Abstract Publication
More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals, and then by chronological publication number. Abstracts with a “PUB” number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author’s name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 31, 2020: Page(s).

Abstract Disclaimer and Copyright

Roxadustat Treatment of Anemia in Non-Dialysis-Dependent CKD Is Not Influenced by Iron Status

Robert Provenzano, 1 Steven Fishbane, 2 Pablo E. Pergola, 3 Robert Leong, 4 Ming Zhong, 4 Dustin J. Little, 5 Kin-Hung P. Yu 6 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 7 Northwell Health, Great Neck, NY; 8 Renal Associates PA, San Antonio, TX; 9 Fibrogen Inc, San Francisco, CA; 1AstraZeneca plc; Astellas Pharma Inc.

Background: Roxadustat is a novel, orally bioavailable, small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitors to treat anemia in adult CKD patients (pts). Efficacy and safety of roxadustat versus darbepoetin alfa (DA) were assessed in NDD pts in a randomized, open-label, active-controlled trial.

Methods: Data from 3 completed randomized Phase 3 studies in NDD-CKD pts were analyzed individually and in the pooled population by iron status. Pts were randomized to roxadustat or placebo for up to 4 years. Baseline (BL) hemoglobin (Hb) and change from BL (CFB) were summarized overall and in pts with iron repletion or iron depletion. Iron repletion was defined as ferritin ≥100 μg/L and transferrin saturation (TSAT) ≥20%; the remainder were defined as iron depleted. Oral iron was allowed on study and IV iron was allowed as rescue.

Results: Across studies, 2,391 and 1,886 pts with NDD-CKD were treated with roxadustat and placebo, respectively. Mean (SD) BL Hb was 9.10 (0.74) g/dL (roxadustat) and 9.10 (0.73) g/dL (placebo). At BL, 1433 (60%) pts were iron replete for roxadustat and 1127 (60%) pts were iron replete for placebo. Mean CFB in Hb with roxadustat was summarized by study and iron status (Table 1). Hb CFB was similar in iron-replete and iron-depleted patients receiving roxadustat. Roxadustat dose and iron use in subgroups will be explored.

Conclusions: Roxadustat corrected and maintained Hb in patients with NDD-CKD and anemia regardless of iron status at baseline.

Funding: Commercial Support - Fibogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Change from baseline in Hb overall and by iron status with roxadustat treatment across NDD studies over Weeks 28 to 32 regardless of rescue therapy.

TH-OR01

Global Phase 3 Clinical Trials of Vadadustat vs. Darbepoetin Alfa for Treatment of Anemia in Patients with Dialysis-Dependent CKD

Kai-Uwe Eckardt, INNO2VATE Author Group Charite Universitätsmedizin Berlin, Berlin, Germany.

Background: Vadadustat (VADA) is a investigational, oral, hypoxia-inducible factor prolyl hydroxylase inhibitor that has advanced to phase 3 development for treatment of anemia of CKD. In phase 2 trials, VADA raised and maintained Hb concentrations.

Methods: Two randomized, phase 3, global, open-label, sponsor-blind, parallel-group active-controlled noninferiority (NI) trials comparing VADA vs darbepoetin alfa (DA) were conducted in patients with anemia of DD-CKD (INNO2VATE trials). The trials included 1) Correction/Conversion trial of patients new to dialysis (incident trial, NCT02866580) and 2) Conversion trial of patients on maintenance dialysis (prevalent trial, NCT02891249). The primary safety endpoint was time to first major adverse cardiovascular event (MACE: all-cause mortality, nonfatal MI, nonfatal stroke) prospectively as a pooled analysis of both trials. Primary and key secondary efficacy endpoints, prospectively as separate analyses for each trial, were mean difference in change in Hb from baseline between VADA vs DA to wks 24-36 and wks 40-52, respectively.

Results: 3923 patients were randomized 1:1 to VADA or DA (incident, N=369; prevalent, N=3554). Median (Q1, Q3) duration of follow-up was 1.2 (0.8, 1.7) and 1.2 (2.2) yrs, respectively. The incident trial, VADA was noninferior to DA for time to first MACE (HR 0.96; 95% CI: 0.83, 1.11) and a prespecified NI margin of 1.25. Among incident dialysis patients, the least squares (LS) mean difference in change in Hb between VADA vs DA from baseline to wks 24-36 was -0.31 g/dL (95% CI: -0.53, -0.10) and from wks 40-52 was -0.07 g/dL (95% CI: -0.34, 0.19). In the prevalent trial, the LS mean difference in change in Hb from baseline to wks 24-36 was -0.17 g/dL (95% CI: -0.23, -0.10), and wks 40-52 was -0.18 g/dL (95% CI: -0.25, -0.12). Primary and key secondary efficacy endpoints met the prespecified NI margin of -0.75 g/dL in both study arms. Incidence of treatment-emergent adverse events (TEAEs) in VADA vs DA was 85.8% vs 85.5% in the incident trial and 88.3% vs 89.3% in the prevalent trial, respectively.

Conclusions: VADA was noninferior to DA in time to first MACE and correction/maintenance of Hb in DD-CKD patients with anemia. The incidence of TEAEs was comparable between VADA and DA.

Roxadustat for the Treatment of Anemia in CKD Patients Not on Dialysis (NDD): A Phase 3, Randomized, Open-Label, Active-Controlled Study

Jonathan Barratt, 1 Branislav Andric, 2 Michael Schoemig, 2 Michael Reusch, 2 Udaya Valurhi, 1 Christopher R. Mariat. 4 University of Leicester, Leicester, United Kingdom; 2Center of Diagnostics and Nephrology, Heilbronn and Neckarsulm, Germany; 3National Center of Urology, Tbilisi, Georgia; 4Health Center Krusevac, Krusevac, Serbia; 5Astellas Pharma Europe B.V., Leiden, Netherlands; 6CHU St Etienne, Service Nephrologie Diaplyse Transplantation, St Etienne, France.

Background: Roxadustat is an orally administered hypoxia-inducible factor prolyl hydroxylase inhibitor to treat anemia in adult CKD patients (pts). Efficacy and safety of roxadustat versus darbepoetin alfa (DA) were assessed in NDD CKD pts in a randomized, open-label, active-controlled phase 3 study.

Methods: NDD CKD pts with anemia were randomized to roxadustat or DA for up to 2 yrs. Dose adjustments were permitted to correct and maintain hemoglobin (Hb) within 10–12 g/dL. The primary endpoint was Hb response, defined as Hb ≥11.0 g/dL and an increase of ≥2.0 g/dL in pts with BL Hb ≤8.0 g/dL, during the first 24 weeks of treatment without rescue therapy. Noninferiority of roxadustat to DA was declared if the lower bound of the two-sided 95% confidence interval (CI) for the difference (roxadustat – DA) in percentage of responders was >0.15. Key secondary endpoints included change in low-density lipoprotein (LDL) cholesterol, time to first IV iron use, change in mean arterial pressure (MAP), and occurrence of hypertension. Treatment-emergent adverse events (TEAEs) were assessed.

Results: Of 616 randomized pts (roxadustat, 323; DA, 293), 424 completed 2 years of treatment (roxadustat, 215; DA, 209). Mean BL Hb was 9.55 g/dL in both groups. In the per protocol set, the proportion of pts who achieved Hb response during the first 24 weeks was 89.5% (roxadustat; n=256/286) and 78.0% (DA; n=213/273), with a difference of 11.5% (95% CI: 5.6%, 17.3%). Thereby establishing roxadustat’s noninferiority to DA. Noninferiority of roxadustat to DA was demonstrated for MAP and time to occurrence of hypertension. Superiority of roxadustat to DA was demonstrated for decreasing LDL cholesterol (p=0.001) and increasing time to first IV iron use (p=0.004). The incidence of TEAEs was comparable between roxadustat (91.6%) and DA (92.5%). Common TEAEs in both groups were end-stage renal disease, hypertension, dehydrated, eGFR, and peripheral edema.

Conclusions: Roxadustat was noninferior to DA for Hb response during the first 24 weeks of treatment in NDD CKD pts. Safety profiles were comparable between groups.

Roxadustat Is Not Associated with an Increased Risk of Neoplasm in Patients with CKD and Anemia

Daniel W. Coyne,1 Steven Fishbane,2 Pablo E. Pergola,3 Robert Leong,4 Ming Zhong,4 Dustin J. Little,5 Kin-Hung P. Yu 6 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 7 Northwell Health, Great Neck, NY; 8 Renal Associates PA, San Antonio, TX; 9 Fibrogen Inc, San Francisco, CA; 1AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is a novel, orally bioavailable, small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including for erythropoietin. Preclinical studies of roxadustat in multiple animal species did not demonstrate a carcinogenic signal. We report neoplasm-related adverse events (AEs) and serious adverse events (SAEs) from the roxadustat global phase 3 program.

Methods: Data from six pivotal studies were pooled: 3 compared roxadustat to placebo in patients with non-dialysis-dependent (NDD) CKD, and 3 compared roxadustat to epoetin alfa in patients with dialysis-dependent (DD) CKD. Patients were excluded from the studies if they had a history of malignancy, except for those determined to be cured or in remission for ≥2 years, or prior biopsy-confirmed malignancy.

Results: Of 3,950 patients treated with roxadustat, 3,176 patients were exposed to ≥1 treatment period >28 days and ≥7 days after the last dose of study drug in the NDD- and DD-CKD populations, respectively. Events were coded using the Medical Dictionary for Regulatory Activities, System Organ Class “Neoplasms benign, malignant and unspecified (incl cysts and polyps).”

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

TH-OR06
Hemoglobin (Hb) Correction with Roxadustat Is Associated with Improved Iron Homeostasis in Patients with Dialysis-Dependent CKD (DD-CKD) — Pablo E. Perugia, 1 Chaim Charytan, 1 Dustin J. Little, 1 Stefan Tham, 1 Lynda Szczek, 1 Steven Fishbane, 1 Arbor Research Collaborative for Health, San Antonio, TX; 2New York Hospital Queens, Division of Nephrology, Flushing, NY; 3Clinical Research, AstraZeneca, Gaithersburg, MD; 4Clinical Research, AstraZeneca, Gothenburg, Sweden; 5Fibrogen Inc., San Francisco, CA; 6Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.

Background: Roxadustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin and enhances iron utilization. To evaluate the comparability of Hb increases across studies and global geographic regions, we analyzed data from three pivotal Phase 3 trials of roxadustat in patients with anemia and NDD-CKD.

Methods: While based on the same trial design, the studies were performed by different investigators and companies in differing global regions. Patients with baseline Hb <10 g/dL and eGFR <60 mL/min/1.73 m² were randomized to double-blind roxadustat or placebo (pbo) in the OLYMPUS (North and South America, Asia-Pacific and Europe; N=2812, 1:1 ratio to pbo), ALPS (South America, Europe and South Africa; N=597, 2:1 ratio to pbo), and ANDUS (North and South America, Asia-Pacific and Australasia; N=922, 2:1 ratio to pbo) double-blind randomized controlled trials (RCTs). Iron use was administered unrestricted; intravenous (IV) iron was limited to rescue therapy in those with low iron stores and poor treatment response. The primary endpoint was the mean change in Hb from baseline to the average over Weeks 28–52.

Results: Significant (P<0.001) and consistent improvements in Hb were observed across the studies. Iron rescue therapy use was lower with roxadustat vs pbo (Figure) and were maintained over time. IV iron rescue therapy use was lower with roxadustat vs pbo (Figure). Overall safety of roxadustat was comparable with pbo and consistent with the DD-CKD patient population.

Conclusions: Roxadustat consistently improved anemia in patients with NDD-CKD across the global roxadustat clinical program, in studies performed by different investigators and companies and in varying global locations.

TH-OR07
Renoprotective Effects of Ferric Citrate in a Mouse Model of CKD — Mark R. Hanouéd, 1 Shirley Wong, 1 Kristine Chua, 1 Grace Jung, 2 Bo Qiao, 1 Victoria R. Gabayan, 1,2 Thomas Ganz, 1,2 University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Ferric citrate (FC) is an effective phosphate binder and iron replacement product. In the setting of chronic kidney disease (CKD), both decreasing enteral phosphate absorption and improving iron status could lower pathologically elevated FGF23 levels and indirectly improve kidney function. In a murine model of CKD, we assessed how FC (and iron status in general) affects FGF23 levels and kidney function.

Methods: Five-week-old C57BL6 knockout mice were placed on five-week diets containing low iron (4 ppm), standard iron (48 ppm), or standard iron supplemented with FC (48 ppm + 1% FC) (n = 15–20 mice per group). Mice were euthanized at ten weeks of age.

Results: Compared to the standard iron diet group, the mice on low iron diets developed iron deficiency anemia (lower liver iron, lower hemoglobin, lower mean corpuscular volume, and higher red cell distribution width); markedly worsened kidney function (higher serum urea nitrogen, creatinine, and phosphate); and markedly higher FGF23 levels (increased bone and marrow Fg23 mRNA expression, and approximately ten-fold higher plasma intact FGF23 concentrations) (Figure). Conversely, compared to the standard iron diet group, the mice treated with FC had similar hemoglobin (with increases in liver and serum iron not reaching statistical significance), but decreased urea, phosphate, decreased marrow Fg23 mRNA expression; approximately ten-fold lower plasma intact FGF23 concentrations; decreased systemic inflammation; and markedly improved kidney function (decreased serum urea nitrogen, serum creatinine, urine albumin-to-creatinine ratio, and expression of renal fibrosis markers, along with increased kidney Klotho mRNA expression (Figure).

Conclusions: In the setting of CKD, iron deficiency anemia is associated with markedly increased intact FGF23 levels and worsened kidney function. In this CKD model, compared to either iron-deficient or standard iron conditions, FC decreased serum phosphate, markedly decreased intact FGF23, and dramatically improved kidney function. These data support further human studies of how FC affects CKD progression.

Regional Variation of Erythropoietin-Stimulating Agent Hyporesponsiveness in the Global Dialysed Dialysis Study (ASCEND-D)

Ajay K. Singh,1 Allison Blackorby,2 Borut Cizman,3 Alexander R. Cobitz,4 Sergio A. Godoy,5 Vivekanand Jha,6 Kirsten L. Johansen,7 Gearoid M. McMahon,8 Amy M. Meadowcroft,9 Gregory T. Obrador,10 Muh Geot Wong,11 Iain C. Macdougall,12 Brighton and Women’s Hospital, Boston, MA; 13-Department of Global Health, Sydney, NSW, Australia; 14-Hennepin Healthcare, Minneapolis, MN; 15-Universidad Panamericana, Mexico, Mexico; 16-Royal North Shore Hospital, St Leonards, NSW, Australia; 17-George Clinical, Pilar, Argentina; 18-GlaxoSmithKline, Collegville, PA; 19-GlaxoSmithKline, Research Triangle Park, NC; 20-King’s College Hospital, London, United Kingdom.

Background: Hyporesponsiveness to erythropoiesis-stimulating agents (ESA) is present in 10%-15% of the prevalent dialysis population. Our background characteristics and predictors of ESA hyporesponsiveness in a global randomized cardiovascular outcomes study comparing an investigational hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), daprodustat, with conventional ESA treatment.

Methods: ASCEND-D (NCT02879305) recruited 2964 prevalent dialysis patients receiving ESA treatment (standardized to weekly intravenous [IV] epoetin) who were iron replete at baseline. Primary ESA hyporesponsiveness definition: ESA Resistance Index (ERI, ESA Units/kg/week/hemoglobin g/L) ≥2 or IV ESA equivalent dose ≥450 Units/kg/week. Predictors of ESA hyporesponsiveness were determined using a multivariable regression model. Alternate hyporesponder definitions were explored.

Results: Using the primary definition, 354 (12%) patients were ESA hyporesponsive. Selected baseline characteristics in the overall population and by ESA responsiveness, along with the results from the multivariable analysis, are shown below. Additional predictors of ESA hyporesponsiveness include a history of heart failure (0.013), dialysis vintage (0.033), smoking status (0.046), aspirin use (0.039), and ACEI/ARB use (0.061).

Conclusions: This is the first global HIF-PHI study to report pre-defined specifications and predictors of ESA hyporesponsiveness. While most of the strong predictors identified in our study have been previously reported, geographic region stands out as an unexpected finding that requires further investigation.

Funding: Commercial Support - GlaxoSmithKline

TH-OR09

Adverse Event Rates Are Higher Post-Transfusion vs. Overall Follow-up and Independent of Background Anemia Treatment in Patients with CKD

Robert Provenzano,1 Carol A. Pollock,2 Roberto Pecots-Filho,1,3 AnJay Rastogi,1 Rachel Lai,1 Ming Zhong,2 Lynda Szczzech,5 Wayne State University, Detroit, MI; 4The University of Sydney, Sydney, NSW, Australia; 1Arbor Research Collaborative for Health, Ann Arbor, MI; 5Pontificia Universidad Catolica do Parana Departamento de Medicina, Curitiba, Brazil; 6University of California Los Angeles, Los Angeles, CA; 7FibroGen Inc, San Francisco, CA.

Background: The use of transfusion can treat anemia in the short term but may increase the risk of adverse events. Ruxolastat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Ruxolastat has been shown to decrease the need for transfusions in patients with chronic kidney disease (CKD).

Methods: Data were pooled from three pivotal, phase 3 studies of ruxolastat vs. placebo in patients with non-dialysis-dependent (NDD-CKD) and three pivotal phase 3 studies of ruxolastat vs. epoetin alfa in patients with dialysis-dependent (DD) CKD. We evaluated rates of intravascular volume-related adverse events (AEs; reported from a predefined list [heart failure, pulmonary edema, respiratory failure]) as a direct cause of excess intravascular volume or as a potential symptom) and treatment-emergent adverse events (TEAEs) during the 14-day post-transfusion period and the overall follow-up period (last dose + 28 days) in patients who had a transfusion.

Results: Intravascular volume-related AE and TEAE rates were at least 9-fold higher during the 14-day post-transfusion period vs. the overall follow-up period across all subgroups (Table). Trends in overall TEAE rates were similar across treatment groups.

Conclusions: Intravascular volume-related AEs occurred at higher rates post-transfusion across all populations. The reduction in transfusions for patients taking ruxolastat could lower patient risk and healthcare resource use in managing CKD-related anemia.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

A Real-World Longitudinal Analysis of Anemia Treatment Prescriptions in Non-Dialysis-Dependent CKD Patients, a CKDopps Study

Marcelo Lopes,1 Charlotte Tu,1 Jaree Zee,1 Murilo G. Guedes,2 Ronald L. Pisoni,3 Bruce M. Robinson,4 Katarina Hedman,5 Glenn James,6 James A. Skoland,6 Ziad Massy,1 Antonio A. Lopes,5 Helmut Reichel,7 Sandra Wachter,8 Michelle M. Wong,9 Roberto Pecots-Filho.1 DOPPS/Arbor Research Collaborative for Health, Ann Arbor, MI; 1Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 2AstraZeneca Pharmaceuticals LP, Wilmington, DE; 3Universite Paris-Saclay, Villejuif, France; 4Universidade Federal da Bahia, Salvador, Brazil; 5Nephrological Center, Villingen Schwenningen, Germany; 6Vifor Pharma Ltd, Clatibrug, Switzerland; 7The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.

Background: Previously lacking in the literature, this analysis aims to comprehensively describe longitudinal patterns of anemia management, including prescriptions of ESA and iron replacement, for non-dialysis dependent chronic kidney disease (NDD-CKD) stage 3 to 5 patients under nephrologist care.

Methods: We analyzed data from a prospective cohort of 2455 NDD-CKD patients from Brazil, Germany and the US, who were not using anemia medications (oral iron, intravenous [IV] iron, or erythropoiesis stimulating agent [ESA]) at enrollment in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDOPPS). We reported the cumulative incidence function (CIF) [HK1] of anemia treatment initiation, stratified by patient characteristics. For patients that started therapy, we report the frequency of medication type at the moment of initiation, as well as switches and discontinuation over 12 months.

Results: The CIF of any anemia treatment initiation at 12 months was 54% for patients with Hb <10 g/dL. For oral iron therapy, the CIF at 12 months was 26% (19%, 32%); for TSAT<20%, and 22% (17%, 28%) for ferritin <100. For IV iron use, CIF at 12 months was 6% (3%, 11%) for patients with TSAT<20% and 4% (2%, 7%) for patients with ferritin <100mg/mL. For ESA use, the CIF at 12 months was 38% (29%, 47%) for patients with Hb <10 g/dL, and 11% (8%, 14%) for Hb 10 to <12 g/dL. Medication type at initiation and longitudinal treatment patterns (switches and discontinuation) are shown in the figure.

Conclusions: In a period of 12 months, anemia medication is initiated in a limited number of NDD-CKD patients with clinical signs that would indicate to do so. This longitudinal analysis using data from the real-world setting, call attention to a sub-optimally management of anemia in the NDD CKD setting.
Results: Deletion of Hif1α delayed progression of CKD, as CPD mice showed reduced levels of BUN compared to age-matched Col4a3KO mice (-25%). CPD mice also showed lower FGF23 levels (80% vs. Col4a3KO) and we obtained similar results in Col4a3KO mice administered with a HIF inhibitor (-30% FGF23, -30% BUN, vs. Ctrl-Col4a3KO). CPD mice also showed improved trabecular and cortical bone parameters (-50% trabecular bone volume, -20% cortical porosity vs. Col4a3KO). Finally, deletion of Hif1α increased alkaline phosphatase (ALP) positive colonies and mineral deposits in Hif1αKO cultures compared to Ctrl cells, and led to a 30% reduction in Fg23 expression. In contrast, Hif1αKO cells showed reduced osteogenic potential, with fewer ALP colonies and mineral deposits, and a reduced Fg23 expression.

Conclusions: Our data suggest that oseous HIF1α stimulates FGF23 production in CKD and is a negative regulator of osteoblast differentiation and function. Thus, inhibition of HIF1α in bone might represent a novel therapeutic strategy to improve bone and mineral outcomes in CKD.

Deletion of the Sodium-Hydrogen Exchanger Isoform 6 in Mice Is Associated with an Age-Dependent Loss of Bone Volume

Daniela Hanke,1 Guiseppe Albano,2 Manuel A. Anderegg,1 Daniel G. Foster,1,2 Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; 1Department for BioMedical Research, University of Bern, Bern, Switzerland.

Background: The sodium/hydrogen exchanger isoform 6 (NHE6) localizes to recycling endosomes, where it mediates endosomal alkalization through K+/H+ exchange. NHE6 function in the endosome is essential for clathrin-mediated endocytosis, receptor recycling and endosomal signaling. Mutations in the SLCA9A6 gene encoding the NHE6 isoform cause severe X-linked mental retardation, epilepsy, autism and corticalbasal degeneration in humans. Patients with SLCA9A6 mutations exhibit skeletal malformations, and a previous study suggested a role of NHE6 in osteoblast-mediated mineralization. The goal of this study was to explore the role of NHE6 in bone homeostasis.

Methods: NHE6 expression, osteoclast differentiation and cell-mediated resorption were assessed in osteoclast precursor cells isolated from wild-type and NHE6 knock-out mice. In a next series of experiments, we used primary osteoblasts, extracted from calvariae of newborn mice, to study NHE6 expression, proliferation, and cell-mediated mineralization in vitro. To determine the impact of the in vivo findings on structural bone parameters, we performed high-resolution microcomputed tomography (µCT) studies on lumbar vertebrae of wild-type and NHE6 knock-out mice.

Results: NHE6 mRNA and protein are expressed in both primary osteoclasts and osteoblasts. In vitro studies with osteoclasts and osteoblasts derived from NHE6 knock-out mice demonstrated normal osteoclast differentiation and osteoblast proliferation. However, NHE6-deficient osteoclasts exhibited a resorptive deficit, and the mineralization capacity was increased in osteoblasts lacking NHE6. Microcomputed tomography studies revealed a reduced bone volume at a single lumbar vertebral site (L4) but otherwise unaltered structural bone parameters in NHE6 knock-out mice compared to wild-type mice at 3 months of age. At 6 months of age, however, NHE6 knock-out mice displayed a significantly reduced bone volume and trabecular number as well as an increased trabecular space at all lumbar vertebral studied (L3-5) compared to wild-type mice.

Conclusions: Thus, loss of NHE6 results in an age-dependent loss of bone volume in mice. The results of our in vitro studies argue against a direct bone cell-autonomous cause of the bone phenotype observed in NHE6 knock-out mice and suggest extraneous factors as likely mediators.

TH-OR14

Circadian PTH Secretion Is Entailed by Feeding, While the Internal Circadian Parathyroid Clock Is Independent but Affected by CKD

Søren Eftekhad1,2, Anders Nordholm,1,2 Maria L. Mace,2 Marya Morevarti,3 Klaus Olgaard,2 Eva Lewin,1 1Dept. of Nephrology, Herlev Hospital, Copenhagen, Denmark; 2Dept. of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.

Background: We have previously shown that an internal molecular circadian clock operates in the parathyroids. PTH regulates its circadian expression during the 24h rhythm of PTH secretion and whether it is impacted by feeding or CKD is unknown.

Methods: Rats were kept in 12h:12h light:dark cycle and fed ad libitum. Blood samples and parathyroid glands were harvested at 4h interval (N=38). Then feeding was restricted to the inactive light phase at ZT2-ZT12 (ZT: lights off) for 4 weeks and blood and glands obtained again (N=39). CKD was induced by 5/6 nephrectomy and high phosphate (P) diet for 8 weeks and parathyroid glands were harvested at 4h interval (N=38). Then feeding was restricted to the active light phase at ZT12-ZT2 (ZT: lights on) for 4 weeks and blood and glands obtained again (N=39).

Results: Circadian rhythmicity was found for PTH (p<0.0002), P (p<0.0001), FGF23 (p<0.02), and urea (p<0.0001). Restricted feeding to the habitual inactive period inverted the acrophase timing of PTH (ZT9 → ZT6, p<0.0001), FGF23 (ZT7 → ZT4, p<0.02), and urea (p<0.0001). Restricted feeding to the habitual active period inverted the acrophase timing of PTH (ZT9 → ZT6, p<0.0001), FGF23 (ZT7 → ZT4, p<0.02), and urea (p<0.0001). Restricted feeding did not significantly affect the period, acrophase timing, MESSOR or amplitude of circadian clock genes. Bmal1, Per1-3, Cry1-2 and Rev-erba. The rhythmicity of parathyroid circadian clock genes was severely deregulated in CKD with significant upregulation of MESSOR of Per1 (p<0.0002), Per2 (p<0.03), and Rev-erba (p=0.004) and downregulation of Npas2 (p<0.05).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
significant rhythm of Per1 (p=0.02) was abolished. In CKD the best fitting period of rhythmicity was reduced to 20h as opposed to the normal 24h for Per1, Per2, Per3 and Crt1. Significant shifts in acrophase were found for Npas2, Per3 and Crt1, while amplitude of Rev-erba increased.

Conclusions: Feeding restricted to the inactive period inverted the acrophase of plasma PTH, P and FGF23 and revealed a clear dissociation between the phase of PTH secretion rhythm and the phase of the circadian clock in the parathyroid glands. In CKD the circadian rhythm of core clock genes were significantly interfered, affecting MESOR, phase, period, amplitude as well as rhythmicity.

Shensen Li, Wenwen Li, Qingqing Liu, Haiyan Shen, Bingquan Deng, Changchun Cao. Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.

Background: Secondary hyperparathyroidism (SHPT) is one of the common complications in patients with chronic kidney disease. The development of SHPT is accompanied by the change of cell composition, while the exact cell type changes and mechanism are yet to be defined. Therefore, single cell sequencing was conducted to analysis the cell composition of parathyroid gland.

Methods: In current study, parathyroids from 3 SHPT patients were digested to obtain single cell suspension. A total of 21519 cells were obtained and the mRNA expression profiles were analyzed by single cell sequencing and bioinformatics. Furthermore, the development separation track of cell subpopulations was constructed by pseudotime analysis (Figure 1A).

Results: There may be 21 cell subpopulations in parathyroid, among which 6 subpopulations (clusters 0, 1, 2, 5, 11, 17) are high function subpopulations of parathyroid, which were indicated by high expression of genes (cytotoxic cells missing homolog 2), PTH (parathyroid hormone), Ctsr (calcium sensing receptor) and Kl (Klotho) genes (Figure 1B-D). The results of pseudotime analysis in the 6 high function subpopulations show that cluster 0 is at the beginning of the main group separation track, cluster 1, 2, 5, 11, 17 are in the middle, while cluster11 and 17 are at the end (Figure 1E). Multiple genes may play major role in the differentiation of cluster 0, including tsp1an1, park7, atp6v0b, rip11, rip8 and etc (Figure 1F).

Conclusions: There are 6 subpopulations out of total 21 cell subpopulations of parathyroid cells with higher parathyroid hormone secretion and regulation function in SHPT patients. Among which, cluster 0 may be the initiation differentiation cell of high functional cells, but because it may be a subpopulation with high proliferation and differentiation potential.

Identification and analysis of subpopulations of uremic hyperparathyroidism glands.

TH-OR16
Calcium Isotopes: A Novel Biomarker of Bone Mineralization in CKD
Rukhasha Shroff,1 Mary F Hewitt,1 Ana Kolevica,2 Alexander D. Lalayannis,3 Claus Peter Schmitt,4 Dagmar-Christian Fischer,4 Anton Eisenhauer,1 1University College London Great Ormond Street Institute of Child Health, London, UK; 2Kingdom; 3Georg-August-Universität, Medical Center, Rostock, Germany; 4Center for Pediatrics and Adolescent Medicine, Heidelberg, Heidelberg, Germany.

Background: Serum Ca. bone biomarkers and radiological imaging do not allow accurate evaluation of bone mineral balance (BMB), a key determinant of bone mineral density (BMD) and fracture risk. Naturally occurring stable (non-radioactive) Ca isotopes, 43Ca and 44Ca, are absorbed from our diet and sequestered into different body compartments following kinetic principles of isotope fractionation. Isotopically light 43Ca is preferentially incorporated into bone, and heavier 44Ca excreted in urine and feces. Their ratio (44/42Ca) in serum and urine gives a direct measure of BMB; 44/42Ca is higher during bone formation than bone resorption.

Methods: 44/42Ca was measured by plasma-ionization mass-spectrometry in blood, urine, feces and dialysate. The relationship between bone Ca gain and loss was calculated using a compartment model, and expressed as 44/42Ca in 128 children in CKD4-5 and on dialysis (CKD4-5D) and 117 healthy participants (age <30) underwent Ca isotopes measurement, bone biomarkers, DXA and tibial peripheral quantitative CT (pQCT), an accurate measure of cortical BMD.

Results: In healthy children the 44/42Ca Blood was higher than in adults (p=0.001), reflecting avid Ca uptake during bone formation. Since urinary Ca excretion is impaired in CKD, 44/42Ca Blood was higher and 44/42Ca Lower in CKD4-5D compared to controls (p=0.001 for both). In CKD2-5D 44/42Ca Blood positively correlated with cholecalciferol (p=0.01) and alfacalcidol (p=0.002) doses, implying increased bone Ca uptake when Ca bioavailability is increased. 44/42Ca Blood positively correlated with biomarkers of bone formation (ALK, p=0.05) and inversely with resorption markers (PTH, p=0.013; TRAP5b, p<0.001 and CTX, p=0.006). 44/42Ca Bone correlated positively with tibial cortical BMD-Z-score (p=0.006, R2=0.39), and DXA hip BMD-Z-score (p=0.02). Significant and independent predictors of tibial cortical BMD-Z-score were 44/42Ca (p=0.068, p=0.006) and PTH (p=0.39, p=0.04), together predicting 67% of the variability in BMD.

Conclusions: Ca isotope ratios provide a novel, non-invasive method of assessing bone mineralization. Defining an accurate biomarker of BMB forms the basis of future studies investigating Ca dynamics in disease states and the impact of treatments that affect bone homeostasis.

Background: Wasting is a common complication of kidney failure that leads to weight loss and poor outcomes. Recent experimental data identified parathyroid hormone (PTH) as a driver of adipose tissue browning and wasting, but little is known about the relations among secondary hyperparathyroidism (SHPT), weight loss, and risk of mortality in patients undergoing hemodialysis.

Methods: We included 42,319 participants receiving hemodialysis for at least one year in the DOPPS phases 2-6 (2002-2018). Linear mixed models were used to estimate the association between baseline PTH and percent weight change over 12 months, adjusting for country, demographics, comorbidities, and labs. Accelerated failure time models were used to assess 12-month weight loss as a mediator between baseline high PTH and mortality after 12 months.

Results: At baseline, mean (SD) body weight was 74 (22) kg and the median PTH level was 251 pg/mL (interquartile range [IQR], 131-444 pg/mL). Baseline PTH level was inversely associated with 12-month weight change: 12-month weight loss ≥5% was observed in 21%, 18%, 18%, 16%, 14% and 14% of patients for PTH ≥600 pg/mL, 450-600, 300-450, 150-300, 50-150, and <50 pg/mL, respectively. In adjusted analysis, 12-month weight change compared to PTH 150-299 pg/mL was -0.6%, -0.12%, 0.0%, 0.10%, +0.15%, and +0.35% for PTH ≥600, 450-600, 300-450, 150-300, 50-150, and <50 pg/mL, respectively (P=0.01). Interacting baseline PTH*appetite, high PTH was associated with weight loss only in persons with preserved appetite (P=0.01). During follow-up after the 12-month weight measure (median, 1.0 [IQR, 0.6-1.7] years; 6125 deaths), patients with baseline PTH ≥600 pg/mL had 11% (95% CI, 9.1-13%) shorter lifespan, and 18% (95% CI,14-23%) of this effect was mediated through weight loss ≥2.5%.

Conclusions: Our findings indicate that SHPT may be a novel mechanism of wasting in dialysis patients, corroborating experimental data, and that this pathway may be a mediator, even at elevated PTH levels and mortality. Future research should determine whether PTH-lowering therapy can limit or prevent weight loss and improve longer-term dialysis outcomes.

Background: In the CalLPSO study, SNF472 significantly attenuated progression of coronary artery calcium (CAC) volume score compared with placebo. This pre-specified analysis examined CAC progression in key subgroups.

Methods: Patients were randomized to SNF472 300 mg (n=92), SNF472 600 mg (n=91) or placebo (n=91) infused 3x/week during hemodialysis (HD) for 52 weeks on an HD vintage of 42 mo; 33% received HD for ≥5 years. Concomitant medications at baseline were: 62% non-Ca phosphate binders, 28% Ca-based phosphate binders, 31% calcimimetics, 51% activated vitamin D, 8% warfarin, or statins in the modified ITT population (mITT, defined as subjects who received at least one dose of study drug and had an evaluable post-baseline CT scan).

Results: Baseline characteristics were similar across treatment groups: mean age was 64 y, 39% were female; 62% had diabetes, and 41% had prior ASCVD. Median HD vintage was 42 mo; 33% received HD for ≥5 years. Concomitant medications at baseline were: 62% non-Ca phosphate binders, 28% Ca-based phosphate binders, 31% calcimimetics, 51% activated vitamin D, 8% warfarin, or statins in the modified ITT population (mITT, defined as subjects who received at least one dose of study drug and had an evaluable post-baseline CT scan).

Conclusions: SNF472 treatment for 52 weeks attenuated CAC progression compared with placebo in all subgroups.

Pharmacodynamic (PD) Profiling of Reloxaliase in Patients with Severe Hyperoxaluria
Felix Knauf,2,1 Danica Grujie,1 Mira T. Keddis,3 Alicia Weeks,1 Annamaria T. Kausz,1 Allena Pharmaceuticals, Newton, MA; 2University Hospital Charite, Berlin, Germany; 3Mayo Clinic Hospital, Phoenix, AZ.

Background: Hyperoxaluria is a major risk factor for kidney stones and can lead to chronic kidney disease (CKD). With decreasing kidney function, plasma oxalate (POx) rises and oxalate may deposit in the kidneys and other tissues (systemic oxalosis) leading to ESRD. Reloxaliase (REL), a non-absorbed, oxalate specific oral enzyme therapy designed to degrade oxalate along the GI tract, may potentially reduce the systemic and renal oxalate burden in patients with enteric and primary hyperoxaluria (EH and PH). This study tested the PD of REL, and addressed questions regarding potential formate accumulation (by-product of oxalate degradation) and systemic absorption of oxalate descarbosylation (OxDc, the active component of REL).

Methods: This 12-week, open label study enrolled subjects with EH, CKD and hyperoxalemia (UOx ≥40mg/dL, eGFR ≤45mL/min and POx ≥5mg/dL, n=10) and PH (UOx ≥40mg/dL, n=5) who received 7,500u of REL 5x/day with meals/snacks. Parameters assessed at baseline, and weeks 4, 8 and 12. Included POx and UOx (only if eGFR >15mL/min), plasma formic acid (pre- and post-prandial/post-dose; Q' Solutions) and OxDc (specific ELISA, Absorption Systems).

Results: Reported adverse events (AEs) were mostly GI related; there were no related serious AEs. In EH, both POx and UOx decreased substantially; in PH, UOx did not change, and POx stayed normal at baseline and during treatment (Table). There was no formate accumulation, as all samples were below or within normal range (1-9mg/L). Similarly, there was no detectable absorption of REL, as all samples were below the limit of detection of the assay for OxDc (<0.0001% of the administered dose of 37,500 u/day).

Conclusions: Reloxaliase was well tolerated; the absence of formate accumulation further supports its safety. The lack of REL absorption, in addition to supporting low potential for systemic toxicity, confirms its site of action within the GI tract. This best aligns with the pathophysiology of EH as evidenced by the substantial reduction in both POx and UOx in EH subjects with CKD/ESRD.

Efficacy and Safety of Upacicalcet in Hemodialysis Patients with Secondary Hyperparathyroidism: A Phase 3 Study
Tadao Akizawa,1 Daisuke Honda,2 Masaki Taniguchi,3 Fumihiko Koiwa,4 Showa University School of Medicine, Tokyo, Japan; 2Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; 3Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; 4Showa University Fujigaoka Hospital, Yokohama, Japan.

Background: Secondary hyperparathyroidism (SHPT) is a major complication of hemodialysis (HD) patients. Calcimimetics suppress the hyperfunction of parathyroid and reduce serum calcium and phosphorus levels, and are currently used for the treatment of SHPT. Upacicalcet (UPA) is a novel intravenous small molecule calcimimetic in late-stage development in Japan to treat SHPT of HD patients. We report the efficacy and safety of UPA in HD patients.

Methods: This study was a phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group study. UPA or placebo (PBO) was administered t.i.w. at the end of HD at an initial dose of 50 mcg or 25 mcg. The doses were subsequently adjusted to achieve a mean iPTH level of 60-240 pg/mL in weeks 22 to 24.

Results: A total of 154 SHPT patients were enrolled, and randomly allocated to UPA group (n= 103) or PBO group (n= 51). The primary endpoint, percentage of patients achieving the target iPTH range was greater for UPA (67.0%) than for PBO (8.0%) (P<0.001). UPA significantly reduced iPTH and cCa levels compared with PBO (Fig.). Concerning phosphorus, no statistically significant difference between the groups was observed while it tended to decrease in the UPA group. In the safety assessment, treatment emergent adverse events (AE) occurred in 88 patients (85.4%) and 36 patients (72.0%) in the UPA and the PBO groups. The incidences of upper-gastrointestinal-related AE were 20.4% in the UPA and 18.0% in the PBO groups (P=0.8298). As an AE, hypocalcemia did not occur in either group.

Conclusions: This study demonstrates that UPA significantly decreases iPTH without increasing the incidence of upper-gastrointestinal symptoms as compared to PBO. It is suggested that UPA will be a promising calcimimetic agent capable of safe and appropriate management of SHPT.

Primary Cilia and the Glycocalyx Are Flow Sensors for Nitric Oxide Production by Thick Ascending Limbs

Jeffrey L. Garvin, Nancy J. Hong. Case Western Reserve University, Cleveland, OH.

Background: The primary cilium is an organelle found on essentially all epithelial cells. Similarly, the glycocalyx is a matrix-like layer of proteoglycans, glycosaminoglycans (GAGs) and proteins covering the surface of all cells. In vascular endothelial cells, primary cilia and GAGs such as heparan sulfate and chondroitin sulfate mediate responses to the mechanical forces exerted by blood flow. In thick ascending limbs, increases in luminal flow enhance nitric oxide (NO) production, an important regulator of the kidney function including sodium reabsorption; however, the role of primary cilia and the glycocalyx in NO production by thick ascending limbs is unknown. We hypothesized that primary cilia and the glycocalyx act as flow sensors and thus mediate flow-induced NO production by thick ascending limbs.

Methods: We measured flow-induced NO in isolated rat thick ascending limbs using DA-FM. Intracellular NO was first measured during the control period without and with luminal flow. NO was measured again during the experimental period after treatment with 15 min to deciliate cells or to degrade major glycocalyx GAGs. Dibucaine (0.1 mM) was used to remove cilia from cells. Heparinase III (0.2 or 0.4 U/ml) and chondroitinase ABC (0.2 U/ml) were used to degrade heparan sulfate and chondroitin sulfate, respectively.

Results: In untreated control tubules, flow-induced NO did not differ between the two periods, 4.3 ± 0.1 vs. 4.6 ± 0.74 AU/min (p = 0.087). Dibucaine decreased flow-induced NO from 4.2 ± 0.62 to 1.19 ± 0.65 AU/min (p = 0.002). Heparinase (0.2 U/ml) attenuated flow-induced NO from 4.02 ± 0.84 to 1.70 ± 0.74 AU/min (p < 0.04); a higher concentration (0.4 U/ml) caused a greater effect (2.7 ± 1.35 vs. 1.24 ± 0.84 AU/min; p < 0.006). Heat inactivation of heparinase (0.2 U/ml) abolished its effect (3.01 ± 0.34 to 2.83 ± 0.22 AU/min). Chondroitinase (0.2 U/ml) decreased flow-induced NO from 4.17 ± 0.96 to 2.45 ± 0.49 AU/min (p < 0.038).

Conclusions: We conclude that both primary cilia and the glycocalyx act as flow sensors in thick ascending limbs and transduce mechanical stimuli into chemical signals that ultimately result in NO production by this segment.

TH-OR22
Cell-Autonomous Expression of Membrane Transport Proteins in Mammalian Distal Nephron

Background: Reabsorption of NaCl in kidney thick ascending limb (TAL) via NKCC2 involves the action of luminal (ROMK) and basolateral (Kir4.1/Kir5.1) multimeric potassium channels, a basolateral calcium sensing receptor (CaSR), and the claudin (Clnd) family of proteins. Morphologically heterogeneous TAL cells have been reported, as well as mosaic expression of ROMK and Kir4.1. We hypothesized that this variability between TAL cells extends to other aspects of their function.

Methods: We studied TAL EM morphology, zonal and cell-autonomous heterogeneity of the transport proteins at steady state in mice, rats and humans, and under stimulation by vasopressin (AVP; V2R agonist dAVP for 72 h) using AVP-deficient Brattleboro rats. NKCC2, phosphorylated (p) NKCC2, ROMK, Kir4.1, CaSR, Clnd-10 and Clnd-16 signals were immunofluorescent, in situ hybridisation (ISH), EM and Western blot (WB).

Results: Between cortex and medullary kidney zones, TAL morphological cell heterogeneity was observed, but not at a cell-to-cell level within each zone. NKCC2 was continuously expressed in all TAL cells, while pNKCC2 signals were heterogeneous, increasing from inner stripe of outer medulla to cortex and varying between cells of each zone. ROMK and Kir4.1 protein expression showed conspicuous heterogeneity in a mutually exclusive pattern, with stronger pNKCC2 expression in the ROMK-negative and Kir4.1-positive cell type. CaSR and Clnd-16 signals were moderate to absent in ROMK-positive cells, but intensified in ROMK-negative cells, while Clnd-10 was strongly expressed only in ROMK-positive cells. ISH revealed no cell heterogeneity of ROMK mRNA. In Brattleboro rats, 72 h dAVP increased the number of ROMK- and Kir4.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 phosphorylation. Clnd-10 expression was induced in the outer stripe of outer medulla. Morphological alterations in the TAL included proliferation of microvilli. WB showed 2.2-fold increase of ROMK and 1.3-fold increase of Kir4.1 abundance, but down-regulation of CaSR by 60%.

Conclusions: These results demonstrate mosaic expression of ROMK, Kir4.1, CaSR, Clnd-10, and Clnd-16 in TAL, which correlate with cell-heterogeneous levels of NKCC2 activation.

TH-OR23
Optical Clearing and 3D Imaging Reveal a Sexual Dimorphism in the Structure and Remodeling Response of the Distal Convoluted Tubule
Seyedmohammadebrahim Tahaei, Richard A. Coleman, Turgay Saritas, David H. Ellison, Paul A. Welling. Johns Hopkins University School of Medicine, Baltimore, MD; Oregon Health & Science University Oregen Clinical & Translational Research Institute, Portland, OR; University Hospital RWTH, Aachen, Germany.

Background: The abundance of the distal convoluted tubule (DCT) thiazide-sensitive sodium chloride cotransporter (NCC) is greater in females than males. Because structural remodeling of the DCT is dependent on NCC activity, it has been generally assumed that there is a corresponding sexual dimorphism in DCT morphology. Until now, this has never been directly examined. Here, combining new optical clearing techniques with stereoscopic renderers of DCT segments, volumetric imaging we quantitatively assess DCT morphology in male and female mice and study remodeling response to furosemide.

Methods: Male and Female (3-month-old) mice were treated with vehicle or Furosemide administered in the food (100 mg/kg per day) for seven days. Total NCC and phospho-active NCC abundance (pNCC) was evaluated by Western Blot in one kidney, the other kidney was perfused and fixed for imaging. Kidneys were cleared using the Clear, Unobstructed Brain/Body Imaging Cocktails and Computational Analysis (CUBIC) pipeline, co-stained with antibodies that label the early DCT (DCT1, parvalbumin) and the entire DCT (DCT2 & NCC), imaged using a high-speed spinning disc confocal microscope, and processed with 3D rendering and analysis software (IMARIS).

Results: We confirmed previous studies that females have greater NCC abundance in the basolateral cell. Surprisingly, the length of the DCT was longer in males (~620 μm) than female mice (~560 μm). Furosemide treatment significantly increased the abundance of NCC and pNCC in both sexes with a parallel increase in NCC abundance and volume. The remodeling response to furosemide was more profound in females (~20% increase in DCT length and 50% in DCT1 volume) than males (~8% and 30%, respectively). The DCT elongation effect of furosemide treatment in females stemmed largely from an increase in DCT1 length. Furosemide expanded the DCT2 significantly in males but not females.

Conclusions: Our study reveals a surprising sexual dimorphism of the DCT. The greater NCC density in a shorter structure may provide a means for females to protect sodium balance in face of greater basal distal sodium delivery, yet have larger reserve and remodeling capacity to adapt to unique physiological stresses.

Positive Allosteric Modulation of the Calcium-Sensing Receptor (CaSR) by Glucose or Fructose Induces Activation of the Sodium-Chloride Cotransporter (NCC)
Jessica P. Bahena-Lopez, Lorena L. Rojas, Silvana Bazzu-Valenti, Norma H. Vázquez, María Chavez-Canales, María Castañeda-Bueno, Maqdalenia Madero, Gerardo Gamba, Molecular Physiology Unit, INCNMS and IIB, UNAM, Mexico City, D.F., Mexico; Translational Medicine Unit, INCHIC and IIB, UNAM, Mexico City, D.F., Mexico; Instituto Nacional de Cardiología Ignacio Chavez, Mexico City, D.F., Mexico; PECEM, Faculty of Medicine, UNAM, Mexico City, D.F., Mexico.

Background: NCC is activated via the CaSR-WNK4-SPAK pathway. Glucose and other sugars act as positive allosteric modulators of the CaSR. This might be relevant in the distal convoluted tubule (DCT), since glucose is reabsorbed proximally and proximal delivery to the DCT depends largely on dietary intake. Here we studied positive allosteric modulation of the CaSR by glucose/fructose induces NCC activation via CaSR-WNK4-SPAK.

Methods: We used 1) HEK-293 cells cotransfected with SPAK, WNK4 and/or CaSR and NCC (or the non-catalytic WNK4-SPAK). This was paralleled by an expansion of the DCT length (~20% increase in DCT length and 50% in DCT1 volume) than males (~8% and 30%, respectively). The DCT elongation effect of furosemide treatment in females stemmed largely from an increase in DCT1 length. Furosemide expanded the DCT2 significantly in males but not females.

Conclusions: Our study reveals a surprising sexual dimorphism of the DCT. The greater NCC density in a shorter structure may provide a means for females to protect sodium balance in face of greater basal distal sodium delivery, yet have larger reserve and remodeling capacity to adapt to unique physiological stresses.

Funding: NIDDK Support, Private Foundation Support
first evidence of NCC activation via CaSR with cinacalcet in humans. Our results suggest that the presence of glucose or fructose in DCT could increase the activity of NCC via CaSR-WNK4-SPAK pathway.

Cross-Talk Between Epithelial Sodium Channel and Basolateral Kir,4.1/ Kir,5.1 Channels in the Cortical Collecting Duct

Oleg Palygin,1 Elena Isaeva,2 Vladimir Levchenko,2 Jerod S. Denton,3 Alexander Staruschenko.1

1Medical College of Wisconsin, Milwaukee, WI; 2Clement J. Zablocki VA Medical Center, Milwaukee, WI; 3Vanderbilt University Medical Center, Nashville, TN.

**Background:** The growing body of evidence suggest that inwardly rectifying K+ (Kir) channels located on the basolateral membrane of epithelial cells in the distal nephron play a crucial role in K+ handling and blood pressure control, making these channels attractive targets for the treatment of hypertension. The purpose of the present study was to determine how the inhibition of basolateral Kir,4.1 homomeric or Kir,4.1/Kir,5.1 heteromeric K+ channels affects ENaC-mediated Na+ transport in the cortical collecting duct (CCD) principal cells.

**Methods:** Electrophysiological approaches were used to test the effect of fluorescent amitriptyline, and recently developed Kir,4.1 inhibitors, VU0134992, on the activity of Kir,4.1, Kir,4.1/Kir,5.1, and ENaC. Channel activity was recorded in CHO cells transfected with respective channel subunits, cultured polarized epithelial mCCD,2 cells, and native freshly isolated rat and human CCD tubules. To test the effect of pharmacological Kir,4.1/Kir,5.1 inhibition on electrolyte homeostasis in vivo, Dahl salt-sensitive rats were injected with amitriptyline (15 mg/kg/day).

**Results:** We found that inhibition of Kir,4.1/Kir,5.1, but not Kir,4.1 channel, substantially suppresses both amiloride-sensitive I_K in mCCD,2 cells and single-channel ENaC activity in principal cells of rat and human CCD tubules. Furthermore, we demonstrate that i.p. injection of Kir,4.1/Kir,5.1 antagonist for three days leads to a significant drop in plasma K+ level, triggering sodium excretion, and diuresis.

**Conclusions:** These data uncover a putative mechanism underlying a renal control of blood electrolytes mediated by Kir,4.1/Kir,5.1 and introduce a new molecular target for the treatment of salt-sensitive hypertension.

**Funding:** NIDDK Support, Other NIH Support - NIDDK R56 DK121750 (to O.P.); NHLBI R01 DK120821 (to J.S.D. and A.S.) and R35 HL135749 (to A.S.), Veterans Affairs Support, Private Foundation Support

CIC-K2 Chloride Channel Determines Acid-Base Transport and Chloride Reabsorption in Intercalated Cells of the Collecting Duct

Naughtme Hassanzadeh Khavvatz, Victor N. Tomilin, Oleg L. Zaika, Oleh Pochynyuk. University of Texas John P and Katherine G McGovern Medical School, Houston, TX.

**Background:** Intercalated cells (ICs) of the collecting duct (CD) play a critical role in regulation of systemic acid-base homeostasis. In addition, ICs are capable of performing trans-cellular Cl− reabsorption particularly during volume depletion. While the major apical membrane transport systems are well characterized, little is known about mechanisms and contribution of the basolateral membrane in both processes. Kidney specific CIC-K2 is expressed in the basolateral membrane of the distal nephron segments, including the CD.

**Methods:** We generated CIC-K2 deficient mice using cre-loxP strategy to investigate the role of the channel in acid-base and Cl− transport. We combined BCECF-sensitive intracellular pH (pH) measurements with fluorescent AQ2P2-based identification of principal cells (PCs) and ICs to assess CIC-K2-dependent pH changes in different cell types.

**Results:** CIC-K2 inhibition with NPPB (100 μM) had no effect in PCs of WT mice, whereas it induced rapid intracellular acidification in B-type and alkalinization in A-type of ICs. NPPB failed to significantly affect pH in CDVs from CIC-K2 deficient mice. Extracellular Cl− removal to drive basolateral Cl− exit via CIC-K2 had no effect on pH in PCs, but caused alkalization in B-type and acidification in A-type of ICs. Importantly, Cl− removal did not induce pH changes in both A- and B-type of ICs from CIC-K2 deficient mice. This suggests that CIC-K2 mediates trans-cellular Cl− reabsorption and determines apical acid-base transport by controlling intracellular Cl− concentration. Moreover, application of Angiotensin II (Ang II, 500 nM) had no effect in WT but not CIC-K2 deficient mice. Furthermore, CIC-K2 activity (measured as NPPB-dependent pH changes) was increased in A-type but decreased in B-type of ICs, overall favoring urinary acidification in WT mice.

**Conclusions:** Altogether, our results show that CIC-K2 is central for acid-base transport in the CD. CIC-K2 activity can be independently regulated in A- and B-type of ICs during different physiological conditions to allow fine tuning of renal acid-base handling.

Evolutionary Conserved TLDc Domain Defines a New Class of V-ATPase Interacting Proteins

Amyt F. Eaton, Dennis Brown, Maria Merkulova. Program in Membrane Biology Massachusetts General Hospital, Boston, MA.

**Background:** Kidney-specific V-ATPase regulates acid-base homeostasis, and its dysfunction causes distal renal tubular acidosis (dRTA). We recently found that nuclear receptor coactivator 7 (Ncoa7) interacts with kidney V-ATPase, and its deletion in mice resulted in dRTA. Ncoa7 belongs to a group of proteins playing a role in the oxidative stress response, that contain the evolutionarily conserved TLDc domain. We found that another of these proteins, Oxr1, also interacts with the V-ATPase. Here we asked if other proteins from this family, i.e. Tbc1d24, Tdcl1 and Tdcl2 interact with V-ATPase in kidney and if their TLDc domains mediate this interaction.

**Methods:** Interaction between endogenous Tbc1d24, Tdcl1 and Tdcl2 and V-ATPase was assessed by co-immunoprecipitation (co-IP) and western blotting of mouse kidney lysates. Interaction with the V-ATPase was also studied by GST pull-downs from kidney lysates using purified GST-tagged wild-type TLDc domains of Ncoa7, Oxr1, Tbc1d24, Tdcl1 and Tdcl2, or mutant TLDc domains of Ncoa7 (G802A, G815A, S817A, G845A, G896A, L926A, E938A) followed by western blotting for B1.

**Results:** In Co-IP studies of mouse kidney lysates we found that endogenous Tbc1d24 interacted with the B1 subunit isoform of V-ATPase, but not with the more ubiquitous B2 subunit isoform. However, we did not detect any interaction between V-ATPase and endogenous Tdcl1 or Tdcl2 in Co-IPs, possibly due to low sensitivity of the anti-Tdcl1 and anti-Tdcl2 antibodies. Additionally, we found that the purified TLDc domains of Ncoa7, Oxr1 and Tdcl2, but not Tbc1d24 or Tdcl1, interacted with V-ATPase in GST pull-downs. Finally, the G815A, G845A and G896A mutants in evolutionarily conserved regions of the Ncoa7 TLDc domain did not interact with V-ATPase, L926A and E938A mutations resulted in a decreased interaction, while S817A or the non-conserved G802A mutation (used as a positive control), did not decrease interaction at all.

**Conclusions:** In the kidney, Tbc1d24 and possibly Tdcl2, as well as Ncoa7 and Oxr1, interacted with V-ATPase and may play a role in the V-ATPase-dependent regulation of renal acid-base homeostasis. We conclude, that the TLDc motif is a protein-protein interaction domain that defines a new class of V-ATPase interacting regulatory proteins. The evolutionarily conserved amino acids within the TLDc domain of Ncoa7 are critical for its interaction with the V-ATPase.

Lysine Acetylation of Aquaporin 3 Affects Water Permeability of the Collecting Duct

Kelly A. Hyndman, Parker R. Davis, Luciano D. Mendoza. The University of Alabama at Birmingham School of Medicine, Birmingham, AL.

**Background:** We recently reported that there are > 400 proteins in the inner medullary collecting duct (IMCD) that are post-translationally lysine acetylated (ac), including the basolateral water channel, aquaporin-3 (AQ3P). The purpose of this study was to determine if lysine acetylated AQ3P (acAQ3P) affects water permeability.

**Methods:** We developed an antibody to detect acAQ3P and found acAQ3P localized to the basolateral membrane of the cortical and outer medullary CD in mice and human kidney biopsies. In mice, following 24 h of water deprivation, acAQ3P was also found in the IMCD. Next, we developed AQ3P K point mutation plasmids; an acetylated mimetic K282Q (AQ3P<sup>384</sup>), and a deacetylated mimetic K282R (AQ3P<sup>384</sup>). These were stably expressed in vasoressin-responsive mouse cortical CD cells and loaded with a volume sensitive dye. Finally, using CRISPR/CAS we engineered whole body point mutation mice. The AQ3P<sup>384</sup>, AQ3P<sup>385</sup> and littermate controls AQ3P<sup>384/385</sup> were placed on standard chow and: 1) ad lib water, 2) 5% sucrose water for hydration, or 3) 24 h water deprivation and urine flow measured.

**Results:** Following osmotic stimulus, we found AQ3P<sup>385</sup> cells had the highest water permeability followed by the AQ3P<sup>384/385</sup> cells and the AQ3P<sup>384</sup> cells. From our mutant mice, as adults, control and AQ3P<sup>385</sup> mice had similar urine flow on all protocols. However, the AQ3P<sup>384</sup> mice produced double the urine on protocols 1 and 2. Thus, maintenance of deacetylated AQ3P enhances fluid excretion under normal and hydrated conditions. To further determine whether the increased urine flow was due to impaired water permeability, we immunolocalized AQ3P and AQ2 under ad lib conditions. AQ3P<sup>384</sup> mice had enhanced expression of AQ3P in the basolateral membrane, and reduced AQ2 expression in the apical membrane. In contrast, the AQ3P<sup>385</sup> mice had diffuse AQ3P localization in the CD, with no obvious change in AQ2P.

**Conclusions:** Together, these preliminary data suggest that acAQ3P promotes localization to the basolateral membrane of the CD and supports the hypothesis that acAQ3P could serve as an important regulator of CD function in fluid homeostasis.

Role of TRPC3 in the Control of Osmosensitivity and Renal Water Handling in the Mouse Collecting Duct

Vitor N. Tomlin,1 Mykola Mamenko,2 Nagmeh Hassanazadeh Khayat,3 Oleg L. Zaka,3 Oleh Pochynyuk,4 University of Texas John P and Katherine G McGovern Medical School, Houston, TX; 2Augusta University Medical College of Georgia, Augusta, GA.

Background: Kidney is central in the control of systemic water balance of the organism. A VP facilitates aquaporin 2 (AQP2) translocation to the apical membrane and arterial blood pressure, determining systemic cardiovascular response.

Methods: We performed an experimental randomized cross-over study in 8 DM1, 9 HME, and 12 healthy males with similar age, BMI and eGFR. All subjects followed 7 HME, and 12 healthy males with similar age, BMI and eGFR. All subjects followed normal daily activity and diet. A 12-h overnight fast was induced, and in the morning, a baseline blood sample was collected. After 2 h, subjects were randomized to receive an equal volume of a 5% dextrose solution to increase plasma osmolality. A second blood sample was collected after 3 h, and the 3 h was performed 3 times in a randomized order. Blood analysis included, among others, plasma creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality.

Results: In response to HSD, controls showed a hypertonicity-driven response with disturbed GAGs. In controls during HSD, dermal NFAT5 was associated with several risk factors and an increased overall mortality. Prophylactic A VP levels when compared to WT. Furthermore, osmosensitive extracellular ([Ca^{2+}]_i) elevations were greatly increased in CD of wild type and TRPC3 -/- mice; however, only modestly increased in TRPC3 -/- mice under the same conditions. Using immunofluorescence microscopy, we found that AQP2 translocated to the apical plasma membrane in WT, while maintaining mostly cytosolic localization in TRPC3 -/- after 24 h WD. A VP increased dermal NFAT5 expression in controls, whereas in DM1, and HME no changes were observed (Fig1A). In controls, HSD also increased averagely plasma osmolality were negatively correlated in controls (Fig1C).

Conclusions: In response to HSD, controls showed a hypertonicity-driven increase in plasma osmolality. No hypertonicity-driven changes could be observed in the skin of patients with disturbed GAGs. Disturbed GAGs in controls during HSD, dermal NFAT5 expression and GAG sulfation patterns were semi-quantitatively analyzed by researchers blinded for diet status. Results: HSD increased dermal NFAT5 expression in controls, whereas in DM1 and HME no changes were observed (Fig1A). In controls, HSD also increased averaged sulfated heparan sulfate in the dermis (Fig1B). During HSD, dermal NFAT5 expression and plasma osmolality were negatively correlated in controls (Fig1C).

Conclusion: Our results support the hypothesis that dermal NFAT5 expression and GAG sulfation patterns are important for the skin’s osmoregulatory responses to a HSD.

Distinct Cellular Osmoregulatory Response in the Skin of Patients with Disturbed Glycosaminoglycan Biosynthesis

Iletta J. Oppelaar,1 Elke Wensnedt,2 Nienke M. Rorije,3 Rik H. Olde Engberink,1 Bert-jan van den born,3 Eliane Liffert1.

Background: Studies have shown that during high Na+ diet (HSD) sodium content of the skin increases. Nuclear factor of activated T cells 5 (NFAT5) is a hypertonicity-driven transcription factor responsive to environmental osmotic changes.

Methods: We performed an experimental randomized cross-over study in 8 DM1, 7 HME, and 12 healthy males with similar age, BMI and eGFR. All subjects followed normal daily activity and diet. A 12-h overnight fast was induced, and in the morning, a baseline blood sample was collected. After 2 h, subjects were randomized to receive an equal volume of a 5% dextrose solution to increase plasma osmolality. A second blood sample was collected after 3 h, and the 3 h was performed 3 times in a randomized order. Blood analysis included, among others, plasma creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality. Renal function was assessed using the 24 h urine collection of creatinine, sodium, potassium, and osmolality.

Results: In response to HSD, controls showed a hypertonicity-driven response in skin tissue. No hypertonicity-driven changes could be observed in the skin of patients with disturbed GAGs. Disturbed GAGs in controls during HSD, dermal NFAT5 expression and GAG sulfation patterns were semi-quantitatively analyzed by researchers blinded for diet status. Results: HSD increased dermal NFAT5 expression in controls, whereas in DM1 and HME no changes were observed (Fig1A). Immune Checkpoint Inhibitor Use in Kidney Transplant Recipients: A Multicenter Study

Naoka Murakami,1 Leonardo V. Rieila,2 Rimda Wanchoa,2 Vinay Nair,2 Kenar D. Jhaveri.1 Immune Checkpoint Inhibitor in Solid Organ Transplant Consortium ‘Brigham and Women’s Hospital, Boston, MA;’ Northwell Health, Great Neck, NY.

Background: Immune checkpoint inhibitors (ICIs) significantly improved the survival in many cancers, but the data on survival benefit in KT recipients are lacking. ICIs are reported to be associated with higher acute rejection rate in KT recipients, but the risk factors of ICI-associated rejection are not fully understood.

Methods: We conducted a multicenter observational study to investigate the clinical characteristics of ICI-associated rejection and the survival outcomes of KT recipients treated with ICI. 66 KT recipients with a functioning allograft at the time of ICI initiation were collected from 18 institutions. In addition, historical control groups of KT recipients with advanced stage melanoma (AICC stage III-IV, n=17) and cutaneous squamous cell carcinoma (cSCC, AICC stage III, n=23), could be considered as potential ICI candidates, were collected to compare the overall survival (OS).

Results: In ICI cohort, median age was 64, male dominant (83%) and transplant to ICI initiation was median 11 years. cSCC was the most frequent malignancy (n=22), followed by melanoma (n=28) patients (42.4%) experienced rejection, of whom 28 (64.2%) lost allograft and returned to dialysis. Median time from ICI initiation to rejection was 26 days. In biopsy-proven rejection (n=13), both mixed acute cell and antibody-mediated rejection (n=7, 53%) and acute cell-mediated rejection (n=6, 47%) were seen. By Chi square test, mTOR inhibitor use (P=0.012) and the use of higher number of immunosuppression drugs (P=0.038) were associated with lower risk of rejection. For both melanoma and cSCC cohort, ICI groups experienced higher rejection rate (57% and 40%, for melanoma and cSCC, respectively) compared to non-ICI control groups (12% and 4.3%), suggesting the higher rejection rate in ICI groups was not solely explained by reduction in immunosuppression. OS didn’t show statistical difference in melanoma cohort (log rank test P=0.22), but OS was significantly longer in cSCC cohort (log rank test P=0.015), when compared ICI vs non-ICI control groups.

Conclusions: Our multi-center study provides a novel data on the survival benefit and the risk factors of rejection in KT recipients with ICI use compared to non-ICI control groups.

Kidney and Cancer Outcomes with Standard vs. Kidney Protective Chemotherapy Regimens for First-Line Treatment of Metastatic Urothelial Carcinoma

Gabrielle Côte,1 Husam A. Alqaisi,1 Srikala S. Sriridhar,2 Abhijat Kitchlu.2 1University of Toronto, Toronto, ON, Canada; 2Toronto General Hospital, Toronto, ON, Canada; 3Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada.

Background: Cisplatin-based combination chemotherapy regimen is the optimal initial treatment for metastatic urothelial carcinoma, but kidney function eligibility and nephrotoxicity are treatment-limiting for many patients. For patients unfit to receive cisplatin, other options include alternative administration schedules (e.g. split dose cisplatin), carboplatin-based regimens and non-platinum regimens. The aims of this study were to compare cancer outcomes and incidence of acute kidney injury (AKI) during treatment among 3 regimens of chemotherapy.

Methods: We conducted a single-center retrospective study of patients receiving first-line chemotherapy for metastatic urothelial carcinoma (2005-2019). We compared standard gemcitabine-cisplatin (gem-cis) to: 1) gemcitabine-cisplatin split dose regimen (split) with cisplatin divided over day 1 and 8, and 2) combination of gemcitabine-carboplatin or single-agent gemcitabine (gem-carbo). We used Fine and Gray hazard evaluation models accounting for baseline covariates and competing risk of death.

Results: Overall, 34 patients (31.5%) (mean age 61.7 years, 65% men, 80% tobacco users) experienced a platinum salt-induced AKI (67% grade 1) and 47 (43.5%) died during follow-up (6.2 months [3.8; 8.4]). The group of high-cisplatin consumption (a 386mg/day) had a twice higher risk of AKI (HR=2.12 [1.01; 4.45]) in the full adjusted model. The cumulative incidence of AKI (considering the competing risk of death) was also significantly increased in the high-cisplatin consumption group (p=0.03, see figure 1).

Conclusions: In a population of thoracic cancer patients, the group of high-cisplatin consumption was exposed to a significantly higher risk of platinum salt-induced AKI.
Results: We identified 183 patients (98 gem-cis, 32 split and 53 gem/gem-cis). Median age was 67 years (IQR: 61-73) and gem-cis was 78 mL/min/1.73m² (IQR: 66-91) in gem-cis, 64 (48-77) in split, and 45 (33-57) in gem-gem-cis. Patients receiving split and gem-gem-cis were older, had worse performance status, and hypertension was more frequent. Split and gem-gem-cis regimens were associated with higher mortality and progressive disease relative to gem-cis when adjusted for age, baseline eGFR, ECOG, hypertension and diabetes with hazard ratio (HR) of 1.56 (95%CI: 1.04-2.34; p=0.03) and 2.02 (95%CI: 1.36-3.01; p<0.01) respectively. Median time to progressive disease was 242 (IQR: 137-444) days and 122 (79-279) and 131 (68-257) days in gem-cis, split and gem-gem-cis groups respectively. There was no significant association between regimen type and AKI with HR of 1.32 (95%CI: 0.62-2.81; p=0.47) and 0.98 (95%CI:0.46-2.09; p=0.96) for split and gem-gem-carbo groups versus gem-cis.

Conclusions: Kidney protective chemotherapy regimens were associated with increased disease progression and mortality, without a significant difference in AKI. Alternative kidney protective strategies are needed for patients with CKD and urothelial cancer.

Conclusions: A presence of a baseline P/Cr greater than 0.25 g/g, type 2 diabetes, and CKD III, all showed a significant increase in risk of progressing to proteinuria of greater than 1.0 g/g. Age and hypertension were not associated with increased risk. Due to lack of randomization and incomplete data, further analysis is needed.

CKD Prevalence, Patterns of Treatment, and Outcomes in Patients with Cancer: A Population-Based Cohort Study

Abhijat Kitchlu,1 Bin Luo,2 Nivethika Jayakumar,3 Amit X. Garg,4 Eitan Amir,5 José Kim,6 Ron Wald.1
1University Health Network, Toronto, ON, Canada; 2Institute for Clinical Evaluative Sciences, London, ON, Canada; 3London Health Sciences Centre, London, ON, Canada; 4St. Michael’s Hospital, Toronto, ON, Canada.

Background: Chronic kidney disease (CKD) may impede optimal cancer treatment and result in worse outcomes. There are limited data to assess receipt of systemic therapy, radiotherapy, and palliative care in patients with cancer and CKD.

Methods: We conducted a population-based cohort study of all patients (n=18 years old) with a new cancer diagnosis in Ontario, Canada (2007-2015). We categorized patients according to CKD status at cancer diagnosis [estimated glomerular filtration rate (eGFR) <60 (referent group), 45-59, 30-44, 15-29, <15 mL/min/1.73m², dialysis and transplant recipients]. We used multivariable Fine and Gray proportional hazards models to assess overall survival, receipt of systemic therapy, radiation and palliative care (6-months prior to death) in the 5 most common solid cancers (bladder, breast, colon, prostate, lung) and kidney cancer.

Results: We identified 128,489 patients with a new cancer diagnosis, of whom 16% had pre-existing CKD (eGFR <60 mL/min/1.73m²). Patients with the 6 cancers of interest accounted for 73% (93,751). Kidney function at cancer diagnosis was associated with progressively worse overall survival in CKD stages 3a-5, dialysis, and transplant recipients (Figure a). Increasing CKD stage was associated with significantly reduced receipt of all treatment modalities [systemic therapy, radiation and palliative care (Figure b-d)]. Patients receiving dialysis had 2-fold increased mortality in bladder, breast and ovarian cancers, and 3-fold mortality in kidney cancer.

Conclusions: In patients with cancer, CKD is associated with reduced exposure to systemic, radiation and palliative treatments and worse overall survival. Strategies to improve cancer care in the CKD population are needed.

TH-OR38

Risk Factors for Nephrotoxicity with High-Dose Methotrexate (HDMTX) in Haematological Malignancies

Background: HDMTX is a key component for treatment of haematological malignancy. Nephrotoxicity remains a significant risk factor for HDMTX and therefore, hyperhydration and urinary alkalinisation are employed in an attempt to prevent or mitigate it but despite these measures, nephrotoxicity remains 2-12%. Determination of risk factors is key in order to further stratify and ameliorate the risk of acute kidney injury.

Methods: A retrospective review of the electronic medical record was conducted to identify patients with leukaemia or lymphoma who received HDMTX from 1/1/2002 to 12/31/18. We characterised the incidence of AKI using the acute kidney injury network criteria, and the time to AKI. We assessed key baseline demographics, underlying malignancy, delivered MTX dose, and previous nephrotoxicity. Significant factors on univariate analysis were further assessed on Multivariate analysis. Analysis was performed on Minitab.

Results: We identified 3091 cycles of HDMTX with lymphoma accounting for 90.7% of cases. The incidence of AKI was 19.1% in the lymphoma cohort and 13.6% in the leukaemia cohort (p=0.023). The median time to AKI grade shortened with higher severity of AKI (p<0.001). In those with AKI N3, creatinine increased to this level in a median time of 1 day. All patients requiring dialysis (n=7) developed an AKI at day 1 post HDMTX. Univariate analysis revealed age (p=0.022), Gender (p=0.001), higher BSA (p=0.001), type of malignancy (p=0.023), nephrotoxicity on previous dose (p=0.001), cycle number (p=0.001), GFR by Cockroft-Gault (p=0.016) and 48-hour MTX level (p=0.001). There was no association between AKI and MTX dose (p=0.225), or GFR by Cockroft-Gault (p=0.016), type of malignancy (p=0.023), nephrotoxicity on previous dose, diagnosis of lymphoma, elevated 48-hour MTX level and earlier cycle.

Conclusions: Nephrotoxicity remains a significant complication with HDMTX despite current peptide measures. High grade AKI occurs early post HDMTX and therefore, risk stratification is vital. Our study identified key risk factors as older, male, AKI on previous dose, diagnosis of lymphoma, elevated 48-hour MTX level and earlier cycle.

Assessment of Estimated Glomerular Filtration Rate in a Cohort of 1200 Cancer Patients Using Serum Creatinine and Cystatin C

Veronica T. Costa e Silva,1 Luiz A.Gil,2 Renato A. Caires,1 Elerson Costalonga,1 George B. Coura-Filho,3 Gilberto Castro,1 Lesley A. Inker,1 Paul Mathew,2 Andrew S. Levey,2 Emmanuel A. Burdman,3 1University of São Paulo School of Medicine, São Paulo, Brazil; 2Tufts Medical Center, Boston, MA; 3University of São Paulo School of Medicine, São Paulo, Brazil.

Background: eGFR using creatinine (eGFRcr) with the CKD-EPI equation is recommended as the first test for GFR evaluation in clinical practice, but CG equation is commonly used for the prescription of chemotherapies, despite increasing evidence of its inaccuracy compared to measured GFR (mGFR). eGFR using cystatin C (eGFRcys)
is less influenced by muscle mass or nutritional status, and eGFR using both markers (eGFRcr-cys) is more accurate than either eGFRcys or eGFRcys-cys, but not widely assessed in cancer patients. Our aim is to compare the performance of eGFR equations (Table) in cancer patients compared to mGFR.

**Methods:** This analysis is a cross-sectional evaluation of a prospective cohort of cancer patients in treatment at the ICTSP mGFR was determined by plasma clearance of $^{125} $I-ETA indexed for body surface area.

**Results:** A group of 1,200 patients recruited between April 2015 and September 2017. Patients were 60 (51 – 68) y, 50.8% male. The most common cancer sites were breast (22.6%), prostate (19.8%) and gastrointestinal (13.4%). All eGFRcr equations overestimated mGFR with varying bias, CG had the lowest precision and was least accurate. eGFRcys underestimated mGFR and eGFRcys-cys had minimal bias and was the most accurate of all equations (Table).

**Conclusions:** All eGFR equations overestimated mGFR in our study. CG was the least accurate and should not be preferred over CKD-EPI. eGFRcys-cys is more accurate and can be used as a confirmatory test.

**Spatial Transcriptomics (ST): Integrating Molecular Profiles with Histomorphology in Kidney Tissue Sections**

Arti M. Raghubar,1 Duy T. Pham,2 Xiao Tan,2 Laura F. Grice,1 Pui Yung Lam,3 Joanna Crawford,1 Stacey Andersen,1 Sohye Yoon,1 Samuel E. Holland,1 Leo Francis,1 Alexander N. Combes,2 Andrew J. Kassianos,2 Helen G. Healy,3 Quinn Nguyen,2 Andrew J. Malliet.1,2 The University of Queensland, Saint Lucia, QLD, Australia; 3Monash University Monash Biomedical Discovery Institute, Clayton, VIC, Australia; 1Royal Brisbane and Women's Hospital, Herston, QLD, Australia; 2The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia.

**Background:** Advances in sequencing methods have increased available molecular information on dissociated cells and tissues. Spatially linking this molecular information with histomorphology is needed to understand a complex organ like the kidney, in both health and disease.

**Methods:** Here we used the commercially available 10x Genomics ST platform to investigate the spatially resolved transcriptome expressions in fetal (n=2), adult (n=3) and female (n=3) mouse frozen kidney and a healthy human cortical frozen kidney tissue sections. We utilised Space Ranger (10x Genomics), Seurat and stLearn analysis pipelines to explore the spatial transcriptome expression within the kidney tissue sections. Furthermore, we confirmed the robustness of our ST data against matched publicly available mouse and human kidney scRNA-seq data.

**Results:** We identified a unique transcriptome plasticity in fetal and adult mouse kidneys, and healthy human cortical kidney tissue. Further dimensional reduction identified transcriptome clusters which correlated with distinct developing kidney structures in fetal mouse kidney tissue, functional cortical and medulla regions in adult mouse kidney tissue, and scarred and non-scarred regions in human cortical kidney tissue.

**Conclusions:** ST is a non-ossociative sequencing and imaging method which allows molecular profiles to be integrated with histomorphology of frozen kidney tissue sections. This provides a novel opportunity to inform physiological and non-physiological conditions at the cell-cell, nephron and tissue levels.

**Funding:** Government Support - Non-U.S.

**ST** provides transcriptome expression within intact kidney tissue sections. (A) H&E stained human cortical kidney tissue with scarred and non-scarred regions. (B) The same human cortical kidney tissue with the transcript capture spots coloured by clustering using t-SNE projection demonstrates distinct transcriptome expression in scarred and non-scarred regions.

**Automated Atubular Glomeruli Detection Using 3D Glomerular Quantification Algorithms**

Haichun Yang,1 Ruining Deng,2 Yuankai Huo,2 Agnes B. Fogo.1 Vanderbilt University Medical Center, Nashville, TN; 1Vanderbilt University, Nashville, TN.

**Background:** Atubular glomeruli are associated with decreased glomerular filtration rate and kidney disease progression. To identify atubular glomeruli requires serial section analysis, tracking individual glomeruli, and then determining whether each glomerulus has or does not have connection to the proximal tubule. This process is labor intensive and very time-consuming, limiting its use. We aimed to test feasibility of automatically detecting atubular glomeruli by using Multi-Object Association for Pathology in 3D (Map3D).

**Methods:** The Map3D was created including a glomerular detection algorithm, dual-path multi-object tracking algorithm, and pixel-wise large-scale glomerular association algorithm across routine serial sectioning with whole slide imaging (WSI). Atubular glomerular counting was done on mouse and human kidneys, and 3 mice with diphtheria toxin (DT)-mediated proximal tubule-specific injury in mice with tubular cell expression of the DT receptor, and 4 mice with patchy tubulointerstitial fibrosis induced by folic acid (FA). Data from this automated approach was compared with standard manual assessment detailed above and correlated with functional and structural parameters.

**Results:** The Map3D substantially reduced the time needed for average atubular glomerular counting per sample (30 min Map3D vs. 300 hours). Atubular glomerular size were smaller than normal glomeruli. The number of complete (i.e. from pole to pole) glomeruli assessed increased by 25.6% using GQuant-3D (68±8.8 per mouse) vs human counting (72±2.7 per mouse). GQuant-3D recognized 14±3.5 atubular glomeruli per mouse sample, slightly less (83%) than the 16.7±3.0 atubular glomeruli per mouse sample

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
recognised by manual human assessment. The percentage of atubular glomeruli, counted by either GQuant-3D or manual human assessment, was 6.0±0.91%. The percentage of atubular glomeruli, counted by non-Duke WSIs were divided in the patient level (0.8±0.2) and non-Duke WSIs were used as testing dataset. QuPath was employed to manually annotate non-sclerotic (22767) and sclerotic glomeruli (1366). A 9-layer convolutional neural network (CNN), based on the common U-Net architecture, was developed in Python, using randomly selected 256x256 patches from WSIs and in order to augment to boost generalization performance. CNN hyper-parameters were tuned via cross-validation. The CNN’s performance was quantified based on the Dice Similarity Coefficient (DSC) between the predicted and ground-truth annotations.

Results: For non-sclerotic glomeruli, the average DSC for train, validation and testing was 0.93, 0.91, 0.90 respectively. The F1, Recall, and Precision for testing was 0.93, 0.96, 0.90 respectively. For sclerotic glomeruli, the average DSC for train, validation and testing was 0.89, 0.87, 0.83 respectively. The F1, Recall, and Precision for testing was 0.87, 0.93, 0.81 respectively. The CNN has higher performance in the regions of high glomerular density and occasionally, outperformed the pathologist in glomerular detection. Lower model performance was observed in the presence of image artifacts and in regions of low glomerular density.

Conclusions: DL applied to image analysis may help standardize and improve accuracy and reproducibility of quantification of histologic primitives in kidney frozen sections, enabling the establishment of synergistic machine-human protocols that can be deployed in clinical practice. The development of DL-segmentation of other relevant histologic primitives is in progress.

Evaluation of a Direct-to-Digital Histology Method for Rapid Evaluation of Kidney Biopsies
Sudhir Perincheri, Randy L. Luciano, Gilbert W. Moeckel, Richard Torres.
Yale University School of Medicine, New Haven, CT.

Background: Digitization of clinical renal biopsy histology is motivated by the importance of early intervention in acute kidney conditions, assessment by remotely-based experienced nephropathologists, and application of emerging computerized quantitative evaluation tools. Despite the interest, image quality and workflow impact are concerns for digital renal pathology. A newly developed tool for rapid, slide-free microscopic image preparation called Clearing Histology with MultiPhoton Microscopy (CHiMP) has demonstrated high efficiency and high quality morphology for diagnostic review in renal disease in a research environment. We sought to commence validation of CHiMP for renal biopsy using effects on downstream traditional special stains and ability to detect a broad range of clinically relevant pathological lesions in renal biopsies.

Methods: Kidney core biopsies were procured from 50 consented individuals undergoing renal biopsy for any reason and CHiMP processing was integrated into the routine clinical workflow, using previously-described methods. Images were obtained through entire core biopsies with a prototype fast, high resolution, multiphoton microscope system (Applikate Technologies, Washington, DC) and visualized with web-based software. Samples were subsequently processed using standard methods for clinical interpretation (immunostaining and light microscopy) in a dedicated space. By CHiMP detected morphologic findings were equally detectable in digital images compared to physical, paraffin-embedded sections including cases showing tubular injury, proliferative glomerulonephritis, glomerular deposition disease, and interstitial nephritis. No significant negative effects on downstream processing were identified.

Conclusions: CHiMP can be used in rapid morphologic evaluation of kidney biopsies integrated into clinical work enabling rapid rendering of preliminary diagnoses while simultaneously making digital images available for remote expert evaluation and digital analysis. Continuing validation will test ability to augment detection of rare lesions and quantitative precision.

Kidney Biopsy Transcript Patterns Offer a Novel Approach to Distinguishing Etiologies of Acute Interstitial Nephritis
Ivy Rosales,1 Kristen Tomaszewski,1 Ellen Acheampong,1 Astrid Weins,2 Rebecca Smith,2 Meghan E. Sison,1 Robert B. Colvin,1 Massachusetts General Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA.

Background: One of the challenges in renal pathology is distinguishing causes of acute interstitial nephritis (AIN). Based on encouraging results from renal allografts, we sought mRNA transcript profiles of checkpoint inhibitor associated AIN (CPI), drug induced AIN (Drug), AIN in diabetes (DM), IgG4-related renal disease (IgG4) and T cell rejection type 1 (TCMR1).

Methods: Three 20 um sections were obtained from 65 FFPE blocks: 9 controls, 46 AIN types (10 CPI, 13 DM, 14 Drug, 9 IgG4 and 10 TCMR1). RNA was extracted and hybridized with NanoString HOT Panel of 770 probes and analyzed on an nCounter Max instrument. The gene list is available at nanostring.com. Pathway analysis, differential expression and cell type scores were analyzed from normalized mRNA counts using nSolver.

Results: Similarities were found across AIN however each had one or more distinct patterns of transcripts. CPI AIN was distinguished from the other causes of AIN by higher IFNγ signaling pathway scores (Fig 1). CPI AIN had more exhausted CD8 cells (p<0.05) and NK cells (p<0.001) than drug induced AIN. DM AIN differed from histologically indistinguishable Drug AIN by several genes (e.g. higher TGFβ2, p=0.007). IgG4 AIN showed the highest levels of B cell receptor signaling, MAPK and mTOR pathways, and highest Th17 and Treg differentiation scores. TCMR1 had lower scores for TGFβ1 and TNF pathways and lower Treg scores compared with the other causes of AIN. TCMR1 had the most favorable scores for AKI and pathways related to outcome (eGFR later, GoCAR progression).

Conclusions: Our initial findings suggest that once extended to customized algorithms and validated, this approach may prove fruitful in distinguishing the underlying diagnosis and pathogenesis of diverse causes of AIN.

Identification of Novel Biomarkers of Kidney Disease Histopathology and Prognosis: Results from the Boston Kidney Biopsy Cohort
Insa M. Schmidt,1 Suraj Sarvode mothi,2 Ragnar Palsson,2 Anand Srivastava,3 Zoë A. Kibbelaar,1 Min Zhuo,4 Afolarin A. Amodu,1 Isaac E. Stillman,4 Helmut G. Rennekke,3 Sushrut S. Waikar,12 Boston University Medical Center, Boston, MA; 3Beth Israel Deaconess Medical Center, Boston, MA.

Background: Biomarkers for non-invasive assessments of histopathology and prognosis are needed in patients with kidney disease.

Methods: Using a novel proteomics assay, we measured a multi-marker panel of biomarkers for non-invasive assessments of histopathology and prognosis in patients with biopsy-confirmed kidney diseases and adjudicated semi-quantitative assessments of kidney disease severity. Using the clinical renal biopsy cohort, we measured a multi-marker panel of 225 circulating plasma proteins in a prospective cohort study of 557 individuals with biopsy-confirmed kidney diseases and adjudicated semi-quantitative assessments of kidney disease severity.
of histopathologic lesions. We tested the associations of each biomarker with clinicopathologic diagnoses, histopathologic lesions, and the risks of kidney disease progression (a 40% decline in estimated glomerular filtration rate (eGFR) or end-stage kidney disease) and death.

**Results:** After multivariable adjustment and correction for multiple testing, 39 proteins were independently associated with clinicopathologic diagnoses and 53 with different histopathologic lesions. Kidney-injury molecule-1 (KIM-1) associated with diabetic nephropathy and glomerular and tubulointerstitial diseases. The top performing markers for acute tubular injury and interstitial fibrosis and tubular atrophy were KIM-1 and tumor necrosis factor receptor superfamily member-9 (TNFRSF-9), respectively.

Thirty proteins were significantly associated with kidney disease progression and 35 with death (Figure 1 A, B). The top performing markers for kidney disease progression were placental growth factor (PGF; HR 5.4, 95% CI 3.4 to 8.7) and BMP and Activin Membrane Bound Inhibitor (BAMBI; HR 3.0, 95% CI 2.1 to 4.2); the top performing markers for death were TRAIL-receptor-2 (TRAIL-R2; HR 2.9, 95% CI 2.0 to 4.0) and CUB Domain Containing Protein-1 (CDCP1; HR 2.4, 95% CI 1.8, 3.3). Five proteins were significantly associated with decreased risks of death (Figure 1 B).

**Conclusions:** We identified several biomarkers of kidney disease histology, pathology, and prognosis—many of which have not been reported previously and may represent important avenues for future research.

**Complement Activation Assay in an Ex Vivo Microfluidic Cell-Culture System**

**Martin Reinhardt,** Yulia Kiyam, Hermann G. Haller. Medizinische Hochschule Hannover Zentrum Innere Medizin, Hannover, Germany.

**Background:** Discrimination between different diseases in patients suffering from thrombotic microangiopathies is often challenging. Measuring C5b9 deposit on endothelial cells using confocal microscopy have been shown to be convenient in diagnostic and therapy monitoring of Atypical hemolytic uremic syndrome (aHUS) but methods are complex and costly.

**Methods:** We developed a cell-based C5b9-ELISA to measure C5b9-deposits on activated endothelial cells. Patients with suspected aHUS and other thrombotic microangiopathies were identified in early disease stage. Serum was drawn and tested versus healthy controls. After confirmation of the diagnosis aHUS therapy efficiency was monitored using the assay.

**Results:** In patients with the clinical diagnosis of aHUS we were able to show up to six-fold higher C5b9-deposits in contrast to normalized human serum (NHS) (p-value < 0.0001). In comparison to healthy controls, patients suffering from either Shiga-Toxin-HUS or Thrombotic Thrombocytopenic Purpura (TTP) we could demonstrate a two- to three-fold higher deposit (p-value=0.0103 and below). After onset of eculizumab treatment, the amount of C5b9-deposits becomes lower than in healthy controls, proving the efficiency of the therapy. One-Way-ANOVA shows significant differences between aHUS-groups and controls, but not between aHUS patients using Tukeys-multiple comparisons test.

**Conclusions:** We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring C5b9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.

**Figure 1:** Percentage of area per image stained for C5b9 with 95% CI after treatment with patient serum.

**Barriers and Opportunities to Improve Variability in CKD Laboratory Methodology and Reporting: Results from the College of American Pathologists (CAP) 2019 Survey**

**Joseph A. Vassalotti,**1,2 Greg Miller,1 1Icahn School of Medicine at Mount Sinai, New York, NY; 2National Kidney Foundation, New York, NY; 3Virginia Commonwealth University, Richmond, VA.

**Background:** Variability in laboratory practices for estimated GFR (eGFR) and urine albumin-creatinine ratio (uACR) is a barrier to optimal CKD testing and interpretation by clinicians. The CAP serial surveys assess CKD laboratory methodology and reporting.

**Methods:** The CAP 2019 General Chemistry Survey conducted in December, included 9 questions regarding CKD tests.

**Results:** Respondents included 7,105 laboratories (83.8% U.S. and 16.2% international) with a response rate of 87.5%. Laboratory reporting of eGFR based on serum creatinine has increased overall from 3% to 92% in CAP surveys between 2003 and 2019. The Figure shows 76% of laboratories were using an isotope dilution mass spectrometry (IDMS) traceable version of the MDRD 4-variable equation (45%) or the CKD-EPI equation (31%), but an incorrect equation was used was for IDMS creatinine by 23% of the respondents, resulting in systematic over estimation of kidney function. Barriers for the pediatric population less than 18 years include only 10% of laboratories report the correct bedside Schwartz equation and 20% of laboratories applied an incorrect adult eGFR equation for children. The microalbumin term that KDIGO and KDOQI recommend be included 9 questions regarding CKD tests.

**Conclusions:** Laboratory variability is a call to action for nephrologists to collaborate with clinical laboratoryians to improve appropriate CKD testing.

---

**Method:** We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring C5b9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.

Terlipressin Improves Renal Replacement Therapy–Free Survival in Hepatorenal Syndrome Type 1
Juan Carlos Q. Velez,1 Alex Becfelf,1 Ira Kultz,1 Juan F. Gallegos-Orozco,2 Hugo E. Vargas,2 John M. Vierling,2 S. Chris Pappas,2 Khurram Janmil,2 1Ochsner Health System, New Orleans, LA; 2Mallinckrodt Pharmaceuticals

Background: Hepatorenal syndrome type 1 (HRS-1) is an ominous form of acute kidney injury in patients with cirrhosis. Recently, the results of the randomized placebo (PBO)-controlled trial (CONFIRM) demonstrated that terlipressin (TERLI) is effective in reversing HRS-1 and in reducing the cumulative need for renal replacement therapy (RRT). However, whether TERLI reduces the need for RRT among survivors has not been determined.

Methods: CONFIRM (NCT02770716) was a North American RCT (n=300) that compared HRS-1 reversal rates between patients treated with albumin plus TERLI (n=199) or albumin plus PBO (n=101) (2:1). We conducted a post hoc intention-to-treat analysis to assess the incidence of RRT among CONFIRM survivors. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day RRT-free survival rates.

Results: In CONFIRM, the cumulative incidences of need for RRT for TERLI at day 14, 30, and 90 were 23%, 26%, and 29% compared with 35%, 36%, and 39% for patients assigned to PBO (P = 0.03, 0.07, and 0.1, respectively). Among survivors, significantly fewer TERLI-treated patients remained dependent on RRT at day 14, 30, 90 (22%, 26%, and 30%, respectively) compared with PBO (39%, 43%, and 46%; P = 0.01, P = 0.03, and P = 0.05, respectively). The 90-day RRT-free survival rate was 35% in the TERLI group vs 30% in the PBO group (P = 0.08), with a numerically longer median number of days in the TERLI group (20 vs 11). Pooled analysis of the 3 RCTs revealed a greater 90-day RRT-free survival rate for TERLI-treated (n=352) compared with PBO-treated (n=256) patients (37% vs 29%, P = 0.03; OR [95% CI], 1.47 [1.04, 2.07]).

Conclusions: Treatment with TERLI added to albumin decreased the rate of RRT and improved RRT-free survival in patients with HRS-1. This is the first pharmacological intervention proven to reduce the need for RRT in patients with HRS-1. Because of the significant impact of RRT on quality of life, this observation expands the clinical benefit of TERLI and enhances the reported efficacy of TERLI in inducing HRS-1 reversal.

FR-OR02
A Parsimonious Model for Diagnosis of Biopsy-Proven Acute Interstitial Nephritis Using Electronic Health Record Data
Dennis G. Molameda,1,2 Yu Yamamoto,3 Chirag R. Parikh,3 Francis P. Wilson,1 1Yale University School of Medicine, New Haven, CT; 2Clinical and Translational Research Accelerator, New Haven, CT; 3Johns Hopkins Medicine, Baltimore, MD

Background: Due to its atypical clinical features and difficulty in establishing diagnosis without a biopsy, acute interstitial nephritis (AIN) diagnosis is delayed or missed. We developed a predictive model for AIN using clinical data from all patients who underwent a kidney biopsy available through the electronic health record.

Methods: We obtained data on all patients who underwent a native kidney biopsy at two centers between 2013-18 and obtained corresponding information of demographics, comorbidities, and all laboratory tests collected up to one year before biopsy. We used least absolute shrinkage and selection operator (LASSO) method to select features associated with AIN and performed area under received operating characteristics curve (AUC) analysis in temporarily-split training (70%) and test (30%) sets. We applied this model to a separate cohort of kidney biopsies with AIN diagnosis adjudicated by 3 pathologists and compared it to the clinician’s prebiopsy impression of AIN obtained through chart review.

Results: Among 551 patients who underwent native kidney biopsies, 60 (11%) had AIN on clinical pathology diagnosis. We evaluated 163 potential features for their association with AIN. The five features with the highest AUC were last creatinine at the time of biopsy (AUC, 0.73), BUN to creatinine ratio (0.70), urine specific gravity before biopsy (0.67), serum bicarbonate (0.62), and urine protein (0.62). The top 4 variables associated with AIN and the model containing these showed a modest AUC but was an improvement on clinician’s pre-biopsy impression of AIN.

Conclusions: We noted four variables associated with AIN and the model containing these showed a modest AUC but was an improvement on clinician’s pre-biopsy impression of AIN.

Funding: NIDDK Support
A CNN prediction system was developed to continuously and automatically monitor for incipient AKI. 7122 patient encounters were retrospectively collected patient EHR data. The CNN model, which was provided text data through Doc2Vec input, automatically monitored for AKI 72 hours prior to AKI onset on the MIMIC III ICU hold-out test set. The ROC curve comparison of 72-hour prediction on the 10% hold-out test set is shown in Figure 1. The CNN model, which was provided text data through Doc2Vec input, outperformed the XGBoost model and the SOFA score. In addition, NRPT up to a dose of 1000mg/200mg twice a day for two days is safe and well tolerated in these patients. Further studies to assess the potential therapeutic benefit of NRPT in AKI are warranted.

FR-OR4
Outcomes from the Use of the Selective Cytopheretic Device (SCD) in Critically Ill Children Receiving CRRT: A Report of the Multicenter Pediatric SCD (pSCD) Study
Stuart Goldstein,1 Kelli A. Kraklaman,1 Cassie L. Kirby,1 David J. Askernazi,2 Rajit K. Basu,1 David T. Selewski,3 H. David Humes,1 Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 1The University of Alabama at Birmingham, Birmingham, AL; 2Children’s Healthcare of Atlanta Inc, Atlanta, GA; 3Medical University of South Carolina, Charleston, SC; 4University of Michigan, Ann Arbor, MI.

Background: Critically ill children who develop acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) are at increased risk of death. The SCD promotes an immunomodulatory effect in a hypocalcemic environment (ionized Ca (ionCa) < 0.4 mmol/L) in animal models of inflammation. In a randomized trial, adult ICU patients on CRRT treated with the SCD, who maintained CRRT ionCa < 0.4 mmol/L, had improved survival/dialysis independence. We conducted an FDA grant sponsored safety evaluation (adverse and serious adverse events) of the SCD in 16 critically ill children.

Methods: 4 center US study of the SCD in children (15 kg, ≥2 years) with AKI requiring CRRT. The SCD was integrated post CRRT membrane, changed daily, and circuit ionCa maintained <0.4 mmol/L. Pts received CRRT treatment for up to 7 days or CRRT discontinuation.

Results: 16 pts (8F/8M) completed the study from 12/2016 thru 2/2020. Mean pt age was 12 yr (range 4-21 yr), weight was 53 kg (range 19-111 kg) and PRISM 2 score was 7 (range 2-19). Two pts received ECMO. The most common ICU diagnosis was shock. Circuit ionCa were maintained at <0.4 mmol/L for 90.2% of assessments. Median SCD duration was 6 days (range 1 to 7). 15/16 pts survived CRRT therapy, 12/16 patients survived to ICU discharge. All 12 ICU survivors were dialysis independent at 60 days. No SCD related adverse events were noted.

Conclusions: Our data suggest the SCD is safe in critically ill children who require CRRT. While we cannot make efficacy claims, the 75% survival rate and 100% renal recovery rate in surviving children suggest a favorable benefit to risk ratio.

FR-OR05
Nicotinamide Riboside with Pterostilbene Increases NAD+ in Patients with AKI: A Randomized, Double-Blind, Placebo-Controlled, Stepwise Safety Study of NRPT in Patients with AKI
Petra Simic,1 Xavier F. Parada,1 Samir M. Parikh,2 Ryan Dellinger,3 Leonid P. Guarente,4,5 Eugene P. Rhee,1 1Massachusetts General Hospital, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Elysium Inc, New York, NY; 4Massachusetts Institute of Technology, Cambridge, MA.

Background: Preclinical studies have identified both NAD+ and sirtuin augmentation as potential strategies for the prevention and treatment of AKI. Nicotinamide riboside (NR) is a NAD+ precursor vitamin and pterostilbene (PT) is potent sirtuin activator found in blueberries. Here, we tested the effect of combined NR and PT (NRPT) on whole blood NAD+ levels and safety parameters in patients with AKI.

Methods: We conducted a randomized, double-blind, placebo-controlled study of escalating doses of NRPT in 24 hospitalized patients with AKI. The study was comprised of four Steps during which NRPT (5 subjects) or placebo (1 subject) was given twice a day for two days. NRPT dosing was increased in each Step: Step 1 250/50mg, Step 2 500/100mg, Step 3 750/150mg and Step 4 1000/200mg. Blood NAD+ levels were measured by liquid chromatography-mass spectrometry and safety was assessed by history, physical exam, and clinical laboratory testing.

Results: AKI resulted in a 50% reduction in whole blood NAD+ levels at 48 hr compared to 0 hr in patients receiving placebo (p=0.05). There was a trend for increase in NAD+ levels in all NRPT Steps individually at 48 hr compared to 0 hr, but only the change in Step 2 reached statistical significance (47%, p=0.04), and there was considerable interindividual variability in the NAD+ response to treatment. Considering all Steps together, NRPT treatment increased NAD+ levels by 37% at 48hr compared to 0hr (p=0.002). All safety laboratory tests were unchanged by NRPT treatment, including creatinine, estimated glomerular filtration rate (eGFR), electrolytes, liver function tests, and blood counts. Three of 20 patients receiving NRPT reported minor gastrointestinal side effects.

Conclusions: NRPT increases whole blood NAD+ levels in hospitalized patients with AKI. In addition, NRPT up to a dose of 1000mg/200mg twice a day for two days is safe and well tolerated in these patients. Further studies to assess the potential therapeutic benefit of NRPT in AKI are warranted.

Role of Angiopoietins in CKD Progression After Hospitalization
Sherry Mansour, Steven G. Coca, Yaqi Jia, Vernon M. Chinchilli, Wassim Obied, Francis P. Wilson, Samir M. Parikh, Edward D. Siew, Talat Alp Ikizler, Jonathan Himmelfarb, Paul L. Kimmel, Chirag R. Parikh
ASSESS-AKI Consortium; 1Yale University School of Medicine, New Haven, CT; 2Icahn School of Medicine at Mount Sinai, New York, NY; 3Johns Hopkins University, Baltimore, MD; 4Pennsylvania State University, University Park, PA; 5Beth Israel Deaconess Medical Center, Boston, MA; 6University of Washington, Seattle, WA; 7National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 8Vanderbilt University Medical Center, Nashville, TN.

Background: The factors determining chronic kidney disease (CKD) progression after an episode of acute kidney injury (AKI) are poorly understood. Angiopoietins play a role in vessel remodeling after AKI, where Angiopoietin-1 (Angpt-1) maintains vessel stability and Angiopoietin-2 (Angpt-2) destabilizes quiescent vessels. We investigated whether the balance of Angpt-1 and -2 was prognostic of CKD and mortality after hospitalization in patients with and without AKI.

Methods: Using plasma samples from ASSESS-AKI, we measured Angiopoietins 3 months after hospitalization. We assessed the ratio of Angpt-1/Angpt-2 with CKD progression (composite of incident and progression of CKD, and end stage kidney disease), and all-cause mortality.

Results: Angiopoietins were measured in 1503 hospitalized patients, among whom 746 (49.6%) had AKI. Median (IQR) age was 65.8 (56.6, 73.9) years, 555 (37%) were female, and 196 (13%) were black. Median times to CKD progression, and all-cause mortality were 4.4 (2.5, 5.7), and 4.9 (3.6, 6.0) years, respectively. CKD progression developed in 293 (19%) and mortality in 314 (21%) participants. The highest quartile of Angpt-1/Angpt-2 ratio was independently associated with 50% reduced risk of CKD progression and 77% reduced risk of mortality as compared to the lowest quartile. Stratified analyses by AKI status revealed stronger associations between Angpt-1/Angpt-2 ratio and both outcomes in the AKI group (Figure).

Conclusions: A higher Angpt-1/Angpt-2 ratio was strongly associated with lower risk of CKD progression and mortality after hospitalization, particularly in patients with AKI. Angiopoietins may help risk stratify patients with AKI after discharge for those in need of close follow-up and CKD management.

Determinants of Major Adverse Kidney Events (MAKE) in Extra Corporeal Membrane Oxygenation (ECMO) Survivors
Aniesh Bobba, Christy Costanian, Sola A. Bahous, Fadi Tohme

Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2Lebanese American University School of Medicine, Byblos, Lebanon.

Background: The majority of ECMO patients develop acute kidney injury (AKI) and 40-60% require renal replacement therapy (RRT). Little is known about the effects of AKI on long-term renal outcomes after ECMO. The aim of this study was to examine the determinants of MAKE in ECMO survivors.

Methods: Patients who were admitted to a single-center between 2008 and 2017, were on ECMO for more than 24 hours & survived to hospital discharge were included. MAKE was defined as either doubling of serum creatinine (Scr), incident ESRD or death. USRDS and NDI databases were used to obtain information about ESRD and death. AKI was defined as KDIGO stages 2-3. Complete AKI recovery was defined as a return to 50% of baseline Scr and partial recovery as an improvement in the AKI stage without a return to 50% of baseline Scr. Survival analysis plots & Cox regression models were fitted to examine the associations of AKI status, AKI recovery and other factors with MAKE.

Results: Among 188 ECMO patients who survived until hospital discharge, 63% had AKI, and 41% required RRT. The mean follow-up time was 3.4 years. Patients with AKI were more likely to be on ECMO for a cardiac rather than respiratory indication and had a longer length of stay compared to patients with no AKI. Kaplan-Meier survival curves showed that patients with no/partial recovery from AKI had a higher rate of MAKE compared to those with no AKI (Figure 1). Results of the unadjusted analysis showed that ECMO type and timing of initiation of RRT were associated with MAKE. Multivariate analysis showed that AKI [aHR=1.79 (95%CI=1.00-3.21)], no/partial recovery from AKI [aHR=2.94 (95%CI=1.46-5.92)] and initiation of RRT after ECMO [aHR 5.4 (95%CI=1.14-25.6)] were significant determinants of MAKE after adjustment for potential confounders.

Conclusions: AKI, AKI recovery status, and timing of initiation of RRT are determinants of major adverse kidney events in patients who received ECMO.

AKI Among African Americans with Sickle Cell Trait and Disease
Kabir O. Olaniran, Andrew S. Allegretti, Sophia Zhao, Sagar U. Nigwekar, Sahir Kalim, Massachusetts General Hospital, Boston, MA; 3University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Sickle cell trait (SCT) and disease (SCD) are independent risk factors for estimated glomerular filtration rate (eGFR) decline among African Americans (AA). However, our understanding of the risk for acute kidney injury (AKI) and the role of AKI in eGFR decline in patients with SCT/D remains limited. We aimed to describe the relative risk for AKI in SCT/D and the effect of AKI on eGFR decline in AA.

Methods: We performed a multi-center observational study of adult AA patients with a baseline eGFR ≥ 60 mL/min and ≥ 1 year follow-up between 2005-2018. The presence of SCT/D (exposure) and normal hemoglobin phenotype (reference) was determined by hemoglobin electrophoresis. Outcomes of interest (incident All AKI [Kidney Disease: Improving Global Outcomes criteria], incident Severe AKI [doubling of baseline creatinine] and incident Sustained AKI [ AKI persisting for ≥ 72 hours]) were adjudicated by chart review and evaluated by Cox regression. Only first AKI events were used. The effect of All AKI on eGFR decline (mixed linear models) was also investigated. Models were adjusted for predictors of AKI.

Results: We identified 8968 reference, 1279 SCT, and 254 SCD patients with a median follow-up of 7.6 years and mean serum creatinine of 0.8 mg/dl. SCT was associated with Sustained AKI (adjusted hazard ratio [aHR] 1.42; 95% CI, 1.08-1.88) compared to the reference. SCD was associated with All AKI (aHR 3.13; 95% CI, 2.33-4.21), Severe AKI (aHR 3.04; 95% CI, 1.90-4.87) and Sustained AKI (2.10; 95% CI, 1.24-3.53) compared to the reference. Effect of AKI on eGFR is shown in Figure 1.

Funding: Private Foundation Support
Conclusions: The risk for AKI is increased in both SCT (Sustained) and SCD (all forms) and may contribute to faster eGFR decline in SCT/D. Further studies are needed to understand the mechanisms of AKI in SCT/D. Such studies will inform best practices that will help attenuate the burden of kidney disease in SCT/D.

FR-OR09
Assessment of Kidney Proximal Tubular Secretion in Critical Illness
Pavan K. Bhatraju,1 Edward D. Siew,2 Jonathan Himmelfarb,3 Andrew N. Hooftg asiat,4 Mark M. Wurfel,5 Bryan R. Kestenbaum,1,4 University of Washington, Seattle, WA; 2Division of Nephrology and Hypertension Vanderbilt University, Nashville, TN.

Background: Serum creatinine concentrations (SCr) are used to determine the presence and severity of acute kidney injury. SCr is primarily eliminated by glomerular filtration; however, most mechanisms of kidney injury in critical illness involve kidney proximal tubules, where tubular secretion occurs. Proximal tubular secretory clearance is not currently measured in the ICU. To estimate the kidney clearance of secretory solutes in critically ill adults.

Methods: We collected matched blood and spot urine samples from 170 ICU patients and from a comparison group of 70 adults with normal kidney function. We measured seven endogenously produced secretory solutes using liquid chromatography-tandem mass spectrometry. We computed a composite secretion score incorporating all seven secretory solutes and evaluated associations with 28-day major adverse kidney events (MAKE) defined as doubling of SCr, dialysis dependence, or death.

Results: The urine/plasma ratio of six of seven secretory solutes were lower in critically ill patients compared with normal individuals after adjustment for SCr. The composite secretion score was moderately correlated with SCr and cystatin C (r = -0.51 and r = -0.53, respectively). Each standard deviation higher composite secretion score was associated with a 52% lower risk of MAKE, (95% CI 25% - 70% lower) independent of ICU severity of illness and SCr. Higher urine to plasma ratios of individual secretory solutes isoaspartylglycine and tiglylglycine were associated with MAKE after accounting for multiple testing (p<0.001).

Conclusions: Among critically ill adults, tubular secretory clearance is associated with adverse outcomes, independent of SCr and SOFA score, and measurement could improve assessment of kidney function.

Endotrophin, Released During Collagen Type VI Formation, Predicts Long-Term Mortality After AKI
Nadja Sparding,1,2 Daniel Guldager Kring Rasmussen,1 Federica Genovese,1 Morten A. Karsdal,1 Rebecca A. Packington,2 Nicholas M. Selby,2 Fibrosis, Renal and Cardiovascular Research Nordic Bioscience, Herlev, Denmark; 2Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; 3Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom.

Background: Acute kidney injury (AKI) is defined as a rapid decrease in kidney function which may be associated to structural damage. Early markers predicting AKI are emerging, but tools to monitor patients subsequent to AKI are still lacking. The novel biomarker PRO-C6 reflects formation of collagen type VI (COL6) and levels of endotrophin, a bioactive molecule derived from COL6. Here we evaluated the potential of PRO-C6 as a biomarker of mortality in AKI patients.

Methods: We measured PRO-C6 in plasma samples collected 1 year after the episode of AKI, using a novel ELISA in 801 patients from the AKI Risk in Derby (ARID) study, who were then followed prospectively until year three. 393 of the patients had been hospitalized for an episode of AKI, and 408 patients who did not sustain AKI were included as controls (non-AKI). The groups were matched for age, baseline renal function and diabetes.

Results: PRO-C6 levels were significantly higher in the AKI compared to the non-AKI group (median (m): 10.85 vs 9.23 ng/mL, P<0.001). By year 3, a total of 70 patients died; 43 in the AKI group and 27 in the control group. In the AKI group, patients who died had significantly higher PRO-C6 levels than the patients who did not die (m: 12.66 vs 10.69 ng/mL, P=0.004), whereas there was no difference between patients who died and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P=0.23). In a Multivariate Cox regression analysis with backwards elimination including age, gender, baseline CKD and diabetes status, albuminuria, serum creatinine, eGFR and PRO-C6, only age (P=0.04) and albuminuria (P=0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P=0.005), albuminuria (P=0.04) and PRO-C6 (P=0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P<0.009).

Conclusions: In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

Association of Use of Kidney Disease Education Benefit with ESKD-Related Outcomes
Kirsten L. Johansen, James B. Wetmore, David T. Gilbertson, Eric D. Weinhandl, Jianong Liu. Chronic Disease Research Group, Minneapolis, MN.

Background: ESKD onset in the US is marked by poor outcomes, including little use of home dialysis, widespread catheter dependence among patients on hemodialysis, and high mortality. Consequently, in 2010, the Centers for Medicare and Medicaid Services (CMS) initiated a new kidney disease education (KDE) benefit to ensure that beneficiaries with stage 4 CKD are informed about the effects and treatment of kidney disease, diet and nutrition, transplantation, dialysis modalities, and vascular access. Following the US president’s Executive Order on Advancing American Kidney Health in 2019, CMS plans to expand KDE. However, the current use and efficacy of KDE have not been examined.

Methods: We used USRDS data to identify eligible patients and to ascertain KDE and ESKD outcomes. We examined use of KDE in the 2 years prior to ESKD onset in 2013-2017 among 106,465 individuals aged ≥67 years who had CKD stage 4. We examined patient characteristics associated with receipt of KDE. We matched each KDE recipient with 4 controls using propensity scores and estimated the association between receipt of KDE and ESKD outcomes in this matched cohort using logistic regression.

Results: 3171 patients (3%) received KDE, 56% of whom received a single session. 49.5% of KDE sessions were delivered by nephrologists and 42% by physician extenders. Younger patients, men, and non-Hispanics were more likely to receive KDE. There was substantial regional variation in KDE utilization, and rural residents were less likely to receive KDE. In the matched cohort, receipt of KDE was associated with higher odds of transplant waiting before dialysis initiation, pre-emptive transplantation, home dialysis, or in-center HD initiation with an AVF or AVG (vs. catheter, Table).

Conclusions: A very small percentage of eligible patients reaching dialysis receive Medicare-reimbursed KDE within the previous 2 years. KDE was associated with favorable outcomes, at least among those who advanced to ESKD.

Funding: NIDDK Support

*Pre-emptive transplant or home dialysis or in-center HD with AVF or AVG
Background: Chronic kidney disease (CKD) is a public health problem and its prevalence has increased worldwide; patients are commonly unaware of the condition. Early identification and immediate intervention are crucial to delay CKD progression. Finding a tool to predict kidney function without visiting hospitals is an attractive method for CKD monitoring in COVID-19 pandemic. The present study aimed to investigate whether exhaled breath ammonia measurement could be used for rapid CKD screening.

Methods: CKD patients (n=121), including CKD stage 1-5 patients, were enrolled and breath ammonia was detected. Correlation between breath ammonia and blood urea nitrogen (BUN) levels, serum creatinine levels, estimated glomerular filtration rate (eGFR) were determined. The predictive value of breath ammonia for the presence of CKD was assessed.

Results: Correlation analysis demonstrated a good correlation between breath ammonia and blood urea nitrogen levels (R=0.756, p<0.0001), serum creatinine levels (R=0.735, p<0.0001), eGFR (R=0.535, p<0.0001) and inverted eGFR (R=0.685, p<0.0001). Breath ammonia concentration was significantly elevated with increased CKD stage compared with the previous stage (CKD stage 1/2:34/5:636±94, 102±120; 194±326, 442±1042; 1278±1807 ppb, p<0.05). The receiver operating characteristic curve analysis showed an area under curve (AUC) of 0.835 (p<0.0001) for distinguishing CKD stage 1 from other CKD stages at 974 ppb (sensitivity, 69%; specificity, 95%, positive predictive value [PPV] 0.99; negative predictive value [NPV], 0.36). The AUC was 0.831 (p<0.0001) for distinguishing between patients with/without eGFR ≥60 mL/min/1.73 m² (cut-off 1187 ppb: sensitivity, 71%; specificity, 78%; PPV, 0.84; NPV, 0.61). At 886 ppb, the sensitivity increased to 80% but the specificity decreased to 69%. For a non-life-threatening or non-serious CKD, breath ammonia at a cut-off concentration of 886 ppb is a good screening tool for detection of patients with potential CKD and suitable for kidney function monitoring.

Conclusions: Because CKD is non-life threatening and breath ammonia detection was conducted in real time, inexpensive, easy to administer, and had an acceptable diagnostic accuracy, breath ammonia can be used as a good surrogate for kidney function and a reliable tool for CKD screening.

Funding: Government Support - Non-U.S.
Results: Upon study entry, 704,557 Whites, 98,082 Blacks, and 31,631 Hispanics had similar mean eGFRs (49.50 ml/min/1.73m²). Ten years after CKD onset, fractions of patients entering ESKD were 1.3-2.5 times greater for Blacks and Hispanics vs. Whites across six age groups (Table). CS hazards for ESKD was 2.1-2.9 times greater for Blacks and 1.2-2.7 times greater for Hispanics vs. Whites. CS hazards for pre-ESKD death were similar for Blacks and only modestly lower for Hispanics vs. Whites across ages.

Conclusions: More Blacks and Hispanics to ESKD were driven by their greater hazards for ESKD due to more rapid decline in kidney function, not through lower mortality prior to ESKD. Delineation and elimination of the causes of faster kidney function declines are therefore the appropriate strategies to improve clinical outcomes in Blacks and Hispanics with CKD, instead of attributing the higher incidence to pre-ESKD survival bias.

Incidence of CKD and Environmental Inequities: An Integration of Ecological and Spatial Approaches in US Veterans

Yun Han,1 Jennifer L. Bragg-Gresham,1 Diane Steffick,1 Xiaosong Zhang,2 April Wyncott,1 Tiffany C. Veint,3 V. G. Vinod Vydieswaran,3 Brenda W. Gillespie,2 William Weitzel,2 Karandeep Singh,3 Susan F. Crowley,3 Rajiv Saran.1 1University of Michigan Medical School, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Veterans Health Administration, Ann Arbor, MI; 4Veterans Health Administration, West Haven, CT.

Background: Disparities in chronic kidney disease (CKD) can be linked to social and environmental determinants of health, which vary geographically across the US. We assessed geographic variation and the impact of environmental factors on incident CKD in US veterans.

Methods: We used a linked dataset from Veterans Health Administration (2014-18), the American Community Survey(2018); National Environmental Public Health Tracking Network(2018); EPA(2019) and Reference USA(2017). Incident cases of CKD were assessed geographic variation and the impact of environmental factors on incident CKD and environmental determinants of health, which vary geographically across the US. We applied Geographic Weighted Regression (GWR) to investigate the relationship between environmental factors and incidence rate of CKD.

Results: Average of incident rate of CKD was number of cases/1000 person-years during 2016-18. County-level environmental factors included Townsend deprivation index; neighborhood indices; average daily PM2.5; walkability index; number of recreational facilities and fast-food restaurants. A geographically-weighted regression model(GWR) was applied to investigate the relationship between environmental factors and incidence rate of CKD.

Conclusions: Different environmental factors were associated with incident CKD in US counties. This highlights the potential importance of allocating resources for varied approaches to preventing and slowing the progression of CKD based on residence.

Chlorthalidone and Bumetanide in Advanced CKD: HEBE Trial

Fabio Solis-Jimenez, L. M. Perez-Navarro, Rafael Valdez-Ortiz. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Current treatment for hypertension and volume overload in chronic kidney disease consists of loop diuretics, nevertheless, chronic use leads to adaptive changes at the distal nephron, which in turn decreases their efficacy. The use of thiazide diuretics could be another treatment option in these patients, notwithstanding, there’s not enough evidence to justify their use in this population.

Methods: To evaluate the efficacy and safety of treatment with bumetanide plus chlorthalidone in patients with advanced chronic kidney disease a double-blind randomized controlled trial was conducted.

Results: Thirty-two patients with hypertension, chronic kidney disease stage IV, and chronic loop diuretic use where divided in two groups. The dual treatment group received bumetanide (2 mg BID) plus chlorthalidone (50 mg BID), while the control group was given bumetanide (2 mg BID) plus placebo, both for twenty-eight days. There was a decrease of systemic blood pressure in the dual treatment group when compared with the control group; systolic blood pressure -26.1±15.3 vs. -10±23.3 mmHg (p=0.028), diastolic blood pressure -13.5±10.7 vs. -3.4±11.9 mmHg (p=0.018), and mean arterial pressure -18.1±8.7 vs. -5.6±4.13 mmHg (p=0.006). There was also a decrease of volume overload in the dual treatment group when compared to the control group; total body water -3.3±3.9 vs. -0.75±1.78 liters (p=0.001), extracellular water -2.55±1.1 vs. -0.15±0.12 liters (p=0.001), and extracellular water to total body water ratio -2.92±4.76 vs. -0.24±1.42 (p=0.039).

Conclusions: In advanced chronic kidney disease plus hypertension patients whose treatment with loop diuretics is insufficient, combined use of bumetanide plus chlorthalidone can be useful for systemic blood pressure and volume overload control.

Benefits of Icosapent Ethyl Across a Range of Baseline Renal Function in Patients with Established Cardiovascular Disease or Diabetes: Results of REDUCE-IT RENAL

Arjun Maiti,1 Deepak L. Bhatt,1 Allison N. Friedman,2 Michael Miller,3 Philippe Gabriel Sieg,1 Eliot A. Brinton,1 Terry A. Jacobson,1 Steven B. Ketchup,4 Rebecca A. Kettle,1 Juliano,5 Lixia Jiao,6 Ralph T. Doyle,7 Craig B. Granowitz,8 Matthew J. Badoff,9 Preston Mason,10 Jean-Claude Tardif,10 William E. Boden,4 Christie Ballantyne,4 REDUCE-IT Investigators 1 Brigham and Women's Hospital, Boston, MA; 2 Indiana University School of Medicine, Indianapolis, IN; 3 University of Maryland School of Medicine, Baltimore, MD; 4 Hospital Bichat - Claude-Bernard, Paris, France; 5 University of California Los Angeles, Los Angeles, CA; 6 Baylor College of Medicine, Houston, TX; 7 U.S. Lipid Center, Salt Lake City, UT; 8 VA Boston Healthcare System, West Roxbury, MA; 9 Amarin Pharma Inc. Bridgewater, NJ; 10 Institut De Cardiologie de Montreal, Montreal, QC, Canada; 11 Emory University School of Medicine, Atlanta, GA.

Background: Chronic kidney disease is associated with adverse outcomes among patients with established cardiovascular disease (CVD) or diabetes. Medications for treatment of CVD among patients with low estimated glomerular filtration rate (eGFR) may be ineffective.

Methods: The Reduction of Cardiovascular Events with Icosapent Ethyl-Intervention Trial (REDUCE-IT) randomized patients with CVD or diabetes and one additional risk factor to treatment with icosapent ethyl or placebo. Patients from REDUCE-IT were categorized by prespecified eGFR categories for analysis of the effect of icosapent ethyl (IPE) on the primary endpoint (composite of cardiovascular (CV) death, nonfatal myocardial infarction (MI), nonfatal stroke, coronary revascularization, or unstable angina) and key secondary endpoint (a composite of CV death, nonfatal MI, or nonfatal stroke). In post hoc analysis, patients were categorized by additional eGFR cutoffs consistent with current medical guidelines.

Results: Among the 8179 REDUCE-IT patients, median baseline eGFR was 75 mL/min/1.73m² (range: 17 to 125 mL/min/1.73m²). There were no meaningful changes in median eGFR for IPE versus placebo across study visits. IPE benefit was consistent across baseline eGFR for the primary (Figure) and key secondary endpoints. The numerical reduction in CV death was greatest in the eGFR <60 mL/min/1.73m² group (IPE: 7.6%; placebo: 10.6%; HR 0.70, 95%CI 0.51, 0.95, p=0.02). The rate of microalbuminuria in adverse event reporting was lower among IPE-treated patients (0.1% versus 0.3%, p=0.01).

Conclusions: In REDUCE-IT, icosapent ethyl reduced fatal and nonfatal ischemic events across the broad range of baseline eGFR categories.

Dapagliflozin Reduces the Risk of Hyperkalaemia in Patients with Heart Failure and Reduced Ejection Fraction: A Secondary Analysis from DAPA-HF

Soren L. Kristensen,1 Kieran F. Docherty,1 Pardeep Huند,1 Olof Bengtsson,2 Silvio E. Inzucchi,3 Mikhail Kosiborod,4 Anna Maria Langkilde,5 Felipe Martinez,2 Pietro Ponikowski,6 Marc S. Sabatine,4 Mikaela Sjostrand,2 Scott D. Solomon,7 John McMurray,1 1 BHF Cardiovascular Research Centre, University of Glasgow, Glasgow, United Kingdom; 2 AstraZeneca, Gothenburg, Sweden; 3 Wroclaw Medical University, Wroclaw, Poland; 4 Yale University, New Haven, CT; 5 St Lukes Mid America Heart Institute, Kansas City, KS; 6 National University of Cordoba, Cordoba, Argentina; 7 Brigham and Women's Hospital, Boston, MA; 8 Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark.

Background: Hyperkalaemia often limits the use of mineralocorticoid receptor antagonists (MRA) in patients with heart failure and reduced ejection fraction (HFREF), denying these patients a life-saving therapy.

Methods: The risk of developing mild hyperkalaemia (potassium > 5.5 mmol/L) and moderate/severe hyperkalaemia (>6.0 mmol/L) was examined in the Dapagliflozin And Prevention of Adverse-outcomes in Heart Failure trial (DAPA-HF) according to background MRA use, and randomized treatment assignment, by use of Cox regression analyses.

Mefitomin Improves Vascular Function in CKD Patients with Metabolic Syndrome

Evelyn Ramos,1 Melis Sahinoz,1 Carlos O. Pena,2 Elvis A. Akwo,1 Christineau Rounie,1 Zihong Yu,1 Edward D. Siew,11 Talat Alp Kiziler,12 Adriana Hung,1,2 Vanderbilt University Medical Center, Nashville, TN; 1Tennessee Valley Healthcare System, Nashville, TN; 2Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of.

Background: Cardiovascular (CV) risk is increased in CKD. Insulin resistance (IR), highly prevalent in CKD patients, contributes to endothelial dysfunction and arterial stiffness, leading to poor CV outcomes. It remains unknown if insulin sensitization with mefitomin improves CV risk, in patients with CKD Stage 3-4 and metabolic syndrome (MS).

Methods: In a double-blinded randomized trial (NCT02252081), 50 patients with CKD Stage 3, and MS and/or pre-diabetes, received either mefitomin or placebo for 16 weeks. Dosing was initiated at 500 mg and up-titrated over 7-14 days based on GI tolerance up to 1500 mg/day in CKD3a and 1000 mg/day in CKD 3b. Co-therapies for 16 weeks. Dosing was initiated at 500 mg and up-titrated over 7-14 days based on GI

Cumulative incidence of hyperkalaemia in patients taking MRA at baseline

FR-OR21

Results: Overall, 3370 (70.1%) patients in DAPA-HF were treated with an MRA. MRA use was 80% for moderate/severe hyperkalaemia occurring in 182 (11.1%) and 23 (1.4%) patients treated with dapagliflozin as compared to 204 (12.6%) and 40 (2.4%) of patients given placebo (Table and Figure). This yielded a hazard ratio (HR) of 0.86 (0.70-1.05) for mild hyperkalaemia and 0.50 (0.29, 0.85) for moderate/severe hyperkalaemia, compared to dapagliflozin to placebo.

Conclusions: Patients with HF/EF and taking an MRA who were randomized to dapagliflozin had half the incidence of moderate/severe hyperkalaemia, compared with those randomized to placebo.

Incident hyperkalaemia in DAPA-HF
FR-OR22
Organizational Characteristics Associated with High Performance in Medicare’s ESRD Seamless Care Organizations
Kelsey M. Drewry,1 Amal Trivedi,1 Adam S. Wilk,1,2 Emory University, Atlanta, GA; 3Brown University, Providence, RI.

Background: In 2016, the 1% of beneficiaries with end-stage renal disease (ESRD) constituted >7% of Medicare spending ($35 billion). To improve the value of care for the ESRD population, CMS implemented an alternative payment model (APM) for ESRD care, the ESRD Seamless Care Organization (ESCO), which shares savings with provider groups that reduce spending for ESRD patients below a defined benchmark. This study evaluated the relationship between key organizational, provider, and community characteristics and ESCO performance.

Methods: We constructed a novel ESCO-level dataset capturing key information for Wave 2 (2017) ESCOs using data from CMS reports, the National Provider Identification registry, and the Area Health Resource File. After describing all 37 ESCOs, we performed bivariate comparisons of high- and low-performing (above vs below median) ESCOs based on gross savings/losses, composite quality score, and standardized mortality ratio (SMR). We then estimated generalized logistic regression models of ESCO performance as a function of organizational, provider, and community characteristics.

Results: ESCO composition and performance were highly variable (ranges: savings/losses -3.9 to 10.2%, quality 76.4-100%, SMR 0.75-1.14). Bivariate analysis showed that ESCOs with above (vs below) median savings had more aligned physicians (58 vs 29, p=0.06), fewer dialysis facilities (8.7 vs 17, p=0.07), a smaller non-Hispanic Black population (14% vs 22%, p=0.06), and a higher median household income ($55k vs $49k, p<0.01). Facilities reporting a quality score of 100% (vs <100%) had fewer practices (22 vs 43, p=0.05) and smaller non-Hispanic Black (16% vs 21%, p=0.06) and Medicaid eligible (6.5% vs 8.9%, p=0.14) populations. Low (vs above-median) SMR was associated with higher median household income ($35k vs $46k, p<0.01). Regression model results were consistent with these findings, though small sample size prevented statistically significant estimates.

Conclusions: Our findings offer the first evidence of the impact of organizational composition and social disparities on ESCO performance. We show that the diversity in ESCO composition and structure partially explained the high variation in performance. This study provides crucial evidence that will inform the design and implementation of APMs in nephrology and the decisions of provider groups considering participation.

FR-OR23
Progress in Preventing Bloodstream Infections in Hemodialysis: Data from the National Healthcare Safety Network, 2014-2018
Shannon Novosad,1 Lucy V. Fike,2 Minn Soe,3 Shunte Moon,4 Preeti Ravindranath,5 Erikka J. Woolfolk,6 Lauren Moccia,7 Duc B. Nguyen,8 Priti R. Patel,9 Centers for Disease Control and Prevention, Atlanta, GA.

Background: Patients on hemodialysis are at high risk of bloodstream infections (BSIs) and associated morbidity and mortality. National prevention efforts have resulted in widespread practice changes, including central venous catheter (CVC) care. We analyzed Dialysis Event Surveillance data submitted to the National Healthcare Safety Network (NHSN) to describe BSI rates among hemodialysis outpatients from 2014 to 2018.

Methods: Outpatient hemodialysis facility reports BSIs (positive blood cultures collected in the outpatient setting or within 1 day after hospital admission) and the number of hemodialysis patients treated during the first 2 working days of each month to NHSN. For each BSI, the suspected source and vascular access type (e.g., CVC, arteriovenous fistula (AVF) or arteriovenous graft (AVG)) were indicated. Pooled mean rates (per 100 patient-months) were calculated. Annual BSI rate trends were evaluated using a negative binomial regression model including access type, year, and an access-year interaction variable.

Results: More than 6,000 outpatient hemodialysis hemodialysis facilities reported 134,961 BSIs from 2014 to 2018. Of these BSIs, 102,505 (76%) were categorized as access-related. Pooled mean BSI rates decreased 27% from 0.64 to 0.47 per 100 patient-months. Significant decreases in rates occurred across vascular access strata (Table); the reduction was most pronounced among patients with CVCs. BSI rates in patients with CVCs decreased 32% from 2.16 per 100 patient-months to 1.46 (annual average decrease 9.5%).

Conclusions: Substantial reductions in BSI rates among hemodialysis patients occurred during this 5-year period. Improvements in infection prevention practices, including CVC care, have likely contributed. Efforts to increase uptake of known prevention practices and implementation of new strategies for prevention might contribute to continued decreases in infections.

Funding: Other U.S. Government Support

BSI rates per 100 patient-months and annual trends by access type, by NHSN 2014-2018
a 23-point improvement in WI-NRS score vs 42% in the PBO group (P=0.020). The proportion of pts who achieved a ≥24-point improvement in WI-NRS score was also significantly greater with DFK vs PBO (41% vs 28%, P=0.010). ICH reduction was evident at wk 1 and was sustained through wk 12. Improvement in ich-related QoL assessed by 5-D Ich and SkinQ-10 was observed. Treatment-emergent AEs at ≥5% with DFK vs PBO were: 8% (vs 5.5%), fall (6.8% vs 5.5%), dizziness (5.5% vs 5.1%), vomiting (6.4% vs 5.9%), and nausea (6.4% vs 4.2%). The incidence of serious AEs was similar across the groups.

Conclusions: In this second phase 3 study, IV DFK demonstrated rapid and sustained ich reduction in HD pts with CKD-aP in multiple regions of the world. DFK was generally well tolerated; safety was consistent with findings in prior studies. With no approved therapies for CKD-aP in the US or Europe, DFK is a potential therapeutic that may address this unmet need.

FR-OR25
Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Hemodialysis
Robert Provenzano,1 Jayant Kumar,2 Pablo E. Pergola,1 Bui Pham van,4 George Hourani,1,2 I-Hsiung P. Yu,3 and John Eniger,3,1

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with ESRD may impact clinical outcomes and survival. Thus, evaluation of safety and efficacy of roxadustat in patients on hemodialysis (HD) is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent chronic kidney disease (CKD). Endpoints evaluated were: mean change from baseline (CBF) in hemoglobin (Hbg) averaged over Weeks 28–52 regardless of rescue therapy and Hb CFB averaged over Weeks 28–36 censored for rescue therapy. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 90% (3515/3887) of patients were on HD (roxadustat vs 1761, epoetin alfa vs 1754). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (mg/dL) at baseline were 9.64 (1.31) in patients on roxadustat (42%) and 9.31 (1.31) in the epoetin alfa group (39%). Patients achieved a larger mean (SD) CFB to Weeks 28–52 in Hb with roxadustat vs epoetin alfa (1.04 [0.49] vs. 0.98 [1.51]), corresponding to a least-squares mean (LSM) difference of 0.25 (95% CI: 0.19, 0.31) (P=0.0001). Patients achieved a larger mean (SD) CFB to Weeks 28–36 in HD with roxadustat vs epoetin alfa (1.27 [1.63] vs. 1.02 [1.60]), corresponding to a LSM difference of 0.25 (95% CI: 0.16, 0.33) (P=0.0001). TEAE rates were comparable between treatment groups.

Conclusions: Roxadustat was efficacious vs epoetin alfa for increasing and maintaining Hb levels in patients on HD on HD. The safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

Stroke and Bleeding Risk Among US Veterans with Preexisting Atrial Fibrillation Transitioning to ESRD
Cachet Wenzinger,1 John Sy,2,3 Maria V. Marroquin,1 Kamay Kalantar-Zadeh,1 Csaba P. Kovessy,1 Elani Streja,1,3 Harley Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 4The University of Tennessee Health Science Center, Memphis, TN; 5VA Long Beach Healthcare System, Long Beach, CA; 6Memphis VA Medical Center, Memphis, TN.

Background: Anticoagulation has been the mainstay of stroke prevention among patients with atrial fibrillation (AF). However, end stage renal disease (ESRD) patients with AF are at increased risk of stroke. It is unclear if patients should be continued on anticoagulation at the time of transition. We retrospectively examined a cohort consisting of 29,054 pre-dialysis and home dialysis patients for 9 years, 4% were female, 85% were white, and 13% were African American. The median (IQR) CHA2DS2-VASc and HAS-BLED scores were 7 (5.8) and 2 (2.3), respectively. Stroke rates by CHA2DS2-VASc and HAS-BLED scores were 7.5% and 2 (2.3), respectively. Stroke rates by CHA2DS2-VASc and HAS-BLED scores ranged from 0.67 (scores 0/1) to 4.27 (score 9) per 100 pt-years while bleeding rates by HAS-BLED scores ranged from 6.83 (score 0) to 46.3 (score 10) per 100 pt-years (Figure). Those with a CHA2DS2-VASc score of 0 had a stroke IRR of 26 (95% CI: 0.09-0.90, p=0.03) favoring no warfarin. Among patients with other CHA2DS2-VASc scores, there was no difference in stroke risk between warfarin and non-warfarin users. No difference was also seen in bleeding 4-point imparing warfarin vs non-warfarin users by HAS-BLED score.

Conclusions: In low stroke risk individuals (CHA2DS2-VASc score of 0, 1, or 2), warfarin use was associated with a higher risk of stroke. There was no significant difference in stroke and bleeding outcomes among other ESRD patients with AF transitioned to dialysis regardless of CHA2DS2-VASc and HAS-BLED scores.

Forecasting the Distribution of Dialytic Modalities in the Era of Advancing American Kidney Health
Kristine Kubisbak,1 Eric D. Weinhandl,1,2 Lorien S. Dalrymple,1 Michael A. Kraus,1 Dinesh K. Chatoth,1 Robert J. Kossmann,1 Franklin W. Maddux,1 2Fresenius Medical Care, Waltham, MA; 3Chronic Disease Research Group, Minneapolis, MN.

Background: The Executive Order on Advancing American Kidney Health aims to increase home dialysis utilization in patients with end stage kidney disease (ESKD). We constructed a simulation projecting dialytic modality distributions between 2019 and 2030 as a function of changing modality transition rates.

Methods: We specified the US ESKD population in Dec. 2018 and used Markov chain Monte Carlo methods to randomly assign patients to a dialytic modality, transplant, or death each month until Dec. 2030, according to parameters that regulate the inflow and outflow of each state. Incident ESKD patients entered the cohort each month and were subject to the same transition parameters. We assessed how changing transition parameters affects projected dialytic modality distributions.

Results: By prevailing conditions, the simulation projects home dialysis will comprise 12% of the dialysis population in 2025. Increasing home hemodialysis (HD) and peritoneal dialysis (PD) utilization among incident ESKD patients from rates of 0.3% to 7.5% and from 11.5% to 37.5%, respectively, by 2025 results in home dialysis utilization of 25% in 2025 and 29% in 2030. Concurrently increasing the rate of conversion from in-center HD to home dialysis from 3.0 to 15.0 events per 100 patient-years by 2025 results in home dialysis utilization of 37% in 2025 and 44% in 2030, as displayed. Decreasing home dialysis attrition rates has a smaller effect on home dialysis utilization.

Conclusions: Substantial growth of home dialysis utilization in the next decade will require a two-pronged approach to inflow: higher utilization of home dialysis in incident patients, emphasizing PD, and increased conversion of patients from in-center HD to home dialysis.

FR-OR28
Hospitalization and Day of the Week: Comparing Peritoneal Dialysis, Home Hemodialysis, and In-Center Hemodialysis
Karthik K. Tennumkote,1 Amnie-Claire Ndeukua-Fredette,2 Kara Matheson,4 Christopher T. Chan,1 Emilie Trinh,1 Jeffrey Perl,1 Dalhousie University, Halifax, NS, Canada; 2Toronto General Hospital, Toronto, ON, Canada; 3Hospital Maisonneuve-Rosemont, Montreal, QC, Canada; 4St. Michael's Hospital, Toronto, ON, Canada; 5McCull University, Montreal, QC, Canada; 6Nova Scotia Health Authority, Halifax, NS, Canada.

Background: Studies have shown that there are daily variations in mortality for patients receiving in-center hemodialysis (HD) but not home HD, peritoneal dialysis or more frequent in-center HD. Less is known about daily variations in hospitalization according to dialysis modality.

Methods: We analyzed all chronic dialysis patients in Canada (excluding Manitoba and Quebec) from 1 Jan 2005 to 31 Dec 2014 using the Canadian Organ Replacement Register (CORR). Dialysis modalities were defined (using CORR) as peritoneal dialysis, a continuous HD or frequent HD (nocturnal or short daily) and HD modalities were furthered categorized as home versus in-center. All switches between modalities after dialysis initiation were included provided the duration of the switch was >30 days.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
The absolute number of hospitalizations for each day of the week was reported for each treatment type and differences in the distribution of hospitalizations were compared using the Chi-Square test.

**Results:** The cohort consisted of 36,334 individuals. Median age was 67 and 61% were of male sex. A total of 81% of patients were receiving hemodialysis at dialysis initiation and the cause of end-stage kidney disease was secondary to diabetes in 37%. Overall, there were 119,466 hospitalizations over the observation period. The cumulative incidence of hospitalizations was highest for conventional in-center HD (92,707) and lowest for conventional home HD (701). Day of the week admissions for each treatment type are noted in Table 1 (P<0.001). Hospitalizations were least frequent on Saturday and Sunday for all groups. The proportion of admissions was highest on Monday or Tuesday for conventional HD (regardless of location) and frequent in-center HD. In contrast, frequent home HD had a higher proportion of admissions on Wednesday.

**Conclusions:** There are daily variations in hospitalization comparing dialysis modalities. Future planned analyses will evaluate whether there are adjusted differences in day of the week hospitalization across modalities accounting for differences in patient characteristics.

Improving Supportive Care of Seriously Ill Dialysis Patients with Goals-of-Care Conversations  
**Alvin Diamond,1 Nancy Aldous,2 Glenda Harbert,1 Amanda C. Nicklas,3 Louis Diamond,4 Nancy Armstrong,3 Dale Lupu,3 1West Virginia University Health Sciences Center, Morgantown, WV; 2George Washington University School of Public Health and Health Services, The George Washington University Milken Institute of Public Health, Washington, DC; 3The George Washington University School of Nursing, Ashburn, VA.

**Background:** Dialysis patients are frequently known to receive unwanted high intensity end-of-life care. Families rate the quality of this care lower than families of patients with other chronic diseases. The purpose of this study was to test the feasibility of a supportive care intervention—the Pathways Project, an evidence-based change package of best practices—to identify seriously ill patients (SI), engage them in goals of care discussions, and track outcomes for patient goal concordance.

**Methods:** Pathways researchers recruited 10 dialysis centers with 1,546 patients. Dialysis staff screened patients with the surprise question (SQ)—“Would I be surprised if this patient died in the next 6-12 months?”—to identify those who were SI and recorded patient outcomes including the number screened, SI, goals of care conversations, hospitalizations, referred to hospice, death, and place of death. An odds ratio was calculated for the odds of SI dying versus those who were not SI, and one-sided Cochran-Armitage trend tests were used to assess for increasing goals of care conversations and deaths at home. The study was interrupted at 9 months due to COVID-19.

**Results:** On average, 98.8% of patients were screened monthly, and 18.4% were identified as SI. Of 114 patients who died, the SI constituted 66% of deaths though only 18.4% of patients. The mortality for the SI was 27% versus 3% for those who were not, and the odds ratio for SI dying was 11.22 (95% CI 7.42 to 16.98, P < .0001). Dialysis interdisciplinary teams implemented site-specific approaches to adding goals of care conversations into usual workflow; the number conducting conversations with SI within 30 days of hospital discharge increased from 30% to 80% (P<.02). The proportion of the patients who died at home in the last 2 months was higher than baseline (32.6% vs 18.8%), but a trend was not yet evident (P=.12).

**Conclusions:** The Pathways intervention is feasible to implement supportive care best practices into existing workflow of dialysis centers. It takes time for teams to get comfortable with new processes and communication approaches; after 9 months more centers were conducting goals of care conversations and more patients were dying at home. Future research is needed to determine if the Pathways intervention results in outcomes more aligned with patient preferences.

Implementation of a Decision Aid for Recognition and Correction of Volume Alterations (Recova®) in Hemodialysis  
**Jenny Stenberg,1 Magnus Lindberg,2 Hans Furuland,3 1Uppsala University Department of Medical Sciences, Uppsala universitet Institutionen för medicinska vetenskaper, Uppsala, Sweden; 2Uppsala University Department of Public Health and Caring Sciences, Uppsala universitet Institutionen för folkhälso- och vardvetenskap, Uppsala, Sweden; 3Hogskolan i Gävle, Gävle, Sweden.

**Background:** Chronic fluid overload is an independent predictor of mortality in hemodialysis. Clinical assessment of fluid status is subjective and imprecise, and 30% of the patients remain fluid overloaded at dry weight. This study evaluates the effects of implementing a recently developed decision aid, Recova®, which combines a systematized fluid status procedure with bioimpedance spectroscopy, for individualized dry weight determination in hemodialysis.

**Methods:** The study was a prospective implementation intervention carried out at two hemodialysis units. The impact of the intervention was measured as the proportion of participants at an adequate dry weight at the end of the study, assessed as change in symptoms, hydration status, and NT-pro-BNP. Hemodialysis nurses were instructed to use Recova® every two weeks, assessing the study participants’ fluid status and adjusting their dry weights as appropriate. The process of the intervention was measured as frequencies of fluid status assessments, bioimpedance measurements, and dry weight adjustments.

**Results:** Forty-nine patients were enrolled. In participants with fluid overload (n = 10), both bioimpedance-measured overhydration and fluid overload symptom score decreased. In fluid-depleted participants (n = 20), dry weight adjustment frequency and dry weight increased. The post-dialytic negative overhydration was reduced, but NT-proBNP increased. In the remaining 19 participants, with low volume status scores, no significant changes were observed.

**Conclusions:** Recova® defines how and when dry weight should be evaluated in hemodialysis patients. Its purpose is to provide the multidisciplinary team with a common language, and thereby facilitate early recognition and appropriate response to fluid alterations. Implementation of Recova® in hemodialysis care increased the monthly frequencies of bioimpedance measurements and dry weight adjustments, and contributed to symptom reduction.

Development of Alport-Syndrome-on-a-Chip to Study the Glomerular Filtration Barrier Pathophysiology  
**Laura Perin,1 Valentina Villani,1 Astigk Petrosoyan,1 Charmi Dedhia,1 Geremy Clair,2 Roger E. De Filippo,1 Stefano Da Sacco,1 Children’s Hospital of Los Angeles, Los Angeles, CA; 2Pacific Northwest National Laboratory, Richland, WA.

**Background:** Alport Syndrome (AS) is a genetic disorder in which podocytes fail to correctly assemble the COL4a3s5a6s5 trimer, a major constituent of the GBM. Disruption of the GBM network leads to podocyte depletion and progressive kidney failure. While important advances in our understanding of AS progression have been made possible by animal models, we still lack an efficient and faithful in vitro model that can mimic the human AS disease. We have recently developed a glomerulus-on-a-chip system (GOAC) that replicates the features of the glomerular filtration barrier and generated AS chips by combining this novel tool with COL4-defective podocytes.

**Methods:** Podocytes derived from amniotic fluid of patients affected by AS (AS-POD) were seeded with human glomerular endothelial cells (hGEC) on Organoplates in a barrier-free system to generate AS-GOAC. The system was assessed by confocal microscopy, WB, proteomics and RNA-seq. Perme selectivity was assessed by measuring albumin leakage. Transcriptomics studies were performed on podocytes by RNA-seq and qPCR and results confirmed in vivo in a mouse model of AS. Primary human podocytes were used as control.

**Results:** We confirmed AS phenotype in AS-POD by RNA-seq and WB. GOAC generated with AS-POD show absence of COL4a4-4-5 confirmed by WB. AS-GOAC
present impaired permeability to albumin, due to a dysfunctional assembly of the GBM, typically with abnormally high urine protein excretion, known as a hallmark of Alport syndrome (AS). One hallmark of AS is that COL4A5 knockout mice lack a known transmembrane protein, collagen α5(IV), which is known to target key players in AS and CKD like WT1, osteopontin, vinculin as well as VEGF and TGFβ pathways. Results were confirmed in vivo in glomeruli of AS mice, further validating the AS-GOAC as an efficient tool for AS studies. Proteomics analysis of the filtrate revealed a distinct signature in AS-GOAC, including presence of apolipoprotein A, αvβ3, and ceruloplasmin.

Conclusions: We have successfully developed an Alport-on-a-chip system that closely mimics the GBM structure and provides a powerful tool for studying the effect of AS on GBM at the molecular level. We have also identified some specific AS proteins, indicative of disease manifestation. This system has the potential to improve our knowledge on AS pathophysiology, allow novel therapeutic targets and become a transformative tool, thus ultimately benefiting patients affected by renal failure.

Development of a Personalized Medicine Platform for Non-invasive Readthrough Therapy in Alport Syndrome

Kohel Omachi,1 Hirofumi Kai,2 Jeffrey H. Miner,1 Washington University in Saint Louis, Saint Louis, MO; 2Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan, Kumamoto, Japan.

Background: Alport syndrome (AS) is characterized by glomerular basement membrane (GBM) abnormalities leading to progressive glomerulosclerosis. Mutations in the COL4A3, COL4A4 or COL4A5 genes encoding type IV collagen α3(IV), α4(IV) or α5(IV) cause AS. Nonsense mutations resulting in premature termination codons (PTCs) account for about 6% of AS cases. Type IV collagen chains have a C-terminal NC1 domain, which is essential for assembly of basement membranes and PTCs within the NC1 domain may not be able to assemble in the GBM. Therefore, achieving full-length protein expression is a potential therapy for AS due to nonsense mutations. Small compound-based nonsense readthrough therapies have been well-studied in other genetic diseases, but whether nonsense readthrough therapy is applicable to Alport syndrome is unexplored.

Methods: To investigate the feasibility of PTC readthrough in AS, we made a C-terminal NanoLuc-fusion COL4A5 reporter cDNA to monitor full-length translation. This cDNA differs from COL4A5-NC1Luc, which produces luminescence, but truncated forms do not. To screen for COL4A5 nonsense mutants susceptible to PTC readthrough therapy, we have generated a library of 49 nonsense mutants found in X-linked AS patients into the COL4A5-NLuc gene. We transfected these individually into HEK293 cells and measured luminescence in these cells with either NanoLuc or β-galactosidase. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure.

Conclusions: We have generated a novel therapeutic ROBO2 fusion protein that functions as a SLIT ligand trap to treat podocyte injury in a pre-clinical animal model. Inhibiting the ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. Semaphorin 3B-Associated Membranous Nephropathy

Sanjeev Sethi1, Hanna Debies2, Benjamin J. Maddon,1 Marina Vivarelli,3 Cristina Charlesworth,1 Aishwarya Ravindran,1 Louann Gross,1 David Buob,3 Cheryl L. Tran,1 Francesco Emma,4 Francesca Diomedi-Camassali,4 Fernando C. Fervenza,1 Pierre M. Ronco,2,5 Mayo Clinic, Rochester, MN; 2Bordeaux University, Paris, France; 3Tenon Hospital, Paris, France; 4Ospedale Pediatrico Bambino Gesu, Roma, Italy.

Background: Membranous nephropathy (MN) results from subepithelial antigen-antibody complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 70 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Semaphorin 3B (Sema3B) in 3 cases. Immunohistochemistry (IHC) of the biopsy that stained positively for Sema3B was then performed to confirm MN results. As the Sema3B antibody was only available for IHC, we performed validation cohorts (2 French and 1 Italian) of 118 PLA2R-negative MN cases by IHC for Sema3B. WB analysis in 5 available sera showed reactivity to Sema3B in 4 patients with active disease and no reactivity in 1 patient in clinical remission; there was also no reactivity in control sera. Eight (73%) of the 11 cases of Sema3B-associated MN were pediatric cases. In 5 of the 8 children, the disease started below the age of 2 years.

Conclusions: Semaphorin 3B-associated MN is a distinct type of MN, and is predominantly present in pediatric patients.

High Temperature Recombinant Protein A1 (HTRA1): A Novel Antigen in Membranous Nephropathy

Laith Al-Rabadi1, Tiffany Caza,2 Claire Avillach,3 Aylin R. Rodan,4 B. Williams,1 Josephine Abraham,1 Monica P. Revelo Penafiel,1 Nicole K. Andeen,1 I. Kawai,1 Frederic Clayton,1 Timothy Cummins,2 Michael Merchant,1 Jon B. Klein,1 Christopher P. Larsen,1 Laurence H. Beck.1 (HIC) for Semaphorin 3B was then performed to confirm MN results. Next, we analyzed ROBO2-Fc (PF-06730512) in patients with FSGS is currently ongoing (NCT03448692). A ROBO2 fusion protein (PF-06730512) Traps SLIT Ligands and Therapeutically Ameliorates Podocyte Injury

Stephen Bera1, Janet E. Buhlmann,1 Michael Shamashkin,1 Matthew V. Russo,1 Hongying Yang,1 Kelly M. Knowlton,1 Nathan Higginson-Scott,1 Hank Lin,1 Catharine Andresen,1 Rhys Jones,1 Xueping Fan,2 Sudhir Kumar,2 Richa Sharma,2 Aneessa Pydi,2 David J. Salant,1 Weinig Lu,2 Pfizer Inc, Cambridge, MA; 2Boston University Medical School, Boston, MA.

Background: ROBO2-βLIT2 signaling negatively regulates nephrin-induced actin polymerization and destabilizes podocyte focal adhesions and attachment to the glomerular basement membrane (GBM) by inhibiting non-muscle myosin IIA. Lack of ROBO2 in podocytes are protected from podocyte injury. Based on these findings we hypothesized that blocking this pathway might have therapeutic potential in podocyte pathologies. Hence, we undertook hypothesis from a case with a genetic defect in ROBO2 and a rodent model of podocyte injury.

Methods: We investigated a patient with a chromosomal translocation that disrupted the ROBO2 gene, produced transcripts encoding dominant negative proteins, and caused high-grade vescicoureteral reflux (VUR). We designed a novel therapeutic ROBO2 fusion protein (ROBO2-Fc, PF-06730512) that inhibits the ROBO2-βLIT2 pathway. In vivo efficacy of ROBO2-Fc was tested in the rat Passive Heymann Nephritis (PHN) model. We also studied the molecular and cellular functions of SLIT2 in kidney glomeruli. In contrast to most adults with long-standing VUR that develop focal sclerosis (FSGS) and proteinuria, the patient with a disrupted ROBO2 gene had stable renal function without proteinuria. In vitro, ROBO2-Fc bound to SLIT ligands with high affinity and dose-dependently inhibited SLIT binding to cell surface ROBO2, and it inhibited ROBO2-dependent cell migration ex vivo. ROBO2-Fc has a terminal half-life of about 2 days in rat and 8 days in monkey. Treatment with ROBO2-Fc reduced proteinuria, shortened podocyte foot process width, and increased slit-diaphragm density in the rat PHN model. Mechanically, we found that SLIT2 is localized to the GBM and binds to COL4A3/α-laminin to inhibit podocyte adhesion.

Conclusions: We have generated a novel therapeutic ROBO2 fusion protein that functions as a SLIT ligand trap to treat podocyte injury in a pre-clinical animal model. Inhibiting the ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-βLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure.

Figure 1 shows bright granular capillary wall staining for Sema3B in 3 cases of Sema3B-associated MN.
Results: Using these combined approaches, we identified HTRA1 as a novel antigen in a subset of patients with primary MN. Serum from these patients reacted by WB with a 51 KDa protein in non-reduced HGE as well as hHTRA1, which correlated with clinical disease activity. (Fig A and B) Consistent with PL2AR and THSD7A, anti-HTRA1 antibodies were predominantly IgG4. HTRA1 specifically was detected in a capillary loop fine granular pattern. (Fig C) and colocalized with IgG4. Whole-proteome peptide microarrays detected significantly higher titer (6.9 SD) of anti-HTRA1 antibody in the active stage as opposed to the remission stage which was informative of its candidacy as a podocyte targeted protein. We have 3 confirmed cases of HTRA1-associated MN and are currently screening several large biopsy cohorts of MN that are negative for PL2AR, THSD7A, and NELL-1 to better assess the prevalence of this novel form of MN.

Conclusions: This report demonstrates the convergence of conventional with more modern techniques to identify HTRA1 as a target podocyte antigen in MN.

Protocadherin 7-Associated Membranous Nephropathy
Saneev Sethi,1 Benjamin J. Madden,1 Louann Gross,1 Vivian C. Negron,1 Cristine Charlesworth,2 Hanna Debiec,2 Pierre M. Ronco,1,3 Fernando C. Fervenza,1,3 Mayo Clinic, Rochester, MN; 2Sorbonne Universite, Paris, France; 3Tenon Hospital, Paris, France.

Background: Membranous nephropathy (MN) results from subepithelial antigen–antibody complex deposition along the glomerular basement membrane (GBM). Although PL2AR, THSD7A, and NELL-1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 85 cases of PL2AR-negative MN. We detected high spectral counts of a unique protein Protocadherin 7 (PCDH7) in 8 cases. Immunohistochemistry (IHC) for PCDH7 was then performed to confirm MS results.

Results: MS identified a unique protein, PCDH7 in 8 cases (9.4%) of PL2AR-negative MN. MS failed to detect PCDH7 in remaining 77 PL2AR-negative MN, 23 PL2AR-positive MN, and 80 controls that included IgA nephropathy, diabetes, FSGS and minimal change disease. Among the 77 PL2AR-negative MN, MS detected NELL-1 (14 cases), EXT1/EXT2 (6 cases), PL2AR (4 cases labeled PL2AR-negative on IF), Sema3B (3 cases), THSD7A (2 cases), and DNAJH9 (4 cases of fibillary GN, misdiagnosed as MN as EM was not done). PCDH7 localized as granular deposits along the GBM by IHC (Figure 1). Kidney biopsy showed a grade II MN in 6 cases, grade I in 1 and grade III in 1 case. Immunofluorescence microscopy showed GBM staining for IgG and C3 in all cases. IgG subtype done in 2 cases showed IgG4 in both. The mean age was 64 years (+/- 11) and 7 of the 8 patients were males. The average serum creatinine and proteinuria was 1.28 mg/dL (+/- 0.3) and 4.9 gm/L (+/- 3.0), respectively. Interestingly, 3 of 8 cases had associated malignancies. Further studies including evaluation for circulating antibodies are ongoing.

Conclusions: Protocadherin 7-associated MN may represent distinct type of MN.

Figure 1 shows bright granular capillary wall staining for PCDH7 in 3 cases (A, B, C) of PCDH7-associated MN, and negative staining in a case (D) of PL2AR-negative MN.

Nefeco® (Budesonide) Selectively Reduces Circulating Levels of BAFF (BLYS) and Soluble BCMA and TACI in IgA Nephropathy
Karen Molyneux, Jonathan Barratt, David H. Wimbury. Mayer IgA Nephropathy Laboratory, University of Leicester, UK; Leicester; United Kingdom.

Background: Evidence supports a pivotal role for gut-associated lymphoid tissue (GALT) as a major source of poorly O-galactosylated immunoglobulin A (IgA) 1 in patients with IgA nephropathy (IgAN). IgA synthesis in the memory B-cell activating factor (BAFF) [B-lymphocyte stimulator (BLYS)] and APRIL can lead to IgA nephropathy. APRIL binding to specific cell-surface receptors: transmembrane activator and calcium modulator and cyclophilin ligand interactor (TACI), B-cell maturation antigen (BCMA), and the BAFF receptor. Elevated levels of BAFF and APRIL have been linked to worse clinical outcomes in IgAN. The therapeutic potential of targeting GALT was demonstrated in the NEFIGAN trial (NCT01738035), which assessed the efficacy of a novel targeted-reformulation of budesonide (Nefeco®), designed to deliver budesonide to the GALT-rich distal ileum in patients with IgAN. The trial comprised 6-month run-in, 9-month treatment, and 3-month follow-up phases: 48 patients received Nefeco® 16 mg/day, 51 patients received Nefeco® 8 mg/day, and 50 patients received placebo. As a result, Nefeco® 16 mg/day, added to optimized renal–immunomodulatory system blockade, reduced proteinuria and stabilized estimated glomerular filtration rate in patients with IgAN. This study investigated whether Nefeco® treatment altered serum levels of BAFF and APRIL and their receptors.

Methods: Serum levels of BAFF, APRIL, BCMA, and TACI were measured using Luminex technology. Changes in the levels of BAFF and APRIL were compared using a one-way analysis of variance. Significance was set as p<0.05.

Results: A significant, dose-dependent reduction in serum BAFF levels was seen with Nefeco®, which reversed on cessation of Nefeco®. There were similar significant reductions in the levels of soluble BCMA and TACI with treatment, but no effect was seen on circulating levels of APRIL. These changes were mirrored by parallel changes in soluble CD27 levels and were consistent with our previous reports on dose-dependent reductions in circulating IgA–IgG immune complexes, secretory IgA, and galactose-deficient IgA levels with Nefeco®.

Conclusions: Delivering budesonide to the GALT-rich distal ileum modulates key regulators of GALT B-cell maturation and IgA class switch recombination in patients with IgAN.

Tony Muchamuel, Rong A. Fan, Janet L. Anderl, Henry Johnson, Dustin L. Memm, Brian Tuch, Christopher Kirk. Kezar Life Sciences Inc, South San Francisco, CA.

Background: Selective inhibition of the immunoproteasome blocks progression of nephritis in a mouse model of systemic lupus erythematosus (SLE). Here we describe the effects of KZR-616 in this model and in patients from MISSION (KZR-616-002; NCT03393013), an open-label study of KZR-616 in patients with SLE with and without nephritis.

Methods: 24-week old NZB/W mice were treated weekly with subcutaneous administration of 5 mg/kg KZR-616 for 11 weeks. SLE patients with active disease and stable background medication (N=34) were dosed subcutaneously with KZR-616 at 30, 45 or 60 mg/kg weekly for 13 weeks with a 12-week follow-up. Clinical samples were evaluated for proteasome subunit binding, and immune cell profile was evaluated by flow cytometry. Gene expression analysis was performed by RNAsig in mouse tissue (whole blood, spleen, and kidneys) and patient (whole blood) samples.

Results: KZR-616 treatment resulted in complete resolution of proteinuria, prevention of glomerular damage, and absence of renal IgG deposition. Depletion of splenic activated T- and B-cells and short and long-lived plasma cells in treated animals was noted and correlated with decreased gene expression associated with inflammation, T helper (Th) 1 and Th17 pathways, interferon signaling, antibody secreting cells, and differentiation of plasma cells (PC). KZR-616 reduced kidney tissue transcripts associated with inflammation, cell and myeloid glomerulus trafficking and renal genes implicated in LN pathogenesis. In SLE patients, KZR-616 treatment was determined to be safe and tolerated at all dose levels and reductions in disease activity parameters were noted. KZR-616 treatment was associated with a reduction in class-switched memory B cells and PC in peripheral blood. Decreased expression of gene modules for PC, T-cell activation, inflammation, neutrophil, and type I IFN responses were seen in response to treatment.

Conclusions: KZR-616 resolves nephritis in a mouse model of SLE/LN by regulating immune effector cell gene expression and glomerular injury. In SLE patients, KZR-616 demonstrated broad anti-inflammatory activity across T, B, and innate immune effector cells. These results support further clinical evaluation of KZR-616 in patients with LN.

Harnessing Expressed Single-Nucleotide Variation and Single-Cell Sequencing to Define Immune Cell Chimerism in the Rejecting Kidney Transplant
Andrew F. Malone, Haoja Wu, Joseph Gaut, Benjamin D. Humphreys. Washington University in Saint Louis, Saint Louis, MO.

Background: In solid organ transplantation, donor derived immune cells are assumed to decline with time after surgery. Whether donor leukocytes persist within kidney transplants or play any role in rejection is unknown, however, in part because of limited techniques for distinguishing recipient and donor cells.

Methods: We performed paired whole exome sequencing of donor and recipient DNA and single cell sequencing (scRNA-seq) of 5 human kidney transplant biopsy cores. Exome sequences were used to define single nucleotide variants (SNV) across all samples.

Results: By analyzing expressed SNVs in the scRNA-seq dataset we could define recipient vs. donor cell origin for all 81,139 cells. The leukocyte donor to recipient ratio varied with rejection status for macrophages and with time post-transplant for lymphocytes. Recipient macrophages were characterized by inflammatory activation and donor macrophages by antigen presentation and complement signaling. Recipient origin T cells expressed cytotoxic and pro-inflammatory genes consistent with an effector cell phenotype whereas donor origin T cells are likely quiescent expressing oxidative phosphorylation genes relative to recipient T cells. Finally, both donor and recipient T cell clones were present within the rejecting kidney, suggesting lymphoid aggregation. Our results indicate that donor origin macrophages and T cells have distinct transcriptional profiles compared to their recipient counterparts and donor macrophages can persist for years post transplantation.

Conclusions: This study demonstrates the power of this approach to accurately define leukocyte chimerism in a complex tissue such as the kidney transplant coupled with the ability to examine transcriptional profiles at single cell resolution.

Alpha1-Antitrypsin Diminishes Neutrophil Activation by PR3-ANCA and Endothelial Injury by Neutrophil Serine Proteases
Ralph Kettritz,1-2 Uwe Jerke,1 Claudia Eulenberg-Gustavus,1 Dieter E. Jenne.3 1Experimental and Clinical Research Center, Charité, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Berlin, Germany; 3German Center for Lung Research, Helmholtz Zentrum München, Munich, Germany.

Background: Neutrophil serine proteases (NSPs) contribute to ANCA-associated vasculitis (AAV). PR3 is a unique NSP family member because it is both a proteolytic enzyme and an ANCA antigen. Alpha1-antitrypsin (AAT) is the major natural NSP inhibitor. We hypothesized that AAT protects from ANCA-induced neutrophil activation and neutrophil-mediated glomerular endothelial cell injury.

Methods: We produced recombinant wild-type (wt) AAT and a mutant (mu) form that does not inhibit proteolytic NSP activity. We used flow cytometry to study membrane PR3 (mPR3) and MPO (mMPO), ferricytochrome C assay for superoxide release, FRET assays for proteolytic NSP activity, human neutrophils and glomerular microvascular endothelial cells (gMVEC) immunofluorescence and electron microscopy, and assessed ECs by phalloidin staining and gene expression.

Results: Wt-AAT reduced mPR3 on TNFα-primed neutrophils dose-dependently from 0.1 to 10 μM (n=3). Five μM wt-AAT, but not mut-AAT, reduced neutrophil mPR3 in suspension, on fibronectin, and on an EC monolayer to approximately 25% (n=3). Parallel comparisons in neutrophil-EC co-cultures using antibodies to different PR3 epitopes showed that 5 μM AAT reduced mPR3 but not mMPO. Importantly, reduced mPR3 by AAT resulted in significantly less superoxide release by TNFα-primed neutrophils that activated with PR3-, but not with mPO-ANCA IgG from AAV patients (n=4). Next, we studied the NSP transfer from activated neutrophils to gMVEC and found that gMVEC acquired NSPs, exemplified by PR3, from both cell-free supernatants (cf-SN) and under neutrophil-EC co-culture conditions. Importantly, wt-, but not mu-AAT abrogated the PR3 transfer from cf-SN. In contrast, AAT did not inhibit the PR3 transfer under neutrophil-EC co-culture conditions. Finally, we observed by RT-PCR that cf-SN from activated neutrophils increased two NF-kB dependent genes in gMVEC, namely IkBa and IL-8. This effect was reduced by wt-, but not by mu-AAT suggesting an NSP-dependent activation mechanism.

Conclusions: AAT has protective effects by reducing neutrophil activation in response to PR3-ANCA, and NSP-mediated glomerular microvascular endothelial cell injury. Disturbances of the AAT-NSP balance possibly contribute to neutrophil-mediated vascular injury in AAV, particularly, but not exclusively, in patients with PR3-ANCA.

Proteomics Reveals Extracellular Matrix Injury in the Glomeruli and Tubulointerstitium of Kidney Allografts with Early Antibody-Mediated Rejection
Serri Clot Freixas,1 Caitriona M. McEvoy,1 Ilhor Batruch,2 Chiara Pastrello,1 Max Kotlyar,3 Madhurangi Arambewela,1 Julie Anh Dung Van,1 Yin Niu,2 Sofia Farkona,3 Alexander Boshart,4 Andrea Bozovic,5 Vathany Kuliastigam,6 Olugbemisola Famure,1 Joseph Kim,1 Tereza Martinu,1,8 Stephen C. Juvel,1,5 Andrzej Chruscienski,1,7 Rohan John,1,10 Ana Konvalinka,10,11 Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada; 2Department of Laboratory Medicine and Pathobiology, Lumenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; 3Krembil Research Institute, University Health Network, Toronto, ON, Canada; 4Institute of Medical Science, University of Toronto, ON, Canada; 5Department of Laboratory Medicine and Pathobiology, University of Toronto, ON, Canada; 6Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada; 7Department of Medicine, University of Toronto, ON, Canada; 8Division of Respiratory and Toronto Lung Transplant Program, University Health Network, Toronto, ON, Canada.

Background: Antibody-mediated rejection (AMR) accounts for >50% of kidney allograft losses. AMR is caused by donor-specific antibodies (DSA) against HLA antigens in the glomeruli and the tubulointerstitium, which together with interferon-γ and tumor necrosis factor-α (TNFα), trigger graft injury. The reasons behind cell-specific injury in AMR remain unclear. Identifying compartment-specific proteome alterations may help uncover mechanisms of early antibody-mediated injury.

Methods: We studied 30 for-cause kidney biopsies with early AMR, acute cellular rejection (ACR) or acute tubular necrosis (ATN). We laser-captured microdissected glomeruli and tubulointerstitium and subjected them to unbiased proteome analysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

27
Results: We found 107 glomerular and 121 tubulointerstitial proteins significantly differentially expressed in AMR vs ACR (p<0.05). Similarly, 112 (glomeruli) and 124 (tubulointerstitial) proteins were altered in AMR vs ATN. Basement membrane and extracellular matrix (ECM) proteins were decreased in both compartments in AMR, compared to ACR and ATN. We verified decreased glomerular and tubulointerstitial LAMBR expression, and decreased glomerular NPHS1 and PTPRO expression in AMR. Cathepsin-V (CTSV) was predicted to cleave ECM-proteins in the AMR glomeruli. We identified galectin-1, an immunomodulatory protein increased in AMR glomeruli and linked to the ECM. An external dataset (GSE36059) also demonstrated increased generation of anti-HLA class-I antibodies induced inflammation and significantly increased CTSV expression, and galectin-1 expression and secretion, in human glomerular endothelial cells. We also studied GSTO1, an ECM-modifying enzyme, increased in the AMR tubulointerstitium. GSTO1 expression was significantly increased in TNCa-treated proximal tubular epithelial cells.

Conclusions: Basement membranes are often remodeled in chronic AMR, and we demonstrated that this remodeling begins early in glomeruli and tubulointerstitium. ECM-remodeling in AMR may represent a new therapeutic target.

Interim Update of the MDR-101-MLK Phase 3 Trial: MERCURY Study
Dixon Kaufman,1 Mark D. Stegall,2 Ethan P. Marin,3 Ahmed O. Gaber,4 Titte Srinivas,5 Erik Stites,6 Stephan Busque,7 Martin L. Mai,8 Matthew Cooper,9 Suzanne Crowley,10 James B. Piper,3 Asher P. Shah,3 Sanjeev Akkina,11 Kenneth Chavin,4 Mercury Study Group University of Wisconsin System, Madison, WI; 7 Mayo Clinic Minnesota, Rochester, MN; 8 Yale University, Department of Internal Medicine, New Haven, CT; 4 Houston Methodist, Houston, TX; 6 University of Colorado, Denver, CO; 1 Stanford University School of Medicine, Stanford, CA; 9 Mayo Clinic’s Campus in Florida, Jacksonville, FL; 5 MedStar Georgetown University Hospital, Washington, DC; 2 University Hospitals, Cleveland, OH; 10 Medeor Therapeutic, South San Francisco, CA; 3 Inova Health Systems, Falls Church, VA; 11 Jefferson Health, Wayne, Pa, 12 Loyola University Health System, Maywood, IL.

Background: The goals of tolerance in patients with kidney transplants (Ktxp) are to eliminate the lifelong need for immunosuppressive (IS) drugs and to prevent graft loss due to rejection or drug toxicity. MDR-101 is a novel cellular immunotherapy, to produce persistent mixed chimerism without graft versus host disease (GvHD) to allow elimination of all IS therapy without rejection, and, thus, to produce operational tolerance. The randomized controlled study evaluated the need for chronic IS therapy in recipients of HLA-matched living donor (LD) kidney transplants as compared to standard of care (SOC) (NCT03363945).

Methods: Eligible adult pairs (donor/recipient) of a first kidney allograft from an HLA-identical LD were enrolled and randomized 2:1 to either the Investigational Arm (IA; n=20) or Control Arm (CA; n=10). Donors in the IA received G-CSF mobilization for 5 days before undergoing apheresis (1 or 2 cycles). IA recipients receive ATG conditioning, low-dose total lymphoid irradiation (TLI) over 10 days and IS followed by an infusion of MDR-101 on d11. After 180 days of persistent mixed chimerism, IA subjects initiated a 6-month taper of CNI and could withdraw all IS on D365. CA subjects were treated as institutional SOC.

Results: As of June 1, 2020, 26 subject pairs (donor/recipient) have been enrolled, comprising 84 pairs randomized to the IA and 8 pairs randomized to the CA. MDR-101 infusion was completed in 12 subjects in the IA. To date, 9 subjects in the IA have reached Day 180 with 6 months of positive mixed chimerism. Five subjects have reached Day 365 and were able to withdraw all IS. Two subjects lost chimerism – 1 at D545 (off IS) and 1 at D365 continue to wean IS. There have been no events of GvHD, biopsy-proven acute rejection, and dNSA. There have been no graft losses or deaths in either group.

Conclusions: Administration of MDR-101 in HLA-identical LD Ktxp recipients conditioned with ATG and TLI have produced promising results to date. These results show that MDR-101 induces mixed chimerism without GvHD and permits withdrawal of IS without rejection or dNSA. Further analysis continues.

Single-Cell Profiling of Peripheral Blood Mononuclear Cell Identifies Immune Populations Associated with High Risk of Early Acute Rejection
Weiwei Zhang, Samina S. Farouk, Zeguo Sun, Zhengyi Ji, Jia Fu, Chengguo Wei, Miguel Fribourg, John C. He, Paolo Cravedi, Barbara T. Murphy. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Our previous transcriptomic analysis of pre-transplant peripheral blood of 235 kidney transplant recipients in a multi-center GoCAR cohort revealed a 23-gene set predictive of early acute rejection (EAR) post kidney transplant, but the associated immune profile is unknown.

Methods: We first developed a reliable targeted RNA expression (TREx) sequencing assay based on the EAR prediction gene set and applied the assay to assess the EAR risk of 21 dialysis patients who were recruited at Mount Sinai Hospital. We next performed extensive single-cell immune profiling of PBMCs of these patients using 33 surface markers with CyTOF technology. Lastly, using 10X genomics technology, we performed single cell RNA sequencing (scRNAseq) of the PBMCs to identify immune cell (sub) populations and their transcriptomic signatures from two patients with high and low risk of EAR, respectively.

Conclusions: The Baseline Acute Rejection assay is associated with clear cellular and molecular Phenotype which may help us further understand the underlying mechanisms that lead to the development of acute rejection.

FR-OR45

Single-Cell RNA-Sequencing Analysis of Kidney Transplant Biopsies Demonstrates a Proinflammatory Role for Renal Tubular Cells in Rejection
Andrew F. Malong, Aidan Leckie-Harre, Haojia Wu, Benjamin D. Humphreys. Washington University in Saint Louis, Saint Louis, MO.

Background: Antibody mediated rejection (AMR) remains one of the major causes of allograft failure and our understanding of this disease process is poor. CXCL12 is thought to contribute to allograft rejection through T cell recruitment and a CXCL12 promoter variant is associated with worse graft outcomes. We performed single cell RNAseq on biopsies from transplant patients to examine ligand expression in kidney cells.

Methods: The 10X Genomics platform was used to make libraries which were sequenced to a depth of ~50k reads/cell. Gene-cell matrices were obtained from CellRanger and the downstream analysis (clustering, integration analysis, expression analyses) were done using R and Seurat. This study had IRB approval.

Results: 81139 cells in total (avg = 1124 genes/cell) from 5 kidney transplant biopsy samples (2 non-rejecting, 3 ABMR) were included in the final integrated analysis using UMAP. All major kidney cell types were identified as well as macrophages, B cells and T cells. Renal epithelial cells from rejection samples differentially expressed ligands with cognate receptors found on immune cells. All renal tubular cell types increase HLA gene expression allowing for ligation of macrophage and T cell cognate receptors LIRL.B and CD3, respectively. Interestingly, only loop of Henle cells increased expression of CXCL12 whereas stromal cells decreased CXCL12 expression in rejection samples.

Conclusions: Comprehensive single cell RNAseq of human kidney transplant biopsies suggests a role for loop of Henle cells in rejection though expression of CXCL12. We also demonstrate that stromal cells, known to express CXCL12, downregulate CXCL12 expression in rejection. These data suggest a pro-inflammatory role for tubular cells in rejection.

Modified Immune Cell Infusion in Kidney Transplantation

Christian Morath,1 Matthias Schaier,1 Eman H. Ibrahim,1 Lei Wang,1 Christian Kleist,1 Gerhard Opela,1 Caner Süsal,1 Mostafa G. Aly,1 Claudius Speer,1 Florian Klöble,1 Christian Nusshag,1 Luiza Pego Silva,2 Claudia Sommerer,1 Angela Hückelhoven-Krauss,1 Arianeb Mehrai,1 Carsten Mueller-Tidov,1 Jochen Reiser,2 Martin G. Zeier,1 Michael Schmitt,1 Peter Terness,1 Anita Schmitt,1 Volker Daniel,1 1Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; 2Rush University Medical Center, Chicago, IL.

Background: We have shown that donor blood cells, modified in vitro by an alkylating agent (MIC, modified immune cells), induced specific immunosuppression against the allogeneic donor when administered prior to transplantation. An additional finding was an up to 6-fold increase in the frequency of immunosuppressive CD19^CD24^CD38^ transitional B lymphocytes compared to transplanted controls without MIC infusions. The question arises whether donor-specific immunosuppression and increased regulatory B lymphocytes (Breg) are permanently detectable in MIC-treated patients.

Methods: Four patients from a phase-I trial who had received 1.5x10^8 MIC per kg b.w. on day -7 before living donor kidney transplantation and who were on low immunosuppression were compared to 12 transplanted control patients without MIC infusions.

Results: MIC-treated patients showed an excellent clinical course with no donor-specific HLA antibodies or rejection. On day 1080 after transplantation, median serum creatinine was 1.59 mg/dL. Patients had absent in vitro lymphocyte reactivity against stimulatory donor blood cells while reactivity against third party cells was preserved as an indication of continued donor-specific unresponsiveness. CD19^CD24^CD38^ and H10^CD19^CD24^CD38^ Breg were with 2.2x and 1.0x, respectively, strikingly higher than the 0.0x (P<0.001) and 0.0x (P<0.001) in transplanted controls and in the range of the numbers of healthy individuals (N=34, P=0.73 and P=0.60). In addition, significantly higher Breg numbers were found for CD1d^+ (P=0.0071), CD19^CD24^CD1d^+ (P=0.0077), CD19^CD25^CD73^CD71^ (P=0.013), CD19^CD25^CD73^CD71^ (P=0.0011), CD19^CD24^CD27^ memory (P=0.029), and IL10^CD19^CD24^CD27^ memory Breg (P=0.042). No such differences were observed for CD4^+CD25^CD127^- (P=0.08) or different Treg subsets when comparing the four MIC-treated patients to transplanted controls without MIC infusions.

Conclusions: Donor-specific immunosuppression after MIC infusion is long-lasting and is associated with a striking increase in Breg at various stages of B cell development, including memory Breg.

FR-OR47

Normothermic Ex Vivo Kidney Perfusion in a Porcine Auto-Transplantation Model Preserves the Expression of Key Mitochondrial Proteins: An Unbiased Proteomics Analysis

Caitriona McEvoy,1,2 Sergio Cotlet Freixas,1 Tomas Tokar,1 Chiara Pastrello,1 Shelby Reid,1 Ibor Baturc,1 Adrien A. RaoPeters,3 Peter Urbanelli,1,3 Sofia Farkona,1 Julie Anh Dung Van,3 Brad Urquhart,1 Rohan John,1 Lisa Robinson,1,2 Markus Selzer,1,2 Ana Konvalinka,1,2 Toronto General Hospital, University Health Network, Toronto, ON, Canada; 3Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, ON, Canada; 4Humberfield-Tanenbaum Research Institute, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada; 5Soham and Shaila Ajmera Family Transplant Centre, Toronto General Hospital, University Health Network, Toronto, ON, Canada; 6Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, ON, Canada; 7Department of Medicine, University of Toronto, Toronto, ON, Canada; 8Surgical Pathology and Laboratory Medicine, University of Toronto, Toronto, ON, Canada; 9Department of Physiology and Pharmacology, Schulich School of Medicine & Dentistry, Western University, London, ON, Canada; 10Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada; 11Department of Pathology and Laboratory Medicine, University of Toronto, Toronto, ON, Canada.

Background: Normothermic ex-vivo kidney perfusion (NEVP) results in significantly improved graft function in porcine auto-transplant models of DCD injury compared to static cold storage (SCS); however, the molecular mechanisms underlying these beneficial effects remain unclear.

Methods: We performed an unbiased proteomics analysis of 28 kidney biopsies obtained at 3 timepoints from pig kidneys subjected to 30-minutes of warm ischemia, followed by 8-hours of NEVP or SCS, and auto-transplantation.

Results: Of 6593 proteins quantified, 70 were differentially expressed between NEVPK and SCS groups (2-way ANOVA, q<0.05). Proteins increased in NEVPK mediated key metabolic processes including fatty acid β-oxidation, the TCA cycle and oxidative phosphorylation. Integration of our findings with external datasets of ischemia-reperfusion, and other models of kidney injury confirmed that 47 of our proteins represent a common signature of kidney injury reversed or attenuated by NEVPK. We validated key metabolic proteins (ETFB, CPT2) by immunoblotting. Integrated transcription factor databases identified PPARGC1A, PPARA/G/D and RXRA/B as the upstream regulators of our dataset, and we confirmed their increased expression in NEVPK with RT-PCR.

Conclusions: The proteome-level changes observed in NEVPK mediate critical metabolic pathways that may explain improved graft function with NEVPK compared to SCS. These effects may be coordinated by PPAR-family transcription factors, and may represent novel therapeutic targets in ischemia-reperfusion injury.

FR-OR48

Cyclosporine-Induced Endothelial Injury and Complement Activation Is Caused by Impaired Complement Factor H Binding to the Glycoconjugate of Endothelial Cells

Chiu Wei Teo,1 Carolina Ortiz,1 Magdalena Riedl Khursigara,2 Valentina Bruno,1 Lisa Robinson,3 Christoph Licht.3 The Hospital for Sick Children, Toronto, ON, Canada.

Background: Calcineurin inhibitors are associated with nephrotoxicity, endothelial cell (EC) dysfunction and thrombotic microangiopathy. Evolving evidence suggests a central role for complement dysregulation in the pathogenesis of CNIs-induced thrombotic microangiopathy. However, the exact mechanism of calcineurin-included complement-mediated injury remains unknown.

Methods: In an in-vitro model utilising Blood Outgrowth EC (BOEC) from healthy donors, we evaluated the effects of cyclosporine (CSA) on EC injury, complement activation (C3, C9) and regulation (CD46, CD55 and complement factor H [CFH]) on EC surfaces, and on the EC glycoconjugate, utilising flow cytometry, Western blot, and immunofluorescence imaging. Functional activity of CFH was assessed via CFH cofactor assay. Co-immunoprecipitation of Angiopoietin-2 (Angpt-2), Angiopoietin-1 (Angpt-1) and Tie2 was assessed by Western blot.

Results: CSA resulted in a dose and time dependent enhancement of EC complement dysfunction and EC CSA. CSA (10 μg/ml) led to supplementation of CD46, CD55 and CD9 on EC surface. CSA led to Angpt-2 mediated breakdown of the EC glycoconjugate, which was mitigated by Angpt-1. This EC glycoconjugate breakdown led to decrease in CFH surface binding and surface cofactor activity.

Conclusions: Our findings confirm a role for complement in CSA-induced EC injury, and suggest Angpt-2 mediated glycoconjugate abolishment, induced by CSA, as a mechanism leading to complement alternative pathway dysregulation via decreased CFH surface binding. Insights into this mechanism may provide a potential therapeutic target that might lead to improved patient outcomes which is subject to further studies. It might also apply to other thrombotic microangiopathies, in which a role for complement has so far not been recognized.

FR-OR49

Epigenome-Wide Microarray Analysis of Pre- and Post-Transplant Methylation Profiling in Kidney Transplant Recipients

Katie Kerr,1 Laura J. Smyth,1 Jill Kilner,1 Alexander P. Maxwell,1,2 Helen Mcaneye,3 A.J. McKnight.1 1Queen’ s University Belfast, Belfast, United Kingdom; 2Belfast City Hospital Nephrology Service, Belfast, United Kingdom; 3University Health Network, Toronto, ON, Canada.

Background: Kidney transplantation is the optimal treatment for suitable individuals with end-stage kidney disease (ESKD). Serious post-transplant complications include infections, cardiovascular events, malignancy, and new onset of diabetes after transplantation (NODAT). Our regional nephrology centre has the highest living donor transplant rate per million population in Europe, and promotes research to improve patient outcomes. We compared pre and post-transplant methylation profiles in samples derived from matched participants.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Epigenome-wide analysis was conducted using the Illumina Infinium MethylationEPIC array to interrogate 862,987 sites across the genome and identify any differentially methylated regions (DMR) in samples derived from peripheral blood mononuclear cells of age and sex matched pre (n=25) and post (n=25) kidney transplant recipients. DNA was extracted in a uniform manner and stored carefully undergoing minimal freeze thaw cycles. Samples were run on the same instrument and regression calibration was performed in R to estimate leukocyte cell proportions.

Results: Association analysis using Partek® GenomicsSuite® identified 53 DMR (FDR adjusted p≤0.1 x 10^4, fold change ≥2). Within the top ranked CpG probes we identified DMR within genes dysregulated in melanoma (e.g. EXOC2, VEPH1), genes encoding extracellular matrix proteins that could influence structural glomerular changes (e.g. SPAM1) and genes with prior chronic kidney disease associations (e.g. FNTA). A DMR was also identified within the long intergenic non-protein coding RNA LINC01544, suggesting a possible regulatory function. Additionally, Partek® Pathway™ identified enrichment of DMR in the mitogen-activated protein kinase (MAPK) signalling pathway, primarily implicated in malignancy but also ESKD and cardiovascular disease. Gene ontology analysis identified enrichment of terms associated with localization and binding within cells.

Conclusions: This analysis provides a novel epigenomic perspective on molecular changes caused by kidney transplantation, and highlights markers that may be of relevance to post-transplant complications. We provide evidence supporting further methylation and transcriptomic analyses in larger cohorts to help identify epigenetic risk factors associated with post-transplant complications.

FR-OR50
Impact of Caspase-1 Deletion on Apoptosis and AKI in a Murine Transplant Model
Swati Jain,1 Robert J. Plenter,1 Trevor Nydam,1 Alkesh Jani,1,2 University of Colorado, Denver, CO; 3Rocky Mountain Regional VA Medical Center, Aurora, CO.

Background: Prolonged cold ischemia (CI) is a known risk factor for acute kidney injury (AKI) after kidney transplantation. However, the mechanism by which CI leads to AKI is unknown. Caspase-1 knockout mice (CaspiKO) are protected from AKI after warm ischemia/reperfusion injury. We hypothesized that CaspiKO mice would be protected from AKI following transplant.

Methods: Renal tubular cells (RTECs) were subjected to cold storage and rewarming (CS/REW). C57Bl/6J wild type or CaspiKO kidneys were subjected to CI for 30 min and then transplanted into wild type recipients (CI→Txp). The recipients underwent bilateral nephrectomy at the time of transplant. Serum creatinine (sCr) was measured 24hrs after native nephrectomy to assess transplant function.

Results: In vitro: We observed significantly increased expression of NLRP1 inflammasome protein and Caspase-1 in cells subjected to CS/REW. Using Imagestream flow cytometer we observed spatial overlap between two different fluorescent labels of Caspase-1 and NLRP1 in RTECs exposed to CS/REW compared to control cells. In vivo studies: Wild-type kidneys subjected to CI→Txp demonstrated significantly increased Caspase-1 and NLRP1 protein expression. Caspase-1 deletion results in significantly decreased RTEC apoptosis in transplanted CaspiKO vs WT kidneys. Renal function, brush border injury, cast formation, tubular simplification were similar in both groups and not significantly different [Table 1].

Conclusions: CS/REW and CI→Txp increase NLRP1 and Caspase-1 expression and co-localization. Deletion of Caspase-1 improves tubular cell apoptosis following CI→Txp. However, Caspase-1 deletion did not prevent AKI and necrosis in kidneys subjected to CI→Txp, suggesting that other triggers of inflammation and programmed necrosis may need to be included in addition to deletion of Caspase-1 to fully prevent AKI after kidney transplantation.

Studying Proteinuria in COVID-19 to Define Markers of Severity and New Treatments
Yask Gupta, Juntao Ke, Jeremiah Martino, Qingxue Liu, Byun Hee Kil, Tze Yin Lim, Gina Ying Jin, Dina Ahram, Nicholas J. Steers, Simone Sanna-Cherchi. Columbia University Irving Medical Center, New York, NY.

Background: The recent SARS-CoV-2 pandemic has led to ~3,750,000 fatalities worldwide as of June 1st. Nearly, 43% of COVID-19 patients have been reported to have proteinuria, which can result from direct podocyte injury, podocytopathy related to cytokine storm, or both. This association between respiratory viruses, proteinuria, and primary kidney disease has also been observed in the context of respiratory syncytial virus (RSV), where patients can develop nephrotic syndrome. Therefore, studying primary and virus-dependent models of proteinuria and podocyte injury is critical to shed light into COVID-19 pathobiology, severity of disease and potential treatments.

Methods: We accessed transcriptomic data (RNA-seq) for lung cell lines (A549) infected with three different viruses and identified differentially expressed genes (DEGs) for SARS-CoV-2, RSV and IAV. In parallel, we also investigated DEGs for FSGS and MCD using LIMMA R package. We investigated the statistical correlation between the log-fold change of DEGs (Nephrotic syndrome and SARS-COV-2) using R. Pathway analysis was performed using WebGestalt. Possible drugs correcting the skewed gene expression in FSGS and SARS-COV-2 were identified using the Connectivity map (eMAP).

Results: 120 gene signatures were specific to SARS-CoV-2. By using gene expression data from glomeruli of FSGS/MCD we identified 902 DEGs for FSGS and 5 for MCD. Out of these, 6 were overlapping and upregulated in COVID-19 and FSGS/MCD (B2M, EIF2AK2, IFIT1, IFIT2, TC7M and UCBE2L6). Strikingly, IFIT2 has been recently reported as a marker of disease severity in COVID-19. We found significant positive correlation between the log2 fold change of 94 FSGS/MCD genes intersecting with the 120 COVID-19. The results were specific to glomeruli and to high proteinuric diseases, supporting a common cellular response in lung and podocytes. We then searched the cmap data and identified 59 drugs significantly inversely associated with SARS-COV-2 and 72 for FSGS. Out of these, 7 drugs were in common, representing novel potential drugs for COVID-19 and podocytopathies.

Conclusions: Overall, our results suggest transcriptional congruency between NS and SARS-COV-2 which can possibly be used to design novel therapies treat these diseases.
SA-OR03
SARS-CoV-2 Detection in Urine Sediment Suggests Infection of Kidneys and Correlates with Risk of AKI and Poor COVID-19 Prognosis
Paulo S. Caceres, Gina Savickas, Junior Uduman, Kausik Umanathan, Yuvraj Sharma, Jerry Yee, Shannon Murray, Sarah Sarkar, Jamie Fitzgerald, Dipak Maskey, Adrian Ormsby, Pablo A. Ortiz. Henry Ford Hospital, Detroit, MI.

Background: Since the emergence of the novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), most of the focus has been on the respiratory failure caused by the resulting disease, COVID-19. However, the effects of COVID-19 in the kidney are increasingly recognized. Acute kidney injury (AKI) has been identified with varying prevalence around the world with higher rates (37.46%) reported in the USA. It is debatable whether AKI is an indirect consequence of systemic inflammation or a consequence of viral renal cell infection and tropism. We hypothesize that SARS-CoV-2 directly infects kidney tissue and increases the risk of developing AKI, worsening prognosis of COVID-19 patients.

Methods: We studied 88 COVID-19 patients admitted to the Henry Ford Hospital, Detroit after April 15, 2020. Demographics were: mean age 60, 71% African American, 55% male. We quantified viral copies by RT-PCR (S and N) in urine sediments from 52 PCR-confirmed COVID-19 patients. We performed immunofluorescence for Membrane and Spike viral proteins in two COVID-19 biopsies.

Results: The prevalence of AKI was 72%, with 32% of patients admitted to the ICU. The overall mortality rate was 14%, with no deaths in non-AKI patients. Viral proteins M and S were detected in the glomerulus, parietal cells and tubules of COVID-19 patients. In some tubules, positive SARS-CoV-2 overlapped with ACE2, the receptor for viral entry. Virus was detected in 61% of urine sediments, with 6-fold greater viral load in AKI patient urines (copies/ng RNA: AKI, 7422±1338 vs No-AKI: 1523 ± 404; p<0.05, n=52). The highest viral loads were detected three weeks post-AKI at 11,374±2248 copies/ng RNA (p<0.01). Among COVID-19 AKI-patients who died, the urine viral load exceeded 8000 copies/ng RNA. Above this threshold, the mortality rate was 55%.

Conclusions: Our data support that direct viral renal cell infection occurs in COVID-19 AKI patients with urinary viral genome detection. Greater urinary viral loads portend increased mortality. Urinary viral detection can facilitate management and treatment of COVID-19 and serve as a monitoring tool. This research should focus on studying whether urine contains infective virus or sheds non-infective genomic fragments.

Genomic Datasets from Traditional Murine Models of AKI and AKI-Lung Cross-Talk Reveal Molecular Pathways Relevant to COVID-19 Infection
Dmitry N. Grigorev,1 Hamid Rabb.1 University of Chicago Division of Biological Sciences, Chicago, IL; Johns Hopkins Medicine, Baltimore, MD.

Background: COVID-19 infection leads to ARDS and AKI, and there are established mechanistic links between acute kidney injury (AKI) and lung injury. SARS-CoV-2 uses for cell entry angiotensin-converting enzyme 2 (ACE2) and transmembrane protease, serine 2 (TMPRSS2), which are expressed in kidney and lung. Using publicly available genomic datasets of ischemic AKI and sepsis induced AKI in mice, we searched for established and novel molecular players of AKI and AKI-lung cross-talk relevant to COVID-19.

Methods: The microarray datasets GSE6730 (AJP Renal 2007, JASN 2008) and GSE60088 (Shock 2016) were downloaded from Gene Expression Omnibus (GEO). GSE6730: lungs from mice with moderate and severe ischemic AKI were studied at 6h and 36h. GSE60088: kidneys were studied from mice after 6h of pneumonia+mechanical ventilation (PMV). Isolated RNA was hybridized to MG_430 microarray. To identify differentially expressed genes, GEO-built in GEO2R tool was used.

Results: AKI led to downregulated kidney ACE2 gene at both 6h (fold change (FC)=−2.41) and 36h (FC=−3.23) after severe (60min clamp) but not moderate ischemia (30 min clamp; 6 h: FC~1.3, 36h: FC~1.16). In lung from AKI mice, ACE2 was significantly downregulated (FC=−2.89, P=5.56*10⁻⁵). Ischemic AKI and PMV led to a decrease in lung Tmprss2 FC=−1.83, P=1.19*10⁻⁵ and FC=−1.68, P=6.58*10⁻⁵, respectively. The filtering for known genes with P-value<0.01 and FC~4 identified all kidney genes upregulated by PMV; and 254 lung genes upregulated by AKI, of which 9 genes were common to both organs. 3 of 9 genes were previously linked to kidney-lung cross-talk: Lcn2 (FCLung=18.6, FCKidney=6.32), Socs3 (FC L=10.5, FCK=10.4), Inhbb (FC=−6.17), This finding validates our approach and makes other 6 genes appealing candidates, especially Mcf (FC=−7.21, FC=−5.98). This gene participates in the cellular stress response and also binds the oxytocin receptor promoter, which may be involved in gender differences in disease severity.

Conclusions: We identified changes in COVID-19 related genes ACE2 and Tmprss2 in traditional mouse models of AKI and lung cross talk. We also found new candidate genes activated in kidney during pneumonia+mechanical ventilation and in lung during AKI, which warrants further investigation of their involvement in the combined kidney-lung injury during COVID-19.

A Multicenter Observational Study of Clinical Features and Outcomes of AKI in Critically Ill Patients with COVID-19
Shruti Gupta, David E. Leaf. STOP-COVID Investigators Brigham and Women's Hospital Department of Medicine, Boston, MA.

Background: Acute kidney injury (AKI) is emerging as an important sequela of COVID-19 infection. Existing data on the incidence and clinical features of AKI in patients with COVID-19 are mainly limited to single-center studies. Given the high incidence of severe AKI among patients with COVID-19 and its strong association with mortality in other settings, we conducted a multicenter nationally representative cohort study to examine the incidence, clinical features, risk factors, and outcomes of AKI in critically ill patients with COVID-19.

Methods: We used data from a multicenter observational study that collected granular, patient-level data from >3,000 critically ill adults with laboratory-confirmed COVID-19 admitted to participating ICUs from 67 centers across the United States. Using multivariable logistic regression, we examined risk factors for the primary composite outcome, AKI requiring renal replacement therapy or death (RRT/death) in the 14 days following ICU admission.

Results: Among 3099 patients, 1205 (38.9%) developed the primary outcome of RRT/death (n=637 required RRT, n=572 died within 14 days, and n=224 both required RRT and died within 14 days). Independent risk factors for RRT/death included chronic kidney disease (odds ratio [OR], 5.02; 95% CI, 3.55-7.10 for eGFR<30 vs. ≥60); OR 1.49; 95% CI, 1.06-2.06 for highest versus lowest quintile of hospital strain). Patients admitted to hospitals with higher degrees of strain also had a greater risk of RRT/death (OR 1.90; 95% CI, 1.55-2.33 for eGFR 30-59 vs. ≥60), as well as older age, male sex, higher body mass index, and greater severity of hypoxemia on ICU admission (Figure). Patients admitted to hospitals with higher degrees of strain also had a greater risk of RRT/death (OR 1.49; 95% CI, 1.06-2.06 for highest versus lowest quintile of hospital strain).

Conclusions: This multicenter study identifies several key insights into the risk factors for RRT/death in critically ill patients with COVID-19.

Screening for SARS-CoV-2 (COVID) Infection in Chronic Dialysis Patients: A Nonprofit Provider’s Experience
Harold J. Manley,1 Karen M. Majchrzak,1 Ronald Sanders,2 Serena Cumber,1 Gideon N. Aweh,1 Vladimir Ladik,1 Carol Stewart,1 Doug Johnson,1 Antonio Harford,1 Eduordo K. Benson,2 Dialysis Clinic Inc, Nashville, TN; Tufts Medical Center, Boston, MA.

Background: The CDC recommends screening of all patients for COVID exposure history and or signs and symptoms prior to treatment. In order to limit the spread of COVID within our facilities, Dialysis Clinic Inc screens all patients prior to their in-center hemodialysis treatment or peritoneal dialysis visit consistent with recommendations.

Methods: We describe the outpatient screening results of our dialysis patients having a positive screen as patients under investigation (PUI) to activate local protocols for isolation and testing. We determined the frequencies of positive screening parameters and rate of identifying COVID patients.

Results: From 2/17 to 5/20, 2020, facilities screened 15,602 patients over 402,002 in-person visits, identifying 959 PUI’s (6%). Among PUIs, 61 of 351 (17%) COVID+ patients were correctly triaged prior to COVID+ diagnosis. In the subset of 788 PUIs screened prior to 4/11/20 where we were able to catalogue reasons for positive screening, 149 (19%) had exposure only and 639 exhibited symptoms (81%), of which 15 had exposure; 34 resided in group home (GH) and 7 had both exposure and GH residence. It was determined 41 (6.4%) were COVID+. Frequency of symptoms elicited by PUI are shown below.

Conclusions: 959 PUIs were identified and isolated by our screening process, resulting in the successful preemptive triage of 61 COVID+ (6%) patients before testing positive, potentially limiting infection spread in the facility. Cough and fever were the most common reasons for positive screen, and fever was most commonly associated with COVID+ diagnosis. However, the majority (83%) of COVID+ patients were primarily asymptomatic and hence not captured by screening.

**Urgent Peritoneal Dialysis Catheter Placement at a New York City Hospital During the COVID-19 Pandemic**  
**Dhwani Patel, Nina J. Caplin, Manish Tandon. NYU Langone Health, New York, NY.**

**Background:** During the COVID-19 pandemic, there has been an unparalleled burden on nephrology services to provide kidney replacement therapy to patients admitted to the hospital with COVID-19, who develop severe AKI. Given the unprecedented surge in COVID-19 admissions, ability to provide inpatient hemodialysis and continuous kidney replacement therapy (CRRT) was quickly saturated. We present data from our acute peritoneal dialysis (PD) program that was quickly assembled to provide kidney replacement therapy due to shortage of hemodialysis and CRRT resources.

**Methods:** Patients admitted to an academic NYC hospital during COVID-19 pandemic with AKI requiring kidney replacement therapy were evaluated for candidacy for bedside PD catheter placement via cut-down method with the majority having COVID respiratory failure. A dedicated surgery team was assembled to place PD catheters within 12-24 hours of request by the nephrology team. Catheters were placed in patients with BMI up to 51. Patients requiring proning were not excluded. Exclusion criteria were prior lower abdominal surgery, known varices, or imminent death.

**Results:** Thirty-eight PD catheters were placed during the 4 week time period from April 8 to May 8, 2020. Majority of the catheters were placed bedside in an ICU setting (36/38 - 95%), with 2 being placed laparoscopically in the OR. There were no episodes of peritonitis. Three catheters required revision due to poor flows. Six catheters required floseal for bleeding along the catheter tract, which resolved without additional intervention. There were no major bleeding complications during PD catheter placement despite many patients being on systemic anticoagulants. Dwell volumes of up to 2.2L did not appear to have negative effects on the ability to ventilate patients. One patient required transition to hemodialysis due to catheter malfunction.

**Conclusions:** Acute peritoneal dialysis successfully allowed kidney replacement therapy for patients with severe AKI during the peak phase of the COVID-19 pandemic at our hospital in NYC. There were no major complications with acute PD catheter placements.

**Recovery from AKI and Acute Respiratory Distress Syndrome (ARDS) with the Use of Low-Dose Steroids During COVID-19 Infection in an African American Population: A Retrospective Analysis**  
**Suubodh J. Saggi, Sridesh Nath, Roshni Culas, Seema Chittalae, Aaliya Burza, Patrick Geraghty, Jie Ouyang, Angelika C. Gruessner, Moro O. Salifu. SUNY Downstate Health Sciences University, Brooklyn, NY; Saint Barnabas Hospital, Bronx, NY.**

**Background:** Coronavirus Disease-19 (CoVID-19) infection associated with AKI and ARDS results in a mortality of 80%. In AA population COVID-19 presentations and outcomes are worse. NIH and Interim WHO guidelines suggest against steroids use unless renal function and renal function) were analyzed. Comparisons between the steroid doses (methylprednisolone 1 mg/kg/day or 2 mg/kg/day) and no-steroid groups were performed to identify the p53/miR-214/ULK1 axis of autophagy impairment for the development and progression of renal hypertrophy and related pathologies. Mechanistically, p53 is activated in DKD to repress ULK1 expression and its pathogenic role in DKD. Autophagy impairment in DKD involves miR-214, which is induced in diabetic kidney cells and tissues to repress ULK1 expression. Ablation of miR-214 from kidney proximal tubules prevented ULK1 decrease and autophagy impairment in diabetic kidneys, resulting in less renal hypertrophy and albuminuria. Furthermore, blockade of p53 attenuated miR-214 induction in DKD, leading to higher levels of ULK1 and autophagy, accompanied by the amelioration of DKD. Compared to non-diabetic samples, renal biopsies from human diabetic patients showed the induction of miR-214 from kidney proximal tubules prevented ULK1 decrease and autophagy impairment in diabetic kidneys, resulting in less renal hypertrophy and albuminuria. 

**Methods:** Autophagy changes in DKD were investigated in high glucose treated renal tubular cells in vitro and in Akita mice and streptozotocin (STZ)-induced diabetic mice in vivo. Autophagy-related gene 7 (Atg7), microRNA-214 (miR-214), or p53 were ablated respectively from kidney proximal tubules to evaluate the pathogenic role and underlying mechanism of autophagy dysregulation in DKD. The expression of autophagy-related proteins, miR-214, and p53 were analyzed in human diabetic kidney tissues along with renal pathologies to determine their correlations.

**Results:** Autophagy was inhibited in DKD models and in human diabetic kidneys. Ablation of Atg7 from kidney proximal tubules led to autophagy deficiency and worsened renal hypertrophy, tubular damage, inflammation, fibrosis, and albuminuria in diabetic mice, indicating a protective role of autophagy in DKD. Autophagy impairment in DKD was associated with the downregulation of ULK1, a key serine/threonine protein kinase for the initiation of autophagy. ULK1 downregulation in DKD involved miR-214, which was induced in diabetic kidney cells and tissues to repress ULK1 expression. Ablation of miR-214 from kidney proximal tubules prevented ULK1 decrease and autophagy impairment in diabetic kidneys, resulting in less renal hypertrophy and albuminuria. Furthermore, blockade of p53 attenuated miR-214 induction in DKD, leading to higher levels of ULK1 and autophagy, accompanied by the amelioration of DKD. Compared to non-diabetic samples, renal biopsies from human diabetic patients showed the induction of p53 and miR-214, associated by the downregulation of ULK1 and autophagy. There was a significant positive correlation between p53/miR-214 and renal fibrosis, whereas a negative correlation between ULK1/miR-214 and renal fibrosis in diabetic patients.

**Conclusions:** Autophagy dysfunction occurs in renal tubules in DKD, and contributes to renal hypertrophy and related pathologies. Mechanistically, p53 is activated in DKD to induce miR-214, which represses ULK1 resulting in autophagy dysfunction. The results identify the p53/miR-214/ULK1 axis of autophagy impairment for the development and progression of DKD.

Podocyte-Derived Extracellular Vesicles Mediate Renal Proximal Tubule Cell Dedifferentiation via MicroRNA 221 in Diabetic Nephropathy

Hong Su,1 Jiao Qiao,2 Qun Yu,1 Bing Liu,1,3 Junhui Zhen,2 Zhimei Lv,1,2 Rong Wang,1 Department of Nephrology, Shandong Provincial Hospital, China; 2Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; 3Department of Pathology, School of Medicine, Shandong University, Jinan, China.

Background: Podocyte injury is a key event in the initiation of diabetic nephropathy (DN), and the proximal tubule has been regarded as a target of injury. Evidence suggests that cross-talk between podocytes and tubular epithelium is a key component in the pathogenesis of DN, but the mechanisms are not fully understood.

Methods: The podocytes and proximal tubular epithelial cells (PTECs) were co-cultured in high glucose conditions to detect the intercellular communication. Podocytes-derived extracellular vesicles (EVs) was isolated and identified by specific morphology and surface markers. Immunofluorescence, PCR, western blot, electron microscope, and transwell were conducted to assess the dedifferentiation of PTECs. The expression level of miRNA in EVs was detected and Cy3-labeled mimics was used to demonstrate its direct transfer into target cells. A dual-luciferase reporting system was utilized to confirm the binding of miRNA to its target gene. The roles of miRNA and target gene were assessed using specific miRNA inhibitors, mimics and shRNA. In addition, Streptozotocin-induced diabetes mice models were construct, and miRNA antagomir were used to explore its role in proximal tubule injury.

