memphis, TN; 3Nagoya Shiritsu Daigaku Daigakuin Igakuka Kenkyuka Igakubu, Nagoya, Japan.

Background: Developing strategies for managing skeletal muscle weakness and loss in kidney transplant recipients (KTRs) is an important clinical challenge. Little is known about the effect of native vitamin D (ViD) supplementation on skeletal muscle in KTRs.

Methods: We conducted a 11-month, double-blind, randomized, controlled trial to assess the efficacy of ViD for improving skeletal muscle weakness and loss in KTRs receiving kidney transplantation within one month. Eligible patients were randomly assigned to a ViD (cholecalciferol, 4000 IU / day) group or a placebo group in a 1:1 ratio. A prespecified secondary endpoints in this study included a percent (%) change in handgrip strength (HGS), and leg strength (LS) for skeletal muscle strength, and skeletal muscle index (SMI) for skeletal muscle mass.

Results: A total of 193 KTRs were randomized, but 6 KTRs were lost before taking the medication. We analyzed 92 KTRs in ViD group and 95 in Placebo group. Dropout during this study were 3 KTRs in Vitamin D group and 2 in Placebo group. In ViD group, at baseline the mean age was 52.2 ± 12.5 years old and the number of males was 28 (30.4%), and in Placebo group, 53.7 ± 11.4 years old and 30 (31.5%), respectively. The mean changes in serum 25-hydroxyvitamin D levels from baseline to the end of this study were 11.2 ± 4.1 to 39.8 ± 13.0 ng/ml in Vitamin D group (p < 0.001) and 11.2 ± 4.1 to 14.5 ± 5.0 ng/ml in Placebo group (p < 0.001). In this study, there were no difference in % changes in HGS, LS, or SMI between those groups, respectively.

Conclusions: ViD supplementation alone appears not to be effective in improving skeletal muscle weakness and loss among KTRs early post-transplantation. Larger-scale trials are warranted to confirm these findings.

PO2508
Effects of Arteriovenous Fistulas on Outcomes of Kidney Transplant Recipients
Yasar Caliskan,1 Ahmet B. Dirim,2 Safak Mirioğlu,2 Ozgur A. Oto,2 Halil Yazici,1 Erol Demir,2 Sedat Saka,2 Nurana Guller,2 Mehmet S. Sever,2 Krista L. Lentine.1 Saint Louis University, Saint Louis, MO, 1Istanbul School of Medicine, Istanbul, Turkey.

Background: Arteriovenous fistulas (AVFs) may exacerbate cardiovascular events (CVE) after kidney transplantation (KTx). We aimed to investigate the long-term effects of AVFs on KTx outcomes.

Methods: Prevalent 168 recipients were categorized at median 2yr. after KTx: recipients with functioning AVF (n=73), recipients with non-functioning AVF (n=62) and recipients without AVF (n=33) on pre-KTX peritoneal dialysis or underwent preemptive KTx. Baseline characteristics, echo findings and endothelial function were compared. During a median 11yr. follow-up after enrollment, CVE were defined as acute coronary syndromes or cerebrovascular accidents; additional outcomes included eGFRs at baseline and end of follow-up, graft failure and death.

Results: Demographic, clinical, laboratory and echo characteristics and endothelial function at enrollment were not significantly different across all groups (Table 1). During follow up, CVE occurred in 9 (12.3%), 5 (8%), and 0 (12.1%) patients in IAVF, nIAVF and noAVF groups, respectively. Groups were comparable regarding graft and patient survival rates (p=0.70). During follow-up, CVE rates were not significantly different across all groups in the period from D1 to D11, as well as from D11 to D23. Groups were comparable regarding graft and patient survival rates (p=0.13 and p=0.87, respectively). During follow-up, functioning AVFs thrombosed in 5 (7%) and were surgically closed in 20 (27%) patients in IAVF group. CVE rate was similar in patients with thrombosed (20%), closed (5%) and still functioning (15%) AVFs (p=0.47). Patient and graft survival rates were significantly lower in recipients with still functioning IAVFs (77% and 73%, respectively) compared to IAVF patients with thrombosed (100% and 100%, respectively) and closed (100% and 95%, respectively) AVFs (p=0.05 and 0.03, respectively).

Conclusions: Long-term CVE rate is similar in KTx recipients with and without patent AVFs. In a subgroup of KTx recipients with functioning AVFs, closure and thrombosis of AVFs may be associated with higher rates of patient and graft survival.
Recurrent Cardiovascular Events After Kidney Transplant Are Associated with Increased Risk for Graft Failure and Mortality

Levion Galapia,1 John C. Lieske,2 Nan Zhang,1 Richard J. Butterfield,3 Mira T. Keddis.1
1Mayo Clinic, Scottsdale, AZ; 2Mayo Clinic, Rochester, MN.

Background: Cardiovascular (CV) disease is prevalent after kidney transplant (KTx). The objective of this study was to describe patients with recurrent CV events in association with allograft function and mortality.

Methods: 1148 consecutive adults that received a KTx between 2011-2013 at a single center were evaluated. CV events were defined as: cardiac: myocardial infarction, heart failure, cardiac arrest requiring resuscitation, and vascular, any stroke, or peripheral vascular disease requiring intervention. Recurrent events were defined as more than one event (either cardiac or vascular).

Results: Mean age was 56.0 years (SD 14.2), 500 (44%) were female, 403 (35%) had diabetes, 1083 (94%) had hypertension, 127 (11%) had prior history of CV events, 602 (53%) required dialysis, and 867 (76%) received living donor KTx. After a median follow-up of 74 months there were 229 (20%) deaths and 217 (19%) CV events, of which 92 (40%) were cardiac, 86 (39%) were vascular, 39 (18%) had both. 119 patients had an isolated CV event and 98 had recurrent CV events (median 3 (range 2,4)). Multivariate analysis revealed the following independent significant predictors of CV events: older age, prior history of CV event, diabetes, hypoalbuminemia and measured GFR. Compared to recipients with no CV events and those with an isolated event, recipients with recurrent CV events had increased: mortality (15% vs 38% vs 45%, p<0.0001) and graft failure (14% vs 26% vs 40%, p<0.0001). Hazard ratio for mortality associated with isolated CV events was 2.66 (1.90-3.73) compared to a HR 3.06 (2.18-4.29) for recurrent CV events, (14% vs 26% vs 40%, p<0.0001). [Figure 1]. Predictors of multiple CV events included measured GFR and age, prior history of CV event, diabetes, hypoalbuminemia and measured GFR. Compared to recipients with no CV events and those with an isolated event, recipients with recurrent CV events had increased: mortality (15% vs 38% vs 45%, p<0.0001) and graft failure (14% vs 26% vs 40%, p<0.0001). Hazard ratio for mortality associated with isolated CV events was 2.66 (1.90-3.73) compared to a HR 3.06 (2.18-4.29) for recurrent CV events, (14% vs 26% vs 40%, p<0.0001). [Figure 1].

Conclusions: Prevalence of recurrent CV events after KTx was 8.5%. Patients with recurrent CV events are at increased risk for mortality and graft failure. Decreased graft function was the primary predictor of recurrent CV events.
PO2512
Utility of the 6-Minute Walk Test in Coronary Artery Disease Screening Before Kidney Transplant
Ximona S. Cheng,1 Daniel J. Waitford,1 Hiroyuki Arashi,1,2 Jane C. Tan,1 William F. Fearon,1,3 (1) Stanford University School of Medicine, Stanford, CA; (2) Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: Coronary artery disease (CAD) screening is a cornerstone of kidney transplant (KTx) evaluation, but existing approaches result in excess testing and low intervention rate. We hypothesize that aerobic performance, based on a simple office test (the 6-minute walk test, 6MWT), may help risk stratify KTx candidates.

Methods: We performed 6MWT in waitlisted patients who were nearing KTx. Results were used for frailty counselling and not for cardiac evaluation. CAD screening was done according to our center protocol: invasive angiogram for patients with long-standing diabetes mellitus (DM) and non-invasive testing for other patients with risk factors and at the evaluating transplant nephrologist’s discretion. We used subdistribution Cox regression and time-dependent receiver operator curve to evaluate time to CAD event (revascularization, myocardial infarction, waitlist removal for CAD, or cardiac death), treating waitlist removal for non-CAD and non-cardiac death as competing events.

Results: Of the 360 patients, 200 and 161 patients had 6MWT results <400 meters and ≥400 meters (~4 metabolic equivalents), respectively. Patients with lower 6MWT results were older (59±10 vs 50±12 years) and more likely to be female (54% vs 34%), have DM (61% vs 33%) or known atherosclerotic disease (44% vs 22%), and have had prior cardiac evaluation (72% vs 61%). They were also more likely to exhibit cardiac symptom during 6MWT (36% vs 6%) and more likely to be censored due to waitlist removal for non-CAD reasons (follow-up 391±33 vs 541±277 days). 6MWT was not associated with CAD event (subdistribution hazard ratio 1.00 [0.90-1.10], 1-year area under the curve [AUC] 0.54). 196 patients had invasive (52%) or non-invasive (48%) CAD testing within 6 months of 6MWT: 6MWT did not predict the CAD test result (odds ratio 0.96 [0.81-1.14], AUC 0.54). Of the 94 patients who had concurrent non-invasive CAD testing, the 1-year AUC of 6MWT, symptom (at rest or during 6MWT), AST guidelines, or non-invasive testing for CAD event were 0.64, 0.52, 0.46 and 0.66 respectively.

Conclusions: The 6MWT did not perform better in risk stratification for CAD events compared to a symptom- or risk factor-based approach.

PO2514
Median Waiting Time of Kidney Transplant Candidates with Initial Estimated Post Transplant Survival Score >90% According to Organ Procurement Organization Waiting Time
Piyavadee Homkrailas, Erik L. Lum, Nakul N. Datta, Suphamai Bunnapradist.
University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: The kidney allocation system (KAS) and the estimated Post Transplant Survival (EPTS) score were introduced in the United States in December 2014. The transplant rate among very high EPTS candidates (>90%) may be impacted by lack of KAS priority, geographic factors based on the living donor procurement organization (OPO), and/or differences in waitlist mortality/delisting. Here we study the impact of new KAS among the candidates with EPTS>90%.

Methods: The Organ Procurement Transportation Network/United Network for Organ Sharing (OPTN/UNOS) data of all first-time transplants have been collected from 2015-2018 were included. Individuals listed for multiple organs, at multiple centers, and age >18 years were excluded. The outcomes included median waiting time to transplant, transplant rate, death rate and delisting rate among candidates with EPTS>90% compared to those with EPTSe<90%. Median waiting time was calculated by Kaplan-Meier model with censoring for still waiting candidates.

Results: A total of 114,870 candidates were included. Candidates with EPTSe>90% (9.74%) had a lower rate of overall transplant compared with EPTSe<90% (30.3% vs. 45.9%, p<0.001), higher rate of deceased donor transplant (87.6% vs. 60.9%, p<0.001), lower rate of living donor transplant (12.8% vs. 39.1%, p<0.001), higher death rate (8.5% vs. 5.73%, p<0.001) and higher delisting rate (22.9% vs. 13.3%, p<0.001). Overall median waiting time to transplant was 444 days (range 188-1,042 days among OPOs) compared to 1,025 days (range 160-1,633 days among OPOs) in those with EPTSe<90% (p<0.001).

Conclusions: Candidates with EPTSe>90% had a longer median waiting time compared to total waitlisted in all but one OPO. Median waiting times were heavily influenced by the lower overall rate of kidney transplantation and living donor transplantation in this group.

PO2515
A Devastating Complication of Encapsulating Peritoneal Sclerosis (EPS) In Two Renal Transplant Recipients
Benjamin Lawson, Zar Chan, Lilly M. Barba. Renal Transplant Program Los Angeles County Harbor-UCLA Medical Center, Torrance, CA.

Introduction: EPS is a rare complication of peritoneal dialysis (PD) which carries great morbidity and mortality. The risk of EPS may be higher in PD patients who undergo renal transplantation as compared to PD patients who do not receive a transplant. Pre-transplant EPS, progressive peritoneal remodeling, cessation of PD and use of calcineurin inhibitors are potential etiologies. We present two unique cases of post-transplant EPS requiring surgical intervention with devastating outcomes.

Case Description: Case #1 A 47-year-old female with end stage renal disease due to congenital kidney disease on PD for 8 years transitioned to hemodialysis due to peritonitis, underwent a deceased donor kidney transplant (DDRT) presented 4 weeks post operatively with nausea, vomiting, and abdominal pain. Imaging showed dilated loops of small bowel concerning for partial small bowel obstruction treated non-operatively with bowel rest. One month later she presented with similar symptoms and small bowel obstruction. Due to failure to improve, she was taken to surgery and was found to have a frozen abdomen with dense adhesions. Lysis of adhesions was complicated by enterotomies and small bowel resection. Multiple enterocutaneous fistulas prohibited wound closure. She is being evaluated for a small bowel transplant and remains on parenteral nutritional support. Case #2 A 39-year-old African female with history of ESRD secondary to Lupus on PD for 11 years received a DDRT. Eighteen months post-transplant, she presented with nausea, vomiting and abdominal pain. Imaging showed a small bowel obstruction treated non-operatively with bowel rest. Three weeks later she required emergent surgery for an acute abdomen undergoing lysis of adhesions, bowel resection and end ileostomy. She required parental nutrition for five months.

Discussion: We report two cases of EPS after DDRT who required surgical intervention with devastating outcomes. Fluid and nutritional support have complicated management and affected quality of life. Given the multifactorial etiologies and potential devastating outcomes of EPS, the pre-transplant evaluation should include a detailed assessment. Furthermore, long term PD patients and those with a history peritonitis should be monitored closely post-transplant.
Background: Approximately 15% of patients on the kidney transplant (KT) waiting list in the US receive peritoneal dialysis (PD), a growing home dialysis therapy for end stage renal disease (ESRD) patients. European guidelines recommend keeping the peritoneal dialysis catheter (PDC) in situ during KT, due to the potential risk for delayed graft function (DGf). With this approach, a 10% risk for post-transplant PDC exit-site infections has been reported. In the US guidelines for PDC removal timing are lacking, and determine by transplant center and operating surgeon’s preferences.

Methods: We retrospectively reviewed the electronic medical records of all patients transplanted between 4/2017-7/2019 at our kidney transplant center. We studied basic donor and recipient characteristics, presence of DGf (defined as dialysis in the first week following KT), time interval between KT and PDC removal, and wound related complications.

Results: Of 259 patients received a KT during the study period, 28 were on PD prior to KT. Of those 10 patients underwent a living donor transplant, 16had a deceased donor, and 2 underwent a simultaneous kidney-pancreas transplant. Sixteen were female, 9were non-Hispanic blacks, and 4were aged ≥65 years. Three received induction with basiliximab (per center’s protocol for recipients aged ≥70 years) and the rest received antithymocyte globulin. PDC was removed at time of KT in 17 patients while in the other 11 recipients PDC was removed 22 days (median) post transplantation. For patients developed DGf, with modality switched to hemodialysis. Three of these had their PDC removed at the time of KT. The 4th patient with DGf who had his PDC catheter left in place, received hemodialysis due to hemodynamic instability. Readmission rates (excluding planned hospitalization for PDC removal) and wound infections were similar between those who had their PDC removed at surgery, and those who did not.

Conclusions: Kidney transplant centers that do not routinely use PD for DGf should remove the PDC at time of kidney transplant to reduce costs and prevent patient and healthcare provider burden of additional surgery. As the prevalence of PD and KT is expected to grow in the near future with the new kidney health initiatives, kidney transplant centers should consider a protocol for optimal care for PDC removal.

PO2517
Could Targeting Dry Weight on Hemodialysis Patients Before Kidney Transplantation Leave Them Too Dry?
Hayam H. Al Dohani,1,2 Eduard A. Iliescu,1,2 Frances Macleod,1 M. Khaled Shamseddin1,3 Queen’s University, Kingston, ON, Canada; 2Kingston Health Sciences Centre, Kingston, ON, Canada.

Background: Delayed graft function (DGf) after kidney transplantation is associated with inferior kidney and patient outcomes. Studies suggest that avoidance of hypovolemia peri-kidney transplantation is associated with a reduced risk of DGf. Hemodialysis (HD) patients that have HD prior to transplant targeting their usual dry weight may be volume contracted pre-transplant and at increased risk for DGf. By definition the dry weight is the state of near maximal volume contraction for most HD patients. The objective of this study is to examine the proportion of HD patients who have a pre-transplant post-HD weight at or below their usual dry weight.

Methods: This is a retrospective study of sequential kidney transplants in HD patients at our center from Jan 2015 to Dec 2019. The primary outcome was the proportion of patients who had an HD session before transplantation that resulted in a post-HD weight equal to or less than their prevalent set target dry weight. Data was extracted from the electronic medical record and chart review. Recipients on home therapies and pre-emptive transplants were excluded.

Results: Of 68 kidney transplants done in the study period, 40 were in-center HD patients with available HD data. They were mean age 54.8±14.5 years, 12 (30%) female, and majority were Caucasian. Twenty-five (62.5%) patients had a pre-transplant post-HD weight equal to or less than their prevalent set target dry weight (mean ± 0.26±0.25 kg). The other 15 (37.5%) patients achieved post-HD weights higher than their usual targets (+0.72±0.41 Kg).

Conclusions: The results of this study suggest that a high proportion of HD patients are at below dry weight after their dialysis and may be hypovolemic before kidney transplantation. This may represent at potentially avoidable increased risk for DGf. Further studies are planned to examine possible associations of achieved post-HD weight prior to transplant with perioperative central venous pressure, IV fluid administration, and graft function. There may be strategies to optimize volume status pre-transplantation to mitigate this risk of DGf including targeting a higher weight on HD or administration of IV fluid to raise weight above the prevalent set target dry weight before transplantation when feasible.

PO2518
Trends in Time to Graft Loss by Dialysis Exposure
Patrick Ahearn, Colin R. Lenihan, John D. Scandling. Stanford University School of Medicine, Stanford, CA.

Background: Preemptive transplantation is believed superior to transplantation after dialysis initiation, and transplantation after shorter dialysis exposure is better than with longer exposure. Considering recent registry reports of improved survival on dialysis, we examined temporal trends of graft loss by time on dialysis prior to kidney transplantation.

Methods: Using the US Renal Data System, we identified adults who underwent first kidney transplant between January 1, 1995 and July 31, 2017. We excluded recipients of simultaneous multiorgan transplants. We used an adjusted Cox model to examine the association between dialysis exposure prior to transplantation (categorized as preemptive, ≤6 months, 6 months-1 year, 1-3 years, 3-5 years, and >5 years) and graft failure within 3 years of transplant. Our model was adjusted for donor and recipient demographic factors, donor type, cause of ESKD, BMI, panel reactive antibodies, diabetes status, and cardiovascular disease status. We organized patients into the following transplant era groupings: 1995-2001, 2002-2006, 2007-2011, and 2012-2017.

Results: A total of 277,158 transplant recipients were studied and 38,364 had graft loss within 3 years. In each era, the hazard ratio for graft loss was lower for preemptive transplant recipients (referent group) compared to all other dialysis exposures except for the group that received less than 6 months of dialysis in the 2012-2017 era (HR 1.06 (95% CI 0.91-1.24)). Those exposed to more than 5 years of dialysis exposure had the highest risk for graft loss within 3 years in all eras, with over 2 times the hazard compared to the referent group in the most recent eras (figure).

Conclusions: Although preemptive transplantation offers the best graft survival across the study period, those transplanted within 6 months of dialysis initiation had similar 3-year graft survival to those transplanted preemptively in the most recent era. The negative association between the longest duration of pre-transplant dialysis and post-transplant survival persists.

Variations in Practice Patterns in Eligibility Assessments Across Kidney Transplant Programs in the United States

Background: Kidney transplant programs are known to vary in terms of their practice patterns given lack of consensus surrounding many aspects of pre-transplant workup. The differences in national practice patterns related to transplant eligibility assessments have not been well described in the contemporary era.

Methods: We conducted a survey of kidney transplant programs in the US to assess current practice patterns as it relates to criteria for prioritizing transplant referrals, candidate evaluation, and determination of eligibility for kidney transplantation. We distributed our survey to 171 adult kidney transplant programs in the US.

Results: 89 (52%) of programs invited to participate in the survey completed it, 45% of which were completed by the Medical Director, 48% by a Transplant Nephrologist, and 7% by other providers. The majority of programs (58%) screened referrals for contraindications to transplantation before scheduling an in-person evaluation (Figure 1). 52% of programs did not prioritize the evaluation of patients with a self-identified living donor candidate when scheduling patients referred for eligibility assessments (Figure 1). Centers differed in the kidney function threshold at which transplant evaluation was begun, and age and body mass index limits for transplantation also varied considerably (Figure 1).

Conclusions: There is wide variation across transplant programs in the assessment of eligibility for kidney transplantation. Further studies are needed to understand how these variations may be associated with access to transplantation and post-transplantation outcomes.

Post-Transplant Diabetes Mellitus in a Single Pediatric Kidney Transplant Center: Risk Factors, Outcomes, and Characterization of Clinical Course
Auli Khanna, Jee-Young N. Ham,1,2 Margret Kamel,1 Kathryn M. Ngo,1 Amanda S. Thomas,1 Rochelle Liverman,1 Roubia Garro,1,2 Emory University School of Public Health, Atlanta, GA; 3Children’s Healthcare of Atlanta Egleston Hospital, Atlanta, GA; 4Emory University School of Medicine, Atlanta, GA.

Background: The prevalence and outcomes of post-transplant diabetes mellitus (PTDM) in pediatric kidney transplant (KT) recipients vary among studies due to the lack of a consistent definition. Risk factors for and pathogenesis of pediatric PTDM are incompletely understood.

Methods: PTDM prevalence, risk factors and disease course was evaluated at a high volume, tertiary care pediatric hospital. We performed a retrospective review of pediatric KT recipients between 2006-2016 to evaluate PTDM prevalence. PTDM was defined as persistent hyperglycemia with serum glucose ≥200 mg/dL, HbA1C ≥6.5%, and requiring antihyperglycemic treatment for a 30 days. Full data were available on all patients transplanted between 2010-2016 and were used to compare demographic and clinical characteristics between PTDM (n=9) and non-PTDM patients (n=173) using Chi-square and Wilcoxon rank sum tests.

Results: Between 2006-2016, 312 patients received KT. Five patients with pre-existing DM were excluded. Fifteen developed PTDM with a prevalence estimate of 4.89 % (95% CI: 3% - 8%) and median time from transplant to DM was 17.6 months (25%-75%: 3 – 83). The majority of PTDM patients had a family history of DM in 1st degree relatives (81%) and were maintained on tacrolimus at diagnosis (67%). PTDM diagnosis and insulin initiation occurred in the context of active rejection episode in only two patients. Despite a more stringent definition of PTDM, insulin therapy was discontinued in 3/15 (20%) patients who continued to be normoglycemic. Comparing patients with and without PTDM during the period 2010-2016 revealed that PTDM patients had higher BMI-Z scores at transplant (p=0.053) and higher average blood glucose during the first week post KT (p=0.095), with no difference in age, gender, race, donor status, or dialysis modality.

Conclusions: A more consistent definition of PTDM and larger studies are warranted to better understand the prevalence, risk factors, and pathogenesis of hyperglycemia and PTDM in children. Detailed patient-level data can provide nuance that may be missed with larger registry studies.

Funding: Private Foundation Support
consistent with diabetic nephropathy (Figure 1), early chronic transplant glomerulopathy, and severe arteriolar hyalinosis. Additional laboratory findings showed serum lipase 34 (Normal 7-60 U/L), amylase 103 (Normal 21-101 U/L), fasting glucose 79 (Normal 65-99 mg/dL), hemoglobin A1c 5.3, and C peptide was 2.03 (Normal 0.80 - 3.85 ng/mL). Despite increasing Benazepril dose to 40 mg daily, UPCR and Cr continued to increase but stabilized in a range of 3800-4500 mg/g and 2.5 mg/dL respectively.

Discussion: Our case suggests that development of DN can be linked to mechanisms independent of hyperglycemia and the usual metabolic disturbances seen in patients with diabetes. A comprehensive restudying of the pathophysiology of DN could further enhance our existing knowledge of the factors implicated in DN, and possibly our ability to develop a more targeted therapy.
PO2525

Health System Encounters in Kidney Transplant Recipients Converted from Immediate-Release Tacrolimus Capsules to Extended-Release Tacrolimus Tablets

Yoonhee P. Ha,1 Jamal Rashid,2 Mary Putt,2 Yu Bin Na,3 Chelsea Sammons,2 Maxwell Norris,2 Gregory Matal,2,1 Brendan Steiner,1 John H. Holmes,1 Roy D. Bloom,2 Peter P. Reese,1,3 Jennifer Trofe-Clark,2,3 Department of Epidemiology, Biostatistics and Informatics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2Department of Pharmacy, Hospital of the University of Pennsylvania, Philadelphia, PA; 3Renal Electrolyte and Hypertension Division, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4Drexel College of Medicine, Philadelphia, PA.

Background: Kidney transplant recipients (KTRs) converted from immediate-release tacrolimus capsules (IR-TAC) to extended-release tacrolimus tablets (ER-TAC) may benefit from reduced dosing frequency and improved bioavailability. However, few studies have characterized health system encounters in these KTRs. Study aims were to (1) determine if conversion to ER-TAC decreased number of dose changes, TAC troughs, and transplant clinic visits and (2) characterize number of dose changes and days to achieve two consecutive therapeutic troughs (5-12 ug/L) under ER-TAC.

Methods: Retrospective review of KTRs at our center transplanted between 2/2010-3/2019, on IR-TAC for ≥90 days, and converted to ER-TAC for ≥90 days. Random-coefficient Poisson regression was used to compare number of dose changes, troughs, and clinic visits during the 90-day pre- and post-conversion.

Results: 64 KTRs met inclusion criteria. Mean (SD) age was 52.8 (13.7) years, 38 (59%) were male, 28 (44%) were Black, and 8 (13%) were in an ER-TAC financial assistance program. Median (IQR) time since transplant was 333 (211-1,483) days. KTRs converted to ER-TAC for: 26 (41%) non-adherence, 12 (19%) high IR-TAC dose, 2 (3%) sub-therapeutic troughs, 2 (3%); and other/unknown, 22 (34%). The incidence rate of dose changes but not troughs or clinic visits decreased significantly post-conversion (Table). For the 24 (38%) KTRs with two consecutive therapeutic troughs within 90 days, median (IQR) number of dose changes was 2 (0-3) and days to achieve two consecutive therapeutic troughs was 33.5 (23.5-63).

Conclusions: The incidence rate of dose changes decreased significantly under ER-TAC, but most KTRs did not achieve two consecutive therapeutic troughs within 90 days of conversion. Closer follow up may be beneficial for these KTRs. Future research should determine if reasons for conversion resolved with ER-TAC.

PO2526

Looking Beyond the Allograft Survival: Long-Term, Five-Year Renal Outcomes in Lung Transplant Recipients

Mohankumar Doraiswamy, Eshtetu L. Obole, Priyamvada Singh, Todd E. Pesavento. Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: With the increase in incidence and overall survival of lung transplant recipients, the risk for chronic sequelae in terms of CKD is on the rise. However, the data trajectories, ACGL, and mortality by 1-year pre-KT weight change, defined as stable weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between recipients with intentional and unintentional weight loss.

Methods: Among 366 KT recipients from a prospective cohort study of frailty and KT, we used adjusted mixed effects models to estimate differences in post-KT BMI trajectories, ACGL, and mortality by 1-year pre-KT weight change, defined as stable weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between recipients with intentional and unintentional weight loss.

Results: Mean age was 53 years, 39% were black, and 39% were female. The majority (64%) had stable pre-KT weight, 12% had weight gain, 14% had unintentional weight loss, and 10% had intentional weight loss. By 3 years post-KT, BMI increased by 0.05 kg/m2 (95% CI 0.02, 0.08 kg/m2) among those with stable pre-KT weight; the increase was similar among those with post-KT weight gain and intentional weight loss. Those with post-pre-KT weight loss had larger increases in post-KT BMI than those with stable BMI (BMI change difference +0.15 kg/m2 [0.04, 0.25 kg/m2]; p<0.01). Unadjusted cumulative incidence of mortality was similar across weight change categories (Figure). Adjusted for age, sex, race, BMI, and donor type, only unintentional weight loss was associated with higher mortality (HR 2.31 [1.24,3.3], p<0.008) and ACGL (HR 2.62 [1.24,3.3], p<0.005) relative to stable weight.

PO2527

Incidence, Risk Factors, and Outcomes of Post-Transplant Erythrocytosis After Kidney Transplantation

Bevann Alzubj,1 Abish Kharel,2 Fauzia Osman, Fahad Aziz, Neetika Garg, Maha A. Mohamed, Arjung Djamal, Didier A. Mandelbrot, Sandesh Parajuli. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Post-transplant erythrocytosis(PTE) is a common condition after kidney transplantation. PTE is known to increase the risk of stroke, pulmonary embolism, and deep vein thrombosis, commonly called vascular thromboembolism(VTE). In the current era of immunosuppressive medication and management, the incidence, risk factors, and outcomes of PTE among kidney transplant recipients(KTR) is unknown.

Methods: This was a retrospective study among all adult KTRs transplanted at our university between 01/2001 and 12/2016. All recipients in the PTE group had at least 2 consecutive Hct levels of ≥51 within the first 2 years of transplant. Controls were selected in a ratio of 5:1 using event density sampling. Patient survival, graft survival, and VTE incidence were outcomes of interest.

Results: Of 4317 kidney transplants during the study period, 214(5%) had PTE and were compared to 1035 controls. While comparing baseline characteristics between PTE and control, KTRs in the PTE group were more likely to be younger, male, have lower BMI, higher prevalence of diabetes as the cause of ESRD and receive a non-heart-beating transplant. Similarly, looking at donor characteristics, the PTE group was likely to receive the kidney from a younger donor and have lower KDPI. The median interval from transplant to the diagnosis of PTE was 9.9 months (IQR 5.89). 13 (6.1%) in the PTE group and 7(6.9%) in control had VTE events. In the multivariable analysis, patients with older age (HR: 0.98, 95% CI 0.97-0.99), higher BMI (HR: 0.97, 95% CI 0.93-0.99, p<0.05) was less likely to develop PTE, while pre-emptive transplant (HR: 3.95, 95% CI 1.74-8.99, p<0.001) was significantly associated with increased risk of PTE. After adjustment for the multiple confounding factors, PTE was not associated with patient mortality (HR: 1.0, 95% CI 0.70-1.43, p=0.99), graft failure (HR: 1.13, 95% CI 0.69-1.83, p=0.61) or VTE (HR: 1.07, 95% CI 0.59-1.96, p=0.81). In a subgroup analysis among PTE with Hct >55 (n=39) compared with controls, similar findings were observed.

Conclusions: In this era, the prevalence of PTE is lower at 5% compared to around 15% in various previous studies. Similarly, there were no detrimental effects of PTE on patient survival, graft survival, or the risk of VTE in the current era.

PO2528

Post-Transplant Outcomes Among Kidney Transplant Recipients with Intentional and Unintentional Weight Loss

Meera N. Harhay,1 Xiaomeng Chen,2 Nadia M. Chu,2 Mara McAdams-DeMarco.2 Drexel University, Philadelphia, PA; 3Johns Hopkins University, Baltimore, MD.

Background: Research has shown that kidney transplant (KT) recipients who lose weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between recipients with intentional and unintentional weight loss.

Methods: Among 366 KT recipients from a prospective cohort study of frailty and KT, we used adjusted mixed effects models to estimate differences in post-KT BMI trajectories, ACGL, and mortality by 1-year pre-KT weight change, defined as stable weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between recipients with intentional and unintentional weight loss.

Results: Mean age was 53 years, 39% were black, and 39% were female. The majority (64%) had stable pre-KT weight, 12% had weight gain, 14% had unintentional weight loss, and 10% had intentional weight loss. By 3 years post-KT, BMI increased by 0.05 kg/m2 (95% CI 0.02, 0.08 kg/m2) among those with stable pre-KT weight; the increase was similar among those with post-KT weight gain and intentional weight loss. Those with post-pre-KT weight loss had larger increases in post-KT BMI than those with stable BMI (BMI change difference +0.15 kg/m2 [0.04, 0.25 kg/m2], p<0.01). Unadjusted cumulative incidence of mortality was similar across weight change categories (Figure). Adjusted for age, sex, race, BMI, and donor type, only unintentional weight loss was associated with higher mortality (HR 2.31 [1.24,3.31], p<0.008) and ACGL (HR 2.62 [1.24,3.31], p<0.005) relative to stable weight.

Conclusions: In this study, pre-KT unintentional weight loss was associated with higher post-KT BMI increases, ACGL and mortality than pre-KT intentional weight loss, stable weight, and weight gain. These results suggest that unintentional weight loss should be identified and addressed in KT candidates, independent of BMI.

PO2520

Obesity and Poorer Renal Allograft Function: Analysis of Longitudinal Data

Ekaton Tantissatamo, Busara Songtainan, Natmicha Leelavivat, Sakdita Saowapa, Possawat Vuthikraivit, Chawit Lopipithit, Natchaya Polpichai, Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA. 1Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 2Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 3Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 4Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; 5Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkla, Thailand.

Background: Obesity is associated with worsened allograft function, but its effect on allograft function after established baseline allograft function at a 12-week post-kidney transplant (KT) is unclear.

Methods: All 105 KT recipients were divided into obese (BMI ≥ 30 kg/m^2) and non-obese groups. Longitudinal data were analyzed by linear mixed model to examine association between obesity and eGFR during the 1st year post-KT.

Results: Mean age was 54±11 years and 64 patients (61%) was female. Seventy-one patients (68%) were obese. Generalized estimating equation revealed that eGFR increased 0.16 ml/min/1.73 m^2 (95% CI 0.09 to 0.23) for every 1 week after KT. Excluding eGFR at 4-week post-KT when baseline allograft function is generally not established, mean eGFR at 12-week post-KT was the lowest and assigned as the baseline allograft function. Given unequal spreading of time when eGFR were measured, a 1-year follow-up was categorized into every 4 and 12 weeks if eGFR were measured before and after a 12-week post-KT, respectively. Spline interaction term was created at the 12-week post-KT as well as categorized time-spline interaction term. By using a linear mixed model and after adjusted for age, gender, type of KT (deceased vs living donor KT), obesity category and its interaction team with categorized time and spline interaction term, obese group had a higher rate of eGFR decline of 2.9 ml/min/1.73 m^2 for every 1 week after KT. Posterior expected median eGFR at 12-week post-KT and rate of eGFR change were taken into the consideration. Pre-KT obesity remains one of the associated factors of poor allograft outcomes, which may be mitigated by pre-KT weight loss.

PO2530

A Call to Action: Finding the Right Kidney for All Potential Recipients

Background: The burden of dialysis among ESRD patients is a huge driver of morbidity, mortality, and cost. Thousands of deceased-donor (DD) kidneys that almost certainly have better outcomes than dialysis are discarded each year. Our center sought to find and transplant kidneys that would reduce waiting time for our patients while preserving post-transplant outcomes consistent with nationally expected results.

Methods: We reviewed 1119 consecutive DDKT recipients transplanted between 1/1/2016 and 12/31/2019 at our center. Endpoints were eGFR by MDRD death-censored graft survival using Kaplan-Meier survival estimation and the Cox Proportional Hazards Model. We reviewed on additional year (2015) for waiting time impact.

Results: DD KT volumes doubled from 2016 to 2019 (191 vs. 384). Growth was attributable to increased acceptance of hard-to-place imported kidneys, including kidneys with AKI (413% increase) and KDPI > 85 (296% increase). In 2016, 46.6% of DD kidneys were imported from outside our DSA and by 2019, 77.3% were imported. Overall one-year patient survival was 96.6% (CI: 95.4-97.6%) and death-censored one-year graft survival was 95.8% (CI: 94.4-97.6%). Recipients with any stage of AKI saw no additional risk vs. donors without AKI (HR 0.94, p=0.854) while death-censored graft survival at one year was 91.9% for recipients of kidneys with KDPI >85 vs 96.7% with KDPI ≤85%, representing significant additional risk (HR: 1.91; p=0.017). This significantly decreased waiting time at transplant across all blood types (6 years in 2015 to 3.9 years in 2019). This benefit was even greater for blood group B (10.7 to 4.3), and significantly reduced the disparity in accrued waiting times for African-American and Hispanic populations. Kidney function was good at 1 year in all groups among those surviving with followup. Mean eGFR by MDRD formula was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors (p=0.4384). Mean eGFR 49.0 in the KDPI > 85% group vs 62.3 in the <= 85% KDPI group (p=0.0001).

Conclusions: Transplant centers can answer the growing demands of patients enduring dialysis to better utilize kidneys that have previously been discarded. Our center demonstrated that it is possible to reduce waiting time, and maintain outcomes using kidneys previously discarded.

Multivariate regression model was adjusted with parameters showing significant difference among the 4 groups according to BMI and pre-sensitization status. Parameters were as follows: Age, Sex, DM, HTN, Fasting glucose, Triglyceride, HDL-cholesterol, Hemoglobin A1c, ESRD causes, Dialysis modality, and Prior KT history.

Methods: KT recipients with suspected oxalosis due to any of the following: inflammatory bowel disease, bariatric surgery, or pancreatic insufficiency from 2015 to 2019 were included. At our institution, pre-KT serum oxalate>30mcmol/L is the threshold for treatment.

Results: 31 patients were identified. Mean age was 58.5 years, 55% were female, 81% white, and 94% first KTx. Most common cause of ESRD was diabetes (45%), and 84% were on dialysis prior to KTx (median 30.5 months). The most common enteric cause was Roux-en-Y gastric bypass (RYGB, 77%) with surgery 11 years (median) prior to KTx. 39% had history of nephrolithiasis. Median peak serum oxalate (SOx) pre-KTx was 24mcmol/L. 87% received deceased donor KTxs and 52% had delayed graft function (DGF). Post-KTx, 36% received calcium with meals for oxalate bind, and 39% had low oxalate diet education. 5 patients had pre-KTx SOx>30mcmol/L at the time of KTx, of whom 4 had DGF and required either longer dialysis (up to 5 hours long) or increased dialysis sessions (up to 6 per week) to reduce SOx levels post-KTx. The median duration of dialysis after KTx was 13.5days. After median follow up of 27.9 months, MD showed significantly lower serum calcium and phosphorus (GFR) was 47.6±1.21mL/min/1.73m2 and 68% of patients had GFR <60. One-year GFR was 48.4±2.4mL/min/1.73m2 which is lower than expected 1-year GFR for our Transplant Center (mean GFR 58±2.06mL/min/1.73m2). RYGB patients (n=24) had lower GFR vs patients with other EH causes (n=7) (1 year: 48.7±2.04.4±5.6±4.9; last follow-up 47.3±2.11 vs 57.5±14.4 mL/min/1.73m2). Only 2 patients had oxalate crystals on protocol allograft biopsy, both with RYGB, and one with DGF and died 22 months after KTx. GFR at 1 year was 34±2.83 mL/min/1.73m2 for these 2 patients.

Conclusions: RYGB is the most common cause of enteric oxalosis in KT recipients. DGF is common and graft outcomes are inferior compared to deceased donor KTxs at our institution. The lower GFR in RYGB patients raise concern for enteric hyperoxaluria as an unrecognized risk for allograft dysfunction.

Middle Cerebral Artery Hemodynamics Is Blunted in Kidney Transplant Recipients

Andrew J. Jurgensen,1 Jaimie Ward,2 Allegra Morton,2 Andrew P. Geise,2 Sandra Billinger,2 Aditi Gupta,1 University of Kansas Medical Center Division of Nephrology, Kansas City, KS; 1University of Kansas Medical Center Department of Physical Therapy and Rehabilitation, Kansas City, KS.

Background: Kidney transplant (KT) recipients have a higher risk of dementia and cerebrovascular events than the general population. Cerebrovascular hemodynamic response (CVR) to constant-load moderate-intensity exercise marks the ability of the brain to respond to increased oxygen requirements with exercise. Blunted CVR seen with vascular disease and aging can increase risk of dementia and stroke. We evaluated the middle cerebral artery blood velocity (MCV) dynamic response in KT recipients and compared it to age matched non-CKD controls.

Methods: 35 KT recipients and 35 healthy controls completed a 90-second rest followed by a 6-minute moderate intensity exercise on a recumbent stepper at a prescribed step rate and workload. We used transcranial doppler (TCD) monitoring for MCV while continuously monitoring heart rate and beat-to-beat mean blood pressure during rest and exercise. Baseline resting MCAV and steady state response during exercise was recorded. Outcome measures included resting MCAV and CVR (MCV during steady state exercise – baseline MCAV) and workload needed to achieve target heart rate. Statistical analysis employed independent t-test.

Results: KT recipients were 52.4±17 years old, 74.3% male, 91.4% white, 22.9% with diabetes, and 91.4% with hypertension. Controls were 54.2±20 years old, 74.3% male, 80% white, without diabetes, and 14.3% with hypertension. Baseline MCAV was similar in the two groups, but the response during moderate intensity exercise differed; CVR for KT recipients was 8.12±0.8 cm/s compared to 12.9±1.4 cm/s for controls (p=0.003) and target workload for KT recipients was 84.1±2.8 watts compared to 123.1±5.3 for controls (p=0.001) (Table 1).

Conclusions: KT recipients have a blunted middle cerebral artery hemodynamic response to exercise compared to healthy controls. This may be due to vascular disease and can explain the higher white matter disease, dementia, and stroke in this population.

Kidney Transplant Outcomes for Patients with Enteric Oxalosis

Mira T. Keddis, Danica Grusic, Annamaria T. Kausz. Mayo Foundation for Medical Education and Research, Scottsdale, AZ.

Background: Patients with enteric disorders associated with hyperoxaluria and systemic oxalate burden (enteric oxalosis) are at increased risk for calcium oxalate deposition causing ESRD. The objective of this study is to evaluate kidney transplant (KTx) recipients with enteric oxalosis at our institution.

Longitudinal Physical Performance Following Kidney Transplantation
Juan M. Lourdes,3 Mayo Clinic, Rochester, MN; 3Mayo Clinic, Jacksonville, FL

Background: Frailty and poor physical performance are strongly associated with poor outcomes in kidney transplantation (KTx). However, the effect of KTx on physical performance remains poorly understood.

Methods: We measured 6-minute walk test (6MWT), meters and 1-minute sit-to-stand test (STS, number of repetitions from standing to sitting position) performances within 1 year prior to KTx. Physical performance indices were re-measured at 3 and 6-months, and 1-year post-KTx. Multivariable linear regression was used to assess which baseline characteristics were associated with 6MWT and STS. Trajectories of 6MWT and STS were assessed by baseline performance using a generalized estimating equation.

Results: Among 85 patients who performed baseline assessments, 39, 33 and 40 completed 3, 6, and 12-month evaluations, respectively. Average age was 53 and average dialysis vintage was 7 years. 49% had diabetes mellitus, 18% had coronary artery disease, 5% had cerebrovascular disease, and 10% had peripheral arterial disease (PAD).

Conclusion: Frailty and poor physical performance are strongly associated with poor outcomes in kidney transplantation (KTx). However, the effect of KTx on physical performance remains poorly understood.

PO2536

Outcomes of Kidney Transplantation in Fabry Disease: A Meta-Analysis
Jie Yan,1,3 Zheng Li,1,3 Guang Song,1,3 Juan J. Anaya,1,3,4 Alia M. Hellman,1,3 Xuan Zhang,1,3,4 Meda Z. Fungu,1,3,4 Mayada Z. Fungu,1,3,4 Marya J. M. Z. Fungu,1,3,4 Shireen G. A. M. Fungu,1,3,4

Background: Fabry disease (FD) is a rare X-linked lysosomal storage disorder with progressive systemic deposition of globotriaosylceramide, leading to life-threatening cardiac, central nervous system, and kidney disease. Current therapies involve symptomatic medical management, enzyme replacement therapy (ERT), dialysis, kidney transplantation, and more recently gene therapy. The aim of this systematic review was to assess outcomes of kidney transplantation among patients with FD.

Methods: Comprehensive literature review was conducted utilizing MEDLINE, EMBASE and Cochrane Database, from inception through February 28, 2020 to identify studies that evaluate outcomes of kidney transplantation including patient and allograft survival among kidney transplant patients with FD. Effect estimates from each study were extracted and combined using the random-effects, generic inverse variance method of DerSimonian and Laird.

Results: Eleven studies including 424 kidney transplant recipients with FD were included. The post-transplant median follow-up time ranged from 3 to 11.5 years. Overall, the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 32.5% (95%CI: 23.9%-42.5%), 14.5% (95%CI: 8.4%-23.7%), and 20.2% (95%CI: 15.4%-25.9%), respectively. A sensitivity analysis limited only to the recent studies (year 2001 or newer when ERT became available), the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 28.1% (95%CI: 20.5%-37.3%), 11.7% (95%CI: 8.4%-16.0%), and 20.2% (95%CI: 15.5%-26.0%), respectively. The pooled estimated rate of biopsy proven FD recurrence was 11.1% (95%CI: 3.6%-29.4%), respectively. There was no significant difference in the risk of all-cause graft failure (P = 0.10) nor mortality (0.48) among recipients with vs. without FD.

Conclusion: Despite possible FD recurrence after transplantation of 11.1%, allograft and patient survival are similar among kidney transplant recipients with vs. without FD.

PO2537

Urinary Supersaturation in Patients with Kidney Transplant Nephrolithiasis
Erin E. Bolen,1 Mitchell Humphreys, Karen L. Stern, Todd Leavitt, Nan Zhang, Mira T. Keddis. Mayo Clinic Arizona, Scottsdale, AZ

Background: Urine supersaturation (SS) has not been reported for kidney transplant (KTx) recipients with de novo transplant-derived nephrolithiasis. The objective of this study was to assess supersaturation studies, treatment, and stone and allograft outcomes in KTx recipients with allograft nephrolithiasis.

Methods: Retrospective review from 2009-2019 of KTx recipients with nephrolithiasis at Mayo Clinic was completed. Stone event was defined as radiologic evidence.

Results: Fifty six transplant nephrolithiasis cases were identified. Mean transplant age was 56.5 (±12.1) years, 32 (57.1%) were male, 46 (82.1%) receiving first KTx, 41 (75.9%) required dialysis, and 17 (30.9%) had stone event prior to KTx. Twenty one (37.5%) had at least 2 stones in the allograft, median stone size was 6 mm, and most common location was the lower pole (n=20 [41.7%]). Median time from KTx to stone event was 1 year. Thirty four (60.7%) had a 24-hour SS study at a median of 2 years after KTx. Select results are shown in Table 1. Of the 34, 14 (41.2%) had a stone event prior to KTx, and 6 (17.6%) had a donor-derived stone. Thirty one (91.2%) had increased SS of calcium oxalate, 17 (50%) calcium phosphate, and 9 (26.5%) uric acid. Thirty two (94.1%) had urine citrate <450mg/24hrs. Management of the initial 56 included potassium citrate in 13 (23.2%), calcium citrate in 10 (17.6%), and dietician referral in 18 (32.1%). Forty five (80.8%) were seen by urology, 28 (50%) needed surgical management, and 14 (27.5%) passed the stone. At median follow-up of 4 years after KTx, 37 (66.1%) had persistent stone disease in the allograft, 3 (5.4%) had graft failure, and 2 (3.6%) had died.

Conclusion: This is the first study of urine SS in patients with transplant-derived nephrolithiasis. Profound hypocitraturia was the most prevalent risk, and increased supersaturation for calcium oxalate crystals predominated. Allograft stone clearance was rare, and many required surgical intervention.

PO2538

Exposure to Tacrolimus Trough Levels Below 6 ng/mL During the First Year Is Associated with Inferior Kidney Graft Survival
Tim Ngu,1,2 Ruth Rahamimov,1,2 Benaya Rozen-zvi,1,2 1Department of Nephrology and Hypertension, Rabin Medical Center Israel, Pethah Tikva, Israel; 2Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv; Israel

Background: Accumulating data indicates that sub-therapeutic levels of calcineurin inhibitors are associated with long-term graft loss. However, while tacrolimus (TAC) was shown to provide adequate immunosuppression with lower acute rejection rate, its optimal maintenance dose for long term graft survival is still unknown. The aim of our study was to determine the minimal TAC trough level, which is associated with improved kidney graft survival.

Methods: We conducted a retrospective cohort study based on the RMC registry. We defined five TAC trough level intervals: 3-4, 4-5, 5-6, 6-7, and 7-8ng/ml. We calculated exposure time for each drug level interval during the first year following transplantation, defined as the cumulative number of days at each interval. This measure
was adjusted to the exposure time below a given interval-level, allowing us to define the threshold for optimal TAC trough level as the upper limit of the interval. We then determined the association between the adjusted exposure time at each TAC level-interval and our primary outcome, death-censored graft survival. **Results:** We included 1417 patients with a median follow up of 5.3 years (IQR 2.9-8.5 years). TAC through interval level of 5-6ng/ml was the highest interval which demonstrated a statistically significant association between exposure time and increased risk of graft loss, even after adjustment to the exposure time below 5ng/ml (HR 1.56, p<0.001). These results remained consistent in an extensive multivariate analysis (HR 1.44, p<0.001) and were not significantly changed when we analyzed for death-related graft survival (HR 1.2, p=0.026) or the first three months and the subsequent nine months separately (HR 1.93, p<0.001, HR 1.56, p<0.001 respectively). Cumulative exposure time above 14 days to TAC trough levels above 6ng/ml was significantly associated with increased risk of graft loss in most studied subgroups including age, gender, donors with high immunologic risk recipients, except for the subgroup of recipients with diabetes. **Conclusions:** Prolonged exposure time to TAC trough level between 5-6ng/ml within the first-year post-transplant was independently associated with increased risk of long-term graft loss. These results imply that keeping TAC trough levels above 6ng/ml during high immunologic risk recipients, except for the subgroup of recipients with diabetes.

**PO2539**

High Intraepithelial Variability of Tacrolimus in Pediatric and Adolescent Renal Transplant Recipients Is Associated with Worse Graft Outcomes

Kim H. Pihrep,1,2 Lynn K. Maceretree,1,2 Mary V. Patton,1,2 Anne M. McGraith,1,2 Rajesh R. Shetty,1 Abanti Chaudhuri,1,2 Paul C. Grimm,1,2 Vaka K. Sigurjonsdottir,1,2 Stanford University School of Medicine, Stanford, CA; 1Lucile Salter Packard Children’s Hospital at Stanford, Palo Alto, CA; 2Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland.

**Background:** High intra-patient variability (IPV) in tacrolimus (TAC) levels has been associated with the development of de novo donor-specific antibodies. The degree of TAC IPV in relation to poor graft outcomes in pediatric kidney transplant patients is unknown.

**Methods:** Patients 0-25 years who were on TAC from 01/2010-01/2018 at a single center were considered for inclusion. Minimum required follow-up time was 12 months. Primary outcomes were formation of C1q+ de novo DSAs (dnDSAs) and high, dnDSAs were identified by routine screening or at investigation of allograft dysfunction. TAC IPV was defined using the mean coefficient of variation (CV) over the immediate 6-month time period prior to each TAC level. All available TAC levels were included in the analysis. Mean CV was calculated using CV from 10 months post-transplant until end of follow-up. Patients were followed until 01/03/2019 or until graft loss. Analyses were performed using descriptive statistics and the Mann-Whitney U test.

**Results:** 225 pediatric kidney transplant patients met inclusion criteria. Median age was 12.5 years (range 15 mo.-21 yrs.). 46% were female, and 24% received a living donor transplant. 51 formed C1q+ dnDSAs and 174 did not. Among patients who formed C1q+ dnDSA, 13/51 (25.5%) lost their graft, compared to 2/174 (1.1%) in patients who did not form dnDSA by C1q. C1q+ dnDSA forms were found in 12 patients; 4 patients did not form dnDSA by C1q (median CV 33.9% vs 26.1%, p=0.0001), including when stratified by age subgroups of 0-12 years (p=0.0217) and 13-25 years (p=0.0001). Patients with graft loss had higher mean CVs compared to those who did not have graft loss (median CV 39.0% vs 25.8%, p=0.0006).

**Conclusions:** High tacrolimus IPV was associated with C1q+ dnDSA formation and graft loss. Tacrolimus IPV is a potential prognostic tool for optimizing transplantation outcomes.

**PO2540**

Impact of Renal Transplantation on Functional Status in Tacrolimus Era

Mahmoud M. Mohamed,1 Karim M. Soliman,4 Hatem Ali,2 Ahmed Daoud,4 Tibor Fulop,4 Vinaya Rao,4 Maria Aurora C. Posadas,4 Michael Casey,4 Ahmed Halawa,4 Ingi Elsayed.4

1The University of Tennessee Health Science Center, Memphis, TN; 2University hospitals of Birmingham, UK; 3Birmingham, United Kingdom; 4Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; 5Medical University of South Carolina, Charleston, SC; 6Ralph H. Johnson V4 Medical Center, Charleston, SC, United States, Charleston, SC; 7University Medical School of Medicine, University of Turku, Turku, Finland; 8University of Manchester, Manchester, United Kingdom; 9Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom.

**Background:** Despite a large body of literature describing survival’s outcome after renal transplantation, little is known about the progress of functional capacity post-transplant. Our aim is to assess the effect of renal transplantation and various factors on functional capacity.

**Methods:** From the United States Organ Procurement and Transplantation Network files, we identified a total of 19,704 renal transplant recipients (RTR) maintained on tacrolimus-based immunotherapy, who had Karnofsky Performance Status Scale (KPSS) defined functional capacity assessment at the time of transplant evaluation with five-years data follow up. Age, gender, ethnicity, functional status, diabetes, body mass index, cold ischemia time, number of previous transplants, panel reactive antibodies, donor type, donor age, HLA-mismatches, number of acute rejection episodes, induction therapies, maintenance immunotherapy regimen were collected. According to KPSS, RTRs were classified according to time of transplantation were divided into 3 groups (A: 13,701 RTRs with mild impairment: ~80%, B: 5,557 RTRs with moderate impairment: 40-80%, C: 446 RTRs with severe impairment: ~<40%). The outcome measured was KPSS functional status five-years post-transplant. Multiple logistic regression analysis was used to assess factors affecting functional status post-transplant.

**Results:** In group A, 86.45% of patients showed improvement in functional capacity, 65.5% in group B, while 88.56% improved in group C (64.57% improved from severe to mild and 23.99% improved from severe to moderate functional capacity). Furthermore, multiple logistic regression analysis showed that steroid withdrawal protocol was associated with significant improvement in functional capacity (OR=1.28, 95% Confidence Interval (95% CI): 1.1 - 1.49, P=0.007), while dialysis duration before transplantation was associated with abnormal functional capacity post-transplant (OR=0.74, 95% CI: 0.61 - 0.89, P<0.003).

**Conclusions:** Renal transplantation is associated with substantial improvement in all stages of functional capacity in RTRs. Steroid withdrawal as well as the duration of dialysis were important novel determinants of functional capacity post-transplant and merit considerations during transplant selection and subsequent immunosuppressive therapeutic planning.

Calcineurin Inhibitor-Based Immunosuppression Has Negligible Negative Effects on Pregnancy Outcomes After Renal Transplantation in the Netherlands

Lisanne M. Koensier,1 Jildau R. Meinders,2 Olivier W. van der Heijden,1 Titta Lely,1 Margriet de Jong,3 Renée G. van der Molen,1 Henk W. Van Haelst,1 Pregnancy After Renal Transplant OUTComes (PARTOUT) Network 1Radboudumc, Nijmegen, Netherlands; 2Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; 3Universiteit Medisch Centrum Groningen, Groningen, Netherlands.

**Background:** Pregnancy among renal transplant recipients (RTR) has increased over the past years, also in patients with compromised renal function and/or proteinuria. Immunosuppressive regimens may influence pregnancy outcomes and it is not yet clear whether replacing a calcineurin inhibitor (CNI) by a CNI-free (CNI-) regimen has a favoring effect.

**Methods:** We therefore retrospectively compared the effect of CNI-based (CNI+) and CNI- immunosuppression in the first trimester of pregnancy on maternal and fetal outcomes in Dutch pregnancies between 1986-2017 in RTR. We identified 129 CNI+ and 125 CNI- single pregnancies. Demographics did not differ except for higher BMI in CNI+ (median 25.3 vs 23.7 kg/m², p=0.01), year of renal transplantation (2000 in CNI+ vs 1989 in CNI-, p<0.01), year of pregnancy (2006 in CNI+ vs 1998 in CNI-, p<0.01) and interval of transplantation to pregnancy (69 in CNI+ vs 121 in CNI-, p<0.01). In the third trimester creatinine levels were significantly higher in CNI+ (127 vs 105 μmol/L in CNI-, p<0.01) but this difference had disappeared 6-18 months postpartum. The percentual change in creatinine from preconception to the third trimester level was slightly different (~3.1% in CNI+ vs 2.2% in CNI-, p=0.05). In both groups, a postpartum on discharge were collected according to tertiary obstetric/nephrologic care programs. Our data do not exclude possible long term negative effects of CNI on overall health, renal function or hypertension in the offspring of these women.

**Conclusions:** Our data indicate that CNI do not negatively influence the course of renal function up to 18 months postpartum, but only lead to a more pronounced increase in serum creatinine levels towards the end of pregnancy. However, the substantial short term loss of renal function and the high rates of premature birth rate and low birthweight classify them as high-risk pregnancies that should be followed carefully in tertiary obstetric/nephrologic care programs. Our data do not exclude possible long term negative effects of CNI on overall health, renal function or hypertension in the offspring of these women.

PO2542
The Natural History of Waitlist Candidates in the United States
Allan Massig, Dorry L. Segev. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Estimates of time to deceased-donor transplantation (DDKTX) generally fail to take into account the competing risks of mortality. Understanding the natural history of KT registrants - their chance of DDKTX/LLKT/mortality based on individual characteristics - can inform referrals for transplantation, counseling for transplant candidates, and allocation policy.

Methods: Using SRTR data on 186,174 waitlist registrants 12/2014-12/2019, we modeled time to DDKTX, LLKT, or waitlist mortality in a competing-risks framework, overall and for clinical and demographic subgroups of patients (based on candidate age, sex, race, ABO blood type, PRA). Competing-risks regression was used to model individual n-year chance of DDKTX/LLKT/mortality based on candidate characteristics.

Results: Among all candidates, 5-year cumulative incidence of DDKTX/LLKT/other removal was 17.3%/34.4%/15.7%/18.1% respectively. 85% of DDKTX recipients received LLKT within 2 years of listing. Pediatric registrants had substantially higher incidence of DDKTX than waitlist mortality (61.7%/vs 1.1%), but adults had higher combined of waitlist mortality/other removal DDKTX, particularly patients above age 65 (44.4%/vs 32.3%) (Figure). Center-level 5-year incidence of DDKTX (DDKTX) 1.3%/44.8% (4.4%/82.6%) (Figure 2).

Conclusions: Despite a focus in the transplant community on small differences in one-year posttransplant outcomes and a reluctance to transplant kidneys with slightly worse expected outcomes, most adult patients wait >5 years for a kidney, incurring substantial waitlist mortality risk. High incidence of waitlist mortality will only be remedied through aggressive efforts to increase the living and deceased organ pool.

PO2543
Unusual Cause of Calcium Oxalate Nephropathy in a Renal Allograft
JoBeth McCoy, Anthony J. Langone. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Crystalline nephropathy is a well-known cause of acute kidney injury that is often overlooked. We present a case of oxalate nephropathy in a renal allograft that led to a rare diagnosis.

Case Description: A 63-year-old female with a kidney transplant for end-stage kidney disease (ESKD) caused by acute interstitial nephritis (AIN) presented with acute kidney injury. Her creatinine on presentation was 2.0mg/dL from her baseline of 1.0mg/dL and increased to around 3.0mg/dL despite hydration. It was decided that she would benefit from allograft biopsy. The biopsy was devoid of any rejection but did have many foci of calcium oxalate crystal deposition with tubular injury. She was planned for a 24-hour urine collection for stone evaluation that showed an elevated urine oxalate level, 140mg. She changed her diet and the 24-hour urine collection was repeated in 3 months with no change. With the continued elevation, genetic testing was sent for primary hyperoxaluria which revealed that she has homozgyote mutation in the AGXT gene, confirming that she has type 1 primary hyperoxaluria. Reevaluation of her biopsy diagnosing AIN before transplant was found to have interstitial multinuclear infiltrate with some crystalization consistent with oxalate. Her particular mutation responds very well to pyridoxine (vitamin B6) so she was started on 600mg per day. Since treatment, her creatinine has stabilized at 3.0mg/dL. Her 24-hour urine evaluation has shown improvement in urine oxalate to 79mg, a 43.5% reduction.

Diagnosis: Hyperoxaluria type 1 (PII 1) is described by recurrence in a renal allograft in only 10% of cases. Delay in the diagnosis is common and results in a significant number of patients who have end-stage kidney disease (ESKD) at initial presentation. The rapidity of progression is determined by the residual enzyme activity and response to pyridoxine (vitamin B6). The definitive cure for PI 1 is liver transplantation that carries significant mortality risk. Medical management includes large fluid intake of greater than 3L/day to decrease tubular fluid oxalate concentration, potassium citrate-citric acid to increase the solubility of calcium oxalate and prevent precipitation, avoidance of oxalate in diet, and high dose pyridoxine to promote the conversion of glyoxylate to glycine rather than to oxalate. A trial of 5mg/kg of pyridoxine is suggested in all PI 1 patients to see how they respond.

PO2544
Secondary Oxalosis with Enteric Oxalate Nephropathy in a Transplant Recipient: Is Mycophenolate the Culprit?
Himmat S. Brar, Nihal M. Ali, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: Secondary oxalosis causing acute kidney injury has been widely reported in native kidneys but its occurrence in allograft kidneys is relatively uncommon. Intestinal malabsorption can be present in transplant recipients as a result of factors reported in the general population such as immunosuppressive medications and some enteral infections. We present a case of enteric oxalate nephropathy as a result of mycophenolate toxicity.

Case Description: A 66-year-old male status post kidney transplant 3 years back for ESKD due to DM and HTN with a baseline creatinine of 1.5 mg/dL presented with a 2-month history of GI symptoms of vomiting, diarrhea and 22 lbs weight loss. He was on tacrolimus, mycophenolate and prednisone for immunosuppression. The patient denied any recent infection or antibiotic use, any medication change, supplements or OTC drug use. The vitals were unremarkable on admission and was anemia was noted. Lab findings showed Na 139, K 5.5, Cl 117, Bicarb 11, AG 22, Ca 9.6, BUN 71 and creatinine 3.5. Lactate and serum osmolar gap were normal. Lipase, amylase, Vit B1 and B6 were normal. UA showed trace ketones and blood with no protein or bacteria. Serology for CMV and BK virus was negative. Tacrolimus level was at goal. MPA level was noted to be elevated at 972 at an office visit 1 month prior to admission with no recent adjustment in dosing. Plasma oxalate was elevated at 3.9. The stools studies and GI panel were negative. CT scan showed a 3mm non-obstructing stone. The renal biopsy showed interstitial fibrosis, tubular atrophy and calcium oxalate deposits with birefringence within the tubules. MMF was discontinued. The patient was given iv fluids and citrate to alkalize the urine. At discharge, his Cr improved with resolution of symptoms.

Discussion: Medication-induced malabsorption should be considered among potential causes of secondary oxalosis. The MMF metabolites indirectly affect lymphocytes in the GI tract leading to mucosal damage with malabsorption and enteric oxalosis. The hyperoxalosis causes saturation of oxalate crystals creating an interstitial nephritis, macrophage recruitment and inflammation leading to tubular atrophy. The transplant recipients with chronic diarrhea and no infection should be suspected for MMF toxicity. The oxalate and MMF levels must be checked and MMF dose should be adjusted accordingly.

PO2545
Prophylactic Use of Eculizumab and Graft Loss in Kidney Transplant Recipients due to Hemolytic Uremic Syndrome in the United States
Richard A. Plasser,1,2 Stephen W. Olson,1,2 Christina M. Yuan,1,2 Lawrence Agodaa,1 Kevin C. Abbott,1 Robert Nee,1,2 Walter Reed National Military Medical Center, Bethesda, MD; 1Uniformed Services University of the Health Sciences F Edward Hebert School of Medicine, Bethesda, MD; 2National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: Among kidney transplant recipients (KTRs) with end-stage kidney disease (ESKD) due to hemolytic uremic syndrome (HUS), recurrence is associated with poor allograft outcomes. We examined the prophylactic use of eculizumab, a monoclonal antibody that binds complement protein C5, and graft loss among HUS KTRs.

Methods: We conducted a retrospective cohort study using the United States Renal Data System. Out of 123,624 ESKD patients transplanted between January 1, 2008 and June 1, 2016, we identified 348 (0.28%) patients who had HUS as the primary cause of ESKD. We then linked these HUS patients to datasets containing the Healthcare Common Procedure Coding System (HCPCS) code for eculizumab infusion. We calculated crude incidence rates of overall graft loss and death-censored graft loss and conducted exact logistic regression, adjusted for recipient age and sex. Patients who received eculizumab prior to or within 30 days of transplant represented the exposure group.

Results: Our final study cohort included 335 HUS KTRs (23 received eculizumab, 312 did not). There were no significant differences in baseline demographic and clinical characteristics between the eculizumab vs. non-eculizumab group. For those who received eculizumab, the median number of infusions per patient was 42 (IQR 16, 66). The median payment amount per patient was $706,518 (IQR 241,237, 1,306,453). Eculizumab was discontinued in 9 of 23 patients (39%), after a median prophylactic duration of 329 days (IQR 127, 791). As shown in the Table, the eculizumab group had no graft loss vs. 20% in the non-eculizumab group, with an adjusted odds ratio of 0.13.

Conclusions: Prophylactic use of eculizumab in HUS KTRs was significantly associated with a lower risk of graft loss. Given the high cost of eculizumab, randomized controlled trials are much-needed to guide prophylactic strategies to prevent graft loss.
PO2547

Post-Kidney Transplant Serum Magnesium Exhibits a U-Shaped Association with Subsequent Mortality

M. Pantano, Beini Lyu, Brad C. Astor, Tripti Singh, Fahad Aziz, Didier A. Mandelbrot, Sandesh Parajuli, Maha A. Mohamed, Arjang Djamali, Neetika Garg. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Hypomagnesemia is common in kidney transplant recipients (KTR), likely due, at least in part, to renal magnesium (Mg) wasting related to calcineurin-inhibitor (CNI) use. The association of serum Mg levels and KTR outcomes may provide insight into the optimal serum Mg levels in this population.

Methods: KTRs between 01/2000 and 12/2016 at a large US transplant center who were alive with a functioning graft at 6 months post-transplant were included. Mean of the outpatient serum Mg level in the baseline period, i.e. 6 to 18 months post-transplant, was used. Cox proportional-hazards regression was used to analyze the association between Mg and all-cause mortality, cause-specific mortality, and risk of new-onset cardiovascular events post-transplant.

Results: 2,131 KTRs met our inclusion criteria. Mean number of Mg measurements per patient in the baseline period was 2.76. A U-shaped association between the mean baseline Mg level and all-cause mortality was observed in both unadjusted analysis and after adjusting for baseline characteristics, including eGFR and CNI levels. A mean Mg of 1.5 - 1.8 mg/dL was associated with the lowest incidence of death (Figure). Compared with Mg of ≤1.5 mg/dL, Mg level 1.5 - 1.8 mg/dL was also associated with higher incidence of mortality due to infection and arrhythmia but not ischemic heart disease or heart failure.

Conclusions: The relationship between serum Mg levels and mortality in KTRs is U-shaped. Interestingly, the risk is lowest with Mg levels 1.5 - 1.8 mg/dL, which represents the lower end of normal (1.6 - 2.6 mg/dL). Mg supplements for levels ≤1.5 mg/dL may be beneficial, but may cause increased renal wasting and diarrhea. Further studies are needed to understand why Mg >1.8 mg/dL but well within the normal range was associated with higher risk despite adjustment for eGFR.

PO2548

Virtual Reality, a New Vision Becoming Our New Actuality: A Retrospective Study Comparing Virtual Crossmatch vs. Physical Crossmatch at Tampa General Hospital

Fernando Moran, Timothy M. Chow, Martin Aldana, John Lunz. Division of Nephrology and Transplantation University of South Florida, Tampa, FL; Division of Internal Medicine University of South Florida, Tampa, FL; LifeLink Foundation Transplantation Immunology Laboratory, Tampa, FL; Florida Kidney Physicians, Tampa, FL.

Background: A crossmatch (XM) is required prior to kidney transplantation to ensure immunological compatibility between recipient and donor. This test is prone to false positive reactivity and can increase cold ischemic time (CIT) especially for organs procured outside the region of the transplanting hospital. Advances in HLA antibody testing and donor HLA antigen typing facilitate the use of a virtual XM (VXM) based on pre-transplant testing results to accurately predict a physical XM (PXM) result. Frequent antibody screening and an accurate history of sensitizing events further ensures that the VXM can predict immunological compatibility, even without retrospective PXM.

Methods: We compared the 6 mo. clinical outcomes of kidney recipients who proceeded to transplant with only a VXM (without retrospective PXM) to those receiving a PXM. 182 recipients with 6 mo. follow-up were reviewed for biopsy data, serum Cr and UPCR. Patients were grouped according to the transplant type (living donor (LD) vs. deceased donor (DD)) and XM type (PXM vs. VXM). LD recipients had a PXM (n=42). Patients with a VXM (n=76) were donor-specific antibody (DSA)-free and had a current tested sample within 30 days. DD recipients had PXM (n=64) due to the presence of DSA (current or historic) or the absence of a current tested sample within 30 days. All patients with PXm had an acceptable flow cytometric XM.

Results: Patients proceeding to transplant with a VXM tended to be less sensitized (32% with PRA ≥50%) compared to DD-PXM (66%) and LD-PXM (49%). For DD recipients, CIT was significantly reduced in patients receiving a VXM (727 vs 871 min; p=0.011). Within the first 6 mo. of follow-up, 67 for cause biopsies were performed. Rejection (T-cell or antibody mediated) was observed in 15 patients (7 DD-PXM, 6 DD-PXM and 3 LD-PXM). Interestingly, antibody mediated rejection was only observed in DD-PXM (n=3) or LD-PXM (n=1) groups.

Conclusions: In our cohort, kidney transplantation with an acceptable VXM was beneficial in reducing CIT and rejection was similar to DD recipients needing a PXM within the first 6 mo. post-transplant. Utilizing VXM helps facilitate kidney transplantation, permits entertaining offers from greater distances, and reduces laboratory burden with similar outcomes to when a PXM is performed.

PO2549

Reassessing RenalTransplantation in Light-ChainDeposition Disease

Background: Light chain deposition disease (LCDD) is a systemic rare condition that usually leads to end stage renal disease. Treatment with a bortezomib-based regimen, followed by autologous stem cell transplantation (ASCT) has been increasingly used with improvements in the response rates and the renal graft outcomes in kidney transplant recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Retrospective study of 6 patients diagnosed of LCDD with complete response but not renal response after hematologic treatment that underwent kidney transplant in our institution between 2010 and 2019.

Results: A total of 6 patients (5 women) were analyzed, with mean age at diagnosis of 47 years, mean eGFR of 18 mL/minute and mean proteinuria of 5.5 g. Deposit was kappa type except in 1 case (heavy and light lambda type chains). In all of them there was an absence of monoclonal component in blood and urine but positive immunofixation in 5 cases (2 only in urine). 3 started chronic hemodialysis during the admission and the others at 3, 5 and 44 months after diagnosis. As hematological treatment, all received bortezomib followed by ASCT, being under complete hematological response at the time of kidney transplant, which was performed at 28 months on average from ASCT. Mean kappa/lambda ratio was 2.6. 3 patients received induction with thymoglobulin and 3 with basiliximab, followed by triple therapy with tacrolimus+prednisone+MTOR inhibitor (4 patients) or mycophenolate (2 patients). After 36 months of mean follow-up after kidney transplant, 3 patients have suffered an hematological relapse, one of them including kidney involvement with graft loss at 46 months post-transplant. The remaining 5 continue with a functional graft with a mean creatinine of 1.54 mg/dL.

Conclusions: When sustained complete hematologic response is achieved but renal impairment with dialysis requirement persists, patients could benefit from a kidney transplant with good results.

PO2550
Granulomatous Interstitial Nephritis and Allograft Failure Secondary to Adenovirus Reactivation

Introduction: With an incidence of about 4% in renal transplant recipients, the typically self-limited adenovirus renders an infrequent propensity to cause allograft failure and life-threatening opportunistic infection in several cases.

Case Description: A 29 year old female with history of living donor kidney transplant due to Henoch Schönlein Purpura (HSP) Glomerulonephritis with subsequent allograft failure underwent deceased donor re-transplantation with Anti-Thymocyte globulin induction. Post-op course was uneventful. Creatinine was 0.8 mg/dL on 4 month follow up. 6 months post-transplant, patient developed gross hematuria with clots, fever and acute kidney injury with creatinine of 2.82 mg/dL. Biopsy revealed granulomatous tubulointerstitial nephritis, extensive intra-nuclear viral inclusions with positive adenovirus immunohistochemistry (IHC). Mycophenolate Mofetil was discontinued and creatinine improved to 1.1 mg/dL. 3 months later, she was admitted for renal failure with creatinine of 7.2 mg/dL. Adenovirus was detected in the serum and urine. Repeat biopsy revealed markedly reactive tubular epithelium, widespread viral inclusions with negative adenovirus IHC; consistent with adenovirus nephropathy. Following a decrease in immunosuppression with improvement in renal function, adenovirus viral load became undetectable in both plasma and urine. The use of Cidofovir was considered for treatment; however, given risk of nephrotoxicity, was ultimately deferred after response to conservative treatment.

Discussion: Recurrence of HSP was in the broad differential given the initial presentation. Given its rarity, a paucity of cases and epidemiologic literature exists in illustrating allograft failure due to adenovirus nephropathy. Further research is not only needed to expand awareness of its presenting features and characteristic biopsy findings, but also, to limit more familiar culprits in masquerading as the elusive adenovirus infection, particularly in light of indeterminate therapeutic modalities.

PO2551
Phospholipase A2 Receptor Antibody Level Directed Management of Membranous Glomerulopathy After Transplant
Irfan Agha,1,2 Amna Ilahi,1,4 Silvi Simon,1,3 Rama Nadella,1,2 Diana Mahbod,1 Richard Dickerman.1 1Dallas Renal Group, Dallas, TX; 2Medical City Dallas Hospital, Dallas, TX; 3Methodist Dallas Medical Center, Dallas, TX.

Introduction: MN can recur after transplantation. Patients with high PLA2R Ab are at higher risk. There is equipoise on how to manage these patients. We present two cases to highlight PLA2R Ab level directed approach to management.

Case Description: Case 1: 35 YO AA female with MN diagnosed in 2013. Failed cytotoxic therapy and started RRT. Received a DD kidney transplant in Sep 2018. Given Thymoglobulin, tacrolimus, mycophenolate and prednisone. Plasma levels should be monitored post treatment to ensure resolution. This approach allows performing biopsy to confirm diagnosis and initiate therapy expeditiously. PLA2R Ab levels should be monitored to direct care: decreasing PLA2R titer 1:2560 by IIF. Titer serially monitored. After an initial decline, titer increase with precipitation of proteinuria noted. Biopsy confirmed early recurrent MN. Treated with 2 doses of Rituximab. Subsequent titer dropped with complete remission. Case 2: 65 YO W male with biopsy demonstrated MN (2015), on RRT since 2017 underwent DD kidney transplant in May 2019. Given Thymoglobulin and maintained on tacrolimus, mycophenolate and prednisone. Pretransplant PLA2 R Ab level was 164 RU/ml by EIA with 3.5 g/g of protein. His PLA2R Ab levels dropped and proteinuria rapidly & durably resolved after transplant. One year out, his PLA2R Ab is at 24 RU/ml with 0.11 g/g protein in the urine and a creatinine of 1.2 mg/dL.

Discussion: High PLA2 R Ab at the time of transplant is a significant risk factor for recurrent MN. PLA2R Ab levels should be monitored to direct care: decreasing PLA2R Ab should be followed conservatively. If Ab levels increase or proteinuria develops, perform biopsy to confirm diagnosis and initiate therapy expeditiously. PLA2R Ab levels should be monitored post treatment to ensure resolution. This approach allows stratification and directed therapy of patients with MN undergoing transplantation and avoids over treatment.

PO2552

De Novo Membranous Nephropathy and Donor-Specific Allotubodies: A Path to the Pathophysiology?
Megan A. Tienyer, Pradeep Varita, Wisit Cheungpasitporn, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: While pathophysiology of post-transplant membranous nephropathy due to recurrence of primary disease is established, less is known about the development of primary de novo membranous nephropathy (dnMN). We report a case of dnMN associated with antibody-mediated rejection in a transplant recipient with end-stage kidney disease secondary to focal segmental glomerulosclerosis (FSGS).

Case Description: A 20-year-old African American female with FSGS status-post deceased donor transplant eight years ago presented with acute lower extremity edema and acute kidney injury concerning for acute rejection. She has no history of prior rejection or medication non-adherence. Ultrasound showed mild hydronephrosis. Biopsy showed Banff Type IB acute-cell mediated rejection (2, I2) and Stage 1 membranous glomerulopathy. Serum phospholipase A2 receptor (anti-PLA2R) antibodies were negative. Donor specific antibodies (DSA) testing revealed the presence of DQ5, DQ7, and DRB1*01:03. Diagnosis of coexistence of Banff Type IB acute-cell mediated rejection, positive de novo DSA, and dnMN was made. She was treated with five doses of antithymocyte globulin (1.5 mg/kg/dose) and plasma exchange (PLEX) followed by dexamethasone, 10 sessions of PLEX and intravenous immunoglobulin (IVIG), and Rituximab. Her Cr improved to 1.2 mg/dL but DSA remained positive. Later on he was restarted on Etanercept which was withdrawn in March 2019. Accordingly, in September 2019, he developed acute kidney injury with Cr up to 1.7 from baseline of 1.3-1.5 mg/dL associated with nephrotic range proteinuria. He had a rise in DSA to DQ7, and developed new DSA to A2 and B60 with positive cytotoxicity crossmatch. Donor derived cell free DNA was elevated at 4.4%. Allograft biopsy showed glomerulitis, peritubular capillaritis with positive c4d, consistent with ABMR. He was treated with high dose steroids, 10 sessions of plasmapheresis with intravenous immunoglobulin (IVIG), and Rituximab. Repeat DSA showed reduction in A2, but no change in DQ7. Her serum Cr improved but his proteinuria remained at nephrotic range.