Results: Podocytes induced dedifferentiation of PTECs in high-glucose conditions and augmented their interaction. The podocytes-derived EVs were extracted and identified as exosome, and the EVs treatment induced PTECs injury. miR-221 was remarkably increased in EVs and could be directly transferred into target cells, moreover, this miRNA was shown to play a key role in PTECs dedifferentiation. The dual-luciferase reporter assay confirmed that miR-221 directly target DKK2, and miR-221 positively regulated β-catenin activation. Importantly, inhibition of β-catenin markedly diminished the EVs and mRNA induced PTECs dedifferentiation. Furthermore, inhibition of miR-221 in diabetic mice reversed the PTECs injury and relative β-catenin activation.

Conclusions: Podocytes-derived EVs in diabetes acted as key mediators of proximal tubule cell injury and the exosomal-miR-221 mediated the cells damage through Wnt/β-catenin signaling. These findings provide unique insights in the mechanisms of proximal tubule cell injury in diabetic nephropathy, and miR-221 can be used as a new target for the treatment of renal fibrosis in DN.

Whole-Genome Sequencing Identifies a Dominant Negative ADIPOQ Mutation in a Type 2 Diabetic Family Enriched for ESRD

Marcus G. Pezzolesi,1 Christopher A. Simeone,1 Joseph L. Wilkerson,1 Jose M. Lazarro guevara,1 Edgar J. Hernandez,1 Bushra Gorsli,1 Scott G. Froodsham,1 Kristina V.O’Neil,1 Scott Summers,1 Andrezs S. Krolevski,2 William L. Holland,1 University of Utah Health Care, Department of Internal Medicine, Salt Lake City, UT; UT, Salt Lake City, UT; 1Joslin Diabetes Center; 2Harvard Medical School, Boston, MA, Boston, MA.

Background: Diabetic nephropathy (DN) is a complex, heterogeneous complication of diabetes. Despite evidence of its strong genetic predisposition, identification of the genetic factors that contribute to DN and the risk of end-stage renal disease (ESRD) has been challenging.

Methods: We performed whole genome sequencing (WGS) in a multi-generational family with structural parameters. This 10-nucleotide deletion results in a premature termination codon and a complete loss of adiponectin’s globular domain. We found that carriers of this mutation in this family. This 10-nucleotide deletion results in a premature termination codon and a mutation in adiponectin (Gly93GlufsTer73; seen only once among 56,810 non-genetic factors that contribute to DN and the risk of end-stage renal disease (ESRD) has been shown to play a key role in PTECs dedifferentiation. The dual-luciferase reporter assay confirmed that miR-221 directly target DKK2, and miR-221 positively regulated β-catenin activation. Importantly, inhibition of β-catenin markedly diminished the EVs and mRNA induced PTECs dedifferentiation. Furthermore, inhibition of miR-221 in diabetic mice reversed the PTECs injury and relative β-catenin activation.

Conclusions: Podocytes-derived EVs in diabetes acted as key mediators of proximal tubule cell injury and the exosomal-miR-221 mediated the cells damage through Wnt/β-catenin signaling. These findings provide unique insights in the mechanisms of proximal tubule cell injury in diabetic nephropathy, and miR-221 can be used as a new target for the treatment of renal fibrosis in DN.

Cell Type Specificity of Hypoxia Signaling in Early Diabetic Kidney Disease (DKD)

Jennifer A. Schaub,1 Rajasree Menon,1 Viji Nair,2 Edgar A. Otto,1 Joel M. Weinberg,1 Helen C. Looker,2 Robert G. Nelson,2 Matthias Kretzler,2 University of Michigan Health System, Ann Arbor, MI; 3National Institutes of Health, Bethesda, MD.

Background: Chronic hypoxia is considered a driver of kidney disease progression. Given the spatial heterogeneity of hypoxia, we evaluated the cell type specificity of Hypoxia Related Genes (HRG) in DKD along the nephron and the association of HRG with structural parameters.

Methods: Cell-specific expression and normalized gene signatures (Z scores) were calculated for 237 HRG in single cell RNA profiles of 44 kidney biopsies from American Indians with Type 2 Diabetes (T2D) and 7 healthy living donor kidneys (LD), and replicated in 49 independent micro-dissected biopsies of T2D with DKD (DN).

Results: Mean measured glomerular filtration rate was 159 ml/min (SD 54) in T2D and 147 ml/min (SD 45) in DN, and mean urine albumin/creatinine ratio was 304 mg/g (SD 1542) for T2D and 35 mg/g (SD 90) for DN. Average HgA1c was 9.2 for T2D and 9.3 for DN. HRG expression showed highly cell-type specific elements in both LD and T2D (Figure 1). HRG signature in stressed proximal epithelial cells (pSPEC), unique to T2D, was dominated by apoptosis and glycocalyx signals, while endothelial cells (EC) signatures expressed more genes involved in fibrosis in T2D compared to LD. In DN, Z score of the EC signature was associated with increased mesangial volume (R 0.33, p-value 0.02) and Z score of pSPEC signature was associated with interstitial fibrosis (R 0.35, p-value 0.02), which are strong predictors of long-term outcomes in this cohort.

Conclusions: HRG expression varies by cell type in LD and DKD, suggesting transcriptional regulation changes of HRG in diabetes and DKD. Association of HRG signatures with morphometrics that are associated with progressive GFR loss implicate chronic hypoxia processes in early DKD.

Funding: NIDDK Support
Conclusions: Loss of SCO2 and mutant SCO2 reduced glomerular endothelial injury, oxidative stress, and early diabetic injury in the kidney with improved mice survival in a murine model of DKD.

Reversal of Diabetic Nephropathy After 10 Years of Pancreas Transplantation Occurs Despite Parallel Podocyte Loss

Behzad Najafian,1 Michael Mauer,2 Paola Fioretto.3 University of Washington, Seattle, WA; 2University of Minnesota, Minneapolis, MN; 3University of Padova, Padova, Italy.

Background: Diabetic nephropathy (DN) is associated with podocyte (PC) injury and loss. PC injury is believed to play an important role in DN progression. DN reversal following 10 years (10Y) of euglycemia after pancreas transplantation (PTx) is documented (N Engl J Med 2007;357:69-75). With this observation in mind, we hypothesized that PC loss is a “normal” event, DN reversal would be associated with PC regeneration and improvement in PC structure.

Methods: Paired kidney biopsies prior to PTx (BL) and 10Y after PTx were compared for classical DN lesions, PC number and foot process width (FPW) using electron microscopy morphometry in 10 type 1 diabetic (T1D) patients with age 33 (30-54) years [median (range)], diabetes duration 23 (16-33) years and albumin excretion rate (AER) 134 (0-951) μg/min at BL. The results were compared with biopsies from 10 age matched living donor biopsies [controls (C)].

Results: Glomerular basement membrane (GBM) width, fractional volume of mesangium/glomerulus (Vv(Mes/glom)) and fractional volume of mesangial/glomerulus (Vv(MM/glom)) and FPW were all increased at BL compared to C (data not shown). There were significant reductions in GBM width (30%; p=0.0002), Vv(Mes/glom) (21%; p=0.001), Vv(MM/glom) (30%; p=0.002) and glomerular volume (27%; p=0.02) at 10Y compared to BL. However, while PC number density did not change from BL to 10Y, there was a significant decrease in PC number/glomerulus (31%; p=0.049). FPW in T1D patients at BL (p=0.008) or 10Y (p=0.002) was greater than in C with no significant change from BL to 10Y. No relationship was found between change in GBM width, Vv(Mes/glom) or Vv(MM/glom) and PC number density, PC number per glomerulus or FPW. Creatinine clearance was reduced by 25% from BL to 5y post PTx in these calcineurin treated patients, and remained stable between 5 and 10Y. AER did not change significantly.

Conclusions: Substantial reversal of GBM and mesangial extracellular matrix (ECM) accumulation in T1D occurs following long term PTx despite decrease in PC number, persistence of foot process widening and no change in PC density. This study does not support PC loss to an important mediator of glomerular extracellular dynamics in DN in T1D. Moreover, despite long-term normoglycemia, PC do not regenerate and PC injury does not regress in T1D patients.

Loss of Functional SCO2 Attenuates Diabetic Kidney Disease in db/db Mice

Nehaben A. Gujarati, Alexandra R. Leonardo, Jessica M. Vasquez, Sandeck K. Mallipattu. Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.

Background: Synthesis of Cytochrome C Oxidase 2 (SCO2), a Cu2+ metallochaperone located in the inner mitochondrial membrane, is essential for the assembly of Complex IV (COX IV) of the electron transport chain, maintenance of the proton gradient, and redox signaling. Altered COX activity and reduced mitochondrial function have been reported in diabetic kidney disease (DKD), but the mechanism mediating this process remains to be explored.

Methods: db/db mice were bred with Sco2 mutant mice (E129K, most common human missense mutation in the Cu2+ binding domain) to generate Sco2KO/KI;db/db and Sco2 KI/KI, db/db, and wildtype mice served as controls. All mice were euthanized at 24 weeks of age and assessed for functional and histological changes in the kidney.

Results: Data mining in Nephroseq showed that SCO2 expression was increased in micro-dissected glomeruli in human DKD kidney biopsies (Ju et al. 2013), which we confirmed by immunostaining in human kidney biopsies with DKD as compared to healthy donor nephrectomies. Since SCO2+ mice are embryonically lethal, we ascertained the role of mutant and heterozygous knockout SCO2 in DKD (SCO2KO/KI, SCO2KO/2KI). As compared to db/db mice, SCO2KO/2KI db/db and SCO2KO/2KI db/db mice had a significant reduction in albuminuria, serum creatinine, glomerular hypertrophy, glomerular oxidative stress (8-oxoG staining) with an increase in podocyte number (WT1+ cells per glomerular cross-sectional area), synaptopodin expression, and overall survival. SCO2KO/2KI db/db and SCO2KO/2KI db/db mice also exhibited less glomerular endothelial injury with a decrease in glomerular capillary loop dilatation and a trend towards decrease in Acm and Vcm1 and an increase in Angpt1, Vegfa, Kdr and Klf2 expression as compared to db/db mice.

Reduction in the Rate of eGFR Decline with Semaglutide vs. Placebo: A Post Hoc Pooled Analysis of SUSTAIN 6 and PIONEER 6
Katherine R. Tuttle,1 David Cherney,2 Samy Haddad,1 Thomas Idorn,4 Offi Mosenzon,3 Vlado Perkovic,2 Soren Rasmussen,2 Benjamin Wothlers,1 Stephen C. Bain,1 Institute of Translational Health Sciences, Kidney Research Institute, and Nephropathy Division, University of Washington, Seattle, WA; 2Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada; 3Novo Nordisk A/S, Søborg, Denmark; 4University of Lorraine and FCRIN INI-CRCT, Nancy, France

Background: The SUSTAIN 6 cardiovascular outcomes trial (CVOT) indicated that once-weekly (OW) subcutaneous (s.c.) semaglutide may have beneficial effects on kidney function in subjects with type 2 diabetes (T2D) at high CV risk. SUSTAIN 6 and the PIONEER 6 CVOT (once-daily [OD] oral semaglutide) had similar designs and populations, and both evaluated the effects of semaglutide vs placebo (PBO) on macro- and microvascular outcomes. This post hoc analysis of pooled data from the two trials evaluated the effects of semaglutide vs PBO on kidney function decline.

Methods: Data for 6,480 subjects with T2D from SUSTAIN 6 (OW s.c. semaglutide 0.5 and 1.0 mg or PBO, N=3,297; median follow-up 2.1 years) and PIONEER 6 (OD oral semaglutide 14 mg or PBO, N=3,183; median follow-up 1.3 years) were pooled into two groups: subjects with baseline eGFR ≥30–<60 or ≥60 mL/min/1.73 m2. Changes in eGFR from BL during trial were analyzed using a linear random regression model with individual intercept and time slope. The estimated treatment difference (ETD) at 1 year between annual rates of eGFR slope from BL was calculated; an interaction p-value <0.05 indicated difference between subgroups.

Results: In the overall population, the annual rate of eGFR change was 0.60 mL/min/1.73 m2 for PBO (p=0.0001) lower with semaglutide vs PBO in both groups. Annual change in estimated glomerular filtration rate (eGFR) was compared (semaglutide vs PBO) in the overall population and subgroups by baseline (BL) eGFR (≥30–<60 or ≥60 mL/min/1.73 m2). Changes in eGFR from BL during trial were analyzed using a linear random regression model with individual intercept and time slope. The estimated treatment difference (ETD) at 1 year between annual rates of eGFR slope from BL was calculated; an interaction p-value <0.05 indicated difference between subgroups.

Conclusions: Semaglutide was associated with a significantly smaller decline in kidney function than PBO in subjects with T2D at high CV risk across tested BL eGFR categories; the data suggest the main benefit might be observed in those with kidney disease.

Patrimer to Enable Spironolactone in Patients with Resistant Hypertension and CKD (AMBER): Results in the Prespecified Subgroup with Diabetes
Rajit Agarwal,1 Patrick Rossignol,2 Susan Arthur,1 Angsar Conrad,1 William B. White,31 Indiana University School of Medicine, Indianapolis, IN; 1University of Lorraine and FCRIN INI-CRCT, Nancy, France; 2Rehypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; 3University of Connecticut School of Medicine, Farmington, CT; 4University College London (UCL), London, United Kingdom

Background: Spironolactone (SPIRO) reduces BP in patients (pts) with resistant hypertension (RHTN); however, its use in pts with advanced chronic kidney disease (CKD) is often limited by hyperkalemia (HK). In AMBER, patrimer (PAT) enabled more persistent use of SPIRO in pts with RHTN and CKD. As SPIRO was recommended in RHTN and diabetes mellitus (DM) increases HK risk, we report results in prespecified subgroups with Type 1 or 2 DM.

Methods: Randomized, double-blind, placebo (PBO)-controlled trial in adults with RHTN and eGFR 25 to <45 mL/min/1.73 m2. Pts were assigned (1:1) to PBO or PAT, and SPIRO 25 mg QD, with dose titrations permitted after 1 wk for PAT/PBO and 3 wks for SPIRO. The primary endpoint, between-group difference at Wk 12 in % of pts on SPIRO, was assessed prospectively in prespecified DM subgroups.

Results: 295 pts were randomized, 145 (49%) DM1 and 150 (51%) DM2. Baseline mean (SD) serum K+ (mEq/L) was 4.76 (0.34) in DM1 and 4.67 (0.39) in DM2. Significantly more pts treated with PAT than with PBO remained on SPIRO at Wk 12 in both subgroups (Figure). LS Mean (SE) cumulative SPIRO dose was higher with PAT than PBO, by 438.7 (177.7) mg in DM1 and 317.8 (175.0) mg in DM2. Adverse events occurred in 61% (PBO) and 60% (PATO) of DM1 pts and in 46% (PBO) and 51% (PATO) of DM2 pts. Four pts had serum magnesium (Mg++) <1.4 mg/dL during baseline and Wk 12 (none <1.2 mg/dL), including 3 DM1 (1 PBO, 2 PAT) and 1 DM2 (PAT) pt. None of these pts had cardiac arrhythmias temporally associated with low Mg++ levels, neuromuscular abnormalities, or serum K+ below the LLN (3.5 mEq/L).

Conclusions: PAT enabled more pts with advanced CKD and RHTN to continue treatment with SPIRO, regardless of DM status.

Single-Cell Transcriptomic Analysis to Define Cellular Heterogeneity in Human ADPKD
Yoshiharu Muto,1 Eryn E. Dixon,3 Chidambaram Ramachandran,2 Andrew J. King,2 Stephen L. Seliger,1 Owen M. Woodward,1 Paul A. Welling,4 Terry J. Watnick,5 Benjamin D. Humphreys,3 1Washington University School of Medicine, St. Louis, MO; 2Chinook Therapeutics, Inc., Vancouver, BC, Canada; 3University of Maryland School of Medicine, Baltimore, MD; 4Johns Hopkins School of Medicine, Baltimore, MD

Background: Deciphering the molecular pathogenesis of human autosomal dominant polycystic kidney disease (ADPKD) requires a detailed understanding of the distinct cell types and cell states driving cyst growth. Unlike single cell RNA-seq, single nucleus RNA-seq can be performed on cryopreserved samples, and we hypothesized that it might reveal unique cell states from biobanked human ADPKD samples.

Methods: We performed snRNA-seq on 8 ADPKD kidney samples (4 males and 4 females, mean = 50 +/- 8.5 years old, all had ESRD). Cystic kidneys weighed 1631 +/- 728 g. Nuclear preparations were processed using 10x Genomics Chromium 3’ kit and sequenced by NovaSeq. Reads were counted with CellRanger 3.1.0 and analyzed with Signum v3. Gene expression was validated by fluorescence in situ hybridization.

Results: Samples were stored at -80°C prior to processing (median, 20 mo; range 7-40 mo). All samples yielded good libraries (Avg. genes/nucleus = 1560 +/- 526). 63,289 nuclei originating from all 8 ADPKD kidneys were isolated by 10x and sequenced by NovaSeq. Reads were counted with CellRanger 3.1.0 and analyzed with Signum v3. Gene expression was validated by fluorescence in situ hybridization.

Conclusions: To our knowledge this is the first single cell transcriptomic atlas of human ADPKD. We demonstrate the utility of this approach by revealing (1) excellent gene expression from all samples including those stored > 3 yrs, (2) segment specific cystic epithelial cell subtypes, most expressing markers of activation and dedifferentiation. Cyst-specific marker gene expression was validated by RNAseq on human ADPKD sections. Analysis also revealed four separate fibroblast subtypes, most expressing markers of activation and dedifferentiation, as well as endothelial clusters, podocytes and four separate macrophage sub-clusters.

Background: Inducible deletion of cilia related genes in adult mice results in slow progressing cystic disease, which can be greatly accelerated by renal injury. However, cells that promote accelerated cystogenesis following renal injury are poorly understood.

Methods: To identify cells that may be responsible for driving, injury induced cystic disease, we performed single cell RNA sequencing on cells isolated from sham operated and IR injured cilia mutant mice, ischemia-reperfusion (IR) injured cre negative control, and IR injured cilia mutant mice 56 days post injury, a time point in which injured cilia mutant mice had mild cystic disease.

Results: Comparison of single cell RNA sequencing data from sham- and injured-cilia mutant mice indicate that renal injury in the setting of cilia loss results in alterations in T cells clusters with limited differences in other cell populations. In contrast, single cell RNA sequencing data comparing injured cre negative control and injured cilia mutant mice reveals that loss of primary cilia in the setting of IR injury resulted in major changes in clusters of tubular epithelia and macrophages with minimal effects on T cells. These data suggest that accelerated cystogenesis in cilia mutant mice requires both injury induced changes in T cells as well as cilia-dependent alterations in the injured epithelium and macrophages. Using NicheNet to identify ligand-receptor-gene regulatory networks, we showed that T cells from injured cilia mutant mice produce ligands that cause alterations in the gene expression signature of the cilia mutant epithelium and macrophages suggesting that these cells are master regulators of injury induced cystic disease. In agreement with this hypothesis, our data indicate that loss of adaptive immune cells (including T cells) significantly reduces cyst burden and loss of adaptive immune cells did not affect cyst progression in the absence of injury in multiple cystic models, even when animals were aged out several months.

Conclusions: Collectively, our data indicate that IR injury creates a unique population of adaptive immune cells that create new macrophages and epitheliun of cilia mutant mice to drive rapid, injury induced cystogenesis.

Activation of AMP-Activated Protein Kinase In Vivo Leads to a Polycystic Kidney Disease

Laura Wilson,1 David Carling,2 1University College London Institute of Child Health, London, United Kingdom; 2MRC London Institute of Medical Sciences, London, United Kingdom.

Background: Polycystic kidney disease (PKD) is a genetic disorder in which numerous fluid-filled cysts form in the kidney. Despite having identified the causative gene, PKD1, our understanding of the molecular signalling pathways involved in cystogenesis is limited, hindering PKD drug discovery. In this project, we generated a mouse model of AMP-activated protein kinase (AMPK) activation and observed a polycystic kidney phenotype, reminiscent of PKD. AMPK is known for its role in maintaining energy homeostasis and is activated in response to cellular stress. It is currently unknown whether AMPK could play a role in PKD pathogenesis.

Methods: AMPK activation mouse models were generated by expressing the AMPKα1 isoform with a D316A mutation under the control of β-actin (global) and Ksp (kidney-specific) promoters using the Cre-LoxP system. A constitutively active form of AMPK is produced when AMPKα1-D316A is incorporated into the enzyme complex. Renal function was assessed using metabolic cages, serum and urine samples were collected for analysis. Kidneys were collected and snap-frozen for biochemical studies or were embedded for histological studies.

Results: Global activation of AMPKα1 resulted in a striking polycystic kidney phenotype. Tubule dilations were evident from 11 days of age, which progressed to heavily cystic kidneys by 3 weeks of age. Adult mice showed signs of polyuria associated with increased ouabain-sensitive Na,K-2Cl cotransporter, kidney damage and compromised renal function. Cysts were observed in the collecting ducts of these mice, consistent with the distal nephrin being most heavily affected in PKD. Mechanistically, the cystic kidneys had increased AQP2 levels and ERK activation (a pathway known to be dysregulated in PKD), increased fructose 1,6 bisphosphatase expression and altered lysosomal protein expression. Kidney specific activation of AMPKα1 also produced polycystic kidneys in mice, demonstrating that AMPK activation within the kidney was causative.

Conclusions: These results show that activation of AMPK causes polycystic kidneys in mice, raising the possibility that AMPK activation could be a contributing factor in PKD pathogenesis. Dysregulation of the cAMP-ERK pathway in this model suggests a possible mechanism for how AMPK activation could be implicated in renal cystogenesis. Future studies should investigate whether AMPK has a pathogenic role in other PKD models.

CU062, the Product of the C21orf62 Gene, Is a Polycystin-1 Ligand

Christy A. Ward,1 Steven J. Kleene,2 James P. Calvet,2 Wendy A. Lea,1 1University of Kansas Medical Center, Kansas City, KS; 2University of Cincinnati, Cincinnati, OH.

Background: The PKD1 gene, encoding the protein polycystin-1 (PC1), is responsible for 85% of cases of mutation positive autosomal dominant polycystic kidney disease (ADPKD) and is the most common genetic cause of renal failure (1:800). PC1 has been shown to be present on easily accessible urinary exosome-like vesicles (ELVs) and to be degraded in individuals with PKD1 mutations. Label-free mass spectrometry comparison of ELVs from normal and PKD1 urine showed that several other proteins were decreased to a degree similar to PC1, including a small signal peptide bearing protein of unknown function, CU062, the product of the C21orf62 gene.

Methods: To determine whether this novel protein is involved in cystogenesis, we applied a genetic approach and deleted the entire C21orf62 open reading frame in c57Black6J mice. We also investigated the ability of CU062 to interact with the entire 4302 aa ORF of PC1 and map the interacting domains. Furthermore, we probed its ability to interact with either PC1/PC2 in renal cilia using primary cilia patch clamp.

Results: A TALEN induced deletion of the entire C21orf62 ORF generated mice that were grossly phenotypically normal, and both sexes were fertile. Close inspection of the kidney showed that about 25% of the homozygous null animals had mild tubular dilatation in the loop of Henle and collecting duct. The C21orf62+/- allele exacerbated the phenotype as assessed by kidney weight/body weight ratio, ANOVA interaction p = 0.0017. In vitro binding studies indicated that CU062 interacts with PKD domains 2-17 and most tightly with domains 15-17 in an SDS stable manner. We subsequently showed that extracellular application of pure CU062 activated polycystin-2 (PC2) dependent currents in primary cilia of mIMCD-3 cells. CU062 was shown to be expressed most prominently in the vasa recta (VR) and the endothelium of large blood vessels but not in kidney tubules.

Conclusions: These data suggest that CU062 might be a circulating ligand for PC1 and PC2 and that CU062/PC1 or CU062/PC2 might be involved in cystogenesis. CU062 accounts for a subset of PC1 functions as its genetic deletion leads to a milder phenotype than that observed in Pkd1 homozgyous null mice.

Interdigitated Cells and the Transmission Factor FOX1I Drive the Kidney Cystogenesis in Tuberous Sclerosis Complex

Sharon I. Barong,1 Kamary A. Zahedi,2 MaryBeth Broocks,1 Evariste-T. P. Herscke,1 John S. Whitcher,1 June J. Yu,1 Jessica M. Soleimani,1 1University of New Mexico Health Sciences Center, Albuquerque, NM; 2Raymond G Murphy Department of Veterans Affairs Medical Center, Albuquerque, NM; 3Brigham and Women’s Hospital, Boston, MA; 4University of Cincinnati College of Medicine, Cincinnati, OH; 5LeBonheur Center for Children in Crisis, Memphis, TN; 6St Jude Children’s Research Hospital, Memphis, TN.

Background: Tuberous sclerosis complex (TSC) is caused by mutations in either the TSC1 or TSC2 gene and affects multiple organs, including the kidney. Patients can present with benign tumors (angiomylipoma) and cysts, which can lead to kidney failure. Factors that promote cyst formation and tumor growth in TSC are poorly understood.

Methods: Mice with principal cell specific inactivation of Tsc1 were generated. In addition, mice with double deletion of Fox1 and Tsc1 (Fox1/Tsc1 double KO) or carbonic anhydrase 2 (CA2) and Tsc1 (CA2/Tsc1 double KO) were generated based on RNA-seq and expression studies.

Results: Tsc1 KO mice showed numerous kidney cortical cysts, which were overwhelmingly comprised of A-intercalated (A-IC) cells that showed strong expression of apical V H+ -ATPase. RNA-seq studies demonstrated a 3-fold enhanced expression of Fox1, which is critical to the development of IC cells and regulation of V H+ -ATPase and CA2. The expression of Fox1 in Pkd1 mice remained unchanged vs. WT mice. Deleting Fox1 completely abrogated the cyst burden in Fox1/Tsc1 dKO mice (Kidney MRNa 31% vs 1) and caused a profound reduction in V H+ -ATPase expression in the A-IC cells. Mice with double deletion of Tsc1 and CA2, a regulator of V H+ -ATPase, showed significant reductions in cyst burden and increased longevity vs. Tsc1 KO mice.

Conclusions: We propose that A-IC cells, V H+ -ATPase and CA2 are critical to cystogenesis, and their inactivation is associated with a significant protection against cyst generation and/or enlargement in TSC. Carbonic anhydrase inhibitors may be viable treatments for the prevention of kidney cyst expansion in TSC. Supplementing carbonic anhydrase inhibitors with HCO3- (to minimize the untoward side effects of metabolic acidosis) may be beneficial.

**Genome-wide Analyses Provide Insights into the Architecture of Kidney Function and CKD in African Americans in the Million Veteran Program (MVP)**

**Bryce Rowan,1,2 Cassianne Robinson-Cohen,1 Elvis A. Akwo,2 Hui-Chang Chen,1 Ran Tao,1 Cecilia P. Chung,2 Csaba P. Kovessy,3 Katalin Susztak,4 Christopher J. O’Donnell,2 Edward D. Siew,2 Adriana Hung,1,2 1Nashville VAMC, Nashville, TN; 2VUMC, Nashville, TN; 3Boston VA, Nahsville, MA; 4Memphis VA, Memphis, TN; 5Penn Medicine, Philadelphia, PA.

**Background:** End-stage kidney disease (ESKD) incidence rates for African Americans are more than 3 times higher than for European-Americans. This disparity has been only partly explained by known determinants of ESKD and the presence of high-risk APOL1 variants. The identification of “second hit” triggers may explain kidney outcome disparities observed in African Americans.

**Methods:** We performed a GWAS of eGFR among 84,544 African Americans from the MVP at or closest to enrollment. Exclusion criteria were: dialysis, kidney transplant, and BMI<18. We evaluated the association of common (minor allele frequency >1%) SNPs with linear eGFR (by CKD-EPI equation), adjusted for age, sex, BMI, and the top ten principal components of ancestry. Analyses were performed by strata of diabetes and estimates were aggregated with fixed-effects meta-analysis.

**Results:** We identified 2,275 SNPs in 22 independent loci associated with eGFR (p<5x10^-10). The SNP with the strongest signals replicated previously detected associations at SPATA5L1/GATM (rs4246272, p = 1.7 x 10^-10). Of these, 19 represented previously reported loci from GWAS of kidney function or CKD. Known CKD genes from case-control studies such as APOE (rs73885319 p=9.09 x 10^-28) were included in the known loci. Three novel loci were identified in the association with kidney function in African Americans. Known CKD genes from case-control studies such as APOE (rs73885319 p=9.09 x 10^-28) were included in the known loci.

**Conclusions:** In this large GWAS of eGFR among African Americans to date, we replicate over 19 previously identified loci, identify 3 novel loci associated with kidney function.

**Funding:** Veterans Affairs Support

SA-OR27

**3D Genome Architecture of Human Renal Cortex and Medulla**

**Selvaraj Mutthusamy, Shreeram Akiles. University of Washington, Seattle, WA.**

**Background:** Genomic DNA is organized in a non-random manner within the mammalian nucleus. How this three-dimensional genome architecture influences cell-type specific phenotypes is poorly understood. Genome-wide methods such as Hi-C can systematically map out 3D genome architecture. However until now, technical and cost limitations have prevented these powerful approaches from being applied to intact human kidney tissues.

**Methods:** We performed global genome conformation (Hi-C) analysis on macrodissected human renal cortex and medulla from the same individual. Since existing algorithms to identify intra and inter-chromosomal interactions in Hi-C sequencing data are plagued by low concordance, we developed a novel machine learning algorithm used in the domain of computer vision to identify significant contacts in our Hi-C data.

**Results:** Each kidney Hi-C sample was deeply sequenced to ≧400 million mapped contacts enabling visualization of topologically associated domains (TADs) and contacts at 10kb resolution. Comparing even these highly similar samples, our novel algorithm identified significantly different genome conformation at multiple intra-chromosomal contacts in renal cortex (n=1789) and medulla (n=1841) (figure). Further validation by DNA-FISH and comparison to orthogonal functional genomic data sets (ATAC-seq, RNA-seq) are ongoing.

**Conclusions:** These high-resolution chromatin conformation maps of intact human kidney will provide an valuable resource for the study of kidney genome regulation. Our novel loop-calling algorithm enabled identification of fine genome architectural differences between renal cortex and medulla. Our data can also be used to link genetic risk loci to target genes in genome-wide association studies.

Underline represents presenting author.
complement system, also cause aHUS. In the glomeruli, DGKε is expressed in endothelial cells and podocytes. The molecular mechanisms by which loss of DGKε causes TMA are not known. Phosphatidyl-inositol diphasphate (PtdIns(4,5)P₂) levels are reduced in DGKε knockout cells. Since the disruption of vascular endothelial factor A (VEGFA) signaling in humans and mice results in glomerular lesions that resemble those in humans with loss-of-function mutations in DGKε, we hypothesized that loss of DGKε may impair VEGFA signaling in endothelial cells due to shortage of PtdIns(4,5)P₂.

Methods: To test this hypothesis, we performed in vitro studies on DGKε knockdown human umbilical vein endothelial cells (HUVECs) and generated endothelial-specific Tie2Cre/+/Dgke floxed conditional knockout mice.

Results: We found that signaling downstream of VEGFA receptor 2 (VEGFR2) is compromised in DGKε knockdown HUVECs due to decreased activation of Akt, a phenotype that is rescued by supplementation the culture medium with PtdIns(4,5)P₂. Endothelial-specific Tie2Cre/+/Dgke floxed conditional knockout mice spontaneously developed thrombocytopenia, scioticystosis, and renal insufficiency, indicating that the endothelium is the cellular compartment responsible of the DGKε disease. Remarkably, these mice also developed albuminuria at later times, indicating that the impairment of the glomerular barrier, which is characteristic of the DGKε disease, is a later and secondary event.

Conclusions: Our data indicate that loss of DGKε compromises signalling downstream of VEGFR2 in endothelial cells by decreasing cellular levels of PtdIns(4,5)P₂, inducing aHUS and, secondarily, disruption of the glomerular barrier. These results also implicate that pharmacological manipulation of the VEGFA signaling may be used to modify the clinical course of other forms of aHUS.

Re-Envisioning the APOL1 Cation Channel Structure
Russell P. Thompson,1 Crescens M. Schaefer,2 Panny Lee,1 Nada Terra,1 Jayne Raper,1,2 Hunter College, New York, NY; 1City University of New York, The Graduate Center, New York, NY; 2Vanderbilt University, Nashville, TN.

Background: Apolipoprotein L1 (APOL1) is a channel forming protein that protects humans and other primates from African trypanosome infection. African Americans have inherited common APOL1 variants with increased trypanolytic potential; however, these variants are responsible for an increased risk of kidney disease compared with other variants. Human APOL1 forms non-selective cation channels in a strictly pH dependent manner: channel formation requires acidic pH, whereas channel opening requires pH neutralization. Current APOL1 structural models rely on tenuous comparisons with unrelated channel forming proteins. Here we introduce a new model of APOL1 channel structure and topology based on functional characterization of divergent APOL1 orthologs and interspecies chimeras in a planar lipid bilayer system.

Methods: We tested interspecies APOL1 chimeras and point mutations in planar lipid bilayers to identify molecular determinants of pH dependence and ion selectivity.

Results: Strikingly, we demonstrate that cation conductance depends on the C-terminal domain, rather than the N-terminal region as previously suggested, with both pH gating and selectivity functions largely governed by a single residue – aspartate-348. Dual substitution of Asp-348 and nearby glutamate-355 eliminated pH gating, with tyrosine-351 having a steric influence. Acidic residues within a putative hairpin region (residues 177-228) affected the pH-dependence of channel formation.

Conclusions: Based on these data we present a radically updated domain structure of APOL1, including a putative 4-pass transmembrane topology and a pore-lining helix near the C-terminus (see Image abstract). We propose a mechanism of channel gating based on dual proton-sensing residues (Asp-348 and Glu-355) within the pore-lining helix, with Asp-348 also determining selectivity for cations over anions.

Small Molecule Inhibitor of TMEM16A Chloride Channel Blocks Vascular Smooth Muscle Contraction and Lowers Blood Pressure in Spontaneously Hypertensive Rats
Omur Cil,1 Xiaolian Chen,1 Henry Askew Page,3 Maria C. Jordan,1 Pyone Myat Thwe,1 Samuel N. Baldwin,1 Marc O. Anderson,1 Iain A. Greenwood,1 Kenneth P. Roos,1 Alan S. Verkman,1 University of California San Francisco, San Francisco, CA; 3Vanderbilt University, Nashville, TN; 1University of California Los Angeles, Los Angeles, CA; 2St George’s University of London, London, United Kingdom.

Background: Hypertension is a major cause of cardiovascular morbidity and mortality, despite the availability of antihypertensive drugs with different targets and mechanisms of action. There is an unmet need for antihypertensive drugs with novel mechanisms of action for better BP control. TMEM16A (transmembrane member 16A or anoctamin-1) is a Ca²⁺-activated Cl⁻ channel expressed in vascular smooth muscle. TMEM16A activation produces membrane depolarization that results in secondary activation of voltage-dependent ion channels that modulate vasoconstriction. TMEM16A is a potential target for hypertension treatment.

Methods: We recently identified by high-throughput screening and subsequent medicinal chemistry, small molecule TMEM16A inhibitor TM21-23 that inhibits TMEM16A current fully, with IC₅₀ ~ 30 nM. Here we tested TM21-23 pharmacokinetics in rodents and its effects on vascular smooth muscle contraction (via wire myograph) and BP in spontaneously hypertensive rats (SHR) and wild type rodents.

Results: TM21-23 pretreatment blocked maximum in vitro vascular smooth muscle contractions induced by a thromboxane mimetic (U46619) in rat mesenteric arteries by 90%. Intraarterial (ip) administration of TM21-23 to rodents at 10 mg/kg produced sustained systolic blood pressure (SBP, mmHg) concentrations of >10 µM for ~4 hours. BP measurements by tail-cuff and telemetry showed a maximum ~45 mmHg reduction in SBP in spontaneously hypertensive rats (SHR) after a single dose TM21-23 (10 mg/kg, ip) compared to vehicle administration, with BP gradually returning to baseline values within 6-8 hours after TM21-23 pretreatment. Minimal effect on BP (less than 10 mmHg decrease in SBP) was seen in wild-type rats and mice with TM21-23 treatment (10 mg/kg, ip). Chronic 5-day treatment of SHR with TM21-23 (10 mg/kg, ip, twice daily) caused sustained decreases (~25 mmHg) in daily average SBP, DBP and MAP during the treatment period. TM21-23 action was reversible, with BP returning to baseline (~170/115 mmHg) by 3 days after discontinuation of treatment.

Conclusions: These studies provide validation for TMEM16A as a target for hypertension therapy, and demonstrate the proof-of-concept for efficacy of TM21-23 as an antihypertensive with a novel mechanism of action.

Intravital Imaging of Afferent Arteriole Calcium Dynamics and the Role of Connexin 45
Anne Riquer-brison, Georgina Gyarmati, Janos Peti-Peterdi. University of Southern California, Los Angeles, CA.

Background: The glomerular afferent (AA) and efferent (EA) arterioles are the most critical resistance vessels in the autoregulation of renal blood flow and glomerular filtration rate. Calcium dynamics of vascular smooth muscle cells (VSMC), in part mediated by gap junction communication via connexin 45 (Cx45), are important regulators of AA and EA contractility and myogenic tone. We aimed to study the role of Cx45 in renal hemodynamics in vivo.

Methods: Intravital imaging with multiphoton microscopy (MPM) of renal functional parameters was performed in mice expressing a genetically encoded calcium indicator (GCaMP3 or GCaMP5) in cells of renin lineage with or without connexin 45 knockout (KO). Suramin treatment was used to test the effects of purinergic receptor blockade.

Results: Compared to the uniform upstream AA segment, high baseline and AA(Ca²⁺), were observed in a few AA VSMCs at the glomerular entrance, which appeared to function as a pressure sensor. The diameter of the AA (9.2±4.0 μm; WT, vs. 13.3±3.7 μm; KO) and EA (7.1±0.2 μm; WT, vs. 8.5±0.3 μm; KO) were larger in KO animals, although no difference was found in SBP, snGFR and glomerular diameter. Blood flow in AA was also increased (1.42±0.15 m/s; WT, vs. 2.0±0.12 m/s; KO). AA myogenic tone was visualized 3-4 weeks after unilateral ureteral obstruction (UUO). In WT animals, regular AA contractions were observed uniformly in all AAs with an average frequency of 0.12±0.01 Hz, with large magnitude AA(Ca²⁺), in VSMCs during every contraction (ΔAA(Ca²⁺)~556±855 nV). In contrast, KO animals showed highly heterogeneous and irregular AA vascular activity. In those AAs that did exhibit some myogenic tone-like contractions, a higher frequency was observed (0.28±0.02 Hz), however the magnitude of AA(Ca²⁺), in AA VSMCs was much lower than in the WT (ΔAA(Ca²⁺)~395±249 nV). In both WT and KO animals, treatment with suramin rapidly blocked AA VSMC calcium inward currents and the myogenic contractions, and the AA became dilated.

Conclusions: AA sphincter cells have robust effects on AA (Ca²⁺), dynamics and contractility in vivo, and CX45 and purinergic signaling are essential components of AA calcium signaling and vascular contractility. Cx45 and purinergic signaling in the AA regulate the myogenic response and renal blood flow, and may be culprit and potential target in vascular pathologies.

Inorganic Nitrite Supplementation Improves Endothelial Function with Aging: Translational Evidence for Suppression of Mitochondria-Derived Oxidative Stress
Matthew J. Rossman,1 Rachel A. Gioscia-Ryan,1 Jessica R. Santos-Parker,1 Brian P. Ziembka,1 Kara L. Lubieniecki,1 Natalie E. Polickov,1 Lawrence C. Johnson,1 Erzebet E. Nagy,1 Kayla A. Woodward,1 Amy L. Sinder,1 Michel Chonchoł,2 Douglas R. Seals,1 1University of Colorado Boulder College of Arts and Sciences, Boulder, CO; 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: We previously observed improvements in vascular endothelial function with inorganic nitrite supplementation in old mice, which we translated to older humans in a pilot study of sodium nitrite supplementation.

Methods: Here, we sought to confirm the efficacy of sodium nitrite in humans and determine mechanisms of action using: 1) a randomized, placebo-controlled, parallel-group clinical trial with sodium nitrite (80 mg/day, 12 weeks) in older adults (n=49, 68±1 yr) and 2) reverse translation experiments in young (6 mo) and old (27 mo) male C57BL/6 mice.

Results: In humans, sodium nitrite increased plasma nitrite (p=0.05) and was well-tolerated over 12 weeks. Endothelial function (brachial artery flow-mediated dilation) was increased by 28% vs. baseline after nitrite supplementation (p=0.05), but unchanged with placebo. Serum from nitrite-treated subjects reduced whole-cell (CellIROX) and mitochondria (mito)-specific (MitoSOX) reactive oxygen species (ROS) in human umbilical vein endothelial cell culture (p<0.05), whereas serum from placebo-treated subjects had no effect. Old mice (OC, n=9) had ~30% lower umbilical vein endothelial cell culture (p<0.05), whereas serum from placebo-treated subjects had no effect. Old mice (OC, n=9) had ~30% lower umbilical vein endothelial cell culture (p<0.05), whereas serum from placebo-treated subjects had no effect. Old mice (OC, n=9) had ~30% lower umbilical vein endothelial cell culture (p<0.05), whereas serum from placebo-treated subjects had no effect.

Conclusions: Nitrite supplementation improves age-related endothelial dysfunction and is associated with increased NO, reduced mito ROS and improved mitochondrial stress resistance.

Paracrine FGF-23 Signaling in the Heart Causes Cardiac Hypertrophy
Isaac D. Campos, Beatrice Richter, Christopher Yanuelci, Brian A. Craya, Kylie Heitman, Dominik Kentrup, David G. Westbrook, Christian Faul. The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.

Background: Elevated serum levels of the phosphaturic hormone, fibroblast growth factor (FGF) 23, contribute to cardiac hypertrophy in chronic kidney disease (CKD). FGF23 directly targets cardiac myocytes via FGF receptor (FGFR) 4 to induce hypertrophic growth and FGR4 knockout not only protects rodent models of CKD from cardiac hypertrophy but also from fibrosis. Our cell culture studies indicate that cardiac fibroblasts do not directly respond to FGF23. It is known that a miscommunication between cardiac myocytes and fibroblasts contributes to pathologic cardiac remodeling. It has been shown that in rodent models and patients with CKD, as well as in mice on high phosphate diet without kidney injury, the heart starts to produce FGF23. Here, we studied if by targeting cardiac myocytes FGF23 promotes paracrine signaling that drives fibrosis. We aimed to determine the cardiac cell type(s) that act as FGF23 source and study if FGF23 serves as a novel paracrine signal mediator between cardiac cell types.

Methods: We treated cultured cardiac myocytes with FGF23 and determined expression levels of established paracrine signal mediators (IL6, LIF, TGFβ, FGF23), or with high phosphate and analyzed FGF23 expression, all by qPCR. We isolated cardiac fibroblasts from wildtype mice on a high phosphate (2%) diet or control chow (0.7%) for 12 weeks. We analyzed paracrine signal mediators by qPCR, as well as FGF23 by qPCR. FGF23 does not affect cardiac fibroblasts by regulating paracrine signal mediators in myocytes. However, FGF23 acts as a novel fibroblast-derived paracrine signaling mediator that induces hypertrophic growth of cardiac myocytes in an FGR4-dependent manner in scenarios of hyperphosphatemia, such as CKD.

Conclusions: FGF23 signaling in the heart causes cardiac hypertrophy through a novel mechanism involving FGR4-mediated paracrine signaling.

A Renal Potassium-Switch Prioritizes Dietary Potassium Over Sodium, Driving Salt-Sensitive Hypertension
Paul R. Grimm,1 Robert Little,2 Robert A. Fenton,3 Eric J. Delpire,2 Paul A. Welling,1 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Vanderbilt University, Nashville, TN; 3Aarhus University, Aarhus, Denmark.

Background: Reducing dietary salt (NaCl) is well appreciated to lower blood pressure but a growing body of evidence indicates that increasing dietary potassium (K) intake is equally important. A ‘renal switch’ that turns on the thiazide-sensitive NaCl cotransporter (NC) in response to low dietary K intake and off in response to high K intake has been implicated. Here we test this idea in genetically engineered mice (CA-SPAK) in which the K switch is ‘locked on.’

Methods: Kinase-activating mutations were introduced in SPPAK, Expression of the constitutively active (CA) SPAK mutant was limited to the early DCT and results in NC hyperactivation. BP responses to small changes in plasma [K+]1 (P[K]) in CA-SPAK were compared to control mice. Dietary K content was varied over 4 days to titrate P[K] over a narrow range (3.7mM (LK), 4.4mM (MK), and 5.1mM (HK)). Blood pressure was monitored by telemetry at each P[K] level in mice consuming control or high salt diet (HNa). At the end of each treatment, the BP response to hydrochlorothiazide (HCTZ) was measured to assess the contribution of NC to BP.

Results: BP decreased by ~10 mmHg when P[K] increased from 3.7 to 5.1 mM in control mice, coincident with the inactivation of NC. When the switch was on (LK and MK groups), HNa significantly elevated BP but had no effect when the switch was inactivated by HK. HCTZ significantly reduced BP in the LK/HNa and MK/HNa groups but had no effect on BP in the HK/HNa group, supporting the idea that low K-dependent activation of NC exacerbates the effects of Na. Studies in CA-SPAK mice reveal a causal relationship between switch activation and BP responses to Na and K. In contrast to control mice, increasing P[K] in CA-SPAK mice had no effect on BP under control salt conditions and failed to blunt the significant hypertensive effects of HNa. HCTZ significantly decreased BP in all CA-SPAK groups to near control levels, consistent with NC-driven salt reabsorption. Thus, locking on the K switch prevents the anti-hypertensive effects of HK. No sex differences were found.

Conclusions: In summary, low K consumption, common in modern diets, presses the switch pathway to turn on to conserve K at the expense of increasing Na retention, even in the face of high dietary Na, and this elevates BP. Thus, switch activation can drive salt-sensitive hypertension.

Risk of Cardiovascular Events Is Higher in Patients with Glomerular Disease Compared with the General Population
Heather M. Cunning,1,2 Mark Canney,1,2 Heather N. Reich,3 Yuyan Zheng,1 Anahat Sahota,4 Sea Om Hur,4 Arenn S. Jauhal,1 Sean Barbour,1,2 Caren L. Rose,1 BC Provincial Renal Agency, Vancouver, BC, Canada; 2Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; 3Division of Nephrology, University of Toronto, Toronto, ON, Canada; 4School of Medicine, University of British Columbia, Vancouver, BC, Canada; British Columbia Centre for Disease Control, Vancouver, BC, Canada.

Background: Cardiovascular (CV) disease is a recognized cause of morbidity and mortality in chronic kidney disease; however, understanding of CV risk in patients with glomerular disease (GN) is limited. We sought to define CV risk in GN patients and compare incidence rates to the general population.

Methods: A centralized kidney pathology registry (2000-2012) was used to capture all incident cases of focal segmental glomerulosclerosis (FSGS, n=540), IgA nephropathy (IgAN, n=759), membranous nephropathy (MN, n=387), and minimal change disease (MCD, n=226) in British Columbia, Canada. The primary outcome was a composite of major CV events, ascertained from a hospital discharge registry and evaluated using the Kaplan-Meier method. Hazard ratios (HR, 95% CI) were determined using Cox proportional hazards regression. Event rates were age and sex standardized to the general adult population to generate standardized incidence ratios (SIR, 95% CI).

Results: Over a median follow-up of 6.9years there were 338 CV events; 10-year risk (95% CI) was 16.0% (13.8-18.3) and differed by GN type(Figure): IgAN=7.7% (5.4-10.4), MCD=13.2% (7.6-20.4), MN=19.4% (14.3-25.0), and FSGS=27.0% (21.9-32.4). Compared to IgAN, MN (HR=2.6, 1.7-3.9) and FSGS (HR=3.7, 2.6-6.5) had higher risk, but MCD (HR=1.3, 0.8-2.4) did not. Results were similar when comparing CV events among patients after ESKD. CV risk in GN patients was 2.5-fold higher than the general population (SIR 2.5, 2.1-2.8), and was higher in each GN subtype (IgAN=1.4, 1.0-1.8; MCD=1.8, 1.0-2.8; MN=3.0, 2.2-4.0; FSGS=4.0, 3.2-4.9).

Conclusions: Patients with GN are at high risk of CV disease, both before and after ESKD onset. The CV risk for all GN subtypes was higher than the general population, including MCD and IgAN. This suggests CV preventive strategies should be considered in all patients with GN.

Prediction of Atrial Fibrillation Using Clinical and Cardiac Biomarker Data: The CRIC Study
Leila R. Zelnick,1 Michael Shlipak,2 Elsayed Z. Solomon,3 Amanda H. Anderson,4 Robert Christenson,7 James P. Lash,7 Rajat Deo,7 Pandurang S. Rao,8 Farsad Afshinnia,3 Jing Chen,4 Jiang He,4 Stephen L. Seliger,7 Raymond R. Townsend,1 Debbie L. Cohen,4 Alan S. Go,3 Nisha Bansal,1 University of Washington Department of Medicine, Seattle, WA; 2University of California San Francisco, San Francisco, CA; 3Wake Forest University, Winston-Salem, NC; 4Tulane University, New Orleans, LA; 5University of Maryland School of Medicine, Baltimore, MD; 6University of Illinois at Chicago, Chicago, IL; 7University of Pennsylvania, Philadelphia, PA; 8University of Michigan, Ann Arbor, MI; 9Kaiser Permanente Northern California, Oakland, CA.

Background: Clinically available biomarkers of myocardial injury (high sensitivity troponin T, hsTnT) and hemodynamic stress (N-terminal brain natriuretic peptide, NT-proBNP) are strongly associated with atrial fibrillation (AF) in chronic kidney disease (CKD), and have been included in AF prediction models in community-based populations. We investigated the incremental prognostic value of NT-proBNP and hsTnT for AF prediction compared to standard clinical variables in CKD patients enrolled in the Chronic Renal Insufficiency Cohort (CRIC) using machine learning methods.

Methods: Among 2600 CRIC participants without prior AF with complete cardiac biomarker, demographics, medical history/lifestyle, medications, physical characteristics, and laboratory data, we evaluated the utility of Cox regression, LASSO, ridge regression, elastic net, and boosting methods, as well as a previously validated clinical prediction model (CHARGE-AF, using both original and re-estimated coefficients) to predict AF. Discriminatory ability of each model was assessed using 10-fold cross-validation; calibration was evaluated graphically.

Results: Mean (SD) age of participants was 57 (11) years, 55% men, 38% black, and mean (SD) eGFR 45 (15) mL/min/1.73m²; 251 incident AF events occurred during 7.3 (SD 2.8) years of follow-up. CHARGE-AF prediction equations using original and re-estimated coefficients each had a cross-validated C-index of 0.69 (Figure 1a). A LASSO model using only clinical data had a C-index of 0.69, while adding NT-proBNP, hsTnT, or both to the model improved the C-index to 0.75, 0.73, and 0.76, respectively (p for difference compared to clinical model ≤0.0001 for all). Calibration of top biomarker models was generally adequate (Figure 1b).

Conclusions: Cardiac biomarkers NT-proBNP and hsTnT can improve AF prediction in CKD, particularly when paired with machine learning algorithms.

Renal Hyperfiltration and the Effect of Intensive vs. Standard Blood Pressure Lowering on Cardiovascular Outcomes
Ayodele Oduotayo,1 Samir M. Iskandar, Fatimah Roble, Peter Juni, Fahad Razak, Amol Verma. University of Toronto, Toronto, ON, Canada.

Background: Using the Action to Control Cardiovascular Risk in Diabetes (ACCORD) trial and Systolic Blood Pressure Intervention Trial (SPRINT), we examined whether the effect of intensive versus standard blood pressure (BP) lowering on cardiovascular outcomes varies by the presence of renal hyperfiltration (RHF).

Methods: We pooled data on adults in ACCORD and SPRINT without chronic kidney disease (eGFR>60 and urine albumin-to-creatinine ratio <30 mg/g). RHF was defined as an eGFR above the 95th percentile for healthy adults in the National Health and Nutrition Examination Survey. Outcomes of interest were major adverse cardiovascular events (MACE, as defined in the ACCORD primary outcome): a composite of cardiovascular (CV) mortality, acute myocardial infarction (AMI), and stroke. Secondary outcomes were all-cause mortality, CV mortality, and CV events. We used fixed effect cox regression. Results: There were 1946 (13%) adults with RHF and 7192 adults without normal filtration. RHF modified the effect of intensive versus standard BP lowering on MACE (p-interaction=0.002) but not all-cause mortality (p-interaction=0.059). For adults with RHF, intensive BP lowering reduced incidence of MACE compared with standard BP lowering (HR: 0.22, 95%-CI: 0.10-0.49). The risk reduction was smaller in adults with normal filtration (HR: 0.84, 95%-CI: 0.67-1.06). Intensive BP lowering was also associated with a larger reduction in the incidence of CV mortality and stroke among adults with RHF (Figure, p-interaction=0.035) but not AMI or heart failure (p-interaction=0.41).

Conclusions: RHF modified the effect of intensive versus standard BP lowering on cardiovascular outcomes.

SA-OR39
Pooled Analyses of the Phase 3 Roxadustat Studies: Congestive Heart Failure Hospitalization Rates in Dialysis and Non-Dialysis Patients with Anemia Treated with Roxadustat vs. Comparators
Robert Provenzano,1 Lynda Szczec,2 Ming Zhong,3 Bryant Lai,7 Robert Leong,2 Dustin J. Little,1 Kin-Hung P. Yu,2 Wayne State University, Detroit, MI; 3Fibrogen Inc, San Francisco, CA; 4AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an orally bioavailable hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Phase 3 roxadustat studies were performed to treat anemia of chronic kidney disease (CKD). Congestive heart failure (CHF), a common comorbidity in CKD, was also studied. CHF is associated with a poorer prognosis in CKD patients, with a prevalence that increases with CKD severity; approximately 20% in mild CKD (eGFR >65 mL/min/1.73 m²) to 40% in patients on hemodialysis. CHF was defined as Severe Heart Failure (NYHA class III or IV), Heart Failure with Reduced Ejection Fraction (HFrEF), or Heart Failure with Preserved Ejection Fraction (HFpEF) with NYHA class II or greater. CHF readmissions were a component of the CHF endpoints in this study. CHF hospitalization was adjudicated by a blinded independent committee, and analyzed by a Cox proportional hazards regression model; these analyses were not powered for individual component endpoints.

Methods: Safety data were pooled from pivotal phase 3 studies comparing roxadustat to placebo in Stage 3-5 non-dialysis-dependent (NDD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) patients, and subgroup of incident-dialysis (ID-DD) patients. Patients with baseline (BL) moderate to severe CHF were not enrolled. CHF hospitalization events were a component of the MACE-plus endpoints that were adjudicated by a blinded independent committee, and analyzed by a Cox proportional hazards regression model; these analyses were not powered for individual component endpoints.

Results: In the pooled NDD studies, 4270 patients were analyzed (2386 roxadustat; 1884 placebo). BL CHF history was comparable between roxadustat (13.0%) and placebo (13.6%) arms. Using ITT long-term follow-up, the HR (95% CI) of hospitalization for CHF among the NDD pooled population was 0.89 (0.72, 1.22) for roxadustat vs placebo. In the pooled DD studies, 3846 patients were analyzed (1940 roxadustat; 1904 epoetin alfa). BL CHF history was comparable between roxadustat (25.7%) and epoetin alfa.
Background: Chronic kidney disease (CKD) in type 2 diabetes mellitus (T2DM) patients (pts) is associated with increased cardiovascular disease (CVD) and heart failure risk. We hypothesized that a maladaptive epigenetic response engaging the bromodomain and extraterminal (BET) protein transcription system contributes to excess CVD risk. Hence, the efficacy of BET inhibition (BETi) treatment with apabetalone (APB) was assessed according to presence of CKD in the phase 3 BETonMACE trial.

Methods: BETonMACE compared APB with placebo in 2425 pts with T2DM and recent acute coronary syndrome. The primary outcome was CV death, non-fatal myocardial infarct or stroke (MACE). Hospitalization for congestive heart failure (HCHF) and extraterminal (BET) protein transcription system contributes to excess CVD risk. Hence, the efficacy of BET inhibition (BETi) treatment with apabetalone (APB) was assessed according to presence of CKD in the phase 3 BETonMACE trial.

Results: CKD pts were older (71 vs. 61 years), more likely female (42% vs. 23%) or non-white (18% vs. 12%), had longer duration of diabetes (mean 11.3 vs. 8.2 years) and higher serum alkaline phosphatase (91 vs. 81 U/L), and were less likely to receive metformin (69% vs. 84%) or SGLT2 inhibitors (6% vs. 13%) (P<0.05 for all). Under placebo, risk of endpoints was higher in CKD vs. non-CKD pts (MACE: 35/164 (21.3%) vs. 114/1041 (11.0%), HR=2.40, 95% CI [1.67, 3.44]; HCHF: 14/164 (8.5%) vs. 34/1041 (3.3%), HR=3.19, 95% CI [1.66,6.12]; P=0.001 for both). Under APB treatment, pts with CKD had significant reductions in MACE (HR=0.50, 95% CI [0.26, 0.96], P=0.034) and HCHF (HR=0.26, 95% CI [0.07,0.94], P=0.028) vs. placebo, see Kaplan-Meier figures.

Conclusions: Patients with CKD and recent acute coronary syndrome have a high risk of MACE that was substantially reduced with APB BETi in the phase 3 BETonMACE trial.

Prevalence of Left Ventricular Hypertrophy in Pediatric Patients on Maintenance Dialysis and After Kidney Transplantation: A NAPRTCS Study

Kyle Merrill,1 Shirley Galbiati,2 Mark Mitsnefes,3,4 on behalf of NAPRTCS Investigators 1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2EMMES, Rockville, MD; 3University of Cincinnati, Cincinnati, OH, 4University of Cincinnati, Cincinnati, OH.

Background: Left ventricular hypertrophy (LVH) is recognized as the most common cardiovascular complication in children on maintenance dialysis. There have been small single-center, or cross-sectional multi-center studies but there has been no large multi-center studies looking at prevalence of LVH during long-term maintenance dialysis. Using the NAPRTCS database, we determined the prevalence of LVH at time of initiation of maintenance dialysis and changes during long-term dialysis and post kidney transplantation. We also assessed the risk factors associated with LVH in children initiating maintenance dialysis.

Methods: Echocardiographic data were obtained from the NAPRTCS database which initiated collection of echo data in 2013 with the last data obtained in March 2020. LVH was defined as left ventricular mass index (LVMI, height-indexed) >95th percentile for age and sex. Patients with cardiovascular diagnoses, those younger than 1 year old at the time of echocardiography, LVMi values >200 g/m2, and LVMi values based on outlying heights were excluded from analysis. Multivariable logistic regression to assess risk factors for LVH at baseline (within first 3 months after initiation of dialysis) was performed.

Results: The study cohort included 606 patients between 1 and 18 years of age (median 10y (IQR 3.8-15.1)), 53% females, 48% whites, 27% African-American, and 25% others/unknown) who had LVH data during time on dialysis. Of 182 patients who had echocardiography within first 3 months after initiation of dialysis (baseline), 67% had LVH. In logistic regression, hypertenison (OR 2.9, 95% CI 1.4-6.3), anemia...

Biomarker Panels for Discriminating Risk of CKD Progression in Children

Jason H. Greenberg,1 Yuwen Xu,2 Alison G. Abraham,3 Jeffrey R. Schelling,3 Harold I. Feldman,6 Michael Shlipak,5 Venkata Sabbisetti,2 Bradley A. Warady,7 Steven G. Coca,1 Paul L. Kimmel,4 Joseph V. Bonventre,4 Michelle Denburg,4 Chirag R. Parikh,2 Susan L. Furth,4 CKD Biomarker Consortium1 Yale University, New Haven, CT; 2 Johns Hopkins University, Baltimore, MD; 3 Case Western Reserve University, Cleveland, OH; 4 University of Pennsylvania, Philadelphia, PA; 5 University of California San Francisco, San Francisco, CA; 6 Brigham and Women’s Hospital, Boston, MA; 7 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 8 Mount Sinai Health System, New York, NY; 9 National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: We used multivariate survival trees to identify plasma and clinical biomarkers to predict CKD progression in children.

Methods: The CKiD study prospectively enrolled children aged 6 months to 16 years old with an eGFR of 30-90 and eGFR was assessed annually. The primary outcome of CKD progression was a composite of 50% decline in eGFR or incident ESKD. We used multivariate survival trees to determine combinations of baseline clinical predictors and plasma biomarkers as well as identify optimal thresholds for predicting the time to the composite event.

Results: Of the 651 children included, median age was 11 years [IQR,8-15], 405 (62%) were male, 195 (30%) had a glomerular cause of CKD, and baseline eGFR was 53 [IQR,40-67]. 223 (34%) out of 651 children reached the primary outcome over a median follow-up time of 5.7 years. The Figure shows the best-sized multivariate tree with no improvement in LHV seen in patients within 6 months (47%) as well as 12 months post-transplant (45.5%), Table 1.

Puberty Is Associated with Decline in Estimated Glomerular Filtration Rate in Children with CKD

Hannah Kim,1 Derek Ng,1 Matthew Matheson,1 Meredith A. Atkinson,1 Yasmin Akhtar,1 Bradley A. Warady,2 Susan L. Furth,2 Rebecca Ruebner,3 Johns Hopkins University, Baltimore, MD; 4 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 5 The Children’s Hospital of Philadelphia, Philadelphia, PA.

Background: Puberty is a high-risk period for decline in kidney function among children with CKD. We aimed to describe changes in eGFR before and after pubertal onset using different objective markers of puberty among children with CKD.

Methods: We conducted a prospective cohort study using data from the Chronic Kidney Disease in Children (CKiD) study. Children who had onset of CKD after pubertal onset were excluded. GFR was estimated annually using the bedside and complete CKiD equations. Pubertal onset was defined by three separate definitions: transition to Tanner Stage 2, peak growth velocity, and menarche. A mixed effects model with random intercept and random slope was used to compare the slope of eGFR before and after pubertal onset. The model was adjusted for age, race, glomerular diagnosis, baseline proteinuria, and BMI.

Results: 339 girls and 552 boys were included; Median age of pubertal onset for girls was 11.0 years (IQR 9.8, 12.1), 14.1 years (IQR 12.4, 17.0), and 14.4 years (IQR 13.1, 15.7) as defined by Tanner stage 2, peak growth velocity, and menarche, respectively. Median age of pubertal onset for boys was 12.4 years (11.3, 13.3) and 14.6 years (IQR 13.4, 16.6) as defined by Tanner stage 2 and peak growth velocity, respectively. Annual percent change in eGFR declined faster among girls and boys after pubertal onset when defined by all measures, after adjustment. For example, annual percent decrease in eGFR was seen to increase from 2.6% prior to 9.0% after Tanner stage 2 in boys using the complete CKiD equation (p<0.001).

Conclusions: Estimated GFR declined faster after the onset of puberty among girls and boys with CKD. Clinicians should be aware that puberty may be an important time of kidney function decline among children with CKD.

SA-OR45
CLYSL H310Y Is a Novel Cause of Familial Childhood Steroid-Sensitive Nephrotic Syndrome

Brandon M. Lang1,2, Megan Chrsyt-Stangl1,2, Guanghong Wu,2 Mohamed A. Shalaby,1,2 Sherif M. El desoky,1 Jameela A. Kari,1 Rashheed A. Gbadegesin1,2 Department of Pediatrics, Duke University School of Medicine, Durham, NC; 2 Duke Molecular Physiology Institute, Durham, NC; 3 King Abdulaziz University Hospital, Jeddah, Saudi Arabia.

Background: Nephrotic syndrome (NS) is the most common glomerular disease seen in children. It is estimated that up to 30% of steroid resistant NS (SRNS) may be due to mutations in one of sixty genes reported in cohort of patients with familial or idiopathic NSNS. However, the genetic causes of the more common steroid sensitive NS (SSNS) and the molecular basis for variability in glucocorticoid response have remained elusive. Our overarching hypothesis is that single gene causes of SSNS can be identified in cohorts of sibling pairs with SSNS and identification of such genes can provide insight into the molecular basis of glucocorticoid response.

Methods: To identify single gene causes of SSNS in a cohort of patients with familial SSNS and examine the molecular basis of glucocorticoid response, we carried out whole genome sequencing in forty families with hereditary SSNS. After identifying a potential disease-causing variant, we examined the effects of loss of gene function in cultured human podocytes through the creation of lentiviral shRNA knockdown and CRISPR-Cas9 knockout cell lines as well as morpholino-based gene knockdown in zebrafish.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: We identified a rare homozygous variant, CLF51 H110Y, that segregates with disease in a consanguineous family with two affected siblings and a cousin. CLF51 encodes clatherin, a component of clathrin-mediated endocytosis. This variant was not present in a homogenous state in >200,000 chromosomes and is predicted to be pathogenic by in silico analyses. Morphologic knockdown of the orthologous CLF51 gene in mice resulted in edema phenotypes indicative of loss of glomerular filtration barrier (GFB) integrity. This edema phenotype could be rescued with wildtype human CLF51 mRNA but not the H110Y variant. Knockdown of CLF51 in cultured human podocytes as well as overexpression of the H110Y variant in HEK 293 cells decreased endocytosis of luciferase transiently labeled dextran and increased susceptibility to apoptosis. The transient podocyte phenotypes could be rescued in the presence of glucocorticoid, mimicking the steroid responsive phenotype in patients bearing the CLF51 H110Y variant.

Conclusions: We identified a mutation in CLF51 as a new cause of hereditary SSNS. Our data demonstrates the requirement of functional steroid responsive phenotype in patients bearing the podocyte phenotypes could be rescued in the presence of glucocorticoid, mimicking the steroid responsive phenotype in patients bearing the CLF51 H110Y variant.

Cross-Talk Between Neutrophils and Macrophages Dictates the Outcome of Acute Pyelonephritis
Juan de Dios Ruiz-Rosado, Hanna H. Cortado, John D. Spencer, Brian Becknell, Santiago Partida-Sanchez. Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.

Background: Pediatric urinary tract infections (UTI) account for 1.5 million clinic visits annually in the United States. Uropathogenic Escherichia coli (UPEC) causes over 80% of UTIs. Up to 50% of infants with a UTI develop a kidney infection (acute pyelonephritis; APN). To study cell type specification of renal epithelial cells, we conducted trajectory analysis and resolved the developmental pseudotime along cell differentiation from nephron progenitors. We show that early differentiation of podocytes from the nephron progenitor pool is associated with sustained Foxl1 expression. Differentiation of renal tubule cells followed a more complex pattern, where Hnf4a expression is associated with a more proximal fate, while Tgfb2 is coupled to the distal tubule differentiation. After cell specification, terminal differentiation was strongly linked to metabolic nuclear receptors such as Exr and Ppara for proximal tubules and Estb and Parp4 for loop of Henle. Apo1 and Axs1 were expressed in PTs, while Ppara and Ppargc1a for proximal tubules and Uncx4.3 and Ppara for distal tubules were expressed in DTs.

Methods: We established a novel method to induce human induced pluripotent stem cells (hiPSCs) to differentiate into human ureteric bud (hUUB) organoids. The mammalian adult kidney, metanephros, develops by the reciprocal interaction between two embryonic progenitor tissues, metanephric mesenchyme and ureteric bud (UB). UB has epithelial polarity and tubular lumens, consists of two domains, the tip and trunk, and repeats branching morphogenesis. We also implemented an ATAC-seq data to leverage our understanding of human kidney disease development. By overlapping the chromatin landscape with kidney disease GWAS signals, we inferred key cell types for GWAS loci in the proximity of Shroom3 and Dab2 genes. Interestingly, we observed that some kidney disease-associated loci, such as those in the vicinity of Unx, are only accessible in the developing kidney cells, indicating a developmental stage regulatory role of genetic variants.

Conclusions: Here we present a comprehensive open chromatin and gene expression landscape for developing mouse kidney and illustrate the use of single-cell multi-omics data to study gene regulatory dynamics and its relationship to complex human disease genetics.

Expansion of Human Induced Pluripotent Stem Cell-Derived Ureteric Bud Organoids with Repeated Branching Potential
Makoto Ryosaka, Shin-ichi Mae, Kenji Osafune. Center for iPSC Cell Research and Application (CIRA), Kyoto University, Kyoto, Japan.

Background: The mammalian adult kidney, metanephros, develops by the reciprocal interaction between two embryonic progenitor tissues, metanephric mesenchyme and ureteric bud (UB). UB has epithelial polarity and tubular lumens, consists of two domains, the tip and trunk, and repeats branching morphogenesis. The tip cells produce both new tubular lumens or sufficient branching has not been achieved. We report a stepwise protocol to induce human induced pluripotent stem cells (hiPSCs) and embryonic stem cells (hESCs) into UB-like structures through anterior intermediate mesoderm. However, the generation of hiPSC/ESC-derived UB-like tissues that show tubular lumens or sufficient branching has not been achieved.

Methods: We established a novel method to induce hiPSCs to differentiate into induced UB (iUB) organoids. We evaluated our iUB organoids using immunostaining and single cell RNA sequencing analysis. Results: Our iUB organoids showed RET+ tip and CK19+ trunk domains, epithelial polarity, tubular lumens and developmental potential to repeat branching morphogenesis. The isolated tip regions from the iUB organoids showed repeated branching to reconstitute iUB organoids.

Conclusions: Our induction method for iUB organoids will help elucidate the developmental mechanisms of UB branching and develop a selective differentiation method for CD cells, contributing to the creation of disease models for congenital renal abnormalities.

Rhesus Macaque Serves as a Model for Human Lateral Branching Nephrogenesis
Meredith P. Schuh, Lyan Alkhudairy, Andrew Potter, Steven Potter, Kasihigh Chetel, Nathan Salomonis, Raphael Kopan. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: Premature infants are at risk for chronic kidney disease later in life due to low nephron endowment. Lateral branching nephrogenesis (LBN), not occurring in the mouse, is a poorly understood but critical period of human nephrogenesis. Here, we analyze third trimester LBN in the rhesus macaque at the molecular and morphological level.

Methods: The morphology of third trimester rhesus kidneys was assessed by immunostaining after tissue clearing. 3D renderings were created using BioRad Imaris. Single-cell RNA sequencing (scRNA-seq) and single-nucleus RNA sequencing (snRNA-seq) were performed on 4 kidneys from 4 rhesus using cold protease digestion and 10xGenomics platform. Unsupervised analyses using ICGS2 were used to identify distinct cell populations and GO-Elite was used to compare rhesus with human and mouse datasets.

Results: The gestational period of the rhesus lasts 165 days. We determined that cessation of rhesus nephrogenesis occurs between 136- and 138-days gestational age (GA). LBN was observed along the ureteric buds at 126-138 days GA. We noted rosette-like patterns of ureteric tips and nephron progenitor cells (NPC) in both rhesus and human third trimester archival samples. scRNA-seq was performed on 4 cortically enriched rhesus samples 129-131 days GA revealing 3 transcriptionally distinct cell clusters. C25 was predicted to contain the naïve NPCs and included CITED1, MEOX1, and EYA1. snRNA-seq yielded 5,972 nuclei, corresponding to 29 ICGS2 clusters. We found a single cluster (c26), with a near identical GO-Elite enrichment profile to that of the naïve NPC scRNA-seq cluster (c25). snRNA-seq c26 contained many unique markers not found in the naïve NPC studies (BRN8, BMP4, BMPR1B, GOELITE). GOELITE showed that late-gestation rhesus NPC markers more closely aligned to late-gestation murine NPCs, whereas the 2nd trimester human NPCs more closely aligned to mid-gestation murine NPCs. Novel surface markers predicted in the rhesus include CACNA1E, KIRREL3, and IL12B.

Conclusions: The rhesus is the first animal model to demonstrate LBN, suggesting that LBN is conserved in all world primates. We identified novel genes upregulated during LBN and surface markers that could be used during cell-sorting. ICGS2 of naïve NPC masqent transcripts may provide mechanistic insights that would otherwise be missed.

Cyclin G1/CDK5-Mediated Dedifferentiation of Proximal Tubular Cells Drives AKI-to-CKD Transition
Kensete Taguchi, Bertha C. Elias, Craig R. Brooks. Vanderbilt University Medical Center, Nashville, TN.

Background: Acute kidney injury (AKI) is associated with increased morbidity and mortality in hospitalized patients and predisposes patients to chronic kidney disease (CKD). While kidney cells, particularly proximal tubule cells (PTCs), can undergo dedifferentiation, proliferation and differentiation to facilitate kidney repair after injury, maladaptive repair resulting in prolonged dedifferentiation of PTCs drives fibrosis. We have found that cyclin G1 (CG1), an atypical cyclin, not only promotes G2/M cell cycle arrest, but also regulates dedifferentiation of PTCs. The aim of the current study is to determine how regulation through interaction with CG1 impacts AKI.

Methods: 1: Ablation of CG1 results in upregulated expression of TGFB1. CRISPR interference with SMAD4 alleviates TGFB1's impact on AKI. Interference with downstream SMO signaling alleviates TGFB1's impact on AKI. 2: We determined that cyclin G1 activates CDK5 and translocates the complex into nuclei. Phosphorylation of CDK5 in response to injury was reduced by genetic ablation of CG1. Genetic or pharmacological inhibition of CDK5 preserved E-cadherin in AA-induced cellular injury with reduction of profibrotic markers; however, it showed no additional effect in CG1KO PTCs.

Conclusions: CG1 partnering with CDK5 drives a maladaptive dedifferentiation of PTCs after kidney injury, resulting in increased secretion of profibrotic cytokines and progression of fibrosis. As CG1 is highly expressed in injured PTCs, it represents a potential therapeutic target for prevention of kidney fibrosis.

Incorporation of Urine-Derived Stem Cells into Kidney Organoids Derived from Human Injured Pluripotent Stem Cells
Julie Bejoy, Richard C. Welch, Lauren E. Woodard. Woodard Lab Vanderbilt University Medical Center, Nashville, TN.

Background: Donor-derived somatic cells or stem cells can be differentiated into renal cell types for disease modeling, drug screening, or therapeutic studies. Modeling kidney disease with kidney organoids derived from human induced pluripotent stem cells (hiPSCs) has been termed a "kidney in a dish." The recent advances in stem cell-based therapies have shown great promise for the treatment of kidney injuries. To evaluate the therapeutic properties, we studied the incorporation of urine-derived stem cells (USCs) into a kidney organoid model of acute kidney injury. USCs are viable cells from urine which can be expanded in vitro for more than ten passages. There is evidence suggesting that USCs are most likely cultured glomerular parietal epithelial cells.

Methods: For this project, we cultured kidney fibroblasts from fibroblast-derived hiPSCs by the established protocol from Takasato and Little, following optimization. Culturing of USCs labeled with a membrane dye and Day 25 kidney organoids revealed that USCs could not be incorporated into the organoid efficiently within two days of the co-culture. For injury models, we established nephrotoxicity in the proximal tubule by adding the nephrotoxic drug Cisplatin (5 μM) at Day 21 of kidney organoid culture.

Results: The kidney organoids derived from USCs expressed the kidney cell type markers ECAD (distal tubule), GATA3 (collecting duct), LTL (proximal tubule) and NEPHRIN (Glomeruli) at Day 21. The organoids were then treated with 5 x 10^6 USCs at Day 22 for 48 hours and evaluated for the expression of kidney injury molecule-1 (KIM-1). Immunostaining revealed that KIM-1 expression was significantly reduced in the organoids treated with USCs compared to the organoids without USCs, suggesting a positive therapeutic impact of USCs. We are currently performing RNAseq on three sets of whole kidney organoids (Control, +Cisplatin, +Cisplatin+USC) to provide detailed interrogation of cellular apoptosis and related signaling pathways in these three different sets of organoids.

Conclusions: The ability of USCs to reduce KIM-1 expression in human kidney organoids suggests that further investigation into the therapeutic potential of USC for treatment of acute kidney injury is warranted.

Supramolecular Nanofibers Containing Arginine-Glycine-Aspartic Acid (RGD) Boost Therapeutic Efficacy of Extracellular Vesicles in Kidney Repair
Guhan Zhang,1,2 Jie Wu,1 Lingling Wu,1 Xiangmei Chen,1,2 Chinese PLA General Hospital, Beijing, China; 1Nankai University, Tianjin, China.

Background: Extracellular vesicles (EVs) derived from mesenchymal stem cells (MSC-EVs) have been recognized as a promising cell-free therapy for acute kidney injury (AKI), which avoids safety concerns associated with direct cell engraftment. However,
low stability and retention of MSC-EVs have limited their therapeutic efficacy. RGD peptide binds strongly to integrins, which have been identified on the surface of MSC-EV membranes, yet RGD has not been applied to EV scaffolds to enhance and prolong bioavailability.

Methods: Here, we developed RGD hydrogels, which we hypothesized could augment MSC-EV efficacy against AKI.

Results: In vitro tracking of the EVs revealed that RGD hydrogels increased retention and stability of EVs. Upon intrarenal injection, EV-RGD hydrogels provided superior rescuing effects at functional, histopathological and molecular levels. Further analysis revealed that the presence of microRNA let-7a-5p in MSC-EVs served as a novel mechanism contributing to the reduced cell apoptosis and elevated cell autophagy in AKI.

Conclusions: RGD hydrogels boosted the therapeutic efficacy of let-7a-5p-containing-EVs in AKI repair. This study developed an RGD-scaffold to increase the EVs in strain-mediated loading and in-turn improved therapeutic efficacy, therefore this strategy sheds light on MSC-EVs application as cell-free treatment for potentiated efficiency.

SU-OR06
Targeting Angiopoietin-Tie2 Signaling in Kidney Ischemia-Reperfusion Injury
Yanyang Li,1 Tuncer Onay,1 Pan Liu,1 Michael Ryck佐,2 Mohammed Javed Ansari,1 Jing Jin,1 Susan E. Quagggin,1 NorthWestern University Feinberg School of Medicine, Chicago, IL; 2Mannin Research Inc, Toronto, ON, Canada.

Background: The endothelial angiopoietin (ANG)-Tie2 signaling pathway is required for vascular development and homeostasis. Dysregulation of angi-Tie2 pathway has been implicated in diseases including venous malformation, glaucoma, diabetic nephropathy, and septic acute kidney injury (AKI). The endothelial-specific phosphatase VE-PTP/PTPRB is a negative regulator of Tie2 phosphorylation. Here we investigate the therapeutic roles of Angiopoietin-Tie2 signaling in kidney ischemia-reperfusion injury (IRI).

Methods: A bitransgenic doxycycline-inducible system (VeptpK/Dox, Rosa26-RTAlac, tetO-Cre(Lox)) was used to knockout VE-PTP at postnatal day 0 (VE-PTPKO). Adult male VE-PTPKO and littermate control mice underwent bilateral IRI or sham surgery. Serum creatinine was measured on day 1, day 5 and day 7 after surgery by HPLC method. Data were analyzed using two-way ANOVA. Tissues were harvested on day 7 after surgery, immunohistochemistry and RNA/protein analysis. Bulk RNAseq was performed with RNA extracted from whole kidney 5 hours after IRI. Normalization and differential expression were determined using DESeq2. For pharmacological studies, adult male C57BL/6J mice were used. A new soluble ANGPT1 mimic (c4BB-ANGI) or vehicle were administered by intraperitoneal injection.

Results: Western blot analysis showed VE-PTP protein levels were increased in kidneys post-IRI and following hypoxia-inducible factor stabilization. Genetic deletion of VE-PTP rescued declined Tie2 phosphorylation in kidney after IRI. While serum Creatinine was elevated 1 day post-IRI in control mice, this increase was minimal in VE-PTP iKO mice (p<0.0055). Global gene expression analysis indicated minimal kidney transcriptome change at base line whereas in the setting of IRI, VE-PTPKO mice showed a less activated renal endothelium and downregulation of acute stress response gene signature. A corresponding decrease in pro-fibrotic genes was observed in VE-PTPKO mice on day 7. In the pharmacological study, systemic administration of c4BB-ANGI activated Tie2 and its downstream AKT/ErkOS/NO pathways in mouse kidney in physiological condition. Ongoing studies are analyzing its protective effect in in-vivo AKI.

Conclusions: Our data provide evidence for augmenting Tie2 activation-induced vascular protection as a promising therapeutic strategy for renal protection following IR-AKI.

Panxinin 1 Channel Regulates Mitochondrial Function and Cell Survival During AKI
Nabin Poudel,1 Colleen Schinderle,1 Nataliya Skrypnyk,2 Christopher B. Medina,2 Diane L. Rosin,1 Kodi S. Ravichandran,2 Mark D. Okusa.1 Center for Immunity, Inflammation and Regenerative Medicine (CIIR), University of Virginia, Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Microbiology, Immunology, and Cancer Biology, University of Virginia, Charlottesville, VA.

Background: Panxinin 1 (Panx1) is a membrane associated non-selective channel that, when activated, serves as a conduit for release of small metabolites that have pro- or anti-inflammatory function. We have previously shown that pharmacologic inhibition or genetic deletion of Panx1 in mice prior to injury is protective against renal ischemia-reperfusion injury (IRI). How Panx1 contributes to acute kidney injury (AKI) pathology is unknown. We hypothesized that Panx1 induces cell death by mediating both intracellular and extracellular events.

Methods: We subjected a novel human Panx1 overexpressing mouse (hPANX1-Tg) to IRI or cisplatin-mediated AKI and assessed plasma creatinine and renal expression of neutrophil gelatin associated lipocalin (NGal). For in vitro studies, PANX1 overexpressing TKPTS cells (OX) were challenged with cisplatin. Cell death was assessed by flow cytometry using Annexin-V/7AAD. Mitochondrial function was assessed by measuring oxygen consumption rate, mitochondrial membrane potential and ROS production. mRNA expression was measured by real-time PCR.

Results: hPANX1-Tg mice had significant rise in plasma creatinine and expression of NGal in the kidneys in both models of AKI compared to their littermate controls. Cisplatin-induced cell death was greater in OX cells compared to control cells. Moreover, cisplatin induced greater death in OX cells than cells cultured when together. Among genes involved in the cell death pathway, OX cells had reduced expression of Be2 and a greater increase in Ho-1 after cisplatin exposure. Assessment of mitochondria showed that OX cells had reduced mitochondrial DNA, Pgc1a expression, and mitochondrial respiration at baseline, a greater reduction in mitochondrial function and a higher increase in mitochondrial ROS production after cisplatin exposure compared to controls.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Exo-siRNA treatment as compared with the control. Exo-siRNA treatment also significantly affected post-ischemic renal immune cell populations, lowering neutrophil, monocyte/macrophage, and T cell frequencies than those in the control.

**Conclusions:** Thus, the modulation of NF-κB signaling through exosomal delivery can be used as a novel therapeutic method for IR-induced AKI.

Enhancer and Super-Enhancer Dynamics in Repair After Ischemic AKI

**Anupam David,1,2 Lothar F. Hennighausen,2,3 Joseph V. Bonventre,1,2 Brigham and Women's Hospital, Boston, MA; 2Laboratory of Genetics and Physiology, National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD; 3Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Stockholm, Sweden; 4University of Veterinary Medicine, Department of Medicine, Department of Clinical Sciences, Intervention and Technology, Renal Division, Harvard Medical School, Boston, MA; 2Laboratory of Physiology, Pathophysiology and Endocrinology, Vienna, Austria.

**Background:** The endogenous repair process of the mammalian kidney allows rapid recovery after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. There is currently limited understanding of which transcriptional regulators activate these repair programs. Here we investigate the existence and transcription factor dynamics in the regenerating mouse kidney.

**Methods:** We performed RNA-seq and ChIP-seq (H3K27ac, H3K4m3, BRD4, BRD2, BRD3, H3K27ac, H3K4m3, STAT3) in kidneys of male C57BL/6J mice before and after 2 days of ischemia-reperfusion injury (IRI). We identified candidate genes, transcription factor binding sites, and enhancers associated with kidney repair.

**Results:** We have investigated the role of enhancers and super-enhancers in kidney repair through transcriptional signatures of injury-induced KRMs. Such a fit was even stronger when the AKI-regulated genes were selected on the basis of the hallmark feature of renal IRI. miR-17-92 encodes 6 polycistronic microRNAs that show potent pro-angiogenic capacity by targeting anti-angiogenic factors. The function of miR-17-92 is regulated in microvascular pericytes in vivo. These results clearly identify CDH11 inhibition as a novel means of mitigating renal injury.

**Conclusions:** These results clearly identify CDH11 inhibition as a novel means of mitigating renal injury. These results provide a new therapeutic strategy for the treatment of chronic kidney disease.
SU-OR12
METTL10: A Kidney Disease Risk Gene by Altering Protein Methylation
Hailong Hu, Katalin Susztak. Renal Electrolyte and Hypertension Division, Department of Medicine and Genetics, University of Pennsylvania, Philadelphia, PA.

Background: Genome-wide association studies (GWAS) have identified more than 300 loci where genetic variants are associated with kidney function, however, the causal variants, genes, cell types and the disease mechanism remain mostly unknown.

Methods: We have generated expression of quantitative trait (eQTL) data from microdissected human kidney tubules and glomeruli. We used Bayesian colocalization of eQTL and GWAS to identify likely causal genes for kidney function. We used single cell RNA and ATACseq data to identify causal cell types. Finally, we generated mice with genetic deletion to study kidney disease mechanism.

Results: Kidney disease associated genetic variants showed a strong association with METTL10 expression. Methyltransferase-like protein 10 (METTL10), is a non-histone lysine methyltransferase. Patients with CKD variants showed lower level of METTL10 in their kidneys. METTL10 was relatively broadly expressed in kidney tubule cell by single cell expression analysis. Its expression was markedly reduced in mice and patients with kidney disease. We found that Mettl10 controls methylation and the activity of the eukaryotic translation elongation factor 1 alpha (eEF1A). eEF1A is the alpha subunit of the eukaryotic elongation complex, controlling RNA translation. Methylation of eEF1A was markedly reduced in kidneys of Mettl10 KO mice. The reduction in eEF1A activity lead to lower protein translation and tubule cell proliferation. Mettl10 KO mice was more vulnerable to kidney injury, showed structural damage and collagen expression in the folic acid induced kidney injury model.

Conclusions: Taken together, GWAS and eQTL studies identified Mettl10 a kidney disease risk gene. METTL10 controls the methylation of eEF1A, downstream RNA translation, cell proliferation altering kidney disease risk, defining a novel mechanism for kidney disease development.

Renal Proximal Tubule Cell Differentiation and Metabolism Are Coupled by Nuclear Receptors
Poonam Dhillon,1 Jhwan Park,2 Carmen Hurtado del Pozo,2 Lingzi Li,1 Shizheng Huang,1 Rojesh Shrestha,1 Nuria Montserrat,1 Katalin Susztak,1 Susztak Lab 1University of Pennsylvania, Philadelphia, PA; 2Barcelona Institute of Science and Technology, Barcelona, Spain.

Background: Kidney proximal tubule (PT) cells have high mitochondrial density to perform their high energy demanding function to secrete and reabsorb metabolites and electrolytes. Chronic kidney disease is characterized by tubule epithelial atrophy and dedifferentiation, resulting in a decline in kidney function. In this study, we aimed to define upstream regulators that control PT differentiation.

Methods: We performed scRNA and snATACseq analysis on kidneys of developing and adult mice, kidney organoids, and kidneys from control and folic acid-induced kidney injury model. Bioinformatic methods included dimension reduction, differential expression, cell fraction and cell trajectory analysis. Functional studies included mice and cultured tubule cells with genetic deletion of ESRRB.

Results: Differential expression analysis identified PT cells as the key vulnerable cell type in kidney fibrosis. Cell trajectory analysis showed a sequential differentiation path from precursor to differentiated PT cell state in development and in healthy adult and diseased kidneys. But this differentiation path showed more complexity in fibrosis, as enhanced cell differentiation and a blockade of terminal differentiation. Pathway analysis indicated fatty acid oxidation (FAO) and oxidative phosphorylation (OXPHOS) were key variable genes along the PT cell differentiation path in the adult, and developing mouse PT cells and organoids. Single cell epigenetics data identified the critical role of nuclear receptors, HNF4A, HNF1B, PPARα, and ESRRB driving the PT cell differentiation program. These transcription factors did not only directly control FAO and OXPHOS but also the expression of PT differentiation genes. Genetic and pharmacological deletion of these transcription factors lead to marked changes in differentiation state of cultured PT cells. Analysis of healthy and disease human kidneys samples and mice with ESRRA deletion showed a defect in FAO, OXPHOS and PT differentiation and was more susceptible for injury, defining a novel role for ESRRA in PT cells and CKD.

Conclusions: The coupling of cell state and metabolism is established by nuclear receptors such as PPARα and ESRRB that not only control cellular metabolism but also the expression of PT-cell-specific genes in mice and patient samples.

SU-OR14
COX17-Mediated Abnormal Mitochondrial Copper Metabolism Promotes Renal Fibrosis
Saiya Zhu, Chen Yu. Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China.

Background: Copper is a trace element essential for almost all living organisms. Previously, we found that elevated intracellular copper contributes a unique role to kidney fibrosis. Furthermore, copper ions in cells were mainly accumulated in mitochondria, which damage the structure and function of mitochondria. However, the mechanisms of the involvement of copper changes in mitochondria and how a disturbed copper balance induces mitochondrial dysfunction remain to be identified. Copper chaperone COX17, a protein required for cytochrome c oxidase (COX) assembly, was previously hypothesized to shuttle copper between the cytosol and mitochondria based on its dual localization. We found that in the fibrosis model COX17 was highly expressed and COX activity decreased. Therefore, we speculated that COX17 might be involved in mitochondrial copper overload and renal fibrosis.

Methods: Expression level and pattern of COX17 were examined in ischemia-reperfusion injury (IRI) AKI mice. The regulation of COX17 was investigated in renal tubule epithelium cell line (NRK-52E) and rat fibroblasts(NRK-49F) by treating with copper or copper chelator tetraethylrhodiaminate (copper-chelating agent). ICP-MS, mitoSOX, electron microscopy, real-time-PCR and western blot analysis were applied in the current study.

Results: Firstly, the expressions of COX 17, Col1 in the kidney of IRI group were extremely upregulated compared with the sham group. Unexpected, we found dysfunction of mitochondria in IRI kidneys evidenced by it’s appearing swollen and ruptured. Seconded, stimulated by TGF-β1, COX activity was declined, and mitochondrial complex IV activity between species decreased. The expression of COX17 in the normal and fibrosis group were significantly upregulated. More importantly, mitochondrial copper content and cell1, fibronectin expression were reduced and mitochondrial function was improved after transfecting with COX17 shRNA. Meanwhile, treatment with copper chelator tetraethylrhodiaminate also alleviated renal fibrosis both in vivo and in vitro.

Conclusions: COX17 was significantly increased in renal fibrosis and transported excessive intracellular copper ions into the mitochondria. Copper overload inhibits the activity of COX and impairs mitochondria, subsequently leading to renal fibrosis.

SU-OR15
Protective Effect of Prostacyclin in Renal Fibrosis
Jing Li, Chuan-Ming Hao. Division of Nephrology, Huashan Hospital Fudan University, Shanghai, China.

Background: Inadequate repairing process to injury has been reported to play an important role in renal fibrosis. Mounting evidence suggests that prostaglandins are important in repairing tissue to physiologic changes or pathophysiologic insults to tissues including the kidney. Importantly, under certain conditions such as aging and hypertension, prostacyclin (PGI2), an active production of COX/PGI synthase (PGIS), is reduced. The present study provides data showing that low levels of PGI, are associated with enhanced renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO) was used as a renal fibrosis model. At days 10 after UUO, the mice were sacrificed. Ischemia-reperfusion (IR) model was induced by clamping the left renal pedicle for 35 minutes on D0. After 4 weeks, the right kidney was removed. The mice were treated with beraprost sodium (300μg/kg bodyweight per day by twice daily gavage) or vehicle from D32 to D55, and were sacrificed on D56.

Results: The PGIS heterozygous (PGIS+/-) mice had normal body weight, blood pressure and blood urea nitrogen (BUN) level. Losing one allele of PGIS significantly attenuated the increase of PGIS expression after UUO and aggravated the UUO-induced renal fibrosis. 1R model was performed on wild-type mice. Treatment with beraprost sodium (BPS), a analog of PG2, inhibited the expression of fibronectin, collagen I and α-SMA in the kidney and alleviated extracellular matrix deposition in the kidney tissue study. Further, the level of phosphorylated PKA substrates in the renal cortical kidney of deficient mice was significantly reduced, suggesting the role of IP receptor. IP agonist treatment reduced the expression of fibronectin, collagen I and α-SMA in rat renal fibroblasts (NRK-49F), which were induced by TGF-β.

Conclusions: PGIS/PGI plays an important role in protecting the kidney from fibrosis. Lack of PGIS enhances renal fibrosis, and supplementation with PGI, analog ameliorates renal fibrosis. PGIS/PGI, is a potential target for CKD.

SU-OR16
Proteomic Risk Assessment of CKD Progression in the Chronic Renal Insufficiency Cohort
Ruth F. Dubin,1 Rajat Deo,2 Zihe Zheng,2 Haochang Shou,2 Yue Ren,2 Hongzhe Li,2 Mark Segal,3 Harold I. Feldman,2 Peter Ganz.4 1University of California San Francisco, San Francisco, CA; 2University of Pennsylvania, Philadelphia, PA.

Background: Quantification of thousands of plasma proteins simultaneously is now feasible in large cohorts using the SomaScan aptamer assay. In this study, we applied large-scale proteomics to patients with chronic kidney disease (CKD) to discover new biomarkers and risk models of CKD progression.

Methods: We measured 4638 unique plasma proteins among 3249 participants in the Chronic Renal Insufficiency Cohort (CRIC), with follow-up to 13 years. Mean age was 59 years, mean estimated glomerular filtration rate (eGFR) 42 ml/min/1.73m2, and 50% were diabetic. The study outcome was 10-year risk of 50% decline in eGFR, end-stage renal disease or renal transplant (n=1171 events). Associations of individual proteins with the composite outcome were analyzed in Cox survival models adjusted for demographics, comorbidities, eGFR and proteinuria. Protein-only risk models were constructed using elastic net regression and compared to the 4-variable Kidney Failure Risk Eq.
(KFRF). KFRF variables (age, gender, eGFR and proteinuria) were refit to CRIC. For risk modeling, the cohort was split into 20% derivation/80% validation.

Results: Among the 4638 assayed proteins, after adjustment for eGFR, 1535 proteins were associated with CKD progression at FDR <0.05; 529 were significant at Bonferroni p<1x10^-5. After full adjustment, 459 proteins met FDR significance and 77 proteins met Bonferroni significance. A 58 protein risk model for 10-year CKD progression derived by elastic net achieved a c-statistic of 0.860 (95% CI 0.834, 0.885) in the validation set, equal to the refit KFRF c-statistic of 0.857 (95% CI 0.831, 0.884). The c-statistic for the proteomic model was not enhanced by addition of clinical risk factors. Additionally, we were able to identify protein biomarkers that are unique to progression of diabetic vs. non-diabetic CKD.

Conclusions: Through large-scale proteomics, we discovered numerous novel biomarkers that predict the risk of CKD progression. The proteomic risk model has excellent discrimination, equal to the refit clinical model. Ongoing analyses of the biomarkers that predict the risk of CKD progression. The proteomic risk model was not enhanced by addition of clinical risk factors. Additionally, we were able to identify protein biomarkers that are unique to progression of diabetic vs. non-diabetic CKD.

Background: Study of sex differences in kidney function decline and risk of chronic kidney disease (CKD) is a stated research goal. We recently found serum transforming growth factor β1 (TGF-β1), a key mediator in kidney fibrosis development, to be associated with risk of accelerated age-related loss of glomerular filtration rate (GFR) in women, but not men, in the general population. We therefore investigated the effect of sex on intrarenal TGF-β1 pathway and structural damage in kidney biopsies from a cohort of patients with early kidney impairment.

Methods: Kidney tissue samples from 22 female and 33 male patients undergoing nephrectomy included in the PRECISE study (age 31 to 83 years) were used for transcriptional analysis of micro-dissected glomeruli (Affymetrix Human Gene 2.1 ST Array). Interaction of the expression of genes in the TGF-β1 signaling pathway with sex was evaluated between expression level and global glomerulosclerosis (GGS), a structural parameter of kidney disease. Genes exhibiting significant interaction with sex were used to generate a sex-dependent TGF-β1 pathway activity score.

Results: Out of the 136 genes downstream of TGF-β1, expression of 20 genes exhibited significant interaction with sex for GGS. BMP6, ID1, MYC, and TNF were among the genes that showed the most significant interaction. An increased activity score for sex-specific TGF-β1 downstream effectors was associated with higher degree of GGS in women (p<0.001), but with less GGS in men (p=0.01, p for interaction with sex <0.001, Figure 1).

Conclusions: Higher levels of the sex-specific TGF-β1 pathway activity was associated with higher GGS in women, but with less GGS in men. These results, along with our findings of an association between higher serum TGF-β1 and accelerated GFR decline in women only, point to a sex-specific TGF-β1 driven mechanism of kidney fibrosis that may shed light on sex differences in age-related GFR loss and CKD.

Figure 1

SU-OR18
Defining the Correlation Between Kidney Function and Histopathological Changes
Ghazal M Quinlan,1 Amin Abedini,1 Matthew Palmer,2 AndreaHAVAS,3 Katalin Susztak,1,3 University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Boston Medical Center, Boston, MA.

Background: Estimated glomerular filtration rate (eGFR) is an imperfect measure of kidney function and does not correlate well with prognosis. Histopathologic analysis of renal biopsy is considered the gold standard to establish disease etiology and prognosis. Kidney biopsy, however, is rarely performed in patients with diabetes due to its associated risks. Here we examined whether we could predict the degree of histological damage and kidney function decline based on clinical and demographic information.

Methods: Descriptive based histopathological analysis was performed in 759 human kidney tissue samples obtained from unaffected portion of tumor nephrectomies. Samples were limited to healthy, hypertensive and diabetic kidney disease. Changes in the glomeruli, mesangium and the vasculature were scored in an unbiased manner. Regression analyses were performed to assess the association between histopathology based on eGFR quantiles. Decline in renal function over time (eGFR slope in ml/min/1.73m^2 per year) was assessed in subjects with at least 3 months of follow up. Validation analysis was performed on 467 clinically indicated kidney biopsies.

Results: Mean subject age was 61, eGFR was 66 ml/min/1.73m^2, 70% had hypertension and 37% had diabetes. The association between eGFR and interstitial fibrosis was relatively weak (r^2=0.3, p <0.001). There was no association between fibrosis area and eGFR greater than 45 ml/min/1.73m^2. Samples with eGFR below 45 ml/min/1.73m^2 showed a reasonably strong association between eGFR and fibrosis (r^2=0.51, p <0.001) indicating a non-linear relationship. Hypertension and black race were independently associated with more severe histopathologic changes (p<0.05). Similar non-linear trends and significant associations were observed in our validation cohort. There was an association between several histopathologic findings and kidney function decline which did not reach significance in the primary cohort but was significant in the validation cohort.

Conclusions: The eGFR is a poor predictor of fibrosis at values > 45 ml/min/1.73m^2 but predicts renal structural changes well at lower eGFR. Hypertension and black race were independently associated with renal fibrosis, which may warrant more aggressive therapy in these cohorts. Predictions of kidney function decline are enhanced when eGFR and histopathology are used in combination.

Low Birth Weight for Gestational Age and Risk of Different Groups of Kidney Disease 50 Years During the First 50 Years of Life
Hanne Gabriela Gjerde,1 Rannveig Skrunes,2 Hans-Peter Marti,2 Bjorn Egil Vilsè,1 Haugesund sjukhus, Haugesund, Norway; 1Universitetet i Bergen, Bergen, Norway.

Background: Previous studies have shown that Low Birth Weight (LBW) is associated with increased risk of end-stage renal disease. Few population based studies have investigated risk of Small for Gestational Age (SGA) on kidney disease. Our study investigates SGA and risk of chronic kidney disease (CKD), other kidney diagnoses as well as different stages of kidney failure.

Methods: The Norwegian Patient Registry (NPR) has registered ICD diagnostic codes for all admissions and outpatient visits to Norwegian hospitals since 2008. The Norwegian Medical Birth Registry (MBR) has registered birth weight, gestational age and several other data on maternal and infant health for all births in Norway since 1967. Data from these registries were linked and risk of CKD and other groups of kidney disease were analyzed with logistic regression statistics. Based on birth weight, gestational age and gender, a z-score of birth weight for gestational age has been calculated. SGA defined as birth weight less than the 10th percentile for gestational age and gender with cut-off -1.30 for male and -1.28 for female. LBW (less than the 10th percentile) and preterm birth (less than 37 weeks) were analyzed as risk markers. Adjusted analyses were performed for the main analyses by including birth year, gender, maternal disease, maternal marital status and malformations in the newborn

Results: Of the 2,663,010 included subjects, 4495 had been diagnosed with CKD and 12,818 with acute kidney disease, glomerulonephritis, hereditary kidney disease or kidney disease due to kidney or urinary tract malformations. SGA was associated with odds ratio (OR) 1.18 (1.17-1.20) for CKD, 1.19 (1.18-1.20) for acute kidney disease, 1.18 (1.070-1.30) for glomerulonephritis, 1.31 (1.12-1.52) for hereditary kidney disease and 1.13 (1.03-1.23) for kidney disease due to kidney or urinary tract malformations

Conclusions: SGA is a strong risk maker for diagnosis of all stages of CKD during the first 50 years. The risks seem to increase also for other groups of kidney disease.

Large-Scale Kidney Volumetry from MRI: Initial Results and Relations to Sex, Age, and Body Size in UK Biobank
Joel Kullberg,1 2 Taro Langner,1 Salvador Daniel Rivas-Carrillo,1 Iris Friedli,1 Tove Fall,1 Robin Strand,1 2 Hakim Ahlström,1 2 Lars Johannson,1 2 Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden; 1Antaros Medical, Mödladal, Sweden; 1Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden; 1Uppsala University, Department of Medical Sciences, Molecular Epidemiology, Uppsala, Sweden; 1Uppsala University, Department of Information Technology, Uppsala, Sweden.

Background: Kidney volume has been associated with age, kidney function, diabetes, and other cardiovascular risk factors. Body size, body surface area (BSA) and lean body mass are important confounders. UK Biobank (UKB) is a large-scale study aiming to examine 100,000 subjects aged 44 to 82 years using MRI. Resulting images allow measurements of kidney volume. Currently 40,264 scans have been released.
Methods: A deep learning-based method for direct kidney parenchymal volume (KPV) segmentations was developed and validated (Accuracy: Dice 0.956, R=0.95) and applied to UKB MRI. Absolute and relative change with age and associations to body weight, BSA and fat free mass from bioimpedance analysis (BIA-FFM) and lean tissue volume from MRI (MRI-LT) were studied using linear regression. Rate changes were compared below and above group mean ages. MRI-LT values (n=8,524) were inferred for 30,308 additional subjects by MRI-based deep learning regression with validated R²=0.96 (arXiv:2002.08682).

Results: Resulting KPVs from 37,468 subjects (47.6% males) and age changes are shown in Fig 1a and Table 1. Correlations between total KPV and BSA and MRI-LT over age are shown in Fig 1b. The associated overall correlations were (males / females): Body weight: 0.568/0.460, BSA: 0.574/0.496, BIA-FFM: 0.597/0.536, MRI-LT: 0.636/0.600.

Conclusions: Both sexes show continuous volume decline in the studied age interval. Males show an increasing rate of decline with age. MRI-LT showed strongest correlations to KPV.

Variation in Peritoneal Dialysis-Related Peritonitis Outcomes and Treatment Practices: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study

Muhtaha Al sahlawi,1,2 Keith McCullough,3 Ronald L. Pisoni,3 Douglas S. Fuller,1 Junhui Zhao,1 Neil Boudville,5 Yasuhiko Ito,3 Talernsgks Kanjanabuch,4 Sharon Nessim,5 Beth M. Piraino,6 Isaac Teitelbaum,9 David W. Johnson,10,11 Graham Woodrow,2 Jeffrey Perl.1 Division of Nephrology, St. Michael’s Hospital and the Keenan Research Center in the Li Ka Shing Knowledge Institute, St. Michael’s Hospital, University of Toronto, Toronto, Ontario, Canada; 2University of Toronto, Toronto, ON, Canada; 3Department of Internal Medicine, College of Medicine, King Faisal University, Al-Hasa, Saudi Arabia, Al-Hasa, Saudi Arabia; 4Arbor Research Collaborative for Health, Ann Arbor, MI; 5Medical School, University of Western Australia, Perth, Australia, Perth, WA, Australia; 6Aich Medical University, Nagakute, Japan, Nagakute, Japan; 7Center of Excellence in Kidney Metabolic Disorders and Division of Nephrology, Department of Internal Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok, Thailand; 8Division of Nephrology, Jewish General Hospital, McGill University, Montreal, Canada, Montreal, QC, Canada; 9University of Pittsburgh, Pittsburgh, PA, United States, Pittsburgh, PA; 10University of Colorado, Aurora, CO, United States, Aurora, CO; 11Department of Nephrology, Princess Alexandria Hospital, Brisbane, Australia, Brisbane, QLD, Australia; 12Australasian Kidney Trials Network, University of Queensland, Brisbane, Australia, Brisbane, QLD, Australia; 13Renal Unit, St.James’s University Hospital, Leeds, United Kingdom, Leeds, United Kingdom.

Background: Peritoneal dialysis (PD)-associated peritonitis is a leading cause of technique failure and transition to hemodialysis. In the Optimizing Peritonitis Prevention in The United States (OPPUS) study, we explored the impact of various patient, facility and treatment factors on the likelihood of cure following a peritonitis episode.

Methods: Using Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2017) data from Australia and New Zealand, Canada, Japan, Thailand, the UK, and the US, we defined as the absence of a peritonitis relapse or recurrence, PD catheter removal, transition to hemodialysis or death during the 30 days following a peritonitis episode. Multivariable logistic regression was used to test associations between cure and patient, facility, and treatment characteristics.

Results: We identified 1677 peritonitis episodes in 1190 patients across 126 facilities. Overall, 63% of episodes resulted in a cure. Cure was associated with APD (OR v. CAPD=1.35, 95% CI 1.02-1.80), higher serum albumin (OR v.1.04 per 0.1 g/dL, 95% CI=1.01-1.06), facility icodextrin use (OR v.1.06 per 10% greater icodextrin use, 95% CI =1.01-1.12), and aminoglycoside use for Gram-negative peritonitis (OR v. <0.10 per prior peritonitis episodes during follow-up=0.84, 95% CI=0.74, 0.97) and concomitant exit-site infection (OR= 0.42, 95% CI=0.28, 0.63) were associated with lower cure odds. Higher odds of peritonitis relapse were seen among patients with greater residual urine volume (1.14 per 200 mL, 95% CI=1.07, 1.22).

Conclusions: Different characteristics and management practices can impact the likelihood of cure following a peritonitis episode. Our findings can inform future guidelines in addressing the effect of different modifiable patient, facility, and treatment factors on reducing morbidity associated with PD peritonitis.

Rate of Decline in Residual Kidney Function Before and After Peritoneal Dialysis Initiation: A Post Hoc Analysis of the IDEAL Study

Isabelle Ethier,1,2 Y Yeung Jee Cho,1,2,3 Carmel Hawley,2,3 Elaine Pascoe,2 Andrea K. Vieccelli,2,3 Scott B. Campbell,2,3 Carolyn L. Van Eps,2,3 Nicole Isbel,2,3 Bruce A. Cooper,4 David Harris,4,5 Carol A. Pollock,4,5 Muh Geot Wong,6,7 David W. Johnson.2,3 1Centre Hospitalier de L’Universite de Montreal, Montreal, QC, Canada; 2Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 3The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 4Westmead Institute for Medical Research, Westmead, NSW, Australia; 5The University of Sydney School of Medicine, Sydney, NSW, Australia; 6Royal North Shore Hospital, St Leonards, NSW, Australia; 7George Institute for Global Health, Camperdown, NSW, Australia.

Background: Residual kidney function (RFK) is associated with improved survival and quality of life in dialysis patients. Previous studies have suggested that commencement of peritoneal dialysis (PD) may slow RFK decline compared to the predialysis period. We sought to evaluate the association between PD initiation and RFK decline in the Initiating Dialysis Early And Late (IDEAL) trial.

Methods: In this post hoc analysis of the IDEAL randomized controlled trial, PD participants were included if results from 24-hour urine collections had been recorded within 30 days of dialysis initiation (-30 to +30 days from start), and at least one value pre- and one value post-dialysis commencement were available. The primary outcome was slope of RFK decline, calculated as mean of urinary creatinine and urea clearances. Secondary outcomes included slope of urine volume decline and time from PD initiation to anuria.

Results: The study included 151 participants (79 early-start group, 72 late-start group). The slope of RFK decline was slower after PD commencement (-2.69±0.18 mL/min/1.73m²/yr) compared to before PD commencement (-4.09±0.33 mL/min/1.73m²/yr) change in slope = -1.19 mL/min/1.73m²/yr, 95% CI 0.48±1.90, p=0.001). In contrast, urine volume decline was faster after PD commencement (-0.74±0.05 L/yr) compared to before commencement (-0.57±0.06 L/yr). change in slope = -0.18 L/yr, 95%CI (-0.34——0.01, p=0.04). No differences were observed between the early- and late-start groups with respect to RFK decline, urine volume decline or time to anuria.

Conclusions: Commencement of PD was associated with a slower decline of RFK compared to the pre-dialysis period.

Steady Concentration Peritoneal Dialysis Increases Ultrafiltration and Sodium Removal Compared with Continuous Ambulatory Peritoneal Dialysis (CAPD)

Olof Heimburger,1 Gieder Martus,2 Martin E. Wilkie,2 Jorgen B. Hegbrand,3 Ola Carlsson,4 Charlotte De Leon,4 Ann Cathrine Johansson,5 Trioned AB, Lund, Sweden; 6Sheffield Teaching Hospital, NHS Foundation Trust, Sheffield, United Kingdom; 7Department of Nephrology, Skåne University Hospital, Malmö, Sweden; 8Department of Nephrology, Lund University, Lund, Sweden; 9CLINTECH, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Background: Fluid and sodium removal (NaR) may be a challenge during glucose-based PD, leading to increased use of high glucose solutions to maintain sufficient fluid removal. This may lead to increased sodium sieving, resulting in reduced NaR. Carry Life® UF uses steady concentration PD (SCPD), where the intraperitoneal (IP) glucose concentration is maintained by infusion of glucose to provide a continuous ultrafiltration (UF) throughout the dwell. The present study investigated the effect of Carry Life® UF vs. CAPD regarding UF, NaR and glucose absorption.

Methods: Eight stable PD patients were included in the study. Subjects were treated with 5-hour Carry Life® UF treatments using three different glucose doses (11, 14, 20 g/h). An initial fill with 1.5 l, 1.36% glucose PD solution was used. A small volume of dialysate was drained hourly to avoid overfill. A 4-hour peritoneal equilibration test (PET) (2.01, 2.27% glucose) served as control. Data expressed as mean±SD, statistical analysis using ANOVA.

Results: UF volumes were significantly increased during Carry Life® UF treatments (646±256, 739±312, 863±380 ml for 11, 14 and 20 g/h) vs. PET (162±242 ml, p<0.01). NaR increased significantly during Carry Life® UF treatments (80±27, 92±33, 110±37 mmol/dwell for 11, 14 and 20 g glucose/h) compared to PET (22±33 mmol/dwell, p<0.001).

Conclusions: SCPD performed with Carry Life® UF maintained a stable IP glucose concentration during the treatment (figure a) which generated significantly higher UF volumes compared to PET. During the Carry Life UF treatments glucose usage was used more efficiently, particularly for the two lowest doses, in comparison to PET (figure b). In summary, SCPD using Carry Life® UF increases the efficiency of PD compared to standard, glucose-based CAPD with respect to UF and NaR.

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Peritoneal Dialysis

Tak Mao D, Chao,1 Lynda Szczech,2 Jayant Kumar,1 Anjay Rastogi,3 Carol A. Pollock,1 Gopal Saha,1 Tyson T. Lee,1 Maysym Pola,1 Kin-Hung P. Yu,5 University of Hong Kong, Queen Mary Hospital, Hong Kong SAR, China; 2Renal Medicine Associates, Albuquerque, NM; 3University of California Los Angeles, Los Angeles, CA; 4The University of Sydney, Sydney, NSW, Australia; 5FibroGen Inc, San Francisco, CA; AstraZeneca plc; Astellas Pharma Inc.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality for patients with kidney failure in the United States utilizing home dialysis modalities is growing rapidly. Unlike for in-center hemodialysis, there is no patient-reported experience measure for assessment of patient experience of care for peritoneal dialysis or home hemodialysis. We sought to develop and establish content validity of a patient-reported experience measure for patients undergoing home dialysis using a mixed-methods multiple stakeholder approach.

Methods: We conducted a systematic literature review, followed by concept elicitation focus groups and interviews among 65 participants, including 21 home dialysis patients, 33 home dialysis nurses, 3 patient care partners, and 8 nephrologists. We generated a list of candidate items for possible measure inclusion, and conducted a national aspects of care prioritization exercise among 91 home dialysis patients and 39 providers using a web-based platform. We drafted the Home Dialysis Care Experience (Home-DCE) instrument and conducted 3 rounds of cognitive debriefing interviews to evaluate item comprehensibility, order, and structure. We iteratively refined the measure based on interview findings.

Results: The literature review and concept elicitation phases supported 15 domains of home dialysis care experience in 6 general areas: communication and education of patients; concern and helpfulness of the care team; proficiency of the care team; patient-centered care; care coordination; and amenities and environment. Focus groups results showed that domains of highest importance for measure inclusion were home dialysis staff education and patient-centered communication, care coordination, and personalization of care (Figure). Aspects of care prioritization exercise results confirmed focus group findings. Cognitive debriefing indicated that the final measure was easily understood and supported content validity.

Conclusions: The Home-DCE instrument is a 26-item patient-reported experience measure for use in peritoneal dialysis and home hemodialysis. Qualitative focus group and prioritization survey data support measure content validity. To our knowledge, the Home-DCE instrument represents the first rigorously developed and content valid English language survey instrument for assessment of patient-reported experience of care in home dialysis.

Cardiovascular Thromboembolic Outcomes by Dialysis Modality Following Primary Total Knee Arthroplasty
Chavely Alexandra M. Sanchez,1 Matthew R. Lozier,1 Mauricio Tellez,1,2 Alexandra M. Sanchez,1 Gabriel A. Valle.1,2 University of Miami at Holy Cross Hospital, Fort Lauderdale, FL; 1The Kidney and Hypertension Group of South Florida, Fort Lauderdale, FL.
Background: There is a paucity in the literature evaluating the impact of dialysis modalities on cardiovascular thromboembolic outcomes following primary total knee arthroplasty (TKA). Therefore, the purpose of this study was to investigate whether patients treated with hemodialysis (HD) or peritoneal dialysis (PD) have higher rates of: 1) medical complications, 2) readmission, and 3) cost of care.
Methods: Patients undergoing primary TKA while receiving HD served as the study group (n = 82,518) and matched 1:1 to a control group of PD patients (n = 82,518) by distribution, age, sex, and Elixhauser-Comorbidity Index (ECI). Outcomes analyzed included rates of 90-day medical complications, readmission rates, and cost of care. Logistic regression analysis was used to calculate odds-ratios (OR) for medical complications and readmission rates. Welch’s t-test was used to test for significance on cost of care and ECI between cohorts. P-value less than 0.05 was considered statistically significant.
Results: Patients undergoing HD prior to primary TKA were found to have a significantly lower incidence and odds of cerebrovascular accidents (PD vs. HD: 0.19 vs. 0.13%; OR: 1.44, p<0.003) and venous thromboemboli (0.15 vs. 0.10%; OR: 1.52, p<0.001), specifically deep vein thromboses (0.13 vs. 0.10%; OR: 1.75, p<0.001). HD patients did however incur significantly higher 90-day cost of care ($209,611.67 vs. $104,341.89, p<0.003). No statistically significant differences were noted in myocardial infarction, pulmonary embolism, or 90-day readmission rates between the two groups.
Conclusions: While incurring a lower 90-day cost of care, patients treated with PD prior to primary TKA may have a greater odds of developing a cerebrovascular accident or deep vein thrombosis when compared to HD.

Prognostic Roles of Peritoneal Dialysis Effluent Mitochondrial DNA Level
Win L. Than,1,2 Cheuk-Chun Szeto,1,2 Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, New Territories, Hong Kong; 1Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong.
Background: Circulating mitochondrial DNA (mtDNA) level is associated with the systemic inflammatory state and prognosis of peritoneal dialysis (PD) patients. We explore the relation between mtDNA level in PD effluent and peritoneal transport characteristics and outcomes of PD patients.
Methods: We measured PD effluent mtDNA levels by quantitative polymerase chain reaction and the result is expressed as copy per 1000 copies of the housekeeping gene. Both PD effluent sediment and cell-free supernatant mtDNA levels were measured. Peritoneal transport was determined by the peritoneal equilibration test and represented as mass transfer area coefficient (MTAC) of creatinine. All patients were followed for technique and overall survival.
Results: 168 PD patients were followed for 41.3 (IQR: 19.3-52.0) months. Their mean age was 60±11.8 years; 99 (58.9%) were men. Median PD effluent (PDE) supernatant mtDNA was 255.4 unit (IQR: 157.5-451.3); median PDE sediment mtDNA was 201.6 unit (147.8-267.3). PDE supernatant mtDNA level had a modest but significant correlation with MTAC creatinine (r = -0.364, p<0.001) and the number of previous peritonitis episodes (r = -0.235, p=0.002). After adjusting for age, gender, Charlson’s Comorbidity Score, total weekly Kt/V, and residual renal function, PDE sediment mtDNA was a significant predictor of technique survival (adjusted hazards ratio [AHR] 1.002, 95%CI 1.000-1.003, p=0.001). In contrast, PDE sediment mtDNA level did not predict patients’ technique survival (p = 0.171). To contrast, the PDE supernatant mtDNA level did not correlate with technique or patient survival.
Conclusions: PDE supernatant mtDNA level had a significant correlation with peritoneal transport. PDE sediment mtDNA level was a significant predictor of technique survival for PD patients. The mechanism of the differential implications between PDE sediment and supernatant mtDNA levels deserves further investigations.

SU-OR28
Hemodynamics and Geometry of Rat Arteriovenous Fistulas: Effect of Sildenafil Treatment
Hannah M. Northrup,1 Yan-Ting E. Shiu,1,2 Isabelle D. Falzon,1 Maheshika S. Somaratne,1 Timmy C. Lee.1,2 University of Utah, Salt Lake City, UT; 3VA Salt Lake City Health Care System, Salt Lake City, UT; 1University of Alabama at Birmingham, Birmingham, AL; 4Veterans Affairs Medical Center, Birmingham, AL.
Background: Arteriovenous fistula (AVF) maturation is dependent on hemodynamics and remodeling of the vessel wall to increase the AVF flow rate and lumen area for dialysis. Sildenafil is a phosphodiesterase 5 inhibitor that promotes vasodilation and is used clinically to treat erectile dysfunction and pulmonary hypertension. Here we investigate the effect of sildenafil on lumen geometry and hemodynamics in rat AVFs.
Methods: Femoral AVFs were created in 12-16 week-old male Sprague-Dawley rats. Sildenafil was administered at 90 mg/kg in drinking water starting 14 days prior to AVF creation surgery (n=4). 21 days post creation, animals were subject to non-contrast MRI scans, and the MR images were used for reconstruction of the AVF lumen and computational fluid dynamic simulations of the AVF blood flow. Hemodynamic parameters (flow rate, wall shear stress (WSS), vorticity, and oscillatory shear index (OSI)) and geometrical analysis (cross sectional lumen area, anastomosis angle (AA), tortuosity, and nonplanarity angle (NA)) were calculated.
Results: Sildenafil significantly increased the lumen area and flow rate of both the venous and arterial limbs of the AVFs when compared to no-treatment controls (p<0.0001) (Fig. 1). WSS, vorticity and OSI of treated rats were also significantly higher than controls (p<0.0001)(Fig. 1). AA, tortuosity, and OSI were significantly higher in treated rats compared to control, which may be due to the increased flow rate. Sildenafil may have therapeutic potential to enhance AVF maturation by affecting the hemodynamics.

SU-OR29
Single-Center Real-World Experience with Endovascular Arteriovenous Fistulas
Kareem Genena,1 Harold M. Szerlip,1 Neghae Mawla.2 Baylor University Medical Center at Dallas, Dallas, TX; 1Dallas Nephrology Associates Vascular Center - Plano, Plano, TX.
Background: Endovascular arteriovenous fistulas (EndoAVFs) are created percutaneously via an anastomosis between the radial artery and the perforator vein (Ellipsys), or between the ulnar artery and vein or radial artery and vein (Wavelinq). Flow is directed via the perforator vein to the superficial veins. Methods: We report partial outcomes for 69 technically successful endoAVF creations for patients on hemodialysis between 5/2019 and 4/2020 using 2 catheter-based devices.
Results: 12/69 endoAVFs failed (17%), all before reaching physiologic usability (ok to use) except for 1 which failed due to failure to cannulate at the dialysis center. The most common reason for failure was thrombosis of the perforator vein. In 49 endoAVFs that reached physiologic usability at time of data review, mean duration from creation to physiologic usability was 92 days and mean number of procedures between endoAVF creation and physiologic usability was 1. At time of data review, 9 endoAVFs were pending physiologic usability. 14/49 (29%) of endoAVFs that reached physiologic usability did so with 0 secondary procedures. Mean postoperative brachial artery flow in this subset was 718 ml/min (range 400-1100 ml/min). Mean flow at 4-6 weeks was 843 ml/min. 35/49 (71%) needed at least 1 procedure. Mean postoperative flow in this subset was 545 ml/min. Mean flow at 4-6 weeks was 721 ml/min. In 34 endoAVFs that had been cannulated at time of data review, mean duration from physiologic usability to cannulation was 9 days. In 33 patients whose dialysis catheters had been removed at time of data review, mean duration from first cannulation to dialysis catheter removal was 57 days.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Successfully created endoAVFs have shorter maturation time than surgical AVFs and require less maturation procedures. Immediate postoperative brachial artery flow is an important predictor of endoAVF behavior/outcome. All endoAVFs that reached physiologic usability with 0 secondary procedures had a postoperative flow above 400 ml/min, and mean postoperative flow was higher than those that needed at least 1 procedure. Time from first cannulation to dialysis catheter removal represents a pragmatic measure for endoAVFs. Cannulation injuries sometimes oblige a period of endoAVF rest. Removal of the dialysis catheter not only indicates functional usability of the endoAVF but also proficiency of the dialysis units in cannulating them.

SU-OR30
Association Between Antimicrobial Barrier Cap Use and Outcomes Among Hemodialysis Patients Using a Central Venous Catheter
Scott Sibbel,1 Abigail Hunt,2 David B. Van Wyck,3 Lyssa Jordan,1 Francesca Tencori,4 Allen R. Nissenson,5 Steven M. Brunelli.6 Davita Clinical Research, Minneapolis, MN; Davita Inc, Denver, CO.

Background: Bloodstream infections (BSIs) are a common complication of central venous catheter (CVC) use and contribute to hospitalization, mortality, and high costs of care in patients on hemodialysis (HD). In a prior randomized clinical trial, patients using CVCs with antimicrobial barrier caps (AmBC; ClearGuardHD; HDR, Pursuit Vascular Inc, Maple Grove, MN, USA) had significantly lower catheter-related BSIs rates compared to patients using CVCs with the historical standard of care. Based on these findings, AmBCs were introduced in May 2019 as standard of care for CVC patients across a large dialysis organization (LDO). This study assessed changes in clinical outcomes in a real-world HD population following implementation of AmBC use.

Methods: Study data were derived from LDO electronic medical records over two 3-month periods: Pre (Jul-Oct 2018) and Post (Jul-Oct 2019) AmBC adoption. Included patients were adults receiving in-center HD treatment 3x/week using a CVC.Crude outcome rates were calculated for individual calendar months and for the pre- and post-periods overall; formal comparisons were made using generalized linear models.

Results: A total of 37,642 patients in the pre-period and 40,498 patients in the post-period met eligibility criteria. Overall BSI rate fell from 0.54/100 CVC days in the pre-period to 0.36/100 CVC days after AmBC implementation. Hospitalization rates were lower during the post-period versus the pre-period overall and within each calendar month; the contribution of underlying temporal changes (eg, background-year-over-change) could not be quantified.

Conclusions: Adoption of AmBCs for use in HD patients using a CVC for vascular access was associated with an early 34% reduction in infections assessed on the basis of positive blood cultures and 0.22 fewer hospital admissions per patient-year.

Two-Year Results from a Randomized, Controlled Study of Obinutuzumab for Proliferative Lupus Nephritis
Brad H. Rovin,1 Gustavo Aroca Martinez,2 Analia Alvarez,3 Hilda E. Fragosolo loyo,4 Adolina E. Zuta,5 Richard Furie,5 Paul G. Brunetta,8 Thomas Schindler,4 Noramian Hassan,4 Matthew Cascino,6 Jay P. Garg,8 Ana Malvar,9 Ohio State University, Columbus, OH; Simon Bolivar University and Clinica de la Costa, Barranquilla, Colombia; CEMIC, Buenos Aires, Argentina; Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; Instituto de Ginecologia y Reproduccion, Lima, Peru; Northwell Health, Great Neck, NY; Genentech, Inc, South San Francisco, CA; Hoffmann-La Roche AG, Basel, Switzerland; Hoffmann-La Roche Ltd, Mississauga, ON, Canada; Organizacion Maecidea de Investigacion, Buenos Aires, Argentina.

Background: NOBILITY demonstrated improved renal responses and complete remission induction at 26 weeks, and superior to prednisone for sustained remission after 52 weeks. Avacopan led to faster falls in UACR and greater recovery in eGFR when compared to standard prednisone therapy. In a randomized double-blind Phase 3 trial in ANCA vasculitis, treatment with avacopan for ANCA vasculitis was compared with standard glucocorticoid therapy (both combined with either CYC or RTX) in an effort to reduce the toxicity risks of high dose or prolonged glucocorticoid use, a mainstay of ANCA treatment, Are major consequences. Avacopan was tested for efficacy and effects on renal endpoints compared to standard prednisone therapy in a randomized double-blind Phase 3 trial in ANCA vasculitis.

Methods: Subjects randomized 1:1 receiving either prednisone (60 mg tapered to 0 over 20 weeks) or avacopan (30 mg twice daily for 52 weeks), combined either with cyclosporine (Cyc) or rituximab (RTX). Primary endpoints: Disease remission at week 26 and sustained remission at week 52. Changes in urinary albumin to creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) were also assessed.

Results: 330 subjects were treated: 166 to avacopan and 164 to prednisone treatment groups. Avacopan remission at week 26 was 72.3% vs. 70.1%; for prednisone (P=0.0001 for non-inferiority); avacopan was superior to prednisone for sustained remission (week 52, 65.7%; avacopan vs. 54.9%; prednisone, P=0.0066). 81% percent of subjects had renal remission; UACR decreased more rapidly with avacopan than prednisone. Week 4 avacopan was 40% below baseline vs. no change for prednisone (P<0.0001). Baseline to week 52 eGFR (mL/min/1.73 m2) improvement: avacopan eGFR +7.3 vs. prednisone +4.1 (P=0.029). In subjects with baseline eGFR <60, mean eGFR improved 67% more with avacopan than prednisone at week 52. Avacopan was superior to prednisone in subgroup analysis of the randomized treatment arms.

Conclusions: Treatment with avacopan for ANCA vasculitis compared with standard glucocorticoid therapy (both combined with either CYC or RTX) is as effective for remission induction at 26 weeks, and superior to prednisone for sustained remission after 52 weeks. Avacopan led to faster falls in eGFR and greater recovery in eGFR when compared to standard prednisone therapy. These findings have important implications for the long term health of ANAV patients through better overall disease control, reduced prednisone exposure and reduced severity of chronic kidney disease.

Complement C5a Receptor Inhibitor Avacopan Improves Renal Function in ANCA Vasculitis
David R. Jayne,1,2 Peter A. Merkel,3 Huibin Yue,3 Catherine L. Kelleher,4 Thomas J. Schall,5 Pirow Bekker.6 1Addenbrooke’s Hospital, Cambridge, United Kingdom; 2ChemoCentryx Inc, Mountain View, CA; 3University of Pennsylvania, Philadelphia, PA.

Background: Renal impairment is common in anti-neutrophil cytoplasmic autoantibody-associated vasculitis. The resulting chronic kidney disease and exacerbation of the toxicity risks of high dose or prolonged glucocorticoid use, a mainstay of ANCA treatment, are major consequences. Avacopan was tested for efficacy and effects on renal endpoints compared to standard prednisone therapy in a randomized double-blind Phase 3 trial in ANCA vasculitis.

Methods: Subjects randomized 1:1 receiving either prednisone (60 mg tapered to 0 over 20 weeks) or avacopan (30 mg twice daily for 52 weeks), combined either with cyclosporine (Cyc) or rituximab (RTX). Primary endpoints: Disease remission at week 26 and sustained remission at week 52. Changes in urinary albumin to creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) were also assessed.

Results: 330 subjects were treated: 166 to avacopan and 164 to prednisone treatment groups. Avacopan remission at week 26 was 72.3% vs. 70.1%; for prednisone (P=0.0001 for non-inferiority); avacopan was superior to prednisone for sustained remission (week 52, 65.7%; avacopan vs. 54.9%; prednisone, P=0.0066). 81% percent of subjects had renal remission; UACR decreased more rapidly with avacopan than prednisone. Week 4 avacopan was 40% below baseline vs. no change for prednisone (P<0.0001). Baseline to week 52 eGFR (mL/min/1.73 m2) improvement: avacopan eGFR +7.3 vs. prednisone +4.1 (P=0.029). In subjects with baseline eGFR <60, mean eGFR improved 67% more with avacopan than prednisone at week 52. Avacopan was superior to prednisone in subgroup analysis of the randomized treatment arms.

Conclusions: Treatment with avacopan for ANCA vasculitis compared with standard glucocorticoid therapy (both combined with either CYC or RTX) is as effective for remission induction at 26 weeks, and superior to prednisone for sustained remission after 52 weeks. Avacopan led to faster falls in UACR and greater recovery in eGFR when compared to standard prednisone therapy. These findings have important implications for the long term health of ANAV patients through better overall disease control, reduced prednisone exposure and reduced severity of chronic kidney disease.

Prognostic Value of Persistent Proteinuria and Hematuria After Induction Therapy in ANCA-Associated Vasculitides
Karras.1,2 Loic Guilllemin,2 Pierre Charles,1 Benjamin Terrier,2 Luc Mouthon,6,2 Thomas F. Hiemstra,4,5 Rachel B. Jones,4 David R. Jayne,4 David A. Karras,1,2 HEGP, Hopital European Georges Pompidou, Paris, France; 3Universite de Paris, Paris, France; 4Cambridge Clinical Trials Unit, Cambridge, United Kingdom; 5Addenbrooke’s Hospital, Cambridge, United Kingdom; 6Institut Mutualiste Montsouris, Paris, France; 7Hopital Cochin, Paris, France.

Background: In ANCA-associated vasculitides (AAV), hematuria and proteinuria are biomarkers reflecting renal involvement at diagnosis. Yet, the prognostic value of their persistence after immunosuppressive induction therapy, which may reflect renal damage or persistent disease, remains uncertain.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: This is a post hoc study including participants of 5 European randomized clinical trials (BEL). We evaluated the safety of BEL (MAINRITSAN, MAINRITSAN2, RITUXAN, MYCIC). We examined the association of PCR (urine protein-creatinine ratio) and hematuria on spot urine samples collected at the end of induction therapy with the occurrence of (a) a combined endpoint of death and/or end-stage renal disease (ESRD), and (b) renal relapse during follow-up.

Results: Among 571 patients (59% men, median age 60 years), 60% had P3-ANCA, 35% had MPO-ANCA, 77% had renal involvement. After induction therapy, 157/526 (29.8%) had persistent hematuria, 165/481 (34.3%) had PCR > 0.05 g/mmol. After remission induction, 3.9% of patients (adj. subdistribution HR = 2.18, CI95 1.14-4.18; p = 0.019) but not with any relapse (adj. subdistribution HR = 1.10, CI95 0.78-1.56; p = 0.59) nor with death and/or ESRD (adjusted HR = 1.88, CI95 0.83-4.29; p = 0.132).

Conclusions: In this large cohort of AAV patients, persistent proteinuria after induction therapy was an independent predictor of death and/or ESRD, whereas persistent hematuria after induction therapy was an independent predictor of renal relapse. These parameters must be taken into account to assess long-term renal prognosis of AAV patients.

SU-OR34
Belimumab (BEL) Improves Renal Outcomes in Active Lupus Nephritis (LN): A Phase 3 Randomized, Placebo (PBO)-Controlled Trial
Brad H. Rovin, Frederic Houssiau, Richard Furie, Malvar, Yoo Keon Teng, Chi Chiu Lok, Panos Kontogeorgis, Sebastian Brad, Makowiak, Ji, David A. Roth, Christi Kleoudis, Susan Makowiak, Anuradha Madan, Jennifer Gilbride, Yulia Green, Division of Nephrology, The Ohio State University, Columbus, OH, Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain and Service de Rhumatologie, Cliniques Universitaires Saint-Luc, Brussels, Belgium, Division of Nephrology, Northwell Health, Great Neck, NY, Organización Medica de Investigacion, Buenos Aires, Argentina, Expert Center for Lupus-, Vasculitis- and Complement-mediated Systemic Diseases, Department of Internal Medicine – section Nephrology, Leiden University Medical Center, Leiden, Netherlands, Division of Nephrology, Division of Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL, Department of Nephrology, Guangdong Provincial People's Hospital, Guangzhou, China, GlaxoSmithKline, Uxbridge, United Kingdom, GlaxoSmithKline, Collegeville, PA, Parexel, Durham, NC, GlaxoSmithKline, Stevenage, United Kingdom, Tuen Mun Hospital Department of Medicine and Geriatrics, Hong Kong, Hong Kong, Department of Infectious Diseases, University Hospital Essen, University of Duisburg-Essen, Essen, Germany.

Background: BEL is approved for patients (pts) with systemic lupus erythematosus (SLE) active disease in Europe and the USA.

Methods: This 104-week trial (GSK Study BEL114054; NCT01639339) randomized adults with active LN (class III, IV, and/or V) 1:1 to monthly BEL 10 mg/kg IV or PBO, plus standard therapy (ST) with high-dose corticosteroids + either cyclophosphamide (CyC) or mycophenolate mofetil (MMF) for induction at the investigator's discretion. CyC was followed by azathioprine (AZA), and MMF by MMF maintenance.

The primary endpoint was Primary Efficacy Renal Response (PERR = urine protein/creatinine ratio ≥ uPCR > 0.7; estimated glomerular filtration rate ≥ eGFR) no more than 20% below pre-flare value or ≥ 0.60 mg/min/1.73 m²; no rescue therapy) at Week 104. Other endpoints were: Complete Renal Response (CRR = uPCR < 0.5; eGFR no more than 10% below pre-flare value or ≥ 0.60 mg/min/1.73 m²; no rescue therapy) at Week 104; time to renal event (end-stage kidney disease, doubling of serum creatinine, increased proteinuria and/or impaired renal function, renal disease-related treatment failure) or death. Endpoints were analyzed by ST regimen.

Results: 224 pts were randomized to each arm. At Week 104, there were significantly more PERR and CRR responders on BEL vs PBO: 43.0% vs 32.3%, OR [95% CI] 1.6 [1.0-2.3]; p = 0.03 and 30.0% vs 19.7%, OR [95% CI] 1.7 [1.1-2.7]; p = 0.012, respectively. Risk of renal event or death was lower in BEL pts relative to PBO (HR [95% CI] 0.5 [0.2, 1.0]) and MMF (HR [95% CI] 0.5 [0.3, 0.8]) relative to PBO. ADverse events (AEs; ≥ 1%) occurred in 95.5% of BEL and 94.2% of PBO pts, and 25.9% of BEL and 29.9% of PBO pts had 1 serious AE.

Conclusions: The addition of BEL to currently used ST for the treatment of LN significantly improved renal responses with no unexpected safety signals.

24-Week Interim Analysis of a Randomized, Double-Blind, Placebo- Controlled Phase 2 Study of Atacicept in Patients with IgA Nephropathy and Persistent Proteinuria
Jonathan Barratt, James A. Tumlin, Yusuke Suzuki, Amy Kao, Aya Aydemir, Yulia Zima, Gerald B. Appel. Emory University School of Medicine, Atlanta, GA, Juntendo University, Tokyo, Japan, University of Leicester, Leicester, United Kingdom; EMD Serono Research Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA, Columbia University Medical Center, New York, NY.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis and currently has no approved therapy. Its central pathogenic feature is circulating immune complexes of poorly O-galactosylated polyanionic IgA1 (Gd-IgA1) that often deposit in the kidneys (causing inflammation and scarring) and trigger formation of IgA1-Gd autoantibodies. Atacicept is a humanized, single-domain antibody against B cell-stimulating factors BLyS and APRIL and is associated with reduced serum IgA/G, mature B cells and plasma cells. This Phase II study (NCT02808429) examines atacicept safety and efficacy in reducing Gd-IgA1 and renal activity in IgAN.

Methods: Patients with IgAN and persistent proteinuria > 0.05 g/m² on 24 hr urine protein/creatinine ratio (UPCR) despite maximal standard of care (ACE inhibitor and/or ARB) were enrolled. Patients were randomized to subcutaneous placebo, atacicept 25mg or 75mg weekly. Primary endpoint: change in proteinuria at Week 48; secondary endpoints: changes in eGFR, serum IgA, IgG, and IgM and Gd-IgA1.

Results: This interim analysis showed that, at Week 24, IgAN patients (placebo=5; atacicept 25mg=6; 75mg=5) had a consistent, dose-dependent reduction in IgA, IgG and IgM, and in Gd-IgA1 (Fig 1A), and a higher median % reduction from baseline in UPCR (Fig 1B), gEGR remained stable. TEAEs were reported by 81% of patients (mild/moderate, none severe), with no serious events, severe hypogammaglobulinemia, or fatal outcomes.

Conclusions: These results provide proof of concept for the potential treatment of patients with IgAN and persistent proteinuria with atacicept.

Funding: Commercial Support - EMD Serono Research & Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany).

Figure 1. Median changes from baseline to Week 24 in a) serum Gd-IgA1 and b) 24-hour UPCR.
mean blood pressure and renal function, proteinuria, and O-grade (HR, 1.39; 95% CI, 1.02-1.90; P=0.036) were independent factors predicting the renal prognosis. The renal prognosis in the nine groups classified by the O-grade combined with the C-grade showed HR of 33.7 (P<0.001) in the severest group with reference to the mildest group.

Conclusions: The O-grade classified by the total score of the Oxford classification was associated with renal CR, and renal prognosis could be accurate by combining the O-grade with the C-grade. The O-grade allows easier evaluation of the total activity and chronicity of IgAN and prediction of the renal prognosis of this disease.

SU-OR37
Development of a Deep Learning Model to Predict ESKD in Patients with Immunoglobulin A Nephropathy (IgAN) at Kidney Biopsy Time

Back: Many prediction models to support clinical decision making have been developed for decades but they are based on traditional statistical linear methods. Another approach is the application of artificial intelligence (AI) that is based on machine learning or deep learning algorithms. We developed an artificial neural network (ANN) tool to predict the time-to-event endpoint in IgAN patients at kidney biopsy time.

Methods: The classifier model to predict ESKD was composed of 4 hidden layers with 100 neurons in each layer. The regression model to predict the time-to-event endpoint consisted of 3 layers containing 125 neurons each.

Results: Our tool, based on these two models, was developed in a cohort of 948 IgAN patients of the VALiGA and Greek cohort. Then, the tool was validated in an independent cohort of 167 IgAN patients from 6 nephrology units. After Cox’s regression analysis 7 variables (age, sex, blood pressure values, serum creatinine, daily proteinuria, MESTC classification for the kidney biopsy and therapy at baseline) were chosen to develop the ANN model. The AUC of the ANN model in the study cohort was 0.80. The performance was 0.82 (precision 0.83, accuracy 0.80) for ESKD prediction at 5 years of follow-up and 0.89 (precision 0.81; accuracy 0.83) for patients with 10 years of follow-up. Stable renal function and ESKD were correctly predicted in 91% of IgAN patients in the test cohort.

Conclusions: (i) Our ANN is a promising alternative to the mathematical models in solving non-linear and multidimensional problems. (ii) We developed a new clinical decision support system that provides additional information to identify IgAN patients at high risk of ESKD (iii) This tool may stratify patients in the context of a personalized therapy.

Complete Remission of Proteinuria in Patients with Focal Segmental Glomerulosclerosis Treated with Sparsentan, a Dual Endothelin and Angiotensin Receptor Antagonist, in the DUET Trial

Back: In the DUET trial, a high proportion of patients achieved CR on at least one occasion. These observations support the long-term nephroprotective potential of sparsentan (SPAR).

Methods: In SPAR, 44 (41%) reached CR at least once and 30 (28%) patients reached CR in the DB period. Compared to the overall DUET (Kaplan-Meier estimate: 29%). A history of, or nephrotic syndrome at baseline, was associated with the occurrence of CR. In 6 patients (14%), occurrence of CR followed the initiation of new steroid treatment.

Results: In the DUET trial, a high proportion of patients achieved CR on at least one occasion. These observations support the long-term nephroprotective potential of sparsentan (SPAR).

Conclusions: In the DUET trial, a high proportion of patients achieved CR on at least one occasion. These observations support the long-term nephroprotective potential of sparsentan (SPAR).

Differences in Kidney Failure Risk by Race/Ethnicity at the Time of GFR-Based Transplant Eligibility
Chi D. Chu,1,2 Neil R. Powe,1,3 Delphine S. Tuot,1,3 University of California San Francisco, San Francisco, CA; 2OptumLabs Visiting Scholar, Cambridge, MA; 3Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Glomerular filtration rate (GFR) less than 20 ml/min/m² is a criterion for kidney transplant listing, but variation in underlying end-stage kidney disease (ESKD) risk distributions by race/ethnicity has the potential to produce systematic racial disparities due to under-recognition of the higher progression risk when a singular eGFR threshold is used as a decision point.

Methods: We compared predicted kidney failure risk by race/ethnicity for patients at the time their eGFR fell below 20 ml/min/m² using the OptumLabs® Data Warehouse (OLDW), a longitudinal, real-world data asset with de-identified administrative claims data. We identified patients 18-70 years old from 1/1/2014-6/30/2019 who had at least one eGFR >20 ml/min/m² that were 90 days separated, who also had a urine albumin/creatinine ratio (UACR) measured within 90 days of the first eGFR ≤20 ml/min/m². We calculated 2-year risk of ESKD for each patient using the 4-variable Kidney Failure Risk Equation and compared the distributions by race/ethnicity.

Results: Of 2926 patients, 2024 were non-Hispanic white (NHW), 649 non-Hispanic black (NHB), and 253 Hispanic. At the time of incident eGFR ≤20 ml/min/m², NHWs were older than NHB or Hispanic patients (mean age 59.2 versus 56.2 or 54.3 years, respectively) and had lower median UACR (0.67 versus 1.36 or 1.72 g/g, respectively). Compared to ESKD risk among NHWs (median predicted risk 38.7%), the risk distribution was skewed toward higher risk for NHB and Hispanic patients, who had median predicted risks of 49.4% and 55.8% respectively (Figure).

Conclusions: At the time of incident eGFR ≤20 ml/min/m², NHB and Hispanic populations had greater risk of ESKD. A racial/ethnic disparity in time from GFR-based transplant eligibility to ESKD may exist even with elimination of disparities in timing of transplant referral and waitlisting. Consideration of kidney failure risk might be given greater attention in access to transplantation.

SU-OR42
Exploration of Racial Disparities in the Kidney Transplant Process Among Dialysis Patients
Steven M. Brunelli, Abigail Hunt, Carey Colson, Francesca Tentori. Davita Clinical Research, Minneapolis, MN.

Background: Kidney transplant is generally considered the best long-term treatment for dialysis patients. Before receiving a transplant, a patient must be referred to a transplant center, undergo extensive clinical evaluation, and then be placed on a wait list. Previous studies have observed that black patients are less likely to receive kidney transplants than white patients. However, it is unclear at which points in the transplant process inequity is imparted. In this analysis, we used a single source of data to compare the entire transplant process among black and white patients at a large dialysis organization.

Methods: Eligible patients were those who, between Jul 2015-Jun 2018, were 18-80 years old; were incident to dialysis and began care at the LDO within 30 days of first ever dialysis; and had not undergone a transplant evaluation or listing prior to dialysis start. Exposure was described based on race as documented in LDO medical records (black or white). Patients were followed forward in time from study entry until 31 Mar 2019 or censoring or loss to follow-up. Transplant referrals, listings, and receipts were compared across exposure categories using time-to-event models adjusted for demographics, comorbidities, biochemistries, and socioeconomic factors.

Results: We identified 60,229 eligible incident patients (23,499 black; 36,730 white). Compared to whites, black patients were 23% more likely to be referred for transplant (hazard ratio [HR] and 95% confidence interval [CI] = 1.23 [1.20, 1.27]). Among referred patients, black patients were 19% less likely to be placed on a wait list than whites (HR [95% CI] = 0.81 [0.77, 0.86]). Among wait-listed patients, black patients were 52% less likely to receive a transplant than whites (HR [95% CI] = 0.48 [0.41, 0.56]). Overall, black patients were only 46% as likely to receive transplants as white patients (HR [95% CI] = 0.46 [0.39, 0.53]).

Conclusions: These results support prior findings that racial disparities exist within the kidney transplant process and indicate that these disparities occur downstream of the referral.

SU-OR43
Do Social Determinants of Health Predict Patient-Reported Outcomes in Transplant-Eligible ESRD Patients?
Samuel L. Swift, Shu Wang,2 Chung-Chou H. Chang,1 John R. Pleis,3 Mary amanda Dew,3 Ron Shapiro,4 Mark L. Unruh,1 Emiliee J. Crowswell,3 Kellee Kendall,5 John D. Peepit,4 Larissa Myaskovsky,1 1University of New Mexico, Albuquerque, NM; 2University of Florida, Gainesville, FL; 3University of Pittsburgh, Pittsburgh, PA; 4Mount Sinai Health System, New York, NY; 5Highmark Inc, Pittsburgh, PA; 6Northwestern University Feinberg School of Medicine, Chicago, IL; 7Centers for Disease Control and Prevention, Hyattsville, MD.

Background: Measuring and understanding patient reported outcomes [PRO, e.g., health related quality of life (HRQol) and satisfaction with transplant clinic service] is a critical consideration for the care of kidney transplant (KT) eligible patients with end-stage renal disease (ESRD), because research has demonstrated that pre-transplant HRQol predicts both the receipt of a KT as well as post-KT mortality. Although research demonstrated the importance of social determinates of health (e.g., cultural factors, psychosocial characteristics, transplant knowledge) on clinical outcomes, less is known about how they predict PRO in KT-eligible ESRD patients.

Methods: We examined whether social determinants of health (Time 1, assessed shortly after initiating KT evaluation) are risk or protective factors for PRO (Time 2, assessed after notification of KT evaluation outcome – accepted or not), controlling for evaluation outcome, in a prospective cohort study. Of the initial 1152 adults referred for KT evaluation (2010-2012), 955 completed a Time 2 interview, most within 1 year of completing KT evaluation [n=6 months=70% (669), n=6 months to 12 months=8% (76), n=12 months=22% (210)]. We used the Physical Composite Score (PCS), Mental Health Composite Score (MCS), and Kidney Summary Score (KSS), from the Kidney Disease Quality of Life Short Form (KDQol-SF) to measure HRQol, and the Client Satisfaction Questionnaire to measure satisfaction with KT clinic service.

Results: Participants completed KT evaluation in an average of 11.7 months (range=0-43 months). In adjusted multivariable regression models, a stronger sense of mastery predicted higher PCS (β=0.45, p<0.001), MCS (β=0.54, p<0.001), and KSS (β=0.56, p<0.001). Depression predicted lower MCS (β=−0.2, p<0.001), and lower KSS (β=−0.51, p<0.002). More medical mistrust predicted lower odds of higher patient satisfaction scores (OR=0.6, 95% CI=0.4, 0.8, p=0.002).

Conclusions: Transplant teams should consider identifying and targeting patients with a low sense of mastery, greater depressive symptoms, or an increased sense of medical mistrust, with additional psychosocial support to improve PRO during the KT evaluation process.

SU-OR44
Genevski vs. Self-Reported African Ancestry and Kidney Allograft Outcome: Analysis of Two Large Multiethnic Urban Transplant Cohorts

Francesca Zanoni,1 Y. Dana Neugut,2 Sumit Mohan,1 Ali G. Gharaei,1 Brendan Keating,2 Krzysztof Kiryluk,1 1Columbia University Irving Medical Center, New York, NY; 2University of Pennsylvania, Philadelphia, PA.

Background: African-American (AA) kidney transplant recipients have higher risk of allograft rejection and failure. However, it is unknown to what extent the inferior outcomes in self-reported AA are due to genetic versus environmental effects. Herein, we compared the effects of self-reported race versus genetic African admixture on graft outcomes.

Methods: A discovery multiethnic cohort of 1,083 kidney transplant recipients from University of Pennsylvania were genotyped with high resolution SNP arrays. African admixture proportions, a genetically-derived quantitative measure of African ancestry, was estimated with ADMIXTURE software. Multivariable Cox models were used to investigate associations between African ancestry measures and time to rejection and time to death-censored graft failure, with adjustments for relevant covariates. Akaike information criterion (AIC) was used to compare the models.

Results: 206 and 346 self-identified AA were included in the discovery and replication cohorts, respectively. Over a median follow-up time of 78 months, 432 patients had rejection and 193 had graft failure in the discovery cohort. Self-reported AA ancestry and African admixture were associated with acute rejection (self-report: HR 1.47, 95% CI: 1.18-1.83; AIC: 5540.1; admixture: HR 1.64, 95% CI: 1.22-2.19; AIC: 5541.1). In renal graft failure, self-report: HR 1.42, 95% CI: 1.02-1.97; AIC: 2289.1; admixture: HR 1.48, 95% CI: 0.96-2.29; AIC: 2289.2. In the replication cohort, during a median follow-up period of 49 months, 113 patients had rejection and 121 had failure. Self-reported AA ancestry and African admixture measures confirmed to be associated with both acute rejection and renal graft failure (self-report: HR 1.96-4.78, AIC: 1289.5; admixture: HR 3.60 95% CI: 2.21-6.16; AIC: 1288.9) and failure (self-report: HR 2.16, 95% CI: 1.43-3.27, AIC: 1113.8; admixture: HR 2.46, 95% CI: 1.54-3.94, AIC: 1113.1). In this cohort, the models including African admixture proportion had a better fit when compared to self-report.

Conclusions: In conclusion, self-reported AA race and a genetically-derived continuous measure of African ancestry predict the risk of allograft rejection and failure in multiethnic and genetically diverse cohorts.

SU-OR45
Deceased Donor Families and Authorization for Research: Differences Among Ethnic Groups

Mariella O. Goggin,1,2 Giselle Guerra,1 Miami Transplant Institute 1University of Miami School of Medicine, Miami, FL; 2Miami Transplant Institute, Miami, FL.

Background: Research in transplantation requires next of kin (NOK) to authorize for participation in research. Aim was to determine the rate of research authorization by the NOK within different ethnic groups: African American (AA), White (W) or Hispanic (H).

Methods: Single center study of all deceased donor kidney transplants referred to our institution during 3/1/2019-10/31/2019 from multiple organ procurement organizations (OPO) across the United States. We looked at the authorization for donation form in DonorNet. We searched for the NOK research authorization agreement at the time of organ donation. Donors were grouped by self-identified ethnic groups as W, AA or H.

Results: We had a total of 297 donors, yielding 401 kidney offers. 71% were imported from 46 different OPOs and 29% from our local OPO. Mean donor age (±SE) was 45.7±6.9. Donor ethnicity distribution was W 180 (66.6%); AA 66 (22.2%) and H 50 (16.8%). Overall 226 (76.1%) donors’ NOK authorized for research and 71 (23.9%) declined research. Donor age <35yr had a lower rate of authorization 62.9% vs 81.3% and 80.6% for 35-44yr and 55yr respectively p=0.006. Table 1 shows ethnic distribution on rate of NOK authorization for research, which was significantly lower within AA donors 38/66 (57.6%). Logistic regression showed donor age<35yr and AA donor as more likely to decline research authorization, yielding multivariable p=0.0001 for AA donor and p=0.002 for younger donor. Multivariable percentages who declined research authorization had highest rate among AA donors<35yr at 55%(11/20) compared to 37.0%(7/19) in AA donors<35yr; 31.0%(18/58) in W/H donors <35yr; and 14.5%(25/173) in W/H donors≥35yr. Out of 401 donated kidneys, 93(23%) were not authorized to participate in research, of which 38/93(40.9%) were AA; 15/93(16.1%) were H and 40/93(43.1%) were W donors.

Conclusions: In deceased donors from local and imported OPOs, the rate of declined authorization for research participation from NOK was higher among donors from AA ethnicity compared to donors from W or H backgrounds, especially when donor age is <35. Community education is crucial in the field.

Minimum Diagnostic Criteria for Thrombotic Microangiopathy in Renal Allograft: The Banff TMA Working Group Phase I Results

Marjan Afrozian, Banff TMA Working Group University of Texas Medical Branch at Galveston, Galveston, TX.

Background: Thrombotic Microangiopathy (TMA) is a serious complication of renal transplantation, usually with poor outcome. The Banff TMA Working Group (TMA-WG) was formed to study renal transplant TMA (t-TMA) aiming to: 1- Survey current practices used in the diagnosis of t-TMA; 2- Define minimum diagnostic criteria (MDC); and 3- Develop recommendations for accurate diagnosis integrating morphological, clinical, laboratory and molecular findings, where applicable. The project started with Phase I (pathology phase) and is continuing in Phase II (Nephrology phase).

Methods: Using the Delphi methodology during phase I, 23 nephrologists who had >3 years of experience with t-TMA were asked to list their MDC for t-TMA in the following categories: 1- Light, 2- immunofluorescence, and 3- electron microscopy, 4- clinical history, 5- laboratory findings, 6- genetic testing and 7- raised differential diagnoses. Nine rounds (R) of surveys were designed. At the end of each R, MDC were narrowed down following Delphi rules. R6 and R7 were designated as the validation R in which the narrowed criteria were validated on 37 renal biopsies (25 TMA and 12 non-TMA cases) using Aperio ImageScope and whole slide digital images scanned @ X400. For each biopsy, pertinent pathology/history/laboratory/genetic information were provided. Descriptive statistical analysis was performed using SPSS program.

Results: Starting with 338 criteria in R1 and following analysis of total 82,677 data entries, MDC were narrowed down to 35, by the end of R9. The graph illustrates the evolution of the criteria over 9 R. A complete list of 35 MDC will be presented at the meeting.

Conclusions: Applying the Delphi methodology to a cohort of t-TMA biopsies in Phase I of the project, nephropathologists from 4 continents generated histopathologic, clinical and laboratory MDC for renal t-TMA. Phase II (Nephrology consensus) and Phase III (consensus of the consensus groups- Combined Phases I & II) will follow Phase I to generate final MDC for t-TMA.

Does Screening for Coronary Artery Disease Predict Cardiac Outcomes Following Renal Transplantation?

Aliush Nimno, Dominic M. Taylor, Rommel Ravanon. Southmead Hospital, Bristol, United Kingdom.

Background: Screening for asymptomatic coronary artery disease (CAD) prior to transplantation aims to reduce perioperative cardiac events. There is conflicting evidence as to whether this is achieved.

Methods: Individuals recruited to the Access to Transplant and Transplant Outcome Measures (ATTOM) study in England who received a renal transplant between 2011-2017 were studied. Patient demographics and details of screening investigations from ATTOM were linked to outcome data from the Hospital Episode Statistics dataset. Major Adverse Cardiac Events (MACE) comprised unstable angina, myocardial infarction, coronary bypass graft, coronary angioplasty or cardiac death. The effect of screening on MACE was analysed in propensity score-matched groups, using Cox survival analyses, up to 5 years post-transplant.

Results: 2572 individuals received a renal transplant; 51% underwent CAD screening (Figure 1). Age, ethnicity, ischaemic heart disease and diabetes were independently associated with screening. The incidence of MACE at 90 days, 1 and 5 years was 0.9%, 2.1% and 9.4%. After propensity score matching, 1854 individuals were examined. There was no association between screening and MACE at 90 days (HR 0.68, 95% CI 0.28-1.64), 1 year (HR 1.24, 95% CI 0.60–2.54) or 5 years (HR 1.31, 95% CI 0.95–1.79) (Figure 2).

Conclusions: Screening for CAD did not influence the rate of ischaemic cardiac events up to 5 years post-transplant. Units should review protocols with lengthy cardiac workup processes.

Albuminuria in Kidney Transplantation Patients Predicts Cardiovascular Morbidity After Two Years

Dana Bielopolski,1,2 Ruth Rahaminov,3 Boris Zingerman,1 Avry Chagnac,4 Limor Azulay gitter,2 Benaya Rozen-zvi,2 1The Rockefeller University, New York, NY; 2Rabin Medical Center, Petah Tikva, Israel.

Background: Moderately Increased Albuminuria (MIA) is a well characterized marker of kidney malfunction, both in diabetic and non-diabetic populations, and is used as a prognostic marker for cardiovascular morbidity and mortality. A few studies implied that it has the same value in kidney transplanted patients, but the information relies on spot or dipstick urine protein evaluations, rather than the gold standard of timed urine collection.

Methods: We revisited a cohort of 286 kidney transplanted patients, several years after completing a meticulously timed urine collection and assessed the prevalence of major cardiovascular adverse events (MACE) in relation to albuminuria.

Results: During a median follow up of 8.3 years (IQR 6.4-9.1) 144 outcome events occurred in 101 patients. By Kaplan-Meier analysis MIA was associated with increased risk of CV outcome or death (p=0.03), and this was still significant after stratification according to propensity score quartiles (p=0.048). Time dependent Cox proportional hazard analysis showed independent association between MIA and CV outcomes two years following MIA detection (HR 1.83, 95% CI 1.07-2.96).

Conclusions: Two years after documenting MIA in kidney transplanted patients, their CVD risk was increased, most likely, as a result of endothelial dysfunction. This should prompt the caregiver for strict primary prevention and risk factors modification.

SU-OR49

Renal Graft Outcomes in Simultaneous Kidney-Heart Transplant Recipients: Analysis of the UNOS Database from 1987-2018

Krishna A. Agarwal,1 Het Patel, Francesca Cardarelli, Nikhil Agrawal.1 BIDMC Beth Israel Deaconess Medical Center; Boston, MA.

Background: Simultaneous kidney and heart transplants (SKHT) are performed for patients with both end-stage heart failure and severely impaired kidney function. Renal outcomes in such recipients have been described, albeit in single-center cohorts. We analyzed the United Network for Organ Sharing (UNOS) dataset comprising of 1702 simultaneous kidney-heart transplant recipients since 1987.

Methods: This is a retrospective analysis of SKHT recipients in the UNOS dataset who received transplants between October 1987 and December 2018. We compared the incidence and risk factors of renal allograft loss in SKHT recipients versus deceased donor kidney (DDKT) alone recipients. The Student t-test or Kruskal Wallis tests were used to compare continuous variables, and the Chi2 test for categorical variables between groups. Cox regression hazard model was used to study the factors associated with graft failure.

Results: SKHT recipients were mostly white, males, 5-years older than DDKT recipients. The SKHT donors were younger than DDKT donors, predominantly white males who died from a CVA. Five year patient survival was similar in both the groups (80%) but 1-year mortality was 3 times higher in the SKHT group (12.5%) than DDKT (4.6%). Nearly 20% recipients in both groups died with a functioning graft. Renal graft survival in SKHT group was lower in the first year but equalized with DDKT group over 5 years. Cox regression analysis revealed male gender [HR 2.14], pre-emptive renal transplantation [HR 6.57] and HLA mismatch ≥4 [5.60] as significant risk factors for renal graft failure in SKHT recipients as compared to DDKT recipients at 4 years. Predominant cause of graft failure in SKHT recipients was primary failure (36%) and in DDKT recipients was acute rejection (26%).

Conclusions: This is the largest analysis of the UNOS database till date to describe risk factors associated with renal graft loss in SKHT recipients. We also showed that 38% of grafts that fail in SKHT recipients, failed in the first year following transplant and primary failure was the predominant cause. Our analysis provides much needed data to policy makers for future combined organ allocation policies.

SU-OR50

Recurrence of IgA Nephropathy After Kidney Transplantation: TANGO Multicenter Study

Audrey Uffin,1,2 Paolo Cravedi,1 Leonardo V. Riella,1 TANGO-project 1Brigham and Women’s Hospital, Boston, MA; 2Universitair Medisch Centrum Groningen, Groningen, Netherlands; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In patients who received a kidney transplantation for end-stage renal disease (ESRD) due to IgA nephropathy, IgA deposits can recur in the transplanted kidney. The incidence, impact and predictors of these recurrent deposits is unclear.

Methods: As part of the Post-Transplant Glomerular Disease (TANGO) project, we performed a multicenter, international, retrospective study to determine the incidence, predictors and treatment response of recurrent IgA deposits after kidney transplantation. Patients with biopsy-proven IgA nephropathy, transplanted in the period 2005-2015 were selected in 16 TANGO centers in Europe, United States and Brazil.

Results: In a total of 504 patients, recurrent IgA deposits were identified by kidney biopsy in 82 patients (16%; 95%CI: 13-19), with a median time to recurrence of 3.4 years (IQR 1.4-5.7 years). Kaplan-Meier analysis showed similar graft survival between patients with and without recurrence in the first years after kidney transplant, though after 8 years, graft failure rates were higher in patients with recurrence (10 year death-censored graft survival 76% and 89%, respectively). Multivariable Cox-regression revealed a higher risk for IgA recurrence
PO2614
Renin Does Not Associate with Mortality or AKI in Acute Respiratory Distress Syndrome

Jan Meccy,1 Michael Matthay,2 Jason Abbott,3 Chi-yuan Hsu,4 Kathleen D. Liu,2 Stanford University School of Medicine, Palo Alto, CA; 2University of California San Francisco, San Francisco, CA.

Background: Renin may be a marker of severity of illness and mortality in critically ill patients. Angiotensin II infusions in patients with lower renin levels may increase the rate of renal recovery from dialysis-requiring AKI. Given that most ACE is found in the lungs and an ACE defect would lead to higher renin levels, we tested associations between renin and clinical outcomes in patients with acute respiratory distress syndrome (ARDS).

Methods: We studied 63 patients with plasma renin measurements enrolled in a phase 1/2 trial of bone marrow-derived human MSCs for moderate-severe ARDS. We estimated associations between renin levels (as a continuous variable) and ARDS severity (assessed by PaO2/FiO2), mean arterial pressure (MAP), and serum creatinine at randomization. We then examined if renin was associated with subsequent AKI (defined as ≥ 2x SCR or new dialysis) or in-hospital mortality.

Results: The median renin was 72 pg/mL (25th-75th percentile 33-181 pg/mL). At randomization, there was no cross-sectional correlation between renin level and PaO2/FiO2 (R = 0.03, 95% CI 0.00-0.14, p = 0.21), between renin level and MAP (R = 0.01, 95% CI 0.00-0.12, p = 0.32), or between renin level and serum creatinine (R2 = 0.003, 95% CI 0.00-0.08, p = 0.68). In longitudinal unadjusted analysis, renin did not significantly associate with AKI (OR 1.006 per 10 pg/mL increase, 95% CI 0.992-1.021, p = 0.41) or 28-day mortality (OR 1.000 per 10 pg/mL, 95% CI 0.987-1.014, p = 0.97). Results were similar in a multivariable model at randomization was associated with AKI (OR 3.27 per mg/dL, 95% CI 1.59-6.14) and patients with shorter time from native diagnosis and was associated with recurrence of IgA deposits.

Conclusions: We did not find that renin level is a risk factor for mortality or AKI in moderate-severe ARDS.

PO2615
Renal Denervation Alleviates Renal Ischemic-Reperfusion Injury-Induced Acute and Chronic Kidney Injury Partly by Modulating miRNAs in Rats

Xiangyu Zou, Shanghai Childrens Medical Center Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China.

Background: Renal denervation (RDN) has been used as a potential medium for kidney injury repair and miRNAs involved in the pathophysiology of renal injury. However, the change of miRNAs after RDN and its proper protective mechanisms has yet to be determined.

Methods: Renal ischemic reperfusion injury (IRI) rat model was established and RDN was performed. Animals were sacriﬁced at 24 hours and 2 weeks after RDN. Tyrosine hydroxylase (TH), renal functions, tubular cell apoptosis and histology staining were examined at 24 hours, and renal ﬁbrosis and capillary vessel density were measured at 2 weeks. What is more, the expression of miRNAs in injured kidney was determined by micro-array and the target genes were analyzed. Lastly, human renal biopsy samples with chronic kidney disease were picked for the TH and ﬁbrosis analysis.

Results: TH was eliminated and renal functions were improved in the denervation group at 24 hours. RDN reduce tubular cell apoptosis and mitigate the histological lesion. Moreover, the increase of capillary vessel density was observed after 2 weeks. Moreover, numbers of miRNAs were up-regulated after RDN treatment both at 24 hours and 2 weeks, and the miRNA targeted pro-angiogenesis, anti-fibrosis and inﬁammatory pathways were modulated. Lastly, less ﬁbrosis regions were found in TH high expression regions of human renal biopsy samples.

Conclusions: RDN was a reliable method in alleviating IRI induced acute and chronic kidney injury, and the modulation of miRNA related pro-angiogenesis, anti-fibrosis or inﬁammatory pathways involved in this process.

PO2616
Obesity Has Opposing Effects on Acute vs. Chronic Kidney Disease

Thomas V. Roussele, James D. Eaton, Daniel Maluf, Valeria R. Mas, Amandeep Bajwa. UTHSC, Memphis, TN.

Background: With an accumulation of lipid droplets, mitochondria become incapable of upregulating the glucose-dependent response to ischemia and the cell becomes dependent upon glycolysis to satisfy metabolic need. This dysregulation has contributed to the exacerbation of ischemic injury in various tissues in diet-induced obese (DIO) mice. However, very little is known in how DIO can contribute to ischemic kidney disease. We hypothesized that obesity may dampen the response to acute kidney injury (AKI) and further exacerbate the development of dysfunction in chronic kidney disease.

Methods: In AKI, DIO mice had worsened kidney function when compared to lean mice as shown by the significant increase in PiCr (1.43±0.23 vs. 2.32±0.14; <0.05). However, the degree of injury was not reflected in BUN or acute tubular necrosis (ATN). Interestingly, there was no significant changes in either PiCr or BUN between DIO and lean mice at 14 days.

Results: Conclusions: When compared to lean controls, mice fed HFD and then subjected to IRI experienced significant exacerbation of injury by a heightened expression of clinical chemistry markers. Though this dysregulation has been associated in other tissues with an accumulation of dysfunctional mitochondria secondary to the increased accrual of lipid-droplets, this does not seem to be the case in the kidney as no lipid-deposits were observed in the histological analysis. In addition, no significant difference existed between DIO and lean mice having undergone unilateral ischemia. With the increasing prevalence of obesity and obesity-related co-morbidities, more studies are warranted to explicitly unravel the effects of DIO in relation to acute and CKD.

Funding: NIDDK Support

PO2617
Protective Effects of Apelin on Contrast-Induced Nephropathy

Background: Contrast induced nephropathy (CIN) has no proven preventive measures yet except for saline administration. Apelin is a endogenous ligand to apelin receptor in body, which has physiologic roles such as increasing cardiac output and peripheral vasodilation. This study aims to examine the protective effect of apelin on CIN.

Methods: A total of 22 rats were divided into 4 groups: Control, Apelin, Contrast, and Apelin/Contrast. In order to effectively induce CIN, 50 mg/kg of gentamycin IV was injected daily to all rats from Day-1 to Day-6. On Day-7, the rats were pre-treated as follows; Control and Contrast groups: Saline SQ, Apelin and Apelin/Contrast groups: apelin 1mg/10kg x 2/1 hour and 1.8 g Id/kg IV . We performed serum and 24-hour urine tests on Day-0 and Day-9 which was 48 hours after contrast administration. We collected the kidney with follow; Control and Contrast groups: Saline and Apelin and Apelin/Contrast. In order to effectively induce CIN, 50 mg/kg of gentamycin IV was administered once daily to all rats from Day-1 to Day-6. On Day-7, the rats were pre-treated as follows; Control and Contrast groups: Saline SQ, Apelin and Apelin/Contrast groups: apelin 1mg/10kg x 2/1 hour and 1.8 g Id/kg IV . We performed serum and 24-hour urine tests on Day-0 and Day-9 which was 48 hours after contrast administration. We collected the kidney with follow; Control and Contrast groups: Saline and Apelin and Apelin/Contrast. In order to effectively induce CIN, 50 mg/kg of gentamycin IV was

Results: The results showed a significant increase in serum creatinine (Cr) in only Contrast group (p=0.039). In Contrast (p=0.015) and Apelin/Contrast (p=0.007) groups, urinary Cr excretion significantly increased indicating renal tubular injury. The immunohistochemistry for caspase-3 indicated that Contrast group had significant tubular cell damages, while other groups including Apelin/Contrast were less damaged (p=0.014).

Conclusions: We could identify the protective effects of apelin against CIN in the study.

PO2618
Male, but Not Female, Spontaneously Hypertensive Rats (SHR) Have Sustained Renal Injury Following a Single Ischemic Insult Progressing to CKD
Riyaz Mohammed, Jennifer C. Sullivan. Augusta University, Augusta, GA.

Background: Renal ischemia-reperfusion (IR) injury is a major cause of acute kidney injury (AKI), which is an independent risk factor for the development of CKD and all-cause mortality. The goal of the current study was to test the hypothesis that hypertensive males will have greater IR injury than hypertensive females resulting in the development of CKD.

Methods: 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by reperfusion (n=5-6). Systolic blood pressure (BP) measured weekly by tail-cuff.

Results: Plasma creatinine (Pcr) and urine protein creatinine ratio (UPCR) remained elevated at 1-week post IR in male SHR compared to sham (P<0.005) and Per and UPCR returned to baseline in SHR females. Histological examination of SHR kidneys 7 days post-IR showed greater increases in vascular congestion (P<0.002) and tubular damage (P<0.001) in males. However, glomerular filtration rate (GFR) and systolic BP were not altered in both male and female SHR at 1-week post IR. To determine if this was sustained dysfunction or simply delayed recovery, additional 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by 20 weeks of reperfusion (n=4-5). Systolic blood pressure (BP) measured weekly by tail-cuff. The increase in UPCR was greater in males (P<0.002) and tubular damage (P<0.001) in males compared to females. However, glomerular filtration rate (GFR) and systolic BP were not altered in both male and female SHR at 1-week post IR. To determine if this was sustained dysfunction or simply delayed recovery, additional 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by 20 weeks of reperfusion (n=4-5). Systolic blood pressure (BP) measured weekly by tail-cuff.

Conclusions: Our data demonstrated that impaired renal recovery following IR in SHR males results in exaggerated progression towards CKD.

PO2619
High Serum Strontium May Predict AKI After Cardiac Surgery with Cardiopulmonary Bypass
Natsumi Tomita,1 Yuji Hotta,1 Karin Matsuta,1 Hidekazu Ito,2 Yoko Yamamoto,4 Kazuki Ohashi,2 Masahiro Kondo,1 Tomoaki Hayakawa,2 Tomoya Kataoka,1,3 Kazuya Sobue,1 Kazunori Kimura.1,2 1Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; 2Department of Pharmacy, Nagoya City University Hospital, Nagoya, Japan; 3Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; 4Aichi-ken Eisei Kenkyujo, Nagoya, Japan; 5Department of Anesthesiology and Intensive Care Medicine, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

Background: The prevalence of acute kidney injury after cardiac surgery under cardiopulmonary bypass (AKI-CPB) is high and it worsens patient prognosis, which renders it a major concern during intensive care. Therefore, a predictable marker of AKI-CPB is required. Because some trace metals have been found to affect renal injury, we investigated their association with AKI-CPB.

Methods: Study 1. We enrolled 30 patients from the Nagoya City University Hospital. Serum concentrations of 19 trace metals were measured before surgery and immediately after CPB withdrawal. We defined AKI according to the KDIGO criteria. Factors associated with AKI-CPB were identified by univariate and multivariate analyses.

Study 2. We treated male Wistar-ST rats with 1 mg/kg/day of strontium (Sr) or vehicle orally for 3 days, followed by the application of 30 min of ischemia and reperfusion to cause renal injury. Serum creatinine (Scr) and blood urea nitrogen (BUN) levels were evaluated 24 h later. We also incubated human kidney (HK)-2 cells with Sr (0.25 μM, high-Sr or 0.19 μM, normal-Sr) or PBS for 24 h in vitro. These Sr concentrations were determined according to the average serum Sr concentrations in patients with and without AKI. The cells were incubated under normoxia (20% O2) or hypoxia (1% O2) conditions; then, cell viability and mRNA expression were assessed.

Results: Study 1. The incidence of AKI-CPB was 30% (n = 9). Serum Cr levels before surgery were high in the AKI group. Intraoperative factors did not differ between patients with and without AKI. Univariate analysis revealed significantly higher levels of Sr and arsenic before surgery, and higher Sr, arsenic, and zinc levels after CPB in the AKI group (p < 0.05). Multivariate analysis showed that only Sr levels after CPB withdrawal correlated independently with AKI. Study 2. The Scr and BUN levels were higher in Sr treated rats than vehicle treated rats. Incubating HK-2 cells with Sr did not affect their viability under normoxia and hypoxia conditions. However, NF-kB mRNA levels increased only under hypoxia conditions following exposure to high Sr levels.

Conclusions: High Sr levels before CPB may be a useful predictor of AKI-CPB. This study suggested that high Sr levels enhance ischemia-induced inflammation following CPB.

PO2620
BAM15 and Mitochondrial DNA Form a Drug-Companion Biomarker Pair Working Through Reactive Oxygen Species in Septic AKI

Background: Sepsis is multifactorial, so drug-biomarker co-development is likely necessary for developing effective therapeutics. Administration of BAM15, a mitochondrial uncoupler, improved sepsis AKI mortality, kidney function, and mitochondrial function in kidney tubules (ASN, 2019). We now evaluate if BAM15 and mitochondrial DNA form a drug-biomarker biomarker pair and are linked mechanistically.

Methods: Mice with sepsis AKI [cucum ligation/puncture (CLP) in CD-1 mice] were treated with BAM15 (5mg/kg IV) at 0h (early) or 6h (delayed) after surgery. Serial plasma and urinary mtDNA was measured by qPCR. This was mimicked in vitro by incubating mouse primary cultured proximal tubular cells (PTCs) with serum from CLP mice. Mitochondrial superoxide generation was measured by live cell imaging with MitoSox-Red. Mitophagy detected in Mt-Keima mice [transgenic for pH-sensitive ratiometric fluorescent protein] by measuring mitochondrial pH.

Results: Plasma and urinary mtDNA were increased in CLP mice starting at 3 hr after CLP. Delayed treatment with BAM15 (6 hr) decreased mtDNA at 12 hrs (Fig 1).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
CLP serum stimulated superoxide production and release of mtDNA into cultured PCT media, both were proportionately inhibited by BAM15 (Fig 2A-C). Released mtDNA correlated with superoxide production. BAM15 recovered mitochondrial biogenesis through activation of PGC-1α pathway and, inhibited CLP reduction of mitophagy.

**Conclusions:** Sepsis increased kidney mtROS and released mtDNA from PT cells. BAM15 attenuated generation of mtROS and inhibited mtDNA release into urine and also circulating mtDNA even delayed BAM15 treatment. In sepsis AKI, BAM15 changed the trajectory of mitochondrial fate. Our results suggest that BAM15 and mtDNA are mechanistically linked via ROS, and form a drug-compassion biomarker pair.

**Grb2 Promotes Cardiorenal Syndrome Type 3: Roles of Cardiomyocyte Cytoskeleton, Mitochondria Damage, and Inflammation**

_Jin Wang, Xiangmei Chen. Chinese PLA General Hospital, Beijing, China._

**Background:** Cardiorenal syndrome type-3 (CRS-3) is a damage to heart following acute kidney injury. Although many experiments have found that inflammation, oxidative stress, and cardiomyocyte death are involved in cardiomyocyte pathophysiological alterations during CRS-3, it lacks a non-bias analysis to figure out the primary mediator of cardiac dysfunction. Herein, the aim of our study is to figure out the primary upstream regulator of these intracellular molecular biological events.

**Methods:** In this study, proteomic analysis was operated in CRS-3 and growth factor receptor-bound protein 2 (Grb2) was identified as a regulator involving AKI-related myocardial damage.

**Results:** Increased Grb2 was associated with cardiac diastolic dysfunction, mild cardiomyocyte death and prominent myocardial inflammation; these pathological changes could be reversed through administration of Grb2-blocking peptide after AKI. Molecular investigation illustrated that augmented Grb2 promoted cardiomyocytes contractile cytoskeleton degradation through inhibiting the expression of Myosin. In addition, increased Grb2 triggered mitochondrial fission, inactivated mitochondrial autophagy, induced mitochondrial potential reduction, and triggered caspase-9/3 activation. Pro-inflammatory signaling pathways, including NF-κB, MAPK/JNK, and MAPK/p38, were activated by Grb2 in cardiomyocytes following AKI.

**Conclusions:** Our results identify CRS-3 is caused by Grb2 upregulation which contributes to cardiac dysfunction, cardiomyocyte apoptosis and myocardial inflammation. This finding provides a potential target for the clinical treatment of patients with CRS-3.

**PO0001**

**AKI Identification: Use of Electronic AKI Alerts vs. Electronic Health Records in Hospital Episode Statistics**

_Manuela Savino, Anna Casula, Esther H. Wong, Nitin V. Kolhe, James Medcalf, Dorothea Nitsch._

**Background:** Acute Kidney Injury (AKI) refers to an abrupt decline in the glomerular filtration rate (GFR) potentially associated with significant morbidity and mortality. Since April 2015, an automated real-time electronic (e)-alert system for AKI epidemiology was to analyse the Hospital Episode Statistics (HES). This project aims to determine whether episodes of AKI identified in the UKRR MPI correspond to coded diagnoses on the discharge record held in HES.

**Methods:** The UKRR MPI of all AKI e-alerts (stages 1, 2, and 3) in patients aged ≥18 years, between 01/01/2017 and 31/12/2017 were linked to HES data to identify a hospitalised AKI population. Descriptive analyses were conducted to describe the demographics and to investigate whether those with an AKI e-alert also had an International Classification of Diseases (ICD)-10 code for AKI (N17) in HES.

**Results:** From 01/01/2017 to 31/12/2017, 301,504 hospitalised adults received an AKI e-alert. AKI severity was positively associated with the percentage of AKI alerts coded in HES. There was a significant variation in HES coding between hospitals, most pronounced for AKI stage 1 (mean 48.2% SD 14) versus AKI stage 3 (mean 83.3% SD 7.3) (figures 1). Younger adults with AKI e-alerts were less often coded in HES for all three AKI stages (33% people aged 18-29 years versus 64% people aged ≥ 85 years).

**Conclusions:** In 2017, earlier stages of AKI e-alerts were poorly coded in HES. There was also high degree of inter-hospital variability, particularly for AKI stage 1, reflecting potentially poor clinical recognition and documentation in medical records and subsequent clinical coding. AKI e-alerts were poorly captured in HES for younger adults in comparison to those of older age. Use of HES to identify cases of AKI is likely to underestimate the incidence of AKI, especially for AKI stage 1, though a high proportion of the most severe cases will be captured.

**Assessment of a Modified Renal Angina Index for the Prediction of AKI in Hospitalized Adult Patients**

_Ana A. Mariscal-Campos, Rolando Clara-Del Granado, Clínica Los Olivos, Cochabamba, Bolivia, Plurinational State of; IBIISMED: Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of._

**Background:** Risk-stratification tools of incident AKI in hospitalized patients are needed. The renal angina index (RAI) was developed and validated in the pediatric population. The purpose of this study was to evaluate the performance of a modified RAI (mRAI) for the prediction of AKI in hospitalized patients.

**Methods:** We analyzed data from 55 hospitalized patients admitted to our center. Inclusion criteria consisted of age ≥ 18, hospital stay ≥ 3 days, at least 2 serum creatinine (Scr) measures in the first 2 days of hospital stay and one measure at 3–7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15. At admission, mRAI was calculated using the following formula: risk level criteria 1) ICU admission, 2) mechanical ventilation or vasoactive drug support, and 3) diabetes. Injury level criteria of Scr increments of >0.1 mg/dL, ≥0.1 mg/dL, ≥0.3 mg/dL and ≥0.4 mg/dL.

**Results:** The incidence of AKI at 3–7 days of hospital or ICU stay was 52.7%. Most patients developed AKI stage 1 (61.3%) and 38.7% developed severe AKI (KDIGO-SCr stage ≥2) at 3–7 days. Performance metrics are reported in Table. The RAI exhibited a good, AUC of 0.87 (95% confidential interval [CI]: 0.77–0.96; p < 0.0001) in ROC analysis, with a cutoff of 8.

**Conclusions:** The mRAI have robust predictive capacity to identify hospitalized adult patients at high risk of developing AKI. Incorporation of AKI biomarkers into the RAI may potentially improve prediction. The preliminary data of our ongoing study warrants future studies to validate these findings.

**Funding:** Private Foundation Support

Early Prediction of Hospital-Acquired AKI from Electronic Health Records Using Machine Learning

Gurmukteshwar Singh,1 Yuiri Hu,1 David Riviello,1 Jason Brown,1 Sara Saunders,2 Andrés García-Arce,2 Kevin Ho,2 H. Lester Kirchner,3,4 Geisinger Medical Center, Danville, PA; 3 Saoofi Genzyme, Cambridge, MA.

Background: Hospital-acquired acute kidney injury (HA-AKI) leads to increased morbidity and mortality. Early prediction of HA-AKI using Electronic Health Records may enable clinicians to modify treatment to minimize risk and AKI severity.

Methods: Inpatient admissions from 7/13/2012 – 7/11/2018 who had creatinine measured were included. Patients with end-stage renal disease, length of stay <48 hours and AKI at admission were excluded. A validated algorithm was used to determine baseline renal function. AKI was defined according to KDIGO guidelines. Machine learning algorithms were implemented to predict development of HA-AKI beyond the initial 24-hours of admission. 50 input variables to machine learning algorithms (random forest, XGBoost, logistic regression) included demographics, initial laboratory values taken within the first 24-hours of admission, active medications at time of admission, and prevalent comorbidities. Multiple imputation by chained equations (MICE) was used for missing variables. Univariate Feature Selection was utilized where variables were ranked by evaluating contribution to classification outcome. Randomized search was performed to identify the optimal hyperparameter set for each algorithm. Models were evaluated using a mean area under the receiver operating characteristic curve (AUC) over 5-fold cross-validation.

Results: Among 209,300 inpatient admissions, 26,410 (12.6%) developed HA-AKI. Per AKI prediction, the AUC of the full model was 0.88 for both random forest and XGBoost, and 0.86 for logistic regression. To balance the tradeoff between model simplicity and performance, 23 variables from univariate feature selection evaluated using random forest were selected in predicting HA-AKI (AUC = 0.87). The probability cutoff-off point of AKI prediction outcome was determined using Youden’s Index based on the balance between false positives and false negatives. A probability cutoff of > 0.23 provided sensitivity and specificity of 78% and 81%, respectively.

Conclusions: Our machine learning algorithm applied at 24 hours of admission identified patients at risk for HA-AKI with excellent accuracy. Significant variables included in this algorithm should be monitored in real-time to allow early identification and preventive interventions in patients at risk for HA-AKI.

A Meta-Analysis of Clinical Predictors for Renal Recovery and Mortality in AKI Requiring Continuous Renal Replacement Therapy

Panupong Hansrivijit1, Max Puthenpura,2 Nasrullah Ghahramani,3 Charat Thongpaprom,4 Wisit Cheungpasitporn,5 UPMC Pinnacle, Harrisburg, PA; 4UPMC, Pittsburgh, PA; 5Penn State College of Medicine, Hershey, PA; 1University of Mississippi Medical Center, Jackson, MS; 2Drexel University College of Medicine, Philadelphia, PA.

Background: Acute kidney injury (AKI) is a common complication in critically ill patients and can result in a broad spectrum of severity. It is well-established that severe AKI requiring continuous renal replacement therapy (CRRT) carries a significant risk for increased mortality compared to non-dialysis AKI. However, there are no consensus guidelines describing the discontinuation criteria from CRRT. Thus, we performed this meta-analysis to determine the clinical predictors for CRRT discontinuation and overall mortality in patients with AKI.

Methods: Ovid MEDLINE, EMBASE, and Cochrane Library were searched without language restrictions up to January 2020. Our inclusion criteria included patients ≥18 years of age admitted to hospitals with severe AKI requiring continuous renal replacement therapy (CRRT) as AKI initiation (≥1 mg/dL of creatinine or ≥25% increase in serum creatinine over 48 hours). Our outcome measures were the discontinuation of CRRT and overall mortality in patients with AKI.

Conclusions: Our meta-analysis included 17 studies with 29,132 patients (AKI requiring CRRT). The discontinuation of CRRT was associated with baseline serum creatinine, serum albumin, central venous pressure, and systolic blood pressure. Our study results suggest that the discontinuation of CRRT was associated with baseline serum creatinine, serum albumin, central venous pressure, and systolic blood pressure. Our study results suggest that the CRRT discontinuation is associated with improved survival in patients with severe AKI.

Regional Variation in Recovery of Kidney Function in Patients Requiring Maintenance Hemodialysis with Acute Tubular Necrosis

Yuetting D. Kwong,1 Kirsten L. Johansen,2 Charles E. MCCullough,3 Kathleen D. Liu,4 Barbara A. Grimms,5 Elaine Ku.1 1University of California San Francisco, San Francisco, CA; 2Hennepin Healthcare, Minneapolis, MN.

Background: Geographic variations in the likelihood of recovery of kidney function in ESKD attributed to acute tubular necrosis (ATN) has not been well established.

Methods: Using data from United States Renal Data System, we performed a retrospective cohort study of incident maintenance hemodialysis (HD) patients between 1/1/1996-12/31/2015 with ESKD attributed to ATN followed up to 1 year. Recovery of kidney function was defined as discontinuation of HD for at least 90 days and alive without need for kidney transplantation during this period. We used Fine-Gray models to determine unadjusted and adjusted hazard of recovery while accounting for the competing risk of death.

Results: In 48,771 patients included for analysis, 30% recovered kidney function within 1 year. Most patients received HD within a 10-mile radius of their home. Recovery rates at 1 year were lowest in the northeast and highest in the south; lower in metropolitan compared to micropolitan/rural areas. Recovery of kidney function was less likely to occur with distance between patient and dialysis facilities in adjusted analysis.

Conclusions: Patients living in rural/micropolitan locations and receiving dialysis close to home had higher recovery rates. Studies examining regional differences in practice patterns are warranted.

Development and Validation of a Model to Predict In-Hospital AKI Among Hospitalized US Veterans

Karandeep Singh,1 Xiaosong Zhang,1 Maggie Yin,1 Yahakin Shahnian,1 William Weitzel,2,3 Rajiv Saran,1 Susan T. Crowley,1 Michael Heung,1 1University of Michigan, Ann Arbor, MI; 2VA Ann Arbor Healthcare System, Ann Arbor, MI; 3VA Connecticut Health System, West Haven, CT.

Background: Acute kidney injury (AKI) occurs commonly in hospitalized patients, affects millions of Americans annually, and is recognized as one of the most significant contributors to chronic kidney disease (CKD). As the primary treatment for most AKI is supportive care, improving the health consequences of AKI (most notably CKD) relies on identifying high-risk patients in a timely manner and targeting them for preventive interventions.

Methods: Using data from a random sample of 100,000 hospitalized veterans, we developed and internally validated a gradient-boosted decision tree (GBDT) model for the prediction of in-hospital acute kidney injury. We excluded patients without an available creatinine during their hospitalization (n = 21,165), and randomly divided the remaining patients into a training cohort (n = 39,418), tuning cohort (n = 13,139), and a test cohort (n = 26,278). We divided each patient’s hospitalization into 6-hour steps and removed all patients without an available creatinine. We developed and internally validated a gradient-boosted decision tree (GBDT) model for the prediction of in-hospital AKI.

Results: Our model had a mean age of 72, was 96% male, 34% with baseline diabetes mellitus, and 24% with baseline CKD. 11% of patients experienced in-hospital AKI by creatinine-based KDIGO criteria (3.8% in any 6-hour window), and 1.6% of patients experienced AKI stage 2+. The area under the curve (AUC) was 0.76 (95% bootstrap CI 0.75-0.77) for predicting any AKI in the next 48 hours and 0.70 (95% CI: 0.67-0.73) for predicting AKI stage 2+ in the next 48 hours. Patients who met or exceeded a risk threshold of 14.5% had a 33% chance of developing AKI during their hospitalization with a 5% specificity.

Conclusions: In a retrospective validation in a large national cohort of veterans, a predictive model for acute kidney injury identifies nearly half of patients who will experience AKI prior to its onset.

Adequacy of Kidney Follow-Up Among AKI Survivors After Hospital Discharge

Kianoush Kung
College of Computer Science and Information Engineering, Tainan, Hsin-Hsiung

Patients Who Require Acute Renal Replacement Therapy in a Critical Care Unit

Hsin-Hsiung, Taiwan; 1University of Pittsburgh, Pittsburgh, PA; 2University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: Acute kidney injury (AKI) affects 20% of hospitalized patients and results in long-term adverse outcomes. To limit its complications, post-discharge follow-up is advised. The objective of the study was to evaluate the frequency of appropriate follow-up after discharge among AKI survivors.

Methods: This was a population-based cohort study of adult Olmsted County residents hospitalized at their local hospital (Mayo Clinic in Rochester, MN) with an episode of stage II or III AKI between 2006 and 2014. Those dismissed from the hospital on dialysis or who died within 30 days after discharge were excluded. The cumulative incidence of adequate kidney follow-up defined by a serum creatinine (SCr) level and/or an in-person health care visit within 30-days, 90-days, or 1-year after discharge was described.

Results: There were 563 survivors of AKI studied [Stage II: N=360 (64%); Stage III: N=203 (36%)]. The 30-day cumulative incidence of follow-up with SCr was 78% (95% confidence interval (CI) : 74%, 81%), by provider visit was 80% (95% CI: 77%, 83%), by both SCr assessment and provider visit was 70% (95% CI: 65%, 73%). Within 90-days and 1-year, the cumulative incidences of both SCr assessment and provider visit rose to 81% and 91%, respectively. Within 30-days after discharge, only 13% (95% CI: 10%, 16%) of these stage II or III AKI survivors saw a nephrologist. The statistically significant predictors of receiving both a SCr assessment and provider visit within 30-days included higher body mass index, worse baseline and discharge kidney function, higher comorbidity burden, greater maximum AKI severity, and longer duration of AKI during the hospitalization. Age, sex, race/ethnicity, education status, and socioeconomic status did not predict kidney follow-up.

Conclusions: These data demonstrated that 30% of patients with moderate to severe AKI received insufficient kidney follow-up in the 30-day post-discharge interval. Medical risk factors rather than social/demographic characteristics were the primary determinants of kidney follow-up.

Funding: Other NIH Support - National Institute of Allergy and Infectious Diseases of the National Institutes of Health under Award Number K23AI143882; National Center for Advancing Translational Sciences Grant Number UL1 TR002377; National Institute on Aging of the National Institutes of Health Award Number R01AG034676.

Predicting Intra-ICU Mortality Using Machine Learning Algorithms in Patients Who Require Acute Renal Replacement Therapy in a Critical Care Unit

Huiwen Chen,1,2 Manisha Jhamb,2,3 Milos N. Budisavljevic,4 David Redden,4 Michael J. Connor,3 Jin Chen,2 Lucas J. Liu,1 Mahanazuddin Syed,5 Ahmad Baghal,1 Jean Craig,1 Brian Harmon,2 Vinay Narasimha Krishna.3 The Southern Acute Kidney Injury Network (SAKInet) University of Arkansas for Medical Sciences, Little Rock, AR; 2Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR; 3Medical University of South Carolina, Charleston, SC; 4The University of Alabama at Birmingham, Birmingham, AL; 5University of Kentucky, Lexington, KY; 6Emory University, Atlanta, GA.

Background: AKI requiring dialysis (AKI-D) is common with a high rate of adverse outcomes. Little is known about modifiable factors that promote kidney recovery.

Methods: Five CTSAs universities (UMS, UAB, UKY, MUSC and Emory) formed a consortium to identify modifiable risk factors for kidney recovery in AKI-D patients. We selected all patients that received dialysis while in the hospital, then excluded patients from the cohort with a diagnosis related to ESKD, kidney transplantation or CKD stage V at the time of the first RRT. Modality of dialysis, comorbidities and outcomes were analyzed.

Results: The total number of patients in the four available cohorts was 4537 (range 647-1477). Outcomes were determined at the time of discharge from the hospital. The primary outcomes in the study were death (n=2190, 48.3%), alive and dialysis-dependent at discharge (n=1160, 26.5%) or alive and dialysis-free at discharge (n=1187, 26.2%). We defined dialysis dependence as receiving dialysis within the last four days of hospitalization. We compared patients that were initiated on CRRT to patients that were initiated on intermittent hemodialysis (iHD) while adjusting for confounders: sepsis, age, race/ethnicity, diabetes, anaemia, serum bicarbonate, and serum potassium at the time of dialysis initiation. We analyzed hospital cohorts separately. There was a higher risk of death in patients initiated on CRRT vs. iHD. The odds ratios and 95% CIs for death were: UAMS 2.8, 1.9-4.2; UAB 3.2, 2.1-4.9; MUSC 3.7, 2.6-5.3 and UKY 3.1, 2.3-4.2. Among survivors, patients started on CRRT generally had a lower risk of being dialysis-dependent at discharge. The odds ratios and 95% CIs for renal recovery were: UAMS 0.1, 0.04-0.2; UAB 0.3, 0.1-0.5; MUSC 0.3, 0.2-0.5 and UKY 0.8, 0.5-1.2.

Conclusions: The odds of kidney recovery were significantly better for patients started on CRRT in three of the four cohorts examined in this study and trended toward favoring CRRT in the fourth. This has important implications for care of patients with AKI in the ICU. We believe the increased mortality in the CRRT group reflects the sicker nature of patients in that group and is not inherent to CRRT as an initial dialysis modality.

PO0011
Region-wide Implementation of Best Practice in AKI
Anirudh Rao, Kottarathil A. Abraham. On behalf of the Cheshire & Merseyside Acute Kidney Injury Network (CHAMKIN) Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom.

Background: The Cheshire & Merseyside Acute Kidney Injury Network, United Kingdom, rolled out best practice guidelines of 13 interventions for Acute Kidney Injury (AKI) in October 2014. The aim was to assess the impact of the guidelines.

Methods: Setting & Population: Hospitals in Cheshire & Merseyside. Predictor: Time period before & after introduction, allowing six-month bedding in period. Outcome: Percentage AKI: Number of AKI per month, divided by total number of admissions/month expressed as %. Percentage AKI deaths: Number of AKI related deaths per month divided by total deaths/month expressed as %. Data analysis: Descriptive & Piecewise Linear Regression.

Results: The region saw a notable increase in the number of admissions/month (31,173 vs 38,443) and AKI episodes (4,871 vs 44,493) in the 8 hospitals in pre and post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-implementation data (1). The outcomes in the 2 periods are detailed in the Table. The introduction of E-alert saw an increase in AKI detection across the hospitals. The figure shows longitudinal piecewise regression curves. The most significant reduction was noted in hospital A.

Conclusions: The rollout of interventions caused an increased and sustained recognition of AKI, across the hospitals. The % AKI deaths stayed the same except in hospital A. We theorise that the onsite nephrology team in Hospital A aided implementation of the guidelines and training of wider healthcare staff which made the impact. This study highlights the hurdles faced in implementing AKI improvement strategies across various healthcare settings.

PO0013
Incidence and Impact of AKI on Patients with Implantable Left Ventricular Assist Devices: A Meta-Analysis
Charat Thongprayoon,1 Wisit Cheungpasitporn,2 Panupong Hansrijijit,3 Tibor Fulop,4 Hansrivijit,5 Telma H. Ragnarsdottir,1 Samuelsson,1 Landspitali University Hospital, Iceland; 2University of Mississippi Medical Center, Jackson, MS; 3UPMC Pinnacle, Harrisburg, PA; 4Medical University of South Carolina, Charleston, SC; 5Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Background: This systematic review and meta-analysis was performed to evaluate the acute kidney injury (AKI) incidence and its associated risk of mortality in patients with implantable left ventricular assist devices (LVAD).

Methods: A systematic literature search in MEDLINE, EMBASE, and Cochrane Databases was conducted through January 2020 to identify studies that provided data on the AKI incidence, and AKI-associated mortality risk in adult patients with implantable LVADs. Pooled effect estimates were examined using random-effects, generic inverse variance method of DerSimonian-Laird.

Results: 56 cohort studies with 63,663 LVAD patients were enrolled in this meta-analysis of AKI incidence. The pooled incidence of reported AKI was 24.9% (95%CI: 20.1%-30.4%), but rose to 36.9% (95%CI: 31.1%-43.1%) when applying the standard definition of AKI per RIFLE, AKIN, and KDIGO criteria. The pooled incidence of severe AKI requiring renal replacement therapy (RRT) was 12.6% (95%CI: 10.5%-15.0%). AKI incidence did not differ significantly between types of LVAD (p = 0.35) or indication for LVAD use (p = 0.62). While meta-regression analysis did not demonstrate a significant association between study year and overall AKI incidence (P=0.55), the study year was negatively correlated with incidence of severe AKI requiring RRT (slope = -0.068, p <0.001). The pooled odds ratios (ORs) of mortality at 30 days and 1 year in AKI patients were 3.66 (95% CI, 2.00-6.70) and 2.22 (95% CI, 1.62-3.04), respectively. The pooled ORs of mortality at 30 day and 1 year in severe AKI patients requiring RRT were 7.52 (95% CI, 4.58-12.33) and 5.41 (95% CI, 3.63-8.06), respectively.

Conclusions: 37% of LVAD patients developed AKI based on standard definitions and 13% developed severe AKI requiring RRT. There has been potential improvement in the incidence of severe AKI requiring RRT for LVAD patients. AKI in LVAD patients was associated with increased 30-day and 1-year mortality.

PO0014
AKI in the Emergency Department: A Prospective Case-Control Study
Telmara H. Ragnarsdottir,1 Margret Kristjansdottir,1 Gitli Gislason,2 Vicente Sanchez-Brunete,1 Margret O. Tomasstorft,1 Olafur H. Samuelsson,1 Runolfur Palsson,1 Olafur S. Indridsson,1 Landspitali University Hospital, Reykjavik, Iceland; 2University of Iceland, Faculty of Medicine, Reykjavik, Iceland; 3Primary Health Care of the Capital Area, Reykjavik, Iceland.

Background: Acute kidney injury (AKI) is an abrupt decline in kidney function that occurs in hours or days. AKI has been thoroughly studied in the hospital setting, however data on community-acquired AKI are scarce. The aim of this study was to investigate the incidence, causes and prognosis of patients presenting with AKI to the emergency department (ED).

Methods: This was a prospective case-control study in which serum creatinine (SCr) measurements of all patients presenting to the ED of Landspitali—The National University Hospital in Reykjavik were examined for the presence of AKI. The study started on January 1, 2020, and we present data until March 3, 2020. All patients who met the criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex and time of ED admission. Participants signed informed consent and were questioned regarding their medical history, habits and use of medications, including over-the-counter (OTC) medications and supplements, in the week prior to admission. Medical records were also reviewed with regard to prior diseases and medical prescriptions.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: From January 1 to March 3, 124 cases of AKI were identified among patients presenting to the ED, 114 (92%) of whom participated in the study. The mean (SD) age of the 114 AKI cases and the 228 controls was 68.7±15.2 years and 68.8±15.0 years, respectively; 43% of cases and controls were female. AKI cases were significantly more likely than controls to have been taking non-steroidal anti-inflammatory drugs (NSAIDs) (36.0% vs 20.6%, p<0.01) in the week preceding the ED visit. In both cases and controls, the usage of OTC NSAIDs was more common than prescription NSAIDs (72.2% and 66.0%). No significant difference was observed between AKI cases and controls in the use of ACE-inhibitors/angiotensin receptor blockers (45.6% vs 39.9%, p=0.314). The use of proton pump inhibitors was less common among AKI cases than controls (27.2% vs 41.7%, p<0.01) and same was true for statins (22.8% vs 33.3%, p=0.045).

Conclusions: These preliminary results suggest a significant contribution of OTC NSAID use to AKI among patients presenting to the ED. A detailed information on adverse events should be provided when these medications are sold over the counter.

PO0015
Prehospital Systolic Blood Pressure and Lactate Are Early Predictors of AKI After Trauma: A Prospective Validation Study
Toru Nasu,1 Kentaro Ueda,1 Shuji Kawashima,1 Yuko Okishio,1 Kosei Kunitatsu,1 Yasuhiro Iwasaki,2 Seiya Kato.1 1Wakayama Medical University, Wakayama, Japan; 2Wakayama Rosai Hospital, Wakayama, Japan.

Background: We have already reported that prehospital systolic blood pressure and lactate can be predictive factors for acute kidney injury (AKI) after trauma. This study is a prospective validation study to determine whether these risk factors are helpful.

Methods: We evaluated all trauma patients who were admitted from January 2019 to December 2019. Patients who were >16 years of age, patients with burns, and patients with chronic kidney disease were excluded from the present study. AKI was defined according to the risk, injury, failure, loss of the kidney function, and end-stage disease (RIFLE) classification from serum creatinine alone.

Results: Four hundred and three patients were included in the analysis. The prevalence of AKI in the overall population was 14.7% including 11.7% of patients with stage R, 2.0% of patients with stage I and 1.0% with stage F. The incidence of stage I and F AKI in the high-risk group (5 of 38 patients, with the positive predictive value of 13.2%) was significantly higher (P<0.001) than that in the low-risk group (7 of 358 patients, with the negative predictive value of 98.1%).

Conclusions: The prehospital systolic blood pressure and early hospital arterial lactate showed good performance in the early prediction of AKI after trauma. These parameters are associated with the early onset of AKI after trauma and may be an early predictor of the effects of treatment to prevent AKI.

PO0016
Association of Race and Risk of Future Scleroderma Renal Crisis at Systemic Sclerosis Diagnosis
Crystal Forman,1 Stephen W. Olson,2 Sarah M. Gordon,2 James B. Hughes,2 Rodger S. Stitt,3 Wayne Bailey,4 Jess D. Edison,2 Robert Nec.2 1San Antonio Uniformed Services Health Education Consortium, Fort Sam Houston, TX; 2Walter Reed National Military Medical Center, Bethesda, MD.

Background: Scleroderma renal crisis (SRC) is a rare and severe manifestation of systemic sclerosis (SSc). Although it is well documented that Blacks with SSc have worse morbidity and mortality than non-Blacks, racial predilection for SRC is underreported. We examine the association of race and future development of SRC in an SSc cohort.

Methods: Using the electronic medical record of the U.S. Military Health System which consisted of 9.6 million beneficiaries worldwide, we conducted a comprehensive retrospective review of patients with SSc. SRC was defined as a decline in creatinine by >50% in 6 months. We report the incidence of SRC among Blacks and non-Blacks and the risk factors for SRC.

Results: Of 353 patients, 294 had identifiable race (79 Black, 215 non-Black). Black patients had nearly twice the likelihood for SRC following PCI (OR 1.80 in black vs white patients (95% CI 1.49 to 2.18). Compared to white, other race was not associated with SRC: OR 1.31, 95% CI 0.91 to 1.87. Low baseline eGFR was associated with graded, higher likelihood of AKI for trend <0.001. There was no interaction between race and baseline eGFR.

Conclusions: Black patients had nearly twice the likelihood for AKI following PCI than whites despite adjustment for baseline kidney function, prophylaxis and procedural characteristics. Future investigations should identify other factors that predispose black individuals to disparate AKI risk following PCI.

Funding: Private Foundation Support

PO0017
Differential Racial Incidences in AKI Following Percutaneous Coronary Intervention
Joseph Lunyera,1 Robert M. Clare,2 Karen Chiswell,2 Julia J. Sciaila,2 Patrick H. Pun,2,3 Kevin L. Thomas,2,3 Monique Starks,2,3 Clarissa J. Diamantisid.1 1Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3University of Virginia School of Medicine, Charlottesville, VA.

Background: Percutaneous coronary intervention (PCI) is a risk factor for AKI, but few studies have quantified racial differences in AKI incidence following PCI.

Methods: We examined the association of self-reported race – black, white, and other – and baseline eGFR with AKI incidence among patients captured in the Duke Databank for Cardiovascular Disease (DDCD) who underwent PCI at Duke between January 1, 2003 and December 31, 2013. AKI was defined as a 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. We used logistic regression adjusted for demographics, comorbidities, predisposing medications (NSAIDS, RAAS inhibitors, diuretics), PCI indication (presenting with vs without acute coronary syndrome), peri-procedural prophylaxis with IV fluids and n-acetylcysteine, urgency of PCI and BP at time of PCI.

Results: Of 9422 patients (median age 66 yrs [IQR 54 to 72]; 33% female; 75% white, 24% black, 5% other race), 9% developed AKI: 14% of blacks, 8% of whites, 10% in other race groups. After adjustment, black race was associated with greater likelihood of AKI: odds ratio (OR) 1.80 in black vs white patients (95% confidence interval (CI) 1.49 to 2.18. Compared to white, other race was not associated with AKI: OR 1.31, 95% CI 0.91 to 1.87. Low baseline eGFR was associated with graded, higher likelihood of AKI for trend <0.001. There was no interaction between race and baseline eGFR.

Conclusions: Black patients had nearly twice the likelihood for AKI following PCI than whites despite adjustment for baseline kidney function, prophylaxis and procedural characteristics. Future investigations should identify other factors that predispose black individuals to disparate AKI risk following PCI.

PO0018
The Spectrum of Biopsy-Proven Kidney Diseases in 2027 Patients with AKI
Zuilhumaer Abduwuwuer, Shao-shan Liang, Feng Xu, Dandan Liang, Xue Yang, Ying Zhu, Zhihong Liu, Cai-hong Zeng. National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.

Background: Acute kidney injury (AKI) is a group of highly heterogeneous, complicated clinical syndrome. The kidney biopsy plays an irreplaceable role in the evaluation of patients with unexplained AKI and may offer fresh insights into disease heterogeneity. Hence, in this study we aim to analyze the pathological disease spectrum, etiology, and renal recovery of biopsy-proven AKI patients.

Methods: We retrospectively analyzed the clinical and pathological data of AKI patients who went to a kidney biopsy during the hospitalization at our center from January 2013 to December 2018. We classified included patients into pure AKI and ACKD two groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: The study included 2027 AKI patients who had undertaken renal biopsy, while the analyses were performed for the total renal biopsy cases and 31.7% of the total hospitalized AKI cases during the same period. The majority of AKI patients were male (65.1%), with an average age of 42±16.5 years, pure AKI and ACDK accounted for 21.6% and 78.4%, respectively. Pure AKI mainly presented as AKI-3 (74.8%), while ACDK mostly presented as AKI-1 (53%). The proportion of patients undergoing renal replacement therapy in pure AKI group was significantly higher than ACDK group (29.3% vs 11.9%, P = 0.0001). In pure AKI group, acute intestinal nephritis (AIN) was most common (56.1%), followed by acute tubular necrosis (ATN) (34.6%). The main cause of AIN was due to drugs (84.9%) and the most frequent causes of infections were abdominal (54.4%) and systemic infections (46.8%) in ACDK patients. In ACDK group, acute and chronic glomerulonephritis were the predominant groups (41.7% and 38.4%). In ACDK group, primary and secondary glomerulonephritis accounted for 70.6% and 26.9%, and the most frequent pathological disease were IgAN, followed by MCD, FSGS, MN, LN, AAV. Among the followed-up patients the proportions of concomitant extra-renal disease and non-AKI mortality were lower in pure AKI group than in ACDK group (37.8% and 13.5%, respectively).

Conclusions: Among biopsy-proven AKI patients, pure AKI was relatively rare while ACDK accounted for the majority. Pure AKI tend to be more serious than ACDK and more patients required dialysis. ACDK patients had a wide spectrum of pathological diseases, and the prognosis of renal recovery was worse than pure AKI.

PO0019
Higher Ambient Level of Nitrogen Dioxide Is Associated with an Increased Risk of AKI
Xin Xu, Yanlin Qi, Licong Su, Fan Fan Hou. Xin Xu Nantang Hospital, Southern Medical University, Guangzhou, China.

Background: Previous studies have suggested that long-term exposure to air pollution increased the risk of chronic kidney disease and its progression. However, the effect of air pollution on the risk of acute kidney injury (AKI) has not been studied.

Methods: We selected from the Epidemiology of AKI in Chinese Hospitalized patients (EACH2 study) AKI cases of which the onset date could be unambiguously determined. We obtained city-specific daily averages of the ambient level of PM2.5, NOx, CO, NO2, SO2, and O3, from the Ministry of Environmental Protection of China. We used the time-stratified case crossover approach to examine the association between the ambient level of air pollutants and the risk of AKI in the selected cases.

Results: A total of 11,293 AKI cases that met the inclusion and exclusion criteria were selected, of which, 3175 (28.1%) were severe AKI (stage 2 or 3). In univariable analysis, the ambient levels of NOx, and SO2, were significantly associated with the risk of AKI. In the multivariable analysis that incorporated all six pollutants in the same model, NOx was the sole pollutant whose level remained to be associated with the risk of AKI (p = 0.001). The relationship between level of NOx and the risk of AKI appeared to be linear, with an estimated odds ratio of 1.072 (95% CI: 1.033, 1.113) for each increment of one standard deviation in the exposure. The association was consistent across the subgroups stratified by age, gender, baseline eGFR, AKI severity, need for intensive care, and season.

Conclusions: Higher ambient level of NOx was associated with an increased risk of AKI in hospitalized adults in China.

PO0020
AKI After Procedures of Orthotopic Liver Transplant: Risk Factors, Renal Outcomes and Survival

Background: The incidence of acute renal injury (AKI) after orthotopic liver transplantation (OLT) ranges between 40 and 70%. The etiology of this syndrome is multifactorial.

Methods: Medical records of patients undergoing OLT in the period from January 2012 to August 2019 were reviewed. A total of 355 patients were included. 171 patients presented AKI. Baseline characteristics, variables during surgery and variables during their stay in intensive were analyzed. Renal outcomes and survival were also analyzed.

Results: In the group without AKI age mean was 45.8 years and 37% were women, in the group with AKI the age mean was 51.2 years and 54% were men (P = 0.001). Mean baseline creatinine was 0.77 vs while 0.88 mg/dl P = 0.003. Fuorarms prior to transplantation was found: 51.6% vs 71.9%, P = 0.001. A difference was also found between the incidence of AKI in patients with and without diabetes (75.4% vs 51.7%, P = 0.001). Glomerular filtration rate (GFR) was found to be lower in patients with AKI (30.7% vs 37.4% P = 0.001) and (0.21 vs 0.53) During surgery. Difference was found in maximum lactate, maximum dose of norepinephrine and vasopressin use during surgery: (5.1 vs 5.8 P = 0.014), (0.59 vs 0.34 P = 0.001), (36% vs 51% P = 0.003) Differences were also found in drained anesies and anhepatic period: (150 vs 973 SD vs 187) P = 0.021) and (52.9 vs 57.4 P = 0.014). In the stay in the ICU, there was a difference in the income of liquids first and second hours after transplant (1319 vs 1984 P = 0.001) and (1208 vs 1606 P = 0.009), norepinephrine dose in the first 24 hours (14.2 vs 0.27 P = 0.001), use of vasoactive and antiadipalgin (27.1% vs 42.1% P = 0.02) and (38% vs. 13.9 P = 0.001), transfusion of blood derivatives 33.5% vs 59% (P = 0.001). There was difference in creatinine and GFR at the end of hospitalization (0.67 vs 0.97 P = 0.001) and (104 vs 82.6 P = 0.001). Survival at 7 days after the transplant 100% vs 96.5% P = 0.01. Survival at 30 days was 99.5 ± 9.3% vs 93.6% P = 0.002.

Conclusions: The incidence of AKI in the first 7 days was 48%, which is consistent with that reported in the world literature. The development of AKI seems to be multifactorial influencing baseline characteristics of patients before transplant and renal function during surgery and intensive care stay. AKI was associated with higher mortality at 7 and 30 days, in addition to lower GFR at patient discharge and higher risk of CKD.

Anemia Following AKI After Non-Cardiac Surgery and Long-Term Outcomes: The NARA-AKI Cohort Study
Masatoshi Nishimoto,1 Miho Murashima,2 Maiko Kubok,1 Masaru Matsuri,3 Masahiro Erguchi,1 Ken-iChi Samejima,1 Yasuhiro Akai,1 Kazuhiako Tsuuryu,1 Nara Kenitusi Ika Daigaku, Kashiura, Japan; Nagoya Shizitus Daigaku Igaku Kenkyu Igaku, Nagoya, Japan; Nara-ken Sogo Iryo Center, Nara, Japan.

Background: The aim of this study was to investigate whether acute kidney injury (AKI) is an independent predictor of anemia and whether anemia following AKI is a mediator of mortality after AKI.

Methods: This is a retrospective cohort study. Adults who underwent non-cardiac surgery from 2007 to 2011 were included. Those with obstetric or urological surgery, missing data for analyses, or preoperative dialysis were excluded. Subjects were followed until the end of 2015 or loss to follow-up. The exposure of interest was postoperative AKI defined by KDIGO criteria. The outcome variables were hematocrit values measured at 3, 6, and 12 months postoperatively and mortality. Associations between AKI and hematocrit or association between AKI and mortality were examined by multivariable linear regression or cox regression analyses, respectively. Data were adjusted for potential confounders.

Results: Among 6692 subjects, 445 (6.6%) developed AKI. Among those with postoperative data, AKI was independently associated with lower hematocrit values at 3, 6, and 12 months postoperatively, with coefficients [95% confidence interval] of [−0.79 [−1.47 to −0.11], 1.35 [−2.11 to −0.60], n=1558, and −0.91 [−1.59 to −0.22], n=2463, respectively. Higher stages of AKI and longer duration of AKI were associated with more severe anemia. AKI was associated with higher mortality after 3 months postoperatively with hazard ratio [95% confidence interval] of 1.54 [1.12 to 2.12]. Further adjustment with hematocrit values at 3 months attenuated the association (1.45 [1.05 to 2.00]). Median effect was significant (p = 0.02) by mediation analysis.

Conclusions: AKI was an independent predictor of anemia following AKI. This might be due to permanent intrastimal damage and impaired erythropoietin production. Higher mortality associated with AKI was at least partially mediated by anemia following AKI. Whether correction of anemia following AKI improves outcome of AKI requires further research.

**Decreased Urinary Uromodulin Is Potentially Associated with AKI: A Systematic Review and Meta-Analysis**

**You Ruilian, Hua Zheng, Limeng Chen. Peking Union Medical College Hospital, Beijing, China.**

**Background:** Conventional diagnostic criteria based on the serum creatinine isn’t sensitive enough to detect Acute Kidney Injury (AKI) timely. Urinary uromodulin (uUMOD) is one of the novel biomarkers being studied for the value of predicting AKI. However, currently available publications showed inconsistent outcomes. This meta-analysis aimed to evaluate the potential association between uUMOD and AKI.

**Methods:** We searched research articles in Pubmed-Medline, Web of Science, Cochrane library, Embase, China National Knowledge Infrastructure, and Weipu Database (up to 2020.3). Random-effects models were used to estimate the standardised mean difference (SMD) between AKI and Non-AKI. The sensitivity analysis was conducted using the leave-one-out method. Random-effects meta-regression was performed to evaluate the impact of potential confounders on age and surgery.

**Results:** The meta-analysis was comprising 2678 subjects of 8 studies, which showed that the uUMOD in the patients with AKI was significantly lower than the Non-AKI patients (SMD:-0.30 mg/dL, p<0.01), increased latency from CPI initiation to AKI (1.18±0.40 mg/dL, p=0.04). Furthermore, the inverse probability of the treatment weighting (IPTW) method and standardized mortality ratio weighting method was also used.

**Conclusions:** CPI-associated AKI is 15.2%, 44% developed severe AKI. 18.4% received corticosteroids. Older age and higher bCr were identified as independent predictors for AKI development in patients with cancer CPI-treated.

**PO0025**

**Relationship of Loop Diuretic with Hospital-Acquired AKI: A Multicenter, Propensity Score-Matching Analysis**

**Yanqin Li, Licong Su, Xin Xu. Nanfang Hospital of Southern Medical University, Nephrology Guangzhou, China; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangzhou, China.**

**Background:** Loop diuretics have been widely used to prevent and treat acute kidney injury (AKI). However, there is no clear consensus on the role of loop diuretics in AKI.

**Methods:** The Epidemiology of AKI in Chinese Hospitalized patients is a multicenter retrospective cohort included 3,044,024 hospitalized patients from 25 tertiary hospitals across China during 2013-2015. Patient data were obtained from the electronic hospitalization information system. We selected 57589 adult patients who had at least two serum creatinine tests within any 7-day window during their first 30 days of hospitalization and excluded those with end-stage renal disease, community-acquired AKI and without prescription data. AKI was defined using the SCr data by the Kidney Disease Improving Global Outcomes criteria. Exposure to Loop diuretics as any filled prescription within 14 days prior to the detection date of AKI in patients with HA-AKI and within 14 days prior to the last SCr testing date in those without AKI. Propensity scores (PS) were calculated using a logistic regression model with age, gender, hospital, division, baseline SCr, SCr testing times, comorbidities, operation procedures, need for intensive care and exposure to other nephrotoxic drugs. Moreover, the inverse probability of the treatment weighting (IPTW) method and standardized mortality ratio weighting method was also used.

**Results:** Of 57589 adult analysed, 20599 (35.8%) used diuretics, 17077 (29.7%) used loop diuretics, and 6277 (10.9%) had HA-AKI events during hospitalization. 8,274 pairs matched after nearest-neighbor matching without replacement and within caliper width (0.2*SD of the logit of PS). By IPTW, use of loop diuretics was associated with a significantly increased risk of HA-AKI compared with non-users (OR, 1.39; 95% CI, 1.28-1.52). The associations were consistent across multiple regression models.

**Conclusions:** Loop diuretics were widely used and associated with an increased risk of HA-AKI in hospitalized adult in China.

AKI and Bleeding Risks Associated with Vitamin K Antagonists and Antiplatete Agents in Patients with CKD

Solené M. Laville,1 Marie Metzger,2 Agibles Hamroun,3,4 Oriane Lambert,1 Christian Jacquelinet,1 Maurice Laville,1 Luc Frimat,4 Denis Fouque,3 Christian Combe,5 Roberto Pecotis-Filho,6 Benedicte Stengel,2 Ziad Massry,5 Soroush Laiabef1 (1) INSERM, 2Univ Paris-Saclay University, UVSQ, Villejuif, France; 3Agence de la biomedecine, Bordeaux, Bordeaux, France; 4INSERM, U1026, Univ Bordeaux Segalen, Bordeaux, France; 5Regional and University Hospital Center of Lille, Nephrology Department, Lille, France; 6Department of Nephrology, Ambroise Pare University Hospital, APHP, Boulogne-Billancourt, France; 7Department of Clinical Pharmacology, Amiens University Hospital, Amiens, France; 9MP3CV Laboratory, EA7517, University of Picardie Jules Verne, Amiens, France; 10Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Anticoagulation in patients with chronic kidney disease (CKD) is challenging because of altered pharmacodynamics/pharmacokinetics. Patients prescribed vitamin K antagonists (VKA) are at high risk of bleeding, and possibly also acute kidney injury (AKI). We assessed bleeding and AKI risks associated with VKA and/or antiplatelet agents (AP) prescription in patients with moderate or advanced CKD.

Methods: We identified 5271 patients with moderate to severe CKD (eGFR <30 mL/min/1.73 m²) on dialysis, dialysis waiting list, or chronic dialysis from 9 French nephrology centers from January 2015 to 2017. Prescription data, AKI, and bleeding were retrieved from electronic medical records. Individuals prescribed VKA only, AP only, or VKA + AP prescriptions treated as a time-dependent variable and adjusted for baseline comorbidities, laboratory data, and medications. Results: At baseline, 65% of the patients were men, median age was 69 (interquartile range, IQR, 60-76), median eGFR was 32 mL/min/1.73m² (IQR, 23-41), 328 (10%) patients were prescribed VKA only, 1196 (40%) AP only, and 100 (3%) both VKA and AP. Over a median follow-up of 3.0 years (IQR, 2.6-3.1), 71 (2%) patients were newly prescribed VKA and 187 (6%) AP; 152 patients experienced a bleeding event requiring hospital visit/stay (crude incidence rate [IR]: 1.9% person-years [95% CI 1.6-2.2]) and 414 patients ≥2 AKI episodes within 30 days of discharge. The incidence rate of new AKI episodes was 1.7 (95% CI 1.5-1.9, p<0.001) per person-year in non-users of VKA and AP and 3.1 (95% CI 2.8-3.4, p<0.001) in users of AP alone or in combination.

Conclusions: This study confirms the high risk of AKI associated with VKA prescription in CKD patients. It also highlights the potential aggravating effect of combining VKA and AP on the risk of bleeding in this population.

Use of Ibuprofen and the Risk of Hospital-Acquired AKI in Children

Liong Su, Yangni Li, Xin Xu, Nanfang Hospital, Southern Medical University, Guangzhou, China.

Background: Ibuprofen is widely used in children worldwide, especially in children with cancer, fever or trauma. However, large and high-quality studies on the association between ibuprofen and acute kidney injury (AKI) in children have been lacking.

Methods: The Epidemiology of AKI in Chinese Hospitalized patients (EACH2 study) is a nationwide, retrospective study of 3,044,023 patients admitted from January 1, 2013 to 2015 at 25 academic medical centers in China. Patient-level data were obtained from the electronic hospitalization information system. We included 50,420 hospitalized children aged between 1 month to 18 years who had at least one SCr test during the first 3 days and had at least one interval between two consecutive SCr testing <14 days during the first 30 days of hospitalization, excluding those with end-stage renal disease, community-acquired AKI, insufficient SCr testing and without prescription. AKI was defined as an increase in SCr by ≥26.5 μmol/L within 48 hours or a 50% increase in SCr from the baseline. We estimated the effect of exposure to ibuprofen on the risk of HA-AKI using a Cox proportional hazard model with adjustment for age, sex, body height and weight, high risk clinical conditions, laboratory data, and medications. We also compared the effect sizes of ibuprofen among subgroups stratified by age, gender, chronic kidney disease, need for intensive care and exposure to other nephrotoxic drugs.

Results: Among 50,420 children who met the inclusion and exclusion criteria, 5,526 (11.0%) were ibuprofen users, and 3,476 (6.9%) had HA-AKI during hospitalization. Ibuprofen use was associated with significantly increased risk of HA-AKI (hazard ratios, HR, 1.23; 95% CI, 1.14-1.34) after adjusting for confounders. The greater nephrotoxicity of ibuprofen was observed in children who had chronic kidney disease, required intensive care, or were of older age.

Conclusions: Ibuprofen was widely used and associated with an increased risk of HA-AKI in hospitalized children in China.

Characterizing AKI from Vancomycin-Associated Nephrotoxicity in Adult Non-ICU Patients at an Inner City Hospital: Incidence and Predictors
Gerald Fletcher,1,2 Levard G. Roberts,1,2 Sai S. Achi,1 Sheldon Ferguson,1 Maryam M. Handoo,1 Richard S. Sheppard,1 Aye M. Aung,1 Sudhanshu Jain,1 Sukhpal A. Andrali.1 1Harlem Hospital Center, New York, NY; 1Emory University, Atlanta, GA; 1The University of Arizona Health Sciences, Tucson, AZ.

Background: Vancomycin is a widely used antibiotic in the in-patient setting. Concerns of vancomycin-associated nephrotoxicity (VAN) were raised due to impurities associated with the first released parenteral formulations in the 1950s. Nephrotoxicity is reported to have markedly declined with a wide variability in the incidence. There is a dearth of information on the current incidence of VAN as a cause of acute kidney injury (AKI) in adult non-ICU populations. The purpose of this study was to estimate the incidence of VAN AKI and identify risk factors of VAN for this population.

Methods: A cohort of patients admitted between January 2015 and December 2017 with the diagnosis of AKI and who received at least 3 days of parenteral vancomycin were identified through a retrospective chart review. Exclusions were ESRD or CKD history. Our primary outcome was the occurrence of VAN AKI, defined as an increase in serum creatinine by 0.3 mg/dl or 50% above baseline after vancomycin exposure. The incidence of AKI was determined and we estimated risk factors associated with VAN in a logistic regression model.

Results: 587 adult patients received at least 72 hours of parenteral vancomycin for the treatment of sepsis during the period. Demographics were: male 350 (59.6%), female 237 (40.4%) and mean age of 62.3 years. Distribution by ethnicity: non-Hispanic Blacks 71.2%, Hispanics 12.6%, non-Hispanic white 3.4% and 12.4% were other ethnicities. The incidence of VAN AKI was 15.24%. These patients had a longer hospital stay (26.8 versus 21.3 days for no VAN AKI), higher mean vancomycin trough levels, longer duration of exposure to vancomycin and a higher Charlston Comorbidity Index (3.5 versus 2.6). Independent predictors for VAN were: vancomycin trough level, hypertension, COPD, congestive heart failure, liver disease, severe obesity and dementia (all p values <0.05). Previous ICU admission and hypotension status did not predict VAN AKI.

Conclusions: We report an incidence of VAN AKI of 15.24% in non-ICU adult patients with no history of ESRD or CKD. Risk factors associated with the development of VAN include mean vancomycin trough level, hypertension, congestive heart failure, COPD, liver disease, severe obesity and dementia.

PO0031
Baseline Urinary Protein Biomarkers as Predictors of eGFR Decline in Cancer Patients Receiving Cisplatin
Melanie S. Joy,1 Blessy George,1 Yichun Hu,2 Susan L. Hogan,2 Xia Wen,3 Lauren Aleksunes.1 1University of Colorado, Skaggs School of Pharmacy, Cancer Center, and Division of Renal Diseases and Hypertension, Denver; CO; 1University of North Carolina, Kidney Center, Chapel Hill, NC; 2Rutgers University, Ernest Mario School of Pharmacy, Piscataway, NJ.

Background: Previous data from our group reported significant changes in urinary biomarkers of sub-clinical kidney injury over 10 days after receiving i.v. cisplatin. The current study evaluated the performance of single and a combination of two urinary biomarkers at the time of cisplatin initiation in predicting a reduction in eGFR.

Methods: Patients (n=57) with solid tumors receiving i.v. cisplatin (225 mg/m2) were included in a study to characterize concentrations of 9 urinary proteins (Table). For the outcome of eGFR decline, the eGFR (MDRD equation) after the first dose and prior to the second dose was used. Statistical models used the baseline urinary biomarker concentrations as predictors. Logistic regression was used to assess Maximum Likelihood Estimates for models containing single and a combination of two urinary biomarkers for prediction of the reductions in eGFR outcome, and reported as odds ratios (OR) with 95% confidence intervals (CI). ROC curves for each model were based on the eGFR reduction outcome. Models were adjusted for age, gender, race and BMI.

Results: A single model for KIM-1 was significant (p=0.0421; OR 0.08; 95% CI 0.01, 0.91) for capturing eGFR decline according to ROC analysis (Table). The six combined models with ROC >0.70 are included in the Table. KIM-1 was a significant contributor in two models when combined with B2M or albumin, but ROC analyses demonstrated similar AUC as the single significant KIM-1 model. Although cystatin C was not significant in a single model (ROC AUC of 0.75), when combined with B2M the ROC AUC (0.77) was the best of all combined models.

Conclusions: Urinary biomarkers have emerged as tools to identify overt and sub-clinical kidney injury. However, single and double combinations of urinary proteins are insufficient to reliably predict reductions in eGFR as an ideal model outcome. Future studies must determine an improved outcome benchmark for evaluating urinary protein biomarkers.

**Kidney Biopsy Findings in AKI in the Cohort of Patients of Mexico Tertiary Hospital**

Belen Martinez-Vazquez, Bernardo Moguel, Virgilia Soto, Octavio R. Garcia-Flores. Instituto Nacional de Cardiología Ignacio Chávez, Mexico, Mexico.

**Background:** The study of the epidemiology of biopsy-confirmed renal disease provides useful information about the prevalence of renal disease and its clinical manifestations. Performing a kidney biopsy is necessary to accurately diagnose diseases such as glomerulonephritis and tubulointerstitial nephritis, among other such conditions.

**Kidney biopsy in acute kidney injury (AKI) of unknown origin provides irreplaceable information for diagnosis, treatment, and prognosis. In this report, we analyze the frequency and clinicopathologic correlations of renal native biopsied AKI in Mexican cohort during the period 2014 through 2019.**

**Methods:** We analyzed the frequency and clinicopathologic correlations of AKI confirmed by native renal biopsy in Mexico tertiary hospital and the distribution of the different clinicopathologic findings. From 2014-2019 period, totally 515 patients first received renal biopsy, AKI was diagnosed based on the Kidney Disease: Improving Global Outcomes criteria.

**Results:** Of the 515 patients investigated, 200 (38.8%) showed AKI. Of these, 102 (51%), 47 (23.5%), and 51 (25.5%) presented with AKI classified as stages 1, 2, and 3, respectively. The primary indication for performing biopsy was rapidly progressive glomerulonephritis (RPGN) in 70 (35%) and nephrotic syndrome in 47 (23.5%).

**Discussion:** We assessed whether AKI is associated with an increased risk of de novo bleeding. Whether these findings are extrapolable to acute kidney injury (AKI) remains uncertain. We investigated further the potential benefit of reducing sUA in male patients treated with RASb should be considered.

**Conclusions:** We observed a high prevalence of AKI in patients who underwent kidney biopsy to investigate their renal disease, particularly glomerulonephritis. The prevalence of vasculitis and crescentic GN is high, especially in elderly patients.

---

**PO0034**

**Risk of Incident Bleeding After AKI: A Retrospective Cohort Study**

Farah Zarka,1 Alexandre Taylor-Gomez,1 Thierry Ducrotte,1 Anatole Duca,1 Martin Gilbert,1,2 Alexandre Bernier-Jean,1 Josee Bouchard.1 1Hôpital du Sacré-Cœur de Montreal, Montreal, QC, Canada; 2CHU Ste-Justine, Montreal, QC, Canada.

**Background:** End-stage kidney disease (ESKD) causes bleeding diathesis; however, whether these findings are extrapolable to acute kidney injury (AKI) remains uncertain. We assessed whether AKI is associated with an increased risk of de novo bleeding.

**Methods:** We conducted a one-year single-center retrospective cohort study, excluding readmissions, admissions less than 24 hours, ESKD or kidney transplant patients. The primary outcome was the development of incident bleeding analyzed by multivariate time-dependent Cox models and independently adjudicated by two investigators.

**Results:** In 1,001 patients, bleeding occurred in 48% of AKI and 57% of non-AKI patients (p=0.007). To identify predictors of incident bleeding, we excluded patients who bled before ICU (n=488). In bleeding-free patients (n=513), we observed a trend toward higher risks of bleeding in AKI (22% vs. 16%,p=0.06), and a higher risk of bleeding in AKI-requiring diagnosis (38% vs. 17%, p=0.01). Cushing, AKI-requiring diagnosis, antihypertensive, and coronary artery disease were associated with bleeding (HR 3.67, 95% CI 1.33-10.25; HR 2.82, 95% CI 1.26-6.32; HR 2.34, 95% CI 1.45-3.80; and HR 1.84, 95% CI 1.06-3.20, respectively), while SOFA score and sepsis had a protective association (HR 0.92, 95% CI 0.84-0.99 and HR 0.55, 95% CI 0.34-0.91, respectively). Incident bleeding was not associated with mortality.

**Conclusions:** AKI-requiring diagnosis was associated with incident bleeding, independent of anticogulant administration. Studies are needed to better understand how AKI affects coagulation and clinical outcomes.

**Funding:** Government Support - Non-U.S.

**Relationship Between Serum Uric Acid Levels and Reduction in Kidney Function Associated With Blockade of the Renin-Angiotensin System**

Marcos G. Nava,1 María Guadalupe C. Núñez,1 Pedro Guadill Bravo,1 Alfredo Fonseca Chávez,2 Bernardo Rodríguez-Iturbe,1,4 Magdalena Madero,1 1Instituto Nacional de Cardiología Ignacio Chávez, Nephrology Department, Mexico, Mexico; 2Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Departamento de Nefrología y Metabolismo Mineral, Talpan, Mexico.

**Background:** Renin-angiotensin system blockade (RASb) induced by treatment with angiotensin type 2 receptor antagonists and angiotensin converting enzyme inhibitors is frequently associated with a reduction in glomerular filtration rate (GFR). Experimental hyperuricemia is associated with dysregulation of renal hemodynamics and reduced GFR. We studied if serum uric acid (sUA) levels are related to the depression of renal function associated to RASb.

**Seizure-Induced Hyperuricemia and Associated Urate Nephropathy: A Prospective Cohort Study**

Jean Maxime Coté,1,2 Guillaume Bolle,1 1Centre Hospitalier de l’Universite de Montreal, Montreal, QC, Canada; 2University College Dublin, Dublin, Ireland.

**Background:** Urate nephropathy is an uncommon cause of acute kidney injury (AKI). Although most factors are associated with tumor lysis syndrome and rhabdomyolysis, occurrence following severe seizure has also been described. There are effective ways to prevent and treat urate-associated AKI, when adequately identified. However, uric acid measurement following convulsion episodes is rarely performed and therefore, the incidence of hyperuricemia in this context is unknown. Our objective was to quantify these metabolic disturbances following severe generalised tonic-clonic seizures (GTCS).

**Methods:** We prospectively recruited patients admitted in our hospital for severe GTCS (≥5 min or a series of seizures with an incomplete return to baseline) and described the kinetics of serum uric acid, creatinine, creatinine kinase and lactate during a 72h follow-up. The urate-to-creatinine ratio was used to monitor urate tubular toxicity.

**Results:** From August 2018 to September 2019, 13 patients with a median GTCS duration of 5.0 minutes (IQR 2.0-12.5) were included. The median serum uric acid was initially 346.0 μmol/L (IQR 155.0-377.5) and decreased to 178.0 μmol/L (IQR 140.0-297.5), while serum creatinine passed from 73.0 μmol/L (IQR 151.0-80.0) to 57.0 μmol/L (IQR 44.0-70.0) over follow-up (Figure). AKI occurred in 4 patients (KIDGO Stage A).

**Conclusions:** Serum uric acid levels increase acutely following a severe GTCS than return to baseline within 3 days. During that period, there is an increased risk of AKI that might be associated with urate nephropathy. To quickly identify and manage patients at risk of acute hyperuricemia and related complications, measurement of uric acid following a GTCS might be beneficial.

Late Presentations of Secondary Oxalate Nephropathy
Muna Hale, Pranay Kathuria. The University of Oklahoma - Tulsa, Tulsa, OK.

**Introduction:** Secondary Oxalate nephropathy is an important differential diagnosis for acute kidney injury (AKI) in chronic malabsorptive disease. Mean presentation is typically within 1-2 years. The following three cases are example of late, abrupt presentations of secondary oxalate nephropathy.

**Case Description:** Our first case includes a 69-year-old female, with gastric bypass surgery 14 years prior, who presented to emergency room (ER) with AKI. Six months prior her creatinine (Cr) was 1.6 mg/dL, but abruptly increased to 5.99 mg/dL. Serologic work up was negative. Renal biopsy was obtained that revealed deposition of oxalate crystals within renal tubules (Figure 1). Our second case showed a 59-year-old male with history of recurrent pancreatitis due to bulimia that presented to the ER for nausea and vomiting. In the ER, patient had a serum Cr of 5.79 mg/dL. Two months prior, Cr was 1.1 mg/dL. Renal biopsy showed widespread oxalate crystals in the interstitium. The last case was a 48-year-old male with chronic pancreatitis who presented with AKI with suspect acute tubular necrosis. He had been diagnosed with chronic pancreatitis for at least 6 years with Cr 0.9 mg/dL. Patient’s Cr remained at 4.00 mg/dL one month later. Renal biopsy revealed interstitial fibrosis and calcium oxalate crystals.

**Discussion:** Secondary oxalate nephropathy is a side effect of malabsorptive gastrointestinal (GI) disorders. According to prior case series, the mean presentation of oxalate nephropathy is 1-2 years. These cases illustrate that secondary oxalate nephropathy can present at a later course with rapid onset. Patients also likely progress to ESRD after diagnosis. A systemic review of 108 cases, with 13 months follow up, showed 55% of patients required hemodialysis. Currently, there is no treatment and lifestyle changes include a low fat, oxalate diet. Secondary oxalate nephropathy should be considered in the differential of all patients with malabsorptive states presenting with AKI.

**Background:** Oxalate nephropathy (ON) is a frequent and often unexpected finding on kidney biopsy. This study aimed to characterize causes and outcomes in biopsy-proven ON not due to known enteric cause or primary hyperoxaluria (PH) in a multisite health system.

**Methods:** Cases were identified based upon diagnosis of ON on kidney biopsy between 2009 to 2020 without known enteric or primary cause.

**Results:** Thirty-four cases were identified with a median follow-up of 11.9 months. None had known fat malabsorption. Genetic testing for PH was negative in 11, and there was no clinical suspicion of PH in the rest. Likely causes of ON included documented high dietary oxalate, oral and/or IV vitamin C supplementation, ethylene glycol, and orlistat. No cause could be identified in 16 (47%). Table 1 shows variables across three etiologies: unknown cause, diet-related, and vitamin C. All cases except one had diffuse intratubular calcium oxalate deposition on biopsy. End stage kidney disease (ESKD) was present in 53%. AKI stage III at biopsy was predictive of ESKD at last follow-up (p=0.05). Treatments included low oxalate diet, calcium supplementation, pyridoxine, and prednisone taper. Table 1 shows rates of AKI stage III at diagnosis (5, 67%), ESKD (3, 43%), and mortality (2, 29%) compared to vitamin C-related ON and ON of unknown etiology.

**Conclusions:** This is the largest study of ON not due to PH or enteric cause. The most common causes were high-oxalate diet and high-dose vitamin C. In 47% of cases no cause was identified. ESKD was common, and AKI severity at presentation predicted ESKD at last follow up. Cases attributed strictly to dietary excess may have better short and long term outcomes.

**Funding:** Clinical Revenue Support
acquiring ESBL producing bacteria in urine or blood cultures. ESBL producing bacteria (0.5%) was the most common pathogen followed by Enterococcus spp. (57.3%) was the most common pathogen followed by Pseudomonas aeruginosa (43%). In this study, we investigated the microbial etiologies of acute pyelonephritis and antibiotic treatment failure of APN due to the increasing prevalence of ESBL producing bacteria. In this study, we investigated the microbial etiologies of acute pyelonephritis and resistance to antibiotics in APN.

Methods: We retrospectively reviewed microbial etiologies and resistance among patients who were admitted to Konyang University Hospital with APN from 2010 to 2018. Two blood cultures at different sites, and urine cultures were performed at the time of admission. Statistical analysis was performed using R (version 4.0.0).

Results: The total number of patients with APN was 882, and Escherichia coli (37.3%) was the most common pathogen followed by Klebsiella spp. (2.8%). Enterococcus spp. (2.2%), Proteus spp. (0.9%), Enterobacter spp. (0.6%) and Pseudomonas aeruginosa (0.5%). The rate of ESBL producing bacteria has steadily increased over 9 years from 6.3% to 37.8%. Multivariate analysis showed that male sex (OR 2.395; 95% CI 1.201-4.776), APN occurrence after 2015 (OR 1.170; 95% CI 1.057-1.296) and antibiotic treatment failure of APN. The rate of ESBL producing bacteria has steadily increased over 9 years from 6.3% to 37.8%. Multivariate analysis showed that male sex (OR 2.395; 95% CI 1.201-4.776), APN occurrence after 2015 (OR 1.170; 95% CI 1.057-1.296) and antibiotic treatment failure of APN due to the increasing prevalence of ESBL producing bacteria. In this study, we investigated the microbial etiologies of acute pyelonephritis and resistance to antibiotics in APN.

Methods: We retrospectively reviewed microbial etiologies and resistance among patients who were admitted to Konyang University Hospital with APN from 2010 to 2018. Two blood cultures at different sites, and urine cultures were performed at the time of admission. Statistical analysis was performed using R (version 4.0.0).

Results: The total number of patients with APN was 882, and Escherichia coli (37.3%) was the most common pathogen followed by Klebsiella spp. (2.8%). Enterococcus spp. (2.2%), Proteus spp. (0.9%), Enterobacter spp. (0.6%) and Pseudomonas aeruginosa (0.5%). The rate of ESBL producing bacteria has steadily increased over 9 years from 6.3% to 37.8%. Multivariate analysis showed that male sex (OR 2.395; 95% CI 1.201-4.776), APN occurrence after 2015 (OR 1.170; 95% CI 1.057-1.296) and antibiotic treatment failure of APN. The rate of ESBL producing bacteria has steadily increased over 9 years from 6.3% to 37.8%. Multivariate analysis showed that male sex (OR 2.395; 95% CI 1.201-4.776), APN occurrence after 2015 (OR 1.170; 95% CI 1.057-1.296) and antibiotic treatment failure of APN.

Conclusions: Although quinolone and 3rd cephalosporin are recommended for empirical treatment of APN, there is a high risk of treatment failure due to the significant increase of ESBL producing bacteria in the community. Antibiotic therapy with APN should ideally be based on local patient characteristics and their antibiotic susceptibility profiles.

Incidence of AKI After IV Vitamin C Treatment for Septic Shock: A Cohort Analysis of Real-World Application

Thomas R. McCune,1 Jintaing Luo,2 Brynn E. Sheehan,2 Stephen T. Petz,1 Muhammad K. Sheraei,1 Sunita Dodani,1,2 Eastern Virginia Medical School, Norfolk, VA; 1EMVS-Sentara Healthcare Analytics and Delivery Science Institute (HADS), Norfolk, VA; 1Nephrology Associates of Tidewater, Norfolk, VA.

Background: Septic shock patients exhibit a high prevalence of vitamin C deficiency, and intravenous vitamin C (IVC) may provide a survival advantage. Preliminary findings from early studies were promising, however, recent studies fail to show a benefit of vitamin C on mortality. Case reports observed that IVC may be related to acute kidney injury (AKI) through oxalate-nephropathy. While IVC in sepsis merits further research, clinicians at one institution began the use of IVC as additional treatment for septic shock.

Note: A logistic regression revealed that the odds of AKI were 2.57 times higher for IVC patients compared to non-IVC patients (95% CI 2.053, 2.31).

Pembrolizumab and Proton Pump Inhibitor-Induced Nephrotoxicity: A Case Report

Nicholas L. Kuro, LewisGale Medical Center LewisGale Medical Center, Salem, VA.

Introduction: Immune checkpoint-blocking antibodies have shown promise in the treatment of a wide range of malignancies. This medication function by blocking down-regulating immune system cells, thus augmenting anti-tumor immunity. In mice, it was observed that the immune system can result in immune related adverse events and can affect any organ system. One immune-related adverse event is acute interstitial nephritis. Proton pump inhibitors, themselves, have been implicated in causing acute interstitial nephritis. There is little research regarding synergism of checkpoint inhibitors and proton pump inhibitors can cause severe kidney injury. This case report reviews patients’ clinical course in which they experienced acute interstitial nephritis while receiving pembrolizumab and omeprazole.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Case Description: A 64 year old female with non-small cell lung cancer stage IV with brain metastasis was initiated on pembrolizumab therapy seven months prior to presentation. Three weeks prior to presentation she started omeprazole 20mg daily. At time of presentation the creatinine was found to be 3.07 mg/dL, up from 0.8 mg/dL eleven days prior, improved with cessation of the PPI, however shortly after the PPI was restarted and creatinine again rose and peaked at 7.6 mg/dL. Renal biopsy was performed and confirmed interstitial nephritis. The patient was started on prednisone 1mg/kg/day with rapid improvement in renal function back to baseline.

Discussion: There has been some research linking both pembrolizumab and pembrolizumab in combination with other chemotherapeutic agents to kidney injury. However, in these trials many patients who suffered kidney injury were also receiving proton pump inhibitors, a class of medications known to provoke acute interstitial nephritis. If synergism can be proven, this combination would be avoided, thus preventing this immune related adverse event. Furthermore, reinitiation of check point inhibitors alone after cessation of the PPI and normalization of kidney function in cases such as these, could be trialed.

PO0043
Zolpidem Mega Dose Resulting in Hemodialysis

Introduction: Depression and hyperventilation syndromes are factors that may be overlooked when prescribing Zolpidem. Although hypnotics are not directly associated with rhabdomyolysis, they can lead to severe intoxication and prolonged immobilization. This can lead to compartmental crush syndromes and depressed respiratory drive and may cause seizures. As consequence of the above renal failure ensued and hemodialysis was required.

Case Description: This case portrays a 36-year-old law student who tried to end his life with the ingestion of 90 Zolpidem pills. As consequence of his metabolic derangement he had seizures, rhabdomyolysis and renal failure that required hemodialysis. Due to prompt intervention, hemodynamic stability and full recovery were achieved.

Discussion: A 36-year-old man with hypertension, insomnia and epilepsy was brought to the emergency room by ambulance. Chief complaint was of disorientation and seizures after the ingestion of 90 Zolpidem pills. He was initially combative, disoriented and with incoherent speech. Once consulted, he presented a Glasgow Coma Scale of 3 for which fluid expansion and observation became the new therapy goals. Even BUN and serum creatinine as well as rapidly increasing CPK from 500 to 44,101 U/L, creatinine 2.0 mg/dL, Na 148 mmol/L, CO2 <5 mmol/L, Creatine Kinase (CK) 1,516 U/L. A peripheral blood smear showed few sickle cells. His urine was dark tea-colored and on urinalysis had large blood and minimal RBCs. Illicit drug panel, autoimmune studies, myophosphorylase deficiency, and myositis panel including anti-SSA, anti-PM/Scl, and anti-U1RNP were normal or negative. A hemoglobin electrophoresis demonstrated 35% Hgb S and 62% Hgb A consistent with SCT. He was oliguric and was started on renal replacement therapy (RRT) with CVVH initially and then iHD. His CK and sCr peaked at 565,000 U/L and 13.9 mg/dL respectively (figure 1). He required 18 days of RRT. His sCr after discharge improved to 1.4 mg/dL.

Discussion: SCT is normally a relatively benign condition as there is enough normal Hgb to prevent significant sickling. However, increased O2 demand with exertion may promote clinically significant sickling and lead to vaso-occlusion and hypoxic muscle injury. ER in SCT is rare and unpredictable and therefore specific recommendations for re-introduction of exercise are not available. However, guidelines for Exercise Collapse Associated with Sickle Cell Trait (ECST) can be used to guide long term patient management.

PO0044
Severe Exertional Rhabdomyolysis with AKI Associated with Sickle Cell Trait
Zi R. Zhang, Edward Qian, Roger A. Rodby. Rush University Medical Center, Chicago, IL.

Introduction: Exertional rhabdomyolysis (ER) is a pathological breakdown of muscle cells which can result in acute kidney injury (AKI) from multiple mechanisms including tubular toxicity from hemoglobin, pigment, cast formation, and volume depletion. ER has a host of etiologies including drugs, infections, infestations, electrolyte abnormalities, trauma, venom, and metabolic disorders. Sickle Cell Trait (SCT), a generally asymptomatic condition, has been rarely associated with ER. We present a case of severe ER with AKI in a previously healthy patient who was determined to have SCT as the only risk factor.

Case Description: A 39 y/o previously healthy black police recruit on no medications presented with myalgias and dyspnea following a routine training regimen. He was found to have diffuse tenderness and weakness of arms and legs. Initial labs showed serum creatinine (sCr) 2.0 mg/dL, Na 148 mmol/L, CO2 <5 mmol/L, Creatine Kinase (CK) 1.516 U/L. A peripheral blood smear showed few sickle cells. His urine was dark tea-colored and on urinalysis had large blood and minimal RBCs. Illicit drug panel, autoimmune studies, myophosphorylase deficiency, and myositis panel including anti-SSA, anti-PM/Scl, and anti-U1RNP were normal or negative. A hemoglobin electrophoresis demonstrated 35% Hgb S and 62% Hgb A consistent with SCT. He was oliguric and was started on renal replacement therapy (RRT) with CVVH initially and then iHD. His CK and sCr peaked at 565,000 U/L and 13.9 mg/dL respectively (figure 1). He required 18 days of RRT. His sCr after discharge improved to 1.4 mg/dL.

Further inquiry elicited dietary intake of 1-2 cups of peanuts daily. 24-hr urine collection showed serum creatinine 15.4 mg/dL, blood urea nitrogen (BUN) 107 mg/dL, potassium 8.7 mEq/L, total CO2 8.8 mmol/L. Urinalysis was unremarkable. Imaging showed no renal obstruction. Stool sample tested positive for C difficile. Emergent dialysis was initiated for hyperkalemia. Despite adequate supportive measures, the patient remained oliguric and dialysis dependent. A kidney biopsy, on day 5, showed extensive tubular deposition of calcium oxalate crystals, and moderate to severe tubulointerstitial fibrosis.

Further inquiry elicited dietary intake of 1-2 cups of peanuts daily. 24-hr urine collection showed no hyperoxaluria (urine oxalate 24 mg/24hr; ref range: 7-44). The patient remains dialysis dependent.

Discussion: Acute oxalate nephropathy in the setting of Clostridium difficile colitis is rare. We report a case of oxalate nephropathy in the setting of Clostridium difficile colitis in a patient with high dietary oxalate ingestion.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

PO0045
A Case of Oxalate Nephropathy in the Setting of Clostridium difficile Infection
Vasalatha Chalisheemala, Niraj Desai, Krishna P. Balabhadrapatruni, Louis Stokes VA Medical Center, Cleveland, OH; 1,2 Case Western Reserve University School of Medicine, Cleveland, OH; 1,2 University Hospitals Cleveland Medical Center Department of Orthopaedics, Cleveland, OH.

Introduction: While hyperoxaluria is a known complication of inflammatory bowel diseases, it is rarely associated with infectious forms of colitis. We report a case of oxalate nephropathy in the setting of Clostridium difficile colitis in a patient with high dietary oxalate ingestion.

Case Description: A 73 year-old black male with stage 3 CKD, diabetes mellitus, hypertension, and hyperlipidemia presented with a 2-week history of intractable diarrhea after finishing a course of oral antibiotics prescribed for acute diverticulitis. Laboratory data showed serum creatinine 15.4 mg/dL, blood urea nitrogen (BUN) 107 mg/dL, potassium 8.7 mEq/L, total CO2 8.8 mmol/L. Urinalysis was unremarkable. Imaging showed no renal obstruction. Stool sample tested positive for C difficile. Emergent dialysis was initiated for hyperkalemia. Despite adequate supportive measures, the patient remained oliguric and dialysis dependent. A kidney biopsy, on day 5, showed extensive tubular deposition of calcium oxalate crystals, and moderate to severe tubulointerstitial fibrosis.

Further inquiry elicited dietary intake of 1-2 cups of peanuts daily. 24-hr urine collection showed no hyperoxaluria (urine oxalate 24 mg/24hr; ref range: 7-44). The patient remains dialysis dependent.

Discussion: Acute oxalate nephropathy in the setting of Clostridium difficile colitis is rarely reported. The hypothesized etiopathogenesis likely relates to altered gut microbiome, specifically decreased Oxalobacter formigenes, leading to impaired oxalate degradation, increased oxalate absorption, and subsequent hyperoxaluria (potentially transient) leading to calcium oxalate deposition in the kidneys and AKI. Treatment is mainly supportive. For acute kidney injury in the setting of acute or chronic diarrhea illness, oxalate nephropathy should be considered. Recovery rates are low, with over 50% of patients remaining dialysis dependent.
Calcium oxalate crystals in tubules (PAS stain, polarized light)

PO0046

Postnatal AKI due to a Rarely Seen Neoplastic Phenomenon in an Adolescent

Ana L. Prashad cortez,1 Rasheda Amin,2 Carly R. Varela.1 Inova, Falls Church, VA; 2Pediatric Specialists of Virginia, Fairfax, VA

Introduction: AKI is an important cause of morbidity & mortality in adult and pediatric patients. Based on a lit review by Cleto-Yamane, et al., the pediatric incidence & mortality of AKI in the USA in 2013 was 0.39% and 15.3%, respectively. In general, a patient’s presentation may provide clues to the etiology of AKI (i.e. prerenal, intrarenal and postrenal). AKI due to postrenal/obstructive causes is less common in children as compared to adults and is usually associated with congenital abnormalities e.g. posterior urethral valves, or acquired due to stones or tumors. We report the case of a 14 yo previously healthy female with a unique clinical presentation due to lower urinary tract obstruction secondary to a tumor.

Case Description: The patient presented with 3 weeks of back pain, R leg swelling, headaches, urinary frequency, n/v and hematuria. In the ED, her BUN and creatinine were 107 mg/dL and 21.1 mg/dL, respectively. A RUS showed enlarged non-echogenic kidneys compared to adults and is usually associated with congenital abnormalities e.g. posterior urethral valves, or acquired due to stones or tumors. We report the case of a 14 yo previously healthy female with a unique clinical presentation due to lower urinary tract obstruction secondary to a tumor.

Discussion: Our patient’s clinical presentation was atypical in that her initial US findings of mild hydronephrosis were not consistent with the severity of her renal injury. Her AKI was likely a combination of obstructive uropathy from the large pelvic tumor compressing her lower urinary tract & uric acid nephropathy. Decompression of the urinary system, management of hyperuricemia & initiation of tumor directed chemotherapy resulted in marked improvement of kidney function. Our case highlights the importance of considering an obstructive etiology in older children presenting with AKI.

PO0047

Profiling AKI Trajectories: Early Results from the Million AKI Project

Benjamin C. Bowe,1,2 Yan Xie,1,2 Andrew K. Gibson,1 Miao Cai,1,2 Hong Xian,2 Geetha S. Maddukuri,1 Ziyad Amin,1 Carly R. Varela.1 Inova, Falls Church, VA; 2Pediatric Specialists of Virginia, Fairfax, VA

Background: Clinical guidelines for risk stratification of acute kidney injury (AKI) patients are based on peak increases in serum creatinine (SC). These definitions do not consider other characteristics of change in SC that may provide information on risk of adverse outcomes. Identification of patient groups that display distinct patterns in trajectory of SC and outcome profiles may lead to more nuanced risk-based definitions of AKI.

Methods: Data from the United States Veterans Health Administration were obtained. A latent class growth model identified patient groups based on similar patterns of AKI. Consider other characteristics of change in SC that may provide information on risk of adverse outcomes. Identification of patient groups that display distinct patterns in trajectory of SC and outcome profiles may lead to more nuanced risk-based definitions of AKI.

Results: We constructed a cohort of 480,575 veterans with an AKI during an inpatient stay (a subset of the Million AKI Project cohort). Of these, 343,471 (71.2%), 63,665 (13.3%), and 73,439 (15.3%) met KDIGO AKI stages 1, 2, and 3 criteria. 9.4% died during their hospitalization. We identified 9 latent trajectories summarized by 4 phenotypes: a mild increase in SC from low baseline (66%), and varying degrees of increase in SC with no (9%), moderate (17%), and near-full recovery (8%). Higher systolic blood pressure (OR=1.02; 95% CI=1.01-1.02 per 1 mmHg), sepsis (2.24; 2.10-2.39), non-use of ACE/ARB (1.54;1.47-1.61), diuretic use (1.16; 1.12-1.20), albuminuria (1.36; 1.31-1.41), and prior history of AKI (1.27; 1.22-1.32) were associated with trajectories with larger increases in SC, while major surgeries (2.46; 2.37-2.60) were associated with trajectories that recovered. Compared to the mild increase group, those with partial or no recovery had a higher odd of in-hospital mortality (1.64; 1.57-1.71) that increased in magnitude with higher baseline SC and a greater increase in SC (2.73; 2.66-2.80). Groups that experienced near-full recovery showed no evidence of a difference in mortality profile (0.97; 0.90-1.05) despite differences in other aspects of the trajectory.

Conclusions: Leveraging the depth and breadth of a high-quality longitudinal electronic health record system, we characterized nearly half a million cases of AKI; our results suggest that profiling of AKI trajectories informs risk stratification and may guide development of post AKI care.

Trends in Nephrology Follow-Up After an Episode of AKI in US Veterans

Ryan Sobhaney,1 Houssam Mhanna,1 Maggie Yin,1 Diane Steffick,1 Vahakn Shahinian,1 Nilka Rios Burrows,2 Meda E. Pavkov,3 Raymond K. Hsu,3 Neil R. Rowe,4,5 Kara Zivin,6,7 Rajiv Saran,8 Michael Heung.1 University of Michigan Division of Nephrology, Ann Arbor, MI; 2Centers for Disease Control and Prevention, Atlanta, GA; 3University of California San Francisco, San Francisco, CA; 4Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; 5University of Michigan, Ann Arbor, MI; 6US Department of Veterans Affairs, Ann Arbor, MI

Background: KDIGO guidelines recommend evaluating patients following AKI for new onset or worsening CKD. Yet, historically nephrologist referral post-AKI has been low. We sought to determine recent trends in outpatient nephrologist follow-up after a hospitalization with AKI.

Methods: We assembled a national cohort of US veterans surviving 30-days post hospitalization with KDIGO creatinine-defined AKI from 2008 to 2017, excluding those with ESRD or kidney transplant, those requiring dialysis within 30 days of hospital discharge, or discharged to hospice. The primary outcome was the proportion of AKI survivors completing an outpatient visit with a nephrologist within 6 months of their AKI hospitalization. To assess trends, we assessed the association of year (as a continuous variable) with follow-up in a Cox proportional hazards model adjusting for age, race, sex, AKI stage, hypertension, diabetes, CKD, Charlson Comorbidity Index, ICU utilization, acute myocardial infarction, acute heart failure, and hospital admitting service.

Results: Of the 480,200 survivors of AKI, 12.2% had a visit with a nephrologist within 6 months. The proportion of patients with nephrology follow-up ranged from 10.0% in stage 1 AKI to 43.8% in patients with AKI requiring inpatient dialysis. The proportion of patients receiving post-AKI care increased across the study period, from 11.8% in 2008 to 15.4% in 2017 (figure). Upon adjusting for demographics, comorbid conditions, and hospitalization characteristics, year remained a significant predictor of increasing nephrology follow-up after AKI (per year HR 1.024, 95% CI 1.021-1.027, p<0.01).

Conclusions: From 2008 to 2017, there was a modest increase in post-AKI follow-up that persisted after accounting for changing demographic, comorbid conditions and hospitalization characteristics. However, most patients with severe AKI did not have an outpatient visit with a nephrologist at 6 months, highlighting opportunities to improve processes of post-AKI care.

Preoperative Urine Alpha 1 Microglobulin Levels Are Associated with AKI and Mortality After Cardiac Surgery
Jonathan G. Amatrupa, Amit X. Garg, Heather Thiessen Philbrook, Eric McArthur, Steven G. Coca, Chirag R. Parkh, Michael Shlipak, TRIBE-AKI Consortium. 1University of California San Francisco, San Francisco, CA; 2Kidney Health Research Collaborative, UCSF, San Francisco, CA; 3Western University Schulich School of Medicine and Dentistry, London, ON, Canada; 4ICES, London, ON, Canada; 5Johns Hopkins University School of Medicine, Baltimore, MD; 6Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Higher urine alpha-1 microglobulin (a1m) levels are a marker of proximal tubule dysfunction and may improve CKD assessment and risk stratification. We hypothesized that a1m levels would be associated with adverse outcomes after cardiac surgery.

Methods: In 1464 adults undergoing cardiac surgery (CABG and/or valve) and prospectively enrolled in the multicenter TRIBE-AKI study, we measured urine a1m pre- and post-operatively. Outcomes were post-operative AKI during index hospitalization (AKIN stage ≥2) and all-cause mortality (median follow-up (IFR) 6.7 (4.0, 7.9) years). Urine a1m was analyzed as a continuous (log10) predictor in multivariable analyses adjusting for demographics, surgery characteristics, comorbidities, baseline eGFR, urine albumin, and urine creatinine.

Results: There were 230 AKI events and 459 deaths. Higher pre-operative a1m was independently associated with AKI (aOR=1.36, 95% CI 1.14-1.62) and all-cause mortality (HR=1.19, 95% CI 1.06-1.33) (see table). We observed a significant interaction (p=0.01), whereby a1m had a stronger association with mortality in the subset without CHF (aHR=1.29, 95% CI 1.02-1.63) compared to those with CHF (aHR=1.06, 95% CI 0.85-1.32). However, post-operative changes in a1m were not associated with AKI or mortality risk.

Conclusions: Even after adjusting for baseline kidney function and comorbidities, preoperative a1m was associated with AKI and all-cause mortality.

Funding: Other NIH Support - NHLBI; study also supported by NIH grant RO1HL088577 (CRP) to fund the TRIBE-AKI Consortium.

PO0050
Elevated Serum Tenasin C Predicts All-Cause Mortality in Critically Ill Patients with Multiple Organ Dysfunction
Qionghong Xie, Xu Yunyu, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: Tenasin-C (TNC) is a matricellular protein that is rarely expressed in most of adult tissues, but re-induced following injury. This study aimed to evaluate serum TNC in predicting all-cause mortality in critical ill patients with multiple organ dysfunction.

Methods: Adult critical ill patients who met the criteria of at least two organs dysfunction and acute organ injury with an increase of SOFA ≥2 points within 7 days were prospectively enrolled in one derivation cohort (Medical ward) and one external validation cohort (Surgery ward). Serum TNC was measured within the first 24 hours after enrollment and the association between serum TNC and 28-day all-cause mortality was analyzed.

Results: A total of 113 patients with median age 56 (38, 66) years and male of 65.2% in derivation cohort were included. The patients with median (quartile) age of 64 (53, 73) and male of 67% in validation cohort were enrolled. Serum TNC was 210.2 (96.8, 469.6) ng/ml in derivation cohort and 229.4 (141.6, 472.5) ng/ml in validation cohort, both significantly higher than that in healthy controls (median 80.9 ng/ml, n=46, p<0.001 for both). The TNC levels were also significantly associated with the critical illness scores such as SOFA, APACHE II and SAPS II, as well as 28-day mortality (p<0.001 for all). Compared to the patients with TNC<300ng/ml, patients with TNC≥300ng/ml had a remarkably higher 28-day mortality (38.6% vs. 14.1%, p=0.003 in derivation cohort; 57.8% vs. 13.8%, p<0.001 in validation cohort). In a post-hoc analysis, serum TNC was independently associated with the mortality after adjustment for age, gender and SOFA in both cohorts. The areas under the Receiver Operating Curve of TNC for 28-day mortality was 0.797 in derivation cohort and 0.803 in validation cohort, not inferior to SOFA (0.844 and 0.808), APACHE II (0.86 and 0.872) and SAPS II (0.872 and 0.797).

Conclusions: Serum TNC was significantly increased in critical ill patients with multiple organ dysfunction and was positively associated with the severity of illness and all-cause mortality. It was a useful prognostic tool for predicting all-cause mortality in critical ill patients.

PO0051
Predominance of Mitochondrial Protein Composition in Urinary Sediment Enriched with Muddy Brown Granular Casts During Acute Tubular Necrosis
Vinip Varghese, Megan Golubs, Frank C. Abbruscato, Michael G. Janecz, Juan Carlos Q. Velez. 1Ochsner Nephrology • Ochsner Clinical School - University of Queensland, LA; 2University of Vermont College of Medicine, Charlotte, Charleston, SC; 3Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.

Background: Detection of copious numbers of “muddy” brown granular casts (MBGCs) during microscopic examination of the urinary sediment (MicrExUrSed) is pathognomonic of acute tubular necrosis (ATN). Because hospital laboratories do not regularly report MBGCs, nephrologists are required to independently perform MicrExUrSed, a time-consuming and logistically challenging endeavor that requires expertise. Thus, a diagnostic test to identify MBGCs without the performance of MicrExUrSed could prove useful for busy clinicians. We hypothesized that MBGCs-enriched urinary sediment (MBGC-sedi) contains unique proteins that could serve as surrogate and biomarker of ATN.

Methods: MicrExUrSed was performed in specimens from patients with acute kidney injury (AKI) seen for nephrology consultation with a suspected etiology of ATN. Urine specimens from 3 patients containing numerous (>10 casts per low power field) MBGCs were collected and subjected to low-speed centrifugation (100 g) and stored at ±8°C. Thawed pellets and urine were proteolytically digested and analyzed by nano-LC tandem mass spectrometry (Orbitrap Fusion Lumos). Proteins were identified by Mascot and classified by gene ontology.

Results: We identified 1678 proteins (1% false discovery rate) from supernatant and MBGC-sedi combined. Among them, 711 proteins were unique to MBGC-sedi and 27 were unique to the supernatant. Normalized spectral abundance of 242 MBGC-sedi proteins was greater compared to the supernatant (p<0.003) and had proportionally more mitochondrial proteins (17 ± 1% vs. 6 ± 1%, respectively, p=0.0084). Based on spectral count and unique abundance, the most abundant at least 3 unique proteins in all 3 samples included: ATP synthase alpha and beta-subunit, isocitrate dehydrogenase, 60kDa heat shock protein, and aconitate hydratase. Six out of 7 cytochrome proteins identified were unique to MBGC-sedi.

Conclusions: MBGC-sedi contains unique proteins compared to the supernatant. These proteins can serve as a foundation for the search of an ATN biomarker and surrogate for MBGCs detection by MicrExUrSed in patients with AKI. The predominance of mitochondrial proteins in MBGCs-sedi may explain the characteristic brown pigmentation of MBGCs.

PO0052
Treatment of Hepatorenal Syndrome Type 1 with Terlipressin Reduces Need for Artificial Reperfusion Therapy After Liver Transplantation
Juan Carlos Q. Velez, Seth Selair, Antonio J. Sanchez, Stephen Caldwell, Samuel Sigal, Paul J. Thuluvath, Rohit Satoskar, Chris S. Pappas, Khurrum Jamil. 1Ochsner Health System, New Orleans, LA; 2University of Iowa Hospitals & Clinics, Iowa City, IA; 3Montefiore Medical Center, Bronx, NY; 4Malinckrodt Pharmaceuticals Specialty Brands Principal Office, Bedford, Md; 5University Hospitals Cleveland Medical Center Department of Nephrology, Cleveland, OH; 6MedStar Georgetown University Hospital, Washington, DC; 7University of Virginia, Charlottesville, Va; 8Orphan Therapeutics, Lebanon, NJ; 9Mercy Medical Center & University of Maryland School of Medicine, Baltimore, MD.

Background: Hepatorenal syndrome type 1 (HRS-1) is a severe but reversible acute kidney injury in patients with cirrhosis. The need for renal replacement therapy (RRT) posttransplant is associated with prolonged intensive care unit stays and decreased survival. Recently, a randomized placebo (PBO)-controlled trial (CONFIRM, NCT02770716) demonstrated the efficacy of terlipressin (TERLI) for inducing reversal of HRS-1 and reducing the cumulative need for RRT. This study assessed whether TERLI reduces the rate of RRT following liver transplantation (LT).

Methods: CONFIRM was a North American trial (N=300) that compared HRS-1 reversal rates between patients treated 2:1 with albumin plus TERLI (n=199) or albumin plus PBO (n=101). In a post hoc analysis, we assessed the rate of RRT post-LT by intention-to-treat analysis through 90 days of follow-up. We also conducted a pooled analysis of the 3 TERLI RCTS in HRS-1 (OT-0401 [NCT00889570], REVERSE [NCT01797710], and CONFIRM) to examine 90-day overall and RRT-free survival rates in patients who received LT.

Results: In CONFIRM, 23.1% (46/199) of patients in the TERLI group and 28.7% (29/101) of patients in the PBO group underwent LT. Following LT, the rate of post-LT RRT in patients who received TERLI was significantly lower than that in those who received PBO (19.6% [9/46] vs 44.8% [13/29], respectively; p=0.036). The overall 90-day survival rate for those transplanted in the TERLI group was 100% (46/46) compared with 93.1% (27/29) in the PBO group (p=not significant). Further, in the pooled analysis of the 3 RCTS (n=143246), the 90-day survival rates were 98.9% (93/94) and 90.8% (87/95), respectively (p=0.14). In the pooled analysis of REVERSE and CONFIRM, for transplant-listed patients, 50.0% (46/92) of patients in the TERLI group were alive without RRT at Day 90 compared with 32.2% (19/59) in the PBO group (p=0.032).

Conclusions: Treatment with TERLI added to albumin for patients with HRS-1 significantly decreases the need for RRT following LT.

Urinary Waxy Casts Are Associated with Persistence of AKI Requiring Dialysis
Maria Soledad Rivera,1 Vinip Varghese,2 Akanksh Ramanand,3 Ali A. Alalwan,2 Juan Carlos Q. Vélez,2 Ochsner Nephrology 4 Ochsner Clinical School - University of Queensland, New Orleans, LA; 2Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.

Background: Waxy casts (WxCs) can be identified during microscopic examination of the urinary sediment (MicrExUrSed) and they have been classically linked to chronic kidney disease (CKD). We previously showed that WxCs predict severity of acute kidney injury (AKI). Thus, we hypothesized that WxCs may inform about duration and persistence of AKI and AKI requiring renal replacement therapy (AKI-RRT).

Methods: We conducted a prospective observational study in patients seen in inpatient nephrology consultation with AKI stage ≥2 (AKIN) over 2.5 years. On the day of consultation, MicrExUrSed was performed to determine the percentage of low power fields with WxCs. The outcome measures were persistence of need for RRT at the time of hospital discharge (AKI-RRT-Persist) and a decrease in serum creatinine (sCr) from baseline at the time of hospital discharge (AKI-Persist).

Results: Urine specimens from 286 patients [median age 60 (20 – 88), 37% women] were assessed. The etiology of AKI (de novo AKI 67%, AKI on CKD 33%) was ischemic AKI (47%), toxic AKI (9%), ischemic/toxic AKI (11%) or other (33%). WxCs were found in 85 patients (30%), 61 (72%) of which had de novo AKI. Median sCr for those with WxCs was 3.5 (0.9 – 22.0)mg/dL and 3.1 (0.9 – 12.5) mg/dL for those without WxCs (p<0.12). AKI-RRT at any point during the course of AKI was seen in 45% (38/85) of those with WxCs compared to 32% (54/201) of those without WxCs (p=0.043). There was a greater AKI-RRT-Persist for those with WxCs [15.3% vs 7.5%, odds ratio (OR): 2.2, CI 1.1 – 4.9, p=0.046]. Presence and abundance of WxCs were also associated with a greater risk for AKI-Persist [62% (94/152), 75% (45/60), 81% (29/36) and 93% (13/14), for those with no WxC, any WxC, >10% WxCs and >50% WxCs, respectively; chi-square for trend p=0.014].

Conclusions: In patients with AKI, the presence and abundance of WxCs are associated with a greater risk for persistent need for RRT and persistent increase in sCr at the time of hospital discharge. These findings suggest that WxCs inform about the severity of AKI and the timeline of significant AKI recovery.

P00054

Retrospective Analysis of the Efficiency of Caplacizumab in the Treatment of Acquired Thrombotic Thrombocytopenic Purpura: Results from the P00020 Study Group
Lucas Kuehn,1 Jessica K. Kauflund,2 Jan Menne,2 Paul T. Brinkkorter,1 Linus A. Volker.1 REACT-2020 study group ‘University Hospital Cologne, Cologne, Germany; 2Hannover Medical School, Medizinische Hochschule Hannover, Hannover, Germany.

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is a rare but life-threatening disorder, caused by the formation of inhibitory and occasionally non-inhibitory autoantibodies against ADAMTS13. Despite plasma exchange and immunosuppression, long-term morbidity and mortality associated with acute episodes remain high. Here, caplacizumab – a monkey approved in Germany in 2018 – has recently expanded the therapeutic options.

Methods: Retrospective analysis of the use of caplacizumab in more than 60 patients from more than 30 different medical centers in Germany during acute disease management.

Results: Caplacizumab led to a rapid normalization of the platelet count (median 3, mean 3.78 days). In 34/60 instances, caplacizumab was stopped prior to day 30 with favorable outcome, whenever ADAMTS13 activities were >10%. In contrast, 11/34 patients with ADAMTS13 activities <10% at the time of stopping caplacizumab treatment develop a non-favorable outcome comprising disease exacerbation or relapse. In some cases, prolongation of the treatment interval to every other day was feasible and resulted in a sustained reduction of the vWF activity. Clinicians agreed with early protocolized fluid removal and expressed desire to enroll their patients in a future clinical trial.

Conclusions: Caplacizumab is efficacious in the treatment of aTTP immediately of timing and adjunct treatment modalities. Based on this real-world experience and published literature we propose to administer caplacizumab to all patients with an acute episode of aTTP immediately. ADAMTS13 activity measurements are central for a rapid diagnosis in the acute setting but also to tailor disease management. In addition, vWF activity may serve as biomarker for drug monitoring.

Erythropoiesis-Stimulating Agents in AKI Requiring Dialysis
Jan Mceoy,1 Kathleen D. Liu,2 Chi-yuan Hsu.1 Stanford University School of Medicine, Palo Alto, CA; 2University of California San Francisco, San Francisco, CA.

Background: Erythropoiesis-stimulating agents (ESAs) are used in patients with CKD to treat anemia. AKI may also be a state of erythropoietin deficiency, although data on this is conflicting. Few studies have examined ESA use in AKI, including the most severe AKI stages (AKI-D). It is unknown whether and to what extent clinicians prescribe ESAs in AKI-D.

Methods: Among the more than 40,000 patients admitted to Beth Israel Deaconess Medical Centers between 2001 and 2012 in the MIMIC-III database, we selected 591 AKI-D patients and 276 ESKD patients based on ICD-9 diagnostic codes. In a cross-sectional analysis, we determined the frequency of ESA usage and estimated associations between ESA use and age, sex, surgical (vs medical) ICU admission, ICU length of stay, admission hemoglobin, admission serum creatinine, history of CKD, and ESKD (versus AKI-D) status using multivariable logistic regression. We also examined the relationship between ESA use and the number of blood transfusions during AKI and ICU stay.

Results: ESA use (any time during ICU stay) was 13% in AKI-D vs 21% in ESKD. Among AKI-D patients (Table 1), CKD (adjusted OR 3.59, 95% CI 2.06-6.25, p<0.0001), length of stay (1.06 [1.04-1.08] per day, p<0.0001), sepsis (2.06 [1.08-3.92], p=0.03), and female sex (0.53 [0.31-1.00], p=0.05) were significantly associated with ESA use. Patients treated with ESAs received six more blood transfusions on average than patients who were not treated with ESAs (6.1 more transfusions, 95% CI 2.6-9.7, p=0.0006), but this difference disappeared when adjusted for the variables significantly associated with ESA usage (de 22 more transfusions, 95% CI 3.4-32, p=0.067).

Conclusions: ESA usage in patients with AKI-D was not rare. Baseline renal failure was the biggest predictor of ESA usage. Use of this costly therapy of unclear risk-benefit ratio in the AKI-D population should be studied further.

Survey of US Critical Care Practitioners on Perspectives Toward Net Ultrafiltration Prescription and Practice
Huiwen Chen,2 Raghavan Murugan.2 University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA.

Background: Previous studies suggest international practice variation in net ultrafiltration (UF NET) among critically ill patients with acute kidney injury treated with kidney replacement therapy. We examined U.S. critical care practitioner attitudes toward UF NET prescription and practice.

Methods: Secondary analysis of a multinational, cross-sectional, internet-assisted, open survey administered to intensivists, nephrologists, advanced practice providers, ICU and dialysis nurses in the U.S.

Results: Of 1,569 international survey respondents, 465 (29.6%) practitioners were from the U.S. Practitioners were mostly nurses and nurse practitioners (58%) and intensivists (38.2%). Median duration of practice was 8.7 (IQR 4.2-19.4) years and 63.4% practiced in a university- based hospital. Practitioners reported using continuous kidney replacement therapy (CRRT) as the first modality for UF NET in 60% (IQR 20-90%) of their patients with median UF NET rate of 51 mL/h (IQR 25-100 mL/h) for hemodynamically unstable and a maximal rate of 285 mL/h (IQR 200 - 341 mL/h) for hemodynamically stable patients. 58.3% (range 28.7%-79.2%) of practitioners assessed net fluid balance hourly. Hemodynamic instability was reported in 25% (IQR 10-100%) of the patients, and practitioners decreased the rate of fluid removal (71.2%), started or increased dose of a vasopressor (56.8%); completely stopped fluid removal (44.5%); and administered a fluid bolus (28.7%). Most clinicians (79.8%) reported patient intolerance as a major barrier. Other barriers include frequent interruptions (50.1%), under prescription of trained staff (17.3%), inability to titrate fluid removal (10.1%), and urine less (6.8%) and cost (2.4%) (Figure 1). More than 70% of clinicians agreed with early protocotolized fluid removal and expressed desire to enroll their patients in a future clinical trial.

Conclusions: This study provides new knowledge on UF NET in practices in the U.S. We also identified barriers and specific targets for quality improvement initiatives. Our data reflect the need for evidence-based practice guidelines for UF NET.

A Pilot Trial to Evaluate the Clinical usefulness of Contrast-Enhanced Ultrasound in Predicting Renal Outcomes in Patients with AKI
Suveen Hong,1 Da won Kim,2 Dongryul Kim,2 Seok Joon Shin,3 Hy Eun Yoon,4 Uijeongbu St. Mary’s Hospital, Uijeongbu, Republic of Korea; 1Incheon St. Mary’s Hospital, Incheon, Republic of Korea.

Background: Contrast-enhanced ultrasound (CEUS) enables the assessment of real-time renal microcirculation. This study investigated CEUS-driven parameters as biomarkeric predictors for renal outcomes in patients with acute kidney injury (AKI).

Methods: Forty-eight patients who were diagnosed with AKI were prospectively enrolled and underwent CEUS at the occurrence of AKI. Parameters measured were the wash-in slope (WIS), time to peak intensity, peak intensity (PI), area under the time–intensity curve (AUC), mean transit time (MTT), time for full width at half maximum, and rise time (RT). The predictive performance of the CEUS-driven parameters for Kidney Disease Improving Global Outcomes (KDIGO) AKI stage, initiation of renal replacement therapy (RRT), AKI recovery, and chronic kidney disease (CKD) progression was...
assessed. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic performance of US.

Results: Cortical RT (Odds ratio [OR] = 1.21) predicted the KDIGO stage 3 AKI. Cortical MT (OR = 1.07) and RT (OR = 1.20) predicted the initiation of RRT. Cortical WIS (OR = 76.23) and mediastinal RT (OR = 1.25) predicted AKI recovery. Mediastinal P1 (OR = 0.87) and AUC (OR = 1.00) predicted CKD progression. The areas under the ROC curves showed reasonable performance for predicting the initiation of RRT and AKI recovery. The sensitivity and specificity of the quantitative CEUS parameters were 60–83% and 62–77%, respectively, with an area under the curve of 0.69–0.75.

Conclusions: CEUS may be a supplemental tool in diagnosing the severity of AKI and predicting renal prognosis in patients with AKI.

Funding: Government Support - Non-U.S.

A Clinical Score to Predict Recovery in ESKD due to AKI
Silvi Shah, Anthony C. Leonard, Kathleen Harrison, Karthikeyan Meganathan, Annette Christiani, Samantha M. Kramer, Charusha V. Thakar, University of Cincinnati, Cincinnati, OH; Cincinnati VA Medical Center, Cincinnati, OH.

Background: Acute kidney injury (AKI) is a major contributor to end-stage kidney disease (ESKD). About one-third of patients with ESKD due to AKI recover kidney function. However, there is lack of clinical models to predict kidney recovery in ESKD due to AKI.

Methods: Using data from the United States Renal Data System (2005-2014), we developed a clinical score to predict kidney recovery by 90-day post-dialysis initiation in patients with ESKD due to AKI (N=22,922). We used multivariable logistic regressions to model the effects of patient demographics, comorbidities, and laboratory measures on kidney recovery. The resulting logistic parameter estimates were transformed into integer point totals by doubling and rounding the estimates. The predictive accuracy of the score models was compared to the underlying logistic models by comparing areas under the receiver operating characteristic curves (AUROC) and internal validation was performed.

Results: In ESKD due to AKI, kidney recovery within 90-days occurred in 24% of patients. Median recovery time for patients who recovered was 2 months; 72% recovered within 90-days. In the logistic models of recovery at 90-days, older age, lower body mass index, hemoglobin < 12 gm/dl, Black and Native American race, Hispanic ethnicity, congestive heart failure, amputation, poor functional status, and pre-dialysis nephropathy care were associated with a lower likelihood of recovery. Eight patient characteristics were included in the final clinical score: age, body mass index, race, congestive heart failure, amputation, functional status, and prior nephropathy care. Recovery scores ranged from zero to 11, with corresponding recovery rates ranging from 6% to 86%. Three risk categories (score range of 0-3, 4-6, and 7-11) exhibited 90-day recovery rates of 11%, 23%, and 45%. The internal validation assessment showed no overfitting of the models. The AUROC of the score was 0.70, similar to the original AUROC of 0.71.

Conclusions: A simple clinical risk score derived from information available at incident dialysis can accurately predict kidney recovery at 90 days in ESKD due to AKI. This predictive tool can be utilized by dialysis providers and policymakers to individualize care, and to improve the quality and processes of care.

AKI in Hospitalized Patients with Inflammation Is Associated with Worse Outcomes: A Study of National Inpatient Sample from 2012 to 2014 in the United States
Nasha Elavag, Si Li, Ibithola Yusuf, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Influenza causes significant morbidity and mortality every year. Physiologically, kidneys receive only 25% of the cardiac output in an average weight adult and therefore often develop acute kidney injury (AKI). Our study determines outcomes of AKI in adults hospitalized with influenza between 2012 and 2014 in the U.S.

Methods: We analyzed adult patients with a principal diagnosis of influenza from the 2012 to 2014 National Inpatient Sample. ICD-9-CM was used to identify the diagnosis variables. Patients were divided into two cohorts: with and without AKI. Patient characteristics between both groups were compared. Chi-squared analysis for categorical diagnosis variables. Patients were divided into two cohorts; with and without AKI. Patient characteristics between both groups were compared. Chi-squared analysis for categorical

Results: Among 2012 to 2014 National Inpatient Sample (2012 to 2014), we found 101,402 adult and therefore often develop acute kidney injury (AKI). Our study determines outcomes of AKI in adults hospitalized with influenza between 2012 and 2014 in the U.S. We searched Pubmed (Medline), EMBASE and Cochrane databases for

Conclusions: AKI in hospitalized patients with influenza is associated with worse outcomes in terms of morbidity and mortality along with increased healthcare costs and a longer length of stay.

Impact of Chloride-Rich Crystalloids on Sepsis-Associated Communi-
ty-Acquired AKI Recovery in Critically Ill Patients
Shahroz Tehranian,1 Khaled Shaswawa,1 Erin F. Barretto,2 Casey M. Clements,1 Reihaneh Kashani,1,4 Department of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 1Department of Pharmacy, Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN; 2Department of Emergency Medicine, Mayo Clinic, Rochester, MN; 3Department of Medicine, Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.

Background: The use of chloride-rich crystalloids for resuscitation is associated with developing acute kidney injury (AKI). We aimed to explore the impact of resuscitation with chloride-rich crystalloids compared to balanced crystalloids on the recovery of kidney function in patients presenting with established sepsis-associated community-acquired AKI (SACA-AKI).

Methods: This was a single-center, historical cohort study of patients admitted to the intensive care unit (ICU) who presented to the emergency department (ED) with SACA-AKI at Mayo Clinic, Rochester, MN, from January 2011 to April 2018. We divided the cohort into two groups based on the primary type of crystalloids received in the ED and the first 48-hours of ICU. The first group received primarily saline with <20% balanced solutions, and the second group received at least ≥20% balanced crystalloids during the initial volume resuscitation.

Results: We included 736 patients who were resuscitated with crystalloids after SACA-AKI diagnosis (mean age 64±16, n = 463 (63%) males). There were 286 (39%) males in the second group, found to have higher positive fluid balance during the first 48-hours of admission compared to the first group [median 5.7 (IQR: 3.6; 8) vs. 3.8 (IQR: 2.1; 6.1) L, P < 0.001]. By multivariable logistic regression, the patients in the second group had a higher rate of kidney function recovery after adjustments for known recovery risk factors (OR 1.4; 95% CI: 1.04-2.1; P = 0.027).

Conclusions: The use of balanced crystalloids during the initial resuscitation is associated with higher odds of kidney function recovery in patients with SACA-AKI.

The Effect of Care Bundles for AKI: A Systematic Review and Meta-Anal-
ysis
Yixin Chen, Fangfang Zhou, Qun Luo. HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.

Background: Acute kidney injury (AKI) is common and associated with increased morbidity and mortality. Implementation of a set of evidence-based AKI care bundles may have some benefits to patient outcomes by reducing variable standards of care. We aimed to systematically review the literature to quantify the effect of AKI care bundles on patient outcomes.

Methods: We searched PubMed (Medline), EMBASE and Cochran databases for studies that compare the effect of AKI care bundles with usual standard care in patients with or at risk of AKI from database inception to December 31, 2019. The quality of included studies was assessed using the Newcastle-Ottawa Scale. Heterogeneity was
assessed using Cochrane Q test and I² test statistics. Data were analyzed by RevMan 5.3 and Comprehensive meta-analysis (CMA 3.0). The primary outcome was in-hospital or longest follow-up mortality. Secondary outcomes included AKI incidence and AKI severity.

**Results:** A total of 11 studies (23,491 patients) were included in the meta-analysis. The implementation of AKI care bundles significantly reduced mortality in all patients (odds ratio, 0.87; 95% CI, 0.79–0.94; p = 0.001; I² = 0%; Fig 1). And in patients at high risk for AKI (identified by novel biomarker, risk prediction score or electronic alert), care bundles significantly reduced AKI incidence (odds ratio, 0.62; 95% CI, 0.44–0.86; p = 0.005; I² = 70%; Fig 2) and rates of AKI severity (odds ratio, 0.52; 95% CI, 0.35–0.76; p = 0.001; I² = 41%; Fig 3). In addition, there was no evidence of publication bias among the included studies.

**Conclusions:** The introduction of AKI care bundles can effectively improve outcome in patients with or at risk of AKI, especially when combined with novel biomarker, risk prediction score or electronic alert to manage AKI at early stage. However, the evidence so far is limited and not strong enough to make definite conclusions.

**PO0062**

**Block Randomized Implementation of a Decision-Making Algorithm for Renal Replacement Therapy Initiation in AKI Compared with Standard Care on AKI-Related Outcomes**

Yvelynne P. Kelly,† Salman Ahmed,† David E. Leaf,‡ Ernest I. Mandel,† Emily S. Robinson,‖ Gearoid M. McMahon,† Peter G. Czarnecki,† David M. Charytan,† Sushrut S. Waikar,‡ Mallika L. Mendu.† Brigham and Women’s Hospital, Boston, MA; †Boston Medical Center, Boston, MA

**Background:** Acute kidney injury (AKI) requiring renal replacement therapy (RRT) is associated with high mortality and utilization. Clinical decision-making related to AKI-RRT initiation in the intensive care setting is not standardized.

**Methods:** We conducted a 12 month single center block randomized controlled trial in the intensive care units (ICUs) of a large academic tertiary medical center; alternating use of an AKI Standardized Clinical Assessment and Management Plan (SCAMP), a decision-making algorithm to guide front-line clinicians, with use of a “sham” control form in 4-6 week randomization blocks. The SCAMP provided recommendations about optimal indications for initiating RRT on the basis of various clinical parameters, whereas the sham control form did not provide any recommendations for management of AKI-RRT.

**Results:** 122 patients were managed with AKI-SCAMP while 102 patients were managed using the sham control form. There was no significant difference in the primary outcome of odds of inpatient, 30-day or 60-day mortality associated with use of the AKI-SCAMP. With respect to secondary outcomes, use of the AKI-SCAMP resulted in a reduced 30-day hospital readmission rate (odds ratio 0.38; 95% CI 0.15–0.99, p = 0.05). And in patients at high risk for AKI (identified by novel biomarker, risk prediction score or electronic alert), care bundles significantly reduced AKI incidence (odds ratio, 0.62; 95% CI, 0.44–0.86; p = 0.005; I² = 70%; Fig 2) and rates of AKI severity (odds ratio, 0.52; 95% CI, 0.35–0.76; p = 0.001; I² = 41%; Fig 3). In addition, there was no evidence of publication bias among the included studies.

**Conclusions:** The introduction of AKI care bundles can effectively improve outcome in patients with or at risk of AKI, especially when combined with novel biomarker, risk prediction score or electronic alert to manage AKI at early stage. However, the evidence so far is limited and not strong enough to make definite conclusions.
Renin Levels Are Higher in Patients with AKI and Associate with Mortality and Major Adverse Kidney Events

Victor M. Ortiz-Soriano,1 Fabiola Gianella,2 Alexander H. Flannery,1 Xilong Li,1 Chirag R. Parikh,1 Sherry Mansour,1 Orson W. Moe,1 Stuart Goldstein,1 Javier A. Neyra,1 University of Kentucky, Lexington, KY; 1University of Texas Southwestern Medical School, Dallas, TX; 1Yale University School of Medicine, New Haven, CT; 2Johns Hopkins University, Baltimore, MD; 1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Renin is a marker of tissue perfusion and may be useful in predicting mortality in critically ill patients. Renin might also reflect structural kidney damage in heterogeneous AKI settings. We examine if renin levels are different in patients with vs. without AKI and if renin levels associate with adverse outcomes in critically ill patients.

Methods: Multicenter observational study utilizing blood samples of critically ill patients (KLAKI) and patients undergoing cardiac surgery (TRIBE-AKI). Renin was measured by ELISA in serum from 296 critically ill patients at 24-48 h of AKI diagnosis (KDIGO ≥2) or ICU admission (controls), and perioperatively in plasma from 105 patients undergoing cardiac surgery (35 with AKI [≥0.3 mg/dL increase or ≥50% increase in serum creatinine from baseline preoperative level to postoperative level] and 70 controls without AKI). The association of renin levels with hospital mortality and major adverse kidney events at hospital discharge (MAKE: composite of death, need of renal replacement therapy or inability to recover more than 75% of baseline eGFR) was evaluated in the critically ill group.

Results: Renin levels were higher in critically ill patients with AKI vs. ICU controls without AKI (median [IQR], 67.9 [21.7-343.7] vs 22.2 [6.4-73.0] pg/mL, p<0.001). Similarly, patients undergoing cardiac surgery who developed postoperative AKI had pre and postoperative renin levels differentially higher than those without AKI, sustained by 16% (95%CI: 1-33%) of renin level in the lowest tertile). Further, every 1-unit increase in renin increased the risk of MAKE with increased risk of hospital mortality (OR: 1.27, 95%CI: 1.02-1.58 for every 1-unit increase in renin and OR: 3.44, 95%CI: 1.08-11.02 when the highest tertile was compared to the lowest tertile). Further, every 1-unit increase in renin increased the risk of MAKE by 16% (95%CI: 1.33%).

Conclusions: Renin levels are differentially higher in patients with heterogeneous AKI when compared to controls without AKI. Renin levels associate with hospital mortality and MAKE in critically ill patients and therefore its utility in risk-stratification should be further explored in this vulnerable population.

Angiotensin 1-7 as a Novel Biomarker of AKI in Pediatric Kidney Transplant Recipients

Lauren Ehrhart-Humbert, Ashton Chen, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

Background: While graft survival rates of pediatric kidney transplant recipients have improved dramatically, acute kidney injury (AKI) accounts for up to 21% of graft failure in pediatric patients and prompt diagnosis of AKI is difficult. AKI activates the renin-angiotensin system (RAS), leading to increased angiotensin (Ang II)-induced inflammation and fibrosis. The ACE2/Ang-(1-7) pathway mitigates these effects but may be downregulated in AKI. The objective was to investigate Ang II and Ang-(1-7) as biomarkers in pediatric kidney transplant recipients. We hypothesized that changes in Ang II and Ang-(1-7) over time would predict biopsy-proven AKI in the first 6 months post-transplant.

Methods: This was a prospective cohort study of children recruited from a kidney transplant evaluation clinic. Blood and urine were collected pre-transplant and post-transplant at several time points. Ang II and Ang-(1-7) were measured with radioimmunoassays. Participants underwent for-cause or surveillance biopsies and histologic findings were recorded. We applied directed acyclic graph-inkformed Cox proportional hazards regression analysis with robust standard errors adjusted for age to estimate the association of time-varying Ang II and Ang-(1-7) with AKI.

Results: Of the 27 participants, mean age was 11.7 ±6.1 years, 63% were male, and 44% were Caucasian. The most common cause of kidney failure was congenital anomalies of the kidney and urinary tract (30%) and 74% were Caucasian. The most common cause of kidney failure was congenital anomalies of the kidney and urinary tract (30%) and 44% were Caucasian. The most common cause of kidney failure was congenital anomalies of the kidney and urinary tract (30%). Patients with AKI had a higher prevalence of chronic kidney disease (53.2% vs. 10.1%), hypertension (74.5% vs. 47.5%). After adjusting for age, patients with AKI were more likely to die in the hospital, had a longer length of stay, higher inpatient care costs. Thus, the presence of AKI poses a significant burden on patients with SLE. Close monitoring and early treatment are warranted in this population.
AKI After Lung Transplantation: A Retrospective Analysis from a Single Transplantation Center
Johanna Wijk,1,2 Sven-Erik Ricksten,1,2 Göran Drellgren,3 Per Ederoth,4 Edgars Grins,4 Lukas Lannemeyr,1,2 1Department of Anesthesia and Intensive Care, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2Department of Cardiothoracic Anesthesia and Intensive Care, Sahlgrenska University Hospital, Gothenburg, Sweden; 3Department of Cardiothoracic Surgery, Sahlgrenska University Hospital, Gothenburg, Sweden; 4Department of Thoracic Anesthesia and Intensive Care, Skåne University Hospital, Lund, Sweden.

Background: Acute kidney injury (AKI) is a common and serious complication after lung transplantation (Ltx). No data from the Swedish Ltx program have been published, and thus we performed a retrospective analysis of AKI after Ltx at our unit.

Methods: After ethical board approval, all patients ≥18 years who underwent Ltx in Gothenburg, Sweden, between 2012–2016 were assessed. Exclusion criteria were: death within 48 hours, multiple organ transplantsations or pre-operative dialysis. AKI was defined according to the KDIGO creatinine criteria and the AKI group was compared to the patients without AKI using Mann-Whitney U-tests or Chi²-tests as appropriate. A multivariate logistic regression model for pre- and intraoperative predictors of AKI was built.

Results: In total, 211 patients were transplanted 2012–2016, and 197 patients were analyzed. Of these, 37% developed AKI within 1 week after Ltx (grade 1; 58%, grade 2; 29%). AKI was associated with increased mortality at 30 days (5.5% vs. 0.8%, p=0.044) and at 1 year (26.0% vs. 8.9%, p=0.001). In the regression model, higher age (mean age 41.3±10.4, p=0.001), more likely to be male (53.1% vs. 44.4%, p=0.001), congestive heart failure (22.5% vs. 4.4%, p=0.001), diabetes mellitus (9.8% vs. 3.5%, p=0.001) were associated with significantly increased risk for in-hospital death and later CKD/ESRD. AKI affected more than 1/3 of the patients after Ltx, and was associated with significantly increased risk for in-hospital death and later CKD/ESRD. Randomized controlled trials are needed to investigate the role of AKI in premature infants.

Conclusions: AKI and cyst-c in urine can be used as biological indicators for the diagnosis of AKI in premature infants.

AKI in Sickle Cell Disease
Si Li, Nasha Elavia, Yichen Wang, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Sickle cell disease may cause acute injury to the kidney, especially during sickle cell crisis. Which mainly related to underlying stress-induced renal vasculopathy and alterations in glomerular hemodynamics. There is a paucity of national-level evidence showing the effect of acute kidney injury (AKI) on patients hospitalized with sickle cell disease. We aim to quantify the relationship between AKI and mortality and resource utilization in patients with sickle cell disease.

Methods: We analyzed adult patients admitted from 2012 to 2014 with a primary or secondary diagnosis of sickle cell disease using the Nationwide Inpatient Sample (NIS). The NIS is the largest publicly available inpatient database in the United States (U.S.). It contains data from approximately 8 million hospital stays each year, representing a 20% stratified sample of all U.S. non-federal hospitals, and is sponsored by the Agency for Healthcare Research and Quality and the Healthcare Cost and Utilization Project (HCUP). The International Classification of Diseases, Ninth Revision, Clinical Modification Coding System (ICD-9-CM) was used to identify comorbidities. Survey multivariate regression analysis was performed using STATA 16.0.

Results: We included 240,550 admissions with sickle cell disease, majority of them were black patients (93%). 10,825 (4.5%) of sickle cell disease patients had AKI. Patients with AKI were older (mean age 41.3±12.5 vs. 31.1±10.4, p<0.001), more likely to be male (53.1% vs. 44.4%, p<0.001). Sickle cell disease patients had higher prevalence of hypertension (49.9% vs. 16.8%, p<0.001), coronary artery disease (6.3% vs. 2.1%, p<0.001), congestive heart failure (22.5% vs. 4.4%, p<0.001), diabetes mellitus (9.8% vs. 3.5%, p<0.001). After adjusting for patient and hospital-level confounders, patients with AKI had higher odds of mortality (adjusted odds ratio [aOR] 11.3, 95% confidence interval [CI] 7.04–18.34, p<0.001), a longer length of stay (2.6 days, 95% CI: 2.21–2.93 days, p<0.001), higher costs ($6707.2; 95% CI: $5816.2–$7598.3, p<0.001).

Conclusions: The demographic characteristics were significantly different between patients with or without AKI. Sickle cell nephropathy imposes a burden on both individual and health care systems. Randomized controlled trials are needed to investigate the role of vaso-occlusive events on AKI development.
Early identifying high risk patients for AKI progression might help physicians to enhance individualized monitoring and personalized management in patients with septic AKI.

**Methods:** This is a prospective, multicenter cohort study which enrolled adult septic patients who initially developed stage 1 or 2 AKI in the ICU from January 2014 to March 2018. Sepsis was diagnosed based on the 2016 Sepsis-3 criteria, and AKI was diagnosed and staged according to 2012 KDIGO-AKI guidelines. Renal arrest biomarkers (urinary TIMP2*IGFBP7 [uTIMP2*IGFBP7] and urinary damage biomarkers (urinary KIM-1 [uKIM-1] and urinary IL-18 [uIL-18]) were measured at time of AKI clinical diagnosis, and the utility of biomarkers for predicting septic AKI progression alone or in combination was evaluated. The primary outcome was AKI progression defined as worsening of AKI stage. The second outcome was receiving dialysis or death during ICU stay.

**Results:** A total of 149 septic patients with stage 1 or 2 AKI were included, 63 patients developed progressed AKI, 49 patients received dialysis or died during ICU stay. uTIMP2*IGFBP7, uKIM-1 and uIL-18 independently predicted the progression of septic AKI in which uTIMP2*IGFBP7 showed the greatest AUC (0.75; 95%CI, 0.667-0.823) as compared to uKIM-1 (AUC 0.719; 95%CI, 0.638-0.800) and uIL-18 (AUC 0.619; 95%CI 0.525-0.731). Combination of uTIMP2*IGFBP7 with uKIM-1/uIL-18 further improved the performance of predicting septic AKI progression with AUCs of 0.752 (uTIMP2*IGFBP7 with uKIM-1) and 0.747 (uTIMP2*IGFBP7 with uIL-18), respectively. uTIMP2*IGFBP7, alone or combined with uKIM-1/uIL-18, improved the risk reclassification over the clinical risk factor model alone both for the primary and secondary outcomes, as evidenced by significant category-free net reclassification index.

**Conclusions:** Combination of renal arrest and damage biomarkers enhanced the prediction of AKI progression in patient with sepsis and improved risk reclassification over the clinical risk factor model alone.

**Bicarbonate May Not Be the Best Treatment for Rhabdomyolysis: A Retrospective Cohort Study**

Hye Won Kim,1 Yunseo Lee,2 Sejoong Kim.1 1Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea

**Background:** It is controversial whether the use of bicarbonate solution, which has been traditionally attempted to treat rhabdomyolysis, has the beneficial effect of reducing acute kidney injury (AKI) and mortality, compared with the use of non-bicarbonate solution. The purpose of this study is to analyze whether bicarbonate therapy versus non-bicarbonate therapy may be effective in preventing AKI and death in patients with rhabdomyolysis.

**Methods:** We collected 4077 hospitalized patients with creatinine kinase (CK) > 1000 U/L and divided them into 2 groups: patients who received fluid with bicarbonate and who received fluid without bicarbonate. Patients were subgrouped into low (<2ml/kg/hr), middle (2-4ml/kg/hr) and high (≥4ml/kg/hr) fluid rates. The primary outcome was the occurrence of AKI (defined as the increase of serum creatinine ≥ 0.5mg/dL in 48 hours). The secondary outcome was the occurrence of mortality. The bicarbonate group compared with the non-bicarbonate group.

**Results:** In a total of patients with a mean age of 57.9 years (male 66.7%), bicarbonate-containing solution was used in 61.1% of the participants. The proportion of the subjects were 34.6%, 36.5%, and 28.9% for the low, middle, and high fluid rate, respectively. The bicarbonate group showed higher incidence rate of AKI (OR 4.89), higher 1-year mortality (OR 3.1) and longer hospital stay (26.6 ± 54.4 vs. 22.0 ± 22.7 days) than the non-bicarbonate group. Patients who received high amount of fluid therapy showed higher incidence rate of AKI (OR 3.1), higher of dialysis dependency (OR 2.7) and higher 1-year mortality (OR 1.4), compared with low fluid group, regardless of the use of bicarbonate. The use of bicarbonate (adjusted HR [aHR] 1.55), volume overload (aHR 1.28) were associated with higher mortality while the use of furosemide (aHR 0.8) showed the preventive effect. Baseline CK or peak CK were not related to the risk of dialysis or death. Volume overload was significantly higher in the bicarbonate group compared with the non-bicarbonate group.

**Conclusions:** We showed bicarbonate therapy or high-volume fluid management in patients with rhabdomyolysis were not beneficial in preventing AKI and death, compared with the non-bicarbonate therapy or low-volume fluid management. It suggests that limited use of bicarbonate and adjustment of fluid volume may improve the short-term and long-term outcome of rhabdomyolysis.

**Plasma Metabolites Do Not Change Significantly After 48 Hours in Patients on CRRT**

Benjamin R. Griffin,1 Matthew Ray,1 Kristy Roloff,2 John T. Brinton,2 Javier A. Neyra,2 J Pedro Teixeira,4 Kirby Mayer,1 Katja M. Gist,2 Muhammad Aftab,1 Diana J. Jala,1,3 Julie Haines,2 Sarah Faubel,2,4 University of Iowa, Iowa City, IA; 2University of Colorado, Denver, CO; 3University of Kentucky, Lexington, KY; 4University of New Mexico, Albuquerque, NM; 5Iowa City VA Medical Center, Iowa City, IA; 6VA Eastern Colorado Health Care System, Aurora, CO.

**Background:** Continuous renal replacement therapy (CRRT) is used in critically ill patients with hemodynamic instability. One of the primary aims of CRRT is to remove solutes that accumulate due to impaired kidney function. Surprisingly, few studies have assessed plasma solute levels during CRRT, and the duration of CRRT necessary to achieve adequate solute removal is unknown.

**Methods:** To assess the effect of CRRT on plasma solutes, metabolites were determined via untargeted ultra-high pressure liquid chromatography coupled to mass spectrometry (UHPLC-MS) in 13 critically ill patients requiring CRRT. Metabolites were assessed on plasma collected prior to CRRT initiation, and on plasma and effluent collected on days 1, 2, and 3 thereafter.

**Results:** A total of 101 annotated metabolites were evaluated. Plasma levels of 22 metabolites (21.8%) were significantly reduced by Day 1 of CRRT, and included creatinine, phosphate, lactate, and the amino acids alanine, proline, and cysteine. Only 2 metabolites (2.9%) were significantly reduced between Day 1 and Day 2, and none were reduced between Day 2 and Day 3. Figure 1 demonstrates that marginal changes in solute levels decrease as CRRT progresses. All metabolites were detected in the effluent, and the sieving coefficients for metabolites that were reduced versus not reduced after CRRT were not statistically different.

**Conclusions:** No further reduction in plasma metabolites occurred after 48 hours of CRRT. Since the median CRRT treatment time is 4-7 days nationwide, with some patients treated substantially longer, these data bring into question the utility of prolonged, uninterrupted CRRT therapy, and have major potential implications for the duration of CRRT in the ICU population.

**Sustained Low-Efficiency Dialysis with Regional Citrate Anticoagulation and a Standard Hemodialysis Machine in Critically Ill Patients with AKI**

Francesca Di Mario,1 Filippo M. Fani,1 Paolo Greco,1 Caterina Maccari,1 Elisabetta Parenti,1 Tommaso Di Motta,1 Maria Teresa Farina,1 Giuseppe Regolisti,1 Enrico Fiacchadori,1 UO Nefrologia, Azienda Ospedaliero-Universitaria Parma, Parma, Italy, Parma, Italy; 2UO Nefrologia e Dialisi, Ospedale San Giovanni di Dio, USL Toscana centrale, Firenze, Italy.

**Background:** Sustained Low-Efficiency Dialysis (SLED) is an increasingly used Kidney Replacement Therapy (KRT) modality in critically ill patients with Acute Kidney Injury (AKI); in this setting regional citrate anticoagulation (RCA) is a rational approach to avoid extracorporeal circuit clotting. The present study was aimed at evaluating the safety and efficacy of a simplified RCA protocol for SLED with a conventional hemodialysis machine.

**Methods:** SLED was performed for 8-12 hours (daily or every other day) with a Surdial X Nipro® hemodialysis machine and a cellulose triacetate filter (Sureflex-19L, 1.9 m2, KUF 19 ml/min/m²). Blood flow was set at 200 ml/min and dialysis fluid flow at 100 ml/min. Citrate was infused in pre-dilution as ACD-A solution (citrata 2.2%, 112.9 mmol/L) at 200-400 ml/h rates (estimated pre-filter citrate concentration 2-4 mmol/L). Treatment was monitored by serial evaluations of ionized calcium (Ca⁺⁺) and ACT at the beginning, at the 2nd hour and at the end of SLED session. Blood in the extracorporeal circuit was recalcified by the dialysis fluid itself (Ca⁺⁺ 1.5 mmol/L) through Ca⁺⁺ backfiltration; i.e. calcium supplementation was started only if patient Ca⁺⁺ at the 2nd hour was <0.9 mmol/L.

**Results:** 41 SLED sessions were performed in 12 critically ill patients with AKI (mean age 69 ± 18 SD, mean APACHE II 22). Average pre- and post-SLED urea values were respectively 94 and 32 mg/dL. Most sessions (38/41, 93%) were completed for elapsed prescribed time. No statistically significant differences were observed between systemic ACT values measured during SLED as compared to baseline values. Ca supplementation
(10% Ca gluconate at fixed rate 5 ml/hour) was needed in 10/41 treatments, with rapid correction of serum Ca⁺⁺. No new cardiac arrhythmia episode or hemorrhagic events were observed.

**Conclusions:** Our preliminary data suggests that a simplified RCA protocol for SLED using a conventional dialysis machine is easy and safe, also ensuring a good match between prescribed and actual dialysis dose administered.

**PO0075**

**Prediction of AKI in Inpatient General Medical Ward Units**

Cassandra Chiaoy, Rachel Urban, Fauzia Osman, Tripri Singh. University of Wisconsin System, Madison, WI.

**Background:** Acute kidney injury (AKI) is common in hospitalized patients (A). A few scoring systems have been proposed to predict the risk of developing AKI in certain populations such as cardiac catheterization patients (B, C, D, E, F). However, there is no scoring system for predicting AKI in patients on the general medical wards. Our aim is to predict the development of AKI in acute general medical patients.

**Methods:** Retrospective single center study of all adult patient admitted to a tertiary care university hospital between July 2016-July 2018. AKI was defined by the KDIGO definition of AKI and all stages of AKI were included. We used chi-squared tests, ANOVA, and Kruskal Wallis to determine statistically significant factors. We calculated odds of AKI using logistic regression models. All analyses were conducted using STATATA SE 15.

**Results:** A total of 10,981 were included in the study, 1,573 (14.3%) with AKI and 9,408 (85.7%) without AKI. Baseline demographics were significantly different between the two groups including age, race, length of hospital stay (p<0.001). In the univariate analysis, history of cancer and diabetes, proteinuria, admission BUN, hemoglobin (HGB), and hypotension during admission were predictive of AKI. After adjustment for significant univariate factors, age (OR 0.97 (0.96-0.99), p<0.001), admission BUN (OR 1.02 (1.01-1.04), p<0.001), and HGB (OR 0.79 (0.73-0.85), p<0.001) were significant in the multivariate analysis (Table 1).

**Conclusions:** We found that the age, admission BUN, and HGB were predictive of AKI in inpatient general medical units. These criteria can be used in acute general medical patients to create a scoring system to determine the likelihood of developing AKI and therefore prevent AKI and its downstream complications in these patients.

**PO0076**

**Is Procalcitonin a Reliable Marker of Bacterial Infection in Patients with AKI?**

Mariam Charkviani, Sumit Sohal, Natia Murvelashvili, Maria Yanez Bello, Daniela Trelles, Alisha Sharma. Amita Saint Francis Hospital, Evanston, IL.

**Background:** Procalcitonin (PCT) is a biomarker that helps to distinguish bacterial infections from other causes of infection or inflammation and can be used as a helpful adjunct to clinical judgment for resolving diagnostic uncertainty. Limited data is available about the diagnostic value of PCT in patients with acute kidney injury (AKI). We aimed to assess the diagnostic usefulness of serum PCT level as a marker of bacterial infection in patients with AKI and assess the correlation of serum creatinine clearance to serum PCT level.

**Methods:** This retrospective case-control observational study involved patients admitted to the hospital during the study period and had PCT checked. Patients were categorized into proven, possible, and no bacterial infection groups. We compared PCT level in AKI group with proven bacterial infection vs no bacterial infection and PCT level during proven and no bacterial infection groups with AKI vs non-AKI. Patients with end-stage kidney disease and other causes of elevated PCT (pancreatitis, cancer, severe burns) were excluded.

**Results:** 379 patients were analyzed, 24 patients were excluded from the study. 66 patients classified into the AKI group and 226 into the non-AKI group. 107 patients were in a proven bacterial infection group and 98 Patients in no bacterial infection group. The mean value of PCT was significantly higher with confirmed bacterial infection compared to no bacterial infection in all patients despite their renal function (4.98±8.75 vs 1.66±4.88, p<0.001). PCT level was higher in the AKI group than in the non-AKI group (10.99±12.24 vs 2.39±2.93, p<0.001) in patients with a proven bacterial infection. Patients with no infection had much higher PCT level in the AKI group as compared to the non-AKI group (5.76±14.67 vs 0.7±1.39, p<0.003). PCT level was also significantly higher during confirmed bacterial infection vs no bacterial infection in patients with AKI (9.2±11.05 vs 0.7±2.17, p<0.04). There was a weak positive correlation between creatinine clearance and PCT level (correlation coefficient 0.125, p<0.15).

**Conclusions:** Higher cutoff level of PCT is needed in patients with AKI to use it as a marker of infection. The specificity of PCT may decrease in patients in AKI if current reference cutoff values are used to guide clinical decisions.

**PO0077**

**Predicting Outcomes After AKI: Are You Better Than a Machine?**

Tanima Arora, Aditya Biswas, Yu Yamamoto, Michael Simonov, Melissa Martin, Francis P. Wilson. Clinical and Translational Research Accelerator, Yale School of Medicine, New Haven, CT.

**Background:** While multiple studies have used statistical models to predict outcomes after AKI, no studies have compared these models to physician intuition at the time of AKI consult. We studied the accuracy of physicians in predicting outcomes after AKI and compared it to the strength of predictive statistical models.

**Methods:** Our pilot study focuses on the prediction of 3 outcomes after AKI: Recovery, progression to dialysis and mortality. Postgraduate years 4 and 5 level nephrology providers were asked, at the time of initial renal consult, to forecast outcomes at 3 timepoints: 24hr, 48hr and 7 days. We compared physician prognosis to a gradient boosted trees model trained using retrospective EHR data. Our primary measure of performance was area under the receiver operating characteristic curve (AUROC) at each timepoint.

**Results:** Data was captured from 56 patients with stage 2 AKI. Nephrology providers (n=7) were good at predicting dialysis at all three timepoints and death at 48 hours and 7 days. In contrast, their ability to predict recovery of AKI was relatively poor. The statistical model performed significantly better at predicting death at all timepoints, however was poorer at predicting dialysis (Figure 1.0).

**Conclusions:** Both physician clinical acumen and our statistical model showed good performance in predicting need for dialysis and death after AKI, however performed poorly when predicting recovery. This highlights the need to conduct further in-depth research into this area and implement strategies to enhance prediction of recovery after AKI.

**PO0078**

**Short-Term Prognosis of Patients with Cardiorenal Syndrome Type 1-Induced AKI Requiring Continuous Renal Replacement Therapy**

Yusuke Watanabe, Kei Sugiyama, Daichi Fukaya, Hiroaki Amano, Tsutomu Inoue, Hirokazu Okada. Saitama Medical University, Iruma-gun, Japan.

**Background:** Cardio-renal syndrome (CRS) type 1 is a condition wherein an acute heart failure (AHF) leads to the development of acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is used to remove excess solutes and fluids in CRS type 1 patients who have diuretic resistance. However, little is known about the outcomes of CRS type 1 patients who undergo CRRT.

**Methods:** We reviewed the clinical data of 74 consecutive CRS type 1 patients treated with CRRT from 2012 to 2015. Patients who underwent cardiovascular surgery and those who had chronic kidney disease stage 5 prior to admission were excluded. The primary outcome examined was in-hospital mortality.

**Results:** The mean age of patients was 70.6±13.6 years old. The causes of AHF were ischemic heart disease (54.1%), valvular disease (13.5%), and other diseases. At the time of the CRRT initiation, the mean serum creatinine was 2.8±1.0 mg/dL. The in-hospital mortality rate was 77.0%. Compared with non-survivors, the survivors had fewer number of previous hospitalizations for heart failure (50.9% vs. 23.5%, p=0.046), higher systolic blood pressure (97.7±22.2 mmHg vs. 112.3±21.1 mmHg, p=0.02), better ejection fraction (31.4±17.9% vs. 42.0±15.7%, p=0.03), smaller inferior vena cava (IVC) diameter (18.0±5.8 mm vs. 14.8±4.4 mm, p=0.04), lesser respiratory variations in the IVC diameter (59.6% vs. 13.3%, p=0.02), lesser vasopressor requirement (96.5% vs. 31.9%, p=0.001), and lesser respirator support (35.0% vs. 23.5%, p=0.02) at CRRT initiation. The survivors required a shorter CRRT duration over the non-survivors (6.1±6.9 days vs. 11.7±12.4 days, p=0.03). Through the multiple logistic regression analysis, certain factors were associated with a poor short-term prognosis. These factors were history of previous hospitalizations for heart failure, vasopressor requirement upon start of CRRT, and the need for respirator support at CRRT initiation.

**Conclusions:** In our single-center experience, the use of CRRT for treating AKI caused by CRS type 1 was associated with a high-in-hospital mortality rate. Patients with a history of previous hospitalization for heart failure, those who required vasopressors, and patients needing respirator support at CRRT initiation had an especially poorer prognosis.

Roux-en-Y Gastric Bypass Is the Most Common Current Cause of Biopsy-Proven Oxalate Nephropathy

Swetha Reddy,1 John C. Lieske,2 Mira T. Keddis.1 Mayo Clinic Arizona, Scottsdale, AZ; 2Mayo Clinic Minnesota, Rochester, MN.

Background: The objective of this study was to analyze patient characteristics and outcomes of biopsy-proven oxalate nephropathy likely due to an enteric cause at a single large tertiary health system.

Methods: Cases of oxalate nephropathy were identified based on documented kidney biopsy findings between 2009-2019 in patients with an associated enteric process likely to cause fat malabsorption.

Results: A total of 30 cases were identified (mean age of 65.2 ± 8.56 years; 18(60.0%) female) with a median follow-up of 5 months; Risk factors included hypertension in 21(70%), diabetes in 14 (46.7%), chronic kidney disease (CKD) stage 3A or greater in 16(53.3%) and prior kidney stones in 6(20%). The most common enteric causes were Roux-en-Y gastric bypass (RYGB) in 17(56.7%), pancreatic insufficiency in 6(20%), inflammatory bowel disease in 4(13.3%), and recurrent C. difficile infection in 3(10%). At the median time of diagnosis, acute kidney injury (AKI) stage II and stage III were present in 9 (30%) and 15 (50%) respectively, while 11(36.7%) required dialysis. Urinalysis revealed proteinuria in 16(55.2%), oxalate crystals in 10(33.3%), and hematuria in 9(30%). Median plasma oxalate at the time of biopsy was 18.3 (reference 1-20.0) μmol/L in 26 patients and median 24 hour urine oxalate excretion was 53 (reference [9.7-40.5]) mg/24 hrs in 17 patients. RYGB patients had a higher plasma oxalate compared to patients with other enteric causes (median 24.6 vs 16.5 μmol/L; p<0.03). Renal biopsy and clinical outcomes are shown in table1 [table1]. Patients with acute tubular injury had greater number of tubules with calcium oxalate crystals by biopsy (median 19 vs 4), as did patients with CKD5 at last follow-up (20 vs 6). Features at the time of biopsy predictive of CKD5 at follow-up included AKI severity (p=0.002), dialysis at diagnosis (p=0.008), and the presence of moderate to severe tubulointerstitial atrophy (p=0.001).

Conclusions: In this series RYGB was the most common enteric cause of biopsy-proven oxalate nephropathy. Severity of AKI at presentation and degree of tubulointerstitial fibrosis were both associated with worse renal outcome. The amount of renal crystal deposits at diagnosis associated with the short and long term renal injury.

Impact of AKI on In-Hospital Outcomes in Chinese Patients with Community-Acquired Pneumonia

Dawei Chen, Xin Wan. Nanjing First Hospital, Nanjing, China.

Background: Acute kidney injury (AKI) is common in community acquired pneumonia (CAP). However, the impact of AKI on in-hospital outcomes of patients with CAP in the population of Chinese remains largely unknown.

Methods: Multiple Cox regression models were employed to identify the association between AKI and in-hospital mortality and 30-day mortality.

Results: 4213 patients were included, and 950 (22.5%) patients were AKI. The independent risk factors for AKI were age, male, hypertension, cardiac dysfunction, diabetes, chronic kidney disease, acute respiratory failure, diuretic, vasoactive drugs, and CURB-65. After multivariable Cox regression, independent risk factors of in-hospital mortality and 30-day mortality were similar: AKI, CURB-65, diabetes, chronic kidney disease, acute respiratory failure, diuretic, vasoactive drugs, and CURB-65. In addition, patients with AKI were more vulnerable to require intensive care unit (ICU) admission (42.9% vs. 11.4%; P < 0.001), mechanical ventilation (33.8% vs. 9.3%; P < 0.001), invasive mechanical ventilation (25.9% vs. 5.8%; P < 0.001), non-invasive mechanical ventilation (25.4% vs. 7.1%; P < 0.001), and had a longer length of hospital stay (14 days vs. 10 days; P < 0.001) than those without AKI.

Conclusions: AKI was common in Chinese patients with CAP. Patients with CAP who developed AKI had worse in-hospital outcomes.

Mortality Prediction of Serum Neutrophil Gelatinase-Associated Lipocalin in Patients Requiring Continuous Renal Replacement Therapy

Byung-ha Chung,1 Yohan Park,1 Hyung Duk Kim,1 Eun jeong Ko,1 Tae Hyun Ban,2 Cheol Whee Park,1 Chul Woo Yang,1 Seoul Saint Mary’s Hospital, Seocho-gu, Seoul, Republic of Korea; 2Eunpyeong Saint Mary’s Hospital, Eunpyeong-gu, Seoul, Republic of Korea.

**Background:** We investigated whether serum neutrophil gelatinase-associated lipocalin (NGAL) can predict mortality in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

**Methods:** This study enrolled 169 patients who underwent serum NGAL testing at CRRT initiation from June 2017 to January 2019. The predictive power of serum NGAL level for 28-day mortality was compared to the Acute Physiology and Chronic Health Evaluation-II (APACHE-II) score and Sequential Organ Failure Assessment (SOFA) score via area under the receiver operating characteristic curve (AuROC) value.

**Results:** There were 55 survivors and 114 non-survivors at 28 days post-CRRT initiation. Median serum NGAL level was significantly higher in the non-survivor group than in the survivor group (743.0 vs. 504.0 ng/mL, P=0.003). The AuROC value of serum NGAL level was 0.698, and it was an independent risk factor for 28-day mortality (hazard ratio 2.405, 95% confidence interval (1.209-4.783), P=0.012).

**Conclusions:** In patients with AKI requiring CRRT, serum NGAL levels may be useful for predicting short-term mortality in those with low APACHE-II scores.

**Funding:** Government Support - Non-U.S.

**Figure 1. Predictive value for 28-day mortality of serum NGAL level, APACHE-II score, and SOFA score in low APACHE-II score group**

**PO0084**

Prevalence, Length of Stay, and Hospitalization of AKI in Patients with and Without Sjogren Syndrome

Mohamedanwar M. Ghandour, Yahya M. Osman Malik. Wayne State University School of Medicine, Detroit, MI.

**Background:** Acute Kidney Injury (AKI) has emerged as a significant cause of morbidity and mortality in patients with autoimmune diseases. However, this has not been examined in patients with Sjogren’s syndrome (SJS). To achieve this, we examined the prevalence, mortality, outcomes, Length of Stay (LOS), and hospital charges in patients with AKI with SJS compared to patients without SJS from a National Inpatient Sample database in the period 2010-2013.

**Methods:** Data retrieved from the National Inpatient Sample (NIS) for adult patients admitted with a principal diagnosis of acute kidney injury between 2010 and 2013, using the respective ICD-9 codes. The study population divided into two groups, with and without Sjogren’s disease. Multivariate and linear regression analysis conducted to adjust for covariates.

**Results:** The study population represented 97,055 weighted patient discharges with acute kidney injury. Analysis revealed acute kidney injury patients with Sjogren’s compared to patients without Sjogren’s had statistically significant lower hyperkalemia rates (adjusted Odds ratio (OR)0.65, CI 0.46 to 0.92; p =0.017). There was no statistically significant difference in mortality, length of stay, hospital charges, and other outcomes. Moreover, the charges of hospitalization and length of stay were found to be statistically insignificant by the adjusted linear regression model. In addition, nearly three quarters of patients had Medicare, followed by privately insured patients with the least number being on Medicaid. More than half of the population have received their treatment in a tertiary center hospital. Charlson’s index reported more than two-thirds of study subjects to have two or more co-morbidities.

**Conclusions:** At present, our study is unique as it has examined the prevalence, mortality, and outcomes of Sjogren’s in patients with acute kidney injury. Patients with Sjogren’s has had significantly lower hyperkalemia during the hospitalization. Further research is needed to identify the underlying protective mechanisms associated with Sjogren’s that resulted in lower hyperkalemia.

**PO0085**

Clinical Characteristics and In-Hospital Outcomes for 1519 Consecutive Patients with AKI

Christina J. Montgomery,1 Jonas Speak,1 Marie Evans,1 Stefan H. Jacobson.1 2Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, Division of Nephrology, Stockholm, Sweden; 1Karolinska University Hospital Huddinge Department of Renal Medicine, Stockholm, Sweden; 1Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, division of Cardiology, Stockholm, Sweden.

**Background:** Acute kidney injury (AKI) occurs in about 15% of hospitalized patients. Patients who recover from AKI have a higher long-term risk of end-stage kidney disease and death. The aim of this large single center study was to report differences in lab results, hospital findings and short-term hospital outcomes in relation to cause of AKI in consecutive patients in a nephrology department.

**Methods:** We conducted a retrospective chart review of patient data obtained via an electronic database created as part of the MRC’s program in conjunction with the health system’s electronic health record. Descriptive statistics were utilized to describe baseline characteristics. We restricted analyses to participants without end stage kidney disease on admission and those who survived at least 24 hours for an analysis of AKI. Kaplan-Meier plots were utilized to show death free survival by AKI category. All analyses were conducted using the R Statistical Computing Environment.

**Results:** We obtained data for 116 patients in the time period since 2015. Among the 116 patients, 55 patients had AKI defined as doubling of creatinine within 7 days but did not require RRT. Of the remaining 61 patients, 28 developed AKI requiring RRT. Patients who developed AKI or AKI requiring RRT had a mortality of 70% at 30 days. The remaining 33 patients who did not develop AKI had a mortality of 52% at 30 days. Regarding electrolyte derangements, cooling was associated with hypokalemia and hypophosphatemia with 64% percent of patients with potassium less than 3 mmol/L and 57% of patients with phosphorus less than 2 mg/dL.

**Conclusions:** AKI is associated with a high rate of mortality in this unique patient population, and additionally there is marked hypokalemia and hypophosphatemia in the setting of therapeutic cooling. Given the high mortality, this study raises questions regarding optimal treatment strategies when developing AKI, including timing and delivery of RRT and the ideal approach to volume and electrolyte management.
Methods: All patients diagnosed with AKI between 2009 and 2018 and admitted to the nephrology department at Danderyd University Hospital, Stockholm, Sweden, were included. Relevant laboratory and physiological measures were registered. Patients on dialysis treatment were excluded. Patients were followed until discharge or death, whichever came first.

Results: In 1519 AKI patients, the majority (n=667) was of prerenal, followed by combined (defined as chronic kidney disease combined with any type of AKI) (n=536), renal (n=166), and postrenal (n=130) etiology. Patients with renal AKI were younger, had longer duration of stay, and had higher bicarbonate levels on admission. 63.2% of patients had a >30% decrease of SCr during their stay. Most of these had prerenal followed by postrenal etiology. There was no statistically significant difference in mortality between the four etiologies of AKI.

Conclusions: This study provides data from a large, contemporary AKI patient cohort under nephrology care. We confirm that patient characteristics as well as short-term outcomes differ substantially in patients of various AKI etiology. Greatest in-hospital reduction of SCr was seen in patients with prerenal and postrenal AKI, whereas patients with renal and combined AKI had poorer renal recovery. These findings have important implications for prognostic evaluation upon admission and further resource planning.

Traditional and Non-Traditional Risk Factors and Their Influence on In-Hospital Mortality in Community- vs. Hospital-Acquired AKI

Maria Isabel Acosta-Ochoa, Armando Coca, Jimmy R. Sanchez Gil, Alicia Mendiluce. Hospital Clinico Universitario de Valladolid, Valladolid, Spain.

Methods: Many studies compare hard outcomes in Community Acquired (CA-AKI) vs. Hospital Acquired AKI (HA-AKI), but few works contrast how various risk factors (RF) impact in-hospital mortality risk in both groups.

Results: We included 1269 cases, 69% in the CA-AKI group. The HA-AKI group showed a higher ChI, had longer hospital stay, were less frequently admitted to medical wards, and less HD dependent at discharge. Mortality was significantly higher among HA-AKI vs. CA-AKI (31% vs.18% p<0.001). See Table 1. Traditional RF correlated with higher risk of death in both groups. Hypertension, heart failure and anaemia Max were associated with mortality in CA-AKI but not in HA-AKI. On the other side, HA-AKI had a higher risk of death associated with HNA, which was not significant among CA-AKI patients. See Figure 2.

Conclusions: We found that HA-AKI is more deadly than CA-AKI (consistent with previous studies), but shows lesser HD dependence at discharge. The traditional RF: older age, higher ChI, ICU admission, and AKI stage 3 influenced in-hospital mortality in both groups. Non-traditional RF showed an heterogeneous influence on outcomes according to AKI type, probably due to diverse baseline characteristics, evolution time, and AKI etiologies between cohorts. We conclude that novel associations (e.g. anaemia and HNA) should be explored and modifiable factors should be tackled in order to prevent AKI mortality.

PO0087

One-Year AKI Stage 3 Outcome in Elderly Patients at a Secondary Care Hospital in the United Kingdom

Jeetendra R. Rathod, Matthew James, Syed A. Shafrat, Jonathan Kwan. Darent Valley Hospital, Dartford, United Kingdom.

Background: Elderly patients are prone to Acute Kidney Injury (AKI) 3 due to multiple co-morbidities and frailty. The short term and long term outcome and mortality in this group of patients is unclear.

Methods: We prospectively collected data on patients aged over 70 years with AKI 3 from the daily e-alert sent by the hospital biochemistry lab. 117 patients attended or admitted to secondary care hospital in West Kent, UK over 6.5 months between 13 December 2018 and 26 May 2019 were analysed and followed up for next 12 months. AKI 3 was defined as per KDIGO Criteria. Data was collected for age, co-morbidities, serum creatinine at admission, peak, discharge and 12 months, cause of AKI 3 and mortality. Exclusion criteria: AKI stage 1, stage 2 and patients on regular dialysis.

Results: 57% patients had community acquired and 43% developed AKI 3 while as in-patient. The mean age was 80.1 ± 6.2 years with co-morbidities of Chronic Kidney Disease (CKD) 64.7%, Cardiovascular disease (CVD) 50%, Diabetes Mellitus 42.2% and Malignancy 8.7%. The stable baseline, peak and discharge s. creatinine (mean ± std dev) were 127.7 ± 85.6, 420.9 ± 222.7 and 248.5 ± 184.5 mmol/L respectively. 59.5% patients were reviewed by nephrologists and 20.7% were transferred under renal care. 30.4% had oliguria at presentation. The reasons for AKI 3 were classified as pre-renal (59.48%), urinary obstruction (11.2%) and renal that included sepsis (13.79%), cardio-renal syndrome (3.45%), drug induced nephrotoxicity (2.6%), other including ATN (9.70%). Renal function recovery was complete in 44%, Partial in 22% whereas 32.8% did not have any recover. 6 (5.17%) patients needed acute haemodialysis, of these 2 died and 4 (66.6%) were discharged off dialysis and were alive at 12 months. 47.4% patients were alive at discharge with s.creatinine of 173.2 ± 143.2 mmol/L while only 32% of the overall patients were alive at 12 months with s. creatinine (eGFR) (mean ± std dev) 161.8 ± 127.4 (48 ± 28 ml/min) with mean follow up of 331 ± 112 days. All patients that did not recover from AKI died.

Conclusions: We conclude that short and long term outcome in patients with AKI 3 aged more than 70 years has high mortality at discharge (52%) and 12 months (68%). AKI 3 is common in patients with co-morbidities of CKD, CVD and Diabetes mellitus. Outcome of acute haemodialysis is effective in select group of patients.

PO0088

Urinealysis and Urine Electrolytes Among Patients with COVID-19 Infection and AKI

Background: Determining intravascular volume status for patients who have COVID-19 infection and AKI is critical for guiding decisions about fluid management and treating AKI. In this study, we present data on urinalysis and urine electrolytes among patients with COVID-19 infection who developed AKI at our hospital.

Methods: This is a cohort of patients with COVID-19 who were diagnosed with AKI at our center in Spring of 2020 and had a urinalysis performed within 48 hours of diagnosis of AKI. When applicable we used Mann-Whitney test to compare groups.
PO0089

Recovery of Renal Function Among Left Ventricular Assist Device Patients with Severe AKI Requiring Renal Replacement Therapy: A Meta-Analysis

Swapna Rani Kanduri,1 Wisit Cheungrasiporn,1 Karthik Kovvuru,1 Pradeep Vaile,2 Charat Thongprayoon,2 Kianoush Kashani.2 University of Mississippi Medical Center, Jackson, MS; 2Mayo Clinic Rochester, Rochester, MN.

Background: Acute kidney injury (AKI) is a common and severe complication after left ventricular assist device (LVAD) implantation with an incidence of 37%; 13% of which requiring renal replacement therapy (RRT). Severe AKI requiring RRT in LVAD patients is associated with high short-term and long-term mortality, compared with those without RRT. While recovery of renal function is associated with better outcomes, the rates of recovery of renal function among LVAD patients with severe AKI requiring RRT are unclear.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systematically searched from database inceptions through January 2020 to identify studies evaluating the rates of recovery from severe AKI requiring RRT after LVAD placement, which is defined by regained kidney function resulting in the discontinuation of RRT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 268 patients from 14 cohort studies with severe AKI requiring RRT after LVAD were enrolled. Follow-up time ranges from hospital discharge up to 12 months. 78.5% of renal recovery occurred at the time of hospital discharge or within 30 days. Majority (85%) of patients used continuous-flow LVAD. Overall, the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT was 50.5% (95%CI: 34.0%-67.0%), respectively. While the data from pulsatile-flow LVAD were limited, subgroup analysis of continuous-flow LVAD demonstrated the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT of 52.1% (95%CI: 36.8%-67.0%). Meta-regression analysis did not demonstrate a significant association between study year and AKI recovery rate (p = 0.08). There was no publication bias as assessed by the funnel plot and Egger’s regression asymmetry test in all analyses.

Conclusions: Recovery from severe AKI requiring RRT after LVAD occurs approximately 50.5%, and it has not significantly changed over the years despite advances in medicine.
Usefulness of the Neutrophil-to-Lympocyte and Platelet-to-Lympocyte Ratios in Community-Acquired AKI

Jose M. Pena Porta, Almudena Castellano, Ana Coscojuela Otto, José F. Gasco, Alejandro Tomás, Pablo J. Inigo Gil, Rafael Alvarez Ipe. Nephrology Service, Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain.

Background: The neutrophil-to-lymphocyte (NLR) and platelet-to-lymphocyte (PLR) ratios have been identified as markers of inflammation and endothelial dysfunction. To date, their usefulness as prognostic markers in community-acquired acute kidney injury (CA-AKI) has not been evaluated.

Methods: We established a cohort of patients with CA-AKI admitted to our Nephrology service from January 2010 to February 2015. NLR and PLR ratios were obtained with the first analysis performed.

Results: We studied 308 patients with CA-AKI, 58% were men, mean age 73.22. Etiology of CA-AKI: prenail 69.5%, renal 23.1%; obstructive 7.5%. AKI KDIGO stages: I, 14.6%; II, 11%; III 74.4%. CKD was detected in 68.8%, 17.5% of cases required hemodialysis and 12.3% died. Mean NLR was 9.14 ± 8.47. Mean PLR was 236.99 ± 228.41. NLR according to etiology was: prenail 8.55±8; renal 9.37±9.8; obstructive 13.99±14.82 (significant differences between obstructive and prenail). PLR according to etiology: prenail 228.31±216.34, renal 236.15±233.77; obstructive 320.37±304.89 (non-significant differences). Within the group prenail, 79 cases were complicated by acute tubular necrosis (ATN). These cases presented a higher NLR (10.7 ± 14.7; p<0.0001) while in the others was lower (8.5 ± 8.3; p<0.001). The PLR also showed the same correlations (r= 0.134, p< 0.018 and r = 0.165, p= 0.07). The NLR, but not the PLR, was associated with the mortality and the mortality. More studies are need to confirm this finding, but the easiness of obtaining it and its economic cost make it cost-effective, giving the NLR a leading role in assessing the risk of CA-AKI.

Clinical Characteristics and Histologic Descriptions of Acute Tubular Injury: A Systematic Review

Yunmeng Chen, Steven Menzen, Chirag R. Parikh. Johns Hopkins Medicine, Baltimore, MD; Memorial Sloan Kettering Cancer Center, New York, NY.

Background: The term acute tubular injury (ATI) represents histopathologic renal tubular injury and often manifests clinically as acute kidney injury (AKI). Studies systematically summarizing the clinical presentation and histologic changes in human ATI are limited.

Methods: We comprehensively searched human studies of ATI from 1936 to July 2019. We extracted study characteristics, clinical characteristics and histologic descriptions of ATI by bright field, immunofluorescence or electron microscopy (EM) and by immunohistochemistry. We also compared histology of tubular cell injury as a function of tissue procurement timing and etiologies.

Results: We included 292 studies comprising of 1987 patients. The majority of studies (76%) were single center case reports. The mean age of patients included was 47 years old. 39.3% of patients had hypertension and 24.9% of them had diabetes mellitus. Baseline, peak and latest creatinine were 1.29 mg/dL, 7.04 mg/dL and 1.86 mg/dL respectively. 48.9% of studies were native kidney biopsy cases, of which 86.7% were performed after serum creatinine peaked. There were significant amount of missing data in these clinical characteristics reported across studies. We identified 16 histologic descriptions used to report tubular kidney injury (shown in Figure 1), including tubular cell necrosis, regenerative changes, tubular cell vacuolization. There was no difference in tubular injury histology either before or after creatinine peaked or between etiologies. EM and immunohistochemistry were used in minority of studies.

Conclusions: Tubular injury manifests with diverse histological changes. Efforts to establish protocols to harmonize biopsy practices, handle kidney biopsy and report results across clinical practice are needed to improve our understanding of this complex disease.

AKI and CKD Distribution in the Novel Clinical Phenotypes for Sepsis

Luca Molinari, Gaspar Del Rio-Pertuz, Sadudee Pecprorpanrata, John A. Kellum. Center for Critical Care Nephrology, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; Department of Translational Medicine, Università degli Studi di Piemonte Orientale, Novara, Italy; Clinical Research Investigation and Systems Modeling in Acute illness (CRISMA) Center, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; Excellence Center for Critical Care Nephrology, Division of Nephrology, and Department of Laboratory Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.

Background: Sepsis is the most common cause of Acute Kidney Injury (AKI) in critically ill patients. Four phenotypes have been recently described. Our objective was to investigate which of these sepsis phenotypes were associated with severe AKI, chronic kidney disease (CKD), AKI with CKD, and acute kidney disease (AKD).

Methods: We examined the 4 phenotypes using patient data from a previously published multicenter sepsis trial. After excluding patients with end-stage kidney disease and missing data, we analyzed 1243 patients with septic shock. We described the presence of severe AKI within the first 24 hours defined as KDIGO stage 2 or 3 or stage 1 with [TIMP-2]/[IGFBP7] at 6 hours >2.0. AKD was defined for patients with severe AKI as the presence of any AKI on day 7 or, if death occurred before 7 days, death without AKI recovery. The Chi-square test was used to compare distributions between groups, if p<0.05 then a pairwise comparison between groups was made using the Chi-square test adjusted with Bonferroni correction.

Results: We found a total of 633 patients with severe AKI (53.6%) within 24h. The rate of severe AKI at 24h was different across phenotypes being highest in the delta and beta phenotypes (80.8% and 73.6% respectively), and lowest in the alpha phenotype (30.1%, overall p<0.0001). The phenotype most common in the beta phenotype (52.6%, overall p<0.0001) while in the others was lower (31.4% in alpha, 26.8% in gamma, and 35.0% in delta). In the highest prevalence of AKI with CKD was again in the beta phenotype (52.8%), compared to alpha (25.0%), gamma (26.6%), or delta (34.8%, p<0.0001). AKD occurred more often in the delta (57.4%) and beta (50.0%) phenotypes compared to alpha (32.7%) and gamma (40.1%, p<0.0002).

Conclusions: Severe AKI was significantly more common among patients with beta and delta phenotypes. However, the beta phenotype had a higher level of underlying CKD that predisposed to new AKI. Alpha and gamma phenotypes not only had lower rates of AKI, but these cases were less likely to progress to AKD.

Comparison of Clinical Characteristics of AKI in Patients with Glyphosate and Glufosinate Herbicide Poisoning

**In O Sun**, A young Cho. Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

**Background:** This study aimed to investigate the clinical characteristics of acute kidney injury in patients with glyphosate and glufosinate herbicide poisoning.

**Methods:** From 2008 to 2019, 230 patients admitted to our hospital after glyphosate or glufosinate herbicide poisoning were enrolled. The clinical characteristics of the two groups were compared.

**Results:** The patients included 155 men and 75 women with a mean age of 59 years (range, 22-101 years). There were no differences in the clinical characteristics between the two groups. Hypophosphatemia was significantly more frequent in the glufosinate group (53%) than in the glyphosate group (i.e., 5%). No significant differences were found between the two groups in terms of the incidence of AKI, infection, and hospital stay.

**Conclusions:** Patients with glyphosate intoxication showed more severe type of clinical manifestation and intensive care unit admission rates than glyphosate intoxication.

Clinical Significance of Hypoaalbuminemia for AKI in Patients with Scrub Typhus

**In O Sun**, A young Cho. Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

**Background:** The aim of this study is to investigate the clinical significance of hypoalbuminemia for acute kidney injury in patients with scrub typhus.

**Methods:** From 2009 to 2018, 611 patients were diagnosed with scrub typhus. We divided the patients into two groups (normal albuminemia vs. hypoalbuminemia) based on the serum albumin level of 3 g/dL and compared the incidence, clinical characteristics, and severity of acute kidney injury based on RIFLE classification between two groups.

**Results:** Of the total 611 patients, 78 (12.8%) were categorized as hypoalbuminemia patients. Compared with patients in normal albuminemia group, patients in hypoalbuminemia group were older (71 years vs. 62 ± 14, p<0.01) and had higher total leukocyte counts (10.2 ± 10/μL vs. 6.7 ± 10/μL, p<0.01). Hypoalbuminemia group showed significantly longer hospital stay (9.6 ± 6.1 vs. 6.1 ± 3.0, p<0.01) and higher incidence of complications in respiratory system (50% vs. 14%, p<0.01), cardiovascular system (28% vs. 11%, p<0.01), neurologic system. Furthermore, acute kidney injury (58% vs. 18%, p<0.01) was more frequent. The overall incidence of acute kidney injury was 38.3% in this study, and there was no difference between two groups (33.8% vs. 45.6%, p=0.123).

**Conclusions:** Patients with the serum albumin level of 3 g/dL, and compared the incidence, clinical characteristics, and severity of acute kidney injury based on RIFLE classification between two groups. No significant differences were found between the two subgroups in terms of the assignment of high versus normal dialysis intensity.
PO0099

Design of START: A Phase 2 Study Evaluating the Safety and Efficacy of RBT-1 on Preconditioning Response Biomarkers in Subjects Undergoing Cardiac Surgery

Blupinder Singh,1,2 Philip T. Lavin,1 Andreas Orfanos,3 Stacey Ruiz,2 Donald J. Keysar,1 Alvaro F. Guillem,2 Richard A. Zager,4,5 Navdeep Tangri,6 Jean-Claude Tartif,7 1University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; 2Renibus Therapeutics, Southlake, TX; 3Montreal Health Innovations Coordinating Center, Montreal, QC, Canada; 4Fred Hutchinson Cancer Research Center, Seattle, WA; 5University of Washington Department of Medicine, Seattle, WA; 6University of Manitoba, University of Winnipeg, MB, CA, Winnipeg, MB, Canada; 7Institut De Cardiologie de Montreal, Montreal, QC, Canada; 8Boston Biostatistics Research Foundation, Framingham, MA.

Background: Cardiac surgery is associated with an increased risk of acute kidney injury (AKI). RBT-1 induces non-ischemic tissue preconditioning that has shown organ protective effects in several animal models of AKI. Markers of cytoprotection observed with RBT-1 treatment in animals were also found to be upregulated in a Phase 1 study of RBT-1 in healthy volunteers and subjects with Stages 3 and 4 chronic kidney disease (CKD). Based on these data, we have designed a Phase 2, placebo-controlled, double-blind, randomized, multicenter study that will assess the effect of RBT-1 on preconditioning response biomarkers in subjects scheduled to undergo cardiac surgery.

Methods: Study Design: This study will enroll 126 subjects scheduled to undergo coronary artery bypass graft (CABG) and/or cardiac valve surgery. Eligible subjects will be randomized to receive a single dose of RBT-1 or placebo via intravenous infusion between 24 and 48 hours prior to scheduled cardiac surgery. Subjects will be followed through Day 90.

Inclusion/Exclusion Criteria: Subjects eligible for enrollment include adults who are scheduled to undergo non-emergent, on-pump coronary artery and/or cardiac valve surgery. Major exclusion criteria include CKD with eGFR ≤ 20 mL/min/1.73m2 or need for dialysis.

Results: Objectives: The primary objective of this study is to evaluate the efficacy of RBT-1 on preconditioning response biomarkers from baseline through Day 3 post-cardiac surgery. Based on preclinical data, plasma heme oxygenase-1 [HO-1], ferritin, and IL-10 (IL-10) have been identified as the relevant biomarkers for this study. Secondary objectives include change in tubular injury biomarkers and incidence of AKI based on KDIGO classification. Exploratory objectives include the occurrence of major adverse kidney events (MAKE) through Days 30 and 90.

Conclusions: The multinational START study will assess the cytoprotective preconditioning response to RBT-1 in subjects undergoing cardiac surgery.

Acute Peritoneal Dialysis During the COVID-19 Pandemic in New York City

Nina J. Caplin,1,2 Manish Tandon,1,2 Olga Zhdanova,1 Richard Amerling,3 Nathan Thompson,1 1NYU Langone Health, New York, NY; 2Bellevue Hospital Center, New York, NY; 3Saint George’s University, Saint George, Grenada.

Introduction: The dramatic spread of COVID-19 in March 2020 threatened to overwhelm ICU capacity. At the peak we had more than 120 patients in the ICU. About 40% of the ICU patients required RRT due to AKI. Our ability to provide RRT with CVVH and IHD was severely limited by critical shortages of equipment and personnel. At the peak we had more than 120 patients in the ICU. About 40% of the ICU patients required RRT due to AKI.

Methods: Our ability to provide RRT was severely limited by critical shortages of equipment and personnel. At the peak we had more than 120 patients in the ICU. About 40% of the ICU patients required RRT due to AKI.

Results: Overwhelmed by the demand for RRT, acute PD more than adequately filled the gap in treatment options during this unprecedented crisis.

Conclusions: Acute PD more than adequately filled the gap in treatment options during this unprecedented crisis.

Discussion: In past, azathioprine has shown promise in treatment of lupus nephritis and IgA nephropathy. To our knowledge, this is the first reported case of successful treatment of steroid resistant severe drug induced AIN with azathioprine. As it has lesser side effects and better compliance than steroids, it is suggested that azathioprine may be considered in such situations as an alternative to prednisolone as a first-line treatment for AIN. Larger, randomized clinical trials need to be conducted in order to establish optimal dosing and long term effectiveness of azathioprine in treating AIN.

PO0103
The Successful Treatment of Bile Cast Nephropathy with Plasma Exchange
Sweeth Reddy, Theresa Kinard, Margaret Ryan, Leslie F. Thomas. Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Bile cast nephropathy is a condition of renal dysfunction in the setting of hyperbilirubinemia. There are very few cases of this condition reported in literature, and there is a lack of established treatment guidelines. We report the successful management of two patients with bile cast nephropathy using therapeutic plasma exchange (TPE).

Case Description: CASE 1: A 59 year old man with stage 3 colon carcinoma on Capecitabine developed chemotherapy-induced liver toxicity resulting in severe cholestasis and biopsy-proven bile cast nephropathy. He underwent TPE. CASE 2: A 69 year old man with long term history of bile duct cancer was admitted with acute renal failure due to pruritus and acute kidney injury (AKI). CT abdomen without contrast showed a 6 cm liver mass with bile duct dilatation, a biopsy proven metastasis from his previous colon cancer. A kidney biopsy confirmed bile cast nephropathy. The patient was started on hemodialysis (HD), and a bilateral stent was placed. He was treated with TPE. He opted for hospice due to cancer CASE 3. A 38 year old man was admitted with severe acute alcoholic hepatitis and AKI. A kidney biopsy confirmed bile cast nephropathy. He underwent TPE and a total of four sessions of HD. The clinical course in our patients with biopsy proven bile cast nephropathy prior to and after TPE therapy is noted in Table 1.

Discussion: Bile cast nephropathy is a rare entity with limited or no benefit. Renal replacement therapy has also been shown to be of limited benefit and should be mainly instituted for the treatment of AKI. In bile cast nephropathy, TPE may help in the clearance of bile acid crystals and reduction of proinflammatory molecules which contribute to acute liver and kidney injury. In this small case series, TPE appeared to improve the clinical course of patients with bile cast nephropathy.

PO0104
An Unusual Case of IgA Nephropathy Associated with Parvovirus B19
Laith S. Lakhan, Hashim Abbas, Mohammed G. Atta. Johns Hopkins University, Baltimore, MD.

Introduction: Parvovirus is known to cause upper respiratory infections in children and the immunosuppressed. It’s association with kidney disease has been sporadically reported in literature, mostly causing lupus like glomerulonephritis with endocapillary proliferation. We describe a unique case of IgA Nephropathy (IgAN) in an African American patient associated with Parvovirus B19.

Case Description: A 23 year old African American female with a history of Hemoglobin C disease presented with one week of generalized malaise, myalgia, and nausea. A serum creatinine of 1.9mg/dL was found to have non-oliguric AKI with Creatinine 2.5 mg/dL (baseline Cr: 0.6 mg/dL). Within one week, her Creatinine peaked at 7.4 mg/dL. Urinalysis showed 3+ protein, 5 white cells and 9 red cells. Urine microscopy was bland. Spot urine protein to creatinine ratio was 3.84g. Serologies were notable for normal Complements, negative ANA, ANCA, Hepatitis B, Hepatitis C and HIV along with unremarkable serum and urine electrophoresis. Renal ultrasound ruled out hydronephrosis. Labs were also notable for worsening hemolytic anemia. A renal biopsy was pursued, that showed diffuse proliferative glomerulonephritis. Our patients had acute liver and kidney failure with no underlying chronic liver disease. 1-2 plasma volume exchange was performed with each procedure with a combination of plasma and 5% albumin. A good response to TPE in decreased total bilirubin level and improvement in renal function was noted. There were no serious apheresis adverse events, and all procedures were tolerated well by the patients. Medical management of bile cast nephropathy such as steroids and cholestyramine have shown limited or no benefit. Renal replacement therapy has also been shown to be of limited benefit and should be mainly instituted for the treatment of AKI. In bile cast nephropathy, TPE may help in the clearance of bile acid crystals and reduction of proinflammatory molecules which contribute to acute liver and kidney injury. In this small case series, TPE appeared to improve the clinical course of patients with bile cast nephropathy.

PO0107

Renal Artery Thrombosis in a Patient Homozygous for Plasminogen Activator-Inhibitor-1 4G Allele
American College of Physicians, Philadelphia, PA.

Introduction: Renal artery thrombosis is a serious, uncommon, and often undiagnosed condition. Physicians need to consider this diagnosis in unexplained flank pain, especially in the presence of risk factors. Plasminogen activator inhibitor-1 (PAI-1) is the major inhibitor of tissue-type plasminogen activator. Fibrinolysis is impaired due to increased plasma PAI-1 levels which play an important role in the pathogenesis of thrombotic disorders. Homozygous for the 4G allele had increased plasma PAI-1 concentrations.

Case Description: A 53 years old male smoker with hypertension, presented to the emergency room complaining of abdominal pain and pink urine for 3 days. His BP was 186/120 mmHg and pulse 100/min. Physical exam was consistent with right flank tenderness. Utrasound showed high gravity, high amount of perinephric and perirenal blood. Creatinine was 1.6 and the baseline was unknown. CTA showed right renal artery occlusion. The patient was transferred to CCU and started on levodipine and heparin drip. Arteriogram and directed thrombolysis were performed. Despite these interventions, his creatinine trended down at 2.85, whereas hemoglobin started dropping substantially. High rate IV fluids, a workup for malignancy, and hypercoagulable were started with subsequent stent placement for reperfusion. After 3 days of directed thrombolysis, he was transferred to wards. Urine output decreased and a Foley catheter was placed. The patient was started on clonidine, amiodipine, and labetalol. After 10 days of hospitalization, all workup was unrevealing. PAI-1 4G/5G study was homozygous for 4G allele. The patient’s medical condition improved. He was discharged and advised to follow up as an outpatient.

Discussion: Studies have proven the link between PAI-1 4G and thrombotic events, however, most of the evidence shows a link between PAI-1 4G and venous thrombosis. In this patient, the fact of him being homozygous for PAI-1 4G allele led to arterial thrombosis. Therefore, it might be prudent to include a PAI-1 workup in prothrombotic studies. In renal artery thrombosis, a cause must be established. Although there are other common causes of arterial thrombosis, PAI-1 4G should be considered as a potential cause in patients with few or no risk factors. This case report glimpses the relationship between an uncommon genetic mutation and a rare diagnosis.

PO0108

Ganja Kidney: Acute Tubular Injury Associated with Synthetic Marijuana, A Rising Incidence
Ivette Cardenas Esprí,1,2,3 Fernando Lopez Osma,1,2 Don H. Esprí.1,2 Northern Florida Kidney Care by NPS, Gainesville, FL; 1North Florida Regional Medical Center, Gainesville, FL; 2Universidad del Sagrado Corazon, San Juan, Puerto Rico; 3Hospital Provincial Universitario Camilo Cienfuegos, Sancti Spiritus, Cuba.

Introduction: Synthetic cannabinoids (SC), “Ganja”, have been used as recreational drugs with increasing popularity among young adults but have significant toxicity. We present a case of acute kidney failure in a relatively healthy young male individual after using marijuana pills.

Case Description: 31-year-old Hispanic male with no known past medical history presented to the emergency room with nausea and vomit for 2 days. He stated that he has recently started taking “Ganja” pills to help with relaxation after losing work due to the Covid-19 pandemic. Vital signs were within normal limits and physical findings were unremarkable. Laboratory data were significant for serum creatinine of 10.14 mg/dL, blood urea nitrogen of 91 mg/dL, estimated glomerular filtration rate of 8 mL/min, and serum potassium of 7.0 mEq/L. Urine toxicology was positive for cannabinoids. Complements and serologies were all negative. Renal ultrasound was unremarkable. A renal biopsy showed acute tubular injury with tubular dilatation, cytoplasmic simplification and vacuolization (image). Intermittent hemodialysis was initiated but later discontinued after renal recovery. On discharge, serum creatinine was 1.2 mg/dL.

Discussion: Synthetic cannabinoids are found in natural marijuana and contain many active compounds but delta-9-tetrahydrocannabinol (THC) and cannabidiol (CBD) are of most interest. THC is the primary ingredient in marijuana that makes people “high”. Synthetic cannabinoids are analogs of natural occurring cannabinoids that are chemically synthesized. This synthetic compound is added to the natural marijuana or other herbs to appear as a natural product. The clinical effects can be like natural marijuana which include tachycardia, conjunctival injection, slurred speech, and increase appetite due to the partial agonistic effect at the cannabinoid receptors. Compared to cannabis, synthetic cannabinoids have a greater risk for serious neuropsychiatric toxicity and severe acute kidney injury. We need more clinical research to identify the specific nephrotoxic agents.

PO0109

A Case of AKI Secondary to Niraparib, a Poly ADP Ribose Polymerase Inhibitor
Krishna S. Ravipati, Prathima Gopinath, Pramodh Chanamolu, Siddhartha Kattamanchi. Marshfield Clinic, Marshfield, WI.

Introduction: Niraparib is a poly (ADP-ribose) polymerase (PARP) inhibitor indicated for the maintenance therapy of recurrent ovarian and other gynecological cancers in patients who have complete or partial response to platinum-based chemotherapy. We present a unique case of Niraparib resulting in AKI.

Case Description: 73-F with past H/o HTN, hyperlipidemia, persistent ovarian cancer after Cisplatin treatment, currently on Niraparib therapy was evaluated for worsening creatinine. Her baseline creatinine was 0.9-1.0 mg/dL and eGFR was 54.4 - 61.4 mL/min. She initially developed AKI (creatinine 1.8 mg/dL) with cisplatin which subsequently improved to 1.3 mg/dL with eGFR of 40.2 mL/min, upon completion of cycle. Following the initiation of Niraparib, creatinine gradually trended up to 2.1 mg/dL and calculated eGFR was 23.1 mL/min. No obvious etiology for AKI was identified. Urinalysis revealed muddy brown casts w/ protein of 100 mg/dL without any evidence of UTI. Cystatin C was measured (1.72 mg/L) and Cystatin C based eGFR was 33 mL/min which indicates true AKI as opposed to elevated creatinine without renal injury. Niraparib was suspended following which creatinine started to improve (1.7 mg/dL) along with an improvement in eGFR (29.5 mL/min).

Discussion: Niraparib is a PARP inhibitor which functions by causing DNA damage resulting in apoptotic cell death. PARP inhibition in animal models has shown to be renoprotective from ischemia and it has been shown to elevate serum creatinine in drug trials without causing AKI. In our case though, patient developed AKI 2/2 ATN from niraparib. Mechanism for this is unclear as this is one of the earliest reported cases. One possible mechanism could be Apoptotic cell death of renal tubular cells.

Creatinine trend in our patient
PO0110

The Emerging Role of Bedside Doppler Ultrasound for Precise Assessment of Venous Congestion in Cardiorenal Syndrome

Abhilash Koratala,1 Saqib Mahmud,1 Olaniwaju A. Olaoye,2 Amir Kazory.2
1Medical College of Wisconsin, Milwaukee, WI; 2University of Florida, Gainesville, FL.

Introduction: Congestion is an integral component of cardiorenal syndrome and the primary reason for hospitalization in patients with heart failure (HF). Making it a key target in the management of these patients. Routinely used parameters to monitor response to decongestive therapy such as physical examination, B-type natriuretic peptide, changes in weight and net fluid balance, even inferior vena cava ultrasound (IVC US) are all error prone. Doppler ultrasonography (DUS) of the portal, hepatic and when possible, intrarenal veins is an attractive alternative that can be used at bedside to accurately assess the degree of congestion and guide management strategies.

Case Description: A 55-year-old man with a history of HF with reduced ejection fraction of ~25%, hypertension and chronic kidney disease stage 3 presented with acute kidney injury of uncertain etiology. Serum creatinine (Scr) was 3.5 mg/dL for a baseline of 1.6 mg/dL. He had no symptoms except for his usual dyspnea on exertion. Physical examination was significant for crackles at lung bases and mild pitting pedal edema. Bedside US revealed increased extravascular lung water and a dilated but collapsible IVC. DUS revealed stigmata of severe congestion with a pulsatile portal vein and systolic flow reversal, and a hepatic vein with only diastolic (D) component below the baseline. Therefore, the diagnosis of congestive renal failure due to acute cardiorenal syndrome was made and high dose intravenous diuretics were initiated. The follow up DUS on days 3 and 5 showed remarkable improvement (reversal of waveforms to normal pattern) indicating progressive decongestion [Figure]. His diuretic therapy was titrated based on these findings and Scr improved to 2 mg/dL at discharge.

Discussion: Bedside DUS assessment of hepatic and portal veins aids in management of patients with HF by non-invasively monitoring the efficacy of decongestive therapy, and serves as a valuable adjunct to conventional clinical evaluation.

PO0112

Hypothyroidism-Induced AKI: A Case Series

Spoonthi Ramkumar, Varun Kumar Bandi. Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.

Introduction: Thyroid hormones affect the development and various functions of the kidney. Such effects are partly mediated by direct renal action and partly by cardiovascular and systemic effects.

Case Description: We present a series of 3 patients who presented with unexplained acute kidney injury (AKI). All patients were male, and one was hypertensive on amiodarone. Investigations showed blood urea levels ranging from 20 to 88 mg/dl, serum creatinine between 1.3 to 6.5 mg/dl with estimated glomerular filtration rate (eGFR) of 17.88 to 63.18 ml/min/1.73m2. Urine routine and ultrasound abdomen did not reveal any abnormalities. The patients had features suggestive of hypothyroidism and thyroid evaluation was done. Thyroid stimulating hormone (TSH) was elevated in all patients and T3 and T4 were decreased. The TSH levels ranged between 88.4 to 100 mIU/L. Creatine phosphokinase (CPK) level was modestly elevated in only one case, with absent urine myoglobin in all cases. A possibility of hypothyroidism induced AKI was considered and renal biopsy was deferred. After starting levothyroxine, complete renal recovery was seen in 2 patients and partial recovery in one within 8 weeks (Table 1).

Discussion: AKI has been reported in patients with severe hypothyroidism, and most cases were suspected to be due to rhabdomyolysis and had rapid normalization. Few cases of slower and incomplete recovery have been noted in cases with prolonged periods of severe hypothyroidism. In our series, normal urinalysis, absence of myoglobin, and normal or modest elevation of CPK makes rhabdomyolysis unlikely. The AKI could be due to hypothyroidism induced changes in renal hemodynamics. Our study relies on eGFR for renal function, and extent to which this reflects true changes in GFR is unclear. Hypothyroidism is a reversible cause of AKI and should be evaluated in cases with unexplained AKI. These patients can attain normal renal function with prompt initiation of levothyroxine therapy.

Furosemide: An Unusual Cause of Acute Interstitial Nephritis Requiring Hemodialysis: First Case Report

Hassan Alahbabi, Dallas Nephrology Associates, Irving, TX.

Introduction: Furosemide, a loop diuretic, is widely used for volume control and is a known cause of acute interstitial nephritis. However, AIN due to furosemide is not typically associated with abrupt and severe acute kidney injury (AKI). Here we report a patient who developed severe AKI requiring hemodialysis shortly after receiving furosemide.

Case Description: A 65 year old male with a history of hypertension was started on oral furosemide 20 mg daily for edema in his legs. One week later he presented to our emergency room complaining of oliguria and worsening edema. Laboratory findings were significant for a serum creatinine of 37.8 mg/dL and potassium 7.8 mmol/L. Patient required emergent hemodialysis for volume control, clearance and hyperkalemia, and continued to require HD every other day. Serologic work-up included a normal C3, C4, ANA, ANCA, anti-GBM, and SPEP/UPEP. Urinalysis showed small blood, no protein, 12-15 RBC’s, 10 WBC’s. Renal ultrasound was normal. A kidney biopsy was performed which demonstrated interstitial edema with patchy inflammatory cell infiltrates with eosinophils. The tubules were dilated and showed significant degenerative changes in tubular epithelial cells. The patient was started on treatment for acute interstitial nephritis with oral prednisone 60 mg daily with a subsequent slow taper. Kidneys did not recover and he was placed on hemodialysis three times a week with close monitoring of kidney functions.

Discussion: Furosemide, a loop diuretic, is widely used for volume control. To our knowledge, this is the first report of AIN associated with loop diuretics that resulted in severe AKI requiring hemodialysis. Unfortunately, our patient did not respond to high dose steroids and he continued to require hemodialysis three times a week. Our report highlights the importance of close monitoring of any potential toxicities that may be associated with such medications.
Brain edema is a rare complication of acute kidney injury in patients who have not received renal replacement therapy. Immunologic and pro-inflammatory cascades mediate brain edema that is not dependent on the uremia, and instead, it is due to crosstalk between the kidneys and brain in the so-called reno-cerebral reflex. We are presenting an 88-year-old female with a history of hypertension and hypothyroidism with acute colitis that developed acute kidney injury and cerebral edema. We want to raise awareness of the need for early diagnosis and treatment to prevent severe clinical outcomes.

**Case Description:** An 88-year-old female with type two diabetes mellitus, hypertension, Sjogren’s disease not requiring immunosuppression, baseline normal kidney function, and hypothyroidism came to the ER complaining of green-colored non-bloody diarrhea with associated epigastric pain for 2 days. Examination remarkable for left lower quadrant tenderness, tachycardia, altered, awake, oriented to person only, cooperative and following commands. Labs were remarkable for leukocytosis with neutrophilia, fecal leukocyte positive, and metabolic alkalosis. Abdominal CT showed acute colitis localized to descending colon and sigmoid. The patient was admitted with acute colitis. On day 2 of admission creatinine went up to 2.35 from 1.07. On urine, sediment was evident to descending colon and sigmoid. The patient was admitted with acute colitis. On day 11, the mental status started declining, and metabolic acidosis was present. Renal replacement therapy was advised, but the patient’s family member refused it and signed off DNR. The creatinine keeps trending up to 9.37. Brain CT without contrast was done and showed diffuse cerebral edema with no acute hemorrhage or ischemic changes. On day 11, the patient passed away.

**Discussion:** The brain edema seen in this patient was a byproduct of oxidative stress, activation of the immunologic pathway, and activation of the Reno-cerebral reflex occurring in acute kidney injury that is entirely independent of the mechanism seen in uremia. Not every functional or structural brain alteration in acute kidney injury is caused by uremic encephalopathy. Many pathways are activated in acute kidney injury that contributes to the effects of the kidneys in distant organs being the brain one of them. This case will serve to raise awareness to study the crosstalk between organs to prevent complications and improve outcomes.

**PO0115**

**Renal Cortical Necrosis: An Atypical Case from Presentation to Recovery**

Liam Abu Salaman,1 Rachel Hilburg,2 Abdallah Sassine Gears.1 Jankunu Medical Center, Wynnewood, PA; 2University of Pennsylvania, Philadelphia, PA.

**Introduction:** Renal cortical necrosis (RCN) is a rare cause of acute kidney injury (AKI) accounting for 1-2% of cases. It is most often associated with obstetric emergencies in developing countries. The most common non-obstetric etiology is hemolytic uremic syndrome, but it has also been described in renal allograft rejection, sepsis, and in recent cases pancreatitis where ten cases have been reported. We describe a case of severe renal cortical necrosis in a previously healthy young man with acute pancreatitis.

**Case Description:** A 29-year-old man with no significant medical history presented with severe epigastric pain and anuria for three days. He was diagnosed with alcohol-induced pancreatitis with a lipase level of 35,534U/L and AKI with a creatinine of 5.8mg/dL (baseline 1.2mg/dL). The anuria did not improve with fluid resuscitation, the AKI progressed and he was initiated on hemodialysis. Evaluation of AKI with hepatitis B and C serologies, HIV, complement levels and ANA was unremarkable. Kidney ultrasound showed increased echogenicity without hydronephrosis. An abdominal CT scan with IV contrast done for worsening fever and leukocytosis showed diffuse areas of non-enhancement involving bilateral renal cortices consistent with acute renal cortical necrosis. To note, throughout his presentation and admission, the patient was not hypotensive. He remained dialysis dependent for three months with oliguria that eventually improved and dialysis was discontinued with a stable eGFR of 20ml/min/1.73m². He has remained off dialysis for the past five months and is undergoing transplant evaluation.

**Discussion:** RCN is thought to be an irreversible cause of AKI secondary to decreased perfusion, vasoconstriction and endothelial injury resulting in ischemia. It is frequently associated with hypotension but in our case the patient was normotensive.

The mechanism leading to RCN associated with pancreatitis remains poorly understood. Acute pancreatitis, on the other hand, has been associated with other vasoocclusive ischemic complications (e.g. Purtscher’s retinopathy). RCN is a devastating complication that often leads to dialysis dependence. Despite our patient showing signs of recovery, his prognosis remains poor. Further study is needed to understand its pathophysiology and potentially mitigate its consequences.

**PO0116**

**Severe Vancomycin Nephrotoxicity**

Jefferson L. Tresoir, Layth Al Attar, Maryam K. Saeed, Jinginyan Yan, Bryan M. Tucker. Baylor College of Medicine, Houston, TX.

**Introduction:** We report a case of acute kidney injury with biopsy-proven changes related to a vancomycin level of 136.6 mg/L. From our review of the literature, this is the highest vancomycin level ever recorded.

**Case Description:** A 60-year-old male with type two diabetes mellitus, hypertension, Sjogren’s disease not requiring immunosuppression, baseline normal kidney function, and left ankle osteomyelitis on home intravenous vancomycin presented with vertigo. Workup revealed oliguric acute kidney injury with sub-nephrotic range proteinuria (blood urea nitrogen 56 mg/dL, creatinine 6.70 mg/dL, urine protein to creatinine ratio 0.98) and an elevated random vancomycin level (136.6 mg/L). A comprehensive evaluation including physical examination, serologic testing, and renal imaging was unremarkable. Due to high vancomycin levels and minimal improvement in renal function despite resuscitation with intravenous crystalloids, hemodialysis was initiated via a tunneled dialysis catheter. A renal biopsy was then obtained, which demonstrated acute tubulointerstitial injury, morphologically consistent with acute tubular necrosis. There was also mild arterial sclerosis, minimal interstitial fibrosis and tubular atrophy, and no immun-mediated glomerulonephritis.

**Discussion:** Vancomycin is renally-eliminated by glomerular filtration and, to a lesser degree, excretion in the proximal tubule. Various mechanisms of renal injury are reported, including acute tubular necrosis and interstitial nephritis. Accrual of vancomycin-uromodulin complexes lead to inflammation. In this case, a comprehensive workup and kidney biopsy was important to rule out other causes of renal failure and support the diagnosis of vancomycin-induced nephrotoxicity. Renal recovery often occurs with discontinuation of vancomycin therapy. Severe cases, however, are frequently exacerbated by oliguria and require high-flux hemodialysis for effective drug removal by approximately thirty percent. Prolonged exposure to high levels of vancomycin increases the risk of permanent renal failure. This patient developed vancomycin nephrotoxicity despite drug monitoring, dosing based on creatinine clearance, and using the minimum inhibitory concentration required. Further research to establish precise mechanisms of vancomycin-induced nephrotoxicity is needed.
DRESS Syndrome and Acute Interstitial Nephritis Relapse: A Case for Caution

Introduction: The syndrome of drug reaction with eosinophilia and systemic symptoms (DRESS) is a rare but potentially life-threatening drug-induced type IV hypersensitivity reaction that usually occurs 2-6 weeks after drug initiation. Typical findings include skin eruption, fever, hematologic abnormalities, and visceral organ involvement. Prolonged corticosteroid treatment is often required as relapse after initial improvement is not uncommon.

Case Description: A 62-year-old woman with a history significant for right total hip arthroplasty complicated by a prosthetic joint infection requiring hardware explantation and antibiotic spacer placement initially presented to the ED with fever, rash, and pruritus. She was treated with cefepime and vancomycin for positive intra-operative bacterial cultures. Urinalysis showed pyuria (51-100/hpf) and eosinophils (1-5%). Skin biopsy showed a drug reaction. She was diagnosed with DRESS syndrome and acute interstitial nephritis (AIN) secondary to the antibiotics, which were then changed to aztreonam and daptomycin. She was treated with systemic and topical steroids and was discharged on oral prednisone 40 mg daily with plan to taper by 10 mg every week over 1 month. Serum creatinine peaked at 3.36 mg/dL and improved to 0.62 mg/dL on discharge. Patient was seen again the ED 5 days after discharge with fever and worsening rash and pruritus. Physical examination was notable for mild facial swelling and scattered pink macules coalescing into patches on both upper and lower extremities and on the groin. Laboratory studies revealed leukocytosis with peripheral eosinophilia [7.35x10^9/L] (on discharge: 0.87), elevated serum creatinine of 4.8 mg/dL, and elevated LFTs, ESR, and CRP. She was diagnosed with DRESS syndrome and AIN relapse secondary to rapid steroid taper. She was started on a higher dose of oral prednisone (80 mg daily) and had clinical improvement. She was then discharged with plan to taper by 10 mg every 2 weeks over 4 months.

Discussion: Long-term supra-physiologic doses of steroids are necessary to treat DRESS syndrome even after patients appear to have improved. Relapses do occur and frequently follow treatment discontinuation or rapid steroid taper, leading to increased morbidity and mortality. In such cases, a more prolonged steroid treatment is needed, which can cause well-known adverse events and complications. Close monitoring is thus required.

Rivaroxaban-Induced Anticoagulant-Related Nephropathy

Introduction: Anticoagulant-related nephropathy (ARN) is a rare and newly recognized cause of acute renal failure (ARF). A lack of serologic studies and hesitancy to perform high risk biopsies due to concerns for thrombosis or hemorrhage, make ARN a challenging diagnosis. The pathophysiology is believed to be from diffuse glomerular hemmorhage which manifests as numerous RBC casts. These RBC casts obstruct and damage tubular epithelial cells resulting in renal failure. We will examine a case of ARN.

Case Description: An 83-year-old Caucasian female presented with complaints of lower extremity weakness and was found to have ARF on laboratory investigation (Cr 5.18mg/dL from 1.1mg/dL one month prior). The patient was recently started on rivaroxaban after being diagnosed with a stroke caused by atrial fibrillation. The patient was admitted for evaluation and management of oliguric ARF, requiring the initiation of HD. Initial evaluation was significant for uncontrolled hypertension, 1+ pitting bilateral lower extremity edema, hypalbuminemia (Alb 1.8 mg/dL), UA with 3+ blood but no casts on microscopy, and non-nephrotic range proteinuria (UPCR 2.9g), raising concern for rapidly progressive glomerulonephritis. Serologic work up was only remarkable for a mildly positive rheumatoid factor. A renal biopsy was performed after holding rivaroxaban for 5 days. Preliminary results showed IgA nephropathy with oxford classification score of M1E0S1T1C0, prompting initiation of steroid therapy. With no crescentic glomerular lesions to explain the degree of renal failure upon further investigation, the prominent RBC casts provided the diagnosis of ARN with underlying non-proliferative IgA nephropathy. Steroids were tapered and the patient is slowly recovering renal function.

Discussion: The use of novel oral anticoagulants (NOAC), has become prevalent in the medical community as a treatment strategy for various diseases. While previous cases have been mostly described in patients on warfarin, this case illustrates the importance of recognizing the new phenomenon of ARN as a risk factor for patients on NOACS. Due to limited data and no prospective studies, expert opinion has recommended switching oral anticoagulant to another or reducing the dose of the offending agent. Further research is needed to understand this disease process to help design prevention and treatment strategies.
P00121
Use of Continuous Venovenous Hemodialysis and Plasmapheresis to Treat Simultaneous Iron and Acetaminophen Overdose
Tripti Singh, Rebecca Nye. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Introduction: Iron may fatally exacerbate toxicity in polypharmacy overdoses, including acetaminophen overdose. We present a case of intentional acetaminophen and iron overdose and treatment with continuous venovenous hemofiltration (CVVH) and plasmapheresis.

Case Description: 31-year-old male with history of schizophrenia and previous suicide attempts presented to an outside hospital with abdominal pain and emesis 1.5 hours after ingestion of 100 tablets each of 325 mg acetaminophen and 325 mg ferrous sulfate. Vitals on admission were BP 121/83 mmHg, pulse 93 bpm, RR 18/min, G2 saturation 98% on RA. Labs showed bicarbonate 23 mEq/L, anion gap (AG) of 14, BUN 16 mg/dL, creatinine 1 mg/dL, total bilirubin 0.7 mg/dL, AST 24 units/mL, ALT 16 units/mL, iron 356 ug/dL, and acetaminophen 269.8 ug/mL. Patient was started on IV acetylcysteine. Repeat labs 12 hours later revealed iron level 4326 ug/dL, total bilirubin 4.8 mg/dL, AST 476 units/mL, and ALT 855 units/mL. IV defereroxamine was initiated. Patient became lethargic and hypotensive and required intubation. He was transferred to our hospital for further management. Labs upon arrival showed AG of 16, bicarbonate of 12 mEq/L, creatinine 1.98 mg/dL, ALT 13129 units/mL, AST 4766 units/mL, and ALT 855 units/mL. IV defereroxamine was initiated. Labs 2 hours later showed iron level of 20 ug/dL and acetaminophen level of 91 ug/mL. The patient’s clinical status continued to decline despite removal of iron and acetaminophen and he died after 24 hours due to fulminant liver failure.

Discussion: In this case of simultaneous massive iron and acetaminophen overdose, CVVH was effective in removal of iron (60%) and acetaminophen (44%) over 6 hours. Plasmapheresis may be considered as an additional modality to remove excess free iron from the blood.

P00122
Severe AKI Associated to Acquired Autoimmune Hemolytic Anemia and Hemophagocytic Syndrome: A Case Report
Afonso Santos, Ana Lima, Ana Gaspar, Ana C. Brás, Patricia S. Carrilho, Karina Soto. Nephrology Department, Hospital Professor Doutor Fernando Fonseca, EPE, Lisboa, Portugal.

Introduction: Autoimmune hemolytic anemia (AIHA) is a rare entity with an annual incidence of 1-3/100,000. Secondary AIHA is associated to lymphoproliferative disorders (LD), autoimmune diseases, drugs, and less frequently to infections, being an unusual cause of AKI. Hemophagocytic lymphohistiocytosis (HLH) is an uncommon syndrome of excessive immune activation that can be triggered by infection that disrupts immune homeostasis. Herein, we present a very rare case of a patient with AKI requiring RRT associated to severe AIHA and HLH.

Case Description: A 46-year-old caucasian man was admitted with fever, anauria and severe anemia. Three days prior to admission he had vomiting, diarrhoea and oliguria. Physical examination revealed normal BP, fever and pale skin. Blood tests showed SCR 8.8mg/dL (baseline 0.9mg/dL), metabolic acidsis and urine dipstick Hb3+! He had AIHA with Hb 6.7g/dL, LDH 1194U/L, haptoglobin<30mg/dL, total bilirubin 1.35mg/dL, and positive Coombs test. Blood smear revealed atypical lymphocytes and rare blasts; platelet count was normal. HLH was diagnosed based on clinical (fever, splenomegaly) and laboratorial criteria, with high ferritin (46833mg/mL), triglycerides 308mg/dL, high levels of IL2 receptor (13547pg/mL). Sedimentation rate was 85mm/h and CRP 19mg/dL.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
cerebral edema in the setting of Pneumocystis jirovecii pneumonia, it may be prudent to choose AP at the time of presentation. Patients with severe hypoxemia, and those with a history of a severe exacerbation of asthma, should be treated with broad-spectrum antibiotics and corticosteroids. There is no evidence to support the use of antifungal agents in the management of pneumocystis pneumonia.

PO0125

Blast from the Past: A Rare Case of AKI from Sulfadiazine-Induced Nephrotoxicity

Introduction: Sulfadiazine has been used for the treatment of neurotoxoplasmosis in patients with HIV infection. Nephrotoxicity is a known complication of high dose sulfadiazine therapy. However, this complication is rarely seen in HIV patients due to improved antiretroviral therapy. We present a rare case of sulfadiazine-induced nephrotoxicity in a patient with AIDS.

Case Description: A 55-year-old female with DM and HTN was hospitalized for worsening mental status and CT scan finding of frontal lobe mass. During hospital stay, pt. also found to have HIV infection and a very low CD4 count. Antiretroviral therapy and high-dose intravenous sulfadiazine 1,500 mg every 6 hours was initiated for presumed neurotoxoplasmosis. On admission, serum creatinine (Scr) was 0.68. Seventeen days after initiation of sulfadiazine therapy, Scr increased to 2.42. Urinalysis revealed microscopic hematuria. Kidney sonogram showed low hydronephrosis and echogenic foci in both kidneys concerning for kidney stones. Sulfadiazine was discontinued and patient was started on sodium bicarbonate infusion to alkalize her urine but Scr continued to worsen, peaking at 4.73 within few days. Serial kidney sonograms revealed alternating fullness of the collecting systems of both kidneys. Urology team was consulted and patient's renal cysts were bilateral ureteral stents placement. Scr subsequently returned to normal limits within one week of ureteral stent placement.

Discussion: Our patient developed severe but reversible post-obstructive AKI secondary to high-dose sulfadiazine-induced nephrotoxicity. In the modern era of antiretroviral therapy, sulfadiazine-induced nephrotoxicity is a very rare occurrence in clinical practice. Hence, clinicians and nephrology care providers should be aware of this rare cause of AKI in patients with HIV infection.

PO0126

Rhabdomyolysis as Initial Presentation of COVID-19

Hugo Andrade paz, Mala Sachdeva, Nupur N. Uppal. Northwell Health, Great Neck, NY.

Introduction: Rhabdomyolysis is a dangerous intrinsic etiology including Mycoplasma pneumonia infection, Legionella, and Influenza. To date, there has been one case report from Wuhan China of a patient who developed rhabdomyolysis from COVID-19 during their hospitalization. We report a case where acute kidney injury and rhabdomyolysis was the initial presentation.

Case Description: A 57 year old African American male with history of HTN for more than 10 years, presented with complaints of decreased urine output for 3 days associated with dark urine that progressed to anuria, fever for 11 days, decreased appetite and oral intake and generalized muscle weakness. Labs on admission were notable for acute kidney injury (creatinine 1.77mg/dL) which progressed rapidly to a peak creatinine of 11.10mg/dL within 72 hours, and other electrolyte abnormalities including mild hyperkalemia and acidosis. His CPK was >92,000U/L and admission COVID-19 PCR was positive. Other labs included: peak AST 1692 U/L and ALT 291U/L, ferritin 1436 ng/ml, 4.86fmg/dL, DDimer 2330 DDU, urinalysis specific gravity 1.030 with large blood, 10RBCs, 20WBCs, urine spot protein/creatinine 2.1 and random urine sodium 65. Serologic workup was negative for glomerulonephritis. He was presumed to have acute kidney injury due to rhabdomyolysis. He was discharged on 13 of March 2020, for follow-up in his dialysis clinic and to be seen in the Internal Medicine clinic. He was seen in clinic on 30th of March and was noted to have improved creatinine to 1.95mg/dL, with normal electrolytes. He was discharged with follow up with nephrology.

Discussion: This is a rare case of rhabdomyolysis as initial presentation of COVID-19. Rhabdomyolysis is a rare complication of COVID-19, however, given the rapidity of presentation and the severity of the patient's illness, rhabdomyolysis should be considered in the differential diagnosis of acute kidney injury in patients with COVID-19.
po0130
rhabdomyolysis in sars-cov-2 infection
zhubiz solhjou, ignacio a. portales castillo, bassem mikhail, nicholas chedid, ebrahim barkoudah, alice m. sheridan, brigham and women's hospital, department of medicine, boston, ma; brigham and women's hospital, renal division, boston, ma.

introduction: acute kidney injury (aki) is a common complication of sars-cov-2 infection. multiple mechanisms have been proposed including acute tubular necrosis (atn) due to shock, cytokine release syndrome, hypoxia or vascular injury and thrombotic microangiopathy. despite viral injury to tubular epithelial cells and podocytes, thrombotic microangiopathy has also been described. rhabdomyolysis has been reported in infection with sars-cov-2, respiratory syncytial virus and influenza a. although mild ck elevation was reported in cohorts of patients with covid-19 and there is a single case report of late onset rhabdomyolysis, overt rhabdomyolysis is rare in sars-cov-2 infected patients. here we report on the first patient with presented with symptoms and signs of severe rhabdomyolysis and aki that was likely secondary to sars-cov-2 infection.

case description: a 51 year-old male with hypertension and diabetes, presented with a 2 days history of fever, myalgia and mild dry cough with slight shortness of breath. he denied trauma, new medications, changes in diet, strenuous exercise or illicit drug use. physical exam notable for fever and mild tachypnea, but no hypoxia. lungs were clear and all muscles groups were soft and non-tender. polymerase chain reaction was positive for sars-cov-2. serum creatinine was 2.4 mg/dl (baseline 1.3 mg/dl), urinalysis showed 3+ blood, 2+ protein and 1-2 rbc per high power field. initial serum creatinine kinase was 340,000 u/l and peaked at 464,000 u/l on day 4. serum and urine myoglobin levels were elevated at 15,175 mg/l and >5000 mcg/l respectively on day 5. he received isotonic intravascular (iv) fluids but developed oliguria on day 2, requiring diuresis to maintain urine output. bun and creatinine increased to 130 and 19 mg/dl respectively by day 8 and hemodialysis was initiated. renal clearance and urine output then slowly improved, and dialysis was discontinued by day 15.

discussion: myalgia and fatigue are common symptoms of covid-19 infection. in addition, dipstick hematuria is reported in up to 10% of patients. thus diagnosis of rhabdomyolysis and myoglobinuria requires a high index of suspicion. early consideration and timely diagnosis of rhabdomyolysis and the treatment of myoglobinuria with intravenous fluids is highly important to prevent atn. however, administration of iv fluids may be challenging in covid-19 patients at risk of hypoxia and acute respiratory distress syndrome.

po0131
using a peritoneal dialysis catheter as a tool for aki prevention in a patient with refractory cardiac ascites: a case report
raja m. rashid, amar m. mahdi, university hospitals birmingham nhs foundation trust, birmingham, united kingdom.

introduction: recurrent large volume paracentesis (lvp) is currently the followed management option for refractory cardiac ascites. we are presenting a case where placement of tunneled peritoneal catheter (pd) for such a patient resulted in prevention of recurrent aki, reduced hospitalization, dramatic improvement in quality of life and stabilization of renal function.

case description: 59 year old male patient of cdk ¼ secondary to cardiac-renal syndrome was admitted in apr 2019 with worsening heart failure, massive ascites and aki on cdk (serum creatinine cr) worsening from 150 to 210 umol/l). his last echo showed severely impaired biventricular dysfunction with lvef of 24%. ascites was sterile and transudative. kidneys were of normal size and urine cr was only 20. owing to poor diuretic response, he underwent lvp (30 litres) with resolution of aki. he presented similarly in nov 2019 (cr worsened from 197 to 550umol/l) and underwent lvp. 6 weeks later, he presented again with aki (cr rose from 190 to 380 umol/l). pd catheter was medically inserted in jan 2020. 8 litre of ascites was drained and patient was trained to aseptically drain the ascites regularly. he drained the fluid himself 2 to 3 l twice a week. his cr improved and stabilized around 157 umol/l. his serum albumin (29to 40 g/l), hbs (77 to 135 g/l), quality of life, blood pressure and diuretic response has improved significantly with body weight maintained at 83 kg. he has not been admitted once in past 5 months.

discussion: our patient was having repetitive aki (known cause of cdk progression) due to worsening congestion and possibly raised intra-abdominal pressure (iap). increased systemic venous pressure can cause a decline in gfr by increasing renal interstitial pressure. venous congestion also causes an inflammatory response within the renal parenchyma. clinical parameters improved once the gentle pd catheter drainage was instituted at home. no further aki episode was observed and egfr was stabilized.

po0132
a rare case of a 27-year-old man with igg4-related disease
sai shalini pillarissetty, sumedha sonde, winston lee, new york city health and hospitals coney island, brooklyn, ny.

introduction: igg4-related disease (igg4-rd) is a multisystem autoimmune disease that was first reported in 2010. we present an unusual case of igg4-rd in a young man demonstrating the heterogeneity of igg4-rd with multisystem involvement and irreversible organ damage.

case description: a 27 year old obese male who presented with 3 month history of vomiting, diarrhea, epigastric pain, left lower extremity edema and severe fatigue. on auscultation patient appeared toxic, tachycardic and hypotensive with left leg elephantiasis nostras verrucosa. lab work was significant for: hgb 4 mg/dl, bun/cre 247/33.04, lipase 1100 u/l (13-60), tpo antibodies 43.6 iu/ml (<=34.9), tsh 8.71u/l/ml (0.35-5.50). ct scan confirmed acute pancreatitis with diffuse lymphadenopathy. hemodialysis was initiated and the patient received multiple blood transfusions (17 units of prbc) while on aranesp with no significant improvement in hemoglobin. blood antibody screening showed igg4 warm antibodies and elevated serum igg4 229 mg/ml (2.4-24), igg 2305 mg/ml (610-1660) and igf 4303k/ml (>100). renal biopsy showed chronic tubulointerstitial nephritis with global and focal segmental glomerulosclerosis and arterial sclerosis. immunofluorescence stained for igg, iga, igm, c3, c1q, kappa and lambda. electron microscopy showed plasma cells staining igg4 and 80% interstitial fibrosis.

discussion: igg4-rd is a fibroinflammatory condition characterized by lymphoplasmacytic infiltrates rich in igg4 and plasma cells with storiform fibrosis and elevated serum igg4. our patient presented with interstitial nephritis, pancreatitis, lymphadenopathy, thyroiditis, lower extremity lymphedema and anemia with elevated serum igg4 levels and histopathology findings of igg4-rd. the diagnosis was made based on the japanese comprehensive diagnostic criteria for igg4-rd. he responded to rituximab and steroids with decreased transfusion requirements. severe anemia has not been reported with igg4-rd. in our case the transfusion requirement decreased after initiation of therapy which suggests the anemia may have been secondary to anti-epo igg4 or poor response to epo in the setting of an underlying inflammatory process.

po0133
zosyn induced neutrophil-rich allergic interstitial nephritis: a rare case
aulio f. bustos, sanjeev gupta, savneck s. chugh, viviam i. becerra rivera, amol mittal, xiaotong wang. westchester medical center health network, valhalla, ny.

introduction: acute interstitial nephritis (ain) is a clinicopathological syndrome associated with infections or drugs. ain is responsible for 1-3% acute kidney injury (aki) cases. drug induced-ain (di-ain) rarely presents with the classic triad of rash,
fever and eosinophilia, and is usually a diagnosis of exclusion. On renal biopsy, typical for DAI-N, renal biopsy can show features of interstitial inflammation rich with neutrophils and interstitial cast formation, which is characteristic of AIN. Patients with AIN usually present with interstitial inflammation rich with eosinophils and plasma cells. Here, we report a Zosyn-induced neutrophil-rich AIN case.

Case Description: A 40-year-old woman with medical history breast cancer came with fever, pain and induration over her left breast. On admission she got Zosyn for suspected breast abscess. Next day, AKI noted, creatinine (Cr) increased from 0.6 to 3.3mg/dL. She remained hemodynamically stable. Laboratory showed no anemia, leukocytosis or peripheral eosinophilia. BUN/Cr of 38/4.7. Urinalysis negative for protein, blood, crystals, casts, white blood cells, red blood cells, nitrites, urinary sodium and chloride <20mmol/L, positive urine eosinophils. Negative autoimmune and hepatitis B/C work up. Blood and urine cultures were negative. Renal bladder ultrasound (US) showed normal kidney size with no sign of infection. Breast US findings were concerning for neoplasm. Zosyn was held and prednisone (1mg/kg) was given for suspicion of DAI-N. Renal Bow was done showing interstitial inflammation rich with neutrophils and neutrophilic cast without glomerular injury. Immunofluorescence with negative IgG, IgA, IgM, C3, C1q, fibrinogen, albumin, kappa and lambda light chains. Electron microscopy was unremarkable. Cr at 3rd day peaked at 4.7mg/dL, then trended down. Upon discharge, BUN/Cr of 2.36. One week after at renal clinic visit her kidney function came back to her baseline. We continued steroids for 3 weeks due to suspicion of AIN as repeated renal imaging and urine culture remained negative.

Discussion: This is a rare case where Zosyn was promptly stopped and prednisone was initiated early in the course of AIN despite neutrophil infiltration on renal biopsy. DAI-N can present with predominant neutrophilic infiltration; however, this makes the diagnosis more challenging. High suspicion, prompt antibiotic discontinuation and early institution of steroid can prevent further kidney injury or potential chronic kidney disease.

PO0134

A Case of BK Polyomavirus-Associated Nephropathy of Native Kidneys in a 19-Year-Old Woman with a History of Orthotopic Cardiac Allotransplantation

A. Wang, LLU nephrology Loma Linda University Adventist Health Sciences Center, Loma Linda, CA.

Introduction: BK polyoma virus associated nephropathy (BKPyV AN) is common among kidney transplant recipients. Approximately one to ten percent of kidney transplant recipients will develop BKPyV AN. BKPyVAN can lead to failure of the transplanted kidney allograft.

Case Description: A 20-year-old woman who had orthotopic cardiac allotransplantation in November of 2016 presented to the hospital in January of 2020 with upper respiratory tract infection like symptoms. Her baseline serum creatinine was 0.59 mg/dl and continued to increase rapidly leading to patient becoming hemodialysis dependent. Urine showed an active sediment; serology including ANCA and anti-GBM were all negative. Patient was empirically started on steroids for possible Immunglobulin A glomerulonephritis and also due to diagnosis of adrenal insufficiency. Renal biopsy subsequently showed crescentic glomerulonephritis with acute tubular injury and a diagnosis of DAI-N was made. Patient was placed on IV fluids while a GN workup was in progress followed by a biopsy and was discharged to be followed up on outpatient. Biopsy demonstrated active glomerulonephritis; crescents were noted in Bowman’s capsule and there was mild tubulointerstitial inflammation. Patient was placed on IV steroids. In this process, dialysis was delayed as the patient continued to improve. Her creatinine trended down to 1.5mg/dL. On discharge, she was started on 5mg methylprednisone once daily for 3 days followed by 0.5mg/kg of oral steroids on discharge and 1 month follow up. 1 month later, her creatinine trended to 5mg/dL, and there were electrolyte disturbances with improvement activities of daily living with adequate urine output. Decision was made to continue oral steroids in an attempt to delay dialysis.

Discussion: Post infectious IgA nephropathy is rare but continues to be important for progression towards ESRD. The infections responsible include E. coli Sepsis and urinary tract infections. Variable approaches have been used to treat or prevent around the inflammatory infiltrates. Immuno-suppressive therapies like cyclophosphamide and rituximab have been typically used for crescentic glomerulonephritis but have shown limited response. Their use in secondary IgA nephropathy has been limited to transplant recipients. Our case demonstrated one of the rare instances in which there was presence of active inflammatory infiltrate in absence of any crescent formation which guided our decision to initiate steroids. In this process, dialysis was delayed as the patient continued to have adequate renal function.

PO0136

Case of Paraneoplastic Paucli-Immune Glomerulonephritis

Golriz Jafari, Masood Mahmood, Anita Kazmarrzian. UCLA Medical Center Olive View, Sylmar, CA.

Introduction: This case highlights the importance of complete systemic evaluation for patients presenting with rapidly progressive glomerulonephritis (RPGN).

Case Description: 58 year old male with history of DM type 2 and hypothyroidism presents with acute kidney injury (AKI). Noteable findings include a rash which was biopsied and due to leukocytoclastic vasculitits. Baseline Cr 0.59 mg/dl and continued to increase rapidly leading to patient becoming hemodialysis dependent. Urine showed an active sediment; serology including ANCA and anti-GBM were all negative. Patient was empirically started on steroids for possible Immunglobulin A glomerulonephritis and also due to diagnosis of adrenal insufficiency. Renal biopsy subsequently showed pauci-immune crescentic glomerulonephritis with 89% of glomeruli with crescents, 74% an active and negative hematuria. Patient was stable on steroids. However further work up revealed a uveal mass which was biopsied and found to be Hodgkin’s lymphoma. Patient was started on chemotherapy however did not make any renal recovery and remains dialysis dependent.

Discussion: This case highlights the importance of thorough evaluation in patients presenting with rapidly progressive glomerulonephritis. Although onset times it is due to a primary renal or renal/pulmonary disorder, paraneoplastic conditions should not be overlooked and need further investigation.

PO0137

Renal Abnormalities in Patients with e-Cigarette, or Vaping, Product Use-Associated Lung Injury (EV ALI)

Josephine Abraham, Miekan A. Stonhill, Martin C. Gregory, Sean J. Callahan. University of Utah Hospital, Salt Lake City, UT.

Background: The use of electronic cigarettes is linked to the development of lung injury. There are no reports to date of renal injury secondary to vaping. Animal studies suggest that vaping could be associated with renal injury (1,2).

Methods: A retrospective chart review of the first twenty cases of patients with EV ALI was performed. We present the urinary abnormalities noted in patients with EV ALI.

Results: Twenty patients admitted for EV ALI underwent urinalysis as part of their laboratory workup. None of these patients had known pre-existing renal disease. All patients except for one had normal creatinine on admission. Proteinuria was seen in thirteen patients (65%) and microscopic hematuria (>4 RBC/hp) was seen in five patients (20%). Urinalysis of patients with microscopic hematuria also showed proteinuria. Patient’s urine was analyzed using the Proteus MAP and the presence of e-cigarette vapor was confirmed in all cases. Patients were not treated with steroids or other immunosuppressant therapies.

Conclusions: EV ALI can be associated with hematuria and proteinuria. In animal studies, e-cigarette vapor is hypothesized to diminish airway barrier function, release inflammatory protein into the circulation creating systemic inflammation leading to distant organ injury and dysfunction (2). There are several limitations to this study. This is a retrospective chart review and long term outcome is unknown as data is lacking. Nevertheless the high prevalence of urinary abnormalities on admission in patient with EV ALI calls for further investigation. While the pathogenesis of vaping-associated renal injury is unclear, urine analysis should be considered in all patients presenting with EV ALI. Ref 1. Impact of e-cigarette refill liquid exposure on rat kidney Golli NE et al. Regul Toxicol Pharmacol 2016 Jun;77:109-16. 2. Chronic inhalation of e-cigarette vapor containing nicotine disrupts airway barrier function and induces inflammation and multiorgan fibrosis in mice Crotty Alexander et al Am J Physiol Regul Interm Comp Physiol. 2018 Jun 1;314(6):R834-R847

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
PO0138
Kidney Biomarkers and Major Adverse Kidney Events in Critically Ill Patients
Alexander H. Flannery,1 Victor M. Ortiz-Soriano,2 Fabiola Gianella,3 Victor E. Prado,2 Robert D. Toto,1 Orson W. Moe,1 Javier A. Neyra,4 University of Kentucky College of Medicine, Lexington, KY; 3University of Kentucky College of Medicine, Lexington, KY; 1University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Several biomarkers of acute kidney injury (AKI) have been examined for their ability to predict AKI earlier than serum creatinine. Few studies have focused on using kidney biomarkers to better predict major adverse kidney events (MAKE), an increasingly used composite outcome in critical care nephrology research.

Methods: Single-center prospective collecting blood and urine samples from critically ill patients with AKI KDIGO stage 2 or above, and matched controls from a single, tertiary care intensive care unit. Samples were collected at 24-48 hours after AKI diagnosis (cases) or ICU admission (controls), 5-7 days later, and 4-6 weeks following discharge for AKI patients. The primary outcome of interest was MAKE at hospital discharge.

Results: Serum/urinary neutrophil gelatinase-associated lipocalin, serum/urinary chemoattractant protein-1 (MCP-1) show promise as biomarkers of chronic kidney disease (CKD) progression in settings such as diabetes mellitus, but their role in the transition from AKI to CKD remains unclear. EGF is produced specifically by renal tubular epithelium of the thick ascending limb and MCP-1 is extensively studied as a marker of kidney inflammation. We evaluated the associations of urine EGF and MCP-1 with CKD incidence or progression after cardiac surgery.

Methods: In this sub-study of the prospective TRIBE-AKI cohort, we evaluated 865 adult patients who underwent cardiac surgery from 2007-2010 at two sites in Canada and the US. We tested the association of first post-operative urine EGF and MCP-1, and the ratio EGF/MCP-1, with the composite outcome of CKD incidence or progression. We assessed for interaction by peri-operative AKI status.

Results: Over a median (IQR) follow-up of 5.8 (4.2-7.1) years, 266 (30.8%) patients developed the composite outcome at an event rate (95% CI) of 55.4 (49.2-62.5) per 1,000 person-years. Elevated levels of first post-operative urinary EGF and MCP-1 were each independently associated with the composite outcome, in opposing directions (Table 1), and the ratio EGF/MCP-1 was strongly associated with decreased risk of CKD incidence or progression in both continuous and categorical analysis (aHR 0.50 [0.33-0.74] for T3 compared to T1). There was no interaction by AKI status.

Conclusions: Urine EGF and MCP-1 may be useful for risk prediction of future CKD outcomes after peri-operative injury in cardiac surgery.

PO0140
Higher Plasma KIM-1 Is Associated with Increased Mortality and Decreased Renal Recovery in Patients with AKI Requiring Renal Replacement Therapy
Yvelyne P. Kelly,1 Finnian R. McCardland,1 Mallika L. Mundu,1 Venkata Sabbisetti,1 David E. Leaf,1 Sushrut S. Waikar,1,2 Brigham and Women’s Hospital, Boston, MA; 2Boston Medical Center, Boston, MA.

Background: Plasma kidney injury molecule-1 (KIM-1), a protein synthesized by renal proximal tubular cells, increases during periods of ischemia and thereby acts as a sensitive marker for AKI severity. We hypothesized that higher plasma KIM-1 levels assessed prior to commencing renal replacement therapy (RRT) would associate with higher mortality and RRT dependence in critically ill patients with severe AKI.

Methods: We measured plasma KIM-1 levels in 806 Day 0 samples from participants in Acute renal failure Trial Network (ATN) trial, a randomized controlled trial of intensive versus less-intensive RRT. For our primary analysis we used a logistic regression model to assess the risk of 28-day mortality and an inverse probability weighted logistic regression model to assess the odds of 28-day renal recovery, per doubling in log-transformed Day 0 KIM-1. Both models were adjusted for components of the ATN trial mortality risk score (age, chronic hypoxemia, CVS disease, malignancy, immunosuppressive therapy, ischemic AKI, post open surgery and vital signs at RRT initiation).

Results: Higher levels of plasma KIM-1 were associated with an increased risk of death within 28 days (adjusted odds ratio 1.15; 95% CI 1.03-1.29; p = 0.02) per doubling in log-transformed plasma KIM-1. Higher levels of Day 0 plasma KIM-1 were also associated with an increased risk of persistent RRT dependence at 28 days (adjusted odds ratio 0.76; 95% CI 0.66-0.87; p = 0.0001) per doubling in log-transformed plasma KIM-1.

Conclusions: Higher plasma KIM-1 levels measured prior to initiation of RRT are independently associated with higher 28-day mortality and lower probability of 28-day renal recovery in critically ill patients with severe AKI.

PO0139
Urine Biomarkers of Risk of Long-Term Kidney Outcomes After Cardiac Surgery: the TRIBE-AKI Study
Steven Menez,1 Dennis G. Moledina,1 Amit X. Garg,1,4 Heather Thiessen Phillbrook,1 Eric McArthur,1 Yaqi Jia,1 Wassim Obeid,1 Sherry Mansour,2 Michael Shlipak,2 Steven G. Coca,2 Chirag R. Parikh,1 TRIBE-AKI Consortium 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Yale University School of Medicine, New Haven, CT; 3Western University Schulich School of Medicine and Dentistry, London, ON, Canada; 4Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; 5University of California San Francisco, San Francisco, CA; 6Kainth School of Medicine at Mount Sinai, New York, NY.

Background: The urine biomarkers epidermal growth factor (EGF) and monocyte chemoattractant protein-1 (MCP-1) show promise as biomarkers of chronic kidney disease (CKD) progression in settings such as diabetes mellitus, but their role in the
Multiple Beneficial Effects of Renal Exosomes on Ischemic Injury

Katherine J. Kelly,1,2 Jesus H. Dominguez.1 1Indiana University School of Medicine, Indianapolis, IN; 2Richard L. Roudebush VA Medical Center, Indianapolis, IN.

Background: Ischemic injury to the kidney and other organs is deadly and expensive. We have demonstrated the effectiveness of adult cell-based therapies in multiple models of renal failure. Given the large benefits of relatively few cells, we hypothesized that exosomes from transplanted cells were the therapeutic effector. We and others have shown benefit with exosomes in renal injury models. To define the mechanisms of benefit from renal exosomes, the effects of exosomes from platelets and dermal epithelia were compared to those of renal exosomes.

Methods: The hypothesis that renal exosomes improve multiple pathways of injury postischemia and contain anti-oxidant and anti-inflammatory cargo was tested in a renal ischemia model. Exosomes from post-ischemic kidneys, platelets or skin were isolated by serial centrifugation. Renal function was estimated from serum creatinine. Oxidative stress markers (serum peroxiredoxin 3 (Prx3), nitrotyrosine) and neutrophil infiltration (CD11b+ cells) were assessed.

Results: Most renal exosomes showed renoprotective effects when compared with platelets or dermal epithelia. Exosomes from post-ischemic kidneys significantly protected renal function and renal tubular integrity compared to platelet or skin exosomes. Oxidative stress was reduced by renal exosomes but not by platelets or skin exosomes. Neutrophil infiltration was reduced by renal exosomes but not by platelets or skin exosomes.

Conclusions: Exosomes derived from kidney cells effect multiple pathways of injury to improve postischemic kidney function.

Funding: Private Foundation Support
Results: Versus controls, all 3 cell types significantly protected renal function and had similar efficacy between AKI (SCR levels, tissue injury scores); but within 14 days, each treatment elicited a significant IgG antibody response (57-99%) against the infused cell type. Rats inoculated i.p. with hASCs and confirmed to have positive immunity to hASCs were no longer renoprotected by hASCs when treated with them for IRI AKI.

Conclusion: While xenogeneic use of MSCs/ASCs is renoprotective, the demonstrated induction of an immune response makes such applications unsafe/ineffective in pre-clinical studies. Caution is advised in interpreting results of studies using cell lines containing xenogeneic expression vectors for genes meant to enhance MSCs' clinical efficacy. (Not U of Utah work)

Point-of-Care Prevention and Treatment of AKI with Adipose-Derived Stem Cells: Efficacy and Cost Advance over Culture-Expanded Bone Marrow-Derived Mesenchymal Stem Cells

Anna Gooch,1 Ping Zhang,1 Zhuma Hu,1 Christoph Westenfelder,1,2 SymbioCellTech, LLC, Salt Lake City, UT; 1University of Utah, Salt Lake City, UT.

Background: Our pre-clinical studies (AJP 2005) and a Phase 1 Clinical Trial (Nat Rev Neph 2010) show that administration of bone marrow-derived, culture expanded, allogeneic Marrow Stromal Cells (MSC) is effective in the prevention and hastened recovery from experimental AKI; and safe and renoprotective in on-pump cardiac surgery patients at high risk for post-op AKI. Significantly, MSC treated unlike historical controls on-pump cardiac surgery patients did not develop Chronic Kidney Disease (CKD) long term (>7 years). Expansion and banking of MSCs is expensive and time consuming. To address these limitations, we compared treatment with syngeneic, culture-expanded MSCs or vehicle to treatment with either syngeneic, minimally manipulated abdominal Adipose Derived Stem Cells (ASCs) or autologous Stromal Vascular Fraction (SVF) immediately isolated from fat, containing ASCs, endothelial precursor and other cells) for efficacy in preventing AKI. ASCs share therapeutically critical activities with MSCs and are in sufficiently high numbers/gram fat to present an alternative to culture-expanded MSCs.

Methods: ASCs and SVFs were isolated by minimal processing from abdominal fat harvested from male Fisher344 (F344) rats. IRI AKI was induced (bilateral renal pedicle clamping x 40 min) in 5 groups of male F344 rats (~200 g b.wt.; n=7 each). Upon reflow, groups were infused (supraparenal aorta) with either (1) 1x10^6 ASCs, (2) 1x10^6 autologous SVF cells, (3) 1x10^6 syngeneic, cultured MSCs, (4 and 5) vehicle in animals with or without fat harvest.

Results: Outcomes were compared to those of sham treated animals (n=7). Renal function assessed by serum Cr (SCr) in ASC or SVF treated animals was significantly better protected, and recovery more rapidly achieved compared to vehicle and MSC treated rats.

Conclusions: Our data suggest therefore that autologous ASCs and the SVF, obtained by minimal manipulation from a patient’s liposaprate, have the potential to treat that same patient with an efficient, inexpensive and safe point-of-care protocol to prevent or treat AKI and prevent subsequent progression to CKD. (No University of Utah resources were used for this work.)

PO0145

Administration of Exosomes from Mesenchymal Stem Cells Provides Effective Survival Benefits and Functional Rescue from Severe, Progressive Ischemia-Reperfusion Injury-Induced AKI in Rats

Anna Gooch,1 Mikhail Skliar,2 Ping Zhang,1 Zhuma Hu,1 Christoph Westenfelder,1,2 SymbioCellTech, LLC, Salt Lake City, UT; 1University of Utah, Salt Lake City, UT.

Background: While administration of Mesenchymal Stem Cells (MSCs) has been demonstrated clinically to prevent Acute Kidney Injury (AKI) such as that caused by cardiac bypass surgery, administration 48 hrs post-injury was found to be ineffective or potentially damaging, likely because the introduction of large cells (~50μm) into the compromised microvasculature may impair renal function. MSCs' renoprotection is mediated by their paracrine release of anti-inflammatory and trophic cytokines and their exosomes. Exosomes signal, post uptake by target cells, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. Since MSC-derived exosomes can prevent AKI we tested whether their small size and ability to move through the compromised renal microvasculature might allow them to provide effective rescue therapy for late stage AKI.

Methods: Exosomes from Sprague Dawley (SD) rat MSCs were isolated post 24 hr culture, purified using the ExoQuick-TC kit, and characterized for size (nanosight), protein and gene expression of relevant markers. 1/4 AKI (52 min bilateral renal pedicle clamp) was induced in female SD rats. If the SCr value on Day 2 was greater than on Day 1, demonstrating progressive AKI, then rats were administered via left carotid artery either 1 ml of Vehicle (PBS; n=8), Exosomes (200 μg protein-equivalent; ~4x10^6 exosomes; n=6), or MSCs (2x10^6; n=6) on Day 3.

Results: 1x10^6 MSCs secrete ~ 4.9x10^10 exosomes and other microvesicles (mode 1.36, median 2.82 X 10^10, 95% CI 4.89 X 10^9 to 9.38 X 10^10) express CD44 and CD29, and carry mRNAs of renoprotective genes expressed in MSCs. While both MSC and exosome administration improved survival over PBS, renal function only showed significant and sustained improvement in exosome-treated rats.

Conclusion: MSC-derived exosome therapy 3 days post progressive AKI, when renal blood flow is significantly impaired and when most clinical AKI is diagnosed, is superior to MSC therapy, likely due to their ability to deliver their renoprotective cargo into the compromised renal microcirculation. These data have, we posit, significant translational promise for the development of an effective rescue therapy for advanced AKI. (No University of Utah resources were used for this work.)

PO0146

Microparticles Released in Response to AKI May Influence Glucose and Salt Metabolism

Begoña Campos,1 Kathleen Harrison,1 Samantha M. Kramer,1 Bassam G. Abu Jawdeh,1,2 Charulas T. Thakar.1,2 University of Cincinnati College of Medicine, Cincinnati, OH; 1Cincinnati VA Medical Center, Cincinnati, OH.

Background: Renal epithelial injury due to ischemia or toxic/inflammatory insults is the primary cause of acute kidney injury (AKI). Due to their high metabolic activity renal tubular epithelial cells (RTPE) are especially vulnerable to damage leading to a clinical syndrome of disturbance in salt, water and glucose homeostasis. We have previously shown that microparticles (MP) derived from renal epithelial cells are released in the setting of kidney injury and can be detected in vitro as well as in human plasma, and can carry the biological activity.

Methods: In this study, we evaluated the release of MP carrying SGLT2, and SLC12A3 (NCC) in response to kidney injury. Immortalized RTPE models were treated with Oxidative stress (H2O2) or inflammatory stress (TNFα) agents by the validated methodology to study in vitro models of AKI. Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against SGLT2, and SLC12A3 (NCC). FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: RTPE models of injury (H2O2) resulted in a significant increase in the release of MP positive for SGLT2 MP 5.49 X 10^10/ml vs 0.10 X 10^10/ml for control cells (p=0.05) and NCC (SLC12A3) 4.2 X 10^10 vs 0.63 X 10^10 for control cells (p=0.05). Similar changes were observed when cells were treated with TNFα (p=0.05) or SGLT2 and NCC. We also confirmed the presence of MP containing SGLT2 and NCC in AKI (104.60 X10^10 /ml and 1.77 X 10^10 /ml respectively). However, when compared to controls, the difference was statistically similar.

Conclusion: This is one of the first reports to confirm that key transporters from renal epithelium can be released and detected as MP in both in vitro and clinical settings of AKI. These findings may provide novel insights into the mechanisms of glucose, salt and water dysregulation during kidney injury and repair.

Glomerular Filtration Fails to Increase During Pregnancy After Renal Ischemia-Reperfusion Injury

Ellen E. Gillis, Michael W. Brands, Jennifer C. Sullivan. Augusta University, Augusta, GA.

Background: Renal demands are increased during normal pregnancy due to the large increase in plasma volume and cardiac output, with a corresponding increase glomerular filtration rate and decreased blood pressure (BP). Recent studies in our laboratory have reported that pregnancy after recovery from ischemia reperfusion (IR) injury results in poor maternal and fetal outcomes, including decreased fetal weight, increased fetal demise, and mild antenatal in the dams. In the current study, we hypothesized that glomerular filtration fails to increase during pregnancy in these dams after recovery from IR.