Discussion: Despite the use of Etanercept in the treatment of graft versus host disease among transplant recipients, it hasn’t been studied as a potential immunosuppressive drug. In our patient, Etanercept seemed to provide anti-rejection effect as shown by two episodes of ABMR with de-novo DSA after the drug’s withdrawal. Close monitoring of renal function and DSA may be warranted once Etanercept or other TNF inhibitors are withdrawn in transplant recipients.

PO2553

Histological Predictors of Graft Failure in Kidney Transplant Recipients
Maria Ajajya, Yong Al Azzi, Purna Bindu Nandigam, Pablo Loarte Campos, Cindy T. Pynadath, Luz E. Liriano-Ward, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: We aimed to identify the predictors of allograft failure in a large cohort of kidney recipients who underwent clinically indicated graft biopsies. We aimed to explore the importance of interstitial inflammation in biopsies with interstitial fibrosis and tubular atrophy(IFTA).

Methods: We retrospectively evaluated 516 patients who underwent transplant biopsy between 1/2009 and 1/2018. Acute and chronic allograft injury scores of Banff classification were used. We sub grouped the patients with chronic allograft injury score of ≥3 or ≥4 and sub grouped per interstitial inflammation (i score=0 and >0)and compared to biopsies with both c i t c v c v ≥ 3 and r o=0.

Results: Biopsies were done at a median 12.5 months after kidney transplantation. The histopathological diagnoses were as follows: acute antibody-mediated rejection (AMR) (6%), acute T-cell mediated rejection (9.3%), chronic AMR (6.7%), transplant glomerulopathy without donor-specific antibody (DSA) (10.2%), recurrent/de novo glomerular disease (10.8%), BKV nephropathy (2.5%), and the rest 54.2% had other diagnosis (normal, acute tubular necrosis, or non-specific IFTA). During a median follow up of 59.3 months after kidney biopsy, 36 %recipients lost their graft. In univariate analysis, the following factors were significant for graft loss: Black race (p=0.005), previous rejection (p=0.001), DSA at the time of biopsy (p=0.014), c i t c v ≥ 3 (p=0.0485), c i t c v ≥ 3 with interstitial inflammation > 0 (p=0.0001), microvascular inflammation (p=0.0052), C4d positivity (p=0.008), serum creatinine at time of the biopsy (p=0.0001), and spot urine protein/creatinine (<0.0001). In the multivariate analysis c i t c v ≥ 3 with i>0 has the highest hazard ratio followed by c i t c v ≥ 3 with i=0, c i t c v ≥ 3 with i=0, black race, creatinine, and proteinuria.

Conclusions: Interstitial inflammation is the best predictor for allograft loss after clinically indicated kidney biopsy regardless of the severity of chronic allograft injury.

PO2554

A Case of Antibody-Mediated Rejection (ABMR) After Withdrawal of Etanercept in a Renal Transplant Recipient
Iris Jill E. Uy, Mohammad Abuzeineh, Sami Alasar, Fizza F. Naqvi, Brandon L. Trollering. Johns Hopkins Medicine, Baltimore, MD.

Introduction: Etanercept is a tumor necrosis factor (TNF) receptor fusion protein that is used to manage several forms of inflammatory arthritis and psoriasis. Herein, we present a renal transplant recipient who was concomitantly treated with Etanercept for psoriasis and subsequently developed two episodes of ABMR after the drug’s withdrawal.

Case Description: A 41-year-old man with history of psoriasis and end stage renal disease due to hypertensive nephrosclerosis and interstitial nephritis who underwent living related kidney transplant from his brother in December 2008. He was being treated for psoriasis with Etanercept which was withdrawn in September 2012. Subsequently he developed rising creatinine (Cr) from baseline of 1.3-1.5 mg/dL associated with de novo donor specific antibodies (DSA) to DR11 and DQ7 with positive cytotoxicity crossmatch. Renal allograft biopsy showed evidence of Banff 2A acute cellular rejection, ABMR, chronic glomerulonephritis and interstitial nephritis. He was treated with high dose steroids, 10 sessions of plasmapheresis with intravenous immunoglobulin (IVIG), and Rituximab. His Cr improved to 1.2 mg/dL but DSA remained positive. Later on he was restarted on Etanercept which was withdrawn again in March 2019. Accordingly, in September 2019, he developed acute kidney injury with Cr up to 1.7 from baseline of 1.3-1.5 mg/dL associated with nephrotic range proteinuria. He had a rise in DSA to DQ7, and developed new DSA to A2 and B60 with positive cytotoxicity crossmatch. Donor derived cell free DNA was elevated at 4.4%. Allograft biopsy showed glomerulitis, peritubular capillaritis with positive c4d, consistent with ABMR. He was treated with high dose steroids, 10 sessions of plasmapheresis with IVIG and Rituximab. Repeat DSA showed reduction in A2, but no change in DQ7. Her serum Cr improved but his proteinuria remained at nephrotic range.

Discussion: Despite the use of Etanercept in the treatment of graft versus host disease among transplant recipients, it hasn’t been studied as a potential immunosuppressive drug. In our patient, Etanercept seemed to provide anti-rejection effect as shown by two episodes of ABMR with de-novo DSA after the drug’s withdrawal. Close monitoring of renal function and DSA may be warranted once Etanercept or other TNF inhibitors are withdrawn in transplant recipients.

Molecular Analysis of Renal Graft Biopsies: Comparing the Edmonton Microscope with the NanoString Human Organ Transplant Panel
Jessica Schmitz, Helge Stark, Stephan Bartels, Danny Jonigk, Philip F. Halloran, Gunilla Einecke, Jan H. Brae sen.1 Hannover Medical School, Medizinische Hochschule Hannover, Institute of Pathology, Nephropathy Unit, Hannover, Germany; 2Hannover Medical School, Institute of Pathology, Hannover, Germany; 3Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany; 4Hanover Medical School, Institute of Pathology, Molecular Pathology, Hannover, Germany; 5University of Alberta, Edmonton, Edmonton, AB, Canada; 6Alberta Transplant Applied Genomics Center, Edmonton, AB, Canada; 7Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany.

Background: The renal transplant biopsy is the diagnostic gold standard and usually evaluated with the continuously expanded and updated Banff classification which is based on descriptive, empirically-derived criteria and thus lacks precision. High-resolution determination of the graft pathology by NanoString analysis, which was developed for formalin-fixed paraffin-embedded-derived (FFPE) RNA, should be a sufficient approach for objective molecular diagnosis of renal transplant biopsies and may improve our understanding of graft biology.

Methods: We used well-annotated surveillance and indication biopsies from 63 patients whose time-matched second biopsy core had been frozen and analyzed by microarray in the INTERCOM/INTERCOMEX study. After reevaluation according to recent Banff consensus, RNA isolation of the FFPE biopsy was performed and led to the development of RNA yields in 53 samples which were further processed for NanoString analysis using the nCounter Human Organ Transplant Panel.

Results: Morphologically, of the 53 samples analyzed (samples from 2011/12 and 2015), twenty-five patients showed no signs of rejection, twelve had borderline rejection,

Donor Biopsy and Kidney Transplant Outcomes in Pediatric Recipients
Ahmad Masihmoushi,1 Christine S. Hwang,2 Malcolm Macconnmar.a,3
1University of Texas Southwestern Department of Surgery, Dallas, TX; 2University of Texas Southwestern Medical Center, Division of Surgical Transplantation, Department of Surgery, Dallas, TX; 3University of Texas Southwestern Medical Center, Division of Pediatric Nephrology, Department of Pediatrics, Dallas, TX; aChildren’s Medical Center, Division of Pediatric Transplantation, Dallas, TX.

Background: Deceased Donor DD kidney biopsies are routinely used in the context of clinical concerns about donor quality in adult kidney transplants. We sought to examine the use of DD kidney biopsies in pediatric transplants. We aim to evaluate prognostic utility of glomerulosclerosis GS level in predicting graft outcomes.

Methods: Data was used from recipients who received kidney transplant between 1994 and 2018 documented in the Scientific Registry of Transplant Recipients database. Pediatric recipients were defined as recipients < 18 years who received DD kidney transplant excluding multi-organ transplants. The recipients were further stratified according to degree of donor kidney GS into 0-5% and > 5% categories. Demographic and outcome data were examined and graft survival was evaluated using STATA 16.

Results: 10,045 pediatric recipients received DDKT during this period. 644 had left and/or right DD kidney biopsies, 548 biopsies had 0-5% GS, 96 biopsies had > 5% GS. Biopsies were mostly performed on kidneys harvested from higher risk donors. There was a significant difference in the number of biopsies performed across regions (region 5 lowest at 2.6% and region 9 highest at 17.5%). There was no significant difference among regions in the number of biopsies performed (region 5 vs. region 9, p = 0.2). There was a significant difference in the number of biopsies performed across regions (region 5 lowest at 2.6% and region 9 highest at 17.5%). There was no significant difference among regions in the number of biopsies performed (region 5 vs. region 9, p = 0.2). There was no significant difference in the incidence of DGF, acute rejection, or chronic rejection.

Conclusions: Although the biopsied kidneys are mostly from higher risk donors, the majority of biopsies have GS level 0-5%. At this level of GS there is no difference in allograft survival compared to DD kidneys without biopsies. Thus utilizing kidneys with GS 0-5% can expand the DD kidney pool and should be strongly considered for use in pediatric population.

PO2558

Predictors and Impact of Nephrocalcinosis in Renal Transplant Population: A Monocenter Retrospective Study
Jessie Beaulieu,1 Léa Thérien,1 Julie Riopel,1 Eva Latulippe,1 David Simonyan,2 Isabelle Houde,2 Mohsen Agharazii,1 Fabrice Mac-Way,3 ‘CHU de Québec-Université Laval, CHU de Québec-Université Laval, Quebec, QC, Canada; 2Centre de recherche du CHUQ, Quebec, QC, Canada.

Background: Persistence of bone and mineral anomalies in post-transplant population has been suggested as contributing factors to nephrocalcinosis (NC) that could lead to graft dysfunction. However, adequate characterization of calcium deposits in biopsies from renal transplant patients are lacking. We thus aimed to determine: 1) the prevalence of NC in renal transplant patients, 2) the factors associated with NC and 3) the impact of NC on renal graft function.

Methods: This is a monocenter retrospective study using a protocolized renal biopsy from CHU de Québec, the Hôtel-Dieu de Québec hospital from 2016-2018. All renal biopsies performed in 2016 at renal transplantation, at 6 and 24 months post-transplant were qualitatively and quantitatively analyzed for NC. Demographic, comorbidities and biochemistry parameters were collected from patients’ records. Appropriate statistical analyses (Pearson’s chi-squared, Wilcoxon-Mann-Whitney, Spearman’s correlation and logistic regression) were performed to assess factors associated with NC and its impact on graft function.

Results: We included 53 patients (mean age of 52±13 years, 55% of men, 94% with hypertension, 23% with peripheral arterial disease and 19% with prior parathyroidectomy). Forty-nine patients (92%) were on chronic dialysis treatment before transplant for a mean duration of 34±29 months. The presence of NC was observed in 14% at baseline, 37% at 6 months and 50% at 24 months. The severity of NC as assessed by the number of calcified foci in the tubulointerstitial compartment also tended to increase over time. Analyses showed that the presence of NC at 6 months was associated with male sex, presence of NC at baseline and high PTH levels (≥ 600 ng/L) at the time of transplant. Presence of NC at 24 months was also associated with prior NC and male sex. Interestingly, the presence of NC at 6 months was associated with use of phosphate supplements immediately after engraftment and with active vitamin D treatment at 6 months. Finally, NC at 24 months was correlated with the level of graft function as expected.

Conclusions: This study reveals that uncontrolled mineral and bone metabolism parameters before renal transplant are associated with development of NC in the post-transplant period that may contribute to deterioration of renal graft function.

PO2559

Outcomes of Biopsy-Proven Acute Rejection (BPAR) in ABO-Incompatible Kidney Transplants (ABOi KTx) Compared with a Propensity-Matched Cohort of ABO-Compatible Transplant Recipients (ABOc KTx)

Background: Although available outcome data is equivocal for its non-inferiority compared to ABOc KTx, the data on graft survival after an BPAR episode are scarce in ABOi KTx.

Methods: Single centre, retrospective study, ESRD patients transplanted between 2014 and 2019 were included. Among 100 ABOc KTx, 37 had BPAR and were included. A matched cohort of 37 ABOi KTx with BPAR were identified as controls from 680 ABOc KTx by propensity score matching (nearest neighbour matching) using recipient age and sex, donor age and sex, donor GFR, HLA match and induction agent used as matching covariates. Rejection rates, BANFF score, response to antirejection treatment, overall graft survival, post rejection graft survival were compared between both the groups.

Results: The hazard ratio for BPAR was 1.4 in ABOi KTx, compared with ABOc KTx. Overall graft survival at 1, 3 and 5 years were 86%, 72% and 50% in ABOc KTx; 97%, 91% and 79% in ABOi KTx, respectively. The post BPAR graft survival at 1 and 3 years were 80% and 63% in ABOi KTx; 92% in both 1 and 3 years in ABOc KTx. ABMR was more common in early period in ABOi KTx and ACR was predominant in late period in both the groups. The response to anti-rejection therapy were similar between two groups, no response group (NR) in the ABOc KTx had the poorest graft outcome, complete response group (CR) in the ABOi KTx had the best graft survival. Between CR, PR (partial response) and NR groups, no histopathological parameters were found significant in ABOc KTx, whereas in ABOi KTx, T1 scores were higher in PR compared to NR group.

Conclusions: The graft survival after an acute rejection depends upon response to antirejection therapy. After an episode of acute rejection, the overall post rejection graft survival was inferior in ABOc compared to ABOi KTx.

Kaplan-Meier curve of 5-year allograft survival for pediatric kidney transplant patients by donor kidney glomerular sclerosis (GS)
PO2561

Impact of Out-of-Hospital Organ Donor Cardiac Arrest and Cardiopulmonary Resuscitation on Donor Kidney Histology and Function

Samir M. Akram, Claudia G. Olano, Nehemias A. Guevara, Lilly M. Babra. Kidney Transplantation Group Harbor-UCLA Medical Center Department of Internal Medicine, Torrance, CA.

Background: The mortality rate of patients listed for kidney transplantation (KT) is 5 per 100-patient years. Due to an organ shortage crisis, expansion of KD pool (KDP) is critical (1). Kidney donors (KD) with out-of-hospital cardiac arrest (OHUS-CA) and cardiopulmonary resuscitation (CPR) have low acceptance rate due to presumed delayed graft function (DFG). Donor CA in controlled setting (in ICU) does not impact KF post engraftment (PE) (2) but impact of OHUS-CA is unknown. We propose that terminal serum creatinine (TSC) and Kidney histology (KH) immediately prior to kidney transplantation predict KF post KT. We did a nested cohort study to study the impact of OHUS-CA and CPR of KDS on KF and KH.

Methods: Our transplant program received thirty-five kidney organ donors offers with a procurement biopsy from UNOS during July to December 2019. Retrospectively we reviewed demographics, pre-hospitalization resuscitation information, hemodynamic data and KH. Four patients were excluded; two had missing data; one patient had ischemic infarct and one patient had kidney tumor. The study cohort (N=31) divided into CA-OHUS (N=16) and No Cardiac Arrest (No-CA, N=15) groups. The change (delta) in serum creatinine (DSC) while under donor management (DM) compared in each group. Hypotension during donor management (H-DM) and acute tubular damage score (ATDS) from donor kidney biopsy compared within each group of the cohort.

Results: TSC and ATDS prior to KT were evaluated as surrogates for KF post engraftment and there was no difference between OHUS-CA and No-CA (standard) donors. Effect of ischemic preconditioning was noted in OHUS-CA group (Table). Longer the duration of CPR greater was the residual KF (Fig 1).

Conclusions: KF and KH in KD with OHUS-CA are similar to standard criteria donors hence should not be prejudiced. This will expand the KDP.

PO2562

Living Donor-Derived APOL1-Associated Collapsing FSGS in a Kidney Transplant Recipient

Irfan Agha,1 II Anna Ilha,1,3 Silvi Simon,1,3 Rama Nadella,1 Diana Mahbod,1 Richard Dickerman.1 1Dallas Renal Group, Dallas, TX; 2Medical City Dallas Hospital, Dallas, TX; 3Methodist Dallas Medical Center, Dallas, TX.

Introduction: Homozygous high risk APOL1 mutations in donors can drive disease in recipients. We present a living kidney recipient with de-novo collapsing FSGS. His donor was homozygous for high risk mutations.

Case Description: 47 YO AA male with CKD due to biopsy proven diabetic nephropathy s/p LUKT in May 2018. Got thymoglobulin (5 mg/kg) with tacrolimus, mycophenolate sodium and prednisone. High risk for CMV (D+ / R-). EBV IgG +. Donor was his 35 years old AA wife. We were not testing APOL-1 on AA donors at the time. At month 6 Cr 1.4 mg/dl, Ur Pr/Cr of 0.22 g/g. Valganciclovir stopped. Two weeks later, Ur Pr/Cr 2.92 g/g. CMV PCR + 276 copies / ml and EBV PCR + 492 copies / ml. PCR for Parvo Virus B-19 as well as DSA negative. Given steroids, plasmapheresis (X3) and IV ganciclovir. Biopsy C/W collapsing FSGS. If negative, including CMV and C4d. Donor tested for and found to be homozygous for APOL1 G1 mutations conferring donor derived APOL -1 gene associated collapsing FSGS, presenting as an acute diffuse podocytopathy. Trends in his renal function, CMV, EBV and proteinuria are tabulated in Figure 1. Treated with RAA5 blockade, antivirals & immunosuppression. He cleared his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituxinab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly.
Pediatric Donor Glomerulopathy in Pediatric En-Bloc Kidney Transplants

Background: Use of pediatric en-bloc kidneys (EBK) have equivalent outcomes to standard deceased donor kidneys and has helped expand the pool of donor kidneys. The size mismatch related hyperfiltration injury in pediatric EBK and pediatric single kidney allografts is associated with pediatric donor glomerulopathy whose effect on allograft outcomes is not well documented.

Methods: We retrospectively reviewed for cause biopsies of pediatric EBK from 1/2015 to 1/2020. Our center performed 37 transplants using pediatric EBK. Recipient weight criteria was ≤ 75 kg to minimize donor-recipient size mismatch. One recipient died with a functioning graft at 4 months; one graft failed due to fungal infection of the vascular anastomosis requiring nephrectomy at 1 month.

Results: Fourteen biopsies were performed in 10 patients between 1 to 24 months after transplantation. Indications for biopsy were: graft dysfunction (10; 3 with proteinuria), proteinuria alone (2), BK viremia with proteinuria (1), and de novo donor specific antibody (DSA) (1). Biopsies from 5 EBK recipients demonstrated pediatric donor glomerulopathy represented by the presence of glomerular abnormalities including subependymal multilayering/remodeling of the basement membrane, segmental glomerulosclerosis, mesangial hypercellularity, mesangial sclerosis, podocyte hypertrophy, and/or segmental mild podocyte foot processes effacement. Ten biopsies also showed thin basement membranes (BM) on EM consistent with the age of the donor kidney. Other diagnostic findings among the entire biopsy cohort were acute cellular rejection (ACR), antibody mediated rejection (AMR), or mixed ACR and AMR (5), acute tubular necrosis (ATN) (3), and pyelonephritis (1). Biopsies with pediatric donor glomerulopathy were performed early after transplantation and were associated with proteinuria. Semi quantitative proteinuria in the 5 recipients at the time of biopsy was 1-3+; 1.2-9.5 g/day in 4. Follow up 4-39 months post-transplant (mean 17 months) in patients with pediatric donor glomerulopathy showed serum creatinine 0.55-2.07 mg/dl (mean 1.13) and urine protein 0.4 to 1.2 g/day (mean 0.73).

Conclusions: Overall, pediatric donor glomerulopathy seen early post transplant period did not appear to negatively affect long-term graft function; this outcome may be related to growth of these kidneys occurring early post transplant.

Renal ultrasound with Doppler (left), renal angiography (middle), post-coiling (right)

Renal Transplant Artery Stenosis and Kinking: An Unusual Association

Haridran Soss Barrios,1 Victor Burgueria,1 Ester Casillas,1 Daniel E. Villa,1 Sara Jimenez Alvaro,1 Irene Martin Capon,1 Milagros Fernandez-Lucas,1,2 Maite Rivera.1,2 1Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Universidad de Alcala de Henares, Madrid, Spain.

Introduction: Renal artery stenosis of the kidney graft associated with kinking is not a frequent finding. As a correctable cause of graft dysfunction it is important to diagnose it as soon as possible to avoid further graft damage.

Case Description: A 62 year-old woman with ESRD due to ADPKD had a deceased donor kidney transplant (KTx) in her right iliac fossa (1 vein/1 artery) anastomosed to external iliac vessels. Immunosuppression:basiliximab, tacrolimus, everolimus and steroids. Creatinine drop halted 2 weeks post-op. Blood pressure was normal, CMV load : undetectable. Tacrolimus level:7-9 ng/ml. A KTx US was done, showing high velocities within KTx renal artery close to the anastomosis, increasing near a kinking image adjacent to the hilum (image 1), not present on Doppler US 1 day post-op. A CT angiography confirmed renal artery stenosis at anastomosis level and kinking of the graft renal artery (image 2). Endovascular angioplasty of the stenotic area without stenting was performed, but unsuccessful. Open surgery vascular reconstruction was carried out a week after angioplasty: renal artery was shortened and reimplanted. Within a week, graft function improved and Doppler US was normal.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Discussion: Renal artery stenosis is a correctable cause of hypertension and graft dysfunction in KTx. Graft renal artery kinking is rare, even more so in association with stenosis, worsening its prognosis as kinking makes angioplasty less effective. Complete Doppler US mapping of the graft’s arteries is essential to make an early diagnosis and nephrologists could do this examination promptly.

PO2567
Proliferative Glomerulonephritis Monoclonal Immunoglobulin Deposits (PGNMID) in a Kidney Allograft Successfully Treated with Rituximab
Rasha Alawieh, Mohankumar Doraiswamy, Seth Schetz, Anjali A. Satoskar, Todd E. Pesavento, Priyamvada Singh. The Ohio State University, Columbus, OH.

Introduction: PGNMID is a rare distinct form of glomerulonephritis (GN) characterized by glomerular monoclonal immunoglobulin deposits. There is no definite treatment for this condition. We present a case of PGNMID in a recurrent renal transplant patient who responded well to rituximab.

Case Description: A 43-year-old male with ESRD secondary to MPGN s/p 3rd renal transplant complicated with failure of previous transplants due to rejections (on cyclosporine and everolimus) presented with worsening pain at the graft site and AKI. Creatinine 5.6 mg/dL (baseline 2.5 mg/dL), UPC 1.5 gm/dL, RBC, and RBC casts on microscopy. Detailed serological, immunological, and infectious workup was negative. Renal biopsy showed mesangial, subepithelial, and subendothelial proliferation with electron dense deposits of IgG1 and IgG3 with kappa predominance most consistent with PGNMID. Monoclonal workup was negative and bone marrow biopsy showed no clear evidence of hematologic malignancy. He received two doses of rituximab in addition to home immunosuppression. Renal function improved to baseline (creatinine 2.5, negative blood, UPC 0.5) and has been stable for past year.

Discussion: GN recurrence in kidney allografts is responsible for around 24% of kidney graft losses. Approximately 70% of PGNMID patients have no detectable monoclonal proteins in serum or urine. Multiple regimens have been used for the treatment of PGNMID after renal transplant, including RAAS blockers, steroids, rituximab, bortezomib and plasmapheresis. Few reported cases of PGNMID responded well to rituximab, and a large prospective multicenter controlled study is warranted to better understand this rare disease.
Case Study of Repository Corticotropin Injection (RCI) Prophylaxis for FSGS Recurrence in Kidney Transplant

Sandheep Venkataraman,1 Barrett R. Crowther,1,2 Monica Grafals,1,2 University of Colorado, Denver, CO; 1University of Colorado Health, Aurora, CO.

Introduction: Idiopathic FSGS recurs post-transplant in one third of cases and is associated with a five-fold higher risk of graft loss.1

Case Description: In this single center pilot case study, 8 patients with biopsy-proven FSGS were treated with RCI prophylaxis 80 units subcutaneously twice a week for 6 months from day of kidneyTx, compared with a group of 6 patients who were treated with RCI later after the diagnosis of FSGS recurrence.

Discussion: All patients received rATG as induction and were on standard immunosuppression with FK, MMF, and prednisone. Patients in the control group were diagnosed with recurrent FSGS between 5-63 days post Tx. There where 3 patients in the study group that developed recurrent FSGS, 2 of them required plex. Patient 1 in the study group had DGF after a live donor kidney Tx from recurrent FSGS. Her protocol biopsy performed one year after transplant and still shows foot process effacement but no fibrosis or sclerosis in light microscopy. All but one patient in the control group have still functioning allografts. Conclusions: This is a small pilot study, but its findings suggest that use of RCI at time of kidney transplant surgery in patients with FSGS decreases the severity of the disease with less fibrosis in follow up biopsies despite the presence of foot process effacement. There may also be a decreased need for plex in the study group, however, further studies are needed to confirm this.

Does Therapeutic Plasma Exchange Improve Kidney Function in Renal Transplant-Associated Thrombotic Microangiopathy?

Karen A. Nahmod, Barbara J. Bryant, Sean G. Yates, Marjan Afrouzian. University of Texas Medical Branch at Galveston, Galveston, TX.

Background: Therapeutic plasma exchange (TPE) is performed in patients with renal transplant thrombotic microangiopathy (t-TMA) to improve the kidney function. The goal of our study is to evaluate the short-term efficacy of TPE in patients with renal t-TMA.

Methods: We retrospectively compared the outcome of TPE-treated vs. non-TPE-treated patients with biopsy-proven diagnosis of t-TMA. Histologic criteria for diagnosis of t-TMA included presence of thrombi in the artery-arteriole/glomeruli, mesangiolysis & double contours, and electron microscopic evidence endothelial cell injury including subendothelial rarefaction/accumulation of fluffy material and mesangial interposition. Both groups received concomitantly other modalities of treatment. Creatinine and creatinine clearance levels were determined at the time of biopsy (T0) and after 1, 3 and 6-months (T1, T3, T6 respectively).

Results: In 13 TPE-treated and 9 non-TPE-treated patients, the mean creatinine levels at 6 months decreased 32.5% and 45% respectively over baseline, while the creatinine clearance increased by 68% and 65% respectively, although not statistically significant (p>0.05). Graph 1.

Conclusions: No significant differences were noted in creatinine or creatinine clearance levels within and between either groups at any time point. Our study suggest that no significant benefit in renal function is associated with performing TPE in patients with renal t-TMA. Larger studies are needed to confirm our data.

Graph 1. Creatinine and Creatinine Clearance Levels (Means±SEM)
PO2571
Patient and Graft Outcomes of Kidney Transplant Recipients with Anti-Human Neutrophil Antigen Antibodies

Background: Antibody mediated rejection (AMR) is a well-established cause of poor graft outcomes in kidney transplant recipients (KTR). While the most common targets are human leukocyte antigen (HLA) antibodies, there are data implicating some non-HLA abs in the process of AMR. Human neutrophil antigens (HNA) are glycoproteins expressed on neutrophil surfaces. Anti-HNA abs have been associated with transfusion-related acute lung injury but their role in AMR in KTR is unclear. The aim of our study was to examine the outcomes of KTR with anti-HNA abs at our center.

Methods: We retrospectively reviewed the medical records of KTR with non-HLA abs between 1/2008-5/2020. Relevant clinical and graft outcome data were obtained. Descriptive statistics were expressed as absolute numbers (%) for categorical data and as medians with interquartile range (IQR) for skewed distribution.

Results: There were 6 KTR with non-HLA abs during the study period, all anti-HNA abs. Three patients (pts) were male (50%), 5 white (83%), and 4 had polycystic kidney disease (PKCD) as primary disease (66%). Median age at KT was 46 (29.75-57). pts’ characteristics, clinical course and outcomes are detailed in Table 1. Five pts developed biopsy-proven AMR at a median of 32 months (13.8-68.2) from KT. During follow-up (f/u), 3 pts had graft loss, 1 of which was re-transplanted while 2 are re-listed but dialysis-dependent. Mean creatinine of the 4 pts with working allografts is 1.21mg/dL (1.14-1.27) at median fu of 68 months(52-105).

Conclusions: We observed varied clinical courses and graft outcomes in our pts, partly due to our small cohort. Although majority developed AMR, it was not necessarily associated to graft loss or shortened graft survival. Of note, PKCD was the primary kidney disease in the majority of pts, similarly observed in one other case series. More studies are needed to determine the specific significance of anti-HNA abs in KTR.

Table 1. Patient and donor characteristics and allograft outcomes.

PO2572
Transplant Outcomes in Children with Lupus Nephritis
Vinna Chaudhry,1 Heather Swank,2 Shirley Galbiati,2 Meredith A. Atkinson,2 Bradley A. Warady,1 Children’s Mercy, Kansas City, MO; 2Johns Hopkins University, Baltimore, MD; 1The Emmes Company LLC, Rockville, MD; 4State University of New York Upstate Medical University, Syracuse, NY.

Background: Children receiving dialysis for end stage kidney disease secondary to lupus nephritis (LN) have decreased survival and a lower likelihood of kidney transplantation compared to children with non-lupus glomerular diseases (NLGN). Whereas a previous North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) analysis reported equivalent patient and graft survival for LN patients when compared to matched controls, a comparison of recent transplant outcomes in children with LN and NLGN has not been conducted.

Methods: Retrospective analysis of the NAPRTCS registry data of subjects <21 years old who received a kidney transplant between 1987–2018. Outcomes for LN patients (n=191) were compared to NLGN patients (n=8675) during pre & post 2000 eras. Statistical analyses included Kaplan-Meier curves and multivariable logistic and Cox regression models.

Results: After adjusting for race, LN patients were less likely (p<0.001) to receive a preemptive transplant (OR=0.12). There was also a trend for LN patients being less likely to receive a living donor (LD) transplant (OR=0.8). When comparing pre- and post-2000 eras, time to 1st rejection and graft survival improved for both LN and NLGN groups, although the graft survival benefit in LN group was not sustained after 3.5 years of follow-up. Time to 1st rejection and graft survival for LN patients remained inferior to NLGN group during both eras (Figure 1 & 2).

Conclusions: LN patients are less likely to receive a preemptive, and possibly a LD transplant. Overall, outcomes for both LN and NLGN transplant patients improved after 2000, but the outcomes of the LN group were inferior to those of the NLGN group during both time periods.

PO2573
Effect of Rituximab Dose on Induction Therapy in ABO-Incompatible Living Kidney Transplantation: A Network Meta-Analysis
Seon Deok Hwang,1 Joon Ho Song,1 Kipyo Kim,1 Woo Yeong Park,2 Seoung woo Loe.1 Inha University, Incheon, Incheon, Republic of Korea; 2Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.

Background: Rituximab is an induction immunosuppressant essential for ABO-incompatible kidney transplantation, but studies on its dosing, which differs between countries and transplant centers, are lacking we retrospectively investigated this phenomenon.

Methods: we retrospectively investigated this phenomenon by including five groups: ABO compatible; placebo; and rituximab 200 mg, 200–500 mg, and 500 mg. Publications were retrieved using CENTRAL, MEDLINE, EMBASE, and Science Citation Index Expanded databases from 1970 to February 2020 and analyzed. Reviews, observational studies, and clinical trials with unclearly defined outcomes or omitted graft failure as an outcome were excluded. We performed direct and indirect network meta-analyses using Bayesian models and ranked different rituximab doses using generation mixed treatment comparison. The GRADE of network meta-analysis approach specified four levels of certainty for a given result: high, moderate, low, and very low. The outcomes were patient survival, graft failure, and infections including bacterial and viral.

Results: Twenty-one trials with 4,256 subjects were analyzed for glomerular filtration rates, graft loss, antibody-mediated rejection, T-cell mediated rejection, fungal infection (Candida), and patient survival rates, which did not differ among four groups. However, incidence of sepsis and cytomegalovirus infection (0.728 and 0.855, 95% confidence interval: 0.572–0.926 and 0.724–0.921, respectively) were significantly lower in rituximab 200-mg group than in other groups.

Conclusions: In conclusion, in ABO-incompatible kidney transplantation, low-dose rituximab is more efficacious than higher doses and reduces serious infection risks. Future studies of large-scale, long-term data and further discussions on using lower rituximab doses are necessary.

PO2574
Delayed Diagnosis of Renal Allograft Uroenteric Fistula in a Pediatric Transplant Patient
Malek Al Barbandi, Patricia A. Arroyo Parejo Drayer, Juan C. Infante, George W. Burke, Jayanthi Chandar, Marissa J. Defreitas, Chryso P. Katsoulis, Wacharee Seeherunvong, Carolyn L. Aibitbol. University of Miami School of Medicine, Miami, FL.

Introduction: The diagnosis of uroenteric fistulae can be challenging and is often delayed for several months after symptoms begin. Here, we describe a rare case of a pediatric patient post en bloc kidney transplant who developed a urinoma post biopsy with a ureteral fistula into the small bowel resulting in profound acidosis and deceptive watery diarrhea.
Case Description: The patient is an 8 year old girl with end stage kidney disease secondary to steroid resistant nephrotic syndrome and focal segmental glomerulosclerosis (FSGS). She underwent a right native nephrectomy and a deceased donor “en bloc” kidney transplant with two separate ureters. She had a renal allograft biopsy for suspected rejection. A few days after the biopsy, she began experiencing watery diarrhea and metabolic acidosis. A comprehensive screening for diarrhea produced inconclusive findings. She was maintained on parenteral nutrition with no oral intake to try to slow the diarrhea. However, the watery diarrhea increased while urine output decreased. Throughout this period, the patient maintained normal kidney function. The watery stool and bladder urine were analyzed for solutes, pH and creatinine. An MRI with contrast was performed which demonstrated fistulization of the distal transplanted ureters into the small bowel. She underwent corrective surgery which identified the fistulous tract which was resected and the ureters were re-implanted. The surgery went well without complications. The diarrhea resolved and she was discharged 2 weeks later with normal renal function.

Discussion: This is a perplexing case of the development of a uroenteric fistula in a pediatric transplant patient that went undiagnosed for almost 3 weeks due to the deceptive nature of the watery diarrhea which was actually urine. An important aspect of the uroenteric fistula is the severe acidosis that results when urine is diverted into the intestinal tract. This occurs in some cases of bladder augmentations that use the intestine. Another important diagnostic tool is the solute excretion in the diarrhea. Despite the watery nature of the diarrhea, the stool was not hyperosmolar and did not contain reducing substances. This made osmotic diarrhea unlikely and a fistula more likely.

PO2575
Effect of Therapeutic Plasma Exchange on Glomerular Filtration Rate in Patients with Antibody-Mediated Rejection
Miguel Maza Moreno, Sergio Hernández-Estrada, Jose H. Cano, Odette Del Carmen Diaz Avendaño, Diana Maldonado Tapia. Nephrology and Transplant Division National Medical Center 20 de Noviembre, Mexico City, Mexico.

Background: AMR is the main risk factor for graft loss, especially after the first post-transplant year. Up to 80% of patients achieve response with immunosuppressive treatment and TPE, although the response is lower in patients with lateAMR. The objective was to determine the effect of TPEonGFR at 0, 1, and 3 months postTPE.

Methods: Retrospective study that included patients with a renal transplant of the CMN“November 20”in Mexico City, from 2016-2019, undergoing membrane TPEforAMR. Analysis was performed using student’s t or MannWhitneyU, repeated measures analysis, and Spearman or Pearson test. Significant p was less than 0.05.

Results: 25 patients with AMR who received TPE were evaluated. Age: 32±11.6 years, 72% from living donor, 52% received Basiliximab. 87% received tacrolimus. 80% of AMR were late. Prevalence of HLAClass II DSA(66%), specifically vs DQandDR (57.2% and 28.8%). There was a significant difference between preTPE GFR and at the end of treatment(Δ=0.015, r=0.53), and no significant differences between preTPE GFR, with 1or3 monthGFR(p=0.58; p=0.36). When evaluating IFTA or histological score(g+ptc), no difference was detected in the GFR at 1or3 months post-TPE. When comparing the effect of the AMR temporality on the GFR, difference was found at 1and3 months (p=0.022; p=0.01) postTPE, with lower recovery of GFR in patients with early AMR. There was a moderate correlation between GFR at the time of diagnosis of rejection and GFR at 3 months postTPE(r=0.68; p=0.01), Fig. 1.

Conclusions: Significant difference was demonstrated between the preTPE GFR and immediate postTPE GFR. In our study patients with early AMR presented a poor response to treatment. The GFRupon admission correlated positively with theGFR detected at 3months post-TPE. This suggests a beneficial effect of TPE over GFRfall during the first 3months after diagnosis.
PO2577
Single-Dose Rituximab and Antithymocyte Globulin (ATG) in Hypersensitized Kidney Transplant Recipients
Aileen Wang, Uerica K. Wang, Megan L. Troxell, Stephan Busque, Colin R. Lenihan. Stanford University School of Medicine, Stanford, CA.

Background: Hypersensitized kidney transplant recipients (calculated panel reactive antibody (cPRA) ≥ 98%), may represent a population at high risk of posttransplant immunologic events. Their optimal induction regimen so far remain uncertain. The goal of this study was to compare 1-year outcomes of patients receiving rituximab and ATG as induction, the majority of whom were hypersensitized, with highly sensitized recipients (cPRA ≥ 80%) who received ATG alone.

Methods: All patients ≥ 18 years received a flow cross-match compatible kidney transplant between December 2014 and May 2020. We excluded patients who underwent pretransplant desensitization, simultaneous multi-organ transplantation, or received 0-HLA antigen mismatched organ. The exposure of interest was receipt of single dose rituximab (500mg) at induction. The 1-year outcomes were 1) patient and death censored graft survival, 2) glomerular filtration rate (GFR), 3) de novo DSA formation, 4) biopsy proven T-cell or antibody mediated rejection, 5) the composite of d/dNDSA and rejection, 6) BK viremia, and 7) CMV viremia.

Results: 70 patients received rituximab and ATG (Ritux) and 39 received ATG alone (Control). The Ritux group were (numerically) younger, more sensitized, received kidneys with a longer cold ischemia time, and lower kidney donor profile index. ATG doses were similar. The majority were deceased donor transplants. 1-year patient and death censored graft survival, mean GFR, incidences of BK viremia and CMV viremia were similar for Ritux and Control. 2 patients with primary graft non-function (1 in each group) and 1 patient with early posttransplant death (in Ritux) were excluded from the remaining outcome analyses (Table 1).

Conclusions: The addition of rituximab to ATG as induction for hypersensitized patients appears to be safe and is associated with excellent 1-year outcomes in patients with highly sensitized kidneys with a longer cold ischemia time, and lower kidney donor profile index. ATG doses were similar. The majority were deceased donor transplants. 1-year patient and death censored graft survival, mean GFR, incidences of BK viremia and CMV viremia were similar for Ritux and Control.

PO2578
Risk Factors and Outcomes of Acute and Chronic Antibody-Mediated Rejection
Allyson Hart1, David P. Schladt,2 Robbin F. Itzler,3 Ajay K. Israni,3 Bertram L. Kasiske1,2 Hennepin Healthcare, Minneapolis, MN; 2Hennepin Health Care, Minneapolis, MN; 3Chronic Disease Research Group, Minneapolis, MN; 4CSL Behring, King of Prussia, PA.

Background: Major gaps remain in our understanding of antibody-mediated rejection (AMR) after kidney transplantation. We examined incidence, risk factors, response to treatment, and effects on outcomes of locally-managed AMR at 7 transplant programs in the Long-Term Deterioration of Kidney Allograft Function (DeKAF) prospective study cohort.

Methods: Consecutive kidney or kidney-pancreas transplant recipients were enrolled in the DeKAF study from October 2005 through April 11, 2015. To determine the effect of AMR on death censored graft survival (DCGS), we performed Cox proportional hazards analyses including AMR as a time-dependent covariate.

Results: Among 3131 kidney and kidney-pancreas transplant recipients, there were 194 with biopsy proven T-Cell Mediated Rejection (TCMR) in the first post-transplant year. 80 of 943 (9%) patients died while 63 (7%) lost their graft and 38 (4%) suffered allograft dysfunction. Death-Death was attributed to a combination of infection (29%), Cardiovascular (CV) disease (29%) and malignancy (12%), a significant proportion of patients who died from either CV disease (43%), infection (26%) or malignancy (20%) had prior biopsy-proven T-Cell Mediated Rejection (TCMR) in 1st post transplant year.

Conclusions: While the causes of death, early allograft loss and dysfunction were diverse, TCMR was the most dominant cause for allograft dysfunction. While Infection (17%) and surgical causes (14%) were the next common associations, donor related disease accounted for 2% of graft losses. Graft Dysfunction-TCMR (42%) was strongly associated with allograft dysfunction in our patient cohort. The other factors associated with Allograft Dysfunction included a). Infection (21%), b). Donor Related causes (11%) and c). Other Causes (15%). Surprisingly ABMR was only noted in 11% of patients with allograft decline.

PO2579
Allograft Loss and Patient Death Among Kidney Transplant Recipients: Is Therapy Nonadherence the Underlying Perpetuator?
Kartik Kalra, Puneet Sood, Rajil B. Mehta, Chethan M. Puttapparaju, Christine Wu, Sundaram Hariharan, Nirav A. Shah. University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: To ascertain causes of allograft dysfunction, loss and death in a cohort of kidney transplant patients.

Methods: Retrospective cohort study, 943 patients with isolated kidney transplants between years 2013-17 were analyzed for the following transplant outcomes: 1. Death-censored allograft loss 2. Graft dysfunction 3. Death.

Results: 80 of 943 (9%) patients died while 63 (7%) lost their graft and 38 (4%) suffered allograft dysfunction. Death-Death was attributed to a combination of infection (29%), Cardiovascular (CV) disease (29%) and malignancy (12%), a significant proportion of patients who died from either CV disease (43%), infection (26%) or malignancy (20%) had prior biopsy-proven T-Cell Mediated Rejection (TCMR) in 1st post transplant year.

Conclusions: While the causes of death, early allograft loss and dysfunction were diverse, TCMR was the most dominant contributor. Non-Adherence was strongly associated with TCMR and was more common in younger patients and those with African American ethnicity. Addressing non adherence in this cohort of patients early with novel interventions could be a key to optimizing patient outcomes in this high risk cohort.

PO2580
Identifying the Causes for Kidney Allograft Failure
Manuel Mayrödorfer, Marcel Naik, Wiebke Duettmann, Klemens Budde. Charité Universitätsmedizin Berlin, Berlin, Germany.

Background: Since it has been proposed that several causes (C) can contribute to graft loss (GL), we analyzed transplant (Tx) recipients in our center and attributed a C to each persistent decline in renal function, finally leading to GL.

Methods: We retrospectively analyzed 1477 Tx, transplanted between 1997 and 2017 in a single center, of which 303 progressed to GL. An adjudication committee consisting of 3 physicians evaluated biopsies, laboratory data and medical history. Nonreversible decreases in renal function were attributed to primary and secondary C.

Results: Overall graft survival for all patients is 93.7% for 1 year, 80% for 5 years and 60.6% for 10 years. The most frequent C leading to GL were intercurrent medical causes (41%), Cardiovascular (CV) disease (29%) and malignancy (12%), a significant proportion of whom were African American. Addressing non adherence in this cohort of patients early with novel interventions could be a key to optimizing patient outcomes in this high risk cohort.

Assessing Cumulative Immunosuppressive Drug Exposure: Metrics, Outcomes, and Implications for Kidney and Non-Kidney Transplant Patients
Cavizhajian Skanthan, Emily Nguyen, Lakindu Somaweera, Madhumitha Rabindranath, Olusegun Famure, Joseph Kim. University Health Network, Toronto, ON, Canada.

Background: Immunosuppressive drugs are used in the long-term management of post-transplant patients to prevent rejection of transplanted organs. Lacking a prior qualitative systematic review on this topic, we aimed to characterize the metrics used to measure cumulative immunosuppressant exposure and their associated outcomes in kidney and non-kidney transplant patients.

Methods: We conducted a literature search using search terms related to immunosuppressants and cumulative exposure in Ovid MEDLINE, Ovid EMBASE, Cochrane CENTRAL, and Cochrane Database of Systematic Reviews. No date restrictions were applied. An additional search was performed on Google Scholar and references of studies included in the primary search were screened. Studies were limited to the English language with adult human transplant patient populations. Study risk of bias was assessed using the Quality in Prognostic Studies Tool where each domain was rated as low, medium, or high risk of bias.

Results: A total of 29 articles were included in our qualitative synthesis. Kidney transplant populations account for 12 (41%) of the studies in our analyses. Fifteen of the articles (51%) calculated the total dose of immunosuppression over the treatment period while 9 (31%) used long term area-under-the-curve (LT-AUC) of trough level concentrations to quantify cumulative immunosuppression exposure. Nine articles found certain cumulative exposure metrics to be predictive of adverse outcomes such as decreased kidney function, cancer recurrence, and bone fractures. Furthermore, an adequate mycophenolic acid LT-AUC was associated with a decreased risk of allograft rejection, while cumulative corticosteroid exposure was not associated with allograft rejection.

Conclusions: This review analyzed a comprehensive set of articles and metrics that predict long-term outcomes of immunosuppressants in transplant patients. The wide variety of metrics studied highlight the lack of agreement on the best measures of drug exposure in transplant patients. Although certain metrics may demonstrate an association with outcomes, future studies should investigate the predictive power and validation of these metrics.

PO2582
Fludrocortisone Corrects Tacrolimus-Associated Hyperkalemia in Renal Transplant Patients
Rouvick Gang, Virginia A. Quan, Mysoor K. Phanish. Epsom and Saint Helier University Hospitals NHS Trust, London, United Kingdom.

Background: Hyperkalemic metabolic acidosis is commonly observed following kidney transplantation. This is often due to calcineurin inhibitors which are known to cause type 4 renal tubular acidosis either due to hyporeninemic hypoaldosteronism or due to direct effect on aldosterone responsive potassium secretion in the distal nephron.

Methods: We report 5 post-renal transplant patients (5 males) on tacrolimus with hyperkalemia treated with daily doses of either 50 mcg (n=3) or 100 mcg (n=2) of fludrocortisone. We retrospectively collected data at 3 time points before and after fludrocortisone. We measured serum concentrations of sodium, potassium, bicarbonate, creatinine and tacrolimus as well as eGFR and blood pressure (BP). We recorded emergency admissions and length of stay (LoS) for treatment related to hyperkalemia. We also compared baseline characteristics and measures of drug exposure (e.g., trough and area-under-the-curve) in patients who received fludrocortisone with those who did not.

Results: Pre and post-fludrocortisone serum concentrations for potassium were 6.3 ± 0.3 mmol/L and 5.1 ± 0.3 mmol/L (p=0.002); venous bicarbonate 18.4 ± 1.8 mmol/L and 20.4 ± 2.0 mmol/L (p=0.108); sodium 135 ± 1.6 mmol/L and 135 ± 2.2 mmol/L (p=0.873); creatinine 184 ± 12.2 mmol/L and 155 ± 10.6 mmol/L (p=0.058); eGFR 39 ± 3.4 ml/min and 47 ± 4.2 ml/min (p=0.035); blood tacrolimus levels 9.8 ± 2.1 ng/mL and 11.2 ± 1.0 ng/mL; BP was 133/69 ± 12.0/9.9 mmHg and 129/70 ± 8.6/6.6 mmHg before and after fludrocortisone respectively. We were able to either reduce or stop sodium bicarbonate after starting fludrocortisone due to increase in serum bicarbonate levels. Prior to fludrocortisone there were 6 episodes of serum potassium greater than 6.5 mmol/L, of which 3 patients required admission for hyperkalemia management, with LoS 1-3 days.

Conclusions: Fludrocortisone corrected hyperkalemic metabolic acidosis with fludrocortisone resulted in rapid normalization of serum potassium. There were no adverse effects on BP, serum sodium levels or clinical evidence of fluid retention. Instigation of fludrocortisone prevented emergency admissions for treatment of hyperkalemia and allowed the clinicians to run adequate tacrolimus levels. Fludrocortisone can be a cheap, safe and effective option for the treatment of hyperkalemia in renal transplant patients on tacrolimus.
PO2583
Changes in Serum Klotho in Kidney Transplant Recipients and Prognostic Marker for Allograft Function: A Systematic Review and Meta-Analysis
Juan A. Medina,1 Charat Thongprayoon,2 Napat Leepaephorn,3 Javier A. Neyra,4 Pradeep Vaitla,1 Franco H. Cabeza Rivera,1 Michael A. Mao,5 William C. Oliver, Jr.1 1Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 2Department of Medicine, Mayo Clinic, Jacksonville, FL; 3Division of Nephrology, Department of Medicine, University of Kentucky College of Medicine, Lexington, KY; 4Renal Transplant Program, University of Missouri-Kansas City School of Medicine/Saint Luke’s Health System, Kansas City, MO.

Background: α-klotho protein is a well-known anti-aging factor that regulates systemic phosphate metabolism. Mutation of klotho in mice can lead to phenotypes resembling human aging. Since klotho expression is highest in the kidney, patients with advanced chronic kidney disease have progressive decline in klotho levels. However, changes in serum klotho levels in kidney transplant (KTx) patients and its prognostic significance on allograft function remain unclear.

Methods: A literature search was conducted using MEDLINE, EMBASE and Cochrane Database from inception through October 2019 to identify studies evaluating 1) change in serum klotho levels after KTx, 2) klotho levels among KTx vs non-KTx patients, and 3) prognostic significance of klotho levels on allograft function after KTx. Study results were pooled and analyzed utilizing random-effects model.

Results: 10 cohort studies with a total of 431 KTx patients were identified. After KTx, there was significant increase in serum klotho levels at (4 to 13 months post-KTx) with mean difference (MD) of 243.11 (3 studies; 95%CI 67.41 to 418.81). Although KTx patients had lower serum klotho level with MD of = -234.50 (5 studies; 95%CI -444.84 to -42.16) compared to healthy volunteers, a study demonstrated comparable klotho level between KTx patients and eGFR-matched controls. Two studies demonstrated high serum klotho levels in deceased donors as prognostic marker for good allograft function within 1 year after KTx (p<0.05).

Conclusions: There is a significant increase in serum klotho levels after KTx. There is potential role of klotho levels as prognostic marker for renal allograft function.

PO2584
Braving the Storm: Cytokine Release Syndrome with Rabbit Antithymocyte Globulin Therapy after Kidney Transplant
Himmat S. Brar, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: Cytokine release syndrome (CRS) is an acute systemic inflammatory syndrome associated with chimeric antigen receptor (CAR)-T cell therapy or therapeutic antibodies. CRS can present with a variety of symptoms ranging from mild flu to severe life-threatening manifestations of shock, vascular leakage, DIC and multi-organ failure. We present a case of a CRS following rATG induction.

Case Description: A 29-year-old female with a history of T1 DM s/p kidney/pancreas transplantation 12 years ago experienced the rejection of transplanted kidney 1 year back. Her home immunosuppression included Tacrolimus, MMF and Prednisone. She underwrote a kidney transplant from a living donor. The induction immunosuppression consisted of rabbit anti-thymocyte globulin (ATG), methylprednisolone and MMF. Two hours after the rATG infusion (1.5 mg/kg) on day 1 of transplant; she developed breathing difficulty, temp of 102.7 R, RR of 25, HR of 160 and fall in BP to 108/55 mmHg. Lab work showed a drop of Hb from 11.4 to 9, platelets from 187 to 126 and WBC from 17 to 9.8. CXR was unremarkable. ECHO showed normal cardiac function. LE Doppler was negative for DVT. The patient was quickly diagnosed to have CRS and instead of giving fluids and causing pulmonary decompensation, she was given Solumedrol, Henarudy and TYLENOL. RATG was discontinued. Cultures were obtained that resulted negative. She improved within a couple of hours with stabilization of vitals. We suspect that the CRS following ATG infusion caused the patient’s acute decompensation, given the temporal following ATG infusion caused the patient’s acute decompensation, given the temporal relationship, rapid recovery following withdrawal and lack of proven infectious etiology. She was finally premedicated and given ATG at a slower rate over 12 hrs and tolerated it well.

Discussion: CRS is an inflammatory cascade that develops within minutes to hours after immunotherapy. The case emphasizes the successful rapid recognition and proper management of CRS in preventing the patient decompensation. The massive cytokine release triggers an inflammatory response leading to capillary leakage, severe hypotension and respiratory failure. The management differs from usual shock as the aggressive hypotension leads to pulmonary edema.1,2 The patient responded to corticosteroids and pressors are the mainstay of therapy and should be administered early. The treatment is largely supportive with ventilation for respiratory failure and steroids for inflammation.

PO2585
Proton Pump Inhibitor Prevalence and Documented Indication in a Small Kidney Transplant Program
Abdulrahman Alkandari, Frances Macleod, M. Khaleed Shamseddin. Queen’s University, Kingston, ON, Canada.

Background: Proton pump inhibitors (PPIs) are commonly prescribed post kidney transplantation, and their use was prevalent in 44-48% of recipients. Prolonged exposure to PPIs could be associated with renal and non-renal adverse outcomes, including hypomagnesemia and hip fracture (OR: 1.39, 95% CI: 1.04-1.84). The objective of this report is to evaluate the prevalence and the documented indication of PPI use in our kidney transplant program, while exploring the potential PPI withdrawal and GERT recurrence in a future Quality Improvement (QI) project.

Methods: This is a retrospective study to assess the prevalence and the documented indications of PPI use among all of kidney transplant recipients in our program by March 31st, 2020. The primary variables were the prevalence of PPI use and the percentage of patients with documented indication of PPI use in our Health Information System (HIS).

Results: Out of 202 kidney transplant recipients, 113 (55.9%) patients were on PPIs (Mean age 58 years, Male 68 (60.2%), mean post-transplant longevity 106 months), compared with 12 (5.9%) patients on H2 blockers. Thirty three (29.2%) patients who used to be H2 blockers were switched to PPI in late 2019 due to contaminated and backordered ranitidine resulting in an adjusted prevalence of PPI use of 39.5% (Figure 1). The indication of PPI use was documented in our HIS as gastro-esophageal reflux disease (GERD) in 53 (46.9%) patients, and as peptic ulcer disease (PUD) in 9 (8%) patients, while its indication was undocumented in 51 (45.1%) patients.

Conclusions: PPI use was prevalent among our kidney transplant recipients similar to other studies. Due to its association with multiple adverse outcomes, better documentation of its indication in the medical record is required. Consideration to withdraw PPI in our kidney transplant recipients and to reassess the risk of GERD recurrence will be assessed in a future QI project.

PO2586
Unexpected Recurrence of Undiagnosed ANCA-Associated Vasculitis in a Kidney Transplant Recipient
Ruchi H. Naik, Heidi M. Schaefer, Saed Shawar. Vanderbilt University Medical Center, Nashville, TN.

Introduction: ANCA Associated Vasculitis (AAV) is one of the leading causes of End-stage Kidney disease (ESKD). The relapses of AAV after kidney transplant are relatively rare. As per the literature, the positive ANCA status in not a contraindication for transplant and patients usually get transplant once in clinical remission. Here, we are describing a unique case of ESKD due to renal limited AAV which was diagnosed retrospectively after the development of the recurrence two months post-transplant.

Case Description: A 69 years old Caucasian female with ESKD presumed due to hypertension received a deceased donor kidney transplant in Oct 2019 after being on dialysis for 4 years. She received almentuzumab for induction followed by tacrolimus, mycophenolate mofetil, and prednisone for the maintenance immunosuppression. Her immediate post-transplant course was complicated by delayed graft function and her creatinine never went down below 2 mg/dl. Allograft biopsy was planned after 2 months due to persistent microscopic hematuria with progressive sub nephrotic range proteinuria. The immuno-histopathology and electron microscopy was suggestive of pan-immune crescentic GN. Her serology workup was positive for ANA, ANCA with high titers of MPO. She lacked any other systemic involvement, and drugs induced ANCA was ruled out. She was treated with a pulse dose of methylprednisone and one dose of rituximab. Gradually her creatinine improved to 1.37 mg/dl with down trending MPO antibody titers within 6 weeks. The review of her chart retrospectively showed clinically asymptomatic ANCA positivity with high MPO titers 3.5 years back, suggestive of recurrence of AAV more than De novo AAV post-transplant.

Discussion: Physician should always be vigilant about the recurrence of the primary disease after transplant, especially when patients have undiagnosed primary kidney disease like AAV, where early diagnosis and treatment in the early stage of the disease is important to optimize results of renal transplantation. A randomized prospective study is needed to answer the question whether the ANCA positivity at the time of transplant is needed to answer the question whether the ANCA positivity at the time of transplant is.
PO2587

A Case of Porphyria Cutanea Tarda After Kidney Transplant

Robert C. Hartley, Laith Al-Rabadi, Fuad S. Shihab, Divya Raghavan. The University of Utah School of Medicine, Salt Lake City, UT.

Introduction: Porphyria cutanea tarda (PCT) is the most common subtype of porphyria and can be associated with kidney failure with reports of kidney transplantation curing the disease. We report the case of a patient who had previously undergone kidney transplantation and developed PCT after transplant.

Case Description: A 40-year-old man with end stage renal disease due to unknown chronic glomerulonephritis status post kidney transplant 4.5 years ago was admitted with non-healing blisters on both hands. Patient initially presented one month earlier with similar symptoms and was diagnosed with bullous impetigo due to methicillin resistance staphylococcus aureus. At that time, he was treated with vancomycin followed by trimethoprim-sulfamethoxazole (TMP-SMX) for a total of 14 days. He was also noted to have cytomegalovirus viremia which was treated with valganciclovir. Patient reported ongoing development of lesions despite antibiotic treatment and presented for follow-up where he was noted to have an acute kidney injury and hyperkalemia. At presentation his medications included mycophenolate sodium, tacrolimus, prednisone, triamcinolone cream and mupirocin ointment. There was no family history of skin disease and he did not drink alcohol. He underwent skin biopsy which was consistent with porphyria or pseudoporphyria. Urine and plasma porphyrins were checked showing elevated uroporphyrin and also elevate heptacarboxyl, hexacharboxyl and pentaclecarboxyl porphyrins with normal coreporphyrin I and III consistent with PCT. Additional workup was notable for a ferritin of 978 ng/mL, hepatitis A, B and C titers inconsistent with current or past infection and HFE gene testing showing the absence of mutations C282Y, H63D and S65C. Patient’s kidney injury resolved with cessation of TMP-SMX and fluid resuscitation. Patient was treated with therapeutic phlebotomy and erythropoiesis stimulating agents along with counseling on sunscreen use and wearing sun protective clothing.

Discussion: PCT is the most common form of porphyria and is associated with hepatitis C, iron overload, estrogen administration and alcohol use. It has also been associated with hemodialysis often with resolution at the time of kidney transplantation. However, elevated iron stores are often present in kidney transplant patients and PCT can be misdiagnosed as bullous impetigo as it was in this case.

PO2588

Recurrent Focal Segmental Glomerulosclerosis After Kidney Transplantation: A Single-Center Experience

Muhammad Ajmal Panezai, Priya Yenebere, John K. Guirguis, Dennis P. Mishler, Oluwafisayo O. Adebiyi, Muhammad S. Yaqub, Tim E. Taber, Asif A. Sharifuddin. Indiana University School of Medicine, Indianapolis, IN.

Background: Recurrent FSGS (rFSGS) after Kidney Transplantation has a high risk of graft loss. However, the natural history, clinical predictors, and response to treatment remain unclear.

Methods: We retrospectively reviewed all transplant patients at our institution from 2000-2019 with a diagnosis of FSGS and identified and sub-analyzed all cases of recurrent FSGS cases (r-FSGS).

Results: Out of 198 transplants, there were 22 (11.1%) events of biopsy proven r-FSGS. Demographics of the rFSGS cases are described in the Table. 27% of cases had recurrence within 1 month of transplant. Treatments given for r-FSGS included ACE/ARB (100%), Therapeutic Plasma Exchange (40.9%), Rituximab (36.3%), conversion to Cyclosporin (36.3%) and Steroids (27.2%). 65% of cases had either a partial or complete remission. Median proteinuria decreased and mean eGFR was improved at 1 year of recurrence (p<0.05). Over a median follow up period of 4.6 years, there was a 59% graft loss with no patient deaths. 31.8% of patients were re-transplanted after initial graft loss of which 42% had recurrence in their re-transplant. As compared to the cases without any recurrence, cases with rFSGS had a significantly lower long-term graft survival (p<0.001). Figure.

Conclusions: Recurrent FSGS continues to be a high risk for graft loss despite a multitude of therapies available.

What Is the Safe Anti-A2 Titer for a Successful A2-Incompatible Kidney Transplantation?

Yory Al Azzi, Pablo Loarte Campos, Gayatri D. Nair, Maria Ajaimy, Luz E. Liriano-Ward, Cindy T. Pynadath, Purna Bindu Nandigam, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: The new kidney allocation system implemented in December 2014 allowed for use of A2/AB donors to B recipients. However, there is no mandate by UNOS regarding what anti-A2 titers are acceptable. We aimed to investigate the safety of kidney transplant in patients with anti-A2 titers equal less than 1/16.

Methods: We performed 41 A2-incompatible kidney transplants at our institution if pre transplant anti-A2 titers were equal or less than 1/16. All patients received anti-thymocyte globulin induction. Patients with donor-specific anti-HLA-antibodies (DSA) received intravenous immunoglobulins.

Results: Of the 41 recipients, 85% were male, 48% African-American, with a median age of 53 (20-73) years. There were 38 deceased donor renal transplants and 3 living related. Median donor age was 42 (16-65) and median KDPI was 52 (2-86). Twenty-one patients had PRA 0% and 8 had pre transplant DSA. Pretransplant anti-A2 titers were 1/2 in 16, 1/4 in 9, 1/8 in 6, and 1/16 in 5 and too weak to titer in 5 recipients. During a median follow-up of 33 months (6-57) patient and graft survival were 100% and 90.2% respectively. Twelve patients underwent a clinically indicated kidney biopsy at a median 28 days post transplant (6-190). There was one case of acute T cell mediated rejection type IIA, and one chronic antibody-mediated rejection which was due to non-compliance leading to graft loss. Interestingly C4d positivity was seen in 9 biopsies, of which 8 did not have any findings of antibody mediated rejection and no microvascular inflammation. Median serum creatinine level at last follow up was 1.3 mg/dL (0.6-3.2) and only 3 patients had spot urine protein/creatinine more than 1 g/day.

Conclusions: A2-incompatible transplantation appears to be safe in patients with anti-A2 titers equal or less than 1/16 with or without DSAs and excellent short-term kidney allograft outcomes. C4d positivity is frequent in allograft biopsies without acute rejection suggesting accommodation to the allograft.

PO2590

Post-Transplant Outcomes for Highly Sensitized Kidney Transplant Recipients with Non-Highly Sensitized Recipients in the Era of the New Kidney Allocation System: A Single-Center Case-Control Comparison

Gaurav Agarwal,1,2 Darnell Mompoint-Williams,1,2 Song C. Ong,1,2 Jayne E. Locke,1,2 Vinenca Kumar,1 University of Alabama at Birmingham 1The University of Alabama at Birmingham, Birmingham, AL; 2The University of Alabama at Birmingham Comprehensive Transplant Institute, Birmingham, AL.

Background: The new UNOS kidney allocation system (KAS) of December 2014, gives substantial priority points to highly sensitized (HS) adult kidney transplant recipients (KTR) with cPRA of 99% or higher. There is a concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the post KAS era are unknown.

Methods: We studied outcomes in HS adult kidney transplant recipients (KTR) and compared them to non-HS KTR in the post KAS era. We included all recipients of deceased donor kidney transplant at the University of Alabama at Birmingham, from December 2014 to March 2020. HS patients were defined as those with cPRA 99% or higher. The HS patients were matched 1:2 with non-HS patients on age, sex, and time of transplant. A Kaplan Meier analysis was performed for patient survival and the combined endpoint of graft and patient survival.

Results: Total of 717 deceased donor kidney transplants were performed during the study period, of which 106 HS KTR were identified. There is a concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the post KAS era are unknown.

PO2591
Who Is at Risk for a Transplant Nephrectomy After Graft Loss?
Peter E. Thorne, Evely Rams, Laura Binari, Gunset C. Kochar, Thomas G. Stewart, Rachel C. Forbes, Saed Shawar, Anthony J. Langone, Khaled Abdel-Kader, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

Background: Patients with failed kidney transplants who subsequently develop clinical symptoms such as fever, allograft pain and gross hematuria usually require a transplant nephrectomy to alleviate symptoms. Identifying patients at risk for a nephrectomy after graft loss may aid clinical decision-making and care at time of, and after graft loss.

Methods: We retrospectively reviewed all patients with death-censored graft loss (DGCL) from 1/2000 to 6/2018 at a single center. We collected baseline demographic and clinical characteristics at time of transplant, at time of, and after DGCL by manual chart abstraction. Data were analyzed using summary statistics. Predictors for nephrectomy were determined a priori. A Cox proportional hazards model was used to quantify the association of age, race, gender, body mass index (BMI) at time of graft loss, diabetes, acute rejection as cause of graft loss, and use of prednisone with the risk of nephrectomy.

Results: The study included 333 patients with DGCL of whom 75 (23%) underwent a transplant nephrectomy. Median (IQR) time from graft loss to nephrectomy was 135 (70, 267) days. Among 292 patients without missing data, baseline and transplant characteristics were as follows: age at transplantation 45 (36, 57), 59% male, 40% black, 20% diabetic, 53% with a deceased donor, 86% on CNI-IS, 71% on prednisone. Twenty four percent and 69% of patients lost their graft due to acute rejection and chronic allograft nephropathy, respectively. At the time of DGCL, BMI was 25.9 kg/m² (22.7, 31.4), SCr 7.5 mg/dl (5.6, 9.6), albumin 3.3 (3.0, 3.8), 86% on CNI-IS, 91% on prednisone. In the Cox model, black race was associated with more than twice greater risk of nephrectomy compared to non-blacks (HR 2.4, 95% CI 1.3-4.3, p=0.01). Older age had a trend for decreased risk of nephrectomy (HR 0.98, 95% CI 0.95-1.0, p=0.06) but this did not reach statistical significance.

Conclusions: Transplant nephrectomies are common after graft loss and black race is associated with increased risk. Closer monitoring of these patients after graft loss may be warranted. Strategies and interventions to reduce the need for nephrectomy warrant further study.

PO2592
Contraceptive Use Among Women with Kidney Transplants in the United States
Silvi Shah, Kathleen Harrison, Annette Christianson. University of Cincinnati, Cincinnati, OH.

Background: Kidney transplant improves reproductive function in women with end-stage kidney disease (ESKD). Little is known about contraceptive use in women with history of kidney transplants.

Methods: Using the United States Renal Data System (2005-2014), we evaluated for each calendar year women with kidney transplantation who were aged 15-44 years with Medicare as the primary payer and linked data from the United Network for Organ Sharing, for up to three years after the date of transplantation. We determined rates of contraceptive use and used multivariable logistic regression to identify factors associated with contraceptive use.

Results: The study cohort included 13,150 women and represented 26,624 person-years (PY). The rate of contraceptive use in women with kidney transplant was 9.5% of person-years. Figure 1 shows the rates of types of contraceptive use from 2005-2013. Compared to women aged 15–24 years, contraceptive use was lower in women aged 30–34 years (OR, 0.67; CI, 0.58-0.77), 35–39 years (OR, 0.36; CI, 0.31-0.43), and 40–44 years (OR, 0.23; CI, 0.19-0.28). Compared to white women, contraceptive use was higher in black women (OR, 1.26; CI, 1.10-1.43) and Native American women (OR, 1.52; CI, 1.02-2.26). Women had lower rates of contraceptive use in the second-year post-transplant (OR, 0.87; CI 0.79-0.94) and third-year post-transplant (OR, 0.69; CI 0.62-0.76) than in the first-year post-transplant. Women with a history of diabetes had a lower likelihood of contraceptive use (OR, 0.80; CI, 0.65-0.99).

Conclusions: Among women with kidney transplants, contraceptive use remains low at 9.5%. Factors associated with a higher likelihood of contraceptive use include younger age and black and Native American race/ethnicity; second- and third-year post-transplant and history of diabetes are associated with a lower likelihood of contraceptive use. The study highlights the importance of counseling for contraceptive use in women with kidney transplants.

Reproductive Health in Kidney Transplant Recipients

Andrea G. Kattah, Fernando G. Cosio, Vesna D. Garovic. Mayo Clinic Minnesota, Rochester, MN.

Background: Women with advanced chronic kidney disease develop menstrual irregularities and infertility that can improve after kidney transplant. However, some women do not have menstrual cycles return after transplant and pregnancy rates are lower than in the general population, which could be due to a combination of biologic and social factors.

Methods: We sent a survey on reproductive health to all women aged 18 to 44 at the time of transplant at all 3 Mayo Clinic sites between 1996 and 2014. We sent a second survey to all non-respondents from the first mailing and then called all remaining women to ask for their participation. We included questions on menstrual cycles, pregnancy, and menopause. Parity at the time of transplant was determined by chart review.

Results: There were 816 unique women, aged 18 to 44 at the time of transplant, in the period from 1996 to 2014. After excluding women who had passed away (n=10), there were 715 eligible women and 190 responded (26.6% response rate). Respondents were more likely to be white and to have had a pregnancy post-transplant. Only 10% of women reported a pregnancy post-transplant, though 14.2% reported actively pursuing pregnancy pre-transplant. Nearly half (42.1%) of women said they were advised not to get pregnant, most often by a nephrologist. There were 61 pregnancies post-transplant, of which 80.1% were planned pregnancies. The majority of pregnancies resulted in livebirths (57%), and miscarriage occurred in 39% of pregnancies. Anemia occurred in 34.2% of women pre-transplant, and 23% of these women did not have cycles return after transplant. The median (interquartile range) age of menopause was 44.5 (36-49) years.

Conclusions: While only 14.2% of respondents reported actively pursuing pregnancy post-transplant, nearly half said they were advised not to pursue pregnancy, often by their nephrologists, which could in part explain low pregnancy rates in the kidney transplant population. While anemia prior to transplant occurred in the minority of women, 23% of these women did not have menstrual cycles return post-transplant. Furthermore, the median age of menopause was much earlier than the general population. These findings suggest that kidney disease and/or transplantation itself may impact long-term gonadal function, which should be a target of future study.

Buffy Coat Methylation Is Representative of Methylation Patterns in White Blood Cell Types in Normal Pregnancy

Rabinie Ghannawi,1 Natasa Milic,2 Sonja Suvakov,1 Wendy White,1 Vesna D. Garovic.1 Mayo Clinic Minnesota, Rochester, MN; 2Medicinski fakultet Univerzitet u Beogradu, Belgrad, Serbia.

Background: Epigenetic changes through DNA methylation are increasingly identified in renal diseases and hypertensive disorders. Our previous studies identified an altered methylation pattern in preeclampsia compared to normotensive pregnancies. Epigenetic studies typically use buffy coat- a heterogeneous cell population- that varies throughout pregnancy and could potentially interfere with DNA methylation results. The objective of the current study was to assess to what extent the buffy coat methylation is representative of the distinct cell types that it contains namely polymorphonuclear leukocytes(PMN) and lymphocytes(LYM) in normotensive pregnant women.

Methods: We performed a pairwise comparison of the differential methylation in the buffy coat, the polymorphonuclear fraction and the lymphocytic fraction drawn from the same individual in normotensive pregnant women (n=29) within the 24 hours prior to delivery. We analyzed 412481 cytosine-guanine (CpG) sites using an Illumina Human Methylation450 BeadChip.

Results: The three pairwise comparisons yielded a small number of probes that are differentially methylated. After multiple testing corrections, the smallest number of differentially methylated probes was found when comparing the buffy coat to the polymorphonuclear group (2.96%). Pathway analysis of the differentially methylated probes identified a matched process involved in leukocyte lineage. The differentially methylated CpG sites preferentially affected the open sea and shelf regions that have little effect on epigenetic regulation.

Conclusions: The buffy coat DNA methylation profile is representative of the PMN and LYM fractions on an Illumina Human Methylation450 BeadChip. The use of buffy coat is an acceptable approach for DNA sampling in DNA methylation studies and separation is only needed when studying lineage specific diseases.

Menstrual Irregularities and Subfertility in Women with Glomerular Disease

Background: Women with CKD are known to have high rates of irregular menses and subfertility (an extended period of unwarranted non-conception). Those with glomerular disease may be at particularly high risk due to exposure to immunosuppression, such as cyclophosphamide, that may lower fertility.

Methods: A women’s health survey was distributed to women ages 18-65 in the Glomerular Disease Collaborative Network, a longitudinal research registry in the southeastern United States. Descriptive statistics were employed to assess responses.

Results: The survey was completed by 192 women (response rate 16%) with stated median age of 45 (IQR 40-52) years. Cyclophosphamide use was reported by 70% (135/192) of women. 80% (154/192) had a history of transplantation, and 23% of these women did not have cycles return after transplant. The median (interquartile range) age of menopause was 44.5 (36-49) years.

Conclusions: While only 14.2% of respondents reported actively pursuing pregnancy post-transplant, nearly half said they were advised not to pursue pregnancy, often by their nephrologists, which could in part explain low pregnancy rates in the kidney transplant population. Furthermore, the median age of menopause was much earlier than the general population. These findings suggest that kidney disease and/or transplantation itself may impact long-term gonadal function, which should be a target of future study.

Pregnancy Outcomes in Women with AKI

Silvi Shah, Kathleen Harrison, Annette Christianson. University of Cincinnati, Cincinnati, OH.

Background: Acute kidney injury (AKI) during pregnancy is a public health problem and is associated with maternal and fetal morbidity and mortality. Literature concerning pregnancy outcomes in women with AKI is scarce.

Methods: We evaluated a retrospective single-center cohort of all women who delivered infants between 2012-2019 at our center (N=21,038) to assess the AKI rate and whether the history of AKI during pregnancy was associated with adverse maternal and fetal outcomes. Using multivariate logistic regression models, we determined factors associated with AKI and pregnancy outcomes.

Results: Overall, 109 deliveries were identified with AKI during pregnancy. AKI rate was 0.5%. The mean age of women was 28 years, 55% were black, and 36% were white. 25% had a history of diabetes and 24% had a history of hypertension. With regards to maternal outcomes, 46% had preeclampsia, 27% had gestational diabetes, 40% had gestational hypertension, and 57% had cesarean section deliveries. Maternal mortality was 4%. With regards to fetal outcomes, among women with AKI during pregnancy, 19% had preterm deliveries, the live birth rate was 85%, the stillbirth rate was 5%, and neonatal mortality was 5%. Diabetes and hypertension were associated with a higher adjusted likelihood of AKI during pregnancy (OR, 4.5; 95% CI, 2.87-7.50 and OR, 5.97; 95% CI, 3.63-9.80 respectively). In the adjusted model, AKI during pregnancy was associated with a 5.6-fold higher likelihood of preeclampsia (OR, 5.57; 95% CI, 3.70-8.39), 2.2-fold higher likelihood of cesarean section delivery (OR, 2.21; 95% CI, 1.50-3.27), and 2-fold higher...

Pregnancy Following Kidney Transplantation: Experience of a Tertiary Renal Obstetric Service Between 1996 and 2020

Sarah Gleeson,1 Michelle Willicombe,1,2 Seva Hassan,1 Daniel Christiadi,1 Philip Webster,1,2 Liz Lightstone,1,2 Imperial NHS Healthcare Trust, London, United Kingdom; Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Compared with dialysis, fertility & pregnancy outcomes are more favourable following transplantation. However, pregnancies post kidney transplant are associated with a higher risk of adverse maternal & obstetric outcomes.

Methods: All transplanted patients attending the renal-obstetric clinic were identified from an in-house database. Further data were collected from their health records.

Results: We identified 52 pregnancies in 39 women. The mean age at delivery was 33±3 years. 57% were white, 17% black & 21% Asian. The cause of ESKD was glomerulonephritis (46%), reflux(17%), unknown/other(27%) & diabetes(10%). 3 patients (5%) miscarried & are not included in further analysis. The mean time from transplantation to pregnancy was 84±56 months. The mean duration of pregnancy was 39±2.5 weeks. Of the 52 pregnancies it was was 48 & 52.9 m/dL. 1 graft was lost during pregnancy (pre-eclampsia eGFR 25, PCR 150); None were lost in the year postpartum. 5 women(12%) have subsequently lost their graft(mean of 4 years postpartum). 1 woman was provisionally treated for rejection during pregnancy; 2 were treated for rejection within 1 month post-partum. 6 others(14%) had a rejection episode - mean time of 38.6±4.2 months post-partum. There were no maternal deaths. 3/19 women checked for Donor Specific Antibodies(DSA) postpartum had a DSA-1 present pre pregnancy & 2 de novo. The mean gestational age was 35±1.3 weeks. 26% were born <33% pre-term & 5 <34 weeks). 18 women(37%) developed preeclampsia. There was one intrauterine death. 66% delivered by caesarean section.

The mean birth weight was 2400±588 grams; 24% were ≤10 percentile.

Conclusions: Pregnancy outcomes in patients with transplants are better compared with those on dialysis(PMID. 27083278). However, complications still occur. The rate of preeclampsia(56%) is representative of the current literature & much higher than for women without transplants. Diagnosing preeclampsia in patients with pre-existing hypertension & proteinuria, as for many of our patients, remains challenging. In our experience, reflected here, there are relatively low rates of rejection & graft loss but high rates of obstetric complications. We believe these patients are ideally managed in a joint renal obstetric clinic.