Methods: Female Sprague Dawley rats (10 weeks of age, n=3) were implanted with telemetry devices into the femoral artery for continuous BP measurements. Following 10 days of recovery, rats were randomized to receive either 45 minutes of warm, bilateral renal ischemia or sham surgery. Rats were then given 1 month to recover. Full recovery from IR was confirmed by return of plasma creatinine and urine protein excretion to baseline prior to mating. Vaginal smears were performed daily once mating began, to identify gestational day 1. Glomerular filtration rate was calculated using creatinine clearance (using 24 hour urine collection from gestational days 19-20 and plasma creatinine on gestational day 20).

Results: BP decreased to a similar extent (7±1.2mmHg in control vs 8±1.2mmHg in IR dams) by gestational day 20, however the decrease in BP was delayed in the IR dams, resulting in an overall higher pressure load as determined by area under the curve analysis (2080±33 vs 2184±16, p<0.05, t-test). Glomerular filtration rate was significantly higher in control dams compared to IR dams (3.1±0.7mL/min vs 1.6±0.1mL/min, p<0.05).

Conclusions: These data suggest that after recovery from IR, the kidneys are unable to appropriately increase glomerular filtration rate during pregnancy. Ongoing studies in the laboratory are focused on alterations in plasma volume expansion during pregnancy to appropriately increase glomerular filtration rate during pregnancy. Ongoing studies in the laboratory are focused on alterations in plasma volume expansion during pregnancy to appropriately increase glomerular filtration rate during pregnancy.

Polyphenolisms in HAVCR1 Alter KIM-1-Mediated Phagocytosis

Ji Yun Lee,1 Brady Shrum,1 Lakshman Gunaratnam.2 1Western University Department of Medicine, London, ON, Canada; 2London Health Sciences Centre University Hospital, London, ON, Canada; 3Sleuch School of Medicine and Dentistry Department of Microbiology and Immunology, Western University, London, ON, Canada.

Background: During renal ischemia reperfusion injury (IRI), necrotic cells, and apoptotic tubular epithelial cells (TECs) undergoing secondary necrosis, release their immunogenic contents into the extracellular milieu, exacerbating inflammation. Kidney Injury Molecule-1 (KIM-1) is a cell-surface glycoprotein upregulated on TECs during acute kidney injury (AKI). We previously uncovered that KIM-1 protects against renal IRI by enabling TECs to bind and engulf dying neighbouring cells, limiting inflammation and tissue damage. The gene encoding KIM-1 (HAVCR1) is highly polymorphic, but the relevance of human KIM-1 polymorphisms in renal IRI has not been well studied. We hypothesized that HAVCR1 variant expressing TECs would have decreased phagocytic activity in vitro.

Methods: Using site-directed mutagenesis, we generated constructs for 3 high frequency HAVCR1 coding variants in addition to an expression plasmid encoding wild-type KIM-1 (pcDNA3-KIM-1). We then expressed the pcDNA3 vector, or HAVCR1 variants in HEK-293 cells using stable transfection.

Figure 1. (A) 25 minutes of ischemia in males (AKIMales) and 34 minutes of ischemia in females (AKIFemales) results in a matched model of kidney injury with no statistically significant difference in normalized glomerular filtration rate measured over the 1 year study. (B) Males developed impaired diastolic function (E’ < A’) and hypertension after AKI. (C) Females maintained normal diastolic function after AKI, but did develop hypertension that resolved by 1 year. (D) 1 year after AKI, males had reduced levels of cardiac ATP whereas females did not.

Results: We report that all 3 variants had altered cell surface KIM-1 expression compared to wild-type. Importantly, the phagocytic uptake of apoptotic bodies was significantly reduced in HEK-293 cells expressing each of the KIM-1 variants compared to those expressing wild-type KIM-1, indicating that mutations in these coding regions contribute to a functional impairment of KIM-1 activity.

Conclusions: This is the first study suggesting that human polymorphic variants in HAVCR1 may have consequences on the functional role of the KIM-1 protein in the kidney. This work strengthens the plausibility of a biological role for KIM-1 during AKI.

Porcine hibernation: An alternative model for experimental hibernation

Porcine models of hibernation have been developed to study the mechanism of hibernation. In this study, we evaluated the metabolism of hibernating pigs using 1H magnetic resonance spectroscopy (MRS). We found that during hibernation, the pigs showed a decrease in total lipid concentrations and an increase in total protein concentrations. These results suggest that hibernation is associated with an altered lipid and protein metabolism.

The metabolism of hibernating pigs was also measured using 13C MRS. We observed an increase in the incorporation of 13C-labeled glucose into fatty acids and triglycerides during hibernation. These findings indicate that hibernation is associated with increased fatty acid and triglyceride synthesis.

Our results suggest that hibernation is associated with altered lipid and protein metabolism, which may provide new insights into the mechanism of hibernation and its potential therapeutic applications.

Methods and Results: We used 1H MRS to measure the concentrations of total lipids, free fatty acids, and triglycerides in the muscle of hibernating pigs. We also used 13C MRS to measure the incorporation of 13C-labeled glucose into fatty acids and triglycerides. Our findings suggest that hibernation is associated with altered lipid and protein metabolism.

Conclusion: Our results suggest that porcine models of hibernation can be used to study the mechanism of hibernation and its potential therapeutic applications.

PD-1 Regulates Metabolic Fitness of Tregs in Protection from Kidney Ischemia-Reperfusion Injury

Murali Dogan, Rajkumar Venkatadri, Vikram Sabapathy, Sandhya Xavier, Didier Portilla, Rahul Sharma. University of Virginia, Charlottesville, VA.

Background: Regulatory T cells (Tregs) protect the kidney in models of ischemia reperfusion injury (IRI) and acute kidney injury (AKI). Previous studies suggested that Tregs from PD-1−/− mice offer no protection from AKI. In this study, we investigated the role of PD-1 in the metabolic fitness of Tregs during kidney injury.

Methods: We induced AKI in male C57BL/6 mice with 26 min bilateral renal IRI. CD4+CD25+ Tregs were isolated from PD-1−/− and PD-1+/+ Foxp3-GFP mice and then injected (100,000 cells/200ul) via tail vein into recipient mice 24h prior to ischemia reperfusion surgery. Kidney function was determined by measuring creatinine and tissue KIM-1 and NAG mRNA expression levels. Histological damage was assessed by light microscopic analysis of H&E stained kidney sections. In different set of experiments, we used mitochondrial staining and metabolic fitness of Tregs, we treated isolated T-cells from PD-1−/− and PD-1+/+ mice and incubated them overnight with anti-CD3/Ab to mimic antigenic stimulation or with high concentration of IL-2, which is critical for Treg survival and function. Mitochondrial membrane potential of Tregs was measured with TMRE to monitor the mitochondrial fitness. FACs-sorted Tregs from PD-1−/− and PD-1+/+ mice were also analyzed for the expression of genes involved in mitochondrial dynamics and biogenesis.

Results: In the mouse kidney IRI, PD-1−/− Tregs offered no protection from AKI. Conversely, PD-1+/+ Tregs reduced mitochondrial mass and mitochondrial membrane potential. In FACs-sorted Tregs, expression of markers of mitochondrial function, antioxidant pathways as well as those for mitochondrial dynamics were remarkably attenuated in the Tregs from PD-1−/− mice as compared to PD-1+/+ mice.

Conclusion: Ability of Tregs to protect kidney from IRI-induced AKI is dependent on PD-1 expression by Tregs. Mitotracker green and TMRE experiments suggest that in the absence of PD-1, Tregs have reduced mitochondrial number and/or function. Tregs require mitochondrial fitness for their development and optimal function. Additionally, these genes may regulate cytoskeleton rearrangement and microtubule movement related to cell motility, granule release and cell division.

ST2/IL33 Signaling Axis in Tregs Critical for Restoring Kidney Tissues Homeostasis on Injury

Vikram Sabapathy,1 Nardos T. Cheru,2 Airi Price,1 Rajkumar Venkatadri,1 Murat Dogan,1 Saleh Mohammad,1 Brian K. Stevens,1 Rahul Sharma.1

University of Virginia School of Medicine, Charlottesville, VA.1 National Institutes of Health, Bethesda, MD.2

Background: Renal diseases are a major cause of morbidity and mortality worldwide. Thus, leading to a great financial burden on health care systems. Inflammation elicited by a variety of cytokines and chemokines is a major player in the initiation and progression of the disease. Interleukin 33 (IL-33) acts as an ‘alarm’ that regulates the immune response during injury. IL-33 acts in an autocrine/paracrine manner through membrane receptor (ST2) aka IL33R or IL-1 receptor-like 1 (IL1RL1), triggering an innate and adaptive immune response. There is no evidence determining the importance of the ST2/IL33 axis in Tregs during kidney injury. In this study, we attempt to delineate the role of the ST2/IL33 pathway in Tregs cells using murine renal injury models and kidney organoids.

Methods: Murine ischemia-reperfusion injury (IRI) model was used to investigate the importance of cell-specific ST2/IL33 signaling using IL1RL1+/+ and Foxp3 cre mice to delete ST2 expression in Tregs. RNA sequencing analysis, flow cytometry, histology, immunohistochemistry, quantitative gene expression, and biochemical analysis were applied to dissect the role of ST2/IL33 signaling. Kidney organoid based 3D cell culture platform was used to setup co-culture experiments with ST2−/− and ST2+/+ Tregs for in vitro evaluation.

Results: The RNA sequencing analysis of ST2-High Tregs indicated higher expression of regenerative factors such as amphiregulin (AREG) and Growth differentiation factor 15 (GDF15). The analysis of regenerative factors such as amphiregulin (AREG) and Growth differentiation factor 15 (GDF15) was used to setup co-culture experiments with ST2−/− and ST2+/+ Tregs for in vitro evaluation. The results showed that ST2−/− Tregs decreased the expression of regenerative factors compared to ST2+/+ Tregs.

Conclusions: Impairment of ST2/IL33 signaling in Tregs leads to worsening of renal function following ischemic injury. This indicating that activation of ST2/IL33 signaling in Tregs mediates the regulation of inflammation, apoptosis, and repair in renal tissue during ischaemia and injury.

we injected adenovirus-associated viral vector serotype 9 (AAAV9)-Sclx into uninjured renal pelvis before IR injury, then assessed morphologic and functional parameters and gene expression in injury repair.

**Results:** We demonstrated that Sclx1 promoted cell proliferation by upregulating cyclin and glycolytic genes, and that cell migration through increasing the expression of matrix metalloproteinases (MMPs) in the cell model. Notably, the overexpression of Sclx1 could suppress inflammation through NF-kB-mediated pathway. Sclx1 target the promoters of amino-terminal enhancer of split (AES) and translocated in liposarcoma (TLS), which are cofactors of NF-kB subunit RelA, and then inhibit the transcription function of RelA in a negative feedback circuit. Sclx1 overexpression resulted in inhibiting inflammation and promoting cell proliferation to reduce kidney damage of mice from IR injury in vivo.

**Conclusions:** Our studies suggested that Sclx1 promoted kidney recovery and regeneration through proliferation/migration and anti-inflammation which might be a potential therapeutic target that can be used to improve kidney repair after IR injury.

**Funding:** Government Support - Non-U.S.

IRF8-Dependent Regulation of Kidney Dendritic Cells in Ischemic AKI

Li Na,1,2 Stefanie Steiger,2 Zhihua Zheng,1 Hans J. Anders,2 Julia Lichtnekert.2

1Division of Nephrology, The Seventh Affiliated Hospital, Sun Yat-sen University, Shenzhen, China; 2Division of Nephrology, Department of Medicine IV, Hospital of the LMU Munich, Munich, Germany.

**Background:** Ischemic acute tubular necrosis is a common cause of acute kidney injury (AKI), which involves a greater functional diversity of mononuclear phagocytes (MPCs) such as dendritic cells (DCs). The deletion of DCs induce more kidney injury and death. The hematopoietic transcription factor IRF8 mediates the phenotype of DC. However, the role of IRF8 dependent mechanism during AKI is not well known. Hence, we hypothesized that the dynamically altered expression of IRF8 in DCs could contribute to AKI.

**Methods:** AKI was induced by transient renal pedicle clamping in C57BL/6J. Kidneys, lymph nodes and spleens were collected on D1, D3 and D7. MPCs were identified by flow cytometry. Expression of IRF8 and MHC II were quantified by IHC. The knockdown of IRF8 was performed by transfecting siRNA in bone marrow-derived DCs (BMDCs). BMDCs were stimulated with necrotic supernatant from tubular epithelial cells or histones and analyzed by phagocytosis assay, T cell differentiation assay, RT-PCR or flow cytometry.

**Results:** In vivo, we identified four distinct phenotypically MPCs with diverse expression profiles of IRF8 during post ischemic AKI. During the late injury and repair phase (D3 and D7), CD11b^hiCD11c^ low R4 subsets significantly increased (Figure), which were identified as CD103^ CD11b^ DCs with significantly upregulated expression of IRF8. This pattern was consistent in spleen and lymph nodes. In kidney, more IRF8^ cells distributed among the tubulointerstitium and the expression of IRF8 increased significantly during D3 and D7. Further, IRF8^ cells showed co-staining with MHCII. The knockdown of IRF8 in BMDCs induced a significant downregulated CD8a^ CD11b^ cells and expression of IL-22 upon necrotic supernatant or histone stimulation. Furthermore, IRF8 knockdown significantly reduced DCs maturation, phagocytosis capacity and naïve T cells polarization.

**Conclusions:** DC-like MPCs appear in the recovery phase of AKI in a IRF8- dependent mechanism. Selective deletion of IRF8 profoundly alters the phenotype of AKI. The hematopoietic transcription factor IRF8 mediates the phenotype of DC. However, the role of IRF8 dependent mechanism during AKI is not well known. Hence, we hypothesized that the dynamically altered expression of IRF8 in DCs could contribute to AKI.

VNN1 Mediates Renal Maladaptive Repair After AKI by Inducing Premature Senescence of Renal Tubular Cells

Kehong Chen, Daping hospital, Chongqing, China; 2Kanazawa Medical University School of Medicine, Kanazawa, Japan; 3Kanazawa Medical University School of Medicine, Uchinada, Japan.

**Background:** Renal maladaptive repair can promote lead to the transition of acute kidney injury (AKI) to chronic kidney disease. Sustained renal interstitial damage catalyzes accelerated senescence of renal tubular cells leading to renal fibrosis after AKI. VNN1 is an extracellular enzyme with panthenylmethylamine activity that indirectly reduces the synthesis of glutathione, causing oxidative stress. This study aimed at investigating the role of VNN1 in senescence of renal tubular cells after renal ischemia-reperfusion (IR) injury.

**Methods:** Thirty male wild BALB/c mice were randomly divided into control group, sham group and IR group. In the IR group, bilateral renal pedicles were clamped for 35 min and reperfusion was performed. The expression of VNN1 was detected. Furthermore, the degree of renal damage and the senescence of renal tubular cells were compared in wild type mice and VNN1 knockout mice after IR injury.

**Results:** Scr, BUN and renal injury score increased significantly at the early stage (3d) of renal injury after IR. Renal fibrosis was observed in the advanced stage (28-42d).

**Conclusions:** Our studies suggested that VNN1 promoted kidney recovery and regeneration through proliferation/migration and anti-inflammation which might be a potential therapeutic target that can be used to improve kidney repair after IR injury.

**Funding:** Government Support - Non-U.S.

CDK4-Related Tubular Epithelial Cell Proliferation Was Regulated by Pax2 in Renal Ischemia-Reperfusion Injury

Keisuke Sakai,1 Yuta Yamamura,1 Yasunori Iwata,1 Norihiko Sakai,1 Miho Shimizu,1 Kengo Furuiuchi,2 Takashi Wada,1 Kanazawa University, Kanazawa, Japan; 2Kanazawa Medical University School of Medicine, Uchinada, Japan.

**Background:** Pax2 is a transcription factor necessary for kidney development. It has been reported that Pax2 is reactivated in tubular epithelial cells at the recovery phase of kidney injury. However, the roles of Pax2 in the regeneration of kidney injury is unknown. Here, we hypothesized that Pax2 reactivation is involved in the regeneration of injured tubular cells.

**Methods:** To determine the function of Pax2 reactivation in mouse proximal tubules, we generated kidney proximal tubule-specific Pax2 conditional knockout (KO) mice. The conditional KO mice were established by KAP (kidney androgen regulated protein) Cre mice and Pax2 flox mice. Six to eight-week old male mice were used for ischemia-reperfusion (IR) injury (left kidney, 60 minutes). The intensity of cell proliferation and fibrosis of injured kidney was evaluated. A Pax2 inhibitor (EG1) was used to evaluate the roles of Pax2 in the hypoxia condition of cultured tubular epithelial cells (0%, 5%, 24 hour).

**Results:** The number of Pax2-positive cells and Pax2 mRNA increased after IR injury. However, the reactivation of Pax2 was significantly suppressed in conditional KO mice (p<0.05). In analysis of interstitial fibrosis, the area of Sirius red staining and the content of hydroxyproline (chemical marker of collagen) were higher those observed in conditional KO mice 14 days after IR injury (p<0.05). Moreover, the expression of CTGF was significantly increased in conditional KO mice (p<0.05). Furthermore, the number of Ki-67 and BrdU positive cells was significantly decreased in the conditional KO mice 14 days after IR injury (p<0.001). In the cell cycle, the number of CDK4-positive cells (G1 phase marker) and the expression of CDK4 were significantly decreased in conditional KO mice (p<0.001). In vitro study revealed that CDK4 mRNA and protein expression were decreased by administration of Pax2 inhibitor, however Cyclin D mRNA and protein expression were not decreased by the inhibitor.

**Conclusions:** Pax2 reactivation may be involved in CDK4-related tubular epithelial cell proliferation. Inadequate Pax2 reactivation (or suppression of Pax2 expression) may be related in exacerbation of kidney fibrosis.

Protein Deacetylase SIRT2 Regulates Exosome Release of GPRC5B for Epithelial Tubule Growth

Sang-Ho Kwon. Augusta University, Augusta, GA.

**Background:** Exosomes, small membrane vesicles, are formed intracellularly within multivesicular bodies (MVBs) and are released extracellularly upon fusion with the plasma membrane. Previously we have shown that exosomal release of GPRC5B, an orphan G protein-coupled receptor (GPCR) promotes epithelial tube growth, and the L-type lectin LMAN2 limits trans-Golgi Network-to-endosomes traffic of GPRC5B. Here, we report the protein deacetylase sirtuin 2 (SIRT2) as a novel interactor of GPRC5B.

**Methods:** Using mass spectrometry, CRISPR/Cas9 genetic manipulation, and imaging, we revealed how LMAN2 regulates exosomal release of GPRC5B.

**Results:** Here, we report the protein deacetylase sirtuin 2 (SIRT2) as a novel interactor of LMAN2. Loss of SIRT2 expression resulted in increased exosomal release of LMAN2, a Golgi resident protein, together with increased exosomal release of GPRC5B. Furthermore, loss of SIRT2 increased total number of extracellular vesicles (EVs) including exosomes, indicating increased MVEB-to-EV flux. Knockout of SIRT2 increased EV release with enlarged late endolysosome, knockout of SIRT2 did not exhibit endolysosome enlargement for increased EV release.

**Conclusions:** Taken together, our study suggests that SIRT2 regulates cargo loading to MVBs and MVEB-to-EV flux through a mechanism distinct from that of SIRT1.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Conclusions: Spns2 is expressed in high abundance in kidney and is localized to the brush border of S1-S2 segment of PT and its expression is validated by WB, quantitative real time PCR and IF. We generated clone with the highest function was evaluated by measurement of plasma creatinine. Spns2 localization and its role was examined by immunohistochemistry. To examine the predictive value of urine tryptophan metabolites in AKI, 71 patients who received a total of 191 HDMTX treatments were prospectively enrolled as a validation cohort. Urine samples were collected within 72 hours before chemotherapy/surgery. AKI was defined by KDIGO criteria. Urine tryptophan metabolites were measured by LC-MS and adjusted by creatinine. The performance of these metabolites to predict AKI after HDMTX/LT was analyzed.

Results: Enzymes of de novo NAD+ synthesis pathway including KMO, KYNU, HAO, QPRT, and ACMSD were detected in renal tubules that were positive for LTL, but not labeled by AQP2, NCCT, nor TPH, consistent with proximal tubule expression. A total of 191 HDMTX treatments were included in the discovery cohort and AKI developed after 35 HDMTX treatments (18.3%). In those who developed AKI, the urinary level of 3-hydroxynitroanilic acid (3-OH AA) was significantly higher while the level of quinolinic acid (QA) was significantly lower compared with those who did not develop AKI (3-OH AA: 4.42[2.74-9.32] vs 3.57[1.86-5.73], p=0.023; QA: 13.43[9.69-22.34] vs 20.64[14.80-32.05], p=0.008). The area under the receiver operating characteristic curve (AUC) of urine QA/3-OH AA for AKI prediction was 0.748. The discrimination ability of the urine QA/3-OH AA on AKI susceptibility was validated in LT cohort, with the AUC as 0.729.

Conclusions: The proximal tubules are an important source of de novo NAD+ synthesis. Reduced urine QA / 3-OH AA ratio is associated with development of AKI. The present study suggests that urine QA / 3-OH AA ratio is a potential biomarker to predict AKI and NAD+ synthesis pathway is a potential therapeutic target.

PO0162
Dietary Omega-3 Fatty Acids After the Lipid Mediator Profile and the Fatty Acid Composition of Membrane Phospholipids but Is Not Enough to Improve Renal Insufficiency

Pavotro Shiroya,1,2 Airi Jo,1 Yusuke Suzuki,3 Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; Department of Biochemistry, Juntendo University Graduate School of Medicine, Tokyo, Japan.

Background: The efficacy of omega-3 fatty acids on ischemia-induced AKI has been reported, but the underlying mechanisms remain poorly understood. There have been no reports that demonstrated how dietary omega-3 fatty acids influenced the components of membrane phospholipids in the kidney. In this study, we focused on the effect of dietary omega-3 fatty acids on the membrane phospholipids components in the kidney, and examined the disease course of ischemia-induced AKI in the presence of the lipid mediator alterable by dietary omega-3 fatty acids.

Methods: Male 4-week-old wild-type Sprague-Dawley rats were fed for 2 months on AIN-93M, which contains 4% soy oil, or modified AIN-93M, which contains 4% perilla oil instead of soy oil. AKI was induced by unilateral ischemic reperfusion with right nephrectomy. Left renal ischemia was induced by using non-traumatic vascular clamps for 30 min. At 24 h after reperfusion, left kidneys and serum were collected. The fatty acid composition of membrane phospholipids and lipid mediators were quantified by HPLC-tandem mass spectrometry (HPLC/MS/MS).

Results: In the kidney of omega-3 diet fed rats, the levels of arachidonic acid-derived proinflammatory lipid mediators, except for 5-HETE, were not reduced compared with omega-6 fed rats. Eicosapentaenoic acid (EPA) and EPA-derived lipid mediators were significantly increased in the kidney of omega-3 diet fed rats. Furthermore, membrane phospholipids which contained EPA and docosahexaenoic acid (DHA) were significantly increased in the kidney of omega-3 diet fed rats. However, there was no significant difference in serum creatinine, blood urea nitrogen or histological damage between omega-3 diet fed rats and omega-6 diet fed rats.

Conclusions: Dietary omega-3 fatty acids altered the lipid mediatorsthe and the fatty acid composition of membrane phospholipids, but was not enough to improve renal insufficiency or histological damage.

PO0163
A Vago-Sympathetic Reflex Mediates Kidney Protection from Ischemia-Reperfusion Injury

Shinji Tanaka,1 Chikara Abe,1,2 Shuqiu Zheng,1 Yusuke Yamaoka,1,3 Jonathan E. Lipsy,1 Natallia Skrypnik,2 Junlan Yao,1 Tsuyoshi Inoue,2 Daniel S. Stornetta,3 Stephen Abbott,2 Diane L. Rosin,2 Ruth Stornetta,2 Patrice G. Guyenet,1 David M. Okusa.1 Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Pharmacology, University of Virginia, Charlottesville, VA.

Background: We generated choline acetyltransferase-channelrhodopsin-2 (ChR2) mice and vesicular glutamate transporter 2 (Vglut2)-ChR2 mice, which express ChR2 in vago-sensory afferent fibers. ChR2 activation of vagal sensory afferent fibers generates the cholinergic anti-inflammatory pathway (PMID: 27088805). Whether the protection is caused by the activation of vagal efferent or afferent fibers needs clarification.

Methods: We generated channelized acetyltransferase-channelrhodopsin-2 (Chat-Chat2R2) mice and vesicular glutamate transporter 2 (Vglut2-ChR2) mice, which express Chat2R2 in vago-sensory afferent fibers. The protective effect of afferent Chat2R2 mice was performed 24 h before bilateral renal IRI, and mice were euthanized 24 h after IRI. Results: Optiopgenic VNS protected kidneys from IRI in both Chat2R2 and Vglut2-ChR2 mice as shown by decreased plasma creatinine, reduced renal Kim-1 expression and improved kidney histology. Next, we sought to identify the circuitry responsible for the renal protection elicited by vago-sensory afferent stimulation (afferent VNS). The protective effect of afferent VNS persisted after blocking the rise in corticosterone with parasympathetic ganglionic blocker hexamethonium. Moreover, ablation of the splenic nerve (VNS) protected mouse kidneys from ischemia-reperfusion injury (IRI) by activating the cholinergic anti-inflammatory pathway (PMID: 27088805). Whether the protection is caused by the activation of vagal efferent or afferent fibers needs clarification.

Conclusions: Stimulation of either vagal efferent or afferent neurons protected the kidneys from IRI. The beneficial effect of afferent VNS requires the spleen and is mediated via a vago-sympathetic reflex.

Sphingolipid Transporter 2 (Spns2) Expression, Localization, and Role in AKI
Nataliya Skrypnik,1 Shuqiu Zheng,1 Sylvia Cechova,1 Nabin Poudel,2 Kevin Lynch,3 Mark D. Okusa.1 Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Pharmacology, University of Virginia, Charlottesville, VA.

Background: The sphingosine 1-phosphate (SIP) transporter Spns2 exports SIP from the cell and regulates the gradient of high circulating SIP levels to low tissue levels. Activation of SIP receptors can protect kidneys from acute injury, but little is known of the role of Spns2 in kidney. In these studies, we investigated the expression, localization, and role of Spns2 in the kidney after ischemia-reperfusion injury (IRI).

Methods: In vivo. Expression of Spns2 mRNA and protein in the kidneys and urine of C57BL/6 mice was analyzed 24 hours after sham surgery or IRI. Spns2 protein was assessed by western blot (WB) of membrane-enriched fractions of kidney. Renal function was evaluated by measurement of plasma creatinine. Spns2 localization and its co-localization with tubular markers in kidney (lens culinaris agglutinin, marker of brush border of S1-S3 segment of proximal tubules (PT) and wheat germ agglutinin a marker of brush border of S3 segment and cytosol of distal nephron) was by immunofluorescence (IF). The role of Spns2 after kidney injury, we pretreated mice 24h before IRI with Spns2 inhibitor (10 and 30 mg/kg, ip). In vitro. We generated clone with the highest Spns2 expression by the method of limited dilutions in TKP Ts; Spns2 expression was validated by WB, quantitative real time PCR and IF.

Results: We demonstrated that the kidney has the highest mRNA expression of Spns2 when compared to other organs (liver, lung, spleen, heart, thymus). We determined that Spns2 is localized to the brush border of S1-S2 segment of PT and its expression is reduced 24h after IRI, while levels of Spns2 protein increased in urine. Pretreatment of mice with Spns2 inhibitor produced dose dependent protection against AKI, as judged by plasma creatinine and Kim1 mRNA expression at 24h after IRI and also induced dose dependent lymphopenia in mice. Spns2-overexpressing cells had increased TGFβ1 mRNA expression.

Conclusions: Spns2 is expressed in high abundance in kidney and is localized to the brush border of S1-S2 segments of the PT. Following IRI, PT Spns2 expression is reduced and appears in the urine. Spns2 can serve as a potential target to prevent AKI, however further studies are needed to determine whether the protective effect of Spns2 inhibitor was due to lymphopenia or to a direct effect of Spns2 expressed in PT.

**Kidney Functional Improvements by a Novel Potent and Selective Vasopressin V1a Antagonist After Ischemia-Reperfusion Injury (I/RI) in Rats**

Karoline Drobnebr, Hana Cernecka, Chantal Fuerstner, Marie-Pierre L. Collin, Mira Pavkovic, Peter Hein, Frank Eitner, Peter Kolkhof. Bayer AG, Wuppertal, Germany.

**Background:** Alteration in renal perfusion is a key pathologic mechanism implicated in the development of ischemic acute kidney injury (AKI). We have reported that activation of V1a receptor decreases renal blood flow (RBF) and oxygenation in settings of increased vasopressin (AVP) levels. Here we studied the role of BAY 2327949, a recently identified potent and selective V1a antagonist, in a rat renal I/R model.

**Methods:** In a first setting, rats were infused with BAY 2327949 (100 μg/min/kg i.v.) or vehicle and baseline measurements were determined for 20 min. Unilateral ischemia was induced by clamping of left kidneys for 15 min, followed by 20 min of reperfusion. RBF and intrarenal oxygenation (pO2) were continuously measured via Laser Doppler Flowmetry. In a second setting, kidney function parameters 24h post I/R as compared to placebo treated rats.

**Results:** Unilateral clamping resulted in an immediate drop of RBF and pO2 that partially recovered during reperfusion (figure). Treatment with BAY 2327949 significantly ameliorated the severity of ischemic hypoxia and resulted in an improved and almost complete restoration of RBF and pO2 during reperfusion (figure). In the second setting, preventive treatment with BAY 2327949 resulted in dose-dependent, significant improvements of kidney function parameters 24h post I/R as compared to placebo treated rats.

**Conclusions:** BAY 2327949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation. For these reasons, BAY 2327949 could become a viable treatment option in conditions of increased AVP levels, such as AKI and CKD.

**Augmenter of Liver Regeneration Protects Kidney from Ischemia-Reperfusion Injury via Regulation of TLR4/ MAPKS Signaling Pathway**

Ying Li,1,2 Weijian Xiong,1,2 The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China; 1ChongqingTraditional Chinese Medicine Hospital, Chongqing, China.

**Background:** Toll-like receptor 4 (TLR4) expressed within the ischemic kidney is a crucial mediator of innate activation and inflammation. The augmenter of liver regeneration (ALR) is an immunoregulator which is highly expressed in kidney upon induction of renal I/R injury. It has been shown that exogenous ALR can protect kidney against I/R injury. However, whether ALR’s protective effect results from its immune regulatory function has yet to be determined. In this study, we show that treating renal I/R induced-rats with recombinant human ALR (rhALR) protects them from kidney I/R.

**Methods:** Rats were randomized into 4 groups as follows: sham-operated group; I/R group; I/R+rhALR1 group; I/R+rhALR2 group. TLR4, neutrophils and macrophages were detected by immunohistochemistry. ERK, INK, and p38 proteins were tested by WB. mRNA of HMGB-1, Biglycan, HAS1, HAS2 and HAS3 was detected by real-time PCR. The cytokines and chemokines were measured by ELISA.

**Results:** This result is corroborated by less tubular damage on rhALR treated rats than those on untreated rats. rhALR treated rats have significantly less apoptosis in tubular epithelial cells, less tubulointerstitial infiltration by neutrophils (24 h) and macrophages (72 h), as well as lower levels of inflammatory cytokines compared to the untreated control rats. Furthermore, rhALR downregulate mRNA expression of endogenous ligands for TLR4 and restrain activation of TLR4 and downstream signaling molecules (ERK, INK, and p38) on rats with renal I/R injury.

**Conclusions:** rhALR protects kidney from I/R injury by regulation of TLR4 signaling pathway

**DPP-4 Inhibitor Attenuated Renal Vasoconstriction Following Ischemia-Reperfusion Injury in Cirrhotic Rats**

Chiao-Lin Chuang,1,2 Hui-Chun Huang,1,2 Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan; 1Department of Medicine, National Yang-Ming University School of Medicine, Taipei, Taiwan.

**Background:** Cirrhotic patients may develop esophageal varices to cope with portal hypertension. Variceal bleeding is usually associated with hypotension and ischemia-reperfusion injury (IRI) which may activate endogenous vasoconstrictors, leading to severe renal vasoconstriction and renal failure (so called hepatorenal syndrome). Previous studies reported that dipeptidyl peptidase-4 inhibitor (DPP4i) could attenuate the endothelin-1 (ET-1) induced vasoconstriction and increase vasodilation. The aim of this study is to delineate the effect of DPP4i in renal vascular reactivity of cirrhotic rats following IRI.

**Methods:** Male S-D rats were used for experiments. Biliary cirrhosis was created by common bile duct ligation (CBDL). Control group received sham surgery (SHAM). After surgery, Linagliptin (3 mg/kg/d) or distilled water (DW) was administered for 28 days. On the 29th day, bilateral renal pedicles were clamped with microvascular clamps for 45 minutes in IRI group. The clamps were then removed followed with 60 minutes of reperfusion. Kidneys were perfused in situ via right renal artery for continuous monitoring of renal perfusion pressure.

**Results:** There was no difference in mean arterial pressure, heart rate, portal pressure, and blood sugar between DW and DPP4i treated rats. IRI enhanced renal vascular response to ET-1 in both SHAM (p=0.027) and CBDL (p=0.025) rats, implying renal vasoconstriction. Compared with corresponding DW-treated rats, DPP4i treatment abrogated renal hyperreactivity following IRI in CBDL rats (p=0.035), but not in SHAM rats (p=0.737).

**Conclusions:** We concluded that DPP4i may attenuate the development of renal vasoconstriction following IRI in cirrhotic rats. The potentially mechanisms remained to be elucidated.

**Endothelial Prolyl-Hydroxylase Domain Proteins Regulate Capillary Rarefaction Following Ischemic AKI and Reprogram Endothelial Metabolism**

Ratnakar Tiwari, Pinelopi P. Kapitsinou. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Endothelial cell (EC) metabolism has emerged as a new regulator of EC behaviour, but its role in capillary rarefaction, a common feature of progressive renal disease, remains unknown. Because EC sense oxygen and metabolic alterations through Prolyl hydroxylases 1 to 3 (PHD1-3), here we wished to define the impact of PHD inactivation on post-ischemic kidney injury outcomes, while in vitro studies focused on metabolic consequences.

**Methods:** Following the induction of renal ischemia-reperfusion injury (IRI), concurrent deletion of PHD1,2,3 was achieved by the Cdh5(PAC)CreER inducible system. Analysis was performed at day 14 post-IRI. Furthermore, we examined the impact of DMOG, a PHD inhibitor on angiogenic capabilities and global metabolic profiles of endothelial cells.

**Results:** Post-ischemic kidneys of PHD1,2,3 knockout showed more fibrosis, as indicated by 68% increase in collagen area (P < 0.005) and significant upregulation of profibrotic genes Lox1, Tgf-β and Acta2 (n = 6-8, P < 0.05) compared to controls. Quantitative analysis of endomembrane staining showed 58% decrease in peritubular capillary density, associated with reduced endothelial proliferation as indicated by Ki-67 immunostaining (n = 4, P < 0.005). Notably, biochemical inactivation of PHDs by DMOG reduced EC proliferation in MTT assay (P = 0.0001) while cell cycle analysis showed decrease of cells in S (~39%, n = 3-4) and G2/M phase (~25%, n = 2, P = 0.04). Furthermore, DMOG reduced EC migration (50%, n = 3, P < 0.005) and tube formation. LC-MS analysis showed a profound effect of DMOG in glycolytic, TCA cycle, lipid and, nucleotide metabolites. Specifically, EC treated with DMOG showed an increase in lactate (1.46-fold, P < 0.05) and significant reductions in citrate (2.2-fold, P = 0.001), alpha-ketoglutarate (2.5 fold, P < 0.05), fumarate (1.4-fold, P < 0.05) and malate (1.3 fold, P < 0.01). Supplementation with citrate partially rescued the proliferation defect induced by DMOG, suggesting that PHDs may affect angiogenic responses through alterations in mitochondrial metabolism.

**Conclusions:** Post-ischemic endothelial inactivation of PHDs promotes peritubular capillary rarefaction and fibrosis following AKI, a response which could involve alterations in mitochondrial metabolism.

**PTEN Protects Against Ischemia Reperfusion-Induced AKI via Regulating TNF-α Mediated Apoptosis**

Huizhen Wang, Aiqing Li. Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.

**Background:** Recently, PTEN, a vital tumor suppressor, has been raised its role in kidney homeostasis. We previous demonstrated that podocyte-specific knock-in of PTEN alleviated albuminuria and glomerulosclerosis in diabetic kidney disease. However, whether PTEN involves in acute kidney injury (AKI) remains unclear.

**Methods:** The levels of PTEN in renal tissue and serum were detected in ischemia-reperfusion (IR)-induced AKI mice with different ischemia time. Expression of PTEN was also detected in IR-induced cultured HK-2 injury with different ischemia and reperfusion time using ATP/glucose depletion that concentration of antibody mimicked the severity of ischemia. Immunoprecipitation and mass spectrometry were combined to analyze differential PTEN-interacting proteins among control, IRI+LV-NC and IRI+LV-PTEN groups. PTEN intervention including knock-down (si-PTEN) and knock-in (lentivirus-PTEN) was performed in HK-2 to reveal the role and mechanism of PTEN in IRI-AKI.

**Results:** PTEN was significantly reduced in renal tissue and serum in AKI mice at bilateral renal artery occlusion for 28 min and 35 min, and reperfusion for 1 day compared with sham group (P < 0.05). Concentration of serum PTEN was negatively correlated with level of serum creatinine (r = -0.87, 95% CI: -0.94 to -0.71). PTEN was also downregulated in IRI-induced HK-2 injury in an antibody concentration dependent manner (P < 0.05). There were 23 upregulated (ACO2, BRCAl, USP30), and 20 downregulated (BIN1, pericentrin, SLC12A5) PTEN-interacting proteins in IRI+LV-PTEN group compared with IRI+LV-Nc group. Gene Ontology enrichment analysis showed that overrepresentation of differential PTEN-interacting proteins functionally related to cytoketonelet, and ATPase activity. Pathway analysis showed a great role of differential PTEN-interacting proteins in apoptosis, and necrosis. Knockdown of PTEN increased the expression of NGAL, CTGF and TNF-α in IR-induced HK-2 injury (P < 0.05), while overexpression of PTEN alleviated IR-induced injury (P < 0.05).

**Conclusions:** PTEN was decreased in renal tissue and serum associated with severity of AKI. knock-down in IRI-AKI mice, suggesting that PTEN is promising to be a serum biomarker for early prediction and evaluation of AKI. PTEN protected HK-2 from IR-induced injury possibly via regulating cytoketonelet and TNF-α mediated apoptosis signal.
PO0170

DNA Repair Factor KAT5 Acts Against Ischemia-Reperfusion Injury Through Promoted DNA Repair and KCC3-Dependent TGF Regulation in Proximal Tubular Cells

Akihito Hishikawa, Kao Hayashi, Toshiaki Monkawa, Hiroshi Itoh. Keio University School of Medicine, Tokyo, Japan.

Background: It is known that an episode of ischemia-reperfusion (IR) results in tolerance to subsequent IR, which is so-called "pre-conditioning (PC) effect". However, the molecular mechanisms of the pre-conditioning effect have not been elucidated. We have recently discovered that DNA double strand break (DSB) repair tolerance factor KAT5 is essential for maintenance of podocyte integrity (Cell Rep. 2019). Here we investigated the role of KAT5 in PC effect.

Methods: Wild-type (WT) mice and proximal tubular epithelial cell (PTEC)-specific KAT5 knockout (KO) mice underwent IR injury by clamping bilateral renal arteries for 30 minutes followed by reperfusion. Ischemic pre-conditioning was performed 1 week prior to IR injury. In vitro studies using cultured human PTECs (HK2 cells) were conducted with ATP depletion by Antimycin A (AMA), an in vitro model of acute tubular cell damage.

Results: Serum UN, Cr, urine NGAL, DNA DSB marker γH2AX and KAT5 expression of the PTECs were increased and chloride transporter KCC3 expression was decreased at 24 hours after IR. IR with PC showed an attenuated increase in serum UN, Cr, urine NGAL and DNA DSBs with accelerated KAT5 and KCC3 expression. Mass spectrometry imaging of the kidney cortex following the first IR demonstrated elevated glomerular adenosine, which is used as a marker of accelerated tubule-glomerular feedback (TGF), whereas it was decreased after the second IR with PC in WT mice, suggesting attenuated TGF in the second IR. Therefore, increased chloride uptake through KCC3 expression of the PTECs were increased and chloride transporter KCC3 expression was decreased at 24 hours after IR. IR with PC showed an attenuated increase in serum UN, Cr, urine NGAL and DNA DSBs with accelerated KAT5 and KCC3 expression. Mass spectrometry imaging of the kidney cortex following the first IR demonstrated elevated glomerular adenosine, which is used as a marker of accelerated tubule-glomerular feedback (TGF), whereas it was decreased after the second IR with PC in WT mice, suggesting attenuated TGF in the second IR. Therefore, increased chloride uptake through KCC3 expression of the PTECs may contribute to the suppression of TGF, which maintained GFR. In KAT5 KO mice, PC effect was attenuated with increased DNA damage and decreased KCC3 expression. In vitro studies showed elevated KAT5 and KCC3 expression following second treatment with AMA. Chromatin accessibility assay showed increased chromatin accessibility of the KCC3 promoter region after the second treatment with AMA. ChiP analysis revealed that KAT5-binding KCC3 promoter region was significantly increased after the second injury compared with the first injury, indicating that elevated KCC3 expression was caused by increased binding of KAT5 to the KCC3 promoter region.

Conclusions: PTEC KAT5 may act against IR injury through promoted DNA repair and regulation of TGF via KCC3 expression.

PO0171

Kidney Proximal Tubular NFkB Essential Modulator Exacerbates Ischemic AKI

Background: Ischemic acute kidney injury (AKI) is a major clinical problem. We previously showed that renal tubular peptidylarginine deiminase 4 exacerbates ischemic AKI by promoting pro-inflammatory NFkB activation pathway via selective citrullination of NFkB Essential MODulator (NEMO). Since NEMO plays important and diverse physiological roles in almost all cell types, here, we tested whether renal proximal tubular (PT) cells play a role in ischemic AKI utilizing mice lacking PT NEMO and by targeting PT NEMO inhibition with mesoscale nanoparticle encapsulated NEMO binding peptide (NBP MNP) delivery.

Methods: We subjected PT NEMO deficient mice, wild type (WT) mice and C57BL/6 mice to 30 min renal ischemia and 24 hours reperfusion (IRIR). C57BL/6 mice received NBP MNP before IRIR injury to test whether selective PT NEMO inhibition attenuates ischemic AKI. Separate cohorts of PT NEMO deficient mice or WT mice were injected with recombinant PAD4 (rPAD4) before 20 min renal ischemia to test whether PAD4-mediated exacerbation of ischemic AKI is PT NEMO dependent. In addition, isolated PT from PT NEMO deficient mice and WT mice were treated with rPAD4 or human PT cells were treated rPAD4 after pretreatment of NBP MNP to determine whether PAD4 activates renal proximal tubular pro-inflammatory signaling via NEMO activation.

Results: PT NEMO deficient mice and C57BL/6 mice treated with NBP MNP were protected against ischemic AKI with decreased plasma creatinine (1.6±0.2, 1.7±0.2 mg/dL), NGAL mRNA (153.6±31.8, 433.2±54.7 fold increase over sham, N=5-7), renal tubular necrosis, inflammation and apoptosis compared to WT or control NEMO treated mice (Cr=2.1±0.3, 2.7±0.2 mg/dL, NGAL=752.8±176.3, 840.8±74.7 fold increase over sham, N=5-7). Exogenous PAD4 exacerbated IR injury in WT mice but not in PT NEMO deficient mice. Furthermore, rPAD4 upregulated pro-inflammatory cytokine and NFkB activation in freshly isolated PT cells from WT mice but not from PT NEMO deficient mice. Treatment of NBP MNP also protected rPAD4-mediated pro-inflammatory cytokine induction in cultured human PT cells.

Conclusions: Taken together, our studies suggest that renal PT NEMO plays a critical role in ischemic AKI by promoting renal tubular inflammation, apoptosis as well as necrosis. Our studies provide novel insight to the pathophysiology of PT NEMO in ischemic AKI, suggesting a potential therapy for ischemic AKI.

Blocking the Histone Lysine 79 Methyltransferase DOT1L Ameliorates AKI

Yingjie A. Guan, Shouqiang Zhuang. Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI.

Background: The Disruptor of telomeric silencing 1-like (DOT1L) gene encodes a histone methyltransferase that methylates lysines 79 of histone H3 (H3K79). DOT1L-dependent H3K79 methylation plays an important role in various physiological and pathological processes, including transcriptional regulation, embryonic development and renal fibrosis. However, its role in acute kidney injury (AKI) tissue injury remains unknown.

Methods: AKI was induced in Male C57/B6 mice by bilateral ischemia-reperfusion (IR) injury or intraperitoneally injection with folate acid (FA). EPZ5676, a highly selective inhibitor of DOT1L (20 mg/kg) or an equal volume of vehicle was administered immediately after IR or FA injection and then daily for two days. Renal function and histology were assessed by serum creatinine and HE staining. Immunohistochemistry and Western blotting were performed to identify tubule injury (NGAL), apoptosis (TUNEL and cleaved Caspase 3), proliferation (PCNA and Cyclin D) and Wnt signaling activation (active β-catenin and β-catenin).

Results: Mice developed AKI at 48 h after IR injury or FA administration as shown by the upregulation of serum creatinine and NGAL expression levels. Pharmacologic inhibition of DOT1L with EPZ5676 resulted in less severe tubular injury as evidenced by reduced renal dysfunction, diminished NGAL expression. Furthermore, the administration of EPZ5676 significantly reduced the number of TUNEL-positive and cleaved Caspase-3-positive tubular cells in kidney tissues. Conversely, renal tubular cell proliferation was enhanced as indicated by increased expression of PCNA and cyclin D. Moreover, DOT1L inhibition by EPZ5676 up-regulated the expression of active β-catenin form and β-catenin.

Conclusions: Our data reveals that blocking DOT1L with EPZ5676 may protect against AKI in mice through inhibition of apoptosis and enhancement of kidney repair by a mechanism involved in the modulation of the canonical Wnt signaling pathway.

Triptolide Treats Renal Tubular Injury Induced by Renal Ischemia-Reperfusion Through Specific Delivery of Kidney-Targeting Nanoplatform

Zeng Tao, Aiqing Li. Southern Medical University Nanfang Hospital, Guangzhou, China.

Background: Triptolide (TP) has been proved to be effective in the treatment of a variety of kidney diseases. Unfortunately, its clinical application is limited because of its high toxicity and low specificity. Here, we report a novel and safe kidney-targeting nanoplatform for specific delivery of TP.

Methods: Nano-polymer MNPs-TP was synthesized by encapsulating TP in a mesoscale nanoparticles (MNPs) with kidney targeting ability. MNPs-TP was injected into mice via tail vein to evaluate its toxicity to organs and immune system, and compared with free TP. The targeting and mechanisms of MNPs-TP treatment were explored by organ imaging, Transwell and other experimental methods. Finally, the model of renal ischemia-reperfusion injury (IRI) in mice was established, and the protective effects and mechanisms of TP and MNPs-TP on renal tubules in different concentrations were compared.

Results: Toxicity test showed serious pathological changes in liver, testes and the proportion of CD4+ /CD8+ in blood of mice in TP group, while MNPs-TP showed no obvious side effect on kidney, liver and immune system. The organ imaging and pharmacokinetic experiments indicated that free TP showed a fast metabolism and no specificity in the distribution of free TP in various organs, while the MNPs-TP showed longer metabolic cycle and clear kidney targeting. Immunofluorescence assay of kidney sections showed that MNPs-TP was mainly concentrated in the cytoplasm of renal tubular cells. After administration of TP at the dose of 0.1mg/kg body weight to the IR mice, the renal function represented by BUN and Scr of IR mice was alleviated. Down-regulation of p-ERK and NGAL suggested that TP could help protect the renal tubules by down-regulating MEK-ERK pathway and alleviated apoptosis of renal tubules. Free TP at the dose of 0.01mg/kg lacked these protective effects, and surprisingly, MNPs-TP kept the protection, which demonstrated that the effective therapeutic dose of MNPs-TP was significantly lower relative to free TP.

Conclusions: MNPs-TP shows a superior therapeutic effect on renal ischemia-reperfusion injury in comparison with TP. Furthermore, MNPs-TP conjugate presented much lower hepatotoxicity and no adverse effect on the immune and genital system. The kidney-targeting MNPs may provide a promising drug delivery platform of hydrophobic drugs for treatment of renal diseases.
of urine NGAL is from the plasma, our next step was to examine the renal handling of plasma NGAL.

Methods: We calculated the fractional excretion of rhNGAL (FE-rhNGAL) = ([urine rhNGAL] / [plasma rhNGAL] x urine creatinine) / [plasma creatinine] x 100. To link proximal tubular (PT) function with plasma and urine NGAL levels, we calculated the fractional excretion of rhNGAL (FE-rhNGAL): FE-rhNGAL = ([urine rhNGAL] / [plasma rhNGAL] x urine creatinine) / [plasma creatinine] x 100. Conversely, glomerular filtration rate (GFR), rhNGAL and mouse (m) NGAL in the plasma and urine, megalin in the urine. To link proximal tubular (PT) function with plasma and urine NGAL levels, we calculated the fractional excretion of rhNGAL (FE-rhNGAL) = ([urine rhNGAL] / [plasma rhNGAL] x urine creatinine) / [plasma creatinine] x 100.

Results: Uninjured vehicle: mice had 100% GFR and low levels of plasma and urine (rh)NGAL. IR (ATI model) and MA (PT injury model): 1% and 29% GFR respectively, increased plasma and urine rhNGAL in both models. Furosemide (PT injury model): GFR~30%, plasma NGAL was slightly elevated, urine rhNGAL was similar to control. FE-rhNGAL was less than 1% in normal and PRA mice, and it was greater than 20% in IR and MA treated mice. mNGAL plasma and urine levels, and FE-mNGAL were similar to rhNGAL levels and FE-rhNGAL respectively. Urine concentration of megalin correlated with FE-rhNGAL in every intervention (see Figure). Megalin is expressed on the brush border of PT and is responsible for the reabsorption of most filtered proteins, including NGAL.

Conclusions: Our data suggest that normal PT function is required for the clearance of plasma NGAL. Consideration of plasma NGAL with FE-NGAL is important to interpret urine NGAL levels and PT function and effectively distinguishes PRA from ATI.

PO0175
A Case Report of Vaping-Related Renal Thrombotic Microangiopathy

Introduction: Acute kidney injury (AKI) and hematuria have been reported in patients with e-cigarette use (vaping)-associated lung injury (EVALI) or E-cigarette use. However, renal pathology is not well understood. We report a case of biopsy proven renal thrombotic microangiopathy (TMA) in a patient with EVALI.

Case Description: A 40-year-old woman with history of vaping tetrahydrocannabinol (THC) and depression presented to emergency room with 2 days of fatigue, body aches, non-productive cough, and dyspepsia on exertion. On admission, BP was 157/85 mmHg, hemoglobin 6.9, platelet count 239, serum creatinine (SCr) 1.76 with 10-30/hpf non-dysmorphic RBC and 2+ proteinuria on urinalysis. Patient failed initial treatment with diuretics and on day 3, was intubated for respiratory distress. By this time, SCr had increased to 4.68 and LDH was quite elevated (1456) but platelet count was normal (194), haptoglobin high (551) and peripheral stiichocytes only occasional. Her EVALI improved with standard care in the next week but renal function further worsened, and hemodialysis was started on day 13. Renal biopsy revealed acute TMA with diffuse endothelial swelling, focal segmental glomerular and arteriolar thrombi and arterioles. Most of the kidney was not taking any medications known to cause TMA. Serologic and infection work up were negative including pneumococcus, HIV, antinuclear, anti-ScI70 and antiphospholipid antibodies. The ADAMTS-13 activity was 48% and serum homocysteine was low (3.8). Imaging studies showed no evidence of malignancy. Functional complement work-up did not reveal increased alternative pathway activity or autoantibodies. On day 20, patient was started on plasma exchange (PLEX) for 5 sessions followed by a slow renal recovery - last hemodialysis on day 22 and now, more than 1 month after last PLEX and after approximately 2 months of vaping cessation, most recent SCr is 2.57.

Discussion: There is no clear association of kidney disease with marijuana use in large population studies but there are case reports of AKI with synthetic cannabinoid use including one report of biopsy proven TMA. Drug-induced TMA is usually a diagnosis of exclusion and temporal correlation. Given the lack of other evident cause of TMA, our case suggests a potential association between THC and/or vaping and renal TMA.

PO0176
A Rare Case of Obstructive Nephropathy with Intratubular Tamm-Horsfall Polyps Secondary to Acquired Hemophilia

Kyle Meissner, Anil Musa, Vikas T. Reddy, Liye Suo, William F. Glass, Jade M. Teakell. University of Texas Health Science Center at Houston, Houston, TX.

Introduction: Acquired hemophilia has been rarely implicated in obstructive nephropathy. We present a case of gross hematuria, bilateral hydronephrosis, and biopsy-confirmed tubulointerstitial nephritis with intratubular Tamm-Horsfall Protein (TfH) polyps. These atypical pathological aggregations of urinary glycoproteins were previously described to be located in renal veins or lymphatics. Our case represents a rare etiology of obstructive nephropathy, with unique pathological findings, secondary to acquired hemophilia.

Case Description: A 64-year-old man with hypertension and tobacco use presented with bilateral flank pain and gross hematuria. After biopsy, the patient developed retropertitoneal hemorrhage requiring embolization. Further studies indicated the presence of a factor VIII inhibitor. He improved with transition from steroids to mycophenolate mofetil. A few months later, his renal function returned to normal with a bland urinalysis, proteinuria less than 100mg/day and resolution of hydronephrosis.

Discussion: We encountered a rare presentation of acquired hemophilia with macroscopic hematuria and AKI. We suspect that bladder clots and associated intraluminal clots resulted in elevated tubular pressures causing obstructive nephropathy and the formation of intratubular TfH polyps. Administration of immunosuppressive therapy and second-line agents should be considered in the differential diagnosis of AKI. We present a case of AKI and anuria where the prompt recognition and management of RA resulted in full recovery of kidney function and avoidance of renal replacement therapy and unnecessary testing.

Case Description: A 40-year-old male with Crohn’s disease status post prior right and left hemicolectomy was admitted with worsening abdominal pain and hematochezia consistent with Crohn’s flare. He underwent open abdomino-perineal resection. Pre-operatively, urology performed cystoscopy and prophylactic bilateral ureteral stent placement. Stents were removed without complication at the end of the case. On post-op day 1, he developed oliguria that progressed to complete anuria. This was associated with rapid rise in serum creatinine up to 5.5 from baseline of 0.6 (Figure 1). The differential diagnosis was broad, including acute tubular necrosis, vascular thrombosis and sepsis. He underwent open abdominoperineal resection which was followed by brisk urine output (~11 L/24 hours) and normalization of serum creatinine.

Discussion: RA is a rare diagnosis that requires high index of clinical suspicion. It is a functional rather than parenchymal disease that can cause dramatic cessation of urine output and AKI. Neurovascular reflex leading to arterial vasoconstriction and ureteric spasm is a proposed mechanism. This case illustrates that acute anuria and AKI after surgical procedures should prompt nephrology consultants to consider this uncommon diagnosis.

Figure 1. Acute rise in serum creatinine on post-op day 1 followed by rapid resolution of AKI after bilateral ureteral stent placement.

PO0177
Reflex Anuria: A Forgotten Urologic Etiology of AKI

Hassan Mahmoud, Jasvinder S. Bhatia. Boston Medical Center, Boston, MA.

Introduction: Reflex anuria (RA) is a rare entity that can lead to severe acute kidney injury (AKI). It was defined by Hull and colleagues in 1980 as “cessation of urine output from both kidneys in response to irritation or trauma to one kidney or its ureter or severe painful stimuli to other pelvic organs”. RA represents a gray area between nephrology and urology, and should be considered in the differential diagnosis of AKI. We present a case of AKI and anuria where the prompt recognition and management of RA resulted in full recovery of kidney function and avoidance of renal replacement therapy and unnecessary testing.

Case Description: A 40-year-old male with Crohn’s disease status post prior right and left hemicolectomy was admitted with worsening abdominal pain and hematochezia consistent with Crohn’s flare. He underwent open abdomino-perineal resection. Pre-operatively, urology performed cystoscopy and prophylactic bilateral ureteral stent placement. Stents were removed without complication at the end of the case. On post-op day 1, he developed oliguria that progressed to complete anuria. This was associated with rapid rise in serum creatinine up to 5.5 from baseline of 0.6 (Figure 1). The differential diagnosis was broad, including acute tubular necrosis, vascular thrombosis and sepsis. He underwent open abdominoperineal resection which was followed by brisk urine output (~11 L/24 hours) and normalization of serum creatinine.

Discussion: RA is a rare diagnosis that requires high index of clinical suspicion. It is a functional rather than parenchymal disease that can cause dramatic cessation of urine output and AKI. Neurovascular reflex leading to arterial vasoconstriction and ureteric spasm is a proposed mechanism. This case illustrates that acute anuria and AKI after surgical procedures should prompt nephrology consultants to consider this uncommon diagnosis.
Case Description: A 39-year-old man with no past medical history referred from another institution with COVID-19 pneumonia, for which he completed 4 days of hydroxychloroquine. On admission, patient was found to have SCo2 of 2.0 mg/dL, which increased to 10.8 mg/dL during a 3-day period. Urinalysis showed dysmorphic RBCs but no casts. Total albumin/creatinine ratio in urine was 3.2 mg/mg and FeNa >1%. Renal ultrasound showed no obstruction or masses. Other laboratory results showed methemoglobinemia (14 mg/dL), acute liver failure, schistocytes in the peripheral smear and a G6PD assay with marked deficiency. Other serologies were negative. Patient reported prior ingestion of 1 g acetaminophen (APAP) every 4 hrs for several days; treated with 48 hrs of N-acetylcysteine infusion. The AKI was complicated by hyperkalemia, severe anion gap metabolic acidosis and volume overload requiring long term renal replacement therapy after failure of resuscitation with crystalloid, albumin, and vasopressors.

Discussion: Our patient presented with significant abnormalities in multiple organ systems, including AKI. An analysis of comorbid conditions and typical AKI diagnostics allowed an expansive differential diagnosis (fig 1). One remaining interrogate was the catch 22: The Vicious Cycle of Malignant Hypertension and Worsening Renal TMA.

Introduction: Renal Thrombotic microangiopathy (TMA) may arise from multiple distinct etiologies. Malignant hypertension is one of these conditions that can precipitate and worsen Renal TMA. The detection of CSB-9 on endothelial cells may help determine the timing and selection of treatment to break the vicious cycle of malignant hypertension and worsening renal TMA.

Case Description: 54-year-old woman with a history of gestational hypertension, presented to the ED with complaints of a viral URI and was found to be in an hypertensive emergency with an SBP in the 260's. She was a non-smoker and did not use drugs or alcohol. She denied having any other symptoms or any recent medication use. Her labs were notable for hemolytic anemia and acute kidney injury with a creatinine of 4.0 mg/dL. Renal ultrasound showed diffusely increased renal cortical echogenicity. Renal biopsy confirmed the diagnosis of acute on chronic tubulointerstitial injury with severe endothelial swelling and onion-skin lesions of renal cortical tufts. Renal function and 62 % of patients with poor outcome had glomerular crescents involving 43–75% of the glomeruli.

Discussion: From this case, we can see that the detection of CSB-9 on endothelial cells may help determine the timing and selection of treatment to break the vicious cycle of malignant hypertension and worsening renal TMA.

Case Description: A 34-year-old woman with a history of gestational hypertension, lupus nephritis and chronic kidney disease progression, and our case highlights the need of future research on their possible role in immune activation. N-acetylcysteine infusion. The AKI was complicated by hyperkalemia, severe anion gap metabolic acidosis and volume overload requiring long term renal replacement therapy after failure of resuscitation with crystalloid, albumin, and vasopressors.

Discussion: Synthetic cannabinoids use should be considered in young healthy patients who present with unexplained AKI, as there are more cases reporting suggesting its direct nephrotoxicity. The etiology of tubulointerstitial injury from synthetic cannabinoids remains elusive, but a dysregulation of the endocannabinoid system in kidneys via endogenous cannabinoid receptors, CB1 and CB2, may be part of the mechanisms of injury. The cannabinoid receptors are now recognized to play potential roles in diabetic nephropathy and chronic kidney disease progression, and our case highlights the need of future research on their possible role in immune activation.

Discussion: This is a case of an elderly male patient who developed AKI with kidney biopsy that showed lupus nephritis; however, ANA and anti-dsDNA antibody were negative and there were no clinical manifestations of SLE. The patient was treated with Methylprednisolone, which was followed by Prednisone and Mycophenolate Mofetil (MMF). On 1-month follow-up, there was improvement in C3 and C4, and 24-hour CrCl estimated the GFR of 35 ml/min; hence, hemodialysis was discontinued. On 6-month follow-up, serum creatinine 1 mg/dL, BUN 14 mg/dL, and GFR >60 ml/min. Our patient’s kidney function recovered; however, there is no definite prediction of RLLLN manifestations of SLE, diagnosed with renal limited lupus-like nephritis (RLLLN).

Case Description: A 76-year-old Caucasian male with no previous history of renal or autoimmune diseases was admitted because of acute kidney injury (AKI). Patient had no history of joint pain and swelling, rash, or oral ulcers. He was not taking NSAID or any other medications. He had a history of smoking over 30 years and was a former smoker. He had a history of hypertension, diabetes mellitus type 2, dyslipidemia, and hyperuricemia. He was on treatment with amlodipine, metformin, and simvastatin. His blood pressure was in the range of 150/90 mmHg on antihypertensive medications. His medical history was significant for acute kidney injury of unknown cause in 2018, which resolved with conservative management. A renal biopsy was performed. Light microscopy revealed diffuse endocapillary hypercellularity and no crescent lesion. There was a full house with global granular mesangial and basement membrane staining for IgG, IgA, IgM, C1q, C3, free kappa and lambda light chains under immunofluorescence microscopy. Electron microscopy revealed mesangial and subendothelial dense deposit and segmental duplication. All these findings are consistent with RLLLN.

Discussion: Synthetic cannabinoids are designer drugs smoked as an alternative to marijuana with lower cost and greater potency. Here we describe a patient who presented with acute kidney injury and diffuse pulmonary infiltrates with recent inhaled synthetic cannabinoids use.

Case Description: A 26-year-old man with history of alcohol and recreational drug abuse including marijuana, tobacco and vaping, presented with acute kidney injury and diffuse pulmonary infiltrates. He recalled attending a party a week ago where he smoked someone else’s marijuana. On presentation, he was hypertensive to 170/115 mmHg with benign physical examination. Laboratory values were significant for serum creatinine of 17 mg/dL and BUN of 162 mg/dL. Urine sediment showed no cellular casts, but some monomorphic red blood cells, rare dysmorphic red blood cells and white blood cells. He had a spot protein/creatinine ratio of 230 mg/g. Chest X-ray showed bilateral pulmonary infiltrates. Renal ultrasound showed normal kidneys. Laboratory studies were all negative including CK, ANCA, anti-GBM, ANA, dsDNA, SFP and legionella urinary antigen. His urine toxicology screen was positive for opiates and cannabinoids. Renal biopsy revealed widespread edema of the interstitium and a mild to focally moderate inflammatory infiltrate involving approximately 80% of the cortical area. Tubular dilation, cytoplasmic vacuolization, and rare mitoses were seen in the tubules. He required hemodialysis, but he had a rapid resolution of his kidney failure with steroid initiation, and a repeat chest CT showed resolution of bibasilar opacities, although with persistent upper lobe ground glass opacities consistent with smoking and vaping-related injury.

Discussion: Synthetic cannabinoids use should be considered in young healthy patients who present with unexplained AKI, as there are more cases reporting suggesting its direct nephrotoxicity. The etiology of tubulointerstitial injury from synthetic cannabinoids remains elusive, but a dysregulation of the endocannabinoid system in kidneys via endogenous cannabinoid receptors, CB1 and CB2, may be part of the mechanisms of injury. The cannabinoid receptors are now recognized to play potential roles in diabetic nephropathy and chronic kidney disease progression, and our case highlights the need of future research on their possible role in immune activation.

PO0182
Postpartum Thrombotic Microangiopathy of Unknown Etiology: Is It Too Late to Save the Kidneys?
John K. Guirguis, S. J. Sher, Simit Doshi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: Thrombotic microangiopathy (TMA) is a rare (0.004%) but life threatening complication in pregnancy. Differentials include uncontrolled hypertension, Hemolysis elevated liver enzymes low platelet count (HELLP) syndrome, atypical Hemolytic Uremic Syndrome (HUS), Thrombotic Thrombocytopenic Purpura (TTP) among others. Lack of randomized trials and absence of gold standard laboratory tests can make diagnosis and treatment challenging. We present a patient with post-partum TMA confirmed on renal biopsy with no conclusive etiology identified.

Case Description: A 36 years old African American patient, GTP5 with history of Hypertension (HTN) and preeclampsia was noted to have blood pressure elevated to 180/103 mmHg during an antenatal care visit at 36 weeks of gestation. Serum Creatinine (scr) was at 0.5mg/dl with urine protein/Cr ratio (UPCR) of 0.75 g/g. She had an induced labor with persistent HTN postpartum. She left against medical advice and was readmitted 10 days later with acute kidney injury (AKI) with scr of 6 mg/dl and UPCR was 4g/g. Urinalysis showed positive protein but no RBCs. BP was elevated to 143/97 mmHg Laboratory data showed AST 33 U/L, ALT 24 U/L, Hb 9.5 g/dL, platelet counts 211 X10^9/L, C3 of 74 mg/dl, C4<2 mg/dl, negative ANA, ADAMTS 13 >94. Cyo results was inconclusive although RF was elevated at 160 IU/mL. Blood smear showed no schistocytes. She was started on pulse steroids therapeutic plasma exchange (TPE) was initiated, no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia results was inconclusive although RF was elevated at 160 IU/mL. Blood smear showed no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia. While awaiting biopsy therapeutic plasma exchange (TPE) was initiated, it was stopped after 3 sessions. Kidney biopsy on day 12 of delivery showed TMA, with negative immune-fluorescence (IF), minimal interstitial fibrosis/tubular atrophy, focal 2/15 glomerular crescents and minimal arterial intimal thickening. Patient became progressively oliguric, requiring hemodialysis. At the time of writing this report, there has been no recovery at 4 weeks as patient remains oliguric on thrice weekly dialysis.

Discussion: Peri-partum care is crucial in early detection and prompt management of TMA in patients with pre-eclampsia/Eclampsia. Benefit of TPE in post-partum period is not well established. A kidney biopsy was obtained but the diagnosis remained elusive with negative IF in setting of reduced complement levels. Further studies should evaluate treatment strategies in the late-presenting patient to avoid irreversible kidney injury.

PO0183
Thrombotic Microangiopathy as a Complication of Malignant Hypertension
Hany Eskarous. Easton Hospital, Easton, PA.

Introduction: Thrombotic microangiopathies (TMA) are defined as disorders characterized by the presence of microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and microthromb. Of all the known TMA, malignant hypertension is one of the most underreported ones.

Case Description: A 23-year-old African American male patient presented to the emergency department with a 2-week history of nausea, vomiting, diarrhea, and abdominal pain. His past medical history is significant for hypertension treated with lisinopril, but the patient is noncompliant with his medication. He had a blood pressure of 245/176 mmHg. Laboratory tests revealed hemoglobin of 10.7g/dl, platelet count of 88,000/microliter, white blood count of 14,300/microliter, blood urea nitrogen of 29 mg/dl, creatinine of 4.7 mg/dl (unknown prior creatinine levels), lactate dehydrogenase of 900 units/l, low haptoglobin, serum potassium of 2.1mg/dl and normal coagulation profile. With control of blood pressure, the platelet counts improved. ADAMTS13 test and stool Shiga toxin were negative. Peripheral blood smear showed schistocytes. Workup for secondary hypertension were all negative. A diagnostic CT guided left kidney biopsy revealed active and chronic TMA.

Discussion: In our patient presenting with renal TMA and severe hypertension, TTP was thought to be less likely as the patient did not have the classical presentation of fever and neurological symptoms. In addition, thrombocytopenia and LDH levels normalized with aggressive control of blood pressure. Hence, plasma exchange was deferred. Since the patient presented with diarrhea, HUS was high on the differential, but a negative Shiga toxin PCR ruled out the possibility. Renal biopsy revealed acute and chronic TMA in renal blood vessels with focal severe arteriolar sclerosis, fibrin, and onion skinning of arteries supporting the diagnosis of malignant nephroclerosis as the cause of TMA.

PO0184
Drug-Induced Thrombotic Microangiopathy from Trimethoprim-Sulfamethoxazole
Krishni A. Agarwal, Lorissa Kruger gomes, Esilda Sula Karreci, Ruth Schulman, Yad K. Heher, Bradley M. Denker. BIDMC Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Thrombotic microangiopathy (TMA) is a common condition manifesting with microangiopathic hemolytic anemia, thrombocytopenia and end-organ damage including, acute kidney injury. TMA can be associated with many clinical syndromes and is most often due to malignant hypertension, malignancy or complement dysregulation but can also be triggered by medications. Here we describe a rare case of TMA caused by trimethoprim-sulfamethoxazole (TMP-SMX).

Case Description: A 62-year-old man with recent diagnosis of Sweet’s syndrome was started on high dose prednisone and TMP-SMX for prophylaxis. He presented 4 days later with confusion, profuse diarrhea and “brown-colored” urine. He was normotensive on exam, without cardiac murmurs, clear lungs, soft non-tender abdomen and no skin rashes. Initial labs showed microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury with hyperkalemia. Blood smear showed schistocytes. He received emergent hemodialysis followed by plasma exchange for suspected TTP/HUS. Extensive workup during his hospital admission revealed a normal ADAMTS13 activity, negative blood and urine cultures, negative 0157:H7 stool antigen, negative urinary streptococcal antigen, negative autoimmune screen, negative hepatitis and HIV serologies, normal vitamin B12 level, normal bone marrow and pan-imaging without malignancy. A renal biopsy confirmed TMA. He remained anure and dialysis dependent on discharge.

Discussion: Patients with TMA have symptoms arising from anemia, thrombocytopenia, renal failure, or from underlying diseases like systemic infections, malignancies or drug toxicities. Once TMA is confirmed, elucidating the cause of TMA is important because there are specific treatments available for primary TMA syndromes like TTP and complement-mediated TMA. High suspicion of TTP requires urgent plasma exchange until ADAMTS13 levels return, and if complement-mediated TMA is likely, the terminal-complement inhibitor eculizumab can be used. Drug-induced TMAs require prompt discontinuation of the drug and supportive management. Trimethoprim-sulfamethoxazole is a rare cause of thrombotic microangiopathy, and the exact mechanism is not understood. Our case highlights the importance of considering TMP-SMX as a potential cause in patients presenting with TMA.

PO0185
Hemoglobin Cast Nephropathy in Rifampin-Induced Hemolytic Anemia
Saqib Mahmud, Carl S. Dernell, Naveel Bal, Abhillash Koratala, Alexander J. Gallan, Daniel A. Sturgill. Medical College of Wisconsin, Milwaukee, WI.

Introduction: Hemoglobin released after intravascular hemolysis causes acute kidney injury (AKI) by various mechanisms including hemoglobin cast nephropathy. This can resemble other causes of AKI such as acute tubular necrosis, acute interstitial nephritis (AIN) and thrombotic microangiopathy (TMA). Few studies have demonstrated immunohistochemically-proven hemoglobin casts on kidney biopsy associated with intravascular hemolysis. Below is a case of Rifampin-induced hemolysis associated hemoglobin cast nephropathy.

Case Description: A 64-year-old female with recurrent pulmonary Mycobacterium Avium Complex (MAC) infection treated with Rifampin, Ethambutol and Azithromycin presented with nausea and vomiting two weeks after starting therapy. Physical exam was remarkable for small purpura lesions on the back. Labs showed a serum creatinine of 6.6 mg/dl, BUN 66 mg/dl, hemoglobin 11.1 g/dl and platelets 9,000/µl. Haptoglobin was normal. LDH was elevated at 507 units/L. A direct antibody test was negative. Urinalysis showed large blood and microscopy showed 2-5 RBCs per hpf and dark granular casts.
Renal ultrasound was unremarkable. Plasma exchange was initiated for possible TMA but discontinued when ADAMTS13 level returned normal. On day four, serum creatinine was 8.1 mg/dL. She received methylprednisolone 120 mg daily for three days due to concern for possible Rifampin induced AIN. A kidney biopsy was planned and hemodialysis was performed to optimize platelet function. Kidney biopsy demonstrated intratubular pigmented casts that were strongly positive for hemoglobin A immunohistochemical stain confirming the diagnosis of hemoglobin cast nephropathy [Figure 1]. She received supportive care with kidney function gradually improving. Creatinine was 2.87 mg/dL on discharge and 1.18 mg/dL four weeks later.

**Discussion:** Hemoglobin cast nephropathy is a rare diagnosis and requires high index of suspicion in patients with hemolysis and AKI. Diagnosis is multifaceted requiring a clinical history, exam, lab workup and most importantly, a kidney biopsy.

**Case Description:** A 39-year-old woman who underwent laparoscopic hysterectomy presented to ED 4 days following surgery with abdominal pain. Her vitals revealed hypotension and tachycardia. Initial laboratory values were as follows: WBCs 18.0x 10^9/L, Na 134 mmol/L, K 4.9 mmol/L, Cl 101 mmol/L, HCO3 17 mmol/L, BUN 45 mg/dL, serum Cr 7.4 mg/dL, lactate 2.4 mmol/L. UA was remarkable for hematuria with 25 isomorphic RBCs/HPF. Abdominal US revealed moderate ascites. An indwelling bladder catheter was placed, and she underwent diagnostic paracentesis, with WBC noted at 1288/µL (35% neutrophils) and ascites-to-serum Cr ratio of 2.14. CT abdomen with IV contrast confirmed a full-thickness tear of the superior wall of the urinary bladder, with the bulb of the indwelling catheter extending beyond the bladder and an associated urinoma surrounding the catheter (Figure 1). She was diagnosed with bladder perforation and underwent open bladder repair emergently. Her serum Cr improved to 0.5 mg/dL in 24 hours.

**Discussion:** Uroperitoneum can result in the reabsorption of urine into the systemic circulation, while sodium and chloride ions move in the opposite direction. This results in hyponatremia, metabolic acidosis, azotemia and rise in serum Cr. Uroperitoneum should be expected when ascites to serum Cr ratio is >1.0. It is essential to recognize that the rise in serum BUN and Cr is due to pseudo-azotemia from the reabsorption of urine and not from true kidney dysfunction. Bladder injury is diagnosed by CT cystography, which was deferred in our patient giving the clear evidence of bladder injury in the CT abdomen. Complex extraperitoneal and all intraperitoneal bladder injuries require surgical repair.
glomerulosclerosis (FSGS). Anabolic steroids are directly toxic to renal glomeruli. Their use is widespread among athletes and bodybuilders seeking to enhance performance and are not benign and their use comes at the risk of renal failure requiring possible long-term replacement therapy and the gravity of his diagnosis. He underwent placement of a tunneled dialysis catheter and was discharged with close outpatient follow up.

PO0189

Triptan-Induced Vascular CKD, the Importance of a Differential Diagnosis

Kevin Mitchell,1,2 Ankur Shah,1,3 Brown University, Providence, RI; Providence Veterans Affairs Hospital, Providence, RI.

Introduction: Triptans are selective (5-HT) receptor agonists resulting in vasoconstriction reversing the vaso dilatory mechanisms of migraine headaches. Animal studies have shown 5-HT2 receptors in the renal arteries and intense vasoconstrictive effect of 5-HT on the renal arteries. We describe a case of progressive CKD with biopsy proven vascular injury due to sumatriptan use.

Case Description: A 52-year-old male with history of CKD stage 3, migraine headaches, and hyperlipidemia presented to nephrology clinic for evaluation of CKD. Review of records revealed a rise in sCr from 1.2 to 2.8 mg/dl over the preceding 4 years. Urinalysis was negative for hematuria, proteinuria, and pyuria. CT revealed symmetric kidneys without dilatation. A kidney biopsy was performed and showed patchy cortical atrophy and interstitial fibrosis with moderate vascular sclerosis and focal remodeling of the glomerular basement membranes consistent with prior vascular injury as well as acute tubular injury. A hematologic evaluation did not reveal an etiology and further history revealed use of sumatriptan 8-10 times per month. After discontinuation of sumatriptan, sCr improved from 2.8 to 2.2 mg/dl.

Discussion: This case highlights the broad differential diagnosis of acute and chronic kidney injury. The biopsy findings of primarily vascular injury were initially felt to be cryptogenic; however, further review revealed the etiology to most likely be triptan induced. After discontinuation of sumatriptan the creatinine improved in spite of increased NSAID use. Currently botulism injections are being used as migraine prophylaxis. This case highlights the importance of a review of all medications and for potential nephrotoxicity.

PO0190

Roid Renal Failure

Margaret Mallari, Priyesh T. Thakkar. AtlantiCare Regional Medical Center, Atlantic City, NJ.

Introduction: Athletes and bodybuilders often utilize anabolic steroids and high-protein supplements to gain muscle mass, however, the use of such performance enhancers comes with a significant risk of renal failure.

Case Description: A 34-year-old male weightlifter presented to his primary care physician with swelling, the patient started Expel, an over-the-counter potassium-sparing diuretic, 2 weeks ago. Labs were significant for bicarb 19 mmol/L (21-30), BUN 166 mg/dL (4-20), creatinine 2.8 mg/dl (0.5-1.3). Urinalysis showed no microscopic hematuria but elevated proteinuria. The patient denied any history of kidney disease or proteinuria.

Discussion: Review of records revealed a rise in sCr from 1.2 to 2.8 mg/dl over the preceding 4 months. After discontinuation of sumatriptan the creatinine improved in spite of increased NSAID use. Currently botulism injections are being used as migraine prophylaxis. This case highlights the importance of a review of all medications and for potential nephrotoxicity.

PO0191

Crystal Clear: A Case of Oxalate Nephropathy

Deanna N. Jones, James L. Pirkle. Wake Forest University, Winston-Salem, NC.

Introduction: Oxalate nephropathy is an uncommon and potentially devastating cause of acute kidney injury that can lead to end-stage kidney disease. Oxalate nephropathy can be hereditary (as in hereditary hyperoxaluria), related to toxins (such as ethylene glycol), medications, like high-dose vitamin C, or enteric malabsorption (such as gastric bypass surgery or malabsorptive disorders). Oxalate nephropathy occurs when calcium oxalate crystals form and deposit in the renal tubules and interstitium, leading to acute tubular necrosis.

Case Description: A 71 year old female with a medical history of pulmonary adenocarcinoma s/p Whipple procedure seven months earlier and chronic kidney disease stage 3 (baseline creatinine 1.0 mg/dL) presented to the hospital with elevated serum creatinine found incidentally on outpatient labs. Initial evaluation was concerning for volume depletion, as she improved with intravenous fluids. Over the next several months, she had repeated hospital admissions with worsening nonoliguric renal failure that seemed to respond to intravenous fluids in the hospital but worsened at outpatient visits. Urinalysis repeatedly showed no microscopic hematuria and low-level proteinuria, and urine microscopy showed coarse granular casts, consistent with acute tubular necrosis. Kidney biopsy was consistent with acute tubular injury and extensive tubular calcium oxalate deposition concerning for oxalate nephropathy.

Discussion: Oxalate nephropathy is a rare complication of pancreatic surgery and ascorbic acid use. Vitamin C is metabolized to oxalate and then excreted in the urine. In malabsorptive disorders, a higher concentration of fatty acids are present in the gastrointestinal tract, which bind calcium, leaving less to bind oxalate, and thus more oxalate is absorbed. High urinary oxalate can cause crystallization in tubules, leading to acute renal failure. Treatment is supportive, with removal of offending agents, oral calcium supplementation, and adequate oral hydration. Despite this, our patient progressed to end-stage renal disease requiring dialysis.

PO0192

A Novel Flow Cytometry Approach Identifies Kidney Mononuclear Phagocyte Subsets Involved in Mouse Kidney Injury Models

Background: Mononuclear phagocytes (MPNs) are heterogeneous in phenotype and function, which reflects their double-edged role as drivers of inflammation and repair after kidney injury. Dissection of this complex network of cells into functional subunits has become an important tool in preclinical kidney injury models. However, the use of traditional approaches is limited due to the complexity of these networks. Here we used a novel flow cytometric approach to phenotype and functionally dissect renal MPNs in two different kidney injury models.

Methods: Dynamic regulation of MPN subsets was monitored over 10d in two frequently used murine kidney injury models: ischemia reperfusion injury (IRI) and unilateral ureter obstruction (UUO). Using flow cytometric markers F4/80 and CD11b, kidney MPNs were phenotypically divided into five distinct subsets, which were further subdivided into functional subsets of proinflammatory M1-like (CD16/32+MHCII+CD206-) and regulatory M2-like (CD206+) cells.

Results: Three of the five renal MPN subsets were heavily contributing to both M1- and M2-like cell pools in both IRI and UUO, highlighting their functional multimodality. However, the use of traditional approaches is limited due to the complexity of these networks. Here we used a novel flow cytometric approach to phenotype and functionally dissect renal MPNs in two different kidney injury models.

PO0193
Microparticles Containing M2 Monocyte and Other Inflammatory Markers Are Released in AKI
Begolia Campos,1 Kathleen Harrison,1 Samantha M. Kramer,1 Bassam G. Abu Jawdeh,1,2 Charulasa V. Thakar,1,2 1University of Cincinnati College of Medicine, Cincinnati, OH; 2Cincinnati VA Medical Center, Cincinnati, OH

Background: Renal epithelial cell injury in AKI and induces a pleiotropic inflammatory cell response. Monocyte phenotypes (M1 = CD14+/CD16−; M2 = CD14+/CD16+) and subsequently derived tissue-resident macrophages play a critical role in inflammation and repair during acute kidney injury (AKI). It is accepted that M1 phenotype serves a pro-inflammatory/phagocytic role, whereas M2 phenotype influences tissue repair and remodeling. We have previously shown that microparticles (MP) derived from renal epithelial cells are released in the setting of kidney injury and can be detected in vitro as well as in human plasma, and can carry the biological activity.

Methods: In this study, we evaluated presence of MP expressing markers of inflammation in AKI (defined by standardized criteria). Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against inflammatory proteins. FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: The average age was 54 years; mean admission creatinine was 1.8 mg/dl, and the time between admission and sample collection was 3-4 days. MP containing M2 Monocyte markers were significantly higher in AKI patients compared to controls (347.03 vs 71.36; p-value: <0.001). MP containing M1 markers were similar compared to controls (177.85 vs 285.40; p-value: 0.19). AKI cases also showed significantly higher levels of MP containing other inflammatory markers: Leukocytes (CD45, p<0.005), eosinophils (CD66b, p<0.0001), and also in platelets (CD42b, p<0.05).

Conclusions: MP containing monocyte/macrophage markers of M2 phenotype are released in the early phase of AKI, which can influence tissue modelling and repair. Moreover, a pattern of MP representing markers of M2 and other inflammatory cells may have prognostic significance to predict the severity of tissue injury or the prospect of recovery.

Role of Glomerular Filtration Rate (GFR)-Modifying Drugs in Prevention of Anticoagulant-Related Nephropathy (ARN)
Sergey V. Brodsky, Ajay kumar Medipally, Min Xiao, Anjali A. Satoskar, Tibor Nadasy, Lee A. Hebert. The Ohio State University Wexner Medical Center, Columbus, OH

Background: Acute kidney injury (AKI) with red blood cell (RBC) tubular casts secondary to different anticoagulants has been recognized as ARN. ARN is seen in patients with underlying kidney diseases. 5/6 nephrectomy (5/6NE) animal model reproduces morphologic features of ARN. One of the possible pathogenetic mechanisms of ARN proposed to be increased GFR. Aim of the current study was to investigate the role of GFR-modifying drugs in prevention of ARN.

Methods: In the study, 28 non-diabetic mice per group were used. 5/6NE rats 3 weeks after the surgery were treated with direct thrombin inhibitor dabigatran (150mg/kg/day) and with GFR-reducing Enalapril (1.5mg/kg/dl) or GFR-increasing Albuterol (4mg/kg/day) for 7 days. Daily monitoring of serum creatinine (Scr), blood pressure and hematuria was performed. Morphology of the kidney was evaluated at day 7 after animals were euthanized.

Results: Dabigatran resulted in gradual increase in Scr (Fig 1), hematuria, acute tubular necrosis (ATN) and RBC tubular casts in all treatment groups. Neither of GFR-modifying drugs significantly changed there parameters. ATN was 0.75±0.27, 0.67±0.25 and 0.79±0.27 in Dabigatran, Dabigatran + Enalapril and Dabigatran + Albuterol treatment groups, respectively. Systolic blood pressure was reduced with Enalapril but did not change significantly with Albuterol. Diastolic blood pressure was not changed significantly with either treatment.

Conclusions: Our data indicate that GFR-modifying drugs do not prevent or aggravate ARN at least secondary to direct thrombin inhibitor.

Tubular β-Catenin Ameliorates AKI by Regulating Apoptosis and Necroptosis
Hongyu Li, Joseph C K Leung,1 Loretta Y.Y. Chan,2 Bin Li,1 Wai Han Yiu,1 Kar Neng Lai,1 Sydney C. Tang,1,2 The University of Hong Kong, Hong Kong, China; Queen Mary Hospital, Hong Kong, China.

Background: Renal tubular β-catenin signaling plays a protective role in acute kidney injury (AKI) but the underlying mechanisms remain debatable. Apoptosis and necroptosis of tubular cells are responsible for the renal dysfunction in AKI. This study aims to investigate the role of β-catenin activation in tubular cell death upon AKI and its underlying mechanism.

Methods: Transgenic ‘Tubcat’ mice conditionally expressing stabilized β-catenin in renal tubules following tamoxifen administration were used to establish septic (LPS-induced) and non-septic (ischemia-reperfusion injury or IRI-induced) AKI models. Tubcat mice and their littermate controls were divided into the LPS and IRI groups. LPS mice received intraperitoneal injection of LPS (20 mg/kg). IRI mice received bilateral ischemia for 28 minutes, followed by 24 hours of reperfusion. All the mice were sacrificed at 24 hours post reperfusion.

Results: The average age was 54 years; mean admission creatinine was 1.8 mg/dl, and the time between admission and sample collection was 3-4 days. MP containing M2 Monocyte markers were significantly higher in AKI patients compared to controls (347.03 vs 71.36; p-value: <0.001). MP containing M1 markers were similar compared to controls (177.85 vs 285.40; p-value: 0.19). AKI cases also showed significantly higher levels of MP containing other inflammatory markers: Leukocytes (CD45, p<0.005), eosinophils (CD66b, p<0.0001), and also in platelets (CD42b, p<0.05).

Conclusions: MP containing monocyte/macrophage markers of M2 phenotype are released in the early phase of AKI, which can influence tissue modelling and repair. Moreover, a pattern of MP representing markers of M2 and other inflammatory cells may have prognostic significance to predict the severity of tissue injury or the prospect of recovery.

Novel Immune Defense Cells of the Kidney Epithelia
Katherine Xu, Run Banlengchit, Abraham E. Simms. Columbia University Irving Medical Center, New York, NY.

Background: Urinary tract infections (UTIs) are one of the most common bacterial infections worldwide, affecting infant boys, older men, and most prominently, women of all ages. It is predominately caused by uropathogenic E. coli and can lead to uresepsis and kidney failure if untreated. We have found a major role for kidney epithelia, specifically the intercalated cells (IC), that are activated in defense against bacteria. Given the heterogeneity of kidney cell types, we hypothesized that there could be other cells that respond to a UTI.

Methods: We performed 10x Genomics single cell RNA-seq (scRNAseq) of whole kidneys from mice with UTI at 12 hrs and from mice without infection. We also performed scRNAseq of IC from lipopolysaccharide (LPS)-induced mice at 0, 8, and 24 hrs using a novel mRNA profiling method, pooled library amplification for transcriptome expression (PLATE)-seq. We used ROSA26α-cre,APtfvβ1b/Cre mice that activated GFP in IC and subsequently sorted GFP+ cells for PLATE-seq.

Results: scRNAsq across 16 samples from 10 mice (5 UTI-Control pairs) yielded 64,760 cells and resulted in populations of all major kidney cell types, as well as rare populations, i.e., pelvic transitional epithelial cells and double positive (DP) collecting duct cells, which have markers of both intercalated and principal cells. By gene set enrichment analysis, we found that DP cells activated genes involved in cell killing and innate immune responses at 12 hrs of UTI. DP cells were also found to be highly transcriptionally active in response to infection in a cross analysis with our dataset from 4-thiouracil-labeled nascent RNAs purified from APtfvβ1b+ cells. scRNAseq on APtfvβ1b+ population after LPS induction (525 cells) further revealed time-dependent activation of immune responses. We found that these IC/DP cells increased Umod expression in both UTI (1.6 fold change; padj=1E-2) and LPS (1.7 fold change; padj=1E-6) analyses. Umod, known to have immune properties, is commonly expressed in the loop of Henle and distal tubule, but may have a novel bactericidal defense role in the IC/DP cells.

Conclusions: We found a novel immune defense role of the double positive collecting duct cells in response to UTI. These transcriptionally active cells induce genes involved in cytokine and innate immunity and can provide new insights into the epithelial defense of the kidney.

Pulsed Ultrasound Improves Dysregulated Oxygen Metabolism and Reduces Tissue Injury in Sepsis-Associated AKI

Background: Sepsis associated acute kidney injury (SA-AKI) results in part from oxygenation septic and non-septic AKI. Tubular β-catenin might play a protective role in AKI by regulating cell death via modulating the p53/Akt signaling pathway. **Funding:** General Research Fund (HKU 17119/18), RGC Collaborative Research Fund (Ref: C7018-16G) and Hong Kong Society of Nephrology Research Grant (2019).

Methods: We used PAM imaging to assay the change of renal blood oxygen saturation (sO2), peritubular capillary (PC) blood flow (BF) and the metabolic rate of oxygen (MRO) in saline- and LPS-treated mice and mice pretreated with US 24 hr before LPS (as described PMID: 25644106). Mice received a single injection of LPS (5 mg/kg, i.p.), and oxygen consumption and blood flow were measured 10-80 min later by PAM imaging with an image penetration depth of up to 200 μm, and MRO was calculated.

Results: Pretreatment with US reversed the early decline observed 30-80 min after LPS and reversed the cortical regions of increased MRO. US treated LPS-induced AKI, confirmed by increased plasma creatinine, mRNA expression of kidney injury marker Kim1 and Ngal 12-24 hr after LPS, and acute tubular necrosis (by H&E staining), was attenuated by US pretreatment. US reduced Kim1 expression in the brush border membrane of proximal tubules in cortex and medulla. US attenuated the increase in IL-6 and IL-1β, but not TNF-α, mRNA expression.

Conclusions: Our results demonstrate that pUS reverses LPS-induced MRO, improves oxygen metabolism and reduces proinflammatory cytokines in SA-AKI. These results provide insight into the mechanisms of kidney tissue protection by US in AKI.

Targeting Gadd34 Upstream Open Reading Frame to Treat Sepsis-Induced Kidney Injury
Ashley N. Kidwell, Bernhard Maier, Pierre C. Dagher, Takashi Hato. Indiana University School of Medicine, Indianapolis, IN.

Background: Sepsis-induced acute kidney injury remains a major clinical problem with no effective therapy to date. We have previously shown that bacterial sepsis causes global transition shutdown via phosphorylation of the eukaryotic translation initiation factor (eIF2α). Under physiological conditions, this eIF2α phosphorylation is counter-regulated by two eIF2α holophosphatases. Of the two holophosphatases, Growth Arrest DNA-inducible Gene 34 (Gadd34) is the only stress-inducible regulatory subunit. Using Gadd34 mouse models, we previously demonstrated a protective role for Gadd34 in the kidney. Herein, we report that Gadd34 is also essential for kidney protection in sepsis.

Methods: Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We designed the upstream regulatory mechanisms of Gadd34 in the inflammatory processes were studied using signaling inhibitors.

Results: We observed a significant decrease in the production of proinflammatory cytokines and chemokines in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF. We also observed that the expression of Gadd34 in the kidney was significantly reduced in Gadd34 5’UTR where a single nucleotide mutation was introduced to abol...
cytokines including IL-6 and CCL-2, whereas treatment with an inhibitor of TLR4 or NFκB signaling suppressed LPS-induced NEAT1 expression.

Conclusions: NEAT1 expression was induced in LPS-activated HK1 model via TLR4-NFκB signaling, suggesting its potential role in the inflammatory process. Our findings open the door to exploit NEAT1 expression as a potential novel therapeutic approach for AKI and other inflammation-related renal diseases.

Background: Renal tubular epitheyal cell FOXO1 on endotoxin-induced AKI

Xinling Zhang, Wei Dong, Guangdong Academy of Medical Sciences, Guangzhou, China.

Methods: In vivo, the mouse model of endotoxin-induced AKI was induced by intra-abdominal injection of LPS (10 mg/kg). The expression of FOXO1 and PGCI-1α in mouse kidney were determined. Then we established a mouse model of renal overexpression of FOXP1 by in situ injection of FOXP1 adeno-related virus in renal cortex before intra-abdominal injection of LPS. In vitro, human proximal tubular epithelial (HK-2) cells were stimulated with LPS (40 ng/ml), then infected with FOXP1 overexpression adenovirus. The morphology changes of mitochondria were observed using mitotracker staining. Mitox-SOX was used to detect the changes of mitochondrial superoxide content and the expression of FOXP1.

Results: In vivo, FOXP1 downregulation in mice RTECs and mitochondrial damage was found in endotoxin-induced AKI. Overexpression of FOXP1 could improve renal function and reduce mitochondrial damage. PGCI-1α was reduced in endotoxin-induced AKI and reversed by FOXP1 overexpression. In vitro, exposure to LPS led to HK-2 cell viability decline, mitochondrial fragmentation, and mitochondrial superoxide accumulation, as well as downregulation of the FOXP1, PGCI-1α and mitochondrial complex I/V. Moreover, over-expression of FOXP1 in HK-2 cells could increase HK-2 cell viability and PGCI-1α expression, and alleviated altered mitochondrial injury and superoxide accumulation induced by LPS. Meanwhile, inhibition of FOXP1 in HK-2 cells by siRNA decreased PGCI-1α expression and HK-2 cell viability. Chromatin immunoprecipitation assays and PCR analysis confirmed FOXP1 binding to the PGCI-1α promoter in HK-2 cells.

Conclusions: In conclusion, downregulation of RTECs' FOXP1 mediated endotoxin-induced AKI and mitochondrial damage. Over-expression of FOXP1 could improve renal injury and mitochondrial dysfunction, at least partly via PGCI-1α-signaling. FOXP1 might be a potential target for the prevention and treatment of endotoxin-induced AKI.

Humanin Improves Mitochondrial Function and Alleviates Renal Tubular Injury in Lipopolysaccharide-Induced AKI

Zhenmeng Xiao, Zhilian Li, Wei Dong, Yuanhan Chen, Xiling Liang, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.

Background: Mitochondria dysfunction is increasingly recognized to be a key role in the pathogenesis of sepsis-induced AKI. Whether Humanin (HN), a well-known mitochondrial-encoded cytoprotective peptide, has similar effect has severe AKI remains unknown. We hypothesize that HN improves mitochondrial function in sepsis-induced AKI.

Methods: LPS (10mg/kg) was given to C57BL/6 mice intraperitoneally to induce murine septic AKI, and HNG (a potent analog of humanin, 1mg/kg) was injected 15 minutes later. Mice were euthanized at 24 h after LPS injection. Blood samples and kidney tissues were collected. Blood urea nitrogen was measured to evaluate renal function. Electron microscopy was used to observe mitochondrial morphology and structure. Renal inflammation (IL-1β, IL-6 and HMGB1) was evaluated by real-time PCR. The expression of PGCI-1α and TFAM, which can promote mitochondrial biogenesis, was measured by real-time PCR, western blot and immunohistochemistry.

Results: HNG significantly reduced blood urea nitrogen levels (62.10±3.535 mg/dl vs. 30.30±2.558 mg/dl, p<0.05). Electron microscopy showed improved mitochondrial damage of renal tubular epithelial cells in the LPS group, such as mitochondrial swelling and deformation and the crista disorder or disappearance. Treatment with HNG restored mitochondrial morphology and structure. Compared with LPS group, HNG reduced the renal expression of IL-1β, IL-6 and HMGB1 and significantly increased the expression of PGCI-1α and TFAM in the kidney.

Conclusions: Our data showed that humanin ameliorated renal dysfunction and attenuated renal tubular injury by alleviating mitochondrial dysfunction in LPS-induced AKI, which may be associated with upregulation of PGCI-1α and its downstream transcriptional factor TFAM.

The Effect of Overexpression of Intestinal Alkaline Phosphatase (IAP) on Intestinal Permeability and Renal Failure in Lipopolysaccharide (LPS) Treated IAP Transgenic (IAPtg) Mice

Siddhartha S. Ghosh, Austin J. Mullaly, Shibba Ghosh, Todd W. Gehr. Virginia Commonwealth University, Richmond, VA.

Background: LPS associated sepsis is known to cause intestinal dysfunction in septic AKI. IAP is known to dephosphorylate LPS and render it inactive. We generated IAPtg mice with overexpressed human IAP. We hypothesized that if IAPtg mice were subjected to septic AKI their kidney function and intestinal barrier permeability will be better preserved than non-transgenic mice.

Methods: IAPtg mice were developed in C57Bl6 background using human chimeric IAP under the control of villin promoter making them tissue specific. IAP overexpression IAP. LPS (10 mg/kg) was given to IAPtg (IAPtg+LPS) and C57Bl6 (C5+LPS) to induce septic AKI. The control IAPtg (IAPtg-LPS) and C57Bl6 (C5-LPS) received saline. FITC-Dextran (FD) was gavaged 2 hours before sacrifice to measure intestinal permeability. Blood, intestine (duodenum, jejunum, ileum), and colon were harvested for biochemical and immunoblot analysis.

Results: Serum urea and creatinine of IAPtg mice were 0.6 mg/dl and 65 mg/dl respectively which were 2 and 1.5 fold lower than C5-LPS mice (p<0.05). Serum FD levels of IAPtg/LPS (1.2 ± 0.1 ng/ml) were 2.5 fold lower than C5-LPS (p<0.05) suggesting improved intestinal integrity. Expression of tight junction protein (ZO-1), pro-apoptotic proteins (Caspase3, Bax), anti-apoptotic protein Bcl2 in the colon, and intestine was measured by immunoblot. ZO-1 expression in the intestine and colon of C5-LPS was significantly lower than IAPtg/LPS (p<0.05). Bax levels were increased in both intestinal and colon of C5-LPS in the IAPtg group (p<0.001). Intestinal and colonic BAX of IAPtg/LPS were lower and Bcl2 higher than C5-LPS (p<0.05). Apoptotic markers of IAPtg/LPS were not significantly different from the control IAPtg/LPS but significantly lower than C5-LPS (p<0.05). ZO-1 expression in the intestine and colon of C5-LPS was significantly lower than IAPtg/LPS (p<0.05) and the controls (p<0.01). Expression of ZO-1 was significantly lower than IAPtg/LPS (p<0.05) and the controls (p<0.01). Expression of ZO-1 was significantly lower than IAPtg/LPS (p<0.05) and the controls (p<0.01). Expression of ZO-1 was significantly lower than IAPtg/LPS (p<0.05) and the controls (p<0.01).

Conclusions: Improved ZO-1 expression probably due to reduced apoptosis decreases intestinal permeability in transgenic mice subjected to endotoxemia. This can suggest decreased inflammation in transgenic mice.

Funding: Private Foundation Support

Changes in NAD and Lipid Metabolism Drive Acidosis-Induced AKI

Milica Bugarski, Susan Ghazi, Marcello Polese, Joana R. Martins, Andrew Hall, Institute of Anatomy, University of Zurich, Zurich, Switzerland. 2Center for Microscopy and Image Analysis, Zurich, Switzerland, 3Department of Nephrology, University Hospital Zurich, Zurich, Switzerland.

Background: The kidney has an important role in maintaining normal blood pH. Mitochondria in the proximal tubule (PT) produce ammonia and bicarbonate from glutamine, and during metabolic acidosis (MA) this pathway (ammoniagenesis) is acutely upregulated. MA is frequently associated with acute kidney injury (AKI); however, to what extent the former causes the latter was unclear.

Methods: Multiphoton imaging of mitochondrial function in mouse kidney cortical slices and in vitro oxygen consumption rate (OCR) in isolated PTs; histological analysis and electron microscopy (EM) in fixed tissue. MA was induced using an established protocol (gavage with 0.4 g/kg NH4Cl).

Results: Acutely lowering extracellular pH to 6.5 decreased mitochondrial NADH fluorescence signal specifically in PTs, without changing total NADH content, baseline OCR or mitochondrial membrane potential. However, maximal OCR was decreased and response to rotenone was exaggerated, suggesting a switch to complex I and increased oxidation of NADH to NAD+, which is required for amionogenesis. PTs in acidic animals displayed intense Oil Red O staining and large multi-lamellae bodies (MLBs), consistent with a major decrease in lipid metabolism. Supplementing or reducing NAD (with lactate) and increasing pH back to 7.4 inhibited/reversed the appearance of MLBs, implying that changes in NAD and lipid metabolism are linked. Histological analysis of acidic animals showed thinning of PTs and shedding of debris, indicative of AKI. Intravital imaging revealed that mitochondria remained energized, but endocytosis of fluorescently labeled dextrans was markedly decreased, confirming a severe functional defect in solute transport. Partially reversing MA with intravenous injection of bicarbonate (0.42 g/kg) or supplementing NAD with nicotinamide (0.4 g/kg, prior to MA induction) both substantially improved dextran uptake.

Conclusions: MA induces major changes in PT NAD and lipid metabolism that result in a functional AKI state, which can be reversed or prevented. These findings might also help to explain why MA accelerates decline in function in chronic kidney disease.

Loss of HDAC8 Leads to H2AX-Induced Cellular Repair and Decreased Epithelial-Mesenchymal Transition in Renal Tubule Epithelial Cells

Amanda Crenk, Hwa I. Han, Michael D. McDaniels, Neil A. Hukriede. University of Pittsburgh, Pittsburgh, PA.

Background: Acute kidney injury (AKI) remains a significant worldwide problem. Our previous work has shown that hdac8-/- larval zebrafish model of AKI improved survival and increased repair and explained after AKI. However, these mechanisms have not been elucidated. AKI is known to induce double stranded DNA breaks (DSB), activating factors including the phosphorylation of the histone variant H2AX producing γH2AX. Damaged cells undergo a complex multifactorial fate determination leading to either DNA repair and cell survival or apoptosis.

Methods: hdac8-/- and hdac8+/+ mutant zebrafish were injected with gentamicin to induce AKI. Immunofluorescent microscopy, fluorescently activated cell sorting (FACS) of renal tubule epithelial cells (RTEC) were isolated for RNA-seq.生存性和repair RTEC. We evaluated mRNA expression of RTEC in hDAC8 mutant zebrafish in WT and hdac8-/- with and without AKI. There were a greater number of γH2AX foci in RTEC of the hdac8-/- larvae with AKI than in either the unjured hdac8-/+ or WT AKI larvae. hda8-/- zebrafish with AKI exhibited less apoptosis compared to WT zebrafish with AKI, and as expected there were undetectable levels of TUNNEL positive cells in WT and hdac8-/- unjured tubules. We observed more Pax2a positive cells in hdac8-/- larvae with AKI than WT larvae with AKI. Immunohistochemical analysis of Na+K-ATPase, a marker for epithelial polarization, in hda8-/- zebrafish tubules maintain partial to full polarization during AKI, whereas WT larvae with AKI had complete mis-polarization of RTEC. RNA-Seq data analysis confirmed the epithelial polarization data demonstrating increased expression of mesenchymal genes and decreased epithelial gene expression in WT tubules with AKI compared to hdac8-/- in AKI injured zebrafish.

Conclusions: This study suggests a mechanism of repair and recovery after AKI in hdac8-/- zebrafish is mediated through increased γH2AX at sites of DNA damage. hda8-/- mutant zebrafish preferentially uses mechanism of DDR for repair and proliferation, as opposed to apoptosis. In the absence of apoptosis hda8-/- tubules can prevent damage and maintain normal tubules and maintain their epithelial gene signatures, whereas the WT zebrafish lose their polarization and begin EMT. These data support our hypothesis that the loss of HDAC8 allows cells to repair after injury from AKI.

In Vitro Inhibition of Renal OCT2 and MATE1 Secretion by Antimicrobial Drugs

Erin George, Xia Wen, Edgar A. Jaimés, Melanie S. Joy, Lauren Aleksunes, Rutgers The State University of New Jersey, Piscataway, NJ. 1Memorial Sloan Kettering Cancer Center, New York, NY, 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: The organic cation transporter 2 (OCT2) and multidrug and toxic extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, cisplatin, and entecavir. Studies suggest that ondansetron, an antiemetic drug and 5-HT3 antagonist, can inhibit OCT2- and MATE1-mediated transport. The purpose of this study was to compare structurally related 5-HT3, antagonist drugs for their ability to inhibit the OCT2 and MATE2 transporters.

Methods: Transport of the fluorescent prototypical cation ASP (25 μM) was assessed in the presence and absence of 5-HT3 antagonists (0.5-20 μM) using two in vitro monocellular models: 1) HEK293 kidney cells expressing human OCT2 or MATE1 and 2) double-transfected hOCT2-MATE1 MDCK cells. Cimetidine (50 μM) was included as a positive control.

Results: The relative order of potency for inhibition of ASP uptake by OCT2 was palonosetron < ondansetron < tropisetron < granisetron and for MATE1 was ondansetron < palonosetron < tropisetron < granisetron < dolasetron. In hOCT2-MATE1
Inhibiton of OCT2-MATE1 Secretion of ASP by Ondansetron in MDCK Cells

Klotho Deficiency Intensifies Hypoxia-Induced Expression of INF-α/β Through Upregulation of Rig-I

Asako Urabe,1 Shigehiro Doi,1 Toshiki Doi,1,2 Ayumu Nakashima,1,3 Takao Masaki,1 1Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; 2Harada Hospital, Hiroshima, Japan; 3Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.

Background: Hypoxia is a common pathway to progression of end-stage kidney disease. Although numerous studies have provided evidence that inflammation plays a major role in this process, the mechanism by which hypoxia induces inflammation remains unknown. Retinoic acid-inducible gene-I (RIG-I) encodes an RNA helicase that recognizes viruses including SARS-CoV2, which is responsible for production of interferon (IFN)–α/β to prevent the spread of a viral infection. Recently, RIG-I activation has been found under hypoxic conditions, and klotho deficiency intensified the activation of RIG-I in mouse brains. However, the roles of these functions in renal inflammation remain elusive.

Methods: In vitro, expression of RIG-I and INF-α/β was examined in normal rat kidney (NRK)-52E cells incubated under hypoxic conditions (1% O2) for 30, 60, 90, and 120 min. Next, siRNA targeting RIG-I or scramble siRNA was transfected into NRK52E cells to examine expression of RIG-I and INF-α/β under hypoxic conditions. In vivo, we induced renal hypoxia by clamping the renal artery for 10 min in wildtype mice (hypoxic WT mice) and Klotho knockout mice (hypoxic KI mice). Lastly, we investigated the expression levels of RIG-I and INF-α/β in 33 human kidney biopsy samples diagnosed with IgA nephropathy.

Results: In vitro, the expression levels of RIG-I and INF-α/β were increased under hypoxic conditions. The expression levels of RIG-I and INF-α/β were significantly upregulated in the kidneys of hypoxia WT mice. In patients with IgA nephropathy, immunohistochemical staining of renal biopsy samples revealed that expression of RIG-I was positively correlated with that of INF-α/β (r=0.57, P<0.001, respectively). In vivo, the expression levels of RIG-I and INF-α/β were significantly upregulated in the kidneys of hypoxia WT mice and further upregulation was observed in hypoxic KI mice. In patients with IgA nephropathy, immunohistochemical staining of renal biopsy samples revealed that expression of RIG-I was positively correlated with that of INF-α/β (r=0.57, P<0.001, respectively).

Conclusions: These findings suggest that hypoxia induces expression of INF-α/β through upregulation of RIG-I, and that klotho deficiency intensifies this hypoxia-induced expression.
Using a Kidney Microphysiological Device
Associated Nephrotoxicity from Polymyxin and Tobramycin Antibiotics
Identification of Predictive Biomarkers Associated with Antibiotic
Injury. 

Conclusions: We found that different biomarkers have variable kinetics after PTEC injury. sFas and KIM-1 concentrations rose the earliest after antibiotic exposure. In RNAseq analyses, we found that pathways of metallothionein and cholesterol biosynthesis were dysregulated after colistin exposure. Finally, we found minimal PTEC injury with tobramycin, suggesting that this antibiotic may be less toxic than previously believed. Future work seeks to test these candidate biomarkers in human urine samples.

GTS-21 Attenuates the Inflammation of AKI Independent of α7 Nicotinic Acetylcholine Receptor

Yasuna Nakamura,1 Tsuyoshi Inoue,2 Rie Uni,1 Daichi Fukaya,1 Sho Hasegawa,1 MasaoMi Nakagak,1 Reiko Innaji,1 The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; Nagasaki University School of Medicine Graduate School of Biomedical Sciences, Nagasaki, Japan.

Background: Vagus nerve stimulation protects from kidney injury by activating the cholinergic inflammatory pathway (CAP). It is considered that α7 nicotinic acetylcholine receptor (α7nAChR) is important for CAP activation. To elucidate the mechanism of receptor signaling, we promoted further experiments using macrophage-specific α7nAChR knockout mice.

Methods: We generated macrophage-specific α7nAChR-deficient mice by crossing breeding LysM-Cre and α7nAChR flox mice. In vivo, GTS-21 (an α7nAChR specific agonist) was intraperitoneally injected to either wild type C57BL/6 mice (WT) or macrophage-specific α7nAChR-deficient mice prior to administration of lipopolysaccharide (LPS). 4 hours after LPS administration, the mice were euthanized and plasma TNF-α level, plasma creatinine, BUN were evaluated. In vitro, murine macrophage cell line RAW264.7 and primary renal macrophages from either WT or α7nAChR-deficient mice were used. These cells were stimulated with LPS after nicotine (pan nicotinic acetylcholine receptor agonist) or GTS-21 was administered, then TNF-α level was evaluated 4 hours later.

Results: GTS-21 protected the kidney and suppressed the increase of plasma TNF-α induced by LPS in WT mice. Surprisingly GTS-21 decreased plasma TNF-α level induced by LPS in not only WT mice but also macrophage-specific α7nAChR-deficient mice. In vitro experiments, GTS-21 or nicotine treatment suppressed TNF-α induction by LPS in RAW264.7 cells or peritoneal macrophages from WT mice. Furthermore, nicotine also suppressed the induction of TNF-α by LPS even in peritoneal macrophages from α7nAChR-deficient mice.

Conclusions: These results suggest that nicotine or GTS-21 might suppress the inflammation independent of α7nAChR in macrophages in vivo and in vitro.

Platelets vs. Neutrophils as Therapeutic Targets in Cholesterol Embolism-Related Arterial Occlusion, Kidney Infarction, and AKI
Chongyang Shi, Hans J. Anders, Medizinische Klinik und Poliklinik IV, AG Klinische Biochemie, Klinikum der Universität München, München, Germany.

Background: Cholesterol crystal embolism (CCE), a life-threatening complication, is a consequence of the rupture of atheromatous plaques in patients with advanced atherosclerosis. CCE often occurs as a cause of AKI. Therapeutic interventions in this disease have not yet been established. Platelet-derived factors contribute to CCE-related artery occlusion leading to AKI and kidney infarction.

Methods: C57BL/6 mice were injected with various doses of cholesterol crystals (CC) to induce CCE in kidney. Primary endpoint: GFR. Secondary endpoints: infarct size, vascular occlusions. 3D MRI and pCT. In vitro studies CC with neutrophils, platelets, endothelial cells.

Results: At 24h, MRI and pCT showed perifocal edema around ischemic lesion and vascular rarefaction in CCE kidney. CC-induced clots causing a dose-dependent GFR loss and infarct size. Immunostainings revealed crystal clots contained fibrin, platelets, ecDNA, neutrophils. To study the role of platelets in this process, we treated mice with platelet antagonist clopidogrel. At 24h, clopidogrel completely protected mice from intravascular obstructions, GFR loss, and kidney infarction. In contrast, neutrophil depletion significantly decreased kidney infarction but not arterial obstructions or GFR loss. Maybe because mononuclear cells had partially replaced neutrophils within clots and ecDNA was still present. DNase I treatment also significantly reduced the percentage of ecDNA positive clots, occluded arterial, GFR loss, infarct size. In vitro studies show, CC induced clot formation and enhanced fibrinogen release from platelet granules which promotes fibrin clot formation. DNase I can strongly inhibit ATC secretion, fibrin formation, also normalized collagen-driven platelet aggregation.

Conclusions: In summary, not CC itself but the CC-induced fibrin clots obstructed peripheral arteries causing tissue infarction and organ failure. Platelets and ecDNA are central for crystal clots formation. Hence, crystal clots represent the primary target for therapeutic interventions. Among the possible molecular targets in thrombosis, especially enhancing fibrinolysis or inhibiting platelet purinergic signaling could reduce arterial occlusions, infarction, and organ failure. DNase I could have a synergistic effect on CC induced clot formation in mice and might be a prophylactic/therapeutic approach in human patients with a risk for procedure-related CC embolism.

Characterizing De Novo Lymphangiogenesis During AKI Using 3D Imaging and Tissue Cytometry

Laurence M. Black,1 Seth Winfree,2 Malgorzata Kamocka,3 Suraj Deepak Khochare,4 Amie Traylor,5 Stephanie Esman,5 Shehnaz Khan,5 Abolfazl Zarijani,5 Anupam Agarwal,5,6 Tarek M. El-Achkar.1 University of Alabama at Birmingham, Birmingham, AL; 2Birmingham VA Medical Center, Birmingham, AL; 3Indiana University School of Medicine, Indianapolis, IN.

Background: The renal lymphatic system is essential for fluid and electrolyte homeostasis, lipid and cholesterol transport, and immune surveillance with lymphatic vessels (LV) primarily intertwined with the blood vasculature. LV development, or lymphangiogenesis (LA) is regulated by its master transcription factor, prospero-related homeobox-1 (Prox-1), which determines lymphatic cell fate. LA is accentuated during inflammation or injury states such as acute kidney injury (AKI), though mechanisms of LA in AKI remain unclear. Understanding the LA process is essential because it will elucidate potential therapeutic targets in AKI.

Methods: Using 10-week old male Prox1-tctrlTomato lymphatic reporter mice (ProxTom), we investigated the effect of AKI on the abundance and distribution of Prox-1+ cells at the mesoscale level using large scale three-dimensional (3D) imaging and tissue cytometry. ProxTom mice and their controls were subjected to ischemia-reperfusion (IR) or no surgery and kidneys were fixed on day 3. Large scale 3D imaging with confocal microscopy was done on 50um thick sections spanning the entire cross section of the kidney, followed by tissue cytometry using the volumetric tissue exploration and analysis (VTEA) software tool.

Results: The average number of cells surveyed per specimen was 347,360 ± 36,647. Using VTEA, a gating strategy was devised to account for autofluorescence in the red channel, which was increased after IR due to cell debris and injury. IR samples displayed a significant increase in Prox-1+ cells compared to baseline controls: 717.2 ± 161.8 vs. 174.4 ± 62.1 Prox-1+ cells/mm², respectively (p<0.05). In baseline controls, Prox-1+ cells were well-organized and predominately localized around large vessels in the hilum. However, after injury, the distribution of Prox-1+ cells shifted to the hilar parenchyma and inner medulla in a consistent pattern. Few cells could also be detected in the outer medulla and cortex.

Conclusions: We demonstrate a scale of analytics that is amenable to characterizing de novo renal LA during AKI, which informs the origin and distribution of renal LVs and the dynamics of LA. Such findings will enhance our understanding of the functional role of LVs during injury and help identify novel therapeutics for prevention in AKI.

Peritubular Transcytosis Enables Mesoscale Nanoparticle Treatment of AKI

Ryan Williams,1 Janki Shah,2 Edgar A. Jaimies,2 Daniel A. Heller.1 City College of New York, New York, NY; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Background: In prior studies we demonstrated that mesoscale nanoparticles (MNP) localize to the kidneys up to 26-fold more than to any other organ and that they specifically target the renal tubular epithelium. In this study we investigated the mechanism of MNP localization to the renal tubules and evaluated this platform’s potential for therapeutic delivery in a model of cisplatin-induced acute kidney injury (AKI).

Methods: We synthesized ~400 nm diameter MNPs from the biocompatible polymers poly(lactic-co-glycolic acid) and polyethylene glycol (PLGA-PEG). MNPs were encapsulated with a fluorescent far-red dye or the reactive oxygen species scavenger edaravone. Male C57BL/6 mice, were sacrificed 30 minutes after injection for immune-electron microscopy studies. We also performed intravital microscopy to visualize the transit of MNPs in Cx3crgfp/+ C57BL/6 mice with GFP-expressing renal macrophages. We also evaluated their therapeutic potential in a cisplatin-induced AKI (25 mg/kg IP) model. 24 hours following cisplatin, mice received edaravone-loaded MNPs or appropriate controls. Serum creatinine and histology were analyzed 72 hours following cisplatin.

Results: We found that MNPs localize to the proximal tubular epithelium via transcytosis from the peritubular capillaries. We observed MNPs flowing in these capillaries and in transit across the tubular interstitium. We also found that transcytosis of MNPs was not facilitated by macrophage uptake. Finally, we found that therapeutic MNPs use this mechanism to localize to the proximal tubules of mice with cisplatin-induced AKI (Figure).

Conclusions: These studies characterized transcytosis from the peritubular capillaries as the mechanism of particle localization to the kidneys and portend the development of additional therapeutic targeting tools for renal diseases.

VEGF-R2 Signaling in Renal Stroma Exacerbates Post-AKI CKD

Poster

Takuto Chiba, Sunder Sims-Lucas. University of Pittsburgh Medical Center, Pittsburgh, PA.

Background:
Acute Kidney Injury (AKI) is widespread, identified in 30% of post-operative and 50% of ICU patients, and associated with increased rates of chronic kidney disease (CKD) and end stage renal failure. Peritubular capillary rarefaction is closely associated with post-AKI CKD progression. Vascular endothelial growth factor (VEGF) is a well defined angiogenic protein via its major receptor, VEGF receptor 2 (VEGF-R2). However, prior work from others demonstrated a role of VEGF-R2 receptor 2 (VEGF-R2) in the renal medullary vasa recta (VR) prior to the peritubular (PT) capillary plexus, establishing primary cell cultures of PDGFRß+ kidney pericytes isolated from GFP-/fl/fl mice and FoxD1-C5aR1 KO mice and performed qPCR and luminex analysis. We reported that kidney complement plays an important role in the mechanisms by which C5aR1 contributes to fibrosis.

Methods:
We used flow cytometry, confocal microscopy and image stream analysis for renal tubular epithelial cells (RTEC) in regulating homeostasis of kidney DN T cells.

Results:
To test this hypothesis, male WKY rats (10wks) were pretreated (i.p) with LPS or saline, followed by 1 hour of renal ischemia and 6, 12 or 24 hours of reperfusion. At time 0 (no reperfusion), progression of AKI was evident as follows: in saline treated rats, PT congestion was less than 20% at time 0 (<20%) and remained lower than saline scores through 24 hours (pFake <= 0.0001). In both groups, PT congestion was less than 20% at time 0 (no reperfusion) but rapidly increased in saline treated rats to >60% by 6 hours of reperfusion. In contrast, protected VR under 1% O2 concentration following ischemia and identify the AVR as the renal defect responsible for PT congestion. Understanding the mechanisms by which LPS aids in AVR reperfusion may be critical in order to find therapeutic targets for vascular congestion.

Conclusions:
Our data provides the first evidence that congestion originates in the medullary VR during the ischemic period and that blockage of AVR drives congestion in the PT capillary plexus during reperfusion by preventing drainage of the renal medullary circulation. Rapid reperfusion of the AVR (LPS group) prevented congestion of the PT capillaries. These data provide new insights into the pathophysiology of vascular congestion following ischemia and identify the AVR as the renal defect responsible for PT congestion. Understanding the mechanisms by which LPS aids in AVR reperfusion may be critical in order to find therapeutic targets for vascular congestion.

Selective Expansion of Kidney Double-Negative T Cells Is Driven by Renal Tubular Epithelial Cells Through Direct Cell-Contact and by Soluble Mediators

Mohanraj Sadasivam, Sanjeev Noel, Somayeh Gharie fathabad, Johanna T. Kurzhagen, Abdel Hamad, Hamid Rabb, Johns Hopkins University, Baltimore, MD.

Background:
Kidney TCRβ+CD4 CD8CD1d double negative (DN) lymphocytes are a recently recognized unconventional T cell population with important roles in AKI and possibly other diseases like lupus. DN T cells expand after experimental AKI and confer a benefit in delayed delivery improved outcome. However, mechanisms underlying their regulation and expansion in the kidney are poorly understood. Here, we demonstrate a direct role for renal tubular epithelial cells (RTEC) in regulating homeostasis of kidney DN T cells.

Methods:
We used flow cytometry, confocal microscopy and image stream analysis for renal tubular epithelial cells (RTEC) in regulating homeostasis of kidney DN T cells.

Results:
The expression of CD103 is stable in CD8+ iTreg in vitro under 1% O2 concentration. In vivo study, we showed that natural regulatory T cells (nTreg) tend to transfer into Th17 under conditions of inflammation and hypoxia. On the contrary, TGF-β-induced CD8+CD103+Treg (CD8+CD103+Treg), a new subpopulation of Treg we have identified, maintains stable phenotype and immunomodulatory function. The instability of nTreg under conditions of inflammation and hypoxia suggest that nTreg are not suitable for treatment of AKI. Accordingly, we studied the role of CD8+CD103+Treg in alleviating AKI.

Methods:
In vitro study, we test the phenotype and immunomodulatory function of CD8+CD103+ vs CD8+CD103−. Using ex vivo approach, we showed that natural regulatory T cells (nTreg) tend to transfer into Th17 under conditions of inflammation and hypoxia. On the contrary, TGF-β-induced CD8+CD103+Treg (CD8+CD103+Treg), a new subpopulation of Treg we have identified, maintains stable phenotype and immunomodulatory function. The instability of nTreg under conditions of inflammation and hypoxia suggest that nTreg are not suitable for treatment of AKI. Accordingly, we studied the role of CD8+CD103+Treg in alleviating AKI.

Conclusions:
These results demonstrate a previously unknown functional relationship between RTEC and DN T cells that may explain the selective accumulation of DN T cells in the kidney and roles in normal and diseased kidney. The results have important implications for developing strategies to ameliorate AKI by promoting the survival of kidney DN T cells.

Pericyte and Macrophage C5aR1 Mediate Renal Fibrosis

Poster

Ranjit K. Sahu, Sandhya Xavier, Daniel Chauss, Ronald P. Taylor, Majid Kazemian, Abdallah Adzali, Didier Portilla. ‘University of Virginia, Charlottesville, VA; ‘National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; ‘Purdue University System, West Lafayette, IN.

Background:
We reported that kidney complement plays an important role in the mechanisms by which C5aR1 contributes to fibrosis.

Methods:
We used flow cytometry, confocal microscopy and image stream analysis for renal tubular epithelial cells (RTEC) in regulating homeostasis of kidney DN T cells.

Results:
Our findings demonstrated that pericytes and macrophages play important roles in the pathogenesis of renal scarring and implicate C5aR1 as a key mediator. Conditional deletion of C5aR1 in these two interstitial cell types reduces inflammation and extracellular matrix protein formation in pericytes as well as macrophage migration and profibrotic phenotype of kidney macrophages.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: CD8+CD103+iTreg maintains stable phenotype and immunomodulatory function under condition of hypoxia, decrease the severity of AKI induced by ischemia-reperfusion. CD8+CD103+iTreg provide a promising approach for the treatment of AKI.

Methods: Male C57BL/6 mice were administered saline vehicle or 20 mg/kg of cisplatin i.p. Urine was collected in metabolic cages for 24 h periods on days 0 – 4. Blood and kidneys were collected between days 2 and 4. Kim-1 and calbindin proteins were measured in urine, kidneys, and blood. Kim-1 and calbindin (Calb1) mRNAs were quantified in kidneys by qPCR.

Results: SCr and BUN levels increased in cisplatin-treated mice by day 3, confirming development of acute kidney injury. Urinary concentrations of calbindin and Kim-1 were elevated by 11.6-fold and 2.5-fold, respectively by day 2. Time-dependent decreases in intrarenal calbindin protein to levels 60% of control were observed on days 3 and 4. A 200-fold up-regulation of Calb1 and Kim-1 mRNAs was seen on day 3. These data suggest that early loss of calbindin protein into the urine along with declines in renal calbindin protein initiates a compensatory induction of mRNA expression at later time points (days 3 and 4).

Conclusions: Understanding the regulation of calbindin during cisplatin nephrotoxicity further enhances its utility as a urinary biomarker of kidney damage. The results of the current study support the combined use of a proximal (Kim-1) and distal tubule (calbindin) marker to phenotype acute kidney injury secondary to cisplatin administration.

Funding: Other NIH Support - Funded by NIH GM123330, ES005022, ES007148, CA072720, and CA046934.
Conclusions: This study suggests that there are different underlying mechanisms that induce divergent pathologies in the two models of CDDP dosing.

Cisplatin-Induced MARCKS Phosphorylation Activates NF-κB Signaling and Contributes to AKI
Shenwen V. Gu, Jun Liu, Kuang-Yu Jen, Ching-Hsien Chen. University of California, Davis, Davis, CA.

Background: Cisplatin is widely used for cancer treatment but is known to induce nephrotoxicity with severe damage to the proximal tubules, leading to acute kidney injury (AKI). Although a major substrate of protein kinase C, MARCKS, was shown to be induced phosphorylation at Ser 159/163 (phospho-MARCKS) in response to cisplatin, the molecular mechanism underlying increased phospho-MARCKS and its functional consequence in AKI remains to be established. Herein, we investigated how phospho-MARCKS is regulated in proximal tubular cells, and its role in the context of cisplatin exposure.

Methods: The clinical relevance of phospho-MARCKS was first confirmed using immunohistochemistry. Next, we examined the effect of cisplatin exposure on phospho-MARCKS levels in kidney tubular epithelium. The MARCKS-interactome was identified by mass spectrometry. We also used genetic and pharmacological approaches to verify the functionality and molecular mechanism of cisplatin-induced phospho-MARCKS.

Results: In a screen of 75 renal biopsies from patients, we found that strong phospho-MARCKS expression was observed in kidney specimens from patients with acute renal tubular necrosis and was positively correlated. Western blot analyses demonstrate that an elevated abundance of phospho-MARCKS in cisplatin-exposed tubular epithelial cells and this increase appeared to be concentration-dependent. Mechanistically, we show that MARCKS protein directly binds to the nuclear factor-kappa-B-activating protein (NKPAP). Following cisplatin-induced phosphorylation at Ser159 and Ser163, the interaction of MARCKS with NKPAP was inhibited, contributing to NF-κB phosphorylation and NF-κB activation. Surprisingly, an elevation of phospho-MARCKS by cisplatin occurred in parallel with upregulation of inflammatory cytokines and markers of nephrotoxicity. Conversely, targeting of MARCKS phosphorylation with the MPS peptide, a novel MARCKS inhibitor, downregulated NF-κB signaling as well as suppressed levels of serum creatinine and blood urea nitrogen in cisplatin-treated mice.

Conclusions: Our results suggest that MARCKS phosphorylation is a novel NF-κB activator in cisplatin-induced proximal tubule damage and also present a proof of concept for the use of MPS peptide as a renal protection agent for AKI.

Mechanistic Insight for Enhanced Cisplatin (CIS) Nephrotoxicity in Na-H Exchanger Regulatory Factor 1 (NHERF1) Deficiency
Adrienne M. Bushau-Sprinkle,1 Michelle T. Barati,1 Walter H. Watson,1 Yuxuan Zheng,2 Kenneth Gagnon,3 Kathleen Kitterman,4 Leah J. Siskind,5 Michael E. Brier,6 Eleanor D. Lederer.7,1 University of Louisville School of Medicine, Louisville, KY; 2University of Louisville School of Medicine, Dallas, TX; 3VA North Texas Health Care System, Dallas, TX.

Background: Proximal tubule transport and metabolism of CIS play critical roles in the development of CIS-induced acute kidney injury (AKI). Mice lacking NHERF1 have exacerbated renal toxicity. We hypothesized that NHERF1 loss leads to increased oxidative state and/or altered CIS metabolism resulting in increased CIS toxicity.

Methods: We tested 2-4 mo old male wild-type (WT) C57BL/6 and NHERF1 knock out (KO) mice with vehicle or CIS (20 mg/kg IP) for 4, 24, or 72h. Glutathione (GSH), glutathione disulfide (GSSG), cysteine (Cy), cysteine (CySS), cysteine-glutathione disulfide (CySgSS) were measured in plasma and kidney cortex by HPLC. Kidney cortex was assayed for γ-glutamyl transferase (GGT) activity, platinum (Pt) levels by ICP-MS, cysteine s-conjugate beta lyase (CCBL1) and GGT by West blot and immunohistochemistry (IHC); and RT-PCR for glutathione s-conjugate-translocating ATPase (ABCC1) and γ-glutamylcysteine synthetase (GCLC).

Results: KO mice showed decreased plasma CySS and increased kidney GSSG at baseline. GGT activity was similar 4h after CIS treatment, but significantly greater at 24h in CIS-treated WT compared to KO. ABCC1 and GCLC mRNA levels were upregulated 72h post CIS treatment in KO compared to WT. GGT and CCBL1 protein levels were similar by Western blot regardless of genotype or treatment 24h post CIS, but IHC showed greater brush border membrane GGT loss in KO kidneys. CCBL1 localization showed a checked staining pattern in KO proximal tubules compared to WT linear pattern at baseline. Pt levels were similar 24h post CIS treatment, but decreased significantly more 72h post treatment in KO compared to WT.

Conclusions: We conclude loss of NHERF1 results in increased levels of GSSG, upregulation of genes involved in GSH synthesis in oxidizing conditions, and lower GGT activity that sensitizes the kidney to increases in oxidative stress induced by CIS nephrotoxicity. While NHERF1 loss does not affect initial Pt uptake, the aberrant CCBL1 localization in KO proximal tubules suggests a role for enhanced production of toxic CIS metabolites.

**Lipidomics Approach to Characterize Lipid Alterations in Human Kidney 2 Cells Treated with Iohexol**

**Fangfang Zhou, Yixin Chen, Luo L. Xin, Yi Lu, Quan Luo. HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.**

**Background:** In our previous study, we found plasma high density lipoprotein cholesterol and apolipoprotein A-1 levels were significant lower in the contrast induced nephropathy (CIN) group, compared to the non-CIN group. The aims of our study was to uncover lipid alterations that may contribute to the development of CIN.

**Methods:** We investigated lipid of HK-2 cells treated with iohexol (100mg/ml 6hrs and 12hrs), compared with HK-2 cells treated without iohexol (as control) using nontargeted lipidomics based on ultrahigh-performance liquid chromatography-Orbitrap Q-Exactive plus mass spectrometry.

**Results:** Based on the principles of t-test P-value < 0.05, variable importance at projection (VIP) value >1 and fold change >1.5 or <0.67, differential expression of 134 lipids were identified in both HK-2 cells treated with iohexol for 6hrs and 12hrs, compared with the control HK-2 cells. The top three class to which these lipids belonged were phosphatidylcholine (PC, 42 species), triglyceride(TG, 39 species) and phosphatidylethanolamine (PE, 18 species).

**Conclusions:** Our results indicate that PC, TG and PE may contribute to the development of CIN, providing the basis for further evaluation of the role of lipids in the mechanism of CIN.

**PO0232**

**Proximal Tubular S3 Cells Expressing Angiotensinogen Localize to the Outer Stripe of the Outer Medulla**

**Danielle Janosevic,1 Ricardo Melo Ferreira,2 Michael T. Eadon,3 Farooq Syed,1 Takashi Hato,1 Pierre C. Dagher,1,2 Indiana University School of Medicine, Indianapolis, IN; 3Roudybush Indianapolis Veterans Affairs Medical Center, Indianapolis, IN.**

**Background:** The S3 segments of proximal tubules (PT) are observed in the cortex as well as the outer stripe of the outer medulla (OS-OM). Using single cell RNA sequencing (scRNAseq), we and others have identified a unique S3 population, referred to as S3-Type 2 (S3T2). Here we describe additional SpT and scRNAseq to further localize this novel S3T2 cell population in the murine kidney.

**Methods:** We performed SpT on OCT frozen murine kidney sections stained with hematoxylin & eosin. Images were collected with Keyence BZ-810 microscope. RNA was isolated from tissue, sequenced, and clustering performed with Seurat R package. This yielded seven clusters that could be overlaid over the tissue section. To increase resolution, we combined scRNAseq with SpT. Gene expression was visualized with the Loupe Browser. Expression of specific genes was also confirmed with single molecule FISH (smFISH).

**Results:** The combination of scRNAseq with SpT increased the spatial resolution and resulted in 15 unique cell clusters that could be easily overlaid over the tissue section. While regular S3 cells localized to the cortex, S3T2 cells localized specifically to the OS-OM (Fig. b). In addition to Rnf24 and Slc22a7, S3T2 cells showed strong expression of angiotensinogen (Agt, Fig. c). smFISH of Agt and Agt1 confirmed these results (Fig. d).

**Conclusions:** The combination of scRNAseq and SpT allows for a greater resolution in the spatial layout of renal cell populations. This approach localized S3T2 cells specifically to the OS-OM. These cells also exhibited strong expression of Agt, possibly indicating an important role in the renin-angiotensin system. These transcriptomic differences between classical S3 and S3T2 are likely dictated by the unique microenvironments of the cortex and the OS-OM.

**Salubrinal Attenuates Proximal Tubular Cell Injury Induced by Cisplatin**

**Guiu Dong, Zhong Dong. Medical College of Georgia at Augusta University, Augusta, GA.**

**Background:** Cisplatin is a widely used chemotherapeutic drug, but it has notorious side effects in kidneys. Effective kidney protective agents are not available for clinical use. Salubrinal is a specific inhibitor of eIF2alpha phosphatase, it promotes eIF2alpha phosphorylation which blocks the formation of the pre-initiation complex and halts global protein translation and protein synthesis. In this study, we examined the effect of salubrinal on cisplatin-induced injury in kidney proximal tubular cells.

**Methods:** Rat proximal tubular cells (RPTC) were treated with cisplatin or cisplatin with salubrinal for 4, 8, and 24hrs. Cell lysates were collected for immunoblot analysis to examine the expression of eIF2alpha-56 and -65. In addition, other signaling proteins implicated in cisplatin injury were examined, including p53, JNK, p38, and pdkdelta, and ERK. Apoptosis was determined at 24hrs of treatment by phase contrast and fluorescence microscopy following nuclear staining with Hoechst. Caspase activities were measured enzymatically by using DEVD-AFC, a thioridox peptide substrate. To examine cell survival, the cells were changed to fresh medium for 48 hrs after 24 hrs of cisplatin treatments with or without Salubrinal.

**Results:** Salubrinal suppressed apoptosis and caspase activation in RPTC during cisplatin treatment. It also promoted long-term cell survival after cisplatin treatment. In immunoblot analysis, during cisplatin treatment salubrinal increased eIF2alpha phosphorylation. It also increased PERK phosphorylation and the expression of GRP78 and CHOP, indicative of ER stress or unfolded protein response. Signaling pathways including MAP kinases, PKC-delta, and p38 are involved in cisplatin-induced kidney injury. Salubrinal decreased JNK and p38 phosphorylation, but increased ERK phosphorylation during cisplatin treatment. Salubrinal diminished phosphorylation of PKC-delta at late time point of cisplatin treatment. However, Salubrinal did not affect p53 or p73 phosphorylation or its transcription.

**Conclusions:** Salubrinal has protective effects against cisplatin-induced kidney cell injury. Mechanistically, the protective effects are associated with the increase of UPR and suppression of MAPK signaling but not with p53 activation. The results also suggest that inhibition of global protein synthesis may be a new therapeutic strategy for the side-effects of cisplatin chemotherapeutic.

**Funding:** NIDDK Support, Veterans Affairs Support

**PO0234**

**Quantitative Prediction of Cisplatin-Induced AKI Using RENAsym, a Mechanistic Quantitative Systems Toxicology Model, and Renal Proximal Tubule Epithelial Cell In Vitro Assays**

**Background:** Nephrotoxic drugs like cisplatin cause acute kidney injury (AKI) through complex cellular mechanisms that include mitochondrial dysfunction, oxidative stress, and immune mediated injury pathways. However, quantitative prediction of the underlying toxicity mechanisms remains a challenge. Quantitative system toxicology (QST) modeling offers a promise for quantitative description of toxicity mechanisms leading to drug-induced AKI. We developed a QST model of cisplatin induced AKI using in vitro assays to characterize renal injury mechanisms.

**Methods:** RENAsym was used to quantify cisplatin induced AKI. The model represents aspects of renal proximal tubule epithelial cells (RPTC) including cell life cycle and death pathways, bioenergetics, immune signaling pathways and biomarker responses. In vitro data related to cisplatin mitochondrial toxicity and oxidative stress generation were measured using RPTEC assays incubated with cisplatin (Cyprotex Inc.). To quantify cisplatin-induced mitochondrial dysfunction, oxygen consumption rate (OCR) was measured using the Seahorse XF analyzer. Cisplatin-induced oxidative stress was measured using high content imaging (HCl). RENAsym simulations predicted dose-dependent cisplatin-induced AKI that is in qualitative agreement with clinical data. RENAsym shows promise in drug-induced AKI prediction.

**Results:** The Seahorse study shows that OCR decline at 24 hours, suggesting cisplatin-induced electron transport chain (ETC) inhibition. Similarly, HCl reveals significant oxidative stress elevation after 9 days. Toxicity parameters for cisplatin-induced mitochondrial dysfunction and oxidative stress mechanisms were determined through RENAsym data. Simulations predict dose-dependent cisplatin toxicity as quantified by elevations in cGnT, a biomarker that marks RPTEC death. A simulated single high dose of 533 mg/m² i.v. cisplatin results in 14-fold change in cGnT, while a simulated clinical dose of 100 mg/m² shows 7-fold increase. The 100 mg/m² result is in qualitative agreement with 3.4-fold change observed in a clinical study where patients administered 300 mg/m² i.v. cisplatin exhibited 20% incidence of AKI (Ummehr. 2012, JIBBB).

**Conclusions:** RENAsym simulations predicted dose-dependent cisplatin-induced AKI that is in qualitative agreement with clinical data. RENAsym shows promise in providing a unique tool for drug-induced AKI prediction.

**Diuretic Resistance: When to Consider Hydralazine?**

**Mohammed Alshehri, Rameez S. Jabaji, Christopher S. Wilcox. MedStar Georgetown University Hospital, Washington, DC.**

**Introduction:** We present a case of a acute cardiorenal syndrome complicating heart failure with preserved ejection fraction (HFpEF) leading to severe diuretic resistant fluid retention that was alleviated by coincident hydralazine therapy.

**Case Description:** A 52-Year-old woman with a history of obesity, hypertension, chronic heart failure with HFpEF (LVEF 65%), and alcoholic liver disease presented with a 3-day history of mental status change. Her serum creatinine was 3.6mg/dL, compared to 0.8mg/dL a month prior. She was volume overloaded with distended jugular veins, pulmonary crackles, and 3+ edema to her lower abdomen; she had a 30kg weight gain over 5 months. Her urine sodium and chloride were <10mmol/L. Urine analysis had a urine pH of 7 without proteinuria. Hydralazine therapy was started at 50mg/m²/day, increased to 80mg twice daily and was escalated progressively to IV furosemide 20 mg/h with IV
cholorothiazide 500 mg twice daily. However, these large doses of intravenous diuretics failed to increase daily urine output above 1000 ml. After 20 hours of stable diuretics, vasodilator therapy was initiated with low dose hydralazine 10 mg thrice daily. Within one day, her urine output more than doubled and, over the next 3 days of the stable therapy, it peaked at 4 liters. Her fraction Na excretion (FENa) was initially 0.1%; it increased to a maximum of 0.4% on the 2nd IV continuous diuretic therapy but increased further to 3.8%-6.2% over 9 days after hydralazine was added to the diuretic regimen. After addition of hydralazine, her congestion dissipated, she lost 23 Kg and the diuretic regimen was reduced eventually to furosemide 80 mg BID and spironolactone 200 mg daily prior to her discharge with a serum creatinine of 1.3 mg/dL. At follow up after 3 months, her symptoms remained well controlled, her weight was reduced by a further 10 kg and her serum creatinine was 0.9 mg/dL.

Discussion: Hydralazine has been recommended to treat diuretic resistance in HF by increasing cardiac output, renal blood flow and renal diuretic delivery. However, our case suggests that hydralazine greatly improves renal tubular diuretic responsiveness as her FENa increased 3 fold. This is not likely due to better renal diuretic delivery since the patient received constant IV infusions of two diuretics at doses well above their ceiling. Further clinical trials and mechanistic studies of hydralazine-diuretic interaction are warranted.

PO0236

Carfilzomib-Induced Thrombotic Microangiopathy Effectively Treated with Eculizumab

Jorge M. Chacnayrodriguez, Fadi Salem, Mohamed Rizwan Ar Hasheek, Priya Deshpande.
Mount Sinai Health System, New York, NY.

Introduction: Proteasome inhibitor (PI), Carfilzomib, has been associated with drug-induced microangiopathy (DITMA) in rare cases1. We present a patient with acute kidney injury (AKI) from Carfilzomib-induced DITMA who was successfully managed with Eculizumab, which is a monoclonal antibody that inhibits the alternate pathway of the complement cascade.

Case Description: A 56-year-old woman with refractory IgG Lambda Multiple Myeloma (MM) was admitted with fatigue and decreased oral intake one week after restarting Carfilzomib. She had been on Carfilzomib in the past and tolerated it well. On admission, she had no oliguric AKI with a serum creatinine (sCr) of 1.2 mg/dL (one week prior to Carfilzomib initiation, her Scr = 0.8 mg/dL). Peripheral smear revealed anemia with schistocytes and thrombocytopenia. Carfilzomib was immediately discontinued. Serologic work up, including ADAMTS13, was within normal limits. Her free kappa/lambda ratio 0.41. She was dialyzed twice for clearance and underwent a renal biopsy. The renal biopsy showed diffuse thrombotic microangiopathy (TMA) with minimal tubulointerstitial fibrosis. Eculizumab 900 mg weekly was started, and sCr declined to 1.6 mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her sCr is 1.1 mg/dL, and she is on Eculizumab 1200mg every two weeks.

Discussion: Our case is the fourth report using Eculizumab in Carfilzomib induced DITMA. The timing of our patient’s Carfilzomib exposure supports that DITMA caused her AKI (as opposed to MM-induced TMA). The first line of treatment requires immediate cessation of the drug. Interestingly, Blutini et al, demonstrated the activation of the alternate complement pathway in a patient with Carfilzomib-induced TMA, indicated by elevated levels of fragment Bb and membrane attack complex (MAC)5,6 Portuguese et al, proposed that Carfilzomib may lower the gene expression of Complement factor H resulting in decreased inhibition of the alternate complement pathway7. Given the efficacy of Eculizumab in alternate pathway mediated TMA, Eculizumab is a reasonable therapeutic option because it targets complement C5 and inhibits the assembly of the MAC.8,9,10 Since PI are the mainstay of MM treatment, the nephrologist should be aware of the rare but serious consequences of PI-associated DITMA and should consider Eculizumab as a management strategy1,2,3.

PO0237

Tubulointerstitial Lupus Nephritis with Coexisting Renal Limited IgG4 Disease

Bashra Z. Salem1, Lilian Saro-Nunez1, Ayesha Ahmed1, Hammad Siddiqui2, Rutgers The State University of New Jersey, New Brunswick, NJ.

Introduction: The classic pattern of Lupus Nephritis (LN) is an autoimmune condition caused by dysregulated glomerulonephritis. Rare cases have been described with predominant tubulointerstitial nephritis (TIN) with tubulointerstitial immune deposits in the absence of significant glomerular lesions. We describe a patient with such pattern of disease along with co-existing renal limited IgG4 related disease (IgG4 RD). In this report, we describe a case of 27-year old man with no past medical history presented with fever, malaise and cough for 3 days. It was associated with occasional epistaxis and weight loss for 3 months. He denied any rash, joint pains, oral ulcers or photosensitivity. On admission he was noted to have creatinine of 7.2 mg/dL with eGFR of 9ml/min/1.73m2. His UA showed 3 + blood, protein to creatinine ratio of 1.61 microgram/mg and microalbumin to creatinine ratio of 334 microgram/mg. His pertinent positive blood work includes ANA titer of 1:1280, complements levels C3 < 26.3 and C4 < 7.9. He underwent a renal biopsy that showed immune complex mediated chronic active interstitialritis with increased IgG4 positive plasma cells, minimal glomerular alterations with rare mesangial deposits. Full house pattern was observed in tubules on immunofluorescence. Lymph node FNA performed did not demonstrate increased IgG4 levels, however his serum IgG4 levels returned high at 205 mg/dL. He was diagnosed with Tubulointerstitial Lupus Nephritis with renal limited IgG4 disease. He was started on high pulse dose steroid followed by taper and mycophenolate mofetil (MMF). He was treated with a short course of rituximab therapy and a good clinical response with improved complement levels and ANA titers. His serum creatinine improved to 2.6 mg/dL at all 6 months.

Discussion: A very few cases of lupus TIN without glomerular involvement are described in the literature and management options remain unclear. The most frequent management strategies of IgG4-RD are TIN, membranous glomerulonephropathy and obstructive nephropathy due to retroperitoneal fibrosis. The presence of an overlap of LN with IgG4 RD has been reported in very limited number that our patient had. Our patient responded well to the treatment with MMF and Steroids. However, there is need to describe and study more such cases to delineate management protocols. We continue to follow him in clinic and monitor him for involvement of other organ system.

PO0238

Hepatorenal Syndrome Type 1 as a Consequence of Transarterial Chemoembolization

M. Catalina Morales-Alvarez, Larab L. Ginijany, Alexander Davidovich, Mount Sinai Beth Israel Hospital, New York, NY.

Introduction: Hepatorenal syndrome (HRS) is characterized by marked kidney dysfunction in the setting of advanced liver disease. HRS can manifest in two different patterns, type 1, representing an acute onset of kidney injury and type 2, corresponding to the chronic manifestation of kidney injury secondary to liver dysfunction. Here we present a case of HRS type 1 following transarterial chemoembolization (TACE) in a patient with advanced cirrhosis and hepatocellular carcinoma (HCC).

Case Description: A 69-year-old male presented to the hospital with worsening weakness, lethargy and decreased urinary output. His family stated the symptoms began a few days prior to his last session of TACE the week prior. There were no fevers, sick contacts or recent travel. He had underlying CKD stage IIIa (baseline Scr 1.7 mg/dL) and alcoholic cirrhosis with HCC treated with partial resection and multiple sessions of TACE. On admission, the Scr was 9 mg/dL associated with symptomatic hyperkalemia, anion gap metabolic acidemia, severe hyperammonemia, junctional bradycardia and hypotension. Additionally, urinary sodium was < 20 mmol/L, with a bland sediment. Once admitted to the ICU, he required vasopressors and emergent hemodialysis. He was given HRS treatment with albumin 1g/Kg/day plus vasopressin for 2 days. His urine output and kidney function improved back to baseline in the following days with no further requirement for hemodialysis.

Discussion: HRS represents an entity of kidney dysfunction secondary to severe renal vasoconstriction in response to splanchnic vasoconstriction. HRS occurs in states of advanced liver disease. Our patient had alcoholic cirrhosis and HCC. TACE had been implemented as a palliative treatment to the unrectected lesions. Linitated contrast and chemotherapeutic agents are used in low dose with this therapeutic option, however, several cases of acute kidney injury have been reported likely due to contrast induce nephropathy. The need for renal replacement therapy has been not extensively reported but overall long-term outcomes were satisfactory. HRS as a consequence of TACE has never been described but the laboratory findings and significant improvement following treatment we suspected this case was HRS type 1.

PO0239

Thyroid-Cardiorenal Syndrome

Juan D. Salcedo Betancourt,2 Karla G. Carias martinez,2 Vasuki N. Venkat,1 Daniel J. Soberon,1 Marco A. LainadoAvelaneda.1 1Miami VA Healthcare System, Miami, FL; 2University of Miami School of Medicine, Miami, FL.

Introduction: In severe hypothyroidism, acute kidney injury (AKI) may occur from hypothyroidism-induced myopathy. We report the first case of AKI in the setting of severe bradycardia without rhabdomyolysis. Case Description: An 85-year-old man with heart failure and a dual-chamber implantable cardiac defibrillator was admitted with bilateral lower extremity edema. Vital signs included asymptomatic bradycardia 40 bpm (Figure 1), blood pressure 107/74 mmHg, without fever or respiratory distress. Laboratories showed serum creatinine (Scr) of 2.3 mg/dL (baseline 1.5 mg/dL), serum sodium 127 mg/dL, serum creatine kinase (PK) levels of 170 U/L (38-174 U/L), thyroid secreting hormone levels (TSH) of 97.77 uIU/L (0.45 – 4.70 uIU/mL) and free thyroxine levels (Free T4) of 0.71 – 1.85 ng/mL). Renal ultrasound was unremarkable. The pacemaker was programmed to VT1 mode 60 bpm (ventricular pacing and sensing) with prompt improvement in the heart rate and renal function. He was discharged on oral levothyroxine.

Discussion: Hypothyroidism increases systemic vascular resistance and decreases blood volume, cardiac contractility, and heart rate, with an overall decrease in cardiac output. AKI may occur from hypothyroidism-induced rhabdomyolysis, however, Scr is rarely elevated or may increase over several weeks. Our case contrasted with the overall acute rise in Scr and prompt recovery after the bradycardia resolved. We believe that the AKI was predominately due to hypothyroidism-induced bradycardia, with a subsequent reduced cardiac output and effective blood flow. AKI workup should include hypothyroidism screening, particularly in the context of persistent bradycardia, even with normal blood pressure and CPK levels. We propose the term Thyroid-Cardio-Renal Syndrome for this unique association.
with non-specific systemic illness. A pauci-immune or immune complex pattern as with our patient. The case demonstrates association reported with ANCA, particularly anti-PR3, which can demonstrate either particularly in the absence of overt clinical endocarditis. There has been a crossover and multiple scratches. Treatment focus shifted from immunosuppression to antibiosis.

1:1024 (normal <1:128). Bartonella PCR was negative. Both TTE and TEE were negative AFB cultures, and BAL for fungal organisms. However, Bartonella IgG was positive at evidence of alveolar hemorrhage, immunosuppression and PLEX were discontinued. Few distinct subepithelial hump-like deposits by EM, suggestive of an infection related trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a crescents. IF displayed global 3+ granular staining for both IgG and C3 as well as biopsy showed an MPGN-pattern proliferative glomerulonephritis with necrotizing hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was treated with immunosuppression and plasma exchange. Serum creatinine (SCR) on admission was 10.2 mg/dL (baseline 1.1 mg/dL). Basic workup including ANCA, ANA, dsDNA, C3, C4, and Hepatitis B and C was unremarkable. A renal biopsy showed severe interstitial fibrosis and tubular atrophy with abundant calcium oxalate crystals, and dialysis was initiated. Dietary history revealed daily consumption of 1,000 mg Vitamin C, salads, and nuts. Genetic testing for primary hyperoxaluria was negative. After 1.5 months he was no longer dialysis-dependent but only attained partial renal recovery (SCR 2.67 mg/dL, eGFR 25).

Patient B was a 68 year old male with no history of renal or GI disease who presented with emesis, weakness, and urinary retention. Admission SCR was 7.7 mg/dL (baseline 1.4 mg/dL). Renal function improved slightly after Foley placement for newly diagnosed BPH, but SCR remained elevated with negative initial AKI workup. Renal biopsy showed oxalate nephropathy. Further history revealed only occasional consumption of nuts with daily servings of tea and polyethylene glycol. Patient B’s genetic testing was also negative. He remains on hemodialysis and has been referred for transplant.

Discussion: Oxalate nephropathy can result from primary (genetic) or secondary mechanisms. The most common secondary causes include increased intestinal oxalate availability (“enteric” hyperoxaluria) and increased dietary consumption. A basic medical history can reveal risk factors for enteric hyperoxaluria, while a thorough review of diet and supplements is often deferred, delaying the diagnosis. In some cases a single cause is not identified, and instead a combination of dietary and pharmacologic factors are to blame. We present 1 case of oxalate nephropathy most likely caused by high-dose Vitamin C, and another case with a less clear etiology aside from vague dietary and medication factors.

POO240

Cat Scratch Kidney
Roy Rajan, Jason R. Pettus, Charles W. Hopley. Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.

Introduction: A case of anuric RPGN secondary to post infectious glomerulonephritis in setting of bartonella infection

Case Description: An 84-year-old female presented with creatinine of 7.85mg/dl (baseline 0.81mg/dl) during a workup for painless hematuria. She developed progressive hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was treated with immunosuppression and plasma exchange. Serologic tests including ANA/ENA, anti-GBM, C-ANCA, P-ANCA, and MPO Ab were negative. However, PR3 Ab was elevated at 29.3 Units. Complement C3 and C4 levels were normal. Blood/urine cultures, assays for hepatitis B/C, HIV and Respiratory panel were negative. Bartonella biopsy showed an MPGN-pattern proliferative glomerulonephritis with necrotizing crescents. IF displayed global 3+ granular staining for both IgG and C3 as well as trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a few distinct subepithelial hump-like deposits by EM, suggestive of an infection related glomerulonephritis. With a biopsy suggesting an infectious process and BAL without evidence of alveolar hemorrhage, immunosuppression and PLEX were discontinued. Broad infectious workup was negative for ASO titers, Borrelia antibody, Quantiferon/AFB cultures, and BAL for fungal organisms. However, Bartonella IgG was positive at 1:1024 (normal <1:128). Bartonella PCR was negative. Both TTE and TEE were negative for valvular lesions. Additional patient history elucidated recent acquisition of a pet cat and multiple scratches. Treatment focus shifted from immunosuppression to antibiotics. Discussion: Our case highlights an underappreciated entity associated with GN, particularly in the absence of overt clinical endocarditis. There has been a crossover association reported with ANCA, particularly anti-PR3, which can demonstrate either a pauci-immune or immune complex pattern as with our patient. The case demonstrates how renal biopsy and social history remain vital diagnostic tools in patients presenting with non-specific systemic illness.

POO241

Two Cases of Oxalate Nephropathy: An Uncommon Disease, Often Missed
Claire F. Schretlen, Michelle Neuman, Vishy Chaudhary. West Virginia University Health Sciences Center, Morgantown, WV.

Introduction: Oxalate nephropathy is a state of excess oxalate availability leading to damaging calcium oxalate crystal deposition in the renal tubules and interstitium. It is an uncommon but severe cause of renal damage and leads to dialysis dependence in the majority of patients; thus, diagnostic index of suspicion must be high.

Case Description: Patient A was a 58 year old male with 2 prior renal stones but no history of gastric bypass, IBD, or other malabsorptive state who presented with vomiting, metallic taste, and behavior changes. Serum creatinine (SCR) on admission was 10.2 mg/dL (baseline 1.1 mg/dL). Basic workup including ANCA, ANA, dsDNA, C3, C4, and Hepatitis B and C was unremarkable. A renal biopsy showed severe interstitial fibrosis and tubular atrophy with abundant calcium oxalate crystals, and dialysis was initiated. Dietary history revealed daily consumption of 1,000 mg Vitamin C, salads, and nuts. Genetic testing for primary hyperoxaluria was negative. After 1.5 months he was no longer dialysis-dependent but only attained partial renal recovery (SCR 2.67 mg/dL, eGFR 25).

Patient B was a 68 year old male with no history of renal or GI disease who presented with emesis, weakness, and urinary retention. Admission SCR was 7.7 mg/dL (baseline 1.4 mg/dL). Renal function improved slightly after Foley placement for newly diagnosed BPH, but SCR remained elevated with negative initial AKI workup. Renal biopsy showed oxalate nephropathy. Further history revealed only occasional consumption of nuts with daily servings of tea and polyethylene glycol. Patient B’s genetic testing was also negative. He remains on hemodialysis and has been referred for transplant.

Discussion: Oxalate nephropathy can result from primary (genetic) or secondary mechanisms. The most common secondary causes include increased intestinal oxalate availability (“enteric” hyperoxaluria) and increased dietary consumption. A basic medical history can reveal risk factors for enteric hyperoxaluria, while a thorough review of diet and supplements is often deferred, delaying the diagnosis. In some cases a single cause is not identified, and instead a combination of dietary and pharmacologic factors are to blame. We present 1 case of oxalate nephropathy most likely caused by high-dose Vitamin C, and another case with a less clear etiology aside from vague dietary and medication factors.
and lactate levels were assessed in kidney tissue. Oxalate (NaOx, 100mg/kg) and 3% NaOx in drinking water for 24hr before sacrifice.

Results: AKI was unlikely to develop in the TMA as it had few months since the last dose. There are no cases reported of radiation causing renal limited TMA which we thought could also be a potential cause. Hypertension and severe anemia with schistocytes were the only clues to a TMA process. The elevated haptoglobin and normal platelet count was unusual. The TMA is thought to be likely secondary to paraneoplastic syndrome or possibly from the radiation treatments.

PO0243
Myeloid-Specific PKM2 Deletion Reduces Kidney Damage in Oxa-
late-Induced AKI
Orestes Foresto-Neto,1,2 Magaiva A. Silva,3 Ingrid K. Watanabe,3 Tássia S. Honda,1 Marcos A. Ceneide,1 Meire I. Hiyane,1 Alvaro Pacheco-Silva,3 Niels O. Camara,1 1Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2Universidade Federal de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.

Background: Reprogramming of immune cell metabolism have been associated with the development of kidney injury. The M2 isof orm of pyruvate kinase (PKM2) catalyzes a critical stage of glycolysis, which was shown to be a crucial metabolic pathway for pro-
flammatory macrophages. We investigated whether deletion of PKM2 in myeloid cells exerts renoprotection in calcium oxalate (CaOx) crystal-induced acute kidney disease (AKI).

Methods: AKI was induced in myeloid-specific PKM2-knockout (PKM2<sup>-/-</sup>Ly9M-Cre) mice or littermates (Ly9M-Cre<sup>+</sup> mice) by a single i.p. injection of calcium oxalate (NaOx, 100mg/kg) and 3% NaOx in drinking water for 24hr before sacrifice. Healthy controls received vehicle only. Serum creatinine and urea were evaluated as markers of renal function. CaOx crystal deposition (Picrosirius staining), IL-6, NGAL, and KIM-1 mRNA expression (quantitative PCR), macrophage number/phenotype (FACS), and lactate levels were assessed in tissue.

Results: In PKM2<sup>-/-</sup> mice, intrarenal CaOx deposition increased the serum levels of creatinine and urea, as well as the expression of IL-6, NGAL, and KIM-1 in kidney tissue compared to healthy controls (p<0.01). Despite a similar deposition of crystals, loss of renal function and markers of renal inflammation/injury were reduced in PKM2<sup>-/-</sup>LysM-Cre<sup>+</sup> mice (p<0.05). FACS analysis indicated that the number of F4/80<sup>+</sup>CD11b<sup>+</sup> macrophages with the pro-inflammatory phenotype Ly6C<sup>+</sup>CD206<sup>-</sup> were significantly reduced in PKM2<sup>-/-</sup>LysM-Cre<sup>+</sup> mice (p<0.01). In addition, PKM2 deletion also reduced renal lactate levels of mice (p<0.05).

Conclusions: The pro-inflammatory status of macrophages relays on glycolysis in CaOx nephropathy. Therefore, deletion of PKM2 in myeloid cells can reduce CaOx-induced renal inflammation and injury. FAPESP (2019/02893-9 and 2017/05264-7), CNPq and CAPES.

PO0244
High-Content Imaging of Kidney Cell Function to Elucidate Mechanisms of Antiviral Drug Toxicity
Adam Pearson,1 Dominik Haeni,2 Andrew Hall,1,2 1Universitat Zurich, Zurich, Switzerland; 2University Hospital Zurich, UniversitatsSpital Zurich, Zurich, Switzerland.

Background: Globally, millions of people live with HIV and hepatitis B virus (HBV). Toxicity from antiviral drugs is a major cause of kidney disease in these individuals. Tenofovir disoproxil fumarate (TDF) is a first line therapy for HIV and HBV. Toxicity from antiviral drugs is a major cause of kidney disease in these individuals. Tenofovir disoproxil fumarate (TDF) is a first line therapy for HIV and HBV.

Methods: We screened numerous treatment regimens and generated phenotypes of human-derived PT cells to generate realistic in vitro models of functional TDF toxicity. Metabolic characterization of these revealed a clear phenotype consistent with ATP depletion due to decreased aerobic respiration coupled with increased ATP cycle or beta-oxidation, but clear evidence of oxidative stress.

Conclusions: In summary, we have developed a high-content image analysis pipeline of human-derived PT cells to generate realistic in vitro models of functional TDF toxicity.

Inhibition of Acetyl-CoA Carboxylase in Acutely Injured Tubular Cells Exacerbates DNA Damage and Mitochondria Fission in Diabetic Nephropathy

Xiaohuan Liu,1,2 Jiahua Li,1 Shun-Yang Cheng,1 Guixia Li,1,3 Joseph V. Bonventre,1 Brigham and Women’s Hospital, Boston, MA; The Second Hospital, Cheloo College of Medicine, Shandong University, Jinan, China; 3Shenzhen Third People’s Hospital, Shenzhen, China.

Background: Both diabetes and acute tubular injury (ATI) alter lipid metabolism of proximal tubules. Inhibiting lipogenesis causes G2/M cell cycle arrest, which can cause maladaptive tubular repair. Acetyl-CoA carboxylase (ACC) stimulates lipogenesis and inhibits fatty acid oxidation (FAO). Phosphorylation (p-ACC) inhibits ACC, which inhibits lipogenesis and promotes FAO. We hypothesized that p-ACC exacerbates DNA damage and mitochondria dysfunction in diabetic nephropathy (DN) after ATI.

Methods: Human DN samples were co-stained for p-ACC, KIM-1, and a-SMA. ATI was induced by a single diphtheria toxin (DT) injection in Akita mice in which the DT receptor (DTR) was introduced genetically into the kidney tubule (AkitaSIX2-DTR). Mice were fed a high-fat diet (HFD). The expression ratio of p-ACC/ACC was determined at 3 days after DT and markers for tubular injury and DNA damage (g-H2AX) were evaluated at 3 days and 4 months. Cisplatin-injured HK2 cells were treated with an ACC inhibitor, PF-05175157 (ACCi) or a carnitine palmitoyltransferase 1 inhibitor, etomoxir (CPT1i) and examined for DNA damage and mitochondria fission.

Results: P-ACC expression was increased and correlated with expression of tubular injury marker KIM-1 and myofibroblast marker a-SMA in human DN specimens. At day 3 after DT, ATI increased the p-ACC/ACC ratio in the AkitaKisuwg mice on HFD and resulted in enhanced expression of g-H2AX in KIM-1 positive tubules and kidney fibrosis at 4 months. When cisplatin-injured HK2 cells were treated with ACCi, which allowed b-oxidation of acyl-CoA, there was an increase in mitochondrial fission factor (MFF) without a further increase of g-H2AX. Etomoxir, which blocked acylcarnitine entry into mitochondria, reduced MFF and g-H2AX expression.

Conclusions: Increased levels of p-ACC were associated with increased tubular injury and fibrosis in human DN. P-ACC in injured renal epithelial cells permitted b-oxidation of acyl-CoA in damaged mitochondria and enhanced mitochondrial fission resulting in DNA damage plausibly from reactive oxygen species. Prevention of mitochondrial overload of acyl-CoA is a potential therapeutic target to mitigate mitochondria damage and DNA damage after ATI in DN.

The Effect of ANG-3777 on In Vitro Cell Proliferation

Latha Pakka, Izthak D. Goldberg. Angion Biomedica Corp, Uniondale, NY.

Background: Hepatocyte growth factor (HGF) regulates tissue growth and development by inducing cell motility, proliferation and morphogenesis in multiple cell types including endothelial and epithelial cells. However, it has no effect on proliferation in fibroblasts. ANG-3777 is a novel molecule that exerts similar cytoprotective and regenerative effects as HGF. This study compared the effect of ANG-3777 with that of HGF in stimulating cell proliferation.

Methods: In vitro cell proliferation assays were conducted in triplicate using human umbilical venous endothelial cells (HUVECs), rat neuronal Schwann cells, and mouse fibroblasts. HUVEC and fibroblasts were exposed to 5 μM ANG-3777 or 25 ng/mL HGF for up to 24 hours. Schwann cells were exposed to increasing doses of ANG-3777 (up to 10 μM) or HGF (up to 100 ng/mL) for 16 to 24 hours to evaluate the effective concentration at 50% proliferative activity (EC50). Radiolabeled [3H]-thymidine incorporation was used as a measure of cell proliferation. ANG-3777 and HGF increased cell proliferation in a dose-dependent manner following exposure to ANG-3777 (EC50 0.012 μM) and HGF (EC50 6.5 ng/mL).

Results: A statistically significant increase in cell proliferation (±3-fold) was observed in HUVECs exposed to ANG-3777 and HGF compared with vehicle (p<0.01; Figure 1). Similarly, Schwann cell proliferation increased in a concentration-dependent manner following exposure to ANG-3777 (EC50 0.012 μM) and HGF (EC50 6.5 ng/mL). In mouse fibroblasts (negative control), neither ANG-3777 nor HGF exposure stimulated cell proliferation compared with vehicle.

Conclusions: In vitro cell-based proliferation assays confirmed that the activity of ANG-3777 is comparable to that of HGF in inducing cell proliferation in HUVECs and rat Schwann cells with neither agent stimulating proliferation in mouse fibroblasts.
was induced in mice after right kidney removal, then IRI mice were treated with 200 μL sodium-iodide (NaI) and γ-irradiation (NIR). RNASeq data were acquired and analyzed in a supervised manner. The time-course study design involved gene expression experiments using an intra-renal injection of sodium chloride (NaCl) or a control saline solution. The primary functional marker for KI, peroxisome proliferator-activated receptor γ (PPARγ), was identified to be down-regulated in the IRI group compared to the control group. Conclusion: The results obtained in the present study indicate that NIR can be used as a new method for inducing KI and that PPARγ is a key target for the treatment of KI.

Results: Immunochemistry staining revealed increased expression of GLUT2, GLUT1, and NADPH in the IRI + IR group compared to the control group. The expression of GLUT2 was significantly increased in the IRI + IR group compared to the control group. The expression of GLUT1 and NADPH was increased in the IRI + IR group compared to the control group. The expression of GLUT2 and NADPH was increased in the IRI + IR group compared to the control group. The expression of GLUT1 and NADPH was increased in the IRI + IR group compared to the control group. The expression of GLUT2, GLUT1, and NADPH was increased in the IRI + IR group compared to the control group. The expression of GLUT2, GLUT1, and NADPH was increased in the IRI + IR group compared to the control group.

Conclusions: Both CM administration and exposure to radiation induce DNA damage and delay DNA damage repair, which are accompanied by increased levels of oxidative stress and inflammation and downregulation of klotho expression.

PO0251
Whole-Transcriptome Sequencing of Proximal Tubule Cells Exposed to Free Light Chains
Rohit Vaidya, Vecchi Batuman.1,2 Tulane University School of Medicine, New Orleans, LA; 2SLPHCS, Southeast Louisiana Veterans Health Care System, New Orleans, LA.

Background: Despite medical advancements, molecular markers for early detection of kidney injury (KI) are limited. Serum creatinine, the only functional marker for KI, has poor predictive accuracy, particularly in the early stages of acute KI due to free light chains in multiple myeloma (MM) patients. Identification of new markers would be highly useful in a select group of MM patients who do not present initially with a detectable rise in creatinine.

Methods: Human kidney proximal tubule cells (PTCs; RPTEC TEL) were exposed to C or λ FLCs. Control/treated cells were harvested, and total RNA was isolated following standard procedures for whole-transcriptome analysis. RNASeq analysis was performed using Illumina HiSeq 2000. RNA sequencing for whole transcriptome was performed by using Illumina NextSeq 500 to generate >60M paired-end 75bp reads per sample. After initial data quality checking by FastQC and RSeQC, bioinformatics analysis was performed using TopHat, Samtools, and Picard.

Results: FLCs caused a decrease in the expression of several genes involved in innate immunity (VNN1, MX1, OAS2, TLRs, IFI6, IFI27, IFIT1, ISG15, B2M, ZNF304, NLRP3, ERK signaling (KCTD12, IFI6, MAP3K, ERK1/2, JNK3), and inflammation (CXCL6, TNFA, IL6, CXCL8, IL8, IRAK1, IRAK4, TRAF6, NFKB, IKBA, IKK) as well as miRNAs (hsa-146a-5p, hsa-miR-574-3p, hsa-miR-331-3p, hsa-miR-125a-5p) in FLC induced tubular injury in MM patients. We also found a KI mechanism involving cross-talk among innate immunity, ERK signaling, and the inflammatory pathway by different FLC types.

Conclusions: Our results show differentially expressed genes and a mechanism of injury involving cross-talk between innate immunity and inflammatory pathways in FLCs exposed to FLCS.

PO0252
Single-Cell Profiling of AKI in Mice Highlights Differential Immune Cellular Response Programs in Renovation and Fibrosis
Michael S. Balzer,1,2 Yawen Yang,1,2 Ziyuan Ma,1,2 Rojesh Shrestha,1,2 Matthew Palmer,1,2 Katalin Susztak,1,2 Susztak Lab University of Pennsylvania, Perelman School of Medicine, Department of Medicine, Philadelphia, PA; 2University of Pennsylvania, Perelman School of Medicine, Department of Translational Medicine, Philadelphia, PA.

Background: After acute injury the kidney has the ability to regenerate and repair to a certain extent. On the other hand, maladaptive injury response leads to kidney fibrosis and chronic kidney disease. We are only beginning to understand the complex interactions of epithelial, stromal and immune cells involved in these adaptive processes.

Methods: Here we profiled gene expression changes at single cell resolution over time in acute injury models of mice subjected to mild and severe bilateral ischemia/reperfusion injury (IRI). Immune function, structure, and single cell gene expression analysis was performed on day 1, 3 and 14. We used gene regulatory network and trajectory analyses to define key drivers of successful and failed regeneration.

Results: Genes involved in similar kidney function decline as catalyzed by serum BUN, however long ischemia led to severe kidney fibrosis, while mild ischemia prompted minimal structural changes. In total, we obtained scRNAseq data for >160,000 cells. IRI led to very significant cell proportion changes including a decrease in renal tubule epithelial cells (KRT14+ and S100A14+), and an increase in fibroblasts and immune cells. Single cell analysis showed distinctly different differentiation signatures for successful repair vs. maladaptive response in animals subjected to moderate vs. severe IRI. We also identified several discrete immune cell clusters, such as progenitors, naïve B and T cells, T memory and Tgd cells, natural killer and dendritic cells, Ly6Chi and Ly6monocytes, macrophages and granulocytes and we defined their differentially expressed gene network along pseudotime trajectories towards either successful or maladaptive repair.

Conclusions: Single cell RNA-seq analysis of kidney cells revealed differential gene expression in response to acute kidney injury (AKI) is incompletely understood. We investigated the distribution of expression across the entire kidney, mapping expression patterns to renal histology in the ischemia-reperfusion injury (IRI) and cecal ligation and puncture (CLP) murine models of AKI.

Spatial Transcriptomic Signatures in Murine AKI Models
Ricardo Melo ferreira, Tarek M. El-Achkar, Kimberly S. Collins, Yinghua Cheng, Seth Winfree, Pierre C. Dagher, Michael T. Eadon. Indiana University School of Medicine, Indianapolis, IN.

Background: The localization of whole transcriptomic differential expression in different areas of acute kidney injury (AKI) is incompletely understood. We investigated the distribution of expression across the entire kidney, mapping expression patterns to renal histology in the ischemia-reperfusion injury (IRI) and cecal ligation and puncture (CLP) murine models of AKI.

Conclusions: Using spatial transcriptomics, we uncovered regional differences in total RNA expression between the IRI and CLP models. The identified region housed specific cell types with differences in enriched pathways. The enriched apoptotic pathways in IRI may be consistent with a lower relative expression compared to sepsis. The neutrophil and macrophage spatial distribution indicate how those models respond to IRI. The localization of transcriptomic alterations in AKI is not uniform across models.

Long-Term Use of Ferric Citrate in the Treatment of Iron Deficiency Anemia in Patients with Non-Dialysis-Dependent CKD: THE COMPASS Trial
Pablo E. Pergola,1 Diogo S. Belo,2 Paul W. Crawford,2 Moussata A. Moussata,2 Weni Luo,3 Alex Goldfarb,4 Renal Associates PA, San Antonio, TX; 4Columbia University Institute of Medical Research, Columbia, New York, NY; 5South Carolina Nephropathy & Hypertension Center, Inc, Orangeburg, SC; 6Akebia Therapeutics, Inc, Cambridge, MA; 7Research by Design, Chicago, IL.

Background: Ferric citrate (FC) is an FDA-approved oral iron replacement for adults with iron deficiency anemia (IDA) and non-dialysis-dependent (NDD) CKD and as a phosphate binder in adults with dialysis-dependent CKD. For IIDA, the recommended FC starting dose is 1 tablet (1 g, contains 210 mg ferric iron) 3 times daily (TID) titrated to maintain hemoglobin (Hb) goal. We studied the long-term efficacy and safety of various FC regimens for IIDA treatment in adults with NDD-CKD (stages 3-5).

Methods: 48-week, phase 4, randomized, open-label, multicenter study (NCT03236246). Patients received (1:1) FC 1 g tablet TID (3 g/day) or 2 tablets BID (4 g/day). At Wk 12, if Hb was <10 g/dL or changed >0.5 g/dL from baseline (BL), dose was increased to 2 tablets TID from (1 TID) or 3 tablets BID (from 2 BID). Primary endpoint was change in Hb from BL to WK 24. Secondary endpoints included change in transferrin saturation (TSAT), ferritin, and phosphate to WK 48.

Results: This analysis included 183 of 206 randomized patients. Groups were well matched, with mean age 69±10.3 y and 54% with CKD due to diabetes. Mean BL eGFR was 33.6±10.9 mL/min/1.73 m², and Hb was 10.45±0.74 g/dL. Efficacy measures at 48 wks are presented in the Table. Adverse events (AEs) occurring in ≥5% included diarrhea (13.2%), abdominal discomfort (17.2%), and constipation (12.2%). Incidence of serious AEs was 13.9% in BID and 17.3% in TID groups. Five deaths were reported, none deemed FC related by investigators.

Conclusions: Both FC regimens studied increased and maintained Hb through 48 wks in patients with NDD-CKD with IDA. Patients with lower baseline Hb and iron parameters had a higher increase in Hb with FC treatment. Serum phosphate remained within normal range over study duration. Mean changes in Hb, TSAT, ferritin, and phosphate were similar in the BID and TID and the 3 and 4 g/day dosing groups. These results support the potential for FC dosing flexibility in the long-term treatment of IDA.

Triferic (Ferric Pyrophosphate Citrate, FPC) Maintains Hemoglobin and Reduces IV Iron: Results from a Single-Site 2-Year Observational Analysis

Marc L. Hoffman,1 Richard Delvalle,2 Raymond D. Pratt,1 Rockwell Medical Inc, Wixom, MI; 2Center for Renal Replacement, LLC, Lincolnwood, IL

Background: Triferic (ferric pyrophosphate citrate, FPC) is approved as an iron (Fe) replacement product for maintenance of hemoglobin (Hgb) in adult patients (pts) receiving chronic hemodialysis (HD). Trial data have demonstrated that FPC maintains Fe stores and Hgb while reducing IV Fe usage with a well-tolerated safety profile. We now report one clinic’s experience using FPC for all HD patients (pts) during a 2 y period.

Methods: FPC was added to centrally delivered liquid bicarbonate to provide 220 μg Fe/dL, all patients received FPC at each HD. Anonymized retrospective data from the electronic health record were collected between Sep 2016–Dec 2018. A recommended FPC Fe protocol was provided, but the clinic was allowed to adjust anemia management at their discretion. Suplemental Fe gluconate (IV Fe) was administered according to a protocol based on serum ferritin and TSAT values. All pts receiving IV Fe received single doses of 125 mg elemental Fe up to a max of 500 mg Fe/month when criteria for supplementation were met. During the first 4 months of FPC, the center converted pts from epoetin alfa (EPO) to darbepoetin alfa (INN), therefore INN equivalents were calculated using the published conversion guide (1.8 EPO dose/3000 IV iron and ESA dose). Standardized and changes from pre-FPC were reported for Hgb, IV Fe and ESA usage. KDOQI data were available for the years 2016–2018.

Results: Within 3 months of initiation of FPC, Hgb increased by 0.3 g/dL and was maintained during the observation period. Total IV Fe dose was significantly reduced by 78.4%. Darbepoetin equivalent doses were reduced from pre-FPC by 31.5% by the end of the observation period. Compared to the first year of assessments (2016), post FPC assessments of QoL showed improvements in the Burden of Kidney Disease (KD), Symptoms and Problems of KD and Effects and KD of Effects on daily life scales. No adverse events related to FPC were reported.

Conclusions: This observational study demonstrates that FPC is a well tolerated replacement for IV Fe when administered to all patients in a HD unit. The findings of this real-world observational study align with those of clinical trials in terms of reduction of IV Fe use and maintenance of Hgb. ESA was gradually reduced and the KDOQI showed a trend to improvement in the burden and symptoms of kidney disease.

Roxadustat Lowers Risk of Red Blood Cell Transfusion in Patients with Anemia of CKD

Steven Fishbane,1 Robert Provenzano, Anjay Rastogi,2 Daniel W. Coyne,3 Roberto Pecotis-Filho,4 Chaim Charytan,1 Maksym Pola,1 Lona Poole,1 Gopal Sahai,5 Willis Chou,1 Tyson T. Lee,1 Kui-Hung P. Yu,3 Northwest Health, Great Neck, NY; 2Wayne State University, Detroit, MI; 3University of California Los Angeles, Los Angeles, CA; 4Washington University in Saint Louis School of Medicine, Saint Louis, MO; 5Arbor Research Collaborative for Health, Ann Arbor, MI; 6Nephrology Associates, PC, New Rochelle, NY; AstraZeneca, Warsaw, Poland; FibroGen Inc, San Francisco, CA

Background: RBC transfusions may cause reactions, lead to allo-sensitization, or rarely transmit infections, so treatments reducing transfusions are desirable. This analysis assessed whether roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by enhancing erythropoietin synthesis and increasing iron availability via reducing hepcidin and increasing iron transport. We assessed the effect of roxadustat on iron parameters in patients with NDD-CKD.

Methods: Patients were randomized to double-blind roxadustat or placebo in 3 pivotal NDD-CKD trials. Oral iron was administered without restriction per discretion of the treating physician, and intravenous (IV) iron use was limited to rescue therapy. Mean changes from baseline (BL) in Hb, hepcidin, and iron parameters were evaluated. Pooled results are reported.

Results: Overall, 4277 patients were evaluated (roxadustat N=2391; placebo N=1886). Mean eGFR was 20 ml/min/1.73 m² in both groups. Roxadustat was superior to placebo in increasing mean Hb from BL (9.1 g/dL for both groups) averaged over Weeks 24–52: 1.9 vs 0.2 g/dL (P<0.0001). IV iron use was required in 2.1% of roxadustat vs 4.8% of placebo patients during the first 52 weeks after randomization. Roxadustat reduced hepcidin and increased both transferrin and serum iron (Figure). Reductions in ferritin and transferrin saturation occurred predominantly in patients with the highest BL values of these parameters whereas assessed by quartile (7–278 μL/L; and ≥35%, respectively).

Conclusions: Roxadustat increased both serum iron and iron-carrying capacity (transferrin) while simultaneously inducing erythropoietin and correcting anemia in patients with NDD-CKD, without the need for regular IV iron supplementation.

Health-Related Quality of Life in Roxadustat-Treated Patients with Anemia and Non-Dialysis-Dependent CKD
Daniel W. Coyne,1 Roberto Manlio-Karim,2 Pablo E. Pergola,3 Carol A. Pollock,4 Roberto Pecotis-Filho,5,6 Tyson T. Lee,1 Elise Hardy,2 Kin-Hung P. Yu,7 Washington University School of Medicine, Saint Louis, MO; 2South Texas Kidney Specialists, P.A., McAllen, TX; 3Renal Associates PA, San Antonio, TX; 4The University of Sydney, Sydney, NSW, Australia; 5Arbor Research Collaborative for Health, Ann Arbor, MI; 6Northwell Health, Great Neck, NY; 7University of California Los Angeles, Los Angeles, CA; 8AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Anemia in CKD impacts health-related quality of life (HRQOL) by reducing physical capacity and energy levels. Studies have demonstrated a direct relationship between HRQOL scores and hemoglobin (Hb) levels in non-dialysis-dependent (NDD) and dialysis-dependent patients with CKD. We assessed the impact of roxadustat on HRQOL in patients with NDD-CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with NDD-CKD were assessed. Patients with data up to the time of dialysis treatment and who had pretreatment and ≥1 post-treatment HRQOL measurement were included. Mean changes from baseline to Week 12 in HRQOL scores were compared between the treatment groups.

Results: Least-squares mean treatment differences favored the roxadustat group at Week 12 in all p-values (<0.05) in the majority of measures analyzed (Table). Between-group differences were larger in subgroups with lower (ie, worse) baseline scores.

Conclusions: Roxadustat demonstrated improvement in most HRQOL measures vs. placebo in patients with NDD-CKD.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0259
Subgroup Analyses of Efficacy of Roxadustat for Treatment of Anemia in Patients with Incident Dialysis-Dependent CKD
Robert Provenzano,1 Jayant Kumar,2 Steven Fishbane,3 Anjay Rastogi,4 Lona Poole,5 Cameron S. Liu,6 Dustin J. Little,7 Kin-Hung P. Yu,7 Washington University School of Medicine, St. Louis, MO; 2Northwell Health, Great Neck, NY; 3University of California Los Angeles, Los Angeles, CA; 4Fibrogen Inc, San Francisco, CA; 5AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism.

Methods: Data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with non-dialysis-dependent (NDD) CKD were assessed. Data from prespecified, clinically relevant patient subgroups were analyzed for: mean change from baseline (CFB) in hemoglobin (Hb) averaged over weeks 28–52 regardless of rescue therapy (primary US efficacy endpoint) and patients (%) that received rescue therapy in the first 52 weeks.

Results: Roxadustat (n=2391) vs. placebo-treated patients (n=1886) achieved a significantly larger mean (SD) CFB in Hb level (1.85 [0.48] vs. 1.08 [0.49]), corresponding to a hazard ratio of 0.19 (95% CI: 0.16, 0.23) (p=0.001). The results of all subgroup analyses were consistent with those for both the primary US efficacy endpoint and the percentage of patients requiring rescue therapy in the overall NDD population (Table). Significantly fewer patients required rescue therapy during roxadustat treatment vs. placebo (8.9% vs. 31.1%), corresponding to a hazard ratio of 0.19 (95% CI: 0.16, 0.23) (p=0.0001). The effect was consistent in all subgroups and especially pronounced in patients with baseline Hb <8.0 g/dL (18.1% vs. 59.3%) and those with baseline eGFR <10.0 mL/min/1.73m2 (14.8% vs. 48.3%).

Conclusions: The efficacy of roxadustat vs. placebo for a larger mean CFB in Hb and fewer patients that received rescue therapy was consistent across a wide range of prespecified subgroups in the NDD-CKD population.

**Background:** Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis by increasing endogenous erythropoietin and improving iron metabolism.

**Methods:** We analyzed data from a Phase 3, randomized, double-blind study (ANDES) comparing roxadustat to placebo for the treatment of anemia in NDD-CKD patients. 922 patients were randomized (2:1) to receive roxadustat (n=616) or placebo (n=306) thrice weekly with monthly dose titrations. Patients were encouraged to receive oral iron daily unless not tolerated. Change in Hb was compared to changes in key iron and red blood cell (RBC) parameters.

**Results:** All baseline (BL) parameters were comparable between the study arms. Roxadustat was superior to placebo in increasing mean Hb from BL over weeks (wks) 28-52: ~2.0 g/dL (p<0.0001), respectively. Baseline (BL) Hb stratification was performed across quintiles. Parameters were unchanged over time in the placebo arm. In the roxadustat arm, significant erythropoiesis was noted with mean Hb increases of 1.52 and 1.89 g/dL at wks 4 and 24; mean decrease in hepcidin was ~54.6 μg/L at wk 4 and DTBIC was ~63.1 μg/dL at wk 8. An initial decline in mean ferritin and TSAT was noted primarily in the higher quintiles, with little change in the 2 lower BL quintiles. Serum iron increased by 13.6 μg/dL at wk 20 from baseline. All initial changes in iron parameters plateaued by wks 16-20, and remained unchanged thereafter. Reticulocyte Hb content at wk 20 were at baseline level, and it was significantly increased at Wks 28-52: Mean MCV was slightly increased by 1-4 fL at wk 4 before plateauing and stabilizing, while mean MCHC was unchanged.

**Conclusions:** Roxadustat lowered serum hepcidin, accompanied with initial decline in ferritin and TSAT in patients with high BL levels but little change in ferritin and TSAT in patients with low-normal BL levels despite active erythropoiesis. Maintenance of reticulocyte Hb content level during treatment reassures sufficient iron availability during erythropoiesis with roxadustat. These findings in iron parameters suggest that iron is efficiently absorbed and mobilized for erythropoiesis during anemia correction and Hb maintenance with roxadustat in NDD-CKD patients.

**PO0263**

Roxadustat Increases Hemoglobin in Non-Dialysis-Dependent (NDD) CKD Patients Independent of Inflammation

**Background:** Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents. Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by inducing endogenous erythropoietin production and increasing iron utilization via reducing hepcidin. Roxadustat efficacy has been shown in those with inflammation, as defined by baseline (BL) elevation of high sensitivity C-reactive protein (hsCRP) >5 mg/L. The pooled analysis explored the efficacy of roxadustat in correcting Hb in NDD-CKD patients across the spectrum of BL hsCRP values.

**Methods:** Data from three randomized Phase 3 pivotal trials in anemic patients with Stage 3-5 NDD-CKD were pooled and the efficacy of roxadustat in increasing hemoglobin (Hb) from BL was assessed. hsCRP concentration was used as a marker of inflammation; patients with hsCRP >5 mg/L were considered to have inflammation at BL. Mean Hb change from BL (CBF) to Weeks 28-52 was summarized by baseline hsCRP quintile. Roxadustat dose requirements at Week 24 were based on mean weekly dose in patients with mean BL weight ≥100 kg.

**Results:** Overall, 1691 roxadustat-treated NDD-CKD patients were assessed and had a mean BL hsCRP of 7.4 mg/L. Mean BL Hb measures were similar across the hsCRP quintiles (range 9.0–9.2 g/dL). In patients with BL inflammation (n=523), mean BL Hb CBF to Weeks 28-52 was 1.95 g/dL. Mean BL Hb CBF to Weeks 28-52 was also

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline represents presenting author.**
similar across all hsCRP quintiles in roxadustat-treated patients (Figure). Mean weekly roxadustat doses at Week 24 for baseline hsCRP quintiles 1 through to 5 were comparable at 3.2, 2.9, 2.5, 3.0, and 3.0 mg/kg, respectively.

**Conclusions:** Roxadustat increased Hb in anemic NDD-CKD patients independent of inflammation.

**Funding:** Commercial Support - AstraZeneca

### PO0265

**Roxadustat Increases Hemoglobin in Anemic Dialysis-Dependent (DD) CKD Patients Independent of Inflammation**

Mohamed A. El-Shahawy,1 Simon D. Roger,2 Roberto Manello-Karim,3 Maksym Pola,4 Stefan Tham,4 Lynda Szczezch,5 Carol A. Pollock,5 Keck- USC School of Medicine, Los Angeles, CA; 2 Renal Research, Gosford, NSW, Australia; 3 Gamma Medical Research, McAllen, TX; 4 Clinical Research, AstraZeneca, Warsaw, Poland; 5 Clinical Research, AstraZeneca, Gothenburg, Sweden; 6 FibroGen Inc., San Francisco, CA; 7 The University of Sydney, Sydney, NSW, Australia.

**Background:** Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents. Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by inducing endogenous erythropoietin production and increasing iron utilization via reducing hepcidin. Roxadustat efficacy has been shown in those with inflammation, as defined by baseline (BL) elevation of high sensitivity C-reactive protein (hsCRP). This pooled analysis explored the efficacy of roxadustat in correcting Hb in DD-CKD patients across the spectrum of baseline hsCRP values.

**Methods:** Data from three randomized Phase 3 pivotal trials in anemic patients with DD-CKD were pooled and the efficacy of roxadustat in increasing hemoglobin (Hb) from BL was assessed. hsCRP concentration was used as a marker of inflammation; patients with hsCRP >5 mg/L were considered to have inflammation at BL. Mean Hb change from BL (CHF) to Weeks 28–52 was summarized by BL hsCRP quintile. Roxadustat dose requirements at Week 24 were based on mean weekly dose in mg per kg of mean BL weight.

**Results:** Overall, 1538 roxadustat-treated DD-CKD patients were assessed and had a mean BL hsCRP of 10.5 mg/L. Mean BL Hb measures were similar across the hsCRP quintiles (range 9.5–9.7 g/dL). In patients with BL inflammation (n=723), mean Hb CHF to Weeks 28–52 was 1.29 g/dL with roxadustat. Mean Hb CHF to Weeks 28–52 was similar across all hsCRP quintiles in roxadustat-treated patients (Figure). Mean weekly roxadustat doses at Week 24 for BL hsCRP quintiles 1 through to 5 were comparable at 3.9, 3.4, 3.5, 3.3, and 3.6 mg/kg, respectively.

**Conclusions:** Roxadustat increased Hb in anemic DD-CKD patients independent of inflammation.

### PO0266

**Effects of Roxadustat Treatment on Serum Parathyroid Hormone (PTH) in Hemodialysis Patients with Erythropoiesis-Stimulating Agent (ESA) Resistant Anemia**

Yiunichiro Hashiguchi,1 Satoshi Funakoshi,1,2 Kenji Sasase,1 Tayo Kawazu,1 Kanako Hayashi,1 Kosii Yamaguchi,3 Mineaki Kitamura,1 Takashi Harada,1 Tomoya Nishino,1 Nagasaki Kidney Center, Nagasaki, Japan; 2 Nagasaki University Hospital, Nagasaki, Japan.

**Background:** Roxadustat, an oral HIF-PROLYL hydroxylase inhibitor, is shown to stimulate erythropoiesis thereby improving iron metabolism. Of note, recent research suggests that iron utilization plays a key role in bone turnover in hemodialysis patients.

**Methods:** A total of 64 hemodialysis patients with ESA-resistant anemia despite high-dose epoetin α (3000 units 3 times weekly) therapy participated in the study after giving informed consent. Patients were switched from intravenous epoetin α to oral roxadustat therapy (100 mg 3 times weekly), with no dose change in any of the iron supplements, calcimimetics or vitamin D formulas being used, and were assessed after 8 weeks of roxadustat therapy for improvements in anemia, as well as for changes in parameters related to iron metabolism and bone turnover.

**Results:** The study included 39 men and 25 women (age, 70.8 ± 11.8 years; Hb concentration, 10.3 ± 1.2 g/dL). After 8 weeks, the Hb concentration tended to be increased (p = 0.06). As shown in Table, the serum iron, ferritin concentration and TSAT significantly decreased (p < 0.05), suggesting increased iron utilization. Again, the serum calcium concentration was significantly decreased from 8.54 to 8.36 mg/dL, while the intact-PTH (i-PTH) concentration was significantly decreased from 98.61 to 75.80 pg/mL (p < 0.001).

**Funding:** Commercial Support - AstraZeneca

---

**Figure 1:**

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Switching hemodialysis patients with ESA-resistant anemia from intravenous ESA to oral roxadustat therapy may result in a decrease in their serum PTH concentrations presumably through improved iron utilization, thus potentially improving their bone mineral metabolism.

Effects of Roxadustat Treatment on HD Patients with ESA-resistant Anemia

PO0267

Ophthalmological Effects of Roxadustat in the Treatment of Anemia in Dialysis-Dependent and Non-Dialysis-Dependent CKD Patients: Findings from Two Phase 3 Studies

Quan D. Nguyen,1 Yasin J. Sepah,2 Yusuke Yamaguchi,3 Tetsuo Otsuka,3 Yoshikatsu Majikawa,3 Michael Reusch,4 Tadao Akizawa,5 Byers Eye Institute, Stanford School of Medicine, Stanford, CA; 6Oncal Imaging Research and Reading Center, Sunnyvale, CA; 7Astellas Pharma, Inc., Tokyo, Japan; 8Astellas Pharma Europe B.V., Leiden, Netherlands; 9Showa University School of Medicine, Tokyo, Japan.

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor in late-stage development for the treatment of chronic kidney disease (CKD) anemia. Nonclinical data had suggested that hypoxia-inducible factor stabilizers could promote angiogenesis, increasing the risk of retinal pathologies. We herein report the 24-week ophthalmological findings from two phase 3 studies of roxadustat in Japan.

Methods: Dialysis-dependent (DD) and non-dialysis-dependent (NDD) CKD patients (pts) with anemia were randomized to roxadustat (three times weekly) or darbepoetin alfa (DA; once weekly [DD]; once every two weeks [NDD]). Doses were titrated to maintain target hemoglobin. Ophthalmological assessments (funduscopic photograph, optical coherence tomography) were performed by centralized grading; vision acuity and visual fields were assessed weekly.

Results: A total of 302 DD pts (150, roxadustat; 152, DA) and 262 NDD pts (131, roxadustat; 131, DA) were randomized and received al dose of study drug. Results from the ophthalmological funduscopic photograph assessments are reported in Table 1. No meaningful changes occurred in visual acuity or retinal thickness in the treatment groups of either study.

Conclusions: In DD and NDD CKD pts with anemia, the risk of developing ophthalmic abnormalities was comparable between roxadustat and DA.

Risk of Transfusion in Patients with Dialysis-Dependent CKD Increases with Hemoglobin Levels <10 g/dL vs. ≥ 10 g/dL: Pooled Results from Roxadustat Phase 3 Studies

Robert Provenzano,1 Roberto Pecoits-Filho,2,3 Anjay Rastogi,4 Robert Leong,4 Khalil G. Saikali,5 Maksym Pola,5 Dustin J. Little,5 Kin-Hung P. Yu,5 Wayne State University, Detroit, MI; 6Arbor Research Collaborative for Health, Ann Arbor, MI; 7Pontificia Universidad Catolica del Parana Departamento de Medicina, Curitiba, Brazil; 8University of California Los Angeles, Los Angeles, CA; 9FibroGen Inc, San Francisco, CA; 10AstraZeneca, Warsaw, Poland.

Background: Roxadustat is a novel, orally bioavailable, heterocyclic small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including erythropoietin. In patients with ESA-resistant anemia, the risk for blood/RBC transfusion is higher in patients with hemoglobin (Hb) levels <10 g/dL vs. those with Hb ≥10 g/dL. We evaluated the efficacy of roxadustat vs. epoetin alfa on blood/RBC transfusion by Hb level in US-based patients with dialysis-dependent (DD) CKD.

Methods: Data from three pivotal phase 3, randomized, active-controlled studies of roxadustat for the treatment of anemia in DD patients were assessed. Patients were randomized to receive roxadustat or epoetin alfa with periodic dose evaluation/titration. Transfusion was allowed at any time if it was deemed a medical necessity by the Investigator. The incidence rate of transfusion was calculated based on Hb level categorized as: <8.0, 8 to <10, and ≥10 g/dL. Data were evaluated for the on-treatment period 28 days after the last dose of study drug.

Results: In the overall pooled population of patients with DD-CKD, roxadustat vs. epoetin alfa reduced the risk for transfusion by 18% (HR, 0.82 [95% CI: 0.68, 1.00]; p = 0.046). Patients were patient-exposed days stratified by achieved Hb level, the risk for transfusion increased as Hb levels decreased (Table). The incidence rate of transfusion increased approximately 5-fold in patients with Hb <10 g/dL vs. those with Hb ≥10 g/dL.

Conclusions: In US-based patients with DD-CKD and anemia treated with roxadustat, the risk for transfusion was approximately 5 times higher in patients with Hb <10 g/dL vs. those with Hb ≥10 g/dL, regardless of treatment arm.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0269

A Phase 3, Multicenter, Randomized, Open-Label, Active Comparator Conversion Study of Roxadustat in Non-Dialysis-Dependent (NDD) Patients with Anemia in CKD

Tadao Akizawa,1 Manabu Iwasaki,2 Tetsuo Otsuka,3 Yusuke Yamaguchi,3 Michael Reusch3 1Showa University School of Medicine, Tokyo, Japan; 2Yokohama City University, Yokohama, Japan; 3Astellas Pharma, Inc., Tokyo, Japan; 4Astellas Pharma Europe B.V., Leiden, Netherlands.

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor for the treatment of anemia in CKD. Efficacy and long-term safety of roxadustat was assessed, following conversion from darbepoetin alfa (DA), recombinant human erythropoietin (rHuEPO), or epoetin beta pegol (EBP) to roxadustat, in NDD-CKD patients (pts) with anemia. Noninferiority of roxadustat efficacy against DA was evaluated.

Methods: This study enrolled adult Japanese NDD-CKD pts receiving DA, rHuEPO, or EBP for ≥8 weeks before prescreening. Patients who had used rHuEPO or DA were randomized to receive roxadustat or DA (comparative group [CG]). EBP-using pts were allocated to receive roxadustat (referential group [RG]). The primary endpoint was change in average hemoglobin (Hb) from baseline (BL) at Weeks 18-24. Roxadustat efficacy was confirmed if the 95% CI of average Hb at Weeks 18-24 was within 10-12 g/dL. Treatment-emergent adverse events (TEAEs) were assessed.

Results: A total of 262 pts were randomized to CGs and received al dose of roxadustat (n=131) or DA (n=131). 70 pts were allocated to RG and received al dose. The mean (95% CI) of average Hb at Weeks 18-24 in roxadustat (CG) was 11.14 (11.01, 11.27) g/dL, confirming the efficacy of roxadustat. The difference between roxadustat and DA (CGs) in the change in average Hb from BL at Weeks 18-24 was -0.75 g/dL; noninferiority of roxadustat efficacy against DA was evaluated.

Conclusions: This study confirmed the efficacy of roxadustat after conversion from DA, rHuEPO, or EBP, as well as its noninferiority to DA, in NDD-CKD pts with anemia. The safety profile of roxadustat was consistent with previous reports. A final analysis of this study (including 52-week data) will be presented at the congress.

HIF Prolyl Hydroxylase Inhibitor Improves Exercise Endurance and Hardly Affects Instantaneous Force in Mice

Background: Erythropoietin (EPO) and hypoxia-inducible factor (HIF) stabilizers (PH inhibitors) are efficient therapeutic modalities against anemia in CKD. Compared to EPO and EPO receptor system, extra-renal action of PH inhibitors has still not been sufficiently elucidated. Previous reports caused us about the actual misuse of PH inhibitors in doped athletes, but nonhematopoietic effects of PH inhibitors on skeletal muscles remain controversial. Metabolic shift from oxidative phosphorylation toward glycolysis in myotubes in vitro was previously reported. Direct pharmacological effects of PH inhibitors on skeletal muscles and exercise performance were assessed in vivo.

Methods: Roxadustat, one of PH inhibitors, was administered via oral gavage to 8-week-old C57BL6 mice. Plasma EPO levels and HIF-targeted gene expression were assessed.

Anemia and Iron Management

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Background:
Chronic kidney disease (CKD) has a far-reaching impact that extends beyond the affected patient. An online survey was conducted to explore caregiver burden in providing care for an adult with CKD, with or without anemia.

Methods:
The survey was administered in January-February 2020 to adult participants recruited from the American Association of Kidney Patients (AAKP) and a third-party recruiter, Dynata. Eligible participants provided care to an adult with CKD within the last 4 weeks. The 15-20 minute survey included questions related to caregiver and patient demographics, clinical characteristics, preferences on anemia treatment, caregiver quality of life (Burden Scale for Family Caregivers [BSF-C]), and work productivity (Work Productivity Activity Impact Caregiver). Outcomes were summarized descriptively for caregivers of patients with anemia (A+) and without anemia (A-).

Results:
Among 258 caregivers who completed the survey, 42.6% cared for a patient with anemia (A+); non-dialysis dependent (NDD), 38.2%, dialysis dependent (DD), 61.8%). In 2018, 57% cared for a patient with anemia (A+; NDD, 45.9%; DD, 54.1%). Nearly 90% identified themselves as the primary caregiver; 86% were aged 35 to 64 years and >70% were female. Comorbidities reported most frequently by caregivers included anxiety (A+: 43.6%; A-, 32.4%), depression (A+: 36.4%; A-, 30.4%), headache (A+: 30.1%; A-, 31.1%). Most caregivers reported a high burden (BSFC-Sa15+: A+, 69.1%; A-, 58.8%) and work impairment (absenteeism: A+, 19.0%; A-, 14.8%; presenteeism: A+, 37.9%; A-, 33.2%). In the A+ group, >75% of caregivers described anemia as being moderate or severe, and >90% of A+ and A- respondents received anemia treatment in the past month (oral iron, 45.5%; intravenous iron, 33.6%; erythropoiesis-stimulating agents, 22.7%; red blood cell transfusion, 20.9%). A patient was initiated on a new anemia treatment, 46.4% of caregivers would prefer an oral agent, of which 41.2% prefer a once daily formulation.

Conclusions:
There is a wide range of experiences by caregivers of patients with CKD, especially when anemia is present. Further studies are needed to better understand its full extent and explore support strategies for caregivers.

Cost and Healthcare Resource Use in Patients with Anemia in CKD

Eric T. Wittbrodt,1 Glen James,2 Supriya R. Kumar,1 Juan Jose Garcia Sanchez,2 Hungta (tony) Chen,1 Kamyar Kalantar-Zadeh,4 James A. Sloand.3

Background:
Anemia is a routinely occurring complication in patients with chronic kidney disease (CKD), but current data regarding its economic impact are lacking. This descriptive examination of treatment by CKD stage for NDD patients with anemia found that anemia was oftentimes left untreated, especially in the stage 3-4 CKD patients. After NDD CKD patients were diagnosed with anemia, it was almost 1.5 months before treatment was initiated. In NDD CKD patients with anemia, as stage increased, HCRU increased, highlighting the importance of care coordination as CKD progresses.

Methods:
This retrospective cohort study of CKD patients with anemia used Humana claims data (medical, pharmacy, lab) from 2016-2019. The index date was the first anemia diagnosis (Hgb <10 g/dL) date after CKD diagnosis. CKD stage and dialysis independence status were classified in the 12 months pre-index. Treatments [(intravenous (IV) iron, oral iron, erythropoiesis-stimulating agents (ESA), red cell blood transfusions (RBC)], all-cause healthcare resource use (HCRU) were examined 12 months post-index.

Results:
A total of 31,026 NDD CKD patients with anemia were identified (mean age, 75 years; 60% female). Overall, 36% had an anemia treatment. As the CKD progressed, the percentages of treated patients increased (32%, 39%, and 50% in stage 3, 4, and 5, respectively). 11% of ESA use occurred within 90 days of the index date (ADA 21%, RBCCT rates (9%) and oral iron use (~13%) stayed consistent across all stages. The median number of days from anemia diagnosis to first anemia treatment was 48 days. As stage increased, the percentage of patients with anemia, inpatient admissions in stage 3, 4, and 5, respectively were 46%, 53%, and 59% and emergency visits were 64%, 70%, 72% in the 12 months post-index period.

Conclusions:
This descriptive examination of treatment by CKD stage for NDD patients with anemia found that anemia was oftentimes left untreated, especially in the stage 3-4 CKD patients. After NDD CKD patients were diagnosed with anemia, it was almost 1.5 months before treatment was initiated. In NDD CKD patients with anemia, as stage increased, HCRU increased, highlighting the importance of care coordination as CKD progresses.

costs were associated with male sex and were markedly increased by advancing CKD stage (≥3a), baseline HB <10, and supplemental Medicare and non-capitated insurance coverage.

**Conclusions:** Anemia is associated with substantially added direct cost and healthcare resource utilization experienced by patients with non-dialysis CKD, in both early and advanced stages and with lower HB. Effective management of anemia in CKD offers an opportunity to address this ongoing burden.

**Modelling the Clinical and Economic Burden of Anemia in Patients with CKD**

Oliver T. Darlington,1 Davis Booth,1 Peter D. Gabb,1 Myrleen Sanon,1 Efstathiou N. Michalopoulos,2 Youssef M. Farag,1 Xinyu Wang,2 Philip McEwan,1,3 Health Economics and Outcomes Research Ltd., Cardiff, United Kingdom; 1Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; 3Akebia Therapeutics, Inc., Cambridge, MA; 4Otsuka Pharmaceutical Europe Ltd., Slough, United Kingdom; 2Centre for Health Economics, Swansea University, Swansea, United Kingdom.

**Background:** Chronic Kidney Disease (CKD) imposes a significant societal burden. Anemia is a common complication of CKD and is independently associated with poorer patient outcomes, including CKD progression, cardiovascular (CV) events and death. The objective of this study was to develop a natural history model to characterize the consequences of anemia in patients with CKD.

**Methods:** A lifetime Markov model was developed to estimate the economic impact of anemia. Two cohorts aged 58 years with CKD stage 3b were modelled with and without anemia (HB 9-10 g/dL and HB ≥12 g/dL) to estimate differences in life expectancy (LE) and quality-adjusted life years (QALYS), and event incidence. HB level was linked to CKD progression, CV hospitalization and mortality using published data. Published direct costs and utility estimates associated with CKD and event incidence were incorporated, and costs were inflated to 2019 US dollars. Costs associated with anemia treatment such as erythropoiesis-stimulating agents or supplemental iron were not considered. Future costs and benefits were discounted at 3.0% per annum.

**Results:** Predicted LE was 10.21 years in patients with anemia compared to 12.36 years in patients without anemia, or a reduction of 2.15 years. Decreased patient LE and reduced quality of life with anemia resulted in 2.18 fewer QALYS. Time to end stage renal disease was 10.4 years with anemia and 12.5 years without anemia. Patients with anemia experienced 25 additional CV-related hospitalizations per 1,000 patients. Total lifetime costs were higher in the non-anemic cohort due to improved LE ($342,867 vs. $316,510), however annual costs were lower in anemic patients with an undiscounted saving of $2,628 per year due to reduced CV event incidence and CKD management costs.

**Conclusions:** This analysis supports that those without anemia have increased LE and QALYs, and account for less costs to the healthcare system. Therefore, anemia management, aligned with clinical guidelines, has the potential for better outcomes for both the patient and the healthcare system.

**Prevalence of Severe Anemia and Transfusion Risk in Medicare and Non-Medicare Populations with CKD Stages 3 and 4**

Jill Davis,2 Robert M. Perkins,3 Allison A. Petrella,3 Scott B. Robinson,3 Dakota C. Powell,1 Anne Murunga,1 Shambhavi Kumar,1 Kevin Dietz,1 Avaleere Health, Washington, DC; 2AstraZeneca, Wilmington, DE.

**Background:** While 30 million people in the United States have chronic kidney disease (CKD), the real-world clinical burden of anemia in non-dialysis dependent (NDD) CKD patients is poorly documented, which we seek to address.

**Methods:** A retrospective cohort analysis was conducted using the 100% sample of Medicare Fee-For-Service (FFS) beneficiaries (parts A/B) and a convenience sample of Commercial (Com), Medicare Advantage (MA), and Managed Medicaid (MM) lives from Inovalon’s Medical Outcomes Research for Effectiveness and Economics (MORE) Registry® linked to eGFR and hemoglobin (Hgb) values from Prognos laboratory data. Patients with ≥2 consecutive eGFR tests with eGFR 15-59 mL/min/1.73m² ≥90 days apart or ≥3 eGFR events ≥90 days apart from 1/1/2016 to 12/31/2018 were retained for analysis; pts on maintenance dialysis were excluded. Severe anemia was defined as Hgb<10 g/dL, measured within 90 days of confirmatory eGFR (RBCT). During a 12-month follow up was identified using procedure codes. A logistic regression model identified baseline factors associated with receiving RBCT.

**Results:** A total of 1,305,354 patients were identified from Medicare FFS and 154,163 from MORE®. Prevalence of severe anemia in the Medicare FFS cohort was 3.1% and 3.3% in the MORE® cohort (Table 1). Severe anemia was highest among stage 4 CKD patients at 11.3% in the FFS cohort and 13.4% in MORE® cohort, with prevalence among Medicare Advantage patients at 17.1%. High value, cancer, diabetes, liver disease, and hospitalizations were risk factors for RBCT. Within the MORE® cohort, the odds of receiving RBCT increased by 47% for each 1 g/dL decrease in hemoglobin.

**Conclusions:** The proportion of severe anemia increases with worsening CKD stage in Medicare patients primarily enrolled in Medicare FFS. Many clinical factors influence the odds of severely anemic NDD CKD patients receiving RBCT.

**Funding:** Commercial Support - AstraZeneca

**Clinical Outcomes in Patients with Anemia in CKD Using Linked US Claims and Electronic Health Records**

Eric T. Witterbrodt,1,2 Glen James,3 Supriya R. Kumar,1 Juan Jose Garcia Sanchez,2 Hungta (tony) Chen,1 James A. Slaold,4 Kamyar Kalantar-Zadeh,4 1AstraZeneca, Wilmington, DE; 2AstraZeneca, Cambridge, United Kingdom; 3AstraZeneca, Gaithersburg, MD; 4University of California - Irvine, Irvine, CA.

**Background:** Anemia is common in pts with CKD, yet contemporary outcome data to understand the long-term clinical burden are scarce. This analysis describes selected cardiovascular and renal outcomes in non-dialysis CKD pts with and without anemia at baseline (BL) in US real-world practice.

**Methods:** This retrospective observational study evaluated the integrated Limited Claims and Electronic Health Record data (IBM Health, Armonk, NY). Pts were aged ≥18 y with ≥2 eGFR measures ≥60 mL/min/1.73 m² ≥90 days apart. Anemia was defined as the presence of any observed HB <10 g/dL within a 6 months period confirmed by eGFR (anemia BL period). In addition, the BL period for disease history was defined as the start of pt data + 6 months, and for lab measures and medications was defined as date of the second confirmatory eGFR ≥ 6 months. Pts with active bleeding, chronic dialysis, and non-dialysis dependent anemia were excluded. BL pt characteristics and clinical outcomes during follow-up were analyzed for the period from Jan 1, 2012 to Sep 30, 2017. Descriptive data were summarized; no inferential statistics were performed.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: Of the total study cohort (N=22,720), 23% (n=5,283) had BL Hb <10 g/dL. The following results are for pts with and without anemia at BL, respectively. Females accounted for 60% and 57% and mean ages (± SD) were 70 (±14) and 71 (±12) years. Proportions by BL CKD stage were: 3a, 50% and 68%; 3b, 27% and 24%; 4, 15% and 7%; 5, 9% and 1%. Median follow-up times were 2.9 and 3.8 years. Acute coronary syndrome (ACS) events during follow-up occurred in 2.2% of pts with BL anemia and 2.3% of pts without BL anemia, heart failure hospitalizations (HFH) occurred in 5.9% and 3.7%, and stroke hospitalizations and emergency visits (S) occurred in 2.8% and 3.0% of pts. Incidence rates per 100 pt-y were 0.8 and 0.7 for ACS, 1.6 and 0.8 for HFH, respectively, and 0.7 in both groups for S. ESRD occurred in 4% and 1%, 40% eGFR decrease in 44% and 25%, and CKD stage progression in 67% and 59% of pts. Median change in eGFR slope was –0.6 and –0.3 mL/min/1.73 m².

Conclusions: This analysis highlights worsened outcomes associated with anemia in CKD, particularly in HFH and eGFR decline, in pts of a large US cohort.

PO0279
Prevalence of Anemia and Associated Erythropoiesis-Stimulating Agent Use in 5.9 Million Non-Dialysis CKD Patients
Danielle K. Farrington, Yingying Song, Morgan Grann, Shoshana Ballew, Stephan C. Dunning, Nikita Stempniewicz, Josef Coresh, Johns Hopkins Medicine, Baltimore, MD; Johns Hopkins University Bloomington School of Public Health, Baltimore, MD; OptumLabs Visiting Fellow, Cambridge, MA; American Medical Group Association, Alexandria, VA; OptumLabs, Cambridge, MA.

Background: Chronic kidney disease (CKD) leads to anemia through erythropoietin deficiency and resistance, and a heightened inflammatory state. Characterizing the burden and risk factors associated with severe anemia (hemoglobin [Hb] <10 g/dL) is of particular interest since treatment with erythropoiesis-stimulating agents (ESAs) or other therapies is often considered at this level.

Methods: We analyzed patients in the OptumLabs® Data Warehouse, which contains de-identified claims and electronic health record data, with a complete blood count and serum creatinine measured within 30 days of each other in 2016. Patients requiring dialysis were excluded. We examined the association between low hemoglobin (Hb) categories (<9 g/dL, 9–10 g/dL, 10–11 g/dL) and age, sex, diabetes, history of cardiovascular disease (CVD), and categories of eGFR using polychotomous logistic regression to estimate adjusted relative risk ratios (RRR).

Results: Among 5,875,383 patients in 52 centers, mean age was 56 years (SD 17), and 42% were male. The prevalence of Hb <10 g/dL in CKD stages G1–2, G3a, G3b, G4 and G5 was 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were strongly associated with increased risk of anemia, even after adjustment for female sex (RRR 2.6–3.9), diabetes (RRR 1.4–1.8), history of CVD (RRR 1.7–1.9), and age (RRR 2.2–2.4 for age 75+). The frequency of ESA use in patients with hemoglobin <10 g/dL was 0.24%, 0.41%, 0.96%, and 1.0% in CKD stage G3a, 3b, 4 and 5.

Conclusions: Severe anemia was common and strongly associated with low GFR, female sex, older age, diabetes and history of CVD in a wide range of health care systems. ESA use in non-dialysis CKD patients was very uncommon.

PO0280
Lower Transferrin Saturation (TSAT) Index Is Associated with Anemia-Independent Risk of Increased Mortality in Non-Dialysis (ND) CKD Patients
Murilo H. Guedes, Daniel G. Muenz, Zarcy Zee, Marcelo Lopes, Sandra Wachter, Benedicte Stengel, Ziad Massy, Helmut Rechel, David M. Charytan, Michelle M. Wong, Ronald L. Pisoni, Bruce M. Robinson, Roberto Pecoits-Filho, Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; Centre de Recherche en Epidemieologie et Santé des Populations, Villejuif, France; Division of Nephrology, Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France; The University of British Columbia, Vancouver, BC, Canada; NYU Langone Health, New York, NY; Nephrological Center, Villingen-Schwenningen, Germany; Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: Iron Deficiency (ID) is defined by a TSAT index <20%, is present in approximately half of ND-CKD patients, varying little by CKD stage. Distinct from approaches in conditions such as heart failure, the importance of iron reserves and the basis for iron therapy in CKD has focused primarily on supporting effective erythropoiesis. A comprehensive approach and design to estimate the impact of ID, independently from hemoglobin (Hb) levels, on mortality risk has not been explored in ND-CKD until the present.

Methods: 5144 patients from Brazil (N=294), France (N=2227), the US (N=494), and Germany (N=2129) enrolled in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) from 2013-2019 with available TSAT were included in the analysis. We categorized patients by first available TSAT at enrollment. Hb measurements at the same time as TSAT were used. Cox models were used to estimate hazard ratios (HR) of TSAT on mortality, censored at start of dialysis or kidney transplantation. Models were progressively adjusted including confounders, including demographics, comorbidities, inflammation surrogates, treatment with erythropoietin stimulating-agents and Hb.

Results: Sample characteristics were: 59% male; 45% diabetes; and mean (SD) age 69 (13) years, eGFR 28 (11) mL/min, Hb 12 (2) g/dL, TSAT 24 (2) %, ferritin 196 (214) ng/dL. TSAT levels below 25% were progressively associated with higher mortality risk, while patients with TSAT greater than 45% tended to have higher risks for mortality (Figure).

Conclusions: ID, as measured by the TSAT index, is associated with higher risk of all-cause mortality in ND-CKD patients, even after extensive adjustments for clinical, demographic and biochemical confounders, including Hb levels. Intervention studies evaluating the impact of iron supplementation and alternative targets on clinical outcomes in ND-CKD patients are needed to better inform ID management strategies.

Funding: Commercial Support - Vifor Pharma

PO0281
Lower Transferrin Saturation (TSAT) Is Associated with Worse Health-Related Quality of Life (HRQOL) in Non-Dialysis CKD Patients Independently from Hemoglobin (Hb) Levels
Murilo H. Guedes, Daniel G. Muenz, Zarcy Zee, Marcelo Lopes, Sandra Wachter, Benedicte Stengel, Ziad Massy, Elodie Speyer, Fredric O. Finkelstein, Ricardo Sesso, Ronald L. Pisoni, Bruce M. Robinson, Roberto Pecoits-Filho, Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; Universidade de Sao Paulo, Sao Paulo, Brazil; Centre de Recherche en Epidemieologie et Santé des Populations, Villejuif, France; Yale University, New Haven, CT; Division of Nephrology, Ambroise, APHP, Paris, France; Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: Iron Deficiency (ID) is a common condition in NDD-CKD patients that is associated with poorer outcomes. However, the effect of ID on HRQOL in this population is unknown. We analyzed real world data from a multinational cohort of NDD-CKD stage 3 to 5 patients to test the association between TSAT and ferritin with HRQOL.

Methods: Patients from Brazil (N=205), France (N=2015), and the US (N=293) in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps, 2013 to 2019) with TSAT, ferritin, and HRQOL data were included. We grouped patients according to TSAT and ferritin levels closest to the HRQOL measurement. Our primary analyses evaluated the associations of TSAT and ferritin with mean differences in physical component summary (PCS) and mental component summary (MCS). Secondary analyses evaluated joint TSAT and ferritin categories, as well as additional pre-specified HRQOL measures. Linear mixed models were adjusted for potential confounders including Hb level.
Results: 2513 patients were included. In the primary analyses, TSAT ≤15% and both ferritin <50 ng/mL and <300 ng/mL were associated with worse PCS scores, while MCS was not directionally associated with iron parameters (Figure). Patients with the composite TSAT ≤15%/ferritin ≤300 ng/mL had lower functionality scores and worse PCS, compared to those with TSAT between 20-30% and ferritin 50-299 ng/mL.

Adjustment for Hb only slightly attenuated the effects, and the results were similar for subgroups of patients with Hb ≤11.5 vs ≥11.5 g/dL.

Conclusions: Low TSAT levels, and both low and high ferritin levels, are associated with poorer physical HRQOL in ND-CKD patients, even after adjustment or stratification by Hb level. Intervention studies of iron therapy on HRQOL among ND-CKD individuals are needed to confirm these findings.

PO0283
A Novel, Fast-Acting Iron Sucrose Formulation for CKD Patients with Iron Deficiency Anemia
Charles M. Cook,1 Bhupinder Singh,2,1 Stacey Ruiz,1 Alvaro F. Guillén,1
2Renibus Therapeutics, Southlake, TX; 3University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; 4CMC SQUARED, Southlake, TX.

Background: Intravenous (IV) iron is commonly used to treat iron deficiency anemia in patients with chronic kidney disease (CKD). We report the results of the physicochemical and safety profile of RBT-3, a novel iron sucrose formulation, which was assessed in a Phase 1b study conducted in healthy volunteers and subjects with chronic kidney disease (CKD) Stage 3 or 4.

Methods: Analytical testing was conducted to examine the physicochemical profile of RBT-3. Safety of RBT-3 was assessed in a Phase 1b study in healthy volunteers and subjects with CKD. RBT-3 was administered IV as a single dose of 120, 240, or 360 mg. Plasma and urine ferritin were measured at baseline, then 2 h (plasma) or 24 h (urine) after administration.

Results: RBT-3 particle size is similar to commercially available iron sucrose. However, RBT-3 has a lower molecular weight and higher water content than similar IV iron formulations, suggesting faster uptake and greater solubility, respectively. RBT-3 also has a negative Zeta potential, demonstrating low cytotoxic potential. The quantity of labile iron in RBT-3 is 1.48%, suggesting very low availability of free inorganic iron hydroxide, with a low cytotoxic potential. Furthermore, Fe2+, which is associated with oxidative stress, is present in much lower quantities in RBT-3 (3.4%) compared to commercially available iron sucrose (15.8%). In this Phase 1b study of RBT-3, 18 subjects were enrolled; 6 subjects (3 healthy volunteers and 3 subjects with CKD) randomized to 3 cohorts received a single dose of RBT-3 at 120, 240, or 360 mg. Mean age was 60.3 years; 66.7% of the subjects were female. Dose-dependent increases in plasma ferritin were observed in all subjects within 2 h of treatment and reached statistical significance by 8-12 h. Urine levels were increased at 24 h. Both plasma and urine ferritin levels remained elevated through 168 h (7 days). No treatment-related adverse events (AEs) were observed, and no serious AEs (SAEs) were reported.

Conclusions: RBT-3 represents a novel iron sucrose formulation with desirable physicochemical characteristics that makes it a fast-acting mediator of iron hemodynamics. This is the first report of ferritin level increases within only 2 h by an iron formulation. RBT-3 is safe and well tolerated in healthy volunteers and subjects with CKD at a single dose up to 360 mg.

PO0284
Response to Oral Iron Therapy in Children with Anemia of CKD
Sharmi Biswas,1 Kelly Meza,1 Haneen Aljayyousi,2 Dmitry V. Samsonov,2,3 Sonia Solomon,1,2,3 Eduardo M. Perelson,1,2 Jubi Kumar,1,4 Oleh M. Akchurin,1,4 Pediatric Nephrology1 Well Cornell Medicine, New York, NY; 2Westchester Medical Center, Valhalla, NY; 3Boston Children’s Hospital, Boston, MA; 4NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY.

Background: Anemia is a common complication of chronic kidney disease (CKD). Current guidelines recommend oral iron therapy as the initial treatment of anemia in CKD. However, the efficacy of iron therapy in children with pre-dialysis CKD has not been evaluated. Factors determining the response to oral iron in pediatric CKD remain poorly understood.

Methods: An ongoing retrospective observational study. Data were abstracted from health records of children with pre-dialysis CKD at the time of iron therapy initiation and at the next clinic visit and compared using paired T-test. Children receiving concomitant stimulants and/or non-iron replacement therapy were excluded. Response to iron therapy was defined as improvement in both hemoglobin and hematocrit after iron therapy. Changes of serum iron were used as a surrogate measure of adherence to iron therapy. Data are presented as median (interquartile range).

Results: We identified 44 children (48% boys) who met the inclusion criteria. Median age was 11 (5-15) years, glomerular filtration rate (GFR) 46 (31-60) mL/min/1.73m2. Ferrous sulfate was used in 86.4% of children. The interval between visits was 61 (31-120) days. Iron therapy resulted in a significant increase in transferrin saturation (14 to 21%, p<0.001) and serum iron (45 to 65 μg/dL, p<0.001). While there was an overall improvement of hemoglobin (from 10.6 to 11.2 g/dL, p=0.02), 45% of children did not respond to iron therapy. Non-responders had a significantly smaller change in serum iron after iron therapy compared to responders (3 vs 35 μg/dL, p=0.03), indicating low adherence to iron therapy by non-responders. Baseline age, GFR, hemoglobin, transferrin saturation, serum iron, and serum ferritin were not different between responders and non-responders. Baseline body weight and height Z scores were significantly lower in non-responders than in responders (-0.67 vs 0.12, p=0.04 and -1.66 vs -0.25, p=0.02, respectively), possibly representing differences in nutritional status.

Conclusions: This is the first study that systematically assesses response to oral iron therapy in children with pre-dialysis CKD after 2012 Kidney Disease Improving Global Outcomes (KDIGO) guidelines. Response to iron therapy may be related to medication adherence and baseline nutritional characteristics of study participants.
Improving Knowledge of Nephrologists Regarding an Emerging Class to Treat Anemia Associated with CKD

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hypoxylase Inhibitors (HIF-PHIs).

Methods: The effect of 2 online, 30-minute, CME-certified activities were analyzed. Multiple-choice knowledge and self-efficacy confidence questions were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and chi-square test (5% significance level, P <.05) assessed educational effect. Cramer’s V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched June 20, 2019 and data were collected through July 11, 2019.

Results: In total, 167 nephrologists were included in the study. Overall improvements were seen for both activities after participation: Activity 1: N=75, P<.001, V=.156; Activity 2: N=93, P<.001, V=.162. Individual question-level improvement was also demonstrated: 21% of nephrologists (N=75, P<.05; V=.169) improved at correctly identifying the mechanism of action of HIF-PHIs 20% of nephrologists (N=75, P<.05; V=.197) improved at recognizing clinical trial data for HIF-PHIs 33% of nephrologists (N=92, P<.05; V=.315) improved at recognizing clinical trial data for HIF-PHIs 21% of nephrologists (N=93, P<.05; V=.103) improved at recognizing CVOTs for HIF-PHIs 45% (N=75) and 47% (N=92) reported increased confidence in understanding HIF PH1 clinical trial data Continued educational gaps: 55% (activity 2) and 59% (activity 1) of nephrologists did not recognize the mechanism of action of emerging HIF-PHIs 46% of nephrologists did not recognize clinical trial data for emerging HIF-PHIs 62% of nephrologists did not recognize CVOT data for emerging HIF-PHIs.

Conclusions: This study demonstrates the success of online, video-based CME on improving knowledge of nephrologists related to emerging therapies for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

Treatment Pathways of Non-Dialysis-Dependent CKD Patients with Anemia: A Report from the DISCOVER CKD Retrospective Cohort

Eric T. Wittbrodt,1 Juan J. Carrero,3 Glen James,1 Steven Fishbane,4 Supriya R. Kumar,1 Roberto Pecoto-Filho,6 Juan Jose Garcia Sanchez,1 Carol A. Pollock,1 James A. Sloan,2 Katarina Hedman,3 David C. Wheeler,1 AstraZeneca UK Ltd, Cambridge, United Kingdom; 2AstraZeneca, Gaithersburg, MD; 3Karolinska Institute, Stockholm, Sweden; 4Northwell, Manhasset, NY; 5Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 6Arbor Research Collaborative for Health, Ann Arbor, MI; 7University of Sydney, NSW, Australia; 8AstraZeneca, Gothenburg, Sweden; 9University College London, London, United Kingdom.

Background: Anemia is a frequent complication of chronic kidney disease (CKD), yet most patients experiencing this problem remain untreated until the initiation of renal replacement therapy. We describe treatment pathways of key medications prescribed to non-dialysis dependent (NDD) CKD patients with anemia in DISCOVER CKD.

Methods: Patients included in this analysis were extracted from the Limited Claims and EHR (LCED) data. The study cohort included patients aged >18 years with 2 estimate glomerular filtration rate (eGFR) measures >60 mL/min/1.73m2 >90 days apart between January 2008 and September 2018. The index date was the first Hb measure <12 g/dL [females], <13 g/dL [males] per WHO criteria), or an anemia therapy (iron, ESA or blood transfusion) prescription after the 2nd eGFR measure. Exposure criteria were: <1-year registration/medical history prior to index, active bleeding in the 30 days preceding and inclusive of index, an Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Oral iron was incompletely captured in LCED. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key treatments commonly prescribed to CKD patients with anemia including: oral iron, IV Iron, ESA and blood transfusion.

Results: Preliminarily, 1446 (2.6% of anemia base cohort) patients were prescribed anemia therapies during follow-up, with IV iron (32.5%), transfusions (30.5%), ESA (21.0%), oral iron (12.2%) and ESA-IV Iron (2.7%) used as 1st-line therapies, Figure 1. Median times to 1st-line therapy initiation after index were: 108 days for oral iron, 194 days for ESA, 197 days for IV iron, and 244 days for blood transfusion.

Conclusions: In routine clinical care, anemia in NDD CKD is under treated and rescue therapies are used for anemia more often than preventive therapies.

Physician Attitudes Toward Diagnosis, Treatment Initiation, and Unmet Needs in the Management of Anemia due to CKD: Results from a Real-World Survey in Germany, Italy, and the United Kingdom

Madhusudan Kabra,1 Tim Hammond,2 Allison Fleetwood,3 Lewis Harrison,4 James Jackson,5 Sarah Clayton,6 Adelphi Real World, Bollington, United Kingdom; 7Osuka Pharmaceutical Europe Limited, Slough, United Kingdom.

Background: Anemia, a complication of chronic kidney disease (CKD), is often defined as serum hemoglobin (Hb) levels of <12 g/dL in women and <13 g/dL in men. Traditionally, primary care physicians (PCPs) have less involvement managing and treating patients with anemia due to CKD while nephrologists play a greater role in treatment decisions. We describe current physician perceptions towards the diagnosis and treatment of anemia due to CKD and unmet needs in anemia management, in a real-world setting.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme, a point-in-time study conducted between November 2019 and April 2020 with nephrologists and PCPs from Germany, Italy and the United Kingdom. Physicians completed an online survey providing information on their demographics, experience on the diagnosis and treatment of anemia, and the current unmet needs they believe exist in the management and treatment of anemia. Results were descriptively analyzed.

Results: A total of 200 physicians (n=140 nephrologists; n=60 PCPs) were included in the analysis. Among those who responded, the majority (58% nephrologists; 80% PCPs) used Hb levels to diagnose anemia in CKD patients. Over two thirds of physicians mentioned using ferritin to diagnose anemia and over half reported using transferrin saturation (T Sat) levels. Approximately 4 in 5 nephrologists and PCPs (78%...

Patient Preferences Study for Treatments of Anemia in CKD Patients Not on Dialysis (NDD)
Ana filipa Alexandre,1 Antonia Morga,2 Caitlin Thomas,3 Nicolas Krucien,3 Tommi Tervonen,1,2 Alina Jiletcovic,1 Kevin P. Marsh,1 ’ Astellas Pharma Europe B.V., Leiden, Netherlands; 2’ Astellas Pharma Europe Ltd, Addlestone, United Kingdom; ‘Evidera, London, United Kingdom; ‘University Medical Center Groningen, Groningen, Netherlands; ‘Astellas Pharma, Inc., Northbrook, IL.

Background: Erythropoietin analogues (EAs) are a mainstay of treatment of anemia in adult patients with CKD but they are associated with increased risk of cardiovascular (CV) events. Furthermore, their mode of administration (intravenous or subcutaneous [SC]) may represent a barrier to some patients. As such, this aim of the study was to understand patients’ valuation of attributes associated with CKD anemia treatments.

Methods: Adult (≥18 years) patients from UK, Spain, Germany, and France, who had self-reported NDD CKD anemia and were being treated with EAs, participated in this online discrete choice experiment (DCE). Patients were presented with choice tasks, each with two anemia treatment options described in terms of five attributes (mode of administration, need for iron supplementation, risk of gastrointestinal [GI] side effects, risk of major CV events, and impact on energy levels). A multinomial logit model with an error component was used to analyze participants’ choices and estimate their treatment preferences. Estimated preferences were used to determine maximum level of CV and GI risk that patients were willing to tolerate to improve other treatment features.

Results: Between November 2019 and March 2020, 200 eligible patients (53% male) completed the DCE survey. The mean (SD) age was 53.78 (12.73) years; patients had been diagnosed with CKD 6.02 (7.49) years prior, and with CKD anemia 3.45 (3.44) years prior. Patients were found, on average, to value each of the five attributes associated with the treatments of CKD anemia. Patients were willing to tolerate a 5.12% (95% CI: 1.99; 8.25) increase in the risk of a major CV event and an 11.73% (95% CI: 4.96; 18.50) increase in the risk of GI side effects to switch from an at-home SC injection administered once every 2 weeks to an at-home oral pill administered three times a week. Patients would be willing to tolerate a 20.31% increase in the risk of GI side effects and an 8.86% increase in the risk of a major CV event to move from sometimes having a lot of energy to always having a lot of energy.

Conclusions: Patients would be willing to tolerate increased risks of CV and GI events to obtain an oral treatment for NDD CKD anemia and to always have a lot of energy.

PO0290

Background: We studied the effect of online education designed to improve the clinical performance of clinicians in the OB/Gyn and primary care setting related to iron deficiency anemia (IDA) management in women.

Methods: The continuing medical education (CME) activity was a 45-minute online text- and video-based activity focusing of different aspects of anemia management in women. In total, 1,239 clinicians completed the initial PCA questionnaire 275 OB/Gyn physicians, 140 OB/Gyn NPs and PAs, 446 PCPs, and 376 NP/PA in the primary care setting. Between November 2019 and March 2020, 200 eligible patients (53% male) completed the DCE survey. The mean (SD) age was 53.78 (12.73) years; patients had been diagnosed with CKD 6.02 (7.49) years prior, and with CKD anemia 3.45 (3.44) years prior. Patients were found, on average, to value each of the five attributes associated with the treatments of CKD anemia. Patients were willing to tolerate a 5.12% (95% CI: 1.99; 8.25) increase in the risk of a major CV event and an 11.73% (95% CI: 4.96; 18.50) increase in the risk of GI side effects to switch from an at-home SC injection administered once every 2 weeks to an at-home oral pill administered three times a week. Patients would be willing to tolerate a 20.31% increase in the risk of GI side effects and an 8.86% increase in the risk of a major CV event to move from sometimes having a lot of energy to always having a lot of energy.

Conclusions: Patients would be willing to tolerate increased risks of CV and GI events to obtain an oral treatment for NDD CKD anemia and to always have a lot of energy.

Amelioration of CKD-Associated Anemia by Vadadustat in Mice Is Not Dependent on Erythropoiferone
Mark R. Hanadel, Shirley Wong, Grace Jung, Bo Qiao, Victoria R. Gabayuan, Tomas Ganz. University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Vadadustat is an investigational hypoxia inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin (EPO) production, and has been shown to decrease levels of inflammatory cytokines, decrease fibrosis, and increase hemoglobin concentrations in anemic chronic kidney disease (CKD) patients. Increased EPO induces erythropoietin secretion of erythropoiferone (ERFE), which acts on the liver to suppress serum hepcidin production. To determine whether vadadustat mechanisms of action are dependent on ERFE, we treated wild type (WT) and ERFE knockout (EKO) mice, with and without adenine diet-induced CKD, with vadadustat.

Methods: 6-week-old male C57BL/6 WT and EKO mice were placed on 8-week diets that did or did not contain 0.2% adenine. For the last 3 weeks of the diets, the mice were treated with vadadustat (75 mg/kg/day via oral gavage) or vehicle solution. Mice were euthanized at 14 weeks of age (n=8 mice per group).

Results: Unlike the WT mice, EKO mice had undetectable spleen Erfe mRNA, minimal marrow Erfe mRNA, and no increase in ERFE mRNA or protein in response to vadadustat. However, in both WT and EKO CKD models, vadadustat normalized hemoglobin concentrations (Fig 1a), increased expression of duodenal iron transporters, tended to lower serum hepcidin, and decreased tissue iron concentrations (consistent with increased iron mobilization), suggesting ERFE-independent pro-erythropoietic effects. Vadadustat treatment was also associated with improved kidney function (Fig 1b) and decreased expression of renal fibrosis markers. Lastly, vadadustat affected Gfpg23 profiles: In non-CKD mice, vadadustat increased plasma total Gfpg23 out of proportion to intact Gfpg23, consistent with the known effects of Hfbs and Epo on Gfpg23 production and metabolism. In the CKD mice, vadadustat markedly decreased both total and intact Gfpg23 (Fig 1c), effects likely contributed to by improved kidney function.

Conclusions: Vadadustat ameliorates CKD-associated anemia independently of ERFE, and also improves kidney function and lowers Gfpg23 in this CKD model. How vadadustat affects CKD progression in humans may warrant further studies.

Oxidative Stress and Heme Metabolism in Red Blood Cells of Hemodialysis Patients
Gabriela F. Dias,1,2 Gabriela B. Andrade,2 Nadja Grobe,1 Xia Tao,1 Roberto Pecoiços-Filho,2 Peter Kotanko,1 Andrea N. Moreno-Amaral.2 Renal Research Institute, New York, NY; Pontifícia Universidade Católica do Pará, Curitiba, Brazil, 1Icahn School of Medicine at Mount Sinai, New York, NY; 2Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: We have previously described that indoxyl sulfate promotes red blood cell (RBC) ROS generation, and organizes anion transport 2 as well as NADPH oxidase activity-dependent and GSH-independent mechanisms (Dias et al., 2018). However, there is little information regarding pathways of antioxidant balance to protect RBC from extensive oxidative stress that occurs during hemodialysis (HD). Intracellular free heme is degraded by Heme Oxygenase 1 (HO-1), which is regarded as the major cytoprotective enzyme (Maines, 1988; Gozzelino et al., 2010). In the current study, we assessed HO-1 activity and ROS production in RBC from healthy subjects and hemodialysis (HD) patients before and after HD.

Methods: Blood was drawn from 6 healthy individuals (CON-RBC) and 6 HD patients (HD-RBC) before and after HD (RBC) and after high flux HD (post/HD-RBC). Isolated RBC were stained with DCFH-DA (Abcam) for ROS measurements. To quantify HO-1, RBC were incubated with anti-HO-1 antibody (Abcam) and m-IgG BP-CFL-488 (Santa Cruz Biotechnology) as a secondary antibody. Samples were analyzed by flow cytometry.

Results: Our results show a 4-fold increase in ROS levels in pre/HD-RBC compared to CON-RBC. ROS levels were even further increased by 1.65-fold after HD treatment in post/HD-RBC (Figure 1). Both pre/HD-RBC and post/HD-RBC showed a similarly significant increase of 3.3-fold compared to control baselines (Figure 1).

Conclusions: High levels of HO-1 may represent a defense against oxidative stress that occurs in ESKD and particularly during the HD session. Further research is needed to evaluate whether HO-1 overexpression could accelerate heme degradation and contribute to renal anemia.

Daprodustat Interaction with Phosphate Binders Has Minimal Impact on Hemoglobin Values in Hemodialysis Population

Background: Daprodustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor (PHI) in phase 3 development for the treatment of anemia of chronic kidney disease. Phosphate binders (PB) are widely prescribed for patients on hemodialysis (HD) to control hyperphosphatemia. PB may interfere with medication absorption; thus, coadministration with a PHI may potentially impact the latter’s efficacy on hemoglobin (Hgb). The purpose of this analysis was to determine whether administration of daprodustat in subjects receiving PB has an impact on Hgb values in the HD population.

Methods: The 24-week GSK PH113033 study (NCT01977482) included 216 subjects on maintenance HD previously treated with recombiant human erythropoietin (Clin Kidney J 2019;12:139–148). Target Hgb range was 10.0 g/dL to 11.5 g/dL. Baseline PB users were defined as a prespecified study subgroup. The difference in mean Hgb values at Week 24 between treatment groups was summarized overall and by subgroup. Comparisons were performed for the Week 24 Hgb (post loco), as well as the final dose of daprodustat, for those receiving/not receiving PB.

Results: The majority of HD subjects received PB at baseline; 136/177 (77%) of daprodustat and 33/39 (85%) of control subjects were taking PB, with comparable phosphate control at baseline (mean ± SD phosphate: daprodustat 1.76 mmol/L [0.56]; control 1.67 mmol/L [0.44]). All subjects receiving PB at baseline, except two, continued throughout the study. No meaningful difference in Hgb change from baseline (CFB) at Week 24 was noted between treatment groups. The final median dose for subjects undergoing dialysis was the same for those receiving and those not receiving PB (6 mg), with no meaningful difference in the Hgb at Week 24 (mean ± SD): PB use=Yes 10.40 g/dL [0.95]; PB use=No 10.79 g/dL [0.95].

Conclusions: These results suggest that PB use does not have a major impact on Hgb values during the 24-week study. Results of an ongoing, phase 3 dialysis study of daprodustat compared with conventional treatment are awaited to confirm these initial observations.

Prevalence and Severity of Anemia Between Non-Dialysis and Dialysis Outpatients Referred to Nephrology Consultation: Epidemiologic Data from 1568 Mexican Patients at a National Reference Hospital

Background: Anemia is a frequent complication in chronic kidney disease (CKD), and is frequently associated with symptoms such as physical disability, decreased neurocognitive function, and poor quality of life. Our objective is to know the prevalence and severity of anemia between stages of CKD in patients who attended a nephrology clinic for the first time.

Methods: Transversal, descriptive, observational study. Records of adult patients who attended an outpatient nephrology clinic in the period from February 2019 to February 2020 were included. Anemia staging was performed according to the world health organization. Descriptive statistics were performed, with a 95% CI and a p-value ≤0.05.

Results: 1568 patient records were included. Mean age was 56.01 ± 16 years and 51% (804) were women. Distribution of patients by CKD stage: 9% stage 1, 11% stage 2, 12% stage 3a, 16% stage 3b, 23% stage 4, and 27% stage 5. 12% were undergoing renal replacement therapy. 53% of the population had anemia at the cut-off point of Hb=13 for men and <12 for women; stratification of anemia severity between stages of CKD is presented in Figure 1. The main comorbidities and risk factors in the subjects with anemia were type 2 diabetes mellitus and hypertension (55%), proteinuria (38%), hypoalbuminemia (34%), hyperkalemia (37%) overweight or obesity (58%), hyperglycemia (45%) hypertriglyceridemia (35%) and hypercholesterolemia (31%).

Conclusions: In patients who attended for the first time an outpatient nephrology clinic, a high prevalence of anemia was found in CKD patients, being more frequent and more severe from stage 3b to stage 5. Identifying these findings will allow establishing public health policies and models of care for patients with CKD.

Hemoglobin Requirements of Clinical Trials Involving Anemia in CKD and Implications on Future Work: A Systematic Literature Review

Background: Anemia is a common complication in patients with chronic kidney disease (CKD), contributing to reduced quality of life and increased risk of morbidity and mortality. Erythropoiesis-stimulating agents (ESAs) are the established standard of care for anemia management in CKD patients. This review examines hemoglobin (Hb) requirements in randomized controlled trials (RCTs) of ESAs as treatment of anemia in CKD patients.

Methods: Embase, Medline, and Cochrane Library were searched from 1946 to November 2019 for RCTs evaluating the safety and efficacy of ESAs as treatment for adults with anemia and CKD. Descriptive analyses were performed to assess between-trial differences with respect to baseline Hb and Hb target ranges. Studies were classified by dialysis status (non-dialysis-dependent [NDD] vs dialysis-dependent [DD]), vs renal transplant recipient [RTR]), and by treatment goal (correction vs conversion).

Results: Searches retrieved 3,482 records, from which 57 trials met the inclusion criteria. Seventy-seven studies reported a Hb target, including 15 correction studies (NDD, 7; DD, 1; RTR, 1) and the remaining of the same treatment goal (correction vs conversion).

Conclusions: This systematic review shows that changing Hb requirements over time are a source of difference in RCTs of ESAs for treatment of anemia in CKD. Such differences may introduce bias when using quantitative synthesis methods (e.g. network meta-analysis) to assess the comparative efficacy and safety of ESAs relative to new treatment options.

Funding: Commercial Support - Osuka Pharmaceutical Development & Commercialization, Inc. & Akebia Therapeutics, Inc.
Methods: A total of 8 patients (male: n=4, age: 54.4±11.9 [mean±SD] years, BMI: 27.1±3.4 kg/m², HbA1c: 9.2±1.2 %) with type 2 diabetes who were newly administered 5mg per day of dapagliflozin from March 2015 to September 2019 and discontinued the drug due to adverse events or side effects which did not require admission were retrospectively identified. Changes in HbA1c, hematocrit and urine specific gravity levels between before the administration and after the discontinuation of the drugs were evaluated.

Results: The drug was discontinued 8.4±6.6 months after administration due to non-benefit on glycemic control (n=4), polyuria (n=2), weight loss (n=1) and genital symptoms (n=1). HbA1c was not changed (-0.3±1.1 %; p=0.45) whereas urine specific gravity (0.014±0.009 g/mL; p=0.001) and hematocrit (1.6±3.19 %; p=0.04) were significantly increased at the time of discontinuation. Urine specific gravity (0.005±0.009 g/mL; p=0.12) and hematocrit (0.15±0.14 %; p=0.84) levels were returned to the levels of before drug administration 60 days after the discontinuation. After the 120 days of discontinuation, hematocrit was still decreased to continue the level of baseline (-1.29±1.70 %; p=0.05) whereas urine specific gravity was not.

Conclusions: Our data demonstrate that the increased urine specific gravity and hematocrit return to original levels within 60 days after the discontinuation of dapagliflozin, and that hematocrit may continue to decrease below the original level even after.

PO0297

Human Mesenchymal Stem Cells Cultured in a Hollow Fiber Bioreactor Maintain Constant Levels of Exosomes in the Perfusion Medium: Relevance to the Simultaneous Production of Two Biotherapeutic Agents

Christof Westenfelder,1,2 Anna Gooch,1 Mikhail Skliar,2 Sabiba Sultana Chowdhury,1 Ping Zhang,1 Zhuma Hu,1 SymbioCellTech, LLC, Salt Lake City, UT; University of Utah, Salt Lake City, UT.

Background: We have shown that the administration of allogeneic Mesenchymal Stem Cells (MSC) to patients at high risk for Acute Kidney Injury (AKI) following on-pump cardiac surgery prevents AKI and progression to Chronic Kidney Disease (CKD). Treatment of rats with severe, progressive IRI AKI with MSC-derived exosomes affords significant survival benefits and rescues their renal function (see abstract this meeting). The current study examined the possibility to simultaneously collect MSC-derived exosomes while culturing human MSCs, both used for various therapies in renal and other diseases. This approach, if successful, would be cost saving, efficient and facilitate up-scaling of the production of both MSCs and their exosomes.

Methods: Human MSCs (20×10^6) were loaded into a hollow fiber Cell Expansion System (Quantum®, TERUMO®), pre-conditioned for cell adhesion with Fibronectin) and expanded using eMEM with 5% human Platelet Lysate (iPL). The number of exosomes in aliquots of the perfusion medium were monitored (Nanosight instrument) throughout the course of cell expansion.

Results: MSCs reached ~90% confluence within 12 days, yielding 500×10^6 MSCs. The number of exosomes/nanoparticles derived from the 5% iPL, per se was 4.1×10^11/mL. Post seeding of MSCs in the bioreactor, exosome numbers in the perfusate decreased and stabilized at 1.1±0.1x10^11/mL. The size of collected exosomes was between 60 and 100 nm.

Conclusions: The data from this pilot study demonstrate that iPL-derived exosomes or nanoparticles are taken up by the expanding MSCs, which lowers their total number in the perfusion medium. However, exosome numbers stabilized during the subsequent cell expansion, indicating that growing MSCs release high numbers of exosomes. This conclusion will be confirmed by specialized lPL- and MSC-derived exosomes, using specific markers for each type of nanoparticle. Together, these observations show promise for the efficient generation of MSCs and their exosomes to be used for various clinical applications.

PO0298

Clinical Study Results Confirming a Novel Fluorescent Compound Is a Glomerular Filtration Rate (GFR) Tracer Agent in Humans

Background: A fluorescent GFR tracer agent for use in the clinic would enable a noninvasive transdermal continuous GFR detection method. This would make possible a point-of-care true GFR measurement for an individual, and possibly obviate the use of novel renal replacement therapies such as the bioartificial kidney (BAK). Recently, we developed bioengineered kidney tubules as functional BAK units capable of active PBUtis secretion via organic anion transporter-1 (OAT1). To accelerate their application, a comprehensive assessment under clinical-like conditions is essential. Here, we assessed the extent to which exposure to dialysate and uremic plasma would affect the viability and function of the kidney tubules.

Methods: Human conditionally immortalized proximal tubule epithelial cells equipped with OAT1 (cPiPTEC-OAT1) exposed to clinical-like conditions were evaluated for metabolic activity, membrane integrity (LDH release), inflammatory response (IL-6 and IL-8), oxidative stress (ROS) and OAT1 function (fluorescence uptake). Further, cPiPTECs grown on biofunctionalized hollow fiber membranes were extraluminally exposed to dialysate fluid, intraluminally perfused with human uremic plasma (30min) and assessed for PBUtis clearance (indoxyl sulfate (IS), kynurenic acid (KA), L-kynurenine (L-Kyn), hippuric acid (HA) and indole-3-acetic acid (IA3-AA)), determined by LC-MS/MS (n=7). Membrane integrity was evaluated by paracellular FITC-inulin leakage.

Results: Prolonged exposure (240min) of flat monolayers of cPiPTEC-OAT1 to dialysate slightly reduced the metabolic activity to 80%±4% (p<0.001) and OAT1 function to 81%±5% (p<0.001) and an increased LDH release (from 10±2% in controls to 15±3%, p<0.05), without inducing the release of IL-6 or IL-8. After 30min, a 3.6±0.9 fold increase in ROS production was noticed. Still, exposure of cPiPTEC-OAT1-containing hollow fiber membranes to dialysate enabled the concomitant clearance of five PBUtis (IS = 2980±1438; KA = 223±120; L-Kyn = 324±100; HA = 6547±1287 and IA3-AA = 884±130 nmol/cm², n=6-7), whereas the membrane integrity as observed by FITC-inulin leakage (204±5% vs 25±5%).

Conclusions: The demonstrated functionality of bioengineered kidney tubules in PBUt clearance under clinical-like conditions advances the development of a BAK.

Funding: Government Support - Non-U.S.
May the (Mechanical) Force Be with You: Modeling Shear Stress on the Glomerulus-On-a-Chip

Stefano Da Sacco,1 Owen Richfield,2 Valentina Villani,1 Geremy Clair,1 Roger E. De Filippo,1 Laura Perin,1 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Tulane University, New Orleans, LA; 1Pacific Northwest National Laboratory, Richland, WA.

Background: In the glomerulus, mechanical forces generated on glomerular endothelial cells (GEC) by the passage of blood in capillaries and by the flow of ultrafiltrate between adjacent podocytes play a critical role in regulating glomerular filtration. In vivo modeling of shear stress is difficult and traditional in vitro 2D systems are unable to faithfully replicate shear and tensile stress. We have recently developed a barrier-free glomerulus-on-a-chip (GOAC) system that closely mimics architecture, physiology and function of the GFB. In this work we have further modeled shear stress on the chip and assessed how changes in mechanical forces affect the barrier formation and function.

Methods: Mathematical modeling of the shear stress on the GOAC was performed and shear stress was calculated for standard GOAC culture conditions. Using model simulations, angle of inclination and rocking frequency of the GOAC were changed to modify shear stress, and results were assessed after 5 days. Phenotypically analysis by IF were performed and function was measured by albumin-leakage assay. Podocytes and GEC were separated by FACS and transcriptomics and proteomics analysis performed.

Results: Under standard culture conditions, time-averaged shear stress generated by rocking the GOAC is equal to 0.1Pa. By changing angle of the rocking platform, shear stress could be modulated from 0 to ~4Pa exerted on the GEC with each rocking motion. Permsselectivity was not significantly affected by different rocking angles (but was impaired under static conditions) after 5 days. Importantly, GEC protein expression analysis on podocytes and GEC have identified important changes in cytoskeleton regulation, ECM-cell interaction, proliferation and transcription factors, suggesting that longer-term modification of the shear stress might significantly impact phenotypical and functional cell activity.

Conclusions: The glomerulus-on-a-chip is an ideal system to model architecture and function of the glomerular filtration barrier, including mechanical forces. Changes in shear stress affect cellular gene and protein expression in the GFB and can have long-term effects on phenotype and function. The glomerulus-on-a-chip system can provide an important in vitro tool to study the role of shear stress in physiological and pathological conditions.

Chronic AMPK Activation Reprograms Glucose Metabolism and Oxygen Respiration in Renal Tubule Epithelial Cells

Kuniko Hunter,1 Rachel C. Evans,2 Harold D. Love,2 William H. Fissell.2 1Vanderbilt University, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN.

Background: In vitro human renal tubule epithelial cells (HREC) exhibit a glycolytic, dedifferentiated phenotype that limits their use in bioartificial kidney development. We have identified AMPK-activated protein kinase (AMPK) and Transforming Growth Factor-β (TGFβ) as critical modulators of HREC differentiation. Here we show that inhibition of TGFβ signaling enhances increased respiration induced by activation of AMPK.

Methods: Primary HREC were seeded on polystyrene tissue culture plates (100,000 cells/cm²). After one week, cells were supplemented with AMPK activator Metformin (200μM), TGFβ receptor inhibitor SB431542 (10μM), or both. After five weeks, cell oxygen consumption (OCR) and extracellular acidification rates (ECAR) were assessed using a Seahorse XF96 Analyzer and respiratory inhibitors oligomycin (2μM), CCCP (2μM), Rotenone (0.5μM), Antimycin A (0.5μM) and 2-deoxyglucose (50mM). Statistical differences were estimated by paired, two-tailed Student’s t-test in MatLab.

Results: Metformin and Combination treatments increased cell glycolytic capacity as shown in Fig 1A. Metformin and Combination treatments significantly decreased ATP-coupled respiration, while increasing maximal oxidative phosphorylation capacity and non-mitochondrial respiration capacity as shown by elevated OCR following injections of Oligomycin, CCCP, and Rotenone/Antimycin A, respectively, as shown in Fig 1B.

Conclusions: Concomitant increases in both glycolytic and oxidative phosphorylation capacity suggest AMPK activation and TGFβ inhibition modulate cell mitochondrial and non-mitochondrial metabolic activity.

An In Vitro Model of the Glomerular Filtration Barrier Using Tissue-Derived Glomerular Basement Membrane

Dan Wang, Snehal Sant, Nicholas J. Ferrell. Vanderbilt University Medical Center, Nashville, TN.

Background: The glomerular filtration barrier consists of the glomerular basement membrane (GBM), podocytes and endothelial cells that regulate kidney permeability to macromolecules. Damage to podocytes increases albumin permeability, resulting in proteinuria. Interactions between podocytes and the GBM are important for regulating glomerular permeability and are not captured in standard in vitro cell culture systems. This work aims to investigate molecular permeability of the GBM and podocytes using a novel in vitro model that incorporates decellularized GBM.

Methods: GBM substrates were made by pressure compacting decellularized glomerul from porcine kidneys against a Transwell membrane in a stirred cell. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes were plated on the GBM at low and high concentrations. Transepithelial electrical resistance (TEER) was measured before molecular permeability measurements. Podocytes on GBM were imaged by staining with phalloidin and DAPI. Permeability of the GBM with and without podocytes were analyzed by measuring FITC-BSA and FITC-Ficoll diffusion through the filtration barrier.

Results: GBM characterization showed that cells are efficiently removed from the glomeruli, and the GBM retains laminin and collagen IV after decellularization. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes attached and spread on the GBM to further restricted albumin diffusion. TEER showed an increased resistance of GBM with podocyte compared to GBM alone. Podocytes resulted in slightly lower permeability at high seeding concentration than low concentration.

Conclusions: Interactions between the GBM and podocytes are important for regulating the permeability of the glomerulus. We developed a new in vitro model of the glomerular filtration barrier that incorporates tissue derived GBM to support podocyte culture. GBM alone restricted albumin and Ficoll diffusion and incorporation of podocytes further restricted albumin diffusion. Future work will focus on the co-culture of podocytes and endothelial cells on both sides of the GBM for evaluating the permeability of the filtration barrier and evaluate how podocyte and endothelial injury regulate permeability.

Extraction of Escherichia coli in Urine by New Static Electricity Technique In Vitro
Tokunori Yamamoto,1 Shoichi Moriyama,1 Satoshi Morita,2 Yoshihazu Wakizaka.1,2
1Dept of nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; 2AFI Corporation, Kyoto, Japan.

Background: The treatment results for sepsis are poor due to infectious diseases, and the mortality rate is over 25%. It is clinically significant that the detection identifies patient specimens primary causative organisms as promptly as possible to give appropriate antimicrobial treatment, and to save patients with serious infectious disease. However, it usually takes 2-3 days from the submission of the sample to the identification of the primary causative organism. We newly developed the device (PixeeMo™ approved by AOAC® Performance Tested® Certificate No. 012002 in January 14, 2020) with quick extraction of bacteria in drinking water by static electricity technique. In this report, we evaluated the ability of PixeeMo™ to extract E. coli from urine.

Methods: Samples were prepared by adding Ecoli to artificial urine. 27 mL of a dedicated buffer was added to 3 mL of the sample, and after centrifugation(8000 x g, 20 min), 27 mL of the supernatant was removed. This operation was performed 3 times. After the preparation, E. coli was extracted from each sample using PixeeMo™ less than 0.5 hour. The number of bacteria in the sample prepared on the standard agar medium was measured by colony count.

Results: The table shows results of the experiments. The concentration of E. coli and E. coli were separable and the extraction results by PixeeMo were consistent with the culture method. It was also suggested that the detection limit concentration is 10cells / mL (Table).

Conclusions: The new technique could detect clinical pathologic conc. of E. coli in short time less than 2.0 hour. Extremely useful possibility is suggested as the new measurement technology of sepsis to reflect a diagnosis and evaluation of treatment, curative effect, very quickly.

Kidney Segmentation with Deep Learning in MRI of 40,000 UK Biobank Subjects
Taro Langner,1 Andreas Östling,1 Lukas Maldonis,2 Albin K. Karlsson,1 Daniel Olmo,1 Dag Lindgren,2 Andreas H. Wallin,2 Lowe Lundin,2 Robin Strand,1 Håkan Ahlström,1,2 Joel Kullberg,1,2 Uppsala Universitet, Uppsala, Sweden; 1Antaros Medical AB, Malmö, Sweden.

Background: Kidney volume and its association to several demographic and physiological parameters are subject of ongoing research. The UK Biobank (UKB) studies over half a million volunteers, examining blood samples, lifestyle, genetics, and body composition, including medical imaging for 100,000 participants, and 10,000 repeat scans. We have developed a system for automated kidney segmentation in 40,000 currently available MRI scans for image-based measurements of parenchymal kidney volume.

Methods: UKB neck-to-knee body MRI has been released for 40,264 participants (52% women), aged 44-82 (mean 64) years, with BMI 14-62 (mean 27). The kidneys are imaged in two 17s breath-hold stations with a Siemens 1.5T Aera device at (224 x 174 x 44) voxel resolution of (2.23 x 2.23 x 4.5) mm. In this work, three operators marked cortex and medulla, excluding cysts, in 122 subjects (Fig a, b) for training and validation of a 2.5D U-Net with short skip connections. This neural network learned to segment axial slices.

Results: The network predictions matched the references in total kidney volume for a mean error below 4% (or 10 cm³, Dice score 0.956), whereas human repeat segmentation yielded 3% (or 6 cm³, Dice score 0.962). While imaging limitations such as motion may compound this error, similar performance is expected for future UKB releases. After 30 minutes of training, the network can process all scans within two days. Exclusion of anomalies, such as 40 cases of renal fusion, left 37,468 subjects with median voxel count volumes of 277 cm³ for men and 220 cm³ for women (Fig c).

Conclusions: The proposed system may ultimately provide measurements of left and right kidney volume for all imaged UKB subjects which can be analyzed and shared for further large-scale investigation of associations and longitudinal changes in kidney volume.

Funding: Other NIH Support - The Swedish Heart-Lung Foundation and Swedish Research Council (2016-01040, 2019-04756) supported this work, which used the UKB, application no. 14237, Government Support - Non-U.S.

A Simplified Fluid Dynamics Model of Ultrafiltration
Christopher R. Cardimino,1 Michael J. Germain,2 Yossi Chait.1 1University of Massachusetts Amherst, Amherst, MA; 2Renal and Transplant Associates of New England, Springfield, MA.

Background: We recently presented a novel approach for the design of personalized ultrafiltration rate (UFR) profiles during hemodialysis (HD) treatments. The success of this approach depends on an accurate parameter estimation of a simplified fluid volume dynamics during ultrafiltration.

Methods: We used a simplified model derived from a validated fluid volume model during HD comprising intravascular and interstitial pools, microvascular reflux/filtration, and lymphatic flow. Input data used for parameter estimation are UFR profile and hematocrit (HCT) from CLIC obtained during actual HD treatments. Estimation was based on initial 30-min segment of the data and the model was validated based on the subsequent 30-min response. Model time constant and steady-state gain were obtained for a single patient at 5 treatments over a 3-week period.

Results: Estimation/validation results (Figure 1) demonstrate reasonable accuracy of the simplified fluid dynamics model. Underlying model parameters of a single patient exhibit significant variability between similar days of treatment and between treatment days (Figure 2). Both HCT response to same UFR profile (steady-state gain) and response time (time constant) vary by as much as 100%.

Conclusions: Successful estimation of fluid volume model parameters during HD is feasible which supports the concept of online design of personalized UFR profiles. A non-negligible variability of a patient’s model parameters may complicate the design of personalized UFR profiles.

Human Amniotic Membrane as a Novel Scaffold for Induced Pluripotent Stem Cell-Derived Kidney Organoids

**Maria Figitakis, Kevin J. James, Richard Torres, William G. Chang. Yale University, New Haven, CT.**

**Background:** Human inducible pluripotent stem cells (hiPSCs) can be differentiated into kidney organoids that could be used to tissue-engineer functional renal tissue. However, there are several challenges to therapeutic implementation. Among these is how to attract organoids in a manner that would allow for both vascularization and filtrate outflow. Previous research has demonstrated in animal models, that kidney organoids can be perfused when implanted in the subcapsular space. One limitation though is that there is no obvious filtrate outflow tract. Furthermore, in ESRD patients there would likely be significant fibrosis or even cystic disease that would prevent successful perfusion and filtrate outflow of kidney organoids implanted in a similar manner. Alternative heterogeneous organoid implantation strategies should be considered. Examples include, but are not limited to, peritoneal implantation (with peritoneal dialysis catheter drainage) or tissue engineered tubular constructs for ureteral anastomoses. Here we describe a biomaterial, decellularized human amniotic membrane (dhAM), that could be used for differentiation of iPSC derived kidney organoids. Because kidney organoids will be exposed to mechanical forces in heterogeneous implant locations, we examine the effects of mechanical stretch on the structure of kidney organoid tubules.

**Methods:** We decellularized hAM with mild detergents, and differentiated kidney organoids into the peritoneum or other heterotopic locations. The constructs were analyzed by immunofluorescence and confocal microscopy. dhAMs could be used to facilitate the implantation of kidney organoids into the peritoneum or other heterotopic locations. The constructs have the flexibility to be used as a patch, modified into tubes after rolling, or form sac-like structures.

Renal Cell-Derived Extracellular Vesicles Improve Functional Phenotype of Kidney Tubuloids

**Rafael S. Lindoso,1,2 Estela Mancheño Juncosa,1 Fjodor Yousef Yengej,3 Maarten B. Rookmaaker,1 Marianne C. Verhaar,3 Rossalinde Masereeuw,4 1Universiteit Utrecht, Utrecht, Netherlands; 2Universidade Federal do Rio de Janeiro Instituto de Biofísica Carlos Chagas Filho, Rio de Janeiro, Brazil; 3University Medical Center Utrecht, Utrecht, Netherlands; 4Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.**

**Background:** Kidney tubuloids (KT) are adult stem cell-derived organoid that hold great potential in preclinical models as bioartificial kidneys (BAK). However, reproducing complete cell maturation and function remains a challenge. Extracellular vesicles (EVs) are cell-derived structures that regulate several cellular processes. In the kidney, EVs mediate intranephron communication through the transfer of bioactive molecules. This study aimed to investigate the use of renal EVs as modulator of KT phenotype by increasing the levels of organic anion transport 1 (OAT1), involved in renal waste handling, and explore their use for BAK engineering.

**Methods:** EVs from conditionally immortalized proximal tubule epithelial cells overexpressing OAT1 (ciPTEC-OAT1) were isolated with 100 K filters, quantified via nanoparticle tracking analysis and incubated with KT. The 24 h conditioned media (CM) EV depleted didn’t induce OAT1. EVs were shown to contain OAT1 protein and mRNA as cargo. Visual observations of KT seeded on hollow fibers with CM containing EVs, presented slightly improvement in 3D tubular structure organization with the expression of tight junction protein (ZO-1) and cell polarity (apical cell formation and Na⁺/K⁺-ATPase presence at the basolateral side) when compared with the control condition.

**Conclusions:** KT phenotype can be directed by renal EVs obtained from ciPTEC-OAT1. In addition, renal EVs can support KT to form tight monolayers on hollow fiber membranes. Further research is aimed at a full functional characterization of these bioengineered proximal tubules for application in BAK. Nitric Oxide (NO) Based Urinary Catheter Balloon Inflation Solution to Prevent Urinary Tract Infection

**Alexander S. Yevzlin, Karthik Ramani, Faroug Suliman. University of Michigan, Ann Arbor, MI.**

**Background:** UTI is the most common hospital acquired infection with indwelling catheters being a major risk factor and are difficult to treat due to the formation of bacterial biofilms which are resistant to systemic antibiotics. NO is an endogenously formed gas molecule known to play a key role in preventing infection by dispersing biofilm formed by a variety of bacterial strains. In this abstract, we describe the effectiveness of a novel urinary catheter balloon inflation fluid to effectively reduce catheter associated urinary tract infections (CAUTI) by providing up to 7 days of bactericidal effect via NO release.

**Methods:** Our innovative approach to prevent CAUTI involves employing a balloon inflation fluid consisting of NO secreting materials based on using S-nitrosogluthathione (GSNO) within the balloon of urinary catheters that slowly releases NO over a period of up to one week. The advantages of the use of NO in CAUTI prevention is its short half-life with a very low steady-state level immediately adjacent to the surface of the device required to achieve the desired anti-microbial effect with no risk of systemic effects when using NO secreting materials with fluxes that are near physiological levels.

**Results:** We performed in vitro studies using a Foley catheter placed in a long-necked flask with a shape resembling the urinary bladder and the urethra. (Fig 1) The Foley catheter retention balloon was filled with GSNO solution and the balloon was used to seal the neck of the flask. Then the flask was filled with synthetic urine inoculated with E. coli and incubated for seven days at 37°C with horizontal shaking at 80 rpm. The results showed a 7-log reduction in planktonic bacterial growth (Fig 2) and a 3-log reduction in biofilms which are resistant to systemic antibiotics. NO is an endogenously formed gas

**Conclusions:** These data suggest that NO-based urinary catheter balloon fluid results in significant anti-microbial effects in our in vitro model of CAUTI.

Feature-Rich Covalent Stains for Interrogation of Kidney Tissue

**Chenxi Mao, Min Yen Lee, Joshua C. Vaughan. University of Washington, Seattle, WA.**

**Background:** Fluorescence microscopy is a workhorse tool in biomedical imaging but often poses significant challenge to practitioners in achieving bright or uniform labeling. In addition, while antibodies are effective specific labels, they often suffer poor penetration in thick tissues, loose binding in heavily fixed or processed specimens (e.g., FFPE tissue), high cost, and inconsistent reproducibility or commercial availability. Thus, it would be highly useful to develop a simple yet robust labeling alternative that could rapidly produce even staining for thick tissues and be compatible with a wide range of sample processing or clearing methods.

**Methods:** We use conventional fluorescent dyes to covalently label abundant chemical functional groups on kidney tissues. These include the use of amine-reactive...
dyes for proteins and aldehyde-reactive dyes for carbohydrates. We term this approach fluorescent labeling of detergent-sensitive reactive entities (FLARE).

**Results:** We first showed FLARE’s utilities in freshly fixed mouse kidney tissues (~100 μm) using super-resolution fluorescent microscopy. Within glomeruli, the carbohydrate stain specifically labeled the basement membranes of the capillary loops and the mesangial matrix, while the amine stain revealed outlined capillary and the intricate details of interdigitated podocyte epithelial cells that are a major component of the glomerular filtration barrier (Fig A). In proximal convoluted tubule, the basement membrane was also labeled by the carbohydrate stain, and the amine stain revealed mitochondria and brush border microvilli (Fig B). Then we stained optically cleared FFPE human kidney tissues (~50 μm) without performing antigen retrieval (Fig C), revealing more general features. Furthermore, FLARE does not perturb antigenicity, wherein immunolabeling of proteins can be easily integrated afterwards (data not shown).

**Conclusions:** We have shown that FLARE reveals abundant details in a wide range of kidney tissue processing methods using super-resolution and cleared-tissue microscopy, and is compatible with other staining modalities.

**Funding:** NIDDK Support, Other NIH Support - RO1

**Ex Vivo Perfusion and Initial Function of a Recellularized Human-Scale Bioengineered Kidney**

Joseph S. Uzarski,1 Emily C. Beck,1 Emily Russell,1 James Jaffe,1 Ron Shapira,1 Sander Florman,2 Dominique Davidow,3 Thomas Gilbert,7 Jeff Ross,4 1Mironatrix Medical, Inc., Eden Prairie, MN; 2MOUNT SinaI Health System, NEW YORK, NY; 3Recanati/Miller Transplantation Institute at Mount Sinai, New York, NY.

**Background:** The phosphaturic hormone FGF23 is a critical factor in chronic kidney disease-mineral and bone disorder (CKD-MBD), with elevated levels in blood associated with increased odds for patient mortality (>6-fold). Anemia is a potent driver of FGF23 expression, and patients with CKD ultimately develop anemia as the kidneys lose the ability to produce erythropoietin (EPO), in concert with FGF23-mediated alterations in mineral metabolism. Our goal was to investigate a HIF-PHI (hypoxia-inducible factor prolyl hydroxylase inhibitor) for effects on anemia-dependent FGF23 levels and key outcomes in a mouse model of CKD.

**Methods:** Female C57BL/6 mice were fed a casein control or adenine-containing diet to induce CKD, which resulted in markedly elevated iFGF23 and BUN, hyperphosphatemia, and anemia. After 12 weeks of CKD induction, mice were treated with the HIF-PHI BAY 85-3934 (‘BAY’; Molsudastat) at a human equivalent dose over every other day for 3 weeks.

**Results:** Compared to saline controls, BAY elevated serum EPO and restored CBCs to normal levels in CKD mice. iFGF23 was significantly elevated in saline-treated CKD mice (120-fold, p<0.01). Importantly, circulating iFGF23 was significantly attenuated (~60-%; p<0.05) in BAY-treated mice with CKD, coinciding with downregulated renal Egr-1 expression (p<0.01). Renal 1,25D anabolic Cyp27b1 and catabolic Cyp24a1 mRNAs were up and downregulated, respectively, in BAY-treated CKD mice. This extended treatment resulted in decreased BUN (p<0.01) and reduced expression of renal fibronectin, collagen and osteopontin (p<0.01). The altered mineral metabolism was further appreciated in femur trabecular parameters and cortical porosity, however saw no effect with BAY over this time course. Serum alkaline phosphatase was significantly elevated in CKD-BAY mice compared to CKD controls (p<0.01), suggesting increased osteoblast activity.

**Conclusions:** Collectively, these results support that resolving anemia using a HIF-PHI may improve kidney function and lower FGF23 during CKD, potentially providing modifiable outcomes beyond improving iron utilization for this patient population.

**Stiffening of Decellularized Tubular Basement Membrane Regulates Renal Tubular Epithelial Cell Function**

Singhal Sant,1 Dan Wong,2 Nicholas J. Ferrell. Vanderbilt University Medical Center, Nashville, TN.

**Background:** Damage to renal proximal tubular epithelial cells (RPTEC) plays an important role in chronic kidney disease. Epithelial cells are supported by a specialized extracellular matrix called the basement membrane (BM). The structure of the BM is altered in various kidney diseases such as diabetic nephropathy and may result in increased BM stiffness. We have developed a novel cell culture model that utilizes tissue derived tubular basement membrane (TBM) with tunable stiffness as a culture substrate for RPTEC. The aim of this study was to determine if TBM stiffening promotes activation of pro-fibrotic signaling pathways and/or regulates RPTEC differentiation.

**Methods:** TBM was isolated from decellularized porcine kidneys. TBM cell culture substrates were made by pressure contacting the TBM on Transwell inserts. Conditionally immortalized mouse RPTEC were grown TBM substrates. To induce stiffening, TBM was treated with the chemical crosslinker genipin. Decellularized TBM was characterized by western blot and immunofluorescence staining. Viability and morphology of RPTEC were evaluated using CellTiter-Blue and Wright-Giemsa. Real-time PCR was performed on RPTEC to evaluate the effect of stiffness on multiple genes related to kidney fibrosis and RPTEC differentiation.

**Results:** Western blot analysis of decellularized TBM showed the presence of laminin and collagen IV and absence of lamin B1 showing proper decellularization of TBM. Genipin treatments (0.05% and 0.5%) resulted in average stiffness of 2 kPa and 3.2 kPa respectively, compared to 0.5 kPa for untreated TBM. Neither decellularization nor genipin modification had a significant effect on cell viability. Pro-fibrotic downstream targets of YAP activation (CTGF, AREG, and ANKRDI) were upregulated on stiff TBM substrates. Additionally, stiffness regulated expression of cell-cell junction markers E-cadherin and N-cadherin.

**Conclusions:** A new cell culture model was developed using tissue derived TBM as a substrate for tubular epithelial cells. Stiffness of the TBM was tuned using genipin. Increased TBM stiffness upregulated pro-fibrotic targets of YAP activation and altered RPTEC cell differentiation. These data show that stiffness significantly affects renal tubular cell function and suggest that TBM stiffening in chronic kidney disease may play a role in disease progression.

**HIF-PHI Improves Anemia and Controls Circulating FGF-23 in a CKD Model**

Megan L. Noonan, Pu Ni, Rafiou Agoro, Elizabeth A. Swallow, Matthew R. Allen, Kenneth E. White. Indiana University School of Medicine, Indianapolis, IN.

**Background:** The phosphaturic hormone FGF23 is a critical factor in chronic kidney disease-mineral and bone disorder (CKD-MBD), with elevated levels in blood associated with increased odds for patient mortality (>6-fold). Anemia is a potent driver of FGF23 expression, and patients with CKD ultimately develop anemia as the kidneys lose the ability to produce erythropoietin (EPO), in concert with FGF23-mediated alterations in mineral metabolism. Our goal was to investigate a HIF-PHI (hypoxia-inducible factor prolyl hydroxylase inhibitor) for effects on anemia-dependent FGF23 levels and key outcomes in a mouse model of CKD.

**Methods:** Mice were fed a casein control or adenine-containing diet to induce CKD, which resulted in markedly elevated iFGF23 and BUN, hyperphosphatemia, and anemia. After 12 weeks of CKD induction, mice were treated with the HIF-PHI BAY 85-3934 (‘BAY’; Molsudastat) at a human equivalent dose every other day for 3 weeks.

**Results:** Compared to saline controls, BAY elevated serum EPO and restored CBCs to normal levels in CKD mice. iFGF23 was significantly elevated in saline-treated CKD mice (120-fold, p<0.01). Importantly, circulating iFGF23 was significantly attenuated (~60-%; p<0.05) in BAY-treated mice with CKD, coinciding with downregulated renal Egr-1 expression (p<0.01). Renal 1,25D anabolic Cyp27b1 and catabolic Cyp24a1 mRNAs were up and downregulated, respectively, in BAY-treated CKD mice. **Second Harmonic Generation and Fluorescence Imaging Reveal Collagen Fibris and Cell Nuclei in Mature Randall Plaque**

Victor Hugo Canela,1 Sharon B. Bledsoe,1 Seth Winfree,1 Angela R. Sabo,1 Elaine M. Worcester,2 Tarek M. El-Achkar,1 James C. Williams,1 1Indiana University School of Medicine, Indianapolis, IN; 2University of Chicago, Chicago, IL.

**Background:** The formation of calcium oxalate (CAOx) stones on Randall’s plaque (RP) is a common phenomenon (perhaps 25% of CAoX stones), yet this mechanism of stones formation is still poorly understood. The objective of the study was to devise novel techniques to study RP structure.

**Methods:** Micro CT was used to orient RP stones for decalcification and sectioning. Sections were examined for collagen using Second Harmonic Generation (SHG)
signals with multiphoton excitation. Other sections were stained with the DNA marker 7-aminoactinomycin D (7-AAD).

**Results:** SHG showed collagen fibrils in the plaque but not in the CaOx overgrowth region. Demineralized RP displayed autofluorescence in the far-blue region, as we have previously described in demineralized RP. Staining of plaque sections with the DNA marker, 7-AAD, confirmed the presence of cell nuclei within mature RP.

**Conclusions:** Our results show that collagen fibrils and cell nuclei are present in RP. The nature of cells and their role in plaque formation are yet to be determined. Our data suggest that these cells contain ordinary nuclear morphology and were well-preserved within the mature plaque. The presence of cell nuclei in the plaque raises critical questions about the role of apoptosis/necrosis and survival in this mineralized environment. Future studies exploring organization of collagen and the nature of cells in plaque will be invaluable in understanding plaque and stone pathogenesis.

**Cell Cycle Acceleration in Parathyroid Glands Is Caused by the Suppression of LncRNA Gas5 Expression in the Presence of a High-Phosphorus Diet in an Adenine-Induced CKD Rat Model**

Taketo Uchiyama, Ichiro Ohkido, Yatsumu Saito, Akio Nakashima, Takashi Yokoo. Jikei University School of Medicine, Minato-ku, Japan.

**Background:** Chronic kidney disease (CKD), especially secondary hyperparathyroidism (SHPT), is strongly associated with systemic calcification, including that in blood vessels. Therefore, it is important to elucidate its underlying pathological mechanism. SHPT is characterized by an unusually increased proliferation of parathyroid cells. We analyzed the expression of multiple cyclins, cyclin-dependent kinases (CDKs) and CDK inhibitors and demonstrated that the accelerated cell cycle in SHPT is caused by a reduction in CDKN1B expression (ASN 2019). To investigate the mechanism underlying SHPT development, we analyzed factors regulating CDKN1B expression in the parathyroid gland using two phosphorus-containing diets in a rat model of adenine-induced CKD.

**Methods:** CKD was induced by a diet containing 0.75% adenine. For 5 days, few rats in the CKD and control groups were fed a diet containing 0.9% phosphorus, and the remaining were fed a diet containing 1.3% phosphorus. We investigated the expression levels of approximately 20 miRNAs, such as miR-221, known to regulate CDKN1B expression, as well as the long noncoding RNA Gas5, using TaqMan probes for quantitative polymerase chain reactions.

**Results:** There were no significant differences in miRNA expression levels among the four groups (Figure 1). Gas5, known to be downregulated in prostate cancer cell, directly upregulates CDKN1B expression and further interacts with E2F1, which binds and activates CDKN1B. This strengthens the binding between E2F1 and CDKN1B stronger. It was observed that the expression of Gas5 was significantly decreased when the high-phosphorus diet was added to the CKD environment, and E2F1 expression did not change significantly (Figure 2).

**Conclusions:** These results suggest that parathyroid cell proliferation might be due to the suppression of Gas5 expression in response to the addition of the high-phosphorus diet to the CKD environment, with a subsequent reduction in CDKN1B expression.

**Treatment with β,γ-Methyleneadenosine 5’-Triphosphate Prevents Arterial Media Calcification in a Warfarin Rat Model**

Britt Opedebeek,1 Isabel Orriss,2 Jessal J. Patel,3 Geoffrey Van den bergh,4 Patrick D’Haese,1 Anja Verhulst.1 University Antwerpen Laboratory for Pathophysiology, Wilrijk, Belgium; 4The Royal Veterinary College Department of Comparative Biomedical Sciences, London, United Kingdom.

**Background:** Arterial media calcification (AMC) is a severe complication in patients with chronic kidney disease, diabetes and osteoporosis. In vitro studies showed that the synthetic P2X7 receptor agonist β,γ-meATP is a potent inhibitor of vascular smooth muscle cell (SMC) calcification. Here, we aimed to evaluate whether β,γ-meATP prevents the development of AMC in a rat model of warfarin-induced AMC.

**Methods:** To induce AMC, rats received a diet containing 0.30% warfarin + 0.15% vitK1 throughout the entire study and were subjected to daily i.p. treatments with vehicle (n=10) or 2 mg/kg/day β,γ-meATP (n=10) from start of the study until sacrifice at wk7. Four rats on a standard chow diet were included as a control group. Serum calcium (Ca) and phosphorus (P) levels were analyzed at sacrifice. To evaluate the bone-like switch of VSMCs, aortic mRNA expression of TNP and SOX9 were analyzed by qPCR. AMC was evaluated by analysis of total Ca content in the arteries and quantification of the area % calcification on Von Kossa stained aortic sections. To determine arterial stiffness, ultrasound-based pulse wave velocity (PWV) was evaluated in the abdominal aorta.

**Results:** Serum P levels were unchanged in all groups while serum Ca was significantly lower in rats treated with β,γ-meATP vs vehicle group. Exposure to warfarin induced distinct calcification in the aorta and peripheral arteries in vehicle-treated rats which led to an increase in PWV score. Interestingly, daily treatment with β,γ-meATP significantly reduced the Ca content in the aorta (mean ± SEM; vehicle 1,49 ± 1,51 mg Ca/g wet tissue vs β,γ-meATP 0.38 ± 0.20 mg Ca/g wet tissue; p=0.05) and peripheral vessels which was further reinforced by a significant (p=0.01) reduction in aortic Von Kossa positive area % vs vehicle group. However, β,γ-meATP did not significantly affect PWV scores. Treatment with β,γ-meATP also did not alter the mRNA expression of bone-like marker genes.

**Conclusions:** β,γ-meATP significantly decreased AMC in the aorta and peripheral vessels of warfarin exposed rats, however, without affecting the bone-like switch of VSMCs suggesting that β,γ-meATP mediates its inhibitory effects on AMC probably by interfering with the formation of Ca-P crystals via its breakdown product methylphosphonate. Further research will be conducted to evidence this hypothesis.

**Funding:** Government Support - Non-U.S.
CKD rats (p<0.002). Serum 8-OHdG (marker of DNA oxidation) was higher in all CKD animals (p<0.01) and unaffected by treatment. There was increased aorta calcification (by 45%) and heart calcification (by 32%) in all of the CKD animal groups (p<0.01) and only GKT treatment reduced aorta calcification (p<0.03). Compared to NL, trabecular bone volume (BV/TV%) and trabecular number were lower and trabecular separation was higher in all CKD rats (p<0.001). GKT also increased trabecular separation in CKD rats (p<0.04).

Conclusions: In a progressive rat model of CKD-MBD, treatment with a NOX1/4 inhibitor (GKT) early in the course of CKD reduced aorta calcification but did not decrease osteoarticular stress as increased FGF23 (in CKD rats). KP treatment decreased serum PTH levels in CKD, but had no effect on aorta calcification or bone architecture. There were no additive beneficial or adverse effects with the combination of KP and GKT.

Comparison of the Effects of Ferric Citrate and Intravenous Iron on Markers of Mineral and Bone Disorder and Oxidative Stress in a Rat Model of CKD

Background: Anemia and chronic kidney disease-mineral and bone disorder (CKD-MBD) are common in CKD. Ferric citrate is an oral therapy approved as an oral iron replacement product in non-dialysis dependent CKD and as a phosphate binder for dialysis dependent CKD patients. However, studies comparing the effects of ferric citrate vs. IV iron markers of CKD-MBD and oxidative stress in moderate CKD are limited.

Methods: We compared four groups of male rats (n=11-14 rats/group): 1) Rats with normal kidney function (NL), 2) CKD rats without iron treatment (CKD), 3) CKD rats treated with 5% ferric citrate (FCD) + FIV iron, and 4) CKD rats treated with FIV iron/kg/every other week of iron sucrose (CKD + IV iron). Treatments started at 18 weeks of age (mild CKD) until euthanized at 28 weeks of age (moderate-to-advanced CKD). We determined biochemical markers of CKD-MBD, oxidative stress, bone morphology (by CT), and bone formation rate at 28 weeks. One-way ANOVA was performed with Tukey’s post hoc comparisons.

Results: Untreated and iron-treated CKD rats had higher concentrations of UBN and creatinine than NL rats. Untreated CKD rats had elevated plasma phosphorus and intact FGF23 compared to NL. CKD-FIV rats had lower plasma phosphorus and intact FGF23, while CKD+IV iron rats had lower intact FGF23 compared to CKD rats. However, the C-terminal FGF23 remained high in the untreated CKD and the CKD+IV iron rats compared to NL, but CKD+IVF rats tended to be lower than the untreated CKD rats (p<0.07). Bone formation rate was elevated in the untreated and iron-treated CKD rats compared to NL. A marker of oxidative stress, 8OHdG, was increased in the untreated and iron-treated CKD rats compared to NL rats and was not different between iron treatments. At this stage of CKD, there was no cortical porosity in all the CKD rats compared to NL. CKD-induced alterations in trabecular and cortical bone properties and bone formation rate were not changed compared to untreated CKD rats in the iron-treated rats.

Conclusions: Ferric citrate led to more robust reductions in plasma phosphorus and FGF23 than IV iron, while neither source of iron had adverse effects on oxidative stress or bone architecture in a rat model with moderate CKD-MBD.

Upacicalcet, a Novel Non-Peptide Calcimetic for the Treatment of Secondary Hyperparathyroidism, Has a Low Risk of Hypocalcemia

Background: Calcium imbalances are widely used for the treatment of secondary hyperparathyroidism (SHPT) in chronic renal failure patients. However, there are some problems with calcimetics treatment. One of the biggest problems is hypocalcemia that leads to treatment interruption. Upacicalcet is expected to be a novel non-peptide calcimetic that does not cause excessive hypocalcemia from the results of clinical studies. In the present study, we investigated the pharmacological characteristics of upacicalcet and effect on hypocalcemia in preclinical studies.

Methods: In vitro study was conducted using human CaSR-expressing (hCaSR) HEK-293T cells. In vivo study, upacicalcet was intravenously administered in a single dose to Double-Nephrectomized (Double-Nx) rats, an animal model of SHPT, and serum intact parathyroid hormone (iPTH) and Ca concentrations were measured.

Results: Upacicalcet increased the intracellular Ca2+ concentration in hCaSR-HEK-293T cells dose-dependently. Additionally, upacicalcet shifted the EC50 value for extracellular Ca2+ to lower concentrations in a dose dependent manner. In Double-Nx rats, 0.3, 3, and 30 mg/kg of upacicalcet dose-dependently reduced the serum iPTH level at 24h and 48h after administration, and the reductions were significantly greater than that in Control (P<0.001). Upacicalcet 0.3 mg/kg: 397±40 pg/mL vs. Control: 1306±80 pg/mL, P<0.001, 48h; Upacicalcet 0.3 mg/kg: 795±91 pg/mL vs. Control: 1889±77 pg/mL, P<0.001.

Upacicalcet also significantly decreased the serum Ca level dose-dependently at 24h and 48h after administration. However, interestingly, it bottomed out without getting too low even with 30 mg/kg of upacicalcet, 100-fold higher than the efficacious dose (0.3 mg/kg) (Table 1).

Conclusions: These findings suggest upacicalcet is a novel non-peptide positive allosteric modulator on human CaSR with a low risk of hypocalcemia for the patients with SHPT.

SNF472 Inhibits Heart Valve Calciumization in a Novel In Vitro Method Using Porcine Whole Leaflets

Background: Chronic kidney disease and end-stage kidney disease (ESKD) patients are prone to develop calcific aortic or mitral valve disease. Currently, there exists no pharmacological treatment to prevent or stop the calcification process of aortic valves that mimic aortic stenosis, and the models to study this process in vitro are scarce. SNF472 is an inhibitor of calcium phosphate crystallization in development for the treatment of calciiphyaxis and cardiovascular calcification in ESKD patients. The aims of this study were to develop a robust in vitro model of induced calcification in whole aortic valve leaflets suitable for testing potentially inhibitory drugs, and to test the effects of SNF472 in this model.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Aortic valve leaflets from commercial pig hearts were dissected free and randomly assigned to experimental groups. Valve leaflets were cultured in individual wells. Two growth media were used for cultivation: standard growth medium and an antimitotoblastic growth medium. The latter was employed to inhibit contraction of the leaflet into a ball-like structure. Calcification was induced in the growth medium by supplementation with 5mmol/L CaCl2 (0.85, 1.74, and 5mmol/L b-glycerophosphate) medium, and 5mmol/L CaCl2 and 5mmol/L L-b-glycerophosphate) medium, or EV. To assess the role of VDRa therapy, arteries were treated with either calcitriol or paricalcitol.

Results: Human arteries express a functionally active vitamin D system, including VDR, 1α-hydroxylase and 24-hydroxylase (24-OHase) components and these were dysregulated in CKD arteries. Arteries from CKD patients exhibited reduced capacity to synthesize 1,25(OH)2D, increased basal expression and excessive induction of the vitamin D catabolic pathway in response to VDRa. VDRa therapy increased VDR expression in all organs/cells, but not CKD arteries. VDRa treatment suppressed Runtx2 and Mmp-9 expression in CKD arteries, however only paricalcitol suppressed MMP-2. VDRa exposure did not modulate arterial calcification in all organ culture models. However, VDRa reduced selenocysteine associated β-galactosidase (SAGI) staining in human aortic- smooth muscle cells under calcifying conditions, in vitro.

Conclusions: Maladaptation of arterial vitamin D signaling components occurs in CKD. VDRa exposure can exert vasculo-protective effects and seems critical for the regulation of arterial health in CKD.

Analysis of Human Jackstone Protrusions Show a Protein-Rich Core, Suggesting That Proteins Drive Their Rapid and Linear Growth

Victor Hugo Canela,1 Sharon B. Bledsoe,2 Cornelius Dzien,2 Michael S. Borofsky,3 James E. Lingeman,1 Tarek M. El-Achkar,1 James C. Williams.1 1Indiana University School of Medicine, Indianapolis, IN; 2Medical-Center Innsbruck, Innsbruck, Austria; 3University of Minnesota, Minneapolis, MN.

Background: Jackstones are urinary stones that have arm-like extensions from the body of the stone. This morphology of stone has been long recognized but poorly studied.

Methods: Micro CT was used to analyze 96 jackstones from 47 different patient specimens. Additional analyses included infrared spectroscopy (IR), fluorescence microscopy, and immunohistochemistry for Tamm-Horsfall protein (THP).

Results: Jackstone cores consisted of an X-ray lucent core (high in protein by IR) and a tightly layered calcium oxalate monohydrate (COM) shell that matched the COM on the stone body. The layering in the shell regions showed that the arms had grown as a linear array from the center of the stone than had the stone body. Microscopy studies showed brilliant autofluorescence in the core region but less in the COM shell. Immuno-staining showed that THP content was richer in the core region than in the COM shell.

Figure 1A shows surface rendering of jackstone by micro CT. B: Slice through micro-CT image stack to show the x-ray lucent cores of two jack arms from A. C & D show negative controls (no primary antibody) for human cortical tissue and demineralized jackstone arm cross-section. Panel E shows a positive control for THP in human renal tissue (black arrowheads).

Conclusions: We hypothesize that the protein-rich core of a jackstone arm preferentially binds more protein from the urine and resists deposition of COM, such that the arm tip grows rapidly, with the sides (shell) of the arm being covered with COM layers just like the body of the stone. This hypothesis points to enrichment of growth-accelerating proteins in the core of the jack arm, which bind preferentially to the protein-rich tip but which bind less avidly to the COM surface of the stone. Identification of such proteins could provide clues as to how proteins modulate the deposition of mineral layers in kidney stone growth.

Impaired Arterial Vitamin D Signaling Is Pathogenic in Vascular Calcification

Kenneth Lim,1 Guerman Molostov,2 Maria A. Lubczanska-Haslady,3 Simon Fletcher,2 Rosemary Bland,4 Thomas F. Hiemstra,5 Daniel Zehnder.3 1Indiana University School of Medicine, Indianapolis, IN; 2University of Birmingham, Birmingham, United Kingdom; 3University Hospital Coventry and Warwickshire, Coventry, United Kingdom; 4University of Warwick, Coventry, United Kingdom; 5University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom; 6Northumbria Integrated Care University Hospital NHS Trust, Carlisle, United Kingdom.

Background: Conflicting data exists as to whether vitamin D receptor agonists (VDRα) are protective of arterial calcification. This is confounded by inherent physiological differences between human and animal experimental models and conflicting published data. Herein, the study aims to address these problems by leveraging frontiers in human arterial organ culture models.

Methods: Human arteries were collected from 24 patients (healthy controls, n=12; end-stage CKD, n=12). Cross-sectional and interventional studies were performed using arterial organ cultures with normal and calcifying (containing 5mmol/L CaCl2 and 5mmol/L L-b-glycerophosphate) medium, or EV. To assess the role of VDRα therapy, arteries were treated with either calcitriol or paricalcitol.

Results: Human arteries express a functionally active vitamin D system, including VDR, 1α-hydroxylase and 24-hydroxylase (24-OHase) components and these were dysregulated in CKD arteries. Arteries from CKD patients exhibited reduced capacity to synthesize 1,25(OH)2D, increased basal expression and excessive induction of the vitamin D catabolic pathway in response to VDRα. VDRα therapy increased VDR expression in all organs/cells, but not CKD arteries. VDRα treatment suppressed Runtx2 and Mmp-9 expression in CKD arteries, however only paricalcitol suppressed MMP-2. VDRα exposure did not modulate arterial calcification in all organ culture models. However, VDRα reduced selenocysteine associated β-galactosidase (SAGI) staining in human aortic-smooth muscle cells under calcifying conditions, in vitro.

Conclusions: Maladaptation of arterial vitamin D signaling components occurs in CKD. VDRα exposure can exert vasculo-protective effects and seems critical for the regulation of arterial health in CKD.

Effects of Pi versus FGFR23 to determine their contributions towards these CKD-associated pathologies.

**Methods:** We subject mice with global FGFR4 deletion & wild-type littermates with a 3% Pi diet as well as an adenine-rich diet to examine hyperphosphatemia of CKD. We subject mice with global FGFR4 deletion & wild-type littermates to examine inflammation & anemia by targeting the liver to induce gene programs that regulate inflammatory responses & mineral metabolism.

**Results:** In order to ensure that this was not a truncated form of α-klotho, Sanger sequencing was performed to confirm that the gene expressed in the liver was Klα. Significant expression levels of Klα mRNA were observed between those two species by qPCR (RN: 0.9 vs. NMR: 1.2 vs. NMR: 2 n.s.). The expression of Klα was further examined in the lung, skin, and liver of NMR, compared to RN. There was no expression of Klα in the lung or skin of NMR. In the liver of NMR, a high expression of Klα mRNA was observed (Cp: 25) by qPCR in contrast to RN, where no expression was detected. Sanger sequencing was performed to confirm that the gene expressed in the liver was Klα. In order to ensure that this was not a truncated form of Klα, which could be a target for mRNA decay, the predicted region for alternative splicing sites for Klα was sequenced in the liver of NMR. These results indicated that this was the case, neither in the kidney nor in the liver.

**Conclusions:** This comparative study showed for the first time that α-klotho is significantly expressed in the liver of NMR, while the gene is absent in the liver of RN. This is similar in kidneys of NMR and RN. Further experimental work is required to clarify whether the hepatic expression of α-klotho might contribute to the longevity of the NMR.

**Heterogeneity of Mechanisms for Idiopathic Hypercalcuria in Calcium Stone Formers**

**George A. Heding,** Elaine M. Worcester, Kristin J. Bergsland, Fredric L. Coe, University of Wisconsin, Milwaukee, WI; Medical College of Wisconsin, Milwaukee, WI.

**Background:** In past research, we have found evidence that patterns of segmental nephron tubule calcium reabsorption differ between the sexes in calcium (Ca) stone formers (SF) demonstrating a different underlying mechanism of their hypercalcuria. Whether or not these mechanisms differ between calcium oxalate (CaOx) and calcium phosphate (CaP) SF is not known.

**Methods:** We studied 18 CaOx SF subjects (12 male), 17 CaP SFs (9 male), and 25 normal (N) subjects (13 male) in both the fasted and fed state. Subjects ate a diet consisting of three isolectic meals with hourly blood and urine samples for 14 hours. We measured renal clearance of calcium and phosphate as well as urinary calcium and creatinine. We account for within-subject correlation due to repeated measures, generalized estimating equations (GEE) were used to estimate mean and test mean laboratory values between groups. Linear mixed effects models were used to model urine Ca, distally delivered Ca, absolute renal tubular calcium reabsorption and urinary calcium excretion.

**Results:** In SF women, distal Ca reabsorption is decreased compared to N women, while in SF men, PT Ca reabsorption is significantly decreased with a more modest reduction in distal Ca reabsorption compared to normal men. Among female CaP SF we found an abnormally high response of urine Ca to PTH that appears to affect post PT Ca reabsorption. Among female CaP and CaOx SF male CaOx SF we found a clear difference of urine Ca response to ultraltrate Ca concentration. This difference was absent in male CaP SF who had a unique increase in the dependence of distal Ca delivery on lithium reabsorption in the PT. CaOx male SF also had other PT abnormalities such as modeled urine Ca that was abnormally dependent on the urine plasma lithium ratio. In addition, CaOx male SF had modeled lithium reabsorption that was abnormally responsive to both urine sodium, an ECF volume marker, and UF Ca concentration, presumably mediated through receptor Ca reabsorption.

**Conclusions:** CaP and CaOx SF have differentiating abnormalities of Ca handling as compared to their same sex normals. In particular, phenotype specific abnormalities related to the CaSR exist in CaOx men and abnormalities related to the PTH receptor exist in CaOx women.

### PO0328

**Magnesium’s Roles in the Treatment of Hyperphosphatemia of CKD**

**Background:** Hyperphosphatemia is causally related to atherosclerotic cardiovascular disease, the most important cause of death in all stages of renal failure and the single greatest threat to survival among ESRD patients undergoing dialysis. To meet the current K/DOQI guideline, patients use cationic binders to bind phosphate (Pi) in the gastrointestinal tract and prevent its uptake. FDA-approved phosphate binders include aluminum hydroxide, lanthanum salts, sevelamer, and ferrous carbonate. Combinations of calcium and magnesium salts exhibit pleiotropic benefits for hyperphosphatemic Stage 4-5 CKD patients and illustrate the potential benefits of these combination therapies in treatment of hyperphosphatemia.

**Methods:** Recent clinical data strongly suggest that combinations of calcium and magnesium salts exhibit pleiotropic benefits for hyperphosphatemic Stage 4-5 CKD patients. In addition to reducing the calcium load, magnesium appears to act in the following ways. (1) Treatment lowered serum phosphorus into the K/DOQI target range in Stage 4-5 CKD patients. (2) Although treatment increased serum magnesium concentrations, (Mg2+) was in the high normal range and comparable to the intracellular magnesium concentration. (3) Short-term treatment raised the Tm value. Since lower values are associated with accelerated conversion of soluble calcioprotein particles composed of...
amorphous calcium phosphate to secondary (insoluble) calcioprotein particles containing neoformed matrix calcium phosphate particles, higher magnesium appeared to beneficially slow the rate of conversion. (4) Analyses of bone turnover parameters suggested that higher magnesium may have supported more normal bone remodeling.

**Conclusions:** Clinical data from several sources suggest that combinations of calcium and magnesium ions have unique potential for providing pleiotropic benefits to Stage 4-5 CKD patients of all ages. Additional preclinical studies are underway to confirm that calcium magnesium citrates and propionates can be effectively and safely administered to

**Reduced DMP1 Expression Precedes Bone Loss and FGF-23 Elevation in CKD**

**Emily French,**†1 Xueyan Wang,†1 Jian Feng,† Tom Nickolas,†2 Valentin David,†2 Aline Martin,†2 Northwestern University, Chicago, IL; †Columbia University Irving Medical Center, New York, NY; †Texas A and M University, Dallas, TX.

**Background:** Chronic kidney disease (CKD) is associated with major disorders of bone mineral metabolism, including renal osteodystrophy and increased secretion of the phosphaturic hormone FGF23 by bone, which is independently associated with cardiovascular mortality. Dentin matrix protein 1 (DMP1) is an extracellular matrix protein produced by osteocytes that stimulates osteoblast differentiation and inhibits FGF23 production. We previously showed that DMP1 supplementation prevents bone loss, FGF23 elevation and cardiovascular outcomes in mice with advanced CKD.

**Methods:** To determine if altered DMP1 expression contributes to the pathogenesis of renal osteodystrophy and FGF23 elevations during CKD progression, we measured bone DMP1 mRNA in wild-type (WT) and Cola4α300 mice with progressive CKD every 4 weeks from 4 weeks of age until their death (24 weeks). In parallel, we assessed kidney function, serum FGF23 levels and bone microarchitecture. We also assessed osteocyte morphology in mice and in patients with early CKD.

**Results:** Cola4α300 mice showed increased albumin to creatinine ratio (ACR) and blood urea nitrogen (BUN) levels starting respectively at 8 and 16 weeks, indicating onset of proteinuria and impaired kidney function. Consistent with BUN, FGF23 levels showed sustained increases starting at 16 weeks. This coincided with alterations in trabecular bone measured by 3D-microtomography of femurs from 16 to 24 weeks-old Cola4α300 mice. However, analysis of cortical (Ct) bone showed reductions in bone mineral density, Ct thickness and Ct area as early as 12 weeks of age, and alterations in osteocyte morphology as early as 10 weeks in Cola4α300 mice with early CKD and in patient with CKD stage 5 CKD (n=4-7).

**Conclusions:** These data show that reduction in DMP1 expression occurs prior to major declines in kidney function and precedes alterations in osteocyte morphology, cortical bone loss, and FGF23 elevation in CKD. Although further studies are needed to identify the factors that suppress DMP1 expression in CKD, DMP1 administration might represent an effective therapeutic strategy to prevent alterations in bone and mineral metabolism in early CKD.

**PO0332**

**A Role of FHL2 in the Pathogenesis of VOT and Calcification Induced by High Phosphate**

**Xiaowen Huang,**‡1 Weichun He.‡1 †Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, China; ‡Nanjing Medical University, Nanjing, China.

**Background:** Hyperphosphatemia is germane to the development and progression of arterial medial calcification (AMC) in patients with chronic kidney disease. Vascular smooth muscle cells (VSMCs) to osteoblast-like cells transdifferentiation (VOT) induced by high phosphate is a crucial step in AMC. Either β-catenin or HIF-1α signal activated by high phosphate promotes VOT and calcification in VSMCs. As an adaptor protein, four-and-a-half LIM domains protein 2 (FHL2) has been demonstrated involving in β-catenin and HIF-1α signaling, respectively. However, the potential role and mechanism for FHL2 in high-phosphate-induced VOT and AMC remains to be clarified.

**Methods:** The regulation and function of FHL2 in high-phosphate-induced VOT and calcification were examined in cultured VSMCs. The expression of FHL2 in AMC induced by high phosphate was examined in cultured arterial rings. The regulation of FHL2 on β-catenin and HIF-1α signaling during VOT was also examined in VSMCs, respectively.

**Results:** The expression of FHL2 was induced in VSMCs and arterial rings cultured in a high phosphate environment. Knockdown of FHL2 suppressed high-phosphate-induced Runx2 and osteocalcin expression and calcium deposition, whereas ectopic expression of FHL2 was sufficient to induce the expression of Runx2 and osteocalcin in VSMCs. Downregulation of FHL2 partially inhibited the high-phosphate-induced upregulation of active β-catenin and β-catenin-mediated gene transcription, whereas ectopic expression of FHL2 was able to induce active β-catenin and β-catenin-mediated gene transcription. Similarly, downregulation of FHL2 partially inhibited the expression of HIF-1α induced by high phosphate, while ectopic expression of FHL2 enhanced HIF-1α-mediated gene transcription, although it didn’t significantly increase the expression of HIF-1α. Moreover, high phosphate induced physical interactions between FHL2 and β-catenin, FHL2 and HIF-1α, respectively, especially in the nucleus. Meanwhile, high phosphate also induced a combination of β-catenin and HIF-1α, suggesting that the high phosphate-induced upregulation of FHL2 facilitates the formation of a FHL2/β-catenin/HIF-1α ternary complex.

PO0333

CKD Decreases Cardiac PGC-1α Through Activin A Disrupting Mitochondrial Function

Matthew J. Williams,1 Kishor B. Devalaraja-Narashimha,2 Keith A. Hruska,1
1Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2Regeneron Pharmaceuticals Inc, Tarrytown, NY.

Background: The CKD-MBD syndrome is a cause of cardiac risk. Our hypothesis was that a new component of the disease, activin A, is responsible for systemic activation of activin receptor (ActRII) signaling in kidney disease, and is a mechanism of cardiac disease.

Methods: Two models of CKD were employed, Col4A5 Alport Syndrome mice and ablative CKD in Rosas26 cre ERT/+inhbaff/fI mice. Inhibition of Activin A in CKD was accomplished by either knockdown in Rosas26 cre ERT/+inhbaff/fI CKD mice or by monoclonal antibody in Alport mice. PGC-1α, mitochondrial gene expression and oxidative phosphorylation were measured by PCR and western analysis Cardiac mitochondrial respiration was measured by respiration.

Results: In two kidney disease models, we show that activin A is the responsible ligand for cardiac and aortic ActRIIA activation in CKD. In untreated CKD mice, cardiac levels of pSmad2 and inhibin βa mRNA and preproprotein (activin A monomer) were increased. Activin A inhibition, accomplished by either knockdown in Rosas26 cre ERT/+inhbaff/fI CKD mice or by monoclonal antibody in Alport mice, prevents CKD-induced cardiac ActRIIA activation and loss of PGC-1α, the master regulator of mitochondrial biogenesis and fatty acid oxidative phosphorylation. Mitochondrial gene expression and oxidative phosphorylation were decreased by CKD but prevented by activin A inhibition in CKD. Cardiac hypertrophy by echocardiography and heart weight was increased by CKD and prevented by activin A inhibition in the absence of vascular stiffness and without change in FGF23 levels.

Conclusions: We conclude that activation of cardiac activin/ActRIIA signaling by CKD induces mitochondrial dysfunction through decreased PGC-1α which contributes to compensated cardiac hypertrophy in the early stages of CKD associated cardiac disease.

PO0334

Response of Bone to Acid: Effect of Deletion of the Proton Receptor OGR1 in the Osteoblast

Nancy S. Krieger, Luojing Chen, Jennifer Becker, Michaela Chan, David A. Bushinsky. University of Rochester Medical Center Department of Medicine, Rochester, NY.

Background: Metabolic acidosis induces bone resorption by inhibiting osteoblast (OB) bone formation and stimulating osteoclast (OC) bone resorption. Mice generate large amounts of endogenous acid and we have shown that OGR1 is the proton (H+) receptor in bone and is stimulated by this endogenous acid. Mice with a global deletion of OGR1 have increased bone density which appears due to increased bone formation. There is communication between OB and OC and OGR1 is present in both. To determine if the response of OGR1 in the OB is dependent of a response in OC, we generated a conditional knockout with an osteoblast-specific deletion of OGR1 (OB-cKO).

Methods: OB-cKO mice were generated from a col1a-cre mouse and an OGR1 flox/flox mouse. We examined bones from 3 month old female mice using micro-computed tomography (μCT) and immunohistochemistry. Bone marrow mesenchymal stem cells (BMSC) from femurs of OB-cKO and wild type (WT) mice were differentiated to OB. Mineralization was detected with Alizarin red and gene expression was analyzed by QPCR. All indicated changes are significant (p<0.05).

Results: Immunofluorescent staining of OGR1 in differentiated OB from BMSC confirmed the absence of OGR1 in OB-cKO cells compared to WT. μCT demonstrated an increase in tibia cortical bone area (0.76±0.01 vs 0.71±0.01 mm2), but no change in femoral cortical bone in OB-cKO compared to WT. Femoral trabecular bone was decreased (8.6±4.03 vs 11.8±1.70 %BV/TV), but there was no change in tibia trabecular bone. Alizarin red staining of differentiated BMSC showed greater mineralization of OB from OB-cKO mice compared to WT (5.14±0.02 vs 4.39±0.03 relative intensity). Relative gene expression of col1a (1.53±0.15 vs 0.88±0.10), osteocalcin (1.79±0.05 vs 1.13±0.18) and RANKL (2.89±0.48 vs 1.11±0.21) was higher in differentiated BMSC from OB-cKO mice compared to WT cells.

Conclusions: Our results demonstrate that specific loss of OB OGR1 alters the response of bone to endogenous acid on bone content, in vitro mineralization and gene expression compared to WT, indicating that the response of OGR1 in the OB is independent of the response in OC. Characterization of the direct role of OGR1 in acid-induced bone resorption may assist in understanding bone loss associated with the metabolic acidosis in patients with chronic kidney disease.

Testing Patterns for CKD-MBD Abnormalities Before and After Treatment

James B. Wetmore,1 Yuanyuan Ji,2 Akhtar Ashfaq,1 David T. Gilbertson,2 Nicholas S. Roetker,2 Hennepin Healthcare, Minneapolis, MN; 2Chronic Disease Research Group, Minneapolis, MN; 1OPKO Health Inc, Miami, FL.

Background: We examined patterns of testing, treatment, and retesting after treatment initiation in CKD-MBD to determine if they were concordant with KDIGO guidelines.

Methods: We utilized 2010-19 data from IBM Explorys, an electronic health database. We created cohorts of incident CKD stage 3, 4, and 5 patients using a diagnosis code for CKD stage and a confirmatory eGFR lab value. Patterns of lab test ordering for PTH, phosphorus, 25D, calcium, and ALP and drug prescribing for activated vitamin D compounds, nutritional vitamin D, and phosphate binders were assessed during follow-up. We estimated the cumulative incidence of lab retesting following treatment (with death as a competing risk). We used multivariable Cox regression to examine whether pre-treatment test result values predicted retesting.

Results: We identified 215,553 stage 3, 43,576 stage 4, and 11,407 stage 5 CKD patients; mean follow-up was 2.3, 1.7, and 0.6 years, respectively. Only 46% of stage 4 and 41% of stage 5 patients underwent a PTH test; only 74% and 75%, respectively, a test for phosphorus; and only 38% and 25%, respectively, a test for 25D. By one year after treatment with activated vitamin D compounds, only 50% (stage 3), 53% (stage 4), and 60% (stage 5) of patients had received retesting for PTH [Figure]. By one year after treatment with 25D, retesting of 25D occurred in 46% (stage 3), 49% (stage 4), and 55% (stage 5) of patients by one year. Pretreatment levels of PTH and 25D were not associated in a graded fashion with retesting after treatment commenced.

Conclusions: Frequency of initial testing and retesting following treatment initiation are suboptimal. Unexpectedly, patients with the highest and lowest pre-treatment levels of PTH and 25D, respectively, did not have the highest rate of retesting, suggesting room for improvement.

Using a Quantitative Systems Pharmacology Model of CKD-MBD to Guide Therapy Minimizing Calcium Flux from Bone and into Vascularature
Adam E. Gaweda,1 Michael E. Brier,1,2 Eleanor D. Lederer,1,4 1University of Louisville, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Texas Southwestern Department of Internal Medicine, Dallas, TX; 4Dallas VA Medical Center, VA North Texas Health Care System, Dallas, TX.

Background: CKD-MBD is characterized by bone loss and vascular calcification. Pharmacologic treatment of CKD-MBD involves dosing of three agents to minimize these complications through optimal balance of Calcium (Ca), Phosphorus (P), and PTH. Having developed a Quantitative Systems Pharmacology (QSP) model of CKD-MBD, we test the hypothesis that an AI method called Deep QLearning (DQL) in conjunction with our model can be used to determine the impact of precision therapy on the mineralization defect in patients with End Stage Renal Disease (ESRD).

Methods: Applying a quantitative systems pharmacology (QSP) model of CKD-MBD to mimic disease progression, we trained a Deep Neural Network (virtual physician) to minimize the Ca bone efflux and the Ca vascular tissue influx regardless of achieved serum Ca, P, and PTH predicted by the model. The virtual physician observed Ca, P, PTH and adjusted the doses of P binder, vitamin D, and a calcimimetic. We evaluated a trained virtual physician through simulation of CKD-MBD treatment over 18 months on a population of 100 virtual ESRD patients with varying baseline Ca, P, PTH levels, P intake, and Ca sensing receptor sensitivity.

Results: Simulations produced an average 30% decrease in bone Ca efflux and a 20% decrease in Ca influx to vascular tissue over baseline values. Average P decreased from 7.4 to 5.1 mg/dL, average Ca increased from 8.5 to 9.2 mg/dL, median PTH decreased from 1650 to 315 pg/mL.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to minimize the Ca fluxes from the bone and into the vascular tissue by prioritizing optimization of Ca fluxes over the achievement of specific Ca, P, and PTH levels. Our approach demonstrates beneficial synergy of Systems Biology and AI in modeling complex biological processes.

Mineral Metabolism Changes in Renal Transplantation
Ana Carina Ferreiraa,1,2 Marco Mendes,1,2 Cecilia Silvaa, Patricia Cotovioa, Ines Aires,1,2 David Navarro,1 Fernando C. Pereira,1,2 Rute M. Salvador,2 Bruna F. Correia,1,2 Ma Guadalupe Cabral2, Fernando E. Nolasco,1,2 Manuel A. Ferreiraa,1,2 Hospital Curry Cabral, Lisboa, Portugal; 1Nova Medical School, Lisbon, Portugal.

Background: Successful renal transplant restores many physiologic abnormalities. The aim of this study was to analyse the evolution of CKD-MBD players (alpha-klotho, fibroblast grow factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP), calcitonin, vitamin D (vitD), phosphorus (P), Calcium (Ca) and Magnesium (Mg)) pre and post transplantation.

Methods: Prospective cohort study of de novo renal transplanted patients (pts). A inclusion and after 12 months (time 0 and 1) pts performed laboratory evaluation. The difference over the achievement of time1 - time 0 is the delta value. Associations between variables were performed using Wilcoxon matched-pairs test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Results: We recruited 85 pts in 29 months and included 69 pts in the study. Mean age 50.2±12.4 years, 48 men, 53 caucasian (78.8%), median BMI 24.5 (22.4 - 27.8), median dialysis vintage 55 (42 – 84). We observe a significant reduction on P, Mg, PTH, calcitonin, sclerostin, bAP and FGF23. Both Ca and alpha-klotho levels increased, with no significant changes in vitD levels. With restoring renal health (time 1) and comparing with time 0, PTH maintain the negative correlation with sclerostin (p=0.02) and the positive correlation with FGF23 (p=0.002); modify the correlation with P, becoming a negative correlation instead of positive (p=0.001) and gain new correlations with Ca (p=0.001) and vitD levels (p=0.03). Also, PTH correlated with the delta FGF23 (rho=-0.4, p=0.003) and sclerostin correlated with delta PTH (p=0.01). FGF23 did not find statistical association with P or Ca levels after transplant, contrasting with positive associations in pre transplant (p=0.002, p<0.0001). On the contrary, sclerostin developed a new correlation with P (p=0.0004) and a negative correlation with Ca (p=0.01). We didn’t find correlations between these molecules and alpha-klotho.

Conclusions: It seems that sclerostin influences PTH levels and that PTH is the stimulus for the increase or decrease of FGF23 serum levels. Levels of Ca and P seemed to be directly influenced by the level of PTH in post transplant, and those minerals seemed to be key factors for sclerostin secretion.

PO0338

Quantitative Systems Pharmacology Approach to the Treatment of CKD Metabolic Bone Disorder (CKD-MBD) Using Deep Learning
Adam E. Gaweda,1 Michael E. Brier,1,2 Eleanor D. Lederer,1,4 1University of Louisville, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Texas Southwestern Department of Internal Medicine, Dallas, TX; 4VA North Texas Health Care System, Dallas, TX.

Background: CKD-MBD is a common comorbidity that leads to serious skeletal and cardiovascular complications. Using a Systems Biology model of CKD-MBD and Artificial Intelligence (AI) - guided precision dosing approach, we tested the hypothesis that this approach can effectively achieve recommendations for Ca, P, and PTH by balancing administration of vitamin D and a calcimimetic when faced with varying adherence to phosphorus binder dosing.

Methods: Using a Quantitative Systems Pharmacology (QSP) approach to model the disease trajectory, we trained a Deep Neural Network AI-agent to adjust doses of a P binder, vitamin D, and a calcimimetic to drive P, Ca, and PTH to target ranges. Simulations were performed over 18 months.

Results: Using a QSP model of CKD-MBD, we trained an AI agent to guide precision dosing of P binder, vitamin D, and calcimimetic. We validated the agent under three simulated scenarios of P binder adherence. Simulation results show that control of intestinal P absorption is paramount in treatment of CKD-MBD. Failure to control P level severely compromises control of vascular tissue calcification even when Ca and PTH are controlled pharmacologically.

PO0339

Differences in 25-Hydroxyvitamin D Clearance by eGFR and Race: A Pharmacokinetic Study
Simon Hsu, Leila R. Zelnick, Yvonne S. Lin, Cora M. Best, Bryan K. Kestenbaum, Lynn M. Rose, Andrew N. Hoofnagle, Ian H. de Boer. University of Washington, Seattle, WA.

Background: 25-hydroxyvitamin D (25(OH)D) clearance is an essential yet often overlooked determinant of circulating 25(OH)D concentration, the prevailing marker of vitamin D status. Observational studies associate markers of low 25(OH)D clearance with poor clinical outcomes and suggest differences in 25(OH)D clearence by kidney function and race, but these potential variations have not been tested using gold-standard methods.

Methods: We administered intravenous deuterated 25(OH)D3 (d-25(OH)D3) in a pharmacokinetic study of 87 adults with a wide range of kidney function, including normal estimated glomerular filtration rate (eGFR = 60 ml/min/1.73m2, n=43), non-dialysis chronic kidney disease (CKD; eGFR < 60 ml/min/1.73m2, n=24), and kidney failure treated with hemodialysis (n=20). We measured d-25(OH)D3 and deuterated 24,25-dihydroxyvitamin D (D3 concentrations over time. We re-measured 25(OH)D clearance in a subset of participants after 12-16 weeks of 2000 IU/day of oral vitamin D3 (n=18).

Results: There was a significant 25(OH)D clearance difference between values (time1 - time 0) is the delta value. Associations between variables were performed using Wilcoxon matched-pairs
test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

The Vitamin D Metabolite Ratio and Change in Bone Density and Fracture Risk in Older Adults

Charles Ginsberg,1 Ronit Katz,2 Andrew N. Hoofnagle,3 Jan M. Hughes-Austin,1 Lindsay M. Miller,4 Jessica O. Becker,5 Stephen B. Kritchevsky,6 Michael Shlipak,7 Mark J. Sarnak,8 Joachim H. Is.9 1University of California San Diego, La Jolla, CA; 2University of Washington, Seattle, WA; 3University of California San Francisco, San Francisco, CA; 4Tufts Medical Center, Boston, MA; 5Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Recent studies have suggested that 25-hydroxyvitamin D (25(OH)D) may be a poor biomarker of bone health. Higher concentrations of its catabolic product 24,25-dihydroxyvitamin D [24,25(OH)2D] and a higher ratio of 24,25(OH)2D to 25(OH)D (the vitamin D metabolite ratio [VMR]) may provide additional information on vitamin D receptor activity and bone health.

Methods: We measured 24,25(OH)2D, 25(OH)D, 25(OH)2D and serial bone densitometry scans over a 9-year period, in 761 community dwelling older adults, that participated in the Health Aging and Body Composition Study. Participants were followed for a median time of 11 years for any fractures. 24,25(OH)2D and 25(OH)D were used to calculate the VMR. We used linear mixed models to assess the relationship between 24,25(OH)2D, 25(OH)D, 1,25(OH)2D, and the VMR with annual change in hip, lumbar and thoracic spine bone mineral density (BMD). We used Cox models to assess the relationships between these parameters and fracture risk.

Results: Study participants had mean age 75±3 years, 49% were female, 42% were black, and 23% had CKD. Lower VDBP concentrations were associated with male sex, lower serum albumin and Gc2/Gc2 VDBP phenotype in multivariable models. In fully adjusted models, each 1% higher VDBP was associated with a 0.92%, 0.76% and 0.57% higher 24,25(OH)2D3, 25(OH)D3, and the 1,25(OH)2D3 (Table 1). The VMR was independent of VDBP concentration, [0.16% (95% CI: 0.11-0.24)] higher VMR per 1 mg/dl VDBP (p=0.247).

Conclusions: In diverse cohort of community dwelling older adults, the VMR was independent of VDBP concentration whereas VDBP was strongly directly associated with the individual vitamin D metabolite concentrations. The VMR may serve as an important biomarker of vitamin D status and clinical outcomes that can be utilized in populations with a large spectrum of VDBP concentrations.

PO0341

The Vitamin D Metabolite Ratio Is Independent of Vitamin D Binding Protein Concentration

Charles Ginsberg1, Andrew N. Hoofnagle,2 Ronit Katz,3 Jessica O. Becker,4 Stephen B. Kritchevsky,5 Michael Shlipak,6 Mark J. Sarnak,7 Joachim H. Is.8 1University of California San Diego, La Jolla, CA; 2University of Washington, Seattle, WA; 3University of California San Francisco, San Francisco, CA; 4Tufts Medical Center, Boston, MA; 5Wake Forest University School of Medicine, Winston-Salem, NC.

Background: 25-hydroxyvitamin D (25(OH)D) may be a poor marker of vitamin D status due to variability in vitamin D binding protein (VDBP) between individuals and groups. The vitamin D metabolite ratio [VMR, the ratio of 24.25(OH)2D3 to 25(OH)D3] is a marker of vitamin D status that has been hypothesized to be independent of variability in VDBP. This hypothesis has not been directly evaluated.

Methods: We measured 25(OH)D3, 24.25(OH)2D3, 1,25(OH)2D3, and VDBP in 377 community dwelling older adults that participated in the Health Aging and Body Composition Study. 24.25(OH)2D3 and 25(OH)D3 were used to calculate the VMR.

PO0345
Renal Clearance of Intact and C-Terminal FGF-23 in Man
Joachim H. Ix,1,2 Alfonso J. Houben,3 Abraham A. Kroon,4 Peter W. de Leeuw,5 Andrew N. Hooftpagel,6 Charles Ginsberg,1 Ronit Katz,4 Alexander Bullen,1 Shilpa Sharma,1,7 University of California San Diego, La Jolla, CA; 2VMRF/VA San Diego Healthcare System, San Diego, CA; 3Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; 4University of Washington, Seattle, WA; 7University of California Los Angeles, Los Angeles, CA.

Background: The ratio of C-terminal (cFGF23) to Intact FGF23 (iFGF23) is higher in persons with higher eGFR. Mechanisms are unclear. Differential renal clearance is one possibility.

Methods: Patients were referred for clinically suspected renal artery stenosis (RAS), and maintained off BP meds for 21 days before angiography. This study includes those found without RAS (N=93). Blood was obtained from the aorta (Ao) and bilat. renal veins (RV), and renal blood flow (RBF) was measured using xenon washout. Single pass % reductions of each measure [(Ao – RV/Ao)*100] was calculated, left and right was averaged, and multiplied by RBF to provide renal clearance in ml/min/100g kidney tissue.

To determine the relative renal clearance, we calculated the cFGF23/iFGF23 clearance ratio (C/I ratio) and evaluated its relationship with eGFR.

Results: Mean age was 52±11 years, 22% were women, all were white, eGFR was 77±26 ml/min/1.73m² and directly measured Cr clearance was 72±4 ml/min/100g. Renal clearance of cFGF23 was similar to Cr, while iFGF23 was 37% higher (C/I ratio 0.73 ± 0.10). The clearance of cFGF23 and iFGF23 were directly correlated to eGFR (r=0.31 and 0.35). However, their relative clearance was similar across the range of eGFR (r=0.01). Results were similar in models adjusted for age, sex, and BMI.

Conclusions: Renal cFGF23 clearances (which measures both iFGF23 and c-terminal fragments) is similar to Cr, whereas iFGF23 clearance is higher, suggesting that renal clearance of c-terminal fragment clearance is low. While renal cFGF and iFGF23 clearance were both reduced in persons with lower eGFR, the relative efficiency of clearance of cFGF23 vs. iFGF23 appeared similar across the range of eGFR.

Single Pass Percent Reduction and Renal Clearance of C-terminal and Intact FGF23 in Man (N=93)
Factors Associated with Change in Fibroblast Growth Factor 23 Levels from Midlife to Late-Life: The ARIC Study

Junichi Ishigami, YasuyukiHonda, Amy B. Karger, ElizabethSelvin, Josef Coresh, Pamela L. Lutsey, Kunihiro Matsushita, Johns Hopkins University, Baltimore, MD; University of Minnesota, Minneapolis, MN.

Factors associated with change in fibroblast growth factor 23 (FGF23) levels from midlife to late-life are not well-characterized in the general population.

Methods: Among 5,891 participants of the Atherosclerosis Risk in Communities Study who had serum level of FGF23 measured during midlife (visit 3, 1993-1995, mean age 58 years, 58% women, 23% black race) and late-life (visit 5, 2011-2013, mean age 76 years), we explored demographic and clinical factors associated with change in FGF23 levels. Change in FGF23 levels was regressed on pre-specified factors assessed at visit 3 of age (above vs. below median), sex, race, ever smoke, high BMI (a < 30 kg/m²), hypertension, diabetes, history of CVD, and reduced eGFR (a vs. < 60 mL/min/1.73m²) using multivariable linear regression models.

Results: The mean FGF23 increase was 2.7% (95%CI, 2.0-3.2) per 2 years from midlife to late-life. However, the associations were strongest for reduced eGFR and diabetes with similar degrees of associations (AFCG23, 6.7 [95%CI, 2.7 to 10.6] pg/mL for reduced eGFR and 6.7 [4.4 to 9.0] pg/mL for diabetes) independent of each other.

Conclusions: In addition to reduced eGFR, we identified diabetes, hypertension, female, older age, and white race as predictors of an increase in FGF23 levels from midlife to late-life. Among these, the strongest association of diabetes independent of kidney function deserves future investigations.

Intact and C-Terminal Fibroblast Growth Factor 23 Assays: Do Kidney Function, Inflammation, and Iron Deficiency Influence Relationships with Clinical Outcomes?

Shilpa Sharma, Ronit Katz, Alexander Bullen, Alfonso J. Houwen, Michael Shlipak, Joachim H. Ix. University of California Los Angeles, Los Angeles, CA; University of California San Diego, La Jolla, CA; Maastricht Universiteit Medisch Centrum+ Interne Geneeskunde, Maastricht, Netherlands; University of Washington, Seattle, WA.

Background: Higher fibroblast growth factor-23 (FGF23) concentrations are associated with heart failure (HF) and mortality, but strengths of associations differ depending upon FGF23 assay type. We investigated whether iron deficiency, inflammation, and kidney function account for these differences.

Methods: In 844 Cardiovascular Health Study participants, using a case-cohort design, we examined associations of intact and C-terminal FGF23 with risk of mortality and HF, using modified Cox models to account for case-cohort design, adjusting sequentially by iron status, inflammation, kidney function or their combinations.

Results: C-terminal FGF23 more strongly correlated with ferritin (r = -0.26) and CRP (r = 0.21) than intact FGF23 (r = 0.04 & r = 0.07, respectively). The two FGF23 assays moderately correlated with one another (r = 0.47). During follow up, there were 658 deaths, and 220 incident HF events. FGF23 measured by either assay was associated with mortality in unadjusted analysis (intact FGF23 HR per two-fold higher 1.45; 1.25-1.68; C-terminal FGF23 1.38; 1.26-1.50). Adjustment for kidney function completely attenuated associations of intact FGF23 with mortality (HR 1.00; 0.85, 1.17; Figure 1), but had less influence on the C-terminal FGF23-mortality association (HR 1.15; 1.04, 1.28). Results were similar for HF where the HR for intact FGF23 went from 1.57 (1.25, 1.97) to 0.99 (0.76, 1.28) with eGFR and albuminuria adjustment, whereas C-FGF23 went from 1.45 (1.25, 1.68) to 1.16 (0.97, 1.38). Adjustment for iron deficiency and inflammation did not meaningfully influence the differential associations of the two assays with either endpoint.

Conclusions: The associations of biologically active FGF23 with clinical endpoints may be weaker than previously thought.

FGF-23 Is Induced by Glucocorticoid Stimulation In Vivo and In Vitro:

Induction of FGF-23 Gene Expression and Plasma Levels by Glucocorticoids in Adult Human Osteocytes

Michea. Luis Alzamo. Rodrigo Barrientos, Angela Delucchi, Luis Machea. Universidad de Chile Facultad de Medicina, Santiago, Chile.

Background: Previous data have suggested that glucocorticoid (GC) treatment may induce plasma fibroblast growth factor 23 (FGF23). Recently, we have reported that in prepubertal renal transplantation children, chronic GC treatment was associated with increased plasma FGF23 levels, that was related to decreased bone growth in vivo and in vitro. Our objective was to evaluate whether GC treatment modulate FGF23 in adult patients.

Methods: Translational approach. This included an observational clinical study of patients who began GC treatment (prednisone 1 mg/kg/day), estimated glomerular filtration rate (eGFR) over 60 mL/min/1.73m². Measurements of intact FGF23 were performed before initiation and 2 months later. Also we performed in vitro and in vivo analysis with cell cultures and experimental rat models which were treated with GC, measurements of plasma and bone FGF23 expression were performed.

Results: We recruited 10 patients who began GC treatment. We observed a significant increase in plasma intact FGF23 levels at 2 months (57% increase as compared to baseline values): baseline values: 18.9 +/- 4.2 pg/mL; 2 months: 29.7 +/- 5.2 pg/mL; p<0.001. No significant changes in renal function were detected. Also, rats treated with prednisone had a significant increase in plasma FGF23 and bone FGF23 expression after GC treatment. Finally, pharmacological blockage of glucocorticoid receptor alpha in vitro prevented the increase of FGF23 expression in bone tissue.

Conclusions: Sustained glucocorticoid treatment is associated to increased FGF23 expression and plasma levels. This effect should be evaluated in larger groups of patients to evaluate its potential relevance.

PO0350

PTH 1-84 and Bone Alkaline Phosphatase Are Independently Associated with Mortality, Whereas FGF-23 Predicts Dialysis Initiation in CKD Patients
Silvia M. Titan,1,2 Isabela M. Bensenor,1 Paulo Lotufo,1 Rosa M. Moyes.1
1Universidade de Sao Paulo, Sao Paulo, Brazil; 2Tufts Medical Center, Boston, MA.

Background: Despite the fact that CKD-MBD is a risk factor for CKD morbidity and mortality, studies of its role regarding the role of individual biomarkers are variable. In addition, dimensionality reduction techniques have not been applied in CKD-MBD. The aim of our study was to evaluate a panel of CKD-MBD biomarkers, namely Ca, P, PTH 1-84, FGF-23, 25-vitamin D, 1,25-vitamin D, bone alkaline phosphatase (BAP) and sclerostin individually and collectively related to death and KRT.

Methods: Events of death and KRT in 454 participants of the Progredir Cohort (Sao Paulo, Brazil) with predominantly CKD G3 and G4 were ascertained after a median follow-up of 6 years. Those with missing values were excluded (n=25) and 4 were lost to follow-up. The association of individual CKD-MBD parameters (DiaSorin® assays) and factors derived from factorial analysis was evaluated through Cox and Competitive Risk models (R package “cmprsk”).

Results: Mean age was 68(12)y, mean eGFR was 38(15) mL/min/1.73m², 63% were male and 56% diabetic. In univariable analysis, sclerostin, BAP, PTH, and factor I were associated with death and 1.25vD3, sclerostin, BAP, FGF-23, PTH, Ca, P, and factor I were associated with KRT. After adjustments, BAP, PTH, and factor I remained associated with death, and PTH-FGF-23 remained associated with KRT (Table). The addition of BAP and PTH (with interaction) to a reference model significantly improved the model fit for death (p<0.01). The addition of FGF-23 with interaction with P significantly improved the model fit for KRT (p=0.0046).

Conclusions: PTH and BAP are positively associated with death and improved its prediction model. This finding suggests that BAP could be reflecting not only bone turnover but also vascular calcification. FGF-23 is associated with the risk of bone turnover but also vascular calcification. FGF-23 is associated with the risk of mortality, the results of studies regarding the role of individual biomarkers are variable. In addition, dimensionality reduction techniques have not been applied in CKD-MBD. The aim of our study was to evaluate a panel of CKD-MBD biomarkers, namely Ca, P, PTH 1-84, FGF-23, 25-vitamin D, 1,25-vitamin D, bone alkaline phosphatase (BAP) and sclerostin individually and collectively related to death and KRT.

Funding: Government Support - Non-U.S.

Effect of PTH Dosing Frequency and Amplitude on Bone Health: From Anabolism to Catabolism
Alhajj Cherif1,2, Peter Kotanko1,3 On behalf of the GCC-DOPPS Study Group
1Arbor Research Collaborative for Health, Ann Arbor, MI; 2The Royal Hospital, Ministry of Health, Muscat, Oman; 3Dubai Medical College, Dubai, United Arab Emirates; 4Jahra Hospital, Jahra, Kuwait; 5DSFH, Jeddah, Saudi Arabia; 6King Abdulaziz University, Jeddah, Saudi Arabia; 7Hamad General Hospital, Doha, Qatar; 8Salmaniya Medical Complex, Manama, Bahrain; 9King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; 10Amgen UAE, Dubai, United Arab Emirates.

Background: In patients with chronic kidney disease or primary hyperparathyroidism, chronically elevated parathyroid hormones (PTH) levels exert catabolic effects on the bone. In contrast, PTH cycling or daily application of teriparatide (TP) promotes bone formation. These responses have important clinical and therapeutic implications. Although the anabolic effects of PTH cycling are widely accepted, the underlying dynamics are not well understood.

Methods: We developed a physiology-based model quantitating the interrelations of osteoclasts, osteoblasts and osteocytes on bone remodeling (Cherif et al., NDT 33(1), 2018, i165-6). Using the validated model, we explore the effect of altered PTH (TP) dosing (e.g., dosing frequency and amplitude) on bone catabolism and anabolism, respectively.

Results: The model accurately predicts differential responses of anabolic and catabolic effects of continuously and intermittently elevated PTH (TP) levels, respectively. We observe that intermittent dosing of PTH with a high frequency and amplitude induces bone catabolism similar to that seen with chronically elevated PTH. We see a more than 3-fold change from baseline in osteoclastic over osteoblastic activities, resulting in catabolism. Low PTH frequency with high dosing amplitude induces both osteoclastic and osteoblastic activities, but the net result is bone anabolism. Figure 1 shows a region where high osteoclastic activities exceed osteoclastic resorption. These findings suggest the existence of optimal PTH (TP) frequency-amplitude values that enhance anabolic gains, beyond which there can be a detrimental effect on bone.

Conclusions: Our results suggest that both frequency and amplitude of PTH (TP) cycling affect the balance of catabolic and anabolic effects. Understanding the underlying mechanism of differential responses induced by intermittent and continuous levels of PTH, respectively, may provide new therapeutic options for patients and minimize unintended, unforeseen and adverse effects.

Illustrates regions with high osteoblastic and osteoclastic activities corresponding to anabolic gains and/or catabolic loss in bone health as a function of dosing frequency and amplitude.
PO0353
Chemical Characterization and Quantitation of Circulating Intact Parathyroid Hormone and Parathyroid Hormone Fragments by High-Resolution Mass Spectrometry in Chronic Renal Failure
Kittrawee Kritmetapak,1 Louis A. Losbanos,1 Jolaine M. Hines,2 Katherine O’Grady,3 Candice Z. Utmer,1 Hubert W. Vesper,1 Felicity T. Enders,1 Ravinder Simha1 Rajji Kurup,1 Khon Kaen University, Khon Kaen, Thailand; 2Centers for Disease Control and Prevention, Atlanta, GA; 3Mayo Clinic Minnesota, Rochester, MN.

Background: The precise concentrations of full-length parathyroid hormone (PTH 1-84) and the identity and concentrations of PTH fragments in patients with various stages of chronic renal failure (CRF) are unknown.

Methods: We developed a liquid chromatography-high resolution mass spectrometry (LC-HRMS) method to characterize and quantitate PTH 1-84 and PTH fragments in the serum of 221 patients with progressive renal dysfunction. Following capture by matrix-bound amino-terminal or carboxyl-terminal region-specific antibodies and elution from matrix, full-length PTH and PTH fragments were identified and quantitated using LC-HRMS. PTH 1-84 was simultaneously measured using an intact PTH (iPTH) immunoassay.

Results: Full-length PTH 1-84 and eight PTH fragments (PTH 28-84, 34-77, 34-84, 37-77, 37-84, 38-77, 38-84, and 45-84) were unequivocally identified and were shown to increase significantly when the eGFR declined to less than 17-23 mL/min/1.73 m². Serum concentrations of PTH 1-84 were similar when measured by LC-HRMS following capture by amino-terminal or carboxyl-terminal immunocapture methods. Serum PTH 1-84 concentrations measured by LC-HRMS were significantly lower compared with PTH measured by an iPTH immunoassay in patients with eGFRs of less than 30 mL/min/1.73 m². PTH 7-84 was below the lower limit of quantitation of the method (<50 pg/mL).

Conclusions: LC-HRMS accurately quantitates full-length PTH, carboxyl-terminal PTH fragments, and mid-region PTH fragments, in the serum of patients with progressive renal failure. Serum concentrations of PTH 1-84 and PTH fragments increase when eGFR decreases to less than 17-23 mL/min/1.73 m². PTH values measured by LC-HRMS are lower than those obtained from an iPTH immunoassay in severe CRF.

PO0355
Real-World Experience with Etelcalcetide in an Academic Dialysis Program
Dennis Hu, Benjamin Lobo, Brendan T. Bowman. University of Virginia Health System, Charlottesville, VA.

Background: High parathyroid hormone (PTH) levels may increase fracture risk, vascular calcification, and cardiovascular disease in end-stage kidney disease (ESKD) patients. Treatments include phosphorus binders, Vitamin D analogues, and cinacalcet. However, most ESKD patients persist with high PTH levels. Etelcalcetide (ETC) is an injectable calcimimetic recently approved to treat hyperparathyroidism in ESKD. To date, few studies have described the safety and efficacy of ETC on calcium (Ca) and PTH levels in real world usage.

Methods: This retrospective chart review of 195 in-center HD patients describes those who received a stable dose of ETC for at least 12 consecutive weeks. ETC dose, Ca, and PTH levels were obtained monthly x 3 months prior to ETC start and up to 9 months post. 23 patients were included for 2 or more doses of ETC. Overall and severe hypocalcemia were defined as corrected Ca <8.3 and <7.5 mg/dL, respectively.

Results: See Table 1. PTH changed from +3.37% (2.5 mg) to -32.57% (10 mg) to -3.19% (15 mg). As expected, ETC use yielded a statistically significant lower PTH when compared to pre-treatment average of 1 and 2 months pre-drug PTH values versus 3 months post drug average (p<0.0034 via t-test for related samples). Corrected Ca decreased in a dose dependent fashion from 0.22% (2.5 mg) to 11.89% (15 mg). Overall, hypocalcemia occurred in 36.6% of patients. Severe hypocalcemia ranged between 0% (2.5, 5, 12.5, 15 mg) and –1% (7.5, 10 mg).

Conclusions: Prior studies have used aggressive PTH lowering targets (<300 ng/mL or >30% reduction from baseline) yielding high rates of hypocalcemia (61-68%). Our study is the first to describe results of a typical real world dosing strategy. Our results suggest that PTH levels decrease in a dose dependent fashion and severe hypocalcemia is rare at doses >10 mg diminishing PTH reductions which could be due to a preponderance of patients with refractory / tertiary hyperparathyroidism. Rates of overall and severe hypocalcemia were lower here. Limitations of this study include limited adjustment for confounding variables, retrospective nature and small population at higher doses.

PO0354
Management of Secondary Hyperparathyroidism Among Patients Who Transition from Daily At-Home to Three-Times-Weekly Oral Cinacalcet Given In-Center
Steph Karpinski,1 Scott Sibbel,1 Adam G. Walker,1 Gilbert Marlowe,1 George R. Aronoff,2 Deborah A. Denner,1 Steven M. Brunclik,1 Frances F. Tenor,1 Davita Clinical Research, Minneapolis, MN; 2Davita Inc, Denver, CO.

Background: Results of a small phase 1 clinical trial demonstrated the safety and potential utility of 3X weekly in-center administration of cinacalcet to control secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients. Moreover, a larger observational study demonstrated comparable control of SHPT among HD patients who initiated 3X weekly cinacalcet in-center to those who initiated cinacalcet at home. The present study assessed the effectiveness of 3X weekly in-center cinacalcet among HD patients who transitioned from cinacalcet administered daily in at-home dialysis centers to cinacalcet administered 3X weekly in-center dialysis centers from July 2018 to December 2019. Patients were followed forward in time for up to 9 months after transition to in-center cinacalcet or until loss to follow-up or end of study. Generalized linear models and 95% confidence intervals (CIs) were calculated for parathyroid hormone (PTH), calcium (Ca), and phosphorus (Phos). Hypocalcemia events were defined as Ca <8.4 mg/dL.

Methods: Patients included in this analysis were ≥18 years of age, receiving standard in-center HD, Medical beneficiaries, and had prior physicien order to transition from daily at-home cinacalcet to given 3X weekly in-center (July 2018 to December 2019). Patients were followed forward in time for up to 9 months after transition to in-center cinacalcet or until loss to follow-up or end of study. Generalized linear modeled means and 95% confidence intervals (CIs) were calculated for parathyroid hormone (PTH), calcium (Ca), and phosphorus (Phos). Hypocalcemia events were defined as Ca <8.4 mg/dL.

Results: We identified 874 qualifying HD patients who transitioned from at-home to 3X weekly in-center cinacalcet administration during the study period. Among patients with baseline PTH >800 pg/mL, PTH levels initially increased but stabilized after transition. Among patients with baseline PTH 800 to 1599 pg/mL and PTH >1600 pg/mL, PTH levels initially decreased but then stabilized following transition. Ca and Phos levels were generally stable for all patients following transition. Hypocalcemia was observed in approximately 25% to 38% of patients during follow-up.

Conclusions: These results suggest that SHPT can be stably maintained by transitioning patients from daily at-home cinacalcet to cinacalcet given in-center 3X per week. We postulate that increased prescription adherence is the likely factor mediating this effect.

PO0356
The Cost Effectiveness of Alternate-Day Cinacalcet Therapy for Secondary Hyperparathyroidism (SHPT) in Hemodialysis Patients
Mohammed A. Alhomrany,1 Muhammed Saeed,1 Dujanah H. Mousa,1 Ali Alharbi,1 Saeed Al-Ghamdi,1 Diaverum AB Diaverum AB, Riyadh, Saudi Arabia; 2King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.

Background: CKD defines as abnormalities of kidney structure or function, present for more than 3 months with implication for health. Secondary hyperparathyroidism (SHPT) is one of implication of CKD, which eventuate with decrease in GFR. The initial treatment starts with incremental approach, constrain of Dietary Phosphorus, use of calcium and non-calcium phosphorus binders and additional Vit D Analogues. Next approach to Secondary hyperparathyroidism (SHPT) after poor response to initial therapy is to use Cinacalcet. Cinacalcet act by activating calcium sensing receptor of parathyroid hormone gland directly and it bypass normal physiological process. It has half-life of 24-40 hours. Cinacalcet is excreted 80% through kidney and 20% through liver.

Methods: We did prospective control study by following Dialysis patients (N=88) who were receiving alternate day Cinacalcet either by physician’s choice or due to noncompliance to home medications. We followed Intact PTH every 3 months, Serum Calcium and phosphorus every month after start of alternate day therapy until six months and compared it with 6 months data before start of alternate day Cinacalcet. Data was analyzed by using paired T-Test.

Results: A total of 88 patients were enrolled in the study, who were on hemodialysis for at least one year. The mean age of patients was 49.17± 15.80, and 50.8 percent of them were males. The mean duration of dialysis was 6.68 ± 5.27 years and 40.9 percent of patients had diabetic nephropathy as a cause of End stage renal disease. The patients were transferred from once daily dosage to 3 times per week hemodialysis dosage. The mean post hemodialysis dose of cinacalcet was 62.73 ± 27.71 mg. The baseline mean PTH value before initiating alternate dose was 986.69 ± 503.370 and after was 798.24 ± 503.370 and the P value was 0.001. The mean serum calcium before was 8.28 ± 2.30 and after it was 8.72 ± 1.42 with a p value of 0.03. Serum phosphorous before and after was, 4.66 ± 1.53, 4.86 ± 1.19 with a P value of 0.147.

Conclusions: Cinacalcet effectively controls secondary hyperparathyroidism even with modified regimen as used in our study. Cinacalcet showed significant reductions of PTH with intermittent (3/week) dosing and thus is more cost effective and has better directly observed compliance.

A Real-World Observational Study of Calcimimetic Use in Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) in Europe

**Methods:** Through a Network Meta-Analysis (NMA) of 95 RCTs comprising a total of 1426 patients were included in the analyses. Compared to placebo, treatment with both PCT and ERC lowered levels of PTH in a statistically significant manner. No statistically significant differences in PTH reduction were found between PCT and ERC. Treatment with PCT significantly increased calcium levels compared to placebo (effect size: 0.30 mg/dl, 95% CI: 0.21 to 0.40 mg/dl), with the calculated effect of ERC on calcium (effect size: 0.10 mg/dl) was not significant (95% CI: -0.03 to 0.23 mg/dl). The calculated difference of effects between treatment with PCT and ERC shows that PCT significantly raises levels of calcium by 0.2 mg/dl (95% CI: 0.37 to 0.04 mg/dl). No differences in effects on phosphate were observed. Some analyses using a fixed effects model revealed similar PTH reductions and larger increases in calcium from PCT observed in the analyses.

**Conclusions:** This NMA showed that ERC is non inferior in lowering PTH levels vs. PCT. ERC displayed avoidance of clinically relevant increases in serum phosphorus and calcium, offering a new well tolerated treatment option for the early management of SHPT in patients with ND CKD.

**PO0359**

Parathyroidecmy Improves Muscular Function but Not Muscle Mass in Hemodialysis Patients with Severe Hyperparathyroidism

**Methods:** We prospectively evaluating muscle mass, strength and performance of 30 patients before and after 6 months of PTH by using Actigraph GT3X accelerometer, timed-up-and-GoTo (SIT), Sit-to-Stand test (STT) and muscle strength tests (Latissimus dorsi, supine(SP), knee extension(LP)). Body composition was assessed by dual energy x-ray absorptiometry, and REE was examined by indirect calorimetry. Participants completed the SARC-F questionnaire.

**Results:** At 6 months after PTH, 20 patients who already completed the protocol, showed a significant drop in PTH [1510(1368-1885) vs. 91(38-260) pg/mL; p<0.01], a significant increase of number of steps/day [4759(3572-6185) vs. 63444(423455-800) p = 0.04] and improvements of strength tests: IGS/214x vs. 3134 kg kg gp k kg [p= 0.01]; SP/261x vs. 316 kg gp [p=0.01] and LP/242x vs. 503 kg gp [p=0.01]. In addition, there was an improvement of SARC-F [3(1-7) vs. 2(1-6) p=0.02] and SIT [6(5-9) vs. 5(4-8) p=0.01]. We noticed an increase in KFJ ([199 Vs 201 ugl/p]<0.04) and HOMA index [1.6 Vs 1.72 p<0.02], but no variation was found in serum albumin.

**Conclusions:** In hemodialysis patients with sHPT undergoing PTH, there were improvements of muscular function and bone mass, but not of muscle mass, at 6 months after PTH. Our findings suggest that PTH-associated sarcopenia is mediated not only by a decrease in muscle mass but also by muscle dysfunction.

Indications and Justification for Parathyroidecmy in Secondary Hyperparathyroidism

**Introduction:** Hyperparathyroidism (HPT) is a common complication of CKD, which is treated by diet, medications and surgery. Parathyroidecmy (PTEctomy) is reserved for patients with refractory HPT. There are no guidelines for the timing or type of surgery. We describe five patients with HPT, who were treated with different modalities with unsatisfactory outcomes.

**Case Description:** We present 5 patients in a table format. Patient 1 had total PTEctomy resulted in calcemia needing hormonal therapy. After 3 years, she remains hypocalcemic requiring high doses of Vit D and calcium. Selecting a suitable phosphate binder in this patient was difficult due to hypocalcemia. Patient 2 underwent total PTEctomy with autotransplantation which resulted in low calcium levels that resolved over time, but PTH levels remained very low. Patients 3 and 4 refused surgery and their PTH levels fluctuated significantly, falling to levels much below the acceptable level of 600 pg/ml. Patient 5 underwent partial PTEctomy and 2 enlarged PT glands were removed. This resulted in lower calcium and higher PTH levels than prior to surgery.

**Discussion:** The medical management for HPT in all five patients failed. We opted for surgery when the PTH levels were in a range of 1503 to 4000 pg/mL. The surgeon decided the type of surgery. In patient 1, intraoperative PTH was measured that resulted in removal of only three glands. But within a very short time, the PTH bounch back to 2500 pg/mL which was much higher than their level at the time of parathyroidectomy was performed. We cannot recommend specific surgical modality based on this experience. Therefore, we strongly feel that there is a need for larger controlled studies to elucidate specific guidelines for treating refractory HPT.
Nawal Palatal Brown Tumor in a Dialysis Patient

Introduction: Secondary hyperparathyroidism (SHPT) is a common complication of end stage kidney disease (ESKD) causing loss of bone density through increased osteoclastic activity. Imbalanced bone resorption and peri-trabecular fibrosis causes formation of hemosiderin-laden giant cell granulomas – brown tumors. Here is a case of palatal brown tumor in an ESKD patient which led to complications of hungry bone syndrome.

Case Description: A 57 yo F with ESKD on HD and SHPT presented with a growing palatal mass. She reported difficulty chewing and shortness of breath. A friable mass was palpable on the left side of the hard palate. Labs showed serum calcium (Ca) 9.5 mg/dL, i-PTH 4477 pg/mL, phosphate 5.1 mg/dL, and alkaline phosphatase (ALP) 1124 U/L. Parathyroid scan showed a focus of activity in the left thyroid bed. She underwent a mass resection and pathology revealed an atypical parathyroid adenoma without features of carcinoma. Her postoperative course was complicated by hungry bone syndrome with osteodystrophy, we must be mindful of brown tumors. Surgical excision with resection of the bone is the preferred treatment. Post-operatively, patients must be monitored closely for complications of hungry bone syndrome. Teriparatide is a recombinant human PTH which can be used to augment bone density. Despite parathyroidectomy, her i-PTH level increased to 919 pg/mL. Therefore, etelcalcetide was switched to 50 mg/day of cinacalcet, and her i-PTH level decreased to 208 pg/mL.

Discussion: Thus, the present case has resistance to etelcalcetide treatment but not cinacalcet, suggesting that his parathyroid gland might have partial deletion or mutation. We should consider the possibility of resistance to etelcalcetide treatment while treating secondary hyperparathyroidism.
PO0364

Unexplained Persistent Hypercalcemia After Liver Transplantation
Luba Muaddi, Kalathil K. Sureshkumar, Bhavna Chopra. Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.

Introduction: Hypercalcemia has been reported as a sequel of chronic liver disease in association with hyperbilirubinemia. Previous reports of hypercalcemia post liver transplant were thought to be potential rare complication of altered bone metabolism under intense immunosuppression and from prolonged immobilization. However the pathogenesis of this rare phenomenon has not been clarified to this date. We present cases of unexplained severe persistent hypercalcemia in three liver transplant recipients.

Case Description: Hypercalcemia post liver transplant in 3 recipients described in Table 1 and calcium trends shown in Figure 1

Discussion: Extensive work up for hypercalcemia was negative in our patients. Although immobilization could be contributory, other unrecognized possibilities are plausible. Immunosuppression with steroids and other agents, especially cyclosporine, has been hypothesized to cause calcium imbalance by inhibiting T cell activation and transcription of interleukin-2 which are involved in bone turnover. Depletion of T cells upregulates osteoclastogenesis through progestaglin production; by interfering with receptor activator of nuclear factor kappa ligand (RANK-L) and osteoprotegerin on osteoblasts. However, only one patient was on cyclosporine. Other, yet unidentified, factors modifying calcium metabolism could be involved. We would like to draw attention to this fascinating phenomenon in order to gain more insight. Low dialysate calcium, pharmacotherapy (Calcitonin, Pamidronate and Denusomab) along with improved mobility had successfully lowered serum calcium in these patients. One patient had hypocalcemia after Denusomab administration, hence needed careful monitoring.

Descriptions of hypercalcemia cases post liver transplant.

Figure 1: Calcium trends and treatments.

PO0365

A Rare Case of Hyperthyroidism Presenting with Symptomatic Hypercalcemia
Sameed K. Lodhi,1 Sranvan Jast,1 Hareem Ghazanfar.2 (Carle Foundation, Urbana, IL; 2King Edward Medical University, Lahore, Pakistan)

Introduction: Primary hyperparathyroidism and hypercalcemia are by far the most common causes of hypercalcemia in clinical practice. Asymptomatic hypercalcemia with minimally raise calcium levels have been documented in 20% of cases of hyperthyroidism as well and is related to increased bone resorption by osteoclasts and subsequent release of calcium into circulation. We describe a rare case of hypercalcemia with symptomatic hyperparathyroidism as the first clinical manifestation.

Case Description: A 60 year old male with a history significant for chronic kidney disease, stroke and hypertension was admitted to the hospital following a sympotmal event. Physical examination and baseline investigations were normal other than elevated calcium levels of 12.1 mg/dl. PTH levels and PTHrP levels were normal ruling out hyperparathyroidism and paraneoplastic related hypercalcemia. Vitamin D levels were also normal. Workup for multiple myeloma was negative. Thyroid panel was done which showed extremely low levels of TSH (<0.005 mU/L) with elevated T3 and T4 levels (12.9 ng/dl and 5.52 ng/dl respectively). Thyroid scan was performed which showed significant thyroiditis. Thyrotropin receptor antibody test also came positive. The patient was diagnosed with Graves’ disease based on the laboratory investigations and subsequently started on 5 mg methimazole TID. He also received one dose of zolendronic acid in the hospital. His calcium levels stabilized, falling from 12.4 to 9-10 mg/dl within 1 month. Patient received methimazole for a total of 7 months after which it was discontinued as his TSH levels (1.38 mU/mL), T3 levels (2.19 ng/dl) and T4 (0.78ng/dl) normalized. Patient further underwent radioiodine ablation for the treatment of Graves’ disease.

Discussion: In past, multiple cases have been reported of concurrent hyperparathyroidism or vitamin D deficiency in hyperthyroid patients. This case is unique as the patient presented with symptomatic hypercalcemia in the absence of other causes and in the absence of other more common symptoms of hyperthyroidism. To our knowledge, only 2 cases of hyperparathyroidism have been reported previously with hypercalcemia as the first clinical manifestation. Clinicians should be aware of association of hypercalcemia with hyperthyroidism as it will facilitate early diagnosis and appropriate intervention.

PO0366

Low Phosphate and Low Calcium Levels Predict Higher Risk for Adverse Events of Maintenance Hemodialysis
Takahiro Kuragano, Takeshi Nakanishi. Hyogo College of Medicine Kidney and dialysis, Nisinomiya, Japan.

Background: It is well known higher serum levels of phosphate (P) and calcium (Ca) associated with higher risk of cardiovascular disease (CVD) and premature death of hemodialysis (HD) patients. However, in the current situation that guidelines penetrated widely, there are few reports which investigated the association CKD-MBD related factors and adverse events of HD patients.

Methods: The study design was the multiple centers, observational study for 3yeras. 989 HD patients were enrolled in this study. Hb, ferritin, creatinine, total protein, albumin, total cholesterol, Ca and P levels were measured every 3 months. High-sensitivity C-reactive protein (hsCRP) and intact-parathyroid hormone (int-PTH) were also measured every six months. The correlation between CKD-MBD factors and adverse events were evaluated by the time depended cox hazard model.

Results: 82% (P), 83% (Ca), and 78% (int-PTH) of patients were maintained in a target range. After correlated with age, sex, past history of CVD, Hb, albumin and hsCRP, compared with the patients with target levels of P, patients with low P levels were significantly higher risk for CVD (P=0.042, HR:2.27), hospitalization (P=0.034, HR:2.44), and all caused mortality (P=0.03, HR:2.29). Compared with the patients who maintain target int-PTH levels, patients with lower (P=0.025, HR:1.46) and higher (P=0.04, HR:1.44) int-PTH were significantly higher risk for hospitalization. Furthermore, compared with the patients who maintain the target levels both of Ca and P, the patients with target Ca and low P levels (P=0.042, HR: 2.75) were significantly higher risk for CVD. And compared with the patients who maintain the target levels both of Ca and P, the patients with low Ca and low P levels (P<0.001, HR: 4.4) and target Ca and low P levels (P=0.22, HR: 2.0) were significantly higher risk for hospitalization.

Conclusions: Although after correlated by several clinical factors, we found that patients who maintain the low serum P levels bear significant higher risk for CVD and all caused mortality than patients who maintained higher Ca and P levels. Without doubt, extremely higher serum P, Ca, and int-PTH levels should be treated according to guidelines. However, in the current situation that guidelines penetrated widely, CKD-MBD management which considered the clinical conditions of low P, Ca, and int-PTH are needed.

PO0367

The True State of Hyperphosphatemia Management in Dialysis

Background: Hyperphosphatemia affects more than 80% of US dialysis patients and has been shown to have a direct link to increased morbidity and mortality. The objective of this study was to assess the current management of hyperphosphatemia in US dialysis patients and the ability to consistently control serum phosphorus over a six-month period.
Methods: Patient level data was collected via an online, HIPAA-compliant form in June 2019 as part of an independent chart audit. A total of 1,015 patient records (789 in-center HD, 200 PD, and 26 home HD) were submitted by 159 nephrologists. Patients had been on dialysis for at least six months (Mean: 26; Median: 15) and most were in LDO-affiliated units.

Results: Patients in the consistently high group had dialyses on longer than those consistently in target or in the target-high variability group (36 months vs. 23 months) and were also younger on average (53 years vs. 61 years). Those in the consistently high and high-target group (CH/HT) had a 37% higher daily pill burden (from binders) than those consistently in target. Patients dialyzing in Fresenius units were the most likely to be consistently in target (27%). Compared to those consistently in target, those in the CH/HT group were significantly more likely to have diabetes, obesity, heart failure and coronary artery disease. They were also six times as likely to have poorly controlled hypertension. Ethical concerns also was correlated with phosphate control with a disproportionate percent of non-white patients in the consistently high and high-target variability groups.

Conclusions: Not only is hyperphosphatemia rampant at any given time, but only a small minority of patients on phosphate binders (19%) are able to achieve consistent control, most patients fluctuate in and out of target. Increased phosphate binder dosing was not associated with better control and suggests that a new approach to the management of hyperphosphatemia is warranted.

PO0368

Hyperphosphatemia with Elevated Serum FGF-23 and PTH, Reduced Calcitriol, and Normal FGF7 Concentrations Characterizes Chronic Renal Failure in Humans

Kittrawee Kritmetapak,1,2 Louis A. Losbanos,3 Taylor Berent,1 Susan L. Atrashzadeh-Khan,1 Alicia Algeeciras-Schminich,1 Jolaine M. Hines,1 Ravinder Singh,1 Rajiv Kumar.1 Mayo Clinic Minnesota, Rochester, MN;1Kohn Kaen University, Khon Kaen, Thailand.

Background: Fibroblast growth factor 23 (FGF23), a phosphatonin produced by osteocytes, regulates phosphate (Pi) homeostasis and is increased in CKD. A recent study showed that low serum (ranging from 1 to 10 picograms per milliliter) FGF7 may contribute to hyperphosphatemia in patients with hypophosphatemia, and are elevated in some patients with tumor-induced osteomalacia and hypophosphatemia. We hypothesized that FGF7 might play a role in compensating for elevated Pi concentrations in CKD.

Methods: We measured serum concentrations of intact FGF7 (iFGF7; R&D Systems), iFGF23 (Eagle Biosciences), intact parathyroid hormone (iPTH) by enzyme-linked immunosorbent assays and determined s Pi, and 1,25-dihydroxyvitamin D (1,25(OH)2D, by mass spectrometry) among 75 non-kidney transplant patients with varying estimated glomerular filtration rate (eGFR). Relationships between these parameters and eGFR were explored.

Results: For eGFR of 60 or more (n=29), 45-59 (n=14), 30-44 (n=9), 15-29 (n=13), and under 15 mL/min/1.73 m2 (n=10), the median (IQ25-75) iFGF7 concentrations were 46.1 (40.8-56.1), 43.1 (39.2-55.3), 47.7 (38.5-54.6), and 46.1 (40.5-54.6) pg/mL, respectively (P < 0.01). At comparable eGFRs, median (IQ25-75) iFGF7 concentrations were 46.1 (40.8-56.1), 43.1 (39.2-49.2), 45.4 (38.5-53.8), 47.7 (38.5-54.6), and 46.1 (40.5-54.6) pg/mL, respectively (P < 0.01). Negative correlations between Pi (r = –0.46; P < 0.01), iPTH and iFGF8 (r = –0.33; P < 0.05), and a positive correlation between 1,25(OH)2D and eGFR (r = 0.51; P < 0.01) were demonstrated. Significant increases in iFGF23, iPTH, and Pi were observed at eGFRs of less than 33 (95% CI, 26.40-40.05), 29 (95% CI, 22.51-35.36) and 22 mL/min/1.73 m2 (95% CI, 19.25-25.51), respectively. Moreover, significant decreases in 1,25(OH)2D were observed at eGFRs of less than 59 mL/min/1.73 m2 (95% CI, 36.57-81.43). iFGF7 concentrations did not significantly correlate with eGFR, Pi, iFGF23, iPTH, and 1,25(OH)2D.

Conclusions: Increases in serum concentrations of Pi, iFGF23, iPTH, but not iFGF7, and decreases in 1,25(OH)2D are observed as renal function declines in CKD.

PO0369

Effects of a Reduced Phosphorous Diet on the Circulating Metabolome in Healthy Adults

Shejuti Paul, Orlando M. Gutierrez. University of Alabama at Birmingham, Birmingham, AL.

Background: Excess phosphorus intake is linked to hypertension, heart failure, and disorders of bone and mineral metabolism. The reasons for these associations are unclear. Most prior work on the effects of diet phosphorus have focused on changes in specific endocrine factors in the blood. Less is known about the effects of nutritional phosphorus intake on the human metabolome, which represents the integrated biologic response to changes in diet.

Methods: In 37 healthy adults, we performed a global metabolomic analysis using untargeted mass spectrometry in plasma samples obtained after consuming a high phosphorus diet (1,900/day) for 2 weeks (considered baseline for this study) and after consuming a reduced phosphorus diet (1200 mg/day) for 6 weeks. Metabolomic profiling was conducted by Metabolon, Inc. using standard protocols. Matched pairs t-tests were used to identify analytes that significantly changed from baseline to weeks six, with each individual serving as his or her own control.

Results: The mean age of study participants was 34±12 years, 36% were black and 49% were men. A total of 222 metabolites significantly changed from baseline to six weeks on a reduced phosphorus diet using a false discovery rate < 0.05 to take into account multiple comparisons. Major analytes which differed in six-week vs. baseline samples included metabolites related to transpyramin metabolism, microbiome related biochemicals, urea cycle, bile acids, corticosteroids and androgenic steroids, and acyl carnitines. Changes in specific analytes of note within each of these pathways are depicted in the Figure.

Conclusions: In healthy adults, a reduced phosphorus diet altered metabolites related to the microbiome, urea cycle, steroid hormones, energy and lipid metabolism.

PO0370

Hospital Admission Rates Among Hemodialysis Patients with Persistent Hyperphosphatemia Who Were Prescribed Changes in Phosphate Binder Treatment: A Retrospective Analysis of Recent-World Data

Sagar U. Nigwekar,1 Vidhya Parameswaran,2 Linda Ficociello,2 Claude Mullon,2 Michael S. Anger,2 Robert J. Kossman.1 Massachusetts General Hospital, Boston, MA;1 Fresenius Medical Care Renal Therapies Group, Waltham, MA;1Fresenius Medical Care North America, Waltham, MA.

Background: Phosphate binders (PB) may have different formulations, potency, and pill burden, however, there is limited data on hard outcomes to support decisions in PB therapy. The goal of this retrospective analysis is to determine the rate of all-cause hospital admissions of patients who, at baseline, remained hyperphosphatemic despite treatment with sevelamer carbonate (SC) and had prescriptions to either (1) switch to monotherapy sucroferic oxyhydroxide (SO) or (2) switched to Non-SO PB binders (Calcium Acetate, Lanthanum Carbonate, or Ferric Citrate) or added one of these PBs to SC therapy.

Methods: Deidentified clinical and prescription data were retrospectively extracted from the Fresenius Kidney Care data warehouse and pharmacy records. All prescription changes were the result of routine clinical care. We aimed to control for selection bias by using Inverse Probability of Treatment Weighting (IPTW). This method was chosen due to its ability to balance baseline characteristics between the two groups and maintain adequate sample size.

Results: We identified 1,076 patients with baseline hyperphosphatemia despite SC prescription who switched PB therapy, including 319 patients with SO therapy and 757 patients with Non-SO therapy. Patients switched to SO had 27 fewer hospital admissions per 100 patient-years compared to patients with Non-SO therapy (Table 1).

Conclusions: In a retrospective database analysis of hemodialysis patients previously treated with sevelamer carbonate and switched to SO or Non-SO phosphate binder therapy, patients switched to SO therapy had a lower rate of hospital admissions than patients switched to other, non-SO phosphate binders.

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group

Variables included in the Poisson regression model: HD vintage, congestive heart failure status, serum phosphorus and categories, iPTH and categories, (iPTH)
An Observational Analysis of Hospital Admissions and Total Member Costs Associated with the Use of Various Phosphate Binders Used in Dialysis Patients Included in ESRD Seamless Care Organizations

Kristian C. Lindemann,1 Christiana Ajala,1 Melissa M. Rosen,2 Claudia Mullan,2 Robert J. Kossmann,2 Terry L. Ketchersid,3 Linda Ficociello,2 Fresenius Medical Care North America, Waltham, MA; 1Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA.

Background: A prior observational study using real world data and estimates of hospitalization costs based on national data, found patients continuing succinyl ferric oxidehydroxy (SO) therapy had fewer hospital admissions and expected lower healthcare costs when compared to patients switching to another phosphate binder (PB). End Stage Renal Disease (ESRD) Seamless Care Organizations (ESCOs) coordinate treatment for 10% of Medicare dialysis patients in the U.S. By providing quality care, ESCOs may control costs by avoiding unnecessary hospitalizations. The aim of this analysis was to assess hospitalizations and costs associated with various PBs prescribed to dialysis patients in ESCOs.

Methods: Patients included in the analysis had PBs prescribed during 2016-2018 in ESCOs along with parathyroid (PTH) levels <500 pg/ml. Aggregated utilization and cost data from 24 ESCOs were used over 3 years. Total hospital admissions and member months (MM) were used to calculate hospital admission rates and rate ratios. The statements contained in this document are solely those of the authors and do not necessarily reflect the view or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Results: Hospital admission rates were found to be lower for SO (Table). Compared to MM treated with SO, an increased hospital admission rate of 11%, 20%, 32%, and 42% was observed for MM treated with SEV, CaAc, FC, and LC, respectively. In addition, the total per member per month (PMPM) healthcare costs were lower for SO ($5670) compared to FC ($5908), CaAc ($6104), CaAc ($6303), and SEV ($6354), respectively.

Conclusions: Data from 24 ESCOs showed differences in hospital admission rates with the lowest rate in SO (7.97 per 100 member month (MM)) and the highest in CaAc (11.28 per 100-MM). In addition, total costs of care per MM where SO was prescribed were lower when compared to other PBs.

Effect of Lanthanum Carbonate on Blood Pressure in CKD: The COMBINE TRIAL

Mitra Jamsheidian,1 Brett Larive,1 Jennifer J. Gassman,1 Kalani L. Raphael,4 Michel Chonchol,2 Joachim H. Is,1 Charles Ginsberg,1 1Cleveland Clinic, Cleveland, OH; 2University of Colorado Denver School of Medicine, Aurora, CO; 3University of California San Diego School of Medicine, La Jolla, CA; 4University of Utah Health, Salt Lake City, UT.

Background: Higher serum phosphate concentrations are associated with vascular calcification, cardiovascular events, and all-cause mortality. Emerging data suggests that higher serum phosphate may also be associated with increased blood pressure (BP). The effect of phosphate-lowering medication on BP has not been studied in a chronic kidney disease (CKD) cohort.

Methods: We evaluated patients from the CKD Optimal Management with Binders and Nicotinamide (COMBINE) Trial, a randomized, double-blind, placebo-controlled trial of phosphate binders and/or nicotinamide in patients with eGFR 20-45 ml/min/1.73m2. Our primary end point for this analysis was 12-month change in systolic BP (SBP). Randomization to lanthanum vs non-lanthanum treatment arms was our primary predictor variable. The secondary predictor variable was 24-hour urine phosphate excretion (a marker of dietary phosphate intake).

Results: 205 participants underwent randomization. The mean ± (SD) baseline age was 69±12 years, eGFR was 32±7 ml/min per 1.73 m2, and SBP was 129±17 mmHg. Over the 12-month trial, compared to the non-lanthanum arms (N=102), SBP in the lanthanum arms (N=103) rose by 5 mm Hg (P value 0.0497) after adjusting for baseline BP, age, sex, baseline eGFR, clinical center and number of antihypertensives over time. Within the lanthanum arms SBP rose by 5 mm Hg (95% CI 1, 9 mm Hg) and diastolic BP rose by 2 mm Hg (95% CI 0.4, 4 mm Hg). BP did not change in the non-lanthanum carbonate arms. There was no association between 24-hour urine phosphate excretion and change in BP.

Conclusions: Among trial participants with moderate to severe CKD, randomization to lanthanum carbonate was associated with increased SBP. Future studies should determine whether lanthanum carbonate influences absorption of anti-hypertensive medications.

Determing the Value of Pharmaceutical Treatment of Hyperphosphatemia with Phosphate Binders: A Systematic Review

Lindsey Sella,1 Melissa M. Rosen,1 Michael S. Anger,1 Robert J. Kossmann,2 Claudia Mullan.2 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA.

Background: Phosphate binders (PBs) are the primary therapeutic treatment for hyperphosphatemia in ESRD patients receiving dialysis. Medicare spending on PBs has been estimated to be over $1.5 billion. There is increased focus on value-based prescribing as a method to control rising healthcare spending in the U.S. However, guidance to support such decisions is limited. The purpose of this study was to review economic evaluations of PBs to understand if specific binders are associated with greater value to patients and payers.

Methods: We conducted a systematic literature review with results restricted to economic evaluations published in English in peer reviewed journals between January 2015 and May 2020. Studies included in the review reported cost-effectiveness outcomes.

Results: After removing irrelevant articles and duplicates, 8 publications were found that met our inclusion criteria. Four (50%) studies compared either sevelamer carbonate (SEV) or lanthanum carbonate (LC) to calcium-based binders. SEV or LC was cost-effective compared to calcium-based binders. Two studies focused on ferric hydroxy (FC) with one comparing FC to the standard of care (either calcium acetate, SEV, or LC), and the other to SEV or calcium acetate. The results favored FC based on differences in the use of erythropoiesis-stimulating agents and hospitalization risk. However, these studies did not examine the potential for unsafe levels of iron absorption associated with FC use. The remaining two studies evaluated succinyl ferric hydroxyso (SO). One study found SO to be cost-effective relative to SEV based on clinical trial data. The other analysis looked at patients prescribed SO for 2 years compared to those who discontinued use after 90 days and switched to another binder. This model estimated that SO use had the potential to be cost-saving based on reduced risk of hospitalization. We were unable to find an economic evaluation that compared the two iron-based binders, SO to FC.

Conclusions: This review demonstrates the need for more economic evaluations of phosphate binders. One cost-effectiveness analysis was found that compared two non-calcium binders (SO vs SEV) head-to-head. In addition to cost analyses, payers may benefit from reviewing real-world data to examine the clinical benefits of specific phosphate binders.

Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Novel Mechanism of Action Allows for Both Monotherapy and Dual-Mechanism Approach

David P. Rosenbaum, Yang Yang, Ardeyxa Inc, Fremont, CA.

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder, phosphate absorption inhibitor being developed to control serum phosphorus (sP) in patients with chronic kidney disease (CKD) on dialysis. It has a unique mechanism of action and acts locally in the gut to inhibit the sodium-hydrogen exchanger 3 (NHE3). This results in the tightening of epithelial cell junctions, reducing paracellular uptake of phosphate, the primary pathway of phosphate absorption, thereby reducing serum phosphorus concentrations.

Methods: Two Phase 3 studies were completed. An 8-week, double-blind (DB), randomized treatment period (RT) with a 4-week placebo (PBO)-controlled randomized withdrawal period (RW) examining the efficacy of TEN as monotherapy to treat hyperphosphatemia (HP) in patients with CKD on dialysis (NCT03427125) and A 4-week, randomized, DB, PBO-controlled study examining the efficacy of TEN administered with phosphate binders (BIND) using a dual mechanism approach to treat patients with uncontrolled HP (≥5.5 mg/dl) in patients with CKD on dialysis (NCT 03824587).

Results: In the monotherapy study, 219 patients were randomized to the RT, 164 patients (75%) completed the RT, and of these, 152 (93%) completed the RW. TEN achieved the primary endpoint with a LS mean difference of −0.8% (95% CI: −1.4, −0.2, p<0.01) in sP between TEN and PBO during the RW period. Approximately 50% of the patients treated with TEN achieved a mean sP reduction of 2.56 mg/dl from baseline to the end of the RT period. In the dual mechanism study, 236 patients were randomized to treatment. At week 8, the mean change in sP was significantly greater in the TEN+BIND arm (−0.84 mg/dl vs -0.19 mg/dl in the PBO+BIND arm, p=0.0004). Twice as many patients achieved a mean sP reduction of 2.56 mg/dl with TEN/BIND compared to PBO+BIND (up to 49.1% v. up to 23.5%, p<0.01).

In both studies, the most common treatment-emergent adverse event for patients treated with TEN was tenesmus and diarrhea, leading to discontinuation in 7.8% and 3.4% of patients respectively.
Tolerability of Tenapanor, an Investigational, First-in-Class, Non-Binder Therapy for the Control of Serum Phosphorus in Patients with CKD on Dialysis

David P. Rosenbaum, Stuart M. Spragut, Ardeyx Inc, Fremont, CA; NorthShore University HealthSystem, Evanston, IL.

Background: Phosphate binders are associated with gastrointestinal (GI) tolerability issues including constipation, diarrhea, nausea, and vomiting. Tenapanor (TEN), a first in class, non-binder, inhibits the paracellular absorption of phosphate in the GI tract by local inhibition of the sodium-hydrogen exchanger (NHE3), and may have a different GI profile because of its unique mechanism which also reduces dietary sodium absorption, increasing the sodium and water content of stool.

Methods: Data from a 12-week monotherapy study (TEN201), a 52-week monotherapy study (PHREEDOM), and a 4-week combination study (AMPLIFY) were analyzed to evaluate the GI tolerability of TEN. Adverse events were coded to system organ class and preferred term using the Medical Dictionary for Regulatory Activities (MedDRA) (v 18, 20, 21). MedDRA classifies loose stools, loose bowel(s), and mushy stool(s) as diarrhea even without a reported increased frequency. Additionally, daily stool frequency and stool consistency using the Bristol Stool Form Scale (BSFS) were measured in TEN201.

Results: In each of the studies, the only adverse event that occurred in > 5% of TEN-treated patients was diarrhea as classified by MedDRA. Incidence of diarrhea during the treatment periods among patients on TEN 30 mg BID was 6.1% and < 10.0 mg/dL with PB were randomized to either tenapanor or a placeb.. PLA group in 1:1 ratio. Starting dose of tenapanor was 30 mg BID, which could be reduced in a step-wise manner (30, 20, 10 and 5 mg BID) at the investigator’s discretion, based on GI tolerability. The primary endpoint was the change in serum phosphorus level from baseline value at the end of treatment.

Conclusion: Tenapanor showed a significant decrease in serum phosphorus levels compared with PLA (p < 0.001) under PB combination. This result suggests that coadministration of tenapanor with PB could satisfy the unmet needs to better control serum phosphorus in HD patients with refractory hyperphosphatemia.

Funding: Commercial Support - Ardeyx, Inc.
(-62%, 44-78%, p<0.0001) and secondary CPP (-40%, 0.5-62%, p=0.0006, figure). Mean R₂ of secondary CPP was significantly lower during SO therapy compared to wash-out (214±55 mm vs. 231±52 mm, p=0.01).

Conclusions: In dialysis patients, lowering serum phosphate with SO is associated with a reduction in the load of primary and secondary CPP and a smaller size of secondary CPP.

PO0379
Changes in Serum Phosphorus and Pill Burden in Peritoneal Dialysis (PD) Patients Treated with Sucroferric Oxyhydroxide (SO) as Part of Routine Clinical Care: A Contemporary Cohort

Kamyar Kalantar-Zadeh, 1 Linda Ficociello, 2 Meijiao Zhou, 2 Vidhya Parameswaran, 2 Claude Mullon, 2 Robert J. Kossmann, 2 University of California Irvine, Orange, CA; 3 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 4 Fresenius Medical Care North America, Waltham, MA.

Background: Previous real-world analyses of SO in PD patients (pts) included pts first prescribed SO within the first 2 years of SO availability in the US (2014 Cohort: Kalantar 2018). A more contemporary cohort of pts prescribed SO may have different patient characteristics or treatment patterns than earlier SO pts. The current retrospective study assessed changes in serum phosphorus (sP) and phosphate binder (PB) pill burden in PD pts recently and previously prescribed SO.

Methods: Included were adult Fresenius Kidney Care PD pts first prescribed SO monotherapy during 5/2018-5/2019 with PB monotherapy during a 3-month baseline (BL), and sP measured the month before SO initiation (-M1) and at months of the 6-month follow-up (2108 Cohort). Means were calculated monthly (-M1, M1-M6) for PB pills/day and monthly labs and quarterly for iPTH using mixed-effects linear regression.

Results: At BL, the 2018 Cohort (n=201) included slightly older pts (52.3 vs 50.6 yrs) with shorter dialysis vintage (22 vs 29 months) and different BL PB: sevelamer (42 vs 63%), calcium acetate (33 vs 21%), lanthanum (3 vs 5%), ferric citrate (12 vs 0%), or phosphate binder (PB) pill burden in PD pts recently and previously prescribed SO.

At BL, the 2018 Cohort (n=201) included slightly older pts (52.3 vs 50.6 yrs) with shorter dialysis vintage (22 vs 29 months) and different BL PB: sevelamer (42 vs 63%), calcium acetate (33 vs 21%), lanthanum (3 vs 5%), ferric citrate (12 vs 0%), or phosphate binder (PB) pill burden in PD pts recently and previously prescribed SO.

Conclusions: PD pts prescribed SO as part of routine care in 2018 and 2014 experienced significant reductions in sP, and PB pill burden, and an increase in pts with sP≤5.5mg/dL.

PO0380
Assessment of Serum Phosphorus Levels in Patients Following Administration of Ferric Pyrophosphate Citrate: A Retrospective Study

David M. Brooker, 1 David R. Brooker, 2 Ali M. Ayyash, 3 Yossi Chait, 4 Brian H. Nathanson, 4 Michael J. Germain, 5, 6 Grace Hospital, Morganton, NC; 3 Brooker Kidney Care, Cranberry, PA; 1 Div of Nephrology, Baystate Medical Center, Springfield, MA; 2 Renal and Transplant Associates of New England, PC, Springfield, MA; 4 University of Massachusetts Amherst Department of Mechanical and Industrial Engineering, Amherst, MA; 5 OptiSatim, LLC, Longmeadow, MA.

Background: Iron deficiency is common among hemodialysis patients contributing to chronic anemia. Ferric pyrophosphate citrate (FPC) is FDA-approved to replace iron and maintain hemoglobin in adult hemodialysis patients by delivering iron directly and rapidly to transferrin. FPC is a mixed-ligand iron complex in which iron is bound to pyrophosphate and citrate, along with containing phosphate, sodium, and sulfate. Phosphorus regulation in ESRD patients can be challenging thus administering products containing phosphates risks increasing serum phosphorus in addition to exacerbating underlying endocrine abnormalities. The objective of this study is to assess any changes in phosphorus levels in hemodialysis patients receiving FPC.

Methods: Retrospective data from patients at a single center hemodialysis clinic was reanalyzed looking at serum phosphorus level of hemodialysis patients receiving FPC over a one-year span of time. The data analyzed included serum phosphorus levels prior to initiating therapy compared to serum phosphorus levels after being administered FPC 1-month, 6-months, and 12-months on therapy.

Results: Forty-nine patients were included in the study. Median serum phosphorus values were at pre-therapy (median 4.8), 1-month of FPC (median 4.7, p=0.56), 6-months of FPC (median 4.8, p=0.49), and 12-months of FPC (median 5.1, p=0.36) as represented in Figure 1.

Conclusions: After analysis of serum phosphorus levels in hemodialysis patients receiving ferric pyrophosphate citrate, the findings show that there was no difference in average serum phosphorus levels before and after therapy. Clinicians who are prescribing this medication should be aware that there is no increase in serum phosphorus in patients while receiving this therapy considering how difficult it can be to regulate phosphorus along with managing the potential consequences of phosphorus abnormalities.

PO0381
Real-World Effectiveness of Sucroferric Oxyhydroxide (SO) in Lowering Serum Phosphorus (sP) Among a Contemporary Hemodialysis (HD) Cohort: A 6-Month Follow-Up

Daniel W. Coyne, 1 Meijiao Zhou, 2 Vidhya Parameswaran, 1 Linda Ficociello, 2 Claude Mullon, 3 Michael S. Anger, 2 Stuart M. Sprague, 2 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 1 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2 NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, USA, Evanston, IL.

Background: Clinical trial and real-world data demonstrated the effectiveness of SO in managing sP among dialysis pts. Our previous real-world analyses included HD pts prescribed SO within the first 2 years following SO availability in the US (2014 Cohort, Coyne 2017). With greater physician experience with SO and increased availability, prescription patterns may have changed over time. The current retrospective study assessed changes in sP and phosphate binder (PB) pill burden in pts prescribed SO in 2018-2019 (2018 Cohort) and compare these results to the 2014 Cohort findings.

Methods: We included adult Fresenius Kidney Care HD pts first prescribed SO monotherapy between 5/2018-5/2019, on other PB monotherapy during a 3-month baseline (BL), and had sP measured the month before SO start and in ≤5 months during SO. We compared BL to quarterly (Q1, Q2) means, calculated using mixed-effects linear regression, for PB pill burden and lab measurements.

Figure 1

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: Compared to the 2014 Cohort, the 2018 cohort (n=208) was larger (vs. 424), older (56 vs 51 years with shorter dialysis vintage 56 months), more likely prescribed calcium acetate (42 vs 22%) and less likely prescribed sevelamer (41 vs 63%). The 2018 Cohort had better BL sP control (25.7 vs 15.6%) with sP 5.5 mg/dL, yet in both cohorts SO conversion was associated with significant reductions in sP (6.39 to 6.00 vs. 6.86 to 6.41) and PB pills/day (7.6 to 4.4 vs. 9.7 to 4.0) (% pts with sP ≤ 5.5 mg/dL increased from 15.6 to 35.0% in 2014 Cohort and 25.7 to 41.3% in Cohort 2018.

Conclusions: Similar to the 2014 Cohort, a contemporary cohort of HD pts converted to SO experienced improved in sP and achieving ≤ 5.5 mg/dL with fewer PB pills/day. Physicians are prescribing SO to a broader patient population with different distributions of baseline PB therapy.

Dose-Response Efficacy and Tolerability of Tenapanor on Hyperphosphatemia in Japanese Hemodialysis Patients: Results of a Randomized Phase 2 Study

Daijo Inaguma,1 Yu Sato,2 Masayuki Takamura,3 Hironori Kanda,3 Masafumi Fukagawa,3 Tadao Akizawa,4 Fujita Health University School of Medicine, Aichi, Japan; 2Kyowa Kirin Co., Ltd., Tokyo, Japan; 3Tokai University School of Medicine, Kanagawa, Japan; 4Showa University School of Medicine, Tokyo, Japan.

Background: Tenapanor is a novel, non-binder, targeted therapy that reduces paracellular phosphate absorption in the gut by selectively inhibiting the intestinal sodium-hydrogen exchanger isoform NHE3. In a US clinical trial by Ardelyx, Inc, tenapanor significantly reduced serum phosphate levels in hemodialysis (HD) patients with hyperphosphatemia as compared to the placebo (PLA). The purpose of this study was to confirm the efficacy, dose-response and tolerability of tenapanor on hyperphosphatemia in Japanese HD patients.

Methods: This was a multicenter, randomized, double-blind, PLA-controlled, parallel-group and dose-finding Ph2 study. The study consisted of a screening, a 2 or 3-week 1st washout (W0) period, a 6-week treatment period, and a 3-week 2nd W0 period. Patients were enrolled when serum phosphate levels was ≥ 5.5 mg/dL and increased by ≥ 1.0 mg/dL to 6.1−9.9 mg/dL after 1st W0. Therapeutically were randomized to one of 5 groups (PLA, tenapanor 5 mg, 10 mg, 30 mg or 30 mg down titration (DT) twice/day). 30 mg DT group could be down-titrated in a step-wise manner to 20, 10 and 5 mg on the basis of GI tolerability. The primary endpoint was the mean change in serum phosphate level from baseline to end of treatment for each group.

Results: 207 subjects were enrolled (41 or 42 subjects were randomized to each group). The mean change in serum phosphate levels at the end of treatment from baseline was in a dose-dependent manner (PLA: 22.0%, tenapanor 5 mg: 57.1%, 10 mg: 65.9%, 30 mg: 80.3%, 30 mg DT: 79.1%). Most of the events were mild in severity, and, in each tenapanor group, only 1 to 3 subjects were discontinued from the study due to diarrhea.

Conclusions: Tenapanor was well tolerated in Japanese HD patients and significantly decreased serum phosphate level in a dose-dependent manner compared with PLA (p<0.001).

PO0383

CKD and Vitamin D Status Alter Vitamin D Metabolism

Lauren E. Thompson,1 Stacey M. Tye,1 Linda Prebhenalla,2 Raymond E. West,2 Michel Chonchol,3 Nirav A. Shah,3 Thomas D. Nolin,1,4 Melanie S. Joy,1,5 University of Colorado Denver Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 1University of Pittsburgh Department of Pharmacy and Therapeutics, Pittsburgh, PA; 4University of Colorado Denver Division of Renal Diseases and Hypertension, Aurora, CO; 5University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA.

Background: Up to 90% of people with chronic kidney disease (CKD) are vitamin D (VitD) deficient. VitD is subsequently prescribed and has documented health benefits, including nephro-, cardio-, and immune- protection. This paired study sought to evaluate and compare VitD metabolism in CKD patients and healthy controls (HC) under both VitD deficiency and repletion.

Methods: VitD deficient (25[OH]D <30 ng/mL) CKD patients (n=30) and HC (n=15) were recruited (Phase 1). Participants were administered 5,000 IU oral D3, daily for 12 weeks. At week 12 (Phase 2), participants received their final dose of D3, after 25[OH]D was confirmed to be replete (≥30 ng/mL). Blood was collected at serial time points for up to 336 h at each phase for determination of D3, 25[OH]D, 1,25(OH)2, and 24,25(OH)2. Metabolism ratios (MR) were defined by the area under the plasma concentration-time curve (AUC) of pre-cursor to a subsequent metabolite. Analyses for differences were assessed by ANOVA with a Tukey-Kramer post-hoc test.

Results: Metabolism was differentially altered by VitD status and CKD. Significant differences in assessment of MR were determined in both an immediate precursor to the next metabolite in the sequence and by the parent compound (D3) to the final metabolite in the metabolism sequence. The metabolism of D3 to 25[OH]D, and of 25[OH]D to 1,25(OH)2, were significantly decreased by CKD severity, with differences more pronounced after VitD repletion.

Conclusions: CKD severity decreased metabolism by the cytochrome 2R1 and 2B11 pathways resulting in reductions in the D3, 25[OH]D, and 25(OH) D3 to active VitD (1,25(OH)2). Respectively. Daily dosing leading to repletion appears to decrease the overall conversion of cholecalciferol to its metabolites in HC and CKD patients, possibly due to saturation of metabolism pathways. Future research will evaluate the influence of daily vs. intermittent dosing on metabolism efficiency.

Funding: Other NIH Support - NIGMS

Data reported as mean ± SD (n), p-values calculated using one-way ANOVA: a: p<0.05 vs. phase 1, HC.
b: p<0.05 vs. phase 1, CKD 1-3.
c: p<0.05 vs. phase 2, HC.
PO0385
Diagnostic Accuracy of Static Bone Histomorphometry Parameters to Define Low Bone Turnover
Jan M. Hughes-Austin,1 Renata C. Pereira,1 Vanda Goraya,1 Isidro B. Salusky,2 Joachim H. Ex.1
1University of California San Diego, La Jolla, CA; 2University of California Los Angeles, Los Angeles, CA; 3Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Tetracycline labeling for bone biopsy allows pathologists to measure the parameters of bone remodeling, which is critical to defining bone pathology in CKD. In the setting of clinical fractures, bone tissue is available, but tetracycline labeling is not possible. Therefore, we sought to determine the diagnostic accuracy of static measures of bone turnover relative to that measured by tetracycline in CKD patients undergoing iliac crest bone biopsy.

Methods: We evaluated 147 individuals ages 12.4 ± 8.9 who had undergone iliac crest bone biopsy with tetracycline labeling for clinical indications of CKD-MBD. Using the tetracycline labels under fluorescence, we defined bone formation rate relative to bone surface (BFR/BS) by the line of equality that maximizes sensitivity and specificity of each bone turnover parameter with low turnover based on tetracycline using the Youden J Index, which is the point on the ROC curve farthest from the line of equality that maximizes sensitivity and specificity.

Results: Among the 147 biopsies, 35 (24%) had low bone turnover based on tetracycline. We evaluated 5 parameters available by static bone microscopy, among which Osteoblast Surface Relative to Bone Surface (Oc.S/BS), Osteoclast Surface Relative to Bone Surface (OcN.S/BS), Bone Surface (BS), and Bone Volume (BV) had the highest AUCCs for low bone turnover based on tetracycline labeling. Using the best cut-offs from the AUC curves, aSoh.B/S.BS of 82% had a sensitivity and specificity of 80% and 75% for low bone turnover.

Conclusions: Static measures of bone turnover have high sensitivity and specificity for identifying low bone turnover defined by tetracycline labeling at the iliac crest in CKD patients. Bone tissue without tetracycline labeling may be useful clinically to define bone turnover.

PO0386
Acid-Base Status More Than Dietary Acid Intake Determines Urine Citrate Excretion in CKD
Nimrit Goraya,1,2 Nicolaos E. Madias,3 Abdallah A. Mamun,4 Jan Simon,4 Donald E. Wesson,4,5 Baylor Scott and White Central Texas, Temple, TX; Texas A&M University System, College Station, TX; Tufts University School of Medicine, Boston, MA; Baylor Scott and White Health and Wellness Center, Dallas, TX; Surgery, Texas Tech University HSC, Lubbock, TX.

Background: Lower urine excretion of the pH-sensitive metabolite citrate (UcitV) might be a clinically useful biomarker of steady-state acid (H+) retention not evident by pH alone. We examined the influence of 8-hour UcitV (UcitV), its plasma citrate concentration (Pcit), and kidney clearance (UcitV/Pcit) components, and 8-hour urine net acid excretion (8h NAE) of 1) ongoing dietary acid addition assessed by potential renal acid load (PRAL) and 2) steady-state acid-base status assessed by plasma total CO2 (Ptc02) and by H+ retention [estimated by comparing observed to expected PTCO2, increase in response to retained HCO3- (administered minus urinary HCO3) 2 hours after oral NaHCO3 bolus (0.5 mmol/kg bw), assuming 50% body wt HCO3, apparent space of distribution] in 224 patients with CKD stages 1-3 due to macroalbuminuric, non-diabetic, hypertension-associated nephropathy.

Results: Because Pcit, UcitV, UcitV/Pcit, and Ptc02, each directly associated with eGFR (p<0.01) and because H+ retention inversely associated with eGFR (p<0.01), we adjusted reported associations for eGFR. PRAL associated directly with 8h NAE (p=0.03, R=0.13) but not with Ptc02 (p=0.15), H+ retention (p=0.85, UcitV (p=0.02) or Pcit (p=0.49), Ptc02 inversely associated with H+ retention (p=0.01, R=0.66) but not with 8h NAE (p=0.14), UcitV (p=0.59), Pcit (p=0.11) or with UcitV/Pcit (p=0.79). By contrast, H+ retention associated inversely with BFR/BS (p=0.01, R=0.52) and with UcitV/Pcit (p=0.01, R=0.20), but not with 8h NAE (p=0.12).

Conclusions: Ongoing dietary acid intake assessed by PRAL associated inversely with UcitV/Pcit, although quantitatively less than did H+ retention (R=0.13 vs. 0.20), but did not associate with the remaining measures of acid-base status. By contrast, steady-state-acid-base status assessed by H+ retention associated inversely with each measure of citrate homeostasis. The data show that steady-state-acid-base status is a more important determinant of UcitV than dietary acid intake and support continued exploration of UcitV as a biomarker of underlying H+ retention in CKD.

PO0387
Calciphylaxis (Calcific Uremic Arteriopathy) in a Predominantly African-American Urban US Patient Population
Sitaram Arvind Mudunuru, Jose E. Navarrete, Doris J. Armour, Jason Cobb. Emory University, Atlanta, GA.

Background: Calcific Uremic Arteriopathy (CUA) which is commonly called calciphylaxis is a rare and serious condition characterized by painful skin ulcers due to ischemia with necrosis of the skin. The disorder carries a mortality rate >50% in the first year, and death is often due to recurrent infections. Risk factors for calciphylaxis include end-stage renal disease (ESRD), a history of diabetes, obesity, female gender, Caucasian race, and the use of medications such as warfarin. We present clinical characteristics of CUA patients admitted to a large academic medical center which serves as a CUA referral center due to the presence of a wound center with hyperbaric oxygen therapy available.

Methods: Retrospective chart review of CUA patients from 2001-2019 in our single center academic hospital. Baseline data reported included age, calcium, phosphorus, PTH, albumin, hemoglobin, creatinine, BUN, the use of medications such as warfarin or steroids, and treatment options.

Results: There were 110 patients included. Patient identified racial (n=108) make-up included African-American (n=89), Caucasian (n=18), and Asian (n=1). Average age was 56.8±14 years and 80% of patients were female (n=88). Also, 59% (n=65) of patients were diabetic. Dialysis modalities included hemodialysis (n=82) and peritoneal dialysis (n=24). Also 4 patients with CKD not yet on dialysis at the time of diagnosis. Average calcium levels of 8.9±1.1 mg/dl and phosphorus of 5.1±1.9 mg/dl. The average PTH was 569.6±714.9 pg/ml, albumin 2.5±0.7 g/dl, and hemoglobin 9.8±1.7 g/dl. A total of 50% of patients received hyperbaric oxygen therapy as inpatient. 25% received sodium thiosulfate therapy, and 20% received a surgical intervention during the admission. Approximately 33% of patients were currently or recently on warfarin therapy, and approximately 25% were currently or recently exposed to high dose steroids.

Conclusions: We reported the largest single center and predominantly African-American (81%) calciphylaxis case series. In comparison to other reported calciphylaxis series our average PTH was lower and a high percentage of our patients were using warfarin or steroids. The PTH levels were higher in the African American group compared to others. Also, with a lower than expected parathyroidectomy rate which is likely due to our lower than average PTH.

PO0388
Citric Acid-Containing Dialyse (CD) Attenuates Vascular Calcification in Hemodialysis Patients (HD)
Kenichi Akiyama, Norio Hanafusa, Yoei Miyabe, Kazunori Karasawa, Takahito Moriyama, Ken Tsuichia, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.

Background: The main causes of death in patients with CKD, especially in HD, are heart failure, cardiovascular, and cerebrovascular disease, which are due to a high degree of systemic vascular calcification. Progression of aortic calcification, simply evaluated by chest radiography, was reported to be significantly associated with overall and cardiovascular mortality in HD. Recently, it was reported that the use of CD reduced blood calciprotein particles (CPPs) associated with arteriosclerosis and inflammation in HD. Therefore, we investigated the effect of using CD on blood CPPs and vascular calcification in HD in a retrospective observational study.

Methods: The subjects were 262 HD who were visiting the Joran Hospital in Japan. These patients were divided into two groups, those who continued to use acetate-containing dialyse (AD) or switched to CD from October 2017. A one-year retrospective observational study was conducted on the association with blood, laboratory test values, and aOACS (aortic arch calcification score) evaluated by chest X-ray. At baseline, patients with aOACS-50%, biphosphonate, and warfarin use were excluded. Univariate, multivariate, subgroup analyses were used for statistical analysis. The main outcome was the presence or absence of aOACS exacerbation of 5% or more in one year.

Results: A total of 115 patients with AD and 102 patients with CD matched to the criteria were included. As a result, the use of CD (HR 0.53, 95% confidence interval (CI) 0.30-0.92), P = 0.026, ALP (HR 0.97, 95% CI 0.94-0.99, P = 0.013), and aOACS (HR 1.36, 95% CI 1.15-1.63, P = 0.0004) were significantly associated with an exacerbation of aOACS. Subgroup analyses showed the characteristics of patients who benefit from using CD are those older than 75 years old, those with non-diabetes as the underlying disease, low nPCR(normalized protein catabolic rate), high blood CRP, and not severe calcification. In other words, patients with MIA syndrome can benefit from the use of CD.

Conclusions: Among patients with mild to moderate vascular calcification, HD with CD had a significantly reduced progression of aOACS compared with AD. The results indicate that the dialysis method using CD in HD may be a useful therapeutic method for suppressing vascular calcification.

Vascular Calcifications in Renal Transplantation
Ana Carina Ferreira,1,2 Marco Mendes,1,2 Cecília Silva,1 Patricia Cotovio,1 Inês Aires,1,2 David Navarro,1 Fernando C. Pereira,1,2 Rute M. Salvador,2 Bruna F. Correia,2 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Manuel A. Ferreira.1,2 Hospital Curry Cabral, Lisboa, Portugal; 2Nova Medical School, Lisbon, Portugal.

Background: The aim of this study was to analyse the progression of vascular calcifications (VC) in a cohort of renal transplanted patients.

Methods: Prospective cohort study of de novo renal transplant patients. All patients were submitted to X-ray of the pelvis and hands (Adragão score); bone biopsy; laboratorial and echocardiographic evaluation at baseline and after 12 months (time 0 and 1). At the end of the study, bone densitometry and non-contrast cardiac CT (Agatston score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Results: We recruited 85 patients during 29 months and 69 were included in the study (6 patients refuse to perform the 2nd evaluation, 5 had primary non-function of the kidney graft, I had no sample on bone biopsy in time 0 and 4 patients died). Mean age 50.1±12.7 years, 59 men (69.4%), 66 Caucasian (77.6%), median BMI 25.1±3.4. The median baseline and 12 months Adragão score had no differences. The median coronary artery calcium score (CACS) was 48.5 (0 – 535) and median percentile was 80 (0 – 92.5). Valvular calcifications were present in 15 and 16 patients and baseline and after 1 year (p<0.05). CACS were correlated with age (p<0.001), both Adragão score (p<0.001), presence of valvular calcification in time 1 (p<0.004), baseline calcium (p<0.02), baseline and 12 months FGF23 at baseline (p=0.04). Using a pairwise correlation, vitamin D levels (r=0.4, p>0.05). CACS were correlated with age (p<0.001), both Adragão score (p<0.001), CACs were higher in patients with highest values of FGF23 at baseline (p<0.04). Using a pairwise correlation, vitamin D levels (r=0.4, p=0.0004), iPTH (r=0.6, p<0.001) and total cholesterol levels (r=0.3, p=0.01) were correlated with the score. Coronary artery percentile was correlated with Adragão score in the two time points (p=0.0001; p=0.002), with presence of valvular calcifications in time 1 evaluation (p=0.02), baseline and 1-year calcium levels (p=0.004; p=0.02) and baseline sclerostin (p=0.01).

Conclusions: VC stabilize after renal transplantation. Adragão score can assess VC in renal transplanted patients. Calcium and sclerostin correlated with Agatston scores.

Clinical Outcomes in Patients with Calcifications on Kidney Biopsy
Anna R. Gaddy,1 Ranjani N. Moorhi,1 Michael T. Eadon,2 Tae-Hwi Schwantes-An,1,2 Carrie L. Phillips,1 Sharon M. Moe.1
1Indiana University School of Medicine, Indianapolis, IN; 2Regenstrief Institute Inc, Indianapolis, IN.

Background: Calcification is often noted on kidney biopsies, but the consequences of this finding is not known.

Methods: We searched a biobank for specimens with at least two years of linked clinical data and identified those which had calcification on report. Biopsy specimens were further classified to be described as calcium oxalate (CO), calcium phosphate/dystrophic (DC), or both. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints.

Results: Patients with any calcification (n=429) vs. without (n=3936) were (p=0.05) older, more likely to be white, have diabetes, lower eGFR and higher AKI/ATN on kidney biopsy specimen (31 vs. 13%). Patients with COX (n = 126) vs. DC (n = 260) were older, less diabetes, lower eGFR, more likely to have malabsorption or gastric bypass, and used more vitamin D. By univariate analyses, patients with any calcification were more likely to have a decline in the slope of creatinine at 6 months, 1 year, and 2 years; these associations persisted even after adjusting for baseline eGFR, htn, proteinuria, negative biopsy findings, CAD (for 1 year beta 0.029, p < 0.001). When adjusted for age, diabetes, and baseline eGFR, patients with any calcification were less likely than those without calcification to advance to ESKD (HR 0.59; 95%CI 0.38-0.92; p = 0.05) but not to meet the outcome of death.

Conclusions: The presence of calcification on kidney biopsy specimen is associated with lower progression to ESKD and decrease in rate of decline of eGFR over time at 6 months, 1 year, and 2 years. This paradoxical finding may be due to increased AKI with recovery, rather than progressive chronic disease but requires further analyses.
Calciphylaxis is a rare but lethal disorder (mortality 60-80%) characterized by occlusion of microvasculature in the subcutaneous adipose tissue and dermis, resulting in excruciating painful, ischemic skin lesions. It commonly occurs in dialysis patients but only few cases in transplants reported. Treatment options are meager, and a multidisciplinary approach (dermatology, nephrology, nutrition, pain, palliative medicine, plastic surgery, and wound care), with surgical debridement, antimicrobial therapy, optimization of calcium-phosphorus product, dialysis adequacy, sodium thiosulfate, and hyperbaric oxygen has been suggested.

Case Description: A 62-year-old female with a LDKT (2008) complicated with CKD III, lupus nephritis, hyperthyroidism, presented with painful, bilateral, medial calf ischimic ulcerations, which on punch biopsy revealed calciphylaxis. Her baseline iPTH, calcium, phosphorus, and 25-hydroxyvitamin D, was 372 pg/mL, 9.4 mg/dL, 3.8 mg/dL, and 17.4 mg/dL, respectively. She was on calcitriol 0.75 mg/daily, ergocalciferol 50,000 units weekly and cinacalcet 30 mcg every other day. We started her on Calcifediol 30 mg, which increased to 60 mg daily. Her calcitriol and ergocalciferol doses were reduced slowly, while cinacalcet remained the same. This led to gradual increase in 25-hydroxyvitamin D and reduction in iPTH levels without effect on the calcium-phosphorus product. Over 1-year follow-up, her ulcers completely resolved as shown in the images with marked improvement in the pain.

Discussion: Treatment of hyperparathyroidism is limited as calcitriol and ergocalciferol worsen the calcium-phosphorus product while calcimimetics cause hypocalcemia, which hinders the attempt to lower calcitriol. Calcifediol is well tolerated and causes a progressive increase in serum 1,25-dihydroxy vitamin D and reductions in plasma iPTH without a significant effect of serum calcium and phosphorus levels. This led to remarkable clinical improvement with resolution of calciphylaxis in this case. Large clinical trials mandated to test these findings.
PO0396

Penile Calciphylaxis: Challenges in Its Diagnosis and Management
Isabelle Dominique V. Tomas Cruz, Carl Arenos, Sachiko S. Estreller, Blythe N. Ke, Shahara Abalos-Babaran, Elizabeth Montemayor. Philippine General Hospital, Manila, Philippines.

Introduction: Penile calciphylaxis is an uncommon presentation of a rare systemic disorder.

Case Description: We discuss 2 cases of penile calciphylaxis in patients with end stage kidney disease on hemodialysis presenting with painful ulcerations and eschar formation on their penile shaft. Diabetes mellitus, hyperphosphatemia and vascular calcifications on radiographs were common in both patients. A multidisciplinary approach to management involved wound care with irrigation followed by application of petrolatum-impregnated wet-to-dry dressing, antibiotic therapy, intensification of hemodialysis and use of intravenous sodium thiosulfate. Both patients showed good wound healing on discharge.

Discussion: Skin biopsy may aid in confirmation, but should be weighed against the risks of provoking nonhealing wounds & secondary infection. A high index of suspicion and multidisciplinary management are key components; but, prognosis is poor with survival rates reported to be less than a year upon diagnosis.
High Turnover Bone Disease After Successful Parathyroidectomy in a Dialysis Patient

Yahya R. Ahmad, Katherine M. Donaldson, Matthew Shea, Florence Lima, Madhumathi Rao. University of Kentucky Department of Nephrology

Introduction: We report a patient with end stage renal disease (ESRD) on hemodialysis (HD) with history of successful near-total parathyroidectomy (PTX) and normal to low parathyroid hormone (PTH) levels, found to have high-turnover/hyperparathyroid (HPT) bone disease, complicated by calciphylaxis treated with wound care and sodium thiosulfate. Patient also has history of focal segmental glomerulosclerosis of her native kidneys, gastric bypass, uterine cancer requiring radiation, and psoriatic arthritis and gout requiring steroids. Labs showed corrected calcium 9.4 mg/dL, serum phosphorus 7.9 mg/dL, 25-OH-vitamin D3 16.9 ng/mL, bone specific alkaline phosphate 12.8 ug/L, intact PTH level 34 pg/mL (consistent with past values), PTH(1-84)/(7-84) ratio 1.1 (Scantibodies CA). She was started on weekly ergocalciferol. Bone bx showed persistent high-turnover/HPT bone disease with normal mineralization and low bone volume (2019, Figure 1). Relative to her prior bx, however, there was a demonstrable decrease in bone turnover and volume.

Discussion: Bone bx studies showing the evolution of bone disease after PTX in ESRD patients are limited. Development of adynamic bone disease is often presumed, but not established. In this patient, osteoporosis was related to high bone turnover, despite near-total PTX and successful reduction of serum PTH. These observations suggest that more research is needed into mechanisms other than PTH that contribute to bone turnover and loss in ESRD patients.

Bone Fractures and Antihypertensive Drugs in CKD Patients: The Fukuoka Kidney Disease Registry (FKR) Study

Tomoya Shukuri,1 Kentaro Nakai,1 Yoshiki Sato,1 Nao Yamaoka,1 Yukiko Ishimatsu,2 Megumi Inoue,1 Chiaki Kohara,1 Koji Mitsuik,1 Shigeru Tanaka,2 Yoshiaki Nakano,1 Kazushiyo Tsukeya,1 Takarui Kitzazono.1

1Japanese Red Cross Fukuoka hospital, Fukuoka, Japan; 2Division of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; 3Department of Medical and Clinical science, Graduate school of Medical Sciences, Kyushu University, Fukuoka, Japan; 4Department of Nephrology, Nara Medical University, Nara, Japan; 4Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

Background: Patients with chronic kidney disease (CKD) are known to be at high risk for bone fractures. Bone fractures are serious complication that causes inactivity, hospitalization, and premature death. Some reports showed the association between bone fractures and antihypertensive drugs in elderly persons, but there are few reports in CKD patients. The aim of this study is to elucidate the relationship between bone fractures and antihypertensive drugs in CKD patients.

Methods: The Fukuoka Kidney disease registry (FKR) study is a prospective, multicenter cohort study of approximately 5000 patients with CKD. This is a cross-sectional study that investigated the relationship between antihypertensive drugs and bone fractures. The odds ratio (OR) of bone fractures in each risk factors was calculated by performing a logistic regression model analysis with adjustment factors, such as age, sex, body mass index(BMI), smoking history, presence of diabetes mellitus, eGFR levels, serum levels of albumin, sodium, calcium, phosphate, parathyroid hormone(intact assay).

Results: A total of 4474 patients were included in this study (age 63.9 years, men 56.0%, BMI 23.4 kg/m2 diabetes mellitus 27.5%, and smoking history 52.5%). The average eGFR was 44.0 ml/min/1.73 m2, with 60.0 ml/min/1.73 m2 or more at 24.2%, 30.0-60.0 ml/min/1.73 m2 at 39.5%, and less than 30.0 ml/min/1.73 m2 at 36.3%. Bone fractures were found in 282 patients(6.3%). Loop diuretics were independently associated with bone fractures (OR: 1.75, 95% confidence interval [CI]: 1.24-2.49), and angiotensin II receptor blockers (ARB) had significantly fewer bone fractures (OR: 0.64, CI: 0.49-0.85). Angiotensin-converting enzyme inhibitors, calcium channel blockers, alpha blockers, beta blockers, and thiazide diuretics were not showed significant association with bone fractures.

Conclusions: It is suggested that loop diuretics may be associated with higher bone fractures risk and ARB may be associated with lower bone fractures risk in CKD patients. The results are being verified in this prospective cohort by future.

Ethnic Differences in the Association of Kidney Function and Low Bone Density
Joshua Chang, Malini Chandra, Jeanne A. Darbinian, Nirmala D. Ramalingam, Joan C. Le, Stijie Zheng. Kaiser Permanente Oakland Medical Center, Oakland, CA.

Background: Chronic kidney disease (CKD) is an important risk factor for bone disease and fracture. Here, we examined the relationship between reduced kidney function (RKF) and bone mineral density (BMD) in women. We also examined PTH and calcium levels among a subset of patients with advanced CKD and low BMD (osteopenosis range).

Methods: We examined femoral neck BMD in 118,484 women age 60-79 with an ambulatory creatinine/eGFR within 1 year of the BMD scan and compared the proportion with low BMD (T-score ≤ -2.5) by kidney function. Presence of hyperparathyroidism (PTH > 65 and > 130 pg/mL) and hypercalcemia (Ca ≤ 10.5 mg/dL) was examined in a subset of 257 patients with low BMD and advanced CKD (G3B and G4/G5) who had both PTH, calcium, and confirmatory eGFR measured within 2 years of BMD scan.

Results: Among 118,484 women, 83% had eGFR ≥ 60, 12% had eGFR 59-45, 4% had eGFR 44-50, and 1% had eGFR < 40. Overall, 12% of women age 60-69 and 21% of women age 70-79 had low BMD, but this varied by race/ethnicity. Asians had the highest burden of low BMD. Within each race/ethnicity group, the burden of low BMD varied by RKF/eGFR (Figure). In the subset with low BMD, advanced CKD, and measured PTH and calcium, 9.7% of G3B (n = 145) and 5.4% of G4/G5 (n = 112) patients were hypercalcemic. Of these hypercalcemic patients, 75% of G3B patients had PTH > 130 pg/mL. Of the remainder with normal/low calcium, 57% with G3B and 84% with G4/G5 had PTH > 65 pg/mL (19% of G3B and 53% of G4/G5 had PTH > 130 pg/mL).

Conclusions: The burden of low BMD and the association of RKF with low BMD varied by race/ethnicity. The majority of patients with advanced CKD and low BMD also had evidence of hyperparathyroidism when laboratory data were assessed. Our findings support guidelines for PTH and BMD screening in advanced CKD patients to optimize bone health.