PO2599

Does Nephrologist Involvement Improve Aspirin Prescribing in Pregnant Women with CKD?

Christin M. Giordano McAluliff,1 Shelby A. Crants,1 Lynsa Nguyen,1 Lisa Zuckerverse,1 Anna M. Burgner,1 Vanderbilt University Medical Center, Nashville, TN; Vanderbilt University School of Medicine, Nashville, TN.

Background: Since 2014, the U.S. Preventative Services Task Force has recommended the use of aspirin beginning at 12 weeks gestation in women at high risk for development of preeclampsia including those with chronic kidney disease (CKD). A prior study at the authors' institution revealed overall low prescribing rates for women with CKD with only 50.5% taking aspirin according to the recommended guidelines.

Methods: The authors reviewed data from pregnancies with delivery between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for pregnancies and then included patients who had diagnostic codes for chronic kidney disease (including solitary kidney); 2.the majority of patients with PE, are healthy before pregnancy and return to well-being after delivery; 3.the familial recurrence of PE and the increased PE recurrence risk in subsequent pregnancies; 4.the increased risk in PE patients with a history of hypertension and CKD later in life; 5.the association between intrauterine poor environment, reduced nephron mass and risk of hypertension and CKD.

Conclusions: In this study, we observed slightly improved placental perfusion and lower fetal demise following prepartum BD treatment; however, the anti hypertensive effects of BD were not sustained through late pregnancy when supplementation was stopped at mid-pregnancy. No improvements in renal function were noted.

PO2600

Low Renin Endorphin and Pregnancy-Related Renal Maladaptation in the Pathogenesis of Preeclampsia

Silvia Oddo,1 Alessandro Forni,2 Giulia Genzone,2 Eugenio Ragazzi,2 Valentina Capone,1 Erich Cosmi,2 Gianluigi Ardissino,1 Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milano, Italy; 1Dept. of Women's and Child's Health, Obstetrical and Gynecological Clinic, University of Padova, Padova, Italy; 2Dept. of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, Italy.

Background: Pre-eclampsia (PE), whose pathogenesis is still unclear, complicates 2%-8% of pregnancies and is responsible of significant maternal and/or perinatal morbidity and mortality. Given the following facts: 1) the incidence of PE is significantly higher in women with chronic renal diseases and hypertension (including solitary kidney); 2) the majority of patients with PE, are healthy before pregnancy and return to well-being after delivery; 3) the familial recurrence of PE and the increased PE recurrence risk in subsequent pregnancies; 4) the increased risk in PE patients with a history of hypertension and CKD later in life; 5) the association between intrauterine poor environment, reduced nephron mass and risk of hypertension and CKD.

Conclusions: In conclusion, we observed slightly improved placental perfusion and lower fetal demise following prepartum BD treatment; however, the anti hypertensive effects of BD were not sustained through late pregnancy when supplementation was stopped at mid-pregnancy. No improvements in renal function were noted.

PO2601

Hypotenremia in Preeclampsia: A Diagnostic and Therapeutic Challenge

Nay Seif, Anand Srivastava. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: A 32-year-old female at 35-weeks gestation with twin pregnancy was admitted for hypertension, proteinuria, and hyponatremia (Figure 1A).

Case Description: She complained of nausea, bilateral vision loss, and pain. Physical exam revealed 3+ generalized edema. Her blood pressure improved with conservative management, and medications controlled her nausea and pain. Figure 1B shows her hospital serum sodium trend. The physical exam, serum and urine studies suggested

Conclusions: Hypotension complicated by hypertension and preeclampsia is rare and may be a sign of severe preeclampsia. This case demonstrates the importance of early recognition and prompt treatment.
hypoventilatory hyponatremia due to nephrotic syndrome. She was placed on fluid restriction. Repeat serum sodium and urine protein to creatinine ratio (UPCR) were 118 mEq/L and 4.4 g/g creatinine, respectively. Her obstetrician decided to perform emergency delivery. Prior to oxytocin induction, she received 3% saline, 0.9% saline, and IV furosemide. Three hours after delivery, serum sodium was 125 mEq/L and UPCR was 0.2 g/g creatinine. Fluid restriction continued for the first 24 hours after delivery and her serum sodium remained stable. Over the next 24 hours, her serum sodium corrected to 138 mEq/L with liberalization of the fluid restriction

Discussion: Hyponatremia in pregnancy may be due to antidiuretic hormone (ADH)-dependent factors, such as “reset” osmostat, diffuse vasodilatation, nausea, and pain. Administration of oxytocin, which is structurally similar to ADH, can also reduce serum sodium. In preeclampsia, hyponatremia may occur due to decreased effective circulating volume secondary to antiangiogenic factors or nephrotic syndrome, non-osmotic release of ADH with consequent water retention, or SIAH. Worsening hypertension with end organ damage are severe features of preeclampsia often requiring emergent delivery, but severe hyponatremia is often overlooked as a severe feature. This case illustrates that patients with preeclampsia may develop severe hyponatremia, which improves after delivery. Refined guidelines should consider severe hyponatremia and its management in preeclampsia.

PO2603

Proteinuria in Early Pregnancy: Role of sFLT-1:PlGF Ratio

Nay Seif, Carla L. Ellis, Shikha Wadhwani. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: A 32-year-old nulliparous woman at 20 2/7 weeks gestation by in vitro fertilization was admitted for hypertension (HTN), proteinuria, and acute kidney injury.

Case Description: She reported no home medications other than prenatal vitamins. Exam was notable only for trace leg edema. Given nephrotic syndrome early in pregnancy and unremarkable hemolysis work-up (Figure 1A), there was concern for acute glomerulonephritis (GN). Renal biopsy showed signs of thrombotic microangiopathy (TMA) (Figure 1B) without evidence of immune-complex mediated GN. As Atypical hemolytic uremic syndrome (aHUS) and Preeclampsia (PEC) were both on the differential, serum was tested for sFLT-1 and PlGF. Based on emerging evidence of alternative complement pathway activation in PEC, Eculizumab use was discussed but there was no indication in this patient. At 22 weeks gestation, serum was tested for sFLT-1 and PlGF ratio >3 and >2 folds of ULN respectively whereas serum lipase (921 U/L) and Amylase (492 U/L) were raised >3 and >2 folds of ULN respectively. As serum lipase >3 times of the ULN range 64%-100% and 99%-100% respectively. More than 3-folds rise of serum lipase above the ULN can also be seen in a variety of other conditions including acute renal failure. Even in 15% cases of HG with normal renal function, serum Lipase can rise by 5-folds. Therefore, clinical and biochemical co-relation is necessary to rule out acute pancreatitis in pregnancy.

PO2604

Hyperelemesis Gravidarum-Induced Acute Tubular Necrosis: A Case with More Than Fivefold Rise in Serum Lipase Level Above the Upper Limit of Normal

Samira Z. Chandra,1,3 Bruna Taveras Garcia,2 Belinda Jim,2 ‘Bangladesh College of Physicians and Surgeons, Dhaka, Bangladesh; ‘Jacobi Medical Center, Bronx, NY; ‘Dhaka Medical College and Hospital, Dhaka, Bangladesh.

Introduction: Hyperelemesis gravidarum (HG) occurs in 0.3 to 10 percent of pregnancies with only 0.8 percent requiring hospitalization. HG usually starts within 4th to 6th week of gestation, peaks around 9th week and fades away between 16th to 20th gestational weeks. In some cases, HG may last until the third trimester. Here we are reporting such a case which was associated with serious complication like acute renal failure. Co-incidently the patient was also found to have serum lipase level 5 times above the upper limit of normal (ULN). Since HG exerts multisystemic manifestations, the unusual pattern of raised serum lipase is often due to associated renal impairment.

Case Description: A 25-year old primigravida at 16th week of gestation was admitted for severe dehydration and acute kidney injury (S. Creatinine 5.1 mg/dL). She was suffering from HG since the beginning of her pregnancy. A month prior to this admission, the patient was hospitalized on multiple occasions for extreme nausea and blood-tinted vomiting. Her initial labs were suggestive of high anion gap metabolic acidosis (anion gap 31.9mmol/L). Urine electrolytes (Na+<20mEq/day, K+<29mEq/day, Cl - <20mEq/day) with FeNa+>31 mmol/L and UPCR = 118 mEq/L and 4.4 g/g creatinine. Repeat serum sodium and urine protein creatinine ratio (UPCR) were 118 mEq/L and 4.4 g/g creatinine, respectively. Her obstetrician decided to perform emergency delivery. Prior to oxytocin induction, she received 3% saline, 0.9% saline, and IV furosemide. Three hours after delivery, serum sodium was 125 mEq/L and UPCR was 0.2 g/g creatinine. Fluid restriction continued for the first 24 hours after delivery and her serum sodium remained stable. Over the next 24 hours, her serum sodium corrected to 138 mEq/L with liberalization of the fluid restriction.

Discussion: Patients presenting with nephrotic syndrome and hypertension ≥ 20 weeks gestation pose a diagnostic dilemma. Renal biopsy is necessary to distinguish PEC from GN but pathological diagnosis of TMA can lead to persistent diagnostic uncertainty. Measurement of circulating angiogenic factors can be useful, with sFLT-1:PlGF ratio >38 supporting a diagnosis of PEC. Further validation and widespread availability of such testing is needed to assist in management of early pregnancy complications.
PO2605
Outcomes of Delivery Hospitalizations Among Pregnant Women with Kidney Transplant in the United States

Api Chewcharat,1,2 Andrea G. Kattah,1 Charat Thongprayoon,1 Wisit Cheungpasitporn,2 Bonniphop Boonpheng,4 Maria Lourdes Gonzalez Suarez,1 Jasmina Craici,1 Vesna D. Garovic,1 1Mayo Clinic Minnesota, Rochester, MN; 2Mount Auburn Hospital, Cambridge, MA; 3University of Mississippi Medical Center, Jackson, MS; 4University of California Los Angeles, Los Angeles, CA

Background: Outcomes of delivery hospitalizations, including acute kidney injury, obstetric and fetal events among pregnant women with kidney transplants (KT) compared to those with no known kidney disease and chronic kidney disease (CKD) stage 3-5 are unclear.

Methods: Hospitalizations for delivery were identified using the enhanced delivery identification method in the National Inpatient Sample dataset from the years 2009 to 2014. Diagnoses of CKD stage 3-5, KT along with obstetric events, delivery methods, and fetal events were identified using ICD-9-CM diagnosis and procedure codes. Logistic regression accounting for the survey weights and matched regression were conducted to investigate the risk of maternal and fetal complications in women with KT as compared to women with no kidney-related diagnosis and compared to women with CKD stage 3-5.

Results: A total of 5,408,215 hospitalizations resulting in delivery were identified, including 405 women with CKD stage 3-5, 295 women with functioning KT, and 5,405,499 women with no kidney diagnosis. Pregnant KT recipients were at higher odds of pregnancy-induced hypertension (OR = 3.11, 95%CI [2.26, 4.28]), preeclampsia/eclampsia/HELLP syndrome (OR = 3.42, 95%CI [2.54, 4.60]), preterm delivery (OR = 2.46, 95%CI [1.75, 3.45]), fetal growth restriction (OR = 1.74, 95%CI [1.01, 3.00]), and acute kidney injury (OR = 10.46, 95%CI [5.33, 20.56]) as compared to women with no kidney-related diagnosis. There were no significant differences in rates of gestational diabetes and cesarean section. Pregnant women with KT had 1.30-time longer length of stay and 1.28-time higher cost of hospitalization. However, pregnant women with CKD stage 3-5 were at higher odds of AKI, preeclampsia/eclampsia/HELLP syndrome and fetal death, and had longer hospital stay and cost of hospitalization compared to pregnant women with KT.

Conclusions: Pregnant women with KT were more likely to experience adverse events during delivery when compared to women with no known kidney disease. However, pregnant women with advanced CKD were more likely to experience serious complications than KT recipients. Women with advanced CKD who wish to conceive might consider conception after transplantation for better pregnancy-related outcomes.

PO2606
Successful Pregnancy in a Patient with Congenital Renal Dysplasia After Initiation of Dialysis

Jennifer C. Tang,1,2 Annika K. Khine,1,2 University of Southern California Keck School of Medicine, Los Angeles, CA; 2Los Angeles County University of Southern California Medical Center, Los Angeles, CA

Introduction: Chronic kidney disease (CKD) is a well-known risk factor for adverse maternal and fetal outcomes including preeclampsia and fetal growth restriction. For those on dialysis, increasing the frequency and duration of dialysis has shown to optimize outcomes. However, it remains unclear if and when pregnant patients with CKD should start dialysis to improve outcomes. We present a patient with congenital renal dysplasia who successfully gave birth after starting dialysis.

Case Description: A forty-one-year-old female with an intrauterine pregnancy of 25 weeks and a history of two miscarriages, preeclampsia, and congenital renal dysplasia presented to nephrology clinic. Patient was unaware of her kidney dysfunction and had residual renal function with a creatinine of 3.76 and urine pr/cr ratio of 1.18. A fetal ultrasound revealed a fetal weight in the 24th percentile, head circumference in the 2nd percentile, and biparietal diameter (BPD) in the 33rd percentile. Therefore, the patient started daily dialysis with longer sessions to optimize fetal outcomes. A repeat ultrasound two weeks later revealed interval growth with a fetal weight in the 24th percentile and BPD in the 45th percentile but with abnormal umbilical artery Doppler findings, an absent end-diastolic flow, and a high velocity in the umbilical artery. The patient returned to the hospital with hypoxic respiratory failure due to parainfluenza virus infection. Further serologic investigation revealed elevated anti-GBM antibodies. A kidney biopsy was performed which demonstrated 100% cellular crescents on light microscopy and negative for mesangial deposition. Further immunofluorescence confirmed the diagnosis. In addition to daily hemodialysis, the patient underwent plasmapheresis and immunosuppression with pulse dose steroids followed by a steroid taper as well as azathioprine and tacrolimus. The patient remained inpatient receiving daily hemodialysis until 28 weeks 0 days when the patient developed uncontrollable hypertension requiring an emergent cesarean section. The patient gave birth to a live male weighing 1.1 kg. Her post-partum course was uncomplicated, though the patient remains dialysis dependent.

Discussion: The treatment of choice in anti-GBM disease is plasmapheresis to remove circulating antibodies and immunosuppression to reduce antibody production. However, pregnancy presents a unique challenge in choosing immunosuppressive agents as both maternal and fetal effects need to be considered. The involvement of high risk obstetricians as well as nephrologists in the care of these patients is imperative to ensure the best possible outcomes.

Identification of Renal Disease in Women with Hypertensive Pregnancies
Hayley Martin,1 Henry A. Kibble,2 Kieran R. Palmer,3 Emmanouil Koutroutsour,1 Amanda M. Holloway,1 Kate Bramham,1,2 Katherine R. Clark.2,1 King’s College Hospital NHS Foundation Trust, London, United Kingdom; 2 King’s College London School of Life Course Sciences, London, United Kingdom.

Background: Hypertension in pregnancy can be associated with renal injury, which may be masked by gestational change. Additionally, pregnancy affords an opportunity to diagnose asymptomatic renal disease. Postpartum assessment enables detection of ongoing renal abnormalities. We aimed to determine prevalence of renal disease in postpartum women with chronic hypertension, pregnancy induced hypertension or pre-eclampsia in a previous or current pregnancy.

Methods: Women with singleton pregnancies seen in a specialist clinic for hypertension with estimated GFR (CKD-EPI) below 90mls/min/1.73m² and/or proteinuria at six-weeks postpartum were offered specialist renal midwifery clinic follow-up.

Results: 143/341 women offered follow-up attended renal clinic (Median 185 (IQR 246.25) days after delivery). 82 (57.3%) women had proteinuria and/or low eGFR.

Conclusions: Over half of women with proteinuria and/or reduced eGFR at six weeks postpartum had sustained evidence of renal disease regardless of hypertensive diagnosis. Postpartum assessment may afford an opportunity to detect renal disease.

PO2610
Sexenenes Markers in Women with Preeclampsia Pregnancies
Sonja Suyakovic,1 Ranine Ghamrawi,1 Hai-tao Tu,2 Wendy White,2 Natasa Milic,1 Joseph P. Grande,3 Vesna D. Garovic.1 Mayo Clinic Minnesota, Rochester, MN; 2 The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by increased angiogenesis and inflammation. Data indicate that preeclampsia is mechanistically related to cellular senescence, an irreversible cell-arrest mechanism which has been increasingly associated with accelerated aging. The aim of this study was to determine if senescence plays a role in the pathophysiology of preeclampsia. To that end, we compared SASP components in blood and fat tissue sections between preeclamptic and normotensive pregnancies, as well as p21 and p16 expression in the fat and kidney tissue samples.

Methods: Blood samples from preeclamptic and normotensive patients at the time of delivery were used to study circulating senescence-associated secretory phenotype (SASP) components. Plasma SASP components were tested using Luminex 200 system. Fat tissue explants (3-5 g) were obtained during the surgery from pregnant women who were clinically indicated for C-section. Kidney sections originated from the autopsy material of patients who died from preeclampsia. Upon protein isolation from fat tissue, SASP components were measured. Fat and kidney tissue sections were immunostained for p16 and p21. Preeclamptic and normotensive participants were matched for age and BMI.

Results: Significant increase of senescence markers were found in blood of preeclamptic pregnancies for NGF (1.30±0.82 vs. 0.77±0.19, p=0.032), MCP1 (316.95±163.95 vs. 207.53±84.78, p=0.047), TNFa (2.79±1.08 vs. 2.06±0.64, p=0.043) and Pai1 (58.03±18.85 vs. 38.12±20.86, p=0.023). Similarly, significant increase in senescence markers was found in preeclamptic pregnancies for MCP1 and TNFa. Expression of p16 was significantly increased in fat tissue, whereas the difference in p21 expression between preeclamptic and normotensive patients was not observed. Expression of p16 in preeclamptic renal sections was significantly higher (p=0.02) than in sections from normotensive pregnancies. The p21 expression did not differ between preeclamptic and normotensive kidney sections.

Conclusions: Women with preeclampsia have higher senescent burden compared to normotensive pregnant women at the time of delivery. Senolytic agents that target senescence may offer the opportunity for mechanism-based therapies.

Effects of Veverimer on Serum Bicarbonate and Physical Function in Women with CKD: A Subgroup Analysis from a Randomized Controlled Trial
Vandana S. Mathur,1 Donald E. Wesson,2 Navdeep Taniguchi,3 Yuri Stavov,4 Dawn Parsell,5 Elizabeth Li,6 Gerrit Klarenbeek,7 David A. Bushinsky,8 Mathur Consulting, Woodside, CA; 4Baylor Scott & White Health and Wellness Center, Dallas, TX; 1University of Manitoba, Winnipeg, MB, Canada; 2Tricida, Inc., South San Francisco, CA; 3PharmaStat LLC, Fremont, CA; 4University of Rochester Medical Center, Rochester, NY.

Background: More women than men have CKD. However, women have been underrepresented in clinical trials. Veverimer is an orally administered, non-absorbed polymer that treats metabolic acidosis by binding and removing HCl from the GI tract. In Phase 3 randomized, double-blind, placebo-controlled trials, veverimer significantly increased serum bicarbonate and improved physical function in acidotic patients with CKD (Wesson et al. Lancet, 2019). Here we analyzed efficacy and safety among the women in these studies of up to one year.

Methods: Physical function was assessed using the Kidney Disease and Quality of Life Physical Function Domain (KDQOL-PFD) which quantifies limitations on daily activities and by performance on the repeated chair stand (RCS) test.

Results: Of the 217 pts randomized, 83 (32%) were women, of whom 81% were post-menopausal (≥55 yrs). Select comorbidities included hypertension (95%), diabetes (64%), and congestive heart failure (30%). At Baseline, mean eGFR in women was 28.4 mL/min/1.73m² and mean serum bicarbonate was 17.3 mg/E. More women receiving veverimer met the primary study endpoint, had a significant increase in serum bicarbonate and improved both KDQOL-PFD scores and RCS time (Table) compared with placebo. The effects of veverimer exceeded the minimal clinically important difference for both KDQOL-PFD (+3 to +5 points) and RCS (-1.7 seconds). Rates of serious, non-serious and GI adverse events were similar in the groups; none required treatment discontinuation.

Conclusions: Given their lower bone and muscle mass, women with CKD may be particularly vulnerable to the adverse effects of metabolic acidosis. We found that in women with CKD and metabolic acidosis, treatment with veverimer significantly improved how women felt and functioned. The safety of veverimer was similar to placebo.

Dietary Magnesium Intake, Risk of Kidney Stone, and Survival in the Women's Health Initiative (WHI)
Harshitha Kota,1 Xuering Wen,2 Chao Chen,2 Jie Tang,3 1Brown University, Providence, RI; 2University of Rhode Island, Kingston, RI; 3University of Florida, Gainesville, FL; 4Brown Urology Brown Physicians Inc, Providence, RI.

Background: The effect of dietary magnesium intake (DMI) on the risk of stone is controversial, and its effect on survival among kidney stone formers is unknown.

Methods: We examined participants enrolled in WHI, a prospective, longitudinal, multicenter study investigating the health of postmenopausal women, and used Cox regression analyses to determine the independent effects of DMI on the risk of incident kidney stone and survival amongst the stone formers.

Results: 145,942 participants were included free of history of kidney stone history at baseline. 83% were Caucasian, mean age was 63. Among them, 6024 (4%) developed incident kidney stone from 2.6 to 3.1 mg/dL. RPGN was suspected and kidney biopsy was performed that showed acute interstitial nephritis or pyelonephritis, due to presence of neutrophils in clumps. His AM cortisol level was 3 ug/dL (10-20). Because of hypotention, polyuria and natriuresis, hydrocortisone and fludrocortisone were started. His serum K level decreased and fludrocortisone was stopped. Over next few days, he became normotensive and his hypotension improved with increasing dose of hydrocortisone. Hypokalemia slowly resolved with potassium supplements.

Conclusions: ANCA are a group of antibodies that bind to antigens of neutrophils, causing systemic vascular inflammation. These autoantibodies can be found in the serum of patients with systemic, small vessel vasculitis and is a biomarker for ANCA-associated vasculitis. A positive staining of ANCA can be classified as: Cytoplasmic, Perinuclear, and Atypical, based on the pattern of IF. In cases with C-ANCA, the staining is diffuse throughout the cytoplasm and the cause of staining is due to antibodies directed against Proteinase 3 (PR3). In cases with P-ANCA, the staining is around the nucleus and it is due to antibodies directed against myeloperoxidase (MPO). A-ANCA can be found in conditions other than vasculitis and does not require immunosuppressive steroids for treatment. A-ANCA can be reported erroneously as P-ANCA or C-ANCA and patients can receive aggressive treatment with high dose steroids. Therefore, we suggest to confirm the ANCA results with MPO or PR3 before initiating aggressive therapy for vasculitis to avoid disastrous consequences.

PUB001
Consequences of Improper Interpretation of ANCA
Aswin Srinivasan,4 Saanstra Mutnuri,4 Nina Zatikyan,1 Shabbir Safiri,2 Mahendra L. Agraharhar,1 1University of Texas Medical Branch at Galveston, Galveston, TX; 2Baylor College of Medicine, Houston, TX; 3University of Houston, Houston, TX; 4HCA Gulf Coast Division, Houston, TX; 5Montefiore Hospital and Medical Center, Montefiore Medical Center, Bronx, NY; 6Creston University, Omaha, NE.

Introduction: Antineutrophil cytoplasmic antibodies (ANCA) is important in suspected vasculitis. False positive or atypical ANCA (A-ANCA) can lead to erroneous interpretation of immunofluorescence (IF) causing disastrous consequences. We present a patient who was initially reported as Perinuclear-ANCA (P-ANCA) positive and was therefore treated with steroids, presented to the ER with dizziness, bradycardia and hypotension. He was weak, fatigued, and unarousable. In the ER, he started on vasopressors and methylprednisolone. His creatinine rose from 2.6 to 3.1 mg/dL. RPGN was suspected and kidney biopsy was performed that showed acute interstitial nephritis or pyelonephritis, due to presence of neutrophils in clumps. His AM cortisol level was 3 ug/dL (10-20). Because of hypokalemia, polyuria and natriuresis, hydrocortisone and fludrocortisone were started. His serum K level decreased and fludrocortisone was stopped. Over next few days, he became normotensive and his hypotension improved with increasing dose of hydrocortisone. Hypokalemia slowly resolved with potassium supplements.

Discussion: ANCA are a group of antibodies that bind to antigens of neutrophils, causing systemic vascular inflammation. These autoantibodies can be found in the serum of patients with systemic, small vessel vasculitis and is a biomarker for ANCA-associated vasculitis. A positive staining of ANCA can be classified as: Cytoplasmic, Perinuclear, and Atypical, based on the pattern of IF. In cases with C-ANCA, the staining is diffuse throughout the cytoplasm and the cause of staining is due to antibodies directed against Proteinase 3 (PR3). A-ANCA can be found in conditions other than vasculitis and does not require immunosuppressive steroids for treatment. A-ANCA can be reported erroneously as P-ANCA or C-ANCA and patients can receive aggressive treatment with high dose steroids. Therefore, we suggest to confirm the ANCA results with MPO or PR3 before initiating aggressive therapy for vasculitis to avoid disastrous consequences.

PUB002
Lymphoma of a Normal Kidney Size
Layth Al Attar, Taqui Khaja, Jingin Yuan, Baylor College of Medicine, Houston, TX.

Introduction: Renal injury has been reported in the setting of hematolymphoid neoplasms. The kidneys can be affected by a variety of mechanisms such as acute tubular necrosis (ATN), paraneoplastic glomerulopathy, and lymphocytic infiltration of kidney parenchyma (LKP). Diagnostic evaluation is important in differentiating mechanism of kidney injury, which will affect management and prognosis. LKP is suggested with clinical findings of bilateral kidney enlargement, acute kidney failure (AKI), or proteinuria.

Case Description: 50-year-old male with new diagnosis of high-grade lymphoma found to have severe kidney failure. Initial work up was unable to explain the underlying process of kidney failure. The patient was managed with volume replacement to alleviate the pre-renal component. Kidney ultrasound had no evidence of enlargement. Kidney function worsened over days and a decision to initiated dialysis was determined. After establishing dialysis access, kidney function demonstrated an improvement trend without dialysis initiation. Kidney biopsy revealed infiltration by atypical lymphoid cells consistent with the Double-Hit Diffuse Large B-Cell Lymphoma (DLBCL). Patient’s kidney function spontaneously recovered. Patient was discharged with plan to start chemotherapy as an outpatient.

Discussion: Our patient was diagnosed with DLBCL. This type of lymphoma accounts for approximately 25 percent of all Non-Hodgkin Lymphomas in the developed world. Clinical presentation of renal involvement includes AKI, proteinuria, or enlarged kidneys on imaging studies. Location of lymphocytic infiltration determines the extent of renal injury and whether interstitial or glomerular. Renal involvement incidence is 2% at time of diagnosis. Extramedullar renal involvement is diagnosed either by biopsy or imaging. Renal involvement can be diagnosed by imaging in 65% of patients. Cases presenting with AKI of interstitial type of lymphomatous infiltration show bilaterally enlarged kidneys and is a biomarker for ANCA-associated vasculitis. A positive staining of ANCA can be classified as: Cytoplasmic, Perinuclear, and Atypical, based on the pattern of IF. In cases with C-ANCA, the staining is diffuse throughout the cytoplasm and the cause of staining is due to antibodies directed against Proteinase 3 (PR3). In cases with P-ANCA, the staining is around the nucleus and it is due to antibodies directed against myeloperoxidase (MPO). A-ANCA can be found in conditions other than vasculitis and does not require immunosuppressive steroids for treatment. A-ANCA can be reported erroneously as P-ANCA or C-ANCA and patients can receive aggressive treatment with high dose steroids. Therefore, we suggest to confirm the ANCA results with MPO or PR3 before initiating aggressive therapy for vasculitis to avoid disastrous consequences.

Metabolic Encephalopathy due to AKI in a Patient with Recent Infusion of Intravenous Immunoglobulins (IVIg)
Sheikh Raza Shahzad, Kelly H. Beers. Albany Medical Center, Albany, NY.

Introduction: IVIg induced AKI is extremely rare (1% of cases). We present a case of AKI requiring hemodialysis secondary to recent IVIg administration.

Case Description: A 61-year-old woman presented with acute onset altered mental status (AMS) for 2 days. Her past medical history included CKD G3, HTN, COPD, PVD, and CAD. A week prior, she received 3 doses of sucrose-containing IVIg for chronic inflammatory demyelinating polyneuropathy. Shortly thereafter, the patient developed a facial rash, poor oral intake, low urine output, and AMS. Labs showed BUN 71 mg/dL, SCr 10.62 mg/dL, baseline Scr 2.6 mg/dL. ABG showed pH 7.07, pCO2 30 mm Hg and HCO3 8 mmol/L. Toxicology screen was negative, CPK and lactic acid were normal. No NSAIDs use was reported. She required only 1 session of hemodialysis with the recovery of renal function and mental status. AIN due to IVIg and/or IVIg induced osmolyte nephrotoxicity may be the culprit for her presentation.

Discussion: IVIg can produce adverse reactions thought to be caused by activation of the complement cascade by the aggregation of IgG. To avoid this, a variety of stabilizing agents, including sucrose, are used. Sucrose is absorbed into proximal convoluted tubular cells and is followed by water due to the changed osmotic pressure. This results in cytoplasmic vacuolization and degeneration of the proximal cells. CKD, HTN, DM, advanced age, dehydration, hyperviscosity, use of sucrose stabilizers, high dose IVIg therapy (400–2000 mg/kg), high rate of IVIg administration, or treatment with other nephrotoxic medications increase the risk of AKI. About 30% of cases require dialysis. The mortality rate is 10%. Adverse renal outcomes usually occur within 10 days of initiation of IVIg, and the duration of renal failure lasts between 3 and 45 days. Most cases resolve spontaneously. Early recovery of renal function can be achieved by dialytic removal of sucrose from the circulation. To make a diagnosis, serum creatinine must be followed for at least 6 months. An association with nephrotic syndrome may be established with the administration of IVIg. A clinical diagnosis is made after ruling out other causes and is confirmed with a renal biopsy. Measures to prevent AKI include using sucrose-free IVIg or amino-acid-stabilized formulations, adequate hydration, avoiding other nephrotoxins and diuretics, reductions in dose, concentration (<5%), and rate of administration (<3 mg sucrose/kg/min) of IVIg.

A Patient with a Record High Blood Urea Nitrogen Value Surviving Without Dialysis
Hay Me Me, Urvashi Hooda, Aditi A. Sen, Amol Mittal, Michael Connery, Westchester Medical Center, Valhalla, NY.

Introduction: The blood urea nitrogen (BUN) has limited value as an index of glomerular filtration rate to access kidney function. It can be increased not only in the setting of acute or chronic renal failure but also in hypovolemic state, gastrointestinal tract bleeding, high catabolic states, and by certain medications. Dialysis is the effective treatment for uremia. However, there is no consensus on when to initiate the dialysis for high BUN in acute kidney injury.

Case Description: A 64-year female with history of hypertension, hyperthyroidism, hyperlipidemia, alcohol use disorder, chronic kidney disease (CKD) with baseline creatinine of 1.5 mg/dL was admitted for head trauma after fall. Patient had poor intake and was only drinking coffee. Patient was not being confused by family. No history of analogistic or herbal supplements usage was present. Laboratory results were significant for BUN of 298 mg/dL, Creatinine (Cr) of 13.5 mg/dL, serum potassium of 5.4 mEq/L, phosphate of 6.1 mEq/L, and severe metabolic acidosis with serum bicarbonate of 10 mEq/L, anion gap of 33 mEq/L, lactate acid of 40 mEq/L. Creatinine kinase level was 253 U/L. Urine studies showed no proteinurina, mild hematuria, without crystals. Urine electrolytes showed sodium of 23 mEq/L and chloride of less than 20 mEq/L. Corona virus disease 2019 (COVID-19) was negative both by polymerase chain reaction and antibody test. All the sepsis work up, urine toxicology and blood alcohol level were negative. Renal ultrasound showed normal bilateral kidney sizes. Patient was aggressively resuscitated with intravenous fluid including bicarbonate and her cognitive function improved without dialysis. Her BUN eventually decreased to 30 mg/dL and Cr to 1.26 mg/dL.

Discussion: CKD patients are susceptible to infection, dehydration and develop multiple episodes of acute on chronic renal injury, subsequently resulted in end stage renal disease. Our patient was taking metoprolol, lisinopril and hydrochlorothiazide for hypertension which could also have prompted her into hypovolemic state without adequate hydration. BUN easily be confused by family. No history of analogistic or herbal supplements usage was present. Blood urea nitrogen (BUN) has limited value as an index of glomerular filtration rate to access kidney function. It can be increased not only in the setting of acute or chronic renal failure but also in hypovolemic state, gastrointestinal tract bleeding, high catabolic states, and by certain medications. Dialysis is the effective treatment for uremia. However, there is no consensus on when to initiate the dialysis for high BUN in acute kidney injury.

Cholesterol Crystal Embolism with End-Stage Renal Failure and Refractory Gastric Ulcers After Abdominal Angiography
Naoki Yamamoto, Koichi Sato, Hisayuki Ogura, Taro Miyagawa, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan.

Introduction: Parkinson’s disease is a progressive neurodegenerative disease with diverse motor and neuropsychiatric manifestations. At the urological system level, it can cause neurologic dysfunction of the bladder but to our knowledge, no dysfunction of the upper collecting system has been described so far.

Case Description: A 67-year-old Lebanese female with a PMH of Parkinson’s disease, HTN, DL, DM II, HF, CKD (1.7), Hypothyroidism, recurrent pyelonephritis and chronic kidney disease stage 3b, stage 3 obesity with a body mass index (BMI) 37.7. she presented with marked increase in blood pressure requiring addition of four new anti-hypertensive medications by discharge. She complained of anemia, severe, right lower quadrant abdominal pain. Patient denied having any recent trauma and had no urinary or gastrointestinal complaints. He was not on any antiplatelet or anticoagulation medications. CT angiogram of the abdomen and pelvis was performed which demonstrated a subcapsular hematoma around the right pelvic kidney. He had AKI with a peak creatinine of 4.2 mg/dL from a baseline of 2.2 mg/dL. He remained non-oliguric, with gradual improvement of his renal functions and never required renal replacement therapy or any intervention for Page kidney. He presented with markedly elevated blood pressure of 190/110 mmHg and his hospital course was significant for sustained elevated blood pressure requiring addition of four new anti-hypertensive medications by discharge. Subsequent imaging showed marked decrease in the subcapsular hematoma in a week.

Discussion: Page phenomenon is a rare but potentially fatal condition that can result from trauma, tumor, vasculitis, renal cyst rupture, or procedures like kidney biopsy. External compression of renal parenchyma can result in interstitial ischemia, tubulointerstitial nephritis and compression of intrarenal vessels thus activation of renin angiotensin system (RAS), resulting in AKI and hypertension associated with Page kidney. Persistently elevated blood pressure unresponsive to medical therapy or gradually enlarging hematoma with worsening renal functions might require percutaneous drainage, capsuleotomy or even nephrectomy. Optimal medical management of Page kidney includes medications targeting the RAS pathway.
Case Description: A 78-year-old male with coronary artery disease, hypertension, hyperlipidemia, diabetes mellitus, and a history of interventional pulmonary disease was diagnosed as hepatocellular carcinoma by transfemoral angiography of celiac and superior mesenteric arteries. He was admitted to the hospital for an operation of hepatocellular carcinoma. Serum creatinine level gradually increased from 1.17 to 5.87 mg/dL with eosinophilia (440/40/L) and high C-reactive protein (CRP) level (4.86 mg/dL). He started hemodialysis ten weeks after angiography and had been suffering from nausea. Endoscopy showed multiple gastric ulcers. Treatment with proton pump inhibitor started, but did not improve. Cyanosis was present in his bilateral toes and skin biopsy showed cholesterol crystal clefts. He was diagnosed with tubular basement membrane and treated with intravenous prednisolone (PSL) 20 mg/day, resulting in decrease of eosinophil, CRP levels and improvement of gastric ulcers. However, he was unable to withdraw from dialysis and developed disseminated cutaneous herpes zoster. Finally, he died of sepsis. Autopsy showed severe erosion of atheroembolic plagues at the level of celiac artery. Cholesterol clefts were present in the vessels of kidney, stomach, intestines, liver, spleen, pancreas, diaphragm, adrenal glands and testes. The distribution of cholesterol crystal embolism was consistent with the site of angiography performed from celiac and superior mesenteric arteries.

Discussion: Cholesterol crystal embolism is caused by not only percutaneous coronary interventions and endovascular surgery but also interventional transfemoral angiography. We need to consider cholesterol crystal embolism when acute kidney injury and refractory gastric ulcers after transfemoral angiography. Although PSL is administered.

Hyperkalemia in Community-Acquired AKI: Associated Factors and Clinical Consequences

Jose M. Peña Porta, Amludena Castellano, Ana Coscojuela Otto, José F. Gasco, Alfredo GómezLombardía, M. Patricia Gil, Ramón Zafra
Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain.

Background: Hyperkalemia (hyperK) frequently occurs in the context of acute kidney injury (AKI). The little about the associated factors and clinical consequences in patients with community-acquired acute kidney injury (CA-AKI). The aim of present study was to analyze it.

Methods: The present study is based on a cohort of patients with CA-AKI admitted to our Nephrology Service from January 1st to February 15th 2015. Hyperkalemia was defined as potassium levels above 5.1 meq/L.

Results: A total of 308 patients were included. The mean age was 73.22±13.9 years. 58.4% were men. Charlson comorbidity index (CCI) was 7.16±2.7 points. The mean of drugs ingested daily was 7.81±3.66 and the length of stay was 12.25±11.69 days. In view of the Etiology of AKI, 69.5% of perirenal AKI and 30.5% non-perirenal ones. 212 patients had previous chronic kidney disease (CKD) (68.8%). Hemodialysis (HD) was required in 54 patients (17.15%). 38 patients (12.3%) died during hospital stay. HyperK occurred in 173 cases (56.2%). Mean potassium was 5.45±1.41 meq/L. There was a significant correlation between potassium and pH as well as between K and CCI. There was an association between hyperK and intake of potassium-sparing diuretics (p=0.001); ACEI/ARB (p=0.003) and beta blocker (p=0.001). Using a multiple linear regression model the equation that predicted serum potassium was: K = 36.44 – (4.4 x pH) + 0.98 (if intake of potassium-sparing diuretics) + (0.10 x CCI). Potassium level did not influence the length stay. Patients with HyperK required HD in a higher proportion (23.7 vs. 9.6%; p=0.01) and also had higher mortality during hospital stay (15.6 vs. 8.1%; p=0.048). After a follow-up over 2 years, 2 patients survived. Kaplan-Meier analysis showed a significant difference (Log Rank (Mantel-Cox): p=0.001) between patients with hyperK and patients that did not present it.

Conclusion: HyperK occurred in just over half of our patients. The potassium level was significantly associated with previous comorbidity, pH and the intake of potassium-sparing diuretics. HyperK patients required HD and died in a greater proportion during hospital stay. Mortality after discharge was higher in patients who presented hyperK. Appropriate measures must be taken to correct hyperK early in patients with CA-AKI.

A Case of Anti-Tubular Basement Membrane Antibody-Associated AKI

Masaki Terao, Takatsugu Iwashita, Akira Kurosawa, Yuta Kogure, Hiroaki Hara, Taisuke Shimizu, Tomonari Ogawa, Hajime Hasagawa
Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kagawake, Japan.

Introduction: We report here a case of idiopathic anti-tubular basement membrane (TBM) antibody-related acute interstitial nephritis (AIN).

Case Description: Our patient was a 44 years man and had no history of renal disease. He was pointed out renal dysfunction of serum Cr 1.50 mg/dL in the health checkup 2 months prior to admission. The patient was admitted to our hospital because of worsening of renal function of Cr 2.89 mg/dL. Because renal dysfunction progressed (Cr 5.31 mg/dL), he was transferred to our hospital on the 2nd day after admission. Physical examination revealed mild hypertension (130/80 mmHg) and a prominent distended abdomen. Laboratory examination revealed a significant increase in creatinine (baseline 1.5 mg/dL), 2,7 points. The mean of drugs ingested daily was 7.81±3.66 and the length of stay was 12.25±11.69 days. In view of the Etiology of AKI, 69.5% of perirenal AKI and 30.5% non-perirenal ones. 212 patients had previous chronic kidney disease (CKD) (68.8%). Hemodialysis (HD) was required in 54 patients (17.15%). 38 patients (12.3%) died during hospital stay. HyperK occurred in 173 cases (56.2%). Mean potassium was 5.45±1.41 meq/L. There was a significant correlation between potassium and pH as well as between K and CCI. There was an association between hyperK and intake of potassium-sparing diuretics (p=0.001); ACEI/ARB (p=0.003) and beta blocker (p=0.001). Using a multiple linear regression model the equation that predicted serum potassium was: K = 36.44 – (4.4 x pH) + 0.98 (if intake of potassium-sparing diuretics) + (0.10 x CCI). Potassium level did not influence the length stay. Patients with HyperK required HD in a higher proportion (23.7 vs. 9.6%; p=0.01) and also had higher mortality during hospital stay (15.6 vs. 8.1%; p=0.048). After a follow-up over 2 years, 2 patients survived. Kaplan-Meier analysis showed a significant difference (Log Rank (Mantel-Cox): p=0.001) between patients with hyperK and patients that did not present it.

Conclusion: HyperK occurred in just over half of our patients. The potassium level was significantly associated with previous comorbidity, pH and the intake of potassium-sparing diuretics. HyperK patients required HD and died in a greater proportion during hospital stay. Mortality after discharge was higher in patients who presented hyperK. Appropriate measures must be taken to correct hyperK early in patients with CA-AKI.

Renal Zygomycosis: A Rare Presentation in an Immunocompetent Patient

Muhammad Nadeem, Ali Hakami, Mansoor A. Qaisar, Bushra Iqbal. King Fahd Central Hospital, Jazan, Saudi Arabia; diaverium regional dialysis centre, Hail, Saudi Arabia.

Introduction: Zygomycosis is a broad term which refers to the infections caused by fungi belonging to the order Zygomycetes. It is an azo-glucovascular opportunistic infection which can usually present in four different ways including pulmonary, gastrointestinal, renal and disseminated disease. Like other opportunistic infections it has predilection for immunocompromised patients however very rarely, it has been reported in immunocompetent patients.

Case Description: Here we report a case of an immunocompetent patient who was affected by renal zygomycosis and presented as a picture mimicking rapidly progressive glomerulonephritis (RPGN). The patient presented with hematuria, proteinuria and high creatinine and was suspected as a case of RPGN initially. CT scan abdomen showed bilaterally smooth tapered distal ends of the renal arteries with non-perfused enlarged kidneys. These findings were consistent with the diagnosis of Zygomyccosis which has angio-invasive nature. Bilateral nephrectomy was done and diagnosis was confirmed on histopathology. The role of AKI in the development of PRES is not entirely understood; however, the hypertension-hyperperfusion theory remains a leading consideration in our patient. Management decisions in our patient included forgoing dialysis, blood pressure control, and the use of anti-seizure medications.

A Triple Threat: Baclofen Toxicity and Posterior Reversible Encephalopathy Syndrome in the Setting of AKI

Daniella E. Lipinicki, Kevin C. Roe. 'Penn State College of Medicine, State College, PA; 2Mount Nittany Medical Center, State College, PA.

Introduction: This is a case of apparent baclofen toxicity and posterior reversible encephalopathy syndrome (PRES). Both conditions are seen in patients with kidney dysfunction but direct association between the two conditions has otherwise been defined. The case highlights areas of special consideration in the evaluation and management of mental status changes in patients with acute kidney injury (AKI). No other reported cases of the combined diagnoses were found on literature review.

Case Description: A 71-year-old female admitted with sepsis due to ESBL E. coli bacteremia and pyelonephritis became unresponsive on her 7th day of hospitalization. The patient had severe renal abnormal nephrologic findings prior to the episode. The patient had been given baclofen 10 mg x 2 doses for back pain within 24 hours of her acute change in mental status. She was non-verbal but opening eyes and withdrawing to pain. The initial presenting signs of infection had been improving with cefotaxime and tazobactum. Serum creatinine time was 4.2 mg/dL on admission and had improved to 2.2 mg/dL (baseline 1.5 mg/dL). AKI was attributed to prerenal physiology and sepsis-associated ATN. Mental status changes were attributed to baclofen neurotoxicity. She then developed evidence of partial complex seizures and subsequent imaging revealed findings of PRES. Levetiracetam, antihypertensives, and continued antibiotic therapy were provided. Systolic blood pressure increased to 180 mmHg with a MAP of 115 during the hospitalization. After several days, the patient recovered completely. Creatinine stabilized at 2.0 mg/dL.

Discussion: Medications are a leading cause of acute mental status changes, especially in patients with impaired kidney function. Our case highlights the risks of baclofen toxicity in improving but impaired kidney function. The clinical-radiopathologic diagnosis of PRES may have been missed without imaging. The varying presentations of this condition are a reminder the importance of an expanded differential diagnosis and the need for a better understanding of the pathology. There is no reported association between PRES and baclofen. The role of AKI in the development of PRES is not entirely understood; however, the hypertension-hyperperfusion theory remains a leading consideration in our patient. Management decisions in our patient included forgoing dialysis, blood pressure control, and the use of anti-seizure medications.
Light Chain Cast Nephropathy in an African-American Woman with Waldenström Macroglobulinemia

Mohamedanwar M. Ghandour, Hillel Sternlicht. Wayne State University School of Medicine, Detroit, MI.

Introduction: Waldenström's macroglobulinemia (WM) is a rare cancer of the lymphatic system due to excess IgM monoclonal protein with a rare renal involvement. Renal involvement is rare with an incidence of 3 cases per million people per year. We describe a case of MW presenting with acute renal failure.

Case Description: A 63-year-old female who admitted to our hospital for influenza B complicated by acute renal failure during the hospital stay, with creatinine up to 6 mg/dL, despite adequate hydration. Electrophoresis revealed a monoclonal component in the gamma region, which classified as an IgM k. A kidney biopsy was performed, showing light chain casts/LPF. Serum immunofixation revealed IgA-kappa in the beta region and a faint IgA-cappa monoclonal protein in the gamma region. Autoimmune and infectious serologic work-up negative. Dapsone was stopped on day 5 and renal biopsy was performed due to ongoing rise in Cr on day 8. Biopsy confirmed diffuse interstitial nephritis with prominent eosinophilic inflammation along with low grade membranous nephropathy favoring secondary, PLA2R negative. Patient started on IV solumedrol followed by oral prednisone taper over 6 weeks. Creatinine improved to 1mg/dL at 3 month follow-up.

Discussion: DI-AIN was attributed to dapsone. Despite withholding this medication, the Cr continued to rise prompting renal biopsy. Studies suggest that early corticosteroid initiation is associated with better outcomes and be considered in patients with no prior kidney dysfunction. In patients with suspected DI-AIN where a biopsy cannot be performed, a trial of empiric steroid therapy may be considered. The finding of secondary membranous nephropathy (MN) was unexpected as to date there has not been any reports of renal disease and EDD. We report a case of secondary MN in a patient with EDD now undergoing a full malignancy investigation.

AKI from Tubular Bleeding from Rivaroxaban (XARELTO)

AKI: Aamir Zuberi, Fatima Zuberi, Nabiha A. Syed, Marisa L. Henderson, Safi Ahmad, Hafsa Zuberi, Aamir Zuberi MD PA, Decatur, TX; University of Texas at Austin, Austin, TX; University of Texas Southwestern Medical Center at Dallas, Dallas, TX; Wake Forest University, Winston-Salem, NC; Texas Tech University System, Lubbock, TX.

Introduction: Anticoagulation induced acute kidney injury

Case Description: A 68-year-old male with history of 7kg weight gain in the preceding 4 wks. & fatigue. History of CAD, COPD and Pulmonary Embolism treated with Rivaroxaban Exam essentially negative except for edema Creatinine 8.4, ultrasound negative, previous creatinine normal, UA positive for blood & protein Dialysis initiated. All serologies negative IVC filter was placed, anticoagulation stopped, and kidney biopsy performed Biopsy showed diffuse intratubular red blood cells, red cells casts, acute tubular epithelial injury, mild interstitial fibrosis, few eosinophils and negative for crescents or vasculitis (images shown below) On follow-up, Pt regained kidney function in 2 months and creatinine remained normal at 1 year.

Discussion: Warfarin related nephropathy is a rare but well-recognized phenomenon, which has also been reported with other anti-coagulation like Dabigatran (Pradaxa), however has not been reported with Rivaroxaban (Xarelto). Warfarin related nephropathy (WRN) and acute kidney injury is sometimes caused by excessive anticoagulation. A biopsy is needed to confirm this condition. Pathogenesis of anticoagulant related nephropathy is glomerular injury, obstruction of renal tubules by RBC casts, and tubular epithelial injury. Histologically, WRN and the biopsy from the patient receiving Rivaroxaban appeared very similar.

**Misleading Serologies in Thrombotic Microangiopathy due to Malignant Hypertension**

**Taqui Khaja,** 1 Rajeev Raghavan,2 William F. Glass,2 Carl P. Walther. 1 Baylor College of Medicine, Houston, TX; 2 University of Texas Health Science Center at Houston, Houston, TX.

**Introduction:** Nephrologists use autoimmune panels to screen for glomerular disease. Some of these markers cause false positives in other systemic diseases which leads to misdiagnosis. We report a rare case of false positive MPO-ANCA and ANA in patient with thrombotic microangiopathy (TMA) due malignant hypertension.

**Case Description:** A 65 year old African American patient with a history of hypertension, breast cancer s/p right mastectomy, and CKD with baseline creatinine of 1 was admitted hypertensive urgency with pressures of 239/123. She had Acute Kidney Injury with creatinine of 6.6 and her work-up revealed new pericardial effusion, thrombocytopenia (platelets of 90), and anemia (hemoglobin of 9). Autoimmune panel was positive for ANA (1:520, speckled) and positive RNP (+8). The presumptive diagnosis was mixed connective tissue disease. Pericapodial necrosis was negative for malignancy and infections. She began dialysis but her renal function never improved. She was discharged dialysis dependent. The patient refused outpatient dialysis and her medications. She was re-admitted few weeks later with uremia and hypertensive urgency with pressures of 299/104. A repeat evaluation showed a newly positive MPO-ANCA (13.4), ANA (1.640, speckled), and a low C3 (72.8). Given the concern for vasculitis, a kidney biopsy was performed. Her biopsy was significant for global glomerulosclerosis, glomerular ischemia, and severe interstitial fibrosis with tubular atrophy. There was extensive arteriolar onion skin intimal fibroplasia with red blood cell fragments. Based on her clinical history, patient had TMA secondary to hypertensive. Her biopsy lacked findings of vasculitis due to an absence of necrotizing crescentic glomerulonephritis and negative immunofluorescent stains. The patient was maintained on hemodialysis and hypertension medications.

**Discussion:** Diseases associated with TMA can have false positive autoimmune markers and they require early recognition. There are cases that show Thrombotic Thrombocytopenic Purpura can produce MPO-ANCA and anti-DNA markers. The markers were correlated to intensity of the disease because the patients with active disease had higher titers. These markers are created secondary to immune dysfunction during TMA. This case also emphasizes the importance of kidney biopsy in order to distinguish between active vasculitis and non-vasculitic diseases.

**Dynamics of Tissue Injury mRNA Expression to Bilateral Renal Ischemia-Reperfusion Injury**

**Samuel J. Pfaff,** 1 Tony L. Richards, 2 Kenneth Minor, 3 Yan Zhang, 1 Craig F. Plato, 1 Kristopher Kuchenbecker. 1 Silver Creek Pharmaceuticals, San Francisco, CA; 2 Plato BioPharma, Inc., Westminster, CO.

**Background:** Acute kidney injury (AKI) secondary to acute renal ischemia is associated with high mortality and morbidity with few effective treatments. The bilateral renal ischemia-reperfusion injury (BRI) model is commonly employed in rodent studies of AKI. While disease progression is well characterized at the organism level, the dynamics of the molecular responses are less well understood. To improve the translational potential of compounds, the current study sought to temporally and mechanistically define the tissue mRNA expression profiles following discrete durations of IRI.

**Methods:** Rats underwent sham or warm, bilateral renal ischemia (30’ or 40’) surgery using PBI’s proprietary vascular clamps. Subsets of rats were sacrificed at 8 timepoints following reperfusion (0-48h), with blood and kidneys harvested at each timepoint for subsequent analyses. Plasma and kidney tissue were analyzed for gene expression via clinical chemistry.

The expression of 100 mRNA transcripts surveying genes across apoptosis, kidney injury, and inflammation/repair pathways were measured by Quantigen.

**Results:** Plasma creatinine, the classical index of renal dysfunction in AKI was ischemia- and reperfusion time-dependently increased upon inception of reperfusion. Concomitantly, kidney injury and inflammation genes were upregulated early (<4hr) and remained elevated compared to shams throughout study duration. Upregulation of pro-apoptotic genes occurred a2hr post-reperfusion, indicating the initiation of programmed cell death. Last, pro-fibrotic genes were upregulated 24-48hr post-reperfusion indicating onset of remodeling. The information content provided by each mRNA expression profile and clinical parameter was determined using a novel statistical framework to identify measures best able to distinguish disease state over 48hr of reperfusion.

**Conclusions:** This study demonstrated the temporal dynamics of response to renal IRI in rats. The early injury phase (<4hr) was defined by mild, but significantly increased plasma creatinine indicating promptly reduced renal function along with upregulated injury response genes. Induction of pro-apoptotic and pro-fibrotic genes occurred during the later phase, in line with exacerbated renal function. Our novel statistical method identified “high information” genes/parameters that can serve as reliable, mechanistic indicators of AKI in future studies.

**AKI, Diplopia, and Altered Psyche: One Rare Case of Extrapulmonary Sarcoidosis**

**Hillary DeRose-Caldwell. Western Reserve Health Education, Youngstown, OH.**

**Introduction:** Sarcoid is a multi-organ system disease primarily affecting the lungs. Pathological diagnosis requires the presence of non-caseating granulomas. Sarcoidosis is a genetic associated autoimmune disease more prevalent in African Americans. Renal sarcoidosis manifests in about 5-20% of patients with hypercalcemia, hypercalciuria, and nephrocalcinosis on normal screening. Renal parenchymal involvement is typically granulomatous tubulointerstitial nephritis. Neuro-sarcoid also occurs in about 1/3 of patients, affecting primarily the cranial nerves. CNS involvement can present with visual and occasionally behavioral changes. Ocular sarcoid presentations include uveitis and retinal lesions.

**Case Description:** 63-year-old white male with a history of rheumatoid arthritis, pulmonary nodules, glaucoma, presented with one year of blurry vision and weird psyche. He was referred to nephrology after an ophthalmologist found intermittent diplopia, transient optic disc swelling and intraretinal hemorrhage. Abnormal labs from 5/2019 with 11/2018 in parenthesis: Scr 2.73 (1.51 mg/dL), BUN 27 (22), Egrf nax 28 (490/mL), Ser Calcium 8.6 (9.2 mg/dL) ACE 73 UI/L, Alc 5.4. Given the worsening CKD IV; the following were drawn: ANA-IFA: positive, speckled pt 1.640, UA bid 10, ion cast 0-5, crs gran cyst 0-5, ur prot rad 24. Renal biopsy demonstrated nonaseating granulomatous interstitial nephritis, numerous nonaseating granulomas with giant cells. He was referred to Cleveland Clinic Sarcoid Clinic and started on 40mg prednisone for renal sarcoid. CXR with prior nodules, no hilar or parenchymal changes. CC Ophthalmology clinic’s fundus exam revealed peripheral hypo-pigmented lesions possibly consistent with ocular sarcoid. Vision had resolved. At 1 month, steroids were tapered with plans to start Azathioprine. The patient’s Ser improved on tapering steroids.

**Discussion:** Less than one in ten patients present solely with extrapulmonary sarcoid. This case demonstrates a rare presentation of neuro-ocular and renal sarcoidosis in the absence of lung findings. Sarcoidosis ought to be considered in AKI or new chronic kidney disease, particularly if a patient presents with other atypical findings such as retinal or optic nerve changes representing a syndrome of multi-organ involvement. Multiple system involvement is a predictor of progression to ESRD. Glucocorticoids are first-line therapy. Most cases respond to steroids.

**Antioxidant Ameliorates Pulmonary Renal Injury in an Experimental Model of COVID-19 Organ Failure**

**Firoozeh Farahmand, Saint Louis University, Saint Louis, MO.**

**Background:** Since the outbreak and rapid global spread of COVID-19 multi-organ involvement has largely influenced prognosis and severe AKI has been an ominous clinical predictor with high mortality. The hyperinflammatory response of the body, associated with oxidative stress is a key player in mechanism of multiple organ failure.

**Methods:** In an experimental model of multiple organ failure of Covid 19 similar to human disease with single injection of Toxoid (TOX) rats were treated with antioxidant curvedol started daily 1wk pre-TOX-injection and continued for 1 wk post-TOX-injection. At 1-week post injection in both TOX+ Antioxidant and TOX groups lungs wet/dry weight ratios were measured to assess edema and lungs and kidneys from both group were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. After sacrificing the animals, kidney and lung were removed for histology.

**Results:** Antioxidant treatment attenuated TOX induced lung and kidney injury and there was histopathological evidence of its beneficial effects. This was associated with decreased oxidative stress and increased activities of SOD and GSHPs in the lung and the kidney.

**Conclusions:** In this experimental model that mimics human Covid 19 multiorgan failure, antioxidant improved survival, lung and kidney injury and also oxidative stress in the kidney. This suggest the beneficial effects of antioxidant as a kidney–lung protective strategy in patients with COVID-19.

**SRP14 Regulated Renal Tubular Apoptosis Induced by Ischemia-Reperfusion Injury via Interaction with RPS7**

**Yun Tang, Yanmei Li, Guisen Li, Yi Li. Department of Nephrology, School of Medicine, Sichuan Academy of Medical Science and Sichuan Provincial People’s Hospital, University of Electronic Science and Technology of China, Chengdu, China.**

**Background:** AKI could easily progress to CKD with increased incidence and mortality. Due to the complex pathogenesis, there is a lack of effective early warning to intervene in AKI.

**Methods:** We performed LFQ proteomic analysis in HK, renal tubular epithelial cells and human kidney (Hep2) cell line. After finding SRP14 as candidate target to prevent AKI upon apoptosis in renal tubular epithelial cells. This study will further study the role and mechanism of SRP14 in regulating MDM2-p53 pathway in apoptosis of renal tubular epithelial cells in AKI. Then analyze the clinical correlation of SRP14 in AKI and explore the possibility of SRP14 as a potential therapeutic target for AKI.
Results: We identified that SRP14 could be involved in apoptosis of renal tubular epithelial cells. In particular, the SRP14 could mediate the MDM2-p53 loop through RPS7 in renal tubular epithelial cells to regulate apoptosis of renal tubular epithelial cells induced by IRI. The AUC value of SRP14 (AUC [Cmax] = 0.774) was close to serum creatinine (AUC [Cmax] = 0.796), suggesting the potential prognostic value of serum SRP14.

Conclusions: This study found that SRP14 regulated renal tubular apoptosis induced by ischemia reperfusion injury via interaction with RPS7 involving MDM2-p53 loop. This finding could provide some novel targets and ideas for AKI control in the future.

PUB020
A Case of Masked AKI
Sitalakshmi J. Iyer,1,2 Clay A. Block,3 (NYU Langone Health, New York, NY; 1VA New York Harbor Healthcare System, Manhattan, NY; 2Dartmouth College Geisel School of Medicine, Hanover, NH.

Introduction: Despite wide recognition of pitfalls, changes in serum creatinine (Cr) and/or a decline in urine output (UO) remain the mainstay of AKI diagnosis. We report a patient whose extremely low Cr and preserved UO demonstrate the problem in reliance on these parameters.

Case Description: 57 F was admitted for respiratory failure due to COVID-19. Her management included tocilizumab, mechanical ventilation, vasopressors, ECMO, and antibiotics. On entry she weighed 54kg and Cr was 0.5 mg/dL. After 5 days, Cr nadir at 0.1 then gradually rose to 0.6 where it remained (day 15). Net fluid balance was 20L. By Cr, her eGFR was 110 mL/min/1.73m2 but by cystatin C (CysC) it was 56.

Discussion: AKI defines AKI by an absolute rise in Cr >0.3mg/dl within 48 hrs, a relative rise in Cr >50% within 1 week, or reduction in UO to <0.5mL/kg/hr for at least 6 hrs. Cr is a flawed AKI biomarker due to uncertainty of the baseline, variability in rate of generation, and elimination by secretion and filtration. Cr generation falls rapidly with critical illness. The impact of volume expansion resulting in hyperfiltration or hemodilution are underrecognized. Antibiotics, diuretics, glucose, ketones and bilirubin may interfere with measurement. UO too is flawed since oliguria may occur in the absence of AKI due to antidiuretic hormone or conversely, UO may be maintained despite AKI due to osmotic diuresis, failure of tubular function or diuretic use. The choice of baseline Cr influences our patient’s diagnosis. If 0.5 is chosen, she fails to meet AKIN criteria, but based on nadir Cr, she has severe stage III AKI. AKI can also be demonstrated by adjusting Cr for volume expansion: measured Cr x (initial total body water [TBW] / cumulative fluid gain) + initial TBW = 1.4 in our patient. Our patient received tube feeds, suffered hyperglycemia resulting in high osmolar load driving an osmotic diuresis. Also, periodic furosemide was given in an attempt to increase her fluid balance. Below normal Cr is generally seen in myopathies, cirrhosis or with drug interference, but hyperfiltration can occur with volume expansion contributing to low Cr. In this case, we believe a baseline small muscle mass, critical illness sarcoenia, and marked volume expansion conspired to mask significant AKI in our patient. Documentation of AKI by measuring CysC led to adjustments in drug dosing.

PUB021
Online Medical Education Significantly Improves Nephrologists’ Knowledge and Confidence for Intravenous (IV) Iron Use in Patients with Iron-Deficiency Anemia (IDA) in CKD
George Boutsalis,1 Sigit D. Trier,3 Chris Allen,1 Jay B. Wish.2 (1Medscape LLC, New York, NY; 2Indiana University School of Medicine, Indianapolis, IN.

Background: Purpose: To determine if online medical education for nephrologists (Neph) could improve their evidence-based knowledge and confidence to use IV iron to treat IDA in non-dialysis (ND) and dialysis dependent CKD patients

Methods: Participants completed a 3-item questionnaire plus confidence assessment before and after watching a 30-minute online video series of 4 expert interviews with slides. A matched pair design was used pre-/post-assessment, with scores compared to assess changes in the proportion of correct responses. A chi-square test assessed statistical significance at the P <.05 level. Launch 01/29/20; data through 04/13/20. Total Neph learners (n=572), Neph assessment completers (n=122)

Results: At baseline, 20% of Neph (n=122) answered all 3 questions correctly, increasing to 61% (P < .001) post-assessment. An average of 61% of all responses were increasing to 61% (< .001) post-assessment. An average of 61% of all responses were ± 0.5 mg/dL of the actual PTH value. The MAE for the 1-, 2-, and 3-month calcium predictions is 0.410, 0.458, and 0.496 mg/dL, respectively. In addition, for the 1-, 2-, and 3-month predictions, 71%, 65%, and 63% of the predictions, respectively, lie within ±0.5 mg/dL of the actual calcium value.

Conclusions: The error distribution of the predictions is such that they 1) may be clinically meaningful as part of an effort to better control PTH, while potentially reducing excessive up-titration of etelcalcetide (and thus cost) and 2) may serve as a benchmark for future modeling efforts. Limitations include: a relatively small data set which precluded the use of other models (e.g., recurrent neural networks) and the dialysis program’s strict criteria for receiving etelcalcetide which led to a study population with significantly higher PTH values than may be encountered in the general dialysis population.

PUB022
Predicting PTH and Calcium Trajectories for ESKD Patients on Intravenous Calcinimetics
Benjamin Lobo,1 Dennis Hu,2 Brendan T. Bowman.2 (1University of Virginia School of Engineering and Applied Science, Charlottesville, VA; 2University of Virginia School of Medicine, Charlottesville, VA.

Background: Patients with End-Stage Kidney Disease (ESKD) often experience secondary and tertiary hyperparathyroidism leading to increased fracture risk, vascular calcification, and increased cardiovascular risk. Traditional pharmacotherapy includes phosphorus binders, Vitamin D analogues, and oral calcimimetics. Despite this, many ESKD patients still have elevated parathyroid hormone (PTH) levels. Etelcalcetide is an intravenously delivered calcimimetic approved to treat hyperparathyroidism. Advantages include a long half-life and IV administration which guarantees drug delivery. Despite this, response of PTH and calcium levels to etelcalcetide remains difficult to predict. A predictive algorithm could assist clinicians in assessing the potential effect of a given dose. As a first step in developing a dosing decision support tool, we present a predictive model that forecasts the 1-, 2-, and 3-month PTH and calcium values for patients receiving etelcalcetide.

Methods: We used tree ensemble (RandomForest) models for their ability to model the data non-linearities. Model inputs were historic data (calcimimetic dosing, labs, dialysis records, demographics, and phosphorus binder orders) and future calcimimetic dosing.

Results: The Mean Absolute Error (MAE) is 205, 227, and 249 pg/mL for the 1-, 2-, and 3-month PTH predictions, respectively. In addition, for the 1-, 2-, and 3-month calcium predictions, 70%, 65%, and 59% of the predictions, respectively, lie within ±25 pg/mL of the actual PTH value. The MAE for the 1-, 2-, and 3-month calcium predictions is 0.410, 0.458, and 0.496 mg/dL, respectively. In addition, for the 1-, 2-, and 3-month predictions, 71%, 65%, and 63% of the predictions, respectively, lie within ±0.5 mg/dL of the actual calcium value.

Conclusions: The error distribution of the predictions is such that they 1) may be clinically meaningful as part of an effort to better control PTH, while potentially reducing excessive up-titration of etelcalcetide (and thus cost) and 2) may serve as a benchmark for future modeling efforts. Limitations include: a relatively small data set which precluded the use of other models (e.g., recurrent neural networks) and the dialysis program’s strict criteria for receiving etelcalcetide which led to a study population with significantly higher PTH values than may be encountered in the general dialysis population.

PUB023
A Rare Case of Staghorn Calculi Complicated by Bilateral Xanthogranulomatous Pyelonephritis
Michael Chang, Gary Dellacerra, Deep Sharma, Joshua M. Stern, Peter Nauka, Wei Chen. Montefiore Medical Center, Bronx, NY.

Introduction: Staghorn calculi are usually unilateral and typically occur in women. Chronic obstruction and infection of staghorn calculi can cause xanthogranulomatous pyelonephritis (XGXP), a rare destructive granulomatous process of renal parenchyma. We describe a case of bilateral staghorn calculi in a man complicated with XGP and worsening renal function.

Case Description: A 64-year-old man with bilateral staghorn calculi and chronic kidney disease (CKD) stage 4 was admitted for fatigue and worsening renal function. He tested positive for COVID-19 by nuclei acid-based test. Serum creatinine increased from 3.5 (2 months ago) to 6.2 mg/dL. Renal ultrasound showed dilated left calyces and large shadowing calculi without hydronephrosis. History was notable for persistently alkaline urine (urine pH ≥6.5), 100% carbonate apatite (dahilite) on stone analysis, and urinary tract infection with Proteus mirabilis. CT imaging revealed bilateral staghorn calculi with “bear paw” signs (left > right), a typical appearance of XGP [Figure]. Compared to a CT scan completed 10 months ago, the left kidney was enlarged with greater low-attenuating spaces indicating worsened XGP; the right kidney decreased in size with less stone burden corresponding to the right percutaneous nephrolithotomy performed 7 months prior. AKI was thought to be related to COVID-19, and surgical intervention was deemed unnecessary. Bilateral XGP likely increased his risk of AKI and hampered renal recovery, and he was subsequently initiated on hemodialysis.

Discussion: In this rare case of staghorn calculi progressed to bilateral XGP, we observed the detrimental effects of staghorn calculi on the kidneys. More research on staghorn calculi is needed to improve the high morbidity and mortality associated with this disease.
Factors Associated with Serum Concentrations of 25-Hydroxyvitamin D (25D) and 1,25-Dihydroxyvitamin D (1,25D) in Stable Hemodialysis Patients

Eiji Ishimura,1 Takahiro Fujimoto,1 Kazunori Masutani,1 Kazunari Higashimoto,1 Nobuya Murakami,1 Shuko Ueda,1 Nobuyuki Kuwamura,1 Akihiro Tsuda,2 Shinya Nakatani,2 Katuhito Mori,2 Senji Okuno,2 Ruusuke Kakiya,1 Masanari Emoto,2 1Meijibashi Hospital, Osaka, Japan; 2Osaka City University Graduate School of Medicine, Osaka, Japan; 3Shirasagi Hospital, Osaka, Japan.

Background: Serum 1,25D, an active form synthesized from 25D, is present in CKD patients (Ishimura, Kidney Int 1999; Wolf, Kidney Int 2007). However, factors associated with 1,25D and 25D are not well known. The aim of the present study is to examine the relationship between 1,25D, 25D and clinical parameters in hemodialysis patients.

Methods: Serum 1,25D and 25D were measured by a RIA2-Ab method and an ECLIA method, respectively, in 108 stable maintenance hemodialysis patients (72 ± 10 years, 64 males, hemodialysis duration: 6.9 ± 7.5 years, 45 diabetics) from December 2019 to February 2020, i.e., in the winter.

Results: Serum 1,25D were 14.6 ± 8.0 pg/ml, demonstrating that 77 patients showed values less than reference ranges of healthy subjects (30-60 pg/ml). Serum 25D were 12.0 ± 4.8 ng/ml, demonstrating that 101 patients showed vitamin D deficiency of < 20 ng/ml. There was no significant correlation between serum 1,25D and 25D in maintenance hemodialysis patients in the present study, although 1,25D and 25D had been reported to show significant, positive correlations both in pre-dialysis CKD patients (Ishimura, Kidney Int, 1999) and in incident dialysis patients (Wolf, Kidney Int 2007). There were no significant correlations between 25D and clinical parameters. However, there were significant, negative correlations between 1,25D and intact PTH (r = -0.344, p < 0.001) and between 1,25D and ALP (r = -0.309, p < 0.02), although no significant correlations were seen between 25D and other parameters, such as Ca and P. In multiple regression analyses, 1,25D was significantly, independently associated with intact PTH and with ALP after adjustments of several clinical parameters (R² = 0.345, p = 0.001: R² 1,25D, p < 0.001, respectively).

Conclusions: In maintenance hemodialysis patients, all patients showed hypovitaminosis D, in terms of serum 25D. 1,25D, even in low serum levels, correlated significantly and negatively with intact PTH and ALP. These results indicated that even low levels of serum active vitamin D, 1,25D, affect the status of CKD-MBD. The results may further indicate that the metabolism of vitamin D should be considered in the pathogenesis and treatment of CKD-MBD.

A Case of Parathyroid Hyperplasia with Single Explosive Growth

Bei Hou,1 Bing Tang,1 Yong Xu,2 Yuanning Li,2 Ninxin Liu,1 Xiang yijia Doctor Group 1Jewel Hospital, Changsha, China; 2Xiang yia Hospital Central South University, Changsha, China.

Introduction: Exploration of parathyroid hyperplasia with single explosive growth

Case Description: A 46.5O Asian man with ESRD has been undergoing regular hemodialysis for 20 years due to glomerulonephritis. The patient has had bone and joint pain for 10 years. In 2018, the measurement of his serum iPTH was elevated and the value was over 1000pg/ml (no data about serum calcium and phosphate levels), and he didn’t have regular treatment. Serum calcium, phosphate and alkaline phosphatase were 2.46mmol/L, 2.44mmol/L and 380U/L, respectively, and serum iPTH was 2205pg/ml in this admission examination. The ultrasonography showed two hyperplastic parathyroid glands. They are 1.3*2.0mm on the right lower side of thyroid gland and 43*18mm on the left lower side. Parathyroid needle scanning showed three hyperplastic parathyroid glands. That is located in bilateral hypothyroidism and left upper sternum,consider parathyroid development, Total parathyroidectomy was successfully carried out with the help of the local anesthesiologist in May 15, 2020. Four parathyroid were excised, which were 0.6*0.5cm in the upper left, 4.9*3.0cm in the lower left, 0.8*0.5cm in the upper right, and 1.5*1.0cm in the lower right (the maximum diameter and length). Pathological diagnosis showed that there was parathyroid nodular hyperplasia in the upper left, lower left, upper right and lower right. PTH values a week after surgery was less than 1.2pg/ml, serum calcium 2.13mmol/L, phosphate was 0.85mmol/L. Patient bone pain disappeared. Patient has been discharged and will be close followed up.

Discussion: Total parathyroidectomy is effective in uremic patients with secondary hyperparathyroidism which has explosive hyperplasia with parathyroid glands.

Acute Changes in Plasma Phosphate After Phosphorus-Standardized Meals in Peritoneal Dialysis: A Randomized Cross-Over Trial

Martin T. Lundin,1 Iain O. Bressendorff,1 Niklas R. Jørgensen,2 Rizwan Butt,1 Ditte Hansen.1 Herlev Hospital, Herlev, Denmark; 2Rigshospitalet Glostrup, Glostrup, Denmark.

Background: Hyperphosphatemia is associated with increased morbidity and mortality in patients with chronic kidney disease. The aim of this study was to assess whether a meal with high phosphorus content affects plasma phosphate in the hours following such a meal among subjects with end-stage kidney disease on peritoneal dialysis.

Methods: This was a single-blinded randomized cross-over trial of 12 subjects on maintenance peritoneal dialysis, in which subjects were randomized to consume a meal with either high or low phosphorus content on two separate trial days. On each trial day plasma phosphate was measured immediately before consumption of the standardized meal, and after one, two, three and five hours.

Results: The mean fasting plasma phosphate at baseline was 1.69 ± 0.22 mmol/L. Plasma phosphate was similar between the two meals at baseline, as well as at one, two, three, and five hours after consumption. The largest observed difference in plasma phosphate between the two meals was 0.15 mmol/L, which occurred five hours after consumption (high phosphorus meal 1.75 ± 0.32 mmol/L versus low phosphorus meal 1.60 ± 0.14 mmol/L (p = 0.06)). Using summary analyses for repeated measures we observed a significant difference in the plasma phosphate between the two meals (p = 0.03).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Our results show that in subjects with end-stage kidney disease a meal with high phosphorus content has only a negligible effect on plasma phosphate compared to a meal with low phosphorus content. Thus, large increases in plasma phosphate cannot be accounted for by a high intake of phosphorus in the hours prior to blood sampling.

PUB027
A Rare Case of Severe Tertiary Hyperparathyroidism in a Patient with ESRD
Jose S. Reyes Oliva, Iritzla Hasan, Zaiyara A. Rivera, Ljubomir M. Ilic. University of Florida College of Medicine -Jacksonville, Jacksonville, FL.

Introduction: Refractory tertiary hyperparathyroidism is defined as severe, persistent & progressive elevation of PTH which cannot be lowered by medical management & associated hypercalcemia, hyperphosphatemia, bone/joint pain and/or fracture, extra skeletal calcification, calciphylaxis & pruritus.

Case Description: A 43-year-old undocumented Hispanic male with PMH of uncontrolled DM, HTN, ESRD (HDX 3/week) & persistent tertiary hyperparathyroidism (on Cinacalcet) presented with multiple bone fractures, bilateral leg weakness, soft tissue calcification & severe renal osteodystrophy. Significant lab findings included PTH 3519pg/mL, phos 6.7mg/dL, Ca 10.9mg/dL & ak phos 804 IU/l were all above goal. X-ray of lower ext. revealed diffuse osteopenia with chronic fracture in distal fibula, midfoot, distal tibia & dislocation of talonavicular joint as well as extensive atherosclerotic vascular calcification & multiple punctate soft tissue calcification. CT spine reported demineralized appearance of vertebral bodies & sarcum, wide erosion of sacrailc joints bilaterally & calcified atherosclerotic disease of abdominal aorta & bilateral interiliac arteries. Patient was diagnosed as refractory tertiary hyperparathyroidism & treated with doxercalciferol, phosphate binders & advised for parathyroidectomy on multiple previous encounters but was unable to do due to health care access issue.

Discussion: Parathyroidectomy which has mortality benefit is indicated in the setting of severe & sustained PTH value above 800-1000 pg/mL, refractory to medical treatment & associated to other indicators like hypercalcemia, refractory hyperphosphatemia, bone pain/fractures & our case has majority of the above mentioned indications. Various other factors including immigration, insurance issues and post-operative intensive care requirements complicated the potential for parathyroidectomy in this patient. Although with advancement of medical field, the symptoms of severe hyperparathyroidism are rarely observed but the manifestations are real if not treated on time as per guideline recommendations.

Progression of CKD Stage G3a Among African Americans
Yelvzyaveta Prysvazhnyuk, Isha Puri, Jic Ouyang, Ernie Yap. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Chronic kidney disease (CKD) stage 3 represents the most of all CKD patients. Stage G3a is divided into G3a (GFR 45–59 ml/min/1.73m2) and G3b (30–44 ml/min/1.73m2) based on findings that showed differential kidney outcomes. Stage G3a has several unresolved paradigms. Firstly, it does not always imply kidney damage. It is recommended that cystatin C be used to confirm in people without manifestation of kidney damage to avoid over-diagnosis. Secondly, it primarily comprises of the elderly, and most will not progress to advanced CKD before succumbing to other causes of death. Thirdly, in people with manifestations of kidney damage, stage G3a becomes an important predictor of disease progression. The influence of ethnicity on eGFR in delineating these aberrancies in CKD G3a is unclear. In this study, we sought to analyze the progression of CKD G3a patients in a predominantly African American cohort.