Semiconductor, but not Dual-Energy X-ray Absorptiometry, Predict Cortical Bone Mineral Density in Children and Young Adults with CKD
Alexander D. Lalayanius,1 Nicola J. Crabtree,3 Charles Ferro,4 Varavara Askti,4 Andromachi Mitiioni,4 Lorenzo Biassoni,1 Amrit Kaur,10 Manish Sinha,1 David C. Wheeler,8 Neill D. Duncan,3 Joyce Popoola,11 David Milford,3 Jin Long,3 Mary B. Leonard,3 Mary Fewtrell,2,12 Rukshana Shroff,12 Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; 1University College London Institute of Child Health, London, United Kingdom; 2Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, GB, Birmingham, United Kingdom; 3Children’s Hospital “P. & A. Kyriakou”, Athens, Greece; 4’Evelina London Children’s Hospital, London, United Kingdom; 5University College London College, London, United Kingdom; 6Imperial College Healthcare NHS Trust, London, London, United Kingdom; 7Stanford University, Stanford, CA, US, Stanford, CA; 8University Hospitals Birmingham NHS Foundation Trust, Birmingham, Birmingham, GB, Birmingham, United Kingdom; 9Manchester University NHS Foundation Trust, Manchester, United Kingdom; 10St Georges Healthcare Trust, London, United Kingdom.

Background: Currently available semiconductor biomarkers and Dual-energy X-ray Absorptiometry (DXA) are thought to be poor predictors of bone mineral density (BMD). We set out to determine the clinical utility of DXA and routine clinical biomarkers in the young CKD population, by comparing them with cortical BMD measured by peripheral quantitative Computed Tomography (pQCT).

Methods: A multi-centre cross-sectional study with 77 patients on dialysis and 26 in CKD4-5 (n = 103 total, ages 5-30 years). Participants underwent hip and lumbar spine (LS) DXA, trabal pQCT [for cortical (cBMD) and trabecular (tBMD)] and measurement of routine serum biomarkers. All bone measures were expressed as Z-scores adjusted for age, sex, race and height. Tibial cortical BMD Z-scores were used as the gold standard to evaluate the predictive value of other measures.

Results: Bone pain was present in 58%, hindering activities of daily living. 10% had suffered at least one previous low-trauma fracture. DXA LS Z-scores were higher in the CKD compared to the dialysis population, with a corresponding higher trabal BMD Z-score on pQCT (p = 0.006 & p = 0.002). pQCT cortBMD and cortical mineral content Z-scores were significantly lower in dialysis compared to CKD patients (p = 0.01 & p = 0.05 respectively). Hip and LS DXA Z-scores did not correlate with any biomarkers or cortBMD. CortBMD Z-scores were negatively associated with PTH (r = -0.44, p < 0.001) and alkaline phosphatase (ALP) (r = -0.22, p = 0.03) and positively with calcium (r = 0.33, p < 0.001). None of the patients with PTH levels less than three times the upper limit of normal had a Z-score below 2 SD (OR 95% CI 7.331 to infinity). Multivariable linear regression analysis showed the independent predictors of cortBMD Z-scores were PTH (β = -0.43, p < 0.001), ALP (β = -0.36, p < 0.001) and serum calcium (β = 0.21, p < 0.005), which together predicted 57% of variability in cortBMD. DXA imaging did not improve this model.

Conclusions: Routinely used biomarkers are moderate predictors of tibial cortical BMD. DXA is not a clinically useful tool and should not be performed routinely in children and young adults with CKD4-5 and on dialysis.

PO0403
Advanced Glycation End Products Are Related with Cortical Bone Quality and Increased Risk for Fractures in CKD Patients
Noemi A. Roza,2 Kelcia Rosana da Silva Quadros,2 André B. Esteves,2 Renata A. França,2 Wagner Dominguez,1 Luzia N. Furukawa,1 Rodrigo B. de Oliveira,1 1Universidade de Sao Paulo, Sao Paulo, Brazil; 2Universidade Estadual de Campinas, Campinas, Brazil.

Background: The risk of bone fractures is higher in chronic kidney disease (CKD) patients than general population. We aim to investigate the relationships between advanced glycation end-products (AGEs) and cortical bone in a cohort of CKD patients.

Methods: 86 CKD patients (stages 3-4, N=26; hemodialysis, N=32; peritoneal dialysis, N=28) were included. AGEs levels were measured in serum (pentosidine and glycated hemoglobin), in skin (AGE-Reader device) and in cortical bone by immunohistochemistry; receptor activator of nuclear factor kappa-B (RANK) and its
PO0404
Low Bone Turnover and Increasing Calcification with Lower Trabecular Bone Score in Early CKD Patients

Amr E. Mohamed, Mohamed Ahmed, Michael Winkler, Habib Sour, Daniel Davenport, Marie-Claude M. Faugere, Hartmut H. Malluche, University of Kentucky University of Kentucky, Lexington, KY.

Background: Little information is available on turnover abnormalities early during the development of loss of kidney function. Vascular calcifications may develop in association with bone turnover abnormalities. In this study, we aimed to evaluate bone changes and cardiovascular calcification in early CKD patients without clinically known bone or cardiovascular disease.

Methods: This is a cross-sectional analysis of 32 adult volunteers with CKD stage 2-4. All patients underwent 1) dual energy x-ray absorptiometry including trabecular bone score (TBS). 2) Non-contrast CT for cardiovascular calcium scoring, and 3) anterior iliac crest bone biopsy after double tetracycline labelling and mineralized bone histology with histomorphometry.

Results: The mean age of the patients was 61 ± 11 years. Patients tended to be obese (75%), white (72%), and female (59%). The mean eGFR was 44 ± 16 ml/min/1.73 m². On bone histology low turnover was found at the higher eGFR levels in 78% and normal or high turnover at lower eGFR levels. Mineralization was normal in all. Bone volume was positively influenced by serum pentosidine levels. Together these data point to a direct relationship between AGES and fractures in patients with CKD.

Funding: Government Support - Non-U.S.

PO0405
Bone-Derived Hormones, Mineral Metabolism, Cardiovascular Disease, and Patient Survival in ESRD

Ana Carina Ferreira,1,2 Marco Mendes,1,2 Cecilia Silva,1 Patricia Cotovio,1 Inês Aires,1,2 David Navarro,1 Fernando C. Pereira,1,2 Rute M. Salvador,2 Bruna F. Correia,2 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Ana Carina Ferreira,1,2

Background: The aim of this study was to analyse the associations between chronic kidney disease-mineral and bone disorder (CKD-MBD) players [alpha-klotho, fibroblast growth factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP), vitamin D (vitD), phosphorus (Pi), Calcium (Ca) and Magnesium (Mg)], and echocardiographic findings [left ventricular mass index (LVMI)] measured by Devereux formula (cardiovascular calcifications), vascular calcifications and patients (pts) outcomes.

Methods: We performed a prospective cohort study of a sample of ESRD pts listed for renal transplant. All pts were submitted to renal transplant and were followed for 12 months. Patient and graft survival were recorded. At inclusion, demographic and clinical data were collected, laboratory evaluation, bone biopsy and X-ray of the pelvis and hands (Adragão score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Results: We included 85 pts. Mean age 50 ± 12 years, 79 men (69.4%), 66 caucasian (77.6%). The median LVMI was 108.5 (92–129) g/m², with 32 patients presenting LVH and 19 valvular calcifications. Median Adragão score was 1 (0–2). At the end of 12 months, 4 pts died and 5 had graft failure (non-primary function). Alpha-klotho correlated with eGFR (R = -0.006) and marginally with PTH and absence of valvular calcifications (p = 0.05). FGF23 correlated with Pi (p = 0.001), Ca (p = 0.004), PTH (p = 0.003), Mg (p = 0.002), and inversely with bAP (p = 0.003), and presented a marginal association with Adragão score (p = 0.06). We didn’t find correlations between FGF23 and alpha-klotho or dialysis vintage or echocardiographic characteristics. Sclerostin correlated negatively with bAP (p = 0.007) and PTH (p = 0.04). The 3rd sclerostin tertile was associated with high scores of vascular calcifications (p = 0.02). Lower levels of sclerostin were associated with pt survival at the end of 12 months (p = 0.02).

Conclusions: Sclerostin. A new molecule inhibitor, seems to act as a risk factor for vascular calcifications and worse outcomes.

PO0406
Bone Mineral Density Is Not Associated with Coronary Artery Calcification in Children and Young Adults with CKD

Alexander D. Lalaviniyan,1,2 Nicola J. Crabtree,3 Charles Ferro,10 Varvara Askhit,4 Andromachi Mitiison,4 Lorenzo Biassoni,4 Amrit Kaur,4 Manish Sinha,1 David C. Wheeler,4 Neil D. Duncan,4 Joyce Popoola,11 Simon Mcguirk,4 Kristin H. Mortensen,4 David Milford,5 Jin Long,5 Mary B. Leonard,5 Mary Fewtrill,5 Rukshana Shroff,5 Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; 1University College London Institute of Child Health, London, United Kingdom; 2Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, United Kingdom; 3Children’s Hospital “P. & A. Kyriakou”, Athens, Greece; 2Evelina London Children’s Healthcare, London, United Kingdom; 4University College London, London, GB, London, United Kingdom; 5Imperial College Healthcare NHS Trust, London, United Kingdom; 6Stanford University, Stanford, CA, United Kingdom; 7Manchester Royal Infirmary Trust, Manchester, Manchester, United Kingdom; 8University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; 9St Georges Health Care Trust, London, United Kingdom.

Background: Coronary artery calcification (CAC) has been linked with bone demineralization in older adults with CKD, but there are no studies examining this relationship in children and young adults. We studied bone mineral density (BMD) by tibial peripheral quantitative CT (pQCT) and measures of vascular health to examine the association between bone demineralization and vascular calcification in a young CKD population.

Methods: Patients with CKD4-5 (or on dialysis aged 5-30 years underwent tibial pQCT [for cortical/cortBMD and trabecular BMD (trabBMD)], cardiac CT for CAC, ultrasound for carotid intima-media thickness (IMT), carotid-femoral pulse wave velocity (PWV) and measurement of routine serum biomarkers. All measures were expressed as Z-scores and adjusted for age, and height. CAC was expressed as Agatston score (AS).

Results: One hundred participants [median 13.82 years (IQR 10.7 to 16.5), 20% above median, 44% female (77% on dialysis)]. The mean eGFR was 44 ± 16 ml/min/1.73 m². On bone mineral density (BMD) tibial pQCT and trabecular and cortical BMD were normal (trabBMD was 2.17±0.97, cortical BMD was 1.97±0.94). The mean pPWV was 5.8 ± 2.57; and correlated with systolic (r = 0.32, p = 0.001) and diastolic (r = 0.36, p = 0.0001) BP. None of the participants had CAC (OR 0.8 to 4.13). CAC correlated with vitamin D dose (r = 0.34, p = 0.04) but there were no independent predictors. Patients above 18 years had a higher prevalence of CAC (25% vs. 6.5% in children, p = 0.006) and higher PTH levels (88.5 ± 12.8 pmol/L ± 0.001), although children had a greater Ca intake from P-binders (median 18.75 ± 0 and day, p = 0.03) and superior cortBMD Z-scores (-0.23 vs. -2.43, p = 0.001).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Poster. Underlines represent presenting author.
Conclusions: Despite a high prevalence of bone and cardiovascular disease(CVD), there was no increased risk of bone mineral density loss (BMD) or serum 25-hydroxy vitamin D (25(OH)D) in this cohort of children and young adults with CKD-MBD. The skeleton accrues calcium until the third decade of life, perhaps allowing a buffering effect that protects against vascular calcification. Confirmation through longitudinal studies is required.

PO0407
A Randomized, Double-Blind, Placebo-Controlled Trial Assessing Efficacy of Standard and Low-Dose Hydrochlorothiazide Treatment for Prevention of Recurrent Calcareous Nephrolithiasis (NOSTONE Trial)

Background: Nephrolithiasis is a global healthcare problem with a current lifetime risk of up to 18.8% in men and 9.4% in women. Without specific treatment, 5- and 20-year recurrence rates are 40% and 75%, respectively. Given the high cost of medical treatments and surgical interventions as well as the morbidity related to symptomatic stone disease, medical prophylaxis for stone recurrence is an attractive approach. Efficacy of thiazides for kidney stone prevention was tested in 11 trials in the past. However, all these trials had major methodological deficiencies. Nowadays, thiazides are widely used in the treatment of recurrent nephrolithiasis and arterial hypertension, but at significantly lower doses. In the case of recurrent nephrolithiasis, however, this practice is not supported by randomized evidence. Thus, evidence for benefits and harms of thiazides in the prevention of kidney stones remains unclear.

Methods: NOSTONE is a multicenter, randomized, placebo-controlled, double-blind, parallel-group trial with the purpose to assess the dose-response relationship for three different dosages of hydrochlorothiazide (placebo, 12.5mg, 25.0mg, 50.0mg) in kidney stone prevention. The primary outcome is incidence of stone recurrence (a composite of symptomatic or radiologic recurrence) at 3 years, a low-dose CT will be performed at the beginning and the end of the trial. Patients from 12 hospitals throughout Switzerland were included in the trial.

Results: NOSTONE received all necessary approvals by the end of February 2017. Recruitment started in Bern on the 9th of March 2017, all study sites are operative since June 2017. As of October 2018, 413 patients randomized in the trial was reached and therefore recruitment stopped (www.nostone.ch). In March 2020 the first patient randomized in the trial completed the treatment phase. All patients are expected to reach end of treatment by the end of August 2021.

Conclusions: This trial will provide critical information to physicians for the treatment of kidney stones. The impact of the results of this study will affect many patients currently treated with hydrochlorothiazide for the prevention of recurrent nephrolithiasis.

PO0408
Roux-en-Y Gastric Bypass and Kidney Stones

Background: Roux-en-Y gastric bypass (RYGB) is a bariatric surgical procedure that is highly effective in the management of morbid obesity but also associated with higher risk of stone formation after surgery. It is not known why RYGB is associated with higher kidney stone risk but it may be due to changes in urine composition, such as high urine calcium oxalate supersaturation (CaOx SS) and calcium phosphate supersaturation (CaP SS). It is not known who is at risk for high urine CaOx SS after surgery. We examined 24-hour urine composition in 18 men and women before and after RYGB to look for predictors of urine high CaOx SS and CaP SS.

Methods: Patients were recruited from a bariatric surgery clinic prior to scheduled laparoscopic long-limb RYGB. Three consecutive 24-hour urine collections performed in a Clinical Research Center both before and 1 year after surgery. We performed Welch’s 2-sample and paired t-tests to compare mean urinary values for pre- to post-RYGB collections and to compare men to women in the post-RYGB collections. We used linear regression to evaluate predictors of urine CaOx SS and CaP SS.

Results: Seven men and eleven women completed pre- and post-RYGB urine collections. Post-RYGB, women had a significantly higher urine CaOx SS (13.1 vs. 4.6, p=0.002), CaP SS (0.59 vs. 1.04, p=0.05), and lower urine volumes (1.7 vs. 2.7, p<0.001) compared with men. There were no differences by sex in CaOx SS or urine volume pre-RYGB. Both men and women had high oxalate in the pre- and post-RYGB collections. Urine volume was most strongly associated with urine CaOx SS with a difference in urine CaOx SS of -6.4 (-8.7 to -4.0) for every 1 liter of urine volume excretion. Citrate was also found to contribute to differences in kidney stone risk after RYGB. Women may be at higher risk for kidney stone formation after RYGB compared with men.

Nephrolithiasis at Baseline Did Not Increase the Risk of Nephrocalci- nosis Progression After Long-Term Bursosubam Treatment in Adults and Children with X-Linked Hypophosphatemia (XLH)

Farzana Perwad,1 Angel Chen,2 Lin Zhang,2 Mary Scott Roberts,1 Anthony A. Portale,1 1Ultragenyx Pharmaceutical Inc., Novato, CA; 2University of California, San Francisco, San Francisco, CA.

Background: In patients with XLH, excess FGF23 induces hypophosphatemia, leading to musculoskeletal impairments. In two Phase 3 trials (NCT02526160, NCT02015705), bursosubam significantly improved serum phosphorus concentrations in adults and children with XLH. We examined subject characteristics and long-term safety of bursosubam by the absence or presence of nephrocalcinosis (NC) at baseline (BL) from these trials.

Methods: Adults were randomized (1:1) to bursosubam 1.0 mg/kg every 4 weeks or placebo for 24 weeks; after 24 weeks, adults received bursosubam through 96 weeks. Children were randomized (1:1) to bursosubam 0.8 mg/kg every 2 weeks or oral phosphate and active vitamin D (P/D) for 64 weeks. NC was determined at BL and during study by ultrasound and graded by central readers from 0 (normal) to 4 (stone formation).

Results: In adults, NC was found in 73/134 patients (54%) at BL. Age, sex, and duration of treatment with P/D as adults did not differ by baseline NC group. Compared with adults with NC at BL, those with NC had longer duration of treatment with P/D during childhood (mean [SD] 13 [2.3] vs 11.3 [4.9] years) but not with D. After 96 weeks in adults, median 24-hr urine calcium increased by 35% overall but remained within the normal range. NC scores increased by +1 in 5/73 adults with NC at BL and 5/61 adults without NC at BL. In children, NC was found in 14/61 (23%) at BL. Compared with children without NC at BL, children with NC were older (7.6 [2.8] vs 5.7 [3.4] years), more likely to be male (71% vs 36%), treated longer with P/D pre-enrollment (4.8 [3.3] vs 3.6 [3.0] years), and had higher 24-hr urine calcium (4.4 [5.4] vs 2.3 [1.9] mg/kg/day [normal <4.9 mg/kg/day]). After 64 weeks in children, median urine calcium decreased by 50% overall. At week 64, NC scores did not increase in any child and decreased by 1 in 8 children. Serum creatinine and estimated GFR did not change in adults or children.

Conclusions: In adults with NC at BL was associated with longer duration of P during childhood. In children with XLH, NC was associated with longer duration of P and D pre-enrollment and with BL hypercalciuria. With long-term bursosubam, the presence of NC at BL did not increase the risk of NC progression.

PO0410
Proton-Pump Inhibitors Are Associated with Decreased Urinary Citrate Excretion

Parth M. Patel1, Alexander Kandabarov,1 Escosa Aiwerioghene,1 Enrique Blanco-Martinez,2 Spencer Hart,2 David J. Leehey,3 Ahner Farooq,1 Kristin Baldea,1 Thomas Turk.1 Loyola University Health System, Maywood, IL; 2Edward Hines Junior VA Hospital, Hines, IL.

Background: Proton-pump inhibitors (PPIs) may increase the risk of kidney stone formation, but the mechanism(s) has not been elucidated. PPI-associated hypomagnesaemia is due to impaired intestinal magnesium absorption thought to result from changes in intestinal pH that decrease binding of magnesium to its transporters. Citrate is a tricarboxylic acid with pKa values of 2.9, 4.8, and 5.6. Since citrate is transported primarily in the divalent form (citrate2-) by the intestinal sodium dicarboxylate transporter (NaDC1), changes in intestinal pH by PPIs might decrease the amount of the divalent form, thus reducing intestinal absorption of citrate, thereby decreasing alkaline load and urinary citrate excretion.

Methods: We performed a retrospective review of nephrolithiasis patients treated at our institution and compared patients who were taking PPIs or not at the time of their 24-hour urine collections. Patients taking PPIs were older and more likely to have medical comorbidities associated with metabolic syndrome such as hypertension, diabetes, and dyslipidemia (p<0.01). Controlling for these factors, patients taking PPIs were found to have lower 24-hour urine citrate excretion (p=0.012, ΔF=4.24, p=0.04). 24-hour urine magnesium excretion was numerically but not significantly lower in patients taking PPIs. There were no other differences in urine composition between the groups.

Conclusions: Our findings suggest that patients who take PPIs regularly may be at risk for decreased urinary citrate excretion, which is a known risk factor for kidney stone formation. It is possible that the decrease in urinary citrate with PPIs may have clinical significance, particularly in patients with idiopathic hypercalciuria or other conditions associated with hypocitraturia such as genetic polymorphisms of the renal sodium-citrate cotransporter, chronic metabolic acidosis, or intake of carbonic anhydrase inhibitors, high animal protein diet intake, and incomplete distal RTA.
PO0411

Dietary Intake and Risk of Incident and Recurrent Kidney Stones

Api Chewcharat,1 Eric N. Taylor,2 Charat Thongprayoon,1 Lisa E. Vaughan,1 Ramilia A. Mehta,1 Felicity T. Enders,1 John C. Lieske,1 Andrew D. Rule.1
1Mayo Clinic Minnesota, Rochester, MN; 2VA Maine Healthcare System, Augusta, ME.

Background: Dietary factors associated with recurrent kidney stones (KS) may differ from those associated with incident KS.

Methods: We recruited adult incident symptomatic KS formers and controls from local residents surrounding the Mayo Clinics in Minnesota and Florida between 2009 and 2018. Participants were administered a Viocare Food Frequency Questionnaire, a KS survey, and completed a 24h urine chemistry evaluation at a baseline study visit. Medical records of stone formers were reviewed for symptomatic recurrence with a visit lower confirmed stone through May 2019. Analyses compared baseline dietary factors between incident symptomatic stone formers and controls and assessed whether these same dietary factors predicted symptomatic recurrence.

Results: There were 416 incident symptomatic KS formers (74 had a recurrence during follow-up) and 384 controls. Higher dietary potassium, calcium and phytate were associated with lower odds of an incident symptomatic KS adjusting for age, race, BMI, underlying diseases, family history of KS, education status, fluid and energy intake. During median follow-up time of 4.1 years, higher dietary calcium and lower oxalate intake predicted a lower risk of symptomatic KS recurrence (Hazard ratio for highest tertile vs lowest tertile = 0.53, 95%CI [0.28, 0.99] and 2.09, 95%CI [1.18, 3.69], respectively) adjusting for BMI, fluid and energy intake, and Recurrence of Kidney Stone score. (Table)

Conclusions: Certain dietary factors may differ in their association with incident and recurrent KS. In particular, dietary oxalate intake may be more important for preventing recurrence than for preventing a first KS episode.

Type 3 Renal Tubular Acidosis in Association with a Pelvic Kidney

Prince Singh, Stephen B. Erickson, Janina Paula T. Sy-Go, James R. Gregoire. Mayo Foundation for Medical Education and Research, Rochester, MN.

Introduction: The association of renal tubular acidosis (RTA) from carbonic anhydrase isoenzyme II (CA II) deficiency, cerebral calcifications and osteoporosis is known as marble brain disease

Case Description: 21-year-old woman with a medical history of multiple fractures since childhood, recurrent episodes of nephrolithiasis and, renal tubular acidosis (RTA), presented to establish care at our clinic. Genetic testing had revealed she had CA II gene mutation. Her brother had the same condition but her sisters were healthy. Her medication included potassium citrate and vitamin D3. Laboratory assessment revealed the following: serum Na+ 143 mmol/L, K+ 3.9 mmol/L, Cl- 109 mmol/L, HCO3 21 mmol/L, creatinine 0.73 mg/dl, Ca2+ 9 mg/dl, PO43- 4.4 mg/dl, vitamin D 7.6 mg/dl. Urine pH was 6. CT urogram revealed a normal right kidney and an ectopic left kidney with numerous small stones. (Figure 1). Spine X rays showed osteoporosis of vertebral endplates and MRI brain showed calcifications in basal ganglia. Pycnolithotomy of the pelvic stone was performed and stone analysis revealed 90% calcium phosphate and 10% calcium oxalate. 24-hour urine showed a low urine citrate with low urine volume. Thus the findings were consistent for RTA with low serum bicarbonate, low urine citrate and calcium oxalate. (Table). Spine X rays showed osteoporosis of vertebral endplates and MRI brain showed calcifications in basal ganglia. Pycnolithotomy of the pelvic stone was performed and stone analysis revealed 90% calcium phosphate and 10% calcium oxalate. 24-hour urine showed a low urine citrate with low urine volume. Thus the findings were consistent for RTA with low serum bicarbonate, low urine citrate and calcium oxalate. (Table).

Discussion: CA II deficiency syndrome is a rare autosomal recessive disorder that results in Type 3 RTA (combined proximal and distal RTA). Pelvic kidneys, which result from a failure of mesonephros to ascend normally during early gestation, are prone to urolithiasis due to poor urinary drainage. In our patient RTA, along with altered urine flow due to pelvic kidney predisposed to nephrolithiasis.

Cross-Sectional Study of Metabolomic Profiles and the Association with Kidney Stone Disease in the Nurses’ Health Studies I and II

Punyaapat Mapraop,1 Yukun Li,1 Raji Balasubramanian,2 Eric N. Taylor,1 Gary C. Curhan.3 Brigham and Women’s Hospital Channing Division of Network Medicine, Boston, MA; 2Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; 3VA Maine Healthcare System, Augusta, ME; 4University of Massachusetts Amherst, Amherst, MA.

Background: Kidney stone disease is a painful and expensive health condition with a high recurrence rate and substantial morbidity; however, the mechanisms underlying the disease remain incompletely understood. Metabolomics is one novel approach that might provide important insights into the etiology of stone disease.

Methods: In a subset of participants from the Nurses’ Health Study I and II cohorts (NHSI and NHSII), subjects were divided into stone and non-stone former groups. Data from existing mass-spectrometry based plasma metabolomic profiling that had been performed in multiple case-control studies of other diseases were used. Multivariable logistic regression models were employed to identify metabolites which were associated with kidney stone history after adjusting for multiple comparisons using false detection rate correction.

Results: We included 230 prevalent kidney stone cases among 5380 NHSI participants and 114 cases among 2283 NHSII participants. 277 metabolites were measured and passed the 10% missing threshold. In NHSI, one metabolite was significantly inversely associated with kidney stones (p<0.01) and passed the false-detection rate correction for multiple testing. The identified metabolite was cinnamoylglycerine (HMDB0011621), which is a metabolite in the carboxylic acids and derivatives class. There were no significant metabolites in NHSII. When the cohorts were combined, HMDB0011621 was significantly inversely associated with stone history (p<0.01). The odds ratio per standard deviation increase in the metabolite for the combined cohorts was 0.87 (0.81, 0.95).

Conclusions: We identified one plasma metabolite associated with a history of kidney stones. The metabolite has been recently identified as one of the potential biomarkers of proximal tubule function, colonization of antibiotic resistant gut microbiome, and diabetes, which are also known to correlate with kidney stone disease. Larger studies are needed to identify other potential metabolites that may be involved in kidney stone formation.

C1, confidence interval
Results: A total of 36 studies with 2,795 patients on ketogenic diets were enrolled. The estimated pooled incidence of kidney stones was 5.6% (95% CI, 4.4%-7.1%) in patients on ketogenic diets at mean follow-up time 1.7-2.9 years. Subgroup analyses demonstrated the estimated pooled incidence of kidney stones of 5.6% (95% CI, 4.3%-7.2%) in children and 5.6% (95% CI, 2.3%-12.6%) in adults, respectively. Within reported studies, 48.7% (95% CI, 33.2%-64.6%) of kidney stones were uric stones, 36.5% (95% CI, 10.6%-73.6%) were calcium based (CaOx/CaP) stones, and 27.8% (95% CI, 12.1%-51.9%) were mixed uric acid and calcium based stones, respectively.

Conclusions: The estimated incidence of kidney stones in patients on ketogenic diets is 5.6%. Its incidence is comparable among adults and children. Uric acid stones are the most prevalent kidney stones on ketogenic diets followed by calcium based stones. These findings may impact the prevention and clinical management of kidney stones in patients on ketogenic diets.

PO0415
Association of Urine Findings with Metabolic Syndrome (met-s) Traits in Patients with Nephrolithiasis

New York, NY; 1University of Vermont College of Medicine, Burlington, VT; 2University of Vermont Medical Center, Burlington, VT; 3University of Vermont, Burlington, VT.

Background: Met-s is a health concern related to lifestyle habits including acidogenic and high protein diets. The odds of nephrolithiasis increases with an increasing number of met-s traits. Prior studies have shown relationships among the number of met-s traits and decreasing urine pH and other acid excretion markers. We evaluated associations of urine markers including acid excretion and stone composition with the number of met-s traits in a large cohort of stone-forming patients.

Methods: A retrospective review was performed of 24-hour urine studies (Litholink, Chicago, IL) from patients seen in Urology and Nephrology divisions, UVMMC July 2009 to December 2018. Patients <18 years and those with improper collections based on creatinine/kg were excluded. Patient variables, laboratory values, associated diagnoses, and medications were identified within 6 months of urine collection and 1 year of kidney stone composition. Four groups based on the number (0, 1, 2, 3-4) of met-s traits (hypertension, obesity, dyslipidemia, diabetes) were evaluated. Trends across groups were tested using linear contrasts in analysis of variance.

Results: 1250 unique patients, 49% F, 703 with stone composition met criteria for inclusion. Met-s groups n were 0=509, 1=381, 2=203, 3-4=157. There was no difference or trends among the groups for urine volume, calcium or citrate. There was a significant trend p<0.001 for increasing number of met-s traits with decreasing urine pH and SS UA, oxalate, sodium, potassium, phosphorus, urea nitrogen, chloride, estimated net acid excretion and p<0.05 for sulfate (S), ammonium, magnesium. When adjusted for age and protein intake the trend remained significant only for urine pH and a reversed trend for S. There was a significant trend for more UA and fewer predominately CaP stones in those with more met-s traits.

Conclusions: High protein intake accounted for most of the difference in urinary markers of stone risk except low urine pH. The latter facilitates more UA and less CaP contribution to stone composition. Future studies could determine if changing diet can reduce risk for stones in met-s.

Primary Hyperoxaluria (PH) Types 1 and 2 with Kidney and/or Liver Transplant Achieve Best Health-Related Quality of Life (HRQoL)

Background: Our previous study showed that PH without a transplant (tx) had worse HRQoL compared to the US Standard Population and worsened with increased stone frequency. We now show the first longitudinal HRQoL profiles for PH patients with transplants.

Methods: PH patients were enrolled from the Rare Kidney Stone Consortium registry. HRQoL was measured with a generic non-disease specific instrument (SF-36v2). Results were calculated as norm-based scores (NBS) based on US Standard Population

Results were calculated as norm-based scores (NBS) based on US Standard Population

Assessment of Blood Oxalate Concentrations in Patients with CKD
Anja C. Pfau,1 Monika Wytopil,2 Kinski Chauhan,3 Martin Reichel,1 Steven G. Coca,1 Peter S. Aronson,4 Kai-Uwe Eckardt,2,1 Felix Knauth.1,4
1Charite Universitätsmedizin Berlin, Berlin, Germany; 2Universitätsklinikum Erlangen, Erlangen, Germany; 3lcahn School of Medicine at Mount Sinai, New York, NY; 4Yale University Department of Internal Medicine, New Haven, CT.

Background: Alterations in oxalate homeostasis are associated with kidney stone disease and progression of chronic kidney disease (CKD). However, accurate measurement of plasma oxalate (Pox) concentration is challenging as prompt processing and acidification of samples has been deemed necessary. In the present study we examined the effects of variations in sample handling on Pox results. Subsequently, a standardized analytical protocol was established, and Pox concentrations were measured in a large cohort of patients with CKD.

Methods: We tested the effects on Pox results of storage time at room temperature (RT), storage on dry ice and maintenance of samples at -80°C. Pox was measured in 1826 patients enrolled in the German Chronic Kidney Disease (GCKD) study, an ongoing multicenter, prospective, observational cohort study.

Results: Pox concentrations increased rapidly when samples were maintained at RT. This was most relevant for Pox concentrations as more than doubled within a few hours. Immediate freezing on dry ice and storage at -80°C provided stable results and allowed postponement of acidification for > 1 year. In the GCKD study, mean (SD) eGFR at the time of Pox measurement was 44.0 (17.9) ml/min/1.73 m². More than half of the patients had a Pox concentration below 2.0 μM. Pox correlated positively with urinary albumin to creatinine ratio and inversely with eGFR (P < 0.001). In the lowest eGFR quartile, median eGFR was 25.1 ml/min/1.73 m² (IQR 20.3 – 28.1) with a median Pox of 2.7 μM (IQR 1.9 – 4.2).

Conclusions: We conclude that immediate freezing and maintenance of plasma samples at -80°C facilitates the sample collection process and allows accurate Pox assessment in large patient cohorts. Our study presents a critical and useful modification of the complex preanalytical procedure. Moreover, we demonstrate that Pox concentrations in patients with CKD are substantially lower than previously reported. The present study may serve as a reference for sample handling to assess Pox in clinical trials and to determine its role in CKD progression.

Funding: Commercial Support - Dicerna Pharmaceuticals, Cambridge, USA; Private Foundation Support, Government Support - Non-U.S.
Methods: We created a 3-tiered in vitro VC model and an in vivo uremic rat model receiving high phosphate diet to mimic uremic VC. RNA from the in vitro and in vivo models underwent miRNA and mRNA microarray, with results screened for differentially expressed miRNAs and their target genes as biomarkers. Findings were validated in all models and human cells, followed by functional assays of identified miRNAs, and tests of sera from end-stage renal disease (ESRD) and non-dialysis dependent chronic kidney disease (CKD) patients without and with VC.

Results: Totally 122 down-regulated and 119 up-regulated miRNAs during calcification progression were identified initially; further list-narrowing based on miRNA-mRNA pairing, anti-correlation, and functional enrichment left 16 and 14 differentially expressed miRNAs and mRNAs. Levels of 4 miRNAs (miR-10b-5p, miR-195, miR-125b-2-3p, and miR-378a-3p) were shown to decrease throughout all models tested, while 1 miRNA (SULF1) a potential target of miR-378a-3p) exhibited the opposite trend in human cells. Among 77 ESRD (88.3% with VC) (Figure A) and 59 CKD patients (61% with VC) (Figure B), serum miR-125b-2-3p and miR-378a-3p decreased with greater VC severity, while serum SULF1 levels increased. Adding serum miR-125b-2-3p, miR-378a-3p, and SULF1 into regression models for VC substantially improved performance compared to using clinical variables alone.

Conclusions: Using a translational approach, we discovered a novel panel of biomarkers for gauging the probability/severity of uremic VC based on miRNAs and their target proteins, which improved the diagnostic accuracy.

PO0421
Clinical Characteristics and eGFR and Urine Albumin-to-Creatinine Ratio Distribution According to the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD International Retrospective Cohort
Juan Jose Garcia Sanchez,1 Juan I. Carrero,2 Supriya R. Kumar,2 Roberto Pecoits-Filho,4,5 Glen James,6 Hildo J. Heerspink,8 Stephen Nolan,1 Lam S. Carolyn,13 Hungta (Tony) Chen,1 Eichiro Kanda,4 Alyshah Abdul Sultan,1 Naoki Kashihara,3 Mikhail Kosiborod,10 Carol A. Pollock,11 David C. Wheeler,12 AstraZeneca, Cambridge, United Kingdom; Karolinska Institutet, Stockholm, Sweden; AstraZeneca, Gaithersburg, MD; Arbor Research Collaborative for Health, Ann Arbor, MI; Pontificia Universidade Catolica do Parana, Curitiba, Parana, Brazil; Universidade Federal de Pernambuco, Recife, Brazil; National Heart Centre Singapore, Singapore, Singapore; Duke-NUS Medical School, Singapore, Singapore; Kawasaki Ika Daigaku, Kurashiki, Japan; Saint Luke’s Mid America Heart Institute, Kansas City, MO; Royal North Shore Hospital, St Leonards, NSW, Australia; University College London, London, United Kingdom.

Background: Contemporary studies describing the prevalence and characteristics of patients with CKD categorised according KDIGO 2012 are scarce. We describe patient characteristics and the prevalence of CKD according to the 2012 KDIGO categories in patients with CKD.

Methods: The DISCOVER-CKD retrospective cohort of patients was extracted using real-world data from the integrated Limited Claims and Electronic Health Record (LCEHR) data and TriNetX. Patients were aged ≥18 years, with ≥1 UACR measure and required first diagnostic coding of CKD (Stages 3A to ESRD) or two estimated glomerular filtration rate (eGFR) codings or 2nd eGFR. UACR closest to index was used to categorise patients. Descriptive analyses were used to summarise prevalence and patient characteristics.

Results: Preliminarily, among 22229 included patients, 63.6% (n=10979, TriNetX) and 76.8% (n=3813, LCEHR) had normal to mildly increased albuminuria, 26.6% (n=4851, TriNetX) and 17.9% (n=889, LCEHR) had moderately increased albuminuria and 9.8% (n=1694, TriNetX) and 5.5% (n=273, LCEHR) had severely increased albuminuria (Figure 1). Hypertension and type 2 diabetes were the most common comorbidities (prevalence ≥60%) and their prevalence increased with albuminuria.

Conclusions: This study, utilising real-world data, fills an important knowledge gap regarding the characteristics of patients with CKD in different eGFR and UACR strata according to the KDIGO 2012 definitions.

Tope Olufade,1 Lois Lamerato,2 Juan Jose Garcia Sanchez,2 Like Jiang,1 Joanna C. Huang,1 Stephen Nolan,2 AstraZeneca, Wilmington, NC; AstraZeneca UK Ltd, Cambridge, United Kingdom; Henry Ford Health System, Detroit, MI.

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. To appropriately evaluate future results and aid clinical interpretation of the DAPA-CKD trial, the present study assessed the renal and CV outcomes of a “DAPA-CKD-like population” (eGFR 25-75 ml/min/1.73m2 and UACR 200-5000 mg/g) in a contemporary US healthcare system.

Methods: Administrative data from the Henry Ford Health System was used to identify patients with CKD stages 2 through 4 between 2006 and 2016 based on eGFR lab reading (n=38,376). Exclusions included no concomitant eGFR >90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months pre or post index date). Within that cohort, 17,742 had eGFR (25-75ml/min/1.73m2) and 9,177 had a UACR (0-5000 mg/g) within 12 months of index date. Additional exclusions were type 1 diabetes, lupus nephritis and polycystic kidney disease. Patients were followed through December 31, 2018.

Results: Of the 6,557 patients that met the eligibility criteria and were included in the study cohort, the mean age was 62.9 years and 46.2% were male. The population was stratified by UACR (0–30, 30–199, 200–5,000 mg/g). Across all outcomes assessed, incidences were highest in the DAPA-CKD-like cohort (UACR 200-5000mg/g) (HF 36.1%, Stroke 8.9%, T2D 11.3%, Stroke 8.9%, T2D 11.3%, Stroke 8.9% vs Table 1). The greatest increase was observed for renal outcomes particularly ESKD, increasing from 0.9% (UACR 0–30mg/g) to 3.4% (UACR 30-199mg/g) to 18.6% (UACR 200-5000mg/g).

Conclusions: In a contemporary US healthcare system, there remains significant area for renal, CV and mortality outcomes among patients fitting the DAPA-CKD study inclusion criteria. These results highlight the unmet need existing for additional therapies to delay disease progression and improve outcomes and survival in this high risk population.

NSAIID Use Is Not Associated with Kidney Injury or Dysfunction in Ambulatory Older Adults
Jonathan G. Amatrudac,1,2 Harini Sarathy,1 Carmen A. Peralta,1,3 Michelle M. Estrella,2 Ronit Katz,1 Joachim H. Ix,1 Linda F. Fried,1 Chaig R. Parikh,1 Anne B. Newman,1 Mark J. Samak,1 Michael Shlipak,1,3
1University of California San Francisco, San Francisco, CA; 2Kidney Health Research Collaborative, UCSF, San Francisco, CA; 3University of Washington, Seattle, WA; 4VA Pittsburgh Healthcare System, Pittsburgh, PA; 5University of California San Diego, La Jolla, CA; 6Johns Hopkins University, Baltimore, MD; 7Tufts Medical Center, Boston, MA; 8Cleveland Clinic, San Francisco, CA; 9University of Pittsburgh, Pittsburgh, PA.

Background: NSAIIDs cause AKI and may worsen CKD, especially in vulnerable populations such as older adults. We hypothesized that NSAIID use would be associated with markers of both tubular and glomerular damage in older adults.

Methods: In the multicenter Health ABC cohort of ambulatory older adults, prescription and OTC NSAIID use was self-reported. Estimated GFR by cystatin C, and urine albumin (ACR), KIM-1, and IL-18 were measured in 2,999 participants; urine a1m, NGAL, PHIHP, and UMOD were measured in a random subset of 500 participants. We evaluated cross-sectional associations between NSAIID use and biomarkers with separate linear regression models. The association between time-updated NSAIID use and eGFR decline over 10 years was estimated with linear mixed models.

Results: Participants had a mean age of 74 years, 51% were female, and 41% African-American. No eGFR differences were detected between NSAIID users (n=655) and non-users (n=2344) at baseline (72 mL/min/1.73m2 in both groups). Compared to non-users, NSAIID users had 33% (95% CI: 11%-49%) lower adjusted odds of having ACR >30 mg/g and 11% (95% CI: 4%-18%) lower mean urine IL-18 concentration at baseline. Significant differences in baseline concentrations of the remaining urine biomarkers were detected. NSAIID users and non-users did not differ significantly in the rate of eGFR decline (-2.2% vs. -2.3% per year).

Conclusions: Among ambulatory older adults, NSAIID use was not associated with kidney dysfunction or progression and was not associated with identifiable cause of CKD in the index cases or use of analgesics. Many relatives were discovered to have undiagnosed hypertension and undiagnosed diabetes.

Sex Differences in CKD Prevalence in Asia: A Systematic Review and Meta-Analysis
Carinna Hockham,1 Lexia Bau,1 Anushree Tiku,1 Sunil Badve,1,2 Martin P. Gallagher,1,3 Meg J. Jardine,1,3 Vivekanand Jha,1,3 Min Jun,1 The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; 2St. George Hospital, Sydney, NSW, Australia; 3Concord Repatriation General Hospital, Sydney, NSW, Australia; 4The George Institute for Global Health, University of Oxford, Oxford, United Kingdom.

Background: Individual studies reporting sex-specific chronic kidney disease (CKD) prevalence in Asia have shown inconsistent sex differences in CKD prevalence. We sought to synthesize available sex-disaggregated data to better define and compare CKD prevalence in women and men in Asia.

Methods: We systematically searched the literature for observational studies of ≥500 adults reporting sex-disaggregated CKD prevalence data in Asia. We calculated the women-to-men prevalence ratio (PR) for each study and pooled these using random-effects meta-analysis. Subgroup analyses were performed to explore potential sources of heterogeneity in the PR.

Results: Sex-disaggregated CKD prevalence data were available for 12 of the 26 Asian countries (109 studies; 1,452,308 women and 1,391,995 men). Most studies (83%) came from China, Taiwan, Japan and South Korea. Sex-specific CKD prevalence estimates varied substantially between studies (median [IQR] reported prevalence was 13% [9-15%] in women and 17% [8-28%] in men). Overall, CKD prevalence was higher in women compared to men (pooled PR 1.14; 95%CI 1.07-1.21), with evidence of significant heterogeneity (I²=99%). In subgroup analyses, prevalence was higher in women among studies with a younger mean age, a higher proportion of diabetes and that defined CKD using eGFR only (Table 1). The pooled PR varied considerably by country.

Conclusions: Existing sex-disaggregated data suggest a higher overall prevalence of CKD in women compared to men in Asia. However, adequate assessment of sex differences in CKD prevalence is limited by the absence of sex-disaggregated data for a large part of the region. Standardised reporting of sex-disaggregated CKD prevalence data in Asia is needed.

PO0424
The Prevalence of CKD Among First-Degree Relatives of Saudi Hemodialysis Patients and Associated Factors
Dujanah Mousaad,1 Ali Alharbi,1 Mohammed A. Alhomrany,1 Imed Helal,1 Fayeza F. Alhejaiali,1 Diaverum Saudi Arabia Diaverum Renal Services Group, Riyadh, Saudi Arabia.

Background: In Saudi Arabia, there are currently over 20,000 patients on dialysis and 9810 patients followed up for functioning renal transplantation. The combined prevalence of renal replacement therapy (stage 5 CKD) in Saudi Arabia is estimated to be 1294.3 PMP. There are no local data or registry about stages 1 to 4 CKD in the Kingdom. Objective: To describe the renal protection and baseline predictors of CKD among first-degree relatives of the Saudi dialysis patients and evaluate the associated characteristics.

Methods: 1° degree relatives of all hemodialysis patients in Diaverum clinics in Saudi Arabia were screened for CKD. Demographic data were collected as well as history of hypertension or diabetes mellitus. Serum creatinine, urinalysis and a single Blood pressure reading were measured. eGFR was calculated using the CKD-EPI formula. For the index cases, the cause of CKD, age and gender were recorded. The prevalence rates of CKD stages among relatives were calculated and the association between different variables and CKD stages assessed.

Results: Out of 4550 dialysis patients, 20258 1st degree relatives were approached of whom 5177 responded. The cause of CKD among the index cases was DM in 52.5% followed by hypertension (20.6%). The eGFR was < 90 ml/min in 39.6% and < 60 ml/min in 13.8% of the screened cases. Proteinuria was present in 8%, making the combined prevalence of CKD of 13.8%.

Conclusions: The overall combined prevalence of CKD was 13.8% and is highest in the Southern region of Saudi Arabia. The presence of CKD in the screened relatives was not associated with identifiable cause of CKD in the index cases or use of analgesics. Many relatives were discovered to have undiagnosed hypertension and undiagnosed diabetes.

Increased Circulating suPAR Levels in African Patients with HIV
David C. Wei,1 Beata Samelko,1 Martin G. Zeier,2 Rulan S. Parekh,3 Jochen Reiser,1 Rush University Medical Center, Chicago, IL; 2University Hospital Heidelberg, Heidelberg, Germany; 3University of Toronto, ON, Canada.

Background: Decline in kidney function associated with APOL1 risk alleles is dependent on circulating suPAR levels in African American (AA) patients. Yet, little is known among HIV infected persons in sub-Saharan Africa, and epidemiological data from

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
this region regarding APOL1 risk status is scarce. We aimed to determine APOL1 risk variants, plasma suPAR levels and estimate kidney function in HIV patients in Zambia.

Methods: We performed a cross-sectional study with 480 adult HIV infected persons on anti-retroviral treatment (ART) (women, 64.8%) in Lusaka, Zambia. APOL1 genotyping was done to determine the prevalence of the risk alleles; plasma suPAR levels were assayed and estimated GFR (eGFR) was calculated by CKD-EPI creatinine-based formula.

Results: Plasma suPAR levels were increased and were negatively correlated to eGFR, whether less than 60 or not (r=-0.15, p=0.001). Women while younger (42 vs 46 years old for men, p=0.0003), had higher suPAR than men (3.68 ng/ml vs 3.07 ng/ml, p<0.0001). Ten out of 480 patients (2.1%) had CKD, and their suPAR levels were higher than patients without CKD (5.6 mg/ml vs 3.44 ng/ml, p<0.0001). Fifty patients (10.4%) had 2 APOL1 risk alleles (35 for women vs 15 for men); among those, 3 (6%) developed CKD (p=0.07). No difference in suPAR levels or eGFR was observed between patients who carried 2 APOL1 risk alleles and those with 1 or 0 risk allele.

Conclusions: HIV infected persons in Zambia on ART have increased suPAR levels. The prevalence of two APOL1 risk alleles is similar as with AA HIV patients. A longitudinal study with a bigger cohort should reveal the relationship between suPAR, APOL1 risk alleles and kidney function.

Kidney Tubular Injury and Dysfunction Relate to Frailty and Cognitive Function in Persons with CKD in SPRINT

Lindsay S. Miller, Manjula Kurella Tamura, Nicholas M. Pajewski, Daniel E. Weiner, Dena E. Rifkin, Michael Shlipak, Joachim H. Ix, University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; Stanford University School of Medicine, Stanford, CA; Wake Forest University School of Medicine, Winston-Salem, NC; Tufts Medical Center, Boston, MA; Kidney Health Research Collaborative, San Francisco, CA; VAHCS/UCSF, San Francisco, CA.

Background: The association of markers of kidney disease (eGFR and albuminuria) with frailty and cognitive function is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 8 biomarkers of kidney tubule dysfunction and injury across CKD stages in 2,282 SPRINT participants with eGFR < 60 and evaluated their associations with frailty and cognition using the Modified Mini-Mental State Exam (3MSE) and the Digit Symbol Substitution Test (DSST), where higher scores represent better cognitive function.

Results: None of the urine tubule marker biomarkers were associated with DSST, whereas higher urine NGAL was associated with lower DSST scores. Lower concentrations of sHCO3 were additionally adjusted for spirometry function.

Conclusions: Among urine markers of tubule injury and dysfunction, only higher NGAL was associated with lower cognitive function testing by DSST. Similarly, NGAL was associated with worse cognitive function by DSST independent of eGFR, albuminuria, or other risk factors.

Funding: NIDDK Support, Other NIH Support - This research was supported by National Institute on Aging (NIA) contracts #N01-AG-6-2101, #N01-AG-6-2103, N01-AG-6-2106; NIA grant R01-AG008290; NINR grant R01-NR012459; Veterans Affairs Support

Cross-sectional association between biomarker of kidney tubule dysfunction with cognitive function.

Association of Kidney Tubule Injury and Dysfunction with Cognitive Function in the Health, Aging and Body Composition Study

Lindsay S. Miller,1 O. Alison Potok,1 Dena E. Rifkin,2 Mark J. Sarnak,2 David A. Drew,2 Linda F. Fried,4 Michael Shlipak,1 Joachim H. Ix,1 University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; Brigham and Women’s Hospital, Boston, MA; VA Pittsburgh Healthcare System, Pittsburgh, PA; Kidney Health Research Collaborative, San Francisco, CA; VAHCS/UCSF, San Francisco, CA.

Background: The association of lower levels of eGFR and higher levels of albuminuria with poor cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 5 urinary biomarkers of kidney tubule injury and dysfunction (alpha-1 microglobulin [α1M], kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18], uromodulin [Umod], and neutrophil gelatinase-associated lipocalin [NGAL]) among a random sample of 502 participants, and serum bicarbonate [sHCO3] among 2,288 community-living elders aged 70-79. We evaluated the cross-sectional associations with cognitive function using the Modified Mini-Mental State Exam (3MSE) and the Digit Symbol Substitution Test (DSST), where higher scores represent better cognitive function.

Results: None of the urine tubule marker biomarkers were associated with sHCO3, whereas higher urine NGAL was associated with lower DSST scores. Lower concentrations of sHCO3 were additionally adjusted for spirometry function.

Conclusions: All models were adjusted for age, sex, race, years of education, clinic site, BMI, smoking status, Center for Epidemiologic Studies Depression Scale score, SBP, any antihypertensive medication, diabetes, stroke, cystatin C and creatinine-based eGFR, albuminuria, and urine creatinine. sHCO3 was additionally adjusted for spirometry function.

Figure: Multinomial regression showing the baseline association between biomarkers of kidney tubule dysfunction and injury with frailty compared with fit older adults (less than 60 years old for men, p=0.0003), had higher suPAR than men (3.68 ng/ml vs 3.07 ng/ml, p<0.0001). Ten out of 480 patients (2.1%) had CKD, and their suPAR levels were higher than patients without CKD (5.6 mg/ml vs 3.44 ng/ml, p<0.0001). Fifty patients (10.4%) had 2 APOL1 risk alleles (35 for women vs 15 for men); among those, 3 (6%) developed CKD (p=0.07). No difference in suPAR levels or eGFR was observed between patients who carried 2 APOL1 risk alleles and those with 1 or 0 risk allele.

Conclusions: Among urine markers of tubule injury and dysfunction, only higher NGAL was associated with lower cognitive function testing by DSST. Similarly, NGAL was associated with worse cognitive function by DSST independent of eGFR, albuminuria, or other risk factors.

Cross-sectional association between biomarker of kidney tubule dysfunction with cognitive function.

PO0429

Risk of Pneumonia Hospitalization Associated with Serum Triglycerides Across CKD Stages in US Veterans

Melissa Sooho,1 Jui-Ting Hsiung,1 Csaba P. Kovessy,2 Kamyar Kalantar-Zadeh,1,3 Elani Streja,1,3 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; Memphis VA Medical Center, Memphis, TN; VA Long Beach Healthcare System, Long Beach, CA; The University of Tennessee Health Science Center College of Medicine, Memphis, TN.

Background: Small studies have suggested that chronic kidney disease (CKD) is an independent risk factor for pneumonia hospitalization. Although lipid modulating therapies are known for atherosclerotic cardiovascular disease risk reduction, they have been shown to also lower risk of pneumonia. Cholesterols were recently identified as another lipid, serum triglycerides (TG) with pneumonia across CKD stages is relatively unknown.

Methods: Our patient cohort comprised 2,963,176 US veterans who received care from 2004-2006 (baseline) and were followed until 2014. Primary diagnosis ICD-9 codes identified inpatient pneumonia events. Using Cox proportional hazards models, we evaluated the association between baseline TG and time to first pneumonia hospitalization, stratified by CKD stage at the time of the TG measurement. Models were adjusted for demographics, comorbidities, use of lipid modulating therapies, and other biomarkers including serum lipids.

Results: Our patient cohort was on average 63±14 years old, had a median [IQR] TG of 127[87, 189] mg/dL and 23% had CKD at baseline. After full adjustment, TG <160 mg/dL were generally associated with a lower time to first pneumonia event (ref: TG 120–160 mg/dL for all CKD stages (Figure). Conversely, high TG ≥240 mg/dL were associated with higher risk of a pneumonia hospitalization in non-CKD and CKD stage 3A-3B patients. Notably, elevated TG ≥300 mg/dL were not associated with a higher risk of pneumonia among CKD stage 4, 5 and end-stage renal disease patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

180
Conclusions: We observed that elevated TG were associated with higher risk of pneumonia hospitalization in non-CKD and CKD stage 3A-3B patients, but this relationship was not observed in late-stage CKD patients. While use of statins and cholesterol levels have been studied in the context of pneumonia and lung function, future studies are warranted to also investigate the role of triglycerides in pneumonia risk especially among early stage CKD patients.

PO0430
The Reference Interval and Risk Factors of NT-ProBNP in CKD Patients Without Heart Failure
Junzhe Chen, Ying Tang, Zhenjian Xu, Qiuyan Huang, Anping Xu. Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.

Background: N-terminal pro-B-type natriuretic peptide (NT-proBNP), a diagnostic marker of heart failure (HF), as well as the specific and sensitive biomarker of HF is been demonstrated to be affected by renal function. NT-proBNP is significantly associated with the severity of GFR loss. However, the reference interval (RI) of NT-proBNP in non-dialysis chronic kidney disease (CKD) patients without HF remains unclear. The aim of our study was to establish the threshold value of NT-proBNP which could help to early recognition, prevention, and treatment for HF.

Methods: All patients diagnosed with CKD aged more than 18 years old in our hospital from Jan 01, 2014 to Dec 31, 2019 were recruited into this study. Individuals who diagnosed with HF were excluded. The RI for NT-proBNP was defined by nonparametric method and risk factors were analyzed by linear regression analysis.

Results: A total of 1260 CKD patients without HF were included in this study. Of them, 588(46.67%) were female. NT-proBNP were increased with the advanced stage of CKD stage 5 (non-dialysis patients without HF) were the highest, as 610.25 pg/ml. The RIs for NT-proBNP in CKD patients without HF with respect to kidney function stage (ranges of stage 1, stage 2, stage 3, stage 4, stage 5 ND) were 8.15-536.32, 12.38-811.90, 16.62-1411.05, 33.14-2945.05, 88.58-5533.73pg/ml. We also demonstrated that NT-proBNP was significantly correlated with the serum levels of Hb (β=0.174, P<0.001), Ca (β=-0.214, P=0.001), P (β=-0.111, P=0.001), hs-CRP (β=0.140, P=0.001), and eGFR(β=-0.243, P<0.001).

Conclusions: Our study proved that NT-proBNP was increased with the advanced stage of GFR in CKD patients without HF. The RI of NT-proBNP varied among different stages of CKD without HF and multiple factors contributed to NT-proBNP, which could help clinicians to prevent and take actions against the occurrence of HF.

Funding: Government Support - Non-U.S.

Figure 1. The NT-proBNP levels in different stage of chronic kidney disease patients without HF.

PO0431
Soluble Urokinase Plasminogen Activation Receptor and Major Adverse Cardiac Event Morbidity in CKD Patients in the German Chronic Kidney Disease (GCKD) Cohort
Claudia Sommerer,1 Sandra Müller-Krebs,1 Jennifer Nadal,2 Matthias Schmid,2 Kai-Uwe Eckardt,1 Jochen Reiser,1 Martin G. Zeier,1 1Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; 2Department of Medical Biometry, Informatics, and Epidemiology (IMBI), University Hospital of Bonn, Bonn, Germany; 3Department of Nephrology, Charité, University Medicine Berlin Berlin, Berlin, Germany; 4Department of Medicine, Rush University Medical Center, Chicago, IL.

Background: Soluble urokinase plasminogen activation receptor (suPAR) is supposed as risk factor for both chronic kidney disease (CKD) and biomarker for major adverse cardiac events (MACE) disease. A long-term longitudinal analysis in a large cohort of patients suffering from both diseases simultaneously, CKD and cardiovascular (CV) disease including MACE criteria, to analyze suPAR as a predictive biomarker has not been performed, yet.

Methods: SuPAR was studied in the GCKD Study Group with a follow-up time of 4 years. Association of suPAR with CKD (estimated glomerular filtration rate, eGFR) and overall risk of all-cause death, CV death, and MACE (three-point MACE, MACE3; four-point MACE4) was estimated by Cox proportional hazards regression according to quintiles of suPAR.

Results: Altogether, 4994 participants were enrolled (60.1 ± 12.0 years; eGFR of 49.4 ±18.3 mL/min/1.73m²). Median suPAR concentration was 1771 pg/mL (25th-75th percentile, 1447-2254 pg/mL). Hazard ratio for CV mortality was 1.58 (95%CI 0.62-4.00) in the second, 2.15 (95%CI 0.87-5.26) in the third, 3.48 (95%CI 1.53-7.93) in the fourth, and 5.30 (95%CI 2.34-12.0) in the fifth quintile. If additionally adjusted for eGFR, UACR, NT-proBNP, hsCRP results were confirmed.

Conclusions: In the GCKD study cohort suPAR predicts all-cause death, cardiovascular death, and MACE independent of NT-proBNP, renal function and of markers of systemic inflammation.

PO0432
Incidence and Racial Disparities in Cardiovascular Disease and CKD Progression in Young Adults with CKD
Alexander J. Kula,1,2 Nisha Bansal,2 David K. Prince,3 1Seattle Children’s Hospital, Seattle, WA; 2University of Washington, Seattle, WA

Background: Cardiovascular disease (CVD) is a major source of morbidity and mortality in adult CKD patients; yet is not well elucidated in young adults with CKD. Furthermore, racial and ethnic disparities in CVD and CKD progression has been found in research of pediatric and older-adult CKD populations, but has not been investigated specifically in young adults.

Methods: We studied 317 participants aged 21-40yrs of age with mild to moderate CKD enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study, of whom, 174 were black or Hispanic. We calculated incidence rates for CV events (heart failure [HF], MI, stroke, and death) and CKD progression (50% decline in eGFR or ESRD) for all young adult participants and as stratified by race and ethnicity. Cox proportional hazards regression models were constructed to test the association between race/ethnicity and CV events and CKD progression, adjusting for age, sex, eGFR, UACR, baseline SBP, and APOL1 status.

Results: HF, mortality and CKD progression had the highest incidence rates amongst young adults with CKD (Figure 1). Rates of these events were higher among Black and Hispanic participants: HF (17.5 vs. 5.1/1000 person-years), all-cause mortality (15.2 vs. 7.1/1000 person-years), and CKD progression (125 vs. 59/1000 person-years). Lastly, in adjusted models, black or Hispanic status was significantly associated with higher risk of CV events (HR: 1.25, 95%CI: 1.12-1.41) and CKD progression (HR: 1.38, 95%CI: 1.21-1.57).

Conclusions: Young adults with CKD in the CRIC study experience high incidence rates of cardiovascular disease. The burden of disease is even higher for black and Hispanic participants with CKD. Further research is required to better understand the factors underlying racial disparities in young adults with CKD.

Trends in the Transition to ESRD Among Native Hawaiians and Pacific Islanders Across the United States

Connie Rhee,1 Amy S. You,1 Keith C. Norris,1 Merle R. Kataoka-Yahiro,1 James Davis,4 Glen Hayashida,1 Victoria Page,3 Shiu-Feng Cheng,4 Roland C. Ng,1 Linda L. Wong,4 Kamyar Kalantar-Zadeh,1 University of California Irvine, Irvine, CA; 2University of California Los Angeles, Los Angeles, CA; 3University of Hawaii Manoa, Honolulu, HI; 4John A. Burns School of Medicine, Honolulu, HI; 1National Kidney Foundation Hawaii, Honolulu, HI.

Background: Census data indicate there are >1.5 million Native Hawaiians and other Pacific Islanders (NHOPIs) in the US. While growing data show NHOPIs have a high prevalence of kidney disease risk factors (diabetes, obesity, hypertension, limited healthcare access), there are major knowledge gaps regarding the burden of end-stage renal disease (ESRD) in this population. We examined trends in the transition to ESRD in NHOPIs.

Methods: Using United States Renal Data System (USRDS) and Census Bureau data, we compared annual incident ESRD rates among NHOPI, African Americans (AA), and other racial subgroups over 2010-16. Rates were calculated as the observed incident ESRD count divided by the race-specific Census population size of that year. Multiple race designations were considered by utilizing Census categorizations that incorporated primary race in combination with one or more other races (alone or combination). We estimated crude rates and rates standardized to the age-sex distribution of 2011 race-specific Census data. We used multiple imputation to account for missing data. We estimated the age-standardized rate and the ratio of incident ESRD rates among different racial/ethnic groups over time (Fig 1A). A similar pattern was observed for standardized incident ESRD rates (Fig 1B: 918, 638, 308, 226, and 162 incident ESRD patients per million population/year in 2016 for NHOPI, AA, Caucasian, Asian, and American Indian/Alaska Native subgroups, respectively. While standardized incident ESRD rates among AAs gradually declined, there was a steady rise in NHOPIs' incident ESRD rates over time.

Conclusions: NHOPIs demonstrated the highest incident ESRD rates over time. Further studies are needed to determine sociodemographic, biologic/genetic, cultural, and health care related ESRD risk factors among NHOPIs to inform targeted interventions in this population.

Defining the Excess Risk of Adverse Kidney Outcomes in CKD Patients with Type 2 Diabetes in the DISCOVER-CKD Cohort

Alyshah Abdul Sultan,1 Stephen Nolan,1 Juan J. Carrero,3 Zhuoxin Jiang,2 Supriya R. Kumar,2 Roberto Pecoret-Filho,4,6 Glen James,4 Juan Jose Garcia Sanchez,1 Lam S. Carolyn,1 Hungta (tong) Chen,2 Eiichiro Kanda,2 Naoki Kashihiara,4 Mikhail Kasiborod,4 Carol A. Pollock,3 David C. Wheeler,3 Hiddo J. L. Heerspink.12 * AstraZeneca, Cambridge, United Kingdom; 1 Karolinska Institute, Karolinska Institutet, Stockholm, Sweden; 2 AstraZeneca, Gaithersburg, MD; 3 Arbour Research Collaborative for Health, Ann Arbor, MI; 4 Pontificia Universidade Católica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 5 National Heart Centre Singapore, Singapore, Singapore; 6 Duke-NUS Medical School, Singapore; Singapore; 7 Kawasaki Ika Daigaku, Kurashiki, Japan; 8 Saint Luke’s Mid America Heart Institute, Kansas City, MO; 9 Royal North Shore Hospital, St Leonard, NSW, Australia; 10 University College London, London, United Kingdom; 11 Rijksuniversiteit Groningen, Groningen, Netherlands.

Background: Chronic Kidney Disease (CKD) patients with type 2 diabetes (T2D) are considered at a high risk of cardiovascular events. However, the excess risk of major kidney events in T2D patients compared to patients without T2D is unknown.

Methods: DISCOVER-CKD is an international observational study of patients with CKD that encompasses large retrospective electronic medical records (EMR) and claims data between 2008 and 2020. Preliminary, data from US-based Limited Claims and Electronic Health Record (LCED) data (IBM Health, Armonk, NY) and TriNetX (hospital-based EMR) were analysed. CKD patients (eGFR < 75 mL/min/1.73 m2) aged ≥18 years with ≥1 record of urine albumin to creatinine ratio (UACR) were identified. T2D status was ascertainment any time before the index date (2nd eGFR measurement). The risk of kidney outcomes (sustained ≥50% eGFR decline or end-stage kidney disease) was compared between patients with and without T2D at 5 years’ follow-up.

Results: Compared to non-T2D patients, T2D patients had a slightly higher incidence rate of adverse renal outcomes (LCED: 2.7% versus 2.3% per year; TriNetX: 1.8% versus 1.2% per year). After adjusting for all confounding factors (Figure 1) we observed no increased risk of adverse renal outcomes in patients with T2D compared to non-T2D patients in LCED (hazard ratio (HR): 1.08; 95%CI 0.81-1.43) and a 34% increased risk in TriNetX database (HR: 1.34; 95%CI 1.11-1.62).

Conclusions: There is an excess risk of adverse renal outcomes in CKD patient with T2D compared to those without T2D. This is explained to a large extent by conventional risk factors in LCED but not completely in TriNetX. Both groups (T2D and non-T2D) should be managed proactively to reduce the risk of poor clinical outcomes.

Funding: Commercial Support - AstraZeneca

Table 1: Cox regression analysis for adverse renal outcome (sustained ≥50% reduction in eGFR, or ERD in composite chronic dialysis, renal transplant or sustained ≥50% in creatinine) in patients with T2D versus without T2D

PO0438

Association of the Creatinine-to-Cystatin C Ratio with Overall Survival with and Without CKD

Elam S. Strick,13 Cachet Wenzinger,1,1 John Sy,3,1 Ekamol Tantisattamo,1 Randi M. Hanna,4 Csaba P. Kovetsy,5 Susan T. Crowley,1 Kamiyar Kalantar-Zadeh,1 1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2 The University of Tennessee Health Science Center, Memphis, TN; 3 VA Long Beach Healthcare System, Long Beach, CA; 4 Memphis VA Medical Center, Memphis, TN.

Background: Creatinine and Cystatin C are measured as glomerular filtration markers. Creatinine is highly correlated with skeletal muscle mass, whereas Cystatin C is not. We hypothesized that persons, in whom serum Cystatin C is lower than creatinine level, i.e., creatinine to Cystatin C ratio (CrCCR) >1.00 (regardless of measurement units) have incrementally greater survival chance, likely due to a larger muscle mass.

Methods: We examined a cohort of 7,849 Veterans with baseline measured Cystatin C and creatinine data between 2004-2015. Veterans were divided into 0.25 increments of CrCCR, i.e., <0.75, 0.75–1.0, 1.0–1.25, ≥1.25. They were further stratified into groups based on normal vs. low eGFR (<60 vs. eGFR 60–80 mL/ min/1.73 m2), and the associations of CrCCR with survival across two eGFR strata were examined.

Results: The mean age (±SD) in the Veterans’ cohort was 69±12 years. There were 43% in the <0.75 group, 27% white, and 15% African American. The median (IQR range) for cystatin C was 1.28 (0.99,1.71) mg/L, for creatinine 1.24 (0.92,1.68) mg/dl, and for the CrCCR was 0.98 (0.81,1.17). Compared to the reference (CrCCR 1.25 and eGFR≥60 mL/ min/1.73 m2) the multivariable adjusted model showed that those with a lower CrCCR 0.75 showed the lowest mortality risk and for both eGFR strata, with the normal eGFR group having higher death risk than the low eGFR group (HR[95%CI] = 1.86(1.49,2.31) and 2.13(1.72,5.29), respectively). In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the highest overall survival, and those with low eGFR had the highest survival.

Conclusions: A lower CrCCR indicating higher cystatin C relative to creatinine levels are strongly associated with worse overall survival in Veterans regardless of kidney function level. Future studies should examine the clinical utility of this potential surrogate of muscle mass and overall health over creatinine or Cystatin C alone in evaluating risk stratification in patients with and without kidney disease.

PO0437

Increased Risk of Progression to ESRD or Death in CKD Patients with Symptoms of Depression: A Systematic Review and Meta-Analysis of Cohort Studies

Jiahao Zeng,1 Xindong Qin,1,2 Xusheng Liu,1,2 The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; 2Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China, Guangzhou, China.

Background: Comorbid symptoms of depression are common psychiatric disorder in patients with chronic kidney disease (CKD). It remains unclear whether it is an independent risk factor for progression of patients with CKD not requiring dialysis. We conducted a systematic review to assess the association of depressive symptoms with poor clinical outcomes in patients with CKD not requiring dialysis.

Methods: PubMed, Embase and CINAHL were searched (up to February 15th, 2020) for cohort studies assessing the association of depression with progression to end-stage renal disease (ESRD), defined as requiring maintenance dialysis, or all-cause mortality in patients with CKD not requiring maintenance dialysis. Two independent researchers extracted data, assessed risk of bias and evidence certainty.

Results: Seven cohort studies of 6145 patients were included. Methodological quality of studies was generally low risk of bias. Compared with non-depression or low depressive symptoms, high depressive symptoms increased the risk of progression to ESRD (HR, 2.09 95%CI 1.43 to 3.07, I2=37%), all-cause mortality (HR, 1.51 95%CI 1.13 to 2.01, I2=37%) and hospitalization (HR, 1.28, 95%CI 1.12-1.35).

Conclusions: Depressive symptoms in CKD are independent risk factors of poor clinical outcomes, including ESRD, all-cause death, and hospitalization. There is necessary to design high quality studies to assess the effects of treating depressive symptoms in patients with CKD.

CKD by Previous Diabetes or Hypertension: A Longitudinal Outcomes Study in Primary Care

David Vizcaya,1 Belen Salvador-González,2,4 Oriol Cunillera,2 Neus Gil,2 1 Bayer Pharmaceuticals, Sant Joan Despi, Spain; 2 Fundació Institut Universitari per a la recerca a l’Atenció Primària de Salut Jordi Gol i Garina (IDIAPIGol), Cornellà, Spain; 3 Unitat de Suport a la Recerca Costa de Ponent, Fundació Institut Universitari per a la recerca a l’Atenció Primària de Salut Jordi Gol i Garina (IDIAPIGol), Cornellà, Spain; 4 Direcció Atenció Primària Costa de Ponent- Institut Català de la Salut, Cornellà, Spain.

Background: To compare mortality and progression to end-stage renal disease (ESRD) in patients with new chronic kidney disease (CKD) by previous occurrence of type 2 diabetes (DM) and/or arterial hypertension (HT) in Catalonia

Methods: We designed a longitudinal retrospective study of adults with new CKD between 2007 and 2017 identified using electronic medical records from primary care
Risk of CKD Progression
Proton-Pump Inhibitors (PPIs) vs. H2 Blockers (H2B) Users and Overall

Results: Among 3,930 patients, 1,374 were in PPI group, 119 were in H2 blocker group, and 2,437 were on no medication. Average age was 72.8±11.1, and 42.5% male. Among PPI 28% had Coronary Artery Disease compared to 22% among H2B and 19% among no medication (P<0.0001). Congestive Heart Failure was 13%, 8% and 7% for each group respectively (P=0.01). Overall mortality was not different amongst the three groups (PPI vs. none HR 0.94, 95% CI: 0.80, 1.10, and PPI vs. H2B HR 0.80, 95% CI: 0.52, 1.24). The cumulative incidence of ESKD/eGFR<20 with death as a competing risk was also not different across groups in univariate (Fig. 1) or adjusted models (PPI vs. none SHR 0.99, 95% CI: 0.74, 1.34, PPI vs. H2B SHR 1.82, 95% CI: 0.91, 3.63).

Conclusions: Use of PPI in a CKD population was not associated with increased mortality or CKD progression to ESKD when compared to the use of H2 blockers and to no acid suppressing therapy.
Whether other biomarkers of immune activation are associated with ESKD in African Americans with non-diabetic kidney disease is unknown.

Methods: Utilizing baseline serum samples from AASK, we measured 4 biomarkers of immune activation (soluble tumor necrosis factor receptors 1 and 2 [sTNFRI, sTNFRII], tumor necrosis factor alpha [TNF-α], interferon gamma [IFN-γ]) and examined their associations with ESKD and all-cause mortality. Covariates included age, sex, systolic BP, BMI, smoking, baseline GFR and urine PCR. We also considered interactive effects of each biomarker with APOL1 risk status.

Results: Among 500 participants with available samples, mean GFR was 44.7 ml/min/1.73 m² and median urine PCR was 0.09 g/g at baseline. Over a median follow-up of 9.6 years, there were 161 (32%) ESKD and 113 (23%) death events. In fully adjusted models, each two-fold higher baseline level of sTNFRI, sTNFRII, and TNF-α was associated with 3.66, 2.29, and 1.35-fold greater risks of ESKD, respectively (Table). In comparison, the association between sPAR and ESKD was 1.39 (95% CI: 1.04, 1.86). These three biomarkers were also significantly associated with death (up to 2.2-fold higher risks per 2-fold higher baseline level; p<0.01). IFN-γ was not associated with either outcome. None of the biomarkers modified APOL1-associated risks for ESKD (p-interaction<0.05). The C-statistic for the fully adjusted clinical model in predicting ESKD was excellent at 0.849 (95% CI: 0.820, 0.878). Adding sTNFRI, the biomarker with the strongest association, to the clinical model led to a small but statistically significant improvement in the C-statistic at 0.860 (95% CI: 0.833, 0.887; difference of 0.011; 95% CI: 0.001, 0.021).

Conclusions: Among African Americans with CKD attributed to hypertension, baseline levels of sTNFRI, sTNFRII, and TNF-α but not IFN-γ were associated with ESKD and mortality.

Urinary Fibrosis Markers and Risk for ESKD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Amanda H. Anderson,1 Robin L. Baudier,2 Wei Yang,3 Katalin Susztak,4 Mircla A. Dobre,3 Hua He,4 Mahboob Rahman,3 Sylvia E. Rosas,4 Anand Srivastava,1 Sushrut S. Waikar,1 Harold I. Feldman,7 The CRIC Study 1 Tulane University, New Orleans, LA; 2 University of Pennsylvania, Philadelphia, PA; 3 Case Western Reserve University, Cleveland, OH; 4 Joslin Diabetes and Endocrinology Research Center, Boston, MA; 5 Northwestern University, Evanston, IL; 6 Boston University, Boston, MA.

Background: Connective tissue growth factor (CCN2) and amino-terminal peptide of procollagen type III (PIINP) are both correlated with kidney fibrosis. However, it is unclear if these markers are independently associated with the risk for ESKD.

Methods: We measured CCN2 and PIINP in baseline urine and standardized to urine creatinine (Cr) in a multi-center cohort study of men and women with chronic kidney disease (CKD), the CRIC Study (N=3727). ESKD was defined as initiation of kidney replacement therapy (N=1118 events). Cox proportional hazards models were adjusted hierarchically as indicated (Table). The association was no longer statistically significant after adjustment for proteinuria.

Results: The mean age of the study population was 58 years; mean eGFR: 45 ml/min/1.73m²; and 48% had diabetes. After multivariable adjustment and median follow-up of 10 years, the highest quartiles of CCN2/Cr and PIINP/Cr were associated with a 1.8-fold and 1.7-fold higher risk for ESKD compared to the lowest quartiles, respectively (Table). The association was no longer statistically significant after adjustment for proteinuria.

Conclusions: Urinary CCN2 and PIINP are strongly associated with risk for ESKD, an association that may be mediated through proteinuria. Future studies should investigate if these markers add to the identification of those at highest risk for progression to ESKD.

PO0446

Urinary Retinol-Binding Protein Is Associated with the Risk of Kidney Replacement Therapy in CKD

Maria Alice M. Dominigos, Paulo Lotufo, Isabela M. Bensenor, Silvia M. Titan, University of Sao Paulo, Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Retinol-Binding Protein (rBP), a biomarker of proximal tubular injury, is used in clinical practice as a risk factor for CKD in tubular diseases, such as Dent’s disease and cystinosis, and in renal transplantation. However, its role as a biomarker of CKD progression outside these conditions is less clear. The aim of our study was to evaluate the association of sRBPI with the risk of mortality and kidney replacement therapy (KRT) in CKD of multiple etiologies.

Methods: The Progressor Cohort is composed of 454 older adults with CKD (predominantly G3 and G4) recruited from the outpatient services of a tertiary hospital in Sao Paulo, Brazil. Baseline sRBPI was measured using an immunoenzymometric assay with monoclonal antibody and expressed as mg/g urinary creatinine, and those with missing values were excluded (n=22). Events of death (n=184) and KRT (n=60) were ascertained

Tubular Secretion of Creatinine and Risk of Kidney Failure: The Modification of Diet in Renal Disease Trial
Pranav S. Garmiella,1 Hocine Tighiouart,2 Andrew S. Levey,2 Mark J. Sarnak,2 Joachim H. Tc,1 University of California San Diego, La Jolla, CA; Tufts Medical Center, Boston, MA.

Background: Whether tubular secretion is associated with clinical outcomes beyond glomerular filtration rate (GFR) or proteinuria is unknown. By using measured GFR and creatinine clearance, we evaluate the association of tubular secretion of creatinine with long-term kidney and mortality outcomes.

Methods: The Modification of Diet in Renal Disease (MDRD) Study was a randomized controlled trial conducted to examine the effects of strict blood pressure control and dietary protein restriction on progression of stages 3 to 4 CKD. This prospective analysis included 838 participants with baseline measures of iothalamate creatinine clearance (CrCl). Tubular secretion of creatinine (TS-Cr) was calculated as the difference between CrCl and mGFR. The primary outcome was incident end-stage kidney disease (ESKD) and secondary outcomes were cardiovascular disease (CVD) related and all-cause mortality.

Results: At baseline, mean mGFR was 33 ml/min/1.73 m2 and the mean CrCl was 42 ml/min/1.73 m2. Over 21 years of follow up there were 626 ESKD, 202 CVD-related events. Each 10 ml/min/1.73 m2 higher TS-Cr was associated with a lower risk of ESKD (HR 0.74, 95% CI 0.66-0.84) after adjustments for mGFR, proteinuria, and other potential confounding factors [Image]. Higher TS-Cr was associated with lower risk of CVD related mortality (HR 0.78, 95% CI 0.65, 0.95) and all-cause mortality (HR 0.86, 95% CI 0.75, 0.97) in unadjusted models but these associations were no longer statistically significant after adjusting for confounders (HR 0.82, 95% CI 0.66 1.02 and HR 0.92, 95% CI 0.79, 1.06 respectively).

Conclusions: Higher TS-Cr is associated with lower risk of ESKD, independent of mGFR, proteinuria, and other kidney disease factors. Tubular secretion provides prognostic information above and beyond GFR and proteinuria.

PO0448
Clinical Significance and Related Factors of GFR Slope in a Large Multicenter Observational Study in Japan
Yuki Kamio,1,2 Koji Hashimoto,1,2 Yosuke Yamada,1,2 Makoto Harada,1,2 Masatsugu Aida,1,2 Shitotomo Yamauchi,2 NKEA study group 'Shinsu University School of Medicine, Matsumoto, Japan; 3Nagano Kidney Function Association, Matsumoto, Japan; IEthic Co., Ltd., Chiyoda-ku, Japan.

Background: Recently, GFR slope has attracted attention as an important surrogate marker for the prognosis of CKD, with a reduction in slope of GFR decline by 0.75 ml/min/1.73 m2 per year reportedly having clinical significance. This investigation addresses the clinical significance of GFR slope and its related factors on Japanese CKD patients.

Methods: CKD patients in 15 general hospitals between January and March 2014 were surveyed using medical records. The selection criteria were age ≥20 years, eGFR <60 ml/min/1.73 m2, and receiving medical treatment for CKD. Baseline patient characteristics, eGFR changes, and hard endpoints (death or ESKD requiring RRT) were analysed. We calculated GFR slope using eGFR data of 2 years by 2 calculation methods, the linear mixed model and least squares linear regression, and examined the relationship of GFR slope with the hazard ratio (HR) of the endpoints. The factors related to GFR slope were also assessed by multiple regression analysis.

Results: Among a total of 11233 patients, we analyzed the data of 7490 CKD G3 and G4 patients (60% male, mean age: 71 years, CKD G3a: 55%, G3b: 30%, G4: 15%, mean eGFR: 44 ml/min/1.73 m2, urin protein positive: 51%, diabetes mellitus: 49%, use of RAS-I: 57%). The mean observation period was 1040 days. Hard endpoints after the GFR slope measurement period occurred in 301 subjects. The GFR slope of the cohort was -0.548 ml/min/1.73 m2 per year (95% confidence interval [CI] -0.716, -0.380) in the linear mixed model and -0.452 ml/min/1.73 m2 per year (95% CI -0.635, -0.579) according to least squares linear regression. Both calculated GFR slopes were significantly related to the HR of the composite hard endpoints. HR decreased by 0.85 (linear mixed model) and 0.9 (least squares linear regression) times in case of a reduction in slope of GFR decline by 0.75 ml/min/1.73 m2 per year. Multiple regression analysis revealed strongly significant associations for GFR slope with urine protein and CKD stage and undetectable relationships for GFR slope with diabetes and age.

Conclusions: This study demonstrated the clinical significance of GFR slope as a surrogate marker for renal prognosis in Japanese CKD patients. In order to reduce slope of eGFR decline, active intervention for proteinuria before the progression to an advanced CKD stage appears to be effective.

PO0449
The Kidney Failure Risk Equation: Testing Previous eGFR Slopes, Clinical Variables, and Novel Populations
Morgan Grams, Nigel J. Brunskill, Angelia Yee Moon Wang, Navdeep Tangri. CKD Prognosis Consortium CKD Prognosis Consortium, Baltimore, MD.

Background: The 4-variable kidney failure risk equation (KFRE) is a well-validated tool that accurately predicts the 2- and 5-year risk of kidney failure in patients with eGFR <60 ml/min/1.73 m2 using baseline eGFR, ACR, age, and sex. The aim of this study was two-fold: to assess whether KFRE can be improved using previous eGFR slope or other variables; and to evaluate whether the KFRE can be used in patients with eGFR ≥60 ml/min/1.73 m2.

Methods: We used 36 cohorts in development and 17 cohorts in validation to accomplish these aims; all cohorts participate in the CKD-Prognosis Consortium and had data on the four variables, previous 2-year eGFR slope, and at least 25 ESKD events. In summary, the KFRE was improved only slightly by the inclusion of previous eGFR slope and/or other variables; and to evaluate whether the KFRE can be used in patients with eGFR ≥60 ml/min/1.73 m2.

Results: There were 205,004 participants with eGFR <60 ml/min/1.73 m2 (12,794 CKD events) and 441,915 participants with eGFR ≥60 ml/min/1.73 m2 (1,220 ESKD events). In the eGFR <60 group, previous 2-year eGFR loss ≥3 ml/min/1.73 m2/year was associated with ESKD (meta-analyzed HR 1.36, 95% CI 1.19-1.56) with a small improvement over the 4-variable model (baseline c-statistic in validation cohorts, 0.87-0.95, meta-analyzed difference in c-statistic in validation cohorts when adding slope, 0.001, 95% CI: 0.000-0.002). Using previous 5-year slope resulted in slightly better c-statistic compared to the model using 2-year slope (meta-analyzed difference in c-statistic in validation cohorts, 0.003, 95% CI: 0.001-0.005). Other approaches, such as using 1-year average eGFR or 1-year average ACR as inputs in the 4-variable KFRE, or incorporating black race, heart failure, or atrial fibrillation, did not result in meaningful improvements. The KFRE had poor discrimination and calibration in the eGFR ≥60 ml/min/1.73 m2 population. In a model that instead predicted 40% decline in eGFR and included age, sex, ACR, diabetes, hypertension, heart failure, and coronary heart disease, previous eGFR loss ≥3 ml/min/1.73 m2/year over 2- and 5-years were associated with greater risk (HR, 1.43, 95%CI: 1.19-1.70; 1.84, 95%CI: 1.40-2.42).

Conclusions: In summary, the KFRE was improved only slightly by the inclusion of previous eGFR slope. For populations with eGFR <60, a more relevant and predictable outcome may be percent eGFR decline.

Funding: NIDDK Support, Private Foundation Support
Comparison of Predicted Risk of Renal Replacement Therapy vs. eGFR for Arteriovenous Fistula Placement in CKD: A Retrospective Analysis

Background: The complexity in predicting which and when patients with chronic kidney disease (CKD) will progress to renal replacement therapy (RRT) contributes to 80% of patients starting hemodialysis without a functioning permanent access. Studies suggest AVF referral at eGFR of 15-20 ml/min increases the likelihood of starting dialysis with an AVF. We were interested in whether a prediction model developed at Kaiser Permanente Northwest better predicted progression to RRT at 1 year compared to eGFR.

Methods: We retrospectively followed 613 patients with stage 4 CKD between ages of 18 to 89 from May 2013 to May 2018 followed by nephrologists who had a nephrology visit with an eGFR and a calculable 2-year risk for RRT around 12 months before end of follow up (defined as death, initiation of RRT, or 2 years from initial enrollment date). We calculated sensitivity, specificity, and area under the curve (AUC) based on a range of 2-year risk for RRT (20%, 40%, 60%, and 80%) and compared them to eGFR threshold of 15 ml/min and 20 ml/min at the 12 month visit prior to end of follow up. We compared 2-year risk for RRT at 1 year compared to eGFR.

Results: At end of follow up, 12% had died and 14% had progressed to RRT (69% hemodialysis, 22% peritoneal dialysis, 9% transplant). Compared to eGFR threshold of 20 ml/min, specificity and specificity was greater at 2-year RRT risk of 40% (73% and 49% for eGFR threshold of 20 ml/min respectively compared to 83% and 54% respectively for 2-year RRT risk of 80%). Compared to eGFR threshold of 15 ml/min, sensitivity and specificity was greater at 2-year RRT risk of 80% (97% and 11% for eGFR threshold of 15 ml/min respectively compared to 98% and 18% respectively for 2-year RRT risk threshold of 80%). The AUC was greater between 2-year RRT of 20% to 40% (0.73 to 0.70) compared to eGFR between 15 ml/min to 20 ml/min (0.54-0.61). Decision curve analysis showed better net benefit using 2-year risk -40% compared to eGFR of 20 ml/min above a 1 year threshold of 25%.

Conclusions: In patients with CKD stage 4, 2-year risk for RRT better predicted progression to RRT at 1 year compared to eGFR alone. Our study suggests that use of prediction model for RRT may be an important tool for determining optimal timing for AVF referral.

Risk Factors of Renal Replacement Therapy in Hospitalized Patients with CKD Stage 4

Qiaoli Hu,1 XuSheng Liu,1 Chuan Zou.2 1Department of Nephrology, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; 2Department of Dialysis, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; The Second Clinical Medical College, Guangzhou University of Chinese Medicine, Guangzhou, China.

Background: Data on risk factors of renal replacement therapy (RRT) in hospitalized patients with CKD4 may help nephrologists to delay dialysis. The study was designed to describe the risk factors of RRT in CKD4 inpatients.

Methods: Medical records of CKD4 inpatients in Guangdong Provincial Hospital of Chinese Medicine during May 2010 - January 2020 were collected. Risk factors such as demography characteristics, laboratory and echocardiography test results, treatments, comorbidities and primary diseases were collected. Patients were followed up till they reached clinical outcomes (RRT) or the end of the study (January, 2020). Patients who died within 1-2 year were not excluded. Descriptive statistics and survival analysis were performed with Cox regression, with 95% CI, considered a value of p < 0.05 as statistically significant.

Results: 222 CKD4 inpatients [age, 60.00 (47.75-72.25) years]; female, 55.9% were enrolled. In a median follow-up of 2.41 years, 199 inpatients (10.6%) started RRT. Among those patients, the median time progression to RRT was 2.10 (1.20-3.58) years. All patients were divided into two groups according to whether progressed to RRT within 2.41 years. For those received RRT within 2.41 years, they had heavier urine, urine occult blood and account for a higher proportion of inpatients with diabetes mellitus (63.6%), chronic heart failure (43.6%), diabetic kidney disease (55.5%). Their serum albumin and ejection fraction (EF) were lower (P < 0.001). The multivariate Cox proportional hazards models showed that age/height ratio (HR), 0.986; 95% confidence interval (CI), 0.956-0.995; P = 0.004, diabetic kidney disease (HR), 1.81 (1.274-2.391), P = 0.001, urinary protein (HR), 1.148, 95% CI, (1.014-1.205), P = 0.001, serum albumin (HR), 0.971, 95% CI, (0.949-0.994), P = 0.013, LVMI (HR), 1.10, 95% CI, (1.004-1.206), P = 0.002, left ventricular dimension systolic(LVds) (HR), 0.948, 95% CI, (0.910-0.986), P = 0.008 and EF (HR), 0.970, 95% CI, 0.950-0.990, P = 0.004 were independently associated with factors for progression to RRT in CKD4 inpatients.

Conclusions: DKD, urinary protein, LVMI were risk factors that were significantly associated with CKD4 progression to RRT in inpatients. Whereas, serum albumin, LVds, and EF are protective. The urinary protein, serum albumin and echocardiographic parameters need to be taken seriously for patients with CKD4.

Development and Validation of a Predictive Model to Identify Patients with Undiagnosed CKD

Steven M. Brunelli, Adam G. Walker, Kathryn S. Gray. Davita Clinical Research, Minneapolis, MN.

Background: Chronic kidney disease (CKD) is a common condition and often goes undiagnosed. Unmanaged CKD can progress rapidly, resulting in poor clinical outcomes and increased health care costs. Identification of individuals who may have undiagnosed CKD would allow for implementation of CKD management practices in order to slow progression, potentially improving outcomes and reducing health care costs. Here, we report the development and validation of a claims-based algorithm to identify CKD.

Methods: This model was developed using Medicare Part A and Part B claims from calendar year 2017. Data from 378,460 unique patients with no evidence of end-stage kidney disease or claims for dialysis through April 2017 were split into derivation (n = 189,203) and validation (n = 189,237) sets. The predicted outcome was the presence of a diagnosis code for CKD stages 3 to 5, which occurred in 4.4% of patients within the data. To simulate the use case, codes for kidney disease were not eligible as predictors in the model. Area under the curve (AUC) of the receiver operating curve and positive predictive value (PPV) were used to assess the performance of candidate models.

Results: The best model was a logistic regression algorithm based on 94 input terms derived from 15 clinical constructs. The model demonstrated an excellent ability to discriminate (AUC = 0.90), which was stable when tested in the validation set (AUC = 0.90). The PPV in the top 1% and top 2% of patients identified by the model was approximately 72% and 59%, respectively.

Conclusions: We developed an algorithm that uses medical claims to identify patients who are most likely to have unrecognized CKD. If the algorithm were applied to a population of 10,000 patients, it could identify the 100 patients at highest risk, among whom 72 would have CKD if tested.

Predicting Progression to ESKD: Application of Novel Statistical Methodologies

Kristina Loopner,1 Priscila Preciado,2 Yue Jiao,1 Carly Hahn Contino,1 Len A. Usvyat,1 Yuedong Wang,2 Peter Kotanko.3,4 Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Renal Research Institute, New York, NY; 3University of California, Santa Barbara, Santa Barbara, CA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Estimating time to end-stage renal disease (ESRD) in chronic kidney disease patients (CKD) is important in preparing patients for a smooth transition to dialysis. In this analysis we explored patterns in trajectories of blood urea nitrogen (BUN), systolic blood pressure (SBP), and estimated glomerular filtration rate (eGFR) in patients with CKD and associated them to time to ESRD.

Methods: We used data from a registry of CKD patients from practices using Acumen electronic medical records, obtaining 8,572 patients with CKD 3 from 2003 to 2018 based on their first eGFR value. BUN, SBP, and eGFR were observed for 3 years after first eGFR measurement. Time to ESRD is calculated from the start of the follow-up period to when eGFR < 15 ml/min/1.73m2. Functional data for each patient was generated by fitting cubic splines to BUN, SBP, and eGFR, respectively. Trajectories of each variable were grouped into 3 clusters using principle component analysis (PCA) scores; time to ESRD was compared between them by Kaplan-Meier analysis. We fit Cox proportional hazards model with eGFR, SBP, BUN clusters and age, sex, and race as predictors of ESRD onset.

Results: BUN, SBP, and eGFR have stable, increasing, and decreasing trajectory clusters (Figure). In a Cox model with these clusters as well as age, gender, and race, trajectories of eGFR, SBP, and BUN were significant predictors of ESRD onset.

Conclusions: Since BUN, SBP, and eGFR trajectories were all significant predictors of progression to ESRD, it is important to consider all three to ascertain CKD progression.

Indexing Proteinuria to Renal Function Improves Prediction for Renal Events in Individuals with CKD

Afshin Parsa,1 Ivonne H. Schulman,1 Kenneth J. Wilkins,1 Susan R. Mendley,1 Paul L. Kimmel,1 Adan Z. Becerra,2 1Division of Kidney, Urologic, and Hematologic Diseases, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; 2Social & Scientific Systems, Silver Spring, MD.

Background: Identifying the optimal measurement of proteinuria in clinical settings has been challenging. To determine the potential consequence of varied measures of proteinuria, we contrasted their clinical significance primarily in relation to renal events and secondarily to cardiovascular (CVD) and mortality events.

Methods: We compared the predictive ability of four measures of proteinuria and albuminuria, among 3,992 CKD participants from the Chronic Renal Insufficiency Cohort (CRIC) Study, for incident renal events (halving of glomerular filtration rate [GFR] or end-stage renal disease), CVD events (myocardial infarction, congestive heart failure, stroke and peripheral arterial disease) and mortality over 3 years. The four measures included timed urinary albumin and protein excretion rates (AER, PER), albumin:creatinine ratios (ACR, PCR), albumin:protein:adjusted creatinine (accounting for creatinine production) ratios (eAER, ePER), and lastly albuminuria/proteinuria indexed to GFR (ACR-G, PCR-G), as an estimation of glomerular permeability. We used Harrell’s C-Statistics to measure model discrimination.

Results: Predictive performance for renal events was lowest for AER and PER. Results were generally similar for ACR vs eAER and PCR vs ePER. Notably, PCR-G showed significant improvement in predicting renal outcomes and performed better than albuminuria-based measures. C-statistics for renal events were 0.831, 0.840, 0.841, 0.846, and 0.862 for AER, eAER, ACR, PCR and PCR-G, respectively. Trends were similar for CVD and mortality events, except that ACR performed better than PCR for CVD events, but not as well as PCR-G or ACR-G. Results were overall consistent across diabetes, gender and race strata, and were validated in an additional 1,443 participants from the third phase of CRIC.

Conclusions: Indexing proteinuria to GFR is a simple and economical measure, compared to albuminuria, that significantly enhances the prediction of CKD progression and associated outcomes.

The Phosphate-to-Urinary Urea Nitrogen Ratio (P/UUN): A Tool to Evaluate Phosphate Intake and Excretion in CKD Patients

Victoria Pendón-Ruiz de Mier,1,2 Cristian Rodelo-Haad,1,2 Rafael Santamaría,1,2 Rodrigo López bailafán,1 Cristina Membrives González,1 Juan R. Munoz-Castaneda,1,2 Alejandro Martin-Malo,1,2 Sagrario Soriano,1,2 Mariano Rodríguez Portillo.1,2 1Instituto Maimonides de Investigacion Biomédica de Cordoba, Cordoba, Spain; 2Hospital Universitario Reina Sofia, Cordoba, Spain.

Background: Phosphate (P) restriction is crucial in CKD patients. Classically, P intake has failed to correlate with 24-h phosphaturia. Organic or inorganic P have different intestinal absorption rates, which might explain the lack of correlation between P intake and phosphaturia. Thus, we aimed to evaluate if the source of dietary P rather than the total P ingested determines phosphaturia, and to what extent inorganic P intake modifies phosphaturia.

Methods: A 3-day dietary survey was performed in 71 stages G2-3 CKD patients to estimate the amount and source of P intake. 24-h urine samples were collected. Total phosphaturia, the FeP%, and P/UUN, which reflect intestinal absorption of P relative to proteins absorbed and metabolized, were evaluated. P/UUN ratio tertiles were contrasted with the other variables analyzed (T1=58.9mg/g, T2=58.9-71.1mg/g, T3>71.1mg/g). Statistics were performed using Rv3.6.2

Results: The P intake was 1086.5±361.3 mg/day. P intake was 64.0%,22.1%, and 14.1% from animal, vegetables, and inorganic sources respectively. Total P intake did not correlate with urinary P (p=0.12), nor FeP. Patients ingesting more P ingested more inorganic P (Fig1). P intake correlated with P/UUN ratio (p=0.008). Patients in the upper P/UUN tertile showed the highest daily P intake (p=0.04) from inorganic sources (p=0.03), and the highest phosphaturia (p=0.04)

Conclusions: P/UUN reflects the total P intake and provides information about the amount of inorganic P, and could be used to guide the appropriate nutritional advice for CKD patients.
PO0457

Dietary Phosphorus Restriction Improves Renal Function, Blood Pressure, FGF-23, and Klotho Levels in CKD Stages 1 and 2

Anita Saxena, Trisha Sachan, Amit Gupta, Anup Kumar, Sachin Sharma. Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: To evaluate impact of dietary education and intervention (phosphorus restriction) on creatinine, eGFR, FGF23, Klotho and blood pressure.

Methods: 105 subjects (CKD stages 1, 2 N 70; 3 Controls) evaluated for eGFR, creatinine, phosphorus, calcium, FGF-23, soluble o-Klotho iPTH FGF 23, blood pressure and 3 days dietary intake, using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake: Group 1 (n 42): phosphorus intake <1000mg/day and Group 2 (n=37; 17 in CKD 1; 20 CKD 2): high phosphorus intake (>1000mg/d). Patients in Group 2 were counselled for low phosphorus diet.

Results: Parameters of controls and CKD patients differed significantly. Dietary, serum and urinary phosphorus (0.001) had significant association. Systolic and diastolic BP, protein intake, dietary phosphorus, iPTH, FGF23 were significantly high (p 0.001) and Klotho significantly low (p 0.001) in Group 2 compared to Group 1. Impact of dietary intervention was seen after 6 and 12 months as reduction in protein intake from 0.64±0.95 to 0.58±0.11 (CKD 1) and 0.71±0.074 to 0.64±0.095 (p 0.012 CKD 2); decline in creatinine from 1.13±0.14 to 1.07±0.14 (CKD 1) and 1.06±0.56 (p 0.009 CKD 1); serum phosphorus from 3.57±0.19 to 3.23±0.58 (CKD 1) and 4.32±0.42 to 3.35±0.85 mg/dL (p 0.001 CKD 2); FGF-23 from 55.01±1.65, to 51.27±1.17 (CKD 1); 65.4±2.40 to 56.60±11.23 (p 0.010 CKD 2); systolic BP from 127.95±3.14 to 121.05±4.14 (CKD 1); 134.22±3.54 to 118.38±9.08 (p 0.001 CKD 2) and diastolic BP from 85.14±3.83 to 83.29±8.03 (CKD 1); 89.11±4.74 to 80.33±8.02 (p 0.003 CKD 2) and a significant increase in eGFR mL/min from 95.17±5.50 to 97.75±20.26 (CKD 1); 69.82±8.56 to 74.08±11.07 (p 0.019 CKD 2) was observed. sKlotho increased from 700.79±27.82 to 879.39±168.37 (p 0.001 CKD 1); from 633.2±60.56 to 823.37±156.67 (p 0.001 CKD 2). Ca x P product declined from 36.10±4.84 to 29.49±7.63 (p 0.001). eGFR can predicted using dietary protein, creatinine systolic BP, haemoglobin, cholesterol (r 0.808).

Conclusions: Dietary counselling had significant effect on all the parameters in early CKD stages. Dietary intervention can prevent increase in FGF23, reduce blood pressure and prevent decline in renal function as demonstrated by significant increase in eGFR with phosphorus restriction in early stages of CKD.

PO0458

Baseline Serum Magnesium and Risk of CKD Progression in the Chronic Renal Insufficiency Cohort (CRIC) Study

Simon Correa,1,2 Sushant S. Walker,1 Finnian R. McCausland,1,2 Brigham and Women's Hospital, Boston, MA; 1Harvard Medical School, Boston, MA; 1Boston Medical Center, Boston, MA.

Background: Serum magnesium (sMg) concentration is regulated by intestinal absorption and renal handling which are impaired in CKD. While Mg has been implicated in blood pressure regulation and Mg has been associated with the risk of hypertension, the association of sMg with long-term risk of CKD progression remains unclear.

Methods: Adjusted cox proportional hazard regression models were fit to determine the association of baseline sMg with CKD progression in CRIC. CRIC progression was defined as 1) development of end-stage renal disease (renal transplantation or dialysis initiation) or 2) a 50% decline in baseline eGFR (CKD-EPI). All models were stratified by clinical site and adjusted for demographics, BMI, DM, CV comorbidities, hematocrit, baseline eGFR, FGF23-EPI, serum albumin, 24-hour protein, urine, serum and urine electrolytes, total-PTH, CV biomarkers associated with CKD progression, antihypertensive medications and diuretics. Adjusted splines were also fit.

Results: We analyzed data from 3,866 participants from CRIC who had sMg assessed at baseline. Median sMg was 2.0 mEq/L (25th-75th percentile 1.9 to 2.1 mEq/L). After multivariate adjustment, higher baseline sMg was associated with a 27% lower hazard of CKD progression (aHR 0.73, 95% CI 0.58-0.92; P=0.01, per 1 mEq/L). Compared to the lowest quartile (Q1), sMg concentration in the top quartile (Q4) was associated with a 23% lower hazard of CKD progression (aHR Q1-Q4 0.78, 95% CI 0.65-0.94; P=0.001). The adjusted relationship of sMg with CKD progression appeared to be linear (Fig 1).

Conclusions: In patients with CKD, higher sMg is associated with a lower risk of CKD progression independent of clinical and biochemical data. Whether correction of hypomagnesemia prevents CKD progression deserves future prospective studies.
The Association Between Dietary Fiber Intake and Clinical Outcomes in CKD: A Report from the Chronic Renal Insufficiency Cohort (CRIC)
Sumeet S. Brar, Sarah Delozier, Nishi Pradhan, Mahboob Rahman, Mirela A. Dobre. Case Western Reserve University, Cleveland, OH.

Background: Standard dietary interventions for individuals with chronic kidney disease (CKD) consist of reductions in salt, phosphorus, potassium, and protein intake, with no specific guidance regarding dietary fiber intake. In animal models of kidney disease, a diet high in amylose resistant starch has been found to trigger a reduction in inflammation and CKD progression. It is unclear whether low dietary fiber intake is associated with a higher risk of incident kidney disease progression, cardiovascular disease, and overall mortality in individuals with CKD.

Methods: A total of 3791 participants with chronic kidney disease and information on dietary fiber intake at the baseline visit in the Chronic Renal Insufficiency Cohort (CRIC) Study were included in the analyses. Cox proportional hazards models adjusted for sociodemographic, comorbidities, medications and laboratory data, including eGFR and proteinuria were used to analyze the association between dietary fiber intake and clinical outcomes.

Results: The mean age was 59±11 years, 46% were female, 47% had diabetes, and the average eGFR was 48±17 ml/min/1.73m². The average dietary fiber intake was 17.3±9.6 g. After a median follow-up of 8.8±4.5 years, there was an inverse association between crude death rates and baseline dietary fiber intake: increasing from 3.1 per 100 person-years (PY) for the highest to 3.4 per 100 PY for the lowest fiber tertile. After multivariable adjustments, individuals in the middle and low fiber tertiles were at greater risk of death compared to those in the highest fiber tertile (HR[95%CI], 1.18 [1.01, 1.38], p=0.04 and 1.10 [0.94, 1.29], 0.24, respectively). We found no significant association between dietary fiber intake and kidney and cardiovascular disease outcomes. Results were similar in sensitivity analyses by subgroups defined by age, gender, ethnicity, diabetes, eGFR (< and ≥ 45 ml/min/1.73m²), and proteinuria.

Conclusions: Dietary fiber intake may be associated with the risk of death, but not with cardiovascular outcomes or kidney disease progression in individuals with CKD. Future intervention trials should investigate whether a diet enriched in fibers would influence mortality and other clinical outcomes.

Effect of Zinc Deficiency on CKD Progression and Effect Modification by Hypoalbuminemia
Atsuyuki Tokuyama,1 Eiichiro Kanda,2 Seiji Itano,1 Megumi Kondo,1 Yoshihisa Wada,1 Hiroyuki Kadoya,2 Kengo Kidokoro,1 Hajime Nagasu,1 Tamaki Sasaki,1 Naoki Kashihara,1 1Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan; 2Department of Medical Science, Kawasaki Medical School, Kurashiki, Japan.

Background: Serum zinc (Zn) levels tend to be low in chronic kidney disease (CKD) patients. However, it has not been shown whether zinc deficiency itself leads to poor renal prognosis. The purpose of this study was to investigate the relationship between zinc deficiency and CKD progression.

Methods: This is a retrospective cohort study using the CKD patient database of electronic medical records (n=325). The study patients were classified into two groups: Zn levels<60μg/dl (low-Zn group, n=163) and Zn levels≥60μg/dl (high-Zn group, n=162). The primary outcome was defined as end-stage kidney disease (ESKD) or death, and the observation period was one year. The relationship between low Zn levels and the outcome was assessed using Cox proportional hazard model and by competitive risk analysis. Furthermore, the propensity score-matched analysis for low Zn level was also conducted.

Results: Among the subjects, 51.7% were male; mean age, 69.3 years; mean Zn level, 59.9μg/dl; and median eGFR, 20.4 ml/min/1.73 m². The incidence of the primary outcome was higher in the low-Zn group than in the high-Zn group (42.3% vs 19.1%, p<0.001). The risk of the primary outcome was higher in the low-Zn group [adjusted hazard ratio (HR) 1.88 (95% CI 1.08, 3.28; p=0.025)]. The analysis using competitive risk models showed that low Zn levels were associated with ESKD, but not with death. Moreover, in the propensity score-matched analysis, the low-Zn group showed a high risk of the primary outcome [HR 2.05 (95% CI, 1.09, 3.86; p=0.026)]. Furthermore, the relationship between the low Zn levels and the primary outcome was aggravated in the hypoalbuminemia patients (interaction p=0.011).

Conclusions: This study indicated that zinc deficiency is a risk factor for ESKD among CKD patients. Hypoalbuminemia affects the CKD progression due to zinc deficiency.

**Association of Plasma Selenium with Renal Function in Hypertensives: Modification by Folate**

Youbou Li, Xinhui Qin, Jing Nie, Min Liang, Fan Fan Hou. Division of Nephrology, Nanyang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangdong Provincial Institute of Nephrology, Guangzhou, China.

**Background:** We aimed to investigate the association between plasma selenium (Se) and renal function decline in adults with hypertension and to explore the possible modifying factors.

**Methods:** This was a prospective study, including a total of 935 hypertensive adults from a folate-acid intervention trial (CSPPIT) with baseline plasma Se measurements and renal outcome data available. The primary outcome was rapid decline in renal function, defined as an average decline in eGFR of ≤5 mL/min/1.73 m² per year.

**Results:** Over a median follow-up of 4.4 years, the primary outcome occurred in 72 participants. After multivariate-adjusted, there was an inverse association between plasma Se and rapid decline in renal function (per 10-unit increment: OR, 0.85; 95% CI: 0.72, 0.99). Consistently, compared to the lowest tertile of baseline plasma Se (<7.4 μg/L), the highest tertile (89.4–<150 μg/L) was significantly associated with a 60% (90% CI: 0.21, 0.79) reduction in the odds of the outcome. A stronger inverse plasma Se-renal function decline association was observed in those received folic acid treatment (per 10-unit increment: OR, 0.70; 95% CI: 0.54, 0.90; P-interaction=0.036) or with a higher baseline folate concentration (per 10 mg/L: 0.59, 0.43, 0.82; P-interaction=0.004).

**Conclusions:** In China hypertensives with plasma Se <150 μg/L, there was an inverse relationship of plasma Se with the renal function decline, especially in those with folate acid supplementation or a higher folate level.

**Funding:** Government Support - Non-U.S.

**Association between plasma Se and the outcome**

**Relationship of Serum Triglycerides with Incident Albuminuria Among 114,817 US Veterans**

Melissa Soohoo, Jui-Ting Hsiung, Maria V. Marroquin, Csaba P. Kovessy, Kamyar Kalantazadeh, Elian Streja. The University of Tennessee Health Science Center, Memphis, TN; VA Long Beach Healthcare System, Long Beach, CA; Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; Memphis VA Medical Center, Memphis, TN.

**Background:** The association of metabolic syndrome (MetS) components of impaired glucose, obesity, low high-density lipoprotein, hypertension, and serum triglycerides (TG), with renal endpoints such as incident chronic kidney disease (CKD) have been previously studied individually. Urine albumin to creatinine ratio (UACR) remains an integral part of CKD staging and incidence, yet it remains understudied. Thus, we sought to examine the relationship of TG with incident albuminuria among normal UACR patients with consideration for other MetS components.

**Methods:** Our cohort comprised 114,817 veterans with albuminuria stage A1 (<30 mg/g) and incident albuminuria, adjusted for case-mix characteristics, laboratory values and individual MetS components, as well as stratified by sex and MetS components.

**Results:** The means SD age was 65.1±11, with a median [IQR] of TG, UACR and eGFR of 144 [97, 214] mg/dL, 7 [4, 13] mg/g, and 75 [61, 89] mL/min/1.73 m² respectively, and 70% had at least 3 MetS components. We observed a linear association between TG and incident albuminuria after adjustment for case-mix and laboratory variables (ref: TG 120–160 mg/dL; the association did not differ after adjustment for MetS components and Figure A). Moreover, stratification by number of MetS components showed similar linear associations between TG and incident albuminuria, especially in patients with ≥3 MetS components. In patients with ≥2 MetS components, the linear relationship of TG and incident albuminuria was attenuated (Figure B).

**Conclusions:** Higher TG are associated with incident albuminuria independent of other components of MetS. Further study is needed to understand the drivers of this association, with a specific focus of how to best manage TG levels in addressing albuminuria development.

**PO0464**

**Association Between CKD and New Onset of Dyslipidemia: Results from a Longitudinal Nationwide Survey**

Takako Kosugi, Masahiro Eriyuch, Hisako Yoshida, Hikari Tasaki, Masatoshi Nishimoto, Masato Kasahara, Kunitoshi Iseki, Koichi Asahi, Kunihiro Yamagata, Tsueo Konta, Shouichi Fujimoto, Ichiei Narita, Yugo Shiibagaki, Toshiki Moriyama, Masahide Kondoh, Tsuyoshi Watanabe, Kazuhiko Tsuruya, Nara Medical University, Kashihara, Japan; 2Osaka City University Graduate School of Medicine, Osaka, Japan; 3Institute for Clinical and Translational Science Nara Medical University Hospital, Kashihara, Japan; 4Nakamura Clinic, Urazoe, Japan; 5Iwate Medical University, Morioka, Japan; 6University of Tsukuba, Tsukuba, Japan; 7Yamagata University Graduate School of Medical Science, Yamagata, Japan; 8University of Miyazaki, Miyazaki, Japan; 9Niigata University, Niigata, Japan; 10Kyushu University Hospital, Kawasaki, Japan; 11Osaka University Health Care Center, Suita, Japan; 12Fukushima Medical University School of Medicine, Fukushima, Japan.

**Background:** Dyslipidemia is a significant risk factor of CVD and seems to be associated with CKD onset and progression. On the contrary, CKD patients have dyslipidemia more frequently than non-CKD patients, but it is unclear whether CDK affects new onset of dyslipidemia.

**Methods:** This is a longitudinal study based on data obtained from the Japanese Society of Health Check and Guidance System. Among 664,926 individuals who participated in this program from 2008 to 2014, we excluded participants who met the following criteria: 1) health check only one time, 2) missing values for creatinine or proteinuria, 3) dyslipidemia at baseline, or 4) medication for dyslipidemia at any point. We evaluated the new onset of dyslipidemia according to a Carotid factor; hypertriglyceridemia (High-TG), hyper-LDL cholesterolemia (High-LDL), hypo-HDL cholesterolemia (Low-HDL), defined as triglycerides ≥150 mg/dL, LDL cholesterol ≥140 mg/dL, or HDL cholesterol ≤40 mg/dL, respectively, and compared between participants with and without CKD. These associations were analyzed using Kaplan-Meier methods and Cox regression analysis after adjustment for clinically relevant factors.

**Results:** During a median follow-up period of 3.1 years, the cumulative incidences of High-TG, High-LDL, and Low-HDL were 45,300, 51,940, and 13,313 participants, respectively, among 305,893 participants (non-CKD: 254,884; CKD: 51,009). In the univariable analyses, hazard ratios (HRs) [95% confidence intervals (CIs)] in CKD vs non-CKD participants were 1.31 [1.27–1.34], 1.02 [0.99–1.05], and 1.70 [1.63–1.77] for High-TG, High-LDL, and Low-HDL, respectively. After adjustment for clinically relevant confounders, adjusted HRs [95% CIs] in CKD participants were 1.16 [1.07–1.3], 0.99 [0.96–1.02], and 1.16 [1.11–1.22] for High-TG, High-LDL, and Low-HDL, respectively.

**Conclusions:** CKD was associated with new onset of High-TG and Low-HDL, but not High-LDL among general population in Japan.
Short-Term Associations of Triglycerides with Atherosclerotic and Non-Atherosclerotic Cardiovascular Disease Hospitalizations Across CKD Stages

Melissa Soohoo,1,1 Jui-Ting Huang,1, 1 Csaba P. Kovesdy,1, 2 Kamary Kalantar-Zadeh,1 2 Elani Streja,1, 3 Harold Simmons Center for Kidney Disease Research and Epidemiology,1, 3 Orange, CA; 4 The University of Tennessee Health Science Center, Memphis, TN; 74VA Long Beach Healthcare System, Long Beach, CA; 1 Memphis VA Medical Center, Memphis, TN.

Background: In chronic kidney disease (CKD) patients, we showed that the risk of atherosclerotic cardiovascular disease (ASCVD) and non-ASCVD events with high baseline triglycerides (TG) incrementally attenuated across worse CKD stages, where high TG was associated with lower risk of non-ASCVD events in late-stage TG. TG levels can change with CKD progression, but associations of time-varying TG with ASCVD or non-ASCVD hospitalizations is unknown.

Methods: We examined time-varying TG with time to first ASCVD or non-ASCVD hospitalization in 2,963,176 US veterans who received care in 2004-2006 (baseline) and were followed to 2014. Events were classified by primary ICD-9 codes. Using time-varying Cox models, we evaluated associations of time-varying TG with first ASCVD or non-ASCVD events stratified by baseline CKD stage, with adjustment for demographics, and time-varying comorbidities and laboratory values.

Results: The cohort was 63±14 years old with a mean [QR] [TG] 127[87,189] mg/dL, and 23% had KD 3A or higher at baseline. TG ≥80 mg/dL was associated with a lower risk of time to first ASCVD event (ref: TG 120–<160 mg/dL) for all baseline CKD stages (Fig A). There was a linear association between time-varying TG and ASCVD events. High TG ≥240 mg/dL had the highest risks for ASCVD, for baseline non-CKD, and CKD 3A-4. Among late-stage CKD patients, the association of high TG and ASCVD was null. We observed an inverse association between time-varying TG with time to first non-ASCVD event (Fig B). Patients with low TG had faster times to first non-ASCVD event for non-CKD and CKD 3A-4, while high TG were associated with slower times in all stages. CKD stage 5D stage renal disease patients with TG ≥240 mg/dL had the lowest risk of non-ASCVD event.

Conclusions: Short-term risk of higher TG with ASCVD or non-ASCVD events incrementally decreased across CKD stages, where risk was lower to null in late stage patients. High TG were associated with lower risks of non-ASCVD across all CKD stages. Investigation is needed to evaluate the pathways involving TG and cardiac events as CKD severity progresses in order to best manage health.

PO0467

Metabolic Acidosis and Progression to Renal Replacement Therapy

Vandana S. Mathur,1 Nancy L. Reaven,2 Susan E. Funk,3 Navdeep Tangri,3 3MathurConsulting, Woodside, CA; 3Strategic Health Resources, La Canada, CA; 1University of Manitoba, Winnipeg, MB, Canada.

Background: Metabolic acidosis is common in advanced chronic kidney disease (CKD) and is associated with its progression (Kraut J. Adv Chronic Kidney Dis. 2017). We de-identified electronic health records (Optum® EHR). 2007 to 2017 were queried to identify patients with non-dialysis CKD Stages 3-5 with ≥2 serum bicarbonate tests 28–365 days apart, ≥40% decline in eGFR from baseline (DD40) per 1 mEq/L increase in serum bicarbonate (median 4.2 yrs, max 11.5 yrs follow-up) were as follows: Asian, 0.942 (CI: 0.917-0.968); Black, 0.976 (CI: 0.969-0.983); Hispanic, 0.970 (CI: 0.956-0.984); White, 0.960 (CI: 0.957-0.963); P< 0.0001 for all groups.

Conclusions: In a large community-dwelling US population, serum bicarbonate was independently associated with adverse kidney outcomes and death in Asians, Blacks, Hispanics and Whites with CKD. Since race and ethnicity are associated with other sociodemographic factors that affect health, further exploration of the potential reasons for the observed range of hazard ratios across groups is warranted.

Relationship Between Metabolic Acidosis and CKD Progression Is Evident Across US Racial and Ethnic Groups

Navdeep Tangri,1 Vandana S. Mathur,1 Nancy L. Reaven,3 Susan E. Funk,3 Donald E. Wesson.1 1University of Manitoba, Winnipeg, MB, Canada; 2MathurConsulting, Woodside, CA; 3Strategic Health Resources, La Canada, CA; 4Baylor Scott & White Health and Wellness Center, Dallas, TX.

Background: Metabolic acidosis is a known risk factor for CKD progression, but little is known about the impact of race and ethnicity on this relationship. We used a large electronic medical record (EMR) database of >100 million patients from all 50 states and insurance types to evaluate the relationship between metabolic acidosis and adverse renal outcomes and death by race and ethnicity.

Methods: De-identified electronic medical records (Optum® EHR), 2007–2019 were queried to identify patients with non-dialysis CKD Stages 3-5, ≥2 years of post-index data or death within 2 years, and grouped by baseline metabolic acidosis (12 to < 22 mEq/L) vs normal serum bicarbonate (22 to ≥30 mEq/L). Pts were classified as Asian (N=1,328), Black (N=15,248), Hispanic (N=4,137), White (N=111,953) or Other (N=3,401). The primary endpoint was the composite outcome of death, kidney dialysis or transplant, or 40% decline in eGFR from baseline (DD40).

Cox proportional hazards models examined the impact of serum bicarbonate on DD40 within each racial/ethnic group, adjusted for age, sex, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, Charlson Comorbidity Score.

Results: Overall, 47,032 patients (34.6%) experienced DD40 events within 2 years: Asian, 35%; Black, 44%; Hispanic, 48%; White, 32%; Other, 48%. Serum bicarbonate independently predicted DD40 in all racial/ethnic groups. Adjusted Hazard Ratios for DD40 per 1 mEq/L increase in serum bicarbonate (median 4.2 yrs, max 11.5 yrs follow-up) were as follows: Asian, 0.942 (CI: 0.917-0.968); Black, 0.976 (CI: 0.969-0.983); Hispanic, 0.970 (CI: 0.956-0.984); White, 0.960 (CI: 0.957-0.963); P< 0.0001 for all groups.

Conclusions: In a large community-dwelling US population, serum bicarbonate was independently associated with adverse kidney outcomes and death in Asians, Blacks, Hispanics and Whites with CKD. Since race and ethnicity are associated with other sociodemographic factors that affect health, further exploration of the potential reasons for the observed range of hazard ratios across groups is warranted.

Lower Urine Citrate Excretion Associated with Advanced CKD Stage Is Mediated by Reduced Plasma Citrate and Decreased Kidney Citrate Clearance  
Nimrit Goraya,1 Nicolaos E. Madias,2 Abdullah A. Mamun,2 Jan Simon,1 Donald E. Wesson.3 1Texas A&M University College Station, College Station, TX; 2Texas A&M University Scott and White Health and Wellness Center, Dallas, TX; 3Tufts University School of Medicine, Boston, MA; 4Surgery, Texas Tech University HSC, Lubbock, TX.

Background: Lower urine citrate excretion (UcitV) might be a biomarker of covert acid (H+) retention in patients with CKD but without metabolic acidosis and so mechanisms that mediate UcitV differences among patients with CKD would help assessment of its biomarker utility. Because longitudinal eGFR decreases in patients with CKD associated with decreasing UcitV (Goraya, et al. AJP 317:F502, 2019), we examined cross-sectional differences in UcitV across CKD stages and mechanisms that mediate such differences.

Methods: We measured 8-hour UcitV (8h UcitV), plasma citrate concentration (Pcit), and kidney citrate clearance (Citrate clearance) in 52 patients with CKD 1 (eGFR=99.5 ± 14.7 ml/min/1.73 m2), 2 with CKD 2 (eGFR=73.4 ± 6.1 ml/min/1.73 m2), and 52 with CKD 3 (eGFR=40.1 ± 7.6 ml/min/1.73 m2) with macroalbuminuric, non-diabetic, hypertension-associated nephropathy. We assessed ongoing dietary H+ intake as potential renal acid load (PRAL) and steady-state acid-base status with plasma total CO2 (PtcO2) and H+ retention, the latter estimated by comparing observed to expected PTCO2, in response to retained HCO3 (administered minus UHCO3.V) 2 hours after oral NaHCO3, bolus (0.5 mmol/kg bw), assuming 50% body weight HCO3 apparent space of distribution.

Results: Although PRAL was not different among CKD 1, CKD 2, and CKD 3 groups (62.4 ± 11.9, 62.9 ± 14.7, and 65.2 ± 7.9 mmol/day, respectively, p=0.47), PTCO2 was progressively lower (26.4 ± 0.7, 25.9 ± 0.6, and 21.6 ± 1.9 mmol/l, respectively, p<0.01) and H+ retention progressively higher (3.9 ± 12.9, 18.2 ± 14.0, and 25.1 ± 13.4 mmol/l, respectively, p<0.01) with advancing CKD stage. 8h UcitV was progressively lower with advancing CKD stage (1.1 ± 0.03, 1.00 ± 0.25, and 0.86 ± 0.10 mmol/l, respectively, p<0.01) as was Pcit (0.16 ± 0.01, 0.15 ± 0.02, and 0.14 ± 0.01 mmol/l, respectively, p<0.01) and UcitV/Pcit (0.015 ± 0.001, 0.014 ± 0.003, and 0.013 ± 0.001 mmol/l, respectively, p<0.01).

Conclusions: Cross-sectional advanced CKD stage was associated with greater H+ retention and lower UcitV, the latter mediated by lower Pcit and lower UcitV/Pcit. The data support that reduced UcitV associated with decreased eGFR reflects underlying H+ retention with reduced body citrate stores and increased citrate conservation through reduced kidney citrate clearance.

PO0471
Urinary Calcium Excretion and Risk of CKD Progression: The CRIC Study  
Jing Liu,1,2 Maria Clarissa Tio,3 Titiayo O. Ilori,1 Ashish Verma,1 Insa M. Schmidt,1,3 Sushrut S. Walkar.1 1Renal Section, Department of Medicine, Boston University Medical Center, Boston, MA; 2Division of Nephrology, Kidney Research Institute, West China Hospital of Sichuan University, Chengdu, China; 3Renal Division, Brigham & Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Hypercalciuria is implicated in nephrolithiasis and nephrocalcinosis, conditions associated with chronic kidney disease (CKD). We aimed to study the determinants of urinary calcium excretion (UCAE) and its association with adverse clinical outcomes in CKD.

Methods: 24-hour UCAE was measured in 3,768 Chronic Renal Insufficiency Cohort (CRIC) participants. We used multivariable linear regression models to determine independent predictors of UCAE in CKD 1, 2, and 3. Cox regression analyses tested the associations of UCAE with incident end stage kidney disease (ESKD), CKD progression (50% eGFR decline or incident ESKD), atherosclerotic cardiovascular disease (ASCVD) events, and death.

Results: Estimated glomerular filtration rate (eGFR) correlated most strongly with UCAE (r=0.47, p<0.001). In both males and females, determinants of UCAE included eGFR, African American race, iPTH, 24-hour urine sodium and phosphate, serum albumin and the use of diuretics and angiotensin receptor blockers (Figure 1). Certain predictors of UCAE differed between sexes: systolic blood pressure and alcohol drinker were associated with UCAE in males, while serum calcium and vitamin D intakes were significantly associated with UCAE in females. Higher UCAE was significantly associated with lower risk of ESKD, CKD progression, death and ASCVD events in unadjusted models. These associations were attenuated after adjusting for baseline characteristics, and for most outcomes the associations became insignificant after adjusting for eGFR.

Conclusions: Predictors of UCAE in CKD differed between males and females. eGFR is extremely strongly associated with UCAE and greatly confounds the associations between UCAE and all the outcomes.

PO0472
Neighborhood Socioeconomic Status and Patterns of Kidney Care: Data from Electronic Health Records  
Lana Ghazi,1,2 Paul E. Drawz.1 1University of Minnesota, Minneapolis, MN; 2Yale University School of Medicine, New Haven, CT.

Background: Electronic health records (EHR) can be leveraged to assess quality of care measures in patients with CKD. Neighborhood socioeconomic status (SES) could be a potential barrier to receiving appropriate evidence-based therapy and follow up. Our goal was to examine whether neighborhood SES is independently associated with quality of care received by CKD patients.

Methods: EHR data for patients seen at a healthcare system in the 7-county Minneapolis/St Paul area and linked census tract data were used. Census tract SES measures used were: median value of owner occupied housing units (wealth), percentage of residents >25 years with a Bachelor’s degree (education), and median household income (income). A patient was considered to be living in low and high SES tracts if they belong to the first and fourth quartile of each SES measure, respectively. CKD quality of care indicators used were: prescription for ACEi/ARB in patients with moderate to severe CKD or mild CKD >300 mg/day; UACR measurement; and CKD identified on the problem list or coded for at an encounter among patients with CKD (eGFR<60 ml/min/1.73 m2). We used a multilevel Poisson regression with robust error variance with a random intercept at the census tract level to estimate the association between each quality of CKD care measure and neighborhood SES.

Results: Of the 16,776 patients who should be on ACEi/ARB, 65% were prescribed these medications. In patients with CKD (n=25,097), UACR was measured in 27% of patients and only 55% of patients with CKD had CKD identified in their EHRs. Barring low neighborhood SES compared to high neighborhood SES was not associated with ACEi/ARB prescription compliance after adjusting for demographics and clinical characteristics (prevalence ratio (PR): wealth-0.90[0.91,1.05], education-1.01[0.97,1.05], income-0.97[0.94,1.02]). Similarly, neighborhood SES was not associated with CKD identification in the EHR after adjustment (PR: wealth-1.02[0.98,1.06], education-1.03[0.98,1.07], income-1.01[0.97,1.06]).

Conclusions: Neighborhood SES is not associated with quality of care received. However, adherence to CKD guidelines is low, indicating an opportunity to improve care for all patients, regardless of SES.

PO0473
Neighborhood Socioeconomic Status, Health Insurance, and CKD Prevalence: Findings from a Large Healthcare System  
Lana Ghazi,1,2 Paul E. Drawz.1 1University of Minnesota, Minneapolis, MN; 2Yale University School of Medicine, New Haven, CT.

Background: The association of neighborhood characteristics and insurance status with chronic kidney disease (CKD) remain unclear. Therefore, we investigated the association of neighborhood socioeconomic (SES) and insurance type with CKD prevalence.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We utilized electronic health record (EHR) data of patients seen at a healthcare system in the 7-county metropolitan area in Minnesota and linked census tract data. Census tract measures (median value of owner occupied housing units (wealth), percentage of residents >25 years with a Bachelor’s degree (education), and median household income (income)) and individual level insurance status (<65 years: Medicaid vs. other insurance; ≥65 years: Medicare vs. supplemental insurance plan) were obtained from the American Community Survey (2008-2012) and the EHR, respectively. A patient was considered to be living in low and high SES tracts if they belonged to the first and fourth quartile of each SES measure. CKD prevalence was defined as having an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m² or proteinuria. We used a multilevel Poisson regression with robust error variance with a random intercept at the census tract level to estimate the association between tract SES [low (first quartile) vs. high (fourth quartile)], insurance, and CKD.

Results: We included 185,269 patients. Tract SES (wealth and education) and insurance are independently associated with CKD prevalence. After adjusting for demographic and clinical characteristics, patients (<65 and ≥65 years) living in low vs. high SES tracts had higher CKD prevalence (Prevalence Ratio PR, 95%CI of low vs. high tract SES for education among patients <65 years: 1.11 [1.05, 1.18] and 1.08 [1.04, 1.12] for patients ≥65 years). Patients (<65 years) on Medicaid vs. other insurance had higher CKD prevalence (PR, 95%CI: 1.51 [1.43, 1.60]). For patients ≥65 years, insurance type was not associated with prevalence of CKD in the fully adjusted model.

Conclusions: In conclusion, we found the patients from low SES tracts and Medicaid recipients (among patients <65 years) have greater rates of CKD compared to patients from high SES tracts and patients with other insurance. These may be two of several socioeconomic and individual factors influencing the complexity of identification, management, and treatment of CKD.

PO0474

Social Determinants of CKD in the Military Health System

Jenna M. Norton, Lindsay Grunwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlmoos. Uniformed Services University of the Health Sciences, Bethesda, MD.

Background: A growing body of evidence suggests that negative social determinants of health—or social risks—contribute to socioeconomic and racial disparities in chronic kidney disease (CKD). One mechanism through which social risks appear to produce disease is by impeding access to healthcare. The Military Health System (MHS) provides healthcare coverage to military personnel, retirees, and their dependents.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. Directed acyclic graphs were developed to understand potential confounding or mediating roles of covariates. Multivariable logistic regression models were used to compare the prevalence of CKD by race, rank, zip code level median household income, and marital status, controlling separately for susceptible confounders (age, sex, active duty status, service branch, and depression) and mediators (hypertension, diabetes, HIV and BMI). For family beneficiaries, the sponsor’s rank and zip code were used.

Results: Of the 3,330,893 MHS beneficiaries in this analysis, 105,504 (3.2%) were identified as having CKD. In confounder-adjusted models, CKD prevalence was statistically elevated in beneficiaries of black vs white race, lower vs higher rank (as a proxy for socioeconomic status), lower vs higher income, and married vs single status (p < 0.001). Expected, associations were partially or fully mitigated when further adjusting for susceptible mediators, indicating the mediators may indeed be on the causal pathway between social risks and CKD.

Conclusions: Racial and socioeconomic disparities persist in CKD under the context of universal healthcare coverage provided by the MHS. While racial disparities may result in part from underlying genetic differences, the presence of disparities by rank and area income suggest social factors remain pertinent despite access to universal healthcare coverage.

PO0475

Low Documentation of Social Determinants of Health Among US Veterans and Medicare Patients with CKD

Yihan Han, Maggie Hilla, Diane Steffick, Alex Wyntcott, Jennifer L. Bragg-Gresham,1 Kara Zivin,2 Nilka Rios Burrows,4 Carla I. Mercado,4 Delphine S. Tuot,5 Neil R. Powe,1,6 Rajiv Saran.1 University of Michigan Division of Nephrology, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3US Department of Veterans Affairs, Ann Arbor, MI; 4Centers for Disease Control and Prevention, Atlanta, GA; 5University of California San Francisco, San Francisco, CA; 6Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: The implementation of ICD-10 codes in 2015 included new codes (Z-codes) to identify social determinants of health (SDOH). One mechanism through which social risks appear to produce disease is by impeding access to healthcare. The Military Health System (MHS) provides healthcare coverage to military personnel, retirees, and their dependents.

Methods: We performed a cross-sectional analysis of data from the Healthy Aging in Neighborhoods of Diversity Across the Life Span (HANDLS) study (Baltimore, MD) during study visit 4. We used multivariable regression to quantify associations between having and least one unmet social need (food insecurity or housing insecurity), and the number of protective measures taken (a proxy for an individual’s ability to seek care), and the proportion of protective measures taken (BP ≤130/80 mmHg, hemoglobin A1C ≤7%, sodium intake <2 g/day, regular physical activity, BMI 20-25 kg/m², and smoking cessation reduce risk of CKD and CKD progression). We evaluated whether having unmet needs was associated with achieving kidney protective measures.

Results: Among 1805 HANDLS participants, 899 (49.5%) reported at least one unmet health-related social need. Compared to those without unmet needs, those with unmet needs were younger (mean age 55.0 versus 57.8 years), more likely to be black (63.7% versus 38.5%), report income <125% of federal poverty level (46.8% versus 31.9%), and had higher eGFR (mean 90.0 versus 85.8 mL/min/1.73m²). The likelihood of achieving a higher number of protective measures was significantly lower for those with unmet needs compared to those without unmet needs (Table). Having unmet needs was significantly associated with lower likelihood of being a non-smoker and engaging in regular physical activity.

Conclusions: Individuals with unmet social needs may be less likely to achieve measures to prevent incident CKD and CKD progression.
**Association Between Air Pollution and Renal Outcomes: A Systematic Review and Meta-Analysis**

**Background:** Although several risk factors of chronic kidney disease (CKD) have been well-established, mainly diabetes and hypertension, many remain less studied, such as chronic exposure to air pollution. Our purpose is to exhaustively summarize the current evidence on the association between air pollution and various renal outcomes.

**Methods:** We searched EMBASE, Pubmed, Web of Science, Cochrane library, and CINAHL database, for relevant records using a combination of keywords related to the type of exposure (O₃, CO, NOₓ, NO₂, SO₂), type of pollutant (polycyclic aromatic hydrocarbons, diesel exhaust particles) as well as modifiers (lower respiratory tract, respiratory system, kidney transplantation failure, nephrotic syndrome, and kidney cancer). Using random-effects meta-analyses, we pooled summary statistics (hazard ratios, odds ratios, or beta-coefficients with their respective 95% confidence intervals) associated with a standardized increased level of each pollutant and presented the results by air pollutant and outcome. Heterogeneity has been assessed using the y² test on Cochran’s Q statistic and quantified I² calculation.

**Results:** Within 1214 eligible studies, 42 articles fulfilling the selection criteria were included in this work (11 cross-sectional, 15 prospective, and 16 retrospective cohort studies). The most significant associations are for PM₁₀ exposure and higher risks of CKD, ESRD, and kidney cancer incidence (HR=1.24 [1.15; 1.34], 1.27 [1.18; 1.36], 1.26 [1.02; 1.57]) respectively, per 10μg/m³ increased level); NOₓ exposure and higher risks of CKD and ESRD incidence; PM₃₅ exposure and higher CKD prevalence, as well as lower renal function (see details in Figure 1). These results should however be interpreted with caution, due to significant between-studies heterogeneity and risks of methodological bias.

**Conclusions:** Chronic exposure to particulate matter and nitrate dioxide seems to be associated with poorer renal outcomes. Further studies are warranted to confirm these results.

---

**PO0477**

**Association Between Air Pollution and Renal Outcomes: A Systematic Review and Meta-Analysis**

**Background:** Among the risk factors of chronic kidney disease (CKD), it is important to consider air pollutants, such as cigarette smoke and fine particulate matter (PM₂.₅), which have been associated with histological damage in some patients with CKD.

**Methods:** We performed a systematic review and meta-analysis of observational studies reporting the association between air pollution and renal outcomes. A PubMed search was conducted using specific keywords related to air pollution and renal outcomes. Studies were included if they measured the association between air pollution and renal outcomes using appropriate statistical methods.

**Results:** A total of 10 studies met the inclusion criteria. The results showed a significant association between air pollution and renal outcomes, with a standardized increased level of PM₂.₅ exposure associated with higher risks of CKD, ESRD, and kidney cancer incidence. The results were consistent across different exposure levels and exposure types (e.g., PM₁₀, PM₂.₅).

**Conclusions:** Chronic exposure to air pollution is associated with poorer renal outcomes. Further studies are warranted to confirm these findings and explore the mechanisms underlying this association.
PO0480
Serum Potassium and Survival Among Advanced CKD Patients
Translation to Dialysis
Yoko Narasaki,1 Kamyar Kalantar-Zadeh,1 Antony J. Ferrey,1 Ekamol Tantisattamano,1 Amy S. You,1 Elani Streja,1 Kaushik Ivaturi,1 Cachet Wenziger,1 Ji-Ting Hsiung,1 Danh V. Nguyen,1 Csaba P. Kovinsky,2 Connie Rhee.1 University of California Irvine, Irvine, CA; 1The University of Tennessee Health Science Center, Memphis, TN.

Background: Most laboratories designate a wide reference range for “normal” serum potassium levels (3.5–5.5 mEq/L), yet the precise concentrations associated with favorable outcomes in chronic kidney disease (CKD) remain uncertain. While dietary potassium is commonly restricted in CKD patients to mitigate hyperkalemia, there may be ill effects of this strategy by restricting healthy potassium-rich foods (fruits, vegetables). We hypothesized that high-normal serum potassium levels are associated with better long-term survival in advanced non-dialysis-dependent (NDD) CKD patients transitioning to dialysis.

Methods: Among 43,798 US Veterans with NDD-CKD transitioning to end-stage renal disease (ESRD) pre-dialysis period (2007/3-2016) and post-ESRD mortalit (Fig 1A) using national Veterans Affairs (VA) data linked to United States Renal Disease System data. Associations of serum potassium levels (categorized as <3.5, 3.5–<4.0, 4.0–<4.5, 4.5–<5.0, and 5.0–<5.5 mEq/L) with all-cause mortality were estimated using adjusted Cox models.

Results: In adjusted Cox analyses, high-normal serum potassium levels ranging from 5.0–<5.5 mEq/L were associated with greater survival (HR: 0.95 [95% CI 0.91-0.98] (Fig 1B). In contrast, serum potassium concentrations at or below low-normal serum potassium ranges were associated with higher death risk (HR: 1.06 [95% CI 1.02-1.09]). The increased risk for the renal end-point was gradually more pronounced at progressively more severe degrees of renal dysfunction (see Figure).

Conclusions: In NDD-CKD patients transitioning to dialysis, serum potassium levels in the high-normal range were associated with greater long-term survival, whereas serum potassium levels at or below low-normal ranges were associated with higher long-term death risk. Further studies are needed to determine whether dietary factors may be a potential mechanistic link underlying these relationships.

PO0481
Hyperkalemia, CKD, and RAAS Inhibition: A Triad with a Fine Balance to Prevent Mortality
Luis F. Goncalves, Mario R. Raimundo. Hospital Beatriz Angelo, Loures, Portugal.

Background: Hyperkalemia (HK) is a common and dangerous complication of CKD. HK is also a complication of beneficial therapeutic agents acting on the RAAS. Our goal was to investigate incidence, prevalence and clinical outcomes of at least one episode of HK in a CKD population outpatient setting. Additionally, we investigated the association of HK with changes in RAAS inhibition and mortality.

Methods: Retrospective analysis of all adult patients referred to a nephrology clinic over a 6 years period. We included CKD stage 3 patients with at least 24 months of follow up and 3 or more serum potassium determinations. The prevalence of HK at first consultation and incidence during follow up were accessed. Patients were split in two groups prior to analysis: A) Patients without any HK episode and B) Patients with at least one HK episode.

Results: Out of the 3008 patients referred, 575 (19.1%) met the inclusion criteria (mean age: 70.4 years; 63.7% male and 94.0% white color). Mean follow-up was 4.1±1.8 years. The prevalence of HK at first consultation was 8.7% and follow up incidence 21.7%. From this cohort, 164 (28.5%) had at least on episode of HK (Group B) and 101 (17.6%) died. During the follow up, RAAS inhibition drugs was removed or not started in 200 (34.8%) and diuretic was initiated in 165 (28.7%). At least one HK episode was associated with Diabetes (65.9 vs 42.3%, p<0.001), Heart failure (36.6 vs 28.0%, p=0.007), Macroalbuminuria (34.1 vs 21.2%, p=0.001), CKD progression (33.5 vs 16.3, p=0.001) higher frequency of diuretic initiation (38.4 vs 24.8%, p<0.001) and higher mortality (27.6 vs 13.7%, p<0.001). The independent predictors of mortality were: At least one HK episode (OR 1.82, 95% CI 1.08-3.04); Heart Failure (OR 1.97, 95% CI 1.16-3.35); Older age (OR per 1 year increase 1.04, 95% CI 1.02-1.07); CKD progression (OR 4.18, 95% CI 2.43-7.19); Patients who maintained RAAS inhibition during follow up (OR 0.50, 95% CI 0.26-0.90); Patients who started RAAS inhibition during follow up (OR 0.38, 95% CI 0.16-0.88).

Conclusions: Our study confirms that RAAS inhibition had and protector and independent impact in mortality when prescribed in CKD early stages. Patients with at least one episode of HK have a higher risk of mortality. All efforts should be made to maintain these therapeutic agents, looking for other ways to control hyperkalemia rather than stop it.

PO0484

Pulse Mass Index and Pulse Mass Pressure Product in CKD Patients

Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuibo, Takashi Yokoo. The Jikei University School of Medicine, Division of Nephrology and Hypertension, Department of Internal Medicine., 3-25-8 Nishi-Shimbashi, Minato-ku, Japan.

Background: Recent studies have conflicting findings on the association between obesity and the risk of chronic kidney disease (CKD). The body mass index (BMI) by itself is an imperfect marker of metabolically unhealthy obesity. The pulse mass index (PMI) and the pulse mass pressure product (PMPP) show strong correlations with the risk of cardiovascular disease and may reflect an individual's metabolic energy state. However, it is still unclear whether PMI and PMPP can be useful parameters for the risk of CKD.

Methods: We retrospectively identified 51 subjects who underwent ambulatory blood pressure monitoring and kidney biopsy simultaneously at the Jikei University Hospital, Tokyo, from 2017 to 2019. All subjects were diagnosed as primary or secondary glomerular diseases and obesity biopsy. The BMI and the PMPP were calculated from the following formula: PMI = BMI × resting heart rate (RHR) / 1730. PMPP = BMI × RHR × systolic blood pressure. We evaluated the clinicopathological findings associated with PMI and PMPP.

Results: Of 51 subjects, the age was 50.3 ± 16.1 years (mean ± standard deviation), and 60.8% were male. The eGFR was 44.4 ± 25.3 mL/min/1.73m². The median glomerulosclerosis index (GI) was 18.3 (interquartile range, 4.7-44.4) %, and the tubular injury level was 17.5 (5.0-36.3) %. The PMI was 0.94 ± 0.23, the PMPP was 21.6 ± 7.3 × 10⁶, and the BMI was 22.9 ± 4.7 kg/m². Both PMI and PMPP were positively associated with GI, HbA1c, and triglyceride, whereas negatively associated with eGFR (P < 0.02 and 0.004; respectively), CKD stages (P = 0.04 and 0.02; respectively) and HDL. Of note, each parameter such as BMI, RHR, and blood pressure was not correlated with either eGFR or CKD stages.

Conclusions: We observed correlations between both PMI and PMPP and kidney function. This study indicates that PMI and PMPP may be possible makers of the relative risk of unhealthy obesity with CKD.

PO0485

Thyroid Status and Mortality Among CKD Patients Transitioning to Dialysis

Jia Li, Amy S. You, Gregory Brent, Elani Streja, Dorsa F. Maryska, Monica Thornhill-Joynes, Yoko Narasaki, Gui-Jing Hsiung, Carin Wenziger, Christina Park, John J. Sim, Danh V. Nguyen, Csaba P. Kovesdy, Kamary Kalantar-Zadeh, Connie Rhode, University of California Irvine, Irvine, CA; 1University of California Los Angeles, Los Angeles, CA; 1Kidney Specialists Medical Corporation, Los Angeles, CA; 1Kaiser Permanente Southern California, Pasadena, CA; 1The University of Tennessee Health Science Center, Memphis, TN.

Background: Hypothyroidism has been associated with higher death risk in non-dialysis dependent chronic kidney disease (NDD-CKD) and end-stage renal disease (ESRD) patients, presumably due to cardiovascular pathways. We examined whether pre-ESRD thyroid status is a predictor of survival in NDD-CKD patients transitioning to dialysis.

Methods: Among US Veterans with NDD-CKD transitioning to dialysis from 10/2007-3/2015, we examined the association of serum thyrotropin (TSH) levels (TSH levels averaged over a three-year pre-ESRD transition period (pre-ESRD prelude period) with post-ESRD mortality. Patients were followed for the outcome for up to three-years, and HRs for all-cause mortality were estimated using expanded case-mix/laboratory adjusted Cox models. In sensitivity analyses, we examined varying pre-ESRD prelude and post-ESRD mortality intervals.

Results: Among 43,416 patients in the primary cohort (three-year pre-ESRD prelude cohort), increasing higher TSH levels >3.0 mIU/L were associated with incrementally higher mortality (ref: TSH 0.5-<3.0 mIU/L): adjusted HRs (95%CI) 1.04 (0.95-1.13), 1.04 (1.00-1.07), and 1.16 (1.11-1.22) for TSH levels of <0.5, 3.0-5.0, and >5.0 mIU/L, respectively. A similar pattern of findings was observed for patients whose TSH levels were examined over one-year and two-year pre-ESRD prelude periods, with follow-up for the outcome of interest for up to one and two years, respectively.

Conclusions: There was a dose-dependent relationship between higher pre-ESRD TSH levels exceeding 3.0 mIU/L and higher post-ESRD mortality in NDD-CKD patients transitioning to dialysis. Further studies are needed to determine the underlying determinants of thyroid dysfunction in CKD, and whether reduction of TSH levels with thyroid hormone supplementation alleviates mortality in this population.

**Incidence of and Risk Factors for Incident eGFR <60 in the REasons for Geographic and Racial Differences in Stroke Study**

Katharine L. Cheung,1 Mary Cushman,1 Deidra C. Crews,2 Suzanne E. Judd,3 David G. Warnock,4 Orlando M. Gutierrez,5 The University of Vermont Larner College of Medicine, Burlington, VT; 3John Hopkins University School of Medicine, Baltimore, MD; 1The University of Alabama at Birmingham School of Public Health, Birmingham, AL.

**Background:** Few contemporary US cohorts examined the incidence of and risk factors for developing a low estimated glomerular filtration rate (eGFR) or whether these factors vary by race, sex or region of US residence.

**Methods:** We studied 11,814 black or white participants with an eGFR >60 mL/min/1.73m² at baseline and who had 10-year follow-up eGFR. Low eGFR was defined as incident eGFR <60 mL/min/1.73m² or at the second visit after a 40% decline from baseline. Incidence rates were calculated overall and by age, sex and race groups. We used Poisson regression to calculate the risk of incident low eGFR, adjusting for demographics, socioeconomic status and clinical factors, and across race, sex and region strata.

**Results:** At baseline, mean age was 62 (±8.1) years, 54% were female, 36% black and 56% resided in the US stroke belt. The overall incidence of low eGFR was 9% and ranged from 4% in those aged 45-54 to 18% in those 75 years and older. Age, systolic blood pressure, diabetes, heart disease, BMI, smoking, lower income, higher education, and residence in the US stroke belt were independent risk factors for incident low eGFR. Blacks had higher risk, accounting for sociodemographic risk factors, but this was fully attenuated after adjusting for clinical factors. Low eGFR risk factors did not differ substantially by race, sex or region.

**Conclusions:** The higher incidence of low eGFR in black compared to white participants was accounted for by modifiable clinical risk factors. Residence in the US stroke belt was independently associated with incident low eGFR in REGARDS participants.

**Funding:** Other NIH Support - National Institute of Neurological Disorders and Stroke, National Institute on Aging.

**High Prevalence of CKD Among Individuals Living with HIV in the United States**

Jennifer L. Bragg-Gresham,1 Ann Andrews,2 Hal Morgenstern,3 Brenda W. Gillespie,4 Neil R. Powe,5 Tanushree Banerjee,6 Rajiv Suran.1 1University of Michigan Medical School, Ann Arbor, MI; 2National Kidney Foundation of Michigan, Ann Arbor, MI; 3University of Michigan, Ann Arbor, MI; 4University of California San Francisco, San Francisco, CA.

**Background:** Chronic kidney disease (CKD) is an important comorbidity among people living longer with human immunodeficiency virus (HIV). We report the prevalence, trends and characteristics of individuals with HIV in the US, with the aim of better understanding this understudied, but important risk factor for CKD.

**Methods:** Data from 22,626 adults aged 20-59 who had consented for HIV testing in the National Health and Nutrition Examination Survey (NHANES: 1999-2014), were analyzed. Those with HIV+ vs. serology were compared with respect to demographics, comorbidities, and social determinants of health in the full sample and those with CKD, as defined by either eGFR<60 mL/min/1.73m² or urine albumin to creatinine ratio of >30 mg/g. Logistic regression was used to assess the odds of CKD by HIV status. Comparisons were assessed using survey weights for all analyses.

**Results:** Prevalence of HIV+ remained stable, from 0.4% to 0.6% during this time period. Individuals HIV+ were older than those HIV- in both the full sample and among those with CKD. A higher proportion of HIV+ than HIV- individuals were black, current smokers, had < high school education, with income <$45k, and reported either Medicare or other government insurance (Table). Among individuals with CKD, those HIV+ had almost twice the prevalence of diabetes (30% vs. 19%, p<NS) and over 4 times higher awareness of their CKD (28% vs. 6%, p<0.002) compared to HIV-. HIV+ vs. HIV- individuals had more than twice the prevalence of CKD (15.3% vs. 7.1%, p<0.002). CKD was associated with HIV+ status [unadjusted odds ratio (OR) = 2.37; 95% CI: 1.36-4.17]. Adjusting for other covariates, attenuated the association only slightly (adjusted OR=2.17; 95% CI: 1.21-3.89).

**Conclusions:** CKD was associated with HIV+ status among younger adults living with the disease in the US. However, larger, longitudinal studies among individuals living with HIV and CKD are needed to increase awareness of this complication among survivors of the disease.
Oxygen Kinetics and Microvascular Function in CKD
Natalie J. Bohmke,1 Meghan G. Ramick,2,3 David G. Edwards,2 Danielle L. Kirkman,1,2 Virginia Commonwealth University, Richmond, VA; 1University of Delaware, Newark, DE; 2West Chester University of Pennsylvania, West Chester, PA.
Background: Patients with chronic kidney disease (CKD) have reduced cardiorespiratory fitness levels that are associated with reduced quality of life and mortality. Impaired oxygen uptake kinetics create a larger oxygen deficit that promotes fatigue. CKD related microvascular dysfunction may contribute to impaired oxygen uptake kinetics by hampering oxygen delivery to the working muscle. The purpose of this study is to investigate the relationship between oxygen kinetics and a measure of microvascular function in CKD.
Methods: 13 patients with stage 3-5 CKD (MeanSD, Age 60±14 years; eGFR 48.5±10.3 ml/min/1.73m²) were included in the analysis. Peak oxygen consumption (VO$_2$max) was measured via breath by breath expired respiratory gas analysis during a symptom limited graded cycle ergometry test. Oxygen kinetics were quantified as mean response time (MRT), the exponential time constant to reach 63% of steady state VO$_2$. MRT was analyzed from three minutes of steady state submaximal cycling (>60% VO$_2$). Microvascular function was assessed as cutaneous vasodilation during local heating coupled with intradermal microdialysis, measured by laser Doppler flowmetry. Results: VO$_2$max was 20.36±8.7 ml/kg/min. A moderate inverse correlation was shown between oxygen uptake kinetics and microvascular function (Figure 1; r=-0.56, p=0.02).
Conclusions: Microvascular dysfunction may contribute to a larger oxygen deficit in CKD patients. Following further studies, microvascular function could serve as a potential treatment target to improve exercise tolerance in these patients.

Trends, Prevalence, and Predictors of Illicit Drug Use in CKD Patients
Nattawat Klomjai,1 Api Chewcharat, Andrea G. Kattah, Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN.
Background: Illicit drugs use is an important problem in general populations and chronic kidney disease (CKD) patients. Since 2012, marijuana has been legalized in several parts of United States, however, the trend and prevalence of illicit drug use in CKD patients in the current era remains unknown.

Methods: We conducted a cross-sectional analysis using the data from the National Health and Nutrition Examination Survey between 2007 and 2018. We calculated the trend of self-reported illicit drug use (marijuana, cocaine, heroin, methamphetamine, and intravenous drug use) and defined current use if the last use was within 1 year of the survey. We then assessed whether the use of illicit drugs is associated with CKD (defined by estimated glomerular filtration rate <60 ml/min/1.73 m² and/or urine albumin-creatinine ratio (UACR) ≥30 mg/g), microalbuminuria (UACR 30-300 mg/g) and macroalbuminuria (≥300 mg/g). Lastly, we assessed any predictors for drug use in CKD patients.
Results: Between 2007 to 2018, there were 22,214 adult patients between 18-59 years of age. Of these, 2,148 had CKD as defined above. CKD patients were significantly older, more likely to be female, obese, cigarette smoker, alcohol drinker, and to have diabetes, and hypertension. We found that prevalence of marijuana (21.9% vs 21.9%, p=0.23), cocaine (4.9 vs 3.6, p=0.95) and methamphetamine (1.5% vs 1.3%, p=0.52) did not differ between CKD and non-CKD. However, heroin use (0.2% vs 0.5%, p=0.02) were significantly lower in CKD compared to non-CKD. Interestingly, there is a significant trend towards increasing marijuana use in CKD patients overtime as prevalence increase from 17.3% in 2007-2010 to 21.7% in (2011-2014), and up to 26.5% in 2015-2018 (p trend 0.02). Recent illicit drug use was not associated with CKD, microalbuminuria or macroalbuminuria. Age, black race, current smoker and alcohol drinking were significant predictors of drug use within 1 year in CKD patients.
Conclusions: In a national sample, marijuana was the most common illicit drug use among CKD patients and the trend of marijuana use in CKD patients is increasing, likely due to marijuana legalization. Age, black race, current smoker and alcohol drinking increase the odds of illicit drug use in CKD patients.

Evaluating the Longitudinal Association of Marijuana Use and Adverse Kidney Outcomes
Flor Alvarado,1 Alan B. Zonderman,2 Michele K. Evans,3 Deidra C. Crews,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2National Institutes of Health/National Institute on Aging, Baltimore, MD; 3Intramural Research Program, NIA, NIH, Baltimore, MD.
Background: Marijuana use has increased for recreational and medicinal purposes, however, its long-term effects on the kidneys remain uncertain. We examined the longitudinal association of marijuana use and adverse kidney outcomes among adults living in Baltimore, MD.
Methods: We used data from the prospective Healthy Aging in Neighborhoods of Diversity Across the Life Span study. Baseline exposure, defined as self-reported never, former, or current marijuana use, and covariates were obtained between 2004 and 2009. In this Baltimore-based cohort, there was no independent association of marijuana use with adverse kidney outcomes among adults living in Baltimore, MD.

Life’s Simple 7 and CKD Progression: Results from the Mexico Chronic Renal Insufficiency Cohort (MCRIC) Study
Magdalena Madery,2 Ana P. Hernandez Martinez,2 Ana K. Fernandez Yepes,2 Jinsong Chen,2 Claire T. Larkin,1 Natalie Meza,2 Eunice Carmona,2 Christopher G. Viamontes,2 Carlos L. Morales Cruz,2 Zuleyma T. Vasquez Vasquez,2 Tania J. Ramos Estrada,2 Arelí d. Avalos Galicia,3 Bernardo Moguel,2 Carlos Linares Kolofon,1 Ana C. Ricardo,1 James P. Lash,2 University of Illinois at Chicago, Chicago, IL; 1Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.
Background: The American Heart Association developed the Life’s Simple 7 metric to promote cardiovascular health. We evaluated the association of this metric with chronic kidney disease (CKD) progression among individuals with CKD living in Mexico.
Methods: MCRIC is an ongoing, prospective observational cohort study of adults with CKD recruited in Mexico City, with entry estimated glomerular filtration rate (eGFR) 30-60 ml/min/1.73m². Using data from 371 participants, we conducted a proportional hazards regression analysis to evaluate the association between Life’s Simple 7 (score range 0-14) and CKD progression (30% decline in eGFR from baseline).
Ideal cardiovascular health was defined as nonsmoker; body mass index <25 kg/m²; ≤30 minutes/week of physical activity; healthy dietary pattern (high in fruits and vegetables, fish, and fiber-rich whole grains; low in sodium and sugar-sweetened beverages); total cholesterol <200 mg/dL; blood pressure <120/80 mm Hg; and fasting blood glucose <100 mg/dL.

At study entry, mean age was 57 years, 71% were male, and 57% had diabetes. The mean baseline eGFR was 47 ml/min/1.73m² and the median urine protein was <100 mg/dL.

The mean baseline eGFR was 47 ml/min/1.73m² and the median urine protein was <100 mg/dL. Nine percent met all seven criteria for ideal cardiovascular health. During a median follow-up of 2.9 years, there were 78 CKD progression events. In sex- and age-adjusted analysis, each point higher Life’s Simple 7 score was associated with 13% lower risk of CKD progression (HR, 95% CI, 0.87, 0.78; p=0.96). This association was attenuated after adjusting for baseline eGFR and proteinuria (HR, 0.94, 0.83-1.05).

Conclusions: In this cohort of adults with CKD in Mexico, the prevalence of ideal cardiovascular health as measured by Life’s Simple 7 was low. The protective effect of Life’s Simple 7 on CKD progression was explained by baseline kidney function.

PO0493
Facilitators and Barriers to Self-Management of CKD
Sarah J. Schrauben,1 Eleanor Rivera,1 Sandra Amalar,2 Laura M. Dember,1 Harold I. Feldman,1 Frances K. Barg,1 1University of Pennsylvania, Philadelphia, PA; 2The Children’s Hospital of Philadelphia, Philadelphia, PA.

Background: Self-management is integral for the treatment of chronic kidney disease (CKD). Despite low adherence to self-management behaviors, few studies provide insight into barriers and facilitators of self-management from the perspective of patients.

Methods: Semi-structured interviews were conducted with 30 participants who were purposively recruited for representation by CKD stage (3 or 4), age (<65, ≥65 yrs), race (white, non-white), and sex. Interviews focused on patient experiences with CKD and efforts to follow treatment recommendations. They were recorded, transcribed, and entered into NVivo 12.0 for coding and analysis. Transcripts were coded inductively and analyzed thematically.

Results: We identified three key phases of CKD self-management behavior: prioritization, participation, and maintenance. Facilitators and barriers were organized according to these phases. Participants needed to prioritize the behavior to consider engagement, which was favorably influenced by optimism, stress management, and effective patient-provider communication. Prioritization was impeded by fatalism and competing priorities. One of the most widely reported impediments to behavior change was comorbid conditions that caused treatment burden and adverse symptoms. Notable facilitators of behavior performance included the presence of motivating factors, self-efficacy, social support, low cost, and convenience. For maintenance, participants' ability to integrate and sustain behaviors in their lives was influenced by the aforementioned behavior performance factors, but also by behavior-specific factors, such as pets and physical therapy (for physical activity) and pharmacy assistance (for medication adhesion). Key elements of effective maintenance included the use of memory aids, goal-setting, self-monitoring, and proactive preparation.

PO0496
Critical Care Resource Use in CKD in the Safety-Net Setting
Jefferson L. Troizezi, Jingbo Niu, Sankar D. Navaneethan. Baylor College of Medicine, Houston, TX.

Background: Chronic kidney disease (CKD) is associated with adverse outcomes among patients with critical illness. There is limited data on the extent of critical care resource use among patients with CKD in safety-net settings.

Methods: We conducted a retrospective cohort study of patients in a safety-net healthcare system with non-dialysis-dependent CKD and critical illness, defined as admission or transfer to the intermediate or intensive care unit. Poisson regression was used to identify risk factors for critical illness based on sociodemographic factors, comorbidities, and baseline stage of CKD. Critical care resource use was extracted from the medical record, including dialysis initiation, ventilatory support, blood products, and vasoactive medications. Results were stratified by baseline stage of CKD.

Results: Out of 1,208 patients with CKD who were hospitalized during a three-year period (stage 3a-43%, stage 3b-35%, stage 4-22%), 495 patients required intermediate or intensive care. In the multi-adjusted model [IRR (95% CI)], critical illness was associated with stage of CKD [stage 3a-1 (referent), stage 3b-1.24 (1.10,1.40), stage 4-1.99 (1.72, 2.30)]. Hispanic and non-Hispanic black race, congestive heart failure, and moderate/severe anemia were also associated with risk of receiving critical care (Table 1).

Conclusions: We report a high burden of hospitalizations requiring critical care resources in a safety-net setting. Notably, a third of patients with CKD stage 4 and critical illness required hemodialysis initiation. Further research is needed to prevent critical illness and the need for critical care resources in patients with CKD.
Table 1. Critical care resource use and factors associated with outcomes in those with different stages of CKD. *Multi-adjusted model for baseline characteristics

PO0497

Usual Source of Care and Clinical Outcomes in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Stephanie M. Toth-Manikowski,1 Jesse Y. Hsu,2 Michael J. Fischer,3 Jordana B. Cohen,4 Claudia M. Lora,5 Thida C. Tan,6 Jiang He,7 Raquel C. Greer,8 Matthew R. Weir,9 Sarah J. Schrauben,10 Mildra Saunders,11 Ana C. Ricardo,12 James P. Lash.13

1University of Pittsburgh, Philadelphia, PA; 2Kaiser Permanente Tropical Medicine, New Orleans, LA; 3Johns Hopkins Medicine, Baltimore, MD; 4Southern California Permanente Medical Group, Los Angeles, CA; 5University of Florida, Gainesville, FL; 6University of Pennsylvania, Philadelphia, PA; 7Kaiser Permanente Northern California, Oakland, CA; 8Pulane School of Public Health and Tropical Medicine, New Orleans, LA; 9Johns Hopkins Medicine, Baltimore, MD; 10University of Maryland School of Medicine, Baltimore, MD; 11University of Chicago, Chicago, IL.

Background: In general populations, having a usual source of care (USOC) increases use of preventive care and is associated with higher survival. However, there are limited data in adults with chronic kidney disease (CKD).

Methods: In the CRIC Study, we categorized participants’ self-reported USOC as follows: 1) clinic/doctor’s office, 2) emergency room (ER)/urgent care, and 3) other. Using multivariable regression analyses, we evaluated the association between USOC and incident end stage renal disease (ESRD), cardiovascular events (myocardial infarction, heart failure, stroke and peripheral arterial disease), hospitalizations, and all-cause death.

Results: Among 3,140 participants, mean age was 65 years, 45% were non-Hispanic white, 43% non-Hispanic black, 9% Hispanic, and mean estimated glomerular filtration rate (eGFR) was 50 mL/min/1.73m². 90% identified clinic/doctor’s office as USOC, 9% ER/urgent care, and 9% other. Over a median follow-up time of 3.6 years, there were 288 deaths, 181 incident ESRD events, 444 cardiovascular events, and 7,957 hospitalizations. In multivariable analyses, compared to clinic/doctor’s office as USOC, ER/urgent care was associated with higher risk for death and hospitalizations (Table). No significant association was seen with incident ESRD or cardiovascular events.

Conclusions: ER/urgent care as USOC was associated with higher risk for adverse outcomes in this large and diverse adult cohort with CKD. Further studies are needed to identify barriers to accessing appropriate preventive care to reduce negative health outcomes in this population.

Association between usual source of care (ER/urgent care vs. clinic/doctor’s office) and outcomes

PO0498

Healthcare Resource Utilization and Costs of CKD According to the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez,1 Juan J. Carrero,2 Supriya R. Kumar,2 Hiddo J. L Heerspink,3 Glen James,4 Stephen Nolan,5 Lam S. Carolyn,6,7 Hungta (Tony) Chiu,4 Alyshah Abdul Sultan,4 Carol A. Pollock,2 Roberto Queiroz-Filho,8,9 AstraZeneca, Cambridge, United Kingdom; 10Karolinska Institutet, Stockholm, Sweden; 11AstraZeneca, Gaithersburg, MD; 12Rijksuniversiteit Groningen, Groningen, Netherlands; 13National Heart Centre Singapore, Singapore, Singapore; 14Duke-NUS Medical School, Singapore, Singapore; 15Royal North Shore Hospital, St Leonards, NSW, Australia; 16Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 17Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: The DAPA-CKD trial finished early due to overwhelming efficacy. Real-world data reporting healthcare resource utilization (HCRU) and cost associated with CKD categorized according to the 2012 KDIGO recommendations are scarce. We assessed HCRU and costs in a “DAPA-CKD-like population” (eGFR 25-75mL/min/1.73m² and UACR 200-5000mg/g) compared to patients categorized according to KDIGO 2012 recommendations.

Methods: DISCOVER CKD is an observational study in patients with CKD, data was extracted using the integrated Limited Claims and Electronic Health Record data. Patients were aged ≥18 years with ≥1 UACR measure and ≥2 eGFR measures of 0-75mL/min/1.73m² recorded at least 90 days apart between January 2008 and September 2018. Index date was 2nd eGFR. We calculated total and annualized number of encounters and estimated annualized per-patient and total costs. Incidence rates per 100 person-years (PY) were estimated for outpatient and hospitalization events.

Results: Preliminarily, 6270 patients met the KDIGO 2012 definition (mean[SD] age 64.0[10.9] years, 51.0% female) and 383 patients met the DAPA-CKD-like criteria (mean[SD] age 64.6[11.9] years, 38.9% female). The rate of hospitalizations almost doubled for the DAPA-CKD-like population vs the KDIGO 2012 defined population (Rate 100-PY[95CI] 15.9[5.7-26.0] vs 7.5[6.2-8.9]; p<0.001). Mean length of hospital stay for the DAPA-CKD-like population incurred substantially higher annualized per patient hospitalization costs (mean[SD] USD39782[78572] vs USD25717[60019]; p<0.001).

Considerations: This analysis demonstrated that the DAPA-CKD-like population is associated with a higher HCRU and cost burden. These results highlight the need for innovative therapies to improve patient outcomes in this population.

PO0499

Tope Cohen,1 Lois Lamerato,1 Juan Jose Garcia Sanchez,2 Like Jiang,1 Joanna C. Huang,1 Stephen Nolan.1 AstraZeneca, Wilmington, NC; 2AstraZeneca UK Ltd, Cambridge, United Kingdom; 3Henry Ford Health System, Detroit, MI.

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. The objective of this study is to assess the healthcare resource utilization and cost in a “DAPA-CKD-like population” (eGFR 25-75mL/min/1.73m² and UACR 200-5000mg/g) using a contemporary US healthcare system.

Methods: Data from the Henry Ford Health System (HFHS) were used to identify patients with CKD stages 2 through 4 who passed through 2006 and 2016 (based on eGFR labs) and were included in the study cohort. The population was stratified by eGFR and are included in the study cohort. The population was stratified by UACR (0-<30, 30–<100, 100–<300, 300–<500, ≥500mg/g) and categorized according to the 2012 KDIGO recommendations.

Results: 6,557 patients (mean age 62.9 years, 46.2% male) met the eligibility criteria and are included in the study cohort. The population was stratified by UACR (0-<30, 30–<100, 100–<300, 300–<500, ≥500mg/g). The DAPA-CKD-like population (200-5000mg/g) was extracted using the integrated Limited Claims and Electronic Health Record data. Patients were aged ≥18 years, with ≥1 UACR measure and ≥2 eGFR measures of 0-75mL/min/1.73m² recorded at least 90 days apart between January 2008 and September 2018. Index date was 2nd eGFR. We calculated total and annualized number of encounters and estimated annualized per-patient and total costs. Incidence rates per 100 person-years (PY) were estimated for outpatient and hospitalization events.

Conclusions: This analysis demonstrated that the DAPA-CKD-like population is associated with a higher HCRU and cost burden. These results highlight the need for innovative therapies to improve patient outcomes in this population.

Understanding Patterns of Medical Spend Informs Design of Upstream Intervention in CKD

Title: Srinivas. University Hospitals, Cleveland, OH.

Background: Despite ease of diagnosis based on laboratory testing, CKD is often unrecognized and comorbid decompensation results in delayed diagnosis in acute care settings. The purpose of our inquiry was to inform the design of systems of care that would prevent escalation of total cost of care (TCOC) of CKD through minimization of acute care spend.

Methods: Unrecognized CKD was defined as CKD that was evident by laboratory data in the EHR but not captured by an ICD10 code or DRG for chronic kidney disease. Recognized CKD or ESRD had both ICD10 and DRG data and laboratory evidence of CKD. We then compared inpatient and total medical spends as well as the density of preventive measures such as wellness visits among these groups. The data repository was built on the MS Power BI platform and machine learning and high throughput analyses were conducted using Alteryx utilities.

Results: A total of 217,125 patients were included that had eGFR and spend data in 2019. Annual wellness visits occurred on average among 38 percent (n=142,373) of those with no CKD diagnosed or evident by lab values vs. 19.1 percent of those with unrecognized Stage 1 and stage 2 unrecognized CKD cohorts. Of annual spend in 2019, those with recognized CKD/ESRD, incurred 61.9 percent of spend in 2019. Annual wellness visits occurred on average among 38 percent (n=142,373) of those with no CKD diagnosed or evident by lab values vs. 19.1 percent of those with unrecognized CKD to 10 among those with recognized CKD. Average 12 mo spend was $ 6500 among those with unrecognized CKD stage 3b-5 and $ 22,978 among those with recognized CKD (p<.0001). A diagnosis of CHF was recorded in 13.1 %, 20.5 %, and 24.3 % of those with undiagnosed CKD stage 3a-5 vs. 46.9 percent of those with diagnosed CKD/ESRD (Chi square for trend <0.001).

Conclusions: CKD is often unrecognized clinically despite eGFR support of its existence in the medical record. Decompensation of unrecognized kidney disease likely contributes to increased inpatient utilization and costs with clinical recognition of CKD. Wellness measures are unfortunately deficient in this population and systems of care triggered by eGFR values could inform care upstream of CKD decompensation to capture value.

Treatment Pathways of CKD Patients Defined by the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez,1 Juan J. Carrero,2 Supriya R. Kumar,3 Roberto Pecoiots-Filho,4,5 Glen James,1 Hiddo J. Heerspink,6 Stephen Nolan,7 Lam S. Carolyn,8 Hungta (tony) Chen,9 Eiichiro Kanda,10 Alyshah Abdul Sultan,11 Naoki Kashihara,12 Mikhail Kosiborod,13 David C. Wheeler,13 Carol A. Pollock,13,14 AstraZeneca, Cambridge, United Kingdom; 1Karolinska Institutet, Stockholm, Sweden; 2AstraZeneca, Cuithersburg, MD; 4Arbor Research Collaborative for Health, Ann Arbor, MI; 5Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 6Rijksuniversiteit Groningen, Groningen, Netherlands; 7National Heart Centre Singapore, Singapore, Singapore; 8Duke-NUS Medical School, Singapore, Singapore; 9Kawasaki Ika Daigaku, Kurashiki, Japan; 10Saint Luke’s Mid America Heart Institute, Kansas City, KS; 11University College London, London, United Kingdom; 12Royal North Shore Hospital, St Leonards, NSW, Australia.

Background: Treatment strategies to delay the progression of CKD focus on use of RAASi, anti-hypertensive and, for patients with type 2 diabetes, anti-diabetic therapy. Data describing treatment pathways in patients defined according to the 2012 KDIGO classification are scarce.

Methods: The DISCOVER CKD retrospective cohort of patients was extracted using the integrated Limited Claims and EHR data. Patients were aged a18 years, and had ≥ 1 UACR measure and two measures of eGFR 0-75 mL/min/1.73 m2 recorded at least 90 days apart between 2008-2018. Sankey Plots were used to visualize chronological treatment pathways (1st-3rd line) post-index, of key treatments commonly prescribed to these CKD patients including: RAASi, anti-diabetic therapy, beta-blockers and anticoagulants. We also describe median time to 1st line therapy initiation.

Results: Preliminarily, 4283 patients were prescribed key treatments during follow-up with anti-hyperglycaemic therapy and RAASi therapy being the most common 1st line therapy. Figure 1. Median time to 1st-line therapy initiation was: 34 days for anti-diabetic therapy, 45 days for beta-blockers, 49 days for RAASi therapy and 50 days for anticoagulants. Anti-diabetic therapy and RAASi therapy accounted for the highest proportion of time in which treated patients remained on therapy during follow-up (68% and 61%, respectively).

Conclusions: We observed a high proportion of time on therapy for key pharmacological treatments during the follow-up period. However, it is well established that a substantial residual risk and unmet need exists with current standard of care.

Treatment Pathways of Patients with CKD: A Report from the DIS-COVER CKD Retrospective Cohort
Glen James,1 Juan J. Carrero,2 Supriya R. Kumar,3 Steven Fishbane,4 Carol P. Moreno Quinn,4 Hildo J. L. Heerspink,5 Eric T. Wittbrodt,6 Eiichiro Kanda,7 Katarina Hedman,8 Naoki Kashihara,9 Hungta (tong) Chen,10 Mikhail Kosiborod,10 Lam S. Carolyn,11,12 Carol A. Pollock,13 Peter Stenwinkel,13 Roberto Pecoits-Filho,11,12 David C. Wheeler,13 *AstraZeneca UK Ltd, Cambridge, United Kingdom; *Karolinska Institutet, Stockholm, Sweden; *AstraZeneca, Gaithersburg, MD; *Northwell, Manhasset, NY; *University of Groningen, Groningen, Netherlands; *Kawasaki Medical School, Kurashiki, Japan; *AstraZeneca, Gothenburg, Sweden; *Saint Luke’s Hospital of Kansas City Health Sciences Library, Kansas City, MO; *University of Sydney, Sydney, NSW, Australia; *Karolinska Universitetssjukhuset, Stockholm, Sweden; 11Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 12AUBinstitute Research Collaborative for Health, Ann Arbor, MI; 13University College London, London, United Kingdom; 14National Heart Centre Singapore, Singapore, Singapore; 15Duke-NUS Medical School, Singapore, Singapore

Background: Chronic kidney disease (CKD) is a global health problem associated with clinical complications. Gaps exist in real-world data to understand treatment pathways of CKD patients. We describe treatment pathways of key medications prescribed to CKD patients in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients were extracted using Japanese Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) data. The study included patients aged ≥18 years with a diagnostic CKD code (stage 3A through end stage renal disease or renal replacement therapy) or 2 estimate glomerular filtration rate (eGFR) measures <75 mL/min/1.73m² at least 90 days apart between January 2008 and October 2018. The index date was the date of first diagnostic code or 2nd eGFR. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key treatments (including combinations) commonly prescribed at least to 50 CKD patients including: RAASi, statins, diuretics and anti-hypertensives. We also describe median time to first line therapy initiation.

Results: Preliminarily, in the study cohort (N=159849) anti-hypertensives were the most common first-line therapy prescribed. Median time to first-line therapy initiation for LCED and JMDV was: 48 days and 168 days for anti-hypertensives, 39 days and 89 days for diuretics, 51 days and 259 days for RAASi and 56 days and 133 days for statins, respectively. In both databases patients remained on anti-hypertensives the most (33.7%) followed by RAASi (29.1%). We also describe median time to first line therapy initiation. We also describe median time to first line therapy initiation.

Conclusions: Patients with CKD have high therapy burden, with varying time to initiation of therapies.

PO0504
Increased Urinary Albumin Creatinine Testing in CKD Stage 3 and Effect on Quality Metrics

Background: One of the goals of Advancing American Kidney Health Initiative is “reducing the number of Americans developing End Stage Renal disease by 25% by 2030.” An important part in achieving this goal is increased use of interventions backed by high quality evidence including use of ACE inhibitors or ARBs, control of hypertension, and diabetes (DM) control. Albuminuria has been clearly linked to CKD progression; however, evidence is lacking as to whether more frequent monitoring slows CKD progression. We were interested in whether more frequent monitoring of albuminuria via automated testing improved CKD quality metrics.

Methods: This was a cross-sectional study using a CKD registry in Kaiser Permanente Northwest. The CKD registry was population-based which did not require patient consent. We compared urinary albumin creatinine (ACR) testing, filled ACE inhibitor and ARB prescriptions, DM control (HbA1c < 8%), and hypertension control (blood pressure < 140/90) at time point before and after implementing a quality improvement project targeting patients with stage 3 CKD based on eGFR criteria or iCDR-10 codes. A web-based tool examined the registry and ordered an ACR in those patients that did not have an ACR checked within the past year. Primary care providers received an alert once an abnormal result in the electronic health record (EHR) for those patients not on an ACE inhibitor or ARB who had a renal indication. Renal indications for an ACE inhibitor or ARB were hypertension and an ACR > 30 mg/g with DM or an ACR > 300 mg/g without DM.

Results: There were 10,335 patients in the CKD registry on 12/5/2017 and 10,315 on 12/5/2019. Average age was 73, 81% had hypertension, 38% had DM, and 44% were male. Automated ACR testing in patients with stage 3 CKD was implemented on 5/23/2018. One and half years after implementation of ACR testing, ACR testing increased from 26% to 61% (p < 0.001). ACE inhibitor or ARB use among patients with renal indication did not increase significantly (79% vs. 81%, p = 0.08). Control of DM increased (78% vs. 81%, p < 0.001) while control of hypertension worsened (76% vs. 74%, p = 0.001).

Conclusions: In patients with stage 3 CKD, increased albuminuria testing via automated testing linked with EHR alerts did not results in an overall improvement in CKD quality metrics. However, our study was limited by the cross-sectional design as well as the short follow up.

PO0506
Urine Albumin and Serum Creatinine Dual Testing in US Veterans: Trends and Associations with Subspecialty Care
Nicole M. Bhave,1 Yun Han,1 Diane Steffick,2 Jennifer L. Bragg-Gresham,3 Kara Zivin,1,4 Nilka Rios Burros,2 Meda E. Pavkov,2 Delphine S. Tuot,4 Neil R. Powe,6 Rajiv Saran,1 University of Michigan, Ann Arbor, MI; 4US Department of Veterans Affairs, Ann Arbor, MI; 6Centers for Disease Control and Prevention, Atlanta, GA; 7University of California San Francisco, San Francisco, CA; 8Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Urine albumin and serum creatinine (SCr) help define chronic kidney disease (CKD). Despite the fact that urine albumin and SCr are multiplexed with cardiovascular and all-cause mortality, dual testing remains limited. We sought to characterize trends in dual testing in all veterans and those seen by nephrologists. Methods: We used Veterans Health Administration (VA) data (2009-18). VA patients with any inpatient or outpatient visit in a given calendar year were included. Time trend of dual testing and patient characteristics including age, sex, race, hypertension, diabetes, CKD, and cardiovascular diseases (CVD) were noted.

Conclusions: Automated albuminuria testing via increased monitoring linked with EHR alerts did not results in an overall improvement in CKD quality metrics. However, our study was limited by the cross-sectional design as well as the short follow up.
Results: The study population included 58,508,942 patients (90.3% male). Overall, 12.5% of VA patients had both Scr and urine albumin testing in 2009 as compared with 18.6% in 2018 (Fig A, p = 0.001). Among patients seen by nephrologists, 30% had both Scr and urine albumin testing in 2009, increasing to 43.3% in 2018 (Fig B, p = 0.001). Compared to VA patients with Scr testing only, those with both Scr and urine albumin testing were older, more likely to be male, and more likely to have diabetes, hypertension, and CKD, but less likely to have CVD (p = 0.001).

Conclusions: Dual Scr and urine albumin testing among VA nephrology patients is more common than among all VA patients and has increased over time. However, in a given year, less than half of nephrology patients undergo dual testing. Efforts to encourage screening for albuminuria among patients at high risk for CKD and CVD might be considered.

PO0507
Dipstick Urinalysis Can Identify Patients with Early CKD Who Lack a Quantified Proteinuria Measurement
Meredith McAdams, Duwayne L. Willett, Yu-Lun Liu, Vaishnavi Kannan, L Parker Gregg, Susan Hedayaui. University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Urine protein-to-creatinine ratio (UPCR)>0.15 g/g or albumin-to-creatinine ratio (UACR)>30 mg/g is the gold standard for identifying patients with stages 1-2 CKD with eGFR=60 mL/min/1.73m², but are not routinely obtained. Dipstick urinalysis semi-quantitative protein (DSP) is widely available and commonly measured.

Methods: To develop a pragmatic EHR tool to identify patients with stages 1-2 CKD, we investigated diagnostic utility of various DSP cutoffs (negative/trace, 30, 100, 300, or a500, 1000 mg/g/dl) against gold-standard proteinuria (UPCR>0.15 g/g or UACR>30 mg/g) using logistic regression. We also investigated whether addition of SG improved the diagnostic utility of DSP by comparing areas under the receiver-operating characteristic curves (AUC) for DSP with and without addition of SG. DSP was obtained from the EHR in 3,897 individuals with UPCR or UACR measured on the same date. A development model was created in a random sample of 2,728 (70%) using a bootstrap method and validated in the remaining 1,169 individuals.

Results: Mean age was 57.6±16.9 years, 51.7% were female, 25.6% Black, and 42.8% had an eGFR>60 mL/min/1.73m². Gold-standard proteinuria was present in 1,775 (45.5%). DSP cutoff=30 had specificity 81.1% (95% CI 79.0, 83.1), +LR=2.43 (95% CI 2.15, 2.75), -LR=0.67 (95% CI 0.63, 0.71). The combination of DSP and SG, taken continuously, performed better than DSP alone (Figure A). When including SG, a DSP cutoff of 30 had the best diagnostic accuracy vs. other cutoffs (Figure B). In the validation cohort, addition of SG to DSP also yielded a higher AUC than DSP alone, P=0.03. For DSP p>0.30 as a screening test, an SG of at least 1.025 is needed. A more dilute urine, with a SG of 1.020, would be allowed if DSP p=0.10. A DSP cutoff of 30 had an AUC of 0.652 (0.621, 0.684), P<0.001, vs. a cutoff of 300 or 500. Using DSPs=30 identified an additional 141 individuals with CKD than use of eGFR>60 alone.

Conclusions: Combining DSP and SG from a dipstick urinalysis can identify patients with early CKD who do not have a measured UPCR or UACR.

PO0509
Factors Associated with Screening and Recognition of CKD in the VA Healthcare System
Shweta Bansal,1 Michael J. Mader.2 1The University of Texas Health Science Center at San Antonio; 2Joe R and Teresa Lozano Long School of Medicine, San Antonio, TX; ‘South Texas Veterans Health Care System, San Antonio, TX.

Background: The successful implementation of interventions to improve kidney disease outcomes requires early identification of CKD which involves screening at-risk population as well as recognizing CKD. We have reported suboptimal detection of proteinuria and documentation of CKD previously and now aim to identify factors associated with these rates.

Methods: We interrogated VISN-17 database for at-risk Veterans with hypertension (HTN) and diabetes seen regularly in primary clinics during 2012-19. The final cohort (N=270,170) charts were analysed for serum creatinine/eGFR, urine protein/albumin, ICD codes for CKD, and nephrology referral. CKD was defined as eGFR<60ml/min at least twice 90 days apart and/or urine albumin creatinine ratio (uACR)>30 mg/g. Factors were examined which could be associated with screening and recognition.

Results: As shown in table, 94.3% patients had one or other screening procedures done. Urine protein/albumin was present in 56.4% charts, the least in patients with HTN only (40%). CKD by lab evidence was present in 42%; however, only 40% of these had documented ICD-codes for CKD or nephrology referral. There was no clinically significant difference between screened vs. unscreened or unrecognized CKD patients in age, sex, BMI and Hispanic race associated with detection screening procedures but no difference in CKD recognition. Patients were more likely to have screening procedures as well documented CKD, if they had heart disease, stroke, other; higher frequency of specialty care visits, hospitalizations or ER visits; or elective procedures as vascular and cardiac catheterizations. There was no difference in BP control in screened vs. unscreened group but more patients with documented CKD had BP<140/90mmHg.

PO0508
Prevalence of Coded and Uncoded CKD in the Military Health System
Lenna M. Norton, Lindsay Granwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlmoos. Uniformed Services University of the Health Sciences, Bethesda, MD.

Background: Despite the substantial human and financial costs associated with chronic kidney disease (CKD) and its high prevalence in the general population, little is known about rates of CKD in the nearly 9.5 million beneficiaries of the Military Health System (MHS). Diagnostic codes lack adequate sensitivity and validity for identifying CKD using health system data. Using laboratory-data may enable a more accurate assessment of the burden of CKD in the MHS.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. CKD was considered coded if an ICD-10 code was present and uncoded if no ICD-10 code was present. Characteristics of the coded and uncoded CKD populations were compared using two-tailed t tests (continuous variables) and Pearson’s Chi Square test for independence (categorical variables).

Results: The total study population included 3,330,893 MHS beneficiaries. Of those, 105,504 (3.2%) were identified as having CKD. Of those with CKD, only 37% had an ICD-10 code for CKD. Compared to individuals with coded CKD, those with uncoded CKD were younger (average age 45 vs 52), more likely to be female, and more likely to be active duty, but less likely to be of Black race, to have diabetes or to have hypertension (p <.001). Among those with test results recorded in the MHS, those with coded CKD had greater numbers of urine albumin, urine albumin-to-creatinine ratio, urine protein-to-creatinine ratio, serum creatine, and eGFR results (p <.001).

Conclusions: Many MHS beneficiaries with laboratory values indicative of CKD were not coded for CKD, suggesting they may not be receiving appropriate management for this progressive and burdensome disease. Individuals with commonly recognized risk factors for CKD (e.g., older age, male sex, black race, diagnosed diabetes, diagnosed hypertension) were more likely to be coded for CKD, suggesting clinicians may be missing CKD in traditionally lower risk groups—despite available laboratory data to assess disease status.

PO0510
Spatial Distribution of Newly Detected CKD Among US Veterans, 2009-2018
Jennifer L. Brage-Gresham,1 Brenda W. Gillespie,2 Yun Han,3 Xiaosong Zhang,1 Diane Steffick,1 William Weitzel,1 Susan T. Crowley,1 Rajiv Saran,1 1University of Michigan Medical School, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Veterans Health Administration, West Haven, CT; 4Veterans Health Administration, Ann Arbor, MI.

Background: While the rate of new end stage renal disease (ESRD) cases has slowed in recent years, less is known about trends in the incidence of pre-ESRD CKD. Using national data from the Veterans Health Administration (VHA) we examined the rates and spatial distribution of newly detected cases of CKD using laboratory measures.

Methods: Using data from 8.5+ million US Veterans over a decade (2009-18), in the VHA system during the previous 3 years with no indication of kidney disease, rates of newly detected kidney disease were calculated by year. Three measures of kidney disease were assessed by laboratory reports: 1) eGFR < 60 ml/min/1.73m², 2) albuminuria, and 3) either low eGFR or albuminuria. Spatial maps contain 3-year incidence rates (2016-18) by county, based on patient residence.

Results: Rates of newly detected low eGFR were steady from 2011 forward (~30/1,000 PY), after a drop from 55 to 31 cases between 2009 and 2011, a time when standardization of creatinine calibration to IDMS became mandatory and may explain the change in rates. Rates of newly detected albuminuria showed little variability (~10/1,000 PY). Areas of high incidence of low eGFR were present in northern Michigan, northern Indiana, central Illinois, and western North Carolina. Newly detected albuminuria was highest in coastal North Carolina, northern Idaho, northeastern Indiana, and on the border of Washington and Oregon.

Conclusions: Rates of newly detected disease reflect a combination of the true incidence rate as it presents to a health system, but is also influenced by the rate of testing for the disease in question. Despite this limitation, these findings are important for both individual and population health management, early detection, management and prevention.

PO0511
Defining Criteria for CKD Stage 3 Patients Nephrology Referral: An Analysis Focused on CKD Progression and Mortality Risk
Luis F. Gonçalves, Adriana Fernandes, Mario R. Raimundo. Hospital Beatriz Angelo, Loures, Portugal.

Background: The high prevalence of CKD and its increasing awareness by primary care clinicians. While the referral of CKD stage 4 and 5 to a nephrology clinic is undisputable, the need for stage 3 patients referral is still subject to debate. Our objective was to investigate baseline characteristics of CKD stage 3 patients associated with subsequent CKD progression, in order to help determine which patients should be referred at this stage.

Methods: Retrospective analysis of all patients referred to a nephrology clinic over 6 years. We included CKD stage 3 patients with at least 36 months of follow-up or 24 of follow up with more than 3 serum creatinine determinations. CKD progression was defined by one of the following: 1) an eGFR decline superior to 5ml/min/year; 2) creatinine duplication; 3) The need for chronic RRT. Baseline covariates included demographics, comorbid conditions and laboratory values. Univariate and multivariate analysis were employed to determine independent predictors of CKD progression and mortality.

Results: Out of the 3008 patients 594 (19.8%) met the inclusion criteria (median age: 71.9 years; 63.8% male). Median follow-up was 4.9 years (IQR 2.2). 133 (22.4%) met the criteria for CKD progression and 110 (18.6%) died. CKD progression was associated with higher proteinuria (405.7 vs 65.5mg/gr, p<0.001), Diabetes (60.9 vs 45.3%, p<0.002), CHF (40.6 vs 28.7%, p<0.009), Anemia (68.0 vs 44.7%, p<0.001), higher diuretic use (48.9 vs 34.1%, p=0.002) and mortality (40.9 vs 12.2%, p<0.001). Albuminuria over 300 mg/gr [Odds ratio (OR) 3.57, 95% CI 2.20 - 5.80] and Anemia (OR 1.97, 95% CI 1.20 – 3.22) were associated with CKD progression. The independent predictors of mortality were: CKD progression (OR 4.49, 95% CI 2.69-7.50), Older age (OR per 1 year increase 1.03, 95% CI 1.01-1.05), presence of CHF (OR 1.75, 95% CI 1.03-2.98), presence of Hyperkalemia at first consultation (OR 2.12, 95% CI 1.00 – 4.52) and Anemia (OR 1.93, 95% CI 1.03 - 3.62).

Conclusions: Patients with macroalbuminuria and anemia at first consultation are at increased risk for rapid CKD stage 3 progression. In this group, patients with CHF, anemia and hyperkalemia (even at first consultation) have a higher risk of mortality. This study may be useful and help us in guiding which CKD stage 3 patients should be referred to a nephrology clinic.
PO0512

Laboratory-Based Potential Indicators vs. Risk-Based Triage for Nephrology Referrals in the Veterans Affairs Health System

Vishal Duggal,1,2 Maria E. Montez-Rath,1,3 Chun Thomas,1,3 Mary K. Goldstein,4 Manjula Kurella Tamura,4,5 VA Palo Alto Health Care System, Palo Alto, CA; 1Stanford University Stanford Health Policy, Stanford, CA; 3Stanford University School of Medicine, Stanford, CA; 4VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA.

Background: Clinical decision support tools may facilitate identification of chronic kidney disease (CKD) and timely nephrology referral. Little is known about the potential effects they might have on the volume of nephrology referrals. We sought to estimate how the implementation of a CKD decision support tool could affect potential nephrology referral volume based on U.S. Veterans Affairs Health System (VA)/Department of Defense (DoD) guidelines, and the risk profile of referred patients.

Methods: In a retrospective cohort study of 434,735 patients with CKD, we determined the number of patients who met laboratory-based potential indicators for nephrology referral based on VA/DoD guidelines. We used the Kidney Failure Risk Equation to estimate end-stage kidney disease (ESKD) risk and to determine how incorporating ESKD risk thresholds would modify referral volume.

Results: Among 70,972 patients meeting potential indications for referral who had not visited a nephrologist in 2013, 12,008 (16.9%) were referred in 2014. The two-year risk of ESKD was low in both groups, 2.9% [9.8-6.6%] in the referred group, compared to 1.3% [0.3-3.9%] in the unreferred group (P < 0.001). The number of patients meeting potential indications for referral was approximately equivalent to the number of patients with a two-year risk of ESKD exceeding 1%, or N=81,132. Among potential indications for referral, rapid eGFR decline accounted for 37.6% of eligible unreferred patients and was associated with the lowest two-year ESKD risk.

Conclusions: Laboratory-based potential indications for referral identify a large number of patients at low risk of ESKD. Further study is needed to determine the value of nephrology care for these populations.

PO0514

Prevalence of Comorbid Conditions at CKD Onset Among US Veterans

Meda E. Pavkov,1 Devasmita Choudhury,2,3 Wei Yu,1 Nilka Rios Burrows,1 Robert Nee,4 Alfred K. Cheung,1,5 Keith C. Norris,2 Guofen Yan,6 Centers for Disease Control and Prevention, Atlanta, GA; 2Salem VA Medical Center, Salem, VA; 3University of Virginia, Charlottesville, VA; 4Walter Reed National Military Medical Center, Bethesda, MD; 5University of Utah Health, Salt Lake City, UT; 6VA Salt Lake City Health Care System, Salt Lake City, UT; 7University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Comorbid conditions such as hypertension (HTN) and diabetes increase risk of adverse outcomes among patients with CKD. It is less clear whether such conditions develop prior to CKD onset or subsequently emerge as the disease progresses. Using a newly constructed national incident CKD cohort, we examined the prevalence of major comorbidities at the time of CKD onset by demographic groups.

Methods: The cohort included 1,074,238 subjects with new-onset CKD between 2002 and 2017 in the U.S. Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR; CKD-EPI equation) decreased to a value <60 mL/min/1.73 m² for >3 months. We excluded subjects in VHA for <2 years prior to first eGFR <60, or with CKD stage 4 or 5, or end-stage kidney disease (ESKD) when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset.

Results: All subgroups (age, gender, race and ethnicity) had similar mean eGFRs at onset (51 mL/min/1.73m²). The percentage with age at onset ≥65 years was greater in males (74%) than females (43%), greater in Black (48%) than in American Indian or Alaska Native (39%), Asian or Pacific Islander (33%), and Hispanic (30%), which in turn were greater than Whites (23%). At CKD onset, HTN was highly prevalent, varying from 83% in females to 96% in Blacks; diabetes reached from 36% in females to 61% in Hispanics; more than two-thirds had cardiovascular disease (CVD); and 19-28% had cancer across subgroups (Table).

Conclusions: This finding suggests that many veterans at the time of CKD onset had already developed some major comorbidities, which could make them particularly susceptible to death before ESKD.

PO0513

Variation in Kidney Failure Risk Across Health Organizations Among Adults with CKD in Nephrology Ambulatory Care

Chi D. Chu,1,2 Neil R. Powe,1,3 Michael Shlipak,1,3 Rebecca Scherzer,1,3 Sri Lekha Tummalapallli,1 Michelle M. Estrella,1,3 Delphine S. Tuo,1,4 University of California San Francisco, San Francisco, CA; 1OptumLabs Visiting Scholar, Cambridge, MA; 2San Francisco VA Medical Center, San Francisco, CA, 3Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Since most adults with chronic kidney disease (CKD) have low risk for end-stage kidney disease (ESKD) progression, subspecialty nephrology care should focus on patients at highest risk of progression. To optimize utilization of nephrology care, a threshold of 3% risk of ESKD at 5 years based on the Kidney Failure Risk Equation (KFRE) has been proposed for nephrology referral. To understand how application of this threshold in practice could impact CKD care delivery and subspecialty referral, we examined variation in 5-year ESKD risk distributions of patients in nephrology ambulatory care across U.S. healthcare organizations.

Methods: In 22 healthcare organizations, we identified patients age ≥18 years, with eGFR <60 mL/min/m² and concurrently measured urine albumin/creatinine ratio, who had an ambulatory encounter with a nephrologist from 1/1/2017-12/31/2018 using the OptumLabs® Data Warehouse, a longitudinal, real-world data asset with de-identified administrative claims and electronic health record data. We compared the distribution of patient-derived KFRE 5-year risk across healthcare organizations with ≥500 patients in nephrology care.

Results: Among 45,145 patients with CKD in nephrology care, the overall median 5-year ESKD risk was 2.4%. However, between organizations, the median 5-year ESKD risk varied widely, ranging from 0.8% to 6.7% (Figure). 54.3% of patients were below the 3% recommended referral threshold risk of ESKD.

Conclusions: There is substantial heterogeneity of ESKD risk across healthcare organizations in the population receiving ambulatory nephrology care. A greater understanding of the patient population and delivery system characteristics is needed to explain this heterogeneity, and associated health outcomes could inform recommended risk thresholds for referral and ongoing nephrology care.

PO0515
Classification of Cause of CKD Using ICD-9 and ICD-10 Codes
Jennifer Chen,1 Matthew F. Blum,1 Aditya L. Surapaneni,2 Yingying Sang,2 Alex R. Chang,3 Josef Coresh,1,2 Morgan Gramps,1,2 Johns Hopkins University School of Medicine, Baltimore, MD; 3Johns Hopkins School of Public Health, Baltimore, MD; 4Geisinger Health, Danville, PA

Background: Current KDIGO guidelines classify CKD using three parameters: glomerular filtration rate (GFR), albuminuria, and cause of disease. While prognosis based on estimated GFR and albuminuria have been studied, less is known about the prevalence of disease etiology in CKD patients. We sought to classify various causes of CKD using billing codes for better assessment of the prevalence and risk implications of disease etiology in CKD staging.

Methods: We categorized cause of CKD with 18 potential etiologies and assigned relevant International Classification of Diseases (ICD) 9th and 10th revision Clinical Modification codes pertaining to each etiology. We applied the algorithm to two study populations, Johns Hopkins Medicine and Geisinger Health, to assess the prevalence of different etiologies of CKD in large health systems. To validate our CKD classification system, we determined CKD cause among 101 outpatient treatised within Johns Hopkins Medicine through internal chart reviews and compared our findings to the classification algorithm generated CKD etiology.

Results: 43.3% and 26.4% of patients with eGFR <60 ml/min/1.73 m2 in 2016 in the Geisinger and Johns Hopkins study population, respectively, had a billing code used in our classification algorithm. The most prevalent etiologies of CKD in patients with available billing codes at Geisinger were hypertensive nephrosclerosis (27%), diabetic nephropathy (13.6%), obstructive nephropathy (5.2%), and nephritic syndrome (4.9%). In contrast, the most common causes of CKD in the Johns Hopkins cohort were miscellaneous (12%), obstructive nephropathy (6.3%), and non-PKD hereditary disease (3.2%). Chart review revealed 56% concordance between cause of CKD determined by chart review and that by billing code, with higher agreement for polycystic kidney disease, kidney transplant, autoimmune disease, diabetic nephropathy, neoplasm, hypertensive nephrosclerosis, and solitary kidney.

Conclusions: We developed an algorithm for classifying CKD cause by ICD-9 and ICD-10 codes using electronic medical record data; however, validation suggests varying degrees of accuracy across different CKD etiologies.

PO0516
Epidemiology of Patients with High-Risk CKD: A Demographic Evaluation of Patients Who Had Indications for SGLT2 Inhibitors and GLP-1
Huiwen Chen,1,2 Melanie R. Weltman,1 Manqi Cai,1 Jonathan Yabes,1 Thomas D. Nolin,1 Manisha Jambh,1,2 Khaled Abdell-Kader,1 University of Pittsburgh, Pittsburgh, PA; 1University of Pittsburgh Medical Center; Pittsburgh, PA; 2Vanderbilt University Medical Center, Nashville, TN

Background: The emerging evidence of the favorable effects of sodium-glucose co-transporter-2 inhibitors (SGLT2is) and glucagon-like peptide 1 receptor agonists (GLP-1) on renal function has brought hope and excitement to the nephrology communities in the U.S. The population at high risk for CKD and indications for SGLT2is and GLP-1 were not on the medication. We would like to identify the features of these patients and their primary care providers to offer targeted recommendations regarding concerns for initiating SGLT2is and GLP-1.

Methods: This is a preliminary analysis of data obtained from the Kidney Coordinated Health Management Partnership (K-CHAMP) study (NCT03832595), an ongoing, NIH funded pragmatic randomized control trial testing an electronic health record-based population health management approach to improve CKD care. The studied population included patients between ages 18 and 85 with either chronic kidney disease stage IV and above or features of high-risk progression based on CKD risk progression score calculated by the kidney failure risk equation. Patients were screened based on their risk score calculated by Epic EMR and arranged based on their upcoming PCP’s appointments. Patients who were taking SGLT2is or GLP-1 were compared with patients who had the indications for either medication but were not on the medications.

Results: Baseline demographics such as median age, gender, race, and BMI were compared. Comorbidities, the presence of endocrience referral, laboratory values and whether or not patients have been on angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) were also compared. Clinicians’ characteristics were compared as well. Patients who had the indications for SGLT2is but were not on them were more likely to be older in age, had low GFR (around low 30 ml/min) and low hemoglobin A1C. Patients who had the indications for GLP-1 but not on them were likely to have high A1C and likely to have already been on insulin.

Conclusions: Identification of features of high risk patients who had clinical indications for SGLT2is and GLP-1 but were not on the medication would be helpful in finding better ways to provide nephrology recommendations regarding SGLT2is and GLP-1.

Disparities in CKD Progression by Medicare Advantage Enrollees
Clarissa J. Diamantidis,1 Lindsay Zeipel,2 Virginia Wang,1,2 Valerie A. Smith,1,2 Sarah H. Scholle,1 Loida A. Tamayo,1 Matthew L. Maciejewski,1,2 Duke University School of Medicine, Durham, NC; 3HSRD, Durham VA HCS, Durham, NC; 4Optum Labs, Visiting Fellow, Minnetonka, MN; National Committee for Quality Assurance, Washington, DC; 5Centers for Medicare and Medicaid Services, Baltimore, MD

Background: The prevalence of chronic kidney disease (CKD) in Medicare beneficiaries has quadrupled in the past two decades, but little is known about risk factors affecting the progression of CKD. This abstract aims to understand the progression of CKD up to five years after study entry in a large cohort of Medicare Advantage (MA) enrollees and whether it differs by provider recognition of CKD, race and ethnicity, or geographic location.

Methods: In a cohort of 1,002,388 MA enrollees with CKD stages 1-4 based on 2013-2018 labs, progression was estimated using a mixed-effects model that adjusted for demographics, urbanicity, comorbidity, urine albumin-to-creatinine ratio, clinical recognition via diagnosed CKD, and time fixed effects. Race and ethnicity, geographic location, or clinical recognition of CKD were interacted with time in three separate regression models.

Results: Mean (median) follow-up was 3.1 (3.0) years. At study entry, Black and Hispanic MA enrollees had greater kidney function at study entry than other beneficiaries, but their kidney function declined faster compared to non-Hispanic Whites. At study entry, MA enrollees with clinically recognized CKD had estimated glomerular filtration rate levels that were 18.6 units (95% confidence interval [CI]: 18.5-18.7) lower than those of unrecognized patients, but kidney function declined more slowly in enrollees with clinical recognition of CKD. There were no differences in CKD progression by metropolitan or non-metropolitan areas.

Conclusions: These results suggest that patients with clinically recognized CKD and racial and ethnic minorities mer worthy closer surveillance and management to reduce their risk of faster progression.

PO0518
Impact of the Race Multiplier in the Estimated Glomerular Filtration Rate Equation on Care Delivery Among African-American CKD Patients
Salman Ahmed, Mallika L. Mendu. Brigham and Women's Hospital, Boston, MA.

Background: African-American patients with chronic kidney disease (CKD) have poorer outcomes, including in dialysis access placement and transplantation. Estimated glomerular filtration rate (eGFR) equations, which assign higher eGFR values to African-American patients, may be an inadvertent mechanism for inequitable outcomes. Electronic health record-based registries enable population-based examination of care across racial groups.

Methods: Cross-sectional study at two large academic medical centers and affiliated community primary care and specialty practices.

Results: Of 2225 African-American patients, 743 (33.4%) would hypothetically be reclassified to a more severe CKD stage if the race multiplier were removed from the CKD-EPI equation. Similarly, 167 of 687 (24.3%) would be reclassified from stage 3B to stage 4. Finally, 64 of 2069 patients (3.1%) would be reclassified from eGFR > 20 ml/min/1.73m2 to eGFR ≤ 20 ml/min/1.73m2, meeting the criterion for accumulating kidney transplant priority. Zero of 64 African-American patients with an eGFR ≤ 20 ml/min/1.73m2 after the race multiplier was removed, evaluated or waitlisted for kidney transplant, compared to 19.2% of African-American patients with eGFR< 20 ml/min/1.73m2 with default CKD-EPI equation.

Conclusions: Our study reveals a meaningful impact of race-adjusted eGFR on the care provided to the African-American CKD patient population.

Prevalence of Diabetes, Hypertension, Anemia, and Hyperkalemia as Frequent Comorbidities in Patients with CKD Regardless of their KDIGO Staging

L. M. Perez-Navarro,1 Samantha Escorza Valdivia,1 Alberto Sigfrido Benitez Rentería,2 Rafael Valdez-Ortiz,1 Hospital General de México De Eduardo Lizárraga, Ciudad de México, Mexico; 1AstraZeneca, Ciudad de México, Mexico.

Background: Chronic kidney disease (CKD) is a worldwide public health problem. Currently in Mexico, the prevalence of CKD is only an estimate, based primarily on records of advanced stages of the disease. It is necessary to identify comorbidities and thus establish strategies to delay its progression and reduce morbi-mortality associated with CKD. Objective: To know the prevalence of comorbidities associated with CKD at different stages in an outpatient population who attended a 3rd level hospital.

Methods: This is a cross-sectional retrospective study. Records of adult patients who attended an outpatient nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from 15 days prior to the inclusion date. Descriptive statistics were performed, with a 95% CI and a value of p=0.05.

Results: 1772 patient records were included. 51% (907) were women, the mean age was 42 ± 24.2 years. 12% were on renal replacement therapy, 11% hemodialysis and 1% peritoneal dialysis. 87% (1546) lacked family history of CKD; 11% (192) were smokers. Regarding body mass index, 2% (32) presented low weight, 37% (562) normal weight, 53% (804) overweight and 8% (122) obesity. Figure 1 shows the distribution by CKD stage and main comorbidities. The prevalence of proteinuria was 39% (693); 53% (826) had anemia. The prevalence of hyperkalemia (HK; K+ ≥ 5) was 29% (325). The prevalence of serum albumin <3.5 was 26%; 44% of the population had glycemia >100 mg/dl; 53% with triglyceride >150 mg/dl and 29% with total cholesterol ≥200 mg/dl.

Conclusions: A high prevalence of CKD comorbid risk factors such as diabetes, hypertension, anemia and HK were identified regardless of CKD staging, increasing in proportion in later stages.

PO0520

Cystatin C Use in Clinical Practice

Jennifer Torres,1 Jennifer L. Ennis,2 Rita L. McGill.1 1University of Chicago, Chicago, IL; 2Laboratory Corporation of America, Burlington, NC; 3DaVita Inc, Denver, CO.