Methods: We performed retrospective chart reviews of patients at our CKD clinic. GFR was estimated based on the MDRD formula. Continuous variables were presented as means+SD. Comparison of continuous variables were performed using one-way ANOVA. Univariate and age and body mass index (BMI)-adjustment analyses was performed by Cox proportional hazards model. IBM SPSS v. 25 was used.

Results: 319 patients were analyzed. Median follow-up was 79.7 months (IQR: 93.9). 259 (80.6%) patients had at least 2-years follow-up. In these patients, the mean annual GFR declines were 4.4±3.8, 2.3±2.1, 1.6±2.7 and 1.4±2.2 ml/min/1.73m2 for stages G2, G3a, G3b and G4 respectively (p<0.001). Univariate Cox proportional hazard analysis showed that CKD G3a, Gb and G4 had relative risks (RR) of progression to G5 of 1.0 (95% CI: 0.5-2.2; p=0.98), 3.8 (1.6-9.1; 0.003) and 194 (8.7-43.0; <0.005) respectively. When adjusted for age and BMI, risks of progression to G5 were: RR=1.3 (1.6-3.0; 0.5), 5.8 (2.3-14.7; <0.005) and 29.6 (12.1-72.2; <0.005) for CKD G3a, G3b and G4 respectively.

Conclusions: In our cohort of predominant African Americans, CKD G3a does not predict disease progression.

PUB029
Is Routine Screening with Serum and Urine Protein Electrophoresis in Evaluation of CKD Justified?
Omar T. Ashour,1,2 Christine A. White,1,2 Eduard A. Iliescu.1,2 Queen's University, Kingston, ON, Canada; ‘Kingston Health Sciences Centre, Kingston, ON, Canada.

Background: Current guidelines for the evaluation of chronic kidney disease (CKD) in Canada do not include routine screening with serum and urine protein electrophoresis to detect for light chain deposit disease (M-spike). We postulated that CKD-chronic kidney disease; AA- African American; BMI- body mass index

PUB030
Is Yakima County a CKDu Hot Spot? A Case Series of CKD in Latino Agricultural Workers
Mark D. Baldwin, Katherine Ackerman, Tara L. Kronen, Polly Wiltz, Lizzie Lamb. PNWU CKDu Investigative Task Force Pacific Northwest University of Health Sciences College of Osteopathic Medicine, Yakima, WA.

Introduction: The first case series of chronic kidney disease of unknown etiology (CKDu) was described in 2002 in sugar cane cutters in El Salvador. This unique diagnosis presented in relatively young men without any of the traditional risk factor associated with renal disease. The common feature amongst cases was strenuous work in extremely hot environments. Yakima, Washington, an agricultural community in the Pacific Northwest, has had the highest average temperature increase in the Pacific Northwest at 3°F over the past 30 years. Average summer temperatures for July and August are 88°F and 89°F, respectively, with detection costs of $ 553.28 per M-spike and $ 1,521.25 per myeloma cost. There were no differences in clinical, demographic, CBC, serum calcium, urine albumin to creatinine ratio, urinalysis, or renal imaging among pts with and without M-spike but sample size did not allow multivariate analysis.

Conclusions: In this study, the prevalence of M-spike in CKD is higher than has been reported in the literature in the general population (5.4 - 18.8 % vs. 3 - 4 %). The cost for testing and interpretation fees for SPEP and UPEP are CDN $ 25.53 and 32.99 respectively, with detection costs of $ 59.13 per MGUS, $ 153.25 per myeloma or amyloid. These costs are consistent with previous studies controlled for inflation (1,2). Routine screening with SPEP and UPEP in the evaluation of CKD may be useful and cost-effective. Larger prospective studies are needed to identify subgroups with higher likelihood of M-spike to target testing. 1. AlHwesh et al. J Am Soc Nephrol 2003 14:295A. 2. Chew et al. Am J Kidney Dis. 1999 Jul;34(1):135-9.
northern regions. At 46.602°N latitude, Yakima is closer to the North Pole than the Equator, and much farther north than other areas where CKDs have been documented. With increasing global temperatures, agricultural workers are on the frontline of climate-related health issues. Further study is necessary to develop awareness, earlier risk factor detection, and effective interventions for these essential and vulnerable members of our communities.

The Correlation Among Management of the Comorbidities and Progression of Renal Dysfunction or Adverse Events for CKD Patients

Takahiro Kuragano, Takeshi Nakanishi. Hyogo college of Medicine: Kidney and dialysis, Nishinomiya, Japan.

**Background:** It is well established that several factors including anemia, hypertension, hyperuricemia, metabolic acidosis, and CKD-MBD are associated with progression of CKD or adverse events of these patients. However, the significant factors which associated with progression of CKD or adverse events under the condition of appropriate control which according to guidelines have not been clarified.

**Methods:** The study was an observational study in a single center for a period of 3 years. In 88 patients with various stages of CKD (not on dialysis) who were treated by nephrologists, Hb, ferritin, iron and albumin and high sensitive C reactive protein (hsCRP), f2microglobulin (MG), HCO3−, and intact-parathyroid hormone (iPTH), in addition to urinary sodium, potassium, calcium, phosphorus protein, and i2MG levels, were measured. All patients were treated according to the clinical practice guideline for CKD. A time-dependent Cox hazard model was applied to evaluate the association between clinical parameters and adverse events.

**Results:** In multiple regression analysis, baseline of lower Hb (β=0.497, P<0.001) and vitamin D 125 (β=0.258, P=0.006), and higher i-PTH (β=0.334, P<0.001), urinary phosphorus (β=0.328, P=0.001), urinary i2MG (β=0.225, P=0.031) and urinary protein (β=0.280, P=0.02) levels were selected as significant predictors of decline of estimated glomerular filtration rate (eGFR) or 1/ creatinine(Cr) at the end of the study. In the Cox hazard model, low calcium (HR: 0.37, P=0.026), high phosphate (HR:5.90, P<0.001), low 125 vitamin D (HR: 0.94, P=0.013), high int-PTH (HR:1.02, P<0.001) level, use of a phosphate binder (HR: 4.95, P=0.012), and use of vitamin D analogs (HR:3.75, P<0.014) are selected as risks for adverse event including initiation of dialysis.

**Conclusions:** In this study, we found that among several factors, anemia and CKD-MBD related factors (phosphate, calcium, vitamin D, int-PTH) were selected as significant predictors for renal dysfunction. Furthermore, the phosphate binder or vitamin D analogs were administrated appropriately, CKD-MBD factors were associated with progression or adverse events of these patients. From these results, we presumed that the early intervention or strict control for CKD-MBD factors might attenuate the risk for adverse events of CKD patients.

**Figure one** shows the crude and the multivariable Cox proportional hazard models using anion gap as tertiles.

**PUB032**

Association of Anion Gap with the Risk of CKD Progression

Ashish Verma,1 Jing Liu,2 Maria Clarissa Tio,1 Ankit B. Patel,1 Sushrut S. Waikar,2 'B Brigham and Women's Hospital, Boston, MA; 'Boston University Medical Campus, Boston, MA.

**Background:** Increased anion gap is a marker of acid retention most reflected in patients with CKD. This study’s objective is to assess whether a higher anion gap is a risk factor for CKD progression.

**Methods:** This prospective cohort study assessed 4131 participants with CKD stage 2 to 4, who enrolled in a chronic renal insufficiency cohort study. Three types of anion gap were used as exposures, traditional anion gap (AG1), Albumin corrected anion gap(AG2), full anion gap(AG3). Multivariable adjusted Cox proportional hazard models were built using the lowest tertile as the reference of all three anion gaps for the composite outcome (50% decline in eGFR or ESRD) and ESRD. Models were adjusted for relevant covariates and baseline eGFR.

**Results:** This study included 4131 participants [mean (SD) age, 60.48(10.21) years; 1788 (43.28%) female]. During 26673.46 person years of follow up, 805 participants reached ESRD and 1138 participants reached a composite outcome of a 50% decline in GFR or ESRD. In a multivariable adjusted model each SD increase in AG1, AG2 and AG3 were independently associated with 10%, 10% and 12% increased risk for CKD progression: hazard ratio (HR) 1.10; 95% CI (1.01-1.21); HR 1.10; 95% CI (1.02-1.20), HR 1.12; 95% CI (1.03-1.21), however each SD increase in AG2 and AG3 was independently associated with a 11% increased risk for ESRD [HR 1.11; 95% CI (1.02-1.21), HR 1.11; 95% CI (1.02-1.22)]. In multivariable adjusted models compared to tertile 1 (<10) those in tertile 3 (>12) had a 33% and 41% higher risk for CKD progression [HR 1.33;95% CI (1.09-1.62), HR 1.41;95% CI (1.16-1.71)] and 32% and 60% higher risk for ESRD [HR 1.32; 95% CI (1.06-1.64), HR 1.60;95 %CI (1.28-2.01)].

**Conclusions:** Higher albumin corrected and full anion gap may be a risk factor for CKD progression and ESRD.

Childhood Risk Factors for Adulthood CKD

Michal Stern Zimmer, Asaf Vivante. Sheba medical center, Ramat Gan, Israel.

**Background:** Chronic Kidney Disease (CKD) is a demographic health challenge, affecting ~ as much as 8 to 18% of the world population. Identifying childhood risk factors for future CKD may help clinicians make early diagnoses facilitating complication monitoring and initiation of preventive interventions for CKD and its accompanying comorbidities. We aim to describe these childhood risk factors that may predict development of overt kidney disease later in life.

**Methods:** PubMed publications (January 2009 - January 2019) were searched for publications by using terms and synonyms for chronic kidney disease (CKD) and specific childhood kidney related risk factors. We also manually searched the reference lists of key articles, reviews and meta-analyses.

**Results:** There are a multitude of childhood risk factors associated with future onset and progression of CKD. These risk factors can be grouped into five categories: genetic factors (e.g. monogenic or risk alleles), perinatal factors (e.g. low birth weight and prematurity), childhood kidney diseases (e.g. congenital anomalies, pyelonephritis, glomerular diseases and acute kidney injury), childhood onset of chronic conditions (e.g. cancer; diabetes, hypertension, dyslipidemia and obesity) and different lifestyle factors (e.g. physical activity and diet).

**Conclusions:** The available published information suggests that the lifelong risk for CKD can be attributed to multiple factors which appear already during childhood. However, results are conflicting on the effects of childhood physical activity, diet and dyslipidemia on future renal function. On the other hand, there is consistent evidence to support close monitoring for high risk populations.

Therapeutic Interventions to Assess Outcomes and Disparities in Chronic Kidney Disease Among Veterans (TRI-CKD)

Keichi Sumida,1 Ankur A. Dashputre,1 Praveen Kumar Potukuchi,1 Fridjof Thomas,1 Jun Ling Lu,1 Miklos Z. Molnar,1 Cachet Wenziger,2 Elani Streja,1 Kamary Kalantar-Zadeh,1 Csaba P. Kovetsy,1 1The University of Tennessee Health Science Center, Memphis, TN; 2University of California Irvine, Irvine, CA.

Background: There continues to be a large unmet need in the management of CKD, due in part to a lack of effective intervention strategies to prevent CKD progression or decrease morbidity/mortality in patients with CKD. There is also a lack of race-specific application of clinical interventions, despite evidence suggesting racial differences in response to various therapies. High quality, large observational studies are essential to provide preliminary results in support of further clinical trials, and to offer race-specifically widely applicable evidence to inform clinical practice in this population when clinical trials are not feasible.

Methods: We established a cohort of 3,565,367 individuals with stable eGFR >60 mL/min/1.73m² during October 1, 2004-September 30, 2006, using an algorithm based on repeated serum creatinine measurements. Data about patients’ demographics, socioeconomic characteristics, comorbid conditions, administered medications, labs, vital signs, vital status, incident CKD and ESRD outcomes were obtained from various VA databases, from Centers for Medicare & Medicaid Services, and from USRDS.

Results: The mean (SD) age of the cohort is 59 (14) years; 93% are male; 16% are African-American; and 24% are diabetic. The mean baseline eGFR is 84 mL/min/1.73m². Individuals are followed longitudinally for up to 13 years. Overall, the crude rates of all-cause death and ESRD are 51 and 0.63 per 1000 patient-years (Figure).

Conclusions: We established a large nationwide cohort of US veterans with normal eGFR. Studies from this cohort will generate a wealth of information to examine therapeutic interventions used to treat various conditions associated with poor outcomes in patients with all levels of kidney function, potentially providing significant clinical, social, and policy implications for the care of US veterans and also for patients with kidney diseases in general.

Treatment Response in Patients with Uncontrolled Gout Co-Treated with Pegloticase and Leflunomide

Karim R. Masri,1 Kevin W. Winterling,2 Brian LaMoreaux,2 1Ben Secours Rheumatology Center, Richmond, VA; 2Horizon Therapeutics, Lake Forest, IL.

Background: Many patients with CKD develop gout with a prevalence α36% in later stage disease. Though oral urate-lowering therapies are used in CKD patients, some may not respond to or cannot tolerate them. Uncontrolled (refractory) gout can be treated with pegloticase (PEGylated uricase enzyme), however, anti-drug antibodies (ADAs) can cause loss of therapeutic efficacy. Compared with pegloticase alone, recent case series show markedly higher response rates with methotrexate/pegloticase co-therapy (42% vs. 80-100%). However, certain considerations with methotrexate use including significant renal or hepatic disease may not be as restricting with leflunomide. This study examined pegloticase response rate in patients co-treated with pegloticase and leflunomide.

Methods: This chart review included uncontrolled gout patients treated with pegloticase (biweekly 8 mg infusions) and oral leflunomide (20 mg/day). Patient, disease, and treatment parameters were examined, along with safety data. Patients receiving ≥12 pegloticase infusions with a serum uric acid level (sUA) ≥6 mg/dL at infusion 12 were considered responders.

Results: 10 patients were identified and included (5 men, 72.7±12.5 years, pre-therapy sUA: 7.1±4.2 mg/dL). Common comorbidities were CKD (90%), hypertension (70%), diabetes mellitus (60%), obesity (60%), congestive heart failure (50%), and coronary artery disease (20%). 7 patients (70%) met responder criteria (26.6±14.0 infusions, sUA at infusion 12: 6.9±1.5 mg/dL). 3 patients were lost to follow-up or discontinued therapy. Gout flare (1 patient, 3 flares), weight loss (1 patient, before pegloticase infusion, deemed unrelated), worsening of kidney/cardiac issues (1 patient, deemed unrelated to treatment), and mild, transient ALT/AST increases (2 episodes, 1 patient) were observed. All treatment-related AEs were known effects of pegloticase or leflunomide.

Conclusions: These findings suggest that leflunomide/pegloticase co-therapy can increase the proportion of pegloticase responders, likely due to attenuation of ADAs. While methotrexate has been shown to increase pegloticase response rates, many gout patients have advanced CKD and leflunomide potentially represents an alternative option for minimizing ADAs.

A Double-Blind, Randomized, Placebo-Controlled with an Open-Label Rollover Extension Phase 2/3 Clinical Trial to Evaluate Safety and Efficacy of US-APR2020 in Subjects with CKD Stage IV

Natarajan Ranganathan,1 Usha N. Vyas,1 Pari Ranganathan,1 Anthony Irvin,1 Alan D. Weinberg,2 2Kibow Biotech, Newtown Square, PA; 3Mount Sinai Health System, New York, NY.

Background: CKD patients experience poor quality of life due to high levels of uric acids in the blood. Renal®P, a Pro/Prebiotic dietary supplement has been in the market since 2010. It is proven to reduce several uric acids in 3 pilot clinical trials with no adverse outcomes. The product is now awaiting FDA-IND approval for a drug trial. This will be a large scale 12-month RCT to validate US-APR2020 as a Live Bio-Therapeutic drug product (LBP) under CBER guidelines.

Methods: (A) 6-month randomized placebo-controlled parallel design in an outpatient setting followed by (B) 6 month Open-Label Rollover Extension which will enroll all patients from study A.

Results: Study end points: As compared to placebo; Primary: 1. Less than 10% adverse event in the study population. 2. Arrest the decline of gFR as per NKF-USFDA guidelines. Secondary: 1. Improvement in any of the basic blood uric metabolic markers. 2. Improvement in any of the basic blood creatinine (CR) or creatinine clearance (CC); 3. Reduction in C-Reactive Protein (CRP) levels. 4. Percent change from baseline in rating scale (Modified SF36 QOL questionnaire) at the end of 6 and 12 month. Tertiary (IN FEW SELECTED SITES): Blood levels of Kidney Injury Molecule (Kim)-1, Neutrophil Gelatinase Associated Lipocalin (NGAL), gut microbiome derived uremic toxins: Indoxyl Sulfate (IS), para-cresyl sulfate (pCS) and Trimethylamine-N-Oxide (TMAO).

Conclusions: This is the first-ever clinical trial proposed using Pre/probiotics US-APR2020 as a Live Bio-Therapeutic drug product (LBP) for CKD IV patients. Being removable, the intervention avoids any possible infection. The addition of US-APR2020 with standard care of therapy may possess excellent potential towards CKD applications worldwide. Formal IND process under CBER/US FDA in progress. Seriously interested clinical PI’s please contact: ranganan@kibowbiotech.com

PUB037

Effects of Tolvaptan on Long-Term Prognosis in CKD Patients

Kazuhito Fukusaka, Yuko Shibata, Shinya Kaname, Kyorin University School of Medicine, department of Nephrology and Rheumatology Kyorin Daigaku, Mitaka, Japan.

Background: Tolvaptan is a novel diuretic agent used for the treatment of intractable edema and SIAOH in Japan, as well as polycystic kidney disease. Purpose: To determine whether tolvaptan prevent worsening renal function or prolongs the time to dialysis induction in pre-dialysis CKD patients.

Methods: A retrospective observational study (case-control study). Eligible patients were CKD patients treated with tolvaptan more than 30 days at our hospital between 2012 and 2018. The control patients were selected from CKD patients without the use of tolvaptan at our hospital that matched base line characteristics using the generated propensity variables. The endpoints were a decline in eGFR of more than 30%, introduction of dialysis, and death. The logistic regression analysis was performed on the indicator of the presence or absence of tolvaptan. Survival analysis was analyzed by the Kaplan-Meier method and tested with log rank, generalized Wilcoxon, and Tarone-Ware. The p-value for the statistic in (A) was 0.015.

Results: A total of 106 patients received tolvaptan during the study period, including 52 who met the study criteria. The median age was 65 years, the mean duration of treatment was 533 days, and the dose was 8.16 mg/day. Of these, 15 cases of diabetes and 6 cases of nephrosis. The normal patient group matched to these cases were CKD patients treated with tolvaptan more than 30 days at our hospital between 2012 and 2018. The control patients were selected from CKD patients without the use of tolvaptan at our hospital that matched base line characteristics using the generated propensity variables. The endpoints were a decline in eGFR of more than 30%, introduction of dialysis, and death. The logistic regression analysis was performed on the indicator of the presence or absence of tolvaptan. Survival analysis was analyzed by the Kaplan-Meier method and tested with log rank, generalized Wilcoxon, and Tarone-Ware. The p-value for the statistic in (A) was 0.015.

Conclusions: Tolvaptan was administered after hospitalization, with an 82.1% increase in urine output and a weight of -4.2% at discharge. The tolvaptan group showed significantly lower eGFR levels when compared to the control group. However, there was no significant difference in the incidence of introduction of dialysis and death between the two groups. Further studies are needed to confirm these findings in a larger population.

Serum Calcium Changes and Renal Function: A Dual Path Track
Julia Lauer, Tiago E. Costa, Giovanni G. Nascimento Santos, Rosa M. Moyse, Rosilene M. Elias. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: Although hypercalcemia is associated with an impairment of renal function, the literature is scarce in demonstrating this relationship in clinical practice. We hypothesized that fluctuations in serum total calcium (tCa) may impact renal function in patients with chronic kidney disease (CKD).

Methods: This is a retrospective study which enrolled 148 patients with at least 2 clinical appointments with concomitant tCa and estimated glomerular filtration rate (eGFR) measurement in the period between January-2017 and December-2019. We collected demographic, clinical, and biochemical data. Up to 3 consecutive measurements were analyzed.

Results: Patients were mostly Caucasian women, aging 66 ± 15 years. Mean eGFR was 45.1 ml/min/1.73m². Hyperparathyroidism (parathyroid hormone > 65pg/ml) was associated with a 2.8-fold increased risk for hypercalcemia (p=0.030). There was a non-linear relationship between change in tCa and change in eGFR, so that when tCa increased above the normal limit, there was a reduction in eGFR. Patients with hyperparathyroidism seem to present a significantly lower risk of impairment in eGFR in the consecutive measurements when compared to other causes of hypercalcemia.

Conclusions: The development of hypercalcemia in patients with CKD is associated with a deterioration of renal function. Therefore, the strict control of serum calcium is advised in these patients.

The Tri-POCUS Approach for Assessment of Volume Status in Critically Ill Patients with COVID-19
Abhilash Koratala,1 Claudio Ronco,2 Olanrewaju A. Olanye,1 Amir Kazory,1
1University of Florida, Gainesville, FL; 2Universita degli Studi di Padova, Padova, Italy; 3Medical College of Wisconsin, Milwaukee, WI.

Background: The volume status of patients with coronavirus disease 2019 (COVID-19) is dynamic and can range from severe hypovolemia (on initial presentation) to overt hypervolemia (after fluid resuscitation) due to its distinct clinical features such as cytokine storm. While lung point-of-care ultrasound (POCUS) is established as an invaluable bedside tool in assessment of volume status of the critically-ill, its use in this setting is limited by expanding lung infiltrates and a tendency for acute respiratory distress syndrome (ARDS).

Methods: We developed a combinational bedside ultrasound program to overcome the limitations of the individual methods of POCUS and provide a more precise evaluation of the volume status in critically ill patients with COVID-19. The Tri-POCUS approach represents concurrent bedside assessment of the lungs, heart (focused cardiac ultrasound [FoCUS]), and the venous system (blood flow pattern in the hepatic, portal and intra-renal veins) (Figure-1).

Results: In patients with COVID-19, distinguishing ARDS from cardiogenic pulmonary edema by lung POCUS alone is challenging due to several overlapping features. FoCUS allows for both static measures of preload as well as dynamic assessment (e.g. volume responsiveness to passive leg raise maneuver). Evaluation of blood flow pattern in the hepatic, portal and intra-renal veins not only can gauge fluid status but it also allows for direct assessment of the congestive state in end organs hence monitoring response to therapy.

Conclusions: The Tri-POCUS program is an extension of our previously published work focused on renal POCUS curriculum. The components of this combinational approach have been selected based on their ability to cover the limitations of each individual method and provide a synergistic effect, especially in clinical settings such as COVID-19 where there is a tendency for rapidly changing volume status confounded by distracting features (e.g. expanding lung lesions).

New-Onset Nephrotic Syndrome in a Child Associated with COVID-19 Infection
Siddharth A. Shah. University of Louisville, Louisville, KY.

Introduction: The COVID-19 outbreak has turned into worldwide public health emergency. The renal histo-pathological features of acute tubular necrosis or thrombotic microangiopathy are reported in adults previously with severe COVID-19 infections. In children, the renal manifestations associated with COVID-19 infection are not widely reported. Here, we describe a case report of a child with new onset nephrotic syndrome associated with COVID-19 infection.

Case Description: 8-year-old boy with no previous significant medical history presented with bilateral eye and facial swelling soon after his parents were diagnosed with COVID-19 infection. He had diarrhea but no fever or shortness of breath. One week after onset of swelling, the boy was also tested positive for COVID-19 infection. Based on clinical findings of significant proteinuria (Urine protein and creatinine ratio of 11.4), hyperalbuminemia (serum albumin of 2 g/dl), and hypercholesterolemia (Total Cholesterol of 384 mg/dl), he was diagnosed having nephrotic syndrome. He responded well to standard-dose prednisone treatment for nephrotic syndrome. In one week of starting prednisone treatment, he went into clinical remission. Lymphopenia continued to be present for 2 weeks after onset of symptoms. There were no complications related to clot formation or secondary infections with this presentation.

Discussion: This is the first case report to our knowledge of pediatric patient presenting with new-onset nephrotic syndrome associated with COVID-19 infection. Although, the burden of disease from COVID-19 is less severe in children, they can present with immune system related kidney disease like nephrotic syndrome. The patient responded well to standard-dose prednisone treatment used typically for new onset nephrotic syndrome.

Recurrent Arteriovenous Graft Thrombosis in COVID-19
Namratra Singhania,2 Saurabh Bansal,3 Girish Singhania,1
1CHI Saint Vincent Health System, Little Rock, AR; 2Mount Carmel East, Columbus, OH; 3University of Illinois at Peoria, Peoria, IL.

Introduction: COVID-19 has been associated with increased risk of hypercoagulability. We report a case of COVID-19-associated coagulopathy leading to recurrent arteriovenous (AV) graft thrombosis in an end-stage renal dialysis (ESRD) patient.

Case Description: 84 yo African American female with ESRD on dialysis via lower extremity AV graft, diabetes and atrial fibrillation on warfarin who was diagnosed with COVID-19 came back again 1 week later and was admitted due to hypoxemia. COVID-19 PCR was again positive. INR was 1.4, D-dimer 3.28mcg/mL, platelet count 114K/mm², mildly prolonged PT, aPTT. She had elevated venous pressures during dialysis. Doppler suggested AV graft thrombosis. Heparin drip was started. Angiography and intravascular ultrasound (IVUS) showed thrombosed AV graft. (Figure 1a,1b) Thrombectomy was successful (Figure 1c,1d) with uneventful hemodialysis afterwards. She was discharged. Next day, she came back again with diabetes. Coronavirus PCR was still positive. INR was 1.9. She again had high venous pressures. Doppler found recurrent thrombosis. Heparin drip was started. Vascular surgery placed dialysis catheter and held thrombectomy till her coronavirus PCR turns negative.

Discussion: Incidence of venous thromboembolism (VTE) can be as high as 58% in patients with COVID-19. All categories of ‘Virchow’s triad’ are involved, endothelial injury (increased cytokines and complements), stasis (immobilization) and hypercoagulable state (changes in prothrombotic factors). Risk factors are males, obesity, heart disease, hypertension, diabetes and ESRD. High D-dimer, mildly prolonged PT, aPTT and thrombocytopenia are common. Full-dose anticoagulation is recommended for documented VTE.
Manage of a Peritoneal Dialysis Unit During the COVID-19 Pandemic

Background: Peritoneal Dialysis (PD) patients are special, as they are mainly independent in a “life-support technique” but susceptible to various potential complications related. This pandemic brought new challenges and PD Units had to be reorganized considering their specific population, human and material resources. We aimed to understand the impact of our restructuration and discuss some lessons learned.

Methods: We retrospectively reviewed the activity and intercurrences at our Unit during the COVID-19 state of emergency declared by our Government, from 19th March to 2nd May (6 weeks), and compared it to the correspondent past two years (table 1). In a normal period, most of our patients are evaluated in a monthly basis. Simple descriptive and Student’s paired T-test analysis were performed.

Results: We managed 34 patients in the correspondent period of 2018, 36 in 2019 and 38 in 2020. Clinical appointments in this 2020 period were realized by phone. Necessary dislocations to the Unit in 2020 included peritonitis, exit-site infections and catheter malfunctioning. No dropouts occurred. There were no positive cases of COVID-19. Student’s paired T-test analysis between 2020 and 2019, plus 2020 and 2018, showed no statistically significant differences in every evaluated phenomenon (except for non-presential appointments; this discrepancy is justified by the Unit’s dynamic, without clinical implications).

Conclusions: Despite the restructuring, we were able to provide more teleassistance and the mean of complications/hospital admissions weren’t statistically worse. Some activities were postponed, but its true impact isn’t yet clear. Will suboptimal care bring long-term complications? Nonetheless, PD technique stands out for favorably, mainly if all the necessary support from medical and nurse staff is guarantee.

Activity and intercurrences at our PD Unit.

Figure 1. (A) GO enrichment analysis on biological process, (B) cell component, (C) molecular function of COVID-19-induced renal injuries; (D) Venn diagram for the cojoined target genes of COVID-19, CKD and AKI; (E) Underlying significant target genes of 8 active compounds.

Exploration on Renal Protective Compounds and COVID-19-Induced Renal Injuries Based on Network Pharmacology and Molecular Docking
Yue-Yu Gu,1,2 Min Zhang,1,2 Yifan Wu,1,2 Xusheng Liu.1,2 1Department of Nephrology, Guangdong Provincial Hospital of Chinese Medicine, Second Affiliated Hospital, Guangzhou, China; 2Guangzhou University of Traditional Chinese Medicine, Guangzhou, China.

Background: The fullscreen of COVID-19 is getting revealed as some of the infected patients had developed severe renal complications. Natural compounds may have protective effects against COVID-19-induced renal injuries. The aim of this study is to explore the interactions and underlying mechanisms between active compounds and COVID-19-induced renal injuries.

Methods: The interaction network of 8 collected natural compounds (Hederagenin, β-sitosterol, Luteolin, Quercetin, Kaempferol, Jaranol, Formononetin and Calycosin) and COVID-19-related target proteins was established by using the pharmacological database. GO and KEGG pathways were also analyzed. Molecular docking was run by AutoDockTools and Discovery Studio.

Results: 259 target genes are potentially related to COVID-19, AKI and CKD. Active compounds may improve COVID-19-induced renal injuries by alleviating the inflammatory response, vascular abnormal changes, cell apoptosis and necrosis in kidneys. The docking results had indicated that 8 compounds may show great possibilities to interact with SARS-CoV-2 main protease 3CL and ACE2 by showing significant binding energy.

Conclusions: Our study may provide molecular evidence and support on compounds from herbal medicines or dietary supplements may serve as potential perspective drugs to protect kidneys from COVID-19-induced renal injuries.

Funding: Government Support - Non-U.S.
Two doses of Tocilizumab (IL-6 inhibitor) were given. Patient improved significantly and PCR on four subsequent tests. She developed progressive hypoxia. Oxygen requirements removal because of pulmonary vascular congestion. She was positive for SARS COV-2 and bacterial infection. Maintenance hemodialysis was resumed with challenging fluid prominence; underlying pneumonia could not be excluded. Patient was admitted to and urine cultures showed no growth. Imaging showed prominent interstitial vascular 15.06, ferritin 2532, She was positive for both influenza and SARS COV-2 PCR. Blood chloride 96, bicarbonate 24, blood urea nitrogen 71, creatinine 13.5, C-reactive protein the exam was within normal limits. Laboratory results showed sodium 138, potassium 5.7, 102, RR 18, oxygen saturation of 99% on 2liters of oxygen. Examination revealed normal.

**Case Description:**

**Introduction:** We report a hemodialysis case having both influenza and COVID-19 who presented without respiratory symptoms and recovered fully with treatment by Interleukin-6 (IL-6) inhibitor.

**Case Description:**

68-year-old Caucasian woman with history of hypertension, diabetes mellitus, obesity, sleep apnea, atrial fibrillation, and ESRD on hemodialysis came to hospital with fever of 102°F. Her symptoms were fatigue, mental status changes, and decreased energy levels. There was no travel history and no contact with COVID positive or suspected COVID patients. On arrival to ER she had temperature of 99.4°F, bp 117/63, HR 102, RR 18, oxygen saturation of 99% on 2liters of oxygen. Examination revealed normal breathing sounds, no wheezing, and functional left forearm arteriovenous fistula. Rest of the exam was with in normal limits. Laboratory results showed sodium 138, potassium 5.7, chloride 96, bicarbonate 24, blood urea nitrogen 71, creatinine 13.5, C-reactive protein 15.06, ferritin 2532. She was positive for both influenza and SARS COV-2 PCR. Blood and urine cultures showed no growth. Imaging showed prominent interstitial vascular prominence; underlying pneumonia could not be excluded. Patient was admitted to COVID-19 isolation unit and empirically started on oseltamivir, Hydroxychloroquine, Zinc sulfate, vancomycin and, piperacillin-tazobactum for influenza, possible COVID and bacterial infection. Maintenance hemodialysis was resumed with challenging fluid removal because of pulmonary vascular congestion. She was positive for SARS COV-2 PCR on four subsequent tests. She developed progressive hypoxia. Oxygen requirements increased to 15 liters tolerant oxygen consistent with acute respiratory distress syndrome. Two doses of Tocilizumab (IL-6 inhibitor) were given. Patient improved significantly and discharged home with two SARS CoV-2 PCR negative results.

**Discussion:** Our case is unique of having both influenza and COVID-19 infection and improved. More studies are warranted to evaluate clinical benefit of the above therapies.

**Underlines represent presenting author.**
developed myalgia. There was no family history of myopathies, or binge alcohol intake beforehand. On physical examination, patient was hypertensive, euvolemic, and afebrile, with normal oxygenation. Chest x-ray showed subtle increased interstitial reticulosis in the perihilar regions and COVID-19 rapid test returned positive. Laboratory data showed very high creatinine kinase (CK) (208,456 U/L). Urinalysis showed trace proteinuria, large blood but only few red blood cells and confirmed myoglobinuria. However, his creatinine was normal (0.8 mg/dL), as well as serum calcium (8.4 mg/dL), phosphate (3.9 mg/dL), and uric acid (5.2 mg/dL) levels. Patient was admitted for treatment of assumed severe rhabdomyolysis. COVID-19 was treated conservatively with oxygen supplementation. Atorvastatin and diltiazem were held, and normal saline and isotonic sodium bicarbonate fluids were administered. CK continued to rise with a peak of 499,020 U/L on day 3, but decreased steadily to 58,745 U/L on day 7. Renal function remained stable all the time. The patient received a proper rise and fall of CK – without impacting renal function. As far as we know, this is the first case of COVID-19 associated rhabdomyolysis with peak CK of 499,020 U/L, without AKI and concurrent electrolyte abnormalities. The relationship to COVID-19 vs. individual genetic susceptibility remains to be explored.

**Discussion:**

There are increasing number of reports of COVID-19-associated rhabdomyolysis, but risk factors and characteristics are fairly known. The clinical and laboratory manifestations are suggestive of COVID-19 associated rhabdomyolysis rather than statin-induced. We are not aware of any other reports documenting such extreme CK values – with a proper rise and fall of CK – without impacting renal function. As far as we know, this is the first case of COVID-19 associated rhabdomyolysis with peak CK of 499,020 U/L, without AKI and concurrent electrolyte abnormalities. The relationship to COVID-19 vs. individual genetic susceptibility remains to be explored.

**CKD Patients on Hemodialysis (HD) with COVID-19 Infection: Characteristics and Outcome**

**Background:** The COVID-19 pandemic has special significance for Chronic Kidney Disease patients on HD. Clinical characteristics and outcome from low resource settings are not well known.

**Methods:** From March 15 2020 until May 20, 2020, quality managers reviewed all patients with confirmed COVID-19 infections in 200 HD centres among MHD patients. For patients with COVID-19 infections: age, gender, geographical zone, type of Insurance, continuity of care was noted, HD characteristics and outcome were reviewed. Comparison of median was done with Mann Whitney-Wilcoxon 2 sample test and proportion with Fisher exact test. All patients were transferred to public hospital for regulatory compliance limiting follow up of HD sessions.

**Results:** 39 out of 18402 patients developed COVID-19 infection. M: F: 28: 11; Age: 54.62 ± 14.92 years. Geographically: East zone:3(7%), North:12(31%), South:5(12%), West:19(50%). Payers: self pay:19(49%), government insurance:15 (38%) and private Insurance:5(13%), 32(82%) Hypertensives, 23(59%)diabetics. Outcome: 8(20%) expired, 18(46%) discharged, 12(31%) in hospital and 1 at home. Mean Hb (77%): 9.81 ± 1.71 g%, Adequacy (74%): 1.30 ± 0.44, Vascular access (72%): 75% permanent access, 7% temporary catheter, 18% tunneled catheter, Albumin (64%): 3.69 ± 0.31.

**Conclusions:** Maintenance HD patients have increased mortality as compared to reports in normal population and is associated with need for intensive care, steroid use and ventilatory support.

Comparison of survivors and non-survivors in maintenance HD patients with COVID-19 infection

**PUB049**

**Starvation-Induced Metabolic Acidosis in a COVID-19-Infected Pregnant Patient**

Muhammad R. Mustaf}. Stony Brook University, Stony Brook, NY.

**Introduction:** Suffolk County in NY was hardest hit with COVID 19. We present a case of a pregnant female with COVID 19 infection and high anion gap acidosis.

**Case Description:** 34 yo female, 33 weeks twin pregnancy, a/w fever, SOB and polyuria. Her oral intake was poor. She was positive for COVID 19. Her T - 100.4°F, sat 99% with O2 by NC at 2 L. She had bibasilar crackles. Both babies were moving. CXR showed multifocal pneumonia. Nephrology was consulted for metabolic acidosis.

A diagnosis of starvation ketosis of pregnancy was made due to anion gap acidosis, high serum beta-hydroxybutyrate and ketonemia. Dextrose 5% with sodium bicarbonate was given. She had C section, remained intubated for 24 hours, recovered well and was discharged on hospital day 7.

**Discussion:** Almost 15% of pregnant patients develop server COVID 19. Pregnant patients with COVID infection are a higher risk group.
Kidney Transplantation in the United States During the Coronavirus Disease 2019 Pandemic: An Interrupted Time Series Analysis
Ekamol Tantisattamo,1,2 Natnicha Leelaviwat,3 Sakrdit Saowapla,3 Natchaya Polpichai,2 Busara Songtanin,3 Possawat Vutthivongkiet,3 Chawit Lopipinsuth.3 Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California, Irvine College of Medicine, School of Medicine, Orange, CA; 4Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 5Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 6Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand.

Background: The number of kidney transplant (KT) in the United States (US) has decreased during COVID-19 pandemic; however, the magnitude of this impact is unclear.

Methods: A period from January 5 to April 18, 2020 was divided into pre- and post-COVID-19 periods by assigning March 1, 2020 as the first day of the post-COVID-19 outbreak in the US. The number of waitlist candidates (WLC) and new KT every 7 days were obtained from OPTN/SRTR. An interrupted time series analysis was performed to examine an incidence rate ratio (IRR) between pre- and post-COVID-19 period by using multiple Poisson regression.

Results: Compared to pre-COVID-19 period, the average number of new KT during post-COVID-19 period decreased (479±3 vs 318±119 cases/week, mean differenceSEM 161±44, 95%CI 67, 255). The number of WLC was relatively stable (mean±SD 65,937±959 cases/week); whereas, it decreased during post-COVID-19 period (61,759±2203 cases/week). Mean incidence rates (IRR) of new KT during pre- and post-COVID-19 periods were 727±58 and 511±176 cases/FWC-week, respectively (Figure 1). The IR of new KT during post-COVID-19 period was 29% lower than those during pre-COVID-19 period (IRR 0.71, 95%CI 0.96, 2.60, 2.63). After adjusted by age group, transplant areas, and time-study period interaction term, the IR of new KT was 3% increase for every one more week during pre-COVID-19 period (IRR 1.03); whereas, there were 12% decrease for every one more week after March 1, 2020 (IRR 0.88). Compared to pre-COVID-19 period, the IR of new KT during post-COVID-19 period was 9% lower for every additional week for each corresponding period (IRR 0.91).

Conclusions: COVID-19 outbreak in the US since March 2020 is an independent factor of a significant decline in the number of new KT. Further information regarding ability of control COVID-19 may direct KT.

Spectrum of AKI in Patients with COVID-19 Infection

Introduction: With the gradual unfolding of the full spectrum of COVID19 manifestations, Acute Kidney Injury (AKI) is emerging as a frequent association & a predictor of disease severity & mortality. We present 3 cases of AKI in COVID19 patients & illustrate the clinical course, management & outcome.

Case Description: The first case was a 50-yr-old male with DM, HTN, & obesity, admitted with pneumonia, dyspnea & diarrhea, developed hypotension, arrhythmia, & required intubation on day 31 of admission. The next case was a hypertensive, obese 57-yr-old female, admitted with pneumonia, worsening dyspnea & respiratory failure without hypotension, was intubated on day 30 of admission. Both of the cases developed AKI with oliguria & progressed to anuric 24 hrs post-intubation. Case 3 was a 72-yr-old female with hypothyroidism admitted with pneumonia, dyspnea, diarrhea, & AKI, was intubated on day 12. All cases had bilateral pneumonia on chest radiograph & significantly raised inflammatory markers (CRP, LDH, Procalcitonin, Ferritin, ALT/AST, d-Dimer, & INR). Peak S. Creat. was 4.1, 6.6, & 3.07 for cases 1, 2, & 3 respectively. Urinalysis for all cases revealed proteinuria, hematuria, pyuria, >4+ prealbumin, and 2+ of UTI for cases 1 & 2. Ultrasound revealed structurally normal kidneys for all cases. Case 1 & 2 were diagnosed as stage III AKI & Case 3 with stage II AKI. All cases received some form of antibiotics, hydroxychloroquine, & heparin for COVID19 and CVVHD for renal support thereafter for case 2. Glomerulonephritis specific work-ups could not be done due to the patient’s clinical status. Among the cases, case 2 made full recovery & discharged, case 1 was stable but hospitalized, case 3 expired on day 14 of hospitalization due to multiorgan failure.

Conclusions: Our cases highlight the inherent variability in causation & clinical course for AKI in COVID19. Interestingly, all 3 cases had the full spectrum of kidney involvement from proteinuria, hematuria to AKI. Although difficult to discern in the absence of biopsy, some potential causes of AKI in these patients include ischemia (renal artery stenosis, hypertension), drugs, cytokine storm syndrome (case 3), or direct COVID19 induced acute tubular injury. Increased vigilance is required to recognize probable causes for AKI and to develop adequate management protocols to limit AKI-related morbidity or mortality.

COVID-19 Infection in Renal Transplant Patients

Background: The SARS CoV-2 pandemic has disproportionately affected vulnerable patient populations including kidney transplant recipients (KTR).

We present 3 cases of AKI in COVID19 patients with high rates of co-morbidity and social deprivation, and provides follow-up care for approximately 1500 kidney transplant recipients. In line with national guidance, COVID-19 testing was largely restricted to those patients presenting to secondary care. When COVID-19 was confirmed or suspected, anti-protiferative drugs were stopped, maintenance corticosteroids increased, and calcineurin inhibitor was stopped in patients requiring admission. We performed a retrospective analysis of clinical presentations and outcomes in kidney transplant recipients with confirmed COVID-19 between 20th March and 31st May 2020.

Results: 25 patients (approximately 1.6%) had confirmed COVID-19. 11 (44%) were female and 14 (56%) male. The median age was 61 years (range 33 – 84 years). 11 (44%) were White - British, 12 (48%) Asian and 2 (8%) Afro-Caribbean. Median time post- transplant was 84 months (range 6 – 360), and more recently transplanted patients were not at increased risk. Respiratory symptoms were the predominant presenting complaint in 19 patients (76%) followed by GI symptoms in 4 (16%). Acute kidney injury (stages 1-3) occurred in 15 patients (60%) with 7 patients (28% of whole population 46% of patients with AKI) requiring renal replacement therapy. 6 patients (40%) recovered renal function at a median follow up period of 28 days (range 14 – 41) without adverse events. 4 (16%) were admitted to ITU for ventilation. 10 patients (40%) died (although one death was not related to COVID-19). Among the patients who died, median age was 65 years and 6 (60%) were male with ethnicitly proportionate to the study population.

Conclusions: The strategy of performing COVID-19 testing only in patients requiring secondary care likely i) underestimates the incidence and ii) overestimates the disease severity. However, our data show that COVID-19 confers significant morbidity and mortality in kidney transplant recipients despite prompt reduction of immunosuppression. These data will inform a revised consent process for those patients awaiting kidney transplantation. Follow up studies are required to assess longer term outcomes, and potential complications in KTRs who have recovered from COVID-19.

COVID-19 Induces a Wasting Syndrome in Hemodialysis Outpatients
Rebecca D. Monk,1 Kristian Vitu,1 Samantha J. Mauser,1 Jaime L. Oenell,3 1University of Rochester Medical Center, Rochester, NY; 2University of Rochester, Rochester, NY; 3Fresenius Medical Care North America, Welham, MA.

Background: COVID-19 (COV) has infected 2852 residents of Monroe County with a death toll of 218 to date. Hemodialysis (HD) patients (pts) are at high risk for developing COV due to multiple comorbidities. Many patients also reside in Skilled Nursing Facilities (SNF) which have high infection rates. One single Fresenius Medical Care (FMC) dialysis facility in the Rochester, NY area with no Tues/Thurs/Sat (TTS) shifts became the designated unit to provide maintenance HD for all COV positive (+) pts in our region until they had 2 negative COV tests. This is a quality improvement review of our patients.

Methods: The study included all 18 pts thus far who received at least one HD treatment in our COV + unit. Demographics and labs – 2 months prior to their first COV test and during the first month in our COV unit were analyzed and compared with data from the 33 COV negative (-) Mon/Wed/Fri (MWF) patients in the same facility. Paired and unpaired T tests were used to determine the statistical significance of observed differences in weight (wt) and labs pre and post COV+ and between COV+ and - pts.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ERSD. 3 initiated HD in the last 2 months. 8 pts were on HD ≤ 1 yr. 11 were hospitalized, 3 were intubated and 2 died. 78% had DM. Compared to 2 months prior to COV + testing, pts lost a mean wt of 8 ± (± 1.8) kg in the first month in our COV + unit (p = 0.0002). Albumin decreased from 3.75 ± (± 0.60) to 3.33 ± (± 0.54) (p = 0.0005) and ferritin rose from 753 ± (± 512) to 1526 ± (± 1147) (p = 0.0019). Potassium and Phos did not change. COV - pts lost no wt. Ferritin was higher in COV + pts (1526 vs 993, p = 0.026). Mean time to first neg COV test was 26 days (range 13 - 55). Importantly, no MWF pts or any staff became COV + during the 2 months of caring for COV+ TTS pts.
Conclusions: While respiratory symptoms of COV are often stressed we noted few symptoms of other diseases. The severity of proteinuria and renal injury observed in this clinically asymptomatic patient highlight an unusual infection-driven mechanism.

AKI in Hospitalized Patients with COVID-19: A Mexican Population

Víctor H. Gomez-Johnson,1 Gina C. Gonzalez-Calderón,1 Antonio Camiro Zúñiga,2 José A. García Gordillo,3 Adolfo Díaz Cabral,1 Alfredo Fonseca Chávez,1 Julio C. Arriaga,1 Jose S. Lopez Gil,4 Javier Zúñiga-Varga,1 Juan Pablo Herrera Felix.1 1Centro Medico ABC, Mexico City, Mexico; 2 Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: Although severe acute respiratory syndrome coronavirus (SARS-CoV-2) infection is primarily a respiratory disease, other organs are also affected. Several pathological studies confirm that SARS-CoV-2 invades kidney tissue causing endothelial damage, glomerular and vascular changes, extensive acute tubular injury and podocyte viral infection. AKI in COVID-19 appears to be frequent, with an AKI incidence of up to 46%, and a 20% requirement for renal replacement therapy (RRT). Patients with AKI show a trend towards worse outcomes and increased mortality. Information on Latin-American population is scarce.

Methods: We created a cohort to describe the incidence, risk factors, and outcomes associated with AKI in hospitalized patients with COVID-19 in Mexico City, excluding patients with a known chronic kidney disease. AKI was defined and classified according to KDIGO guidelines.

Results: We included 127 patients. 11 patients (8.66%) met the criteria for severe COVID-19, and were more likely to have AKI (81.82% vs. 54.31%, p=0.078). Of the 72 (56.69%) patients that had AKI, 48% were diagnosed at the time of admission. Patients with AKI were more likely to be men (61.7% vs. 42.2%, p=0.043) and older (55.68 years vs. 48.89 years, 0.018). With regards disease severity, 72% of them had a grade 1 AKI. 7 patients (9.72%) had grade 3 AKI, 4 of which needed renal replacement therapy. Overall length of stay was longer in patients with AKI (12 days vs. 7 days, p=0.003). A nonsignificant trend towards stay in critical care units was observed. 3 out of 127 patients died, all 3 had AKI.

Conclusions: Amongst our studied population, AKI was associated with a longer length of stay and with a trend towards a more use of critical care services. The lack of association of AKI with mortality could be due to the low overall in-hospital mortality of COVID-19 patients (2.4%).

AKI Lingering in a Patient with Novel Coronavirus

Marc Saad, Brandon Kirshner, Reuben K. Ellis. Mercer University, Macon, GA.

Introduction: Renal manifestations of the novel Coronavirus infection has been reported during the actual pandemic. While the renal injury was more pronounced in critically ill patients, the levels of AKI, proteinuria and hematuria predicted the severity of the infection. We are reporting a severe case of AKI and proteinuria with SARS-CoV-2 infection out of proportion of its clinical manifestation.

Case Description: This is a 55 year old African American male patient with PMH of hypertension, aortic valve replacement on Warfarin, anticoagulation and CKDI-II b with baseline eGFR of 50 ml/min/1.73m2 (creatinine of 1.5 mg/L) and recent diagnosis of COVID-19 related gastroenteritis 10 days prior to presentation, was admitted with general malaise and decreased intake. He had no cardiac nor respiratory symptoms. He was afebrile and physical examination was non remarkable. His labs were significant for BUN of 129 mg/dL and creatinine of 22.0 mg/dL. His blood glucose was 88 mg/dL. Urinalysis showed glucose 100 mg/dL, 0-3 RBCs, 10-10 WBC with a protein/creatinine ratio of 12.8 mg/g. His renal ultrasound showed increased cortical echogenicity with edema. His serological workup was unrevealing with negative hepatitis B and C testing, low ASO levels, negative ANA, Anti-PR3, Anti-MPO and Anti-GBM antibodies. He had normal C3, C4 and negative serum immunofluorescence with free kappa/lambda ratio of 1.7. His Alb was 1.7g/dL with triglycerides levels of 184 mg/dL. A kidney biopsy was deferred for its high complication rate. The levels of AKI, proteinuria and hematuria suggested the severity of the infection. We are reporting a severe case of AKI and proteinuria with SARS-CoV-2 infection out of proportion of its clinical manifestation.

Discussion: Variable histopathological lesions (FSGS, collapsing glomerulopathy, podocytopathy and tubular interstitial disease) has been described in the renal manifestations of the novel coronavirus. While its physiopathological mechanisms remain unclear, the severity of proteinuria and renal injury observed in this clinically asymptomatic patient highlight an unusual infection-driven mechanism.

AKI Patients with COVID-19 and Kidney Disease: Who Fared Best?

Micaela Antionus, David Jackson, Sadananda V. Athial, Michael T. Shiel, Huw Davies. Swansea Bay University Health Board, Swansea, United Kingdom.

Background: COVID-19 poses the greatest global challenge in modern day healthcare. Chronic Kidney Disease (CKD) patients are classed as ‘high risk’ in terms of the morbidity and mortality associated with COVID-19. We present data from a large centre encompassing a 24-bed inpatient renal ward, 2 in-centre haemodialysis (HD) units and a large ITU. We aim to compare and contrast clinical outcomes for COVID-19 patients with renal disease.

Methods: Observational analysis was performed on 61 patients (mean age 65y), all positive for COVID-19. Patients were stratified according to their renal status at the point of contracting the virus (table 1).

Results: Acute Kidney Injury (AKI) (n=24; mean age 67y) – 23 of 24 patients were intubated and ventilated in ITU. 18 died. 4 remain on haemofiltration (1 patient transplanted for Extracorporeal Membrane Oxygenation). Only 1 patient required ventilatory support and survived with resolution of the AKI. 1 patient requiring invasive ventilation survived with recovery of renal function. Chronic HD (n=20; mean age 68y) – 20 prevalent adult HD patients tested positive for COVID-19. 10 recovered and discontinued HD. 10 died. Kidney Transplant Recipients (KTR) (n=4; mean age 59y) – 3 were managed as outpatients and have recovered with functioning grafts. 1 died.

Conclusions: AKI patients had the poorest outcomes in terms of need for ventilatory support and mortality. 50% of chronic HD patients with COVID-19 died. Despite immunosuppressants, only 4 KTRs (total cohort of 352) contracted COVID-19. The introduction of virtual transplant clinics, minimisation of face-to-face contact and efforts on shielding may have influenced this. These data aim to reinforce the international collaborative against this global pandemic.

COVID-19: Angiotensin Receptor Blocker to the Rescue?

Srikanth Thiruvordutho, Theesitha Srikant,2 Lewis Katz School of Medicine at Temple University, Philadelphia, PA; 2Sichuan University West China Medical School, Chengdu, China.

Background: An unusual suspect has been incriminated in the Coronavirus outbreak, Renin-angiotensin-aldosterone system (RAAS). RAAS is an intriguing system that holds many mysteries that are still waiting to be unraveled and explored.

Methods: Angiotensin-II (Ang II) is well known for its proliferative and vasoconstrictive effects and the important role of ACE2 in controlling Ang II formation and angiotensin receptor blockers (ARB) for inhibition of Ang II receptor binding. Angiotensin-1-7 (Ang 1-7) along with ACE2, in the other hand, known to have vasodilatory, antiproliferative and overall protective effects. Given the beneficial effects of ACE2 and Ang 1-7, it would make sense to potentiate this pathway for our sake, especially in the setting of lung injury.

Results: In the recent years, it’s been shown that Coronavirus is not only using the ACE2 to enter the cell, but also decreasing ACE2 expression at the same time. This is detrimental. ACE2 expression seems to be decreased in elderly and elevated in obese. It is very interesting to see that COVID severity varied among these individuals, likely due to the precarious balance between the amount of viral entry and activity of ACE2/ Ang-1-7. If we can upregulate the expression of ACE2 by some mechanism, this would in turn increase the production of beneficial Ang 1-7. But with upregulated ACE2, one must make sure that there is a competitive substrate for ACE2, in order to make the Coronavirus binding of ACE2 difficult. A suitable candidate for that substrate, is Ang II, ARB, as opposed to ACE1, would seem to increase the levels of Ang II, while upregulating the expression of ACE2. Theoretically, we could reap the benefits of enhanced ACE2 expression while competitively inhibiting Coronavirus binding to ACE2, by the increased levels of Ang II. Titrating up ARB dosing as tolerated by the patient, will be necessary for the above mechanism to work effectively.

Conclusions: Increasing ACE2 and Ang 1-7 receptor binding, will determine the degree of benefit of ARBs in diminishing Coronavirus infectivity and severity. Tolerability to ARBs, will also be a limiting factor when treating the patients. Studying ACE2 levels, Ang 1-7/Mas receptor activity in different patient populations and the correlation between Coronavirus infection and severity, would be of value in the forthcoming months in the world of RAAS.

COVID-19 Financial Ramifications on the Pediatric Nephrology Workforce
Darcy K. Weidemann, Allison C. Redpath, Isa Ashoor, Children’s Mercy Hospitals and Clinics, Kansas City, MO; University of Missouri Kansas City, Kansas City, MO; LSU Health New Orleans, New Orleans, LA; University of Wisconsin System, Madison, WI.

Background: The adverse impact of the COVID-19 pandemic on state and federal budgets, coupled with widespread lockdown measures, and reduced non-COVID-19 clinical volume has forced healthcare and academic organizations to adapt to declining revenues. We examined the financial ramifications of the pandemic on the pediatric nephrology workforce.

Methods: Online survey distributed to active members of the American Society of Pediatric Nephrology (n=997) over 2 weeks in May 2020.

Results: Response rate was 16% (n=144). Most respondents (34%) were 35-44 years old, followed by 45-54 years old (24%). Most were White (65%) followed by Asians (24%). Respondents resided in the South (31%) followed by the Northeast (29%) and Midwest (22%). Most were faculty (92%) in early career stage (Assistant Professor, 31%), affiliated with a free-standing children’s hospital (55%) or a children’s hospital within an adult hospital (36%), working full time (79%) with an average of 60% effort dedicated to clinical activities. Most acknowledged feeling worried about the long-term financial ramifications of COVID-19 on their employer (88%) and their own financial future (75%).

Figure 1 summarizes the financial repercussions reported. The majority (47%) were unclear whether they will be expected to assume increased clinical duties once stay-at-home orders are lifted, however, 44% reported new childcare or eldercare responsibilities.

Conclusions: Overwhelming concern regarding employee and employer financial security exists among practicing pediatric nephrologists in the context of the COVID-19 pandemic. Uncertainty, institutional hiring freezes, compensation reduction, and increased duties in one’s personal life all pose additional threats to a specialty with an already looming workforce shortage. Comprehensive strategies to prevent attrition and burnout are required to sustain the pediatric nephrology workforce during recovery from the COVID-19 pandemic.

Not All Coronavirus a Patients Are Dying from Broncho-Pneumonia:
Most Might Be Dying from Cerebro-Neurologic-Vascular Diseases and Cardiovascular Complications
Yahya Sagliker, Hasan S. Sagliker, Piril Sagliker Ozyaknak, Nuray Paylar, Sagliker Nephrology and Hypertension Unit Cukurova Universitesi Tip Fakultesi, Adana, Turkey; Sagliker Nephrology and Hypertension Unit, Adana, Turkey; Ceyhan State Hospital, Ceyhan, Turkey; Karlova State Hospital, Bingol, Turkey; Karaisali Community Health Center, Adana, Turkey.

Introduction: Acute bronchopneumonia is not sufficient to explain deaths. Lungs, brain-nerves - heart- cardiovascular system might be playing key roles. Three are playing together. In last days, lungs and brain and heart suddenly are stopping.

Case Description: Key places are neurological conjunction systems between brain, lungs and cardiovascular systems. All organs are being regulated by last two systems. All mentioned activities are being regulated in those systems. All decisions and functions of human are giving there

Discussion: A neurologist and a cardiologist must be involved in treatment in late stages. This is vital. 1-Pulmonologists are following lungs. 2-Pulmonary-toracal surgeons should think two sided bronchial tubes from outside. 3-Cardiologist must follow EKG continuously. Echocardiography must be performed every day. They must know well inside of heart and must question which drugs are taking. 4-Neurologists must perform MRG for brain, back lower brain and should make EEG, every day. AFFECTION-REACTION-EFFECTING-INFORMING BACK rules must be controlled. They must detect neurotransmission system is from top to bottom as I have written above like so called zig-zig-zig system or reverse neurotransmission system is occurring as zig-zig-zig system to destroy body. If it is so this strange system can be called from now on in "SAGLIKER'S REVERSE NEUROLOGICAL WORKING SYSTEM."

A Case of Novel Coronavirus Disease 19 in a Chronic Hemodialysis Patient with Severe Cardiovascular Disease
Weichen Zhang,1 Huazhou You,1 Li Yuan,2 Min Song,2 Kangjie Wang,1 Shengjing Li,1 Yijian Chen,4 Li Ni,1 1Department of Nephrology, Huashan Hospital Fudan University, Shanghai, China; 2Department of Nursing, Huashan Hospital Fudan University, Shanghai, China; 3Department of Pulmonary and Critical Care Medicine, Huashan Hospital, Fudan University, Shanghai, China; 4Institute of Antibiotics, Huashan Hospital, Fudan University, Shanghai, China.

Introduction: Patients on maintenance hemodialysis (MHD) are vulnerable to COVID-19. MHD individuals are usually old with chronic comorbidities while these features are all risk factors of poor prognosis.

Case Description: Our patient was a 79-year-old female with ESRD and had been on MHD for 12 years in Wuhan. She had a history of severe coronary heart disease. The patient firstly reported fever, chest tightness and cough. One week later, she developed diarrhea and the chest CT indicated “viral pneumonia”. Her COVID-19 testing was reported positive, and she was admitted to the hospital with SpO2 of 92% and high level of hs-CRP, cardiac troponin I (TNI) and creatine kinase MB isoenzyme. She was prescribed oxygen therapy, methylprednisolone, intravenous immunoglobulin, prophylactic anticoagulation and CRRT therapy. Her respiratory condition improved gradually and COVID-19 testing showed negative. However, on admission day 19, the patient presented psychiatric symptom, and was considered as secondary higher-level cognitive impairment since she received regular CRRT therapy without using drugs which could cause mental disorders. Two days later, her chest X-ray showed lung infection advanced with increased hs-CRP and PCT indicating bacterial infection. We prescribed meropenem and vancomycin. Meanwhile, there was an increasing trend of TNI, and electrocardiogram indicated acute coronary syndrome (ACS). Clopidogrel, aspirin and atorvastatin were prescribed immediately. Unfortunately, on admission day 22, the patient suffered cardiac arrest and was declared dead after active rescue. The cause of death was considered as cardiogenic shock and ACS.

Discussion: To our experience, personalized immunomodulation therapies against “cytokine storm” including steroid, intravenous immunoglobulin and CRRT might play...
Pink Urine in a Patient with COVID-19

Mengqin Ma, Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.

Introduction: Pink urine syndrome has been reported as a rare symptom described after surgery and propofol anesthesia. COVID-19 is not only manifested as a respiratory disease characterized by viral pneumonia, but also damage such as kidney, heart, blood and nervous system especially in severely ill patients.

Case Description: A 56-year-old man was diagnosed as severe COVID-19. He was admitted to ICU and underwent the tracheal intubation. During this treatment, propofol was used to sedate. He suddenly excreted cloudy pink urine on that day (Figure 1). There were some pink crystals in the urine bag and pink sediment at the bottom of the urine bag (Figure 2, Figure 3). His urine dipstick showed a specific gravity of 1.02, pH 5.5, blood (1+) and protein (1+). He had no urinary tract symptoms and his urine cultures were normal. His blood gas analysis showed pH was 7.3. His colour of urine gradually returned to normal when the patient was given intravenous Sodium bicarbonate injection.

Discussion: Pink urine syndrome is a phenomenon in which uric acid precipitates into the urine due to reduced urinary pH. Propofol can increase the excretion of uric acid in the urine. Lower urine pH will reduce the solubility of uric acid crystals, promoting the formation of amorphous uric acid crystals, which exhibit a characteristic pink color. At the same time, metabolic acidosis may aggravate this phenomenon. COVID-19 has been reported to invade cells mainly through ACE2 receptors, ACE2 receptor is strongly expressed in the proximal tubule of the kidney, causing acute tubular necrosis. It has suggested that the kidney is one of the main targets of COVID-19. While considering the pink urine syndrome might caused by propofol, we speculate that COVID-19 could damage the renal tubule which affect its reabsorption of uric acid, which may worsen the uric acid crystallinity.

Urinary Abnormalities and Urinary Sediment Findings in COVID-19 Patients

**Background:** Coronavirus disease 2019 (COVID-19) is a new disease of pandemic proportions. There are only a few reports about urinary abnormalities in this disease, and to our knowledge there are no reports about the usefulness of urinary sediment on prognosis. Our aim was to describe the urinary abnormalities in COVID-19 and to assess the utility of urinary sediment on prognosis in COVID-19.

**Methods:** Prospective, single-center study, in patients diagnosed with COVID-19 (with a positive RT-PCR test), who were admitted to our hospital, from April 2020 to date, and whose urine sample could be obtained at admission to the isolation wing.

**Results:** 22 patients were included. 17 (77.3%) had proteinuria, 12 (54.5%) had microscopic hematuria, and 9 (40.9%) had leukocyturia. Granular casts (with a Chawla cast scoring index greater than 3) were present in 8 (36.4%) patients. Of the 8 patients with granular cast, 6 developed an AKI (75%), 2 required hemodialysis (25%) and 3 died (37.5%). Of the 14 patients whose urinary sediment was classified as bland, 5 developed an AKI (35.7%), none of them required hemodialysis, and 2 subsequently died (14.2%).

**Conclusions:** The urinary sediment is a cheap, available tool for the prognosis of need for hemodialysis or death in patients diagnosed with COVID-19, and should be taken into consideration in the assessment of these patients by the Nephrology department.

**PUB066**

Repurposing Baby Monitors in COVID-19

Sobia N. Khan, Sandeep K. Mallipattu. Stony Brook University, Stony Brook, NY.

**Introduction:** As of May 2, total of 1,130,075 confirmed cases resulting in 65,605 deaths were reported in US. Nearly 3.2% of individuals with COVID-19 develop AKI and have been reported to require dialysis. Initial reports from Wuhan, the burden of acute kidney injury was relatively low, about 3% -9%, subsequent analysis have demonstrated increase in the incidence to 15%.

**Case Description:** In February, 376 hemodialysis and 59 CRRT while in March, 273 hemodialysis and 30 CRRT offered in our hospital. During pandemic bed capacity doubled from 650 to 1317 beds. Physical space gained by converting ambulatory surgical centers and ambulatory locations. In April, observed 1,811 COVID-19 patients admitted within; B) a granular cast with several isomorphic erythrocytes.

To minimize the risk of exposure in COVID-19 isolation rooms we implemented telemonitoring strategy. We identified baby monitors could serve “read-to-go” telemonitoring. VTech Baby Monitor 7” display. HD camera uses WiFi connection to capture movements and sounds which helps in monitoring the patients in real-time. The camera ability to pan 360 degrees, tilts 82-degrees and zooms ten times to enable viewing of the dialysis monitor and patient. Two-way voice communication allows easy communication between patient and nursing. Before hemodialysis nurse sets up camera by the patient’s bedside (1 camera facing the dialysis monitor other camera facing patient and the dialysis access). Dialysis nurse visualize through the handheld monitor. Telemonitoring system COVID-19 patients undergoing hemodialysis we observed zero positive COVID-19 dialysis staff
Impact of Ethnicity on COVID-19 Infection and Mortality Amongst In-Centre Haemodialysis Patients
Gregor D. Young, Noam Roth, Kieran McCafferty, Suzanne H. Forbes, Andrea Cove-smith. Royal London Hospital, London, United Kingdom.

Background: It is reported that patients of BAME origin are at greater risk of infection and death due to COVID-19. We describe outcomes in an inner city, ethnically diverse in-centre haemodialysis (HD) population during the pandemic.

Methods: A total of 1253 patient electronic records were analysed retrospectively. 207 infections were recorded -197 patients tested positive for Sars-Cov-2 on validated nasopharyngeal PCR analysis and 10 patients included due to high clinical suspicion. Ethnicity data is self-reported. All COVID-19 positive patients were isolated for subsequent dialysis sessions. Whole-cohort screening confirmed the rates of infection.

Results: Overall rate of infection amongst the group was 16.5% (n=207), hospitalisation 7.5% (n=94) and death 3.5% (n=44). Within COVID-19 infections, hospitalization rate was 45% and mortality 21%. Seven patients received critical care and two were intubated. Ethnicity data are shown in table 1: There was no significant difference in rates of COVID infection between ethnic groups. The risk of infection in BAME patients was not significantly greater than in white patients (p=0.24, OR 0.79, 95%CI 0.55-1.14). The mean age of those who died from COVID did not differ from the entire cohort (62 vs 63.2 years). Males made up the majority of both the baseline cohort (61.2%) and those infected with COVID (58.5%). 71% of those who died were male. Body mass index did not differ between the group as a whole and those infected with COVID. Rates of diabetes mellitus did not differ significantly between those infected with COVID and those who died.

Conclusions: We have defined COVID infections and outcomes within a real-life, large haemodialysis population. Hospitalisation and mortality rates were high, and patients self-reporting as black or Asian were over-represented in the infected group compared to the baseline prevalent HD population. Higher rates of death were observed in black and asian groups but conclusions are limited by small numbers. Larger collaborative studies are required to expand on these findings.

COVID-19 Management in New York City Kidney Transplant Recipients: Before and After the Apex

Background: Kidney graft recipients receiving immunosuppressive therapy may be at heightened risk for Covid-19 and adverse outcomes. We aimed to study how practice patterns and outcomes changed before and after the peak incidence of cases in New York City.

Methods: We reviewed 68 consecutive adult kidney graft recipients from our center diagnosed with SARS-CoV-2 from March 13, 2020 to May 25, 2020. We compared outcomes of those treated from March 13 until the apex of infections on April 14 (Phase 1), and those treated from April 15th to May 25, 2020 (Phase 2).

Results: Characteristics of both Phase 1 and Phase 2 patients are described in Table 1. Inflammatory markers were lower in the second phase as was patient mortality. Changes in management strategies between the two phases are highlighted in Figure 2. Graft loss occurred in 4 patients (6%) and there were 5 deaths (7%).

Conclusions: Data from our study suggest that management strategies of immunosuppressed patients changed over the course of the Covid-19 Pandemic in New York City, including less use of hydroxychloroquine, and increased use of novel agents such as remdesivir. Additional data are needed to better understand if the decrease in patient mortality during the second phase is attributable to better management or lower inflammatory response in the setting of Covid-19 illness.
Effect of COVID-19 Infection in Three Patients Treated with Rituximab

Anushya Jevabalan, Reza Zonoozi, Jillian Rosenthal, Karen A. Laliberte, John Niles. Massachusetts General Hospital, Boston, MA.

Background: Rituximab (RTX), a monoclonal antibody against the CD20 antigen found on B lymphocytes, is widely used for glomerular diseases. It may be advantageous in COVID19 given the exaggerated immune response and cytokine storm elicited by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) or could be detrimental given the impaired response to infections in immunocompromised patients.

Methods: We examined the clinical presentation and outcomes of 3 patients undergoing treatment with RTX who were infected with SARS-CoV-2.

Results: 2/3 patients had complication of severe hypoxemia with evidence of pulmonary infiltrates on imaging. Both had underlying ANCA vasculitis with a history of pulmonary involvement. Both were treated with remdesivir and one received convalescent plasma. The patient who received convalescent plasma was SARS-CoV-2 RNA negative at 3 weeks. The patient who received remdesivir but not plasma remained positive for SARS-CoV-2 RNA at 7 weeks and was negative for IgM and IgG antibodies at 4 weeks. The third patient recovered without hospitalization and had a first negative RNA test at 3 weeks and was positive for IgG antibodies when tested at 7 weeks despite a confirmed zero B cells by flow cytometry.

Conclusions: 3 out of 3 patients who developed SARS-CoV-2 infections while on RTX recovered. A larger review of individuals on RTX therapy infected with SARS-CoV-2 should be examined to study the association between B cell depletion and COVID19.

AKI Following Hemolysis Related to Hydroxychloroquine Treatment for COVID-19 in a G6PD-Deficient Patient

Introduction: COVID-19 is associated with significant morbidity and mortality. As a potential treatment, Hydroxychloroquine (HCQ) is actually widely used. Concern has arisen about side effects of HCQ. Here, we describe severe AKI following HCQ administration for COVID-19.

Case Description: A 65-year-old patient has been admitted for fatigue. His treatment was glimepiride, lercanidipine for T2DM and arterial hypertension. Initial evaluation has aroused about side effects of HCQ. Here, we describe severe AKI following HCQ administration for COVID-19.

Case Description: A 65-year-old patient has been admitted for fatigue. His treatment was glimepiride, lercanidipine for T2DM and arterial hypertension. Initial evaluation has aroused about side effects of HCQ. Here, we describe severe AKI following HCQ administration for COVID-19.

Discussion: The residual enzyme activity of G6PD deficiency determines the severity of clinical manifestations which are usually triggered either by fava bean ingestion or drugs, and are dose-dependent. This patient had a severe deficiency and he received a loading dose of an at-risk drug. Both induced hemolysis crisis. AKI is a rare complication of AHA related to G6PD deficiency. The need for renal replacement therapy seems exceptional. Renal recovery could be incomplete. Severe G6PD deficiency can manifest late in life. HCQ should be used with caution given potential severe side effects. We then recommend early monitoring of hemolysis parameters.

COVID-19 in Kidney Transplant Recipients

Rachana Marathi, Paul W. Davis, Franco H. Cabeza Rivera, Wisit Cheungsapattison, Swetha Rani Kanduri, Karthik Kovvuru, Pradeep Vaitla. University of Mississippi Medical Center, Jackson, MS.

Background: Coronavirus disease 2019 (COVID-19) is caused by Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Kidney transplant recipients are at a higher risk for complications due to comorbid conditions and concurrent immunosuppression. We like to describe a small cohort of kidney transplant recipients with COVID-19.

Results: A total of 8 kidney transplant recipients were diagnosed with COVID-19 with a mean age of 58 yrs (26-78), predominantly African American (7/8), mean duration of 3 weeks and was positive for IgM and IgG antibodies when tested at 7 weeks despite a confirmed zero B cells by flow cytometry.

Conclusions: 3 out of 3 patients who developed SARS-CoV-2 infections while on RTX recovered. A larger review of individuals on RTX therapy infected with SARS-CoV-2 should be examined to study the association between B cell depletion and COVID19.
from transplant 3.5 yrs (1.5-11 yrs). All patients have HTN (8/8), half the patients have Diabetes Mellitus-2 (4/8). Common presenting symptoms are fever and shortness of breath. 6/8 patients required hospitalization. 8/8 patients were managed with a reduction of immunosuppression, primarily by decreasing the dose or holding the anti-proliferative agent. 1/8 patients died, 4/6 discharged from hospital, 1/6 still admitted to the hospital with resolution of fever and cough. 6/8 patients required supplemental oxygen. 2/6 patients required ICU stay and 1/6 required mechanical ventilation and renal replacement therapy. 3/6 hospitalized patients received hydroxychloroquine/ Azithromycin combination and 1/6 received Remdesivir. Median hospital stay is 5 days with a mean of 9 days. The patient who required mechanical ventilation and renal replacement is the only recipient who died from COVID-19 at our transplant center. 

Conclusions: COVID-19 is a novel infection primarily presenting with fever and shortness of breath. The course of illness appears to be severe with the majority of patients requiring supplemental oxygen and a third of hospital admitted patients required ICU stay. Reduction of immunosuppression appears to be helpful, however, no control group available. COVID-19 affected population is predominantly predominantly Caucasian patients (7/8) and older recipients with age > 50 yrs (7/8).

Cases of COVID-19 Reported in a Predominantly White Rural Hemodialysis Cohort
Ravi K. Thimmisetty. Nephrology Associates, Cape Girardeau, MO.

Background: COVID-19 is a novel coronavirus disease causes by the severe acute respiratory syndrome coronavirus 2. Because of its high infectivity rate, WHO described the disease as a Pandemic on March 11th 2020. Severe infections were reported in adults with underlying comorbid conditions, therefore hemodialysis patients are not an exception. We are reporting COVID-19 cases in a rural hemodialysis center predominantly Caucasian patients.

Methods: We reviewed the cases of confirmed and suspected COVID-19 infections in our dialysis center. Precautions were taken promptly after COVID-19 infection become Pandemic. All patients were taken temperature check at the entrance door, surgical face mask was provided, sanitizers were provided, social distancing was followed. All physicians and dialysis staff followed the same guidelines. All suspected and confirmed cases should get two negative SARS CoV-2 PCR tests for acceptance at our dialysis center.

Results: Out of 71 dialysis patients, men and women were 56% and 43%. 73.2% of them were Caucasians and 23.9% were African Americans. There were one confirmed COVID-19 disease who was hospitalized for about a month. She acquired from a community spread. She improved and resumed schedule after two negative SARS CoV-2 PCR results. Four people were sent to hospital for having cough, fever, dyspnea, all of them were negative for COVID-19 infection. In our dialysis unit, 55.7% of patients have diabetes, 83% have hypertension, 47.8% of them have both diabetes and hypertension. Patient with confirmed COVID-19 fall into age group of 65-79 yrs. 35.2% of the patients fall into age group of 65-79 yrs. On the following day he was brought to a local ER after 3 large projectile emesis. Labs revealed BUN/Cr 80/9.4. He was given1 liter IVF and was transferred to our hospital. He had watery brown-greenish stools, although he denies diarrhea or abdominal pain. Meds included Insulin, statins, heparin, SSRI, and donepezil. At our ER, the patient was awake, alert, oriented to self and year. T 98.3, BP 119/71, P 119, RR 18, SpO2 95% on RA. PE was unremarkable. Bladder scan: 150 ml. Lab: WBC 10.9, Hb 13.3, Plt 207, Na 130, K 4.0, Cr 79, bicarb 17, BUN 85, Cr 8.6, Ca 7.3, Phos 6.6, Alb 3.2. LFT was normal. FeNa = 1.5%. UA: pH 5, prot 1+, Glu 50, RBC 5, WBC 4, with amorphous sediments. Three of six patients were clear. Renal ultrasound: kidneys with normal size and echogenicity. No obstruction. Patient was admitted to the COVID ward. Patient’s nausea and vomiting stopped upon his admission, although his watery stools lingered. He was treated with IV fluid to optimize his hemodynamics. Over the next 5 days patient’s serum Cr decreased to 4.9.

Discussion: Since the COVID-19 pandemic, GI symptoms and AKI are often regarded as complications of the overall respiratory illnesses. Patients with only GI symptoms were often not suspected for COVID-19. The causes of this patient’s AKI included both, mechanically induced AKI- possibly secondary to sepsis, and direct viral (SARS-CoV-2) cytotoxicity. Regarding direct viral cytotoxicity, postmortem data has shown the presence of coronavirus-like particles in podocytes and tubule cells. While the direct viral effect to the kidneys is still not understood, treatment with conventional approaches may significantly improve renal outcome.

De-Differentiation of Human Urine-Derived Stem Cells to SIX2+/CITED1+ Cells by 3D Tubuloid Culture
Julie Bejoy, Richard C. Welch, Lauren E. Woodard. Woodard Lab Vanderbilt University Medical Center, Nashville, TN.

Background: In contrast to pluripotent stem cell-derived organs which take nearly one month to derive for kidney, adult stem cell (ASC) derived organs can be derived within 7 days of culture without exogenous factors. As any epithelium is formed from direct ectodermal epithelial development. Protocols have been generated to derive organs or spheroids of intestine, liver, prostate, pancreas, stomach, salivary gland, breast, colon and taste buds from ASCs. These 3D cultures have been used for disease modeling and personalized medicine approaches. Recent work from the Hans Clevers lab showed that cells derived from the urine of a patient with cystic fibrosis could be made into kidney epithelial tubular organoid structures termed “tubuloids.”

Methods: These tubuloids cultures developed quickly and exhibited many of the hallmark features of an intact tubular epithelium. The tubuloid culture media includes Wnt signaling enhancers, EMT inhibitors, and fibroblast growth factors which are all reported to be essential for kidney development. We applied this tubuloid 3D culture protocol [MOU1] to our cultures of human urine-derived stem cells (USCs). USCs were isolated from the epithelial cells lining the glomeruli that are shed into the urine. The USCs from healthy adult donors were grown on 96 well U-bottom suspension culture plates in tubuloid media for 10 days. The 3D tubuloid-like structures harvested at Day 10 were stained for both early nephron progenitor markers and tubulic precursor markers. 

Results: Tubuloid-like spheres derived from USCs expressed both nephron progenitor markers SIX2 and CITED1 as well as tubulic cellar precursors Pax2 and Pax8.
In contrast, the starting USCs lack PAX2, SIX2 and CITED1. [MOU1] We will next quantify the expression of these and other nephron progenitor markers over the time course of 3D culture.

**Conclusions:** Our results suggest a new method to derive patient-matched SIX2+/CITED1+ cells from non-invasive urine samples.

Comparative Evaluation of Orthostatic Hypotension in Patients with Diabetic Nephropathy

Gamze Aydin, Rumeyza Kazancioglu, Omer C. Elcioglu, Meltem Gursu, Serra Aran, Aysegul Yabaci. Bezmialem Vakfi Universitesi Tip Fakultesi, Istanbul, Turkey.

**Background:** Orthostatic Hypotension (OH) affects 5-20% of our population. Our study investigates the prevalence of OH in diabetic nephropathy patients (DNP) and the factors affecting OH in comparison with other chronic kidney disease patients (CKDP).

**Methods:** Patients presented to the nephrology clinic and consented were included in the study. DNP were defined by renal biopsy and/or clinical criteria. CKDP of same sex, age and eGFR were matched to DNP. Demographic parameters and medications were obtained from the records. OH was determined by mayo clinic criteria. Same researcher used the electronic device to measure the blood pressures (BP). All samples were taken and analyzed the same day for biochemical and hematological parameters and albuminuria.

**Statistical analyzes were performed with IBM SPSS22.0 program.**

**Results:** 112(51F,61M, mean age:62,56a±9,35 years) DNP and 94(40F,54M, mean age:62,23a±10,08 years) CKDP were included. 70.5% DNP vs 61.7% CKDP had OH (p=0,181). The mean change in systolic BP in DNP was 21,50±16,10mmHg and it was 16,63±9,03mmHg in diastolic BP. In CKDP mean change in systolic BP was 22,1±13,90mmHg and it was 5,96±6,80mmHg in diastolic BP. There was no difference between the groups in systolic BP (p=0,797), but it was present for diastolic BP (p=0,025).

60.0% of 74.7% M patients had OH (p=0,026). Uric acid levels were 7.18mg/dl in OH patients and 6.36mg/dl in non-OH (p=0,017). Blood albumin level was not different in two groups (p=0,902). 73.7% of patients on calcium channel blockers developed OH (p=0,015) and OH developed in 80.6% of 36 patients on alpha blockers (p=0,049).

**Conclusions:** Our study demonstrated OH is frequent among DNP and there was no difference compared to CKDP. It is important to check OH in all CKDP as it is more common than thought.

Clinical Practice Gap Analysis of CKD in Type 2 Diabetes from Identification to Diagnosis to Management

Amy Larkin,1 Kelly L. Hanley,2 George L. Bakris.3 1Medscape LLC, New York, NY; 2UCHicago Medicine, Chicago, IL.

**Background:** Understanding clinical practice gaps in the identification, diagnosis and management of CKD in patients with T2D can inform development of tools to improve physician practices.

**Methods:** A survey instrument of 25 multiple choice, knowledge- and case-based questions allowed participants to assess their knowledge, attitudes, and confidence with regard to CKD in T2D. The survey was available online to physicians across the globe without monetary compensation or charge. Respondent confidentiality was maintained and responses were de-identified and aggregated prior to analyses. Initial data collection occurred from February 26, 2020, to April 20, 2020.

**Results:** To date, 193 nephrologists completed the full assessment. Physicians demonstrated gaps in the following areas. When asked how satisfied nephrologists were with current treatment approaches for managing CKD in patients with T2D, 10% selected very satisfied, 74% selected moderately-mostly satisfied, and 16% slightly-not satisfied.

**Conclusions:** This educational research on assessment of physicians’ clinical practices yielded important insights into clinical gaps related to identification, screening, diagnosis, and management of CKD in patients with T2D. Further studies are planned to assess the effect of medical education on decreasing these clinical practice gaps.

Practice Patterns of SGLT2 Inhibitor and GLP-1 Agonist Treatment in Eligible Type 2 Diabetes Patients Before and After the Publication of the 2018 ADA/EASD Position Statement

Bijn Thajudeen, Wei Xiang Wong, Saeed Bidar, Sevag C. Boyadjian, Wina Youssman, Amy N. Sussman, Frank C. Brosius. Banner University Medical Center Tucson, Tucson, AZ.

**Background:** The ADA/EASD published a position statement in October, 2018 on the prevention of atherosclerotic CVD events in diabetic patients focusing on the use of SGLT2 inhibitors (SGLTI1) and GLP-1 agonists(GLP1A). The objective of this study is to determine the practice patterns of endocrinologists and nephrologists in implementing current societal recommendations for use of SGLT2 and GLP1A.

**Methods:** This study had two phases, a retrospective phase and prospective phase to determine utilization of SGLT2/GLP1A before and after the publication of ADA/EASD position statement. All subjects with type 2 diabetes and CVD/CKD who were at least 18 years of age and who were followed at the endocrinology and/or nephrology clinics were included in the study. Eligible patients had a minimum of two clinic visits in either endocrinology and/or nephrology clinics during either the retrospective phase (October 2017 - September 2018) or prospective phase (October 2018 – September, 2019). Information collected included utilization of SGLT2/GLP1A, Hba1c, eGFR, new CVD events and adverse effects of SGLT2/GLP1A therapy. Primary outcomes measured was the change in percentage of eligible patients treated with an SGLT2/GLP1A.

**Results:** A total of 113 charts were reviewed. Only 18 patients(15.9 %) were on either SGLT2/GLP1A at the end of prospective phase. By the end of prospective phase, 25 patients (22.1%) were on one of these agents. Out of 28 patients with Hba1c more than 8 at the end of retrospective phase, percentage of patients on SGLT2/GLP1A at the end of prospective phase remained the same. Utilization of SGLT2/GAPA ranged 11% to 28.9%. There was no statistically significant difference between the groups treated with SGLT2/GLP1A compared to group not treated with these agents in terms of Hba1c (P value 0.94) or eGFR (P value 0.35).

**Conclusions:** Despite the new recommendations, a substantial number of patients are not on SGLT2/GLP1A even if the diabetes is not controlled adequately. However this lack of adherence to protocol doesn’t seem to affect the diabetes control or change in renal function. We need larger studies to further explore the practice patterns of physicians and its impact on outcomes.

A Study on an Early Marker of Renal Damage in Known Diabetics Living in an Urban Slum of Hyderabad, India

Rahay K. Ranga,1 Mahesh Kumar Mummid,2 Rhonda Dzakpasu.1 1Georgetown University, Washington, DC; 2National Institute of Nutrition, Hyderabad, India.

**Background:** India is the nation with the second largest prevalence of type 2 diabetes mellitus in the world, with an estimated 69.2 million people having the condition as of 2015. In the surrounding as a whole, 78.3 million people live with type 2 diabetes, out of which 52.1% are undiagnosed. 44% of all cases of nephropathy are caused by type 2 diabetes mellitus.

**Methods:** There are two goals for this cross-sectional study: i) to measure the prevalence of microalbuminuria and albuminuria in type 2 diabetic patients and ii) to determine associated factors that elevate a diabetic’s risk for kidney disease. The study was done with 100 type 2 diabetics from Adda Gatta, Hyderabad, India. We performed urinalyses to measure urinary albumin, and gave a modified WHO STEPS questionnaire to assess lifestyle risks.

**Results:** 42 of the 100 patients surveyed were normoalbuminuric, 46 were microalbuminuric, and 12 were albuminuric. Significant risk factors were: being older than 44, having type 2 diabetes for longer than 6 years, drinking alcohol, and smoking.

**Conclusions:** The prevalence of microalbuminuria in type 2 diabetic people is quite a bit higher than it was in previous studies. Primary prevention needs to be emphasized in this population so that future generations don’t get type 2 diabetes mellitus. If patients get their serum creatinine checked, then should nephropathy arise, then it will be detected earlier, and treatment could start earlier. Future studies could ask questions regarding stress on the questionnaires, as well as check the patients’ serum creatinine, blood pressure, and lipid profiles.

**Funding:** Private Foundation Support, Government Support - Non-U.S.

PUB081

**The Miraculous Shrinking Kidney**

**Introduction:** Glomerular hyperfiltration is common in conditions such as diabetes and obesity and can result in glomerular hypertrophy and organ growth as well as corresponding GFR increase. When hyperfiltration results in proteinuria this is a poor prognostic sign for CKD progression and needs to be managed appropriately. With this case report, we document dynamic progressive reduction in sizes of almost 18 and 16 cm kidneys, associated with resolution in proteinuria, after weight loss.

**Case Description:** A 70-year-old man with type II diabetes mellitus with retinopathy, hypertension, and morbid obesity was referred to nephrology for very enlarged kidneys and proteinuria. Of note, two weeks prior he had undergone a gastric bypass surgery. Prior to gastric surgery his BMI had been as high as 41.6 kg/m2. Kidneys measured 17.7 cm on the right and 15.9 cm on the left. His spot protein to creatinine ratio pre-gastric bypass was 2,388 mg/dL. Due to the significant growth of the kidneys, concern was initially for an infiltrative process and kidney biopsy was considered. However, the patient had just had gastric bypass surgery for weight loss, so the decision was made to serially monitor kidney sizes as hyperfiltration was high on the differential. With weight loss surgery and dietary changes, within six months, the patient had lost sixty pounds and decreased his BMI to 32.5 kg/m2. His A1C had decreased from 8.1 to 6.9. He was able to stop insulin and was maintained on metformin 1000mg bid and sitagliptin 100mg. His urine protein to creatinine ratio dramatically reduced from around 2388 mg/dL to normal level of 78 mg/g.

**Discussion:** This case illustrates dynamic change in kidney size by imaging with large weight loss as well as successful remission of sub-nephrotic range proteinuria following gastric sleeve surgery, extensive weight loss and glucose control.

PUB082

**Multiple Targets on Sodium Excretion with SGLT2 Inhibitors, Furosemide, and Spirolonactone Improves Diuretic Resistance in Patients with Diabetic Nephropathy on CKD Stage 3-4: A Pilot Study**

Wei T. Liang, Renmin Hospital of Wuhan University, Wuhan, China.

**Background:** At stage 3-4 of chronic renal disease, patients with diabetic-induced renal dysfunction are not sensitive to the conventional diuretic therapy based on loop diuretics and thiazide diuretics, leading to the earlier renal replacement at stage CKD 3-4. The lower sodium excretion could contribute to the development of diuretic resistance. The protective effects of SGLT2 inhibitors on cardiovascular is contributed by metabolic regulation and osmotic diuretic effect of glucose due to extra excretion of Glucose. The present study aims to investigate the efficacy and safety of SGLT2 inhibitors on the diuretic resistance of diabetic nephropathy at CKD 3-4 stage.

**Methods:** Patients with Diabetic nephropathy at CKD3-4 stage were administrated with furosemide + hydrochlorothiazide for 3 days with urine volume <1000ml, sodium urinary excretion >90mmol followed by Dapagliflozin/Canagliflozin once a day for 7 days.

**Results:** 3 male and 7 female patients with diabetic nephropathy were included, aged 51-80 years, with eGFR 60-4.6 ml/min, and 3 patients presented with cardiac insufficiency. Urine volume was 800±300/24 hours before treatment and 2000±500/24 hours after treatment. Sodium excretion in urine was 80±20mmol/24 hours before treatment and 150±50mmol/24 hours after treatment. The average net weight change was -3.5±2.2 kg. The Scr increased by 30%±5% before and after treatment, and the renal function in 2 patients increased by >30% after 7 days of treatment, and returned to the level of Scr before treatment after 7 days of treatment with Dapagliflozin/Canagliflozin. Electrolyte levels were comparable before and after treatment.

**Conclusions:** The diuretic regimen based on SGLT2 could significantly improve the resistance of diabetic nephropathy patients to loop diuretics, increase urinary sodium excretion, and slightly elevate renal function in the short term without affecting blood electrolyte level. The efficacy and safety of long-term use of SGLT2 in diabetic nephropathy patients at CKD3-4 stage need further investigate in larger sample size.

PUB083

**Peripheral Neuropathy in a Hemodialysis Patient with a Normal Serum Vitamin B12 Level:**

**Introduction:** Many hemodialysis patients suffer from vitamin B12 deficiency, usually due to inadequate nutritional intake. Besides, food sources of vitamin B12 contain high concentrations of electrolysates, which are harmful to these patients. Thus, they are restricted to foods with low vitamin B12 content. Moreover, high-flux dialyzers remove vitamin B12 molecules from circulation, leading to vitamin B12 deficiency. We report a hemodialysis patient presenting with peripheral neuropathy and a normal serum vitamin B12 level whose symptoms improved with monthly vitamin B12 injections after excluding other differential diagnoses of peripheral neuropathy.

**Case Description:** An 86-year-old man with a history of ESRD on hemodialysis for 3 years along with HTN and CAD presented with fatigue, muscle weakness, and numbness of his extremities for 3 weeks. He was taking aspirin, dipyridamole, finasteride, tamulosin, and pravastatin. His dietary history was significant for poor nutritional intake. Laboratory findings showed Hb 10.6 g/dl, MCV 102 fl, RBS 87 mg/dl, potassium 4.6 mmol/L, and BUN 42 mg/dl. Common causes of peripheral neuropathy in ESRD patients, such as uremic neuropathy, diabetic neuropathy, and hyperkalemia were excluded. Further evaluation revealed a normal serum vitamin B12 level of 421 pg/dl and a normal follic acid level of 11.4 ng/ml. Given his risk factors for possible vitamin B12 deficiency in target tissues, he was treated with monthly vitamin B12 1000 mcg injections and followed up regularly. His symptoms improved significantly after four months of injections.

**Discussion:** In hemodialysis patients, chronic inflammation impairs uptake of circulating vitamin B12 by peripheral tissues leading to decreased production of transcobalamin II, increased synthesis of transcobalamin I and III with further accumulation of vitamin B12 in blood. In addition, despite normal or high serum vitamin B12 levels, these patients may suffer from vitamin B12 deficiency in target organ and show symptoms such as fatigue and peripheral neuropathy. Therefore, it seems reasonable to consider vitamin B12 supplementation in these patients after excluding other causes of peripheral neuropathy. Further studies are highly recommended.

PUB084

**Hemodialysis Prescription in Ethylene Glycol Overdose: A Mathematical Approach**

Muhammad T. Shakoor, Jie Tang. Warren Alpert Medical School of Brown University, Providence, RI.

**Introduction:** The timely management of Ethylene glycol (EG) overdose is essential. Hemodialysis (HD) is indicated for rapid elimination of its toxic metabolites. We introduce a case diagnosed shortly after presentation prior to the availability of the blood EG level and share calculations that were used to precisely and accurately estimate the clearance of EG through HD.

**Case Description:** A 61-year-old male presented with unresponsiveness. Labs were notable for anion positive metabolic acidosis with anion gap 28, osmolal gap 57, along with stage 2 AKI. His whole blood lactate was >171 meq/L, with a venous lactate of 0.5 meq/L. EG intoxication was diagnosed based on high lactate gap (16.6) and calcium oxalate monohydrate crystals in his urine sediment. He was given fomepizole and eculizumab, an expensive HD prescription. We calculated HD prescription based on a simple calculation which we have been using reliably to calculate HD duration and post HD EG level. His predialysis EG level was 71 mg/dl. To calculate the EG removal via HD, we need patient's weight and EG clearance (ClEG) which we have been using reliably to calculate HD duration and post HD EG level. His weight and EG clearance (ClEG) for the F200 filter under Qb400 ml/min and Qd 800 ml/min is 147 ml/min. We decided to dialyze him for 4 hours. His post HD EG level was estimated to be: KG of EG = 240 min (HD time) * 147 ml/min (ClEG) + ClEG, for the F200 filter under Qb400 ml/min and Qd 800 ml/min is 147 ml/min. We decided to dialyze him for 4 hours. His post HD EG level was estimated to be: KG of EG = 240 min (HD time) * 147 ml/min (ClEG) + ClEG .

**Discussion:** Generally, the diagnosis of EG intoxication is delayed and calculation of HD prescription remains a challenge due to lag in obtaining serial EG assays in clinically useful time frame. We present a case of EG toxicity that we were able to diagnose promptly without waiting for EG blood levels, and we present a simplified approach to determine the duration of HD based on a single EG assay. This calculation can be used to individualize HD treatments and avoid over or undertreatment of intoxication.

The Estimation Formula of Phosphorous, Potassium, and Salt Amounts Excreted into Urine in Hemodialysis Patients

Momoko Fukazawa,1 Shunichiro Urabe,1 Motoko Kato,1 Yukie Kitajima,2 Akihito C. Yamashita,1 Toru Hyodo.1 Ejin Clinic, Hiritakura, Japan; 2Tokyo University of Technology School of Health Sciences, Shinagawa, Japan; 1Hosei University, Koganei, Japan.

Background: We elucidated the contribution of residual renal function (RRF) to the phosphorous, potassium and salt excretion and established the estimation formula of these amounts which are excreted into urine by RRF of hemodialysis patients.

Methods: We collected the 24 hour urine from 22 hemodialysis patients (mean age: 73±12.1 years old, dialysis history: 31±29.3 months, 15 males, 12 diabetics). The urine volume, phosphorous, potassium and salt amounts in the 24 hours urine and creatinine clearance were determined. The correlation coefficients among the urine volume, amounts of phosphorous, potassium and salt, and creatinine clearance (Ccr) were calculated. Results: The mean urinary volume was 862±421 mL/day. The mean phosphorous amount in the urine was 114±55.9 mg/day, potassium 418±2212.4 mg/day, and salt 4.7±2.6 g/day. Ccr was 3.7±1.8 mL/min. There was a significant positive correlation: urine volume vs phosphorous amount (r=0.759, p<0.001), urine volume vs potassium amounts (r=0.662, p<0.001). (Phosphorous amounts in the urine=101× [24 hours urine(L)/28] (Potassium amounts in the urine=334× [24 hours urine(L)] +130). There was a significant positive correlation between urine volume and salt amounts excreted into urine (r=0.915, r2=0.84, P<0.001). (Salt amounts in the urine=5.7× [24 hours urine(L)] -0.2).

Conclusions: As for phosphorous and potassium, if 24 hour urine volume is known, the amount of urinary excretion of phosphorous and potassium can be roughly estimated. As for salt, if 24 hours urine volume is known, the amounts of urinary excretion of salt can be estimated with 84% accuracy. Measuring urine volume in hemodialysis patients can estimate solute excretion roughly.

Treatment of Uremic Tumoral Calcino sis in Maintenance Hemodialysis Patients

Guibao Ke, Fengxia Zhang, Xueqin Chen, Hong Zhang, Shuai C. Dou, Zhiwen Liu, Shi Wei, Xining Liang, Shuangxin Liu. Department of Nephrology, Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.

Background: Uremic tumoral calcinosi s (UTC) is a rare disease with metastatic tissue calcification in maintenance hemodialysis (HD) patients. However, limited data are available on treatment of UTC in HD patients. This article mainly discusses the diagnostic findings and efficacy of treatment in HD patients with UTC.

Methods: A retrospective analysis was conducted on the data of 13 cases of UTC, including their clinical features, biochemical indicators, imaging findings, diagnosis, therapeutic methods and follow-up results. Parathyroidectomy (PTX) or drug treatment were determined based on intact parathyroid hormone (iPTH) levels and clinical symptoms.

Results: All of 13 patients were diagnosed as UTC definitely by imaging examination. During Haemodialysis

Conclusions: Although most UTC patients have an increased iPTH, a small number had lower iPTH levels. Based on iPTH levels and clinical symptoms, the patients were treated with PTX or drug therapy. With proper treatment, UTC disappeared without the need for surgery to remove calcinosis tissue.

Funding: Government Support - Non-U.S.
Conclusions: It has been demonstrated that flow balance error and fluid removal attainable with SC® lies well within the acceptable standards permitted for haemodialysis machines, demonstrated across a range of clinically relevant parameters at dialysate flow rates of up to 500ml/min.

Clinical Performance of the Optiflux® F160NR Dialyzer

Jill M. Meyer,1 Dylan Steer,2 Lisa A. Weber,3 Mayuri Thakuria,4 Chiang-Hong Ho,4 Claudy Mullon,5 Robert J. Kossmann.4 California Institute of Renal Research, Chula Vista, CA; 4California Institute of Renal Research, San Diego, CA; 4Research Management Inc./ Kansas Nephrology Research, Wichita, KS; 3Freensius Medical Care North America, Walhalla, MI.

**Background:** Subjects in the clinical trial (NCT# 0356663), An Open-Label Clinical Study to Assess the Performance of the Dialyzer with Endexo® in End-Stage Renal Disease Subjects, were dialyzed with the Optiflux® F160NR dialyzer, followed by the new dialyzer with Endexo. This sub-analysis reports the safety and performance of the Optiflux® F160NR dialyzer.

**Methods:** Subjects prescribed three-weekly HD for at least 30 days at three US study sites were enrolled in the study. The Optiflux F160NR dialyzer study period included 12 HD treatments. Performance and safety assessments included URR, spk/U, serum albumin and a-2-microglobulin levels with removal rates measured pre and post HD, complement activation, and Adverse Events (AEs).

**Results:** Sixteen subjects were screened. Twenty-three subjects were enrolled in the study (median age 64 years, females 73.91% and white 73.91%) and completed 288 HD treatments with the Optiflux F160NR dialyzer. Four subjects discontinued the study due to missed visits, not related to adverse events. 19 subjects completed all 12 HD treatments per protocol (n=228 dialysis sessions). Delivered HD parameters are presented in Table 1. No SAEs were reported during the study. Four subjects reported at least one adverse event not device related. Mean (SD) reported for enrolled subjects were: 80.5% (4.5) for URR, 1.9 (0.3) for spk/U, 47.1% (7.4) for corrected a-2-microglobulin removal rate and an increase of 8.3% (8.2) post HD for serum albumin. Complement activation was measured Pre HD and 30 min Post HD start and showed no overt activation for C3a, C5a and sC5b-9.

**Conclusions:** HD treatments were well tolerated and URR and spk/U were high with the Optiflux® F160NR dialyzer. Serum albumin levels increased post HD. Complements showed no overt activation.

**Funding:** Commercial Support - Freensius Medical Care North America

Table 1. Delivered HD for completed subjects (n=19, 228 HD sessions)

Dialysis Disequilibrium Syndrome: Severe Irreversible Brain Injury Following Hemodialysis

Fatima Ballout, Pravir V. Baxi, Roger A. Rodby. Rush University Medical Center, Chicago, IL.

**Introduction:** Dialysis disequilibrium syndrome (DDS) is a clinical complication of hemodialysis characterized by neurological symptoms attributed to cerebral edema that rarely occurs in ESKD patients following their first HD treatment. Treatment is primarily preventative, aimed at decreasing the rate of urea clearance to reduce subsequent osmotic fluid shifts. We describe a case of DDS with severe neurological sequelae in a patient with acute on chronic kidney disease.

**Case Description:** A 39 yo man with CKD 4 presented with dyspnea, lethargy and confusion. Initial labs showed a Na 133 mmol/L, K 7.9 mmol/L, BUN 281 mg/dl and creatinine 38.6 mg/dL. HD was initiated for treatment of uremia and hyperkalemia. Two hours after the start of HD, the patient had a tonic-clonic seizure followed by cardiopulmonary arrest. Lab data post-arrest showed a Na 133 mmol/L and BUN of 112 mg/dL (Fig 1). In the subsequent days, the patient remained in a comatose state. MRI of the brain revealed cortical restricted diffusion in both cerebral hemispheres and bilateral basal ganglia, concerning for hypoxic-ischemic injury. His clinical status did not improve over 3 months. He required a tracheostomy and PEG tube placement with HD dependency on discharge.

**Discussion:** DDS remains a rare clinical phenomenon which typically occurs with initiation of HD in those with severe azotemia and advanced CKD. Risk factors include pre-existing neurological conditions, hypothermia, and higher starting BUN levels. While the pathogenesis remains debated, DDS is believed to be due to a reverse osmotic effect that occurs due to a faster decline of urea within the blood versus the brain creating osmotic disequilibrium with subsequent movement of water into the brain causing cerebral edema. Idiogenic osmoles may also be involved. Recognition of patients at high risk is crucial as it provides an opportunity to implement preventative strategies including reduced HD treatment time with lower blood flows aimed at more gradual clearance of urea.

**Results:** HD treatments were well tolerated and URR and spk/U were high with the Optiflux® F160NR dialyzer. Serum albumin levels increased post HD. Complements showed no overt activation.

**Funding:** Commercial Support - Freensius Medical Care North America

Sustained High-Dose Chronic CRRT Fails to Attenuate Severe Lactic Acidosis in an Immuno-therapy-Resistant Case of Malignant Melanoma with Liver Visceral Crisis

Mabel S. Tan, Han K. Tan. Singapore General Hospital, Department of Renal Medicine, Singapore, Singapore.

**Introduction:** Lactic acidosis is the most common cause of metabolic acidosis in hospitalized patients. Though of little proven benefit, continuous renal replacement therapy (CRRT) has been suggested as treatment in some patients. We describe a rare case of a patient with lactic acidosis who received nineteen days of high dose CRRT.

**Case Description:** A 65-year-old Chinese female with melanoma and extensive liver metastasis presented in a visceral crisis. She was given combination of nivolumab and ipilimumab which was projected to take 1 month to work. She had severe lactic acidosis with serum lactate of 17mmol/L on admission despite normal renal function. After a failed trial of medical therapy, CRRT was started purely for lactic acidosis. A spot measurement of effluent lactate was 15mmol/L while the corresponding plasma lactate was 16.3mmol/L, suggesting sieving coefficient of 0.92. Switching to a lactate free dialysis fluid multiBic did not help. Despite uninterrupted CRRT for 19 days, and repeated increase of effluent dose to peak of 5L/hour, giving lactate clearance of 76.7ml per minute, there was no improvement. She eventually demised 4 days after cessation of CRRT.

**Discussion:** We describe an unfortunate case where 2 specialties tried hard to save this young patient from the fatal complications of her aggressive tumor. Type B lactic acidosis is better described in hematological malignancies but there are increasing reports in solid organ tumors, most with extensive hepatic involvement. We present the first case of melanoma causing lactic acidosis reported in literature till date. While CRRT, convective therapies, bicarbonate-based dialysis fluids have been suggested as treatment for lactic acidosis, there is little proven benefit. In our case, we combined all 3 strategies, persisted at high dose for 19 days with no success. 2 learning points: Firstly, lactic acidosis in the absence of hypoperfusion (Type B) is not uncommon and equally dangerous. Secondly, while dialysis removes lactate to some extent, it is at best a temporizing measure. Addressing the underlying cause takes priority. Dialysis, regardless of dose, modality and tuning is less likely to affect outcome.

**PUB092**

Primary Caregiver Burden in a Hemodialysis Clinic in Mexico: Prevalence and Caregiver-Related Risk Factors

Eduar Solis, Joselyn Rivera, Juan M. Ardanuy Izurte. Medica Santa Carmen, San Miguel de Allende, Mexico.

**Background:** Dialysis treatment is defined as a family disease. Primary caregiver is the main person who takes the responsibility for and supports the patient; caregiver burden can be defined as the strain or load borne by a person who cares for a chronically ill family member. The Zarit survey is a psychometric instrument designed to grade caregiver burden, recommended and validated among caregivers of patients in hemodialysis.

**Methods:** A descriptive study was conducted among primary hemodialysis caregivers from a dialysis clinic in Guanajuato, Mexico. Zarit Scale (A validated 22-item questionnaire with five item ranged from 0=never to 4=always) was applied in order to identify presence and level of caregiver burden. Caregivers of patients less than 3 months were excluded. Social and demographic data related were also collected. Data was analyzed for descriptive statistics using T-test and Chi square for comparison between groups.

**Results:** A total of 86 primary dialysis caregivers answered the survey via personal interview with one of the investigators. Most responders were female (77%) with a mean age of 47±15 years old. Seventy seven percent were married and almost all had an occupation (95%): homemaker (43%) was the most common. We found that couples take care of patients in 42% of cases, followed by parents (27%). Interestingly, 46% of responders did not take own recreational time and some of them (38%) were diagnosed with some chronic illness. More than half (56%) usually take care of 1 to 3 more persons along with the patient and meantime of life spent caring was 2 years. Any level of caregiver burden was identified in 67%, most of them (86%) in a slight level. There were not statistical differences between groups with none and any burden.

**Conclusions:** ESRD affects not only patients but also the people who take care of them. Caregivers burden is prevalent in our clinic. Caregivers are predominantly female
partners who have to cope with patients care along with attendance of other relatives and often the need to work for economic support of their families. These results should be added to the public health burden of ESRD in Mexico.

Conclusion: Everyone of us should be aware how our daily activity influence on the environment. Both, medical industry and nephrologists are responsible for decreasing the quantity and weight of medical waste produced during dialysis treatment. Careful proceeding with the disposables (proper procedures, medical staff training and awareness) will directly help to make the HD treatment more cost-effective and help to protect our planet.

PUB095
Early Intervention of Continuous Hemodialysis Filtration Is Effective to Improve Acute Kidney Injuries and Mortality in Patient with Propofol-Related Infusion Syndrome
Masuko Iwasaki,1 Hitoshi Suzuki,1,2 Aiko Wakahayama,2 Maiko Akira,1 Yusuke Suzuki,2 1Juntendo University Urayasu Hospital, Urayasu, Japan; 2Juntendo University Faculty of Medicine, Tokyo, Japan.

Introduction: Propofol related infusion syndrome (PRIS) is a fatal syndrome that often develops under the long-term propofol infusion at high doses. The main features of the PRIS consist of cardiac failure, rhabdomyolysis, acute kidney injury, and severe metabolic acidosis. High dose propofol, but also supportive treatments with catecholamines and corticosteroids, act as triggering factors. Propofol is usually administered at 0.3–4.0 mg/kg/hr or less to the sedation of adult patients, and is not administered beyond 7 days to prevent PRIS. We report here a case of PRIS developed rhabdomyolysis, acute kidney injury, and severe metabolic acidosis under the dose of propofol within the safety dose.

Case Description: A 41-year-old woman was operated cervicotoracic posterior longitudinal ligament ossification. After the operation, maximum 3.5 mg/kg/hr of propofol was used for sedation treatment of severe pneumonia under the mechanical ventilator. Catecholamines was also used to support hemodynamics. However, unidentified hemorrhage and impaired blood pressure were prolonged, then administration of propofol was discontinued on POD6. Acute kidney injuries (sCr2.3mg/dl), metabolic acidosis and high serum CK (79300U/L) due to rhabdomyolysis were observed on POD8. Continuous hemodialysis filtration (CHDF) therapy was initiated, and hyperthermia, oxygenation, impaired hemodynamics and renal dysfunction were gradually improved.

Finally, cardiac failure and renal function were totally recovered.

Discussion: Propofol impairs fatty acid utilisation and mitochondrial activity. Imbalance between energy demand and utilisation is a key pathogenetic mechanism, which may lead to cardiac and peripheral muscle necrosis. CHDF may effective to maintain renal function and acid-base equilibrium through removal of metabolites induced by mitochondrial damage, such as lactate and creatine kinase. PRIS particularly when combined with catecholamines can be lethal and we suggest early intervention of CHDF is effective to improve renal injuries and mortality.

PUB096
The Conduct of Sponsored Trials Has No Association with Dialysis Facility Clinical Quality Outcomes
Vladimir Rigoson,1 Yue Jiao,1 Lori Viennet,1 Joanna Willetts,1 Sheetal Chaudhuri,2 John W. Larkin,1 Len A. Usvyat,2 Jeffrey L. Hymes,2 Robert J. Kossman,2 Franklin W. Maddux,2 Kurt Mussina.1 1Fresenius Renal Research, Waltham, MA; 2Fresenius Medical Care, General Medical Office, Waltham, MA; 3Fresenius Medical Care North America, Waltham, MA; 4Fresenius Medical Care AG & Co. KGaA, General Medical Office, Bad Homburg, Germany.

Background: There is a paucity of clinical trials conducted in nephrology vis-à-vis other fields (Baigent, et al. 2017). The lack of knowledge on impacts of trial conduct on dialysis facility operations can create barriers between stakeholders. We aimed to assess clinical quality target achievement in dialysis facilities conducting trials versus matched facilities with similar attributes that were not involved in research activities.

Methods: We used data from adult (age ≤18 years) hemodialysis patients treated at a network provider network in the United States during 2017 to 2018. Facilities that did not participate in trials were matched to research facilities using 1:1 matching on logit metrics in dialysis facilities that conducted trials versus matched facilities not involved in research (Figure 1).

Conclusions: We found no significant differences between mean facility-level quality metrics in dialysis facilities that conducted trials versus matched facilities not involved in research (Figure 1).

Funding: Commercial Support - Fresenius Medical Care
Impact of Major Surgical Operations on Clinical Outcome in Dialysis Patients

Background: We aimed to study the impact of major surgical operations on clinical outcome in patients with haemodialysis (HD) or peritoneal dialysis (PD).

Methods: We retrospectively evaluated the records of all patients on HD and PD, who had been treated for at least 3 months at our outpatient clinics between January 1, 2014 and December 31, 2018. In addition to clinical and laboratory parameters, data on each major surgical operation performed was recorded.

Results: Among the 202 patients, 133 (66%) were on HD and 69 (34%) on PD. The mean age (±SD) was 58.3 ±14.5 years, 48% were female and 28% had diabetes mellitus. Forty-seven patients (23%) had a major surgical operation. The operation types were cardiovascular in 14 patients, orthopaedic in 11, gastrointestinal in 6, parathyroidectomy in 5 and brain, pulmonary and breast in 1 patient each. Operations were emergent in 10 patients (21%) and elective in the others (79%). Among the whole study population, 59 patients (29%) died during the study period. In Kaplan-Meier analysis (Figure), mean (±95% CI) survival time in operated patients was 43 months (57 to 49 months), while it was 49 months (46 to 52 months) in the others (p=0.001). Fifteen out of 23 deaths (65%) among the operated patients occurred in the first month after surgery. Severe perioperative complications (arrhythmias, hypervolemia, hypotension, bleeding, acute coronary syndrome, respiratory failure and cerebrovascular event) were recorded in 17 (36%) of the operated patients, of whom 16 died (p=0.001). Although did not reach a significant level, mortality rate tended to be higher after emergent operations than that after elective operations. Cox regression analyses revealed that age (RR 1.033, 95% CI 1.010-1.057, p=0.005), diabetes (RR 2.581, 95% CI 1.474-4.521, p=0.001), preoperative C-reactive protein level (RR 1.005, 95% CI 1.002-1.007, p=0.001) and having a major surgical operation (RR 1.868, 95% CI 1.068-3.268, p=0.028) were the independent predictors of mortality.

Conclusions: Although prospective studies with a higher patient number are needed to confirm, our study shows that, in addition to age, diabetes and inflammatory status, having a major surgical operation is an independent risk factor for mortality in dialysis patients.

Outcomes of Ceftolozane/Tazobactam Recommended Doses in Treating Multidrug-Resistant Bacteria in Critically Ill Patients Using Renal Replacement Therapy

Wasim El Nekidy,1,2 Leen Oyoun Alsaoud,3 Nizar M. Attallah,1 Laila Riekib,4 Fadi A. Hijjazi,5 Ahmad R. Nusair,3 Jihad Mallat,4 Islam Ghazi.1 1Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; 2Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH, 3University of the Sciences in Philadelphia, Philadelphia, PA; 4Trillium Health Partners, Mississauga, ON, Canada.

Background: Ceftolozane/tazobactam (CEF/TAZ) is a new broad spectrum cephalosporin effective against Multi-drug Resistant (MDR) bacteria. The clinical outcomes of the recommended dose of CEF/TAZ in patients utilizing renal replacement therapies are lacking. The purpose of this study was to evaluate the clinical and microbiological efficacy of CEF/TAZ in treating MDR in patients utilizing continuous venovenous hemofiltration (CVVH) and intermittent hemodialysis (IHD).

Methods: A retrospective cohort study was conducted at our quaternary care hospital between May 2015 and December 2019. We reviewed all hospitalized adults who had MDR Pseudomonas aeruginosa or MDR enterobacteriaceae treated with CEF/TAZ while utilizing CVVH or IHD.

Results: We identified 11 patients who met the inclusion criteria with a mean age of 63.0 ±17.8 years and a mean weight of 63.8 ±15.7 kg. All patients were critically ill, needed mechanical ventilation, and used vasoressors. All 11 patients had pneumonia, one of them developed secondary bacteremia and two had decubitus ulcer. Nine patients had MDR pseudomonas aeruginosa while two had MDR E. coli and Klebsiella pneumonia. Six patients were on IHD, while the remaining 5 patients were on CVVH. The most commonly used dose for CVVH was 450 or 750 mg intravenous (IV) every 8 hours (only one received 1500 mg at the same frequency). For IHD, the common dose was 450 mg IV every 8 hours. Of the 7 patients who had repeated cultures, three had microbiological cure and four had clinical cure. Two patients expired within 30 days and 3 more expired within 90 days. Two of the patients who had clinical cure, had recurrence within 4 weeks.

Conclusions: The efficacy of the recommended CEF/TAZ dose in patients utilizing RRT is uncertain. Pharmacokinetics and pharmacodynamics studies are urgently needed to determine the adequacy of CEF/AEI dosing in this population.

Does Dialyzer Surface Area Alone Adjusted to Body Surface Area Have Any Clinical Impact on Adequacy: A Single-Center Observation Study in Saudi Arabia

Najlaa Almalki, Ahmad S. Ghanem, Azharuddin Mohammed. Armed Forces Hospitals Administration in Taif Region, Taif, Saudi Arabia.

Background: Dialysis adequacy using sp Kt/V is a standard KPI in HD units, determined by dialyzer clearance(K), Volume of distribution urea(V) and treatment time(t). Increase in larger dialyzer size (t, V being constant) is a norm to improve Kt/V during HD as the patients gradually lose residual kidney function. However initial and subsequent dialyzer prescription using Body Surface Area(BSA) instead of Weight(V) is less well studied. We looked into effect of BSA and DSA on Kt/V.

Methods: 163(n=) patients receiving in-center HD on Gambio dialyzers (Polyflux, Revecache) studied. Demographic and clinical data collected. Patients were stratified into 4 groups based on their dialyzer surface area (DSA) as 1.4, 1.7, 1.8 and 2.1 m². For each group, we then calculated BSA(Bois Bois method), HD vintage, treatment time(hours), Access type, sp Kt/V (Dougirdas) and % pts with inadequate sp Kt/V , <1.2. Hemoglobin during HD as the patients gradually lose residual kidney function. However initial and subsequent dialyzer prescription using Body Surface Area(BSA) instead of Weight(V) is less well studied. We looked into effect of BSA and DSA on Kt/V.

Results: Our patients were representative of any HD center in terms of demographics; age 57.8 ±18.3, 50.9%Males, 28.2% DM, vintage 59.3±51.2, BMI 25.1±6, BSA 1.7±0.3 and Kt/V 1.7±0.4. The use of dialyzer with DSA’s 1.4, 1.7, 1.8 and 2.1 were 63.2%, 55.5%, 8.6% and 22.1 %. Among 4 groups, there was no significant difference in terms of age, treatment time, vascular access and hemoglobin, Image 1. But when DSA and BSA were stratified for adequacy, there was a modest linear trend of decreasing Kt/V with increasing BSA among 4 increasing DSA groups. Although all met the minimum sp Kt/V of 1.2, the proportion of patients with inadequate Kt/V were increasing despite their increasing dialyzer sizes. Factors. For equilibrated Kt/V, adequacy could just be borderline for larger patients.

Conclusions: Dialyzer size change in itself may not be effective in achieving target Kt/V as BSA increases; attention must be paid to increasing dialysis time. Dialyzer prescription, adjusting for BSA may be more appropriate, particularly in large patients.
**PUB101**

**High Ultrafiltration Rate: Is It Bad? A Case Report of a Patient on Hemodialysis for 29 Years with High Ultrafiltration Rate**

Aziz U. Seedy, Diaverum, Riyadh, Saudi Arabia.

*Introduction:* High ultrafiltration on Hemodialysis stresses cardiovascular and could have negative effect on survival. This is the notion of many studies done in line with High ultrafiltration. However, dismissing the other side of coin, cumulated effect of fluid removals,.Cardiovascular overload on cardiovascular system.

*Case Description:* We present a case 60 year male develop proteinuria lost follow up, presented with CKD 5, started on hemodialysis which he is on for 29 years now. He was hypertensive to start with later became normotensive. His intradialytic weight gain is 4.5 to 5.5 liters, which he tolerates well without any episode of intradialytic hypotension. We report a case of successful emergent PD with high bicarb dialysate in an actively dying patient not tolerating standard renal replacement therapies.

*Discussion:* Except Carpal, tunnel Syndrome for which he had surgery, clinically stable, normal biochemical parameters and acceptable cardiovascular status with this entire very remarkable journey.

**PUB102**

**The Influence of Different Hemodialysis Frequency on Maintenance Hemodialysis Patients**

Hou Li. the first affiliated hospital of Xi’an Jiaotong University, Xi’an, China.

*Background:* To investigate the effects of different dialysis frequencies on anemia, nutritional status, calcium and phosphorus metabolism, renal function indicators in patients.

*Methods:* The general data of MHD patients in our center from 2017 to 2019 and annual laboratory monitoring indicators (including HGB, SF, Bun, Scr, Ca, P, iPTH, ALP, ALB, ABG, urine volume and eGFR, were used to compare in patients with different hemodialysis frequency groups (Group A: 2 times/week; B: 3 times/2 weeks; C: 3 times/ week).

*Results:* There were 269 patients (163 males, 106 females), with an average age of 52.65±14.982 years. There were statistical differences among HGB, Ca and ALB, but no statistical differences among SF, P, iPTH, ALB, Bun and Scr. The three-year overall compliance rate evaluation found that the overall compliance rate of HBG and Ca significantly increased. It was found that the compliance rates of HGB and Ca at the dialysis frequency of 2 times a week were significantly lower than those of the other two groups, but there is no difference for P, iPTH and ALB.

*Conclusions:* Different from western countries or developed areas, the frequency less than 3 times is more twice in the western region in China. In this study, the average of HGB and Ca in patients with dialysis 3 times a week is significantly higher than other groups with low-frequency, and the compliance rate of HGB and Ca in group with the dialysis 3 times a week increased significantly. The results suggested that the higher frequency group was better in anemia and calcium correction.

**PUB103**

**Achromobacter Xylosoxidans, Subspecies Denitrificans, Exit Site Infection, and Aeromonas Hydrophlia Peritonitis: Rare Infections in Peritoneal Dialysis Patients**

*Background:* Achromobacter xylosoxidans, species denitrificans, exit site infection in peritoneal dialysis patient is rare and will be reported. A second case of rare peritoneal infection caused by Aeromonas hydrophilia peritonitis will also be reported. Both are gramm negative microorganisms and are usually found in wet environments, causing infections in immunocompromised patients. Both cases occurred in the same rural city and in the same dialysis facility.

*Methods:* The cases involved conducting interviews with patients and documenting each visit. All observations and visitations were assessed in the dialysis center of a rural area. Previous data of cases with similar rare pathogen caused peritonitis were also analyzed.

*Results:* The patient with exit site infection, Achromobacter xylosoxidans, was treated with oral ciprofloxacin for 3 weeks resulting in a slow improvement of the exit site. During treatment the patient experienced erythema, discomfort, and discharge. At the end of the treatment, repeat cultures drawn from the exit site were negative. The patient with Aeromonas hydrophilia peritonitis is currently being treated with intraperitoneal gentamicin.

*Conclusions:* Achromobacter xylosoxidans and Aeromonas hydrophila are both rare bacterial infections that have a history of causing infections in immunocompromised individuals exhibiting multiple risk factors. We reported exit site infections and peritonitis in end stage kidney disease patients. Both infections have been treated without any adverse effects or removal of peritoneal dialysis catheters.

**Bicarbonate-Rich Peritoneal Dialysis as Salvage Therapy for Metabolic Acidosis**

Elise L. Stephenson, Ryan A. Carver, Jessica R. Burgess, Thomas R. McCune. Eastern Virginia Medical School, Norfolk, VA.

*Introduction:* Use of peritoneal dialysis (PD) in ICUs in developed nations is limited. The need for emergent dialysis is often considered a contraindication for peritoneal dialysis and the large peritoneal surface area is often neglected in the resuscitation of critically ill patients. We report a case of successful emergent PD with high bicarb dialysate in an actively dying patient not tolerating standard renal replacement therapies.

*Case Description:* A 36 yo male with no medical history sustained multiple gunshot wounds. He was found to have multiple injuries in the small bowel including the duodenum. Two 15-french drains were placed at the time of surgery. While initially stable, he gradually developed worsening hypotension and declining oxygenation requiring a bedside laparotomy that evening. A severe metabolic acidosis remained refractory to standard therapy. CRRT was started briefly but he was unable to tolerate due to worsening hypotension. His pH worsened (pH 6.97) with bicarb 6mmol/L and lactate (LA) 26.9mmol/L. Family said their goodies and he was made DNR. Methylene blue was given without hemodynamic change. Given his young age, inability to tolerate CRRT and intraperitoneal access already available, decision was made for emergent PD as a final effort to control refractory acidosis. Approximately 1L of 1.5% peritoneal dialysate with an additional 300 mLq sodium bicarb/2L bag was instilled for a 30 minute dwell time. Within an hour, his labs showed pH 7.12, bicarb 15mmol/L, LA 16mmol/L and his vaspressor requirements decreased. After four exchanges, CRRT was initiated. His acidosis resolved within 24 hours and he was vaspressor free by 36 hours. He was extubated, dialysis dependent and continues to recuperate.

*Discussion:* PD in developed nations is often a forgotten modality for acute renal failure. We found only 2 published reports since 1980 using PD in the ICU for metabolic control. Our case describes successful use of high bicarbonate PD in the ICU to control refractory acidosis and achieve hemodynamic control. Data is lacking on the use of emergent PD in trauma patients and within ICUs despite its relative case and low cost. High bicarbonate PD is an option for refractory acidosis in the critically ill.

**Myoclonic Seizures and Altered Mental Status in a Patient on Peritoneal Dialysis Treated with Piperazine**

Sandra J. Jimenez Acosta,1 Gustavo A. Guzman,2,3 Daniel F. Arroyo Ariza,2,3

1Universidad de los Andes, Bogota, Colombia; 2Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia; 3Healthy Medical Center, Zipaquira, Colombia.

*Introduction:* Here we present the case of a man on automated peritoneal dialysis (APD) with altered mental status and myoclonus after the self-administration of piperazine, an anthelmintic. This case illustrates how dangerous self-medication can be in patients with chronic kidney disease. Additionally, it shows that neither peritoneal dialysis nor hemodialysis appear effective methods for piperazine clearance in patients on renal replacement therapy (RRT).

*Case Description:* A 66-year-old man was brought unresponsive and with myoclonus to the ER. His past medical history included diabetes mellitus, with diabetic neuropathy that lead to ESRD. He was started on RRT 1 year before presentation; initially hemodialysis but later APD. He had no history of seizures or any other neurological disease. Physical examination on admission revealed a dehydrated, ill-looking patient. He was unresponsive to verbal commands. Myoclonus predominantly in his left arm was noticed. Initially we
suspected bacterial infection as the cause of the altered mental status, empirical antibiotic treatment was initiated. However, the patient’s symptoms persisted, requiring care at the ICU and intubation. Further interrogation of the patient’s family revealed that he had self-administered a full bottle of piperazine hexahydrate. An infectious cause was ruled out and no clinical improvement was achieved with antiepileptics. At this point piperazine intoxication was our most likely diagnosis. After a week of APD we decided to switch RRT to sustained low efficiency hemodialysis (SLED). He received two sessions. Gradually the patient’s mental status improved and was discharged with his usual APD.

Discussion: The most common symptoms of piperazine intoxication are myoclonus, decreased level of consciousness and ataxia. Few data is available regarding the dialyzability of this medication, and neither PD nor HD seem effective treatment options. Hemoperfusion seems a suitable alternative. Clinical improvement in this case may be due drug metabolism, independent of treatment. We want to highlight the importance of education in renal patients, specially in the dangers of self-medication. Fortunately, our patient had a full recovery. But that may not be the case of other patients who inadvertently poison themselves with “safe” medications, like piperazine.

**PUB106**

**Two-Year Follow-Up of Quality Indicator Compliance in a Large International Peritoneal Dialysis Institution**

**Background:** Peritoneal dialysis (PD) practice is not universally homogeneous. Best clinical practices are not completely understood as reference values are often obtained from small sized populations and/or frequently based on chronic kidney disease (CKD) and/or hemodialysis data. Objectives: To evaluate two years of follow up of compliance with PD-related quality indicators (QIs) following definition of new targets in an international PD network.

**Methods:** All English and Spanish language CKD and PD guidelines were reviewed. Twelve QIs were considered being of significant relevance and targets for these QIs were defined (see table). Retrospective data analysis

**Results:** Achievement of QI targets for years 2017-2018 is shown in table (image). Variability among countries not shown.

**Conclusions:** There was a significant increase in QIs achievement in 2018 vs. 2017. A75% of patients met the target for the following variables: total weekly Kt/Vurea, 24 h fluid removal, mean arterial blood pressure and serum albumin. Peritonitis rates are clearly over International objectives and were improving. Due to the lack of referral source data, these series may help to understand PD practice and outcomes in a global setting.

**PUB107**

**Acyclovir-Induced Encephalopathy in a Patient on Peritoneal Dialysis**

Aireen Kate M. Kuan, Shamir Hasan, Yuriy Khanin, Hugo Andrade paz, Nupur N. Uppal, Mala Sachdeva. *Northwell Health, Great Neck, NY*

**Introduction:** Acyclovir is an antiviral agent that is used for treatment of diverse viral pathologies. The regular pharmacokinetics for acyclovir is altered with kidney dysfunction. At present, our knowledge regarding treatment of acyclovir neurotoxicity in patients undergoing peritoneal dialysis (PD) is limited, as only few case reports have been published. We describe a case of acyclovir induced encephalopathy in a PD patient that was successfully treated with hemodialysis.

**Case Description:** 34F with a history of systemic erythematous lupus (on prednisone, celecoxib and plaquenil). ESKD on peritoneal dialysis (PD), subclinical hypothyroidism, anemia and hypertension was admitted for her lesions of her lips and right eyelid. She was initiated on intravenous acyclovir at a dose of 500mg daily. 24 hours later, she developed acute confusion which progressed to include myoclonus, lethargy and coma. Labs on admission revealed hemoglobin 10, Na 137, K 4.6, CI 92, CO2 22, BUN 64, Cr 20.85. CT head was negative. EEG did not reveal any epileptiform activity. Lumbar puncture and brain MRI did not show any evidence of viral encephalitis. Acyclovir neurotoxicity was considered as the etiology for her severe encephalopathy. Acyclovir was held and her CCPD prescription was increased but she continued to remain encephalopathic. A decision to initiate hemodialysis (HD) was made. After the first HD session, her mentation slightly improved. She received a total of 3 HD sessions, after which her mental status completely returned to baseline. Given that she improved after discontinuation of acyclovir and with HD this confirmed her diagnosis of acyclovir induced neurotoxicity. She was switched back to PD after recovery.

**Discussion:** Dose adjustment for acyclovir is recommended in patients with ESKD. Even when the acyclovir dose is adjusted for these patients, it can still cause neurotoxicity. This complication seems to be more common in those on PD likely due to the slower removal of the medication with PD. Clinicians need to be aware of this potential adverse event, as this diagnosis needs prompt recognition and treatment. Clearance of acyclovir with PD is not completely understood and in fact PD was not adequate to help with clearance in our patient despite increasing her prescription. The modality of choice for clearance of acyclovir in toxicity is hemodialysis.

**PUB108**

**The Analysis of Risk Factors for the Patients with Venous Needle Dislodgment and Bleeding During Hemodialysis**

Hsuan Ming Lin, Wen H. Wu, Hsiang Wei Hu.1,2 1Aran Nan Hospital, China Medical University, Tainan, Taiwan, Tainan City, Taiwan; 2Department of Healthcare Administration of I-Shou University, Taiwan, Kaohsiung, Kaohsiung, Taiwan; 1National Cheng Kang University, Tainan, Taiwan; 2Acusense Biomedical Corp., Tainan City, Taiwan.

**Background:** A puncture of vascular access is commonly used in clinical treatment, such as hemodialysis or central venous catheters. Leakage or infection associated with Venous needle dislodgement (VND) is a high risk of fatality. However, only a few studies are focusing on patient disease, medication, and other risk assessments. Therefore, this study aims to explore the risk factors of patients with venous needle dislodgment and bleeding and hope to establish the risk classification.

**Methods:** This study was a prospective study conducted in the hemodialysis unit of Tainan Regional Hospital. During the three months from July 2019 to Sep 2019, we collected clinical data, including patient sex, gender, diseases, records of dialysis access leakage, anti-coagulant dose, and a risk assessment form. We compared the data between the two groups of patients who have at least one risk in the risk assessment form. We analyzed the data with STATA™. P<0.05 was defined as significant.

**Results:** In the study period, seventy-one patients were included in this study, with an average age of 63.0 (± 1.19 years) and 46 males (64.79%). The patients with any risk in the risk assessment form were considered the high-risk group. There were 72 venous needle dislodgment and bleeding in 32 patients during the study period. In the below feature, gender, high-risk group or not, diabetes, high blood pressure, exposure to Benzodiazepine, the experience of Intradialytic hypotension, exposure to warfarin, or dosage of anti-coagulant, there was no statistic significant between the patients experienced at least one episode of VND and others.

**Conclusions:** Between patients experience VND or not, we did not find any significant association in not only conventional factors or other factors. However, this study provides a reference for future research.

Catheter Malposition: Unacceptable Reason for Access Dysfunction

Yuliya Sharakova, Mohamed Hassanein, Evamaria Anvari, Tushar J. Vachharajani. Cleveland Clinic, Cleveland, OH.

Introduction: In 2017, 80% incident and 20% prevalent patients in the US received hemodialysis (HD) with a catheter (CVC). CVC placement with ultrasonography and fluoroscopy guidance (FG) is an accepted standard of care to avoid early mechanical complications. Early dysfunctional CVC (dCVC), defined as malfunction in <1 week of insertion is often due to a malpositioned tip leading to inadequate HD and a higher risk of bacteremia. We present a series of early dCVC, a preventable complication.

Case Description: Case 1: 42 y/o male had left IJV non-tunneled CVC placed for continuous dialysis therapy. Encountered multiple episodes of circuit clotting soon after initiation of therapy despite heparinization. The CVC tip was found to be abutting against the innominate vein wall preventing adequate blood flows. An attempt to place a tunneled right subclavian vein catheter at bedside, without fluoroscopy was unsuccessful. Chest XR showed the CVC tip in the left IJV. Case 2: 30 y/o male with a pre-existing right port cath was attempted several episodes of non-sustained ventricular tachycardia, 2 days after a newly placed left dialysis CVC. Chest XR showed port cath had disconnected and migrated to the right ventricle. Removal of the dislodged port cath led to resolution of arrhythmia. Dialysis CVC was preserved. Case 3: 49 y/o obese female had poor blood flows (300 ml/min) in catheter and frequent alarms that failed to improve despite tPA and port reversal. dCVC resulted from tip retraction from right atrium into SVC requiring replacement with a longer CVC. Case 4: 65 y/o female with left IJV tunneled CVC, placed under FG, had poor blood return 2 days after placement. The CVC tip had migrated to the right innominate vein. Catheter was replaced successfully. Case 5: 70 y/o male encountered cloting of the continuous dialysis circuit soon after initiation with a left IJV CVC, requiring replacement of circuit to continue with therapy. Evaluation showed a short CVC with tip abutting against superior vena cava (SVC) wall and required replacing with a longer CVC.

Discussion: Recognizing and troubleshooting early dCVC is an essential learning milestone for a nephrology trainee. Evaluation of a dCVC includes chest XR, forceful saline flush and appropriate use of IPA. Most of these mechanical complications are preventable with proper training and utilizing imaging tools during the procedure.

Percutaneous Transluminal Angioplasty in Arteriovenous Fistula Dysfunction Secondary to Vascular Stenosis

Mohammed Sheeb Ahmed Khan, Vinod Kumar. Aster Medcity Aster Medcity, Kochi, India.

Background: Arterio-venous fistula (AVF) is the lifeline of a hemodialysis patient and the number of vascular accesses in a hybrid in a patient. Vascular stenosis necessitates vascular intervention or creation of a “de novo” AVF. In this study we aimed to evaluate the outcome of percutaneous transluminal angioplasty (PTA) in arterio-venous fistula due to vascular stenosis.

Methods: This is a prospective study of two years (02.05.17 to 02.05.19). Records of patients admitted to our hospital were obtained from hospital archives and images from the hospital radiology imaging system. Demographic characteristics, duration of dialysis, stenosis or occlusion level, patency rates of AVF were evaluated. All procedures were performed by interventional radiologists in a hybrid in a patient. Antegrade, retrograde, or both antegrade and retrograde punctures were used, depending on the site of the stenosis as deemed on preoperative ultrasound. A complete angiogram from the proximal arteriovenous anastomosis to the central venous outflow was performed in all cases. A successful percutaneous balloon angioplasty was defined when there was no more than 30% residual stenosis (KDQI). AVF patency rates were assessed at six months and one year.

Results: Total number of patients studied were 16. The average age was 66.6 years. All were hypertensive and diabetics comprised 75% of study group. Coronary artery disease was established in 81.25%, and two patients were known to have chronic liver disease. Most common type of AVF was the left brachio-cephalic (62.5%), followed by radio-cephalic (37.5%). Average dialysis vintage of AVF at the time of procedure was one year. Previously failed AVF was present in two patients. There were 18 vascular stenosis in 16 patients. The most common site of stenosis was the venous cannulation zone (62.5%), followed by anastomotic site stenosis (31.25%) and central vein stenosis (18.75%). Successful PTA was done in 12 patients. There were no complications; hemodialysis was resumed with native AVF after the procedure. The AVF patency rate at three months was 100%, six months was 75% and at one year it was 37.5%. Four patients were lost to follow up. Mean follow up was 9.41 ± 6.79 months. None underwent a repeat PTA.

Conclusions: Percutaneous transluminal angioplasty is effective for salvaging arterio-venous fistula in majority of hemodialysis patients.

A Tale of Two Accesses: The “Less is More”

Sherif Metwalli, Anilk. Agrawal, Khaled Boubes. The Ohio State University, Columbus, OH.

Introduction: Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). We present 2 patients with ‘imperfect’ accesses where a conservative approach avoided potentially problematic interventions.

Case Description: Case 1 A 24 year old man started hemodialysis (HD) in 1992 due to IgA nephropathy. He received a kidney transplant in 2000 which failed in 2005 requiring resumption of HD. His vascular access was through multiple bilateral failed arteriovenous (AV) fistulae and AV grafts requiring numerous access interventions including tunneled HD catheter placements, angioplasties, and thrombectomies. He has also developed severe contrast allergy, making any further supervised interventions difficult. Since 2005 he has been dialyzing through a right upper extremity AVF complicated by central venous occlusion causing mild right arm swelling. Last resort vascular access options including a femoral AVG and a HeRo graft were contemplated. However, clinical decision making based on the presence of extensive collateral circulation, we opted for a conservative approach instead utilizing low blood flow rates. He has been doing well on this prescription for the last 3 years with adequate dialysis and swelling resolution. Case 2 A 67 year old woman with ESKD started peritoneal dialysis (PD) 2 years ago. PD was complicated by recurrent malpositioning of PD catheter with the catheter tip repeatedly migrating to the right upper quadrant. Changing the catheter insertion site and suturing it to the bladder wall did not prevent tip migration. Transition to HD was contemplated but she was able to continue with PD albeit with position changes to allow for complete drainage of PD fluid. Despite occasional sluggish drainage of PD fluid, the patient continued on PD for a total of 15 months before receiving a kidney transplant.

Discussion: These 2 cases illustrate the importance of dialysis access function as well as the dilemma of both the patient and provider when it becomes dysfunctional. The cases, however, also demonstrate that anatomical perfection is not always necessary to achieve adequate function. In both cases, a conservative approach followed the patient to optimize dialysis through their existing ‘malfuctioning’ access and avoided further interventions that could result in worse complications, proving the adage ‘Less is More’ still true for dialysis access.

What Are Nephrologists’ Preferences Related to Continuing Medical Education?

Amy Larkin, Donald Blatherwick. Medscape LLC, New York, NY.

Background: Understanding how clinicians prefer to learn and participate in continuing medical education (CME) can help providers of such education design more engaging and effective activities that can potentially further improve nephrologists’ clinical performance.

Methods: Medscape conducted a 10 question, online, incentivized survey in November 2018. Respondents’ confidentiality was maintained and responses were de-identified and aggregated prior to any analysis.

Results: Most preferred duration for a CME activity: 30 minutes (51%) Followed by 15 minutes (31%) Most preferred format for a CME activity: online (76%) Most preferred for format for an online CME activity: video and text (45%) For online CME, most preferred instructional design format: case-based (56%) Most important factors in selecting online CME activities: content description (60%) and learning objectives (56%) The most important factors in selecting which symposia to attend at a scientific congress were content (60%), learning objective (41%), and faculty (33%). Most common ways of becoming aware of available professional education activities: invitation from online providers (79%) and societies (74%) The majority of participants reported that in the past 12 months they have learned something from CME that changed their practice (86%) Successful learning is more impactful and clinically meaningful than a single activity (80%)

Conclusions: CME activities have an impact on changing clinician practices. Learner preferences for nephrologists related to live and online CME were identified. Most prefer participation in multiple activities that are online, 15-30 minutes, case-based, video and text description, learning objectives, and faculty play an important role in learner participation. These data should inform development of future CME activities that are engaging and impactful.
Online Education Effectively Improves Nephrologists' Knowledge, Competence, and Confidence Related to Hyperkalemia Management

Background: To improve outcomes for patients, clinicians must be able to implement evolving standards of care and apply relevant data on hyperkalemia management. We sought to determine if an online continuing medical education (CME) curriculum could improve hyperkalemia management.

Methods: The online CME curriculum consisted of 4 activities. Of these, 3 were 30-minute video panel discussions. A repeated pairs pre-/post-assessment study design was used and McNemar’s test assessed educational effect for each activity. The last activity comprised two patients presenting in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions using a 2-tailed paired t-test to determine P values. The activities launched in 2019 and data were collected for 4-12 weeks.

Results: Education significantly improved physicians’ knowledge, competence, and performance managing and treating hyperkalemia. A 40% relative increase was observed among nephrologists related to knowledge of clinical trial data related to hyperkalemia. Nephrologists also significantly improved their knowledge and competence regarding the use of therapeutics in practice, with a relative increase of 16% observed. Case based simulation had a strong and significant positive impact on physicians’ performance in the treatment of hyperkalemia. The % of physicians who decided to start preferred potassium-binder more than tripled after education.

Conclusions: Some gaps still remain after education. Over 40% physicians are still not equipped with the right information regarding clinical trial data and the use of therapeutics in practice. In addition, an average of 40% physicians are still not making the right decision to start preferred potassium-binder. As such, further education needed in these areas.

Optimizing On-the-Go Learning Utilizing Short Modules on Topics Related to Nephrology

Kirun Munir. Farah Daccueil. Stony Brook University Hospital, Stony Brook, NY.

Background: Residents and medical students are expected to formulate evidence-based treatment plans by keeping up with the most recent guidelines but that can be difficult given our schedules. In such circumstances, it is ideal to learn bite-sized pieces on the go.

Methods: We created two modules about Phosphorus Binders and Oral Hypoglycemic Agents using a friendly graphic interface called Prezi. These modules were estimated to take 10-15 minutes and were accompanied by a total of seven content related questions that were compiled from Uworld Step 3 Question Bank, John Hopkins Primary Modules, and hospital courses of patients seen at Stony Brook. Survey monkey was utilized to create the pre and posttest. The modules were sent to third and fourth year medical students. Data was collected for 10 days.

Results: Wolconx signed rank test was utilized to evaluate the effectiveness of the modules. Unfortunately, only six students completed the hypoglycemic module of which two had no improvement in scores, no statistical significance was achieved. However, four of the six students had improvement in posttest scores by at least one point. Improvement in the posttest scores for the phosphorus module was significant as of the nine students who completed the phosphorus module, eight had an improvement by at least 1 point (W 36, p=0.008).

Conclusions: The observation of improved posttest scores for the phosphorus module supports the use of short lessons using a friendly graphic interface such as Prezi.
Ethylene Glycol Poisoning with Near-Normal Osmolar Gap: A Diagnostic Challenge
Moeed Ahmed, Cliff Janikowski, Aiza Ahmad, Lee E. Morrow. Creighton University School of Medicine, Omaha, NE.

Introduction: Ethylene glycol poisoning is classically associated with a high anion gap metabolic acidosis (HAGM). Neurological and gastrointestinal symptoms predominate early while renal failure and death occur if not diagnosed and treated promptly. The diagnosis is usually suggested by HAGM and an elevated serum osmolal gap in the setting of a suspected ingestion. Rarely, the serum osmolal gap may be close to normal which can delay the diagnosis or lead to a misdiagnosis. We report a case of ethylene glycol ingestion with near-normal serum osmolal gap.

Case Description: An 85-year-old man with a past medical history of Dementia presented to the Emergency Department with altered mental status, restless and elevated creatinine of 1.4 mg/dl (baseline 1.2mg/dl). History was difficult to obtain. Vital signs were normal and the physical exam was remarkable only for altered mental status. CT scan of the head did not reveal any acute abnormality. Laboratory workup revealed HAGMA (anion gap = 21 mEq/L, arterial blood pH = 7.62, serum bicarbonate = 9.3 mmol/L, lactic acid = 2.2 mmol/L) with a near-normal serum osmolal gap (12 mOsm/kg). Urinalysis, urine drug screen, blood ethanol, beta-hydroxybutyrate, acetaminophen and salicylate levels were normal. Given a high clinical suspicion for toxic alcohol ingestion, the patient was treated with IV fluids and fomepizole. Over the next few days, his mental status improved, and repeat laboratory workup demonstrated correction of the anion and serum osmolal gaps. Additional history obtained later from his family increased the suspicion for toxic alcohol ingestion. Ethylene glycol level, a send out lab, eventually was normal.

Discussion: The workup for a HAGMA should include evaluation of the serum osmolal gap in the setting of a suspected toxic alcohol ingestion. Although uncommon, the absence of an elevated serum osmolal gap should not prohibit treatment for toxic alcohol ingestion when the clinical suspicion is sufficiently high.

Compensatory Rules for Simple Acid-Base Disorders
Mohammad Amin Fallahzadeh,1 Mohammad Kazem Fallahzadeh Abarghouei,2 Michael Emmett.1 1Department of Internal Medicine, Baylor University Medical Center, Dallas, TX; 2Division of Nephrology, University of California San Francisco, San Francisco, CA.

Background: Most acid-base compensatory equations are based on limited numbers of human observations. We searched the literature for all studies addressing the issue of acid-base disorder compensation. We then utilized all the available data to create an acid-base compensation diagram and generate more accurate compensatory equations.

Methods: We used 84 published articles that evaluated the acid-base blood gas parameters of patients with simple acid-base disorders. We extracted the measured bicarbonate and PCO2, and the authors were requested to send us the full text of articles to calculate the most accurate compensatory formulas for simple acid-base disorders.

Results: Our database was comprised of 3806 observations with simple acid-base disorders. Our results generally agreed with the Goldberg acid-base nomogram except for hyperkalemia which was better described with severe metabolic alkalosis (Figure 1). The best proposed formula in the literature for simple acid-base disorders and the compensatory formulas generated by our data are illustrated in Table 1.

Conclusions: Although the formulas described in the literature perform relatively well in predicting the appropriate compensatory response to simple acid-base disorders, more accurate predictive formulas were developed.

Table 1. The best proposed equations in the literature and most accurate formulas for simple acid-base disorders

Hypernatremia Three Ways
Jordan R. Evans,1 Shweta Bansal.2 1US Army Brooke Army Medical Center, Fort Sam Houston, TX; 2University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: Hypernatremia is a disorder commonly seen in hospitalized patients. It is often caused by dehydration from low water intake, GI, or urinary losses. We present a case in which there were 3 distinct etiologies of hypernatremia that developed during the same admission.

Case Description: A 55 year old male with Down Syndrome and epilepsy was admitted from his nursing home for altered mental status and a 2 day history of lethargy and low oral intake. On admission, he had hypotension, tachycardia, and altered cognition from baseline but otherwise had unremarkable exam. He was diagnosed with klebsiella UTI, acute kidney injury, and hyponatremia. He was started on ceftriaxone and given 1 L of normal saline for hypovolemic hypotension, later switched to a continuous D5W infusion. Pertinent blood and urine chemistry after a liter of saline is shown in table 1. Over the next 4 days, sodium corrected slowly to 144 mmol/L, creatinine returned to baseline, and the D5W infusion was replaced with tube feeds. On day 6, he was again found to be hypernatremic but with polyuria. Urine chemistry (table 1) suggested osmotic diuresis which was attributed to high protein tube feeds. The polyuria and hypernatremia resolved with a change in feeds and D5W infusion. Meanwhile, he was found to be in status epilepticus and intubated for prolonged hypoxia. Despite maximal anti-epileptic treatment, he continued to have frequent seizures. On day 9, he again had polyuria and hypernatremia but this time with lower urine osmolality (table 1). A central DI process was considered due to hypothalamic injury from status epilepticus, which has been reported seldomly. The urine osmolality increased to 413 mOsm/kg 2 hours after desmopressin 2 mcg SQ, confirming the suspicion. His serum sodium and urine volume remained in

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

824
normal limits on scheduled desmopressin doses over next week; however, on day 15 family requested withdrawal of care due to ongoing seizures and futility of care.

Discussion: Our patient developed 3 episodes of hyponatremia during same admission, all due to different etiologies. This case highlights the importance of careful ongoing assessment of history and lab parameters since the best treatment strategy may change for the same diagnosis during the same admission.

Nephrotoxicity is induced after amphotericin B inserts into tubular cell depletes intracellular glutathione resulting in increased levels of 5-oxopropyl. Patients, like the one reported here, with malnutrition, female gender, sepsis, and kidney dysfunction are especially susceptible as they have lower glutathione levels leading to faster 5-oxopropyl accumulation despite standard dosing of amphotericin. Prompt recognition is essential for treatment with acetaminophen cessation and bicarbonate supplementation. Use of acetaminophen as an analgesic alternative to opioids is recognized is essential for treatment with acetaminophen cessation and bicarbonate supplementation. Clinical awareness of predisposing conditions and close monitoring of patient’s acid-base and kidney status can help us mitigate this underrecognized complication of acetaminophen use.

Introduction: Amphotericin B is the drug of choice for most life-threatening fungal infections. Nephrotoxicity is a common adverse reaction of this medication and its lipid complex formulation is an alternative to ameliorate this risk. Renal Tubular Acidosis (RTA) is an uncommon but major complication that can occur, and close monitoring should be performed for rapid identification and management. We hereby present the case of a patient who developed distal RTA secondary to amphotericin B lipid complex.

Case Description: A 59-year-old male patient without known medical history was admitted to Hematology-Oncology Ward with acute Myeloid Leukemia. Chemotherapy with cytarabine and idarubicin was initiated. The patient developed pancytopenia secondary to chemotherapy nadir and septic shock dependent of vasopressors. In addition, the patient suffered an intractable sinus congestion that lead to a biopsy in which invasive fungal sinusitis secondary to Aspergillus was revealed. Amphotericin B lipid complex was started and resulted in improvement of the infectious process. However, the patient developed a stage three acute kidney injury with associated hypokalemia of 2.9 mmol/L, hypophosphatemia of 129 mmol/L, and mixed high and normal anion gap metabolic acidosis of 21.4 mmol/L. Noted findings were consistent with distal RTA and high anion gap component due to renal failure. Amphotericin B was changed to another anti fungal and potassium and bicarbonate were replaced. Treatment led to resolution of azotemia, electrolyte, and acid-base disturbances.

Discussion: Nephrotoxicity is induced after amphotericin B inserts into tubular cell membranes and creates pores that increase permeability, leading to kaliuresis and back diffusion of secreted hydrogen ions. Although this effect is less common with liposomal amphotericin, it has been described in the literature. In addition, the risk increases in diffusion of secreted hydrogen ions. Although this effect is less common with liposomal

PUB123
Treatment Pattern of Hyperkalemia Among Patients Presenting Emergency Department in China Jianming Bian, Li Zuo, Houyu Zhao, Xu Han. Department of Pharmacology, Chinese People's Liberation Army General Hospital, Beijing, China.

Background: In China, the treatment pattern of hyperkalemia (HK) among patients presenting emergency department (ED) is not well described.

Methods: Data containing hospital information system (HIS) records of 157 hospitals, covering 30 provinces in China were extracted from Beijing Data Center for Rational Use of Drugs. Patients aged 18 years old in ED with record(s) of HK, defined as serum potassium (S-K) >5.0mmol/L, from 2015.1.1 to 2017.12.31 were included. The diagnosis rate was defined as the proportion of HK episodes that have diagnoses records. Treatment rate was defined as a proportion of HK episodes that have records of any HK treatment including diuretics, glucose injection + insulin (G+I), calcium injection, sodium bicarbonate, potassium binder or dialysis. Retesting rate was defined as the proportion of HK records that have potassium retest record(s) within 1 day.

Results: A total of 36,615 ED patients with S-K ≥5.0mmol/L each were included. The overall HK diagnosis rate was 9.2%. Diagnosis rates increased by the severity of HK, patients with S-K ≥7.0 mmol/L showed the highest diagnosis rate of 31%. The overall treatment rate within 2 days was 45.3%, treatment rates increased by the severity of HK. Analyzing the HK episodes with HK treatment, G+I (used in 72.4% of HK episodes), loop diuretics injection (used in 50.36% of HK episodes) were most commonly used, while oral potassium binders, including sodium polystyrene sulfonate and calcium polystyrene, were used only in 0.2% of HK episodes. Combined treatments were observed, among which a combination of G+I and loop diuretics injection was used in 10.4% of episodes and a combination of G+I, diuretics injection, calcium injection and sodium bicarbonate was used in 7.4% of episodes. Subgroup analysis of HK treatment in patients with chronic kidney disease showed that, G+I (used in 71.7% of episodes), loop diuretics injection (used in 61.2% of episodes) were most commonly used. The overall retesting rate within 1 day was 19.36%. Patients with S-K 5.0-5.5 mmol/L were retested less frequently (15%) than those with S-K ≥5.5 mmol/L (22.4-30.6%).

Conclusions: In China, the diagnosis and retesting rates of HK in ED patients was relatively low. Glucose injection + insulin was commonly used to treat HK in ED, while oral potassium binders were rarely used. Combination of treatments was common.
therapy is of utmost importance in patients with clinical suspicion of a hematologic malignancy, and hypoxia. A 56 year old woman presented with right knee pain due to septic arthritis. Her admission labs were notable for a sodium of 124 mEq/L, Cr 4.76 mg/dL. Her anion gap was -3 and her serum osmolality was measured as 316 mOsm/kg, with a 50 mOsm/kg osmol gap. Her total protein was noted to be 12.6 g/dL, albumin 2.1 g/dL, with a total bilirubin of 11.1 mg/dL, and glucose 69 mg/dL. Her bicarbonate was 137 mEq/L consistent with pseudohyponatremia. UAC and UPC were 187 mg/w and 780 mg/g respectively. SiEP and UEIP ultimately demonstrated monoclonal IgG kappa. Her total protein increased to 13.7 g/dL, she subsequently became lethargic and developed epistaxis. Further labs revealed a hyperviscosity syndrome with a serum viscosity of 9.2 cP. Her WBC was 140 K/mm3. She underwent 3 sessions of plasmaspheresis and her pseudohyponatremia resolved (Na 139 mEq/L) and total protein improved to 8.9 g/dL. SAG increased to 7. Her mental status and epistaxis improved. Subsequent bone marrow biopsy confirmed 65% plasma cells. She underwent 3 sessions of plasmaspheresis and her pseudohyponatremia resolved (Na 139 mEq/L) and total protein improved to 8.9 g/dL. SAG increased to 7. Her mental status and epistaxis improved. Subsequent bone marrow biopsy confirmed 65% plasma cells. She underwent 3 sessions of plasmaspheresis and her pseudohyponatremia resolved (Na 139 mEq/L) and total protein improved to 8.9 g/dL. SAG increased to 7. Her mental status and epistaxis improved. Subsequent bone marrow biopsy confirmed 65% plasma cells. She underwent 3 sessions of plasmaspheresis and her pseudohyponatremia resolved (Na 139 mEq/L) and total protein improved to 8.9 g/dL. SAG increased to 7. Her mental status and epistaxis improved. Subsequent bone marrow biopsy confirmed 65% plasma cells.
was started on IV hydration, dexamethasone, rasburicase, and allopurinol. On the fifth hospital day, the patient was stable, and white blood cell count decreased by approximately 50 thousand/μL. Two days after, laboratory values were remarkable for hyperkalemia of 6.1 mmol/L, blood urea nitrogen of 66.2 mg/dL, creatinine of 2.61 mg/dL, hyperphosphatemia of 8.3 mg/dL, and a corrected calcium of 7.1 mg/dL. These findings were suggestive of TLS following chemotherapy, along with the development of a non-oliguric stage three acute kidney injury. The next day, the patient had adequate urine output, stable blood pressures, no signs of volume overload or uremia, but laboratory values revealed worsening renal parameters and an increased calcium-phosphate product above 65 μM2. Consequently, hemodialysis was performed with good tolerance and response to treatment.