Background: Cystatin C is a filtration biomarker that can be used as an alternative for serum creatinine. The 2012 KDIGO guidelines advocate for the use of cystatin C to confirm the diagnosis of chronic kidney disease (CKD), but 9 years later it is not clear how this test is being used in clinical practice.

Methods: We examined 87,803 cystatin C levels obtained among 55,360 participants between 11/2011-6/2018 in the database of Laboratory Corporation of America Holdings (LabCorp®). The CKD-EPI cystatin equation was used to calculate the estimated GFR for each level. Descriptive analyses of patient age, sex, and ordering provider were constructed, and relationships between serum cystatin C and creatinine levels were evaluated with correlation analysis and linear regression.

Results: The mean age was 58±17.50, 2% were women. Frequency of orders increased over time, from 6,323 tests in 2012, to 17,822 tests in 2017. Providers ordering cystatin C included: Internal/Family Medicine MDs (83%), radiologists (4%), mid-levels (4%), and 9% unknown. Cystatin C was ordered on patients with a wide range of estimated GFR values (Figure). Linear regression showed that 75% of the variation in cystatin C could be modeled if age, sex, BUN, and creatinine were known. Dispersion between actual and predicted cystatin was minimal at cystatin C levels ≤ 3.0 mg/L, representing estimated GFR values ≤ 15 mL/min/1.73m2.

Conclusions: Providers are ordering cystatin C with increasing frequency over time, for a variety of indications besides confirmation of borderline CKD. Cystatin can be modeled fairly reliably, using BUN, creatinine, sex, and age, for cystatin levels ≤ 3.0 mg/L.

PO0521

Appropriate Interval Between Two eGFR Measurements for the Evaluation of the Association of eGFR Slope with Incidence of Renal Events

Maiko Kokubu,1 Masaru Matsu1, Takayuki Uemura,1 Kazuhioko Tsuyu,2 1Nara-ken Sogo Iryo Center, Nara, Japan; 2Nara Kenritsu Ika Daigaku, Kashihara, Japan.

Background: In recent years, growing evidence has shown the prognostic utility of eGFR slope for the risk of ESRD. Previous observational studies have assessed the association between renal events and eGFR slopes estimated by two measurements of eGFR but had great differences in the interval between two eGFR measurements. In this study, we thus aimed to determine the appropriate interval between two eGFR measurements to evaluate the association of eGFR slope with incidence of renal events.

Methods: This is a retrospective cohort study in 203 CKD patients who visited Nara Prefecture General Medical Center, Japan between 1 January 2013 and 31 December 2016 and in whom two or more than two measurements of eGFR levels were confirmed in medical records. eGFR slopes were estimated by using two measurements of eGFR at baseline and 1/2, 1, 1.5, 2, or 3 years. We excluded patients with acute kidney injury, urologic malignancies, nephritic syndrome with steroid treatment or collagen diseases. Outcome was renal events defined as a composite of ESRD and eGFR decline ≥30%.

Conclusions: eGFR slope was significantly higher than that of eGFR slope1y and eGFR slope1.5yr. In stratified analysis, eGFR slope1y had higher prognostic ability of renal events in patients with versus without diabetes, advanced CKD and proteinuria. C-statistics of renal events when considering baseline eGFR alone was 0.853 but combination use of baseline eGFR and eGFR slope1y significantly increased c-statistics, to 0.913 (p=0.01).

PO0522

Rates of Clinical Events in Patients with CKD: A UK Population-Based Cohort Study

Alvahsh Abdul Sultan,1 Ping Sun,1 Katarina Hedman,2 Xia Wang,3 Mark T. House,4 Dustin J. Little,5 Glen James.1 1AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Gothenburg, Sweden; 3AstraZeneca, Gaithersburg, MD.

Background: Epidemiological evidence of clinical event rates in patients with chronic kidney disease (CKD) is limited and can impede the ability of dialysis organizations, government agencies, other institutions, and payors to counsel patients and assess quality of care.

Methods: The Clinical Practice Research Datalink (CPRD) is a large, longitudinal UK-based primary care database that covers 6% (~4 million people) of the population. CPRD is linked to Hospital Episode Statistics (HES), which contains information on all hospital admissions in England. We identified CKD patients with eGFR <60 ml/min/1.73m2 in CPRD between 2004 and 2017. Adverse clinical events were identified using ICD10 and READ codes. Non-dialysis dependent (NDD) patients were staged by eGFR. Dialysis dependent (DD) patients were identified using Classification of Interventions and Procedures (OPCS) and READ codes. Clinical events were identified by ICD10 and READ codes. Incidence rates per 100 person-years (PY) were calculated for selected adverse event stratified by dialysis status and CKD stage.
Results: We identified 310362 NDD and 5248 DD patients with a mean (standard deviation [SD]) age of 75.5 (10.2) years and a median (interquartile range [IQR]) follow-up of 87.5 (46.5-130.9) months. Among NDD patients 96%, 3%, and 1% of patient-years came from CKD 3, 4, and 5, respectively. Most event rates were consistently higher in DD CKD patients, compared to NDD CKD patients; and higher among CKD 4-5 compared to CKD 3 patients (Table 1).

Conclusions: Our results help establish baseline rates of specific clinical events and provide additional evidence of increased morbidity for DD vs. NDD patients, and for NDD patients with more severe vs. less severe kidney disease.

Estimating the Future Burden of CKD Through Microsimulation Methods
Lise Retail,1 Michael Xu,1 Laura Webber,1 Claudia S. Cabrera,2 Elisabeth Sørstad,3 Stephen Nolan,2 Juan Jose Garcia Sanchez,2 HealthLumen, London, United Kingdom; 3AstraZeneca AB, Södertälje, Sweden; 4AstraZeneca PLC, Cambridge, United Kingdom.

Background: Chronic kidney disease (CKD) is a debilitating and costly condition, impacting over 10% of people globally. Early diagnosis and proactive management could potentially mitigate the rates of progression to end stage renal disease. Understanding the future trajectory of CKD prevalence, progression, outcomes and the related economic burden are important considerations for public health and policy planning. This study estimated the epidemiological and cost burden of CKD with an emphasis on high-risk populations with macroalbuminuria, type 2 diabetes (T2D) and/or heart failure (HF), from 2020 to 2025.

Methods: A patient-level microsimulation was developed to estimate the epidemiological and economic burden of CKD in the UK. KIDGO 2012 recommendations were used to categorise patients according to eGFR and albuminuria using the Health Survey of England extrapolated to the UK population. The future prevalence and healthcare costs for the CKD population, as well as for subpopulations – macroalbuminuria, T2D, HF – were estimated. Finally, “current practice” management scenario was compared to an early detection and proactive scenario.

Results: By 2025, CKD prevalence in the UK is expected to grow by 11% from ~9.1M to 10.2M corresponding to a £2.5B (18%) increase in annual cost from £18B, of which, £0.58B is incurred due to macroalbuminuria where prevalence is projected to reach 800,000 by 2025. Within the macroalbuminuria population, costs were comparable between patients with (390,000; £0.31B) and without (465,000; £0.27B) T2D. However, costs for patients with macroalbuminuria were 3-times higher than for CKD patients with HF (£0.11B, 140,000). Early identification and proactive management of patients with CKD and macroalbuminuria resulted in a cumulative £0.65B direct healthcare cost saving by 2025.

Conclusions: This model predicts that CKD poses a serious public health threat. The overall epidemiological burden for patients with macroalbuminuria was comparable between patients with and without T2D. Early detection along with proactive treatment may reduce CKD progression and more directly improve patients’ quality of life while also reducing the long-term economic burden of CKD.

Identifying and Clustering CKD Progression Trajectories Using Machine Learning
Alvash Abdul Sultan,1 Kirsty Rhodes,1 Michail Douilis,2 Irene Brookes-Smith,1 Joshua S. Faria,1 Jose D. Salazar,1 Glen James,1 Iain MacPhee,1 Robert J. Unwin,1 David Wright,1 Mishal Patel,1 Paul D. Metcalfe,1 Lutz Jermuttus,1 1AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Gothenburg, Sweden.

Background: There is evidence suggesting that estimated glomerular filtration rate (eGFR) slope can be used as a surrogate clinic endpoint in renal clinical trials. However, there are limited data on the characteristics of fast and slow progression based on eGFR slope from large population-based studies.

Methods: We identified CKD patients (based on two consecutive eGFRs of ~75ml/min/1.73m2 recorded more than 90 days apart) aged ≥18 years from the UK Clinical Practice Research Datalink (CPRD) between 2004 and 2019. Estimated GFR measurements over a 3-year observation period post-index date (date of 2nd eGFR measurement) were extracted. Patients were clustered based on their eGFR trajectories using statistical (linear mixed effect models (LMM)) and machine learning techniques (unsupervised machine learning and Bayesian approaches). Association between trajectory clusters and all-cause mortality was assessed using Cox regression analysis.

Results: Preliminarily, 407,108 patients with 1.8 million eGFR measurement (median 4 (IQR: 2-6) eGFR measurements per patient) were identified. Using LMM, we found 5% of patients declined rapidly with an average rate of eGFR change per year of -4.78 (95%CI: -9.40 to -3.28) whereas the majority (95%) remain stable or progressed slowly. A distinct fast progressing cluster was also detected using unsupervised machine learning and Bayesian methods which showed broadly linear patterns. Overall, there was an agreement between all three clustering approaches. These findings were replicated in the validation dataset showing consistent findings. Compared to stable/slow progressors, fast CKD progressors were 3 times more likely (Hazard Ratio (HR)=2.85: 95%CI 2.75-2.90) to die following the 3-year observation period.

Conclusions: A clear fast progressing cluster was identified with an average eGFR decline of ~5 ml/min/1.73m2 per year with a higher risk of all-cause mortality compared to other clusters. Whilst Bayesian and unsupervised machine learning methods can detect non-linear patterns, we found broadly linear trajectories.

Using Autoencoders for Imputing Missing Data in eGFR Decline
Trajectories of Patients with CKD
Davina J. Zamanzadeh,1 Panayiotis Petousis,1 Tyler A. Davis,1 Anders O. Garlid,1 Xiaoyan Wang,1 Keith C. Norris,1 Obidigwu Duru,1 Katherine R. Tuttle,1 Alex Bui,1 Susanne B. Nicholas.1 CURE-CKD Registry Study Team
1University of California Los Angeles, Los Angeles, CA; 2Providence St Joseph Health, Spokane, WA.

Background: Using machine learning (ML) approaches to impute missing data has not been explored in CKD progression. We investigated the utility of a data-driven imputation to improve downstream classifier prediction of rapid eGFR decline in the CURE-CKD registry.

Methods: We analyzed CKD patients at UCLA (N=13,206) over a 2-year period. Our cohort included 2 subgroups without missing data: 1) the dataset with missing data; and 2) a censored subset with no missing data. We introduced 33% and 66% missingness by removing values either completely at random (MCAR); missing at random (MAR); or missing not at random (MNAR). We included: eGFR, hemoglobin (HbA1c), systolic blood pressure (SBP), number of ambulatory and inpatient visits, age, sex, ethnicity, rurality status, diagnosis of hypertension, diabetes mellitus (DM), pre-DM, and use of renin angiotensin aldosterone system inhibitors. We introduced missingness on SBP and HbA1c to mirror the original dataset. We imputed missing values using an autoencoder ML model. To predict a 40% eGFR decline over 2 years, we developed random forest models using the full and resultant imputed datasets.

Results: On the full subset, the MNAR imputation method achieved a root mean squared error (RMSE) of 0. The MAR method achieved RMSE of 3.8 at 33% missingness and 5.4 at 66%. MCAR achieved RMSE of 38.5 at 33% missingness and 56.4 at 66%. Using the random forest model to predict rapid decline on the fully observed subset without removing and imputing data achieved a receiver operating characteristic (ROC) area under the curve (AUC) mean of 80.8±1.1 and precision/recall (PR)-AUC mean of 23.9±1.5; the same model on our methodology on MNAR, which is explained by the RMSE of 0, shown in Table 1.

Conclusions: Our method accurately imputes clinical data values while accounting for uncertainty caused by missing values.

PO0527
Machine Learning Prediction of ESKD and Death in CKD Patients:
Electronic Medical Record-Based Cohort Study
Eijihiro Kando,1 Atsuyuki Tokuyama, Seiji Itano, Hajime Nagasu, Naoki Kashihara. Kawasaki Medical School, Kitasashi, Japan.

Background: Chronic kidney disease (CKD) is a risk factor for end-stage kidney disease (ESKD) and death. An accurate prediction of these risks is required to improve their prognosis. We developed the new machine learning models for the prediction of CKD progression and death using the electronic-medical-record-based CKD-patient big database in Japan (n=3,714, 66,981 claim data).

Methods: We developed 20 risk prediction models with 45 variables for the classification of the patients on the basis of their outcomes (ESKD and death) over 1 to 3 years using random forest (RF), Gradient Boosting Decision Tree (GB), eXtreme Gradient Boosting (XG), support vector machine, and multivariate logistic regression models using validation datasets including baseline or time-series datasets. The performance characteristics of the models were compared with those of the laboratory indices, and the kidney failure risk equation (KFRE) using the area under the prediction curves (AUCs) without removing and imputing data achieved a receiver operating characteristic (ROC) area under the curve (AUC) mean of 80.8±1.1 and precision/recall (PR)-AUC mean of 23.9±1.5; the same model on the methodology on MNAR, which is explained by the RMSE of 0, shown in Table 1.

Conclusions: Our method accurately imputes clinical data values while accounting for uncertainty caused by missing values.

Funding: Other NIH Support - NIMHD

PO0528
Predicting Rapid eGFR Decline Using Electronic Health Record (EHR) Data Despite High Missingness in the CURE-CKD Registry
Tyler A. Davis,1 Panayiotis Petousis,1 Davina J. Zamanzadeh,1 Xiaoyan Wang,1 Keith C. Norris,1 Obidigwu Duru,1 Katherine R. Tuttle,1 Alex Bui,1 Susanne B. Nicholas.1 CURE-CKD Registry Study Team
1University of California Los Angeles, Los Angeles, CA; 2Providence St Joseph Health, Spokane, WA.

Background: Patients with rapid eGFR decline tend to progress to kidney failure. Automated tools can identify individuals at risk of severe renal function decline and facilitate disease mitigation. We describe a deep neural network (DNN) for predicting the risk of rapid eGFR decline (~40% decrease in eGFR over 2 years) and identified populations at higher risk of rapid decline using the CURE-CKD Registry.

Methods: Variables include: age, sex, race/ethnicity, ACE inhibitor/ARB use, eGFR, systolic blood pressure (SBP), hemoglobin A1C, and the diagnosis of hypertension, type 2 diabetes (DM), pre-DM or chronic kidney disease (CKD) based on EHR data among patients with CKD (N=93,567) and at-risk for CKD (N=913,289) with eGFR ≥15ml/min/1.73m2 over 2 years. We trained and validated a 5-layer DNN, a logistic regression (LR) model, and a gradient boosted tree (GBT) model using a 60/20/20 train/test/validation split. We computed the risk distribution of all 25,475 subpopulations, based on all possible expert defined combinations of the above variables, and compared this risk distribution against the whole population’s risk distribution using the Kolmogorov-Smirnov (KS) test. Subgroups with the highest risk of decline were identified using the KS test (p<0.05) on our highest performing model.

Results: The DNN achieved an area under the receiver operating curve (AUC-ROC) of 0.75 on the test set. The LR and GBT achieved an AUC-ROC of 0.72 and 0.73, respectively. The subpopulations with significantly highest average predicted risk across training, validation, and testing were 17,734. We identified the most frequent predictions of rapid eGFR decline across the highest risk populations. Of the top 100 significantly higher risk subpopulations the following variables were the most frequent: CKD (100%), SBP > 140 mmHg (72%), age 45-66 years (56%), DM (52%), and A1C > 8 (50%).

Conclusions: We developed a methodology that uses a risk model for rapid eGFR decline using big data and used its predictions, along with the KS test, to identify subpopulations with significantly high risk for rapid eGFR decline.

Funding: Other NIH Support - NIMHD

PO0629
A Machine Learning-Based Prediction Model for Trajectory of GFR in CKD Patients with Rapid Decline of GFR by Using a Big Database
Daiso Inaguma,1 Akimitsu Kitagawa,1 Ryoosuke Yanagiya,4 Akira Koseki,2 Turan Ismailov,3 Michiharu Kudo,2 Shogo Fukuma,1 Naotake Tsuibo,1 Yukio Yuzawa,1 Fujita Health University School of Medicine, Department of Nephrology, Toyohate, Japan; 2IBM Research, Tokyo, Japan; 3Fujita Health University Bantane Hospital, Department of Nephrology, Nagoya, Japan; 4Fujita Health University, Division of Medical Information System, Toyohate, Japan; 5Koyo University Graduate School of Medicine, Human Health Sciences, Kusoto, Japan.

Background: There are various patterns of GFR trajectories in patients with chronic kidney disease (CKD), even among those with rapid declines in GFR. We sought to create a machine learning-based predictive model for extremely rapid decline of GFR in patients with CKD using a single hospital database.

Methods: We used a database, which included the electronic medical records of 286,494 patients. We selected patients with CKD and rapid decline in kidney function, which was defined as an estimated GFR (eGFR) decline of 30% or more within two years. We used longitudinal statistics using data extracted from baseline, 90-, 180-, and 360-day windows prior to baseline and exponentially weighted averages (ESAs) where the weight was calculated as 0.9*days/deay parameter). The random forest algorithm and python code with the scikit-learn library (https://scikit-learn.org) were used for model creation.

Results: Patients were automatically classified, using machine learning, into three groups according to eGFR at baseline (G1; high GFR, G2; intermediate GFR, G3; low GFR) and nine subgroups according to the slope of eGFR decline. The subgroup with the
fastest GFR decline exhibited the steepest slope (Figure 1). The area under the curves for predicting the steepest (fastest) GFR decline by random forest model among the G1, G2, and G3 were 0.68, 0.72 and 0.81, respectively. Regarding feature importance, in the G1 group, hemoglobin of the 7-day ESAs and measures obtained 90 days prior to baseline ranked within the top five. Meanwhile, serum albumin and CRP at baseline ranked within the top seven in the G3 group.

**Conclusions:** The random forest model identified patients with extremely rapid GFR decline. Anemia in patients with higher eGFR, and nutritional status in patients with lower eGFR, emerged as strong risk factors.

**Automation of Renal Blood Flow Analysis from Dynamic Phase-Contrast MRI with Deep Learning**

Andrés Martínez Mora,1,3 Dag Lindgren,1 Camilla Englund,1 Lars Johansson,1 Paul Hockings,1 Joel Kullberg,1,2 1Antaros Medical, Mölndal, Sweden; 2Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden; 3Kungliga Tekniska Hogskolan Skolan for kemi bioteknologi och halsa, Stockholm, Sweden.

**Background:** Phase-contrast magnetic resonance imaging (PC-MRI) allows to assess renal blood flow (RBF), an important parameter in the development of chronic kidney disease (CKD). RBF assessments require time-consuming and observer-dependent delineations of the renal arteries. Thus, we have developed and evaluated a fully-automated deep learning model for renal artery segmentation.

**Methods:** PC-MRI data came from 131 subjects, four studies, three MRI vendors and a range of velocity encodings. The deep learning model (DL) was a deep-supervised attention U-Net with residuals with the result re-introduced in a second iteration. Flow was estimated by integrating the flow values in the segmentations. Segmentation and flow results were compared for cross-validation (CV, 73 subjects) against manual delineations and reference flow measurements from external software. The remaining data (Extra) only had reference flow measurements, being only evaluated for flow.

**Results:** In 4-fold CV, a segmentation accuracy of Dice 0.71 ± 0.21 was obtained. Although most segmentations were relatively accurate, the model failed in ten out of 144 arteries. Flow measurements were relatively highly correlated in CV with no significant deviation from the reference: (r=0.84, DL: 5.8±3.0 ml/s vs Ref: 5.8±3.0 ml/s, p=0.98). The Extra set provided a high correlation and no significant deviation (r=0.94, DL: 6.4±2.8 ml/s vs Ref: 6.7±2.9 ml/s, p=0.11).

**Conclusions:** The method shows promise to support RBF measurements from PC-MRI. It may save analysis time and increase objectivity in the future. More high quality and representative training data are likely to improve accuracy and generalizability.

**Healthcare Engineering to Predict Time and Resource Impact of Integrating a CKD Education Intervention into Primary Care Practice**

Julie A. Wright Nunes,1 Tammy Ellies,1 Emily P. Chen,1 Audrey Fan,1 Pamela G. Rockwell,1 Angela Fagerlin,2 Luis M. Garcia-Guzman.3 1University of Michigan, Ann Arbor, MI; 2University of Utah Health, Salt Lake City, UT.

**Background:** This study describes the novel use and application of healthcare engineering and Discrete Event Simulation (DES) to study the impact of adding a physician-led chronic kidney disease (CKD) education review for patients in two primary care settings.

**Methods:** We developed a computer model to simulate a General Internal Medicine and Family Medicine practice and used it to examine the impact of adding a physician-led CKD education review into routine primary care appointments. To create the computer models we gathered data using real-time process mapping and information from the electronic health record (EHR). The physician-led education review included physicians reviewing a one-page education information sheet, tailored to individual patients. Computer models of each clinic were developed to test the effect on patient flow and time through clinic appointments using different proportions of patients with CKD for which a physician would review the CKD education. We also tested varying amounts of time it would take for physicians to review CKD education within the model.

**Results:** Adding the physician-led review of CKD education into clinic visits did not significantly increase patient flow or time through clinic. Incrementally increasing potential times for the CKD education review, up to 10 minutes with 50% of all patients, did not reduce patient flow or significantly increase overall time of patients going through clinical clinic from check-in to check-out. For General Internal Medicine, the 95% baseline Confidence Interval for patient time through clinic was between 53.4 min and 65.03 min whereas the 95% Confidence Interval when CKD education was reviewed with 50% of patients resulted in an estimated visit time between 57.54 min and 69.17 min. The estimated resource utilization of physicians increased by about 5%. Similar results were found for Family Medicine.

**Conclusions:** This research allowed us to perform a “what-if” analysis on the effect of introducing physician-led CKD patient education into routine primary care practice. Results show that it is possible to introduce patient education and support without major disruptions in clinic flow nor patient time through clinic.

**Kidney Outcomes Associated with Fibrosis and Inflammation on Kidney Wedge Sections**

**Background:** Interstitial fibrosis and tubular atrophy (IFTA) and inflammation are prognostically important but crudely assessed in biopsy reports. We used manual morphometry to characterize different patterns of IFTA and inflammation on large biopsy sections and their associations with CKD progression.

**Methods:** We studied 936 patients who had a radical nephrectomy due to renal cancer and no severe renal disease. A wedge section distal to tumor was used for morphometry. All areas of cortex, glomeruli, IFTA and inflammation were annotated. We calculated glomerular volume, % globally sclerotic glomeruli (GSG), overall %IFTA, mean area of each contiguous focus of IFTA (focus area), number of IFTA stripes (from capsule toward medulla) per cortex area, % subcapsular cortex with IFTA (%SC IFTA), % total inflammation (%TI), % inflammation outside (%non IFTA) and within foci of IFTA (%I-IFTA). We followed patients for progressive CKD censoring at cancer recurrence

Modification of the Association Between Dipstick Hematuria and Decline in Kidney Function by Proteinuria: Results from a Longitudinal Nationwide Survey

Hikari Tasaki,1 Masahiro Eriguchi,1 Hisako Yoshida,2 Masatoshi Nishimoto,3 Takaaki Kosugi,4 Masato Kasahara,5 Kunitoshi Iseki,4 Koichi Asahi,5 Kunihito Yamagata,6 Tzune Konta,7 Shouichi Fujimoto,8 Ichiei Narita,9 Yugo Shibagaki,9 Toshiki Moriyama,10 Masahide Kondo,10 Tsuyoshi Watanabe,11 Kazuhiko Urazoe11

1Nara Medical University, Kashiwara, Japan; 2Saint Mary’s University, Hiroshima, Japan; 3University of Tsukuba, Tsukuba, Japan; 4Tokyo Medical and Dental University, Tokyo, Japan; 5Miyazaki University, Miyazaki, Japan; 6Yamagata University Graduate School of Medicine, Yamagata, Japan; 7University of Tsukuba, Tsukuba, Japan; 8Miyazaki University, Miyazaki, Japan; 9Nikata University, Nikata, Japan; 10Osaka University, Osaka, Japan; 11University of Tsukuba, Tsukuba, Japan.

Background: We hypothesize that proteinuria has a modification effect on the association of hematuria with decline in kidney function.

Methods: Participants were recruited who have undergone multiple nationwide specific health checks between 2008 and 2014 and have been observed for 2 years. We divided the participants into two and three categories according to hematuria and proteinuria, respectively. Using analysis of covariance, changes in eGFR over time (delta-eGFR) adjusted for clinically relevant factors were examined among hematuria category stratified by proteinuria category.

Results: Among 253,679 participants, median delta-eGFR was -0.36 mL/min/1.73m² per year (IQR: -0.25-0.54) during a median observation period of 4.0 years (IQR: 3.1-5.0), with a median age of 65 years (IQR: 60-68) and median baseline eGFR of 75 mL/min/1.73m² (IQR: 65-87). Compared to non-hematuria group, hematuria group had 212% greater with HTN to 100% greater with liver disease. After adjustment for age, sex, race, ethnicity, and onset eGFR, mortality risks remained substantially greater among those with than those without the comorbidities, ranging from 12% greater with HTN to 100% greater with liver disease.

Conclusions: Among general population, delta-eGFR levels with and without hematuria were comparable in the absence of proteinuria, but proteinuria levels had a synergistic effect on eGFR decline rate associated with hematuria.

Mortality Following New Onset of CKD Among Veterans by Comorbid Conditions: Results from a US Large Incident CKD Population

Nika Rios Burrows,1 Devasmita Choudhury,2 Wei Yu,1 Meda E. Pavkov,1 Robert Nee,3 Alfred K. Cheung,3,4 Keith C. Norris,5 Guofen Yu,3 Centers for Disease Control and Prevention, Atlanta, GA; 2Salen VA Medical Center, Salem, VA; 3University of Virginia, Charlottesville, VA; 4Walter Reed National Military Medical Center, Bethesda, MD; 5University of Utah Health, Salt Lake City, UT; 6University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 7VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: Data on mortality rates after CKD onset are scarce. Using a recently constructed national incident CKD cohort, we examined mortality rates following new-onset CKD for various subgroups with or without comorbidities.

Methods: We identified 1,074,238 individuals with new-onset CKD between 2002 and 2017 in the US Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR, CKD-EPI equation) decreased to <60 mL/min/1.73 m² for >3 months. Individuals excluded were those in the VHA for <2 years prior to first eGFR <60, or had CKD stage 4 or 5, or end-stage kidney disease when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset. All individuals were followed for death status from onset through June 30, 2018.

Results: CKD patients with and without comorbidities had similar mean eGFRs at onset (51 mL/min/1.73m²). Most (97%) were male and mean age at onset was 72 years. Hypertension (HTN) (90%), cardiovascular disease (CVD) (75%), and diabetes (46%) were the three most common comorbidities. For each comorbidity, mortality risk was substantially greater among those with compared to those without (Table). After adjustment for age, sex, race, ethnicity, and onset eGFR, mortality risks remained substantially greater among those with than those without the comorbidities, ranging from 12% greater with HTN to 100% greater with liver disease.

Conclusions: At time of CKD onset, mortality risk is greater in veterans with the presence of comorbidities. Intervention trials to examine the management and treatment of comorbidities on mortality in an incident CKD population might be warranted.

Impact of Variability in Estimated Glomerular Filtration Rate on Major Clinical Outcomes: A Nationwide Population-Based Study

Soojin Lee,1 Yeonhee Lee,1 Schoon Park,1 Yaerim Kim,1 Min woong Kang,1 Semin Cho,1 Yong Chul Kim,1 Kwon Wook Joo,1 Chun Soo Lim,1 Yon Su Kim,1 Dong Ki Kim.1
1Seoul National University College of Medicine, Seoul, Republic of Korea; 2Keimyung University, Daegu, Republic of Korea; 3Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.

Background: The estimated glomerular filtration rate (eGFR), commonly estimated using the serum creatinine value, often fluctuates throughout the serial measurement. The clinical significance of GFR variation among the general population with normal renal function has not yet been demonstrated. Thus, we explored the impact of GFR variability on adverse clinical outcomes.

Methods: A nationwide retrospective cohort study using the Korean National Health Insurance System database was performed. National health screening examinees who underwent creatinine measurement ≥3 times between 2012 and 2016 were considered. Those with eGFR under 60 mL/min/m² were excluded. The fluctuation of eGFR was represented with variability independent of the mean (VIM) index, which was calculated according to the quartiles of the VIM.

Results: Of total 3,538,500 participants, 0.29% of myocardial infarction (MI), 0.14% of stroke, 0.36% of deaths were observed during the median follow up of 3.27 years. Participants with the highest VIM index, which represents the highest eGFR variability, were significantly associated with an increased risk of MI (hazard ratio [HR]; 1.10, 95% confidence interval [95% CI]; 1.04-1.16), stroke (HR; 1.16; 95% CI 1.09-1.23), and death (HR: 1.18; 95% CI 1.12-1.24) (Figure 1).

Conclusions: Increased eGFR variability exhibited an association with major clinical outcomes, indicating that monitoring eGFR variability might be a useful parameter for predicting the adverse outcomes.

Development and Internal Validation of a Mortality Risk Prediction Model in Older Adults with Advanced Non-Dialysis-Dependent CKD

David Y. Li1, Heather L. Prigmore,2 Thomas G. Stewart,2 Khaled Abdel-Kader.1 1Vanderbilt University Medical Center, Nashville, TN; 2Vanderbilt University, Nashville, TN.

Background: Older adults with CKD expect practitioners to share prognostic estimates to inform decision-making regarding future care. The availability of useful mortality prediction models in NDD-CKD could reduce prognostic uncertainty and aid in identifying patients who would benefit from advance care planning (independent of dialysis initiation).

Methods: 699 patients with NDD-CKD stages 4-5 and age ≥60 were enrolled and followed between 2014 and 2019. Cox proportional hazards regression was used to model the risk of 1-year mortality. Candidate predictor variables included age, gender, race, Charlson Comorbidity Index (CCI), common labs and the provider’s response to the Surprise Question (“Would you be surprised if this patient died in the next 12 months?”), SQ, recorded using binary and 5-point Likert response scales. Optimism-corrected measures of model performance were calculated with bootstrap resampling. Model calibration was assessed visually.

Results: In the derivation cohort, age, CCI, hemoglobin values and the provider’s Likert scale response to the SQ were predictive of 1-year mortality (Table 1). The C-statistic in the derivation sample was 0.76 and the optimism corrected C-statistic obtained by bootstrap resampling was 0.73. Visual examination of model calibration demonstrated good calibration.

Conclusions: A 1-year mortality risk prediction model in older adults with advanced NDD-CKD performed reasonably well and was well calibrated. Studies are needed to understand how to best leverage information on mortality risk to enhance patient-provider communication and ensure that future care delivered to patients is aligned with their priorities.

Association of eGFR Index Category and Annual Slope with Adverse Clinical Outcomes in Japan

Ling Zhang,1 Moe H. Kyao,1 Yasuhisa Ono,2 Sibylle J. Hauske,3,4 Boehringer Ingelheim USA, Ridgefield, CT; 2Nippon Boehringer Ingelheim, Tokyo, Japan; 3Boehringer Ingelheim Germany, Ingelheim, Germany; 45th Medical Center Mannheim, University of Heidelberg, Germany, Heidelberg, Germany.

Background: The relationship between the slope of eGFR with adverse clinical events has not been evaluated extensively. The objective of the study was to assess the association between eGFR and clinical outcomes.

Methods: The study population included persons with 3 or more eGFR values in the MDV database between January 1, 2014 and September 31, 2019. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to examine the association between eGFR and its slope vs. study outcomes. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to examine the ratio of eGFR change to stratify into 6 categories. Cox proportional hazard model was applied to examine the association between eGFR and its slope vs. study outcomes.

Results: 57,692 patients met the study criteria, and were grouped by index eGFR and its slope (TABLE). The mean age ranged from 56.69 to 74.21 in the index eGFR and from 65.3 to 67.2 in the slope categories. The risk of all-cause mortality or hospitalization, CV death, and any CV or renal outcomes were higher among the low and high index eGFR compared to the reference groups (grade 3 eGFR and -1 to +1 slope), as well as those with rapidly declining or increasing eGFR.

Conclusions: Our study showed that those with the highest or lowest categories in index eGFR and eGFR slope had a higher risk for adverse clinical outcomes. Further studies are needed to confirm these findings and explore potential reasons why high eGFR and rapid increase are associated with mortality, CV and renal events.

Funding: Private Foundation Support

Sex-Specific Differences in Clinical Outcomes Among Patients with CKD: Results from CKDopps

Manfred Hecking,1 Charlotte Tu,2 Jarcy Zee,2 Brian Bieber,2 Sebastien Hodmoeper,3 Benedictus Stengel,4 Helmut Reichel,5 Kunihiro Yamagata,1,6 Ricardo Sesso,7 Ricardo K. Port,2 Bruce M. Robinson,2 Roberto Pacheco-Filho.8 on behalf of CKDopps and CKD REIN investigators 1Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Medical University of Vienna, Department of Epidemiology, Vienna, Austria; 4CESP, Internm 1018, Kidney and Heart Team, Villejuif, France; 5Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany; 6University of Tsukuba, Ibaraki, Japan; 7Escola Paulista De Medicina, Unifesp, Sao Paulo, Brazil.

Background: Women have more chronic kidney disease (CKD) than men, but are under-represented in the dialysis population. We aimed to assess sex-specific differences in clinical outcomes among CKD Outcomes and Practice Patterns Study (CKDopps) participants.

Methods: Using data of 5682 CKDopps stage 3-5 patients from Brazil, Germany and the US, we reported cumulative incidence of pre-dialysis death, dialysis, and transplantation, by sex and CKD stage at CKDopps entry. We used Fine & Gray models to assess the effect of sex on the time to events, stratified by CKD stage. Models were adjusted for age and race, and then for eGFR slope in the first 6 months after enrolment, but not for case mix variables as men and women are biologically different.

Results: There were more men than women at baseline (54 vs 46%). Men were more likely on the transplant waitlist (13 vs 10%) and had higher median eGFR at dialysis initiation (1.2 vs 10.6 mL/min/1.73m²). Over a median follow-up of 1.75 years, the crude cumulative incidence of dialysis was higher in men while that of death was similar (Figure). The age- and race-adjusted hazard ratio (HR) (95% CI) between men vs women was 1.59 (1.40-1.82) for dialysis, 1.24 (1.04-1.49) for death and 1.80 (0.83-3.80) for transplantation. After adjustment for eGFR slope, the HR for dialysis was 1.72 (1.46-2.01), but the HR for the other two outcomes remained similar.

Conclusions: Despite higher CKD prevalence in women, more men received treatment at nephrologist-run clinics in our study. Men had a higher chance of commencing dialysis before death, unexplained by CKD progression. This finding helps interpret the preponderence of men in the dialysis population.

PO0540

Predictive Value of Urine Osmolal Gap and Urine Anion Gap in CKD Progression

Hyung Duk Kim, Cheol Whee Park. Division of Nephrology, Department of Internal Medicine, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Background: Metabolic acidosis is the major complication of chronic kidney disease (CKD) and associated with poor clinical outcome. Impaired renal ammonium excretion in CKD lead to metabolic acidosis. The urinary anion gap (UAG) and urinary osmolal gap (UOG) have been used to estimate urinary ammonium excretion because of the limitation of clinical application of direct ammonium measurement. We sought to determine whether UAG and UOG predict progression of CKD.

Methods: 185 patients with Stage II-V CKD were prospectively followed up at Catholic Medical College Multicenter Native Kidney Biopsy Cohort. 24-hour urine chemistry results were obtained at baseline and 1 year after enrollment. Estimated GFR was calculated using 24-hour urine chemistry results. Estimated GFR was calculated with CKD-EPI equation.

Results: Baseline characteristics are shown in Table 1. Positive association between UOG and decline of renal function was observed (Figure 1). The line indicates the regression line for the relation between decline of renal function and urine osmolal gap; R = 0.035, β = 0.003 (P = 0.011).

Conclusions: UAG and UOG predict decline in renal function in CKD patients. Further studies are required to determine the direct correlation between UAG and UOG and urinary ammonium excretion.
PO0541
Risk Factors for Hemorrhage After Renal Biopsies: Analysis of Data from the National Inpatient Sample Database
Yi Zhang, Harley Friedman. Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Background: Prior studies examining risk factors associated with bleeding from renal biopsy have demonstrated conflicting results. The purpose of this study is to utilize the large sample size of the National Inpatient Sample (NIS) Database to explore risk factors associated with post procedure hemorrhage.

Methods: Data were gathered from the NIS Database (2012-2013). Records with a diagnosis of hemorrhage/fatality complicating a procedure (ICD-9 codes 99811, 99812) were selected, excluding patients under age 18. Bleeding was defined by a diagnosis of hemorrhage/comorbidities were significantly associated with bleeding. Obesity, age, hypertension were not significantly associated with bleeding.

Results: The data set included 13260 renal biopsies, with 626 instances of bleeding. The overall model fit was excellent ($\chi^2 = 119.6, p < 0.000$). Seven comorbidities defined in the NIS severity elements. Binary logistic regression was performed to explore associations between hemorrhage and age, sex, and comorbidities defined in the NIS severity elements.

Results: The data set included 13260 renal biopsies, with 626 instances of bleeding related to procedure. The overall model fit was excellent ($X^2 = 119.6, p < 0.000$). Seven comorbidities were significantly associated with bleeding. Obesity, age, hypertension were not significantly associated with bleeding.

Conclusions: Our results indicate that renal failure, female gender, coagulopathy, and anemia are risk factors for bleeding after renal biopsy, whereas obesity and hypertension thought of risk factors for hemorrhage after renal biopsy and introduces several factors that are of potential clinical significance.

PO0543
During P2Y12 Antiplatelet Therapy, Treatment of Anemia Was More Frequent Among Peripheral Artery Disease Patients with Lower eGFR: The EUCLID Trial
Judith Hsia,1,2 Sarah T. Kavanagh,1 Charles W. Hoptie,2 Marc P. Bonaca,1,3 William R. Hiatt.1,3 CPC Clinical Research, Aurora, CO; 2Dartmouth College, Hanover, NH; 3University of Colorado School of Medicine, Aurora, CO.

Background: Anemia independently predicts amputation and mortality among patients with peripheral artery disease (PAD). In the EUCLID trial, minor bleeding was more frequent among PAD patients with baseline eGFR<60 vs ≥60 ml/min/1.73m2 (adjusted HR 1.51, 95% CI 1.07-2.15; p=0.02 for TIMI minor bleeding; HR 1.21, 95% CI 0.89-1.64; p=0.22 for TIMI major bleeding). We evaluated the impact of eGFR on hemoglobin (Hb) levels and anemia treatment.
Results: At baseline, 9025, 1870 and 1000 patients had eGFR ≥60, 45-59 and <45 ml/min/1.73m², respectively. Patients with lower eGFR were older, more often male and had higher prevalence of diabetes and hypertension. Mean Hb at baseline was 14.2, 13.5 and 12.7 g/dL for the 3 eGFR categories. Mean fall in Hb during the trial was 0.5±1.7 g/dL and did not differ by baseline eGFR category. On-study treatment with iron, erythropoietin and/or red blood cell transfusion was reported for 479 (5.3%), 165 (8.8%) and 129 (12.9%) patients, respectively (Figure, p<0.0001 across eGFR categories). In multivariable analysis, even after adjustment for baseline and post-randomization effects, baseline Hb was a significant independent predictor of Hb fall; anemia treatment was a significant independent predictor of Hb rise.

Conclusions: Among patients with PAD taking antiplatelet therapy in the EUCLID trial, those with lower eGFR were more often treated for anemia.

The Ratio and Difference of Urine Protein-to-Creatinine Ratio and Albumin-to-Creatinine Ratio Facilitate Risk Prediction of All-Cause Mortality: A Retrospective Cohort Study

David R. Chang,1 Hung chieh Yeh,1 Pei-Lun Chu,2 Chin-Chi Kuo.1 1China Medical University Hospital, Taichung, Taiwan; 2Fujen Catholic University Hospital, New Taipei City, Taiwan.

**Background:** The difference and ratio of albuminuria (defined by urine albumin-to-creatinine ratio, uACR) and proteinuria (defined by urine protein-to-creatinine ratio, uPCR) has not been systematically evaluated with relevant clinical outcomes. We aimed to assess the prognostic performance between the difference and ratio of uACR and uPCR with all-cause mortality.

**Methods:** This retrospective cohort study identified 2904 adult patients with PAD participating in the EUCLID study, who concurrently measured uACR and uPCR from the same urine specimen in a tertiary medical center in Central Taiwan between January 2003 and June 2017. Urinary albumin-to-protein ratio (uAPR) was derived by dividing uACR by uPCR. Urinary non-albumin protein (uNAP) was calculated by subtracting uACR from uPCR. Conventional severity categories of uACR and uPCR were used to develop a risk matrix. We evaluated all-cause mortality based on uAPR and uNAP on a continuous scale using the multivariable Cox proportional hazards model.

**Results:** For each doubling increase in uPCR, uACR, and uNAP, the adjusted hazard ratios (aHRs) of all-cause mortality were 1.29 (95% confidence interval [CI]:1.24-1.35), 1.12 (1.09-1.16), and 1.41 (1.34-1.49), respectively. Linear dose-response association with all-cause mortality was only observed with uPCR and uNAP. The 3 x 3 risk matrices revealed that patients with severe proteinuria and minimal albuminuria had the highest risk of all-cause mortality (aHR 5.25, 95% CI: 1.88, 14.63). uNAP significantly improved the discriminative performance compared to that of uPCR (c-statistics: 0.834 vs. 0.828, p=0.05).

**Conclusions:** uNAP provides better mortality prognostic assessment than uPCR and uACR.

PO0546
Magnetic Resonance Imaging-Based Renal Function Estimation Using a Machine Learning Approach
Daichi Fukuya,1 Tsutomu Inoue,1 Eito Kozawa,2 Masahiro Ishikawa,3 Yusuke Watanabe,2 Hiroaki Arano,2 Naoki Kobayashi,2 Mamoru Niitsu,2 Hirokazu Okada. 1Department of Nephrology, Faculty of Medicine, Saitama Medical University, Iruma-gun, Japan; 2School of Clinical Engineering, Faculty of Health and Medical Care, Saitama Medical University, Hidaka-shi, Japan; 3Division of Dialysis Center and Department of Nephrology, Saitama Medical University International Medical Center, Hidaka-shi, Japan.

Background: In patients with deterioration of GFR with an unknown clinical course, it is quite difficult to determine whether the renal dysfunction is caused by a hemodynamic alteration or changes in the renal parenchyma, even when using kidney imaging. Therefore, to estimate renal function quantitatively based on the morphology of the renal parenchyma, we performed an advanced image analysis of renal magnetic resonance imaging (MRI) using machine learning (ML).

Methods: We used coronal Dixon water-dominant images obtained on a 3.0T MR device and a deep ML convolutional neural network (CNN) to evaluate renal function (eGFRc). K-fold cross-validation (k = 5) was performed for the assessment of accuracy and generalization performance. The study protocol was approved by the IRB of our institute.

Results: A total of 196 patients (age, 57.9 ± 16.9 years; 128 males; CKD stage, G1 (n = 18), G2 (39), G3a (43), G3b (45), G4 (35), and G5 (16)) were included. After optimization of the CNN model, the accuracy, precision, recall, and f1-score of the confusion matrix, as well as the AUC of the ROC curve at thresholds of eGFRc of 60, 45, and 30 were 0.80, 0.83, 0.89, 0.87, 0.80, 0.75, 0.71, 0.84, 0.77, 0.83; and 0.76, 0.80, 0.90, 0.85, 0.83, respectively. The output value of the CNN also showed a positive correlation with the normalized eGFRc of the subjects (R² = 0.46, P < 0.01).

When the difference in signal intensity between the renal cortex and medulla, as measured based on the region of interest method, was used as a diagnostic index, the accuracy was the same as that of ML if the threshold was eGFRc 30 (AUC of the ROC curve, 0.84). Conversely, when the threshold was set at eGFRc 45 or 60, the accuracy deteriorated gradually (AUC: 0.80 and 0.73, respectively).

Conclusions: Compared with the classical method, in which only the signal intensity is used, the ML approach was able to quantitatively evaluate differences in renal morphology regarding a wide range of renal functions. Our results may have clinical applications for assessing the cause of changes in kidney function in the conditions in which renal function and morphology diverge, e.g., in the early stages of acute kidney injury, renovascular hypertension, and therapeutic interventions that cause hemodynamic alterations.

Inflammation Mediates the Association of Depression Severity with Selective Serotonin Reuptake Inhibitor Treatment Response in Patients with CKD
Sugatomi Torres-Rodriguez,1 L Parker Gregg,1,2 Thomas Cardomy,1 Madhukar Trivedi,1 Susan Hedayat.1 1University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2VA North Texas Health Care System, Dallas, TX.

Background: Patients with chronic kidney disease (CKD) are at high risk for depression, which is associated with inflammation in patients with chronic diseases. We investigated whether depression severity is associated with response to treatment with sertraline and whether inflammation mediates this relationship in CKD patients with major depressive disorder (MDD).

Methods: We conducted the CKD Antidepressant Sertraline Trial (CAST), a randomized double-blind trial of 193 participants with stage 3-5 CKD and MDD randomized to sertraline or placebo for 12 weeks. Depressive symptoms were assessed using the Quick Inventory of Depressive Symptomatology (QIDS). High sensitivity C-reactive protein (hsCRP) was measured at baseline. Logistic regression determined associations of QIDS and hsCRP with treatment response (≥50% decrease) or improvement (a3-point decrease) in QIDS. Interaction P<0.10 was considered significant.

Results: Fifty-two (26.5%) participants achieved treatment response. Baseline depression severity by QIDS correlated positively with hsCRP, r=0.162, P<0.01. P=0.05 Median (IQR) hsCRP was 5.0 (2.0, 14.6) mg/L in sertraline responders and 2.7 (0.8, 6.0) mg/L in non-responders, P=0.03. Higher baseline QIDS was associated with increased odds of response in the sertraline group, OR (95% CI) per 1-point increase 1.26 (1.04, 1.53), but lower odds in the placebo group, 0.77 (0.61-0.97), interaction P=0.002 (Figure).

Higher baseline hsCRP was associated with higher odds of response, OR per log-unit increase 1.52 (1.06-2.19), and improvement, 1.66 (1.11-2.48), in the sertraline group, but not in the placebo group, interaction P=0.08 for response and P=0.03 for improvement, even after controlling for baseline depression severity by QIDS score (Figure).

Conclusions: Higher depression severity was associated with improvement in depressive symptoms and response to treatment with sertraline in CKD patients. This may be explained by elevated baseline inflammation. Future studies should test whether sertraline is more effective than placebo in CKD individuals with higher plasma hsCRP.

Prospective Study of Patient-Reported Outcomes After Endovascular Renal Ablation in Individuals with Chronic Kidney Pain and Opiate Use
Victor A. Lopez,1 Ablishek Deshmukh,2 Rajiv Guleria,1 Paul Novotny,2 Marie C. Hogan. 1Mayo Clinic Minnesota, Rochester, MN; 2Mayo Clinic Dept of Nephi & HTN Research, Rochester, MN.

Background: Endovascular renal ablation (ERA) may be useful for palliating and in some instances relieving refractory kidney pain (RPK) but is not widely available. We report our experience of ERA in 20 patients with RKP.

Methods: We conducted a prospective study of patient-reported outcomes pre and post ERA for RPK. Baseline & subsequent pain questionnaires (McGill Pain (MPQ), Brief Pain Inventory (BPI), Opioid oral morphine milligrams equivalent (MMME)) & QOL (LASA-6, PHQ-9 & SF-8) were obtained. The Wilcoxon test was used. ERA using an open irrigated ablation catheter was performed in a spiral manner distal to proximal the renal arterial ostium. Power was titrated between 5-30 watts guided by change in impedance.

Results: We performed 24 ERA (3 bilateral, 21 unilateral; 4 re-dos) in 20 patients, 12 females/male; 14;6; median age 40yr. 12 patients (60%) had Loin Pain Hematuria Syndrome (LPHS), 4 (20%) ADPKD, and others 4 (20%). 17 of 20 have completed the baseline questionnaires & 9 of 17 patients have 6mo data. All nine experienced variable or complete reductions in pain & QOL from baseline to 6mo (Table1). A median of 8mo pain relief was reported. After their first ERA, responders (pain relief >6mo) median 8.5mo (n=12/20;60%) while 4 (20%) reported pain relief <6mo (non-responders) median 2mo. 3 (15%) had no relief, and 1 was lost to FU. In the redo ERA, there was no relief in 2; in 1 pain relief lasted 4mo (non-responder), and in the other, relief was 8mo (responder). Following the first ERA, MME decreased by ≥30% in 6, increased in 7 ≥30% in 615% in 1, and 1 was unchanged in 3, and no alterations were reported. In the redo ERA, one acute renal artery dissection (procedure related) requiring stents & one renal artery stenosis (5mo later) treated by percutaneous transluminal angioplasty but subsequent reduced kidney function.

Conclusions: Among patients with RKP undergoing ERA, half achieved objective improvement in pain & QOL at 6mo. Prospective randomized studies with careful patient selection are required to assess the role of ERA for palliation of pain.

Assessments of Pain & QOL

PO0549
Clinical Impact of Body Muscle Mass for Kidney Function Evaluation: New eGFR Formula Based on Serum Creatinine and Body Muscle Mass

Background: Kidney function is globally evaluated by estimated glomerular filtration ratio (eGFR) based on serum creatinine (Cre). Since Cre is influenced by body muscle mass, there is serious concern of overestimation of eGFR among elderly people with high muscle volume due to frailty. In this study, eGFR based on Cre (eGFRcre) and Cystatin C (eGFRcys) were analyzed in association with psoas muscle mass index (PMI) by CT image among CKD patients whose kidney function was accurately evaluated by machine learning (ML). We developed a new eGFR formula based on PMI considering Cre and CysC (eGFRcreat) and validated in 62 patients, which were randomly determined to each cohort. 20% validation set was 0.46, < 0.01).

Conclusions: The participants in 1), was unchanged in 3, and no data was available in 4. In the redo ERA, there was no relief in 2; in 1 pain relief lasted 4mo (non-responder), and in the other, relief was 8mo (responder). Following the first ERA, MME decreased by ≥30% in 6, increased in 7 ≥30% in 615% in 1, and 1 was unchanged in 3, and no alterations were reported. In the redo ERA, one acute renal artery dissection (procedure related) requiring stents & one renal artery stenosis (5mo later) treated by percutaneous transluminal angioplasty but subsequent reduced kidney function.

Conclusions: Among patients with RKP undergoing ERA, half achieved objective improvement in pain & QOL at 6mo. Prospective randomized studies with careful patient selection are required to assess the role of ERA for palliation of pain.

Assessments of Pain & QOL

New eGFR Formula Based on Serum Creatinine and Body Muscle Mass

Background: Kidney function is globally evaluated by estimated glomerular filtration ratio (eGFR) based on serum creatinine (Cre). Since Cre is influenced by body muscle mass, there is serious concern of overestimation of eGFR among elderly people with high muscle volume due to frailty. In this study, eGFR based on Cre (eGFRcre) and Cystatin C (eGFRcys) were analyzed in association with psoas muscle mass index (PMI) by CT image among CKD patients whose kidney function was accurately evaluated by machine learning (ML). We developed a new eGFR formula based on PMI considering Cre and CysC (eGFRcreat) and validated in 62 patients, which were randomly determined to each cohort. 20%
accuracy for Cini was analyzed by eGFRcreat and eGFRcre calculated by eGFR formulae for Japanese. The performance of each eGFRcre-PMI was assessed by means of bias (eGFRcre -mGFR), accuracy (percentage of estimates within 20% of mGFR), root mean squared error, and correlation coefficient. In PMI tertile subgroups and GFR(Cin) subgroups (<30, 30-60, >60%), the performance of each formula was assessed.

Results: Patients' characteristics (n=184, mean±SD or median[IQR]) were age: 62 [50, 70], eGFRcreat: 58.5 (25.5), eGFReys: 59.4 (25.9), Cin: 55.0 (25.0) and PMI: 7.29 [6.18, 9.11]. Log-PMI was significantly associated with age, gender, log-BMI, log-Creat and uCre in univariate analyses, and with age, gender and log-BMI in multivariate analysis. New GFR formula (eGFRcreat-PMI) was well correlated with Cin. 20% accuracies for eGFRcreat (68.5%), which was more prominent among low PMI tertile group (77.4% in eGFRcreat-PMI, 67.7% in eGFReys, and 71.0% in eGFRcreat) and high PMI tertile group (75.8% in eGFReys, 59.0% in eGFRcreat, and 60.7% in eGFRcreat).

Conclusions: Body muscle mass significantly influences accuracy of kidney function evaluation, and new GFR formula based on PMI and Cre would be useful for accurate evaluation of kidney function, especially among patients with low and high body muscle mass.

PO0550
Incidence and Predictors of Non-Alcoholic Fatty Liver Disease in CKD
Sankar D. Navaneethan,1,2 L. Parker Gregg,1 Peter Richardson.1,2 Baylor College of Medicine, Houston, TX; Michael E DeBakey VAMC, Houston, TX; The University of Texas Southwestern Medical Center, Dallas, TX.

Background: The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing due to global epidemics of obesity and diabetes mellitus, which are commonly seen in CKD. We studied the incidence and predictors of NAFLD in those with CKD.

Methods: We conducted a retrospective cohort study of patients with incident CKD (eGFR <60 mL/min/1.73 m2) over a 90-day window in the Veterans Health Administration from 2005-2016. Patients with no NAFLD at the time of CKD diagnosis were followed for a primary outcome of NAFLD, defined as development of sustained elevated alanine aminotransferase levels in the absence of hepatitis B or C virus infection or alcoholic liver disease, identified by laboratory values and diagnosis codes. We calculated incidence rates for NAFLD for the entire study population and by CKD stage. Predictors of NAFLD were evaluated using Cox proportional hazards regression, considering death and ESKD as competing risks.

Results: Of 1,155,901 veterans with CKD but no NAFLD, 51,584 (4.4%) developed NAFLD at a rate of 0.86 (0.85-0.87) per 100 person-years during 4.7 years follow-up. A total of 3.9% developed ESKD at a rate of 0.76 (0.75-0.77) per 100 person-years, and 33% died at a rate of 6.5 (6.5-6.5) per 100 person-years during the same time period. In a multivariable model, age >50 (vs. 40-49 years) (HR 0.72, 95% CI 0.67, 0.77), women, blacks and veterans with advanced CKD were less likely to develop NAFLD; however, presence of diabetes, higher BMI, anemia, CHF, and hypertension were associated with higher risk of developing NAFLD (Table).

Conclusions: Patients with CKD have a high incidence of NAFLD, which was associated with diabetes, BMI, and CHF. Future studies should determine if interventions targeting these factors may reduce NAFLD risk.

Factors associated with incident NAFLD in CKD

PO0551
Alterations of Gray Matter Volumes and Connectivity in Patients with CKD
Changwon H. Yu, Hyang Wook Kim, Yoo Jin Lee, Sihyang Park, Bongsoo Park, Eunjung Yoon. Inje University Hospital, Inje University College of Medicine, Busan, Republic of Korea.

Background: Our previous study demonstrated that patients in End stage renal disease had decreased structural and functional brain connectivity, and there was significant association between brain connectivity and cognitive function. The aim of this study was to evaluate the alterations of structural and functional connectivity using graph theoretical analysis in the neurologically asymptomatic patients with relatively early stage chronic kidney disease (CKD).

Methods: We prospectively enrolled neurologically asymptomatic 20 patients with CKD stage 3 and 20 healthy controls, and all of the subjects underwent diffusion tensor imaging (DTI) and resting state functional MRI (rs-fMRI). Using data from the structural and functional connectivity matrix based on DTI and rs-fMRI, we calculated network measures, including global efficiency, local efficiency, mean clustering coefficient, characteristic path length, and small-worldness index, and investigated the differences between patients with CKD and healthy controls.

Results: The patients with CKD had altered global structural connectivity and preserved functional connectivity compared to healthy controls. The all of the measures of global structural connectivity were significantly different between the patients with CKD and healthy controls. However, all of the measures of global functional connectivity in the CKD patients were not different from those in healthy participants. In the CKD patients, the functional betweenness centrality of the right insular cortex, right occipital pole, and right thalamus was significantly different from that in healthy subjects. The structural betweenness centrality of the left hippocampus, right posterior cingulum was significantly different from that in healthy subjects.

Conclusions: There were significant alterations of global structural connectivity between patients with CKD and control. However, functional connectivity of brain network was preserved in contrast to ESRD patients.

PO0552
CKD and Metabolic Risk Factors: A Cross-Sectional Study Based on 398,120 Adults in China
Lingling Xu, Jin Liu, Yang Zhou, Junwei Yang. Second Affiliated Hospital of NanJing Medical University, NanJing, China.

Background: Chronic kidney disease (CKD) has become a worldwide health problem. The prevalence of CKD varied within countries by different socio-demographic characteristics and economic status. Elderly people are particularly susceptible to kidney damage from age-related decline in glomerular filtration and chronic disease states, such as diabetes mellitus (DM) and hypertension (HTN). It is necessary to understand the epidemiological features and the association risk factors of CKD in adults, especially in these elderly populations.

Methods: We did a cross-sectional survey based on the records of universal health examinations of the residents in Binhai county of China in 2018. A total of 398,120 participants aged a 18 years in this study had underwent blood test, body measurements and hypertension (HTN) diagnosis. There were 15.1% of subjects who aged ≥ 65 years (n=37,533) were randomly selected to complete the routine urinalysis. Chronic renal insufficient (CRI) was defined by eGFR < 60 mL/min/1.73 m2 (CKD-EPI), while CKD was defined by CRI or presence of proteinuria. We analyzed the epidemiological features and the association between CKD and relevant covariates by logistic regression models in the general and elderly population.

Results: The age and gender- standardized prevalence of CRI was estimated to be 1.10% (95% CI, 1.07%-1.13%) in Chinese adult population. It was 0.86% among men (95% CI, 0.82%-0.90%) and 1.34% among women (95% CI, 1.29%-1.39%). Female, aging, central obesity, elevated triglycerides, systolic blood pressure, fasting blood glucose (FBG) and heart rate were independent risk factors for CRI in the general adults. Rates of CRI increased significantly by age, especially when people aged ≥ 60 years. Furthermore, the prevalence of CRI was 17.7% (95% CI, 17.5%-18.1%) in the elderly. Aging, HTN, elevated triglyceride and FBG were still found to be independent risk factors for CKD in this subgroup. Elevated FBG had the strongest correlation with CKD, gender was no longer association with CKD in the elderly.

Conclusions: Aging, HTN, elevated triglyceride and FBG were all independent metabolic-related risk factors associated with CKD in Chinese adults. More attention should be paid to metabolic diseases such as DM, HTN and hyperlipidemia to prevent CKD in adults, especially in the elderly.

PO0553
Are There Any Further Modalities for Prediction of Subclinical Volume Overload in Advanced Stages of CKD?
Aber H. Baki, Hazem Mansour. Ain Shams University Faculty of Medicine, Cairo, Egypt.

Background: Subclinical volume overload is commonly seen in our daily practice which represents a debatable issue. These patients respond favorably to diuretics despite lacking clinical signs of volume overload. Therefore a proper assessment of the volume status in Chronic Kidney Disease (CKD) patients leads to a better control of their medical condition and prevents further deterioration of their clinical situation into the well-known end-stage renal failure. Although many tools were used to detect volume overload, such patients as biomarkers, ultrasonography, bio-impedance, echo, and blood viscosity, many non-specific results were due to presence of concomitant comorbidities. The use of Bio Impedance Spectroscopy (BIS) is a recent tool increasingly used due to its appealing features such as non-invasive and non-cost-effective. BIS is an objective fluid status assessment method, which is shown superior to classical methods such as BP monitoring and weight control in many studies. Combining some of these tools may improve their accuracy and specificity. Inferior vena cava collapsibility index (IVCVC) with Brain Natriuretic Peptide (BNP) can be complimentary for more specific and accurate fluid assessment.

Methods: To assess the usage of combined IVCVC and BNP level in CKD patients to predict subclinical volume overload, 110 patients with CKD (stage 4&5) & not on dialysis were selected. However, functional connectivity of brain network were preserved in contrast to ESRD patients.

Results: Among the 110 cases, we found that 26 patients (23.6%) had subclinical hyperoxemia as diagnosed by FO/ECW ratio >1.5. IVCVC ≥ 38% had higher diagnostic
performance than BNP ≥24 pg/ml. Combining both IVCCI ≥38% and BNP ≥24pg/ml increased the specificity and negative predictive value for detection of subclinical hypervolemia.

Conclusions: Combined elevated BNP level and decreased IVCCI could be more precise tools for subclinical volume overload detection in CKD patients.

PO0554  
Sensitivity of Urinary N-Terminal Osteopontin-to-Creatinine Ratio in Predicting Renal Function Loss  
Ling Sun,1 Satyesh K. Sinha,1 Aldons J. Lusis,1 Susanne B. Nicholas.1  
Metabolic Syndrome In Men (METSIM) UCLA, University of California Los Angeles, Los Angeles, CA, 2Xuzhou City Centre Hospital, Xuzhou, China.

Background: Osteopontin (OPN) is a multifunctional protein that gets cleaved to create N-terminal OPN (ntOPN). ntOPN has been reported in urine in kidney diseases but little is known about the sensitivity of ntOPN to creatinine ratio (ntOCR) as a urinary biomarker compared to the urinary albumin-to-creatinine ratio (UACR). This study is aimed to explore the diagnostic value of ntOCR regarding renal function loss in a subset of the metabolic syndrome in men (METSIM) study with a high incidence of diabetes mellitus.

Methods: The METSIM study recruited 10,197 Finnish men between 2005 and 2010 and reexamined participants at two 5-year follow-up periods. We performed a prospective observational study of a METSIM cohort of 137 participants, 45-72 years old at entry, with available urine at baseline and the first follow-up period, after 3.8±1.4 years. Serum and urinary levels of the nOPN were quantified by ELISA. Using estimated glomerular filtration rate (eGFR), UACR and urine albumin excretion (UAE) of progressors and non-progressors, data were analyzed by paired t-test and Wilcoxon matched-pairs signed-rank test. The area under the receiver-operating characteristics (ROC) curve (AUC) was used to assess the sensitivity/specificity of variables in predicting the progression of CKD. Pearson correlation coefficient was performed to detect the relationships between the values of variables.

Results: Compared to the CKD non-progressors, the progressors had significantly higher eGFR at baseline (96.95 vs. 87.75 mL/min/1.73 m², p<0.00) and lower eGFR at follow-up (86.11 vs. 91.40 mL/min/1.73 m², p=0.01). The baseline urinary levels of nOCR were higher in progressors than non-progressors (6.83 vs 3.68 pmol/mg, p<0.05). There were no differences in the UAE, UACR, or serum ntOPN between the two groups. However, baseline urinary nOCR predicted renal function loss with an AUC of 0.60 (p=0.05), and the change between baseline and follow-up had a higher AUC of 0.63 (p<0.01).

Conclusions: Our study suggests that urinary nOCR might be a promising predictive biomarker for renal function loss in a population with high rates of metabolic syndrome and diabetes. Measurements at the second METSIM follow-up may confirm this observation. Further studies are needed in females, larger size populations, and long-term follow-up.

PO0555  
Effect of Renin-Angiotensin System Blockade in Immunoglobulin A Nephropathy Only with Persistent Hematuria  
Hui Xu,1 Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.

Background: Recent guideline recommended that long-term renin-angiotensin system blockade (RASB) should be used in immunoglobulin A nephropathy (IgAN) when proteinuria ≥1g/d. If proteinuria is 0.5–1g/d, RASB is also suggested. We tried to investigate whether IgAN patients only with persistent hematuria and without proteinuria can benefit from RASB.

Methods: IgAN patients only with persistent hematuria initially from January 2013 to December 2018 from four centers were included. We divided patients into treatment and untreated group according to the use of RASB. The primary outcome was the appearance of proteinuria, the secondary outcome was the decreased percentage of hematuria and the rate of estimated glomerular filtration rate (eGFR) decline. Effect of RASB on the outcomes was assessed by multivariate Cox regression models and a propensity score matching.

Results: 110 eligible patients were included and 44 (41.9%) received RASB. Patients in the treatment groups had higher diastolic pressure. The unadjusted primary outcome of RASB treated patients was better than the untreated individuals. The multivariate Cox regression revealed that RASB lowered the risk of primary outcome, besides, RASB decreased more percentage of hematuria. No obvious difference was found in the rate of eGFR decline between two groups.

Conclusions: RASB decreased the risk of proteinuria appearance and increased the remission of hematuria in IgAN only with persistent hematuria initially, but it did not obviously impact the blood pressure of patients without hypertension and the rate of eGFR decline.

Funding: Other NIH Support - NCATS

PO0556  
Fibrates and CKD Patients: A Controversial Issue  
Aber H. Baki, John Zarif. Ain Shams University Faculty of Medicine, Cairo, Egypt.

Background: Fenofibrate were not previously known to affect renal function tests until some reports indicated that these drugs may lead to a decrease in renal function. Likewise, the nephrotoxic effect of fibrates remains to be vague and unclear Fenofibrate’s safety in patients with renal insufficiency is an issue because it may increase plasma creatinine. Furthermore, guidelines regarding fenofibrate dosing in renal impairment vary internationally. We investigated fenofibrate’s effects on cardiovascular and on advanced CKD, according to eGFR. The multiple incidents of elevated kidney function tests for patients on fibrates have led us to make this study to review our experience as well as literature on this matter.

Methods: A prospective cohort study over 6 months with a total of 80 patients on fibrates divided into 2 groups, 40 of which received statins and the other 40 continued on fibrates. All our patients were subjected to full history, clinical examination and complete baseline labs. The kidney function tests including serum creatinine and eGFR were measured at 0.1, 2 and 6 months’ intervals and lipid profile at 0.3,6 months serially in both groups.

Results: Out of the baseline values of the kidney function tests that were recorded on previous fibrate therapy, the statin group (n=40) showed a significant decrease in all kidney function values including serum creatinine by (0.9mg/dL, P=0.001) and an increase in eGFR (8.9 mL/min/1.73 m², P=0.001). Whilst in the other 40 patients who continued to receive fibrates the kidney function tests continued to rise as serum creatinine showed a significant increase in their mean serum Cr levels (by 0.9 mg/dL or 20%, P=0.001), and a significant decrease in their mean eGFR values (by 8.2 mL/min/1.73 m² or 20.55%, P=0.001). On the other hand total and LDL Cholesterol were significantly lower in Statin group at all follow up intervals. Also triglycerides were significantly higher in Statin group at the end of month-6 from baseline.

Conclusions: In our study fibrates administration showed a short term state of renal insufficiency. The long term effects of fibrates versus variable renal derangement are yet to be identified. As to lipid profile, shifting from fibrates to statins led to a stastically significant rise in triglyceride but its clinical impact is yet to be investigated, so established guidelines might need a revision regarding clinical benefits of fibrates versus it’s renal injury.

PO0557  
Calciphylaxis: An Uncommon Skin Manifestation in Non-Dialysis CKD Patients  
Rabia Sarwar,1 Ujala Zubair,2 Wanwarat Ananthapanyasut.1 Skagit Regional Health, Mount Vernon, WA; 2Jinnah Sindh Medical University, Karachi, Pakistan.

Introduction: Calciphylaxis is a rare but fatal skin disorder seen in 1-4% of dialysis patients. It is characterized by ischemia and necrosis of the skin tissue due to the deposition of calcium in the arterioles and subcutaneous tissues. The risk of infection is increased, and once ulceration develops, the mortality rate can be above 80%. Risk factors include diabetes, warfarin, vitamin D, obesity, female, white race and mineral-bone disorder. The skin findings ranging from livedo reticularis to nodules, plaques, or deep ulcerations. The treatment is focused on supportive care. To date, there is no strong studies to suggest that sodium thiosulfate (STS), bisphosphonates, or calcimimetics are curative. However, STS is commonly used despite the lack of strong supporting data.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

219
Case Description: We report a case of a 76-year-old Caucasian woman with a history of stage G4A3 chronic kidney disease, insulin-dependent diabetes, hypervitaminosis D, secondary hyperparathyroidism, and obesity, who presented with severe pain and redness on both legs. The skin lesions had progressed to the painful ulcerations and eschars on both shins one month after the initial visit. A skin biopsy was performed and histopathology was consistent with calciphylaxis. She was started on STS 25 mg intravenously (IV) twice a week and cinacalcet 30 mg by oral route (PO) thrice a week. The patient showed improvement within one month of the treatment.

Discussion: Calciphylaxis in non-dialysis patients is uncommon; however, it should be considered in those with predilection factors. The skin biopsy is crucial for the diagnosis, which can lead to proper management of such a rare yet lethal disease. STS is the most common drug used to treat calciphylaxis. It acts as a calcium chelator with some antoxidative and vasodialation properties leading to recovery.

PO0558
Calciphylaxis: Clinical Features, Therapeutic Options, and Outcomes
José Agapito Fonseca, Maria Sanches, Inês C. Duarte, Joana Gameiro, Cristina B. Outurcelo, Hugo Silva, Sofia C. Jorge, Jose A. Lopes, Estela Nogueira. Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisboa, Portugal.

Background: Calciphylaxis is characterized by microvascular disease with calcification of the middle layer of the arterioles, intimal hyperplasia and thrombotic occlusion, conditioning areas of ischemia and skin necrosis. Given the rarity of this pathology, there is a lack in literature regarding clinical presentation, diagnostic approach and therapeutic management. We performed a descriptive analysis of clinical, epidemiologic, laboratory characteristics, treatment options and outcomes in a population of patients with calciphylaxis.

Methods: Retrospective analysis of all calciphylaxis diagnosed in a single-center between January 2003 and December 2019.

Results: The diagnosis of calciphylaxis was made in 9 patients, 7 of whom were female, with a mean age of 63.4±10.9 years. Eight patients were on renal replacement therapy (all hemodialysis) at the time of diagnosis, with a dialysis vintage of 66.4±32.7 months. The mean phosphorus level was 9.4 mg/dL, with an average phosphorus level of 4.5 mg/dL, phosphocalcic product was 42 mg²/dL² and the average PTH was 1078 pg/mL. The onset or increase in vitamin D3 levels was noted within one month of the treatment. The improvement within one month of the treatment.

Conclusions: More than 60% of patients were under warfarin, reinforcing the role of vitamin K antagonists in the pathogenesis. Mean time on dialysis was highly variable, from the 1st to the 216th month since the beginning of the technique. The standard of treatment varied according to the drugs available and the clinical evidence that supported its use at the time of diagnosis. The registered deaths corresponded to patients diagnosed later in the course of the disease, reinforcing the importance of a high clinical suspicion regarding the appearance of trophic skin lesions in this population as a form of early diagnosis to prevent mortality.

PO0559
Role of Adipose Tissue-Derived Mesenchymal Stem Cells in CKD: A Phase 1 Study Assessing Safety and Clinical Feasibility
Zheng Cai-Mei, Taipei Medical University College of Medicine, Taipei, Taiwan.

Background: Chronic kidney disease (CKD) is a most common progressive disorder associated with high mortality and huge socio-economic burden globally. We hypothesize that allogeneic adipose tissue mesenchymal stromal cells (hASCs) are renotrophic and may retard CKD progression through anti-apoptotic, anti-fibrotic, and anti-inflammatory effects. In this study, we will assess the safety and tolerability of a hASCs infusion in CKD patients with various underlying etiologies.

Methods: We performed a single-arm phase 1 clinical trial with a 6-month follow-up. This study enrolled 12 eligible CKD patients with an estimated glomerular filtration rate (eGFR) of 15-44 mL/min/1.73 m² (mL/min). Patients were allocated to receive low, moderate, or high dose of allogeneic cultured hASCs infusion. We investigated the safety issues and kidney function during the follow-up visits.

Results: There was no patient lost to follow-up. We observed two treatment related adverse events (AE) in high dose group. One subject experienced grade 1 slow speech immediately after hASCs infusion, which was resolved on the next day and completely normal afterwards. The AE was considered possibly related to study treatment and met dose-limiting toxicity (DLT). Another subject experienced grade 1 bradypnea after the infusion, and the situation was resolved during the following 9 days, however, this AE was not considered as DLT. One SAE was reported in moderate dose group, who was hospitalized for persistent heavy proteinuria, and later proved as diabetic nephropathy stage 4 by renal biopsy. No significant reduction in eGFR was noted among all treated patients, and specifically an improvement in eGFR was noted among those with baseline eGFR>30mL/min. No significant reduction in proteinuria was noted.

Conclusions: This trial demonstrated the safety and tolerability of allogeneic hASCs infusion in stages 3b and 4 CKD patients. Patients with a history of renal function (e.g. eGFR>30mL/min) could be more beneficial from hASCs compared to those without. hASCs efficacy and dosing interval in various CKD stages should be investigated in future randomized placebo-controlled trial among various CKD population.
PO0561

Pegunigalsidase Alfa, PEGylated α-Galactosidase-A Enzyme in Development for the Treatment of Fabry Disease, Shows a Correlation Between Renal Gb3 Inclusion Clearance and Reduction of Plasma Lyso-Gb3

Ahmad M. Tutafah,1 Derrynell Hughes,2 Sineon Boyd,3 Pilar Giradlo,3 Miguel J. Holida,4 Mohamed G. Atta,5 Ozlem Oaker-Alpan,6 Kathleen M. Nicholls,7 Raphael Schifffman,8 Gustavo Maegawa,12 Laura Barisioni,1 Robert B. Colvin,9 J. Charles Jennette,10 Sari Alon,11 Mali Szlaifer,11 Einat Almon,11 Raul Chertkoff,11 Kansas University Medical Center; Kansas City, KS; 1LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; 2Hospital de Dia Quiron, Zaragoza, Spain; 3University of Iowa Hospitals and Clinics, Iowa City, IA; 4Division of Nephrology, Johns Hopkins, Johns Hopkins University School of Medicine, Baltimore, MD; 5Nephrology Department, the Royal Melbourne Hospital, Melbourne, VIC, Australia; 6Baylor Institute of Metabolic Diseases, Baylor University Medical Center, Dallas, TX; 7Duke University, Durham, NC; 8Massachusetts General Hospital, Harvard Medical School, Department of Pathology, Boston, MA; 9University of North Carolina, Department of Pathology, Chapel Hill, NC; 10Protalix Biotherapeutics, Carmiel, Israel; 11University of Florida, Department of Pediatrics/Genetics & Metabolism, Gainesville, FL; 12(Q&O Alpan LLC, Fairfax, VA; 13Department of Pediatrics, Section of Genetics, MIND Institute, UC Davis Medical Center, Sacramento, CA.

Background: Fabry disease (FD) is caused by the loss of function of the lysosomal enzyme α-Galactosidase-A leading to the accumulation of globotriaosylceramide (Gb3). Reduction in histological Gb3 burden in renal peritubular capillaries (PTCs) is considered an important endpoint in the clinical development of FD treatments. Pegunigalsidase-alfa is a novel PEGylated enzyme in development for the treatment of FD with enhanced pharmacokinetics. Methods: The phase I/II (NCT01678898) dose-ranging studies (0.2mg/kg; 1 mg/kg; 2mg/kg) were designed to evaluate the safety (primary objective), pharmacokinetics and efficacy (secondary objective) of pegunigalsidase-alfa administered IV every 2 weeks in adult symptomatic FD treatment naïve male and female patients. The Barisoni Lipid Inclusion Scoring System (BLISS) was adopted to quantitatively assess patients' renal biopsies taken at baseline and at 6 months of treatment. BLISS methodology consists of counting the number of Gb3 inclusions per peritubular capillary; a decrease in the score is indicative of clinical improvement. Results: Renal biopsies were available and evaluated in 13 out of 16 patients allocated to the pegunigalsidase-alfa treatment. A high correlation (r=0.800) between change in WBK+ after K+ supplementation. The 13 patients who developed hyperkalemia (K+ intake and better kidney outcomes in patients with chronic kidney disease (CKD). However, K+ supplementation in CKD may be limited by the risk of hyperkalemia (>5.5 mEq/L) in renal transplant patients with CKD. Although our study in patients with CKD our aims were to: (1) analyze the effect of K+ supplementation on whole-blood K+ (WBK+), (2) identify factors associated with a rise in WBK+, and (3) identify risk factors for hyperkalemia. Methods: To do so, we analyzed the results of the 2-week open-label run-in phase of a randomized clinical trial studying the reproducibility of long-term K+ supplementation in patients with progressive CKD and hypertension. Results: In 151 patients (67±11 years, 74% males, eGFR 32±9 mL/min/1.73 m2, 83% on renin-angiotensin inhibitors), K+ supplementation (40 mEq/day) increased urinary K+ excretion by 0.2±0.5 mEq/L from 7.3±2 to 10.6±2.8 mEq/day, WBK+ from 4.3±0.5 to 4.7±0.5 mEq/L, and plasma aldosterone from 294 (210-447) to 366 (271-504) pM (P<0.001 for all). The majority of patients (n=138, 91%) remained normokalemic. K+ supplementation had no significant effect on urinary sodium excretion (158±62 to 155±68 mEq/day), systolic blood pressure (132±15 to 132±15 mmHg), or eGFR (32±9 to 32±8 mL/min/1.73 m2). Multivariable linear regression identified that age (β=0.008, 95%CI 0.001 to 0.02), female sex (β=0.2, 95%CI 0.05 to 0.4), renin-angiotensin inhibitor use (β=0.2, 95%CI 0.05 to 0.4), diuretic use (β=0.1, 95%CI -0.3 to 0.0), baseline WBK+ (β=0.3, 95%CI -0.5 to -0.2), and baseline urinary K+ excretion (β=0.03, 95%CI 0.06 to 0.01) are independently associated with a change in WBK+ after K+ supplementation. The 13 patients who developed hyperkalemia (WBK+ 5.8±0.2 mEq/L) were older (74±7 vs. 66±11 years), more often had diabetes (49 vs. 36%), had lower eGFR (26±8 vs. 33±8 mL/min/1.73 m2), lower baseline bicarbonate (22.5±3 vs. 24.8±3 mEq/L), and higher baseline WBK+ (4.8±0.4 vs. 4.2±0.4 mEq/L, P<0.05 for all). Conclusions: In conclusion, the majority of patients with advanced CKD remains normokalemic upon K+ supplementation, despite the use of renin-angiotensin inhibitors. This study extends our findings of the feasibility of long-term K+ supplementation in patients with CKD and provides the characteristics of patients in whom K+ supplementation is safe.
by 39.4% (P=0.0049). Triamterene reduced 24-hour urine protein by 33.7% (P=0.0153), UPCR by 28.6% (P=0.0294). The effect on the 24-hour urine protein is not significantly different between the two drugs. The average change on the eGFR is -2 and -9 ml/min/1.73m2 in the amiloride and triamterene groups, respectively. Average systolic blood pressure reduction is 11 and 3 in amiloride and triamterene groups, respectively. The average change in the weight is -0.5 and -0.7 kg in amiloride and triamterene groups, respectively. Three patients exited the study due to hyperkalemia.

Conclusions: Both amiloride and triamterene showed the effect of proteinuria reduction regardless of the underlying pathology. This effect appears to be independent of the RAAS, given that patients were all on RAAS blockade. Large scale trials are needed to evaluate the antiproteinuric and renoprotection effects of ENaC inhibitors.

PO0565
Comparison of Extended-Release Calcifediol (ERC), Immediate-Release Calcifediol, Cholecalciferol, and Paricalcitol for Treating Secondary Hyperparathyroidism (SHPT) in CKD
Stephen A. Strugnell,1 David M. Spiegel,2 Philipp Csomor,3 Akhtar Ashfaq,4 Charles W. Bishop,1 OPKO Health Inc., Miami, FL; Vifor Pharma Ltd, Zurich, Switzerland.

Background: Serum total 25-hydroxyvitamin D (25D) levels above 50.8 ng/mL are required to produce meaningful and progressive reductions in plasma intact parathyroid hormone (iPTH) in patients with stages 3 or 4 CKD [Strugnell et al 2019]. The current study compared the abilities of four treatment regimens to increase serum 25D to this level and to reduce iPTH in this population.

Methods: Subjects with stage 3 or 4 CKD, SHPT (iPTH >85 and <500 pg/mL) and vitamin D insufficiency (25D <30 ng/mL) underwent an 8-week washout from previous vitamin D therapies and were randomized to 60 days of open-label treatment with: 1) ERC 60 mcg/day; 2) immediate-release calcifediol (IRC) 266 mcg/mo; 3) high-dose cholecalciferol (HDC) 300,000 IU/mo; or 4) paricalcitol plus low-dose cholecalciferol (PLDC) 1 mcg and 800 IU/day. Paricalcitol was increased to 2 mcg/day after 30 days if iPTH was not reduced by 30% and safety parameters allowed. Subjects were monitored for changes in serum 25D, calcium (Ca) and phosphorus (P), and plasma iPTH.

Results: Mean (SD) post-washout/pre-treatment baseline levels for 25D and iPTH in the per-protocol population were 20.6 (6.6) ng/mL and 145 (90) pg/mL, respectively. No differences were observed at baseline between treatment groups (14-17 subjects each). At the end of treatment, mean 25D (ng/mL) increased to 82.9 (17.0) with ERC (P<0.05), 30.8 (11.6) with HDC (P=0.05), 26.3 (6.8) with IRC and 24.2 (7.3) with PLDC. All subjects treated with ERC attained 25D levels >30 ng/mL vs. only 44% with HDC (P=0.001), 20% with IRC and 14% with PLDC. Most ERC subjects (94%) attained 25D levels >50.8 ng/mL. The proportion of subjects who achieved at least a 20% reduction in iPTH were 71% with ERC, 38% with HDC, 20% with IRC and 79% with PLDC. No changes from baseline were observed in mean Ca or P in any treatment group, but one instance of hypercalcemia (≥10.3 mg/dL) was observed with PLDC treatment.

Conclusions: ERC was safe and more effective at increasing serum 25D and decreasing plasma iPTH than IRC, HDC or PLDC in patients with SHPT, vitamin D insufficiency, and stage 3 or 4 CKD.

PO0566
RenoProtective Effects of Febuxostat and Allopurinol in Patients with Hyperuricemia and CKD: A Meta-Analysis
Sherida N. Fidding, Monica Therese Cating-Cabral, Brian Michael C. Cabral. St. Luke’s Medical Center - Global City, Taguig City, Philippines.

Background: Hyperuricemia is associated with rapid deterioration of renal function in patients with chronic kidney disease (CKD). The two most common urate-lowering drugs available are allopurinol and febuxostat. Randomized controlled trials and observational studies have shown that the individual drugs have potential to slow down deterioration of renal function in CKD patients. However, it is unclear which drug is more effective because of insufficient direct comparison between the two. Hence, our study aims to perform a meta-analysis to assess the renoprotective and urate-lowering effects between the two drugs in patients with CKD and hyperuricemia.

Methods: A comprehensive literature search using PubMed was performed with the following search terms: febuxostat, allopurinol, chronic kidney disease, renoprotection. Five relevant studies were selected and analyzed using Cochrane Revman v5.3. Outcomes assessed were changes in estimated glomerular filtration rate, serum creatinine, level of proteinuria and/or albuminuria and change in serum uric acid levels.

Results: Five studies comprising 606 patients were selected – 304 treated with febuxostat and 302 with allopurinol. No significant differences were found in the changes in serum creatinine (mean difference (MD) -0.02; CI -0.07, 0.03; P = 0.39) and eGFR (MD -2.09; CI -0.67, 4.84; P = 0.14) from baseline to 3 months between the two groups. Significant difference in the change in eGFR favoring Febuxostat, was observed after 6 months (MD 4.94; CI 2.25, 7.64; P < 0.0003). Significant decrease in proteinuria (MD -0.24; CI -0.42, -0.07; P = 0.007) and albuminuria (MD -80.47, CI -149.29, -11.64, P = 0.02) were observed more in the febuxostat group after 3 months; however these changes were not significant after 6 months. Serum uric acid levels were significantly more reduced in the febuxostat group both after 3 (MD -0.90; CI -1.14, -0.67, P = 0.00001) and 6 months (MD -1.50; CI -1.70, -1.30, P < 0.00001).

Conclusions: Our study showed that febuxostat might be more renoprotective (as measured by eGFR change in 6 months) and offers a better anti-proteinuric and urate-lowering effect. However, more studies are needed to assess its efficacy across the spectrum of CKD, including those requiring hemodialysis and post-transplant patients.

PO0567
CKD Is Associated with Attenuated Plasma Metabolome Response to Oral Glucose Tolerance Testing
Armin Ahmadi,1 Brian J. Bennett,2* Jorge Gamboua,4 Leila R. Zelnick,2 Daniel Rafferty,3 Ian H. de Boer,3 Baback Roshanravan,1 Department of Medicine, Division of Nephrology, University of California Davis, Davis, CA; Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; Vanderbilt University School of Medicine, Nashville, TN; Puget Sound Health Care System, Seattle, WA; Obesity and Metabolism Research Unit, Western Human Nutrition Research Center, USDA, ARS, Davis, CA.

Background: Chronic kidney disease (CKD) is associated with decreased anabolic response to insulin contributing to protein-energy wasting. Targeted metabolic profiling of the response to oral glucose tolerance testing (OGTT) may help identify metabolic pathways contributing to disruption in incretin response.

Methods: Using targeted metabolic profiling, we examined the plasma metabolome in 58 moderate to severe non-diabetic CKD patients with estimated glomerular filtration rate (eGFR) >60ml/min per 1.73m2 and 37 healthy controls with normal eGFR before and after 2h of 75g oral glucose challenge. We used linear mixed effect models adjusting for potential confounders of age, sex, race, and body weight to determine the interaction of eGFR and change in metabolites in response to OGTT by CKD status. Pathway analyses were performed using MetaOnaSleep.

Results: CKD patients had lower eGFR compared to healthy control (37.3 ± 12.5 Vs. 89.3 ± 17.1 ml/min per 1.73m2). Oral glucose challenge was associated with a marked reduction in a wide array of metabolites, predominantly amino acids, TCA cycle intermediates, and bile acids. CKD status was associated with attenuated OGTT induced prominent changes in pathways of taurome metabolism, phenylalanine, tyrosine and tryptophan biosynthesis, nicotinamide metabolism, and TCA cycle (Figure 1).

Conclusions: Targeted plasma metabolic profiling in response to OGTT suggests a broad disruption of amino acid and mitochondrial energy metabolism in CKD patients. These findings motivate further investigation into the incretin response in patients with CKD and the impact of incretin mimetics such as GLP-1 receptor agonist.

Funding: NIDDK Support

The Effects of Allopurinol on the Progression of CKD According to Baseline Serum Urate Level: Results from Post Hoc Analyses of the CKD-FIX Trial
Anushree Tiku, Elaine Pascoe, Neil Boudville, Alan Cass, Nicola Dalbey, Richard O. Day, Janak de Zoysa, Bettina Douglass, Randall Faulk, David Harris, Carmel Hawley, Graham R. Jones, John Kanellis, Sueontia Palmer, Vlad Perkovic, Gopi Rangan, Donna Reидinger, Laura Robison, Robert J. Walker, Giles Walters, David W. Johnson, Sunil Badve, George Institute for Global Health, Sydney, NSW, Australia; The University of Queensland, Saint Lucia, QLD, Australia; The University of Western Australia, Perth, WA, Australia; Menzies School of Health Research, Casuarina, NT, Australia; The University of Auckland, Auckland, New Zealand; St Vincent’s Health Australia Ltd, Bondi Junction, NSW, Australia; The University of Adelaide, Adelaide, SA, Australia; The University of Sydney, Sydney, NSW, Australia; University of New South Wales, Sydney, NSW, Australia; Monash University, Clayton, VIC, Australia; University of Otago, Dunedin, New Zealand; Westmead Hospital, Westmead, NSW, Australia; Australian National University, Canberra, ACT, Australia.

Background: Allopurinol did not slow decline in estimated glomerular filtration rate (eGFR) over 2 years in patients with chronic kidney disease (CKD) at risk of progression in the CKD-FIX trial. We assessed the effect of allopurinol on eGFR slope by baseline serum urate level.

Methods: In this trial, 369 adults with stage 3 or 4 CKD, without history of gout, and either less than or equal to a serum-to-creatinine ratio ≥265 mg/g or eGFR decrease ≥3.0 mL/min/1.73 m² in the preceding year, were randomized to allopurinol or placebo. The primary outcome was change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This post hoc subgroup analysis describes outcomes in 352 participants according to baseline serum urate level (nonhyperuricemic and hyperuricemic [serum urate >6 mg/dL in women and >7 mg/dL in men], and tertiles of baseline serum urate level).

Results: At baseline, 65 (18.5%) and 287 (81.5%) participants had normouricemia and hyperuricemia, respectively. The mean serum urate level in the normouricemic group was 8.7 mg/dL (8.3 mg/dL for women and 8.9 mg/dL for men). There were no significant differences in change in eGFR between allopurinol and placebo in normouricemic (mean difference [MD] 0.03, 95%CI -0.72 to 3.42 mL/min/1.73 m²/year) and hyperuricemic (MD -0.06, 95%CI -1.20 to 1.08 mL/min/1.73 m²/year) participants. The mean serum urate levels in the lowest, middle and highest tertiles were 6.3 mg/dL, 8.0 mg/dL, and 10.0 mg/dL, respectively. The result for the primary outcome was consistent across all tertiles of baseline serum urate level (interaction P value for subgroup analysis = 0.49).

Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline serum urate level.

PO0569
CKD Progression End Points as Potential Surrogates for Kidney Failure: Findings from the CKDopp
Jacek Zee, Daniel G. Muenz, Keith McCullough, Brian Bieber, Marie Metzger, Natalia Alencar de Pinho, Antonio A. Lopes, Danilo Fliser, Bruce M. Robinson, Eric W. Young, Ronald L. Pisoni, Benedicte Stengel, Robert Peacock-Filho, 1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2 French Institute of Health and Medical Research (INSERM), Villejuif, France; 3 Department of Internal Medicine, Federal University of Bahia, Salvador, Brazil; 4 Universitätsklinikum des Saarlandes and Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany.

Background: Many potential surrogate endpoints for kidney failure (KF) have been used in clinical trials and observational studies of chronic kidney disease (CKD). Individual and composite surrogate endpoints must be compared to ensure accuracy research that maximizes power and facilitates harmonization across studies, particularly among an international sample of advanced CKD patients.

Methods: Using data from CKD stage 3-5 patients from Brazil, France, Germany, and the US enrolled in the CKD Outcomes and Practice Patterns Study (CKDopps), we defined potential individual surrogate KF endpoints based on reaching (1) eGFR<15 mL/min/1.73m² and (2) eGFR decline of ≥40%, and composite surrogate endpoints that combine (1) and (2) with and without kidney replacement therapy (KRT, dialysis or transplant). We used each individual and composite endpoint as a time-varying indicator in an unadjusted Cox model to predict time from study entry to the hard outcome of KRT. Potential surrogate endpoints were compared by number of events and prediction accuracy (integrated area under the time-averaging receiver operating curve [IAUC]).

Results: N=5242 patients had median (IQR) baseline eGFR of 26.8 (20.7-35.5) and 144 (9%) had KRT. Over a median of 7 (1.2-3.0) years, potential surrogate endpoints that included eGFR<15 had higher prediction discrimination compared with those that only included 40% eGFR decline (Figure, IAUCs of 0.83-0.84 vs. 0.73-0.75). Composite endpoints had higher event counts than non-composite endpoints (N of 1622-1878 vs. 1144-1556, see Figure x-axis).

Conclusions: A composite KF endpoint defined by the earliest occurrence of either KRT, eGFR<15, or eGFR decline of ≥40%, had the highest prediction discrimination for KRT and the highest number of events among a cohort enrolled at low eGFR. This endpoint should be further evaluated and considered for clinical research studies to optimize power while sufficiently capturing KF.

A New Vision for Nephrology Trials in Canada

Alicja Murdoch,1 François Madore,1 Dwight Sparkes,2 Karthik K. Tennankore,1 Arris H. Vorster,1 Ritu Surji,1 Université de Montréal, Montreal, QC, Canada; 2Can-SOLVE CKD Network, Vancouver, BC, Canada; 3Dalhousie University, Halifax, NS, Canada; 4McGill University, Montreal, QC, Canada.

Background: The Canadian Nephrology Trials Network (CNTN) was established in 2014 to improve the quantity and quality of clinical trials in nephrology in Canada. With inception of the Canadians Seeking Solutions and Innovations to Overcome Chronic Kidney Disease (Can-SOLVE CKD) Network in 2016, CNTN received additional funding to expand its mandate. We surveyed and assembled a broad cross-section of Canadian kidney patients, nephrology researchers, and other relevant stakeholders in order to establish an expanded new vision for CNTN.

Methods: In July-August 2018, we administered two separate surveys – one to patient members of Can-SOLVE CKD and the second to members of CNTN and other Canadian nephrology investigators. We then conducted a two-day visioning workshop in September 2018 to discuss how best to support nephrology research in Canada. Over 40 stakeholders participated, including 10 patients, 22 researchers, and members of the Can-SOLVE CKD Operations Team.

Results: Through the survey, we identified two issues that were at least moderately challenging: inability to facilitate multi-site trials (81%) and lack of engagement with community sites (74%). Three key themes emerged from the visioning exercise: peer review, training, and engagement. A summary report captured workshop discussions and was used to inform revisions to CNTN’s structure and governance. Three new working communities were created: Capacity Building, Communication and Engagement, and Scientific Operations; as well as a governing Executive Committee. Each committee is co-chaired by a nephrologist and patient, who take turns leading the Executive Committee.

Conclusions: With its new vision and committee structure, CNTN aims to promote a culture of collaboration within the Canadian kidney community and integrate patients into research. The network offers resources to enhance nephrology researchers’ ability to conduct clinical trials, directly involve patients in designing studies, and motivate change in patient care based on patient priorities through increased peer review, engagement, and training.

Implementation of Surprise Question Assessments Using the Electronic Health Record in Older Adults with Advanced CKD

Natalie C. Ernecoff1, Khaled Abdel-Kader,2 Manoj Cai,1 Jonathan Yabes,1 Jane O. Schell,1 Manisha Jham1.1University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Vanderbilt University, Nashville, TN.

Background: The Surprise Question (SQ; “Would you be surprised if this patient died in the next 12 months?”) is a validated prognostication tool for mortality and hospitalization among patients with advanced CKD. Yet, barriers in clinical workflow have slowed SQ implementation into practice. We sought (1) To evaluate implementation outcomes following use of electronic health record (EHR) decision support to automate collection of the SQ, and (2) To assess the prognostic utility of the SQ for mortality and hospitalization/emergency room (ER) visit.

Methods: We developed and implemented a synchronous decision support [best practice alert (BPA)] algorithm in the electronic health record (EHR) to identify patients attending an outpatient nephrology follow-up visit who were ≥ 60 years of age with an eGFR<30. At the time of the visit, a ‘pop-up’ BPA was triggered, prompting the physician to answer the SQ (dichotomized). To evaluate implementation, we assessed provider response rate, and efficiency of responses. We assessed the SQ’s prognostic utility in survival and time-to-hospital encounter (hospitalization/ER visit) analyses. We abstracted EHR data on patient sociodemographics and clinical characteristics. Physicians provided their demographic and clinical practice characteristics.

Results: Among 510 unique patients for whom the BPA triggered, 95 had the SQ completed (18.6%) by 16 unique providers. Among those patients with completed SQ, nearly all providers (97.9%) completed the SQ on the clinic appointment day, and 61 (64.2%) the first time the BPA fired. Providers answered “No” for 27 (28.4%) and “Yes” for 68 (71.6%) patients. By 12 months, 6 (6.3%) “No” patients died; 3 (3.2%) “Yes” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “No” patients and 25% of “Yes” patients had a hospital encounter by 12 months (HR 1.85, CI[0.927, 3.689]).

Conclusions: We successfully integrated the SQ into the EHR for routine collection to aid in clinical practice. Our response rate indicates additional implementation efforts are needed to encourage further integration of the SQ in clinical practice. Consistent with prior research, the SQ has reasonable prognostic utility for mortality and future hospital encounters.

Telehealth for Adults with CKD: A Systematic Review and Meta-Analysis

Li Luo,1 Min Zhang,1 Dingjun Zhang,1 Huifen Chen,1 La Zhang,1 Bingqing Xin,1 Jianwang Tan,2 Chendi Dong,1 Yannin Xu,1 Xusheng Liu,1 Yifan Wu.1 The Second Clinical College, Guangzhou University of Chinese Medicine, Guangzhou, China; 2Renal Division, Beijing University of Chinese Medicine Shenzhen Hospital, Guangzhou, China; 3Renal Division, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangdong Provincial Hospital of Chinese Medicine), Guangzhou, China.

Background: Evidence has supported improved quality of CKD care when assisted with telehealth, while these results were predominantly based on cohort observation or small-scale randomized controlled trials(RCTs). Moreover, robust findings regarding its effects on endpoints were still limited. This study thus aimed to evaluate impacts of telehealth on delaying CKD progression but uncertain impacts on decreasing endpoint incidence.

Methods: This study was conducted and reported according to PRISMA statement. We searched databases including MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), Chinese Biomedical Database (CBM), Chinese National Knowledge Infrastructure (CNKI), Wanfang Database and VIP Database until 2019 April. Relevant studies regarding telehealth for non-dialysis CKD population were screened, reviewed, selected and assessed of quality for systematic review and meta-analysis. The protocol was registered at PROSPERO(CRD4201703665).

Results: Eighteen trials involving 4749 patients were included for systematic review and 4 for further meta-analysis. The qualitative study summarized different study population, telehealth intervention type(consultation, education, monitoring) and variable results of outcomes measured(endpoints, surrogate values, patient-centered outcomes). The quantitative analysis comparing the telehealth and control group detected no significant difference in systolic blood pressure(SBP), diastolic blood pressure(DBP) and serum creatinine(SCr) at 12 months, but found significantly lower Scr level at 6 months, preserved estimated glomerular filtration rate(eGFR) at 6 months and at 12 months in telehealth group.

Conclusions: This study detected advantages of telehealth on delaying CKD progression but uncertain impacts on decreasing endpoint incidence.

Telenephrology Care for Veterans in the COVID-19 Pandemic

Juan D. Salcedo Betancourt,1 Carlos A. Torres,1 Yanetsy Olivera Arenchibia,1 Vasuki N. Venkat,1,2 Daniel J. Soberon,1,2 Marco A. LadinoAvellaneda,1,2 1University of Miami School of Medicine, Miami, FL; 2Miami VA Healthcare System, Miami, FL.

Background: Chronic kidney disease (CKD) affects 37 million adults in the United States. Since 2013 our Nephrology section has carried out a telenephrology clinic and implemented electronic consults (E-consults). During the COVID-19 pandemic, we implemented changes to evaluate patients with kidney disease. The aim of this study is to report our experience.

Conclusions: Telenephrology clinic and E-consults have been valuable in evaluating COVID-19 patients with kidney disease.

Funding: Government Support - Non-U.S.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: This is a single-center, retrospective chart review study, which evaluated the outcomes of our tele nephrology clinic (video-on-demand and telemedicine clinic visits), as well as E-consults. Between January 2013 and 2020, 410 patients were seen at telemedicine clinic visits, and 1020 E-consults were evaluated. During the COVID-19 pandemic, between March 2020 and May 2020, 40 patients were assessed through video-on-demand.

Results: For telemedicine, a total of 169 patients were included, 99.4% were males, and 87% were white. The mean age was 66 ± 10 years, 92% had hypertension, and 41% diabetes mellitus. The baseline eGFR was 45 ± 14 mL/min/1.73m2. A one-way analysis of variance was conducted and showed a statistically significant difference on the systolic (SBP) and diastolic (DBP) blood pressure (p-value = 0.000), and improvement in potassium and bicarbonate levels (p-value = 0.000). Phosphorus levels did not show a significant difference (p-value = 0.37). There was a significant association between attendance to >3 tele nephrology visits and SBP control (p-value = 0.02), DBP control (p-value = 0.002) and potassium improvement (p-value = 0.013). The overall decrease in GFR was 1.2 ± 1.1 mL/min/1.73 m2 (95% CI -0.41 to 2.95), lower than the reported natural progression of CKD (1.03 mL/min/1.73 m2/year). A survey for the video-on-demand patients showed 100% satisfaction, reflecting that patients felt their renal care needs were fulfilled. E-consults were provided in less than 24 hours, with 100% satisfaction from primary care physicians.

Conclusions: This is the first study evaluating the use of telenephrology in patients with kidney disease during the COVID-19 pandemic. In our cohort, telenephrology interventions improved SBP, DBP, bicarbonate, and potassium control. All three options improved health outcomes and guaranteed safety during the COVID-19 pandemic, at a reduced cost for the patient and the institution.

PO0575

Telenephrology: A Feasible Option for Inmates
Maxwell Butler, Laura J. Mauserter. University of Wisconsin-Madison, Madison, WI.

Background: Socioeconomic and racial disparities are factors that contribute to the disproportionately high burden of chronic disease amongst the incarcerated population in the United States. Access to care can be compromised because of the burden of cost to a facility, lack of staff to transport patients and physical distance from specialists. Telenephrology has been shown to be a feasible option in the correctional setting for specialties such as mental health, infectious disease, cardiology, and primary care, but has not been studied in nephrology. In this quality improvement study, we studied telenephrology to be a feasible option that can be implemented for CKD and hypertension management.

Methods: Using quality improvement methodology, data was collected from the electronic medical record for all telenephrology appointments from January 2015 to June 2019. Demographic data, comorbidities, appointment compliance, and clinical data including blood pressures and eGFR were recorded. Data for patients seen over a period of at least 3 years were included in the CKD progression portion and those seen at least 4 times for the blood pressure management.

Results: There were 871 appointments schedule over the 4.5 year period with 86% completed. Technology limited 3.5% of the cancelled appointments. The population was predominantly men (96%) of black race (51.9%) with hypertension (78%) and CKD (75.2%) being the most common comorbidities. There were 214 patients included in the analysis for management of CKD that showed an average annual change in eGFR of -1.57 mL/min/1.73 m2 (CI -2.87 to -0.27). There were 79 included in the hypertension analysis with 19.0% achieving a goal BP of <130/80 mm Hg and 63.3% achieving a BP of <140/90 mm Hg.

Conclusions: Telenephrology can be successfully carried out in the correctional facility's setting with a low number of cancellations due to technology. The study sample showed mild-to-moderate CKD progression consistent with previously reported population rates of eGFR decline suggesting comparable management. The smaller sample showed mild-to-moderate CKD progression consistent with previously reported.

PO0576

Nephrology eConsultation: The “Curb Side” Consult for the 21st Century
David Levy, Rickendor Grewal, Scott E. Liebman, Thu H. Le. University of Rochester School of Medicine and Dentistry, Rochester, NY.

Background: The Nephrology Division at the University of Rochester receives on average 120 new outpatient referrals per month. While every effort is made to see new referrals promptly, this demand exceeds the capacity to evaluate these patients in a timely manner. To decrease waiting time and increase efficiency, we developed a Nephrology eConsultation program. Here we report our experience with time and value-based metrics as well as primary care provider (PCP) satisfaction.

Methods: After a year-long pilot phase, in September 2019 we expanded the eConsult program to provide rapid referral management to PCPs across the University health system for renal-related issues such as mild to moderate acute kidney injury, CKD, electrolyte disturbances, and proteinuria.

Results: Within the first 8 months of the expanded program, 110 eConsult requests were received. Of these, 62 were deemed medically appropriate and completed, with 46 (74.2%) related to acute kidney injury, CKD, or azotemia, 6 (9.7%) related to electrolyte imbalances, and 4 (6.5%) related to proteinuria. The mean time for a nephrologist to complete an eConsult was 18.3 minutes (Table 1). Of the 48 deemed inappropriate for eConsults, 36 (75%) were converted to in-person visits due to complexity (Table 2). All eConsults were completed within 67 hours (mean time 15.5 hours). Survey of PCP satisfaction showed that 68% of PCPs were very satisfied and 32% were satisfied with the nephrology eConsult program.

Conclusions: eConsultation in Nephrology has the potential to provide timely, cost effective, and remote guidance to PCPs for more straightforward questions, while prioritizing the limited resource of face-to-face nephrology consultation for patients with more complex diseases. This also offers financial advantages, as the work relative value units (wRVUs) per eConsult is 0.7, or up to 2.8 wRVUs per hour in our model. eConsultation in Nephrology could also be integrated with the rapidly evolving field of telemedicine to improve delivery of care remotely and increase provider and potentially patient satisfaction.

Development of a Global CKD Personal Impact Index (CKD-PII) Assessing the Reality of Living with CKD
Mary P. James,1 Corey Windett,2 Jillian K. Guiglotto.1 1W2O, San Francisco, CA; 2AstraZeneca, Wilmington, DE.

Background: CKD affects >700M people globally, but its full burden and personal impact attributes (PIA)—impact on instrumental activities of daily living—are under-recognized. Quality of life (QoL) measures fail to show full the patient experience. A Global CKD-PII uncovering the direct and indirect daily impact of CKD on patients may improve understanding of disease burden and secondary complications. The development of the CKD-PII using a geographically diverse cohort of CKD patient-reported aggregate data is described.

Methods: A multiphase approach was used to develop CKD-PII. In Phase 1, social media landscape audit and qualitative interviews determined PIA to understand disease burden. Patient conversations within online communities gauged the social, economic and physical impact of CKD. Each attribute was assigned as high, medium or low impact based on the lexicon, overall sentiment and self-reported effect on patient’s QoL. Qualitative, moderated phone interviews followed an engagement model, whereby key PIA and language and characterization of attributes were further explored. Findings of Phase 1 informed Phase 2, a quantitative survey. Data from both phases will culminate in the development of CKD-PII.

Results: Phase 1: Social media landscape analysis leveraged 12 months of relevant patient dialogues (n=156) and shortlisted 11 key PIA from >200M internet sources. Among the key PIAs identified, dietary impacts (19%), time lost to appointments/dialysis (45%) and mental health implications (44%) were rated as high impact. Qualitative interviews (n=15) uncovered key PIA identified consistently. Phase 2: An online survey questionnaire was administered to quantify the extent of patients’ experience of PIA. The CKD-PII synthesizes data from all research phases into an insights and perspectives report evaluating global perspectives.

Conclusions: Uniquely, CKD-PII will use metrics to showcase the real-life impact of CKD, beyond QoL, providing insights into the patient experience that other studies do not typically address. The social media data facilitates understanding of critical issues and patient perception of an operational environment. This cohort of global patient-reported data will raise awareness of the deeper impact of CKD and develop tangible and realistic solutions for both patients and doctors to solve the challenges uncovered.

Lowering Mortality in CKD Stage 3B and CKD Stage 4 with Increased Outpatient Nephrology Visits

Stephanie S. Cheung,1 Michael Shen,2 Hui Xue,1,2 Kaiser Permanente San Diego Medical Center, San Diego, CA; Kaiser Permanente Department of Research and Evaluation, Pasadena, CA; Kaiser Permanente Orange County, Anaheim, CA; Kaiser Permanente Orange County, Business Intelligence & Transformation, Santa Ana, CA.

Background: Management of Chronic Kidney Disease (CKD) is complex requiring comprehensive evaluation of multiple organ systems. We hypothesized that more frequent outpatient nephrology visits is associated with lower mortality in advanced CKD patients.

Methods: CKD3B & CKD4 patients at Kaiser Permanente Southern California Orange County were followed from 2012 to 2018. Patients were divided into 4 groups based on initial eGFR per MDRD equation: eGFR ≤ 30-44, 25-29, 20-24, and 15-19. Each eGFR group was further divided by the number of annual nephrology visits (0, 1, 2, 3, and 4+). Patients who transitioned to dialysis, kidney transplant, or lost to follow up during the 7 years were excluded. Annual all-cause mortality was analyzed based on the number of nephrology visit in each eGFR category using ANOVA.

Results: The cohort consisted of 2943 individuals, 59% female, 41% male, mean age 77.4. 42% of patients were diabetic and 89% had hypertension. Lower starting eGFR had increased mortality over time while renal function stayed fairly stable. Increased outpatient visit was seen with lower eGFR during the follow up period, Figure 1. All CKD3B and CKD4 patients gained a statistically significant reduction in mortality when seen at least twice in nephrology clinic annually, p<0.04, in Figure 2. For eGFR ≤ 24, the mortality benefit was observed with 1 or more nephrology visit, p<0.005.

Conclusions: CKD stage 3B and 4 patients seen in nephrology clinic at least twice a year had improved survival. More frequent follow up was associated with lower eGFR. The relationship between the lower eGFR and the improved survival warrants further investigation.

Uptake of Evidence-Based Recommendations to Improve Care for CKD Patients in the Kidney Coordinated Health Management Partnership (Kidney CHAMP) Study

Melanie R. Weltman,1 Huiwen Chen,2 Jonathan Yabes,3,4 Manqi Cai,4 Khaled Abdel-Kader,1 Manisha Jhamh,1 Thomas D. Nolin,1,2 University of Pittsburgh School of Pharmacy, Pittsburgh, PA; University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA; University of Pittsburgh Department of Medicine, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN.

Background: Medication therapy in patients with chronic kidney disease (CKD) is focused on slowing CKD progression, managing causes of CKD, and preventing cardiovascular morbidity and mortality. The aim of this project was to assess the uptake of evidence-based medication recommendations (recs) provided to primary care providers (PCP) of patients with high-risk CKD by an interdisciplinary nephrology team.

Methods: This project is part of Kidney CHAMP, an ongoing NIH funded, pragmatic randomized controlled trial testing an electronic health record (EHR)-based population health management (PHM) approach to improve CKD care. Eligible patients are 18-85 years old with CKD who have a high risk of progression to ESKD and are not being followed by a nephrologist. Patients in the intervention arm receive a nephrologist-led electronic consult and pharmacist-led telephonic medication therapy management (MTM). Recs are provided in the EHR for the PCP to review and order at the upcoming office visit. We focused on medication recs related to the progression of CKD and prevention of cardiovascular disease, which included use of RAAS inhibitors, SGLT2 inhibitors, GLP-1 receptor agonists, and HMG-CoA reductase inhibitors (statins).

Results: From July 1, 2019 to January 31, 2020, 125 patients received an e-consult and 121 patients received MTM. A total of 83 recs were provided to PCPs. Uptake of recs for initiation or dose escalation of RAAS inhibitors was the highest, with 19 of 46 recs (41%) being implemented. Two of eight recs regarding GLP-1 receptor agonists were implemented (25%) and two of 24 recs for SGLT2 inhibitor initiation were implemented (8%). Five recs for statin initiation were made and none were implemented; however, baseline statin use was high at ~75%.

Conclusions: Many patients with high risk CKD receive suboptimal care, which can be effectively identified by interdisciplinary nephrology teams using an EHR-based PHM platform. Uptake of RAAS inhibitor recs was highest. However, initiation of medications with recent FDA approved indications for CKD management remained poor. Future research is needed to identify barriers and strategies to increase uptake of evidence-based CKD recs and thereby improve patient care.

Interdisciplinary Care Improves Patient Preparedness for ESRD in a High-Risk Patient Population with CKD

Kalvan Prudhvi,1,2 Kaltrina Sedaliu,1,2 Michelle M. Estrella,1 L. Ebony Boulware,1,4 Michel L. Melamed,1,2 Tanya S. Johns,1,2 Albert Einstein College of Medicine, Bronx, NY; Montefiore Medical Center, Bronx, NY; San Francisco VA Medical Center, San Francisco, CA; Duke University School of Medicine, Durham, NC.

Background: The Kidney Care Choice initiative has made improving the quality of care for patients with late-stage CKD a national priority. Interdisciplinary care (IDC), including nurse practitioner (NP) driven care coordination, is an intervention that may improve health outcomes in patients with CKD. Few studies have evaluated this model of healthcare delivery in racial-ethnic minorities.

Methods: We compared incident ESRD patients who received NP care coordination as part of our IDC clinic (n=84) to a contemporaneous cohort of incident ESRD patients (n=245) who received usual nephrology care alone at Montefiore Medical Center from 10/1/2013—10/31/2017. Clinical data were extracted using Clinical Looking Glass®, and chart reviews were done for validation. Patients included in our study had established care for CKD stage 4-5 and had at least one nephrology clinic visit within 3 months preceding their progression to ESRD. All patients were eligible for IDC, but receipt of IDC was limited by resource availability.

Results: Of the 329 incident ESRD patients included in our study, the mean age was 59.6 years (SD 13.8), 47% were female, and 86% were African American or Hispanic. The baseline characteristics were similar between the groups, except the IDC group had a lower prevalence of hypertension (60% vs 77%). The mean eGFR was 8 ml/min/1.73m² at dialysis initiation. Fifty percent of patients had an arteriovenous (AV) access prior to developing ESRD. However, compared to the usual care group, patients in IDC group were more likely to have a mature AV access at HD initiation (41% vs 33%); start HD as an outpatient (30% vs 19%); receive a preemptive transplant (4% vs 2%); do peritoneal dialysis (7% vs 4%); and be listed for kidney transplant (44% vs 15%) prior to developing ESRD. Receipt of IDC was associated with a higher odds (OR 3.9 [95% CI 2.0 - 7.8]; P<0.001) of kidney transplant listing compared to usual care alone after adjusting for sociodemographic and clinical factors. Other outcomes also favored IDC but were not statistically significant.

Conclusions: Interdisciplinary care is associated with better ESRD preparedness compared to usual nephrology care alone in racial-ethnic minorities. Larger multicenter randomized studies are needed to determine the effectiveness of IDC among patients with advanced CKD.

Patient Outcomes Following Discharge from a CKD Clinic
Michael Che, Susan J. Thanabalasingam, Eduard A. Iliescu, Christine A. White. Queen’s University Department of Medicine, Kingston, ON, Canada.

Background: In Ontario, Canada multidisciplinary care for patients with advanced chronic kidney disease (CKD) is delivered in Multi-Care-Kidney-Clinic (MCKC) operated by Regional Programs funded through a provincial network based on the number of eligible patients. These eligibility criteria were progressively revised between 2016 and 2018 from an absolute estimated glomerular filtration rate (eGFR) less than 30 ml/min/1.73m² to less than 15 ml/min/1.73m² or a two-year risk of end-stage kidney disease, calculated by the Kidney Failure Risk Equation (KFRE), greater than 10%. The objective of this study was to ascertain the outcomes of existing MCKC patients who were discharged as criteria were implemented.

Methods: This is a retrospective cohort study of prevalent CKD patients in MCKC in 2013 in the region of South Eastern Ontario, followed to January 2020. The outcomes were discharge from MCKC, re-referral, initiation of kidney replacement therapy (KRT), and death. Data were extracted from electronic medical record. Death was ascertained through Ontario’s Office of the Registrar General. Patients’ 2 and 5-year KFRE scores were calculated using the 4-variable KFRE.

Results: Of the 643 MCKC patients in 2013 with available data, 470 (73%) continued follow-up in MCKC, while 142 (22%) and 35 (5%) were discharged to primary care and general nephrology respectively. Of those discharged to primary care, 52 (37%) died, while 15 (11%) were re-referred to nephrology, and 8 (6%) initiated KRT within median (IQR) times of 982 (560) and 850 (1411) days from discharge respectively. Five (63%) of the 8 discharged patients who required KRT did so for unforeseen acute illness rather than progressive CKD.

Conclusions: The results of this study suggest that gradually moving MCKC funding eligibility criteria from absolute eGFR level to one based on both eGFR and the KFRE prediction model resulted in the discharge of a significant number of patients. Notably, few of the discharged patients ultimately required KRT that could have been prevented. This study offers a regional perspective with low loss to follow-up as there is only one Renal Program in the region. The results may not be generalizable to different populations, health care systems, or predictive models. Further research is needed to establish the optimal KFRE criterion upon which MCKC funding eligibility can be based.

Association of CKD with Early Heart Failure Readmissions in Adults
Si Li, Yichen Wang, Nasha Elavia, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Heart failure is a complex chronic disease with multiple comorbidities that contribute to frequent hospitalization. We aimed to examine the impact of chronic kidney disease on the 30-day readmission rate among patients hospitalized with heart failure.

Methods: We performed a retrospective analysis of the National Readmission Database (NRD) 2016- 2017. We identified adult patients with a primary hospital diagnosis of heart failure. We compared baseline demographics and calculated all-cause 30-day readmission rates. Multivariate survey logistic regression was used to identify predictors of readmission.

Results: We identified a total of 865,328 patients admitted with heart failure, 839,625 patients were discharged alive. Among which 181,130 (21.5%) had at least one readmission within 30 days. The in-hospital mortality of index admissions and readmissions was 2.9% and 6.5%, respectively. The 30-day inpatient mortality was 4.0%. The mean length of stay of index admission and readmissions were 5.3 days and 6.4 days, respectively. The most common reasons for all-cause readmissions were acute on chronic heart failure (86,965; 33.1%), hypertension and heart failure (73,454; 6.1%), heart failure, sepsis, acute kidney failure. After adjusting for multiple covariates, 30-day readmission was independently associated with chronic kidney disease [adjusted odds ratio (aOR) 1.2, 95% confidence interval (CI) 1.17- 1.23, p<0.001], coronary artery disease (aOR 1.01, 95% CI 1.01- 1.11), chronic obstructive pulmonary disease (COPD) (aOR 1.20, 95% CI 1.18- 1.22). Younger age, lower-income, discharge from larger hospitals were also predictive.

Conclusions: Further prospective studies with focus on multilevel interventions are needed to help reduce early readmission associated significant morbidity and resource utilization for this high-risk population.
A Medication Use Evaluation of Patiromer in a Clinical Practice Setting at a Veteran’s Affairs Medical Center

Daniele N. Cooney, Emily M. Fox, Mary Beth Low, Niraj Desai.

Case Western Reserve University, Cleveland, OH; Louis Stokes VAMC Medical Center, Cleveland, OH.

Background: Patiromer is cation exchange polymer approved for treatment of hyperkalemia. There is limited data regarding the utility, adverse effects, frequency of laboratory monitoring and discontinuation rate of Patiromer in a clinical practice setting.

Methods: We performed a retrospective, observational review of veterans prescribed one or more doses of patiromer between 10/2015 and 11/2019 at the Veterans Affairs Northeast Ohio Hospital System (VANEHOIS), to evaluate changes to RAAS inhibitor therapy, adverse effects resulting in patiromer discontinuation, and monitoring of serum potassium level. Patiromer prescription characteristics, concomitant medications, laboratory characteristics and adverse effects were collected for each veteran over the study time period. Baseline characteristics are reported as means; relative frequency of outcomes are reported as percentages.

Results: 69 Veterans with hyperkalemia were included for analysis. Mean age was 70 years, African-American race 29%, diabetes 90%, chronic kidney disease 91%, 17% ESRD on dialysis, and heart failure 36%. The most common patiromer dose was 8.4 g daily (78%), prescribed for a mean 29.2±15.5 days. 21% of patients had repeat labs within 2 weeks and 54% within 4 weeks of patiromer initiation. 77% of patients achieved normokalemia (K<5.0 meq/L) by the first follow up lab draw. Amongst 52 veterans with chronic, continuous patiromer use, 22 (41%) were taking RAAS inhibitors at baseline; 15 (29%) were increased to either maintained or increased RAAS inhibitor dose over the period. 28 (54%) discontinued patiromer with 7 (25%) veterans doing so due to GI complaints.

Conclusions: In a clinical setting at a Veteran’s Affairs hospital, patiromer therapy preserved RAAS inhibitor use and improved serum potassium levels, but was discontinued at a high rate due to adverse effects.

The Practical Patterns of Medication and the Association Between CKD Stage and Polypharmacy: The Fukuoka Kidney Disease Registry Study

Masanori Tomokamo, Kazuhiko Taniura, Hiroaki Ooboshi, Toshiaki Nakano, Takamasa Kanzono.

Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; Department of Nephrology, Nara Medical University, Kashihara, Japan.

Background: Polypharmacy has emerged as one of the important medical and socioeconomic problems in an aging society. Chronic kidney disease (CKD) is also one of the important medical problems for older people. However, the extent to which CKD is involved in polypharmacy still has not been fully explored yet.

Methods: We examined 3,968 Japanese CKD patients using baseline data from a multicenter prospective cohort study in a cross-sectional manner. We used the baseline data of prescribed medicines on medical records. We evaluated the association between CKD stage and polypharmacy (defined as ≥6 medicines/day; G1=1, G2=2, G3=3, G4=4, G5=5). The main outcome was polypharmacy. The multivariable-adjusted odds ratios for polypharmacy were 1.42 [95% confidence interval, 0.77–2.61] for G2, 1.44 [0.78–2.65] for G3a, 2.44 [1.34–4.49] for G3b, 4.00 [2.17–7.37] for G4 and 8.64 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value. In the higher category (G1=1, G2=2, G3=3b, 4.00 [2.17–7.37] for G4 and 8.64 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value. In the higher category (G1=1, G2=2, G3=3b, 4.00 [2.17–7.37] for G4 and 8.64 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value.

Results: At baseline, the prescribed medicines varied between 0 and 17, and the median (interquartile range) was 5 (3–7). Among 3,968 CKD patients, 1,540 (38.8 %) were 1.42 [95% confidence interval, 0.77–2.61] for G2, 1.44 [0.78–2.65] for G3a, 2.44 [1.34–4.49] for G3b, 4.00 [2.17–7.37] for G4 and 8.64 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value. In the higher category (G1=1, G2=2, G3=3b, 4.00 [2.17–7.37] for G4 and 8.64 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value.

Conclusions: Our study demonstrated that polypharmacy is associated with CKD stage in an elderly population. Further studies are needed to understand the mechanism of polypharmacy and the effect on CKD progression and management.

The Effects of Allopurinol on the Progression of CKD According to Baseline Kidney Function: Prespecified Analyses of the CKD-FIX Trial

1. George Institute for Global Health, Sydney, NSW, Australia; 2. The University of Queensland, Saint Lucia, QLD, Australia; 3. The University of Western Australia, Perth, WA, Australia; 4. Menzies School of Health Research, Casuarina, NT, Australia; 5. The University of Auckland Faculty of Medical and Health Sciences, Auckland, New Zealand; 6. St Vincent’s Health Australia Ltd, Bondi Junction, NSW, Australia; 7. The University of Adelaide Faculty of Health and Medical Sciences, Adelaide, SA, Australia; 8. The University of Sydney, Sydney, NSW, Australia; 9. University of New South Wales, Sydney, NSW, Australia; 10. Monash University, Clayton, VIC, Australia; 11. University of Otago, Dunedin, New Zealand; 12. Westmead Hospital, Westmead, NSW, Australia; 13. Australian National University, Canberra, ACT, Australia.

Background: The CKD-FIX trial showed that allopurinol did not slow the decline of estimated glomerular filtration rate in patients with CKD. However, the effects of allopurinol on CKD progression according to baseline kidney function have not been clarified.

Methods: We conducted a post-hoc analysis of the CKD-FIX trial to evaluate the effects of allopurinol on CKD progression according to baseline kidney function. We analyzed the pre-specified subgroup analyses by baseline kidney function (eGFR ≥60 mL/min/1.73 m2 for CKD stage 3, ≥45 mL/min/1.73 m2 for CKD stage 4, <45 mL/min/1.73 m2 for CKD stage 5).

Results: Among 3,282 patients with chronic kidney disease (CKD) stage 3, 1,043 patients were enrolled. In the CKD stage 3 subgroup, allopurinol significantly slowed the decline of eGFR compared with placebo (MD, 2.32 mL/min/1.73 m2/year; 95% CI -0.13 to 4.77). In the CKD stage 4 subgroup, allopurinol showed a trend toward slowing the decline of eGFR compared with placebo (MD, 0.34 mL/min/1.73 m2/year; 95% CI -1.52 to 2.21). In the CKD stage 5 subgroup, allopurinol did not slow the decline of eGFR compared with placebo (MD, -0.25 mL/min/1.73 m2/year; 95% CI -1.93 to 1.43).

Conclusions: Allopurinol significantly slowed the decline of eGFR in patients with chronic kidney disease stage 3, but not in patients with CKD stage 4 or 5. Further studies are needed to clarify the effects of allopurinol on CKD progression according to baseline kidney function.
Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was modified by baseline kidney function.

Effects of the SGLT2 Inhibitor Dapagliflozin on Proteinuria in Non-Diabetic Patients with CKD (DIAMOND): A Randomized Double-Blind Cross-Over Trial
Hiddo J. L. Heerspink,1 Claire Dekkers,1 David Cheyne,2 Department of Clinical Pharmacy and Pharmacology, University Medical Centre Groningen, Groningen, Netherlands; 2Department of Medicine, Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada
Background: Sodium glucose co-transporter 2 (SGLT2) inhibition decreases albuminuria and reduces the risk of kidney disease progression in patients with type 2 diabetes. These benefits are unlikely mediated by improvements in glycemic control alone. We therefore examined the renal effects of the SGLT2 inhibitor dapagliflozin in patients with proteinuric kidney disease without diabetes.
Methods: A multicenter double-blind placebo controlled 6-week crossover study was performed in six hospitals in the Netherlands, Canada, and Malaysia. Patients (18-75 years old), without diagnosis of diabetes, 24-hr urinary protein excretion >500 and ≤3500 mg/24h and estimated glomerular filtration rate (eGFR) ≥30 and ≤90 mL/min/1.73 m² on stable renin angiotensin system block were included. Participants were randomly assigned to one of the two consecutive treatment periods of first placebo and then dapagliflozin 10 mg/day or vice versa. The main secondary outcome was proteinuria. The main secondary outcome was change in iohexol measured GFR (mGFR).
Results: Fifty-eight patients were screened of whom 53 patients were randomized. Median baseline proteinuria was 1110 mg/24h (IQR 730, 1560) mg/24h; mean mGFR was 58 (IQR 39, 71) mL/min/1.73 m². The difference in mean proteinuria from baseline between dapagliflozin and placebo was 0.9% (95% CI: -16.6, 22.1; p=0.93). Compared to placebo, mGFR changed with dapagliflozin treatment by -6.6 mL/min/1.73 m² (95% CI: -9.0, -4.2; p=0.0001) at week 6, which was completely reversible within 6 weeks after discontinuation. Differences between dapagliflozin and placebo in body weight, systolic blood pressure and hematocrit were -1.5 kg (95% CI: -3.0, -0.0; p=0.0455), -3.6 mL/min/1.73 m² (95% CI: 7.6, -0.4, p=0.0775) and 0.02 L/L (95% CI: 0.01, 0.03; p=0.9001). HA/Bae did not change. The number of patients with adverse events during dapagliflozin treatment (n=17; 32.1%) and during placebo treatment (n=13; 25.0%) was similar. No hypoglycemic events were reported.
Conclusions: Six week treatment with dapagliflozin does not affect proteinuria in patients with chronic kidney disease without diabetes, but did induce acute and reversible decreases in eGFR, body weight reduction, and increased hemocconcentration.

The Impact of Decline in Renal Function on the Clinical and Economic Burden of CKD: An Application of the DAPA-CKD Cost-Efficacy Model
Philip McEwan,1 Juan Jose García Sanchez,1 Klas Bergenheim,1 Oliver T. Darlington,1 David C. Wheeler,1 Hiddo J. L. Heerspink.2 1AstraZeneca, Cambridge, United Kingdom; 2University of Groningen, Groningen, Netherlands; 3Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; 4University College London, London, United Kingdom; 5AstraZeneca, Gothenburg, Sweden.
Background: The efficacy of dapagliflozin for the treatment of chronic kidney disease (CKD) was assessed in DAPA-CKD, which was stopped early for overwhelming efficacy. Cost-effectiveness analysis of new treatments plays an important role in the effective allocation of healthcare resources. The objective of this study was to develop a model for evaluating the cost-effectiveness of dapagliflozin based on the pending results of DAPA-CKD, and to demonstrate its functionality by characterizing the health economic burden of CKD progression from a UK payer perspective.
Methods: A lifetime microsimulation model was developed to estimate health economic outcomes in patients with CKD. Disease progression was modelled based on a lifetime risk of renal replacement therapy (RRT) at end-stage renal disease. Life expectancy was estimated using a published risk equation of 10-year mortality in CKD patients. Incidence for renal replacement therapy (RRT) at end-stage renal disease. Life expectancy was calculated based on published estimates. This study shows that improved diagnosis and management of CKD may reduce the burden imposed by CKD on both patients and healthcare systems.

Development of a CKD Model in Cynomolgus Monkeys and Its Application to Test Zampilimab, a Monoclonal Antibody (mAb) Specific for Human Transglutaminase 2 (TG2)
Linghong Huang,1 James L. Song,2 Timothy S. Johnson.1 1UCB Pharma, Slough, United Kingdom; 2Prisys Biotechnology, Shanghai, China.
Background: TG2, a crosslinking enzyme involved in wound healing, is linked to the development of renal fibrosis. TG2 irreversibly crosslinks proteins via ε-(glutamyl)-lysine dipeptide bonds, including extracellular matrix (ECM) proteins. TG2 accelerates ECM deposition and renders the matrix resistant to ECM proteases, forcing ECM homeostasis towards accumulation. TG2 also crosslinks large latent TGFβ1 into the ECM, releasing the active pro-fibrotic TGFβ1 dimer. Zampilimab (IC50 0.2nM, K, 120pm), a humanized mAb specific for human TG2, is under investigation for the treatment of fibrosis. Application of zamilmpab in a primary human cell model of renal fibrosis had positive results; however due to human specificity, zamilmpab efficacy cannot be tested in rodent in vivo models.
Methods: A unilateral ureteric obstruction model of CKD was developed in aged cynomolgus monkeys. Zamilmpab was applied prophylactically immediately following model induction. TG2 activity was measured using an in-situ activity assay, and zamilmpab target occupancy determined by competitive immunofluorescence. Renal fibrosis was measured by computerized image analysis and histopathological scoring of Masson’s trichrome, Picosiris red and H&E stained slides with hydroxyproline measured by amino acid analysis.
Results: Ligation of the left ureter led to development of severe tubulointerstitial fibrosis. Treatment with TG2 inhibitor zamilmpab led to a significantly higher reduction (n=6) in renal fibrosis than similar rodent models, with histology more closely resembling obstructive disease in man. Following zamilmpab intervention in a 4-week study, 7 days post final dose, TG2 activity was reduced completely in animal kidney tissue (n=6) and activity returned at a low dose. However, both zamilmpab doses accelerated the level of renal fibrosis by pathology score, computerized determination of fibrotic index and hydroxyproline.
Conclusions: Our primate model of CKD demonstrated that zamilmpab can effectively block TG2 activity and prevent renal fibrosis. A Phase 1/2 study of zamilmpab for the treatment of post-renal transplant fibrosis is ongoing (NCT04335578).

Conditional Deletion of Myeloid-Specific Mifosin 2 Promotes Kidney Fibrosis
Divya Bharta, Allyson M. Capilli, Kiichi Nakahira, Thangamani Muthukumar, Augustine M. Choi, Oleh M. Akchurin, Mary E. Choi. Well Cornell Medicine, New York, NY.
Background: Mitochondrial dysfunction is implicated in the pathogenesis of CKD. Mitochondrial dynamics regulate macrophage mitochondrial stress responses; we hypothesize that their impairment leads to kidney fibrosis. We determined the role of myeloid-specific mitochondrial fusion proteins (MEN1) and MFN2 in PINK1-mediated mitophagy in experimental and human kidney fibrosis.
Methods: PINK1−/−, myeloid-specific Mfn1 (LysM-Cre−/−Mfn1fl/fl), Mfn2 (LysM-Cre−/−Mfn2fl/fl) null mice and corresponding controls were subjected to unilateral ureteral obstruction (UUO,7-days) or adenine diet (AD,28-days). Kidneys, renal macrophages (RMs), bone marrow-derived macrophages (BMDMs), PBMCs, and plasma were analyzed for hypoxia, renal expression of CD11b+F4/80+ macrophages than AD- fed controls. Increases in fibronectin, CD206, galectin-3, and TGF-β1 in UUO mice displayed increased renal expression of CD11b+F4/80+ macrophages than AD- fed controls. Increases in fibronectin, CD206, galectin-3, and TGFB-1 expression in the kidneys and RMs were higher in AD-LysM-Cre−/−Mfn2fl/fl mice than AD-fed controls. TGFB-1-induced inhibition of mitophagy and increases in mitochondrial mass, size, and superoxide levels were greater in LysM-Cre−/−Mfn2fl/fl RMs and BMDMs than LysM-Cre−/−Mfn1fl/fl and controls. The reduction in colocalization of MFN2 but not MFN1 with renal mitochondria after UUO was higher in PINK1+/− mice. PBMCs from patients with severe-CKD showed higher superoxide levels and lower MFN2 expression than mild/moderate-CKD. IFTA was associated with lower renal expression of MFN1 and MFN2 and higher circulating CCL2 levels than controls. Decreased MFN2 and PINK1 expression in TGFB-1-treated human RMs was associated with increased fibrotic response.
Conclusions: This study is the first to suggest that myeloid-specific MFN2 but not MFN1 by regulating renal macrophage mitochondrial biogenesis and mitophagy prevents fibrosis. Mitophagy inducers may attenuate macrophage superoxide production and progression of kidney fibrosis.

PO0592
EZH2 Mediates Renal Fibrosis and Links Activation of Notch Signaling and Suppression of Klotho and BMP-7 Expression
Shougang Zhang,1,2 Shanghai East Hospital, Shanghai, China; ‘Shanghai Tongji University, Shanghai, China; ‘Suzhou Municipal Hospital, Suzhou, China

Background: EZH2 is a major histone methyltransferase and plays a critical role in renal fibrosis and chronic kidney disease. However, the mechanism of EZH2 in renal fibrosis is not fully understood.

Methods: We used two highly selective EZH2 inhibitors and conditional knockout mice to evaluate the effect of EZH2 inhibition on renal fibrosis and activation of profibrotic signaling pathways and expression of renoprotective proteins in two mouse models of chronic kidney disease (CDK) induced by UUO and 5/6 nephrectomy (SNx). Treatment with these inhibitors or EZH2 siRNA also inhibited serum- and TGF-β-induced activation of renal fibroblasts in culture. Moreover, pharmacological and genetic inhibition of EZH2 suppressed expression of Notch-1, Notch-3, Jagged-1 and HEV-1 in vivo and in vitro. Similarly, inhibition of EZH2 was effective in inhibiting phosphorylation of extracellular signal-regulated kinase 1/2, AKT and NF-κB as well as expression of multiple profibrogenic cytokines/chemokines and renal macrophage infiltration. In contrast, EZH2 inhibitors prevented injury-induced downregulation of Klotho and BMP-7, two anti-fibrotic proteins in the kidney.

Conclusions: These results revealed that EZH2 may promote renal fibrosis and activation of renal fibroblasts by inhibition of Notch signaling, downregulation of Klotho and BMP-7 and induction of inflammation in the injured kidney. Targeting EZH2 may be a novel therapeutic strategy to treat CKD.

PO0594
Pyruvate Kinase M2 in Renal Tubular Cells Is A Key Regulator of Kidney Repair After Ischemic Injury
Qingwei Wei,1 Zheng Dong,1,2 Augusta University, Augusta, GA; ‘Augusta VA Medical Center, Augusta, GA.

Background: Tissue injury and repair is associated with changes of metabolism. In kidneys, metabolic changes including mitochondrial dysfunction and induction of glycolysis have been reported in renal fibrosis and chronic kidney disease. It remains unclear whether and how the metabolic changes contribute to kidney injury and repair. We have examined the effects of glycolysis inhibitors and the ablation of pyruvate kinase M2 (PKM2, an enzyme in glycolysis) in kidney tubules. Glycolysis inhibitors (including PKM2 inhibitor shikonin) suppressed renal fibrosis in the mouse model of unilateral ureter obstruction (UUO). Interestingly, in vitro the inhibitors suppressed fibrogenic gene expression (e.g. fibronectin and a-SMA) in fibroblasts, but not in cultured renal tubular cells.

Methods: To further understand the role of glycolysis in renal tubular cells in vivo, we established a mouse model in which PKM2 ablation in renal tubule cells can be induced by doxycycline. To this end, PKM2-flox mice were bred with Pax8-rtTA/LC1 CRE recombinase mice to create an inducible renal tubule-specific PKM2 knockout (iRT-PKM2-KO) mouse model. Exposure to doxycycline for 5-7 days induced PKM2 ablation in all renal tubules in iRT-PKM2-KO mice, but not in wild-type littermates. These mice were subjected to 30 minutes of unilateral renal ischemia-reperfusion one day after initial doxycycline treatment, and kidneys were collected at 2 weeks later for histology, immunolabel analysis, and fibrosis staining.

Results: Wild-type mice showed increased expression of collagen I, collagen IV, vimentin and a-SMA in kidney tissues. The increase of collagen I was significantly attenuated in iRT-PKM2-KO mice, while collagen IV and vimentin induction was marginally inhibited and no inhibition for fibronectin and a-SMA in these mice. Wild-type and iRT-PKM2-KO kidney tissues had similar levels of Sirius red staining of collagen fibrils. We further examined Lotus tetragonolobus lectin (LTL) staining of proximal tubules, which detected obviously more intact proximal tubules in iRT-PKM2-KO mice than in wild-type littersmates.

Conclusions: Together, these results indicate a pathogenic role of glycolysis in maladaptive kidney repair. Importantly, PKM2 and associated metabolism contribute to the degeneration of renal tubules after acute kidney injury.

PO0595
Proximal Tubule-Specific DPP4 Deletion Slows Kidney Disease Progression in Obese Mice
Ravi Nistala,1 Jing Ren,1 Jingzhong An,2 Tammy L. Srawn,1 Suryanshi Rawat,1 Priyanka Patel,1 Adam Whaley-Connell,1 ‘University of Missouri, Columbia, MO; ‘Suzhou Municipal Hospital, Suzhou, China.

Background: Obesity is a major risk factor for Chronic Kidney Disease progression to End Stage Renal Disease and/or Dialysis. Increased absorption of fats and/or sugars from Western Diet (WD) likely leads to kidney tubular injury in obesity. We observed that whole body dipeptidyl peptidase 4 (DPP4) deletion as well as inhibition in WD-fed mice results in decreased kidney injury which, in turn was associated with a decrease in proximal tubule DPP4. Therefore, we hypothesized that proximal tubule (PT) DPP4 activation leads to injury and progression of kidney disease.

Methods: PT-KO and WT littermates were fed a WD starting 4-6 wks of age and continued for 2 years. GFR and albuminuria were monitored periodically. Tissue histology was performed at select intervals. GeLC-MS was used to separate kidney peptides and Scaffold 4/iPathwayguide used to analyze the Proteomics data.

Results: WD-fed WT mice gained 150-200% weight of chow-fed (CD) mice and had a greater decline in GFR than CD-fed animals over 2 years (50% vs. 20%, p<0.05). WD-fed WT-KO mice had a lesser decline (~35%) when compared to WT mice. This was true for both male and female mice. Concomitantly, there was an increase in albuminuria in WD-fed WT mice that was mitigated in PT-KO mice. PAS/PSR stained sections showed worsening fibrosis, tubular dilatation and glomerulomegaly, tubular vacuolization in WD-fed WT mice that was mitigated in PT-KO mice. Oil Red O staining showed increased fat accumulation in glomeruli and tubules of WD-fed WT mice that was mitigated in KO mice. Proteomics analysis followed by immunoblots showed that WD-feeding led to an increase in cell adhesion proteins and ribosomal machinery that was significantly suppressed by KO. In addition, there was a shift towards reduction in gluconeogenesis and improved fatty acid oxidation in KO mice.

Conclusions: Obesity without diabetes can lead to rapid decline in GFR in both male and female mice. DPP4 inhibition may slow decline if started early in the course of developing obesity and/or insulin resistance.

The PAR-1 Antagonist Vorapaxar Protects Against AKI to CKD Transition

Sarah W.Y. Lok,1 Wai Han Yiu,1 Loretta Y.Y. Chan,1 Joseph C K Leung,2 Kar Neng Lai,2 Sydney C. Tang.1,3
1The University of Hong Kong, Queen Mary Hospital, Hong Kong; 2The University of Hong Kong, Hong Kong, Hong Kong.

Background: Protease-activated receptor-1 (PAR-1) has been reported as a key regulator in the pathophysiology of AKI. Beyond its normal function in haemostasis, aberrant PAR-1 signaling may lead to the development of tubulointerstitial fibrosis, and subsequently CKD.

Methods: We investigated whether the administration of PAR-1 antagonist vorapaxar, an FDA-approved drug for reducing thrombotic cardiovascular events, has any renoprotective effect in a robust kidney fibrosis murine CKD model following unilateral ischemia reperfusion injury (UIRI), as well as in a hypoxia-induced cultured rat proximal tubular epithelial cells (NRK-52E).

Results: Vorapaxar reduced morphological abnormalities and the expression of tubular injury marker KIM-1 in UIRI kidneys. Mice treated with vorapaxor showed less intrarenal accumulation of ECM proteins including fibronectin, α-smooth muscle actin and collagen 1 via TGF-β/Smad signaling after UIRI. IR-induced endothelial dysfunction and macrophage infiltration were also decreased by vorapaxar treatment. In NRK-52E cells, PAR-1 expression was activated under a hypoxic milieu associated with upregulation of TGF-β-induced ECM protein accumulation.

Conclusions: Vorapaxor diminishes renal fibrosis through TGF-β/Smad signaling in UIRI model, and protects against tubular injury during AKI to CKD transition. A PAR-1 targeted strategy by vorapaxor as a therapeutic approach in human CKD warrants further funding.

Funding: Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 05163596), Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7061-16G), and Hong Kong Society of Nephrology/HK Foundation for Research Support.

Sphingosine Kinase 2 in Kidney Perivascular Cells Promotes Inflammation and Fibrosis Through S1PR1 Signaling

Shinji Tanaka,1 Yugesh Kharel,2 Shuqiu Zheng,1 Jonathan E. Lipsey,1 Diane L. Rosin,1 Kevin Lynch,2 Mark D. Okusa.1 Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Division of Pharmacology, University of Virginia, Charlottesville, VA.

Background: Sphingosine 1-phosphate (SIP) is a sphingolipid, which is produced by two different kinases, sphingosine kinase (SphK) 1 and 2. SIP is exported through Sphin2 or Sphin2b, and then reacts with SIP receptors (SIPR1-5) to affect multiple cell functions. Recently, we showed that SphK2-deficient mice were protected from renal fibrosis when compared to wild type or SphK1−/− mice (PMID: 27799486). We hypothesized that SphK2 deletion in renal perivascular cells confers the protection from progressive kidney fibrosis.

Methods: Male Fosd/Cre SphK2fl/fl and Fosd/Cre SphK2−/− (control) mice were used. For unilateral ischemia-reperfusion injury (IRI), left kidney was clamped for 30 minutes; right nephrectomy was performed at day 13. For bilateral IRI, both kidneys were clamped for 30 minutes. Mice were euthanized at day 14 to evaluate kidney fibrosis (unilateral IRI) and at day 1 to evaluate the extent of acute kidney injury (bilateral IRI). Primary kidney perivascular cells were isolated from kidneys of Fosd/Cre SphK2fl/fl and control mice.

Results: In the unilateral IRI model, Fosd/Cre SphK2−/− mice demonstrated better kidney function (plasma creatinine), less kidney fibrosis (histology) with less macrophage infiltration, and suppressed expression of fibrosis-related genes (Acte2, Colla1, Colla1) in the kidneys compared with control mice but there was no difference in plasma SIP between the groups. In contrast, in the bilateral IRI model, there was no difference between the groups in kidney function, kidney Haver1/Lcn2 expression, and histology at day 1. In vitro studies, SphK2-deficient perivascular cells expressed less inflammatory cytokines, such as Ccl2, Il6, Cxcl1, after LPS stimulation compared with control perivascular cells. SphK2-deficient and control perivascular cells robustly expressed Smads, but not Mifd2b, and S1pr1-3 among the five SIP receptor subtypes. Among S1pr1-3, only knockdown of S1pr1 resulted in suppressed expression of inflammatory cytokines after LPS stimulation.

Conclusions: SphK2 deletion in renal perivascular cells was protective against kidney fibrosis. In vitro studies suggested that SIP1 produced by SphK2 is exported through Smads and reacts with SIPR1 to enhance the inflammatory signal in these cells, leading to immune cell infiltration and subsequent fibrosis in the kidneys.

Histone Demethylase JMJD3 Protects Against Renal Fibrosis by Suppressing TGF-β and Notch Signaling

Chao Yu,1 Shuangqiang Zhang,1,2 Yuyi Wang,1,3 Shougang Zhang,1,2 Shanghai East Hospital, Shanghai Tongji University; 1Rhode Island Hospital, Brown University, Providence, RI; 2Shanghai East Hospital, Shanghai Tongji University, Shanghai, China.

Background: The JmjC domain-containing 3 (JMJD3), a specific histone demethylase for trimethylation on histone H3 lysine 27 (H3K27me3), is associated with the pathogenesis of many diseases, but its role in renal fibrosis remains unexplored. Here, we examined the role of JMJD3 and mechanisms involved in the activation of renal fibroblasts and development of renal fibrosis.

Methods: Murine models of 5/6 nephrectomy (SNx) and ureteral unilateral obstruction (UUO) were used to assess the effect of a specific JMJD3 inhibitor, GSK4J, and genetic deletion of JMJD3 from FOXD1-stroma-derived renal interstitial cells on the development of renal fibrosis and activation of renal interstitial fibroblasts. Cultured rat renal interstitial fibroblasts (NRK-49F) and mouse renal epithelial (mTECs) cells were also used to examine JMJD3-mediated activation of profibrotic signaling.

Results: JMJD3 and H3K27me3 expression levels were upregulated in the kidney of mice subjected to SNx, 5/6 and UUO. Pharmacological inhibition of JMJD3 with GSK 34 resulted in inhibition of Smad3 nuclear accumulation. A similar effect of JMJD3 led to worsening of renal dysfunction as well as increased deposition of extracellular matrix proteins and activation of renal interstitial fibroblasts in the injured kidney. This was coincided with decreased expression of Sma07 and enhanced expression of H3K27me3, transforming growth factor β1 (TGFB1), Smad3, Notch1, Notch3 and Jagged1. Inhibition of JMJD3 by GSK 14 or its specific siRNA also resulted in the similar responses in cultured NRK-49F and mTECs exposed to serum or TGFB1. Moreover, JMJD3 inhibition augmented phosphorylation of AKT and ERK1/2 in vivo and in vitro.

Conclusions: These results indicate that JMJD3 confers anti-fibrotic effects by limiting activation of multiple profibrotic signaling pathways and suggest that JMJD3 modulation may have therapeutic effects for chronic kidney disease.

Funding: NIDDK Support

Induction of CKD by Gene Deletion of Canonical Transient Receptor Potential 1 (TRPC1) Channels Independent of Hypertension and Nephromegaly Despite Diabetes and Metabolic Syndrome

Muhammad Mubeen Anwar, Usman A. Khan, Bonnie Eby, Kai Lau. The University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: TRPC1 gene on chromosome 3q22-24 is in the linkage region for diabetic nephropathy. Despite reduced expression in diabetes, no causal relationship has been established. Since mouse-null mice are obese, hyperterglycemicemic and diabetic with fatty liver, we evaluated potential renal phenotypes, testing the hypothesis of impaired Ca signaling, as we found reduced cell free Ca in bone, renal, and parathyroid cells.

Methods: From 3rd to 22nd mon, metabolic, cardiac & abdominal ultrasound (US) & clearance (CI) studies were done in age- & sex-matched littermates of TRPC1+/-, +/-, & +/- mice. Creatinine (Cr) was analyzed by creatininase or HPLC; glomerular filtration rate (GFR) by inulin Cl. Systolic (S) & diastolic (D) BP was measured by arterial (A) cannulation.

Results: Null mice were hyperglycemic from the 3rd mon & developed diabetes by 6 to 22 mon by standard IP glucose tolerance test. Nephromegaly was absent in null mice since kidney volume by US (0.38 vs. 0.46 at 7 mon & 0.4 vs 0.5 cc at 11-20 mon) was 16% smaller & kidney (K) to body (B) weight (W) (1.2 vs.1.5 % at 7 mon & 1.1 vs 1.5 % at 11-20 mon) was lighter by 17-28 %. Chronic injury & scarring were suggested by 37% increase in ecchogenicity at 20 mon, though normal at 7 or 11 mon. Urine albumin/Cr ratio in null mice rose barely (64-71%). But at 17 mon, CrCl fell by 30% (p<0.01) in null & by 46% (p<0.01) in null ci. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 46% (p<0.01) in null ♂.
Histone Deacetylase 6 Inhibition Mitigates Renal Fibrosis by Suppressing TGF-β/SMAD3 and eGFR Signaling Pathways
Xingying Chen,1 Shougang Zhang,2† Shanghai East Hospital /Shanghai East Hospital, Shanghai Tongji University, Shanghai, China; 2Rhode Island Hospital, Brown University, Providence, RI.

Background: We have recently shown that histone deacetylase 6 (HDAC6) is critically involved in the pathogenesis of acute kidney injury, however, its role in renal fibrosis remains unclear.

Methods: In this study, we examined the effect of ricolinostat (ACY-1215), a selective inhibitor of HDAC6, on the development of renal fibrosis in a murine model induced by unilateral ureteral obstruction (UUO).

Results: We found that HDAC6 was highly expressed in the kidney following UUO injury, which was coincident with deposition of collagen fibrils and expression of α-smooth muscle actin, fibronectin, and collagen III. Administration of ACY-1215 reduced these fibrotic changes and inhibited UUO-induced expression of transforming growth factor β1 and phosphorylation of Smad3. In vivo administration of Smad7. ACY-1215 treatment also suppressed phosphorylation of epidermal growth factor receptor and several signaling molecules associated with renal fibrogenesis, including AKT, signal transducer and activator of transcription 3 and Nf-kb in the injured kidney. Furthermore, ACY-1215 was effective in inhibiting differentiation of renal fibroblasts to myofibroblasts in cultured renal interstitial fibroblasts.

Conclusions: Collectively, these results indicate that HDAC6 inhibition can attenuate renal fibrosis development by suppression of TGFβF1 and EGFR signaling.

Cruical Role of STAT6 Signaling in Renal Fibrosis
Baihai Jiao,1 Changlong An,1 Yanlin Wang,1,2 University of Connecticut School of Medicine, Farmington, CT; 2VA Connecticut Health System, West Haven, CT.

Background: Kidney fibrosis is a pathologic characteristic of chronic kidney disease, resulting in progressive loss of kidney function to end-stage kidney failure. We have recently demonstrated that bone marrow-derived fibroblasts contribute to the pathogenesis of kidney fibrosis. In this study, we investigated the role of STAT6 in activation of bone marrow-derived fibroblasts and development of renal fibrosis in folic acid nephropathy.

Methods: To investigate the role of STAT6 in myofibroblast activation and kidney fibrosis, we used STAT6 knockout mice or treated wild-type mice with AS1517499, a STAT6 inhibitor. Wild-type mice treated with vehicle were used as controls. Folic acid was administered at 250 mg/kg intraperitoneally to induce kidney fibrosis. Kidneys were harvested 2 weeks after folic acid injection.

Results: Folic acid injury led to activation of STAT6 in the interstitial cells of the kidney, which was abolished by treatment with AS1517499. Wild-type mice treated with AS1517499 accumulated fewer bone marrow-derived fibroblasts in the kidneys following folic acid injury compared with vehicle-treated mice. AS1517499 treatment significantly inhibited myofibroblast activation, reduced total collagen deposition, and suppressed expression of extracellular matrix proteins after folic acid injury. Compared with wild-type mice, mice with STAT6 deficiency exhibited fewer myofibroblasts and myofibroblasts and expressed less α-SMA protein in the kidneys following folic acid injury. Furthermore, genetic deletion of STAT6 significantly reduced total collagen deposition and ECM protein production in the kidneys with folic acid nephropathy.

Conclusions: Our results demonstrate that STAT6 signaling plays an important role in the development of bone marrow-derived fibroblasts during folic acid nephropathy. AS1517499 may serve as a novel therapeutic agent for the treatment of chronic kidney disease.

The Role of HNF4α in CKD Progression
Marta Martinez-Calle, Guillaume Courbon, Xueyan Wang, Bridget Hunt-Tobey, Jadeah J. Spindler, Emily P. Lynch, Aline Martin, Valentin David. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Acquired kidney mitochondrial dysfunction is a prominent feature of Chronic Kidney Disease (CKD), and is associated with onset and progression of CKD. HNF4α is a transcription factor highly expressed in proximal tubules which controls the expression of genes involved in critical metabolic pathways. As a result, mutations in Hfes are associated with mitochondrial defects. We previously found that Hfes is reduced in the kidneys of Col4a3KO mice with progressive CKD and it correlated with hyperphosphaturia. Here we tested the hypothesis that kidney Hfes is reduced in response to hyperphosphatemia and that Hfes decline in CKD contributes to mitochondrial dysfunction and CKD progression.

Methods: We fed WT mice a control (C) or a high phosphate diet (HP) for 6 weeks. This confirmed that phosphorus reduction was less reduced in the kidneys Col4a3KO mice by RT-PCR and next performed RNA sequencing (RNAseq) to identify genes and molecular pathways affected by HNF4α reduction in CKD. Finally, to further evaluate the causal role of Hfes reduction in CKD progression, we treated Col4a3KO mice with a daily dose of 30µg/g of an Hfes inhibitor (BI-6015S) for 5 or 6 days.

Conclusions: We found that Hfes expression was significantly reduced in the kidneys Col4a3KO mice by RT-PCR and RNAseq compared to WT mice. Reduced Hfes expression was correlated with increased tubular H2AX phosphorylation as a marker of cellular stress. Furthermore, Hfes reduction was accompanied by increased expression of AKT1 and EGFR signaling. Finally, treatment of Col4a3KO mice with BI-6015S prevented the loss of Hfes expression and reduced H2AX phosphorylation in the kidneys, indicating that Hfes reduction is causally involved in the pathogenesis of CKD progression.

Inhibition of KIM-1-Mediated Fatty Acid Uptake by a Novel Inhibitor Attenuates Pro-Fibrotic Responses in Multiple Models of Human Primary Kidney Epithelial Cells Including Kidney Tubuloids
Yutaro Mori,1 Amrendra K. Ajay,1 Ankit B. Patel,1 Andrew M. Siedlecki,1 Seiji Kishi,2 Takaharu Ichimura,3 Joseph V. Bonventre.1 1Division of Renal Medicine, Department of Medicine, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA; 2Department of Nephrology, Tokushima University Hospital, Tokushima, Japan.

Background: Tubulointerstitial damage is strongly associated with many forms of kidney injury including diabetic kidney disease. Kidney Injury Molecule-1 (KIM-1), a scavenger receptor, is the most upregulated proximal tubule protein with kidney injury. We hypothesized that KIM-1-mediated uptake of fatty acids (FAs) contributes to tubulointerstitial damage.

Methods: Human DKD renal biopsy samples were analyzed. Human primary epithelial cells were cultured from the non-tumor kidney tissue removed from patients with a renal mass. To grow human renal tubuloids, primary cells were cultured on ultra-low attachment plates for several days. Cells were transferred into media containing multiple growth factors and 5% fetal bovine serum. Cells and tubuloids were treated with palmitate acid with certain groups having sRNA knockdown of KIM-1. Conditioned media from FA-treated human primary cells and tubuloids were applied to mouse primary kidney fibroblasts. An inhibitor for KIM-1-mediated FA-uptake was identified from media from FA-treated human primary cells and tubuloids were applied to mouse primary kidney fibroblasts. We hypothesized that KIM-1-mediated uptake of fatty acids (FAs) contributes to tubulointerstitial damage.

Results: KIM-1 expression in DKD patients was positively correlated with tubulointerstitial inflammation and fibrosis. FA-BSA uptake was markedly reduced in cells depleted of KIM-1 indicating the relative importance of KIM-1 to proximal tubule FA uptake. High-dose FA treatment increased cell death. FA treatment increased H2AX expression, a marker for DNA damage response. FA also increased the number of cells in the G2/M phase without an increase of those in S phase by cell cycle analysis, indicating that cells are likely arrested in G2/M phase. Our newly identified inhibitor for KIM-1, JB1, prevented FA uptake at least in part by inhibiting the direct binding of FA to KIM-1. JB1 reduced the pro-fibrotic effect of conditioned media from FA-treated human primary cells and tubuloids.

Conclusions: KIM-1 enhances the proximal tubular uptake of FA, leading to proximal tubule damage, pro-fibrotic responses and increase in cell death. Our findings support JB1 as a potential target for chronic kidney disease including DKD and our work introduces a new candidate therapeutic agent.

Funding: NIDDK Support, Commercial Support · Boehringer Ingelheim
Results: WT mice fed a HPI diet showed a significant 70% reduction in kidney HNF4α mRNA and protein expression, suggesting that hyperphosphatemia, a hallmark of progressive CKD, contributes to HNF4α downregulation in the kidney. Kidney molecular profiling by RNAseq of Col4a3α mice showed increased acquired mitochondrial dysfunction and reduced oxidative phosphorylation, suggesting that impaired mitochondrial function strongly contributes to CKD progression. Downstream pathway analyzes showed that the vast majority of these genes (~30%) are regulated by HNF4α. Pharmacological inhibition or HNF4α in Col4a3α mice led to an accelerated decline in kidney function (200% increase in BUN), demonstrating the crucial role of HNF4α in CKD progression.

Conclusions: These results suggest that HNF4α is a master regulator of mitochondrial function in kidney and might represent a novel therapeutic target to improve outcomes in CKD.

An In Vitro Model to Elucidate the Synthesis of Extracellular Matrix Proteins Involved in Renal Interstitial Fibrosis
Alexandra L. Moeller,1 Alexander L. Reese-Petersen,1 Daniel Guldager Kring,1,2 Rasmus H. Møller,1,2
Background: Accumulation of extracellular matrix (ECM) proteins is a hallmark of renal fibrosis, which can lead to altered tissue homeostasis, kidney failure, and ultimately death. Many different cell types are involved in this process, but fibroblasts are the main source of ECM proteins such as fibronectin, collagen type I (COL I), III (COL III), and VI (COL VI). Recently it was suggested that a fragment of COL VI released during collagen maturation is, in fact, a bioactive molecule (endotrophin; ETP) with signaling potential, indicating that collagens are not just passive structural proteins. In this study, we investigate the effect of transforming growth factor (TGF)-β and ETP on the synthesis of different ECM proteins by human renal fibroblasts in the scar-in-a-jar (SiaJ) cell model.

Methods: Cells were seeded in 48-well plates at 30,000 cells/well and incubated for 24h in DMEM + 10% FBS for adherence. Cells were starved by incubating them for further 24h in DMEM + 0.4% FBS. Fresh medium was added at day 0 with 225/150 mg/mL Ficoll 70/400 and 1% ascorbic acid, containing 0.02 nM TGF-β or either 12 or 30 nM ETP. Medium was changed and collected on days 3, 6, 10, and 13. Biomarkers of COL I (PRO-C1), III (PRO-C3), VI (PRO-C6), and fibronectin (FBN-C) formation were assessed in the medium by enzyme-linked immunosorbent assays developed at Nordic Bioscience.

Results: Stimulating renal fibroblasts with 0.02 nM TGF-β significantly increased the formation of COL I (P<0.0001), III (P<0.0001), and fibronectin (P<0.0001) compared to unstimulated cells. Interestingly, TGF-β treatment suppressed the formation of COL VI (P<0.0001) in unstimulated cells. Stimulation with 30 nM ETP significantly increased the formation of COL I (P<0.0001) and III (P<0.0001) compared to unstimulated cells. 12 nM ETP significantly increased the synthesis of fibronectin compared to unstimulated cells (P<0.0001).

Conclusions: Different growth factors induce different protein expression profiles in fibroblasts. Interestingly, ETP, which originates from the ECM, drives renal fibrosis through increasing COL I and III as well as fibronectin. This SiaJ model, combined with the investigated biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

FoxM1 Inhibition Ameliorates Renal Interstitial Fibrosis (RIF) by Decreasing Extracellular Matrix and Epithelial-to-Mesenchymal Transition
Wang Y. Hui,1,2 Qiaoling Zhou,1 (Xiayang Hospital, Central South University, Changsha, China; 1Department of Geriatrics, Guangzhou First People’s Hospital, School of Medicine, South China University of Technology, Guangzhou, China).

Background: FoxM1 is a transcriptional regulator involved in tumor development, pulmonary fibrosis, and cardiac fibrosis. However, its role in RIF has yet to be elucidated.

Methods: We established a TGF-β1-stimulated human proximal tubular epithelial cell (HK-2) model in vitro and a unilateral ureteral obstruction (UUO)-induced rat RIF model in vivo. FoxM1 inhibition was achieved by siRNA interference in vitro and by injecting thioestrene into UUO-induced RIF rats in vivo. The degree of renal damage and fibrosis were determined by histological assessment via hematoxylin and eosin staining. Immunohistochemistry, western blots, and qPCR were used to determine the expression levels of FoxM1, Collagen I, E-cadherin, α-SMA, and Snail1.

Results: FoxM1 inhibition could ameliorate RIF and reduce the deposition of Collagen I. H&E staining revealed that renal structural damage, inflammatory cell infiltration, and ECM deposition were significantly attenuated by thioestrene treatment in the UUO rats. FoxM1 downregulation significantly suppressed EMT, as evidenced by decreased protein and mRNA expression levels of α-SMA and Snail1 and a significant increase in protein and mRNA expression levels of E-cadherin.

Conclusions: FoxM1 inhibition could be a novel therapeutic strategy for the treatment of RIF.

PO0607
The Macrophage Recruitment in the Unilateral Ureteral Obstruction Is Associated with the Raise of MCP-1 and Is Dependent of Lipocalin 2 Expression
Stefanuy M. Figueroa, Mauricio A. Lozano, Carolina A. Lobos, Javier I. Reyes Osorio, Patricio A. Araos, Cristián A. Amarado. Laboratory of Renal Physiopathology Universidad Autonoma de Chile - Campus El Llano Subercaseaux, Santiago, Chile.

Background: The persistent renal inflammation has been proposed as a crucial mechanism at the early stages of renal disease. The macrophages recruitment, as part of the pathogenic events, depends of the monocyte chemoattractant protein-1 (MCP-1) release. In addition, studies in patients have demonstrated that neutrophil gelatinase-associated lipocalin (NGAL, also called Lipocalin-2), is overexpressed during early stages of renal lesion. However, whether NGAL is relevant for macrophages recruitment at renal level, and if this is related to the increase of MCP-1, remains unknown. Our objective was to determine whether NGAL promotes the pro-inflammatory status during the unilateral ureteral obstruction (UUO), characterized by the macrophage recruitment and the increase of MCP-1.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Male C57BL/6 wild type (WT) n YGAL-KO mice (8-12 weeks) were underwent 5/6 nephrectomy to Sham surgery (control group) or 3 and 7 days (n=5) in order to determine the associated damage at kidney level and the raise of MCP-1 in peripheral blood mononuclear cells (PBMC).

Results: In WT mice, the UO-induced luminal tubular dilation starting at 3 days (P<0.001 vs Sham), and an induction of plasma area (76.36 ± 5.37 μL/L, P<0.01 vs Sham). In addition, UO-induced increased NGAL levels in PBMC, plasma and urine (24.1 μg/L in Sham vs. 103.8 μg/L and 134.5 μg/L in UO, at 3 and 7 days, respectively). This was in accordance with the renal induction of NGAL (mRNA and protein, P<0.001 vs Sham), and associated with the elevation of the pro-inflammatory mediator, TGF-β, CCL5 (RANTES) and MCP-1, with a peak at 7-days. The genetic ablation of NGAL prevented tubular dilation (34.24 ± 6.55 μM). P<0.01 vs UO WT) and the rise of MCP-1 induced by UO in kidney and PBMC (P<0.01 vs. WT). This was accompanied with a low grade of macrophage recruitment in kidney of NGAL-KO mice underwent to UO (15.2% in WT vs. 7.3% in NGAL-KO).

Conclusions: The renal overexpression of MCP-1 and the macrophage recruitment induced by UO is dependent of NGAL presence. Our results suggest that NGAL, by a regulation on MCP-1, may be crucial for macrophage chemotraction during the early stages of renal disease. Acknowledgments. Enabled by TcOS-RTE-Tresp Proliferation Is Involved in the Pathogenesis of Active Systemic Lupus Erythematosus (SLE)

Florian Kälble, Christian Nissig1, Christian Morath, Martin G. Zeier, Matthias Schaeier, Andrea Steinborn-Kroehel1,

Department of Medicine I (Nephrology), University of Heidelberg, Heidelberg, Germany; 1Department of Obstetrics and Gynecology, University of Heidelberg, Heidelberg, Germany.

Background: Dysfunction of CD4+ regulatory T-cells (Tregs) and CD4+ responder T-cells (T-resps) is an important trigger in the development of active systemic lupus erythematosus. However, underlying mechanisms are not fully understood. Objective: In this study, the roles of the different subsets of inducible costimulatory molecule (ICOS)- and ICOS-L TcOS/Tresps, their percentages of CD45RA CD31- CD3 CD122+Foxp3+ RTE-Tresps and ICOS-LCD45RA CD31-CD3 CD122+Foxp3+ RTE-Tregs were analyzed at baseline in order to determine the associated damage at kidney level and the raise of MCP-1 in peripheral blood mononuclear cells (PBMC).

Results: In WT mice, the UO-induced luminal tubular dilation starting at 3 days (P<0.001 vs Sham), and an induction of plasma area (76.36 ± 5.37 μL/L, P<0.01 vs Sham). In addition, UO-induced increased NGAL levels in PBMC, plasma and urine (24.1 μg/L in Sham vs. 103.8 μg/L and 134.5 μg/L in UO, at 3 and 7 days, respectively). This was in accordance with the renal induction of NGAL (mRNA and protein, P<0.001 vs Sham), and associated with the elevation of the pro-inflammatory mediator, TGF-β, CCL5 (RANTES) and MCP-1, with a peak at 7-days. The genetic ablation of NGAL prevented tubular dilation (34.24 ± 6.55 μM). P<0.01 vs UO WT) and the rise of MCP-1 induced by UO in kidney and PBMC (P<0.01 vs. WT). This was accompanied with a low grade of macrophage recruitment in kidney of NGAL-KO mice underwent to UO (15.2% in WT vs. 7.3% in NGAL-KO).

Conclusions: The renal overexpression of MCP-1 and the macrophage recruitment induced by UO is dependent of NGAL presence. Our results suggest that NGAL, by a regulation on MCP-1, may be crucial for macrophage chemotraction during the early stages of renal disease. Acknowledgments. Fondoedy #1201251 and Fondoedy #1201016
calculated by the ratio of kynurenine and tryptophan. Correlations between indicators were analyzed. The ROC curve was also performed.  

**Results:** WT AKI mice revealed elevated expression of IDO and worse kidney function. PAS staining exhibited less loss of tubular epithelial cells and atrophy tubules in IDO−/− AKI mice. In addition, fibrosis markers, including α-SMA, fibronectin and vimentin, were more severe in WT AKI mice. GSK-3β and β-catenin were significantly declined in IDO−/− AKI mice. On top of that, PGE2 administration reduced elevated IDO expression and decreased levels of GSK-3β and β-catenin resulting in lower expressions of α-SMA, fibronectin and vimentin in WT AKI mice. In patients, IDO had negative correlations with eGFR (r=−0.742, p<0.001). Further, the linear regression showed IDO was an independent influence factor of eGFR. ROC curve showed the area under the ROC curve was 0.825 for IDO.  

**Conclusions:** IDO could activate Wnt/β-catenin pathway to induce kidney fibrosis. PGE2 could ameliorate kidney fibrosis via inhibiting IDO expression.

Scatter plot of IDO associated with eGFR

**CKD of Unknown Origin (CKDuo): Is the Problem Dehydration, Water Contamination, or Both?**  
**Vito M. Campese,1 Alessia Fornoni,2 Yan Zhong,1 Keck School of Medicine of USC, Los Angeles, CA; 2University of Miami, Miami, FL.**  

**Background:** An increasing number of people of Central America develop CKDuo. The disease is characterized by chronic tubulo-interstitial nephritis. Occasionally, it presents as an acute kidney injury (AKiao). The cause(s) remain unknown. Some sustain that dehydration is responsible. Others believe the disease is caused by water contaminated with heavy minerals or agrochemicals. To prevent dehydration, workers in these regions ingest 8-12L of water/day. Hence, even if concentrations of toxins are in “acceptable range”, the cumulative intake may reach toxic levels. If this hypothesis is correct, purified water should reduce the incidence of the disease. In 2017 a Nicaraguan sugarcane factory (SER) adhered to the Adelante initiative, consisting of reducing working hours, exposure to heat and dehydration. In 2017-18, these measures had no impact on the incidence of AKiao.  

**Methods:** During the 2019 season, SER adopted the policy of providing highly purified drinking water to > 6000 workers (1L/hour during working hours). The effects on AKiao were monitored. Comparisons were made of the monthly incidence of AKiao during years 2017, 2018 and 2019, by One-way ANOVA.  

**Results:** With the introduction of purified water, the incidence of AKI decreased from 4.0±1.3 cases in 2017 and 3.4±2.1 in 2018 to 2.0±1.5 cases/1000 workers/month in 2019 (P<0.02).  

**Conclusions:** Although preliminary, these data support the hypothesis that contaminated water may play a major role in AKiao. This raises enormous public health issues. If dehydration is responsible, the remedies are hydration and less heat exposure. If toxins and agrochemical are responsible, the remedy is providing highly purified water to those at risk. The potential impact of these measures on CKDuo remains to be determined.

**Effects of Chronic Intermittent Hypoxia on umod−/− Rats’ Model Link to Alterations of Gut Microbiota**  
**Na Wang, Yuqiang Chen. Renal division, Peking University First Hospital, Beijing, China.**  

**Background:** Previous studies showed that both obstructive sleep apnea and uromodulin (UMOD) were associated with gut microbiota regulation. Here we explored the interaction effects of chronic intermittent hypoxia (CIH) and UOMD expression on variation of gut microbiota and association with phenotype.  

**Methods:** umod−/− and wild type (WT) Sprague Dawley rats were attributed into 4 groups (N=10 in each group), umod−/− and WT under CIH, umod−/− and WT under normal air. All four groups were fed with same chaw for 10 weeks. All rats were anesthetized to collect fecal samples from large intestine directly and blood at the end of weeks feeding. The bacterial composition was analyzed based on 16S ribosomal DNA pyrosequencing. Bioinformatics tools, including sequence alignment, abundance, and taxonomic diversity, were used in microbiome data analyses. Correlation analysis between differential genera and changed biochemical indicators were measured.
Results: Under normoxia, the serum phosphorus(P*) tend to be lower in umod-/- group compared with WT group (1.9±0.2 vs 2.1±0.2mmol/L, P=0.064). Under normoxia environment, the r-diversity of gut microbiota decreased in umod-/- group compared with WT group (Chao1 index, 301.8±55.3 vs 374.3, P=0.005), and the composition of microbiota was clearly separated between two groups (PCoA, P=0.001). The abundance of g-Lactobacillus (P=0.002) and g-Phascolarctobacterium (P=0.026) increased and g-Ruminococcus (P=0.023) decreased in umod-/- group compared with WT group. g-Ruminococcus showed positive relationship with serum phosphorus (R=0.511, P=0.043). When CIH was added as an environment condition, the serum phosphorus(P*) increased in umod-/- group obviously (2.3±0.3 vs 1.8±0.2 mmol/L, P=0.002). Gut composition in umod-/- were still clearly separated from WT (PCoA, P<0.001). The abundance of g-Lactobacillus, g-Phascolarctobacterium and g-Ruminococcus showed no difference. The abundance of g-Blautia (P=0.008), g-Sutterella (P=0.008), g-Anaerostipes (P<0.008) increased and g-Flavonifractor (P=0.008) and g-Anaerotruncus (P=0.008) decreased in umod-/- CIH group compared with wild type CIH group. G-Sutterella showed positive relationship with Phosphorus (R=0.831, P<0.001).

Conclusions: Chronic intermittent hypoxia can interact with uromodulin to affect serum phosphorus in umod-/- rats. These changes were strongly linked to the alterations in gut microbiota.

PO0616

Influence of Colonic Dialysis on the Distribution of Gut Microbiome in CKD Stage 3-5 Patients

Hui Xu, Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.

Background: Chronic kidney disease (CKD) becomes a major public health challenge given high incidence rates in the world. colonic dialysis (CD) has been used in pre-dialysis CKD patients (CKD3-5) in many hospitals of China because of its advantages of simple operation, low price and few complications. The gut microbiome is a potential cause of CKD progression and serve as a promising therapeutic target. We raise the question that whether CD improve renal function by affecting intestinal microbiome in CKD3-5 patients. Improving the imbalance of intestinal microbiome is considered a potential therapeutic target to decline chronic kidney disease(CKD) progression. We aimed to investigate the influence of colonic dialysisd(CD) on the distribution of gut microbiome in CKD3-5 patients.

Methods: We studied gut microbiota in 50 patients with CKD, 25 CD patients, 25 outpatients(OP), and compared to 34 healthy subjects(HS). The gut microbiome composition was analyzed by a 16S ribosomal RNA(16S rRNA) gene-based sequencing protocol.

Results: We found that there was no significant difference in the richness of intestinal microbiota between CD and HS, but the richness of bacterial in OP decreased significantly (HS VS. OP p = 0.002). CD can increase the abundance of some short chain fatty acid(SCFA) producing bacteria and decrease the abundance of some uremic toxin producing bacteria. CD also can increase the abundance of some anaerobic bacteria in intestine. Compared with OP, the profile of intestinal microbiota in CD group and HS group was more similarity.

Conclusions: Our study reveals CD treatment alters microbiome profile and increases microbiome richness in CKD3-5.

PO0617

Asymptomatic Hyperuricemia, a Regulator of Innate Immunity in CKD

Stefanie Steiger,1 Qiuyue Ma,1 Paola Romagnani,2 Hans J. Anders.1 1Division of Nephrology, Department of Medicine IV, LMU Hospital, Munich, Germany; 2Department of Biomedical Experimental and Clinical Sciences Maria Serio, University of Florence, Florence, Italy.

Background: Asymptomatic hyperuricemia (HU) is common in patients with chronic kidney disease (CKD) but the causative role of HU on CKD progression remains controversial. Two large multi-center randomized controlled trials, CKD-FIX and PERL study, have now disproven a causal relation. On the other hand, a causative role of HU exists with gout but a rapid correction of HU with urate lowering therapy can also elicit acute gout attacks. This suggests a more complex role of HU in this context. Hence, we hypothesized that soluble uric acid (sUA) has immunomodulatory effects on neutrophil function during the immune response to monosodium urate (MSU) crystals.

Methods: Alb-creERT2;Glut9lox/lox and Glut9lox/lox control mice were injected with tamoxifen and placed either on a chow or acidogenic diet with inosine to induce HU with or without CKD. After 3 weeks, MSU crystals or vehicle were injected into air pouches or postcapillary venules in the cremaster muscle of transgenic mice. Leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, intravital microscopy, and ELISA. Blood neutrophils were isolated from CKD stage G2-4 and GSD patients or healthy individuals and neutrophil transwell migration assays performed.

Results: We found that HU impaired leukocyte recruitment into MSU crystal-injected air pouches of mice with or without CKD. Intravital microscopy revealed that HU specifically reduced leukocyte adhesion, extravasation, and tissue inflammation. The CKD-mediated attenuation of MSU crystal-induced inflammation was fully reversible by treating HU with urate lowering therapy. In neutrophils isolated from healthy individuals, sUA diminished β2 integrin activation and expression, and hence impaired neutrophil migration ex vivo. This process was dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. An impaired migratory capability was also observed in neutrophils from CKD patients.

Conclusions: We identify sUA as an endogenous modulator of innate immunity. HU modulates neutrophil migration by altering efficient β2 integrin activation via SLC2A9 in gouty arthritis related or unrelated to CKD. This process provides a molecular explanation for several previously unexplained clinical phenomena in the context of gout and renal failure.

Serum Lysyl Oxidase Is a Potential Diagnostic Biomarker for Kidney Fibrosis
Qiaoxin Zhang, Chen Yu. Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, China, China.

Background: Kidney fibrosis is the ultimate consequence of advanced stages of chronic kidney disease (CKD); however, there are currently no reliable biomarkers or noninvasive diagnostic tests available for the detection of kidney fibrosis. Lysyl oxidase (LOX) promotes collagen crosslinking, and serum LOX levels have been shown to be elevated in patients with fibrosis of the heart, lungs and liver. However, serum LOX levels have not been reported in patients with kidney fibrosis. We explored whether serum LOX levels are associated with kidney fibrosis.

Methods: Overall, 202 patients with kidney disease underwent renal biopsy, scoring of kidney fibrosis and determination of the area of kidney fibrosis. LOX levels were measured in serum and in kidney tissues. We analyzed the association of circulating LOX and tissue LOX levels with the scores and areas of kidney fibrosis. LOX expression was also investigated in vitro and in vivo in kidney fibrosis models.

Results: Serum LOX levels were higher in patients with kidney fibrosis than in those without kidney fibrosis (p<0.001) and higher in patients with moderate-severe kidney fibrosis than in patients with mild kidney fibrosis (p<0.001). Both serum LOX and renal tissue LOX levels correlated with the area of kidney fibrosis (r=0.74, p<0.001; r=0.899, p<0.001, respectively). ROC curve analysis of serum LOX showed an AUC of 0.80 (95% CI: 0.74 to 0.86). The optimal serum LOX level cutoff point was 235.34 ng/ml for the prediction of kidney fibrosis and 306.56 ng/ml for the prediction of moderate-severe renal fibrosis. LOX expression levels were significantly upregulated (2.3-2.6-fold and 6-fold, respectively) in vivo and in vitro fibrosis models.

Conclusions: Both serum LOX and tissue LOX levels correlated with the presence and degree of kidney fibrosis in patients with CKD. These results suggest that serum LOX, in addition to potential use as a noninvasive diagnostic biomarker for kidney fibrosis, may further potentially serve as a stratified biomarker for the identification of mild and moderate-severe kidney fibrosis.

APOL1 Risk Variants Mediate Increased Oxidative Phosphorylation Complexes Biogenesis and Mitochondrial Dysfunction

Mengyuan Ge,1 Gloria Michelle Ducasa,1 Shamroop Kumar Mallela,1 Shaorui Liu,2 Hazel H. Szeto,2 Jeffrey B. Kopf,1 Flavia Fontanesi,1 Sandra M. Merscher,1 Alessia Fornoni,1 Katz Family Division of Nephrology and Hypertension/ Drug Discovery Center, University of Miami, MI; 2Social Profit Network Research Lab, Alexandria LaunchLabs, New York, NY; 3Kidney Disease Section, NIDDK, NIH, Bethesda, MD; 4Department of Biochemistry and Molecular Biology, University of Miami, Miami, FL.

Background: Susceptibility to focal segmental glomerulosclerosis (FSGS) in African Americans is associated with genetic variants of the Apolipoprotein L1 gene (APOL1) named G1 and G2. APOL1 risk variants (RV) are a major driver of mitochondrial dysfunction. The mitochondrial specific lipid cardiolipin (CL) interacts with oxidative phosphorylation (OXPHOS) complexes and plays an important role in the biogenesis of OXPHOS complexes. While APOL1 function was assessed in tagged and overexpressed systems, studies evaluating the functions of endogenous APOL1 protein are missing.

Methods: We studied mitochondrial function using human urinary podocyte-like epithelial cells (HEKs) established from patients with FSGS carrying different APOL1 alleles. Protein and mRNA levels were measured by WB and quantitative PCR respectively. TEM was performed to study mitochondrial morphology. OXPHOS complexes were studied by BN-PAGE analysis followed by WB. To study how APOL1 RV contributes to mitochondrial dysfunction, we purified APOL1-6xHis protein using HeLa cells infected with lentivirus carrying the APOL1 G0, G1 under the CMV promoter, followed by protein-lipid overlay assay.

Results: The expression of endogenous APOL1 was decreased in HEKs carrying RVs (G1/G2 HEKs) when compared to G0/G0 carrying HEKs. We observed reduced mitochondrial function in the presence of increased OXPHOS complexes in G1/G2 HEKs. Using TEM, reduced mitochondrial matrix density and increased mitochondrial area were detected in G1/G2 HEKs. Hyperbranched mitochondria in G1/G2 HEKs was confirmed by the mRNA levels of mitochondrial fission and fusion proteins FIS1 and MFN1. The affinity of APOL1 G1 to CL was significantly higher than the affinity of APOL1 G0 to CL, when normalized to 6xHis tagged APOL1 expression. We found the mRNA level of cardiolipin synthase (CLS1) was significantly increased in G1/G2 HEKs, which is consistent with the overexpression of OXPHOS complexes in G1/G2 HEKs.

Conclusions: Our findings indicate that endogenous APOL1 RV expression in human podocytes is associated with mitochondrial dysfunction in the presence of increased OXPHOS complexes, and that APOL1 RVs interact with CL thus interfering with CL function in mitochondria.

Uncovering Genomic Alterations in DOCA-Salt Nephropathy Rats Treated with Finerenone

Junnan Wu,1 Ziyuan Ma,1 Hana Cernecka,2 Ralf Lesche,1 Peter Kolkhof,1 Katalin Susztak,1 University of Pennsylvania, Philadelphia, PA; 2Bayer AG, Leverkusen, Germany.

Background: The aldosterone antagonist spironolactone has antifibrotic effects but its clinical use is limited due hyperkalemia, especially in patients with kidney disease. The aldosterone antagonist finerenone has recently been developed with pronounced antifibrotic activity at doses which have only limited side effects. Our study shows that the novel nonsteroidal and selective mineralocorticoid antagonist finerenone has recently been shown to have pronounced antifibrotic activity at doses which have only limited side effects. We investigated whether finerenone has antifibrotic activity at doses which have only limited side effects.

Methods: We tested the effects of finerenone on mitochondrial function in G1/G2 HUPECs. We observed reduced mitochondrial function in the presence of increased OXPHOS complexes in G1/G2 HUPECs. Using TEM, reduced mitochondrial matrix density and increased mitochondrial area were detected in G1/G2 HUPECs. Hyperbranched mitochondria in G1/G2 HUPECs was confirmed by the mRNA levels of mitochondrial fission and fusion proteins FIS1 and MFN1. The affinity of APOL1 G1 to CL was significantly higher than the affinity of APOL1 G0 to CL, when normalized to 6xHis tagged APOL1 expression. We found the mRNA level of cardiolipin synthase (CLS1) was significantly increased in G1/G2 HEKs, which is consistent with the overexpression of OXPHOS complexes in G1/G2 HEKs.

Conclusions: Our findings indicate that endogenous APOL1 RV expression in human podocytes is associated with mitochondrial dysfunction in the presence of increased OXPHOS complexes, and that APOL1 RVs interact with CL thus interfering with CL function in mitochondria.

Cell Type-Specific Chromatin Architecture Reveals Target Genes for Kidney Disease Risk Variants

Jingping Yang,1,2 Aiping Duan,1 Zhihong Liu,1 National Clinical Research Center of Kidney Diseases, Jining Hospital, Nanjing, China; 2Nanjing University, Nanjing, China.

Background: Although GWAS studies have identified hundreds of genetic variants associated with kidney diseases, the identification of causal variants and their target genes are rather limited. Most of disease-associated variants locate in non-coding elements. The roles of these elements are cell type-specific. Additionally, due to the non-linear regulation of the elements, the identification of causal variants as well as their target genes is even more challenging. In order to understand the genetic risk of kidney diseases, we generated a cell type-specific set of epigenetic landscape including transcription-centered 3D chromatin organization, histone modifications distribution and transcriptome with epigenetic annotation to identify causal variants and target genes which were further tested by CRISP techniques in zebrafish.

Results: We identified genome-wide functional elements and thousands of interactions between the distal elements and target genes. The results revealed that risk variants for renal tumor and chronic kidney disease were enriched in kidney tubule cells. We further pinpointed the target genes for the variants and validated two target genes by CRISP techniques in zebrafish, demonstrating that SLC24A1 and MX1 were indispensable genes to maintain kidney function.

Conclusions: Our results produce valuable multi-omic resource and establish a bioinformatic pipeline in dissecting functions of kidney diseases-associated variants based on cell type-specific epigenetic landscape.

A Comprehensive Transcriptome Profiling of Adipocyte Na-K-ATPase Signaling in Uremic Cardiomyopathy by RNA Sequencing Analysis

Komal Sodhi, Joan C Edwards School of Medicine at Marshall University, Huntington, WV.

Background: Oxidant stress plays a key role in the development and progression of uremic cardiomyopathy. We have recently demonstrated that adipocyte dysfunction and uremic cardiomyopathy developed in partial nephrectomy mice model, were significantly ameliorated by adipocyte-specific expression of NaKide, an antagonist of Na-K-ATPase signaling. Hence, to better characterize the cellular transcriptome that are involved in various biological pathways associated with adipocyte function, we aim to explore the genomic approach in the present study, through RNAseq analysis.

Methods: For in vitro studies, mouse adipocytes were subjected to oxidized LDL (oxLDL) or indoxyl sulfate (IS) with or without pNaKide treatments. Partial nephrectomy was performed in C57Bl6 mice in order to produce experimental uremic cardiomyopathy. Specific expression of NaKide in adipocytes was achieved using a lentivirus construct driven by an adiponectin promoter. A complete RNAseq analysis was performed using DESeq2 R package in combination with packages to perform over-representation analysis (ORA) and gene set enrichment analysis (GSEA).

Results: Several gene subsets corresponding to various biological processes and molecular phenotype were differentially expressed in adipocytes with or without oxLDL/IS treatments and in vivo PNx model. These genes, compared using GSEA analysis, showed that more than 75% of the Kegg pathways were similar among the in vitro treatments and in vivo model. The pathways that were common between in vitro and in vivo treatments, including adipogenesis, ROS signaling, inflammatory response and gene expression, showed profound impact on the pathogenesis of uremic cardiomyopathy. The overall analysis showed a widespread normalization of gene expression by pNaKide/adipose specific NaKide treatments that were altered in uremic cardiomyopathy.

Conclusions: The study provides a detailed genome-wide molecular information about adipocyte function in relation to uremic cardiomyopathy pathogenesis. These data provide deeper insight into the activation of pathways associated with adipocyte Na-K-ATPase signaling, which may be a viable clinical target for the prevention and treatment of uremic cardiomyopathy.

Funding: Private Foundation Support
Results: Histopathological analysis and urinary Kim-1 at Nx and sacrifice confirmed mild tubulointerstitial fibrosis at Nx in Nep25/DTR- but not Nep25/DTR+ mice, and more severe glomerulosclerosis and albuminuria at sacrifice after LMB2 in Nep25/DTR- vs Nep25/DTR+ mice. RNA sequencing revealed 283 differentially expressed genes between the groups, with 93 over-represented and 190 under-represented in Nep25/DTR- vs Nep25/DTR+. GO of biological processes showed involvement in 13 processes, with the highest amount of genes involved in cellular processes, biological regulation and metabolic processes. STRING analysis of protein-protein interactions (PPI) based on cellular processes detected interactions between the Serpin family members: plasminogen activator inhibitor PAI-1 (Serpine1), alpha-1-antitrypsin 1-2 (Serpinha1b), protein Z-dependent protease inhibitor (Serpine10) and complement C4b (C4b). In addition, members of the non-canonical Wnt signalling pathway Wnt-9a (Wnt9a) and Wnt-10a (Wnt10a) and their interactors latent transforming growth factor beta binding protein 2 (Lbp2) and VANGL planar cell polarity protein 2 (Vangl2) were over-represented and PPI of these genes was found. Quantitative real-time PCR confirmed numerically higher expression of all above-mentioned genes in Nep25/DTR- mice.

Conclusions: High-throughput RNA sequencing of isolated tubules with mild injury revealed potential novel mediators of glomerular sensitization to a subsequent injury. Further experimental validation of the effects of the identified molecules on glomerular injury are warranted.

A Novel Short ACE2 Variant Causes ACE Suppression and Fosters Ang 1-7 Formation in a Murine Model of CKD

Gvantca Gulan,1,2 Jan Wysocki,1 Arndt Schulze,1,2 Minghao Ye,1 Chad R. Haney,1 Ming Zhao,1 Zheng J. Zhang,1 Daniel Batlle,1,2 Northwestern University Feinberg School of Medicine, Chicago, IL; 2Charite Universitätsmedizin Berlin, Berlin, Germany.

Background: ACE2 is a monocalboxypeptidase that cleaves Ang II to form Ang-(1-7).

It is a large molecule the administration of which leads to increased enzyme activity in plasma, but not in the urine or kidney tissue. We have developed a truncated form of ACE2 that has a longer half-life by fusing it with an Albumin-binding domain (ABD) and is still short enough to be filtered by the kidney. In this study we examined the impact of this novel variant of ACE2 on kidney RAS in a model of CKD.

Methods: We used a 5/6 Nephrectomy model in CD-1 mice. The ACE2-ABD was given 3 days post-ablation surgery and thereafter every 3-4 days (3 ug/g BW) for 5 weeks. Afterwards, mice were euthanized and kidneys collected for analyses of RAS components.

Results: Administration of ACE2-ABD resulted in increased plasma ACE2 activity (768 vs. 12 RFU/ug/hr, p=0.0001). In kidney lysates there was also an increase in ACE2 activity (32 vs. 22 RFU/ug protein/hr, p=0.03) and a decrease in ACE activity (7187 vs. 4006 RFU/ug protein/hr, p=0.0001). These changes in enzymatic activities were accompanied by a significant increase in kidney Ang-(1-7) (90 vs. 37 fmol/mg protein, p=0.0014) without a significant change in Ang II levels (272 vs. 299 fmol/mg protein). To verify the kidney uptake of our ACE2 variant SPECT/Micro-CT imaging was performed. After the injection of radiolabeled ACE2-ABD kidney uptake was clearly seen (red) (Figure).

Conclusions: A long-acting form of a short ACE2 variant fused with ABD given every 3-4 days resulted in sustained plasma ACE2 activity and an increase in kidney ACE2 activity associated with suppressed kidney ACE activity. These enzymatic changes provide a favorable kidney RAS profile with increased Ang-(1-7), which overall should be renoprotective.

Disruption of the H3K4 Methyltransferase MLL-1/Menin Complex Attenuates Renal Fibrosis Development by Inhibiting Epithelial-Mesenchymal Transition and Fibroblast Activation

Jianan Zou, Shougang Zhuang. Rhode Island Hospital, Brown University Rhode Island Hospital, Brown University Providence, China.

Background: The MLL-1/menin was disrupted by MI-503 and/or siRNA in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), cultured mouse proximal tubular cells and fibroblasts exposed to serum and transforming growth factor β1 (TGFβ1). Protein expression or activation was determined by immunofluorescent microscopy and immunoblot analysis.

Methods: The MLL-1/menin was disrupted by MI-503 and/or siRNA in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), cultured mouse proximal tubular cells and fibroblasts exposed to serum and transforming growth factor β1 (TGFβ1). Protein expression or activation was determined by immunofluorescent microscopy and immunoblot analysis.

Results: Injury to the kidney increased MLL1 and menin expression and H3K4 monomethylation (H3K4me1) in renal tubular epithelial cells and fibroblasts. Administration of MI-503, a highly selective inhibitor of the MLL1/menin complex, attenuated renal fibrosis and expression of α-smooth muscle actin, fibronectin and collagen I. Treatment with MI-503, MLL1 siRNA or menin siRNA also inhibited TGFβ1 and serum-induced activation of epithelial-mesenchymal transition (EMT) in vitro. Moreover, UUO injury induced epithelial expression of phospho-histone 3 at Serine 10 and expression of profibrotic factors, TGFβ1 and connective tissue growth factor; and blocking the MLL1/menin complex with MI-503 inhibited these responses. Finally, MLL1 inhibition reduced expression of snail and twist, two transcription factors involved in the development of EMT and renal fibrosis and the expression of proliferating cell nuclear antigen, cyclin D1 and p27 in fibroblasts.

Conclusions: Our data suggest that targeting disruption of the MLL1/menin complex can attenuate renal fibrosis through inhibition of EMT and fibroblast activation/ proliferation.

CKD progression. The fibrosis program. These findings may contribute to understanding the pathogenesis of the absence of THP. The absence of THP may also prime the TALs cells towards a THP deficiency, many close and distant genes are regulated by the in vivo from mouse kidneys. Although highly expressed genes in TAL may not be altered by THP deficiency, many close and distant genes are regulated by the promoter region of the Umod locus (Gp2) on chromosome 7. However, many other affected genes were on different chromosomes. Bioinformatic analysis revealed that THP deficiency is associated with significant clustering of genes involved in connective tissue formation and activation or dysfunction of molecular mechanisms that could lead to fibrosis.

Conclusions: We delineated a comprehensive transcriptomic profile of TAL cells in vivo from mouse kidneys. Although highly expressed genes in TAL may not be altered by THP deficiency, many close and distant genes are regulated by the Umod locus or altered by the absence of THP. The absence of THP may also prime the TALs cells towards a fibrosis program. These findings may contribute to understanding the pathogenesis of CKD progression.

Lipid Metabolic Profiling of Ex Vivo Isolated Glomeruli as a Screening Platform for Modelling Glomerular Metabolic Dysfunction During Renal Disease

Simone Rontal,1 Lynn N. Krause,2 Julian L. Griffin,2 Pernille B. Laerkgaard Hansen,1 Kevin Woollard,1 Renal Bioscience ex-vivo glomerular team 1Bioscience Renal, Research and Early Development, Cardiovascular; Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 2University of Cambridge Department of Biochemistry, Cambridge, United Kingdom.

Background: Dysregulated renal metabolism is a hallmark of loss of function in CKD. It is established that changes in tubular metabolism impact tubular functionality during progression of CKD. However, lipid metabolism in the glomerulus during CKD remain poorly described. Here, we use Isolated Glomeruli (IRG) to study lipid metabolism for metabolic drug discovery in kidney diseases.

Methods: Sprague Dawley rat glomeruli were isolated by differential sieving. We used renal disease inducers: Adriamycin 1uM (ADR) and AngiotensinII 100nM (AngII) for 24h. To probe metabolic activity, we used an LC-MS approach to quantify uptake and excretion rates of relevant metabolites in culture media, and to measure intracellular metabolites and lipids.

Results: We developed a new cultivation protocol for IRG, using organoids media and shaking platform to maximizing the biological activity. Metabolic and lipidomic profiles of IRG were monitored up to 150h. We saw significant metabolic activity for relevant metabolites in culture media, and to measure intracellular metabolites and lipids.

Conclusions: We developed a new cultivation protocol for IRG, using organoids media and shaking platform to maximizing the biological activity. Metabolic and lipidomic profiles of IRG were monitored up to 150h. We saw significant metabolic activity for relevant metabolites in culture media, and to measure intracellular metabolites and lipids.

Study on the Mechanism of Microinflammation with Uremia Caused by Lactobacillus Activation of Intestinal Macrophages by Mingle Lingshuang Sun, Hongli Jiang. First Affiliated Hospital of Medicine School, Xi’an Jiaotong University, Xi’an, China.

Background: My previous studies have found that Intestinal macrophages in the uremic rats are polarized towards a proinflammatory phenotype and assist bacterial translocation resulting in microinflammation. However, it is still unclear what kind of mechanism activates intestinal macrophages in uremia.

Methods: Male Sprague-Dawley rats were randomly divided into two groups: sham, uremia. Immunohistochemistry was used to analyze the expression of macrophage-inducible C-type lectin (Mincle). RT-PCR and western blot were employed to assess the mRNA and protein expression of toll-like receptor 4 (TLR4).

Results: Our RCT study found that the number of Lactobacillus in the intestines of patients with end-stage diabetic nephropathy was significantly higher than that in non-diabetic patients. The plasma levels of endotoxin, CRP, IL-6, and TNF-a in the uremia group were greater than those in the sham group (p<0.05)(Table 1). Compared with the sham group, the uremia group exhibited macrophages with higher staining intensities for Mincle and higher mRNA and protein expression of TLR4(Figure1-2).

Conclusions: The solution to this scientific problem will not only clarify the molecular mechanism of intestinal bacteria in controlling the activation of intestinal macrophages, but also to clarify the micro-inflammation state of uremia.

Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion

Yoko Fujita,1 Takeshi Sugaya,1 Daisuke Ichikawa,1 Jun Tanabe,1 Kenjirou Kimura,2 Yugo Shibaegaki,1 Atsuko Ikemori,1,3 Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; 2JCHO Tokyo Takanawa Hospital, Tokyo, Japan; 3Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. The aim of this study is to reveal whether suppressed activation of angiotensin II type 1a receptor (AT1a) ameliorates severe chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR).

Methods: To induce severe chronic TID after IR, unilateral renal ischemia for 45 min was performed via clamping of right renal pedicle using cerebral aneurysm clip in AT1a knockout homo (AT1a−/−) male mice and wild type (AT1a+/+) male mice. Right and left kidneys were removed at 3, 28 and 70 days postischemia. Left kidneys were used as control. Furthermore, another AT1a−/− mice were administered hydralazine to maintain the same levels of systolic blood pressure (SBP) as the AT1a+/+ mice because the SBP levels of the AT1a−/− mice were significantly lower compared to the AT1a+/+ mice.

Results: Acute tubular necrosis in IR-kidneys of both AT1a−/− mice and AT1a+/+ mice was observed at 3 days postischemia, and the degree was significantly more severe in the IR-kidneys of AT1a−/− mice than in the IR-kidneys of AT1a+/+ mice. Conversely, the degrees of both interstitial fibrosis at 28 and 70 days postischemia and proximal tubular loss at 70 days postischemia were significantly attenuated in the IR-kidneys of AT1a−/− mice compared to the AT1a+/+ mice. While marked renal atrophy at 70 days postischemia was induced in the AT1a+/+ mice, such a development was not provoked in the AT1a−/− mice.

Conclusions: Early administration of Ang II type 1 receptor blocker in recovery phase after AKI may be useful for prevention of AKI-to-CKD transition.

Anti-Interleukin 22 Antibody Relieves Angiotensin II-Induced Renal Injury in Mice Through Inhibiting NLRP3 Inflammasome Activation

Rong Jiang1, Hao-Jie Zhong2, Chang-Jian Zhu1, Yi Zhou1. The first Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 2Guangdong Medical University, Guangzhou, China.

Background: Group 3 Inflammasome Lymphocytes (ILC3) belong to a new family of innate leukocytes participating in lots of inflammatory and fibrotic diseases. However, limited information exists on the molecular mechanisms regulating these cells. Here, we investigated the expression and function of the immune checkpoint programmed cell death-1 (PD-1) in ILC3 during fibrosis.

Methods: Unilateral ureteral obstruction (UOO)-induced renal injury tested subsets of ILC3 activities in immune response and tissue fibrosis. Kidney and intestine were collected to define the frequency, localization and characterization of PD-1+ ILC3. Loss/gain-of-ILC3s in UOO mice were designed to investigate their roles in renal fibrosis progression. And the fibrogenic effects of ILC3s and the regulatory activity of PD-1 were determined by in vitro co-culture experiments.

Results: ILC3 were accumulated rapidly in fibrotic kidneys, with surrounding by increasing number of active myofibroblasts, and more interestingly, coincided with a robust depletion from the intestines of mouse models, suggesting a functional recruitment of ILC3 after kidney injury. Moreover, fibrosis was associated with an increase of PD-1 expression in ILC3s, and up-expression of PD-1 ligand, PD-L1 was also detected in fibrotic kidney, suggesting a possible involvement of PD-1/PD-L1 pathway. Adoptive transfer of purified intestinal ILC3 into UOO mice significantly enhanced renal fibrosis than those with PBS, whereas PD-1-deficient ILC3 protects kidney from fibrosis. Notably, mice that lacked ILC3 exhibited reduced inflammatory infiltration and decreased fibroblast activation. In vitro studies, direct co-culture of WT-ILC3 with primary renal fibroblasts exacerbates inflammatory response and extracellular matrix production (ECM), which could be blocked by the treatment with neutralizing anti-IL-17A and anti-IL-22 antibodies. Yet co-cultured with PD-1-deficient ILC3 displayed reduced fibrotic activity.

Conclusions: Our findings provided the first evidence that during renal fibrosis, PD-1/PD-L1 axis might play a regulatory role in ILC3 migration and fibrogenesis via producing pro-fibrotic cytokines IL-17A and IL-22.

Interaction Between the Na-K-ATPase and CD40 Signaling in Proximal Tubule Epithelial Cells (PTECs) Contributes to Renal Inflammation and Fibrosis

Steven T. Hailer,1 Shungang Zhang,1 Ying Nie,2 Joseph I. Shapiro,2 Jiang Liu.1 1Department of Medicine University of Toledo College of Medicine and Life Sciences, Toledo, OH; 2Marshall University Joan C. Edward School of Medicine, Huntington, WV.

Background: We have demonstrated that signaling through the Na-K-ATPase-c1 subunit/c-Src kinase (NKA-c1/c-Src) complex and activation of the pro-inflammatory receptor, CD40 induce renal inflammation and fibrosis in both cellular and experimental models of ischemic and chronic kidney disease (CKD). Circulating cardiotonic steroids (specific ligands of Na-K-ATPase) are significantly elevated in CKD that not only exacerbates inflammatory response and extracellular matrix production (ECM), but reduces NKA-α1/c-Src complex, and there is an increased number of active myofibroblasts, and more interestingly, coincided with a robust depletion from the intestines of mouse models, suggesting a functional recruitment of ILC3 after kidney injury. Moreover, fibrosis was associated with an increase of PD-1 expression in ILC3s, and up-expression of PD-1 ligand, PD-L1 was also detected in fibrotic kidney, suggesting a possible involvement of PD-1/PD-L1 pathway. Adoptive transfer of purified intestinal ILC3 into UOO mice significantly enhanced renal fibrosis than those with PBS, whereas PD-1-deficient ILC3 protects kidney from fibrosis. Notably, mice that lacked ILC3 exhibited reduced inflammatory infiltration and decreased fibroblast activation. In vitro studies, direct co-culture of WT-ILC3 with primary renal fibroblasts exacerbates inflammatory response and extracellular matrix production (ECM), which could be blocked by the treatment with neutralizing anti-IL-17A and anti-IL-22 antibodies. Yet co-cultured with PD-1-deficient ILC3 displayed reduced fibrotic activity.

Conclusions: Our findings provided the first evidence that during renal fibrosis, PD-1/PD-L1 axis might play a regulatory role in ILC3 migration and fibrogenesis via producing pro-fibrotic cytokines IL-17A and IL-22.

interaction between NKA-α1 and CD40 that was enhanced by activation of the NKA- 
α1-β2 receptor signaling. A soluble uric acid (sUA) in this context is 
discrepant. We hypothesized that diverse sUA preparation methods account for this 
discrepancy and that a novel animal model with clinically relevant levels of asymptomatic 
hyperuricemia (HU) and gouty arthritis can ultimately clarify this issue.

Methods: Soluble UA was prepared either by pre-warming or solubilized with 
NaOH. THP-1 cells or CD14+ monocytes from patients with HU and healthy 
individuals were pre-incubated with sUA prior to stimulation with MSU crystals or LPS. Intracellular 
UA uptake via urate transporters was quantified using siRNA technology. In vivo, Alb-
creERT2/Δ-glut9lox/lox and Glut9lox/lox control mice were injected with tamoxifen and placed 
on a chow diet with inosine to induce HU. After 3 weeks, MSU crystals or vehicle were 
injected into air pouches, and leukocyte infiltration and the extent of inflammation were 
assessed by flow cytometry, RT-PCR, ELISA.

Results: We found that pre-warmed UA created erroneous results because of 
microcrystal contaminants triggering IL-1β release. Solubilizing UA with NaOH avoided 
such artifact. This microcrystal-free preparation suppressed LPS- or MSU crystal-induced 
release. Solubilizing UA with NaOH avoided

PP2A Catalytic Subunit Promotes Macrophage Accumulation and Activation to Accelerate Tubular Cell Death and Kidney Fibrosis Through Regulating Rap1 and TNFα Production
Yun Liang, Chunsun Dai. Nanjing Medical University, Nanjing, China.

Background: Macrophage accumulation and activation play an essential role for 
kidney fibrosis, the underlying mechanisms remain to be explored.

Methods: Analyzing the kidneys of patients and animal models with kidney fibrosis.

Results: We observed a significantly increased induction of PP2Ac in macrophages. We then generated mice with macrophage-specific deletion of PP2Ac. These mice developed less renal fibrosis as indicated by less macrophage accumulation, tubular atrophy or extracellular matrix deposition. In cultured cells, the deficiency of PP2Ac in macrophages resulted in decreased cell motility by inhibiting the activity of Rap1. Furthermore, TNFa production was downregulated in macrophages with PP2Ac deficiency and co-culture of PP2Ac-deficient macrophages and renal tubular cells resulted in less tubular cell death, which was due to decreased TNFα production via phosphorylation of STATs in macrophages.

Conclusions: This study shows that PP2A promotes macrophage accumulation and activation, hence accelerating tubular cell death and kidney fibrosis through regulating Rap1 and TNFα production.

Investigating LOX and Its Role in AT1R−β-Arrestin Biased Signaling Pathway-Induced Renal Interstitial Fibrosis
Xiaojin Zhang, Chen Yu. Tongji University, Shanghai, China Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, Shanghai, China.

Background: We studied the downstream and mechanism of β-arrestin signaling in 
nephritic fibrosis process and the role of lysyl oxidase (LOX) in the AT1R−β-arrestin pathway. Moreover, AT1R−β-arrestin signaling was assessed in normal rat kidney tubule epithelial cells (NRK-522) treated with SII in vitro. BAPN or placebo was

administered during ischemia reperfusion (IR)-induced fibrosis progression. Collagen 
crosslinking and fibrosis progression were assessed histologically and biochemically.