Discussion: The criteria for hemodialysis in this case of a non-oliguric euvoletic patient with acute renal failure secondary to TLS was founded on an elevated calcium-phosphate product, as opposed to more common indications such as anuria, fluid overload, or persistent electrolyte disturbances. The prognosis for complete recovery of renal function is excellent if dialysis is initiated early to rapidly reduce serum uric acid and phosphate concentration. This emphasizes the importance of a prompt assessment of the calcium-phosphate product as an indication for renal replacement therapy in the setting of tumor lysis syndrome.

Rising from Death: A Case of Life-Threatening Hyperkalemia

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Introduction: Hyperkalemia affects the cardiac conduction and can result in fatal consequences. We describe a rare case of life threatening hyperkalemia presenting in setting of hyperglycemia, sepsis and shock and manifesting as new ST elevation in anterior leads, which resolved with correction of hyperglycemia.

Case Description: A 63-year-old male with intellectual disability and diabetes presented in state of shock after refusing his medications for last 5 days. His vitals on arrival were pertinent for hypothermia (T 29.1°C) and hypotension (56/30 mm Hg). He had cold and clammy extremities and Glasgow Coma Scale of 5. Cardiovascular and bicarbonate levels improved with conservative management without need for renal replacement therapy. Subsequent transthoracic echocardiogram was negative for acute ischemic changes and repeat EKG showed sinus rhythm and resolution of ST changes. The creatine kinase (CK) levels were normal but troponin T high sensitivity were elevated.

Discussion: Severe hyperkalemia is dangerous and can result in cardiac arrest. Our patient presented with very high potassium levels, however hypertensive state might have reduced cardiac output and prevented immediate cardiac arrest. Hyperkalemia in setting of uncontrolled hyperglycemia usually responds to medical management if the patient is not anuric. Moreover, pseudo infarction as seen in this case is a rare manifestation of hyperkalemia. With the recent emphasis on reducing door-to-balloon times in acute myocardial infarction, it is important to be aware of its association with hyperkalemia as it usually resolves with reduction of the serum potassium levels.
An Unusual Cause of Rhabdomyolysis

Esilda Sala Karroci, Larissa Kruger gomes, Ruth Schulman, Krishna A. Agarwal, Amar Pandit, Bradley M. Denker. Beth Israel Deaconess BIDMC, Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Rhabdomyolysis results from muscle cell injury and often leads to AKI. Common causes include trauma, medications, electrolyte abnormalities, and metabolic myopathies. The clinical presentation includes muscle pain, dark urine, and possible oliguria. Here, we present an unusual etiology of rhabdomyolysis resulting from sustained hyperosmolarity due to severe hyperglycemia and hypernatremia.

Case Description: 23-year-old male with no significant medical history presented with fatigue, shortness of breath, nausea, vomiting, and severe muscle pain, diarrhea. Despite drinking large amounts of fluids, he felt thirsty, with frequent urination. Family history: diabetes. Social history: no alcohol, smoking or drug use. No prescription/OTC medicines, or herbal supplements. Vital signs were notable for a heart rate of 110-120 beats/min. He appeared lethargic. Physical exam showed dry mucous membranes and tachycardia, otherwise unremarkable. Initial laboratory values showed blood glucose of 1132 mg/dL, Cr 3.5 mg/dL, Na 147 mEq/L (see table). Urine showed glucosuria and ketones, sediment was bland. He was started on an insulin drip. Corrected Na was 172 with a free water deficit 10L. Initially given 3L NS bolus followed by 1/2NS maint. Blood was drawn to look for rhabdomyolysis in HHS. It is unclear why our patient showed such a severe response to HHS. In up to 50% of HHS cases, this is an extreme case and highlights the importance of looking for rhabdomyolysis in HHS.

The clinical presentation includes muscle pain, dark urine, and metabolic acidosis (CO2 16 [22-30 mmol/L]). Ionized calcium (iCa) was low at 3.34 [4.60 - 5.30 mg/dL] and metabolic acidosis (CO2 16 [22-30 mmol/L]). Ionized calcium (iCa) was low at 3.34 [4.60 - 5.30 mg/dL] and phosphorus 4.6mg/dL [2.2 - 4.6 mg/dL]. His intact parathyroid hormone (PTH) was elevated at 121 [14.0 - 72.0 pg/mL], however, his PTH went back up to his previous baseline at 220 pg/mL. He was discharged from the hospital with close outpatient follow up.

Discussion: Hyperparathyroidism and hypocalcemia (6.3 mg/dL [8.6 - 10.5 mg/dL]), hypomagnesemia (0.6 mg/dL [0.6-2.6mg/dL]) and metabolic acidosis (CO2 16 [22-30 mmol/L]). Ionized calcium (iCa) was low at 3.34 [4.60 - 5.30 mg/dL] and phosphorus 4.6mg/dL [2.2 - 4.6 mg/dL]. His intact parathyroid hormone (PTH) was elevated at 121 [14.0 - 72.0 pg/mL]; however, this was relatively lower than his baseline of 200-250 pg/mL. After adequate magnesium repletion and discontinuation of patiromer, his Calcium improved to 8.4 mg/dL, iCa improved to 4.20mg/dL, and his PTH went back up to his previous baseline at 220 pg/mL. His AKI improved following placement of a ureteral stent.

Hypokalemic Periodic Paralysis

Margaret Mallari, Tamim H. Naber, Omar M. Shahaateet. AtlantiCare Regional Medical Center, Atlantic City, NJ.

Introduction: Hypokalemic periodic paralysis (HOKPP) is characterized by transient episodes of muscle weakness and inability of muscle movement associated with hypokalemia. The paralysis typically affects the arms and legs, though the diaphragm and the tongue may also be affected.

Case Description: A 50-year-old female with tobacco use and significant alcohol consumption presented with progressive upper and lower limb weakness, numbness, and paresthesias that worsened over the past 2-3 months. She also reported fever, sweats, and unintentional 40-lb weight loss over the past 3 months. The patient did not use of diuretics and laxatives. Labs revealed serum potassium 1.9 mmol/L (3.5 - 5.2), phosphorus 2.2 mg/dL (2.5 - 4.5), bicarb 43 mmol/L (21-30), and a venous blood gas of 7.61/50/25/50, which is consistent with metabolic alkalosis. EKG demonstrated U waves and ST depressions significant for severe hypokalemia. She was admitted for severe hypokalemia and was given oral and IM potassium. Vitamin D was 16.0 ng/mL (30-100), which is suggestive of hypovitaminosis D. TSH and cortisol were normal, thus ruling out thyrotoxicosis and Cushing’s, respectively. Serum aldosterone and renin levels were normal, thus ruling out adrenal involvement. The Transtubular K+ Gradient was calculated to be 4, indicating a renal tubular wasting of potassium. In addition to renal potassium wasting, the cellular shift of potassium in the setting of chronic malnutrition and prolonged alcohol use exacerbated the severe hypokalemia. The patient’s potassium was repleted, and she was discharged from the hospital with close outpatient follow up.

Discussion: Hypokalemic periodic paralysis is characterized by transient episodes of muscle weakness in the setting of hypokalemia. HOKPP manifests itself as a sudden onset of weakness ranging from mild transient weakness of the arms and legs to paralysis of the diaphragm and accessory muscles, resulting in lethal respiratory failure. HOKPP can be triggered by a stressor, such as a viral illness or by specific medications, such as insulin or beta-agonists. HOKPP is important to rule out when evaluating a patient with abrupt onset of paralysis or weakness, especially in patients with no history or risk factors of other pertinent disease, such as stroke. The failure to diagnose and properly treat HOKPP can be fatal. It is vital to address the underlying cause of hypokalemia to prevent the recurrence of HOKPP.

A Novel Frameshift Mutation of COL4A5 Identified by Whole-Exome Sequencing in a Chinese Family with Alport Syndrome

Jun Zhang, Wenyu Gong, Xiaxia Xiong, Hui-gun Li. Division of Nephrology, Department of Medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

**Background:** Alport syndrome is an inherited kidney disease caused by the defects in type IV collagen, approximately 80% of which is caused by X-linked mutations in the COL4A5 gene. This study explores a novel frameshift mutation of COL4A5 responsible for renal disorder in a 3-generation Han Chinese pedigree.

**Methods:** We enrolled the proband and his family members from a village in Sichuan province, and collected the family history and clinical data. Clinical examinations were performed to evaluate the phenotypes of the family. Blood samples from the proband and the other eight family members were collected for genetic screen. Whole exome sequencing (WES) was applied in the proband to find out the potential genetic variants, and then the variant within the family was verified by Sanger sequencing.

**Results:** The 31-year-old male proband and his elder brother had ESRD, binaural sensorineural hearing loss and ocular lesions. Further, his three male cousins received hemodialysis and all died from ESRD between 18 and 25 years old. The 90-year-old maternal grandmother, one maternal aunt and one female cousin had only microscopic hematuria without gross hematuria, proteinuria, impaired kidney function or extrarenal symptoms. Genetic analysis identified a novel deletion mutation (c.422_428del) in exon 7 of COL4A5 gene which located on the X chromosome in the proband. The c.422_428del variant was also detected in the proband’s grandmother and four other affected family members. The proband’s father and three unaffected family members had not found this variant. This mutation was results into frameshift followed by formation of a truncated protein, which is responsible for translated protein rather than complete deficiency seen in autosomal recessive disorders. Our results provide a signal of more complicated genetic inheritance in type IV collagen, approximately 80% of which is caused by X-linked mutations in the COL4A5 gene, which were significant for screening and genetic diagnosis for Alport syndrome.

Elevated Ambulatory Blood Pressure Is Associated with a Progressive Form of Fabry Disease

Federica Rossi,1 Einar Svarstad,2 Hassán O. Elsaid,1 Agnese Binaglia,1 Letizia Roggero,1 Sara Auricchio,1 Hans-Peter Marti,2,3 Federico Pieruzzi,1,4 1Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; 2Department of Clinical Medicine, University of Bergen, Bergen, Norway; 3Department of Medicine, Haukeland University Hospital, Bergen, Norway; 4Nephrology and Dialysis Unit, ASST-Monza, San Gerardo Hospital, Monza, Italy.

**Background:** Published data on hypertension incidence and management in Fabry Disease (FD) are scanty and it remains to be shown how much high blood pressure (BP) contributes to organ damage in these patients. Therefore, we have assessed BP values and their correlations with clinical findings in a cohort of FD patients.

**Methods:** Between January 2015 and May 2019, all adult FD patients (n=32) referred to our institute were enrolled; they were Caucasians (n=24 females, n=8 males) with an average age of 50±12.2 years. Data regarding hypertension were obtained by ambulatory BP monitoring (ABPM), home self-monitoring and office measurements. Patients were defined as hypertensive according to 2018 ESC/ESH Guidelines. The severity and the stability of FD were assessed with the Fabry Stabilization Index (FASTEX). Organ involvement and hypertension risk factors were also evaluated.

**Results:** The ABPM revealed elevated BP in 18.75% (n=6) of the FD population and 50% (n=3) of this group was diagnosed with masked hypertension. All these patients were females with an average age of 58±9.9 years. They presented a lower (p=0.046) glomerular filtration rate compared with the normotensive patients (77±17.7 and 89.3±21.4 ml/min/1.73 m², respectively) and a more advanced cardiac hypertrophy with a higher LVPWd (p=0.044) and LVMi (p=0.033). Four of them (66.7%) were classified as progressive by the FASTEX score while the majority of the normotensives (84.6%) were stable (Figure 1). No correlation (p=0.428) was found between the category of GLA mutation and the development of hypertension.

**Conclusions:** Newly detected hypertension is found in a restricted portion of stable FD patients, while it becomes more prevalent in clinically progressive cases. The use of ABPM is of paramount importance to reveal masked hypertension which can contribute to the progressive worsening of the organ failure. We recommend a standardised ambulatory long-term BP monitoring program and timely antihypertensive intervention to improve the outcome of FD patients.
Findings of Whole-Exome Sequencing in a Tunisian Man with Congenital Anomalies of Kidney and Ureteral Tract and Dilated Cardiomyopathy
Sabra Aloui,1 Majdi Nagara,2 Salima Ltaief,1 Ahmed Letaief,1 Manel Ben salah,1 Mouna Hamouda,1 Meriem Ben salem,1 Habib Shkiri,1 Ridha Mrad,2 Sonia Abdeljuk,1 1Department of Nephrology, Monastir University, Monastir, Tunisia; 2Department of Human Genetics, Charles Nicolle Hospital, Tunis, Tunisia; 3Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia.

Background: Congenital Anomalies of Kidney and Ureteral Tract (CAKUT) is a paediatric concern but can be diagnosed in adults adding challenges in the identification of CAKUT’s etiology. To date, there are more than 50 single-gene disorders known to underlie CAKUT. Furthermore, a substantial number of CAKUT causes are extremely rare in the general population. Whole exome sequencing (WES) has been proposed as the solution in some cases.

Methods: Whole exome sequencing and case study of an adult with CAKUT, cardiomyopathy, factor7 and other anomalies

Results: It is about a 30-years-old Tunisian man. He was referred to our unit for renal failure. His parents are second degree consanguine. He was hospitalized at age 2 years for dehydration. He had a brother with Parkinson disease started early at age of 20 years. He was hospitalised at age 29 in cardiology unit for heart failure. Explorations revealed dilated cardiomyopathy (DCM) and an elevated plasmatic creatinine. Physical examination showed a peculiar facies with crying facial expression when laughing, dental anomalies, mild mental retardation, strabismus, large prominent earlobes, brachydactylia, right cryptorchidism and normal blood pressure. Laboratory exams confirmed kidney failure: creatinine at 900μmol/L without proteinuria or haematuria. Prothrombin level was low to 50%, the exploration revealed a factor VII deficiency. Ultrasound scans showed a single right kidney of reduced size. We concluded at chronic renal failure due to tubulointerstitial nephritis associated with urofacial syndrome, DCM and factorVII deficiency. The diagnosis of a CAKUT with OCHOA syndrome was suspected but heart failure and factor VII deficiency were not explained. A whole sequencing exome was performed. It reversed the Osha syndrome and revealed two other possible genetic etiologies of CAKUT: a Kabuki syndrome and a Sensenbrenner syndrome. It also revealed a mutation of TTN, the gene encoding the sarcomere protein titin, explaining the DCM.

Conclusions: Exome Sequencing have a dual role as a discovery and diagnostic Tool. It’s clinical utility will be discussed especially in in countries with strong consanguinity and low-income as in North Africa

ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis: A Positively Rare Cause of RPGN
Amrani Narouyan, Wafa Dawahri, Paru P. Kathapla. Mercy Hospital Medical Center, Chicago, IL.

Introduction: Pauci-immune crescentic necrotizing glomerulonephritis (PICGN) is the most common subset of RPGN. Most cases of PICGN are antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides; however, about 10-30% of patients are ANCA negative. Several studies have suggested that ANCA-negative PICGN has a lower incidence of extra-renal involvement, a poorer prognosis, and often dialysis dependent. Unfortunately given our limited understanding of the pathophysiology of ANCA-negative PICGN, current therapy is similar to ANCA-positive despite its worse prognosis.

Case Description: 60-year-old female presented for hypertension emergency. She had an elevated creatinine (Cr) of 1.48; baseline was 1.29 two weeks ago. Her Cr worsened to 2.05. Renal biopsy was consulted. Initial differential included acute drop in BP from restarting medications. UA showed 2+ protein, quantified 2 grams/gCr and RBC > 100. Findings of ANCA testing negative. Several studies have suggested that ANCA-negative PICGN has a lower incidence of extra-renal involvement, a poorer prognosis, and often dialysis dependent. Unfortunately given our limited understanding of the pathophysiology of ANCA-negative PICGN, current therapy is similar to ANCA-positive despite its worse prognosis.

Discussion: Since patients with ANCA-negative PICGN have few extra-renal manifestations, they are often dialysis dependent and have a worse prognosis, early recognition is crucial. The diagnosis primarily relies on performing a kidney biopsy rather than serological testing, otherwise the diagnosis may be missed. Early initiation of empiric therapy is appropriate to minimize the degree of irreversible injury and delay dialysis initiation. The use of deferasirox in non-renal fibrotic lesions in renal biopsy may predict treatment response. ANCA negative PICGN is a rare diagnosis; this case highlights why it is important to keep this diagnosis in the differential and why novel treatment options are needed.
Case Description: A 32-year-old female with prior history of gestational hypertension presented to our hospital with a three-day history of bilateral lower extremity edema and periorbital swelling. On exam, profound periorbital edema and 2+ pitting edema up to the knees bilaterally was noted. Labs were consistent with a creatinine level of 5.0 mg/dL up from her baseline of 0.5 mg/dL three months prior. Urinalysis and random urine testing confirmed proteinuria of almost 19 grams per day. Renal ultrasound was obtained showing normal sized kidneys with increased echogenicity. Kidney biopsy was obtained and results were consistent with collapsing FSGS. Secondary workup for etiology of FSGS came back positive for Parvovirus B19 infection. Along with diuresis, decision was made to start IVIG kidney protection therapy. Initially, patient had improvement in kidney function post treatment and patient was followed up in clinic. However, required hemodialysis for one month.

Discussion: FSGS is commonly associated with nephrotic syndrome and stems from podocyte abnormalities. Podocyte detachment and death lead to segmental sclerosis, which is the hallmark pathophysiology of FSGS. Kidney biopsy is used to diagnose FSGS and characterized by the presence of sclerosis of at least one glomerulus on histologic examination. Histologically there are five classifications of FSGS with collapsing carrying the worst prognosis. Treatment is typically aimed at controlling proteinuria, edema, and cholesterol. In our patient with Parvovirus B19 induced FSGS, we used IVIG with prednisone therapy but no improvement. Further research is needed to find treatments for Parvovirus B19 induced FSGS for better outcome.

PUB145
A Whole Genome-Wide Arrayed CRISPR Screen in Primary Organ Fibroblasts to Identify Regulators of Kidney Fibrosis

Background: Robert J. Turner, Stefan Gola, Carina Wollnik, Nils Burkhardt, Ina Sternberger, Uwe Andag, Hauke Cornils Kidney fibrosis presents a hallmark of chronic kidney disease. With ever-increasing patient numbers and limited treatment options available, novel strategies for therapeutic intervention in kidney disease are warranted. Fibrosis commonly results from a wound healing response to repeated or chronic tissue damage, irrespective of the underlying etiology, and can occur in virtually any solid organ or tissue.

Methods: whole genome-wide arrayed CRISPR screening high content imaging

Results: In order to identify targets relevant for kidney fibrosis, we employed CRISPR screening in primary human kidney fibroblasts. Selected hit genes were validated.

Conclusions: We demonstrate that CRISPR technology can be applied in primary kidney fibroblasts and can furthermore be used to conduct arrayed CRISPR screening using a high-content imaging readout in a whole genome-wide manner. Hits coming out of this screen were validated using orthogonal approaches and present starting points for validation of novel targets relevant to kidney disease.

PUB146
Dual Positive Anti-Glomerular Basement Membrane Disease and ANCA Disease: A Diagnostic Challenge
Avishek Tandon, Kevin Fu, Avi Z. Rosenberg, Renu Regunathan-Shenk, Division of Kidney Disease and Hypertension, George Washington School of Medicine and Health Sciences, Washington, DC; Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD.

Introduction: Double-positive disease (DPD), defined as coexistence of anti-glomerular basement membrane (Anti-GBM) disease and an anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAN), is rare disease associated with variable outcomes. These patients often do not have typical presentation of either anti-GBM disease or AAN, making diagnosis a challenge.

Case Description: A 59-year-old male with history of hypertension presented with 1 week of fatigue and decreased urine output. Initial labs revealed a serum creatinine of 11.6 mg/dL and blood urea nitrogen of 133 mg/dL. Urinalysis showed specific gravity of 1.025, pH 5.0, 1+ protein, large blood, and 11-20 RBCs/hpf. Serological workup including anti-nuclear antibody, complement C3 and C4, HCV, hepatitis B and C were all unremarkable. The patient then developed hemoptysis and anuria. He was initiated on hemodialysis. Renal biopsy revealed extensive cellular and fibrocellular crescents, diffuse tubular injury with RBC casts, and 30% interstitial fibrosis and tubular atrophy. Immunofluorescence was negative. Further investigation revealed an elevated Anti-GBM titer, elevated anti-myeloperoxidase antibody and negative anti-proteinase 3 antibody. He was treated with methylprednisolone 1g intravenously for 3 days then daily prednisone 60mg and one dose of cyclophosphamide 1g intravenously. He was then transferred for initiation of plasmapheresis and received 8 sessions with normalization of Anti-GBM and ANCA titers. He also received another dose of cyclophosphamide 1g. He remained dialysis-dependent upon discharge.

Discussion: The variable presentation of DPD may cause a delay in diagnosis. DPD patients have a greater tendency to recover renal function but a higher risk of relapse. Early recognition and aggressive treatment is essential.

PUB147
Transcriptomic Profiling of Collagens in Proteinuric Kidney Disease

Background: The purpomycin aminonucleoside nephropathy (PAN) model is associated with proteinuria and matrix accumulation. We tested the hypothesis that renal COL1A1 and COL3A1 are differentially expressed genes in PAN nephropathy.

Methods: Adult Wistar rats were administered water (sham) or PAN (~100 mg/kg, IP) and urine protein (24-hour) was measured on Days 4, 8, 12 and 21. Animals were sacrificed on Day 21, the left kidneys retrieved, and renal COL1A1 and COL3A1 mRNA levels measured using quantitative polymerase chain reaction.

Results: The rat PAN model was associated with increased proteinuria (*, p<0.01 vs. sham). Compared to the sham cohort, renal COL1A1 and COL3A1 mRNA expression levels were increased, 1.86-fold (p<0.05) and 8.4-fold (p<0.01), respectively, in the PAN cohort. Proteinuria correlated directly (r=0.9) and significantly (p<0.01) with renal COL3A1 mRNA expression level.

Conclusions: Renal COL1A1 and COL3A1 mRNA expression levels are elevated in proteinuric kidney disease. Since COL3A1 mRNA expression is associated with increasing proteinuria, targeting type III collagen might prove beneficial. Funded By: United States Department of Defense - PR180780/ W81XWH1910448

PUB148
C3 Glomerulonephritis: Diagnostic Challenges and Overlap Syndromes
Krishna A. Agarwal, Esilida Sula Karrecci, Larissa Kruger gomes, Ruth Schulman, Isaac E. Stillman, Stewart H. Lecker, Theodore I. Steinman, Bradley M. Denker. BIDMC Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: C3-glomerulonephritis (C3GN) is a rare complement-mediated GN, with an incidence of 1-3:1,000,000. Spectrum of presentation can range from asymptomatic hematuria and proteinuria to a full blown acute GN with hypertension, hematuria, and renal insufficiency. Serum C3 levels are typically low. Diagnosis is confirmed by renal biopsy. The underlying mechanism appears to be dysregulated alternate complement pathway, triggered by genetic, environmental or a combination of both factors. Medical management addresses blood pressure, proteinuria, and dyslipidemia. Immunosuppression with glucocorticoids, antimetabolites, and anti-complement agents is used alone or in combination. Here we present 2 cases of biopsy-proven C3GN, mimicking infection-associated GN (IAGN) and TTP/HUS.

Case Description: Case 1: A 49-year-old man presented with 4-5 days of fevers, chills, nausea, vomiting and diarrhea. Labs revealed mild thrombocytopenia, proteinuria, microscopic hematuria and a low C3 level. Blood cultures revealed Streptococcus pyogenes. His hospital course was marked by rapidly progressive pancytopenia and hemodialysis-requiring acute renal failure. He received a single dose of ecclizulam empirically due to concern for atypical HUS, but platelet counts improved too rapidly.

to be consistent with eculizumab benefit. Kidney biopsy revealed acute tubular injury with 70% of GOM did not have detectable monoclonal serum protein. Like other reported cases, he responded well to a bortezomib based regimen.

PUB51B
A Challenging Case of Renal-Limited Vasculitis
Mounim Ahmed, Bashar Ramadan, Eric Magliulo, Dongpo M. Salas, Jocelyn A. Taylor, Khalid Bashir. Creighton University School of Medicine, Omaha, NE.

Introduction: Anti-neutrophil cytoplasmatic autoantibody (ANCA)-Associated Vasculitis (AAV) is an autoimmune disease that causes inflammation of blood vessels and has a wide spectrum of clinical presentation. It can present as multisystem or renal-limited disease. The typical renal presentations that of a rapidly progressive glomerulonephritis (RPGN). We present an interesting case of renal-limited vasculitis with atypical features.

Case Description: A 76-year old male with a past medical history of Hypertension (treated with hydralazine) and CKD Stage 3 presented with weakness and shortness of breath for about two weeks. Physical exam and vitals were unremarkable. Laboratory workup revealed AKI with creatinine of 6.5 mg/dl. Uramyc revealed microscopic hematuria and proteinuria (urine protein/creatinine ratio of 0.9). Renal ultrasound was unremarkable. Serologic workup including ANA, C3, C4, anti-GBM Ab, HbsAg, HbsAb and HbcAb was unremarkable. However, p-ANCA titer was high (1:160). He was treated with IV fluids. Interestingly, he continued to have good urine output as well as improvement in serum creatinine to 4.8 mg/dl and was discharged from the hospital.

Follow-up renal function panel in two weeks showed worsening serum creatinine of 6.8 mg/dl. The patient was readmitted to the hospital. Repeat serologic workup revealed p-ANCA, titers of 1:320 and elevated MPO IgG of 78 U/mL. Renal biopsy revealed pauci-immune glomerulonephritis. Steroids and rituximab were initiated as treatment. Due to worsening kidney function, patient was started on hemodialysis. He remained dialysis dependent with no significant renal recovery. Given atypical features of disease presentation, hydralazine was considered to be an etiologic agent hence, and was discontinued.

Discussion: We present a case of renal-limited vasculitis with atypical features making the diagnosis very challenging. Firstly, the patient remained nonoliguric through the first hospital course. Secondly, his serum creatinine improved with supportive treatment leading to his discharge with presumptive diagnosis of ATN. In summary, ANCA associated GN may present with nonoliguria as well as waxing and waning renal function. Atypical features of AAV should raise concern for drug-induced etiology.

PUB512
Collapsing Focal and Segmental Glomerulosclerosis with Thrombotic Microangiopathy Found on Renal Biopsy in a Patient Receiving Intravitreal Aflibercept for Age-Related Macular Degeneration
Ramy M. Hanna,1 Gautam M. Phadke,2 Kenar D. Jhaeveri,1 Irma Kurtz,2 Kantry Kalantar-Zadeh,1 UC Irvine, University of California Irvine, Orange, CA, 3University of North California Los Angeles, Los Angeles, CA, 4Northwell Health, Great Neck, NY, 5University of North Dakota, Columbia, OH.

Introduction: Intravitreal Vascular Endothelial Growth Factor (VEGF) Receptor blockade medications are used for a variety of retinal diseases. These include age related macular degeneration (AMD), diabetic macular edema (DME), and central retinal vein obstruction (CRVO). Reports of absorption of intravitreal agents into systemic circulation have increased in number, and confirmation of depletion of VEGF has been confirmed. Increasingly there are studies and case reports showing worsening hypertension, proteinuria, renal dysfunction, and glomerular disease. The pathognomonic findings of systemic VEGF blockade, thrombotic microangiopathies (TMs) are also being increasingly reported. One variant of TMs that has been described is collapsing focal and segmental glomerulosclerosis (cFSGS). cFSGS has been postulated to occur due to VEGF-induced chronic glomerular hypoxia. We present the third reported case of cFSGS in the setting of intravitreal VEGF blockade, a chronic TMA component was crucially found on biopsy.

Case Description: This patient is a 74-year-old non-diabetic male receiving aflibercept for age-related macular degeneration. The patient presented with bilateral visual loss. On examination, he responded well to a bortezomib based regimen.

A Case of IgA Vasculitis in Liver Cirrhosis
Jayesh B. Patel, Swe Zin Mar Winhtuo, Daniele G. Holanda, Lama A. Noureddine. University of Iowa Hospitals and Clinics, Iowa City, IA.

**Introduction:** IgA vasculitis (previously termed Henoch-Schönlein purpura) is a systemic immune-complex mediated condition characterized by predominant IgA deposition in microvessels. We present a case of biopsy-proven IgA vasculitis involving skin and kidneys in a patient with known liver cirrhosis.

**Case Description:** A 71-year-old man with liver cirrhosis due to chronic ETOH use presented to ER with ER with a one-month history of progressive rash and pedal edema. He denied arthralgias, melena, hematemesis, abdominal pain, or fever. Diffuse, erythematous, palpable, non-pruritic petechial lesions were noticed on bilateral thighs, arms, and anterior abdominal wall with few lesions coalescing to purpura. Laboratory evaluation revealed an elevated creatinine at 1.7 mg/dL. Urinalysis showed dysmorphic erythrocytes, leukocytes, and proteinuria. ANA was positive (1:320), C3 slightly low with normal C4, Cryoglobulin, RA factor, SPEP, ANCA, anti-dsDNA, HBsAg, antibodies to HIV, HCV, rickettsia, and syphilis were negative. Peritoneal fluid culture was sterile. Kidney biopsy revealed severe proliferative glomerulonephritis, cellular/fibrocellular crescents and mild interstitial fibrosis. Skin biopsy revealed dense pervaicular neutrophil infiltration with fibrin deposition and erythrocyte extravasation consistent with leukocytoclastic vasculitis. He was diagnosed with IgA vasculitis and treated with pulse IV steroids followed by oral taper along with monthly IV cyclophosphamide infusions. Petechial lesions improved markedly but renal function was unchanged at 4-month follow-up. Unfortunately, the patient died 5 months after initial presentation due to complications of underlying liver disease and secondary infection.

**Discussion:** IgA vasculitis, more commonly observed among children than adults, manifests clinically as palpable, blanching purpura, arthritis, urticaria, palpable and non-pruritic petechial lesions, and kidney injury. Adults commonly develop ESRD in one of three circumstances. Similar to crescentic IgA nephropathy, a combination of IV followed by oral steroids and IV cyclophosphamide is recommended in patients with rapidly progressive renal failure with more than 50% crescents on renal histology. In our case, the patient had an underlying liver disease which is an independent risk factor associated with glomerular IgA deposition due to inadequate clearance. The degree of contribution to the pathogenesis of IgA vasculitis remains unknown.

A Remission Case with Obsolescent IgA Nephropathy in Aspirin Plus Eicosapentaenoic Acid
Shimichiro Kogga. Section for Nephrology and Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo 168-8541, Japan.

**Introduction:** In case of evading immunosuppression therapy to IgA nephropathy, ACEI, ARB, or both has statistically improved renal prognosis evaluated in urine protein(UP)

**Case Description:** A 68-year-old woman was referred to nephrologist with complaint of bilateral leg edema accompanied with proteinuria and microscopic hematuria to acute nephritic syndrome, with oliguria, edema, hypertension, and acute kidney injury (AKI). It most often occurs in children of developing countries. Its incidence is not well characterized in elderly individuals but is thought to be extremely rare. We report a case of PSGN in an elderly female complicated by hypertensive urgency and heart failure.

**Case Description:** An 89-year-old female with history of COPD, HFpEF, CKD stage 3a presented with lethargy and weakness. She was treated for bronchitis 3 weeks prior and initially improved but then developed progressive dyspea and swelling in her lower extremities. On presentation, BP was 252/120, CXR showed cardiomegaly and pulmonary edema. Labs revealed a creatinine of 2.72 (baseline 1.4). She was started on IV diuretics, BIPAP, and nortriptyline drip with improved BP control. She remained oliguric.

Nephropathy was consulted due to no improvement in urine output despite bunetamide and thiazide diuretic challenge. Renal ultrasound was unremarkable. The patient was negative. She required emergent hemodialysis (HD) as her kidney function failed to recover. A renal biopsy showed chronic tubular and arteriolar changes with noted glomerular endocapillary immune-complex glomerulonephritis, concerning for post-infectious GN. She ultimately required an arteriovenous fistula for long-term HD.

**Discussion:** PSGN primarily occurs after an upper respiratory infection or impetigo. It is less common in adults, however, is associated with a worse prognosis compared to children, with less than 25% achieving full recovery of renal function. Unlike children, the patients aged to present with etiologies of lower respiratory infections (LRI) and UTIs. Studies show the time between infection and renal injury may be little to none, as infections in the elderly is often nonspecific and might go unrecognized. Our patient had an AKI after a LRI, resulting in significant oliguria and lack of renal recovery leading further work up with a biopsy. It is therefore imperative that providers consider PSGN as a differential diagnosis in elderly patients with severe AKI. Treatment is mainly supportive, and patients, like ours, might require HD.
Underline represents presenting author.

Our patient, it is an intriguing question based on new evidence. Certainly, her underlying mechanism connecting these conditions remains poorly understood. Here we present a patient with profound hypothyroidism and idiopathic membranoproliferative changes consistent with class IV/V lupus nephritis. Eculizumab was discontinued and she was started on cyclophosphamide and pulse dose steroids. Her kidney function continued to decline and she eventually required hemodialysis. Serial echocardiograms revealed improvement in cardiac function and she was discharged from the hospital on dialysis.

Discussion: TMA can occur with autoimmune diseases. Although the mechanism remains unclear, there is evidence of complement activation leading to injury. For these cases, there is no evidence that treating TMA itself changes outcomes. It is important for clinicians to discuss diet changes and received blood pressure medications. Some patients also received steroids and immunosuppressants. Frequency of monitoring kidney function varied and created anxiety for both patients and caregivers. Understanding the patient journey, Perceptions, and Burden Associated with Immunoglobulin A Nephropathy (IgAN): A Qualitative Study

Patient Journey, Perceptions, and Burden Associated with Immunoglobulin A Nephropathy (IgAN): A Qualitative Study

Nancy Zaour,1 Miriam Maylendörfer,2 Susanna Walda,2 An chees T. George,3 1Novartis Pharma AG, Basel, Switzerland; 2IPSOS SA, Basel, Switzerland; 3Novartis India Hyderabad, Hyderabad, India.

Background: There is a lack of published evidence on patient perspectives in IgAN; a rare condition that can progress to end stage renal disease (ESRD). The objective of this study was to understand the patient journey, disease perceptions and burden of disease from the patients’ perspective.

Methods: This qualitative study was conducted after review board approval through a moderated online bulletin board platform and by telephone interviews, to allow comprehensive answering of pre-defined questions. Participants were recruited via physician referral and were screened to ensure eligibility and willingness to participate. Analysis was conducted using a combination of various qualitative analytical tools.

Results: Eight participants with a confirmed diagnosis of IgAN from North America and Europe, aged 29–58 years participated. Diagnosis was often incidental as symptoms were underestimated or unnoticed. Participants were overwhelmed to learn they were diagnosed with a chronic disease and many did not understand the seriousness of the outcomes associated with the same. Post diagnosis, participants were referred to a nutritionist to diet changes and received blood pressure medications. Some patients also received steroids and immunosuppressants. Frequency of monitoring kidney function varied and created anxiety for both patients and caregivers. Understanding the patient journey, Perceptions, and Burden Associated with Immunoglobulin A Nephropathy (IgAN): A Qualitative Study

RETINAL DRUSEN IN AUTOIMMUNE-MEDIATED AND PAUCI-IMMUNE GLOMERULONEPHRITIS

Philip A. Harraka,1 Heather G. Mack,2,3 Deb J. Colville,1 David Barit,1 David Langsford,1 Timothy J. Pianta,2 Judith A. Savige,1 1The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; 2The University of Melbourne Department of Surgery (Ophthalmology), Melbourne, VIC, Australia; 3Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia.

Background: Membranous nephropathy (MN) is the most common type of primary glomerular disease. It is characterized by subepithelial immune complexes, located in the mesangial region of the Bowman’s capsule. The pathogenesis of MN is not fully understood, but several factors have been implicated, including genetic susceptibility, infections, and environmental factors. Retinal drusen have been described in one individual with membranous nephropathy and linear IgG deposits in Bruch’s membrane of another with anti-GBM disease. In contrast, pauci-immune membranoproliferative glomerulonephritis to determine how often drusen are observed in individuals with antibody-mediated or pauci-immune glomerulonephritis to determine how often drusen occur in each group.

Methods: This was a cross-sectional observational case-series of individuals with antibody-mediated (n=15, membranous n=9, anti-glomerular basement membrane (GBM) n=6) or pauci-immune (n=16, granulomatosis with polyangiitis n=7, microscopic polyangiitis n=7, eosinophilic granulomatosis with polyangiitis n=2) glomerulonephritis recruited from a general hospital in an Australian tertiary-care hospital. Two-field colour fundus images were obtained with a non-mydriatic camera (CANON, Japan). Images were coded and assessed for drusen count, location and size by two trained graders using the Wisconsin Age-Related Maculopathy Grading Grid. Central drusen counts a 10% were considered abnormal.

Results: Four (27%) individuals with antibody-mediated disease (membranous n=2, anti-glomerular basement membrane (GBM) n=2) but only 4% (1/25) with pauci-immune disease. Gender, mean age and disease duration were not different between the two groups. Conclusions: These results suggest that retinal disease occurs together with glomerulonephritis when the target antigen is found in both locations. Retinal drusen may be a useful biomarker for some forms of glomerulonephritis, and drusen pathogenesis may explain in part the pathogenesis of glomerular immune deposits. In addition, treatments that target retinal drusen may also be useful in antibody-mediated glomerulonephritis.
Introduction: Circulating permeability factors (CPF) may be involved in the pathogenesis of some forms of FSGS that are non-responsive to intensified immunosuppression and exhibit a rapidly progressive course. The role of CPF-mediated FSGS is indicated by the post-transplant recurrence of proteinuria and its response to TPE. Moreover, experimental animals injected with plasma from patients with FSGS can develop proteinuria. While TPE in patients with post-transplant recurrence can prevent graft failure, evidence to support its use in resistant FSGS in native kidneys is lacking.

A retrospective analysis of a 62-year-old Caucasian female presented with anasarca and nephrotic-range proteinuria (5.0 g/day) in March 2018. Kidney biopsy revealed minimal change disease. The first 14 months of her course were complicated by steroid resistance, side effects of high-dose steroids and calcineurin inhibitors (CNI), recurrent AKI, CNI/ ARB-induced hypertension, and worsening of proteinuria with CNI reduction. She received 4 doses of rituximab (375 mg/m²) during that period. Genetic testing for the steroid-resistant nephrotic syndrome was negative. In June 2019, a trial of 10 TPE sessions resulted in a significant improvement in proteinuria (UPCR=1.8±2.0), which worsened over the following 4 months after discontinuation of TPE (UPCR=4.0). Repeat kidney biopsy revealed FSGS. Given the previous response to TPE, a central-venous port was placed for long-term TPE in December 2019. The patient received TPE twice a week for the first 6 weeks. With improved proteinuria, TPE was tapered to twice a month with maintenance partial remission (UPCR =1.5) for the last 5 months. The patient is off ARB, on a minimal dose of CNI. The symptoms associated with nephrotic state and the side-effects of multiple drugs have resolved.

Discussion: This case highlights the dilemma of therapeutic decision-making in patients with resistant FSGS. Long-term TPE successfully maintained symptom-free sustained PR and stabilized renal function. TPE has become the preferred choice of our patient to avoid the toxic effects of long-term intensive immunosuppression. More studies are required to study the efficacy and safety of TPE in patients with native kidney FSGS resistant to therapy.

Association Between Anti-GBM Titers and Kidney Inflammation with a New Activity Score

Background: Anti-glomerular basement membrane (anti-GBM) disease is a rare glomerulopathy characterized by rapidly progressive loss of kidney function, leading to end stage kidney disease in a significant amount of cases. The main objective of our study is to determine whether anti-GBM titer correlate with rate of activity in renal biopsy and long-term kidney survival in patients with anti-GBM, hence identifying patients who would potentially benefit from more intensive treatments.

Methods: A retrospective analysis was performed on anti-GBM cases from 2007 to 2018 with both positive biopsy and serology. Anti-GBM levels and kidney function at admission, diagnosis, change, treatment, and kidney biopsy findings were collected. All biopsies were reevaluated by a single, blinded pathologist. Based on a recent study by Van Daalen et al, we developed an activity score. The score was divided in a glomerular and interstitial section. In the glomerular section, a sclerotic pattern (>50% of glomeruli) was given 0 pts in activity and 3 in chronicity, a mixed pattern was given 1 pt in activity and 2 in chronicity, and a crescentic pattern (>50% with cellular crescents) was given 3 pts in activity and 0 in chronicity. In the interstitial section, the presence of fibrosis and atrophy, was given between 0 and 3 pts in chronicity and the presence of tubulitis or interstitial infiltrate with neutrophils were given points in activity (0 to 3 respectively). Spearman correlation was performed between anti-GBM levels, our biopsy score, and kidney survival at follow-up.

Results: Twelve cases were identified, 9 were males, mean age was 54. Anti-GBM at admission ranged from 40 to 1517 U/ml. Ten patients were treated with cyclophosphamide, 1 with rituximab plus cyclophosphamide and 1 with only rituximab. The median number of therapeutic plasma exchange sessions was 8 (range 6-12). High antibody titers correlated with greater activity on biopsy (r =0.6, p =0.04) and lesser chronicity (r =-0.7, p =0.02). Kidney loss at follow-up (35 months) was 92%.

Conclusions: These results suggest that patients who present higher titers have more acute inflammation, and therefore could benefit from more intensive treatment. It would be interesting to study this score in larger cohorts in order to produce more definitive conclusions.

Antisynthetase Syndrome and Nephrotic Syndrome

Noe Martinez murillo, Jorge J. Font, Jonathan Chavez, Joana G. Navarro gallardo, Jose A. Torres, Christian P. Flores. Universidad de Guadalajara, Guadalajara, Mexico.

Introduction: The presence of anti-synthase syndrome and IgA nephropathy is unusual. Symptoms similar to other diseases that affect the connective tissue: Lupus, Rheumatologic and Dermatologic.

Case Description: A 39-year-old female with acute renal failure due to a one day history of shortness of breath. Her admission was complicated by polymicrobial sepsis, severe hypotension, acute renal failure, worsening of proteinuria and dysphagia to solids then to liquids. The diagnostic approach for the cases of rheumatological diseases is addressed, with negative ANA, positive ANCA 1:10 (MPO (-) and PR3 (-), Low C3 complement and positive Anti J01 and Anti R0 52 ++. Electromyography was performed reporting normal sensory neuroconduction as well as motor conduction. Muscle biopsy showed the presence of perimysial infiltrate. Renal biopsy showed mesangial proliferation and immunofluorescence with IgA. Symptoms progress to type 2 respiratory insufficiency, severe hypercapnia, starting with methylprednisolone 3 doses with slight improvement, adding immunoglobulin at dose of 2 g / kg, recovering muscle strength, respiratory parameters and decreasing CPK.

Discussion: IgA nephropathy is an atypical manifestation in patients with antisynthetase syndrome, only 3 cases have been reported, the pathophysiological origin is unknown, the most accepted hypothesis is humoral activation.
Case Description: A 46-year-old male with a history of Intravenous (IV) drug use and hepatitis C presented with shortness of breath and chest pain. Patient was found to have Methylcellulose Resistant Staphylococcal bacteria and tricuspid valve endocarditis. Physical examination was positive for bilateral leg edema and pan systolic murmur over left lateral sternal border. Initial serum creatinine was 1.54 mg/dl (baseline 1.0 mg/dl). Urine analysis revealed proteinuria and hematuria, and the sediment was consistent with isomorphic WBCs and RBCs with many granular casts. Renal US revealed right kidney 11.6 cm and left kidney 13.5 cm in maximum dimension with no hydronephrosis. All serology tests were negative except for a low C3 and positive cryoglobulins. The percutaneous renal biopsy showed proliferative GN (diffuse proliferative GN) with focal MPGN pattern in two glomeruli and rare crescent (in one glomerulus), full house immunofluorescence (IF) with IgA co-dominance and both capillary wall and mesangial staining (IgA 3+, IgG1 2+, IgM 2+, C3 3+, C1q 1+) and small subepithelial (hump-like) and both small and large subendothelial deposits on ultrasonography. Final biopsy diagnosis was given as IgA-cadominant staphylolococcal infection-associated glomerulonephritis (SAGN). Patient was treated with eight weeks of IV antibiotics and underwent supportive hemodialysis during hospitalization. He was discharged home off hemodialysis and followed up in outpatient clinic for Chronic Kidney Disease stage IV.

Discussion: The presence of nephrotic syndrome in this patient presents a challenging scenario and MPGN secondary to hepatitis C may be considered a differential here although SAGN is a stronger contender based on clinical and biopsy findings and protein-range proteinuria, though not common, has been described in SAGN and endocarditis-associated GN cases in variable percentages, ranging from 6-48%.

PUB168

Unmasking of Pancreatobiliary Carcinoma in a Patient with Fibrillary Glomerulonephritis

Avneek Singh Sandhu,1 Harold J. Duarte,1 Natallia Maroz.1,2 Kettering Health Network, Dayton, OH; 2Wright State University, Dayton, OH.

Introduction: Fibrillary Glomerulonephritis (FGN) is a rare disease with known malignancy correlation. Cancer can be discovered simultaneously with the diagnosis of FGN or later in the course of the disease. As per our knowledge, this case is a first description of rapidly progressing pancreatobiliary carcinoma (PBC) associated with FGN.

Case Description: 49 y/o white woman presented to the nephrology office with proteinuria of 1.3 g/day and hematuria. She had a past medical history of smoking (>20 years) and hypertension. Serologic workup and urology evaluation were unrevealing. Kidney biopsy reported FGN with minimal interstitial scarring. Oncology referral was made to rule out hidden malignancy. She had an unremarkable CT scan of the chest and abdomen, PAP smear, mammogram, colonoscopy as well as normal chemical evaluation and ultrasound of thyroid. Patient quit smoking and had conservative medical therapy. Introduction of ACE-I 1.25 mg oral in proteinuria to 0.6 g/day. Unfortunately, she had decline in creatinine from 0.6 to 1.0 mg/dl, and worsening of proteinuria to 1.3 g/day associated with edema and weight gain. Therapy with Acthar® injections was initiated at the dose of 80 units thrice weekly. Patient had rapid improvement in proteinuria and swelling, and after 12 months of therapy, Acthar® dose was reduced to 40 units twice weekly. Creatinine remained stable. 24 months after the initial presentation and 13 months from Acthar® therapy initiation, she developed acute pancreatitis. Imaging studies showed pancreatic pseudocyst. Unfortunately, her pain did not resolve. During the second hospitalization, a month later, HIDA scan and EGD performed with un reveling results. She was managed with pain medications and Acthar® therapy was uninterrupted. Patient underwent MRCP 3 months after the initial presentation, which showed pancreatic mass and multiple liver lesions. Biopsy of the liver lesions demonstrated poorly differentiated PBC. Palliative chemotherotherapy was initiated but was not tolerated by the patient. Patient deceased 4 months after the development of pain symptoms.

Discussion: Consideration of a hidden malignancy is a part of FGN management. PBC is a devastating cancer with dismal survival. Conducting an aggressive and repetitive work up for malignancy in patients with a new diagnosis of FGN may improve outcomes.

PUB169

A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Following Influenza Infection

Merv Postolcioglu1,2 1Kent Hospital, Warwick, RI; 2Brown University Department of Medicine, Providence, RI.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is relatively a new entity. It is a form of monoclonal gammapathy with renal significance. Our patient was presented with this rare disease triggered by very common illness, influenza infection.

Case Description: A 61-year-old female with a past medical history of chronic kidney disease stage IIIIB, and type 2 diabetes mellitus presented to the hospital with gross hematuria for 1 week and right-sided flank pain started within last 24 hours. The patient was diagnosed with influenza A infection 10-days before her hospital admission and treated with Oseltamivir. She was started on ciprofloxacin after 1 week due to concern for pneumonia. In the emergency room, she was hypertensive otherwise hemodynamically stable. Her physical exam was significant for right-sided costovertebral angle tenderness. BMP showed creatinine at 2.7 mg/dl which was 1.33 mg/dl at baseline. She was diagnosed with acute kidney injury and started on IV fluid resuscitation. Her urinalysis revealed 58/HFP red blood cells and 7/HFP white blood cells. The kidney ultrasound was normal. CT abdomen and pelvis did not show any evidence of

836
urotheliosis or hydronephrosis. Urine albumin/creatinine ratio was 470.8 mg/g in a spot urine sample which was 104 mg/g before admission. Serum C3 level was normal at 134 mg/dL (reference: 88-201). Anti-streptolysin O antibody (ab), c-ANCA (antineutrophil ab), p-ANCA, anti-glomerular basement membrane ab were negative. Her immunoglobulin G level elevated to 1,740 mg/dL (reference 649-1618), kappa level elevated to 1,470 mg/dL (reference 750-1276), and lambda level elevated to 774 mg/dL (reference 269-638). Serum electrophoresis did not show M-spike and serum immunofixation test was negative for monoclonal gammopathy. Kidney biopsy was recommended by nephrology which revealed endocapillary-proliferative glomerulonephritis with linear glomerular capillary wall staining for IgG-kappa. She did not receive any immunosuppressive treatment as her kidney function returned to baseline without intervention.

Discussion: PGNMID is a rare form of glomerulonephritis which can mimic immune-complex glomerulonephritis especially in a patient with an infection. Therefore, considering renal biopsy with light-chain and IgG staining is crucial for proper diagnosis.

PUB170 Dual Positive Myeloperoxidase and Proteinase 3 Antibodies and Class V Lupus Nephritis in an Elderly Female with Cocaine Use Aniruddh R. Gons1, Molly Fisher2, Daniel Schwartz2, Mary J. Dominguez2, James M. Pullman1,2.1, Montefiore Medical Center, Jack D Weiler Hospital, Bronx, NY; 2Montefiore Medical Center, Bronx, NY.

Introduction: Cocaine contaminated with levamisole is a reported cause of dual positive ANCA vasculitis and rarely has been associated with lupus nephritis. We present a case of an elderly female who presented with unexplained acute kidney injury (AKI) and chronic cocaine use and was found to have dual positive ANCA and Class V lupus nephritis.

Case Description: A 70-year-old female with a history of hypertension, coronary artery disease, atrial fibrillation on warfarin, pre-diabetes, history of breast cancer status post lumpectomy, baseline serum creatinine (SCR) 0.8 mg/dL was sent to the emergency room after being found to have a SCr 6.0 mg/dL on outpatient labs. Urinalysis was significant for proteinuria and microscopic hematuria. Urine protein-creatinine ratio was 2.7 g/g. Workup revealed positive anti-nuclear antibody titer of >1:320, double-stranded DNA antibody titer 270 IU, myeloperoxidase (MPO) antibody of 5.1 Al and proteinase 3 (PR3) antibody of 1 Al. Serum complement 3 was 149 mg/dL and complement 4 was 31 mg/dL. She had no clinical symptoms of systemic erythematosus lupus (SLE) or systemic vasculitis. Urine toxicology was positive for cocaine. She was pulsed with steroids due to concern for a rapidly progressing glomerulonephritis and then underwent kidney biopsy, which demonstrated full house immunofluorescence with IgG predominant subepithelial deposits, few mesangial deposits and mild acute tubular injury. No proliferative glomerular lesions or crescents were observed. She was initiated on mycophenolate molifit with improvement in SCr to 3.88mg/dL and proteinuria to 1.2g/g.

Discussion: Dual positive (MPO and PR3) ANCs have been reported in patients with lupus nephritis, but rarely in the setting of class V lupus nephritis. Although our patient’s history of cocaine use may explain positive MPO and PR3 antibodies, she did not have the pauci-immune crescentic glomerulonephritis often seen with ANCA, but rather an immune complex, non-inflammatory glomerulopathy. Given her unusual presentation was nephrotic Syndrome (39.4%). Lupus Nephritis contributed 27.9%, followed by Membranoproliferative glomerulonephritis (15.4%) Focal segmental glomerulosclerosis (13.5%), IgA nephropathy (11.5%), amyloidosis (7.7%), Crescentic glomerulonephritis (5.8%), Thrombotic microangiopathy (4.8%), Vascular nephropathies (3.8%), Minimal change disease (3.8%), Membranous nephropathy (2.9%), Postinfectious glomerulonephritis (1.9%) and Diabetic nephropathy (0.96%). Table (2). Eighteen patients (62.1%) of lupus nephritis belonged to ISN/RPS class IV, seven patients belonged to class III, and four patients belonged to class V. Conclusion: Histopathological patterns of glomerular disease may indicate regional and ethnic variations that could point towards genetic or environmental influence. This might help in effectively managing this disease by identifying the predisposing factors.

Introduction: Collapsing glomerulopathy (cFSGS) is most commonly seen in association with Human Immunodeficiency Virus infection (HIVAN) and can also occur in association with viral and non-viral infections, autoimmune diseases, malignancy and drug exposure. Patients typically present with rapidly worsening renal function and nephrotic syndrome. We report a case of cFSGS due to Hemophagocytic lymphohistiocytosis (HLH).

Case Description: A 41-year-old man with acute myeloid leukemia and allogenic cancer status post lumpectomy, baseline serum creatinine (SCr) 0.8 mg/dL was sent to the emergency room after being found to have a SCr 6.0 mg/dL on outpatient labs. Urinalysis was significant for proteinuria and microscopic hematuria. Urine protein-creatinine ratio was 2.7 g/g. Workup revealed positive anti-nuclear antibody titer of >1:320, double-stranded DNA antibody titer 270 IU, myeloperoxidase (MPO) antibody of 5.1 Al and proteinase 3 (PR3) antibody of 1 Al. Serum complement 3 was 149 mg/dL and complement 4 was 31 mg/dL. She had no clinical symptoms of systemic erythematosus lupus (SLE) or systemic vasculitis. Urine toxicology was positive for cocaine. She was pulsed with steroids due to concern for a rapidly progressing glomerulonephritis and then underwent kidney biopsy, which demonstrated full house immunofluorescence with IgG predominant subepithelial deposits, few mesangial deposits and mild acute tubular injury. No proliferative glomerular lesions or crescents were observed. She was initiated on mycophenolate molifit with improvement in SCr to 3.88mg/dL and proteinuria to 1.2g/g.

Discussion: Dual positive (MPO and PR3) ANCs have been reported in patients with lupus nephritis, but rarely in the setting of class V lupus nephritis. Although our patient’s history of cocaine use may explain positive MPO and PR3 antibodies, she did not have the pauci-immune crescentic glomerulonephritis often seen with ANCA, but rather an immune complex, non-inflammatory glomerulopathy. Given her unusual manifestation of late-onset lupus nephritis, we hypothesized that chronic cocaine use may have led to an altered immune response and autoimmune disease, as rarely described for SLE in young men with chronic cocaine use.

PUB172 Epidemiology of Glomerular Diseases in Minia Governorate: A 5-Year Single-Center Experience Waleed Hassan1, Hisham Mostafa2.1 The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2Minia Nephrology and Urology University Hospital, Minia, Egypt.

Background: Studying the pattern of glomerular diseases gives an important insights about factors associated with its development or progression. Methods: This is a retrospective study includes 312 patients underwent kidney biopsy at Minia university hospital between 2014 to 2019. The aim of this study was to highlight the histopathological patterns of glomerular disease in Minia governorate. Results: A total of 312 biopsy-proven glomerular diseases were reported. The mean age was 31.65±13.77 years, 61.5% were females Table (1). The most common clinical presentation was nephrotic Syndrome (39.4%). Lupus Nephritis contributed 27.9%, followed by Membranoproliferative glomerulonephritis (15.4%) Focal segmental glomerulosclerosis (13.5%), IgA nephropathy (11.5%), amyloidosis (7.7%), Crescentic glomerulonephritis (5.8%), Thrombotic microangiopathy (4.8%), Vascular nephropathies (3.8%), Minimal change disease (3.8%), Membranous nephropathy (2.9%), Postinfectious glomerulonephritis (1.9%) and Diabetic nephropathy (0.96%). Table (2). Eighteen patients (62.1%) of lupus nephritis belonged to ISN/RPS class IV, seven patients belonged to class III, and four patients belonged to class V.

Conclusions: Histopathological patterns of glomerular disease may indicate regional and ethnic variations that could point towards genetic or environmental influence. This might help in effectively managing this disease by identifying the predisposing factors.
A for Amyloidosis
Muhammad Y. Jan, Simit Doshi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: We present a case of osteomyelitis related amyloidosis presenting as acute injury (AKI) with nephrotic range proteinuria.

Case Description: A 62 years old male with type 2 diabetes mellitus and hepatitis C (transplant) was admitted with complaints of bilateral foot pain of 3 weeks duration leading to inability to ambulate. Work up revealed pedal wounds with drainage and imaging was consistent with osteomyelitis. Blood cultures were positive for methicillin sensitive Staphylococcus aureus (MSSA) which was treated with IV antibiotics. Baseline serum creatinine (sCr) was 2.0 mg/dL and sCr on admission was 3.85 mg/dL, which was thought to be from acute tubular necrosis related to sepsis from osteomyelitis. Work up of AKI revealed nephrotic range proteinuria of 4.7g, hematuria without dysmorphic red blood cells and monoclonal kappa IgM spike on serum protein electrophoresis. Kappa/Lambda ratio was 8.6g/dL with serum albumin of 1.9g/dL. Hemoglobin A1c level was 4.6%. Left below knee amputation was performed and patient was transitioned to 4 weeks of oral cephalaxin. sCr on discharge was 2.9. On clinic follow up, repeat labs showed non-resolution of AKI as well as nephrotic range proteinuria of 6.8g and a kidney biopsy was obtained. His wound was healing slowly and antibiotic duration was extended. Kidney biopsy showed no glomerular obsolescence or hypercellularity. Mesangial and glomerular capillary walls showed Congo Red Positive deposits. Thickening of glomeruli was noted with segmental duplication. Tubular atrophy and interstitial fibrosis was 20%. Staining was positive for serum amyloid A (AA) in glomeruli, arterioles, and tubular basement membranes. Immunofluorescent staining was negative. Electron microscopy showed mesangial expansion with randomly arrayed extracellular fibrils with solid cores and a mean diameter of 9.8 nanometer.

Discussion: Patient completed extended oral antibiotic therapy for osteomyelitis with resolution of M spike on SPEP and improvement of creatinine to baseline. Deposition of IgA was 95%, C3 15-20 cm) and lymphadenopathy (negative BM and lymph node biopsy). ADAMTS13 level was 50 and plasmaspheresis was stopped. Further infections and autoimmune workup was negative. Renal biopsy showed a TMA process and C5b-9 staining was positive in the glomerular and arteriolar vessels. Serum C5b-9 level was elevated (343). A genetics panel showed no variant associated with AHUS nor predisposition to poor response to eculizumab. He was discharged with eculizumab maintenance and dialysis. Recently, his labs improved with a Cr of 1.5 and platelets of 163.

Discussion: Here, typical features of hemolysis were missing, and diagnosis was made on renal biopsy with findings of TMA and C5b-9 stain. Ongoing understanding of causes for AHUS include hereditary (complement and DGKE gene mutations) and acquired (infection, autoantibodies to complement, drug toxicity and autoimmune). Although genetic panel was negative, it cannot be ruled out as genetic mutations are only identified in 50-70% of cases. Shiga-toxin and pneumococcal-HUS are causes, but here we found rare C.difficile-induced cause. Patient was successfully treated with eculizumab. Thus, AHUS is elusive and clinically challenging in diagnosis.

Factors Related to Clinical Efficacy of Corticosterone Combined with Tonsillectomy for IgA Nephropathy
Ryo Yamamoto, Yuta Kogure, Mai Aoyagi, Kaori Takayangi, Minoru Hatano, Takatsugu Iwashita, Hajime Hasegawa. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kagawa, Japan.

Background: IgA nephropathy (IgAN) is the most frequent primary glomerulonephritis in Japan. Treatment combining tonsillectomy with intermittent intravenous methyl prednisolone (PSL) and alternate-day oral PSL (TSP therapy) may be sometimes chosen, and results from multiple prospective multicentered studies have been reported for its clinical usefulness. However, the treatment selection criterion has not been cleared. We retrospectively analyzed the patients who underwent TSP therapy in our facility, and investigated the factors associated with efficacy of this therapy.

Methods: Subjects are 63 patients with IgAN who underwent TSP therapy in our hospital from April 2012 to July 2019. Intravenous methyl PSL 500 mg/day was administered for 3 days in the first 2 weeks after tonsillectomy, followed by oral PSL 30 mg every other day. The protocol was repeated 3-times every 2 months, then PSL was tapered off. Treatment evaluation was performed 6 months after initiation of the therapy. When urinary protein was 0.5 g/gCr or less or decreased by 50% or more, and the urine red blood cell count was less than 20 per microscopic field, the treatment was considered to be effective.

Results: The mean age of enrolled patients was 36.2 ± 13.5 year, eGFR 75.2 ± 23.6 mL/min, urine protein 0.92 ± 0.81 g/gCr, and serum IgA 332. 9 ± 141.2 mg/dL. Thirty-two patients were effective and 31 patients were non-effective at 6 months after the start of the therapy. Clinical parameters showing significant difference between the two groups were age (33.2 ± 13.5 in responder vs 39.4 ± 10.9 in non-responder, p<0.02), diastolic blood pressure (71.2 ± 10.1 in responder vs 78.5 ± 13.2 in non-responder, p=0.017) and serum IgA (368.3 ± 174.3 in responder vs 296.2 ± 84.0 in non-responder, p=0.024). Logistic-regression showed a significant association with respect to efficacy only for serum-IgA (OR=1.010, 95% CI 1.00-1.02, p=0.047). Cut-off level of serum IgA to the efficacy of TSP therapy by ROC-analysis was 291 mg/dL (AUC=0.675, sensitivity=0.842, specificity=0.571).

Conclusions: Serum IgA levels may be a reference for predicting the efficacy of TSP therapy for IgAN.

An Elusive Case of Renal Failure in a Patient with Atypical Hemolytic Uremic Syndrome
Frank A. Portugal, Ayesha Ahmed. Robert Wood Johnson University Hospital, New Brunswick, NJ.

Introduction: AHUS is microangiopathic hemolysis, thrombocytopenia, and AKI with normal ADAMTS13 and absence of STEC. It involves activation of complement via alternative pathway causing TMA with end-organ involvement. Causes can be complement regulation deficits, infections, and drugs. Here is a rare case of AHUS after a Cdifficile infection, requiring dialysis.

Case Description: 19-year-old man with OSA, ADHD, and obesity had a 3-week course of diarrhea and fever. Cr was 2.15, platelet 143, and tested + for C.diff and was on po vanco then flagyl. Given worsening symptoms, he went to the ER and Hb was 13.9, platelets 24, WBC14.8, BUN 130 and Cr 8.4. He had low complements (C4=7.9, C3 46.2), few schistocytes on peripheral smear, mildly elevated LDH and high-normal haptoglobin. He began dialysis, plasmaspheresis and had a renal biopsy. Imaging showed splenomegaly (15-20 cm) and lymphadenopathy (negative BM and lymph node biopsy). ADAM13 level was 90 and plasmaspheresis was stopped. Further infections and autoimmune workup was negative. Renal biopsy showed a TMA process and C5b-9 staining was positive in the glomerular and arteriolar vessels. Serum C5b-9 level was elevated (343). A genetics panel showed no variant associated with AHUS nor predisposition to poor response to eculizumab. He was discharged with eculizumab maintenance and dialysis. Recently, his labs improved with a Cr of 1.5 and platelets of 163.

Discussion: Here, typical features of hemolysis were missing, and diagnosis was made on renal biopsy with findings of TMA and C5b-9 stain. Ongoing understanding of causes for AHUS include hereditary (complement and DGKE gene mutations) and acquired (infection, autoantibodies to complement, drug toxicity and autoimmune). Although genetic panel was negative, it cannot be ruled out as genetic mutations are only identified in 50-70% of cases. Shiga-toxin and pneumococcal-HUS are causes, but here we found rare C.difficile-induced cause. Patient was successfully treated with eculizumab. Thus, AHUS is elusive and clinically challenging in diagnosis.

IgA Nephropathy in a Patient with Beta-Thalassemia Minor: A Case Report
Andres C. Perez-Ortiz,1 Carmen Avila-Casado,2 Gregorio T. Obrador.1 Universidad Panamericana, Ciudad de Mexico, Mexico; 2University Health Network, Toronto, ON, Canada.

Introduction: IgA nephropathy (IgAN) is the most prevalent type of primary glomerulonephritis worldwide. There are few reports on IgAN development in thalassemia, especially among beta-thalassemia trait (minor) carriers.

Case Description: A 52-year-old male Mexican patient was evaluated for hypertension, hematuria, proteinuria, and rising serum creatinine levels. His history included an ischemic cerebrovascular accident and beta-thalassemia minor (trait). He was treated initially, by another provider, with hydrochlorothiazide/irbesartan and carvedilol for hypertensive nephropathy. Despite treatment, he continued with rising creatinine levels. Then, he was switched to irbesartan only. During this period, the patient developed metabolic acidosis treated with NaHCO3. When referred to our care, we began our approach by completing biochemical and immunodiagnostics assessments (IF), ultrasound imaging (USG), and pathology for glomerulonephritis. On biopsy, we observed IgA nephropathy with advanced nodular glomerulosclerosis and grade II interstitial fibrosis. On IF, IgA, C3, lambda, and kappa chains (mild) were positive. IgG, IgM, C3q were negative. On USG, we documented renal replacement lipomatosis. The patient had microcytic hypochromic anemia, but GBM, C3, C4, ANA antibodies were negative. We managed successfully with irbesartan, amiodipine, NaHCO3 then furosemide.

Discussion: To our knowledge, there are only three additional cases of IgA nephropathy among beta-thalassemia minor. All, including ours, shared as chief complaint rising serum creatinine, hypertension, and persistent microscopic hematuria. However, one report noted bilateral sensorineural hearing loss and prior psychosis under treatment, which may be a syndromic disease presentation. A common feature also is negative antinuclear, anti-DNA, anti-neutrophil cytoplasmic, anti-glomerular basement membrane antibody, HBV, HIV, serum complements antibodies. Significantly, at the time of biopsy, all cases had fibrosis in various degrees ranging from partial to global sclerosis with fibrous crescents. Notably, prior cases occurred in Asian ethnicities, were IgAN is prevalent; our case is the first Hispanic affected patient.
Sudden Explosive Onset of Collapsing FSGS in the Setting of Influenza: An Unusual Presentation

Amaresh R. Vanga, Varun Malhotra. Eastern Virginia Medical School, Norfolk, VA.

Introduction: Collapsing FSGS (Focal Segmental Glomerulosclerosis) is often seen in the setting of HIV, pannoniculate use, parvovirus infections. Here we present a case that was explosive in onset and was associated with influenza.

Case Description: Elderly African American male in his 60s presents with flu-like symptoms. His influenza swab was positive. His past medical history was significant for occasional cocaine use, hypertension, parathyroid adenoma, hypercalcemia, prostate cancer. His vitals revealed BP 107/64 | Pulse 61 | Temp 97.2 °F (36.2 °C) | Resp 16 | SpO2 97%. Physical examination was benign. His creatinine was 6.9. His baseline creatinine was 1.8 (for the past few years) and thought to be related to his hypertension. Other labs indicated corrected calcium of 11, potassium of 5.9, Co2 of 18, hemoglobin of 8 with normal platelets, and WBC. USG(Ultrasound) of kidneys revealed obstructing 3mm left UJV stone with hydronephrosis. UA revealed 3 plus protein with moderate blood, 10-20 RBC per HPF, bacteria. He was started on antibiotics and a double JJ stent was placed. His stone disease is probably a manifestation of parathyroid adenoma. He was awaiting parathyroidectomy and was maintained on sensipar in the interim. His creatinine continued to increase and peaked at 7.5 mg/dl. However repeat urinalysis revealed significant proteinuria and on quantification, it was 17g with albumin of 2. He also had lower extremity edema indicative of nephrotic syndrome. Of note, he did not have proteinuria a week before his hospital admission. At this point, a renal biopsy was undertaken and was noted to have collapsing glomerulopathy with 80-90 percent effacement of foot processes. The patient continued to improve to creatinine of 2.4 with improvement in urine output at which point he was discharged on ACE-I.

Discussion: Collapsing FSGS in probably related to complex interplay of multiple factors including infection, acute kidney injury due to other etiologies, genetic risk factors such as APOL1. Recent cases of COVID-19 related AKI point towards the possibility of collapsing FSGS as the etiologic mechanism, especially with APOL1 association. Though it is traditionally described in the setting of infections like parvovirus and HIV, there could underlying common mechanisms for infections that may not be exclusive to these and may expand to other infectious etiologies like influenza, COVID.

Hypoaalbuminemia Out of Proportion to Proteinuria in a Patient with Nephrotic Syndrome

Chidi Egwim, Javier Jaramillo Morales, Laura Binari, Gautam B. Bhave. Vanderbilt University Medical Center; Nashville, TN.

Introduction: Hypoaalbuminemia is a fundamental characteristic of nephrotic syndrome, with most of the albumin loss resulting from urinary excretion. As such, the degree of proteinuria in a glomerular process often mirrors the serum albumin. The differential and work-up changes when there is discordance between the two.

Case Description: A 68-year-old African American man presented with three weeks of a worsening cough, diarrhea, and progressive swelling. His past medical history was notable for dysphagia secondary to esophageal rings with dilations in the past, acute myeloid leukemia s/p allogeneic stem cell transplant and deep vein thrombosis. His stem cell transplant was a year prior to presentation, and he was tapered off MMF and to a lower dose of tacrolimus with prednisone. On physical exam, he had gross anasarca. His labs were notable for a serum creatinine of 1.5 mg/dL from a prior baseline of 1.3 mg/dL. His albumin was 1.2 g/dL with a spot urine protein to creatinine ratio of 3.12 and 24-hour urine protein of 3.5 g/day. A lipid panel showed a cholesterol of 391 and a LDL of 292. Serologies for hepatitis and lupus were negative. Complement levels were normal and no monoclonal protein was seen on serum/urine electrophoresis. A serum PL2-R was negative. He underwent a kidney biopsy that demonstrated subepithelial glomerular, mesangial, and tubular basement membrane deposits consistent with secondary membranous nephropathy. Staining for PLA2-R was positive. He was started on Rituximab and continued treatment as an outpatient.

Discussion: Here we describe a case of nephrotic syndrome in which the degree of hypoaalbuminemia was not consistent with the amount of proteinuria. This discordance represents a defect in the homeostasis of albumin typically seen in nephrotic syndrome. At a steady state, albumin synthesis is balanced by albumin catabolism and urinary loss. In nephrotic syndrome, catabolism is decreased while synthesis and urinary loss increases. The patient’s history of diarrhea and dysphagia suggested that he had either increased catabolism from non-renal GI losses or decreased synthesis due to poor intake. This case highlights alternative laboratory findings in membranous nephropathy and a framework for understanding the differences.

Renal Response and Its Predictive Factors of Lupus Nephritis: A Two-Year Cohort of 77 Hospital-Based Patients

Zhiming Lin, Junnei Feng, Jun Zhang, Changlin Zhao, Zhen Wu. Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; Department of Vasculocardiology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: To evaluate the renal response rates of lupus nephritis (LN) patients undergoing standard treatment during a two-year follow-up and investigate its predictive factors.

Methods: A prospective cohort study enrolled 77 clinically diagnosed LN patients was carried out. All patients underwent standard treatment according to Joint European League Against Rheumatism and European Renal Association-European Dialysis and Transplant Association (EULAR/ERA-EDTA) recommendations or American College of Rheumatology (ACR) guidelines for the management of LN. Regular visits were performed every 6 months until 2 years. Data on renal response and clinical characteristics were collected and analyzed.

Results: Among 77 patients, 41(53.2%) and 15(19.5%) patients achieved complete response (CR) and partial response (PR) at 6 months after induction therapy, respectively. With every 6-months visits, 53(68.8%) patients completed the whole 2-year follow-up. CR was achieved in 38(71.7%) and 59(49.4%) patients developed CR and PR at 2 years. During follow-up, serum creatinine (SCr) and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score showed a significant decrease as compared to baseline data, while estimated glomerular filtration rate (eGFR) and C3 level gradually elevated. In multivariate regression model, immunological disorder (OR 4.73, 95%(CI 1.00-22.40, p<0.05), eGFR (OR 1.04, 95%(CI 1.02-1.07, p<0.001) and SLEDAI (OR 1.21, 95%(CI 1.05-1.40, p<0.01) at baseline were found to be associated with CR/PR at 6 months as compared to non-responders.

Conclusions: Nearly 70% LN patients achieved renal response after 6-months standard induction therapy, and the renal response rates were higher after 2 years. Renal function and disease activity showed a significant improvement during follow-up. Besides, immunological disorder, higher baseline eGFR and SLEDAI were predictive factors for renal response.

AKI After Eculizumab Interruption in a Case of C3 Glomerulopathy
Mostafa F. Elshirbeny, Mohammed E. Hussain, Essa Abuhelaiqa, Awaïs Nauman.
Hamad Medical Corporation, Doha, Qatar.

Introduction: C3 glomerulopathy (C3G) is a newly recognized rare disease characterized by predominantly glomerular deposition of complement C3. Treatment with the C5 complement inhibitor eculizumab may be a therapeutic option but due to rarity of the disease, predicting tools of the outcomes remain largely unknown.

Case Description: Here we report 25-year old female patient who was referred to nephrology clinic with renal impairment, hematuria, and proteinuria. Kidney biopsy results revealed membranoproliferative changes with predominant C3 deposits, suggestive of C3 glomerulopathy. Genetic testing revealed two unrelated mutation in C3 gene, likely not related to C3G. Patient was responding well to oral steroid and MMF with remission of proteinuria and normalized serum creatinine. She was relapsed again, 1 year later with hematuria and nephrotic proteinuria. Steroids and MMF were resumed with no response then started on eculizumab, after which she achieved partial remission with reduction in proteinuria and urine protein. During next 2 years, patient missed eculizumab in 2 occasions. The first, when she missed one dose followed by mild rise in serum creatinine which improved after eculizumab resuming and few months later she missed two doses then presented with severe AKI requiring dialysis. Was started on steroids and eculizumab was resumed with no improvement in kidney function and patient still dialysis dependent.

Discussion: Despite looks like safe and valuable therapeutic option in patients with C3G but the response to eculizumab is heterogeneous and when to discontinue the therapy still unsolved problem as transient interruption of the therapy sometimes complicated with AKI which may be severe enough to end with ESRD like this case.

Serum creatinine results during 40 months of follow up

Pathological Features and Clinical Course of IgA Nephropathy Patients with Isolated Hematuria
Yusuko Fukao,1 Hitoshi Suzuki,1,2 Toshiki Kano,1 Yuko Makita,1 Maiko Nakayama,1 Mingfeng Lee,1 Rina Kato,1 Yusuke Suzuki,1 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Faculty of Medicine, Chiba, Japan.

Background: Microscopic hematuria is the most common manifestation of IgA nephropathy (IgAN). There are a few studies identifying the remission rate of microscopic hematuria as an important clinical predictor of deterioration of renal function. Microscopic hematuria caused by glomerular microvasculitis may have clinical significance. Renal biopsy was performed rarely in case with isolated hematuria. Renal pathological features and the renal prognosis of IgAN patients with isolated hematuria are unclear. Thus, there are no established treatments guides. In present study, we evaluated the pathological features and clinical course in IgAN patients with isolated hematuria in our cohort.

Methods: We retrospectively recruited 47 biopsy proven patients with IgA nephropathy who showed isolated hematuria at real biopsy from 2012 to 2017. We evaluated renal pathological findings in those patients. Moreover, we analyzed clinical course during 24 months from the diagnosis. Thirty of these patients were treated with steroid pulse therapy combined with tonsillectomy (TSP group) and the others were conservatively treated (CT group). In CT group, only three patients were treated with renin-angiotensin system inhibitor. We analyzed clinical parameters, such as, levels of urinary red blood cells, onset of proteinuria, eGFR and serum IgA.

Results: Although age, sex and degree of hematuria at the time of renal biopsy were not significantly different between the TSP and CT group, baseline eGFR was significantly lower in TSP group (88.7 versus 105.9 mL/min/1.73 m²). Of note, 51% of patients showed crescent or endocapillary proliferation. At the end of observation period,
remission rate of hematuria in TSP group (100%) was much higher than that in CT group (66.7%). Moreover, immunosuppression therapy was effective to prevent significant decline in kidney function.

Conclusions: We clarified that more than half of patients with isolated hematuria showed crescent or endocapillary proliferation in present study. Immunosuppression therapy is effective for those lesions. Thus, even in the patients with isolated hematuria, conservative treatment can be a risk for deterioration of renal function.

IgG4-Related Disease Presenting with Membranous Nephropathy

Elizabeth Peper1, Julal E. Hakemi2. 1Edward Via College of Osteopathic Medicine - Carolinas Campus, Spartanburg, SC; 2Palmetto Nephrology, Orangeburg, SC.

Introduction: Pauci-immune glomerulonephritis (PIGN) is most commonly associated with a rapidly progressive course towards renal failure, although rarely, an indolent course may be observed. PIGN has a frequent association with either MPO- or PR3-antibodies and is associated with extra-renal manifestations. We report a patient with slowly declining renal function over the course of two years that had a renal-limited MPO-antibody associated pauci-immune glomerulonephritis.

Case Description: A 61 year old Caucasian female with controlled hypertension, hypercholesterolemia, and prediabetes without complaints was noted by her PCP to have a slowly rising creatinine over two years. A nephrology referral was made with new onset 1+ pitting edema in the bilateral, distal lower extremities and a creatinine of 1.7mg/dL. Urinalysis at this point showed a sediment and 2g/g of creatinine to protein. A renal ultrasound showed structurally sound kidneys. Common infectious causes of renal disease were excluded.

C3 and C4 were normal and MPO-PR3-ELISA were negative. C4d in serum and renal biopsy was negative. C4 was normal and C4d were not seen to be if there was an autoimmune cause. A positive MPO prompted a renal biopsy which yielded a sample of 50 glomeruli with 15 completely sclerosed, 4 with crescent formation, and moderate to severe interstitial fibrosis and tubular atrophy. This confirmed the diagnosis of MPO associated PIGN. Immunosuppression was begun with a rituximab based therapy, but the second dose of rituximab was interrupted due to severe back pain combined with nausea and vomiting. Creatinine was elevated at 3.6mg/dL from 2.2mg/dL the day before. Methylprednisolone was tapered and further infusions were not pursued due to development of deranged liver function tests, hospitalization for diverticulitis, development of uncontrolled DM, and severe psychological symptoms. Over the following two months, the patient’s creatinine has trended down to 1.5 mg/dL.

Discussion: Her consistently rising creatinine was the main driver to begin immunosuppressive therapy despite having moderate to severe interstitial fibrosis and tubular atrophy. Rituximab based therapy was shown in the RAVE trial to be non-inferior to cyclophosphamide for induction of remission in ANCA associated disease. This combination may also have superior relapse rates and a better safety profile in comparison with cyclophosphamide. Her improving creatinine suggests that even an incomplete regimen might have conferred some benefit.

PUB185

IgG4-Related Disease Presenting with Membranous Nephropathy

Elena Zakharaeva1, Elena Kuznetsova2. 1City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation; 2N.N. Fedorenko medical institute nepreryvnogo professional'nogo obrazovaniya, Moskva, Russian Federation.

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a condition, affecting multiple organs. Retropitoneal fibrosis with obstructive nephropathy and interstitial nephritis are most typical kidney damage. Rare cases of glomerular disease, including membranous nephropathy (MN), had been described. Search for IgG4-RD with renal biopsies and diagnosed as PGNMID between January 2016 and December 2017.

Case Description: Method

In 73 years old Caucasian female with a history of arterial hypertension, diabetes, skin patchy hyperpigmentation, asthma and nasal polypsymptoms manifested in 2016 with the weight loss and skin rash. 9 months later, at admission, she was undernourished, with multiple skin scratchs, pedal edema, and otherwise unremarkable physical exam; her blood pressure was 150/90 mm Hg, vital signs were normal. Work up demonstrated nephrotic syndrome and marked eosinophilia (32.6% - 2.6-10^9/L). Her blood chemistry tests, serum and urine immunocommunity, p and c ANCA, anti-GBM and anti-CEP-RA were within normal range. Kidney biopsy showed MN with IgG3, C3, kappa and lambda fine granular deposits on the capillary loops periphery. Her anti-PLAR2 antibodies titer was <1:10; kidneys, abdomen, neck and pelvis ultrasound, chest CT, gastroscopy and colonoscopy were unremarkable. Tests for parasitic infections and mycoid hypersyrnthetic syndrome markers (FP1/L1- PDGF-Rα and ETV6-PDGFβR) were negative. IgG4 level was 1.9g/L (0.8-1.4) – 29.2% (4.0-5.0). We diagnosed IgG4-RD and started her on oral prednisone 40 mg daily. Her skin rash resolved immediately, in a month her eosinophil count became normal, two months later she achieved partial remission of nephrotic syndrome. We added cyclosporin A and slowly tapered prednisone. At the latest follow-up visit January 2020, she was doing well, with the complete remission of nephrotic syndrome, preserved kidney function and normal IgG4 level.

Discussion: Clinical presentation was suggestive for ANCA-associated vasculitis or systemic sclerosis, not confirmed by serology and kidney pathology findings. The search for the hypersyrnthetic syndrome causes was negative, and only IgG4 testing gave a clue to the diagnosis. Steroids allowed controlling hypersyrnthetic symptoms, but no kidney biopsy was performed.

We conclude that IgG4-RD should be considered in differential diagnostics of membranous nephropathy

PUB186

Role of Therapeutic Plasmapheresis in ANCA-Associated Vasculitis: A Single-Center Study

Aglia Chalkia1, Alexandros G. Panagiotopoulou2, Panagiota E. Giannou1, Dimitris Kourniotis1, Athanasia Kapota1, Margarita Mpora2, Dimitrios Vassilopoulos2, Dimitrios I. Petras3. 1Nephrology Department, Hippokration General Hospital, Athens, Greece; 2Joint Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine - Clinical Immunology - Rheumatology Unit, 2nd Department of Medicine, Athens, Greece.

Background: Recently Pexivas trial showed no benefit of plasmapheresis (PEX) in ANCA-associated vasculitis (AAV), even in patients with alveolar hemorrhage, but is this the end of PEX in AAV? The aim of this study is to describe the indications, method and complications of PEX, as well as whether PEX is associated with improvement in renal function and survival at 12 months.

Methods: Retrospective study of 28 patients with severe manifestations of AAV, who had received PEX adjunctive to conventional therapy for the first episode of AAV or in relapse.

Results: We recorded twelve patients receiving PEX. This group (n=12) had an average age at diagnosis 79 years and was followed for a median period of 20 months. In 75% of the patients MPO-ANCA was positive, in 17% ANCA negative and in 8% double positive anti-GBM/ANCA. On admission, all patients had abnormal renal function with average creatinine 5mg/dl±12.12 and the majority of patients (9/12) were dialysis dependent. Indications for plasmapheresis were: alveolar hemorrhage in 33%, renal impairment in 25% and combination of the two above in 42%. Plasmapheresis was performed using filtration and fresh frozen plasma as replacement fluid. The mean number of plasmapheresis treatment was 8 (1-19 days) and the average intertime between admission and first plasmapheresis treatment was 3 days. No episodes of severe infection or death were recorded during plasmapheresis. All patients received concomitant therapy with Cyclophosphamide and corticosteroids while Rituximab was added in 3 patients. Hiperkalanemia was managed in 8 patients (100%). After one year, 75% of the patients had renal recovery (cre±5mg/dl±12.12 vs cre±2-6mg/dl±16.1, p=0.06) and 67% of the patients who required hemodialysis at the time of diagnosis, during the first year became independent of dialysis (75% vs 33%, p=0.5). Finally, survival rate at the end of the first year was 83%.

Conclusions: Plasmapheresis is quite often used in daily clinical practice with remarkable results in dialysis independence and survival, without serious complications.

PUB187

Retrospective Analysis of Five Cases of Proliferative Glomerulonephritis with Monoclonal IgG Deposition Regarding Their Clinical Course and Responses to Therapy

Takatsugu Ishiwata, Minoru Hatano, Koki Ogawa, Ryo Yamamoto, Yuta Kogure, Hajime Hasegawa. Saitama Medical Center, Saitama Medical University, Kagawa, Japan.

Introduction: Background At present, limited knowledge is obtained regarding pathophysiology and clinical course of proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID). It is rarely diagnosed by renal biopsy, and there is no established therapeutic strategy for this disease. We report clinical course and responses to the therapy of 5 cases diagnosed as PGNMID in our facility.

Case Description: Method Five cases (3 males and 2 females, median age 62 years) with renal biopsies and diagnosed as PGNMID between January 2016 and December 2019 were retrospectively analyzed regarding the transition of eGFR and urine protein level by the treatment. Three of 5 cases were treated by steroid alone in combination with intravenous methyl prednisolone (PSL) 500 mg/day for 3 days and oral PSL 30 mg/day. Remaining 2 cases were treated with intravenous methyl PSL and oral PSL followed by Cyclophosphamide intravenously (750 mg/day, twice) or orally (100 mg/day, daily) administration and Rituximab (500 mg/body, twice) administration.

Results Light microscopic findings were MPGN type in all cases, and immunofluorescent staining showed 4 cases were IgG3-kappa and only 1 case was IgG3-lambda. Three cases of the first month of the treatment had partial remission (KIDIGO diagnostic criteria, defined as a urinary protein level of < 0.3-3.5 g/day and a reduction of ≥ 50% from baseline), and all had partial remission at 6 months. Hematuria was observed at the start of treatment in three cases and disappeared in only one case by the treatment. And, the remarkable deterioration of renal function was not observed during the clinical course. However, two cases showed the increase of urine protein after about one year from mPSL administration, and IVCY and RTX were administered, but urine protein and hematuria were not decreased, and mPSL was administered again. In one case, the improvement of the urinary finding was scarce even after the increase in the administered steroid.

Discussion: Conclusion Our results suggest that the treatment responsiveness to IVCY and RTX is poor, that steroids are more responsive to initial therapy, that disease activity increases with dose reduction (a steroid-dependent condition), and that treatment responsiveness to steroids may decrease after relapse.

AA Amyloidosis and CKD in a Patient with Coexisting Hepatitis C Infection and Crohn Disease
Arteern Pirveridian, Monica E. Corral, Grace Mcнутt, Julio P. Zavala Georflnio.
University of the Incarnate Word, San Antonio, TX.

Introduction: AA amyloidosis is in the differential diagnosis of patients with proteinuria and may lead to chronic kidney disease (CKD). It is usually associated with chronic inflammatory conditions like rheumatoid arthritis which is implicated in 40% of cases. Crohn’s disease (CD) is also recognized as an underlying etiology. We present a patient with chronic Hepatitis C infection (HCV) and CD who developed proteinuria and CKD in a relatively short period of time.

Case Description: 33-year-old man with a past medical history of CD, HCV, and cocaine/heroin abuse with frequent IV drug use presented to the ED with complaints of bilateral lower extremity swelling and tenderness. Initial laboratory studies were significant for a creatinine of 4.56 and nephrotic range proteinuria. On review, his creatinine had been trending up from 0.75 mg/dl to 4.09 mg/dl in the last year. Secondary work-up for proteinuria including: ANA, RPR, RF, ANCA, C3, C4, Cryoglobulin with reflex, ds DNA Ab, UPEP, and SPEP w/ immunofixation screenings all yielded negative results. S. cerevisiae Ab IgA was 51.5, a positive confirmation of patient’s CD. HCV antibody test was positive with a positive HCV RNA. Renal biopsy was performed and revealed AA amyloidosis with severe interstitial fibrosis and tubular atrophy.

Discussion: AA amyloidosis is a disorder characterized by the overproduction of extracellular proteins that deposit and subsequently cause organ and tissue impairment. It is often attributed to chronic inflammatory/infectious diseases. Though literature about the incidence of AA amyloidosis in people afflicted with HCV is limited, incidence in individuals afflicted with CD has been reported to be between 0.5%-8%. AA amyloidosis has also been found to be a major cause of CKD in IV drug users. One UK study found that up to 35% of these patients have associated HCV. There are reports of increased CD “flares” in patients undergoing treatment for chronic HCV, which may suggest that the coexistence of both diseases may lead to worse morbidity. Our case is unique due to the coexistence of two chronic diseases that lead to inflammatory/infections processes known to be involved in the pathophysiology of AA amyloidosis. This co-existence may lead to a faster progression of CKD and overall worsening outcomes.

Awareness of Association of ANCA Vasculitis and Aortic Aneurysm Can Improve Survival
Sonali天然气, Jitendra Kumar. QRG Hospital, Faridabad, India.

Introduction: ANCA vasculitis is a small-medium vessel vasculitis which is characterized by systemic necrotizing inflammation of blood vessels. Aortic aneurysm is a very rare complication of ANCA vasculitis. We describe a case of such association and highlight the need for guidelines for its screening in patients diagnosed with ANCA vasculitis.

Case Description: 40 year old man with no known medical history presented with renal failure and was started on dialysis. Kidney biopsy showed pauci immune crescentic glomerulonephritis. As per KDIGO guidelines, he was treated with steroids, cyclophosphamide and plasmapheresis after which he recovered from dialysis. 3 months later, he presented with hematemesis and shock. Due to worsening hematemesis and shock, upper endoscopy was done which revealed aorto-esophageal fistula and patient died of shock with no time for surgical intervention. On retrospective analysis, we found that unfolding of aorta seen on chest xray 3 months ago was likely aortic aneurysm which had increased in size and ruptured.

Discussion: To the best of our knowledge, this is the first case reported from India. The reason we think ANCA vasculitis is associated with aortic aneurysm is because it has been proven by biopsy in case reports in the past and in few of them, aneurysm had even decreased in size with chemotherapy. Also, it is surprising that such degenerative condition would occur without any risk factor like smoking, atherosclerosis, history of hypertension, or family history of connective tissue disorders in such a young patient.

Since both ANCA vasculitis and aortic aneurysm are rare pathologies, it is reasonable to consider that they are related when occurring together. Again, Its rapid expansion and rupture within a span of 3 months favors an underlying association. This case highlights that nephrologists should be aware of such association, screen the patient on presentation and then at intervals likely earlier than recommended for aortic aneurysm of other etiologies.

Atypical Presentation of Microscopic Polyangiitis

Introduction: MPA is an uncommon disease, more common in men, in white and Asian populations and whose incidence increases with age. We describe an atypical presentation of MPA

Case Description: 48-year-old female patient, no relevant past medical history, who came to the ER with a 2-week history of bradypnea, gait disturbances, arthralgia, lower limb pain. On PE non-blanching red-purple papules were noted. A lab panel showed increased creatinine at 5.79 mg/dl (baseline Cr was 1.09), microscopic hematuria and sub-nephrotic proteinuria. Kidney ultrasound was normal, urinary sediment showed dysmorphic RBC with RBC casts. She was placed an acute catheter for HD prior biopsy. Immunological panel showed positive ANCA, specificity for PR3 antigen; C3 and C4 levels were normal; the rest of the panel and HIV, HBB and HCV serologies were negative. CT showed maxillary sinusitis, lungs were normal Skin biopsy showed a leukocytoclastic vasculitis and kidney biopsy showed a pauci-immune necrotizing glomerulonephritis, with diffuse extra-capillary proliferative lesions, mild interstitial fibrosis; no granulomas. Patient was diagnosed with a MPA, and treatment was started with IV GC and RTX. Patient was discharged to continue treatment in the out-patient clinic and currently has received a second dose of rituximab, with no need for hemodialysis and a creatinine of 2.5 mg/dl. (7 days after starting treatment)

Discussion: MPA is a rare disease with unknown frequency in Mexico. Our case was atypical since it presented in a Hispanic female younger patient, with a histopathological phenotype of MPA but positive to PR3, with no respiratory involvement and no upper airway destructive lesions

Kidney Changes: Stop That Drug!

Latoya N. Gayle, Gene C. Otonyce, Nia Flemming, Marc S. Zelkowitz, Englewood Hospital and Medical Center, Englewood, NJ.

Introduction: Drug associated antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (DAV) with rapidly progressive glomerulonephritis (RPGN) is rare. Historically linked to antithyroid drugs, new evidence implicates almost every pharmacological class. Fortunately, it is catastrophic. Prompt diagnosis & cessation of the offending agent is paramount. This is a case of DAV-RPGN secondary to diltiazem.

Case Description: 76-year-old male with T2DM, cirrhosis, HTN & MM in remission, diltiazem, propranolol, insulin, presented to an outside hospital with 10 days of weakness, decreased appetite & leg swelling. On exam BP 191/79, T97°F & anasarca was present. Labs showed Na128, K5.3, Cl100, bic19, BUN79, creatinine (Cr) 2.8, increased to 4.18 by admission day 10, Ca 7.6, phos 4.7, WBC 8.8, Hb 9.4 & PLT 214. CT abdomen showed renal cysts, mild ascites & no hydropneumonia. Renal biopsy showed nonspecific glomerulitis associated with positive pANCA, MPO, ANA, DS-DNA, Rf & low Cr. He received IV methylprednisolone for 3 days, followed by prednisone 60mg od, transferred to our hospital, then started on cyclophosphamide 15mg/kg q2 weeks with plasmapheresis. There was suspicion for DAV secondary to diltiazem. Anthisthine Ab(ANA) was sent & diltiazem stopped. Electron microscopy showed subendothelial deposits & intracellular macromages suggestive of SLE. Ab(ANA) was positive with negative cryoglobulin. Diagnosis of drug induced SLE from diltiazem with p-ANCA positive RPGN was made. He was discharged on prednisone 60mg daily with slow taper & Rituximab. Cr at discharge was 1.6.

Discussion: DAV is an elusive diagnosis due to limited epidemiological data & identical features to primary ANCA associated vasculitis (PAAV). Although there is no clear definition, CHCC2012 describes it as “Vasculitis associated with probable specific etiology”. Pathophysiology of drug induced ANCA formation & DAV is poorly understood. Possible mechanisms include reversal of epigenetic silencing & increased MPO & PR3 autoantigen expression in neutrophils, if in hyalurondase, or formation of reactive intermediate species by PTU that act as MPO substrates. Regardless DAV must be differentiated from PAAV. It may present with lower Cr, urinary protein & CRP levels, tendon xanthomas, ANA & Ab. Treatment involves drug cessation of the offending agent & immunosuppression, with improved prognosis compared to PAAV.

C3 Glomerulonephritis: Can Therapy Be Individualized?

Sarah C. Noris,1 Marina Noris,2 Richard J. Smith.1 Queen’s University, Kingston, ON, Canada; 1Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy; 2Iowa State University; Ames, IA.

Introduction: C3 is a rare form of glomerulonephritis with variable clinical course. Therapeutics traditionally include corticosteroids, MMF and plasma exchange. Complement directed therapies remain under investigation. We report a case of C3Nef and C5Nef positive C3GN treated with ecuclizumab.

Case Description: A 31 year old female was diagnosed with membranoproliferative glomerulonephritis (MPGN) in 2006 at age 19. She was treated with high dose prednisone for 6 months with no response. Conservative therapy was instituted. She was referred for tumour centre for evaluation in 2018. At this time she was nephrotic with proteinuria 12g/day, serum albumin 21 g/L, serum creatinine 101 μmol/L and low C3 was 0.15 (0.8-1.9) and normal C4 at 0.13 (0.13-0.4). Repeat kidney biopsy revealed C5Nef positive C3Nef and C5Nef positive podocyte effacement consistent with MPGN. As complement functional testing suggested targeted terminal complement pathway defect and of C5Nef treated with ecuclizumab. We have demonstrated a case of C3Nef with positive C3 adn C5Nef with cell surface activation of complement, classical and terminal complement pathway involvement. This highlights the importance of complement function studies to help aid the localization of complement pathway defect, and to individualize therapy.

A Rare Case of NSAID-Induced Minimal Change Disease

Navneet Kaur,1 Sanja H. Patino, Gopika Dasari,1 Eric J. Checchio,1 Marc Richards.1 Florida Atlantic University Charles E Schmidt College of Science, Boca Raton, FL; 1Boca Raton Regional Hospital Inc, Boca Raton, FL.

Introduction: Nonsteroidal anti-inflammatory drugs (NSAIDs) can cause acute tubular necrosis (ATN) via inhibition of prostaglandin synthesis, and vasorestriction. Drug-induced minimal change disease (MCD) is postulated to be due to a reduction in renal perfusion and glomerular filtration rate. We present a case of NSAID induced acute renal failure (ARF) due to ATN and MCD in a 37-year-old adult.

Case Description: A 37-year-old male with no medical history came to the ED with 1 week of vomiting, abdominal pain, and reduced urine output. He attributed his symptoms to food poisoning but sought evaluation after no improvement. Over the last 2 weeks, he had no upper respiratory infection and dental pain for which he took 1g of ibuprofen daily. Labs yielded a BUN of 104mg/dL, creatinine (Cr) of 16.9mg/dL, and urine protein to creatinine ratio of 5.85. Renal ultrasound showed no hydropneumonia. Abdominal CT showed diffuse colitis. Dialysis was initiated for uremic colitis. Workup for ARF was negative for hepatitis, HIV, and autoimmune markers. Kidney biopsy revealed podocyte effacement and nonspecific minimal deposits with severe ATN. Immunofluorescence showed nonspecific mild granular tubular and glomerular IgG deposition. Electron microscopy noted widespread podocyte effacement consistent with MCD. Prednisone 60 mg daily was started. Within 48 hours olugria resolved and dialysis was discontinued. Cr at discharge was 3.6. After a slow taper of steroids, he had a full recovery.

Discussion: Although NSAID-induced ATN is well understood, it is unusual to see ATN causing ARF with oliguria in a young patient with no comorbidities. Nephrotic syndrome induced ATN has been specifically documented in association with MCD. This is likely the mechanism of ATN development in our patient with drug-induced MCD. MCD is the most common cause of nephrotic syndrome in children but accounts for only 10-15% of adult cases. Data evaluating drug-induced MCD in adults is limited to a few case series and retrospective studies associating NSAIDs with acute interstitial nephritis, rather than ATN, as the cause of MCD. Contrary to our case, NSAIDs have shown to reduce proteinuria in idiopathic nephrotic syndrome. Corticosteroids are the first-line therapy, and adults with MCD require prolonged therapy with a slow taper. The majority of ARF induced by MCD is reversible, with complete recovery of renal function.

Kidney Aging and Estimation Equations for GFR in Beijing

Lennan Xu, Yonghui Mao. Beijing Hospital, National Center of Gerontology; Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Beijing, China.

Background: When evaluating renal function, eGFR data show significant variation across different equations, particularly in elderly patients. Here, we investigated how age affected renal function in healthy subjects in Beijing and compared different eGFR equations for the evaluation of renal function.

Methods: We recruited all patients undergoing routine assessment in our hospital between January 2012 and December 2014. For each patient, we recorded age, gender, and Cr. Kidney function was evaluated by five equations: CKD-EPI, MDRD, MDRD5c, FAS and BIS.

Results: A total of 46,713 subjects were enrolled. Subjects were 16 - 100 years of age and were followed-up for 3 years. All subjects showed an increase in sCr and decrease in eGFR with increasing age. For males, there was a more obvious and significant reduction of eGFR in the elderly; but in older females, eGFR did not tend to change. Different equations showed good consistency (the intraclass correlation coefficients (ICC) was 0.849 for males, and 0.817 for females). The CKD-EPI equation yielded slightly higher eGFR and was the most advanced CKD according to sCr levels. There was no obvious trend for age-related change in the 3-year mean rate of eGFR change when compared across age groups. For subjects aged over 70 years, the MDRD and MDRD5c equations yielded significantly higher eGFR data and the BIS produced the lowest eGFR values.

Conclusions: The annual rate of GFR change was not associated with age. Different eGFR equations yielded data that varied across different populations of patients and sCr levels. We were unable to identify a specific equation for use in the elderly Chinese population.

A comparison of different eGFR equations across all age groups. (A) Male. (B) Female.

Comparison of eGFR equations for different serum creatinine levels. (A) Male. (B) Female.
A Workplace Wellness Program Results in Improvements in Physical Activity and Blood Pressure in the Staff of a Hemodialysis Clinic

Alexis King,1 Alana P. Harris,1 Luis M. Perez,2 Kenneth R. Wilund,2 1University of Illinois at Urbana-Champaign, Department of Kinesiology and Community Health, Urbana, Ill.; 2University of Illinois at Urbana-Champaign, Division of Nutritional Sciences, Urbana, Ill.

Background: Evidence indicates that health and wellness programs in the workplace provide numerous benefits with respect to altering indices of health. The purpose of this study was to assess the feasibility of a workplace wellness program (WOW) as a means of improving blood pressure by participation in habitual physical activity (PA) and improving dietary choices among the staff at a hemodialysis clinic.

Methods: 26-staff members age(46.5±12.2);BMI: 28.7±5.6 kg/m2) from a hemodialysis clinic (nurses, technicians, social workers, dietitians, and administrative staff) participated in the 12-week WOW program that consisted of weekly counseling sessions, the provision of educational resources, PA incentive challenges, and healthy dietary choices challenges. Body weight(kg), height(cm), blood pressure, BMI, 24-hr dietary recalls, PA behaviors (IPAQ), and waist/hip circumference(cm) were collected at weeks 0(baseline), 6, and 12 following the conclusion of the intervention. Statistical analysis was performed using SPSSv.24. All primary and secondary outcomes were assessed by one-way Analysis of Variance (ANOVA) comparing values at the different testing time points, with significance at p<0.05. Paired sample t-test was used to test the questionnaire (IPAQ) data that was collected at baseline and post intervention.

Results: The program also resulted in improvements in several health related metrics. This included reductions in body weight (1.07±0.31 kg, p<0.05), body mass index (p=0.03), waist circumference (cm 96±9±14.8; p=0.005), and hip circumference (cm 111±7±13.6;p=0.05). Systolic blood pressure change was non-significant but trending toward significance (p=0.08), while diastolic blood pressure was reduced (p<0.05). There were significant changes in PA behavior, specifically walking behavior (p<0.05), as indicated by the IPAQ.

Conclusions: The WOW program demonstrated increased measures in the staff’s PA. As a result, this led to the improved health outcomes which included body weight reductions, BMI improvements, lowered hip and waist circumference, and improved diastolic blood pressures values. The study suggests that a workplace wellness program has the potential to improve health indices of the staff of hemodialysis clinics and may positively impact the health behaviors in the hemodialysis patients under their care.

Frailty Changes in Patients on Hemodialysis After an 8-Week Exercise Intervention

Rick Ward. Wise Health System Dialysis Center Wise Health System, Decatur, TX.

Background: The Fried frailty phenotype defines frailty as having at least 3 of the following: unintentional weight loss, decreased grip strength, slow gait speed, exhaustion, and decreased physical activity. The vulnerability inherent in frailty is exacerbated in the elderly. Even small increases in prevalence of frailty in the elderly population are of concern. In this study, the prevalence of frailty was assessed in the staff in the hemodialysis clinic.

Methods: 11 patients from the Wise Health System Dialysis Center in Decatur, TX (6 in the experimental group, 5 in the control group). The experimental group received a supervised elastic band resistance and cycling ergometer program 3 days per week (6 in the experimental group, 5 in the control group). The experimental group received

Results: Of the 623 patients visiting each institution, 300 were enrolled in this study. The mean age was 61.9 (0.36) years, with mean duration of HD 30.7 (0.39) months. 116 patients (38%) were female and 112 (44%) had diabetes or renal disease. In total, there were 225 patients (73%) were evaluated as frail. The prevalence of frailty increased steadily with age and was more prevalent in the diabetes mellitus patients. A multivariate logistic regression analysis revealed that the factors independently associated with frailty were the following: age, Charlson comorbidity index, DM, SARS, SD. There was no relationship between the duration of HD and frailty status. Anxiety and depression symptoms by SAS and SDS were identified in 52.6% and 72.0% of HD patients. MHD patients had both anxiety and depression generally higher frailty score. The coexisting frailty and psychological disorder were present in 45.0% patients. There was an additive effect of psychological disorder and frailty on nutritional status. For the groups with frail and psychological conditions and no frail and no psychological conditions, both serum albumin and creatinine decreased.

Conclusions: This study demonstrated that anxiety and depressive symptoms are associated with prevalent frailty in Southern Chinese MHD patients. Older age, diabetes mellitus, CCI and lower serum albumin were associated with frailty among patients on MHD. Anxiety and depressive symptoms are independent risk factors of frailty.

Potassium Binders for Treatment of Hyperkalemia: Patient Survey Examining Side Effects, Tolerability, Palatability, and Interference with Daily Activity

Myungjin G. Kim, Maura A. Watson, Christina M. Yuan, Walter Reed National Military Medical Center, Bethesda, MD.

Background: Even mild hyperkalemia is associated with increased mortality. There are three FDA-approved oral potassium binders for outpatient treatment of non-life-threatening hyperkalemia: sodium polystyrene sulfonate (SPS), patiromer, and sodium zirconium cyclosilicate (ZN-9). Specific studies of patient experience, satisfaction, and adherence have not been conducted for any of the three agents. We surveyed outpatients regarding their experience with these medications, including taste, texture, tolerability, and interference with daily activity.

Methods: An online, anonymous survey of outpatients a148 years old who were dispensed SPS, patiromer, and/or ZN-9 from September 2017 to August 2019 at military treatment facilities in the National Capital Region was conducted over 8 weeks. Respondents were invited by letter including the survey url (with a reminder at 4 weeks). Survey questions included queries about demographics, medical diagnoses, medications associated with hyperkalemia, side effects, taste, palatability, and daily activity interference.

Results: 212 qualifying individuals were invited to participate. Response rate was 16% (34/212). All respondents were a51 years old. 36% were on RAASIs. 28 respondents had used SPS, 6 had used patiromer, and 1 had used ZN-9. 18% of respondents treated with SPS vs. 0% treated with patiromer reported side effects. 1 reported discontinuing SPS without informing their physician due to side effects. 48% reported diarrhea with SPS, 50% reported constipation with patiromer. Respondents favored taste and texture of patiromer vs. SPS (72 vs. 56 for taste, and 70 vs. 50 for texture, with a scale rating of 100 being best), and reported more difficulty swallowing SPS vs. patiromer (3% vs. 0%). Side effect severity and interference with daily activity were the same (2 and 3 respectively for both SPS and patiromer, scale of 0-10, 10 being worst).

Conclusions: Respondents who used patiromer reported better palatability and fewer side effects than those who took SPS. However, side effect severity and daily activity interference were equivalent between SPS and patiromer. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the official policy or position of the Department of the Army/Navy/Air Force, the Department of Defense, nor the US Government.
**Method**: A face-to-face survey was conducted in a random convenience sample of pts in CKD and FM clinics. Patients chose answers from 5 Likert style questions about PBE assessing their beliefs regarding difficulty in finding foods in restaurants, affordability, ability to get proteins and vitamins, and ability to find good tasting recipes. A mean score was calculated with lower score indicating more difficulty (PBE-score). Diet adherence was based on 24hr recall and analyzed using ASA-24 software. Comparisons are by t-test unless noted.

**Results**: Mean age was 54.3±2.5 yrs. There were 16 (36%) males and 29 (64%) females with 40 black (89%), 36 (80%) had not completed college. 23 (51%) had an -18% HD interval. 20 (43%) had diabetes and 36 (80%) had hypertension. 30.4±1.6 with 41% >30. There were no differences in these variables between clinics. CKD pts had a higher creatinine (2.0±0.3 vs 0.8±0.5) more positive attitude towards PBE (PBE-score 2.5±0.7 vs 1.1±0.3, p<0.05) and more ate cholesterol (411±2.6 vs 287±1.9, p=0.034), fatty acid (14±154 vs 17±181, p=0.054) and dietary sodium (5±5.27 vs 0.42±0.16, p=0.048) and drank more fluid (249.0±33.5 vs 136.7±16.7, p=0.005) than FM pts, but fruit/veg intake was poor. PBE-score did not correlate with dietary intake of any nutrient in either group.

**Conclusions**: In our populations pts with CKD had a more positive attitude towards plant-based eating. 2. CKD pts ate more cholesterol with higher intake of eggs and fatty seafood. 3. Despite difference in attitude there was no difference in actual vegetable intake between groups. 4. The positive attitude of CKD pts towards PBE suggests that education will be successful in this group, especially as they appear to be following the recommendation to increase fluid intake. The poorer attitude in FM patients should be addressed as the population as a whole has a high prevalence of hypertension, obesity and diabetes and all patients could benefit from PBE.
A variety of HF populations (e.g., acute, chronic, carrying mechanical circulatory device) and the median number of included parameters was 7. There was substantial variation across models in the reporting of the kidney related parameters as well as the studied outcomes. While no study included eGFR, serum creatinine and BUN were included in only 6 and 4 studies respectively. Interestingly, serum chloride level was included in none of the included models, while serum sodium level in 4.

Conclusions: The current evidence on the prognostic prognostic value of hypochloremia for adverse outcomes in HF is keeping with distinct physiologic mechanisms relating it to rennin secretion and modulation of renal tubular sodium transport. However, we found that there is still a lag in its integration into contemporary predictive models of HF. This observation highlights the need for revisiting these models in backdrop of emerging data and explore whether incorporation of hypochloremia, or replacing hyponatremia by hypochloremia, would add to their predictive value.

PUB204
Long-Term Ambient PM2.5 Exposure Associated with Major Cardiovascular Risk Factors in a Large Chinese Population-Based Study Jianfeng Lin, Hua Zheng, Peng Xia, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: The association between long-term exposure to ambient air pollution and hyperlipidemia or overweight is still controversial. We aimed to investigate the relationship between long-term exposure of PM2.5 and cardiovascular risk factors in a large multi-provincial and multi-ethnic Chinese adult sample.

Methods: We recruited 19,236 adult participants from 2007 to 2010 in 6 provinces of China (Chinese Physiological Constant and Health Condition Study, CPCHC). A questionnaire, physical examination, and biochemical tests were performed. The PM2.5 data used were derived from aerial optical depth with the GWR model and GFS/Chem method.

Results: The average age of the participants 42.7±16.12 years and nearly half were male (47.0%). Annual average PM2.5 exposure 1-year before the CPCHC study was 33.4 (14.0-53.4) μg/m3. Multivariate linear regression showed that each 10μg/m3 increment of PM2.5 was associated with 0.025% (95%CI: 0.011%, 0.040%) decrease of cholesterol and 0.098% (95%CI: 0.083%, 0.113%) decline of BMI. Adjusted by age, sex, education, ethnicity, physical activity, and smoking, logistic regression indicated that PM2.5 exposure still associated with the prevalence of hyperlipidemia (OR = 0.958, 95%CI: 0.942, 0.974) and overweight (OR = 0.925, 95%CI: 0.911, 0.939). PM2.5 exposure was also corresponded to elevated SBP (0.048%, 95%CI: 0.034%, 0.063%) and an increased prevalence of hypertension (OR=1.020, 95%CI: 1.001, 1.039).

Conclusions: Long-term PM2.5 exposure was associated with an increased prevalence of hypertension, decreased prevalence of hyperlipidemia and overweight.

PUB205
Predictive Models for Prognosis of Cardiovascular Events (in 5 Years) in Asian Patients with CKD Wentao Hu, Xin Liu, Shaomin Li. the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background: Chronic kidney disease (CKD) is viewed as a major health problem worldwide. However, independent influencing factors related to the prognosis of CKD patients (especially in cardiovascular events) is still potential to be exploited, and few researches on predictive models for individualized prognostics in CKD patients were published, especially in Asian area. Therefore, we are willing to evaluate independent influencing factors in regard to prognosis of CKD patients and build predictive models for individualized prognosis in CKD patients.

Methods: 1246 participants were included in this cross-sectional study. All date were used in univariate Cox proportional hazards regression models and multivariable Cox regression analyses (P<0.05). Then, 1246 participant were divided into two cohort (development cohort and validation cohort). we will establish one best predictive model by the means of CINDEX, AIC, NRI, IDI.

Results: In the Cox regression analysis of cardiovascular events, we found that HGB, K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors. In the development cohorts, we found that the model (K, pre-albumin, HGB, HF, CKD) is the best prediction model of cardiovascular events (P=0.088*1.93584*APoB + 0.00356*pre-albumin + 0.00679*HGB + 1.11488*heart failure - 0.22131*K - 0.10215*CKD progression) is the best prediction model of cardiovascular events.

Conclusions: Lower HGB is independent protecting factor of cardiovascular events, and higher K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors of it. And we establish the best prediction model (P=0.088*1.93584*APoB + 0.00356*pre-albumin + 0.00679*HGB + 1.11488*heart failure - 0.22131*K - 0.10215*CKD progression) of cardiovascular events (in 5 years).

PUB206
Epidemiology of Cardiovascular Risk Factors in Hemodialysis Patients in a Tertiary Care Hospital Muntazir Ali Sayed,1 Navneet K. Guri,1 Adil A. Akbani,1 Ali Hamza,1 Sadiq Ali Sayed,2 Farhin N. Sayed,2 Sayed Mohd Tahir Rizvi,3 Desi Doctors Aricenna Medical College, Lahore, Pakistan; 4National Pirogov Memorial Medical University, Vinnytsya, Ukraine; 5Rajiv Gandhi Chhatrapati Shahu Maharaj Government Medical College and CPR Hospital, Kolhapur, India; 6Government Medical College, Patiala, India; 7KI Somiya College of Engineering, Mumbai, India.

Background: Cardiovascular events remains the leading cause of mortality in patients with end stage renal disease (ESRD) and the risk of cardiovascular events is 10 to 20 times higher in ESRD as compared to general population. The main objective of this study was to evaluate the prevalence of traditional cardiovascular risk factors in the population of ESRD outpatients on chronic hemodialysis in a tertiary care center in Kolhapur city of Western India.

Methods: All patients undergoing regular hemodialysis for ESRD in the tertiary care center of CPR Hospital were considered for inclusion in the retrospective study. Clinical and demographic data were obtained from the medical records, whereas laboratory records were obtained as the most recent result in the six preceding months. Adequate statistical tests were carried out and for all tests, a p-value <0.05 was considered statistically significant.

Results: A total of 1937 patients were included from the data of 2 years from May 2018 to April 2020 at our institute. Their average age was 61.3 years old, 69.3% were males. The prevalence of cardiovascular risk factors observed was 89.3% for hypertension, 83.9% for dyslipidemia, 75.3% for sedentary lifestyle, 49.7% for tobacco use, and 43.5% for diabetes. In a multivariate adjusted analysis, we found that sedentary lifestyle (p = 0.041, PR 1.15 – 95%CI: 1.09 – 1.17), dyslipidemia (p = 0.021, PR 1.05 – 95%CI: 1.01 – 1.11), and obesity (p < 0.0001, PR 1.88 – 95%CI: 1.59 - 2.95) were more frequent in women; and hypertension (p = 0.019, PR 1.03 – 95%CI: 1.01-1.17) and tobacco use (p = 0.009, PR 1.31 – 95%CI: 1.97 - 4.67) were more often found among patients under 65 years old. Sedentary lifestyle was independently associated with time in dialysis less than 12 months (p < 0.001, PR 1.33 – 95%CI: 1.19 – 1.43).

Conclusions: The population in chronic hemodialysis in the city of Kolhapur presents a high prevalence of cardiovascular risk factors. These findings confirm the high-risk cardiovascular profile of hemodialysis patients. Prospective studies and clinical trials are needed to further clarify interventions that can be transformed in public health strategies to prevent cardiovascular death in hemodialysis patients.

PUB207
Prevalence and Associated Risk Factors of Pre-Hypertension and Hypertension Among University Students in Bahrain Amjad E. El Agroudy. Arabian Gulf University, Manama, Bahrain.

Background: The increase of hypertension in the developing countries may be connected with the economic transition within those countries. This study aimed to assess the prevalence of prehypertension and hypertension among university students and their associated risk factors.

Methods: The study used a cross-sectional design. Data were collected from February 2019 to May 2019 at the Arabian Gulf University Campus in Bahrain. A total of 411, randomly selected students aged 17 to 24 years (196 males, 215 females) were included in the study. The data were gathered through a self-completed structured questionnaire, which included data about nutritional lifestyle, sleep, exercises, family history and smoking pattern. In addition, blood pressure and body mass index were measured. Systolic and diastolic blood pressure measurements were taken by trained personnel.

Results: The mean age was 20.4±1.9 years. Normotensives constituted 61.3% (n=252), prehypertensives formed 30.7% (n=126), and hypertensive students comprised of 8% (n = 33). The overall proportions of hypertension and prehypertension were higher among male students (81.8 and 69.8%) than female students (18.2 and 30.2%), respectively.
Higher body mass index was associated with significantly high prevalence of hypertension (47.3%), overweight (33.2%), and obesity (17.5%). The Univariate analysis showed an association between hypertension and age, sex, body mass index (BMI), nutritional lifestyle, sleep duration, physical activity, smoking pattern and family history (p < 0.05). Multivariate logistic regression analysis revealed a significant association between hypertension and the above stated factors.

Conclusions: The findings of this present study highlighted the prevalence of hypertension (8%) and prehypertension (30.7%) among university students in Bahrain. The findings are consistent with previous studies associated with high prevalence factors (age, sex, body mass index, smoking, sleep duration, physical activity and family history of hypertension). The results of this study recommended that periodic screening and monitoring of students for hypertension should be done to the university students.

A Combined Effect of Sacubitril/Valsartan and Evolocumab on Chronic Heart Failure in an ERSD Patient

Hun M. Aung,1,2 Aye M. Thida,1,2 Myat E. Mon,3 Phyo Wai Khine,1 May T. Zin,2 Banya M. Win,2 Kyaw Hla,2 Alexander M. Swan,2,* Interfaith Medical Center, Brooklyn, NY; *Nephrology Hypertension Renal Transplant & Renal Therapy, LLC, Avenel, NJ;1 Woodland Medical and Mental Health Center, Brooklyn, NY; Rutgers New Jersey Medical School, Newark, NJ.

Introduction: End-stage renal disease (ESRD) patients generally have underlying risk factors for coronary artery disease and heart failure (HF) such as hypertension and diabetes mellitus. In fact, chronic HF is highly prevalent and is one of the leading causes of death in these patients. We report a combined effect of sacubitril/valsartan and evolocumab on chronic HF in an ESRD patient.

Case Description: A 63-year-old man with a history of chronic HF for 3 years, along with hypertension, diabetes mellitus, hypercholesterolemia, coronary artery disease, status post coronary artery bypass graft with multiple stents, and ESRD on hemodialysis, presented with worsening dyspnea over 2 months (NYHA Class IV). His medication list included enalapril, metoprolol, clopidogrel, glipizide, repaglinide, allopurinol, and folinic acid. He was on maintenance hemodialysis for 15 years. His creatinine was 10.4 mg/dL on admission.

On presentation, he had AKI, hypokalemia, metabolic acidosis, and electrolyte abnormalities. His 24-hour urine sodium was 245 mEq/day. He had high renin activity with low aldosterone levels. His urine sodium/potassium ratio was 15. The patient was started on enalapril and furosemide.

The patient presented with anasarca, peripheral edema, hypotension, tachycardia, and increased heart rate. His blood pressure was 90/45 mm Hg. He was started on intravenous fluid resuscitation, as well as cytochrome c repleting fluid. His urine output was 30 mL/h, and his creatinine clearance was 7 mL/min. His hemoglobin was 9.8 g/dL. Given these findings, a diagnosis of PLA2R associated membranous nephropathy was made. Bumetanide was started for management of fluid overload with good effect. Given proteinuria improved significantly after stopping therapy, sunitinib may have contributed to worsening of the underlying nephrotic syndrome. Ultimately, a decision was made to restart sunitinib with a plan to treat the membranous nephropathy with rituximab.

Discussion: Our patient developed hypertension and nephrotic syndrome, ultimately found to be PLA2R associated membranous nephropathy, in the setting of sunitinib use. It is possible that in our patient, sunitinib contributed to worsening of the nephrotic syndrome, as evidenced by the fact that proteinuria improved with stopping the TKI. While TKIs have been implicated in the development of proteinuria and nephrotic syndrome, it is important to rule out other possible causes to allow for continuation of oncological therapy if deemed necessary.

Conclusions: We present a case of a patient presenting in stage III acute renal failure with Lamba light chains measured at a level almost 9 fold greater at 3684 mg/dL. While TKIs have been implicated in the development of proteinuria and nephrotic syndrome, it is important to rule out other possible causes to allow for continuation of oncological therapy if deemed necessary.

Fanconi Syndrome and Acute Interstitial Nephritis: A Toxic Combination Associated with Ifosfamide

Hafsa, Nissreen El Fadawy, Miroslav Sekulic, Arshad Rashidi. University Hospitals, Cleveland, OH.

Introduction: Ifosfamide is an alkylating chemotherapeutic agent used in the treatment of various soft tissue tumors. Nephrotoxicity associated with ifosfamide is less frequently reported in adults. We describe a patient with Ewing sarcoma, who presented with AKI, nephrotic syndrome, and proteinuria. Given this is a rare presentation, we sought to present our case in the literature.

Case Description: A 17-year-old female with a history of Ewing sarcoma treated with ifosfamide (3000 mg/m2) and doxorubicin. On presentation, she had AKI, hypokalemia, metabolic acidosis, and electrolyte abnormalities. Her 24-hour urine sodium was 245 mEq/day. She was started on intravenous fluid resuscitation, as well as cytochrome c repleting fluid. Her urine output was 30 mL/h, and her creatinine clearance was 7 mL/min. Her hemoglobin was 9.8 g/dL. Given these findings, a diagnosis of PLA2R associated membranous nephropathy was made. Bumetanide was started for management of fluid overload with good effect. Given proteinuria improved significantly after stopping therapy, sunitinib may have contributed to worsening of the underlying nephrotic syndrome. Ultimately, a decision was made to restart sunitinib with a plan to treat the membranous nephropathy with rituximab.

Discussion: Our patient developed hypertension and nephrotic syndrome, ultimately found to be PLA2R associated membranous nephropathy, in the setting of sunitinib use. It is possible that in our patient, sunitinib contributed to worsening of the nephrotic syndrome, as evidenced by the fact that proteinuria improved with stopping the TKI. While TKIs have been implicated in the development of proteinuria and nephrotic syndrome, it is important to rule out other possible causes to allow for continuation of oncological therapy if deemed necessary.

Conclusions: We present a case of a patient presenting in stage III acute renal failure with Lamba light chains measured at a level almost 9 fold greater at 3684 mg/dL. While TKIs have been implicated in the development of proteinuria and nephrotic syndrome, it is important to rule out other possible causes to allow for continuation of oncological therapy if deemed necessary.
AKI Associated with Immune-Checkpoint Inhibitors: Management Challenges and Dilemmas Without Renal Biopsy

Hui Zhan Tan, Jason Choo Chon Jun. Singapore General Hospital, Singapore, Singapore.

Introduction: There is much to be learnt about renal lesions seen in patients with acute kidney injury (AKI) associated with the use of immune-checkpoint inhibitors (ICI). Acute tubulointerstitial nephritis is the most common, with glomerulonephritis (GN) being increasingly recognized.

Case Description: A 61 Chinese male presented with generalized arthralgia and AKI with nephritic-nephrotic syndrome on a background of Stage IV metastatic clear cell RCC and left radical nephrectomy. At presentation, he was on treatment with pembrolizumab (PD-(L)1 inhibitor) and axitinib (VEGF receptor TKI). Investigations revealed 24hr TUP of 8.26g/day and peak serum creatinine (Scr) of 605 μmol/L (CTCAE G3; baseline Scr 117 μmol/L). Autoimmune markers and complements were negative. Patient was counselled for but refused a high-risk renal biopsy. Pembrolizumab was discontinued. High dose prednisolone was initiated for renal and rheumatological IRAE. Scr improved to 226 μmol/L at 3 months but his nephritic-nephrotic state persisted. Risks and benefits of empiric mycophenolate mofetil were discussed extensively and patient opted to continue with corticosteroid (CS) monotherapy. His subsequent clinical course was complicated by community acquired pneumonia and herpes simplex virus oral mucositis, before eventually succumbing to polymicrobial sepsis from acute cholecystitis despite optimal management.

Discussion: The clinical presentation of our patient is highly suggestive of an underlying GN. In view of concurrent rheumatological IRAE, we postulated that his AKI was related to ICI use. Empiric use of high-dose CS resulted in partial improvement in renal function but persistence of nephritic-nephrotic state, suggesting that CS monotherapy is suboptimal. Without histological data, directed therapy was not possible. However, given the rarity and heterogeneity of ICI associated GN, success of previously tried agents was limited to case reports and optimal treatment remains unknown. In view of this uncertainty, hesitancy with the empiric use of immunosuppressants beyond CS is understandable. While we await further research, in-depth discussion of treatment risk and benefits, especially infective complications, during shared decision making remains a key element in the optimal care of this unique population with advanced malignancies and often, limited life expectancy.

Amitraterone-Induced Rhabdomyolysis as an Unusual Cause of AKI Requiring Hemodialysis

Juan Carlos Garcia Yanez,1,2 Hospital Aranda de la Parra, Leon, Mexico; Universidad de Guanajuato - Campus Leon, Leon de los Aldama, Mexico.

Introduction: A 86-year-old male diagnosed with metastatic, castration-resistant prostate cancer (mCRPC) treated with abiraterone (Zytiga) for 3 months was admitted to the emergency department due to hypoxia, worsening fatigue and lethargy.

Case Description: After being diagnosed with prostate cancer, the patient had been subject to a radical prostatectomy 10 years prior to admission; 12 months prior to admission he developed deep-vein thrombosis that required endovascular treatment. The patient was prescribed daily 10mg rivaroxaban and 5mg prednisone for 1 year. For over 4 years, the patient had an irregular consumption of esomeprazole, atorvastatin and risperidone. Upon admission to the emergency department laboratory analysis revealed a diaytic emergency: serum creatinine of 6.1mg/dL, urea 295 mg/dL, BUN 139mg/dL and potassium of 7.3mEq/L. The patient refused renal replacement therapy. Aggressive hydration and treatment with calcium gluconate, IV insulin and beta-agonist administration was initiated. Subsequently he developed anasarca, hypotension, metabolic acidosis, hyperkalemia and respiratory distress. He was intubated and treated with haemofiltration. Subsequently he developed ARDS, IHD and multiple organ failure. In view of concurrent rheumatological IRAE, we postulated that his AKI was related to abiraterone use. Empiric use of high-dose CS resulted in partial improvement in renal function but persistence of nephritic-nephrotic state, suggesting that CS monotherapy is suboptimal. Without histological data, directed therapy was not possible. However, given the rarity and heterogeneity of ICI associated GN, success of previously tried agents was limited to case reports and optimal treatment remains unknown. In view of this uncertainty, hesitancy with the empiric use of immunosuppressants beyond CS is understandable. While we await further research, in-depth discussion of treatment risk and benefits, especially infective complications, during shared decision making remains a key element in the optimal care of this unique population with advanced malignancies and often, limited life expectancy.

Bilateral Renal Burkitt Lymphoma Presenting with Persistent Lactic Acidosis in an HIV-Negative Patient

Oscar A. Garcia Valencia,1,2 Juan D. Salcedo Betancourt,1,2 Victor G. Becerra-Gonzalez,1,2 Karla G. Carias martinez,1,2 Marco A. LadinoAvellaneda,1,2 1Jackson Memorial Hospital, Miami, FL; 2University of Coral Gables, FL; 3Miami VA Healthcare System, Miami, FL.

Introduction: Burkitt lymphoma is an uncommon and aggressive B-Cell lymphoma accounting for <1% of adult Non-Hodgkin Lymphomas. The ileocecal region is the most common affected area, but it can involve extra nodal sites including the kidney. Renal involvement is usually asymptomatic and requires a high degree of suspicion to prevent early complications.

Case Description: 63 years old non-smoker, HIV negative male with a history of an incidentally found left medial upper pole exophytic perinephric hematoma on CT 2 months prior to presentation, presented to the ED complaining of acute on chronic lumbar back pain. Noted afebrile, BP 86/52 mmHg with orthostatic changes, HR 92rpm, RR 20rpm and SO2 96% on RA somnolent but arousable, pale, no abdominal, spinal or costovertebral tenderness. Laboratories showed Hb 8.2 (14.7 a month prior), WBC 17,000, Na 126, Sodium bicarbonate 16, Anion gap of 22, Lactic acid 5.0 and potassium of 7.3mEq/L. The patient refused renal replacement therapy. Aggressive hydration and treatment with calcium gluconate, IV insulin and beta-agonist administration was initiated. Subsequently he developed anasarca, hypotension, metabolic acidosis, hyperkalemia and respiratory distress. He was intubated and treated with haemofiltration. Subsequently he developed ARDS, IHD and multiple organ failure. In view of concurrent rheumatological IRAE, we postulated that his AKI was related to abiraterone use. Empiric use of high-dose CS resulted in partial improvement in renal function but persistence of nephritic-nephrotic state, suggesting that CS monotherapy is suboptimal. Without histological data, directed therapy was not possible. However, given the rarity and heterogeneity of ICI associated GN, success of previously tried agents was limited to case reports and optimal treatment remains unknown. In view of this uncertainty, hesitancy with the empiric use of immunosuppressants beyond CS is understandable. While we await further research, in-depth discussion of treatment risk and benefits, especially infective complications, during shared decision making remains a key element in the optimal care of this unique population with advanced malignancies and often, limited life expectancy.
Clinicians need to be aware of this potential adverse effect related to oxaliplatin therapy, extent carboplatin have been known to cause electrolyte disturbances, in particular hypomagnesemia. However, case reports of oxaliplatin associated magnesium wasting are limited. This can be partially explained by the fact that oxaliplatin is protein bound and cannot readily accumulate in the kidney tubules to mediate nephrotoxicity, as is the case with carboplatin which is not protein bound. Magnesium deficiency is an under recognized entity, however it can precipitate potentially fatal cardiovascular dysfunction.Clinicians need to be aware of this potential adverse effect related to oxaliplatin therapy, as its prompt diagnosis and treatment can prevent the associated complications.

**Introduction:** Immune related adverse events (irAEs) associated with immune checkpoint inhibitors (ICIs) are increasing in frequency. We report a case of sarcoid involvement in both the kidney and heart receiving this therapy. Sarcoïd-like / granulomatous lesions from ICI are reported to be as high as 5% based on case series and registries. In all reported cases, patients presented with lymph node, skin, or lung involvement. We present the first case of sarcoid lesions in the heart in a patient being treated with immune checkpoint therapy.

**Case Description:** A 62-year-old male with stage IV metastatic melanoma received ipilimumab and nivolumab. In March 2020 he was admitted with acute kidney injury, with high index of suspicion to diagnose GiTMA early in the course of the disease. Mainstay of management is withdrawal of the offending drug and supportive care. In all reported cases, patients presented with lymph node, skin, or lung involvement. We present the first case of sarcoid lesions in the heart in a patient being treated with immune checkpoint therapy.

**Discussion:** Use of ICI has dramatically improved patient survival; however, there is a growing appreciation for adverse events that can be associated with increased morbidity. To our knowledge, this is the first case of sarcoid involvement in both the kidney and heart. Our case highlights the need for aggressive approach to ICI toxicity when clinical work-up is unrevealing. The timely manner that both kidney and heart biopsies were performed may be a side effect from the patient receiving this therapy. Sarcoïd-like / granulomatous lesions from ICI are reported to be as high as 5% based on case series and registries. In all reported cases, patients presented with lymph node, skin, or lung involvement. We present the first case of sarcoid lesions in the heart in a patient being treated with immune checkpoint therapy.

Prevalence is around 10% of all membranous nephropathy (MN) cases. Anti M-type dose >90–120 g/m² are risk factors for AKI. Management is mainly supportive such as notable given lower cumulative dose (11.25 g) resulting in nephrotoxicity. Case reports 10 g/mg creat. Urine sediment exam showed granular casts. He had proximal RTA and proteinuria and 3+ glycosuria and protein creatinine ratio was 4.69 and on repeat, it was associated hypokalemia and hypophosphatemia. Urine pH was 8 and patient had 2+ developed a non-anion gap hyperchloremic metabolic acidosis around that time. There chemotherapy with ifosfamide, carboplatin, etoposide (carboplatin and etoposide – day 1 tract symptoms. No NSAID use. No IV contrast exposure. No hypotension. Patient got throat and non-productive cough. Patient did not have any vomiting or diarrhea or fever in past who was admitted for ICE chemotherapy. Patient reported fatigue and chills, sore Urinothorax: A Rare Cause of Pleural Effusion Anusha Ananda,2 Abigayle Kallapur,2,1 Juan Gables, FL; 2Jackson Memorial Hospital, Miami, FL

Introduction: Hypertrophy of the prostate (BPH) is a common cause of obstructive prostatitis in old men. Here we present a case of a 62-year-old Hispanic man with BPH who was found to have an additional rare cause of hypocomplementemia, namely 10-19% membranous nephropathy (RMC). The patient had a long history of intermittent dysuria and acute retention of urine. Laboratory data were remarkable for serum creatinine of 2.7 mg/dl. Urinalysis showed 2+ proteinuria and 3+ glucose and protein creatinine ratio was 4.69 and on repeat, it was 10 g/mg creat. Urine sediment exam showed granular casts. He had proximal RTA and Fanconi syndrome due to ifosfamide nephrotoxicity. He was managed with supportive treatment with repletion of potassium and phosphate and bicarbonate drip. This was notable given lower cumulative dose (11.25g) resulting in nephrotoxicity. Case reports mention nephrotoxicity mostly in children with 60-120 g cumulative dose. Discussion: Ifosfamide induced AKI is reversible but can be permanent. Biopsy shows tubular injury/necrosis with swollen mitochondria. Ifosfamide enters proximal tubule cells via OCT 2. Chlordecone aldehyde is the toxic metabolite produced by ifosfamide that causes kidney injury. Usually,CKD, previous cisplatin exposure and cumulative dose >90–120 g/m² are risk factors for AKI. Management is mainly supportive such as repletion of deficient electrolytes and renal replacement therapy if indicated. Possible recurrence of underlying cancer. Additionally, age-appropriate cancer screening for all newly diagnosed MN cases is essential. We hope this report shall serve as a means for further discussion and research in onco-nephrology.

that gemfibrozil may affect the active site of both KAT I and KAT II. Results of the molecular docking suggested that gemfibrozil at 50 μM, 500 μM and 1 mM decreased KYNA production in vitro to 47% (\(P<0.001\)) and 26% (\(P<0.001\)) of control value, respectively. At 100 μM, 500 μM and 1 mM concentration decreased KYNA activity in vitro to 66% (\(P<0.001\)), 56% (\(P<0.001\)) and 52% (\(P<0.001\)) of control value, respectively. Moreover, gemfibrozil at 500 μM and 1 mM concentration decreased of control value, respectively. Results of the molecular docking suggested that gemfibrozil may affect the active site of both KAT I and KAT II. Publicly available microarray data suggested that the expression of KAT-coding genes does not change after gemfibrozil administration.

Conclusions: Gemfibrozil decreases KYNA production in rat kidney in vitro through inhibition of KAT I and KAT II isoenzymes. Present results indicate a novel mechanism of gemfibrozil’s action in the kidney. Its potential role in nephrotoxicity needs verification in upcoming studies.

MRI lower extremity: Diffuse fatty replacement of all of the muscles of the bilateral thighs, with no loss of overall muscle bulk. This could be due to muscular dystrophy or end-stage myositis.

Successful Treatment of the Pediatric Case with Anti-MDA5 Antibody-Positive Interstitial Lung Disease by Plasma Exchange Therapy

Christina Yonezawa,1 Shinya Kitajima,1 Hisayuki Ogura,1 Koichi Sato,1 Taro Miyagawa,1 Tadashi Toyama,1 Akinori Hara,1 Yasunori Iwata,1 Noriko Sakai,1 Miho Shimizu,1 Taizu Wada,1 Takashi Wada,1 Kanazawa University Hospital Department of Nephrology, Kanazawa, Japan; 2Kanazawa University Hospital Department of Pediatrics, Kanazawa, Japan.

Introduction: Anti-melanoma differentiation-associated gene 5 (MDA5) antibodies are a type of myositis-specific autoantibodies. They are strongly related to rapid progressive lethal interstitial lung disease (ILD) with dermatomyositis. We experienced the 2 years old pediatric case with refractory anti-MDA5 antibody positive ILD and successfully treated with plasma exchange (PE).

Case Description: Two years old girl with normal development showed acute lower extremity weakness, dysphagia and face erythema three months before admission. She developed non-productive cough and fever. She visited nearby hospital one month before admission and was diagnosed as bilateral pneumonia with high KL-6 titer (2500 U/mL). Antibiotics had no effect and she admitted to another hospital. Additional examination revealed the high titer of anti-MDA5 antibody (1270 index) and normal creatinine (0.3 mg/dL). She also exhibited Heliotrope rash and Gottron’s sign. She was diagnosed as anti-MDA5 antibody positive juvenile dermatomyositis with ILD. Methylprednisolone pulse therapy (mPSL) and intravenous cyclophosphamide therapy were started but ILD was sustained. She transferred to our hospital for additional therapies. On the second hospital day, intravenous immunoglobulin was given and intravenous rituximab therapy was added on day 7 and 16. In spite of eradication of CD20-positive cells, her symptom was not improved. Therefore, we carried on PE with albumin-based replacement solution. After three courses of PE, the titer of anti-MDA5 antibody decreased to 83 index from 980 index on admission and her respiratory status was significantly improved.

Discussion: The mortality of anti-MDA5 antibody-positive ILD was reported as 20-30% regardless of intensive immunosuppressive therapy. Previous studies reported that anti-MDA5 antibody-positive ILD patients had high level of serum inflammatory cytokines and cytokine levels were related to the disease activity of ILD. Lowering them may have a crucial therapeutic effect for anti-MDA5 antibody-positive ILD. Plasmapheresis therapy might be one of options to treat anti-MDA5 antibody positive patients with dermatomyositis complicated ILD.

Use of Lisinopril in an Adolescent with “Extreme Dipper” Autonomic Hypertension Profile

Siddharth A. Shah,1 University of Louisville, Louisville, KY.

Introduction: The interaction between renin angiotensin aldosterone system and autonomic nervous system for blood pressure (BP) control is described. Angiotensin type-1 receptor activation in hypothyroidism increases activity of parasympathetic pre-synaptic neurons as well as increases permeability of blood brain barrier to angiotensin. ADHD stimulant medication may be associated with cardiac autonomic dysfunction in children. Standard deviation (SD) of systolic BP (SBP) may be a better measure to study autonomic BP pattern particularly with nighttime extreme dipper hypertensive profile.

Case Description: A 16-year-old non obese male presents with hypertensive urgency; BP of 168/102 mm Hg and symptoms of headache and vomiting. He was maintained on stimulant medication for ADHD that was stopped at initial presentation. The evaluation of secondary causes of hypertension was negative. He was started on Ca channel blocker. Four months after initial presentation, the 24-hour ambulatory BP monitoring (ABPM) study was done that showed hypertensive profile with extreme nighttime dipping. SD of SBP was 24.29 suggesting significant BP fluctuations (Figure-1). He was started on Lisinopril at the dose of 20 mg daily. ABPM study was repeated 3 months latter (Figure-2). There was marked improvement in daytime BP fluctuations (daytime SD of SBP-8.48) without worsening nighttime BP dipping. Dizziness on changing posture was not reported.

Discussion: ACE inhibitors may be considered as an option for treatment of autonomic hypertension in adolescents with extreme nighttime dipping BP profile.
**PUB230**

**Influence of Biopsy Prognosis on Graft Survival**

Cristina Andrades Gómez, Jorge Calvillo-Arbiizu, Miguel angel Pérez valdivia, Gabriel Bernal blanco, Jose Luis Rocha Castilla. Hospital Universitario Virgen del Rocio, Sevilla, Spain.

**Background:** Renal transplantation is the best alternative renal replacement option for patients with advanced chronic kidney disease. However, the supply of young donors is limited, and does not cover the demand of patients on the renal transplant waiting list. For this reason, older donors are being used, and a high discard rate of those organs exists based on pathological results (score) of the preimplant renal biopsy. There are several methods to evaluate the quality of the kidneys and the Kidney Donor Profile Index (KDPI) has acquired special relevance to decide the performance of preimplant renal biopsy. Based on the score, a preimplant renal biopsy is performed, which is decisive in certain cases. However, there is poor evidence to support this decision, which can be described as “conservative,” since there is not enough certainty that there is influence of the preimplant biopsy score influences graft survival.

**Methods:** 389 biopsies of kidney transplant donors of cadaver donors in brain death and asystole type III were included. Donors in asystole type II, combined and live, were excluded. Samples were examined by the same pathologist and in paraffin (no case by freezing). A graft survival analysis was performed based on the results of the renal biopsy (score). Likewise, a multivariate analysis of graft survival was carried out including, in addition to the results of the renal biopsy, results such as the age of the donor and recipient and the KDPI.

**Results:** Graft survival was compared between two transplant subpopulations in our hospital based on whether a preimplant biopsy was performed. According to the data used there are no significant differences in graft survival between transplants in which biopsy has been performed or not.

**Conclusions:** The preimplant biopsy score by itself and the evaluation of the different histological components in the biopsy have no influence on graft survival. We believe that predictive indices that combine donor and recipient histological and clinical variables should be implemented.

**PUB232**

**Hypercalcemia Secondary to Hyperthyroidism: A Unique Cause of Renal Failure in a Kidney Donor**

**Introduction:** Hyperthyroidism is associated with increased bone resorption resulting in hypercalcemia (HCA). Chronic HCA leads to defect in concentrating ability of kidneys by downregulation of aquaporin-2, calcium deposition in medulla, impairing osmotic gradient resulting in polyuria and persistent pre-renal state. HCA causes renal vasoconstriction leading to acute tubular injury (ATI) followed by atrophy and interstitial fibrosis (IFTA).

**Case Description:** We present a case of a 70 yr old female who donated a kidney 5 yrs ago with serum creatinine (Cr): 1.18mg/dL and Calcium (Ca): 10.2mg/dL at 2 yr f/u. At routine 3 yr f/u, Cr of 4.4mg/dL, BUN of 70 mg/dL, and Ca of 12.6mg/dL were noted. Kidney biopsy showed ATI, severe IFTA, negative for any immune deposits (Figure 1A). Work up of HCA revealed; PTH: 5 (18.5-88 pg/ml), 25(OH)D: 55 ng/ml, 1-25(OH)D: 70 ng/ml, angiotensin converting enzyme level: 42 (9-47 U/L), serum urine protein electrophoresis: negative, PTHrp: < 2 pmol/L, Vit A: 76.82 (22-69.5ug/dl) and detailed cancer work up was negative. CT scan revealed enlarged thyroid nodule (biopsy negative for cancer) and nuclear scan showed overactive thyroid nodule(Figure 1B). Thyroid studies [TSH: < 0.005 (0.35-3.7 uIU/ml), FreeT4: 2.49 (0.76-1.46ng/dl)] were treated with radioactive iodine, methimazole and low dose steroids. After 9 months labs improved-

**Discussion:** To our knowledge we report the first case of irreversible renal failure in a kidney donor due to prolonged HCA from hyperthyroidism eventually requiring KTxs. Progression of renal disease from prolonged HCA may be due to limited renal mass as a solitary kidney. Hence, prompt treatment and correction of hyperthyroidism and hypercalcemia may help in preventing progression of renal disease.
Outcomes in Kidney Transplantation from Increased-Risk Donor Organs: A Single-Center Experience

Maria L. Safar-Boueri,1,2 Jean M. Francis,2 Northwestern University Feinberg School of Medicine, Chicago, IL; 2Boston University, Boston, MA.

Background: Despite their lower Kidney Donor Profile Index (KDPI) score and demonstrated survival benefit of transplantation as compared with remain on dialysis, Public Health Service increased-risk donor (IRD) organs continue an underutilized source for transplantation.

Methods: This is a single-center retrospective cohort conducted at Boston Medical Center. Patients receiving IRD organs from 2016 and 2019 were evaluated. Baseline characteristics and outcomes one year after transplantation were described.

Results: We included 41 patients receiving IRD organs. Donors tended to be younger, with lower KDPI scores and good kidney function. Most common cause of death was anoxia from drug intoxication. Patients receiving IRD organs had stable kidney function at one year, with >70% having an estimated glomerular filtration rate (eGFR) of >60 mL/min. None of the patients became positive for HBV, HCV or HIV.

Conclusions: Patients receiving IRD organs did not show a higher risk of infection or poor renal outcomes in this single-center population.

Results: A total of 39 patients, 30(76.9%) patients were male, a mean age(29.5), 38(97.4%) had a history of dialysis, 21(53.8%) they were transplanted by a living donor, cold ischemia an average of 127 min, days in hospital an average of 5.3, serum phosphorus prior kidney transplant an average 5.7(2.3) mg/dl, in the ANOVA analysis a mean serum creatinine (Group A=0.9, B=2, C=2.1 mg/dl), a mean GFR (Group A=101, B=65, C=48.7 ml/min), a mean urea (Group A=4423, B=3027, C=1865 ml/day) at discharge were compared; A vs B urea P=0.03 IC=-1121/3913, creatinine at discharge P=0.1 IC=-2.6/0.2, GFR discharge P=0.03 IC=-1.9/1.7, A vs C urea P=0.07 IC=256/3527, creatinine at discharge P=0.01 IC=-4.2/0.4, GFR at discharge P=0.01 IC=-8.5/9.7, AUC of 0.9, with a cutoff value of 3.6 mg/dl have a TFG >60 ml/min P=0.001.

Conclusions: Patients who decrease serum phosphorus to normal or inclusive ranges of hypophosphatemia after immediate kidney transplantation, have better renal function than those who have hyperphosphatemia at discharge, serum phosphorus may be a predictor of optimal GFR in this patients.

Baseline characteristic, ANOVA test, ROC curve.

PUB236
Routine Monitoring of Donor-Specific Antibodies During the First Year of Kidney Transplant: Is It Underrated?

Background: Kidney transplant (KT) recipients with de novo donor-specific antibodies (DSA) are at risk of graft loss. DSA could lead to a decline in kidney function due to antibody-mediated rejection (ABMR), or be asymptomatic. Efficacy and cost-effectiveness of routine DSA monitoring are not known. Confirmation of ABMR with kidney biopsy is advised. We aim to study the utility of routine DSA monitoring (RDM) in predicting rejection in asymptomatic pediatric KT recipients.

Methods: After IRB approval, a retrospective chart review of patients who had RDM was done. Patients with clinical suspicion of rejection were excluded from the study. Demographic data and clinical features were analyzed using descriptive statistics. Continuous and categorical variables were analyzed using the student’s t-test and Fisher’s exact test respectively. A p-value <0.05 was considered statistically significant.

Results: Four out of 17 (24%) patients were tested positive for de novo DSA. There were no significant differences in age, gender, race, type of transplant, or serum creatinine between patients with positive and negative DSA. Three out of four (75%) patients had an ABMR, in the platelet count – 100 K/mm), progressive anemia (Hemoglobin 11.5 to 6.8 g/dl) and diarrhea in the setting of newly diagnosed CMV viremia (CMV DNA 1164 to 9177 IU/mL at months 8 and 9 respectively). Lactate dehydrogenase increased to 841 U/L with a normal haptoglobin and no reticulocytosis. Schistocytes were seen on a peripheral blood smear. ADMATS-13, anti neutrophilic antibodies H, I, B, C3, C4, and stool panel tests were unremarkable. FK506 was switched to Cyclosporin (CYC) after diagnosing TMA. After clearance of CMV viremia and stopping valganciclovir, neutropenia resolved. Creatinine fell from 7 to 4.5 mg/dl at month 10-11. Plasmapheresis (PP) and IVIG were initiated for suspected non-HLA antibody mediated rejection (AMR) with CYC.

Discussion: The constellation of TMA, CMV viremia, tubulitis, microvascular inflammation and myelosuppression, poses dilemmas in balancing management as FK506, CYC and AMR may all be contributory, in isolation or combination to TMA. We elected to maintain a calcineurin inhibitor and mycophenolic regime in the face of TMA and CMV due to the risk of florid rejection, and initiated PP with IVIG.

PUB239
Hypofibrinogenemia as a Risk Factor of Bleeding After Plasmapheresis with Centrifuge in Renal Transplantations with Active Humoral Rejection
Mayra M. Matias Carmona,1,2 Sergio Hernandez-Estrada,1,2 Jose H. Cano,1,2 Odette Del Carmen Diaz Avendaño,1,2 Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico;3 Universidad Nacional Autonoma de Mexico Facultad de Medicina, Universidad Nacional Autonoma de Mexico Facultad de Medicina, Mexico, Mexico.

Background: Humoral rejection represents an important cause of graft loss, multiple therapeutic approaches have been implemented, therapeutic plasma exchange (TPE), is part of them, however one of its main complications as hypofibrinogenemia due to the risk of bleeding, which represents a challenge due to the risk of immunization in the event of a transfusion and even limiting the continuity of treatment due to the risk of bleeding imminent due to the presence of low figures during the platelet count of the session, for confirmation if hypofibrinogenemia (<100 mg/dl) after sessions of TPE with centrifuge is an absolute risk factor for bleeding that warrants the need for transfusion or cessation of therapy.

Methods: In the period from June 2017-May 2019, 25 Mexican kidney transplant patients with diagnosis of active humoral rejection, without previous coagulation abnormalities, were submitted to TPEA a total of 5 sessions per patient were granted in an average of 10±2 days, with measurement of fibrinogen levels before and after each session as well as daily clinical evaluation of active bleeding

Results: The age range was 21-35 years, 44% were female, the causes of ERCT up to 52% were not reported, cadaveric donor transplantation predominated in 52%, The initial average fibrinogen value was 397 mg/dl, after the 1st session a reduction of 33% was observed, with an average value of 133 mg/dl. The lowest level was 43 mg/dl, the most important bleeding event was documented during the 4th session. Only 1 major bleeding event was documented due to epistaxis that required transfusion. This event was after the 3rd session, with fibrinogen of 79 mg/dl. At the end of TPE treatment, fibrinogen levels normalized in all patients, with no further bleeding events

Conclusions: Despite the strong association of hypofibrinogenemia and bleeding, only one major bleeding event was reported in our population. There were no other events despite having level as low as<50 mg/dl, therefore we consider close surveillance as the main measure during TPE leaving the transfusion only in the context of active bleeding. The blood tissue is rich in immunoglobulins and therefore favors the host’s immune response, is paradoxical to remove antibodies and grant new ones with transfusions. Hypofibrinogenemia did not limit the continuity of treatment, concluding its treatment in a timely manner.

PUB237
De Novo Thrombotic Microangiopathy Associated with Cytomegalovirus Infection and Alloreticivity: A Fork in the Road of Immunomodulation
Sanar A. Medany, Karim M. Soliman, Michael Casey, Maria Aurora C. Posadas, Vinuya Rao. Medical University of South Carolina, Charleston, SC.

Introduction: De novo thrombotic microangiopathy (TMA) may yield cross-roads of diverging therapeutic approaches, not well delineated. We describe such a case in the setting of Cytomegalovirus (CMV) viremia and suspected rejection.

Case Description: A 52-year-old female with presumed nephrotic nephropathy received a deceased donor kidney transplant (KDPI 73%) complicated by progressive allograft dysfunction after 6 months. Anti-thymocyte globulin was used for induction, steroids, mycophenolate and pre-emptive maintenance of immunosuppression. With step-wise rise in serum creatinine (baseline 1.7 mg/dL) to 2.5, 3 and 4 mg/dL at months 6, 8 and 9 months post-transplant respectively, three allograft biopsies were obtained. Secondary focal segmental glomerulosclerosis, moderate-severe interstitial fibrosis and tubulitis, and a mild tubulitis were seen in all biopsies with mild glomerulitis and peritubular capillaritis in the last two, and TMA in the last biopsy. C4d and HLA DSA were consistently negative. Despite methylprednisone given at month 8, creatinine continued to rise to 7 mg/dl by month 9. The course was complicated by leukopenia, brief thrombocytopenia (plated count – ~ 100 K/mm), progressive anemia (Hemoglobin 11.5 to 6.8 g/dl) and diarrhea in the setting of newly diagnosed CMV viremia (CMV DNA 1164 to 9177 IU/mL at months 8 and 9 respectively). Lactate dehydrogenase increased to 841 U/L with a normal haptoglobin and no reticulocytosis. Schistocytes were seen on a peripheral blood smear. ADMATS-13, anti neutrophilic antibodies H, I, B, C3, C4, and stool panel tests were unremarkable. FK506 was switched to Cyclosporin (CYC) after diagnosing TMA. After clearance of CMV viremia and stopping valganciclovir, neutropenia resolved. Creatinine fell from 7 to 4.5 mg/dl at month 10-11. Plasmapheresis (PP) and IVIG were initiated for suspected non-HLA antibody mediated rejection (AMR) with CYC.

Discussion: The constellation of TMA, CMV viremia, tubulitis, microvascular inflammation and myelosuppression, poses dilemmas in balancing management as FK506, CYC and AMR may all be contributory, in isolation or combination to TMA. We elected to maintain a calcineurin inhibitor and mycophenolic regime in the face of TMA and CMV due to the risk of florid rejection, and initiated PP with IVIG.

Kidney Transplant Recipients Suffer Fewer Complications After Adrenergic Surgery
Ankur P. Chouhey,1 Darren Abbas,1 Jonathan Demeter,1 Afshin Parsiakia,2 Jorge Ortiz.1 1The University of Toledo Medical Center, Toledo, OH;2Westchester Medical Center, Valhalla, NY.

Background: Chronic immunosuppression after kidney transplant (KT) is a known risk factor for developing a malignancy. While occurrences of other cancers have been well documented, there is paucity of data regarding the incidence and effects of adrenergic tumors after renal transplant. We aim to evaluate the differences in short-term outcomes between renal allograft recipients and the general population undergoing adrenergic surgery.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. The population of interest was adults with a kidney transplant undergoing adrenergic surgery. ICD-9 codes were used to identify the procedures. Sample mean with standard deviations, and Student’s t tests were calculated for categorical variables. Odds ratios were computed using weighted data. Multivariable linear regressions were utilized to compare outcomes at transplant and non-transplant centers.

Granulomatous Tubulointerstitial Nephritis in a Kidney Transplant Recipient
Mohamed Hassanein, Leal C. Herlitz, Cyndee Miranda, Aimen Liaquat, Richard A. Fatica. Cleveland Clinic, Cleveland, OH.

Introduction: Granulomatous tubulointerstitial nephritis (GTIN) is a rare pathological diagnosis accounting for 6% of all causes of tubulointerstitial nephritis (TIN). Causes of GTIN include fungal and tuberculous infections, sarcoidosis, and medications. We describe a case of GTIN in a kidney transplant recipient (KTR).

Case Description: A 65-year-old male with a history of diabetes mellitus, hypertension, active pulmonary and ocular tuberculosis (TB), and a deceased donor kidney transplant 8 years prior was admitted for acute kidney injury (AKI). Medications included nonsteroidal anti-inflammatory drugs, riluzole, carvedilol, insulin, and tacrolimus. Serum labs showed: creatinine (Cr) 2.65 mg/dL (baseline Cr 1.3 mg/dL), corrected calcium 13.2 mg/dL, and tacrolimus trough level 7.6 mg/mL. Urine sediment examination and kidney ultrasound were unremarkable. Further workup for hypercalcemia revealed: parathormone (PTH) 7 pg/mL, 1,25-dihydroxy-vitamin D 54.3 pg/mL, PTH related peptide <2 pg/mL, and angiotensin-converting enzyme 47 U/L. Kidney biopsy showed TIN and non-caseating granulomas (figure A) with negative acid-fast bacilli (AFB) staining, bacterial, and fungal polymerase chain reaction. He was treated with prednisone taper over 6 weeks with complete resolution of AKI and hypercalcemia.

Discussion: GTIN in KTRs is rare, with an incidence of <1% in transplanted kidney biopsies. AKI and PTH-independent hypercalcemia with a negative workup for other causes of AKI should prompt a kidney biopsy. Granulomas with multinucleated giant cells can help differentiate GTIN from acute rejection – the most common cause of TIN in KTRs. Despite negative T-cell staining of the biopsy tissue sample, it was impossible to exclude tuberculous GTIN in our patient who was on anti-tuberculous therapy. Cautious initiation of steroid therapy can be effective in these cases.

Kidney Transplants from Deceased Donor After 11 Days of Hemodialysis
Ankur P. Chouhey, Obi Ekwenwa, Michael Rees, Jorge Ortiz. The University of Toledo Medical Center, Toledo, OH.

Introduction: There is little consensus on the use of organs from donors with acute kidney injury (AKI) for kidney transplantation. Previously, the longest reported duration of dialysis before donation was 4 days. We detail the first successful kidney transplant from a donor after 11 days of hemodialysis.

Case Description: Donor was a healthy 41-year-old male with severe injuries from a car accident. He suffered severe AKI from rhabdomyolysis requiring 11 days of hemodialysis. Peak and terminal creatinine (Cr) were 4.55 and 3.23, creatine kinase was 10,582 U/L, and KDPI was 37%. Biopsy showed no vessel or interstitial injury, or global glomerulosclerosis. No casts were seen on urinalysis. Recipient was a 60-year-old female from a matched donor with ESRD from IgA nephropathy, on dialysis for 2 years with EPTS of 41%. Cold ischemia time (CIT) and pump time were 32 and 103.5 hours. Post-operative DGF required two dialysis sessions. Recipient 2 was a 61-year-old male with ESRD from diabetes, on dialysis for 6 years with an EPTS of 90%. CIT and pump time were 26 and 24 hours. Profuse bleeding from graft biopsy site and pseudoaneurysm formation required treatment with transfusions, and dialysis for DGF. He was readmitted with hyponatremia and carbapenem resistant enterobacteriaceae sepsis, requiring nephrostomy tube and antibiotics.

Discussion: Careful selection based on donor youth, good health without comorbidities, and injury by rhabdomyolysis were crucial in this case. Moreover, biopsies revealed excellent histology, with good flow and resistance on perfusion pump. These factors made the kidney's acceptable for transplant despite DCD donor with prolonged dialysis and CIT. Both patients received Tacrolimus, Mycophenolate mofetil, and Prednisone. On follow up, recipients were dialysis independent and making urine. Complications in recipient 2 required prolonged hospitalizations, but none of the adverse events were due to donor AKI. Take Aways This case report is a novel opportunity to understand the extent of kidney transplantation after AKI. Despite 11 days of hemodialysis and DCD donor, procurement was possible because AKI due to rhabdomyolysis is transient and resolves within weeks. AKI donor-recipient matching is an individualized process. Clinician decision-making with rigorous donor and recipient selection is paramount in transplanting AKI organs. Post-operative DGF management is crucial in restoring graft function.
Rapid Renal Allograft Failure Following Recurrence of Lupus Nephritis 12 Years After Renal Transplant

Sreedevi koppisetti Jenigiri, Jayesh B. Patel, Prerna Kumar, Christie P. Thomas, Sarat C. Kuppachi. University of Iowa, Iowa City, IA.

Introduction: End stage kidney disease (ESRD) secondary to lupus nephritis (LN) is an important complication of systemic lupus erythematosus (SLE) for which the treatment of choice is to undergo a kidney transplant (KT). Following a KT, patients rarely develop recurrent lupus nephritis (RLN), but when they do, most events of recurrence occur within a few years after KT. We describe the case of a young Caucasian lady who underwent a living related KT for LN and maintained stable renal function for 12 years, and then developed severe RLN that was unresponsive to treatment.

Case Description: A 34-year-old developed LN and her kidney biopsy (KB) demonstrated global sclerosis with immune complex glomerulonephritis with positive serum antinuclear (ANA) and antinuclear antibodies (ACA) in 2006. She received living related KT in 2007. Her post-transplant course was complicated with the development of Banff grade IIa acute cellular rejection 1-month later, which was treated with steroids. She remained free of treatment and attained a baseline creatinine (Cr) measuring 1.2 to 1.3 mg/dL. She maintained on tacrolimus, mycophenolate mofetil (MMF) and prednisone. Her MMF was replaced with azathioprine during an uneventful pregnancy in 2011. She had a slight increase in her baseline Cr over the years but maintained a stable Cr measuring 1.4-1.6 mg/dL. In 7/2019, the Cr suddenly increased to 3.9 mg/dL with proteinuria and microscopic hematuria. Her platelet counts, complement, ANA, ANCA and double stranded DNA levels were normal. A KB demonstrated features of thrombotic microangiopathy, diffuse proliferative GN with focally crescentic LN and full house pattern on IF. Despite treatment with intravenous steroids and cyclophosphamide, her renal allograft function deteriorated, she required dialysis by 11/2019.

Discussion: Even patients with stable renal function maintained on standard immunosuppressive medications many years after transplantation are at risk of RLN. Our case demonstrates that RLN can manifest suddenly, and with a lack of usual laboratory features characteristic of a lupus flare. Further studies are necessary to better identify reasons for lupus recurrence in patients with long standing stable renal function.

Rapid Renal Allograft Failure Following Recurrence of Lupus Nephritis 12 Years After Renal Transplant

Vatsalya Korus, Imran Y. Gani, Azem A. Mohammed, Rajan Kapoor, Sandeep A. Padala. Augusta University, Augusta, GA.

Introduction: Adenovirus can lead to serious conditions in the immunocompromised transplant recipients. It infects urothelium and causes acute hemorrhagic cystitis and either nephritis or acute rejection causing functional deterioration of transplanted kidney.

Case Description: A 55-year-old male with history of ESRD on hemodialysis treatment: 3 were submitted to radiotherapy (RT), 1 to chemotherapy (CT) and 2 had both RT and CT. Pegylated liposomal doxorubicin was the drug of choice. At follow-up, 1 patient remains with normal kidney function, 1 with chronic graft dysfunction and 2 lost their KT (one by antibody-mediated rejection 3 months after KT diagnosis, and one by chronic graft dysfunction after 19y of KT, 14y after KT). Three patients have already died (with graft function) one directly to the KS.

Conclusions: Despite the scarcity of published series on KTR, the experience of KS in our center is in line with the literature, since it’s more common in man, the incidence is higher in the first 2 years after transplant and cutaneous lesions were the main presentation.

In our series, a lower incidence of KS in the last decade has been reported. However, thorough surveillance in higher-risk groups, as HIV patients, should not be forgotten. However, thorough surveillance in higher-risk groups, as HIV patients, should not be forgotten.
Late-Onset Recurrent Granulomatous Interstitial Nephritis in Transplanted Kidney with Successful Treatment: A Case Report
Fatmah Yamani,1 Miroslav Sekulic,1,2 Arksarapuk Jittirat,1,2 1Case Western Reserve University, Cleveland, OH; 2University Hospitals Cleveland Medical Center, Cleveland, OH.

Introduction: End stage renal disease (ESRD) secondary renal sarcoidosis is rare and likely due to hypercalcemic nephropathy. There is limited data on recurrent renal sarcoidosis post kidney transplant. We report a case of unusually late onset, recurrent sarcoidosis in transplanted kidney with successful treatment.

Case Description: A 65 year-old female with history of pulmonary sarcoidosis and ESRD due to sarcoidosis related-granulomatous interstitial nephritis (GIN) received a renal transplant in 2008. She was maintained on tacrolimus, mycophenolate(MMP) and prednisone. Baseline serum creatinine (SCr) had been 1.5 mg/dL. In 2017, patient was diagnosed with recurrent metastatic colorectal cancer. In 2019, her SCr increased to 3 mg/dL. A transplant kidney biopsy showed non-necrotizing GIN. She was treated with prednisone 40 mg daily. SCr decreased to 2.3 mg/dL. 3 months later, a repeat transplant kidney biopsy showed resolution of GIN. Prednisone dosage was tapered.

Discussion: GIN related to sarcoidosis has an overall estimated occurrence at 0.18 % of native kidney biopsies. GIN in transplanted kidney due to recurrent sarcoidosis has been reported ~17%. Risk factors for recurrence include primary renal disease related to sarcoidosis and a shorter delay between the last sarcoidosis flare and renal transplantation. Recurrence typically occurred shortly after transplantation, averaging 13 months after transplantation. More studies on treatment of recurrent renal sarcoidosis are warranted. We report a case of late onset recurrent GIN, occurring 11 years after transplantation with successful treatment.

Elevated Donor-Derived Cell-Free DNA as an Indication for Kidney Transplant Biopsy
Aileen Transplant Biopsy

Background: Donor derived cell-free DNA testing (dd cf-DNA) is increasingly employed for post-kidney transplant monitoring and may influence the decision to proceed with indication biopsy. The goal of this study was to identify those patients in whom the finding of an elevated dd cf-DNA was a key factor in the decision to obtain a kidney biopsy and to review 1) their biopsy findings and 2) any resulting treatment.

Methods: We reviewed the charts of 73 patients who underwent kidney transplant biopsy and had at least 1 dd cf-DNA (AlloSure) test performed. Ten patients underwent biopsy prompted primarily by an elevated dd cf-DNA level. Biopsy findings and resultant therapeutic interventions were abstracted.

Results: The median time from transplant to biopsy was 25.5 months. 2/10 patients had a normal biopsy. 5/10 had histological findings consistent with antibody mediated rejection (ABMR) with or without concurrent T-cell mediated rejection (TCMR). 2/10 had TCMR and 1/10 had recurrent glomerulonephritis. Of those with ABMR, 1/5 had a de novo HLA donor specific antibody (DSA) and 3/5 had positive non-HLA antibody (AT1 receptor antibody (AT1R)). 8/10 patients had a therapeutic intervention following biopsy. Dd cf-DNA decreased following treatment in 4/7 patients and did not change or worsened in 3/7 patients with available follow-up dd cf-DNA testing.

Conclusions: Kidney transplant biopsies in patients with an elevated dd cf-DNA frequently yield findings that warrant therapeutic intervention. Kidney transplant biopsy should be considered in patients with elevated dd cf-DNA, even if otherwise stable. Our observations warrant further examination on the utilization of long term dd cf-DNA monitoring, particularly in immunologically high-risk kidney transplant recipients.

Disseminated Nocardiosis in Renal Transplant Recipient
Mohamedanwar M. Ghandour, Marecena S. Zachariah. Wayne State University School of Medicine, Detroit, MI.

Introduction: Nocardiosis is an uncommon opportunistic Gram-positive bacterial infection caused by aerobic actinomycetes in the genus Nocardia. Nocardia can cause localized or systemic suppurative diseases involving eyes, kidneys, skin, lungs, bone, and Central nervous system. Disseminated Nocardia is a rare condition, seen among immunocompromised patients.

Case Description: We report the case of a 55-year-old African American kidney transplant recipient on maintenance immunosuppression, who was diagnosed with cutaneous and pulmonary Nocardiosis. Presenting symptoms were shortness of breath, bilateral lower extremities pain and swelling. Tissue culture grew gram-positive bacilli specified as Nocardia farcinica from thigh and gluteal abscesses (figure 1). CT thorax showed bilateral reticulonodular opacities (figure 2). Patient was managed with immunosuppression reduction and specific treatment with high dose Bactrim in conjunction with linezolid. Combination antibiotics were continued for four weeks, thereafter Bactrim alone was continued for twelve months, at which point all lesions had healed.

Discussion: Nocardiosis with systemic involvement carries a poor prognosis. The reported patient had disseminated Nocardiosis involving lungs and skin, though lungs were thought to be the primary source of infection. However, early diagnosis and appropriate antibiotic coverage, had a favorable outcome, in a renal transplant recipient. Recommended treatment duration is 6 to 12 months with frequent imaging.
Native Kidney Cytomegalovirus Nephritis

Sandra Bindrog, Paul D. Killen, Mona D. Doshi. University of Michigan, Ann Arbor, MI.

Introduction: Cytomegalovirus (CMV) is the most common opportunistic infection in solid organ transplant (SOT) recipients and is estimated to affect 15-30% of high-risk SOT recipients. Typical manifestations of CMV end-organ disease includes colitis, esophagitis, and hepatitis. However, active CMV nephritis is rare, reported in less than 1% of renal biopsies. We present a case of CMV nephritis in a high-risk kidney transplant recipient who completed six months of CMV prophylaxis four weeks prior to presentation.

Case Description: A 66-year-old man with a history of liver transplantation was hospitalized on post-transplant day 230 for worsening kidney function (serum creatinine 4.40 mg/dL, baseline 2.0 mg/dL) and fatigability. The patient’s history was notable for cryptogenic cirrhosis and hepato-renal syndrome. Immunotherapy consisted of tacrolimus (target 8-10 ng/mL), mycophenolate mofetil (MMF), and prednisone. The recipient was CMV seronegative and the donor was CMV seropositive. He received ganciclovir for CMV prophylaxis in first six months of transplantation, per protocol. The early post-transplant course was complicated by reactivation of muco-cutaneous herpetic simplex virus-1, and Clostridium difficile colitis. On presentation, patient reported fatigue, loose stools, and nausea. He was afebrile and had a normal white blood cell count. Serum creatinine was 4.40 mg/dL (baseline 2.0 mg/dL). Urinalysis was positive for 3+ leucocyte esterase with a full field of leucocytes and 10-50 red blood cells per high power field. Urine culture grew >10^5 cfu/mL of Pseudomonas aeruginosa species. A normal renal ultrasound was noted. He was treated with intravenous (IV) cefepime. To evaluate the cause of the persistent renal failure, a renal biopsy was performed, revealing acute tubular injury and focal severe interstitial nephritis. CMV intra-nuclear and cytoplasmic inclusions were visualized and confirmed by immunohistochemical staining. Plasma CMV DNA levels by quantitative PCR were 40862 IU/mL. Treatment consisted of IV ganciclovir at induction doses adjusted for renal clearance, followed by maintenance dose ganciclovir. His renal functions improved.

Discussion: We report a rare manifestation of CMV disease with evidence of CMV in native and transplanted kidney. Clinicians should have a high suspicion for late onset CMV diseases as a diagnosis in at risk SOT recipients with signs and symptoms of genitourinary tract.

Unusual Presentation of Ramsay-Hunt Syndrome in a Kidney Transplant Recipient

Daniela Via Reque Cortes, Géssica S. Braga Barbosa, Marcelo P. Menezes filho, Thomas D. Ferreira, Jose O. Reusing, Elias David-Neto. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Introduction: Herpes-virus reactivation has long been recognized as occurring more frequently in immunocompromised individuals. There are only a few cases of Ramsay-Hunt Syndrome described after transplantation. We report a case of a kidney transplant recipient (KTR) with an atypical course due to multiple cranial nerve involvement.

Case Description: A 70-year-old man with a history of chronic renal failure on hemodialysis, diabetes, hypertension, and chronic lung disease presented to our hospital after being diagnosed with a left atrial myxoma at another institution. He had undergone a deceased-donor kidney transplant ten years before, and maintained on mycophenolate mofetil (1.5 g/d), tacrolimus (2 mg/d) and prednisone (7.5 mg/d). His last biopsy was unremarkable. He recently received intravitreal injections of fluocinonide and ranibizumab. A nasolacrimaloryngoscopy showed unilateral paralysis of the left vocal cord with saliva aspiration. Computed tomography scan of cranium, neck and thorax excluded expansive lesions. Blood polymerease chain reaction test detected Varicella-Zoster Virus (VZV). Due to severe dysphagia with significant weight loss, reaching 35 kg, he received enteral nutrition through a nasogastric feeding tube during 12 weeks. He gradually recovered motor function of the 7th and 10th cranial nerves. Six months after the onset of symptoms, the patient is under full immunosuppressive therapy and feeding through mouth with occasional choking to some solids.

Discussion: Reactivation of pre-existing VZV in cranial sensory ganglia causes Herpes Zoster, which is characterized by a painful erythematous rash in the affected dermatome. Ramsay-Hunt Syndrome occurs when VZV affects neurons of the geniculate ganglion. When it occurs unusually with multiple cranial neuropathies it leads to a potential missed diagnosis and delayed treatment.

Incidence and Risk Factors in Mexican Patients with Diarrhea After Kidney Transplantation

Results: 92 patients were evaluated. Thirty two diarrhea episodes were recorded in 28 patients from January 2014 to December 2018 in the Nephrology and Kidney Transplant Department at the Centro Medico Nacional 20 de Noviembre in Mexico City. Annual cumulative incidence was 58.7% and was performed in at-risk patients with no history of diarrhea. The cumulative incidence was calculated for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.

Methods: Cohort, analytical, retrospective study, were included kidney transplant patients from January 2014 to December 2018 in the Nephrology and Kidney Transplant Department at the Centro Medico Nacional 20 de Noviembre in Mexico City. Annual cumulative incidence calculation was performed. The incidence regression was used for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.

Due to severe dysphagia with significant weight loss, reaching 35 kg, he received enteral nutrition through a nasogastric feeding tube during 12 weeks. He gradually recovered motor function of the 7th and 10th cranial nerves. Six months after the onset of symptoms, the patient is under full immunosuppressive therapy and feeding through mouth with occasional choking to some solids.

Discussion: Reactivation of pre-existing VZV in cranial sensory ganglia causes Herpes Zoster, which is characterized by a painful erythematous rash in the affected dermatome. Ramsay-Hunt Syndrome occurs when VZV affects neurons of the geniculate ganglion. When it occurs unusually with multiple cranial neuropathies it leads to a potential missed diagnosis and delayed treatment.

Use of Donor-Derived Cell-Free DNA to Identify Allograft at Risk by Late Surveillance

Amna Agha,1,3 Anna Iha,1,2 Diana Mahbod,1 Rama Nadella,1 Irfan Agha.1,3 1Dallas Renal Group, Dallas, TX; 2Methodist Dallas Medical Center, Dallas, TX; 3Medical City Dallas Hospital, Dallas, TX.

Introduction: Monitoring allograft function remains inadequate. Many allografts sustain subacute injury not detected in time resulting in poor long-term outcomes. Traditional tools utilized (creatinine, proteinuria and DSA) are insensitive and imprecise. The gold standard, allograft biopsy, is invasive and expensive. DD CF DNA has emerged as a sensitive and specific marker of allograft injury. This test is valuable in the early detection of allograft injury.

Case Description: A 66-year-old man with end stage renal failure due to accelerated hypertension had a deceased donor transplantation in 2018. Before receiving his transplant, his peripheral blood counts were relatively normal. Patient was discharged nine days after operation with haemoglobin of 8 g/dl. Approximately five weeks following transplantation, the patient was found to have profound anaemia with haemoglobin level falling to 57 g/dl but white cell and platelet count remained normal. Following investigations, patient was found to have parvovirus B19 with positive DNA titre. Since then patient was transfusion dependent with two weekly red cell transfusion. Patient had two courses of IVIG, however, showed only transient improvement in viral DNA titre with no haematological improvement. Finally, tacrolimus was switched to cyclosporin A and showed rapid improvement within two weeks.

Discussion: Persistent parvovirus B19 infection can occur in immunocompromised host due to impairment of the neutralizing antibody response and/or cellular immunity thus failure to clear the virus. Tacrolimus, on the other hand, is believed to be an immunosuppressive agent without significant potential for myelosuppression. In this case, temporal relation of withdrawal of tacrolimus with improvement of anaemia suggests an etiological role of tacrolimus. The close inverse relationship between viral DNA PCR titre and erythropoietic activity reflected by the improvement of refractory anaemia shows the close relationship between early renal allograft injury and parvoviruses. Parvovirus B19 infects erythroblasts and is believed to be the cause of the persistent renal failure, a renal biopsy was performed. The incidence regression was used for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.

Use of Donor-Derived Cell-Free DNA to Identify Allograft at Risk by Late Surveillance

Anna Iha,1,2 Diana Mahbod,1 Rama Nadella,1 Irfan Agha.1,3 1Dallas Renal Group, Dallas, TX; 2Methodist Dallas Medical Center, Dallas, TX; 3Medical City Dallas Hospital, Dallas, TX.

Introduction: Monitoring allograft function remains inadequate. Many allografts sustain subacute injury not detected in time resulting in poor long-term outcomes. Traditional tools utilized (creatinine, proteinuria and DSA) are insensitive and imprecise. The gold standard, allograft biopsy, is invasive and expensive. DD CF DNA has emerged as a sensitive and specific marker of allograft injury. This test is valuable in the early detection of allograft injury.

Discussion: Persistent parvovirus B19 infection can occur in immunocompromised host due to impairment of the neutralizing antibody response and/or cellular immunity thus failure to clear the virus. Tacrolimus, on the other hand, is believed to be an immunosuppressive agent without significant potential for myelosuppression. In this case, temporal relation of withdrawal of tacrolimus with improvement of anaemia suggests an etiological role of tacrolimus. The close inverse relationship between viral DNA PCR titre and erythropoietic activity reflected by the improvement of refractory anaemia shows the close relationship between early renal allograft injury and parvoviruses. Parvovirus B19 infects erythroblasts and is believed to be the cause of the persistent renal failure, a renal biopsy was performed. The incidence regression was used for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.
Ab positive by EIA with a level > 40 units/ml. Treated for Acute active ABMR due to ATG with plasmapheresis and IVIG for four sessions. Creatinine stable at 0.9 mg/dL. All 10 patients were alive and treatment at 1.5 years.

Discussion: Monitoring allograft function, especially late after transplant, can be difficult given lack of sensitivity and precision of traditional markers. DD CF DNA Allosure down to 1% after treatment.

Conclusions: The percentage of recipients in the low DD CF DNA group had significantly lower risk of acute cellular rejection compared to recipients in the high DD CF DNA group. These results suggest that monitoring DD CF DNA levels could be a useful adjunct in detecting early acute cellular rejection.

PUB258

Early Graft Dysfunction due to Banff 2A Rejection in a Non-Sensitized Cross-Match-Negative Recipient

Thành Cao, Nceeraj Sharma. University of Southern California University of Southern California, Los Angeles, CA

Introduction: With the introduction of potent immunosuppression, the incidence of acute rejection has dropped to < 1% in the first year following transplant. However, acute rejection remains a major cause of early graft dysfunction. The incidence of acute rejection in the first year following transplant is 1-2% lower in living donor kidney transplants (LDKT) compared to deceased donor kidney transplants (DDKT). Ideally, immediate graft function should be expected after LDKT. We present a case report of early acute cellular rejection 26 hours after an ABO compatible, HLA crossmatch negative LDKT.

Case Description: A 65-year-old Caucasian male with ESRD due to anti-GBM disease presented for a LDKT from his 68-year-old wife. He was ABO compatible, HLA crossmatch negative, and 0% for both T-Flow and B-Flow PRA. Induction was with Basiliximab 20mg and Methylprednisilone 500mg and achieved immediate diuresis. He became anuric by 16 hours post-op, and a for-cause biopsy was done on POD 2 which showed Banff 2A acute cellular rejection with negative C4D. Patient was treated with rabbit anti-thymocyte globulin (rATG) with total dose 3mg/kg divided over 4 doses and Rituximab 1g. He achieved diuresis at 250mg for 5 days. Immunosuppression was intensified and target tacrolimus levels were increased to achieve trough levels between 10-12 ng/mL. The patient has maintained excellent allograft function six months post-transplant with baseline serum creatinine baseline 1.8-2.0 and eGFR 34-38.

Discussion: Risk factors for acute rejection include multiple human leukocyte antigens (HLA), mismatches, a high panel reactive antibody (PRA), presence of donor specific antibodies (DSA), ABO blood group incompatibility, positive HLA crossmatch, prolonged cold ischemia time greater than 24 hours, African American ethnicity, and inadequate induction regimen. For patients with high risk factors for rejection, 2009 KDGE guidelines recommend induction regimen with lymphocyte-depleting agents such as rATG rather than IL-2 receptor monoclonal antibody such as Basiliximab. This case report focuses specifically on the development of ACR in a low risk living donor transplant. We speculate that the development of ACR in this low risk patient was likely due to the HLA mismatches and possibly induction with Basiliximab. This case report poses the question of whether more intensive induction therapy should be considered in low risk patients with presence of HLA mismatches and the long-term allograft outcomes following acute rejection.

Aspirin Prescribing Practices and Characteristics of Pregnant Women with CKD

Christin M. Giordano McAluliffe,1 Shelby A. Crants,2 Lynsa Nguyen,1 Lisa Oronde,3 Anna M. Bergstrom4 Vanderbilt University Medical Center, Nashville, TN; 4Vanderbilt University School of Medicine, Nashville, TN

Background: Women with chronic kidney disease (CKD) are at a higher risk for pregnancy complications compared to women without CKD. The U.S. Preventative Services Task Force has recommended use of low-dose aspirin in women with a high risk for development of preeclampsia, including women with renal disease since 2014. The authors sought to assess the characteristics of pregnant women with CKD and aspirin prescribing practices at their institution.

Methods: The authors performed a retrospective chart review of data from pregnancies in women with CKD who delivered between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for chronic kidney disease and proteinuria. We included pregnancies that had a formal diagnosis of CKD and those in whom baseline creatinine did not decrease at least 0.3 mg/dL during pregnancy. We excluded pregnancies that ended prior to 12 weeks. Means, standard deviations, medians, and interquartile ranges were used for continuous variables, and frequency and proportions were used for categorical variables, as appropriate.

Results: A total of 149 pregnancies were included. The mean age at due date was 30.8 (std. dev 5.6) with 27.5% of advanced maternal age. The majority (51.7%) were obese, with an overall mean BMI of 32.8 kg/m2 (std. dev 8.2). 15.4% had a history of prior pre-eclampsia. Just over half (57.5%) had been diagnosed with CKD prior to or during pregnancy with the most common underlying etiologies being type 2 diabetes mellitus. Of these, the mean baseline creatinine, obtained within 1 year of pregnancy, was 1.13 mg/dL (std. dev 0.69). Of 149 pregnancies included, 62 (42.3%) were prescribed aspirin prior to 28 weeks of gestation. Overall, 36.2% (54/149) were diagnosed with pre-eclampsia. Of those with a formal diagnosis of CKD prior to pregnancy, 52.9% were prescribed aspirin and 42.4% developed pre-eclampsia.

Conclusions: Chronic kidney disease is a well-recognized risk factor for pre-eclampsia with guidelines recommending the prescribing of aspirin to pregnant women with CKD. This study demonstrated low overall aspirin prescribing rates with relatively high rates of pre-eclampsia at a single institution.
Magnesium Intake, Bone Mineral Density, and the Risks of Falls and Fractures in Post-Menopausal Women with Kidney Stone

Harshitha Kota,1 Xuerong Wen,2 Chao Chen,3 Jie Tang.1,4 Brown University, Providence, RI; 2University of Rhode Island, Kingston, RI; 3University of Florida, Gainesville, FL; 4University Medicine Foundation Inc, Providence, RI.

Background: Kidney stone formers are a unique patient population at high risk for fall and fractures due to dysregulated calcium homeostasis and early bone loss. Magnesium is an important component of bone, but its relation to falls and fractures among stone formers is unclear.

Methods: We performed regression analyses to determine the independent effect of dietary magnesium intake (DMI) on bone mineral density (BMD), and risks of fall and bone fracture among incident stone formers identified in the Women’s Health Initiative (WHI), a prospective longitudinal multicenter study investigating the health of post-menopausal women.

Results: Out of a total of 145,942 WHI participants free of kidney stone history at baseline, 6024 developed kidney stone after 1,601,750 patient years of follow up. Among these incident stone formers, 82% were Caucasian, 23% were above age 70. Mean DMI was 304 mg/day, 30% had high DMI defined as >348 mg/day, 38% had medium DMI defined as 241-348 mg/day and 32% had low DMI defined as <241 mg/day. A total of 238 (4%), and 2581 (43%) incident stone formers had low BMD and new falls or fractures, respectively. Both low dietary calcium intake and active smoking associated with reduced BMD (p<0.05), but DMI did not affect BMD in the multivariate regression analysis, β=1.6, p=0.4. Older age, black race, history of diabetes, history of either parent having broken bones after age 40 all associated strongly with risks of fall and bone fracture (p<0.05). However, DMI again did not have such significant association after adjustment for demographics and potential confounding factors, β=1.7, p=0.4.

Conclusions: DMI does not appear to affect BMD and the risk of fall or bone fracture among post-menopausal women.

Effect of Finerenone on CKD Outcomes in Type 2 Diabetes

George L. Bakris,1 Rajiv Agarwal,2 Stefan D. Anker,2 Bertram Pitt,4 Luis M. Rualplo,8 Peter Rossing,7 Peter Kolkhof,9 Christina Nowack,10 Patrick Schloemer,1,11 Amer Joseph,11 Gerasimos Filippatos,12 on behalf of the FIDELIO-DKD Investigators Department of Medicine, University of Chicago Medical Center, Chicago, IL; Richard L. Roudebush VA Medical Center and Indiana University, Indianapolis, IN; 2Department of Cardiology (CfV) and Berlin Institute of Health for Regenerative Therapies, German Centre for Cardiovascular Research Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; 3Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; 4Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research immac12, Madrid, Spain; 5CIIBER-CHV, Hospital Universitario 12 de Octubre, & Faculty of Sport Sciences, European University of Madrid, Madrid, Spain; 6Steno Diabetes Center Copenhagen, Gentofte, Denmark; 7Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; 8Research and Development, Preclinical Research Cardiovascular; Bayer AG, Wuppertal, Germany; 9Research and Development, Clinical Development Operations, Bayer AG, Wuppertal, Germany; 10Urology, Cleveland Clinic, Cleveland, OH; 11Cardiorenal Translational Laboratory and High-Impact Clinical Trials investigators 12Steno Diabetes Center Copenhagen.

Background: Patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) remain at risk of CKD progression despite guideline-directed therapies. Mineralocorticoid receptor (MR) overactivation may drive CKD progression through inflammatory and fibrotic processes. Finerenone, a novel, nonsteroidal MR antagonist, reduces albuminuria independent of hemodynamic effects. We assessed the long-term efficacy and safety of finerenone in slowing CKD progression in patients with CKD and T2D.

Methods: This global, phase 3, double-blind study randomized 5734 patients from 48 countries (1:1) to oral finerenone or placebo. Patients with T2D, urine albumin-to-creatinine ratio 30–500 mg/g and estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73 m2, treated with optimized renin–angiotensin system blockade, were included. The primary outcome was time to kidney failure, sustained eGFR decline ≥40% from baseline or renal death. The key secondary outcome was time to cardiovascular (CV) death, non-fatal myocardial infarction, non-fatal stroke or heart failure hospitalization.

Results: Mean patient age was 65.6 years; 70.2% were male. At baseline, mean eGFR was 44.3 mL/min/1.73 m2 and median UACR 852 mg/g. The primary outcome occurred in 504/2833 (17.8%) and 600/2841 (21.1%) patients treated with finerenone and placebo, respectively (hazard ratio [HR]=0.82; 95% confidence interval (CI) 0.73–0.93; p=0.0339). Overall treatment-emergent adverse events were balanced between groups. The incidence of hyperkalemia-related treatment discontinuation was higher with finerenone than placebo (2.3% and 0.9%, respectively). Finerenone significantly reduced kidney and CV outcomes in patients with T2D and advanced CKD and was well tolerated. While the primary adverse event (2.3% and 0.9%, respectively).

Conclusions: Finerenone significantly reduced kidney and CV outcomes in patients with T2D and advanced CKD and was well tolerated. While the primary adverse event (2.3% and 0.9%, respectively). Finerenone significantly reduced kidney and CV outcomes in patients with T2D and advanced CKD and was well tolerated. While the primary adverse event (2.3% and 0.9%, respectively).

Sequential Treatment with Tacrolimus and Rituximab vs. Alternating Corticosteroids and Cyclophosphamide in Primary Membranous Nephropathy (PMN)

Gema Fernandez-Juarez,1 Jorge E. Rojas-Rivera,2 Anne-Els van de Logt,12 Joanne Crawford,3 Angel M. Sevilla,2 Fernando Carvajal-Fontan,3 Ana Avila,1 Cristina Rabasco,1 Virginia Cabello,1 Marian Goicoechea,1 Luis F. Quintana,1 Irene Agraz,18 Ana M. Romera segorbe,1,11 Amir Shabaka,1 Mario Espinosa,8 Jesus Egido,7 Gerard J. Lambeau,1 Pierre M. Ronco,4 Manuel Praga,2 Nephrology, Hospital Universitario Fundacion Alcorcon, Madrid, Spain; 2Nephrology, Hospital Universitario 12Octubre, Madrid, Spain; 3Nephrology, Hospital Universitario 12Ocotubre, Madrid, Spain; 4Research and Development, Preclinical Research Cardiovascular; Bayer AG, Wuppertal, Germany; 5Research and Development, Clinical Development Operations, Bayer AG, Wuppertal, Germany; 6School of Medicine, Department of Cardiology, Attiun University Hospital, National and Kapodistrian University of Athens, Athens, Greece.

Background: A cyclical corticosteroid-cyclophosphamide regimn is recommended for patients with PMN at high risk of progression. RTX monotherapy and calcineurin inhibitors have shown efficacy in inducing remission, but relapses are very common after discontinuation of calcineurin inhibitors.

Methods: In a randomized and open-label controlled trial, 86 patients (pts) with PMN at high risk of progression after a 6-month observation period were assigned to receive a 6-month cyclical treatment with corticosteroid and cyclophosphamide (n=43) or sequential treatment with tacrolimus (full-dose for 6m and tapering for another 3m) and RTX (1 g at 6m) (n=43). Primary outcome was complete or partial remission of membranous syndrome at 24m.

Results: The primary outcome occurred in 36 pts (84%) in the Cs-cyclophosphamide group and in 25 pts (58%) in the tacrolimus-RTX group (RR 1.44 95%CI 1.08-1.92). Complete remission at 24m occurred in 26pts (60%) in the corticosteroid-cyclophosphamide group and in 15pts (26%) in the tacrolimus-RTX group (RR 2.36 95%CI 1.34-4.16). Immunological response was faster in the corticosteroid-cyclophosphamide group and associated with remission at 24m. Relapses occurred in 1 pt (2.7%) in the corticosteroid-cyclophosphamide group, and 3 pts (12%) in the tacrolimus-RTX group. The rate of serious adverse events was similar in both groups.

Conclusions: Treatment with corticosteroid-cyclophosphamide induced remission in a significantly greater number of patients with PMN than tacrolimus-rituximab.

EMPEROR-Reduced: Empagliflozin and Outcomes in Heart Failure and CKD

Faiez Zannad. The EMPEROR Reduced trial steering committee and investigators INT CRCT, Universite de Lorraine, Nancy, France.

Background: In EMPEROR-Reduced, empagliflozin reduced cardiovascular death and heart failure hospitalizations and slowed the progressive decline in kidney function in heart failure and a reduced ejection fraction (HFrEF), with or without diabetes. We explored the effect of empagliflozin on cardiovascular and kidney outcomes, across the spectrum of kidney function.

Methods: 3730 patients were randomized, of whom 1978 (53%) had prevalent chronic kidney disease (CKD) (eGFR≥60ml/min/1.73m2) or an UACR≥300mg/g. The key outcomes were (1) a composite of cardiovascular death or hospitalization for heart failure; (2) total hospitalizations for heart failure; and (3) eGFR slope; the last was supported by a prespecified composite renal outcome (defined as a profound sustained decrease in eGFR, chronic dialysis or transplant). The median follow-up was 16 months.

Results: Patients with prevalent CKD had a higher rate of CV and kidney events. Empagliflozin reduced the risk of cardiovascular death and hospitalization for heart failure by 25% (P<0.001), reduced total hospitalizations for heart failure by 30% (P<0.001) and reduced the composite of chronic dialysis, transplant and renal death by 50% (P<0.01). All three benefits were seen consistently in patients with and without CKD (figure) and were apparent even in patients with severe impairment (eGFR from 20 to 30ml/min/1.73m2). Empagliflozin significantly slowed the yearly loss of eGFR and was well tolerated regardless of the level of baseline kidney function.

Conclusions: In patients with HFHF, empagliflozin reduced serious heart failure and serious adverse kidney outcomes, and slowed the decline in kidney function, regardless of the presence or absence of CKD and across a broad spectrum of baseline kidney function.

Global Phase 3 Clinical Trials of Vadadustat vs. Darbepoetin Alfa for Treatment of Anemia in Patients with Non-Dialysis-Dependent CKD

Glen M. Chertow, PROTECT Author Group Stanford University School of Medicine, Stanford, CA.

Background: Vadadustat (VADA) is an investigational, oral, hypoxia-inducible factor prolyl hydroxylase inhibitor which has completed patient enrollment in its phase 3 development for treatment of anemia of chronic kidney disease (CKD). In phase 2 trials, VADA safely raised and maintained hemoglobin (Hb) concentrations.

Methods: We conducted two randomized, phase 3, global, open-label, sponsor-blind, parallel-group, active-controlled noninferiority trials comparing oral daily VADA to parenteral darbepoetin alfa (DA) in patients with anemia of non-dialysis dependent (NDD)-CKD (PROTECT program). The PROTECT program included (1) Correction trial of patients previously not on erythropoiesis-stimulating agents (ESA) (ESA-untrained NDD-CKD trial, NCT02668347) and (2) Conversion trial of patients previously on an ESA (ESA-treated NDD-CKD trial, NCT02680574). The primary safety endpoint of PROTECT program was to first time major adverse cardiovascular event (all-cause mortality, nonfatal myocardial infarction, nonfatal stroke), prespecified as a pooled event-driven analysis of both trials. Primary and key secondary efficacy endpoints, prespecified as separate analyses for each trial, were difference in mean change in Hb between baseline and weeks 24-36 and weeks 40-52, respectively, comparing VADA vs DA.

Results: In total, 4708 patients were screened for the ESA-untreated NDD-CKD trial, and 1751 were randomized. Most (N=1061) were from the United States; the remainder were from Europe or elsewhere. A total of 2961 patients were screened for the ESA-treated NDD-CKD trial, 1752 of whom were randomized. Most (N=1060) were from Europe or non-United States/non-European countries; the remainder were from the United States. The database was locked on July 31, 2020. Topline data and results of these global trials will be available in September 2020.

Conclusions: The trials will test if oral daily VADA is noninferior to parenteral DA, a common ESA, in patients with anemia of NDD-CKD, with respect to cardiovascular safety and hematologic efficacy.

Oral Intradialytic Nutritional Supplements and Mortality in Hemodialysis Patients: A Cluster-Randomized, Pragmatic Clinical Trial

Daniel E. Weiner,1 Karen M. Majchrzak,2 Cindy D. Kinnard,2 Hocine Tigliouart,2 Todd Marren,2 Eduardo K. Lacson,2 Doug Johnson,2 on behalf of Dialysis Clinic Inc, Nashville, TN.

Background: Dialysis is a catabolic state and observational studies suggest that administering oral nutritional supplements to hemodialysis patients with low serum albumin during the dialysis session may reduce mortality. Whether there are benefits in patients with normal serum albumin remains unstudied.

Methods: The Health Effects of oral Protein Supplements in HD (HELPs-HD) Trial was an open-label cluster randomized pragmatic trial, comparing the effects of an intensive oral nutritional supplement protocol in which prevalent hemodialysis patients received supplements at every dialysis session regardless of serum albumin to standard care, in which supplements were administered to patients with albumin below 3.5 g/dL. As part of standard care, all incident patients received supplements for the first 90 days of dialysis. Following randomization of facilities to either the intensive or standard protocol, patients in facilities provided informed consent via waiver of consent documentation. The study intervention lasted from January 2017 to March 2020, and patients were enrolled through December 2019. The primary outcome, all-cause mortality, was assessed from medical records.

Results: Among 10,043 hemodialysis patients randomized from 105 participating DCl facilities, mean age was 63 years, 56% were men, 56% Black, and 46% had diabetes as primary cause of kidney failure; 32% were incident to dialysis. Supplement use was 2-fold higher in the 53 clinics randomized to the intensive protocol. Over median follow-up of 21 months, there were 3628 deaths, 35.8% in the intensive and 36.5% in the standard group, with an unadjusted rate of 20 deaths per 100-person years in both groups. In unadjusted Cox models, those randomized to the intensive protocol had similar outcomes to those randomized to the standard protocol (HR 1.02 [0.92, 1.14]); results were similar in models adjusted for age, sex and race and between incident and prevalent patients.

Conclusions: Discussion In a large, national population of hemodialysis patients, there was no difference in mortality between patients randomized to a standard oral nutritional supplement protocol, with receipt of supplements only when serum albumin was low, as compared to an intensive protocol, with receipt of supplements regardless of serum albumin.

Reducing the Burden of Dialysis Catheter Complications: A National Approach (REdUCING)

Martin P. Gallagher,1,2 Sradha S. Kotwal,1,3 Girish S. Talaulikar,4 Nicholas A. Gray,5 Kevan Polkinghorn,6 Stephen P. McDonald,7 Alan Cass,8 on behalf of the REDUCCTION Investigators The George Institute for Global Health, Newtown, NSW, Australia; 2University of Sydney, Sydney, NSW, Australia; 3Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; 4Renal Services, ACT Health, Canberra City, ACT, Australia; 5Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; 6Monash University, Clayton, VIC, Australia; 7Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; 8Monzies School of Health Research, Charles Darwin University, Casuarina, NT, Australia.

Background: The major morbidity and cost from the use of central venous hemodialysis catheters is the increased risk of catheter-related blood stream infection (HD-CRBSI). Clinical practice remains variable and broad-scale, systematic interventions to reduce this burden have not been tested in randomized trials. The REDUCCTION trial aimed to systematically measure the rate of HD-CRBSI at a national level and test the effect of a multifaceted, evidence-based intervention upon the rate of HD-CRBSI in Australia.

Methods: This stepped wedge, randomized trial, clustered at the renal service level, included all patients receiving a central venous hemodialysis catheter in a participating renal service. After baseline data collection, services were randomly assigned to one of three time points (April 2018, Sept 2018, March 2019) for implementation of an intervention package based upon current evidence and guidelines. The primary outcome was the intervention’s effect upon the study wide service-level rate of HD-CRBSI (per 1000 catheter days).

Results: A total of 37 renal services in all Australian states and territories participated in the trial between Dec 2016 and March 2020. Preliminary analysis shows that 5246 catheters (3506 patients) were inserted during the baseline phase and 4610 catheters (3144 patients) in the intervention phase, representing more than 1.1 million catheter days of exposure and over 300 adjudicated HD-CRBSI events. Final analysis is currently in progress with results presented at the Annual Meeting.

Conclusions: The REDUCCTION trial has systematically measured the use of HD CVCs in near real-time and demonstrated the feasibility of implementing a suite of evidence-based interventions in haemodialysis care. The study outcomes will have implications for future research and practice in dialysis access.

Regional Citrate vs. Systemic Heparin Anticoagulation During Continuous Kidney Replacement Therapy Among Critically Ill Patients with AKI: A Randomized Clinical Trial
Alexander Zabeck,1 Mira Kuelmlar,1 Detlef Kindgen-milles,1 Peter Rosenberger,2 Sean M. Bagshaw,1 John A. Kellum,2 Melanie Meersch,1 1Department of Anesthesiology; Intensive Care and Pain Medicine, Universitätsklinikum Münster, Münster, Germany; 2Center for Critical Care Nephrology, University of Pittsburgh, Pittsburgh, PA

Background: Although current guidelines suggest the use of regional citrate anticoagulation as first-line treatment for continuous kidney replacement therapy in critically ill patients, the evidence for this recommendation is based on few clinical trials and meta-analyses.

Methods: To determine the effect of anticoagulation strategies on filter lifespan and mortality, a parallel-group, randomized multicenter clinical trial was conducted in 26 centers across Germany between March 2016 and December 2018. Patients were randomized to receive either regional citrate (n=300) or systemic heparin anticoagulation (n=296) for continuous kidney replacement therapy. The two co-primary outcomes were filter lifespan and 90-day all-cause mortality. Secondary endpoints included bleeding complications and new infections.

Results: Among 638 patients randomized, 596 (93.4%) patients (mean age, 67.5 [±12.4] years, 183 (30.7%) women) completed the trial. Median filter lifespan was 47 [IQR, 19-70h] in the regional citrate and 26h [IQR, 2-51h] in the systemic heparin group; absolute difference (AD) 15% [95% CI, 11h to 28h]; P<0.001]. 90-day all-cause mortality was 51.2% [150/300] in the regional citrate and 53.6% [156/296] in the systemic heparin anticoagulation group (adjusted AD, -6.1% [95% CI, -12.6% to 0.4%]; adjusted HR, 0.79 [95% CI, 0.63 to 1.00]; unadjusted P=0.05; unadjusted AD, -2.4% [95% CI, -10.5% to 5.8%]; unadjusted HR, 0.91 [95% CI, 0.72 to 1.13]; unadjusted P=0.38). Compared with systemic heparin anticoagulation, the regional citrate anticoagulation group had significantly fewer bleeding complications (15/300 [5.1%] vs. 49/296 [16.9%]; AD, -11.8% [95% CI, -16.8% to 6.8%]; P=0.001) and significantly more new infections (24/300 [68.0%] vs. 164/296 [55.4%]; AD, 12.6% [95% CI, 4.9% to 20.3%]; P=0.002).

Conclusions: Among critically ill patients with acute kidney injury receiving continuous kidney replacement therapy, anticoagulation with regional citrate, compared with systemic heparin anticoagulation, resulted in significantly longer filter lifespan. The trial was terminated early and was therefore underpowered to reach conclusions about the effect of anticoagulation strategy on mortality.

Background: The Dapagliflozin And Prevention of Adverse Outcomes in Chronic Kidney Disease trial (DAPA-CKD) assessed the sodium glucose co-transporter 2 inhibitor dapagliflozin in patients with chronic kidney disease (CKD) with and without type 2 diabetes. This pre-specified analysis explores outcomes according to underlying etiology of kidney disease in this study.

Methods: Among critically ill patients with acute kidney injury receiving continuous kidney replacement therapy, anticoagulation with regional citrate, compared with systemic heparin anticoagulation, resulted in significantly longer filter lifespan. The trial was terminated early and was therefore underpowered to reach conclusions about the effect of anticoagulation strategy on mortality.

Conclusions: Among critically ill patients with acute kidney injury receiving continuous kidney replacement therapy, anticoagulation with regional citrate, compared with systemic heparin anticoagulation, resulted in significantly longer filter lifespan. The trial was terminated early and was therefore underpowered to reach conclusions about the effect of anticoagulation strategy on mortality.

Electronic Health Record Alerts for AKI: A MultiCenter Randomized Clinical Trial
Francis P. Wilson,1 Melissa Martin,2 Yu Yamamoto,3 Harold I. Feldman,2 Jason H. Greenberg,1 Sherry Mansour,2 Dennis G. Molehida,2 Paul M. Palevsky,3 Chirag R. Parikh,4 Michael Simonov,5 Medicine, Yale University School of Medicine, New Haven, CT; 6University of Pennsylvania, Philadelphia, PA; 7University of Pittsburgh, Pittsburgh, PA; 8Johns Hopkins University, Baltimore, MD

Background: Despite its strong association with adverse clinical outcomes, acute kidney injury (AKI) is often not recognized during clinical care. It is unclear whether automated alerts for AKI improve clinical outcomes.

Methods: Double-blinded, multicenter, parallel, randomized, controlled trial of an electronic AKI alert versus usual care (no alert). Adult participants across 6 hospitals were electronically identified and randomized via a best practice alert build in 1:1 fashion to the two study arms. The primary outcome was a composite of AKI progression, receipt of dialysis, or death at 14 days.

Results: 6,030 patients were randomized over 22 months. The primary outcome occurred in 653 (21.4%) patients in the alert group and 622 (20.9%) in the usual care group (relative risk 1.02, 95% confidence interval [CI] 0.93 to 1.13, p=0.67). Per-hospital analysis revealed worse outcomes in the two non-teaching hospitals (N=765, 13%), where alerts were associated with a higher risk of the primary outcome of 1.49 (95% CI, 1.12 to 1.98, p=0.006). More deaths occurred at these centers (15.6% in the alert group vs. 8.6% in the usual care group, p=0.003). Certain AKI care practices were increased in the alert group but did not appear to mediate these outcomes.

Conclusions: Alerts did not reduce the risk of our primary outcome among hospitalized patients with AKI. The heterogeneity of effect across clinical centers should lead to a re-evaluation of existing AKI alerting systems.

Associations Between Achieved Hemoglobin and Cardiovascular Outcomes in the Pooled Phase 3 Roxadustat Studies of Non-Dialysis-Dependent Patients with Anemia of CKD

Steven Fishbane,1 Robert Provenzano,2 Pablo E. Pergola,3 Lynda Szczep,4 Robert Leong,5 Khalil G. Saikali,4 Ming Zhong,4 Tyson T. Lee,4 Dustin J. Little,4 Lars Frison,4 John Houghton,5 Kin-Hung P. Yu.4, (Northwell Health, Great Neck, NY; 2Wayne State University, Detroit, MI; 3Renal Associates, PA, San Antonio, TX; 4Fibrogen Inc, San Francisco, CA; 5AstraZeneca, Gaithersburg, MD, AstraZeneca, Molndal, Sweden.

Background: Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, promotes erythropoiesis and increases bioavailability of iron. In phase 3 studies, roxadustat-treated patients achieved and maintained hemoglobin (Hb) values of ≥11.5 g/dL. We examined the associations between achieved Hb levels and cardiovascular outcomes in non-dialysis-dependent (NDD) patients with anemia of chronic kidney disease (CKD).

Methods: We analyzed pooled data from 3 pivotal, phase 3 studies of patients with anemia of NDD-CKD who received roxadustat. Incidence rates of adjudicated MACE (all-cause mortality, MI, and stroke) and MACE+ (MACE plus heart failure and unstable angina requiring hospitalization) were evaluated based on 1) Hb level immediately before the event and 2) maximum Hb level in the first 12 treatment weeks.

Results: Overall, 2391 patients were randomized to roxadustat. The mean (SD) baseline Hb of 9.1 (0.74) g/dL increased to 10.95 (0.76) g/dL over weeks 28-52. The MACE and MACE+ rates were highest when Hb was < 8 g/dL decreasing as Hb increased to 11.12 g/dL and 12 g/dL (Table).

Conclusions: In the NDD-CKD population, roxadustat corrected anemia and maintained Hb to 11±1 g/dL during weeks 28-52. MACE and MACE+ incidence rates were lowest when achieved Hb levels were ≥11 g/dL.

Continuous Low-Dose Iron Sucrose or Periodic High-Dose Ferric Carboxymaltose Therapy in Hemodialysis Patients (COPEFER): A Randomized Controlled Noninferiority Trial

Bernhard O. Bielek,1 Matthias Lorenz,2 Rosella Monteforte,3 Thomas Prikoszovich,1 Michaela Gabriel,1 Michael Wolzt,1 Andreas Gleiss,1 Gere Sunder-Plassmann,1 Nephrology and Dialysis, Medizinische Universität Wien Universitätsklinik für Innere Medizin III, Wien, Austria; 2Center for Medical Statistics, Informatics, and Intelligent Systems, Medizinische Universität Wien, Wien, Austria; 3Section for Medical Statistics, and Department of Clinical Pharmacology, Medical University of Vienna, Vienna, Austria.

Background: Intravenous iron is a cornerstone in the treatment of anemia in chronic hemodialysis patients. However, optimal dosing and frequency of administration is unknown and varies widely between centers. We compared the impact of equal cumulative doses of ferric carboxymaltose (FCM), which is not yet approved for use in hemodialysis patients, and iron sucrose (IS) administered as either a high dose bolus or low dose maintenance iron dosing strategy on hemoglobin concentration, iron balance, use of erythropoiesis stimulating agents (ESA), and adverse events in prevalent chronic hemodialysis patients.

Methods: We performed an open-label randomized controlled non-inferiority trial in 245 patients on hemodialysis since 1994. A total of 480 iron atoms/m² were administered. The IS arm received 100 mg every two weeks, the FCM arm 500 mg every 10 weeks. Hemoglobin, iron markers, ESA use, C-reactive protein (CRP), phosphate, and liver enzymes were assessed. Primary end-point was the difference in hemoglobin at week 40 from baseline. A non-inferiority margin of 0.8 g/dL between both groups was pre-specified. Secondary end-points were differences in ferritin, transferrin saturation (TSAT), and ESA use.

Results: 108 patients completed the study. By 40 weeks non-inferiority criterion was not met (Hb increased by 0.47 g/dL (95% CI 0.35 to 0.59) in the FCM compared to the IS arm. In intention-to-treat analysis hemoglobin was significantly lower in the FCM arm compared to the IS arm (p = 0.046 g/dL (95% CI -0.92 to -0.01). At week 40, ferritin was 29.7% (95% CI 6.6 to 46.1) and TSAT was 27.7% (95% CI 16.3 to 38.6) lower in the FCM compared to the IS arm. ESA dosing, CRP, phosphate, and liver function parameters did not differ between groups. Adverse events that caused intermittent drug discontinuations and infections occurred more often in the IS arm.

Conclusions: IS administered more frequently at lower doses maintained hemoglobin and iron stores more effectively than FCM administered less frequently but at higher doses. However, FCM appeared safe in dialysis patients where we observed less infections compared to the IS group.

**A Prospective, Double-Blind, Randomized, Placebo-Controlled Intervventional Study to Evaluate the Safety and Efficacy of Enzobiotics in Pre-Dialysis CKD Patients**

Anita Saxena,1 Chakko K. Jacob,2 Sanjay Sreenivasa,3 Bangovan Veerappan,4 Amol R. Mahaladar,5 Amit Gupta,6 Anantha subramani Rajagopal.1,7 Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India; 8Nephrology, Baptistie hospital, Bangalore, India; 9Nephrology, Vision and Manipal Hospitals, GOA, India; 9Nephrology, KG Hospital, Coimbatore, India; 10Statistics, Indian Statistical Institute Delhi Centre, Coimbatore, India; 9Nephrology, Saptagiri Institute of Medical science, bangalore, India.

**Background:** Synbiotics and proteolytic enzymes supplemented in CKD prevent formation of uremic toxins (UT) generated by undigested protein. Aim: Affect of Enzobiotics in reducing generation of P-Cresols and Indoxylsulfate and quality of life in pre dialysis patients.

**Methods:** Double blind, randomized, placebo controlled multicentric clinical trial CTRI/2019/01/017070 conducted over 90 Days. Eighty CKD stages 3-5 ND subjects from 5 centers divided into two groups of 40 each: group A received 1 Enzobiotic capsule TID, Group B 1 placebo capsules TID, for three months 5 minutes before food. Blood samples taken on visits 1 and 4 to measure serum creatinine, p cresols, indoxyl sulphate (IS), platelet count (PC) hsCRP etc.

**Results:** Placebo increased p-cresol by 21% while drug reduced by 23%. Enzobiotic reduced indoxyl sulfate by 500 µg/ml (from 17200 to below 16700) with reduction in creatinine. The potential patients above p-cresol level of 20 mg/l between drug and placebo after 90 days were found to be 55% for placebo against 33% for drug. If testing is not available, Indoxyl sulfate and p-Cresol can be predicted by 2 equations (applied for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. Adversity ratio reduced significantly from 0.3362 to 0.1736 P-Value for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. A
dversity ratio reduced significantly from 0.3362 to 0.1736 P-Value for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. A
dversity ratio reduced significantly from 0.3362 to 0.1736 P-Value for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. A
dversity ratio reduced significantly from 0.3362 to 0.1736 P-Value for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. A
dversity ratio reduced significantly from 0.3362 to 0.1736 P-Value for patency) SF36 standard questionnaire revealed improvement in quality of life of treatment group. A

**Conclusions:** Enzobiotics improve make gut microbiome favourable, can delay dialysis in CKD patients by reducing uremic toxins, CRP, thrombocytopenia and improve cardiac performance, lipid profile, and quality of life.

**Effect of Ertugliflozin on Initial eGFR Decline and Chronic Slope: Analyses from the VERTIS CV Trial**

David Chemey,1 Bernard Charbonnel,2 Francesco Cosentino,3 Richard E. Pratley,4 Samuel Dagogo-Jack,5 Weiichung J. Shih,6,7 Darren K. Magueire,8,9 Robert Frederich,10 Mario Maldonado,11 Jie Liu,12 Anmpey Pong,13 Chih-Chin Liu,14 Christopher P. Cannon.15 University of Toronto, Toronto, ON, Canada; 16Universite de Nantes, Nantes, France; 17Karolinska Institute & Karolinska University Hospital Solna, Stockholm, Sweden; 18AdventHealth Translational Research Institute, Orlando, FL; 19University of Tennessee Health Science Center, Memphis, TN; 20Rutgers School of Public Health, Piscataway, NJ; 21Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 22University of Texas Southwestern Medical Center, Dallas, TX; 23Parkland Health and Hospital System, Dallas, TX; Pfizer Inc., Collegeville, PA; 24MSD Limited, London, United Kingdom; 25Merck & Co., Inc., Kenilworth, NJ; 26Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA.

**Background:** SGLT2 inhibitors induce an initial reversible eGFR dip, based on natriuresis-induced reductions in glomerular pressure, with a return toward baseline over time in adults with T2DM. Preservation of the chronic eGFR slope by natriuresis-associated effects (ie, hematocrit) were larger in the eGFR decrease tertile (Fig A, B). The ertugliflozin eGFR decrease tertile had the smallest decline in chronic eGFR slope (Fig C, D). Chronic slopes were similar across the placebo group tertiles and the rate of decline uniformly more rapid (Fig D). Mean placebo-adjusted effect of ertugliflozin on chronic eGFR slope (Weeks 6–156 [95% CI]) was 1.19 (0.95, 1.42) mL/min/1.73 m2/year (Fig E) and >0.75 mL/min/1.73 m2/year in all subgroups.

**Conclusions:** The initial eGFR dip may influence several clinical effects of ertugliflozin. Ertugliflozin has favorable effects on eGFR slope in patients with T2DM and ASCVD.

Canagliflozin Across the Spectrum of Kidney Function and Albuminuria: Integrated Data from CANVAS and CREDENCE

Brendon L. Neuen,1 Jie Yu,1 Qiang Li,1 Vlad Perkovic,2,3 Clare G. Arnott,1 Bruce Neal,1 Hidd J. L. Heerspink,1 Rajiv Agarwal,1 George L. Bakris,1 Christopher P. Cannon,1 Dick de Zeeuw,1 David M. Charytan,4 Adeera Levin,2 Gian Luca Di Tanna,1 David R. Matthews,5 Carol A. Pollock,5 David C. Wheeler,5 Kenneth W. Mahaffey,6 Meg J. Jardine.1
1The George Institute for Global Health, Newtown, NSW, Australia; 2UNSW Sydney, Sydney, NSW, Australia; 3University of Chicago, Chicago, IL; 4Indiana University School of Medicine, Indianapolis, IN; 5Rijksuniversiteit Groningen, Groningen, Netherlands; 6New York University School of Medicine, New York, NY; 7The University of British Columbia, Vancouver, BC, Canada; 8University College London, London, United Kingdom; 9Stanford University School of Medicine, Stanford, CA; 10Harvard University, Cambridge, MA; 11University of Oxford, Oxford, United Kingdom.

Background: People with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) are at very high risk of cardiovascular events and kidney failure. While canagliflozin reduces the risk of these outcomes, the consistency of this effect across all levels of estimated glomerular filtration rate (eGFR) and urinary albumin:creatinine ratio (UACR) remains uncertain.

Methods: We pooled individual participant data from the CANVAS Program (n=10,142) and CREDENCE trial (n=4,401) to assess the effect of canagliflozin on a primary composite outcome of myocardial infarction, stroke, heart failure, doubling of serum creatinine, kidney failure, cardiovascular or kidney death. The effect of canagliflozin was assessed using Cox regression models with treatment by subgroup interaction terms stratified by trial.

Results: 2,051/14,543 (14%) participants experienced the primary outcome over a median follow-up of 2.5 years. Overall, canagliflozin reduced the risk of the primary outcome (HR 0.77, 95% 0.70-0.84; Figure). The magnitude of relative benefit increased as eGFR declined (P-trend<0.0007; Figure) with some evidence of greater relative benefit at higher UACR (P-trend=0.057; Figure). Lower eGFR and higher UACR levels were independently associated with cardio-renal risk. Consequently, absolute risk reductions increased more than 5-fold across lower eGFR categories and more than 9-fold across higher UACR categories (Figure).

Conclusions: Canagliflozin reduces the risk of cardio-renal outcomes in people with T2DM; the magnitude of relative and absolute protection varies by severity of CKD.

Funding: Commercial Support - Janssen funded the CANVAS and CREDENCE trials. This analysis was not specifically funded and conducted independent of the trial sponsors.

Ferric Pyrophosphate Citrate Injection: No Clinical Drug Interaction with Unfractionated Heparin in Hemodialysis Patients

Raymond D. Pratt, R&D, Rockwell Medical Inc, Wixom, MI.

Background: Ferric pyrophosphate citrate (FPC) is a unique iron (Fe) replacement product indicated to maintain Fe balance and hemoglobin (Hgb) concentration in adult hemodialysis patients (HD). FPC can be administered via the dialysate (D) or as an intravenous (IV) preparation (Triferic® AVNU injection 6.75 mg Fe/4.5 mL for IV administration). A clinical study of the effects of unfractionated heparin (UFH) mixed with FPC was conducted.

Methods: An open-label, randomized 3-period, crossover trial, investigated the effects of FPC mixed with UFH compared with delivery of UFH and FPC by separate routes in 12 HD patients. The primary endpoint was the Anti Xa activity of UFH + FPC compared to UFH alone and UFH and FPC administered IV separately. Secondary endpoints were the activated prothrombin time (aPTT), thrombin time (TT) and serum iron profile (sFe). Effects were analyzed using the bioequivalence parameter of area under the concentration-time curve (AUC0-t). Safety was assessed by recording adverse events (AE) and a visual dialyzer clotting scale (VCS).

Results: Coadministration of FPC+UFH pre dialyzer, met bioequivalence criteria for anti Xa activity of UFH compared to UFH alone or UFH and FPC separately. [Figure 1]. The FPC +UFH mixture had no impact on the AUC0-t values of PTT or TT. The concentration-time profiles for sFe and TSAT were comparable. FPC was well tolerated with no reported adverse events. The VCS showed no detectable clotting of the dialyzer with any combination of UFH and FPC.

Conclusions: The results of this study demonstrates no clinically significant drug-drug interaction between FPC and UFH on the anticoagulation effect as assessed by anti Xa activity, aPTT, and TT or on the ability of FPC to deliver iron when these agents are co-administered as a single admixture. All treatments were well tolerated. These results support coadministration of IV FPC and UFH as an admixture to HD patients.

A Pilot Trial of Fistula vs. Graft Access Strategy in Older Adults on Hemodialysis

Mariana Murea, Todd W. Robinson, Shahriar Moosavii, Gregory B. Russell.
Wake Forest School of Medicine, Winston-Salem, NC.

Background: It is unclear whether surgical placement of an AVF confers significant clinical benefits over an AVG in older adults with ESKD.

Methods: In this pilot randomized, parallel-group, open-label trial, patients ≥65 years old with ESKD, no prior AV access, on HD via a tunneled central venous catheter (CVC), referred for AV access placement by their nephrologist, were randomly assigned (1:1) to surgical placement of AVG or AVF.

Results: Of 122 older adults on HD with no prior AV access, 24% expired before or were too sick for surgery referral. Of 46 eligible patients, 36 consented and randomized to AVG (n=18) and AVF (n=18) placement; 13 (72%) and 16 (89%) underwent index AV access placement, respectively (Figure 1). At median follow-up of 321.0 days, primary AV access failure was noted in 31% in each group. Successful cannulation occurred in 8% and 44%, and surgical re-interventions in 23% and 25% (Table 1). AV access infection was seen in 62% in AVG and 8 (50%) in AVF group; median time to successful cannulation was 75.0 and 113.5 days, respectively. Endovascular procedures were recorded in 38% and 44%, ≥2-microglobulin, compared to a high-flux dialyzer (Elisio-17H) in the US (Weiner et al. 2020). The purpose of this study is to perform a cost-consequence analysis for comparison of healthcare costs between HDx and conventional high-flux hemodialysis (HD).

Background: In a 24-week, open-label RCT, expanded hemodialysis (HDx) via the Theranova 400 medium cut-off dialyzer had superior reduction ratios of large middle molecule uremic toxins such as κ and β free light chains, complement factor D, TNF-α, and β2-microglobulin, compared to a high-flux dialyzer (Elisio-17H) in the US (Weiner et al. 2020).

Background: The Theranova 400 was an expanded HD via the Theranova 400 medium cut-off dialyzer had superior reduction ratios of large and middle molecules uremic toxins such as κ and β free light chains, complement factor D, TNF-α, and β2-microglobulin, compared to a high-flux dialyzer (Elisio-17H) in the US (Weiner et al. 2020). The purpose of this study is to perform a cost-consequence analysis for comparison of healthcare costs between HDx and conventional high-flux hemodialysis (HD).

Results: There were 86 patients (389 patient-months) in the Theranova group and 85 patients (366 patient-months) in the Elisio group. All-cause hospitalization rate was 43% lower with Theranova compared to Elisio (RR=0.57; p=0.069). Frequency of ESA use was 46.5% in the Theranova group compared to 55.8% in the Elisio group, but doses were similar between the two groups. Both frequency and dose of iron were similar between the two groups. Average annual cost of hospitalization was $3,925 lower with Theranova compared to Elisio. Annual cost of ESAs and iron were similar between the two groups, although the cost of ESAs was $400 lower in the Theranova group. Compared to Elisio, the average annual cost of Theranova was $4,340 lower per patient. Hospitalization rate and length of stay were the main drivers of cost in the model.

Conclusions: This study provides evidence that, in addition to Theranova’s superior removal of large middle molecules, Theranova may also be a cost-saving therapy driven largely by reduction in patient hospitalization events.

Intermittent Pneumatic Compression Promotes Presurgery Cephalic Vein Dilation: Preliminary FACT Trial Results

Tej M. Singh. Vascular Surgery, El Camino Hospital, Mountain View, CA.

Background: Arteriovenous fistulas (AVF) are the preferred for hemodialysis access with suitable (2.0-2.5 mm) veins. AVF maturation has been poor globally and often leads to increased catheter contact time and costs. Intermittent compression of upper arm veins may aid in forearm vein dilation pre-surgery to assist in AVG placement and maturation with size expectations and effectiveness.

Methods: This was a prospective, IRB approved trial. A novel intermittent pneumatic compression device [Fist Assist® (FA)] was applied to upper arms below the shoulder to allow cyclic compression of 60 mm Hg four hours daily for 90 days. Sixteen (n=16) Stage 4 chronic renal failure (CRF) patients were in the study arm to test arm cephalic vein dilation. Vein size was measured and recorded at baseline and after 90 days by duplex measurement of the cephalic vein with a tourniquet. Clinical results: vein size at particular locations was recorded and tested for significance using a paired-difference t-test.

Underline represents presenting author/disclosure.

B7
Results: Sixteen (n=16) mostly African American patients were involved in the first interim evaluation of the device in a USA FACT trial. All patients were in compliance with the study and followed the study protocol. No major complications or adverse effects were noted in any patient except one non-device related rash. Differences were noted with the measurements done with a cuff in the vein sizes in the forearm (FA) and upper arm (UA) but not significant. FA3M : 3-Month Vein diameter (AP), with cuff, at 1 cm above elbow UA : Enrollment-Vein diameter (AP), with cuff, at 1 cm above elbow UA : Enrollment-Vein diameter (AP), with cuff, at 1 cm from radial bone UA3M : 3-Month Vein diameter (AP), with cuff, at 1 cm above elbow UA : Enrollment-Vein diameter (AP), with cuff, at 1 cm from radial bone Difference between mean of (FA3M-FA) : t = 1.72, p-value = 0.03 for Clinical Effectiveness: FA: 18%± 2.5 mm and 33% reached 2.0 mm or greater UA: 44% ± 2.5mm and 20% reached 3.0 mm or greater.

Conclusions: Early application of a novel, intermittent pneumatic compression device may be successful in preparing forearm veins in Stage 4 CRF patients. The early study results of the FACT trial show statistical significance in vein size improvement, distensibility, and clinical effectiveness to reach predetermined size goals.

Efficacy and Safety of Rapid Intravenous Correction vs Slow Continuous Correction with Hypertonic Saline in Patients with Symptomatic Hyponatremia: A Randomized Clinical Trial (SALSA Trial)

Seon Ha Baek,1 Sejoong Kim,2 Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea; 2Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Few high-quality evidences have clarified whether hypertonic saline is best administered as slow continuous infusion therapy (SCI) or rapid intermittent bolus therapy (RIB) for symptomatic severe hyponatremia.

Methods: To compare the efficacy and safety of RIB and SCI with hypertonic saline in patients with symptomatic severe hyponatremia. Design Prospective, investigator-initiated, multi center, open-label, randomized controlled study from 24 August 2016 until 21 August 2019 Setting Emergency rooms and wards of three general hospitals in South Korea Participants: 178 patients aged 18-80 years with symptoms and blood-corrected serum sodium (sNa) ≤125 mmol/L were included. Interventions Either RIB or SCI of 3% hypertonic saline for 24-48 hours stratified by the severity of clinical symptoms. Main outcome and Measures The primary outcome was overcorrection as follows: increase in the sNa level by >12/18 mmol/L within 24/48 hours. Secondary outcomes included efficacy and safety of the treatment approaches. SNa concentrations were measured at every 6 hours for 2 days.

Results: Patients (mean age 73.1 years, 45% male, mean sNa concentrations 128±3 mmol/L) were randomly assigned to RIB (n=87) or SCI (n=91). Overcorrection occurred in 17.2% and 24.2% in RIB and SCI groups, respectively (absolute risk difference, -6.9% [95% CI -18.8% to 4.9%]). RIB group showed lower incidence of re-lowering treatment than SCI group (41.4% vs 57.1%; absolute risk difference, -15.8% [95% CI -30.3% to -1.3%]; number needed to treat [NNT]=6.3). Groups did not differ in terms of efficacy in increasing sNa concentrations or improving symptoms but RIB showed better efficacy in achieving target correction rate within 1 hour (32.2% vs 17.6%, absolute risk difference 14.6% [95% CI 2% to 27.2%]; NNT=6.8).

Conclusion: Both RIB and SCI therapies of hypertonic saline for treating hyponatremic encephalopathy were effective and safe, with no difference in the overcorrection risk. However, RIB had a lower incidence of therapeutic re-lowering treatment and tended to have a better efficacy in achieving sNa within 1 hour than SCI. RIB could be suggested as the preferred treatment of symptomatic hyponatremia, consistent with the current consensus guidelines.

Rituximab vs. Cyclophosphamide in the Treatment of Membranous Nephropathy: The RI-CYCLO Trial
Elisa Delbarba,1 Domenico Santoro,2 Loreto Gesualdo,1 Antonello Panini,3 Federico Alberici,1 Gian Marco Ghiglieri,2 Pietro Ravani,1 Francesco Scoclarì,1 
1 ASST Spedali Civili di Brescia, Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Lombardia, IT, public/health, Brescia, Italy; 
2 Università di Messina, Università degli Studi di Messina, Messina, Sicilia, IT, academic, Messina, Italy; 
3 Istituto Giannina Gaslini, Genova, Italy; 
4 Università degli Studi di Brescia, Brescia, Italy; 
5 University of Calgary, Calgary, AB, Canada; 
6 Azienda Ospedaliera Brotzu, Cagliari, Italy; 
7 Azienda Ospedale Policlinico, Bari, Italy.

**Background:** Guidelines for membranous nephropathy (MN) management recommend cyclical corticosteroid-cyclophosphamide regimen (CYC) in patients with heavy proteinuria. Rituximab (RTX) may be a viable alternative, but head-to-head comparison is lacking.

**Methods:** Aim of this pilot RCT was to estimate the effects of RTX vs CYC regimen in MN, while assessing the feasibility of a larger trial. After a run-in of at least 3 months, patients with nephrotic syndrome were randomized to receive RTX (1g two weeks apart) or CYC. Complete remission (CR) was defined as proteinuria ≤0.3 g/day. Primary outcome was CR at 12 months; secondary outcomes included CR+PR at 12 and 24 months.

**Results:** 116 pts were screened, 74 randomized. Baseline median serum albumin was 2 g/dl and proteinuria 6 g/day in both arms. At 12 months, 6/37 pts (16%) in the RTX arm and 2/37 pts (5%) in the CYC arm had CR (OR according to “intention to treat”ITT analysis 0.4, 95% CI 0.13-1.23, OR “according to protocol” PP 0.28, 95% CI 0.08-0.95). 23/37 (62%) in the RTX arm and 27/37 (73%) in the CYC arm had CR+PR (OR ITT analysis 0.61, 95% CI 0.23-1.63, OR PP 0.11, 95% CI 0.42-2.98). Probabilities of CR and CR+PR at 24 months were 0.42 (CI 0.26-0.62) and 0.83 (CI 0.65-0.95) in the RTX arm and 0.43 (0.28-0.61) and 0.82 (0.66-0.93) in the CYC arm. Serious adverse events occurred in 7 and 5 pts, in the RTX and CYC arm, respectively.

**Conclusions:** Although the probability of CR was lower in the RTX arm at 12 months, the probability of CR at 24 months and of CR+PR at 12 and 24 months was similar in the two groups. No difference in side effects was found. While the efficacy of RTX and CYC in MN appears to be similar, a larger trial adequately powered would be difficult to perform.

The Immunoglobulin G Degrading Enzyme Imilidase for the Treatment of Anti-GBM Disease: The GOOD-IDES 01 Trial
Marten Seecelmark,1,2 Fredrik Uhlin,1 Elisabeth Sonesson,3 The GOOD-IDES Study Team 1Clinical Sciences, Lunds Universitet, Lund, Sweden; 2Medical and Health Sciences, Linköpings universitet, Linköping, Sweden; 3Hansa Biopharma, Lund, Sweden.

**Background:** Anti-GBM disease is an ultra-rare small vessel vasculitis with a yearly incidence below 2 per million. Most cases present with rapidly progressive glomerulonephritis and despite aggressive treatment with plasma exchange and cyclophosphamide renal survival is poor, at least for those presenting with advanced kidney injury. Imilidase has been shown to cause depletion of circulating and kidney bound anti-GBM within a few hours, but it is not known if this leads to an improved outcome.

**Methods:** We conducted an international multi-center one-arm open-label study giving a single dose of 0.25mg/kg of imilidase (non-proprietary name for Idex® – Immunoglobulin G Degrading Enzyme of Streptococcus pyogenes) on top of standard of care (ClinicalTrials.gov: NCT03157037). Main inclusion criteria were eGFR <15 ml/min/1.73m² and circulating anti-GBM antibodies. Main exclusion criteria were moderate or severe lung hemorrhage, dialysis dependency > 5 days and/or oliguria >48 hours. The primary outcome was dialysis free survival at 6 months.

**Results:** At 17 tertiary referral hospitals in 5 European countries 15 patients (6 women) were recruited between June 2017 and January 2020. Their median age was 60 years (range 19-77) and 5 were double positive for anti-GBM and ANCA. At inclusion 10 patients were dialysis dependent including 5 that were oliguric/anuric; the remaining 5 patients had eGFR of 7-14 ml/min. 6h hours after imilidase no patient had anti-GBM above the reference range. Return of antibodies prompting plasma exchange was seen in 10 patient 4 to 22 days after imilidase (median 7 days), and they received a median of 8 session (range 2-17). At six months 10 patients were dialysis independent (median eGFR 27 ml/min, range 16-67), one was dead and 4 had developed ESRD. A favorable response was seen also in some patients that were anuric on inclusion and in some with 100% crescents. The safety profile was good; there were 7 serious adverse events (SAEs) reported but no serious unexpected suspected adverse reaction (SUSAR).

**Conclusions:** Imilidase leads to rapid clearance of anti-GBM which seems to widen the window of opportunity for treatment thereby increasing the chance of renal survival in difficult to treat patients with anti-GBM disease.

PO2640
Phase 2 Study of N-Acetylmannosamine (ManNac) for Glomerular Diseases
Marjan Huizinga,1 Jodi Blake,2 William Gahl,1 Jeffrey B. Kopp,2 1Medical Genetics Branch, NIHGRI, NIH, Bethesda, MD; 2Kidney Disease Section, NIDDK, NIH, Bethesda, MD.

**Background:** Sialic acid residues provide anionic charges to proteins, including those of the glomerular filtration barrier. Lectin analysis of kidney biopsies showed glomerular hyposialylation in nphrotic diseases, this may contribute to podocyte dysfunction and proteinuria. We showed in nephrotic mouse models that oral ManNac, an uncharged precursor of sialic acid, normalized glomerular sialylation and markedly decreased proteinuria. ManNac is also being studied to treat the rare hyposialylation disorder GNE myopathy (NCT04231266); it could be repurposed for patients with glomerular hyposialylation.

**Methods:** Phase 1 Results: A phase 1 study (NCT02639260; IND 125,192) of ManNac in 7 nephrotic subjects showed that oral ManNac was safe and well-tolerated. Plasma free sialic acid levels peaked ~10h after ManNac dosing, remained elevated beyond 48h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. No adverse events occurred with increased plasma free sialic acid levels. Most subjects receiving ManNac twice daily showed a 26-54% reduction in urine protein/creatinine ratio (UPCR), which appeared to correlate with the degree of glomerular hyposialylation.

**Results:** Phase 2 Design: An open-label phase 2 study will include assessment of longer-term pharmacokinetics, safety and efficacy. We will enroll 12 adults with focal segmental glomerulosclerosis, minimal change disease or membranous nephropathy, UPCR >2g/g, eGFR >45 ml/min/1.73m² and glomerular hyposialylation. Glomerular sialylation will be assessed by lectin analysis of previous diagnostic biopsies. Subjects will receive oral ManNac twice daily for 12 weeks, with clinical evaluations at baseline, interim and at the end of the study. Study outcomes will include safety and reduction of UPCR. Exploratory outcomes will include quality of life, patient-reported outcomes and improvement in eGFR.

**Conclusions:** Oral ManNac therapy might benefit subjects with glomerular hyposialylation. ManNac has minimal toxicity, is well tolerated, is easily administered, shows a trend to reduction of proteinuria, and could replace or augment existing therapies. The results of the planned phase 2 trial might offer a new therapeutic approach for primary and perhaps secondary glomerular diseases. Such results may change medical practice by including assessment of glomerular sialylation in the analysis of renal biopsies.

**Funding:** NIDDK Support, Other NIH Support - NIHGRI Support