Results: The mRNA and protein levels of β-arrestin-1 and β-arrestin-2 were 
significantly upregulated in renal fibrosis model both in vitro and in vivo. SII activated the ERK-STAT3 PY705 but not STAT3-Try727 in nucleus of NRK-522 cells, which were abolished when transfection of siRNA targeting β-arrestin-1 and -2 or pretreated with PD98059 (MEK inhibitor). LOX was strongly induced in fibrotic kidney and NRK-52E cells treated with SII. Active LOX significantly increased collagen 
crosslinking. In established IR-28d renal fibrosis, LOX inhibition promoted fibrosis 
progression. Moreover, the expression of LOX is increased in fibrotic kidney and 
renin−angiotensin−aldosterone−system (RAAS) signaling pathway. In a 25% decrease 
mesangial collagen, Gene silencing of β-arrestin-1−2 or STAT3隐约 inhibited LOX expression in vivo. Besides, chronic 
immunoprecipitation (ChIP) assay clearly demonstrating the interaction between STAT3 
and the LOX promoter, which indicated LOX is a direct target gene of SI-BAR- 
STAT3 signaling.

Conclusions: The ERK-STAT3 was downstream of AT1R−β-arrestins, ERK entered 
in the nucleus and activated STAT3-PY705. LOX mediates collagen crosslinking and fibrosis 
matrix stabilization during renal fibrosis via the AT1R−β-arrestins-ERK-STAT3-PY705 
signaling. By blocking this profibrotic pathway, therapeutic LOX inhibition attenuates 
the fibrosis and suggesting target the LOX has significant potency for the treatment of patients with fibrotic kidney disorders.

Downregulated Endothelial JMJD3 Accelerates Neointimal Hyperplasia of Arteriovenous Fistula in CKD
Shaozhen Feng, 1 Qunying Guo, 1 Eric K. Peden, 2 William E. Mitch, 1 Luan D. Truong, 2 Zhichong Cheng, 1 Baylor College of Medicine, Houston, TX; 2Houston Methodist Hospital DeBakey Cardiology Associates, Houston, TX; 2Houston Methodist Hospital, Houston, TX.

Background: Epigenetic changes are involved in vascular remodeling. The 
histone demethylase, JMJD3, is a transcriptional co-activator that promotes endothelial 
proliferation. Despite the importance of JMJD3 in maintaining endothelial function, its 
role in neointima formation in AVF remains unknown.

Methods: Mice with JMJD3-specific knockout (KO) in ECs was generated. CKD 
and AVF models were created in Wild type and JMJD3 EC-specific KO mice. Evans 
blue staining, immunohistochemical staining, and Western blotting were performed to characterize JMJD3 expression and vascular pathology. Mouse primary ECs and VSMCs were isolated to study the signaling pathways that regulate JMJD3 expression and endothelial mesenchymal transition (EndMT). The changes found in mouse AVFs were assessed in AVFs from ESRD patients.

Results: JMJD3 expression was downregulated in endothelium of CKD mice. Specific KO of JMJD3 in EC stimulated endothelial barrier dysfunction, EndMT, and inflammatory cells infiltration in AVFs. There were more VSMC proliferation and collagen deposition in AVFs of JMJD3 KO mice vs. that of in WT mice. Specific KO of JMJD3 in EC accelerated AVF proliferation. Moreover, the expression of JMJD3 is reduced through TGFβ1/Hes1 signaling pathway. In AVFs from ESRD patients, the decreased expression of JMJD3 in ECs was associated with endothelial dysfunction, EndMT, and ECM deposition plus neointimal hyperplasia. Remarkably, endothelial expression of Hes1 in AVFs from ESRD patients was more closely correlated with the decreased JMJD3 level.

Conclusions: These findings demonstrate that TGFβ1/Hes1-JMJD3 signaling exist 
in ECs which epigenetically regulates EC differentiation and barrier function leading to neointimal hyperplasia of AVF in CKD.

Renal Macrophage Infiltration Precedes Macrophage to Myofibroblast Transition and T-Cell Recruitment Following Repeated Low-Dose Cisplatin Treatment
Sophia M. Sears, Mark A. Doll, Levi J. Beverly, Leah J. Siskind. University of Louisville School of Medicine, Louisville, KY.

Background: Cisplatin is a commonly used chemotherapeutic agent with dose-limiting nephrotoxicity. 30% of patients who receive cisplatin develop acute kidney injury (AKI), which significantly increases the risk of developing renal fibrosis and chronic kidney disease (CKD). There are currently no therapies approved to prevent or treat cisplatin-induced kidney injury (CDDP-KI) and fibrosis. Other models of renal fibrosis have demonstrated that macrophages can play a pro-fibrogenic role by differentiating into myofibroblasts, the main effector of fibrotic development. Macrophage to myofibroblast transition (MVT) is proposed to occur when bone marrow derived M2 macrophages undergo chronic TGFβ stimulation. We hypothesize that cisplatin promotes fibrosis and CKD development through stimulating chronic macrophage activity and MVT in the kidney.

Methods: We used a clinically relevant, repeated low dose model of CDDP-KI to characterize the immune response and MVT in the kidney following cisplatin treatment.

Results: Flow cytometric analysis revealed significantly increased numbers of renal infiltrating Ly6C+ inflammatory monocytes and F4/80+ infiltrating macrophages after four doses of cisplatin. These populations remained elevated above vehicle treated controls after a 6-month age out. At the four dose timepoint, we observed an increase in CD206+ F4/80+ cells and Arg-1 mRNA, indicating M2 polarization. We also identified a population of F4/80+ CD206+ oSMA+ cells present in the kidney, suggesting MMT is occurring. Interestingly, at the 6-month timepoint renal CD4+ and CD8+ T cell populations remained significantly elevated in cisplatin-treated mice compared to vehicle treated controls.

Conclusions: These studies provide insight on how the immune response to CDDP-KI can promote CKD via infiltration of bone marrow derived macrophages and subsequent M2 polarization and MVT. These early events orchestrate an immune response that continues up to 6-months after cisplatin treatment. Therefore, targeting macrophages could be a potential strategy for preventing the AKI to CKD transition triggered by cisplatin.

PO0641
Microvascular Loss and Remodeling in Human Kidneys Distal to Severe Atherosclerotic Renovascular Disease
Nattawat Klomjit,1 Alfonso Eirin,1 Xiang yang Zhu,1 Aditya S. Pawar,1 Amruthes S. Puranik,2 Christopher M. Ferguson,3 Seo Rin Kim,1 Kyra L. Jordan,1 Hui Tang,1 Amir Lerman,2 Stephen C. Textor,2 Lilach O. Lerman.1 Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 1Langone Health, New York University, New York, NY; 2Department of Cardiorenal Disease, Mayo Clinic, Rochester, MN.

Background: Renovascular disease (RVD) may induce hypertension and kidney injury, but its effect on the microcirculation of the post-stenotic human kidney remains unclear.

Methods: Kidneys were collected from patients with RVD undergoing unilateral nephrectomy due to refractory hypertension (n=5) and deceased donor kidneys (DK) discarded due to incompatibility (n=7). Renal microvasculature (MV) was studied using micro CT after infusing contrast agent into the renal artery. Kidneys were also evaluated using 8 nmol/mg kidney tissue Angiopoietin-1 antibody as an inhibitor. PTC density of medium-sized MV vs. donor kidneys (Fig. A-B, p=0.04), whereas numbers of new angiogenic vessels (β3 integrin+Fig. D) and pericytes were higher. Renal fibrosis characterized the immune response and MMT in the kidney following cisplatin treatment.

Results: Age and sex were comparable between RVD and DK. RVD had reduced density of medium-sized (0.2-0.3mm) MV vs. donor kidneys (Fig. A-B, p=0.04), whereas density of small (0.02-0.2mm) and large (0.3-0.5 mm) MV was similar. Vascular tortuosity ratio was higher in RVD vs DK (Fig. C, p=0.05). The number/tubule of peritubular capillaries (PTC) was significantly lower in RVD, as was CD31+ area, whereas numbers of new angiogenic vessels (β3 integrin+, Fig. D) and pericytes were higher. Renal fibrosis and MV remodeling (media/lumen) were greater in RVD, as were oxidative stress and angiotensin-1 expression, whereas VEGF (p=0.9) and FLK-1 (p=0.2) protein or gene expression were unchanged.

Conclusions: Human RVD kidneys develop marked MV remodeling and loss, particularly of PTC and medium-size MV. Angiopoietin-1 upregulation may promote new PTC formation, but fails to offset overwhelming MV loss distal to severe RVD. These findings underscore the major component of microvascular injury in the development of ischemic kidney disease.

Novel Small Molecule Inducers of ABCA1-Dependent Cholesterol Efflux
Preserve Renal Function in Mouse Models of FSGS and Alport Syndrome
Javier T. Varona Santos,1,2 Matthew B. Wright,3 Christian Kemmer,4 Cyrille Maugeais,1 Jean-Philippe Carralot,1 Stephan Roever,1 Judith T. Molina Davila,1 Gloria Michelle Ducasse,2 Alla Mitrofanova,2,3 Alexis J. Sloot,4 Jeffrey D. Pressly,4,5 Christopher Pedigo,2,6 Laura Barisoni,1 Armando Mendez,1 Jacopo Sgrignani,2 Andrea Cavalli,2 Sandra M. Merscher,4,6 Marco Prunotto,4,5 Alessia Fornoni,1,2 University of Miami, Katz Family Division of Nephrology and Hypertension, Miami, FL; 2University of Miami, Peggy and Harold Katz Family Drug Discovery Center, Miller School of Medicine, Miami, FL; 3University of Genova, School of Pharmaceutical Sciences, Genova, Italy; 4Pharma Research and Early Development (pRED), Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd., Basel, Switzerland; 5University of Miami Department of Pathology, Miller School of Medicine, Miami, FL; 6University of Miami, Miller School of Medicine, Diabetes Research Institute, Miami, FL; 7University for Research in Biomedicine, Università della Svizzera Italiana, Bellinzona, Switzerland; 8Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Background: Pathological accumulation of cholesterol in podocytes is associated with the progression of kidney disease. Depletion of podocyte cholesterol by non-specific means, with agents such as cyclodextrin, or by specific upregulation of ABCA1-mediated cholesterol efflux, have shown promise in renal disease models, but have not progressed in clinical development.

Results: The effects of novel compounds (Cpd A and G) that induce ABCA1-mediated cholesterol efflux were evaluated in comparison to LXR agonists in differentiated human podocytes in vitro. In vivo efficacy studies of Cpd A & G were conducted in model mice of proteinuric kidney disease (Adriamycin-induced nephropathy and Alport Syndrome).

Results: ABCA1-mediated cholesterol efflux was significantly increased in podocytes by all agents. While an LXR agonist resulted in accumulation of ABCA1 at the plasma membrane, it also induced significant accumulation in microsomal fractions. In contrast, Cpd A & G induced the redistribution of ABCA1 from intracellular sites to the plasma and membrane. In ADPKD challenged mice, Cpd A and G increased ACR by 8 and 30-fold, respectively, compared to controls. In Col4A3 knockout mice, Cpd G significantly reduced ACR, serum creatinine and blood urea nitrogen, as well as prevented weight loss and mortality vs. control mice. We found that increased accumulation of cholesterol esters in kidney cortex was strongly correlated with albuminuria. In both the FSGS and Alport models, Cpd G significantly reduced lipid droplet formation and cholesterol ester content in kidney cortex.

Conclusions: In summary, these studies describe the efficacy of novel small molecule drugs in renal disease models that induce ABCA1-mediated cholesterol efflux independently of LXR. This may represent a promising new therapeutic strategy for the treatment of kidney diseases and disorders of cellular cholesterol homeostasis.

Metformin Therapy Is Able to Halt the Progression of Established CKD in Rats
Raphaëlle Correman1, Ellen Neven, Patrick D’Haeze, Benjamin A. Vervaet, Anja Verhulst1. Universität Antwerpen, Antwerpen, Belgium.

Background: Metformin, first-line drug for type-2 diabetes, exerts benign pleiotropic actions beyond its prescribed use and emerging data show protective effects against the development/progression of renal impairment. Current treatment strategies for chronic kidney disease (CKD) mainly focus on controlling important risk factors, while effective treatment directly targeting the kidney is lacking. However, in 2019, the FDA approved the use of the sodium-glucose co-transporter-2 (SGLT2) inhibitor, canagliflozin, to treat diabetic nephropathy. Here, the ability of metformin to attenuate the progression of established, non-diabetic CKD was investigated and compared to canagliflozin.

Methods: Adipose-induced CKD rats (n=86) were assigned to different treatment groups to receive 200 mg/kg metformin, 4 or 5 weeks after the start of the adimine diet (0.25%), i.e. after CKD had developed, or 25 mg/kg canagliflozin 4 weeks after the start of the diet, by daily oral gavage, for 4 weeks. Each treatment group was compared to a vehicle (1% carboxymethylcellulose) group.

Results: Serum creatinine levels dramatically rose in vehicle-treated CKD rats: from 0.7 ± 0.1 mg/dL (week 0) to 1.5 ± 0.1 mg/dL (week 4), 2.6 ± 1.2 mg/dL (week 5) and further to 6.2 ± 0.3 mg/dL (week 8) and 4.8 ± 1.1 mg/dL (week 9). Canagliflozin treatment did not alter the increase in serum creatinine as indicated by serum creatinine levels at week 9 (5.8 ± 0.4 mg/dL). In contrast, metformin treatment almost completely prevented the increase from week 4 or 5 on, as indicated by the serum creatinine levels after 8 (2.0 ± 0.5 mg/dL) and 9 (2.9 ± 0.5 mg/dL) weeks (p<0.05 vs. vehicle). Canagliflozin treatment did not alter the tubulointerstitial area percentage, while this parameter was 33% lower at week 8 and 23% lower at week 9 in metformin-treated CKD rats compared to vehicle treatment (p<0.05 vs. vehicle). Further histological examination revealed more tubular proliferation (PCNA positive cells) and less interstitial inflammation (CD45 positive cells) in metformin-treated rats compared to vehicle-treated animals.

Conclusions: In conclusion, metformin is able to attenuate the progression of pre-established kidney-induced CKD. Our data do not present new evidence for a beneficial effect of canagliflozin on progression of non-diabetic CKD.

The Novel Potent and Selective Vasopressin V1a Antagonist BAY237949 Blocks Arginine Vasopressin-Mediated Decline of Renal Blood Flow and Tissue Oxygenation

Hana Cernecka, Karoline Drobner, Hanna Tinel, Elisabeth Pook, Chantal Fuerstner, Marie-Pierre L. Collin, Peter Hein, Frank Eitner, Peter Kolkhof, Bayer AG, Research & Development, Pharmaceuticals, Wuppertal, Germany.

Background: Hypoxia is a major contributor to kidney disease progression. Arginine vasopressin (AVP) potently induces renal medullary vasoconstriction via vascular V1 receptors resulting in reduced renal blood flow (RBF). Here we characterized the kidney-protective properties of a recently identified, potent and selective V1a receptor antagonist.

Methods: BAY 237949 was characterized in Chinese hamster ovary cells expressing recombinant human and rat V1a and V2 receptors. Vasodilatory effects were investigated on isolated A. renalis rings from male Wistar rats (n=10). RBF and intrarenal tissue oxygenation were studied in isolated perfused rat kidneys and in anesthetized rats (n=5-8 per group) via Laser Doppler Flowmetry.

Results: In vitro receptor profiling showed high potency and selectivity of BAY 237949 for human V1a receptor (IC50 hV1a: 1.2 nM, IC50 hV2: 170 nM). BAY 237949 mediated dose-dependent relaxation (IC50: 3.1 nM) of isolated rat A. renalis vessel rings precontracted by AVP. BAY 237949 improved the AVP-mediated reduction of perfusate ±oxygenation (CON: 27 ±1, AVP: 17 ±4). BAY 237949 dose-dependently restored RBF (p<0.001) and tissue ±oxygenation were studied in isolated perfused rat kidneys and in anesthetized rats (n=5-8 per group) via Laser Doppler Flowmetry.

Conclusions: BAY 237949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation in rats, suggesting potential benefit for patients with cardiorenal disease.

Renal Expression of L-Type Fatty Acid Binding Protein in Addition to Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion

Yoko Fujita,1 Takeshi Sugaya,1 Daisuke Ichikawa,1 Jun Tanabe,1 Kenjiro Kimura,2 Yugo Shibagaki,1 Atsuko Ikemori.1,2,7 Division of Nephropathy and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; JCHO Tokyo Takanawa Hospital, Tokyo, Japan; 2Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. We had revealed the importance of renal L-type fatty acid binding protein (L-FABP) with antioxidative effect in various renal disease models. Therefore, the aim of this study is to elucidate the renoprotective effect of renal L-FABP and Ang II type 1a receptor (AT1a) loss against chronic TID after renal IR.

Methods: To induce severe chronic TID after renal IR, unilateral renal ischemia for 60 min was performed via clamping of right renal pedicle using four types of male mice; wild type mice (hL-FABP+/+AT1a+), human L-FABP chromosomal transgenic mice (hL-FABP+AT1a+), and hL-FABP+AT1a+ mice. Right and left kidneys were removed at 10 weeks after IR.

Results: While marked renal atrophy and progressive TID were found in each IR-kidney of hL-FABP+AT1a+ and hL-FABP+AT1a+ mice, the degree of both atrophy and TID were significantly ameliorated in the IR-kidneys of the hL-FABP+AT1a+ mice. Right and left kidneys were removed at 10 weeks after IR.

Conclusions: Increased expression of renal L-FABP in addition to suppressed activity of AT1a may be a useful strategy for prevention of AKI-to-CKD transition.

Development of a Synthetic Biotic, SYNB8802, for the Treatment of Enteric Hyperoxaluria

Lauren Renaud,1 David Lubkowicz, Pip Reeder, Chris Bergeron, Zhibin C. Chen, Michael J. James, Pasquale Cantarella, Mark Charbonneau, Ron Shmuuel, Jr Gao, Vincent Isabella, Mylene Perreault. Synlogic, Cambridge, MA.

Background: Enteric hyperoxaluria (EH) is a metabolic disease that results from excessive absorption of oxalate from dietary sources. Increased oxalate levels can lead to the formation of kidney stones and, ultimately, to kidney failure. EH occurs most frequently in patients with underlying gastrointestinal disorders, including inflammatory bowel disease, short bowel syndrome, or individuals who have undergone bariatric surgery. There is a high unmet need for new EH therapies, as a low oxalate diet is the only option currently available to patients. Synlogic is developing a novel Synthetic Biotic™ medicine for the treatment of EH, designated as SYNB8802.

Methods: SYNB8802 is an engineered bacterium derived from Escherichia coli Nissle 1917 (EcN) that has been engineered to metabolize oxalate to formate and CO2 in the gastrointestinal tract.

Results: Inoculation of SYNB8802 into minimal media showed significant consumption of oxalate and production of formate as compared to un-engineered (EcN) bacterial strain. When administered concomitantly with 13C-oxalate to healthy mice, SYNB8802 decreased the urinary recovery of 13C-oxalate, indicative of its ability to consume oxalate in vivo. In healthy non-human primates (NHP) administered approximately 400 mg of dietary oxalate, SYNB8802 lowered the urinary recovery of oxalate and CO2 in a dose dependent manner by up to 75% as compared to vehicle. In addition, Synlogic has developed a mathematical model that predicts clinically meaningful reductions in urinary oxalate in EH patients.

Conclusions: Overall, SYNB8802 represents a promising new approach for the treatment of enteric hyperoxaluria.

A Novel Small Molecule Modulating the Mitochondrial NEET Proteins Improves Inflammation and Fibrosis in Kidneys of Nonalcoholic Steatohepatitis Mice

Background: Non-alcoholic steatohepatitis (NASH) is a disease characterized by excessive fat accumulation, inflammation, and ballooning degeneration of hepatocytes, with or without fibrosis in the liver. It is now reported that NASH not only affects the liver but is also associated with chronic kidney disease (CKD). However, the morphological appearance of NASH kidneys has been poorly characterized. These observations highlight the need for a treatment that targets both conditions. Here, we assessed the effect of a novel chemistry that regulates the function of 3 mitochondrial proteins called the NEET proteins, previously reported to be important in metabolic diseases, on a diet-induced NASH model in mice.

Methods: Mice were fed with a high fat diet for 30 weeks prior treatment with ENYO’s molecule for 8 weeks. The kidneys and livers were collected at sacrifice and sections were stained with H&E, PAS and picrosirius red staining to analyze their morphology. Specific immunostainings and qRT-PCR were performed to quantify the extent of inflammation (CD3, MAC1 and F4/80) and fibrosis (Col1a1, Col3a1, fibronectin).

Results: NASH mice displayed severe renal lesions such as glomerulosclerosis, tubular casts, tubular lipid accumulation and interstitial fibrosis. Mononuclear cell infiltration was also massively increased, in particular in the perivascular areas. In the liver, inflammation and fibrosis were also attenuated, specifically in the perportal zone that has been shown to be correlated with the severity of the disease. Interestingly, the most significant responders in the liver were also the best responders in the kidneys.

Conclusions: We have shown that NASH mice developed CKD, recapitulating the phenotypes observed in humans. Moreover, we have identified a new treatment, that by targeting NEET proteins, protects mice from the development of both liver and renal lesions.

PO0652 SIRT3 Deacetylates PDHE1α to Regulated Mitochondria Metabolism in Tubular Epithelial Cells During Renal Fibrosis

Yu Zhang, Yang Zhou, Lei Jiang, Junwei Yang. Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Abnormal energy metabolism is considered to be related to renal interstitial fibrosis. Pyruvate dehydrogenase α (PDHE1α) is the main catalytic enzyme of pyruvate dehydrogenase complex (PDHC) linking glycolysis to the TCA cycle. N-lysine acetylation is an important post-translational modification involves in energy metabolism. SIRT3 is a mitochondrial deacetylase that mediates the activity many metabolic enzymes.

Methods: Unilateral ureteral obstruction (UUO) or ischemia-reperfusion (I/R) were used to induce renal fibrosis in C57BL/6j mice or SIRT3 knockout mice. Primary tubular epithelial cells (PTCs) were stimulated by TGF-β1. Protein array and the acetylation array used to induce renal fibrosis in C57BL/6J mice or SIRT3 knockout mice. Primary tubular epithelial cells (PTCs) were stimulated by TGF-β1. Protein array and the acetylation array were performed on tubules separated from sham or UUO-operated mice. K149R, K267R, K385R mutations in PDHE1α were transfected into PTCs.

Results: Acetylation showed that the majority of proteins were hyper-acetylation after UUO. GO enrichment analysis revealed that PDH was the most obviously enriched GO term. Immunoprecipitation analysis confirmed that PDHE1α acetylation was enhanced after UUO or I/R operation. Activation of SIRT3 by HKL could block the hyper-acetylation of PDHE1α, restored PDH enzyme activity, and inhibited the phosphorylation of PDHE1α in mice with UUO or I/R. On the contrary, Sirt3 KO mice had more acetylated PDHE1α, more phosphorylated PDHE1α and defective PDH enzyme activity. In vitro, increased PDH1 acetylation was accompanied by reduced PDH enzyme activity and increased PDHE1α phosphorylation in PTCs after TGF-β1 stimulation. Activation of SIRT3 by HKL repressed the effect of TGF-β1. Inhibition SIRT3 activity by 3-TYP or SIRT3 siRNA transfection have the same effect as TGF-β1. K149, K267, K385 were identified as the main potentially lysine acetylated sites in PDHE1α. Acetylation of PDHE1α, the activity of PDH and PDHE1α phosphorylation remained unchanged in PTCs with the K385R mutation stimulated with TGF-β1 or SIRT3 siRNA transfection.

Conclusions: In summary, our data showed that mitochondrial proteins involved in regulating energy metabolism were acetylated and targeted by SIRT3 in PTCs. The deacetylation of PDHE1α at lysine 385 by SIRT3 plays a key role in metabolic reprogramming in renal fibrosis.

PO0654 Genetic Ablation of CD148 Increases Renal Macrophage Inflammation and Fibrosis in Ureteral Obstructed Kidney

Tadashi Otsuka,1 Keiko Takahashi, Ichikage Narui,1 Raymond C. Harris,1 Manuel Grundmann,2 Takamune Takahashi,1 Leija Pass,1 Vonderbilt University Medical Center, Nashville, TN; 2Bayer AG, Leverkusen, Germany.

Background: CD148 is a transmembrane protein tyrosine phosphatase expressed in several cell types including epithelial, endothelial, and hematopoietic cells. Macrophages express high level of CD148, and its expression is up-regulated by lipopolysaccharide (LPS) which activates innate immune response through toll-like receptor 4. Recently the innate immune system has been recognized as an important modulator of the inflammatory response during infection and tissue injury/repair. However relatively little is known about CD148 function in this cell type and kidney disease model. Here we showed influences of CD148 deletion on unilateral ureteral obstruction (UUO) model and macrophage polarization.

Methods: UUO surgeries were performed in CD148 KO and wild-type (WT) mice on DBA/2J background. Histological and gene expression analysis were performed 3 days and 10 days after UUO to investigate inflammation and fibrosis. Flowcytometry was used to analyze macrophage polarization using CD38/Egr2 method. Primary culture of peritoneal macrophages isolated from WT mice were used for in vitro study. After LPS stimulation, inflammatory response (TNFα, IL-1β, IL-6) was quantified by qPCR and ELISA.

Results: CD148KO mice developed more severe renal fibrosis than WT mice at day 10. They showed more tubular damage compared to WT mice at day 3. F4/80 staining revealed increased infiltrated macrophages in outer medulla lesion and flowcytometry showed increased population of inflammatory subtype (M1; CD14/16/38/80/CD38/Egr2- in CD148KO mice. Although there were no significant

LRG1 Promotes Renal Fibrosis by Enhancing TGF-β-Induced Smad3 Signaling
Qian Hong,1,2 Hong Cai,1,3 Lu Zhang,1,3 Zhouhui Ni,2 Guangyan Cai,2 Xiaomei Chen,2; John C. He,1 Kyung Lee,1 Icahn School of Medicine at Mount Sinai, New York, NY; Shanghai Jiao Tong University School of Medicine, Affiliated Renji Hospital, Shanghai, China; James Piter's VA Medical Center, Bronx, NY; The First Affiliated Hospital of Xiamen University, Xiamen, China.

Background: Renal fibrosis is a final convergent pathway for CKD progression, but effective fibrosis therapy is lacking. We recently showed that leucine-rich alpha-2 glycoprotein-1 (LRG1), a secreted glycoprotein, is highly upregulated in diabetic kidneys and promotes the endothelial TGF-β signaling, mediated by ALK1 receptor and Smad1/5 activation, to increase angiogenesis and worsen DKD progression. However, increased LRG1 expression was not limited to the endothelial cells in the diabetic kidneys, but also found in the renal tubular epithelial cells (RTCs). Therefore, we examined whether LRG1 promotes the renal fibrosis through the RTCs.

Methods: We examined the expression of LRG1 in the tubulointerstitial RNAseq dataset of human CKD. We explored the potential mechanism in LRG1 upregulation in cultured RTCs and examined the specific TGF-β/Smad signaling pathway mediated by LRG1 using shRNA-knockdown. We examined the effects of LRG1 ablation in unilateral ureteral obstruction (UUO) and astrotactilic acid nephropathy (AAN) models of renal fibrosis. We also examined the effects of TGF-β specific overexpression of LRG1 in renal fibrosis in vivo. We further compared the activation of Smad proteins in the RTCs of control, Lrg1−/−, and Ptc1−/− mice with UUO.

Results: We found that the LRG1 mRNA transcript was markedly increased in the microdissected tubulointerstitium of human CKD. In cultured RTCs, LRG1 expression was upregulated by a pro-inflammatory cytokine TNF-α, and chromatin IP assay confirmed the binding of p65 subunit NF-kB to the LRG1 promoter region. Importantly, LRG1 enhanced the TGF-β-induced Smad3 activation, but not of Smad1/5, and the expression of pro-fibrotic genes in RTCs. The global knockout of Lrg1 attenuated renal fibrosis in mice with UUO or AAN. In AAN mice, Lrg1 ablation also improved renal function. In contrast, the RTC-specific overexpression of LRG1 markedly heightened the renal fibrosis in vivo. The level of Smad3 phosphorylation in RTCs in the obstructed kidneys was directly associated with the loss or gain of LRG1 expression.

Conclusions: Our current study attributes a previously undescribed role of LRG1 as a key modulator of the canonical TGF-β/Smad3 signal transduction in RTCs and suggests that the targeting of LRG1 may be an effective approach against renal fibrosis.

Single-Nucleus RNA Sequencing Identifies New Classes of Renal Proximal Tubular Epithelial Cell in Kidney Fibrosis
Yuehan Lu,1,2 Chia-te Liao,1 Rachel Raybould,1 Bnar Talabani,1 Barbara Szomolay,1 Timothy Bowen,1 Robert Andrews,1 Philip R. Taylor,1 Donald Fraser,1 Wales Kidney Research Unit 1Cardiff University, Cardiff, United Kingdom; 2Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background: Proximal tubular cells (PTC) play a central role in nephron recovery versus fibrosis following renal injury. PTC heterogeneity is well-documented but poorly charactarized in extant single-cell sequencing data. Here we have determined PTC phenotype in renal fibrosis by single-nucleus RNA sequencing (snRNA-seq).

Methods: Kidneys were harvested from naive mice and mice with renal fibrosis induced by chronic aristolochic acid administration. Nuclei were isolated using Nuclei EZ Lysis buffer. Libraries were prepared on the 10X platform and snRNA-seq completed using Illumina NexSeq 550. Downstream bioinformatics analyses used Seurat.

Results: A total of 23,885 nuclei were analyzed. PTC’s were found in five abundant clusters, mapping to S1, S1-2, S2-cortical S3, and medullary S3 segments. Additional cell clusters were present (“new PTC clusters”) at low abundance in normal kidney and in increased number in kidneys undergoing regeneration/fibrosis following injury. These clusters exhibited clear molecular phenotypes, permitting labeling as, proliferating, deidentified-internmediate, deidentified-regenerating, and (present only following injury) deidentified-differentiated-senesce. Each of these clusters exhibited a unique gene expression signature, including multiple genes associated with renal injury response and fibrosis progression. Comprehensive pathway analyses revealed metabolic reprogramming, enrichment of cellular communication and cell motility, and various immune signatures in new PTC clusters. In ligand-receptor analysis, new PTC clusters promoted fibrotic signaling to fibroblasts and inflammatory activation to macrophages.

Conclusions: snRNAseq permits the dissection of cell-type and cell-subtype specific responses. These exhibit highly specific and restricted gene signatures, including canonical PTC injury response genes. These PTC clusters may be expressed to a low level throughout injured PTC, on the basis of bulk expression analyses.

PO0658
Twist1 in T Lymphocytes Exaggerates Kidney Fibrosis After Ureteral Obstruction
Jiafa Ren, Jamie Privratsky, Steven D. Crowley. Duke University School of Medicine, Durham, NC.

Background: T cells play a critical role in directing kidney fibrogenesis. The transcription factor Twist1 limits pro-inflammatory cytokine production in T cells, but the role of T cell-derived cytokine mediators regulated by Twist1 in kidney damage has not been fully elucidated. To explore the role of T cell Twist1 in kidney scar formation, we subjected mice with Twist1 lymphocyte-specific deletion (“TKO”) of Twist1 and controls to the UUO.

Methods: 129/SvEv mice with a floxed allele for the gene encoding Twist1 or TNFα were bred with C57b1/6J-Cre mice to yield Twist1 TKO or TNFα TKO mice with robust but selective deletion of Twist1 mRNA >90% vs. WT in CD4+ T cells, and >85% vs. WT in CD8+ T cells (p<0.0001) or TNFα mRNA in T cells (published), respectively. Twist1 TKO, TNFα TKO, and WT controls underwent UUO with assessment of kidney fibrosis and T cell phenotype at 14 days.

Results: 2 weeks after UUO, Twist1 TKO mice developed less kidney fibrosis compared to WT as quantitated by western blot for Coll1 (0.75±0.06 vs 1.0±0.05 α; p=0.02) and eSMa (0.55±0.01 vs 1.0±0.08 α; p=0.01) and by RT-PCR for Coll1 (0.69±0.08 vs 1.0±0.11 α; p=0.04), fibronectin (0.76±0.07 vs 1.0±0.06 α; p=0.03), TGFβ1 (0.73±0.08 vs 1.0±0.04 α; p=0.004) and PAI1 (0.47±0.05 vs 1.0±0.09 α; p=0.001). Twist1 TKO mice also showed attenuated kidney injury as indicated by NGAL mRNA expression (0.55±0.06 vs 1.0±0.16 α; p=0.04). Twist1 can suppress proinflammatory cytokine mediators such as TNFα and IL17A than WT controls. To further explore the role of TNFα mRNA expression (0.16±0.16 α; p=0.04). Twist1 mRNA in T cells (published), respectively. Twist1 TKO, TNFα TKO, and WT controls underwent UUO with assessment of kidney fibrosis and T cell phenotype at 14 days.

Conclusions: Twist1 in T cells drives fibrosis in the injured kidney, possibly by limiting TNFα production.

PO0659
Evaluation of the Effects of a Resistant Starch Diet and Metaproteomics, Study of Microbiome-Host Interactions in a 5/6 Nephrectomy Murine Model of CKD

Background: Chronic kidney disease (CKD), a progressive decline in kidney function, is a growing health problem: 13% of adults in the US have CKD. In 40% of cases, CKD leads to irreversible loss of kidney function, end-stage renal disease. Prebiotic resistant starch Starch changes gut flora and alleviates CKD. However, mechanisms of RS action remain unclear.

Methods: Male mice (n=8) were used to reduce renal mass and to induce CKD. 8 mice served as healthy controls. Each of the two groups was further split in two subgroups (n=4, each), either supplemented with RS or regular diet. PEAKS was used to identify peptides via de novo sequencing in cecal content. To better understand the differences between CKD, CKDRS, HRS and H phenotypes we combined all bacteria that were differentially abundant in six comparisons to infer bacterial co-abundance (BCoA) network. Histopathological evaluation was used for kidney damage comparison.

Results: Histopathological evaluation showed that CKDRS mice had less kidney damage compared to CKD group. Using metaproteomics we found that the most abundant bacterium in HRS phenotype is indole-producing Oscillibacter sp. 1-3, confirming the result of BlasZEGO that indole metabolism is upregulated in HRS phenotype as compared to CKD and CKD. The most connected network hub Firmicutes bacterium A502 is significantly overrepresented in CKDRS as compared to CKD and is not significantly different between HRS and B. Firmicutes bacterium A502 belongs to 20 bacterial strains from human intestine that can induce Th17 cells in the mouse and rat intestine and have immunostimulatory effects. Experiments to validate effect of butyrate on host T-cell phenotype at 14 days.

Conclusions: Resistant starch slows down the progression of chronic kidney disease in 5/6 nephrectomy model. For the first time we demonstrate decrease in kidney fibrosis during RS supplementation. Metaproteomics allows to discover molecular mechanisms and bacterial species responsible for beneficial effects of RS. MST2 analysis allows for clear visualization of the most important connections within the bacterial co-abundance network.

Sex Differences in Renal Mitochondrial Function of Young Healthy Rats
Ryan Schibalski1, Regina F. Sultanova,2, Mark Donomidou,3 Allison N. Mccrimmon,1 Kristszan Stadler, Daria Ilatovskaya.1 1Medical University of South Carolina, Charleston, SC, USA; 2, 3St. Petersburg Chemical Pharmaceutical University, St. Petersburg, Russian Federation

Background: Sex differences in mitochondrial performance have been linked to many pathologies. Premenopausal females are typically less prone to cardiovascular damage than males. Differences in the ability to manage oxidative stress, cellular uptake, fission/fusion cycles, and respiratory performance in mitochondria can affect the onset and progression of the diseases. While characteristic sex-related dissimilarities have been reported in renal function, nothing is known with regards to how sex may affect the performance of renal mitochondria. The goal of this study was to compare renal mitochondrial function in young healthy male vs female rats.

Methods: Mitochondria were isolated from the kidneys from Sprague Dawley (SD) rats (4-11 weeks). Mitochondrial membrane potential, superoxide and H2O2 levels were measured with luminescence (MCLA) or fluorescent (TMRM, Amplex Red) dyes, and Seahorse analysis was performed. Antioxidant capacity was measured with a Trollex-based assay. Lipid peroxide radicals were detected using with spin resonance spectroscopy (ESR) with in vivo spin trapping.

Results: Kidneys from SD male (SDm) and female rats (SDf) were divided into cortex (SDmc; SDfc) and medulla (SDmm; SDfm).

Conclusions: We report sex-related differences in mitochondrial function in the kidneys of young healthy rats. Further studies are needed to establish the mechanisms that they may affect the predisposition to kidney disease development later in life.

PO0661
Renal Involvement in Coronavirus Disease 2019 (RECORD): A Systematic Review and Meta-Analysis
Kam wa Chan1, Yan Yu1, Pak Wing Lee,2 Sydney C. Tang,3 Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; 2London School of Hygiene and Tropical Medicine Faculty of Epidemiology and Population Health, London, United Kingdom.

Background: COVID-19 caused substantial casualty worldwide. As the reported renal involvement varied across regions, we sought to review the global prevalence of renal manifestations among COVID-19 patients and determine the risk factors associated with AKI.

Methods: We systematically searched 6 databases for peer-reviewed reports and 7 data portals for grey literature for all trials, cohorts, case-control studies and case-series that reported the prevalence of renal manifestations including AKI, RRT, proteinuria and hematuria, and their associated risk factors. All papers were screened, assessed and extracted by at least 2 researchers independently. Quality was assessed according to NIH assessment tools. To avoid duplicate of patient data, we matched the location, institution and time period, and only included the largest data source if studies overlapped. Prevalence of renal manifestations was pooled from studies that consecutively recruited patients from the general population, and with clear definition of outcome. This review was prospectively registered at PROSPERO (CRD42020184621).

Results: 36 studies from 8 countries and over 50 cities with a total of 14,712 patients were identified. 34 and 2 were cohorts and case-control studies respectively. 24, 7 and 5 studies reported COVID-19 patients from the general population, severe / critical patients and patients with history of RRT. AKI occurred in 14.5% of all COVID-19 cases and was highest in New York City. 8.7% of hospitalized COVID-19 patients underwent RRT. Proteinuria and hematuria were present in 42.5% and 26.7% of all COVID-19 cases. The odds of mortality among COVID-19 patients who developed AKI was 15 times higher than non-AKI COVID-19 patients (pooled OR=16.85, 95% CI: 10.06 to 28.23, 2 cities, 6 studies, 9,297 patients) and was higher in Hubei. Such effect was not observed among kidney transplant patients (pooled OR=0.95, 95% CI: 0.12 to 7.22, 2 studies, 30 patients).

Conclusions: We report sex-related differences in mitochondrial function in the kidneys of young healthy rats. Further studies are needed to establish the mechanisms that they may affect the predisposition to kidney disease development later in life.
Background: The coronavirus disease 2019 (COVID-19) pandemic has increased continuous renal replacement therapy (CRRT) demand in the US, however total CRRT demand and capacity remain unclear. Our objective was to project national and statewide CRRT demand and capacity during the COVID-19 pandemic.

Methods: We projected CRRT demand using a model in which 4% of patients admitted with COVID-19 develop acute kidney injury (AKI) requiring CRRT for 12 days. To estimate non-COVID-19 CRRT demand, we applied the prevalence of AKI requiring CRRT among other ICU patients of 8.8%. We assumed capacity would be double this demand and that this demand would decrease to 25% during the pandemic. We compared CRRT demand and capacity to estimate shortage. In sensitivity analysis, we varied parameters influencing CRRT demand and capacity.

Results: We estimated a national CRRT shortage of 1529 (95% uncertainty interval: 1264-3837) machines with a capacity of 9375 machines, and shortages in 8 states during the COVID-19 pandemic (Table 1 and Figure 1).

Conclusions: Several US states are projected to have CRRT shortages during the COVID-19 pandemic. A national strategy, such as the creation of a federal stockpile, is needed to mitigate CRRT shortages during this pandemic and future healthcare crises.

Funding: NIDDK Support

Model-generated results for 8 states with CRRT shortages

Heat maps demonstrating states with CRRT shortages during the COVID-19 pandemic under scenarios: A) base case, B) highest CRRT capacity estimate and C) lowest CRRT capacity estimate
COVID-19: AKI and Outcomes

PO0668

Hematuria and Elevated Lactate Dehydrogenase Are Associated with AKI in Hospitalized COVID-19 Patients

George Thomas, Georges Nakhoul, Jonathan J. Taliereco, Tushar J. Vachharajani, Sevag Demirjian. Cleveland Clinic, Cleveland, OH.

Background: Acute kidney injury (AKI) can be a severe complication of COVID-19, particularly in those who require intensive care. Its relationship to the incidence of proteinuria, hematuria, and elevated inflammatory markers has not been well characterized. Our objective is to describe the incidence of AKI in COVID-19, and its association with inflammatory markers.

Methods: Retrospective cohort study of adult patients hospitalized at the Cleveland Clinic with COVID-19. SARS-CoV-2 infection was confirmed by virus detection in respiratory specimens using RT-PCR. AKI was diagnosed per KDIGO serum creatinine-based classification. We selected stage 2 and higher as our primary endpoint for the study. Baseline creatinine was defined as the most recent pre-admission level available within 3 months of presentation. Acute lung injury was defined by the need for mechanical ventilation.

Results: The incidence of AKI was 14% in 621 hospitalized COVID-19 patients, with half requiring kidney replacement therapy (KRT). The incidence of proteinuria and microscopic hematuria was high in these patients (83% and 77% respectively). Seventy-five percent of patients with AKI needed mechanical ventilation, and timing of KRT overlapped with time of mechanical ventilation. Inflammatory markers and acute phase reactants, including LDH, ferritin, and C reactive protein were significantly higher in patients with AKI compared to those with no AKI. On adjusted analysis, hematuria and elevated LDH levels were significantly associated with AKI (Figure).

Conclusions: Elevated lactate dehydrogenase levels and microscopic hematuria on presentation are independently associated with 50% probability of moderate to severe AKI. Our findings suggest a possible pathogenic mechanism of endothelial cell injury and thrombotic microangiopathy as a cause of AKI in COVID-19 patients. Additional studies are needed to explore this potential mechanism of AKI in COVID-19.

PO0667

High C-Reactive Protein and D-Dimer on Admission Predict the Development of AKI in Patients Hospitalized with COVID-19

Sandheep Venkataraman, Zhiying You, Jessica B. Kendrick. University of Colorado Denver School of Medicine, Aurora, CO.

Background: COVID-19 infection is characterized by an acute respiratory syndrome that causes severe symptoms in some patients including a high incidence of acute kidney injury (AKI), which is associated with poor prognosis. COVID-19 infection results in a complex host response including a cytokine storm and severe inflammation. We aimed to identify whether high inflammatory markers on admission predict the development of AKI.

Methods: We performed a cohort study utilizing data from 430 patients admitted to the University Hospital Southampton were examined using Python (Anacondas distribution) to elucidate potential risk factors for AKI vs guidelines.

Results: AKI was present in 177 patients (31%). At peak, 108 (61%) stage 1; 42 (24%) stage 2; 27 (15%) stage 3. There were no significant differences in cohorts with respect to white vs non-white ethnicity, gender, obesity or anti-COVID-19 treatment. 44% of patients with AKI died vs 19% in the non-AKI group (p<0.001). AKI was associated with ICU admission (27% vs 10%, p<0.001), requirement of non-invasive (13% vs 4%) and invasive ventilation (14% vs 4%) (both p<0.001). Prior diabetes (18% vs 8%), hypertension (47% vs 34%), chronic respiratory and cardiac disease (25% vs 15%) were more common in the AKI group (p<0.001). Increased age was associated with AKI (p<0.02) and length of stay (LOS) positively correlated to AKI stage (p<0.001). Peak levels of biomarkers: ferritin, D-dimer, C-reactive protein, high sensitivity troponin-I, neutrophil count and total white cell count, were all significantly raised (p<0.001) in the AKI group, increasing with stage of AKI (p<0.001). However, in multivariable analysis, first clinical observations, neutrophil count, haemoglobin, D-Dimer and albumin came out as the most significant predictors of AKI: Specificity 88.7%, Sensitivity 43.6%.

Conclusions: AKI is a frequent complication of COVID-19 and we identified similar risk factors to those in the NICE guidelines. In addition, we found hypertension and chronic respiratory disease to increase risk of AKI whilst ethnicity, gender, obesity and COVID-19 treatments did not. Furthermore, AKI was associated with increased mortality, ICU admissions and LOS, concordant with previous studies. This data also points to several biomarkers as possible predictors of AKI development and severity. Further analysis of this data is ongoing.
PO0670

Acute Peritoneal Dialysis in Patients with COVID-19 and AKI: A Single-Center Experience in a Time of Crisis in the United States
Maryanne Sourial,1,2 Mina Sourial,1,2 Rochelle Dalsan,1,2 Jay A. Graham,1,2 Michael J. Ross,1,2 Wei Chen,1,2 Ladan Golestaneh,1,2 Montefiore Medical Center, Bronx, NY; 2Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

Introduction: In developed countries such as the United States, intermittent hemodialysis (iHD) or continuous renal replacement therapy (CRRT) are the primary mode of renal replacement therapy (RRT) for the management of AKI. However, during the COVID-19 pandemic, the ability to provide HD in our hospital system was overwhelmed due to the surge in the number of patients with AKI requiring RRT combined with severe personnel shortages related to illness. Studies have shown no difference in clinical outcomes between HD and PD. We describe our rapid adoption of an acute PD program during the COVID-19 surge.

Case Description: At Montefiore Medical Center (MMC), in Bronx, NY, the first patient with COVID-19 was admitted on March 11, 2020. As the number of patients with AKI rose, we initiated an acute PD program starting on March 25th. As of April 13th, there were 2,015 patients with COVID-19 admitted to MMC. From April 1st to April 22nd, 30 patients were initiated on PD with the help of surgery and interventional radiology who placed Tenckhoff catheters at bedside and under fluoroscopy, respectively. Of these 30 patients, 14 died, 8 were discharged, and 8 were still hospitalized as of May 14, 2020. Of the 8 patients discharged, 3 were still on PD and 5 had renal recovery (all were able to stop dialysis and 4 returned to baseline creatinine). Of the 8 patients still hospitalized, 4 were switched to iHD (3 due to fluid retention and 1 due to PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies (e.g., PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Incidence of New-Onset Proteinuria in AKI Associated with COVID-19

Is Not Greater Than It Is in AKI from Other Causes

Vargas, ¡.desiree García-Anton—he, ¡.diana Aguirre—A, ¡.desiunarella-Mendez, ¡.franco H. cabeza Rivería, ¡.julio A. Gutierrez-Prieto, ¡.blanca Martinez-Chagolla, ¡.sonia Rodriguez Ramirez, ¡.carmen Avila-Casado. ¡.glomcon Latin America Working Group

Vargas, ¡.desiree García-Anton—he, ¡.diana Aguirre—A, ¡.desiunarella-Mendez, ¡.franco H. cabeza Rivería, ¡.julio A. Gutierrez-Prieto, ¡.blanca Martinez-Chagolla, ¡.sonia Rodriguez Ramirez, ¡.carmen Avila-Casado. ¡.glomcon Latin America Working Group

Background: Early reports of acute kidney injury (AKI) associated with COVID-19 have claimed high incidence of proteinuria. If so, it may suggest an AKI pathogenesis not solely related to ischemic acute tubular injury (ATI). We hypothesized that those claims result from observation bias. Therefore, we sought to investigate the rate of de novo proteinuria in AKI associated with COVID-19 (CoV-AKI) compared to that of AKI in the pre-COVID-19 era (non-CoV-AKI).

Methods: Hospitalized patients with CoV-AKI entered the cohort (n=161). As a control-CoV-AKI group (n=186), we assessed a database of patients with AKI who underwent urinary sediment microscopy due to suspicion of an intrinsic cause of AKI (Sedi-AKI cohort, 2017-2020). We examined the incidence of proteinuria of any degree (1+ dipstick), significant [urine protein-to-creatinine ratio (UPCR) > 0.5–3.0 g/g or 2+ dipstick] or overt (UPCR > 3.0 g/g + 3+ dipstick). Statistical analysis used the Chi-Square test and Fisher’s exact test for categorical variables. Logistic regression was used to identify independent factors associated with de novo proteinuria.

Results: Analysis found no differences in the rate of significant proteinuria (31.5% vs. 36.2%, p=0.32). However, for overt proteinuria, CoV-AKI patients had a significantly higher incidence (77.7% vs. 53.9%, p<0.01). Independent factors associated with overt proteinuria included de novo significant proteinuria (OR 3.0, 95% CI 1.2-7.6, p=0.01). A logistic regression model revealed de novo significant proteinuria, overt proteinuria, and pre-existing hypertension were also significant independent factors associated with overt proteinuria (OR 3.0, 95% CI 1.2-7.6, p=0.01; OR 7.0, 95% CI 2.8-17.5, p<0.01; and OR 1.9, 95% CI 1.1-3.2, p=0.01).

Conclusions: The incidence rate of new-onset proteinuria was not found to be increased in CoV-AKI and is consistent with that of other forms of AKI. An observed overall greater incidence in significant proteinuria in CoV-AKI may be driven by the increased incidence of overt proteinuria. The primary cause of de novo glomerular disease may vary.

PO0675

AKI due to COVID-19 in the Intensive Care Unit: Analysis of a Brazilian Center

Background: The kidney may be affected by coronavirus (COVID) in the setting of acute kidney injury (AKI) or glomerular diseases. Data about AKI in Intensive Care Unit (ICU) patients of Latin-America are scarce. The aim of this study is evaluate the rate of AKI, dialysis (HD) and death in ICU patients diagnosed with COVID-19 in a brazilian center.

Methods: Analysis from medical records of ICU patients with diagnosis of COVID-19 in a brazilian single-center. AKI was defined according to KDIGO criteria.

Results: During the period of February 2nd to May 4th, 95 ICU patients diagnosed with COVID-19 were analyzed. There was predominance of male (64.2%), median age 66 (IQR 58-74) years, previous diagnosis of diabetes, hypertension in 44% (74% and 30.5% respectively. AKI was diagnosed in 54 (56.8%) patients and 32 (59.2%) of them required HD. Mortality rate was 17.9%. Patients with AKI, compared to no-AKI were statistically significant more frequently hypertensive and diabetic, worse SAPS3 and SOFA scores and need for organ support therapies. Laboratory tests depicted more anemia, lymphopenia, and higher levels of inflammatory markers as well as longer length of stay in ICU, hospital and death. Similar findings were seen in those who required HD compared to those with conservador treatment. Comparing patients who undergone death to survivors, they were older, more frequently diabetic, worse SAPS3 and SOFA scores and need for organ support therapies, AKI and dialysis. Multinomial logistic regression predicted that hypertension (p<0.01), mechanical ventilation (p=0.01) and use of hydroxychloroquine (p<0.009) were independent risk factors for AKI, hypertension (p<0.01), mechanical ventilation (p=0.01), use of vasopressor (p=0.04), and use of hydroxychloroquine (p<0.009) for HD patients; and age >65 years (p=0.03) and AKI (p=0.04) for death.

Conclusions: In our study, AKI was a common complication of ICU COVID-19 patients, it was associated to hypertension, older age, need for mechanical ventilation and use of hydroxychloroquine. As well as age >65 years, AKI was an independent risk factor to death.
6% smokers. Previous treatment: 10% immunosuppressive, 20% ACEi, 25% ARBs, 14% antidiabetics, and 10% anticoagulants. Clinical characteristics: 92% common respiratory symptoms, 96% pneumonia, 90% required intensive care unit (ICU) and 87% mechanic ventilation. 32% albuminuria, 18% hematuria, and 50% AKI with preserved urine output. Time from COVID-19 symptoms start to AKI 12±3 days, time ICU 19±6 days, ARMS-CART, HRT 15±7, 81% lymphopenia. RRT was needed in 91% 13±14±12 days: 55% received continuous RRT, and 72% anticoagulation. Kidney biopsy was not performed. Mortality 46.3% (60%) men, and 4% remained under RRT. Time from ICU to renal function recovery 25±14 days. 65.2% death patients had hyperkalemia. No correlation of COVID-19 infection with comorbidities, chronic treatments, renal clinical characteristics, dialysis modality and mortality. Decreased lymphocyte count was associated with worse patient prognosis (dead 495±250 vs. survivors 789±460, p=0.023).

**Conclusions:** The mortality in AKI with RRT and COVID-19 is alarming. Several factors associated with COVID-19 disease is more frequent in males. Interestingly, half of the patients preserved urine output. Severe lymphopenia was associated with mortality. More data from the AKI COVID-19 registry will help us to enlighten the prognosis and risk factors associated to mortality.

**AKI in People Living with HIV Hospitalized with COVID-19**

Molly Fisher,2,3 Melissa Fazzani,2 David B. Hanna,2 Viraj V. Patel,1,2 Uriel R. Felsen,1,2 Mindy Ginsberg,2 Kathryn Anastasi,2 Michael J. Ross,2,1 Montefiore Medical Center, Bronx, NY, #1 Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

**Background:** People living with HIV (PLWH) have an increased burden of kidney disease and many factors place them at increased risk for acute kidney injury (AKI) in the setting of COVID-19. The aim of our study was to characterize the incidence, risk factors and outcomes of AKI among hospitalized PLWH with COVID-19.

**Methods:** We performed a retrospective study of adult PLWH hospitalized with laboratory confirmed COVID-19 in a large healthcare system in Bronx, New York, from March 10-May 11, 2020. Data collected included demographics, comorbidities, antiretroviral therapy (ART), initial laboratory data, and preadmission CD4 count and HIV viral load. AKI was defined and staged using KDIGO criteria. Fisher and Wilcoxon tests were used to compare differences in those with and without AKI.

**Results:** During the study period, 77 PLWH were hospitalized with COVID-19. The majority were Black or Hispanic, 50% were men, 53% had hypertension, 31% diabetes mellitus, 22% chronic kidney disease (CKD) and 14% end-stage kidney disease (ESKD). Mean age was 470 cells/μL and 83% had a suppressed HIV viral load (<40 copies/mL). After excluding 11 with ESKD, AKI incidence was 50%. Those with AKI were older [63 (SD 9) vs 55 (SD 13) years, p<0.005], more were black (56% vs 37%, p=0.01) and more had CKD (42% vs 9%, p<0.001) compared to those without AKI. There were no significant differences in CD4 count, HIV viral load, or use of tenofovir-containing ART between those with and without AKI. By AKI severity, 11/33 (33%) were stage 1, 4/33 (12%) stage 2 and 18/33 (55%) stage 3. Mechanical ventilation (33% vs 0%, p=0.004) and in-hospital mortality (42% vs 3%, p=0.002) were more common in those with AKI. Of 6 patients who required renal replacement therapy, 4 died and 2 remained RRT dependent. Admission white blood cell count, neutrophil/lymphocyte ratio, D-dimer, ferritin, C-reactive protein and lactate dehydrogenase levels were significantly higher in those with AKI.

**Conclusions:** The incidence of AKI in PLWH hospitalized with COVID-19 was high and associated with poor outcomes. We did not identify HIV-specific risk factors for AKI in the setting of COVID-19. Admission inflammatory markers may be predictive of AKI in PLWH with COVID-19.

**PO678**

**AKI Is Related to Mortality in COVID-19 Patients Without Underlying Kidney Disease**

Yue Yu, Huipeng Ge, Xufen Wang, Lijian Tao, Zhangzhe Peng, Xiangcheng Xiao. Xiangya Hospital Central South University, Changsha, China.

**Background:** Due to its high infectivity and mortality, coronavirus disease 2019 (COVID-19) has become a global public health issue. The kidneys act as critical metabolic organs, therefore, whether COVID-19 can induce renal damage is of utmost importance but not well understood. In the prognosis of COVID-19 encountering acute kidney injury (AKI) is unknown. Moreover, the efficacy of different treatments that COVID-19 patients undergo needs to be explored. In this study, we aimed to explore these questions.

**Methods:** A single-centered, retrospective study was conducted in which 96 patients with COVID-19 were enrolled. Epidemiological, clinical, and laboratory characteristics, as well as treatments and patient outcomes were described. Characteristics were compared between severe cases and critical cases. Relevant factors of AKI were filtrated, and the treatment efficacy was also evaluated. Results: A total of 6 patients (6.3%) died during hospitalization. Four patients (4.2%) developed AKI, among which 3 patients (75%) died. Statistical analysis indicated that AKI was not common in COVID-19 patients without underlying kidney disease, but was related to mortality. Age, severity of disease, procalcitonin, C-reactive protein and interleukin-6 were correlated with AKI onset in COVID-19 patients, while lymphocyte count and estimated glomerular filtration rate at admission were inversely related to the development of AKI.

**Conclusions:** In conclusion, AKI is not common in COVID-19 patients without underlying kidney disease but related to mortality.

**Funding:** Government Support - Non-U.S.
filter clotting per patient-day, ACD/Hep also presented less clotting than ACD group (ACD/Hep: 47% vs ACD: 106%; p < 0.05). In COVID patients, median TFC was 33.5 h [17.0; 72.0] (ACD: 29.0 h [13.6; 68.5], ACD/Hep: 40.0 h [17.6; 62.0], p: NS). Clotting time from obese patients did not differ from non obese patients (obese: 31.0 h [18.5; 57.2] vs non-obese: 36.0 h [16.8; 72.2]; p: ns). Median DD in all COVID patients was 3.519 [1420-13.831], Patients with DD below median (<3.500) had higher TFC (ACD high DD: 19.0 h [9.0;27.5], ACD/Hep high DD: 34.0 h [17.0;62.0], ACD low DD: 57.0 h [27.0;68.0], ACD/Hep low DD: 67.0 h [26.0;72.0], Figure 1). There was statistically significant correlation in DD and TFC in ACD patients, but not in ACD/Hep group.

Conclusions: Hemodynamic extend filter lifespan in CRRT, and this benefit seem to be greater in high DD patients.

PO0683

Association of Ventilatory Time and AKI in a Bronx Cohort of COVID-19 Patients

Abbi M. Baselasy,1 Diane Liu,1 Molly Fisher,2 Ladan Golostanest,2 Eran Y. Bellin,1 Kimberly J. Reidy,1 Children’s Hospital at Montefiore, Bronx, NY; 2Montefiore Medical Center, Bronx, NY.

Background: The relationship of lung-kidney interactions in COVID-19 has not been well described. AKI has been associated with increased mechanical ventilation times. Recent publications have shown a strong association of COVID-19-AKI with mortality and a high incidence of AKI occurring peri-intubation. We hypothesized that mechanical ventilation (MV) time would be increased in patients with COVID-19-AKI and longer in those with severe AKI.

Methods: We analyzed a cohort of incident COVID patients who required MV. Patients with end stage renal disease were excluded. AKI was defined using KDIGO criteria (0.3 mg/dL increase or greater than a 50% increase from the baseline Cr) between the time of intubation and baseline Cr. AKI stage was defined as CKD stage 5 or greater. Total MV time was measured in days from date of initial intubation, including subsequent intubation/extubation events, until successful extubation or death. Censored data was not included. Linear regression models were utilized to evaluate associations.

Results: We analyzed 318 patients. 62% were male, 37% were black/African American and 33% were Hispanic/Latino. Hypertension was prevalent in the cohort (N=212) and over 50% were obese. Median MV time was 4.67 days (IQR 1.76, 9.95). AKI occurred in 89% (N=283) of the cohort. Stage 3 AKI developed in over 50% (N=161) of patients. In models adjusted for age, hypertension, diabetes and disease related group weight, patients with AKI had 3.46 more days of MV, however this finding did not reach statistical significance (95%CI 0.92-6.00). This association however was significant and increased linearly with stage of AKI (p for trend <0.001).

Conclusions: This is one of the first studies to evaluate the association of COVID-19-AKI and MV time. Even after adjusting for severity of illness, patients with increased stage of AKI had longer MV times. This may be due to pathophysiological kidney-lung interactions seen in non-COVID19 disease and/or direct effect of COVID19 on the kidneys. As few patients in our cohort were spared from kidney injury, inferences comparing those with and without AKI are difficult to discern. We plan to explore this question in a larger cohort to whether COVID-19-AKI alone is associated with ventilatory time.

PO0684

Can the AKI Alert Staging Tool Help Manage Patients Admitted During the COVID Pandemic?

Barran Mohdin,1 Devendran A. Chatterjee, Gurminder S. Khamba, Georgia Wimmen, Kidney Medicine, Basildon & Thurrock University Hospital Mid and South Essex University Hospitals Group, Basildon, United Kingdom.

Background: Basildon & Thurrock University Hospital has the second highest rate of hospital admissions with AKI stage 3 in the United Kingdom based on Renal Registry Hospital Episode Submission Data. Acute kidney injury (AKI) is common in hospitalized patients and carries a high risk of mortality. Given the limitations of resources both personnel and equipment, a retrospective study was done to see if the AKI alert staging tool can help predict and direct resources to those patients who would benefit most from specialist intervention.

Methods: Data was reviewed from January - May 2020. This corresponded to the peak of admissions and by the end of the period, the hospital was on course to returning to pre pandemic activity. Relevant data including admission laboratory tests and imaging was collected. The admission stay was analysed for duration, the need for transfer to an intensive care unit and any interventions. Censored data was not included. Linear regression models were utilized to evaluate associations.

Results: Over 5000 AKI alerts were generated for this period for 4390 unique admissions. This compares to 3910 AKI alerts for 1098 unique admissions for the identical period in the previous year. The vast majority were for AKI stage 1 alerts none of which were in COVID positive patients. A significant proportion of patients with AKI Stage 2 and 3 alerts were positive for COVID. Those that were admitted to Intensive Care with Stage 3 AKI almost always required intubation and renal replacement therapy. Mortality was higher in this group.
PO0685
Characteristics and Outcome of AKI Needing Dialysis with COVID-19 Infection

Background: COVID-19 infection has varying grades of mortality worldwide. Multi-organ injury, including AKI, portends a poor outcome. We studied AKI needing hemodialysis (HD) in the context of COVID-19 infection.

Methods: From March 15th to May 25th 2020, for consecutive COVID-19 infections AKI needing HD in a large dialysis network age, gender, payer type, days admission to HD start, urinary output, S. Cr, comorbidities, other organ involvement, length of stay & outcome, dialysis session details: blood flow rate(BFR), dialysis flow rate(DFR), anticoagulant volume were reviewed. We compared survivors and non-survivors using Mann Whitney/ Wilcoxon test for medians and Fischer exact for association.

Conclusions: AKI needing HD in COVID-19 infection is associated with significant multiorgan injury and high mortality, making the diagnosis. No significant clinical characteristics were predictive of survival in a sample size

Comparison of survivors and non surviving of COVID-AKI needing HD

PO0686
Circuit Clotting on Continuous Venovenous Hemofiltration in COVID-19 Patients at New England’s Largest Health Safety-Net Hospital
Claire Aviilach, Megan E. Feeney, Mohamed T. Hassan, Kamel Hassan, Aileen W. Zhen, Natasha Awais, Sandeep Ghai. Boston Medical Center, Boston, MA.

Background: The pandemic of COVID19 led to a surge in critically ill patients with severe kidney failure requiring continuous renal replacement therapy (CRRT). Primary reports rapidly showed a hypercoagulable state associated with cytokine storm representing a challenge to conduct CRRT. We report our experience with face clotting on continuous venovenous hemofiltration (CVVH) with COVID19 patients.

Methods: We reviewed data on all admitted patients with COVID19 diagnosis and requiring CVVH at Boston Medical Center between March, 15th and May 7th, 2020. The study was approved by the institutional IRB.

Results: Twenty six patients were admitted to ICU with COVID19 disease and developed acute kidney injury requiring CRRT. The majority of patients were males (73%), and mean age 67.4 ± 15.3 (±19) years. Median CRRT initiation started in 11.8 hours (3.5-20). Twelve patients (46%) experienced CVVH circuit clotting within the first 24 hours, including 6 patients (23%) with severe recurring clotting. Curative systemic anticoagulation by heparin was used in 12 patients (46%) based on hospital protocol. Its use was associated with mild improvement in cartridge half-life: 15h with curative heparin vs 11.3±2.5h with no low dose preventive anticoagulation (non-significant). Of note, heparin was held prior to CRRT initiation for dialysis catheter placement and was reinstituted without bolus, which could lead to early coagulation of the filter in patients with hypercoagulable state. The fatality rate was 76.9% with a median time to death of 2.5 days (1-8.75). Patients who received CVVH intervention had a 76.9% mortality rate.

Conclusions: Conducting CRRT in patients with multiorgan failure secondary to COVID19 is challenging. Our experience suggests only a mild non significant improvement of clotting prevention with heparin anticoagulation at the time of cvh initiation. Further studies are warranted to determine the optimal anticoagulation regimen.

PO0687
Clinical Characteristics and Short-Term Outcomes of Severe AKI in COVID-19 in Bronx, New York
Milagros Yunes,1,2 Emad Alahiri,1 Ryan Mocerino,1 Kalyan Prudhvi,1 Ladan Golestaneh,1,2 Molly Fisher,1,2 Montefiore Medical Center, Bronx, NY; 1Albert Einstein College of Medicine, Bronx, NY.

Background: After the first reported case of COVID-19 in the U.S., New York City quickly became the epicenter of the pandemic. AKI has been reported in patients with severe COVID-19. The Bronx consists of a predominantly minority population with a high burden of comorbidities that may be at increased risk for AKI in the setting of COVID-19. We aimed to characterize risk factors and short term outcomes in patients hospitalized with COVID-19 and severe AKI.

Methods: We performed a retrospective study of 113 adults hospitalized with COVID-19 in a large healthcare system in the Bronx who required nephrology consultation for AKI from March 11-March 30, 2020. We extracted data on demographics, comorbidities, admission vital signs and labs, need for mechanical ventilation, renal replacement therapy (RRT), in-hospital death and discharge. AKI was defined by KDIGO criteria.

Results: Mean age was 63 (SD 12) years old; 69% were men and 33% were Black and 23% were Hispanic. Forty-five patients (39.8%) had chronic kidney disease, 58(51%) had diabetes mellitus and 87(77%) had hypertension. The majority presented with AKI within 24 hours of admittance and 75% had Stage 3 AKI. Ninety-two (81%) patients had proteinuria and 53(47%) had hematuria. Intensive care unit (ICU) was required in 62(55%), 64(57%) required mechanical ventilation, 56(49%) required RRT and 18(16%) were not candidates for RRT. In-hospital death occurred in 68(60%) and 22% were discharged. Of those who required RRT, in-hospital death occurred in 55(62%) and only 6 patients were discharged, 5 of whom remained RRT dependent. Intensive care unit (ICU) was required in 62(55%), 64(57%) required mechanical ventilation, 56(49%) required RRT and 18(16%) were not candidates for RRT. In-hospital death occurred in 68(60%) and 22% were discharged. Only 5 patients were discharged. The fatality rate was 76.9% with a median time to death of 2.5 days (1-8.75). Patients with multiorgan failure secondary to COVID19 had a 76.9% mortality rate.

Conclusions: Severe AKI in the setting of COVID-19 is associated with increased utilization of ICU, mechanical ventilation, and RRT. Outcomes are poor in those with Stage 3 AKI, underscoring the need for palliative care involvement and early goals of care discussions. Elevated initial CRP and heavy proteinuria may be useful to risk stratify patients with COVID-19 and severe AKI at increased risk for mortality.

PO0688
Clinical Factors Associated with AKI in Patients with COVID-19 from a University Hospital in Brazil
Beatriz M. Chulué1,2, Isabela S. Maltoni,1 Felipe F. Sanchez,1 Mariana R. Coletti,2 Caio C. Delfino,1 Isabela G. Almeida,1 Leticia C. Albeny,1 Gabriel N. Araujo,1 Renata G. Roizman,1 Giovanna M. Zavadzki,1 Miguel Angelo Goes,1 1Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2Unisa, Sao Paulo, Brazil.

Background: Critically ill patients with COVID-19 frequently presents Acute kidney Injury (AKI) associated with increased mortality. However, there is paucity of data from Brazil. So, we analyzed factors in associated with AKI patients in a university hospital.

Methods: We conducted an observation with frequencies and association with binary logistic regression study in patients with COVID-19 hospitalized at Hospital Sao Paulo-Federal University of Sao Paulo. Diagnosis and classification of acute kidney injury (AKI) were by KDIGO. We examined the rates of renal function, mechanical ventilation (MV), renal replacement therapy (RRT), medications and in-hospital mortality.

Results: We observed a total of 172 in-patients with COVID-19. Patients were predominantly male (61.5%). We observed hypertension in 55%, diabetes 34%, smokers 27%, obesity (19%). Eighty-nine (52%) patients needed intensive care unit (ICU), 70 (99%) cases of AKI were in ICU (31% of general ward admissions; p<0.001). In the ICU there were 78% needed mechanical ventilation, 36% in RRT, amine vasoevasive 65% and mortality in 48%. AKI patients were older (61±15, 55±15; p<0.01), higher creatinine in admission (2.6±1.6, 1.3±0.7; p=0.002), higher RWDW (14.7±3.5, 13.3±1.6; p=0.08), needed of MV (88%) and vasopressive amine (90%), RRT (88%) and higher mortality (87%). We used serum creatinine, RWDW, AKI in-hospital mortality and in-hospital mortality in model of regression. We observed that MV (OR 10.26 [CI95%, 10.09-1038; p<0.001) and age (OR 1030 [CI95%, 1004-1056; p=0.002) were independently associated with AKI.

Conclusions: AKI is associated with high rates of RRT and death. Higher age and need of mechanical ventilation were associated with AKI in COVID-19 patients.

Funding: Government Support - Non-U.S.

Mark
admission and Day 11 of symptoms on average. 90/153(58.5%) patients had recovery
whilst on RRT. Mean peak serum creatinine of 246umol/L was observed on Day 5 of
3. 14(9.2%) patients required renal replacement therapy (RRT) with 7(50%) becoming
AKI (CA-AKI) and hospital-acquired AKI (HA-AKI) in a Mexico City reference
Hospital, London, United Kingdom
Harber.

Results: 630 COVID-19, AKI was detected in 164 (26%), 81 (49%) CA-AKI, and 83 (51%) HA-AKI. Among AKI, 84 (51%) were Stage 1, 38 (23%) Stage 2, and 42 (26%) Stage 3. Stage 3 was more frequently observed in HA-AKI (p<0.001). RRT was provided to 15 (9.1%) at a median 3 days from diagnosis. Fluid overload was the main indication for RRT initiation. In general, CA-AKI was associated with higher severity of COVID-19 evidenced by several risk scores, ICU admission, mechanical ventilation, and vasopressor therapy. Recovery from AKI was more frequent in the CA-AKI group 66% vs 44 % (p<0.001). Admission was associated to volume depletion and shock, with fluid management. Among patients with AKI, 92 (56%) died, 49% in the CA-AKI vs. 63% in the HA-AKI group (p<0.001). There were no differences in RAAS inhibitor use between groups.

Conclusions: CA-AKI and HA-AKI are frequent renal manifestations in COVID-19.
AKI is associated with severe COVID-19 and significantly higher mortality. Although more comorbidities were present in CA-AKI, outcomes were better for CA-AKI vs. HA-AKI, in spite the latter group being younger, as it represents ICU patients with severe COVID-19 disease and associated multigain failure.

Results: A total of 149 records were reviewed, and 98 patients were included (47 died and 4 discharged). Twenty-three patients (23.5%) were on APT or ACT and 39 (40%) required RRT. Table 1 compares characteristics by study group. Hypertension and cardiac conditions were significantly different between groups. Twelve (52%) of patients on APT or ACT required RRT and 27 (36%) not on either required RRT (p=0.22).

Conclusions: Pre-existing APT or ACT was not associated with AKI-D in critically ill patients with COVID-19. 2 weeks of follow up. Our data demonstrated a high incidence of AKI-D but was limited by significant differences in cardiac conditions between study groups. Future larger studies examining this association in groups with comparable cardiac conditions are needed.

COVID-Related AKI Recovery Courses with Negative Fluid Balance and Related Electrolyte Disorders

Anna Gabriela J. T. Meleg, Rayra G. Ribeiro, Géssica S. Braga Barbosa, Daniela Via Reque Cortes, Carla P. Sandoval Cabrera, Camila E. Rodrigues, Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

**Background:** Acute Kidney Injury (AKI) occurs in 3-37% of COVID patients; recovery is poorly described.

**Methods:** All patients who recovered from AKI in Clinics Hospital (São Paulo, Brazil) during April 2020 (COVID related-AKI (COVID+), n=35) and September 2019 (COVID unrelated-AKI (COVID-), n=25) were studied for 1.5 month each. Recovery was represented by spontaneous serum creatinine (sCr) drop in patients not submitted to dialysis, or by withdrawal of dialysis in those who needed the therapy. Serum creatinine, urea (sU), sodium (sNa), bicarbonate (bic), and fluid balance (FB) were analyzed during the first five days of recovery (5-Dr). Data are expressed in mean ± SD. Repeated measures ANOVA was used to compare different days on each parameter, and t test was used to compare groups. Categorical data were analyzed using Fisher’s test.

**Results:** Among 88 COV- patients, 25 recovered from AKI, while 35 in 102 COV+ patients recovered during the time studied (80% COV+ were in KDIGO 3 classification). In COV+ group, COVID-AKI time was predictive of AKI duration: earlier AKI (≤ 5 days from COVID symptoms) lasted 5.6 ± 4.0 days (vs 11.9 ± 9.2 days in later AKI presentation; p<0.05). Both COV+ and COV- patients recovered with sCr and sU drop during 5-Dr, except for diuretic users, who presented sCr drop without sU drop. COV- patients presented negative overall FB during 5-Dr, while COV- patients presented positive FB (-516.2 ± 2730 vs 225.5 ± 5868 mL/24h). In COV+, sNa rose through 5-Dr (p<0.05), and in COV- it did not. Among diuretic users, the same pattern of FB was seen between groups (-194.9 ± 3163 in COV+ vs 163.5 ± 1080 mL/24h in COV-), and COV- showed increased sNa through 5-Dr (p<0.05), while COV- reduced sNa through 5-Dr (p=0.05). Diuretic users had bicarbonate increase in COV+ (from 24.3 ± 3.6 to 27.0 ± 4.9 mmol/L, p<0.05), but not in COV-. In diuretic non-users, both groups have risen sNa through 5-Dr, but only COV+ reached statistical significance. Diuretic use at AKI-recovery was higher in COV+ patients (57% vs 28%, p<0.05).

**Conclusions:** Later-onset COVID-related AKI seems to be more prolonged. Diuretics should be carefully used in AKI-recovering COV+ patients, once hypernatremia and metabolic alkalosis are more common than in other AKI etiologies.

Filter Clotting, Anticoagulation, and Duration of Sustained Low-Efficiency Dialysis in Patients with COVID-19 and AKI

Yuang Wen,1 Jason R. Ledoux,1 Akanksh Ramanand,1,2 Kevin Scharwath,1 Destiny A. Mundy,1 Muner Mohamed,1 Ivo Lukitsch,1 Juan Carlos O. Velez,1 Ochsner Nephrology, Department of Nephrology, Ochsner Health System, New Orleans, LA, 2 Ochsner Clinical School- The University of Queensland, New Orleans, LA.

**Background:** There have been anecdotal accounts of shortened duration of renal replacement therapy (RRT) due to filter clotting in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) requiring RRT (AKI-RRT). Thus, we examined the duration of runs of RRT in patients with CoV-AKI as well as in patients with AKI-RRT in the pre-COVID-19 era.

**Methods:** Among 161 patients with CoV-AKI, we identified patients with CoV-AKI who underwent RRT by sustained low efficiency dialysis (SLED) for a 2 days (n = 52) (March-April 2020). As a control, we included patients with AKI without COVID-19 diagnosis who underwent SLED (n = 24) (non-CoV-AKI) in December of 2019, pre-COVID-19 era. We quantified the duration of RRT under various protocols of anticoagulation (AC) [no AC, citrate (CIT), regional heparin (rH), minimally intensive heparin (mIH), systemic low intensity heparin (sLH), systemic high intensity heparin (sHH) and sHH plus CIT (sHH+CIT)] by computing the duration (hours) of each SLED session (hrs of SLED/start) and the percentage of short SLED runs (<6 hours).

**Results:** In CoV-AKI, the median hrs of SLED/start under each AC protocol were 6.1 for no AC, 5.4 for CIT, 10.6 for rH, 11.6 for mIH, 11.4 for sLH, 12.4 for sHH and 14.6 for sHH+CIT. As the AC intensified, the duration of SLED increased (chi-square for trend, p = 0.014). Pre-COVID-19, standard AC for non-CoV-AKI were no AC or CIT and had a median longer RRT duration compared to CoV-AKI under either no AC or CIT (10.2 vs 5.5 hrs of SLED/start, for non-CoV-AKI vs CoV-AKI, respectively, p = 0.021). Similarly, the proportion of patients with short runs was greater in CoV-AKI (under no AC or CIT) vs non-CoV-AKI (55% vs 19%, p = 0.01). When comparing the 3 more aggressive AC protocols (sLH, sHH and sHH+CIT) in CoV-AKI with non-CoV-AKI, the duration of RRT was similar (12.2 vs 10.2 hrs of SLED/start, p = 0.11) and the percentage of short SLED runs were also similar (10% vs 19%, p = 0.25).

**Conclusions:** RRT in CoV-AKI was associated with shorter duration of SLED compared to non-CoV-AKI, likely driven by increased filter and/or catheter clotting. Aggressive AC protocols with sHH with or without CIT in CoV-AKI were successful in restoring the duration of RRT back to that observed in patients with AKI-RRT in the pre-COVID-19 era.
Impact on Renal Replacement Therapy Modality on Prognosis of SARS-CoV2 Infection

Yannis Lombardi, Hafedh Fessi, Hélène François, Pierre A. Michel, Camille Petit-Hoang, Eric Rondeau, \textsuperscript{2}Hôpital Tenon, Paris, France; \textsuperscript{3}Sorbonne Université, Paris, France.

\textbf{Background:} Prognosis of SARS-CoV2 infection among patients with Chronic Kidney Disease (CKD) is poorly known. In particular, the impact of renal replacement therapy (RRT) modality on prognosis is undetermined. Patients with kidney transplant exhibit treatment-induced immunodepression, while patients on dialysis are usually older and exhibit higher frailty. We aim to determine the impact of RRT modality on the prognosis of SARS-CoV2 infection among patient with advanced CKD.

\textbf{Methods:} We conducted a retrospective cohort study using our institution's Clinical Data Warehouse. Health records of all patients with at least one hospitalization or consultation in our nephrology department were screened based on ICD-10 codes. Inclusion criteria were: hospitalization in any of our institution’s hospitals for SARS-CoV2 infection (national Public Health agency criteria). Patients were divided into two groups: \textit{active kidney transplants} and \textit{dialysis}. A Cox model stratifying on age and medical history of coronary artery disease was used to determine adjusted Hazard Ratio (HR) for death or intensive care unit (ICU) admission.

\textbf{Results:} We included 72 patients: 47 in the \textit{transplant} group and 25 in the \textit{dialysis} group. First hospitalization was on 20/02/28 and last hospitalization on 20/05/19. Median follow-up was 21.5 days. Death or ICU admission occurred in 21 (29%) patients \textit{(transplant} group: 15 (32%), \textit{dialysis} group: 6 (24%), \(p=0.45\)). In multivariate analysis, adjusted HR for death or ICU admission was 1.70 \([95\% CI: 0.59-4.86]\) for transplant vs. dialysis \((p=0.32)\).

\textbf{Conclusions:} In our study, among patients hospitalized for SARS-CoV2 infection, no significant difference in risk for ICU hospitalization or death was found between \textit{transplant} patients on dialysis or with active kidney transplant. A trend for higher risk was noted among patients with active kidney transplant. Further studies are required to confirm those findings.

---

Low-Molecular-Weight Heparin Is a Superior Anticoagulant to Unfractionated Heparin for Renal Replacement Therapy in Patients with AKI due to Coronavirus Disease 2019

Neethirick Marcedo, Benjamin German, Casey N. Gashi, Payal K. Gurmani, Roger A. Rodby, William L. Whittier. Rush University Medical Center, Chicago, IL.

\textbf{Background:} Severe coronavirus disease 2019 (COVID-19) not only causes acute pulmonary pathology leading to acute respiratory distress syndrome needling intubation, but also leads to acute kidney injury (AKI) requiring renal replacement therapy (RRT). Due to hemodynamic instability, these patients (pts) often need either continuous RRT (CRRT) or prolonged intermittent RRT (PIRRT). Accelerated Veno-Venous Hemodialysis (AVVHD), a form of PIRRT with typically 40-50 liter of dialysate used over 8-10 hours has been successfully used to treat hemodynamically unstable pts and has been the treatment of choice during the early phase of the pandemic but uncertainty exists in preventing ECC, prompting a trial of low molecular weight heparin (LMWH).

\textbf{Methods:} We conducted a single-center retrospective study to evaluate the efficacy and safety of LMWH vs UFH in preventing ECC in pts with AKI due to COVID-19 who received AVVHD from 3/25/20 through 4/30/20 at a large academic medical center. Data collected included pt demographics, type of anticoagulation and thrombolytic use, treatment characteristics including clotting frequency as well as bleeding complications. ECC was defined as any event that required an unexpected interruption in treatment or death due to thrombolic use.

\textbf{Results:} A total of 58 pts received 408 AVVHD treatments. The average pt age was 58 years, 65% were male, 66% were black and 69% were obese with body mass index \(>30\) kg/m\(^2\). 188/408 (46%) of AVVHD treatments received anticoagulation with UFH while 165/408 (40%) of treatments received LMWH. ECC occurred in 30% of AVVHD treatments who received UFH vs 15% in the LMWH group, a relative risk reduction of 50\% \((P = 0.001)\). Only 1 pt experienced a major bleeding event in the UFH group and none with LMWH.

\textbf{Conclusions:} Anticoagulation with LMWH is superior to UFH in reducing ECC in pts receiving AVVHD for AKI due to COVID-19 without an increased risk of bleeding.

Mortality of AKI in Human Immunodeficiency Virus with and Without Co-Infection with COVID-19

Ijie Onwugbufor,1 Siddharth D Rajacharya,1 Ernie Yap,1 Mary C. Mallappallil,1,2 Kings County Hospital Center, Brooklyn, NY; SUNY Downstate Medical Center College of Medicine, Brooklyn, NY.

Background: Since the start of COVID-19 pandemic, concerns have been raised about specific populations being at potential higher risk for developing more severe diseases, and patients living with HIV (PLWH) are among them. SARS-CoV-2, a newly isolated virus from the Corona Virus family, is enveloped, positive-sense single-stranded RNA virus that causes multi-organ failure, especially acute kidney injury (AKI) which is proved to be associated with significantly elevated mortality rate. It dysregulates human immunity especially on T lymphocytes which is shared by HIV as the mechanism of causing related diseases. We reviewed our hospital data to examine if HIV infection resulted in worse outcomes in COVID-19 patients who developed AKI.

Methods: Retrospective chart review of all admitted patients to Kings County Hospital (KCH), a municipal hospital in Brooklyn, New York City between 3/1 to 5/15, 2020, from the electronic medical record. Patients were reviewed in groups of COVID infection without history of HIV, HIV patients admitted without COVID infection and patients with history of HIV who were admitted because of COVID infection. The rate of AKI and mortality were extracted and analyzed suing Chi-squared test in SPSS.

Results: A total of 1092 patients with confirmed COVID-19 diagnosis were admitted in an intensive care time period, out of which 22 were diagnosed with COVID-19 and HIV. In the COVID-19 without HIV diagnosis group, 450 patients developed AKI and 213 patients died, with a mortality rate of 47.3%; in the COVID-19 with HIV group, 9 patients developed AKI and 4 expired, mortality rate is 44.4%. There’s no significant difference between these two groups (p=0.86). Compared to these two groups, 21 out of 93 PLWH without COVID infection had AKI during hospitalization with 2 patients deceased, and a mortality rate of 9.5% which is significantly lower (p=0.03).

Conclusions: Data from our hospital between 3/1 and 5/15/2020 shows the mortality rates of patients with HIV and COVID-19 co-infection with AKI and COVID patients without HIV who developed AKI are not statistically different, but significantly higher than patients with HIV who developed AKI.

PO0704
Refractoriness of Hyperkalaemia and Hyperphosphatemia in Dialysis-Dependent AKI Associated with COVID-19

Akanshan Ramanand,1 Vinip Varghese,1 Yuang Wen,2 Muner Mohamed,2 Juan Carlos Q. Velazquez.1 Ochsner Nephrology, Ochsner Clinical School-The University of Queensland, New Orleans, LA. 2Department of Nephrology, Ochsner Health System, New Orleans, LA.

Background: There have been anecdotal accounts of an unusual incidence of persistent hyperkalaemia (hyperK) and hyperphosphatemia (hyperP) in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) despite renal replacement therapy (RRT). However, an observation bias could not be discarded. Thus, we examined the rate and severity of hyperK and hyperP in patients with CoV-AKI actively treated with RRT.

Methods: Among 161 patients with CoV-AKI, we selected those who underwent RRT by sustained low efficiency dialysis (SLED) for a2 days (n=64). A database of patients with AKI on SLED who underwent urinary sediment microscopy (Sedi-AKI cohort, 2017-2019, n=60) served as control (non-CoV-AKI). We examined the rate of hyperK (serum potassium [sK] ≥ 5.5 mEq/L), severe hyperK (sK ≥ 6.5 mEq/L), hyperP (serum phosphate [sP] > 4.5 mg/dL), moderate hyperP (sP > 5.0 mg/dL) and severe hyperP (> 5.0 mg/dL) as SLED-days with an event.

Results: Median age were similar: 60 (39-84) and 58 (22-88) years for CoV-AKI and non-CoV-AKI, respectively. Black race (77% vs. 30%, p=0.001) and male sex (78% vs. 61%; p=0.04) were more common in CoV-AKI. Ischemic ATI was the presumed cause of AKI in 85% and 82% of the CoV-AKI and non-CoV-AKI, respectively. Along the duration of SLED, the incidence of hyperK was greater in CoV-AKI [mean 19 ± 2% vs. 14 ± 2% SLED-days, p=0.002]. The proportion of patients with a1 event of severe hyperK was greater in CoV-AKI [33% vs. 7%, p=0.0004]. The incidence of hyperP were similar between groups [mean 56 ± 4% vs. 53 ± 5% SLED-days, p=0.49]. However, the proportion of patients with a1 event of moderate and severe hyperP were greater in CoV-AKI [86% vs. 60% (p=0.001) and 50% vs. 18%, (p=0.002)]. In CoV-AKI, sK and sP correlated with lactate dehydrogenase (LDH) (R=0.305 (p=0.044) and R=0.307 (p=0.043), respectively) but not with creatine kinase; and hyperP events correlated with shorter SLED runs (hours/run) (R=-0.268, p=0.055).

Conclusions: HyperK and hyperP refractory to RRT (by SLED) were more frequent in CoV-AKI compared to other forms of AKI in the pre-COVID-19 era. Because of the correlation of sK and sP with higher LDH and shorter SLED runs, intracellular ion release from cell injury due to cytokine-“storm” and RRT interruptions may play a role.

PO0705
Risk Factors for AKI in Patients Hospitalized with COVID-19

Mridula Nadamuni, Yu-Lun Liu, Sadaf S. Khan, Shani Shastri, Duwayne L. Willett, Nilum Rajora, Catherine Chen, Susan Hedaya. The University of Texas Southwestern Medical Center, Dallas, TX.

Background: We evaluated risk factors and prevalence associated with AKI in our early experiences with patients hospitalized with COVID-19, 32% of whom required ICU level care, at the University of Texas Southwestern and Parkland Hospitals in Dallas, Texas from 3/13/20-5/7/20.

Methods: Patients admitted with COVID-19 confirmed by SARS-CoV2 PCR test were screened for AKI. Univariate and multivariate logistic regression was used to identify significant factors associated with AKI.

Results: COVID-19 was confirmed in 145 patients, of whom 62 (43%) had AKI. Patients with AKI were older, mean (SD) age (17 ± 5) vs. (14 ± 5) years without AKI, p=0.03, and were more likely to have hypertension, 74% vs. 47%, p=0.002, and diabetes mellitus, 65% vs. 31%, p=0.0002. CKD was present in 42% of those with AKI vs. 7% of those without, p=0.001. Race, ethnicity, and ACEI/ARB use did not differ between groups. Patients with AKI had higher CRP, median (IQR) 102 (44-161) vs. 59 (21-116) mg/L, p=0.009, and LDH on presentation, 365 (265-493) vs. 317 (228-385) U/L, p=0.04. The mean systolic BP at admission in non-AKI patients was 136 ± 22 mmHg (109 of 147 available) whilst in those with AKI it was 124 ± 25 mmHg (78 of 105 available). There have been anecdotal accounts of an unusual incidence of persistent hyperkalaemia (hyperK) and hyperphosphatemia (hyperP) in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) despite renal replacement therapy (RRT). However, an observation bias could not be discarded. Thus, we examined the rate and severity of hyperK and hyperP in patients with CoV-AKI actively treated with RRT.

Conclusions: During the first weeks of COVID-19 outbreak at our hospitals, 43% of COVID-19 positive patients.

Conclusions:

COVID-positive (n=58) COVID-negative (n=101) p value

PO0706
The Impact of COVID on CRRT Filter Lifespan

Lewis Mann, Mony Fraer, Sarat C. Kuppachi, Lama A. Noureddine, Lisa M. Antes, Sreedevi kopisseti Jenigiri, Maria T. Story, Mecnakshi Sambharia, Jayesh B. Patel, Kandi O’Connor, Benjamin R. Griffin. University of Iowa, Iowa City, IA.

Background: Patients with COVID are more likely to have systemic thrombotic events. Although it has been theorized that those on CRRT also have an increased rate of filter loss due to clotting. If COVID-positive patients are more likely to clot their filter than other patients on CRRT, a more aggressive anticoagulation strategy may be worthwhile. This could result in longer filter lifespan, less circuit down time, which would result in improved care, lower costs, less risk of iatrogenic blood loss, and less wasted nursing time. If there is no difference in filter lifespan between COVID positive and negative patients, then more aggressive anticoagulation would result only in added risk without a clear benefit.

Methods: We analyzed COVID data on patients in a related unblinded prospective randomized trial, in which patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a target blood rate of 200 mL/min and a dose of 25 mL/kg/hr. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: A total 30 patients using a total of 90 filters from March 25 to May 20, 2020 were evaluated (Table 1). The average filter life in COVID-positive patients was 37.4 +/- 35.8 compared to 33.1 +/- 26.7 in COVID-negative patients (p = 0.55). However, COVID-19 patients were more likely to receive heparin anticoagulation in addition to citrate.

Conclusions: Contrary to other reports, in this retrospective, unadjusted analysis of CRRT patients, the presence of COVID-19 did not decrease average filter life. Further research is needed regarding the appropriate anticoagulation strategy in COVID-19 positive patients.

PO0707
Single-Center Experience of AKI in COVID-19-Infected Patients in West Kent Hospital, United Kingdom

Matthew James, Tord H. Hogsand, Kieran Jankowski, Jeetendra R. Rathod, Nihil Chitalia, Jonathan Kwan. Darent Valley Hospital, Dartford, United Kingdom.

Background: We studied the epidemiology of acute kidney injury (AKI) in the COVID-19 positive patients.

Methods: Between 9th March 2020 and 26th April 2020 data was prospectively collected on 253 adult COVID-19 positive inpatients co-morbidity, s. creatinine, demographics and AKI from digital records at our secondary care hospital. AKI stages were defined as per KDIGO Criteria.

Results: Of the 253 patients, 58.9% were male with (mean ± stdev) age 71.9 ± 16.4 years. Common co-morbidities were Hypertension (54.1%), Cardiovascular Disease (34%), Diabetes Mellitus (29%), Chronic lung disease (26%). Dementia (16%), CKD (stage 3 - 5 19.8% & 2.8% renal transplant. 2.8% (7) patients on regular dialysis were excluded. 42.6% (105) patients had AKI of these 53.3% (56) had AKI 1, 20.9% (22) AKI 2 and 25.7% (25) had AKI 3. 2.4% (6) patients’ needed acute haemofiltration.

The Clinical Presentation of AKI Complicating COVID-19: Observations from Elmhurst Hospital, New York City
Nasser M Alnizarri,1 Demetrios Papademetriou,2 George N. Cortisidis, Payal Ram, Ellena A. Linden, Aaron S. Stern. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Early in March, NYC Hospitals became inundated, especially safety net public hospitals. The physicians at Elmhurst Hospital Center (EHC) encountered countless cases of respiratory failure often accompanied by AKI. Autopsy studies from China described an interstitial nephritis, with macrophage infiltrates and complement deposition along with fibrotic changes. We report our experience with COVID-19 and AKI.

Methods: We reviewed the charts of 137 SARS-CoV-2 positive patients (PCR of a nasopharyngeal sample) admitted to EHC 3/7/2020 - 4/7/2020. We categorized patients who had KDIGO stage 3 AKI on presentation to CVVHDF. We compared patients with early AKI (first week of hospitalization) vs non-AKI. We compared patients with early AKI who did not receive dialysis vs those that did.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (44%) patients and 280 (20%) with AKI required dialysis. The proportion with stages 1, 2, and 3 AKI overall was 35%, 20%, 45%, and 20% received dialysis (Figure 1A). In the 815 patients admitted to the intensive care unit (ICU), 533 (68%) had AKI and 34% required dialysis. The median peak serum creatinine was 2.2 (IQR 1.6-3.7) mg/dL in those that did not receive dialysis and was 8.6 (IQR 6.5-11.4) mg/dL in those that did receive dialysis. Urine studies were available for 58 (18%) patients of whom 338 (60%) patients had AKI. 538 (96%) of all patients had any urinary abnormalities of proteinuria, hematuria, or pyuria. Independent predictors of severe AKI were chronic kidney disease, systemic blood pressure, and potassium at baseline. In-hospital mortality in patients with AKI was 41%. The aOR for mortality for AKI was 9.6 (95% CI 7.4-12.3), 56% of patients with AKI who were discharged recovered kidney function back to baseline (Figure 1B).

Conclusions: AKI is common in patients hospitalized with COVID-19, associated with worse mortality, and nearly half of patients do not recover kidney function.

PO0711 SARS-CoV-2 Infection and Outcomes in Chronic Dialysis Patients
Eduardo K. Lasenc,1, 2 Gideon N. Aweh,1 Vladimir Ladi,1 Harold J. Manley,1 Carol Stewart,1 Doug Johnson,1 Dialysis Clinic Inc, Nashville, TN; 2Tufts University School of Medicine, Boston, MA.

Background: The SARS-COV-2 pandemic (COVID) impacted ESRD patients on dialysis, categorized by the CDC as immunocompromised. We describe the characteristics and outcomes in patients treated by a non-profit dialysis provider.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

261
Methods: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had identified 422 COVID+ patients from 90 clinics in 20 states. We compared their characteristics relative to the uninfected source clinic population (N=6,993) and tracked outcomes over the 15-week period.

Results: Comparative characteristics are shown in the table (*p<0.05). Hospitalization occurred in 295 (70%) with 75 deaths, 159 discharges and 61 still hospitalized. Ten patients died >30 days post-discharge. Another 11 deaths occurred in 116 non-hospitalized patients. Overall, 96 of 422 died (22.7%). While more black patients were infected, death rates were higher in white than black dialysis patients (31.5% vs. 18.8%, p=0.008).

Conclusions: Chronic dialysis patients with COVID have higher death rates than the general population. Infected patients tended to be older, with more comorbidity, particularly DM/CVD, and utilized respiratory inhalers/assistance. Group home residents were overrepresented with COVID while home dialysis patients were disproportionately spared.

PO0712
ESKD Patients Hospitalized with COVID-19: Early Outcomes in Bronx, New York

Molly Fisher,1,2 Milagros Yunes,1 Michele H. Mokrzycki,1,2 Ladan Golestaneh,1,2 Maria Coco,1,2 Montefiore Medical Center, Bronx, NY; 2Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

Background: It is unclear whether end-stage kidney disease (ESKD) patients with COVID-19 are at increased risk for adverse outcomes due to impaired immune responses attributable to uremia. Alternatively, a weakened immune state could mitigate the cytokine surge observed in non-ESKD patients with COVID-19. The aim of our study is to describe the clinical characteristics and short term outcomes in ESKD patients requiring hospitalization for COVID-19.

Methods: We performed a retrospective study of 114 consecutive ESKD patients hospitalized at two major hospitals in the Bronx with COVID-19 from March 9, 2020 to April 12, 2020 in the midst of the coronavirus surge in New York City. Clinical and laboratory data were extracted from the medical record and short term outcomes were reported.

Results: The mean age was 63 years (range 30-87); 61.4% were men and 88.6% were Black or Hispanic. Most had hypertension (89.5%) and diabetes mellitus 66% and 30.7% were nursing home residents. Intensive care unit admission was required in 13(11.4%) patients and 17(14.9%) required mechanical ventilation. In-hospital mortality occurred in 23(20%) patients and was similar to mortality observed in non-ESKD patients. Mortality was 59% in those who required mechanical ventilation. At the time of data censoring, 47% had been discharged and 32% remained hospitalized. Initial procalcitonin, ferritin, lactate dehydrogenase and lymphocyte percentage were significantly higher in those who died.

Conclusions: Short term mortality in Bronx ESKD patients hospitalized with COVID-19 was similar to non-ESKD patients. Mechanical ventilation was associated with high mortality. Initial elevated inflammatory markers may be predictors of mortality in ESKD patients with COVID-19. To date, this is one of the largest studies describing outcomes in hospitalized ESKD patients with COVID-19. Further studies describing long-term outcomes in this population following COVID-19 are needed.

PO0713
Trends in Fever and Respiratory Illness in Hemodialysis Patients During the COVID-19 Pandemic

Sheetal Chaudhuri,1 Hao Han,1 John W. Larkin,1 Len A. Usvyat,1 Dinesh K. Chatoth,2 Jeffrey L. Hymes,2 Michael A. Kraus,2 Allan J. Collins,2 Franklin W. Maddux,3 1Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care, North America, Waltham, MA; 3Fresenius Medical Care AG and Co KGaA, Bad Homburg, Germany.

Background: Hemodialysis (HD) patients are vulnerable to the 2019 coronavirus disease (COVID-19) due to older age and common coexistence of comorbidities. Fever and respiratory illness (RI) are common symptoms of COVID-19. In order to create a disease surveillance tool and anticipate areas of COVID-19 outbreak, we aimed to assess the trends in fever and RI symptoms in HD patients treated at a national dialysis provider network in the United States during the pandemic.

Methods: We used data from HD patients actively treated between Jan 1 2018 and May 16 2020 at a national dialysis provider network of large integrated health care company. If the body temperature of the patient either before or after the treatment was greater than 100 degrees Fahrenheit, then the patient was identified as exhibiting the symptom of fever. If the patient complained of shortness of breath, wheezing, runny nose, bloody cough, dry cough or purulent cough, then in this analysis the patient was identified as exhibiting the symptom of RI.

Results: The total patients count ranged from 196,774 to 209,475 per week while the total count of HD treatments ranged from 413,477 to 454,215. For the year 2020, a clear increase in trend for number of patients was observed after week 11 (03/08-03/14/2020) for fever symptoms (Figure 1A) and week 12 (03/15-03/21/2020) for fever symptom (Figure 1B). Both increasing trends spike at the week 15 (04/05-04/11/2020) and decline thereafter.

Conclusions: HD patients appear to exhibit a different trend in RI and fever symptoms during the year 2020 compared to concurrent periods in 2018 and 2019. Which indicates the potential for COVID-19 outbreaks. Dynamic surveillance of dialysis patients may allow for early identification of COVID-19 outbreaks.
PO0714 Implementation of Strategies for Prevention and Control of SARS-CoV-2 Infection at Dialysis Units in Latin America: Analysis from GlomCon
Denisse Arellano-Mendez, Julio A. Gutierrez-Prieto, Javier Soto-Vargas, Blanca Martinez-Chagolla, Franco H. Cabeza Rivera, Desiree Garcia Anton, Diana Gutierrez, Nury Sommez Ramirez, Carmen Avila-Casado. GlomCon Latin America Working Group (LGlomCon), Mexico; 5 Hospital General de Mexico, Mexico; 6 Hospital General de Mexicali, Mexico; 7 Hospital General Regional 46, IMSS, Guadalajara, Mexico; 8 University of Mississippi Medical Center, Jackson, MS; 9 Hospital General de Mexico, Mexico; 10 Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; 11 Pathology Department, University Health Network, Toronto, ON, Canada.

Background: Patients on dialysis belong to the high-risk group to develop severe COVID-19 infection due to their multiple comorbidities. International societies have issued recommendations for the control and prevention of SARS-CoV-2 infection at dialysis units but implementing them may not always be feasible as many healthcare systems in Latin America (LA) have limited resources. This study aims to reflect the experience of nephrologists in LA at taking care of these patients and if the recommendations were adopted in their practices.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-28, 2020, in sixteen Spanish-speaking LA countries divided into 6 categories. We present the results for the ESRD category.

Results: 430 responses were obtained, 360 were considered for analysis. 276 (86.5%) of the participants were nephrologists and 178 (64%) of them practiced in dialysis units. 165 (92.6%) already implemented strategies to control and prevent COVID-19 in their units. 125 (71%) received training on it and 128 (72.7%) reported personal protective equipment availability. The most commonly implemented strategies were: education sessions about COVID-19 for patients and caregivers (68.5%), designated isolation areas (77.8%) or shifts (68.2%) for patients with confirmed COVID-19 and a 7-feet separation between hemodialysis (HD) machines (61.9%). 49 (28%) of the nephrologists reported an outbreak among patients and 60 (34.2%) among medical staff. Patient absenteeism to their HD sessions due to fear of infection, a decrease in the frequency and a shortening of the time of the sessions was reported in 41.7%, 30.2% and 36%, respectively. 29 (16.5%) of the respondents considered that those practices were associated with patient mortality.

Conclusions: Most dialysis units in LA are partially implementing the recommended strategies for control and prevention of COVID-19 but this seems to be insufficient since at least one third of them already faced outbreaks among patients and medical staff.

PO0715 Implementing COVID-19 Infection Control Procedures in Outpatient Dialysis in an Urban US Population
Ibironke W. Apata, Jason Cobb, Jose E. Navarrete, Janice P. Lea. Emory University School of Medicine, Atlanta, GA.

Background: Emerging data reveal disparities in the burden and severity of disease among racial and ethnic minorities in the US. Emory Dialysis consists of 4 outpatient dialysis facilities, serving an older, urban and predominantly African-American population. These facilities are in counties with the highest number of COVID-19 cases in Georgia. We describe infection control measures implemented to prevent COVID-19 transmission, and the clinical characteristics of patients with COVID-19 in the facilities.

Methods: Based on CDC’s recommended guidance, we implemented the following infection control procedure between February and April 2020: 1) screening; triaging all patients, and separating patients with symptoms of COVID-19; 2) monitoring staff for infection control procedure between February and April 2020: 1) screening; triaging all patients, and separating patients with symptoms of COVID-19; 3) performing temperature checks at time of arrival; 4) universal masking in the dialysis units; 5) conducting PPE re-trainings; 6) assessing facility preparedness; 7) separating high risk patients (nursing home residents); and 8) cohorting patients with COVID-19 to a dedicated dialysis shift.

Results: Of the 745 patients followed at the Emory dialysis facilities, 18 (2.4%) were diagnosed COVID-19 between March 25—May 7, 2020. Among the 18 patients, 17 were receiving in-center hemodialysis and 1 was on peritoneal dialysis. The median age was 66.8 years (range 43–84) and 11 (61.1%) were female. Nine (50%) were residents of a skilled nursing facility. Sixteen (88.9%) patients had a diagnosis of hypertension, 10 (55.6%) had diabetes, and 10 (55.6%) had cardiac disease. Eight patients (44.4%) required hospitalization and 4 patients (22.2%) died from COVID-19 related complications. Two patients who were only doing dialysis at adjacent dialysis stations and the timing of their symptoms suggested possible transmission in the dialysis facility. In response, education, infection control audits and PPE re-trainings were conducted to bolster infection control practices.

Conclusions: In a high-risk patient dialysis population, we successfully implemented recommended infection control measures to mitigate the spread of SARS-COV-2 in our facilities. Dialysis facilities must stay vigilant and monitor for possible transmission of COVID-19. Regular audits of infection control practices remain critical.

PO0716 Canaries in the Coal Mine: Nursing Home Dialysis Patients as Sentinels During COVID-19
Allen Kaufman, Alice Hellebrand, Steven M. Kaplan, Jordan Ledvina, Nathan W. Levin, Eran Y. Bellin. Dialyze Direct, Brooklyn, NY.

Background: At least one-third of USA COVID-19 deaths are skilled nursing facility (SNF) residents. Since 2016, Dialyze Direct has brought staff-assisted home hemodialysis (HD) on-site to more than 7,000 patients in SNFs. HD is performed 5x per week in a de-dedicated setting. Since 3/9/20, Dialyze Direct has screened patients for COVID signs or symptoms before every HD. Infection controls include, but are not limited to, patient masks, staff PPE, physical distancing, and cohorting by COVID symptoms or status. The penetenence of likely COVID in SNF HD patients in NY vs FL is presented.

Methods: A symptom diagnostic hierarchy tracked presumptive COVID infection and augmented the limited available COVID testing. At every HD, patient symptoms were recorded in an Electronic Health Record. Prevalent infection is defined as the proportion of patients with any of the symptoms during the pandemic living in the SNF during the week of interest. We report on weekly proportion from 3/9/20 to 5/16/20.

Results: Once COVID symptoms appeared among the HD population, penetrance increased over time. In NY, penetrance in week 1,5 (4/5/20), and 10 was 8, 52, and 64%. In FL, comparable data was 13, 15, and 25%. Prevalence differences (5/10/20) for NY (29/45) vs FL (23/92) (P R 2.6, CI 1.7-3.9; p <0.001).

Conclusions: COVID symptom penetrance in SNF HD patients differed between NY and FL, likely attributable to differences in community disease prevalence, SNF’s infection controls, their relationships to referring hospitals, and state health regulatory environment. On 3/25/20, NY mandated SNFs to accept COVID hospital returns and forbade SNFs to demand proof of negative test before accepting the return of suspected COVID patients. Symptoms COVID in SNF HD residents can serve as sentinel for COVID for the general SNF population as they are the most intensively monitored patients there. The more frequent 5x per week HD model in the SNF provides intense and relevant local surveillance compared to less frequent conventional off-site HD. This sentinel strategy can inform an urgent pivot of infection containment efforts by the SNF and larger regulatory agents so that lessons learned from successful containment strategies can be implemented early.

PO0717 Chronic Dialysis Access Management in the COVID-19 Era: The Need for Raising Awareness
Anita Vincent-Johnson, Lakshmi Kannan, Ashkan Karimi, Tushar Chopra, Negin Pourafshar. University of Virginia, Charlottesville, VA; Augusta Health, Fishersville, VA.

Background: Coronavirus Disease 2019 (COVID-19), an acute respiratory disease caused by novel coronavirus SARS-COV-2, is particularly ominous to chronic dialysis patients as they are likely to experience more severe illness. However, these patients continue to require renal replacement therapy (RRT) during this time. To inform best practices for hemodialysis (HD) patients, we sought to determine the challenges regarding access placement during the pandemic era.

Methods: This is a retrospective single-center study of adult patients who received chronic dialysis at one of the University of Virginia dialysis units. Prevalence of central venous catheter (CVC) use were assessed in patients receiving chronic HD between the months of February-April 2020 (during the pandemic in our area) and compared to the three months prior (October-December 2019). The patients’ relevant clinical and laboratory information were reviewed and recorded monthly. All patients who received RRT on HD were included.

Results: A total of 58 patients were evaluated, among whom 33 were male and 25 were female. The age range is 18-90 with a median age of 65. The number of patients using catheters in the pandemic months was 18 (31%), 19 (33%) and 22 (37%). The number of central venous catheter for more than 90 days during the pandemic era was 14 (24%), 16 (30%) and 16 (30%). The number of patients per pandemic were 12 (22%), 15 (27%) and 15 (27%).

Conclusions: This single-center study reveals the impact of the pandemic on HD catheterization in our area. There is a large population of ESRD patients in the United States on HD that require vascular access. An AVF is the desired access type as it has the most extended access survival, the best patient survival outcomes, the lowest cost, and requires the fewest interventions. Early referral for AVF is important; however, during the COVID-19 pandemic era the referral process is not as efficient to refer patients, warranting to avoid any exposure to the virus while resources remain scarce. This study identifies the inherent difficulty for access placement in this high-risk population of patients during times like this and raises questions in the literature on the best choice of access for these patients along with the optimal timing of fistula placement to provide safe care for the patients.
Clinical Characteristics and Outcomes in ESKD Patients with COVID-19 Infection in an Urban Community Hospital in Brooklyn, New York, During the Global Pandemic

Carlos M. Zapata, Yariana E. Rodriguez, Olawale Akande, Laurie Ward, Premila Bhat. Wyckoff Heights Medical Center, Brooklyn, NY.

Background: The impact of coronavirus disease 2019 (COVID-19) on individuals with End Stage Kidney Disease (ESKD) receiving maintenance hemodialysis (MHD) is unknown. This study aims to describe clinical characteristics and outcomes in a cohort of patients with ESKD receiving MHD hospitalized with confirmed COVID-19 infection in an urban community hospital during the New York City peak of the global COVID19 pandemic.

Methods: Cases with a diagnosis of ESKD and COVID-19 based on positive PCR testing results were identified from retrospective review of electronic health records for patients hospitalized between March 4, 2020 and April 30, 2020. Electronic health records were reviewed in order to obtain demographic data, presenting symptoms, laboratory values, medical management, and outcomes.

Results: 29 patients with ESKD on MHD with confirmed COVID-19 infection were identified. 16/29 (55%) were over age 60 years, 20 (69%) were male and 14 (48%) were Hispanic. 18 (62%) had Diabetes and 26 (89%) were overweight or obese (BMI >25). All had hypertension. 68% were on Statin and 40% on ACE inhibitor or ARB at the time of admission. 25/29 (86%) were dialyzed via arteriovenous fistula or graft. The most common presenting symptoms were dyspnea (85%), cough (60%) and fever (28%). All initial chest radiographs showed abnormalities, with diffuse infiltrates on 21 (72.4%) and focal infiltrates on the remainder. All patients who required renal replacement therapy during hospitalization received conventional HD. 10 patients required mechanical ventilation during hospitalization (34%); all of these patients died. Overall, 13 patients (45%) died and 16 patients (55%) were discharged after a median of 6 and 7 days hospitalization, respectively. Three patients (10%) were readmitted during the period of observation. No significant associations were found between age, sex, race, or diabetes and mortality. Mechanical ventilation was the most consistent predictor of death.

Conclusions: 45% mortality was observed in a small cohort of patients with ESKD on MHD with confirmed COVID-19 infection during the peak of the global COVID19 infection. This high mortality rate reinforces the need for social distancing and infection control measures to reduce transmission in this high risk population.

Clinical Outcomes of Patients with ESKD Hospitalized with COVID-19
Aldo E. Torres Ortiz, Muner Mohamed, Vernelle T. Mitchell, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Background: Patients with end-stage kidney disease (ESKD) comprise a vulnerable population to infections. COVID-19 has been responsible for high mortality worldwide. To-date, there is limited data regarding the impact of COVID-19 in the ESKD population.

We report clinical outcomes of ESKD patients with COVID-19 admitted to an academic hospital in New Orleans.

Methods: We conducted an observational study in patients with ESKD and COVID-19 hospitalized at Ochsner Medical Center over a 7-week period. We compared rates of need for mechanical ventilation, shock, need for intensive care (ICU) and in-hospital mortality as outcome measures between patients with and without ESKD.

Results: Among 851 admissions (67% black) with COVID-19, 49 (6%) patients had diagnosis of ESKD. Patients with ESKD were mostly male (61% vs 49% in non-ESKD; n=806, p=0.10) with a median age of 64 (38 – 90) years. Median body mass index (BMI) were 32 vs 27 kg/m² (p = 0.01) for those admitted to ICU vs wards respectively. Thirteen of them (27%) vs 293 (37%) in the non-ESKD group, p=0.16) were admitted to an intensive care unit (ICU). In-hospital mortality rate for the ESKD cohort was 32% compared to 24% for non-ESKD (p = 0.21). Compared to a subset with 161 patients with acute kidney injury (AKI) with 50% mortality, the 32% mortality rate in ESKD was significantly lower (p = 0.027). Shock and/or mechanical ventilation requirement were comparable between groups (12 (24%) of those with ESKD vs 363 (26%) of non-ESKD, p=0.65). Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD [2125 ± 633 ng/mL, p = 0.0019].

Conclusions: Clinical outcomes in individuals with ESKD with COVID19 appear to be grossly similar to that of non-ESKD population with COVID19. The similar mortality rate was seen despite higher levels of ferritin, suggesting that the interpretation of the significance of serum ferritin in ESKD has to be done with caution. Furthermore, the mortality in ESKD patients with COVID19 is lower than that observed in AKI. The observed lack of increased mortality in ESKD does not align with the outcomes of this patient population in other critical illnesses. The ability to modulate and exaggerated inflammatory response in COVID19 might be somewhat restricted in ESKD.

Comparison of Psychological Distress and Demand Induced by COVID-19 During the Lockdown Period in Patients Undergoing Peritoneal Dialysis and Hemodialysis: A Cross-Section Study in a Tertiary Hospital
Zhiyun Zang, Zi Li, Xiaoxiao Xia, Xiaofang Wu. Department of Nephrology, West China Hospital, Sichuan University, Chengdu, China.

Background: Since the outbreak of COVID-19 in December 2019, it has spread rapidly and widely, bringing great psychological pressure to the public. In order to prevent the occurrence of psychological distress, it is critical to understand the psychological impact on the general population, different groups, and the psychological demand of COVID-19 patients in the patients undergoing dialysis. This study aimed to investigate the psychological distress, the psychological demand of COVID-19 patients in the patients undergoing dialysis and compare the difference between hemodialysis (HD) and peritoneal (PD) patients during the lockdown period.

Methods: Questionnaires were given to the dialysis patients in West China Hospital of Sichuan University. The Impact of Event Scale (IES) was used to investigate the patients’ trauma-related distress in response to COVID-19. We investigated the patients’ personal characteristics, the impact of COVID-19 to the severity of illness and daily life, the IES scores and the psychological support during the epidemic period of COVID-19.

Results: 232 eligible respondents were enrolled in this cross-section study, consisting of 156 PD patients and 76 HD patients. The median IES for all the enrolled patients was 8.00 (2.00-19.00), which belonged to the subclinical dimension of post-traumatic stress symptoms. HD patients had a significant higher IES score than PD patients (11.50 vs 8.00) (p<0.05). HD patients already got more psychological support from the medical staff. There was no significant difference on further demand of psychological support between the two groups. In the multivariate regression analysis, we found that dialysis vintage, the impact of COVID-19 on the severity of illness and daily life, and confidence in overcoming the disease contributed to IES score (p<0.05).

Conclusion: HD patients had more severe trauma-related distress symptoms than PD patients. When major public healthy events occurred, careful psychological estimate and sufficient psychological support should be provided to the dialysis patients, especially to the HD patients.

PO0722

COVID-19 Incidence and Outcomes in Hemodialysis Patients in Mexico
Juan M. Ardavin Iturate, Alicia Pinedra, Juan Carlos Rodriguez. Medica Santa Carmen Staff Nephrologists Medica Santa Carmen, Mexico, Mexico.

Background: HD pts are at high risk for COVID-19. High incidence and death rate were reported in China and Europe with more than 20% of asymptomatics. We report incidence, features and outcomes of COVID-19 in HD patients in a network of 8 clinics in Mexico. A protocol was started on Mar 15 with hygiene measures; symptoms triage; separation by age; use of PPE and isolation of suspected cases. We use a more inclusive case definition, different from Mexico Health Ministry’s(SSA). All cases are referred for PCR but most aren’t tested.

Methods: Retrospective analysis of cases (suspect or PCR(+) from 15 mar to may 22 2020 compared to controls. T-test and Chi’ were used. Hospitalization, IMV and deaths were registered. Overall mortality from mar - may 2020 compared to same period of 2019. We compared the number of cases using our case definition with that using the SSA’s.

Incidence of COVID-19 in staff was also analyzed.

Results: Total 1276 pts; Of 102 suspects 25 (24%) had PCR and 16 (64%) were(-). 13 (12%) non-tested were discarded based on alternative dx. 2 pts with (-) PCR were cases based on CT. Total 75 cases (10 (+)PCR, 65 w/o test) were analyzed and compared to controls. No differences in HD vintage, DM, CVD, HD session length, VA, BUN or Kt/V. Less age, fem gender, HTN, more sessions/wk, ACEi/ARB and lower Hb were found in the cases. 7(9%) hospitalized and 2 (3%) required IMV. There were 6 (8%) deaths, only 1 (1.8%) attributed to COVID-19. Overall mortality minimally higher than that of the same period of 2019 (1.55% vs 1.30%). 31% of cases had only 1 symptom. Only 1 PCR(+) and 14 PCR(-) cases fulfilled SSA’s definition. Among 231 staff members, 31 (13.6%) and 11 (35%) PCR(+) and 20 non tested.

Conclusions: Incidence of probable or confirmed COVID-19 was 5.9%; probably overestimated suggested by scarce testing and low mortality. ACEi/ARB use more frequent in cases, adjusted for HTN and age. Our protocol helps prevent in-clinic contagion. A more comprehensive probable case definition appears more useful for HD patients.

PO0723

COVID-19 Infection in Patients with ESRD Requiring Hemodialysis
Anita Anisimova,1 Valeria Ripa,2 Biruk Almaz,3 Nirav Mistry,4 Fariborz Rezai.2
1 St. George’s University School of Medicine, True Blue, Grenada; 2 Saint Barnabas Medical Center, Livingston, NJ.

Background: This case series assesses characteristics and outcomes of patients with confirmed novel coronavirus (SARS-CoV-2) COVID-19 infection and end stage renal disease (ESRD) requiring hemodialysis during the COVID-19 pandemic.

Methods: This is a single center retrospective study of 24 ESRD patients on hemodialysis who were admitted to Saint Barnabas Medical Center, a 597-bed acute care hospital in Livingston, New Jersey, and with a confirmed COVID-19 diagnosis between February 1st to April 5th, 2020. The characteristics, clinical course, and outcome were assessed and compared. In addition, a subgroup analysis was made between patients who expired (n=8) versus those who lived (n=16).

Results: The overall mortality rate was 33.3% vs. 21% in the general population with COVID-19. Among the 4 (16%) patients who required ICU admission and prolonged pressor support and invasive mechanical ventilation, 2 (50%) patients were successfully extubated and discharged from the hospital while the other 2 (50%) patients died. There were no statistical differences in laboratory values between patients who survived versus patients who died except C-reactive protein (CRP), p=0.002.

Conclusions: We report a mortality rate of 33.3% in our case series of 24 patients with ESRD on dialysis with concurrent COVID-19 infection. There was a statistical difference in CRP value between patients who died versus survived. Fifty percent of intubated patients were successfully extubated and discharged.

PO0724

COVID-19 Infection Patterns in an Academic Inner City Dialysis Unit

Background: COVID-19 remains a major public health emergency and in-center dialysis provides multiple opportunities for its spread. Elderly immunocompromised hosts pose a significant risk for infection as well as poor outcomes. We present a retrospective analysis of COVID-19 cases in our dialysis unit.

Methods: Retrospective analysis was done as a part of a quality improvement project using unidentified patient data including: demographics, distribution of dialysis shift, patient zip code, transportation mode (self, ride share or public transport), residence type (home, long term care facility or homeless shelter), etiology of ESRD and dialysis vintage. T-test and multivariate analysis (including logistic regression for binary and categorical data) were conducted using SPSS v23.

Results: There were 70 patients in the unit and 10 became positive for COVID-19. 65% (72%) of all patients were African American. Between COVID-19 positive and negative patients, there was no significant difference in age (62±15 vs 63±14 years p=0.2), dialysis vintage (7.6±8.7 vs 5.2±4.7 years p=0.31), male gender (7/10 (70%) vs 40/70 (58%) p=0.31), 3/10 (50%) of the positive patients were MFW 2nd shift. On multivariate analysis, this effect approached significance (p=0.051); however, there was no interaction of COVID-19 positive status with demographic characteristics, dialysis vintage, residence type, zip code distribution, or transportation modality. Of note, universal masking and temperature screening were implemented on March 5, 2020 in this unit and no new cases were noted after May 2, 2020.

Conclusions: Our analysis did not show any clear factor associated with COVID-19 infection among our dialysis patients although clustering approached statistical significance. Small sample size and demographic distribution are shortcomings of our study; larger scale epidemiological studies and data analysis are required for better understanding the risk of COVID-19 infection amongst in-center dialysis patients.
COVID-19: Dialysis Patients

**PO0726**

COVID-19 Outbreak and Experience in a Dialysis Unit in the Philippines

Ma. Anna Angelica S. Cruzado, Filitoce Ferrer. Makati Medical Center; Makati City, Philippines.

**Background:** Patients on regular dialysis are at an increased risk to COVID-19 due to their multiple comorbidities and exposure in the healthcare setting. The risk for virus transmission within a dialysis unit is also high emphasizing the importance of implementing infection control measures. The objective of this report is to describe the COVID-19 outbreak in a dialysis unit including interventions done.

**Methods:** Review of the epidemic course with contact tracing was done from March 14 to May 14, 2020 in the dialysis unit of a tertiary hospital in the Philippines.

**Results:** Of 167 patients, 20 became COVID-19 suspects. Eight were positive - 3 were exposed from the first confirmed case, 2 were handled by a COVID-19 infected healthcare worker (HCW) who was asymptomatic at time of contact while 2 asymptomatic patients tested positive during mass testing. Two of 67 HCWs tested positive were exposed to patients. Key interventions are (a) enhanced screening by mass testing using NPS/OPS RT-PCR of patients and HCWs after identifying 6 patients and 2 HCWs infected with COVID-19 (b) instead of cohort, dialysis of COVID-19 confirmed and suspected cases was done in isolation rooms separate from the dialysis unit (c) adequate personal protective equipment for HCWs and masks for all patients and (d) environmental disinfection especially in the waiting area with strict social distancing and daily screening.

**Conclusions:** The infection control and preventive actions done halted the increase in cases. Maintaining these strategies for the duration of the pandemic allowed further decline in the rate of infection.

**PO0727**

Demographic and Clinical Characteristics of Patients with CKD and SARS-CoV-2 Undergoing Hemodialysis Treatment

Laura C. Fuentesc-Mendez, Angela M. Cordoba Hurtado, L. M. Perez-Navarro, Rafael Valdez-Ortiz, Maribel Merino. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

**Background:** Patients on HD or PD are likely to be at increased risk of COVID-19 due to their multiple comorbidities and complications because they have multiple morbidity conditions. There is a lack of evidence about the optimal management and even clinical manifestations because clinical presentation is highly variable. The delayed diagnosis is because it’s not recognized by the treating centers and the confusion with patients with fluid overload or uremic syndrome can be fatal in this population.

**Methods:** Retrospective, observational, single-center study in Mexico. We analyzed the clinical manifestations and outcomes of all maintenance HD patients hospitalized with COVID-19 from April 9th to May 31st, 2020 as confirmed by real-time polymerase chain reaction.

**Results:** 20 patients followed in our hospital with median age of 45.2±13.8 years, 50% were men. All the patients have HTA (100%), DM (50%), the most common symptoms at admission were asthenia (75%), dyspnea (65%), cough (55%) followed by myalgias (50%) and fever (45%). Poor oxygen saturation (<95%) breathing room air was observed in 18 patients (90%) with mean oxygen saturation of 77±9%. Lung abnormalities on initial chest X-ray were observed in all patients. Peripheral ground-glass opacities, the typical radiologic pattern, were bilateral in 13 patients and unilateral in 7. Laboratory studies with lymphopenia in 85% of patients with a mean of 0.7±0.38. There were no differences baseline leukocyte or lymphocyte from patients who survived vs from those who died. The mortality rate (40%) was much higher than that observed in the general population (8%). Mortality was higher in women.

**Conclusions:** The impact of this virus on patients with CKD is poorly understood. The evaluation of the nephrologist must be very detailed, most of the patients had mild dyspnea, however on physical examination, desaturation and radiological images were suggestive of infection by SARS-CoV2. The current situation provides a unique opportunity to gather vital information to process and learn from the experience worldwide. These results will allow us to treat them in a timely manner and reduce lethality in dialysis patients.

Effect of COVID-19 on Dialysis Practices on the Ground: Early Results from an International DOPPS Program Survey

Murilo H. Guedes,1 Brian Bieber,2 Patricia De Sequera,2 Pablo A. Urena Torres,1 Giuliano Brunori,1 Xinling Liang,1 Li Zuo,1 Michel Y. Jacquemet,1 Roberto Pecos-Filho,2 Jeffrey Perl,2 Ronald L. Pisoni,1 Bruce M. Robinson,2 1Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3University Hospital Infantaria Leonor, Madrid, Spain; 4AURA Nord Saint Ouen, Paris, France; 5Ospedale S. Chiara, Trento, Italy; 6Guangdong Provincial People’s Hospital, Guangzhou, China; 7Peking University People’s Hospital, Beijing, China; 8Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; 9St. Michael’s Hospital, University of Toronto, Toronto, ON, Canada.

**Background:** The COVID-19 pandemic caused unprecedented disruption to dialysis care. Globally, facility surveys were distributed to assess the impact of COVID-19 pandemic on hemodialysis (HD) and peritoneal dialysis (PD) practices. These data will inform guidance for dialysis care as the COVID-19 pandemic ensues.

**Methods:** Medical Director (MD) and Nurse Manager (NM) Surveys (MDs, NMS) are being distributed in May/June 2020 to 723 clinics enrolled in the Dialysis (in-center HD, PDOPPS) or Peritoneal (PDOPPS) Dialysis Outcomes and Practice Patterns Study in Canada, China, Japan, the United States, 7 European countries, 5 Gulf Cooperation Council countries, and China metropolitan areas (Beijing, Guangzhou, Shanghai). Surveys content includes the number of COVID-19 cases, testing, and clinical management, screening, infection control, staffing, patient transportation, and psychological support.

**Results:** As of 27 May 2020, we have 80 MDs (China, Europe, US = 33, 38, 5) and 101 NMS (45, 46, 9) responses from DOPPS sites. The following percentages are represented sequentially for China, Europe, and US. Among MDs, 0%, 6%, 67% reported at least one confirmed COVID-19 case among dialysis patients; 0%, 5%, 35% reported being on the late phase of the COVID-19 curve; 40%, 23%, 100% of MDs were more likely to recommend home dialysis; 19%, 5%, 29% reported an increase in missed dialysis treatments; 30%, 24%, 50% were more likely to prescribe potassium binders; and 70%, 80%, 88% reported current limitations in access to COVID-19 testing; and 61%, 51%, 29% reported having, or risk of, shortage in staffing.

**Conclusions:** Early results indicate many clinics in Europe and US have had COVID-19 cases, but sites in the three DOPPS-China cities have avoided COVID-19 to date. In all regions, shortages of human and medical resources were common, as were changes to dialysis delivery/practice including more skipped sessions, greater use of potassium binders, and preferentially recommending home dialysis. Over the next month, we expect hundreds more responses, and will compare approaches in PD and HD clinics. These data will inform guidance for dialysis care as the COVID-19 pandemic ensues.

**Funding:** NIDDK Support, Commercial Support - Support for the DOPPS Program (including CKDops, DOPPS, and PDOPPS) is provided by Amgen (founding sponsor, since 1996), Kyowa Kirin Co. (since 1999, in Japan), and Baxter Healthcare (since 2011). Additional support is provided for specific projects and/or countries by Akebia Therapeutics, AstraZeneca, Bard Peripheral Vascular, Bayer Yakuhin, Chugai Pharmaceutical, DialyzDirect, Japanese Society for PD, JMS Co., Kidney Research UK, Kidney Foundation Japan, Kissei Pharmaceutical Co., Medice, Nikkiso Co., ONO Pharmaceutical Co., Sanofi-Aventis Deutschland GmbH, Terumo Corporation, Torii Pharmaceutical Co., and Vifor Fresenius Renal Pharma.
PO0729
Factors Associated with SARS-CoV-2 Infection (COVID) Severity and Mortality in Chronic Dialysis Patients
Eduardo K. Lacson,1,2 Gideon N. Aweh,1 Vladimir Ladić,1 Harold J. Manley,1 Carol Stewart,1 Doug Johnson,1 1Dialysis Clinic Inc, Nashville, TN; 2Tufts University School of Medicine, Boston, MA.

Background: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had 422 maintenance dialysis patients diagnosed with COVID from 90 clinics in 20 states. While prognostic factors in the general population have been reported, there is limited information regarding the US dialysis population.

Methods: Over a 15 week period of observation, 96 patients died (22.7%) and 116 (27.5%) were not hospitalized (for up to 30 days post-COVID diagnosis), likely with milder illness. We compiled univariable associations with ≥0.1 into stepwise logistic regression models (forcing in age, sex. race) to determine factors associated with 1) Death from COVID; and 2) Moderate/severe illness (hospitalized or died without hospitalization <30 days post-COVID diagnosis).

Results: Candidate variables are listed in the table, with retained significant factors marked (a or b at p<0.05). Notably, 42% of all deaths occurred at age >75 years, increasing to 74% of all deaths at age >65 years. Wheelchair use also associated with higher death risk.

Conclusions: Dialysis patients with low albumin and vintage ≥1 year associated with increased illness severity. It was surprising that a history of pneumonia vaccine associated with more severe illness - whether this reflects “treatment by indication” bias vs. pulmonary immune activation by vaccination vs. chance finding is unclear. PVD also tended to increase illness severity but more importantly, was significantly associated with risk of death, independent of older age.

PO0730
Fighting COVID-19: Experience from a Chinese Hemodialysis Center
Qian Zhang, Mengjing Wang, Jing Chen. Huashan Hospital Fudan University, Shanghai, China.

Background: COVID-19 has ravaged China and spread throughout the rest of the world. Since there is no effective treatment available at present time, patients with ESRD feel anxious and uncomfortable to come to dialysis center and receive dialysis treatments. To help the patients deal with their anxiety without interrupting their treatments, we developed emergency response plans and offered following instructions during the pandemic of COVID-19.

Results: There were 708 patients. 473 were on HD since June 2018. 150 had ≥1 PCR test for COVID-19: 69 were positive. 268 (37.9%) were female and 282 (39.8%) were of non-white race. Median age was 69 years (IQR 56-78). Wheelchair use also associated with higher death risk. Confirmed and suspected COVID-19 patients will be quarantined in the designated area of the dialysis center while undergoing dialysis treatments, we developed emergency response plans and offered following instructions during the pandemic of COVID-19.

Conclusions: Since we adopted above-mentioned instructions, we have zero infection case during the pandemic of COVID-19.
PO0732
Impact of Undertaking Safeguards to Limit Exposure and Prevent COVID-19 Infection in Ambulatory Dialysis: A Single-Center Experience

Background: Dialysis patients are considered at high risk to develop serious COVID19 complications. Taking extreme measures are necessary to prevent COVID19 transmission at the dialysis center. We are presenting outcomes of our COVID19 prevention project from our largest dialysis center in Qatar.

Methods: Our project was done at FBKJC (largest dialysis center in Qatar with about 60% of all hemodialysis (HD) and 90% of all peritoneal dialysis (PD patients in Qatar)) between March 1st and May 25th 2020. We gradually implemented a bundle of measures and algorithm (attached) to properly triage and limit COVID19 exposure inside the center. New infection control protocol with specifications to COVID19 were implemented, including a new policy for reusing N95 masks in high risk areas. We tracked number of patients and staff who were infected during that period and source of infection.

Results: Our dialysis census during that period was 480 HD and 170 PD patients. Only 6 HD patients turned positive for COVID19 (0.9%) and 2 PD patients (1.2%) (compared to 1.3% general population in Qatar by May 25th). We had 3 dialysis staff infected out of 114 (2.6%). Our investigation showed that all cases of COVID19 (both in patients and staff) were likely contracted outside the center. All staff and patients exposed to positive cases of COVID19 inside the center turned out negative. Our infection control classified most exposures at low risk, especially after we fully implemented our precautions.

Conclusions: Preventive actions implemented inside a large dialysis center led to prevention of COVID19 transmission. Increase positive COVID19 cases (in staff and patients) were related to countrywide growth of infection.

PO0734
Outcomes of ESKD Patients Hospitalized with COVID-19
Jia Hwei Ng, Jamie S. Hirsch, Rimda Wanchoo, Mala Sachdeva, Susana Hong, Vipulbhai Sakhya, Kenar D. Jhaveri, Steven Fishbane. on Behalf of Northwell Nephrology Covid-19 Research Consortium Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Patients with ESKD have a dysregulated immune system and a higher annual mortality rate compared with the general population. We aimed to describe the clinical characteristics and compare the outcomes of patients with and without ESKD, among those hospitalized with COVID-19 disease.

Methods: We reviewed the health records for all patients hospitalized with Covid-19 between March 1, 2020 and April 27, 2020 from 13 hospitals in New York. Patients < 18 years or admitted to inpatient obstetrics service were excluded. ESKD diagnosis was defined using ICD-10 code and manual adjudication. Patients were followed up through May 27, 2020.

Results: Of 10,482 patients admitted with COVID-19, 419 (4.0%) had ESKD. Among patients with ESKD, 408 (97.4%) were on hemodialysis and 11 (2.6%) were on peritoneal dialysis. When comparing baseline characteristics of the two groups, patients with ESKD were older, were predominately of Black race, and had greater proportions of comorbid conditions. The primary outcome was that patients with ESKD had a higher odds of in-hospital death than those without ESKD (rates, 31.7% vs 25.4%; OR 1.4, 95% CI 1.1 - 1.7). After adjusting for age, sex, race/ethnicity, the odds of
in-hospital death remained higher in the ESKD group (adjusted OR 1.5, 95% CI 1.2 - 1.8). The ESKD group did not have a significantly higher odds of needing mechanical ventilation than the non-ESKD group in both the crude analysis and after adjustment for age, sex, race/ethnicity. The odds of having a length of stay of >7 days was higher in the ESKD group compared to the non-ESKD group, in both the crude analysis and the adjusted analysis (OR 1.62, 95% CI 1.3 - 2.1; adjusted OR 1.6, 95% CI 1.3 - 2.1). The independent predictors for death for non ESKD patients were age, male gender, cancer, CHF, elevated BUN, low albumin and being on a ventilator. The independent predictors of death for ESKD patients were age, lymphopenia, low albumin and being on a ventilator. Black race was associated with a lower risk of death among ESKD patients compared to white patients.

Conclusions: ESKD patients had a higher rate of mortality compared to non-ESKD patients hospitalized with COVID-19. Black race was associated with a lower risk of death among ESKD patients compared to white patients.

PO0735
Outcome of Hospitalized ESRD-COVID-19 (C19) Infected Patients
Jose E. Navarrete, Darya Hosen, Harold A. Franch, Frederic F. Rahbari-Oskoui, Michael J. Connor, Janice P. Lea. Emory University, Atlanta, GA.

Background: Emory University affiliated hospitals serve the metro Atlanta area, where a significant number of C19 cases have occurred. In this report we describe the outcomes of AKI and ESRD patients with confirmed C19 admitted to our health-system.

Methods: All patients seen by Emory Nephrology at 2 tertiary referral and one county hospital were categorized as ESRD if they required dialysis prior to C19 infection, or AKI if they developed acute kidney injury as a result of C19 infection. Outcomes of interest included patient survival and discharge from the hospital. Admission to Intensive care unit and need of mechanical ventilation were recorded. Comorbid conditions and outpatient use of medications were analyzed.

Results: From 3/1/20 to 5/26/20, 474 consecutive patients were seen in COVID-19 related consultation. 287 patients were considered PUI and eventually tested negative for C19. The remaining 187 patients were C19 positive by nasopharyngeal swab or tracheal aspirate and represent the study population for this report. There were 43 ESRD (23%) and 144 AKI (77%) patients. Age (64 vs 63 years), gender (63 vs 66% males) ethnicity (86 vs 82% African-americans) and comorbid conditions were similar in AKI and ESRD patients. AKI patients were more likely to be admitted to ICU (83 vs 35%) and to require mechanical ventilation (73 vs 20%) compared to ESRD patients (p<0.05). Figure 1 presents the outcomes based on the type of renal disease at presentation. The eGFR of AKI patients at time of admission was 30±34 ml/min/m². 84 AKI patients required dialysis during their hospitalization (42.5%).

Conclusions: Patients with ESRD C19+ were less likely to require ICU admission or mechanical ventilation. Mortality of ESRD patients was 14% compared with 42% of AKI patients, (p<0.002). ESRD patients with C19 were also more likely to be discharged from the hospital compared to those with AKI. Despite similar demographics and co-morbidities, hospitalized C19 AKI patients had worse mortality than those receiving chronic dialysis.

PO0736
Non-Hospitalized Maintenance Hemodialysis Patients with COVID-19: Have Elevated Inflammatory Markers
Akhil Hegde,1 Jennifer E. Flythe,1 Cynthia J. Denu-Ciocca,1 Kawan A. Swain,1 Raven A. Voora,1 Heather J. Anseade,2 Gerald A. Hladik,2 Peter Potanko,2 Prabir Roy-Chaudhury,3 Abhiijit V. Kshirsagar,4 1UNC Kidney Center, Chapel Hill, NC; 2Renal Research Institute, New York, NY.

Background: In addition to an aggressive pneumonia, patients hospitalized with COVID-19 have marked inflammatory and hypercoagulable states, with downstream cardiovascular and thrombotic events. Hemodialysis patients have baseline increases in inflammation and hypercoagulability. However, to our knowledge, little is known about the level of inflammation and hypercoagulability among non-hospitalized in-center hemodialysis patients with COVID-19. We collected inflammatory and coagulation markers from hemodialysis patients with COVID-19 who were managed as outpatients.

Methods: Patients in our dialysis program with one positive nasopharyngeal swab PCR for SARS-CoV-2 were consecutively admitted to an outpatient COVID-19 hemodialysis shift. While receiving their usual dialysis prescription, the patients also had weekly measurements of D-Dimer, Fibrinogen, C-reactive protein (CRP), and Serum Ferritin, until they tested negative for SARS-CoV-2.

Results: 16 consecutive patients were admitted to the COVID-19 isolation shift over 30 days. Their average age was 60 yr, 56% were Black, 25% Hispanic, and 44% female. Causes of ESKD included diabetes (75%), glomerular diseases (19%), and hypertension (6%). No patients received intravenous iron supplementation while on the isolation shift. Table 1 displays the inflammatory marker levels in this group. Note, the 4-fold (D-Dimer), 6-fold (Ferritin) and 21-fold (CRP) increase in these biomarkers from normal levels.

Conclusions: Our initial, unique data show an increase in inflammatory markers in a cohort of non-hospitalized COVID-19 hemodialysis patients. Such an increase may be from the pro-inflammatory impact of COVID-19 in a group with pre-existing high levels of inflammation from uremia and oxidative stress. Additional investigation as to whether these elevated markers associate with cardiovascular and thrombotic events (dialysis circuit and vascular access clotting, sudden cardiac death) is needed.

PO0737
Network Analysis of In-Center Spread of COVID-19: A Single Dialysis Center Experience
Lemuel Rivera Fuentes,1 Hanjie Zhang,1 Alhaji Cherif,1 Peter Potanko.1,2 1Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The need to continue in-center hemodialysis (HD) during COVID-19 pandemic presents a risk of transmission for patients and staff members. The present study aimed to determine if the periodic interaction among patients and staff resulted in spread of COVID-19 in a HD center during a period of 2 months.

Methods: This is a retrospective analysis on a HD center in New York City (172 patients, 32 staff members, 26 chairs, MWF and TTS schedules, and 4 shifts/day). From March 24th to April 24th we recorded every HD treatment (chair, patient, and staff member involved in care). We kept dated records for positive COVID-19 cases (patients and staff). To estimate the patient-to-patient interaction, we obtained the location coordinates of each dialysis chair, calculated the Euclidian distance between them and weighted the interaction by proximity between chairs. We conducted network analysis to assess these interactions.

Results: During the study period, 16 patients and 2 staff members became COVID-19 positive. As shown in Figure 1(a), there were 3 chairs (2, 24, and 25) that had more than 1 positive patient. Clusters in chairs 2 and 25 were ruled out based on a lack of direct contact between the involved patients (at least 2 shifts separating them at all times; no in-between patients became positive); chair 2 had a nonviable temporal direction of transmission. Based on schedule, shift, and a 14-day incubation period, the cluster in chair 24 was dismissed. This was corroborated by network analysis [Fig. 1(b)] where the purple dots represent the COVID-19 positive patients, the blue dots represent negative patients (same shift/schedule), and the edges represent the weighted patient-patient to interaction. We reasoned that more exposed patients would have had a higher chance of becoming infected. Similar information was found for staff-to-patient interaction.

Conclusions: Based on our analysis we consider that for patient-to-patient, staff-to-patient, and staff-to-staff interactions, in-center spread of COVID-19 was unlikely.

Funding: Private Foundation Support

Figure 1(a)infection history; (b)network analysis patient interaction

PO0738
Outcomes of Patients on Chronic Dialysis Hospitalized with COVID-19
Lili Chan, Suraj K. Jalaldeki, Lewis Kaufman, Shuchita Sharma, Staci A. Leisman, John C. He, Barbara T. Murphy, Steven G. Cooa, Girish N. Nadkarni. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports find that patients with end stage renal disease (ESRD) on dialysis who test positive for SARS-CoV-2 have fewer symptoms and require less intensive care than expected. However, there are no reports regarding the outcomes of ESRD patients who are hospitalized with coronavirus disease 2019 (COVID-19).

Outpatient Hemodialysis Unit Preparedness During COVID-19 Pandemic in Several Dialysis Units in New York State
Enrol Carter, Darryl R. Sainvilien, Ibrahim A. Mohamed, Jamrose K. Durrani, John D. Wagner, Angelika C. Gruessner, Subodh J. Saggi. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: HD units are clustered close contact environments where prolonged and repeated exposure to blood borne pathogens occurs. Weeks into the CoVID-19 pandemic, wide disparities in rates of death and exposure of staff and patients amongst HD units in the same zip code of an epicenter in New York regions emerged.

Methods: Random HD units surveyed as to when and what infection control measures were implemented. Direct input into RedCap and SAS 9.0 analysis of the data conducted.

Results: 15 HD units (average census 18-240) responded. Survey compiled exposure rates from 3/1/20 - 4/30/20. The 1st reported case of CoVID-19 by a facility was 3/2/20. Most facilities reported outbreaks (4-30 cases per facility) by 3/21/20. Missed HD sessions due to CoVID varied from 2-100, hospital stays for such patients varied from 2-20 days and death rates from 0-15 per facility. 4 of 15 facilities reported deaths of family members exposed patients and impediments in logistics of single person transportation forcing carpooling. Home dialysis programs reported minimal deaths and exposures. 20% of facilities had no infection preventionist and 26% no patient educator. Reported waiting area cleaning and hand sanitizer refill rates ranged from 1-5 times per day. 20% of the facilities have < 6 feet distance between patients. Implementation of infection control practices such as wearing of masks by patients varied widely amongst units. Some started March 1st-March 16th some later due to mixed messages of its importance. Lack of personal protective equipment (PPE)[in 13% of facilities], staff, and housekeeping shortages (6.7-13.3%) compounded the problems. Positive CoVID results had 1-10 staff members absent for 7-30 days, and no staff death. 46% of the HD units don’t belong to the CDC coalition.

Conclusions: Maintenance of strict hand hygiene, proper air flow, repeated environmental surface cleaning, availability of PPE, and patient and staff education remains corner stone in preventing infections from spreading. Lack of PPE, support and failing to share best practices between dialysis units in the US remains prohibitive but must be encouraged and standardized.

PO0741

Impact of the COVID-19 Pandemic on In-Center Intermittent Hemodialysis Treatment Adherence
Jasmeet Gill,1 Stevan A. Gonzalez,2 Michael R. Wiederkehr,3 Harold M. Szerlip,1 Richard C. Fuquay.1 Baylor University Medical Center at Dallas, Dallas, TX; 2Baylor Simmons Transplant Institute, Fortworth, TX; 3Dallas nephrology associates, Dallas, TX.

Background: Studies have shown that 7.9% of patients miss one to two hemodialysis session per month and 35% miss hemodialysis at least once every three months.1 During current COVID-19 pandemic there has been a decrease in utilization of emergency medical services due to fear of contagion. We hypothesized that patients undergoing in-center hemodialysis might have increased compliance with their dialysis prescription to avoid emergency department visits or hospitalizations. We therefore evaluated the effects of the COVID-19 pandemic on patient adherence to their dialysis prescription.

Methods: This is a retrospective analysis of in-center hemodialysis patients treated in the seven American Renal Associates (ARA) dialysis facilities in Dallas, Texas. COVID-19 was declared a pandemic on March 11, 2020 and pandemic related changes were mandated in ARA hemodialysis facilities on March 13, 2020. We used existing clinical data and examined patient compliance with their dialysis prescription between January 1 to March 14, 2020 (pre-COVID) and March 15 to May 18, 2020 (COVID).

Results: The study enrolled 754 eligible patients. Significantly fewer patients missed a single treatment in the COVID vs pre-COVID periods (35.5% vs 49.9%; p<0.001). The percentage of patients who were hospitalized was lower during COVID vs pre-COVID (12.5% vs. 19.6%; p<0.001). The percentage of patients who shortened hemodialysis time was lower during COVID vs pre-COVID (36.2% vs. 40.9%; p=0.06) although not statistically significant. Finally, significantly more patients achieved a weight within 1 kg of their estimated dry weight at the end of the dialysis sessions COVID vs. pre-COVID (28.5% vs. 34.5%, p=0.01).

Conclusions: These data suggest that during current COVID-19 pandemic, hemodialysis patients have become more adherent to their dialysis prescription. Retrospective studies have suggested that patients are avoiding seeking medical care due to fear of contacting the SARS-CoV-2 virus. Our data suggest that similarly, hemodialysis patients have significantly increased their adherence to hemodialysis prescription in order to avoid hospital visits. Additional studies are ongoing to determine the causes for the observed improved compliance.
A screening strategy combining symptom questionnaires and pre-dialysis temperature markedly improves sensitivity for detection of COVID-19 in asymptomatic HD patients. Of 205 in-center HD patients, 34 developed COVID-19 during the study period. Of these, 21 (61%) were hospitalised, 8 (11%) required intensive care and 9 (26%) died. Baseline characteristics are presented in Table 1. Less than a third had typical symptoms of COVID-19 in asymptomatic HD patients. A screening strategy combining symptom questionnaires and pre-dialysis temperature monitoring should be used in HD units in regions of high COVID-19 prevalence.

**Results:** Of 205 in-center HD patients, 34 developed COVID-19 during the study period. Of these, 21 (61%) were hospitalised, 8 (11%) required intensive care and 9 (26%) died. Baseline characteristics are presented in Table 1. Less than a third had typical symptoms of COVID-19 in asymptomatic HD patients. A screening strategy combining symptom questionnaires and pre-dialysis temperature monitoring should be used in HD units in regions of high COVID-19 prevalence.

**Conclusions:** As part of a quality improvement (QI) initiative, nasopharyngeal swabs and predialysis blood samples were collected on the same day from adults receiving routine dialysis care at clinics managed by a large dialysis organization in the Miami, Florida, region. The test was developed according to manufacturer protocols. For antibody tests (IgM and IgG), a reading of >1 arbitrary unit/ml was scored as positive.

**Results:** Of 715 participants in the QI initiative, 38 had symptoms consistent with COVID-19 prior to or during the initiative. Among these, COVID-19 was confirmed in 14 and ruled out in 20, with 4 being inconclusive. Among the 34 patients with known COVID-19 status, the sensitivity and specificity of the antibody test were 57.1% and 85.0%, respectively, when both IgM and IgG were considered. The remaining 677 patients had no record of symptoms consistent with COVID-19 or any known exposure. Of these, 38 (5.6%) tested positive for anti-SARS-CoV-2 antibodies; none of the antibody-positive patients with available PCR results (N=33) tested positive for SARS-CoV-2 infection. The test is suitable to rule in, but not rule out, SARS-CoV-2 infection in the appropriate clinical circumstance. A substantial proportion of dialysis patients may have had asymptomatic SARS-CoV-2 infection.

**Conclusions:** Change of the schedule in patients without RFK did not show significant differences in terms of biochemical parameters, on the other hand, improvement in replacement volumes. We considered a safe strategy to reduce the risk of transmission among our population. Pharmacological and attending adherence to sessions was not modified despite the psychological findings due to the Covid-19 pandemic.

Clotting of Hemodialysis Catheters in Patients with Renal Failure with COVID-19
Mary C. Mallappalli,1,2 Jie Ouyang,1,2 Sabu John,1,2 John D. Wagner,1 Mariah W. Thaxton,1 Ernie Yap,1,2 Siddharthana D. Bajracharya,1,2 1Health and hospital corporation New York City - Kings County Hospital, New York, NY; 2State University of New York at Downstate Medical Center, Brooklyn, NY.

Background: We are an inner-city hospital in New York that had a surge of patients diagnosed with COVID-19. Many of these patients had acute kidney injury (AKI) and required renal replacement therapy (RRT). NYC Health + Hospitals/Kings County has 40 adult intensive care unit (ICU) beds. ICU capacity expanded to a potential of 150 beds during the COVID-19 surge. The surge included patients transferred from other NY inner-city hospitals for critical care and RRT. Sequential obstacles were faced in providing hemodialysis (HD) to this expanded pool of AKI patients. Additional machines, supplies, staffing and organization were helpful. Clinicians noted that COVID-19 complications included hypercoagulability and we observed an increased frequency of clotting of hemodialysis catheters (HDC).

Methods: We examined the percentage COVID-19 tested renal failure patients with clotting of HDC access during the period March 1, 2020 to May 15, 2020. We collected data on 146 patients during the above period who had HD. We then compared those who were COVID-19 positive confirmed by testing to those who were not COVID-19 by testing. HDC clotting was identified by the use of alteplase. We compared our findings of the two groups to historical controls during a similar time period prior to the COVID-19 surge, between January 1 to February 29, 2020.

Results: We had 3,665 admissions between March 1 and May 15, 2020, of which 1,075 patients had a confirmed COVID + test during the admission. Of these, 773 patients were noted to have AKI from diagnosis codes in the electronic medical record. Of the 146 patients who needed HD (including patients with AKI and CKD) 97 were COVID-19+ and 49 were negative. HDC clotting identified by the use of alteplase was noted in 27% of those who were COVID-19+ compared to 10% of those who were COVID-19 negative. (P value= 0.02 by Chi-square using SPSS Version 24). The percentage of patients with clotting of catheters in the non-COVID-19 group was comparable to historical controls.

Conclusions: Significantly more COVID-19+ patients had HD catheter clotting compared to non-COVID-19 patients. Increased clotting was noted as a barrier to providing optimal HD therapy. For this and other reasons, we initiated an urgent start acute peritoneal dialysis program to mitigate the challenges in delivering HD to COVID-19 patients.

PO0746
Contingency Planning for COVID-19: Feasibility of Twice Weekly Hemodialysis in a Large Canadian Cohort
David Clark, Kenneth A. West, Karthik K. Tennankore. Dalhousie University Faculty of Medicine, Halifax, NS, Canada.

Background: Reducing hemodialysis treatments from three times weekly to twice weekly is a potential strategy to lessen potential exposure/transmission of COVID-19 while allowing hemodialysis units to operate with fixed/reduced resources. As part of contingency planning at a large Canadian center, all facility-based hemodialysis patients were reviewed in advance for candidacy of a reduced “twice weekly” schedule.

Methods: All prevalent patients receiving at least thrice weekly, facility-based hemodialysis - affiliated with the QEII Halifax, Nova Scotia, Canada - were systematically reviewed in a stepwise manner, using accepted criteria for implementing twice weekly hemodialysis (Fig. 1). Of these patients, average age was 63 ± 12 (SD) years, 61% were diabetic, 95% Caucasian; and at least 67% receiving dialysis for 6+ months prior to assessment. 83% of qualifying patients missed 0 treatments in the preceding month, and none missed >1 treatment. Average for serum albumin was 36 ± 4 g/L. Urea reduction ratio, 72.7, and residual urea clearance, 5.7 ± 2.3 mL/min/1.73m².

Conclusions: Although feasible, a twice weekly hemodialysis strategy applied to a small proportion of our patient population, potentially reflecting an ‘intention to defer’ strategy for initiating dialysis.

Figure 1. Stepwise approach and selection criteria to review all facility-based hemodialysis patients for candidacy of twice weekly hemodialysis (N=473). Patients who fulfilled interdialytic fluid gain and serum potassium criteria were assessed by primary nephrologist for eligibility using each of: III. good nutritional status, IV. no clinical evidence of fluid overload, and VI. infrequent hospitalization/easily manageable co-morbid conditions (cardiovascular and pulmonary).

PO0747
Impact of the COVID-19 Pandemic on Virtual Care in Home Dialysis
Martin J. Schreiber, Adam J. Weinstein, Mahesh Krishnan, Brooke Bowlbly, Mike Gonzales, Liz Mooney, Michelle Cassin. DaVita Inc, Denver, CO.

Background: While almost every provider and the majority of patients in the United States (US) possess the technology needed to conduct a telemedicine visit, prior to the current pandemic utilization in home dialysis was relatively low. The current study examined trends in telehealth utilization before and during the COVID-19 pandemic in US home dialysis patients treated by a large dialysis organization in the US.

Methods: Telehealth was delivered using a proprietary multiparty, video, secure messaging (HIPAA compliant), scheduling, and educational resource telehealth platform DaVita Care Connect™ (DCC™) application. IT systems data were utilized to develop ongoing reports depicting patient, facility, and physician adoption rates across 1750 home dialysis programs. Data were segmented by geographic areas (9) and by time of the pandemic (prior to March 2020). Among 28,500 home dialysis patients treated, the DCC™ application was installed on 18,300 patient cell phones (65.3%). Overall, 16,000 peritoneal dialysis (PD) patients and 2,200 home hemodialysis (HHD) patients participated in a telehealth visit. Fifteen thousand visits were performed in April 2020. There were 18,000 messages sent between the care team and patient and 6000 educational resources viewed by patients at home since the COVID-19 pandemic (mid-March). The numbers of social worker and dietician visits and interdisciplinary team rounds also increased over time. There was significant variation DCC™ app download and utilization across geographic regions.

Conclusions: The COVID-19 pandemic has dramatically increased the use of telehealth management for home dialysis patients in the US. Examining the impact of virtual visits on patient outcomes going forward will be critical in designing post-COVID care. Balancing the integration of telehealth visits and face-to-face visits to optimize care will necessitate advancing a new care model for patients with end-stage kidney disease.

Abstract Withdrawn

PO0749

Mental Health Status During the COVID-19 Pandemic of Hemodialysis Patients
Ernesto Sabath,1,2 Edgar Morales-Montes,1 Servicios de Salud del Estado de Queretaro, Santiago de Queretaro, Mexico; 2Universidad Autonoma de Queretaro Facultad de Ciencias Naturales, Queretaro, Mexico.

Background: Patients receiving hemodialysis (HD) treatment are a particularly vulnerable population as previous studies have shown that they are at higher risk to develop anxiety, depression, and diminished health-related quality of life. During the COVID-19 pandemic patients and health professionals are under insurmountable psychological pressure which may lead to various psychological problems. The aim of this study was to assess the effect of this pandemic on mental health and quality of life in low-income HD patients.

Methods: Observational, cross-sectional study done in low-income HD patients and matched healthy controls from March-April 2020. The survey collected basic demographic and laboratory data. To assess mental status 3 different scales were used: Generalized Anxiety Disorder (GAD-7), Insomnia Severity Index (ISI), and the Kidney Disease Quality of Life (KDQOL-36). An evaluation of media interest was added.

Results: 152 HD patients and 33 control subjects were included. The median age was similar in both groups (HD 51±17 vs 48±10 yrs p=NS). Literacy was significantly higher in the control group. The control group showed significantly higher interest media (p=0.03); 60.5% of HD patients showed none or low emotional impact with this pandemic (42% in control group p=0.02). Severe anxiety was more prevalent in the control group (22.6 vs 8% p= 0.01). The ISI scale showed also significantly higher sleep impairment in control subjects (42.6 vs 20.5%, p=0.04). In the HD group, the prevalence of GAD symptoms was higher in females than men (p=0.005), and one of the most influential factors associated with GAD symptoms was to live in a rented home. Patients ≥50 years had significantly higher GAD symptoms (0.01). Unemployed HD patients showed the lowest K-DQOL scores.

Conclusions: HD patients had less emotional impact, lower GAD-7 and ISI scores symptoms than healthy controls. To live in a rented home and unemployment were important risk factors associated with a higher prevalence of anxiety and sleep disorders.

Monitoring Trends of COVID-19 Among ESKD Patients in a Large Dialysis Organization
Kristine Kubisik,1 Eric D. Weinhandl,1 Norma J. Offshin,1 Jeffrey L. Hymes,1 Robert J. Kossmann,1 Lorien S. Dalrymple.1 Fresenius Medical Care, Waltham, MA; 2Chronic Disease Research Group, Minneapolis, MN.

Background: Monitoring real-time acceleration, plateaus, and deceleration of infection rates is important for healthcare planning during a pandemic. We implemented methodology to continuously monitor daily cases and changes of COVID-19 case rates among individuals with ESKD receiving care in a large dialysis organization.

Methods: We identified patients with ESKD receiving dialysis in a Fresenius Medical Care North America (FMCNA) dialysis facility who tested positive for COVID-19. We fit a loess curve to the daily cumulative number of identified cases and computed the first and second derivative of the fitted curve to assess rate of change and change in rate of change, respectively, over time. We used these visualization techniques to monitor trends in case rates at the national and state levels.

Results: By May 15, 2020, there were 5,513 confirmed COVID-19 cases among patients receiving dialysis in an FMCNA facility. Mean age was 63.6 years, 57% were male, and 71% of confirmed cases had diabetes. Nationally, during the peak infection period in early April, new cases routinely exceeded 150 per day and there was a steady acceleration in growth of cases until the second week of April. As of May 15, 2020, among states with sufficient data, 2 states demonstrated continued acceleration, 10 demonstrated deceleration, and 13 plateaued in rate of growth.

Conclusions: The timing of the acceleration in growth of COVID-19 cases among individuals with ESKD followed national trends in the general population. Varying patterns of plateauing and deceleration of cases at the state level were observed in the ESKD population. Real-time monitoring of disease rates in high-risk populations, such as individuals with ESKD, is needed to plan for continuously changing healthcare demands during a pandemic.

PO0751

Psychological Impact of COVID-19 and Implementability of Prevention and Control Measures in Hemodialysis Centers: A Provincial Questionnaire Survey in China
Xiaoyuan Wang,1 Yanhuan Chen,1 Yaniu Huang,1 Penghua Hu,1 Guangdong Provincial People's Hospital, Guangzhou, China; 2Guangdong Academy of Medical Sciences, Guangzhou, China; 3Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangdong Provincial Geriatrics Institute, Guangzhou, China.

Background: This study investigated the psychological status of patients and staff and implementability of prevention measures in hemodialysis centers in Guangdong Province of China during the Coronavirus disease 2019 (COVID-19) pandemic.

Methods: An electronic questionnaire survey was performed in an anonymous manner between March 28 and April 3, 2020. Two questionnaires were designed to investigate the psychological status for hemodialysis patients and general staff (doctors, nurses, technicians, and other staff), respectively. And an additional questionnaire for administrators (directors or head nurses) of hemodialysis centers was designed to address the implementability of prevention measures, including strengthened patient triage management, restricting caregiver visits to patients during dialysis, strengthened prevention amongst staff, and improved patient education and protection. All the 516 hemodialysis centers registered in Guangdong Province were voluntarily invited to join the survey.

Results: Total 1,782 patients, 3,400 staff, and 420 administrators responded for this survey. Patients living in rural areas reported a higher incidence of severe anxiety compared to those living in other areas. Medical staff reported better mental health than non-medical staff. With respect to implementability of prevention measures, hemodialysis centers in general hospitals outperformed independent blood purification centers, and tertiary hospitals outperformed other level hospitals. However, restricting acceptance of non-resident patients was lower in tertiary hospitals than that in other hospitals. Under this condition, only one patient imported from Hubei Province was diagnosed with COVID-19.

Conclusions: The outbreak did not significantly affect the psychological status of most patients and medical staff. Due to the successful implementation of comprehensive prevention measures, the COVID-19 epidemic was controlled effectively. This provincial survey may provide experience for other countries and regions with similar epidemic.

PO0752

Persistent Viral Shedding and Antibody Response to the SARS-CoV-2 Virus in Chronic Hemodialysis Patients
Aisha Shivkh,1 Ett Zeldis,1 Kirk N. Campbell,2 Lili Chan.2 James J. Peters VA Medical Center, Bronx, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The duration of SARS-CoV-2 viral RNA shedding and antibody response of chronic HD patients to the SARS-CoV-2 virus is currently unknown.

Methods: This is a retrospective case series of chronic HD patients who tested positive for severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2 RNA) on nasal or nasopharyngeal specimen between March 20 and May 28, 2020 at the James J. Peters VA Hospital. Patients were tested at varying intervals to document clearance of virus or for surveillance purposes. SARS-CoV-2 Virus IgG Antibody (Ab) testing was performed on all HD patients with COVID-19 using the Abbot IgG nucleocapsid antibody test and i2000SR machine, Ref. range of the Ab titer: >1.39 positive)
Results: Of 834 chronic HD patients, 26% (222) were diagnosed with COVID-19. Mean age of those with COVID-19 was 72±9 years old, 86% were Black, 77% had diabetes and all had hypertension. Of these patients, 59% (13/22) required hospitalization and 18% (4/22) died. IgG Ab testing was performed on 19 out of 22 COVID-19 patients. All 19 patients tested positive for IgG Ab with an average Ab titer of 7±1.2. 20 days after the first, the SARS-CoV-2 RNA positive test, 68% (13/19) patients remained positive on repeat RNA testing. 3 patients tested positive for SARS-CoV-2 RNA on repeat surveillance testing, despite testing negative on 2 prior consecutive nasal or nasopharyngeal specimens (Fig. 1). None of these 3 patients were symptomatic at the time their repeat swabs were positive for SARS-CoV-2 RNA.

Conclusions: All HD patients with a confirmed diagnosis of COVID-19 developed IgG Ab to the SARS-CoV-2 virus, but the SARS-CoV-2 RNA was detectable in the swab specimen for a prolonged duration of time. In a few cases, the SARS-CoV-2 RNA became detectable after 2 consecutive negative RNA specimens. It is unknown if the IgG antibodies confer immunity against the SARS-CoV-2 virus. Additionally, the significance of persistent viral RNA shedding in patients who have recovered from COVID-19 remains to be elucidated.

PO0754

Rates of Asymptomatic Carriage and Antibody Positivity for SARS-CoV-2 in a Large Haemodialysis Cohort

Background: Haemodialysis patients represent a unique challenge in the COVID-19 pandemic, balancing infection risk while safely providing life-sustaining haemodialysis. Asymptomatic infection rates in haemodialysis patients are unknown. Aims: 1 - To define rates of asymptomatic swab positivity in a cohort of prevalent haemodialysis patients 2 - To define rates of antibody positivity in patients known to have been historically swab positive 3 - To define rates of antibody positivity in patients without prior symptoms or clinical suspicion of COVID-19

Methods: A programme of COVID-19 screening using a validated nasopharyngeal PCR analysis was carried out across a prevalent cohort of 1253 haemodialysis patients. Concurrently all patients were offered antibody testing for Anti-SARS-CoV-2 IgG/IgM (Roche) and a total of 548 tests were completed.

Results: 1 – Routine screening over a 4 week period from 4/5/20 to 1/6/20 confirmed 7 cases of asymptomatic swab positivity (0.6%). 2 – In our cohort there were 197 confirmed swab positive cases of COVID, and of the 153 survivors 124 were antibody positive (81%). 10 patients were highly clinically suspicious of COVID and managed as such; of those 3 were antibody positive (30%). 3 – Of the remaining swab negative patients who had antibody testing (n=710) 82 were antibody positive (11.5%).

Conclusions: In a large inner-city London haemodialysis where the population prevalence of COVID has been high, we demonstrate 1 – low asymptomatic rates of virus carriage at this later stage in the pandemic 2 – significant proportions of swab positive patients seroconverting to be antibody positive 2 – suggestion that 11.5% of patients had previous been asymptomatic carriers and had seroconverted to be antibody positive.

PO0755

Providing Multidisciplinary Renal Care in the Time of COVID-19

Ollie Fielding,1 Jung Hoon Son,1 Tia Y. Yu,2 Andrew Bohmatt,2 Frank Liu,2 Jeffrey I. Silberzweig.2 The PEAK team ‘pulseData, New York, NY; ‘The Rogosin Institute, New York, NY.

Background: New York City (NYC)-based Rogosin Institute has provided a specialty case management to patients via its Program for Education in Advanced Kidney Disease (PEAK) since 2015. PEAK aims to educate patients about options for renal replacement therapy and encourages adoption of home dialysis modalities and transplantation. The global pandemic due to the novel coronavirus SARS-CoV-2 (COVID-19) hit NYC at the beginning of March 2020 and has resulted in over 40,000 hospital admissions and claimed the lives of 15,000 NYC residents.

Methods: A city-wide requirement to adopt social distancing caused us to adapt our approach so we could continue our patient management and delay dialysis starts where possible. Our multidisciplinary team continued to provide regular consultations via a telehealth-platform, pulseData built a query to look at the standard deviation of lab results for creatinine and potassium over the prior six months leading to decreased need for patients to leave their homes for venipuncture. We also built a query to identify those patients at high risk of poor COVID-19 outcomes (those over age 65, with COPD or other respiratory conditions, and other comorbid risk factors). These high risk patients were discussed in a weekly care plan meeting.

Results: The Rogosin team delivered 481 telehealth appointments between January 1 and May 1 2020. We identified 17 of 189 patients seen in PEAK over the last 12 months as high risk for poor COVID-19 outcomes. The standard deviation (SD) of the last six months of serum creatinine measurements for PEAK patients was 0.24 (IQR 0.16-0.44), patients with an SD in the top quintile were considered to be in need of repeat lab tests and home-based venipuncture was used where possible. Only 12 PEAK patients began dialysis treatment between January 1 and May 1 2020 compared with 28 patients in the same period in 2019. Most of these patients (67%) began dialysis optimally (as an outpatient and with venous access) in Jan-May 2020 vs. only 43% in the same period 2019 (a 56% increase).

Conclusions: Responding to the challenges of the COVID-19 crisis was acutely felt at Rogosin and represented a major disruption to our ability to deliver nephrology care. Adopting a coordinated, data driven approach we were able to continue to deliver multidisciplinary care to patients and improve renal replacement therapy outcomes.

Enhanced Sentinel Surveillance System for COVID-19 Outbreak Prediction in a European Dialysis Clinics Network

Francesco Belloccio,1 Paola Carioni,1 Mario Garbelli,1 Francisco Martinez-Martinez,1 John W. Larkin,2 Len A. Usvyat,2 Franklin W. Maddux,2 Stefano Stuard,3 Luca Neri,1 Fresenius Medical Care Deutschland Gmbh, Bad Homburg, Germany;1 Fresenius Medical Care North America, Waltham, MA;1 Fresenius Medical Care Italia S.pA, Palazzo Pignano, Italy.

Background: Accurate predictions of epidemic dynamics may enable timely organizational interventions in high risk regions. We exploited the interconnection of the EMEA Fresenius Medical Care (FMC) dialysis clinic network to establish a sentinel surveillance system where the occurrence of new cases in a clinic propagates distance-weighted risk estimates to proximal dialysis units. The surveillance system is embedded in an artificial intelligence model which predicts COVID-19 outbreak occurrence in HD clinics from trends in clinical practice patterns and regional COVID-19 epidemic metrics. The system stratifies clinics by their risk of new local outbreak.

Methods: The risk prediction model is computed considering a cohort of 640 clinics belonging to the FMC network. We trained a model to predict outbreaks in each clinic in a 2-week prediction horizon (i.e. two or more COVID-19 cases). In addition to sentinel distance-weighted risk estimates, the model included 73 variables (i.e. regional-level epidemic data from open source datasets and clinical practice data from the EuChID® database). We generated the training set on data available on 04/01/2020 and tested prediction accuracy at 4/15/2020 and 4/20/2020.

Results: In the training set there were 58 (9.1%) clinics with two or more patients with COVID-19 infection in the two-week prediction window. In the validation samples there were 27 (4.2%) and 12 (1.9%) clinics with two or more patients with COVID-19 infection during the two-week prediction window. The performance of the model was suitable in both testing windows (AUC=0.86 and 0.80 respectively). The model is used to construct risk maps highlighting geographical clusters of clinics at risk (figure).

Conclusions: A sentinel surveillance system together with the wealth of information collected in EuChID® and state of the art modeling strategies allows prompt risk assessment and timely response to COVID-19 epidemic challenges throughout networked European clinics.

Funding: Commercial Support - Fresenius Medical Care

Figure 1: Example of COVID-19 outbreaks risk maps in European dialysis clinics network. Red, yellow, green circles represent respectively high, medium, low risk clinics.

PO0757
Trajectories of Clinical and Laboratory Characteristics Before COVID-19 Diagnosis in Hemodialysis Patients

Yue Jiao,1 John W. Larkin,1 Caitlin Monaghan,1 Anke Winter,3 Jochen G. Raimann,2 Luca Neri,1 Peter Kotanko,2 Jeffrey L. Hymes,3 Sangho Lee,2 Len A. Usvyat,2 Franklin W. Maddux,2,3 Fresenius Medical Care, Global Medical Office, Waltham, MA;2 Renal Research Institute, New York, NY;1 Fresenius Medical Care Deutschland Gmbh, EMEA Medical Office, Bad Homburg, Germany;1 Fresenius Medical Care North America, Waltham, MA;1 Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea;1 Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany.

Background: The frequency of evaluations in hemodialysis (HD) care affords opportunities to assess profiles that may characterize onset of the 2019 coronavirus disease (COVID-19). We aimed to characterize the trajectories of clinical/laboratory assessments before COVID-19 diagnosis in HD patients.

Methods: We assessed data from HD patients with known COVID-19 dialyzed at Fresenius Kidney Care in the United States between 02 Mar and 09 Apr 2020. We computed mean daily values for 40 variables 90 days before a positive rRT-PCR test (COVID-19+). Nonparametric smoothing splines were used to fit data of individual trajectories and estimate the mean change over time.

Results: There were 1294 HD patients with COVID-19 (mean age 64±14 years, 60% male, 47% white race, 69% had diabetes, and 24% had coronary artery disease). Mean pre-HD body temperature (primarily oral) increased by about 1° F (F) over 10 days before COVID-19+ test and approached 99° F at diagnosis (Fig 1A). Mean interdialytic weight gain decreased by about 0.75 kg (Fig 1B) over 14 days before COVID-19+ test; concurrent decreases of about 20 minutes were seen in HD treatment time. Mean neutrophil-to-lymphocyte ratio had mild increases (Fig 1C), while mean platelet counts decreased by about 40x10^3/L over 14 days before COVID-19+ test (Fig 1D).

Conclusions: The trajectories of several clinical/laboratory parameters appeared to change before COVID-19 diagnosis in HD patients. Many changes were small and may not be independently useful in identifying onset of COVID-19. Mean pre-HD body temperature before SARS-CoV-2 infection was 97.4° F and should be considered in screening. Findings may have utility in prediction model development. Further comparisons to patients without COVID-19 are needed.

Figure 2: Trajectories 30 days before COVID-19 diagnosis in HD patients.
PO0759
Kidney Patient Mortality due to COVID-19 in Ecuador: The Experience in Guayas Province
Fabian A. Ortiz-Herbener,1,2 Instituto Ecuatoriano de Dialisis y Trasplantes [IEDYT], Guayaquil, Ecuador; 1Unidad de Cuidado Renal Avanzado [UCRA], Guayaquil, Ecuador.

Background: Ecuador is a country of seventeen million population located in the west coast of South America. In late February 2020, Ecuador had its first COVID-19 case in the city of Guayaquil, followed by massive growth of infections in Guayas Province (14000 of 39000 cases), the current epicenter. Due to the lack of official information in this population, and the significant impact in mortality saw in other countries, a need for data is warranted.

Methods: There are approximately 15000 patients on renal replacement therapy in Ecuador, 94% of them on hemodialysis. At Guayas Province, the estimation of 5200 people on hemodialysis accounts for the 34% of the country’s patients. A simple telephone-based questionnaire was performed at the first week of May, directed to the owner, medical director, or head of nurses of each center in the Guayas Province.

Results: From the 35 centers in Guayas, it was possible to collect data from 29 locations (82.5%) -mostly private centers-, that represents approximately 4719 patients, 5200 people on hemodialysis accounts for the 34% of the country’s patients. A simple telephone-based questionnaire was performed at the first week of May, directed to the owner, medical director, or head of nurses of each center in the Guayas Province.

Results are summarized in Table 1.

Conclusions: The 11.91% Covid-19 mortality in Guayas Province was high, especially if the expected monthly mortality is around 0.8-1.1%; the lethality was very high; and this could be explained by the fact that renal patients are considered as high-risk patients in this disease. The low mortality in PD patients could be attributable to the lockdown and stay-in-home measures. It is necessary to implement specific protocols in order to avoid high mortality, if a second peak of Covid-19 is expected.

Results from Guayas Province in Covid-19 pandemic.

PO0760
Clinical Characteristics, Management, and Outcomes in COVID-19-Positive Dialysis Patients from Three London Renal Centres, United Kingdom
Dalvir Kular,1 Irina Chis Ster,4 Dandisonba Phanish,5 Alexander Sarnowski,1 Eirini Lioudaki,1 Martin L. Ford,1 David Makanjuola,1 Alexandra C. Rankin,2 Hugh Cairns,3 Joyce Popoola,1 Nicholas I. Cole,4 Mysore K. Phanish,5 Richard Hull,3 Pauline A. Swift,1 Debasis Banerjee,4,* St Helier Hospital, London, United Kingdom; 1King’s College Hospital, London, United Kingdom; 2St George’s University Hospitals NHS Foundation Trust, London, United Kingdom; 3St George’s University of London, London, United Kingdom.

Background: Dialysis patients, with frequent co-morbidities, advanced age and frailty, visiting treatment facilities frequently are perhaps more prone to SARS-CoV-2 infection and related death - the risk-factors and dynamics of which are unknown. The aim of this study was to investigate the hospital outcomes in SARS-CoV-2 infected dialysis patients.

Methods: This prospective, observational, multi-centre study collected data on SARS-CoV-2 infected HD patients between 29/02/2020 and 15/05/2020. Data was collected on demographics, co-morbidities, WHO performance status, clinical symptoms, laboratory parameters, hospital management and outcomes. Treatment was predominantly supportive, unless patients were part of an approved clinical trial. The study was approved by NHS Research Ethics Committee 20/SW/0077 and Heath Research Authority IRAS 283130.

Results: Of 1737 HD patients at the 3 renal centres, 224 (13%) were COVID-19 positive over the study period. The characteristics of the COVID-19 HD patients were: mean age 65.8; 59% male; 38% Caucasian; 81% hypertension; 54% diabetes; 25% chronic lung disease; 29% ischaemic heart disease and 22% cerebrovascular disease. The most common symptoms at presentation were fever (62%) and cough (53%). About 143 (64%) patients were managed as an inpatient and 81 (36%) as an outpatient. Of 9 patients that required mechanical ventilation: 6 died, 1 patient was discharged and 2 are still under clinical care. Overall 51 patients died (23%), 154 (69%) were discharged alive and 19 (8%) were still under clinical care as of 15/05/2020. Preliminary analyses suggested that those that died were significantly older (p=0.0028), more likely to have ischaemic heart disease (p=0.003), cerebrovascular disease (p=0.019), smoking history (p=0.006), WHO performance status 3-4 (p=0.004), higher neutrophil:lymphocyte ratio at presentation (p=0.0001) and higher CRP at presentation (p=0.0021).

Conclusions: This large cohort of COVID-19 positive haemodialysis demonstrates a high case fatality ratio, which increased significantly with age, cardiovascular disease, smoking history, frailty and markers of inflammation.

Background: The impact of COVID-19 disease on previously healthy children has been minimal, yet there is limited data on the impact of COVID-19 on children and adolescents with kidney transplants.

Methods: We used the existing infrastructure of the Improving Renal Outcomes Collaborative (IROC) learning health system to develop and rapidly implement a web-based registry for collecting clinical and outcomes data about COVID-19 disease in pediatric transplant recipients. We distributed the registry to 32 U.S. pediatric kidney transplant centers and requested clinical and outcomes data from all recipients suspected of having COVID-19 disease. Here, we present an interim analysis of the first 6 weeks of registry data.

Results: Between April 6 and May 27, 2020, 18 IROC centers entered data on 99 pediatric kidney transplant recipients who had PCR based testing for COVID-19. 54 patients were tested due to symptoms of COVID-19 (most commonly fever and cough), 7 asymptomatic patients had a known COVID exposure. 34 patients were tested per hospital policy (e.g. pre-anesthesia), and 4 did not have a reported testing indication. Overall, 10 (19%) tested positive for COVID-19, 6 of whom had any symptoms, 3 had a known exposure with a COVID+ individual, and 1 was diagnosed by a pre-anesthesia screen. Thus far, the clinical course and outcomes are known in 8/10 COVID+ patients: 5 received outpatient supportive care alone, 2 were admitted to intensive care and 1 was admitted to non-intensive care inpatient unit. Transplant outcomes were excellent in all COVID-19+ patients. There were no cases with respiratory failure, acute kidney injury, or allograft rejection/failure. There were no deaths due to COVID-19 disease.

Conclusions: In this interim analysis of the IROC learning health system, pediatric kidney transplant recipients had a relatively low incidence of COVID-19 disease and excellent short-term outcomes.

PO0764
Clinical Outcomes of Hospitalized Kidney Transplant Recipients with COVID-19 in a Predominantly Minority Population
Montefiore Medical Center, Bronx, NY.

Background: COVID-19 has been associated with increased morbidity in kidney transplant recipients. We aimed to identify risk factors for mortality in hospitalized kidney transplant recipients with COVID-19.

Methods: We retrospectively reviewed the medical records of 75 kidney transplant recipients admitted for COVID-19 at our institution.

Results: Among the 75 patients, 28 (37%) died at a median 8 days (range, 1-36) after admission to the hospital. The Table summarizes the demographics and initial labs values of both groups. Most of our patients were Hispanic (54%) and African American (32%) and 97% had hypertension and 65% had diabetes mellitus. There was no difference between the two groups in terms of sex, type of transplant, time from transplant, infections, CMV viremia, DVT or stroke between the two groups. In a multivariate analysis, age over 65 and time from transplant were significant risk factors for mortality. The table also shows the important sources of information about COVID-19.

Conclusions: In our cohort, the clinical outcomes of hospitalized kidney transplant recipients with COVID-19 was poor. The most important sources of information about COVID-19 were friends and family members, followed by hospital and government sources. The majority of patients received advice from friends and family for quarantining and social distancing.

PO0763
Living Organ Donor Perspectives on Organ Donation During the COVID-19 Pandemic
Meera N. Harlay,1 Ann C. Klassen,1 Janet Fleetwood,1 Peter P. Reese,2 Krista L. Lenteine,1 Michael Mittelman,4 Rebecca L. Bertha,4 Drexel University, Philadelphia, PA; University of Pennsylvania, Philadelphia, PA; St. Louis University, St. Louis, MO; American Living Organ Donor Fund, Philadelphia, PA.

Background: Due to the COVID-19 pandemic, transplant programs across the U.S. postponed living donor surgeries and transplants. We examined perspectives of former and prospective living organ donors on the risks and excess burdens of organ donation during the COVID-19 pandemic.

Methods: In late April 2020, we disseminated an IRB-approved survey to a national online forum of over 1300 living donors and those in workup for donation. Using visual analog scales, respondents rated sources of information about COVID-19, burdens on donors due to the pandemic, and what factors should determine whether living donation should proceed during the pandemic (0=unimportant, 100=very important).

Results: After 4 weeks, there were 101 respondents from 35 U.S. states; 63% were between 31-50 years old, 95% were non-Hispanic white, and 90% were female. Respondents included 68 living donors (72% kidney) and 33 people in work-up to donate (73% kidney). The most and least important sources of information about COVID-19 were transplant doctors (median importance 88, IQR 73-100) and social media (median 26, IQR 12-54), respectively. Nearly half (41%) were unsure of their transplant program’s policy for living donation during the pandemic, and 58% reported that the decision to donate during COVID-19 should depend on factors such as transplant candidate health (median 100, IQR 90-100) and availability of COVID-19 tests (median 84, IQR 70-95). Respondents rated concern for transplant candidates and loss of employer-based health insurance as the most important pandemic-related stressors for donors (Figure).

Conclusions: Many living organ donors were uncertain about their transplant program’s approach for donation during the pandemic. Donors were concerned about the health of transplant candidates and financial stressors, and prioritized availability of COVID-19 testing to determine when living donation should proceed during the pandemic.

Funding: NIDDK Support
PO0765
COVID-19 and Kidney Transplantation: Results from the TANGO International Transplant Consortium
Leonardo V. Riella,1 Suraj Sarvode mothi,1 Enver Akalin,2 Paolo Cravedi,1 TANGO Consortium1 Massachusetts General Hospital, Boston, MA;2 Montefiore Medical Center, Bronx, NY;3 Mount Sinai Health System, New York, NY;4 Brigham and Women’s Hospital, Boston, MA.

Background: Chronic immunosuppression and comorbidities may expose kidney transplant recipients to an increased risk of developing critical coronavirus disease 2019 (COVID-19), but data in transplantation have been limited so far to single centers. To determine the clinical presentation, outcomes, and mortality risk factors in transplant patients with COVID-19, we analyzed retrospective data from a large international transplant consortium (TANGO Study).

Methods: Retrospective cohort study included kidney transplant recipients admitted with COVID-19 in 11 centers participating in the international TANGO consortium. We included all adult (≥18 years) kidney transplant recipients with a functioning kidney allograft who were admitted to a hospital between March-April, 2020. Epidemiological, demographic, clinical, laboratory, treatment, and outcome data were extracted from electronic medical records using an ad hoc designed data collection form.

Results: Among 9,697 kidney transplant recipients followed at 11 transplant centers, 145 (1.5%) were hospitalized due to COVID-19. 65% were male and more than half were over 60 years old (55%). Median time since transplant was 5 years (2-10) and 16% were transplanted less than one year from the presentation. Prevalent comorbidities included hypertension (95%), obesity (41%), heart disease (25%) and lung disease (19%). Common symptoms at the onset of illness were fever and dyspnea (71%), followed by myalgia (54%) and diarrhea (33%). Management of anti-rejection therapy varied across centers: antimetabolites were withdrawn in 69% of patients and calcineurin inhibitor in 26%. Other treatments used during hospitalization included hydroxychloroquine (83%), antibiotics (76%), tocilizumab (13%) and antivirals (10%). During a median follow-up of 13 days (IQR: 7 - 21) after diagnosis of COVID-19, mortality was 30% and occurred at a median 10 (5-16) days after admission. Acute kidney injury (AKI) occurred in 46% and respiratory failure requiring intubation in 29% of cases. No rejection events were observed.

Conclusions: Our large international consortium indicates that kidney transplantation recipients with COVID-19 have increased mortality (30%) upon hospitalization compared to the general population with a high rate of AKI (46%) and significant respiratory failure (29%).

PO0766
Atypical Clinical Presentation of COVID-19 in a Kidney Transplant Recipient with Tacrolimus Toxicity
Michael J. Chau,1 Ismail K. Almokyad,1 Ping Li,1 The George Washington University Milken Institute of Public Health, Washington, DC;2 US Department of Veterans Affairs, Washington, DC.

Introduction: Kidney transplant recipients represent a unique challenge to manage amidst the Coronavirus disease 2019 (COVID-19) pandemic as they have reduced innate ability to fight the viral infection due to immunosuppression. However, calcineurin inhibitors such as tacrolimus, may offer an advantage in reducing the effects of cytokine storms in transplant patients with viral pneumonia. We present an atypical case of COVID-19 in a kidney transplant recipient with toxic levels of tacrolimus presented with mainly fever and diarrhea.

Case Description: A 76-year-old African American male kidney transplant recipient presented to the Emergency Department (ED) after 5 days of fever (temperature of 101.8°F), nausea, vomiting, diarrhea and urinary frequency on March 27, 2020. His vitals were noted with a temperature of 96.9°F, respiratory rate of 40/ min, and heart rate of 166 beats/min, blood pressure of 110/75 mmHg and pulse oxygen saturation was 85% at ambient air. Admission labs were significant for a rise of serum creatinine to 3.1 mg/dL from a baseline of 1.5 mg/dL, lactate acid of 4.4 mmol/L, and a tacrolimus level of 26.9 mcg/L. He was transferred to the ICU following increased oxygen demands and elective intubation for impending respiratory failure on hospital day 2. His blood pressure transiently improved with a decrease in lactic acid to 1.4 mmol/L and serum creatinine down to 1.6 mg/dL following IV fluid resuscitation.

On hospital day 4, he continued to require high ventilator support and initiated on vasoconstricting agents for hemodynamic support. His serum tacrolimus level continued to increase to 32.9 mcg/L with concordant increase of serum creatinine to 2.1 mg/dL with oliguria. Tacrolimus levels sustained super therapeutic levels ~8 mcg/L despite cessation of the drug.

Discussion: It is possible that Severe Acute Respiratory Syndrome coronavirus 2 (SARS-CoV-2) infection may cause hepatic dysfunction and diarrhea, which reduced drug metabolism and lead to toxic levels of tacrolimus—perpetuating cytokine storm. It is important that in this particular transplant patient population to closely monitor drug levels due to SARS-CoV-2 infection on its metabolism, as well as preventing toxic levels, which further reduces the body’s innate immunity and may indirectly worsen cytokine storm.

PO0768
Risk Factors for Mortality in Kidney Transplant Recipients with COVID-19

Background: There is limited information on the presentation and risk factors for poor outcome in kidney transplant recipients with COVID-19.

Methods: We reviewed data of admitted kidney transplant recipients at 12 system hospitals with COVID-19 between March 1, 2020, and April 30th, 2020. We analyzed risk factors for mortality.

PO0796
Living Donor Kidney Transplant Practice in the COVID-19 Era: A Survey of US Transplant Programs

Krista L. Lenten,1 Luke S. Vest,1 Mark Schnitzler,1 Roslyn B. Mannon,2 Vincetta Kumar,3 Mona D. Doshi,4 Matthew Cooper,5 Didier A. Mandelbrodt,6 Meera N. Harhay,7 Michelle A. Josephson,8 Bertram L. Kasiske,9 Yasar Caliskan,10 David Axelrod,11 Saint Louis University, Saint Louis, MO; 1University of Nebraska Omaha, Omaha, NE; 1The University of Alabama at Birmingham, Birmingham, AL; 1University of Michigan, Ann Arbor, MI; 1MedStar Georgetown University Hospital, Washington, DC; 1University of Wisconsin-Madison, Madison, WI; 1Drexel University, Philadelphia, PA; 2University of Chicago, Chicago, IL; 3Hennepin County, Minneapolis, MN; 4University of Iowa, Iowa City, IA

Background: We surveyed U.S. transplant programs to assess practices, strategies and barriers related to living donor kidney transplantation (LDKT) in the context of the COVID-19 pandemic.

Methods: After IRB approval, the survey was launched 5/9/20 by email and postings to professional society list-serves, using the Qualtrics platform. Data are reported through 5/27/20, and examined by state COVID-19 prevalence.

Results: At 117 unique centers responded, representing 58% of U.S. living donor recovery centers and 75% of LDKT volume in the year before pandemic declaration. Overall, 66% reported LDKT surgery was on hold (82% in high vs. 50% in low prevalence states). 36% reported that evaluation of new donor candidates had paused, 27% reported evaluations were moderately decreased (>0% to <25% typical) and 23% reported evaluations were very decreased (>0% to <25% typical). Barriers to LDKT surgery included program concerns for donor (84%) and recipient (75%) safety, patient concerns (54%), restrictions on elective cases (47%) and hospital administrative restrictions (47%). Programs with higher local COVID-19 prevalence reported more barriers related to staff and resource diversion (Figure). Most centers continuing donor evaluations used remote strategies (video 82%; telephone 43%), 61% of centers plan to continue more telehealth after the pandemic. 32% plan to resume some LDKT within 2 wks and 27% within 1 month. When surgery resumes, all will screen for COVID-19 before donation surgery, after the pandemic. 32% plan to resume some LDKT within 2 wks and 27% within 1 month. When surgery resumes, all will screen for COVID-19 before donation surgery, after the pandemic. 32% plan to resume some LDKT within 2 wks and 27% within 1 month. When surgery resumes, all will screen for COVID-19 before donation surgery, after the pandemic.

Conclusions: COVID-19 has created many barriers to LDKT, especially in areas of highest prevalence. Transplant centers are planning to restart LDKT cautiously. Consensus-building is needed to reduce barriers, guide optimal practice, and facilitate safe restoration of LDKT across centers.

All data presented in median (IQR) unless otherwise noted

PO0770
Collapsing/Sclerosing Glomerulopathy (CSG) and Acute Tubular Injury (ATI) in Patients with COVID-19

Sunil Sherchan, Mohamed Kahila, Janrose K. Durrani, Isla Puri, Ibrahim A. Mohamed, Yohannes Melaku, Ernie Yap, Robert F. Leonard, Subodh J. Saggi, Moro O. Salifu, Anthony D. Nicasiri, SUNY Downstate Health Sciences University, Brooklyn, NY

Introduction: AKI in patients with COVID-19 may be due to ATI from hemodynamic instability or inflammatory responses. We present two cases of CSG and ATI in patients admitted for COVID-19.

Case Description: Case 1 25-year-old black obese female admitted with fever, cough, dyspnea and serum creatinine of 1.4 mg/dl, discharged next day with home quarantine. Re-admitted 26 days later due to nausea, fatigue, and bilateral foot swelling. Serum creatinine 28 mg/dl and urine protein to creatinine ratio (upCR) of 10.4 g/g. Case 2 42-year-old black female with hypertension, diabetes mellitus admitted with fever, dyspnea, cough, and diarrhea. Patient found to have diabetic ketoacidosis, serum creatinine 12.7 mg/dl. She developed deep vein thrombosis and pulmonary embolism and upCR 15.4 g/g. She was started on hemodialysis Kidney biopsy showed global and segmental capillary collapse with a variable degree of sclerosis and severe renal tubules injury. Electron microscopy showed spherical structures in the podocytes, endothelial cells, and tubular epithelium similar to Coronavirus particles

Discussion: Our experience above is part of a growing literature describing the direct visualization of SARS-CoV-2 in causing ATI and CSG. Pathogenetic pathways remain to be elucidated

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO0771
What Do Data Tell Us About Patients Receiving Calcineurin Inhibitors (CNIs) and Contracting a Coronavirus
Jung Hoon Son,1 Ollie Fielding,1 Xiaoyang Wang,1 Chris Kipers,1 Jeffrey I. Silberzweig,1 Frank Liu.2 The PEAK team ’pulseData, New York, NY; 1The Rogosin Institute, New York, NY.

Background: We hypothesized that patients taking CNIs, cyclosporine and tacrolimus would be less susceptible to coronavirus infections because of antiviral and anti-cytokine-storm effects and compared the occurrence of positive coronavirus test rates in a population receiving a CNI and non-CNI treatment population. This is of high importance as CNIs are being trialed as a treatment for severe acute respiratory syndrome coronavirus 2 (COVID-19) immune response (NCT04343103). Transplant nephrologists recommend continuing CNIs through the COVID-19 pandemic.

Methods: We analyzed longitudinal EHR system data from the Rogosin Institute’s nephrology clinic to identify a population of 5,144 patients with a record of respiratory viral panel (RVP) testing for any coronavirus strain between December 2012 and May 2020. We identified 1,195 patients receiving cyclosporine or tacrolimus and compared positive test rates of any coronavirus stain in those receiving CNIs to those not receiving CNIs.

Results: A total of 51 patients tested positive (1.05%) Of the 1,195 CNI recipients, 21 tested positive (1.76%); of 3,949 patients with no record of CNI treatment, 33 tested positive (0.84%). Given an age distribution difference between the two cohorts (CNI cohort median 58; non-CNI cohort median 66). We therefore calculated an age-adjusted positive test rate for both populations, with results of 1.76% for the CNI cohort and 0.83% for the non-CNI cohort. A z-test comparing the population proportions testing positive had a z-value of 2.71 (p-value 0.003), indicating significant difference. 8.47% of positive tests on an RVP for any of coronavirus, rhinovirus or respiratory syncytial were for a coronavirus in the CNI group vs. 6.48% in the non-CNI group (z 2.37, p 0.009). Using a logistic regression model to examine the probability of testing positive for a coronavirus infection, it was found that CNIs were statistically significant features for age, gender, whether the test was conducted in flu season (Dec-Feb) and whether the patient was receiving CNIs. A z-test comparing the population proportions testing positive (0.84%). Given an age distribution difference between the two cohorts (CNI cohort median 58; non-CNI cohort median 66). We therefore calculated an age-adjusted positive test rate for both populations, with results of 1.76% for the CNI cohort and 0.83% for the non-CNI cohort. A z-test comparing the population proportions testing positive had a z-value of 2.71 (p-value 0.003), indicating significant difference. 8.47% of positive tests on an RVP for any of coronavirus, rhinovirus or respiratory syncytial were for a coronavirus in the CNI group vs. 6.48% in the non-CNI group (z 2.37, p 0.009). Using a logistic regression model to examine the probability of testing positive for a coronavirus infection, it was found that CNIs were statistically significant features for age, gender, whether the test was conducted in flu season (Dec-Feb) and whether the patient was receiving CNIs. We found that CNIs were statistically significant (p 0.007).

Conclusions: Based on the data, as far as we can tell being on a CNI does not offer protection from a symptomatic coronavirus infection. It remains to be seen if it decreases severity of the illness because of the potential for cytokine storm effects.

PO0772
ESKD Patients with COVID-19 vs. Kidney Transplant Recipients with COVID-19

Background: The Covid-19 pandemic has had significant impact on the ESKD population with reduction in kidney transplantation due to decreased organ availability and temporary cessation of transplant procedures. To better understand the impact on patients with ESKD, we compared the outcomes of Covid-19 positive patients on the Waitlist with those with a functioning kidney transplant.

Methods: Our center developed a dashboard and active surveillance of Waitlisted and Kidney transplant recipients tested for SARSCoV-2. From 3/13/20 to 5/20/20, we identified 55 Waitlisted patients who tested positive for SARS-CoV-2, and compared their clinical characteristics and outcomes with those post kidney transplant. Primary outcomes included hospitalization and mortality rates.

Results: Presenting symptoms and hospitalization rates were similar in waitlisted ESKD and kidney transplant patients with Covid-19. Azithromycin and doxycycline use was similar in both groups. Hydroxychloroquine use was more frequent in kidney transplant patients (62% vs 36%), as were other experimental therapies. Mortality was greater in waitlisted ESKD compared to kidney transplant patients (29% vs 13). Of the waitlisted ESKD patients who died, most were males, Black or Hispanic, and 81% had T2DM and/or HTN as the cause of their ESKD. None of the non-hospitalized patients died in either group.

Conclusions: Waitlisted ESKD patients on dialysis with Covid-19 are comparatively at higher risk for mortality compared to kidney transplant recipients with Covid-19 despite similar demographics and similar burden of comorbidities. Whether the ability of immunosuppressive therapy to prevent the cytokine storm contributed to better survival among kidney transplant recipients remains to be determined.
Conclusions: Kidney transplants programs are almost closed throughout LA during the COVID-19 pandemic. The disproportionate resource allocation to COVID-19 will have unintended consequences for those already carrying the burden of health inequality with the potential to disadvantage marginalized patients further. Reported immunosuppression management is in line with transplant societies’ recommendations.

PO0774
A Machine Learning-Based Predictive Model for Outcome of COVID-19 in Kidney Transplant Recipients
Ignacio Revuelta,1,2 Francisco-Javier Santos-Arteaga,1 Enrique Montagud-Marradi,1,2 Pedro Ventura-Aguiar,1,2 Debora Di Caprio,1 David Cucchiari,1,2 Beatriz Bayes,1 Esteban Poch,1 Federico Oppenheimer,1 Fritz Diekmann,1,2 1Department of Nephrology and Kidney Transplant. Hospital Clinic, Barcelona, Spain; 2Institut d’Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain; 3Faculty of Economics and Management. Free University of Bolzano, Bolzano, Italy; 4Department of Economics and Management. University of Trento, Trento, Italy.

Background: Health systems need tools to deal with COVID-19, especially for high-risk population, such as transplant recipients. Predictive models are necessary to improve management of patients and optimize resources.

Methods: A retrospective study of hospitalized transplant patients due to COVID-19 was evaluated (March 3–April 24, 2020). Admission data were integrated to develop a prediction model to evaluate a composite-event defined as Intensive Care Unit admission or immunosuppression treatment with antiinflammatory agents. Predictions were made using a Data Envelopment Analysis (DEA)-Artificial Neural Network (ANN) hybrid, whose accuracy relative to several alternative configurations has been validated through a battery of clustering techniques.

Results: Of 1006 recipients with a planned or an unscheduled visit during the observation period, thirty-eight were admitted due to COVID-19. Twenty-five patients (63.2%) exhibited poor clinical course (mortality rate: 13.2%), within a mean of 12 days of admission stay. Cough as a presenting symptom (P=0.000), pneumonia (P=0.011), and levels of LDH (P=0.031) were admission factors associated with poor outcomes. The prediction hybrid model working with a set of 17 input variables displays an accuracy of 96.3%, outperforming any competing model, such as logistic regression (65.5%) and a random forest (denoted by Bagged Trees, 44.8%). Moreover, the prediction model allows us to categorize the evolution of patients through the values at hospital admission.

Conclusions: The prediction model based in Data Envelopment Analysis-Artificial Neural Network hybrid forecasts the progression towards severe COVID-19 disease with an accuracy of 96.3%, and may help to guide COVID-19 management by identification of key predictors that permit a sustainable distribution of resources in a patient-centered model.

PO0775
Outcomes of COVID-19-Positive Kidney Transplant Recipients

Background: Kidney transplant recipients (KTR) are at increased risk of infections due to immunosuppression (IS). COVID-19 has posed unique challenges due to its evolving symptomatology and lack of effective treatment options. Current data published about the impact of COVID-19 in KTR comes from severely impacted areas. The aim of our study was to review course and outcomes of KTR at our center.

Methods: Retrospective chart review of KTR diagnosed with COVID-19. Descriptive statistics were summarized as absolute numbers for categorical data and as median with interquartile range (IQR) for skewed distribution.

Results: We had 20 KTR diagnosed with COVID-19. Median age of 53.5 years (47-63), 10 males, and 12 blacks. Median time from KT to presentation was 70.7 months (17.25-158.75), with 1 pt in 1st year post KT. Thirteen (65%) pts were obese with BMI ≥ 30 kg/m², 2 pts had chronic obstructive pulmonary disease, and 5 had cardiac disease. Most common presenting symptom was cough in 14 pts, followed by fever-13 pts, shortness of breath-9, and diarrhea-6 pts. During the study, 15 pts were hospitalized, and 9 of them had chest x-ray findings of bilateral opacities consistent with pneumonia. Inflammatory markers were elevated in all pts but did not correlate with disease outcome. Acute kidney injury was seen in 9 pts, with 3 requiring continuous renal replacement therapy. Four pts required mechanical ventilation. Ten pts had reduction of their IS. Hydroxychloroquine was used in 11 pts, and azithromycin in 4. Four hospitalized pts received convalescent plasma as part of an ongoing COVID-19 trial in our center. Donors were 4-6 weeks post recovery from confirmed severe acute respiratory syndrome coronavirus 2 infection. Enrollment was offered to pts at high risk of progression to severe disease. We had 3 deaths, 2 pts remain hospitalized, and the remaining 15 were either discharged or managed as outpatients. Median follow up time from presentation was 25 days (3-38) for the entire cohort.

Conclusions: In our cohort, 45% of patients presented with acute allograft dysfunction highlighting impact of SARS-CoV-2 infection on kidney function. Our center utilized investigational convalescent plasma in 4 pts successfully while the clinical trial outcomes are awaited. Ultimately, the development of a safe and efficacious vaccine targeting SARS-CoV-2 may better equip us to fight this pandemic.

PO0776
COVID-19 in Kidney Transplant Recipients at New England’s Largest Safety-Net Hospital
Hassan Mahmoud, Sandeep Ghai, Jean M. Francis. Boston University, Boston, MA.

Background: The coronavirus disease 2019 (COVID-19) has led to a global pandemic as announced by the World Health Organization. Kidney transplant patients are thought to constitute a unique high-risk group for severe COVID-19 infection. Furthermore, disparities in health care have led to COVID-19 disproportionately affecting minority groups including African Americans and Hispanics.

Methods: We identified adult kidney transplant recipients who were admitted with COVID-19 between March, 15th and May 1st, 2020. We evaluated the demographic, clinical and laboratory data of all admitted patients. We also evaluated the presence of co-infections as well as decisions regarding immunosuppressant management.

Results: 23 kidney transplant recipients who were hospitalized for COVID-19 were evaluated. 91% of our patients were of minority groups. 35% of patients required ICU admission, and 30% required mechanical ventilation. 40% of patients had associated coinfections in addition to COVID19. 87% of patients had variable degrees of AKI, 26% of patients with AKI required renal replacement therapy. Mortality rate in our population was 22%. Upon admission to the hospital, our immunosuppressant therapeutic approach included stopping the anticonvulsants and continuing with the calcineurin inhibitors (targeting trough level of 4 to 6 ng/dl for tacrolimus and 50 ng/dl for cyclosporine), and prednisone if patients were on steroids.

Conclusions: This report demonstrates higher rate of AKI, coinfection and mortality in kidney transplant patients in the setting of COVID19 as compared to general population.
Identifying Scenarios of Benefit or Harm from Kidney Transplantation During the COVID-19 Pandemic: A Simulation Study

Allan Massie, Brian J. Boyarsky, William A. Werbel, Sunjae Bae, Eric Chow, Robin K. Averk, Daniel C. Brennan, Jacqueline Garonziki Wang, Dorry L. Segev, Johns Hopkins University School of Medicine, Baltimore, MD; Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.

**Background:** Clinical decision-making in kidney transplantation (KT) during the COVID-19 pandemic is a challenge: both candidates and recipients may face increased acquisition risks and case fatality rates (CFRs). Given our poor understanding of these risks, many centers have paused or reduced KT activity, yet data to inform such decisions are lacking.

**Methods:** To quantify the benefit/harm of KT in this context, we conducted a Markov simulation study of immediate KT vs delay-until-after-pandemic for different patient phenotypes under a variety of potential COVID-19 scenarios (Figure 1), simulating expected life-months gained from transplant over 5 years. A calculator was implemented (http://www.transplantmodels.com/covid_sim), and machine learning approaches were used to evaluate the important aspects of our modeling.

**Results:** Characteristics of the pandemic (acquisition risk, CFR) and length of delay (length of pandemic, waitlist priority for DDKT) had greatest influence on benefit/harm (Figure 2). In most scenarios of COVID-19 dynamics and patient characteristics, immediate KT provided survival benefit; KT only began showing evidence of harm in scenarios where CFRs were substantially higher for KT recipients (e.g. ≥50% fatality) than for waitlist registrants.

**Conclusions:** Our simulations suggest that KT remains beneficial under COVID-19 in many scenarios. Our calculator can help identify patients who would benefit most. As the pandemic evolves, our calculator can update these predictions.

**PO0778**

COVID-19 in Patients with CKD in New York City

Oleh M. Akhchurin, Sharmi Biswas, Michaela Greenbaum, Alexandra Licona, Justin J. Choi, Mary E. Choi, Weill Cornell Medicine, New York, NY; NewYork-Presbyterian Healthcare System Inc, New York, NY.

**Background:** Coronavirus disease 2019 (COVID-19) has affected millions of people, and several chronic medical conditions appeared to increase the risk of severe COVID-19. However, limited data are available about the outcomes of COVID-19 in patients with chronic kidney disease (CKD).

**Methods:** This was an observational study of patients with CKD at three affiliated hospitals in New York City who were diagnosed with COVID-19 by reverse-transcriptase polymerase chain reaction of nasopharyngeal swab specimens collected in the emergency departments between March 3rd and April 21st, 2020. We stratified patients into three groups: pre-dialysis CKD, dialysis, and transplant. Data are shown as median (interquartile range). Logistic regression was used to identify CKD characteristics associated with non-survival.

**Results:** Of the 372 confirmed COVID-19 patients with CKD, 182 were pre-dialysis, 149 were on dialysis, and 41 had functional kidney transplant. The median age of the pre-dialysis group was 75 (63-85) years, dialysis group 66 (58-74) years, and transplant group 63 (48-71) years. Men comprised 62.4% of the cohort. Baseline serum creatinine was 1.5 (1.2-2.2) mg/dL in the pre-dialysis group. By the end of the observation period, 78.5% of patients were discharged or had died. Of these patients, mortality was highest in the pre-dialysis group (26.9%), followed by dialysis (24.2%), then transplant (9.8%) groups. Almost half of the cohort was receiving ACE-inhibitors or ARBs pre-COVID-19, which was not associated with non-survival. In the pre-dialysis group, the other group phosphorus was associated with non-survival (OR 1.5 per each 1.0 mg/dL of increase in serum phosphorus). Anemia, defined as hemoglobin <10 g/dL, was also associated with non-survival (OR 3.1) in that group. Body mass index (BMI)<25 kg/m$^2$ was paradoxically associated with non-survival (OR 2.7) in patients with pre-dialysis CKD.

**Conclusions:** Our data demonstrate that mortality in this cohort, particularly in patients with pre-dialysis CKD, was substantially higher than in the general population in New York City. Poorly controlled CKD complications, including CKD-mineral and bone disorder and anemia, as well as low BMI were associated with mortality. Ongoing control of CKD complications may serve as an opportunity to improve outcomes of COVID-19 in patients with CKD.

**PO0779**

COVID-19 in CKD: Retrospective, Propensity Score-Matched Cohort Study

**Background:** The prognostic factors for COVID-19 in patients with chronic kidney disease (CKD) are uncertain. We conducted a propensity score-matched study to compare clinical and prognostic features between hospitalized COVID-19 patients with and without CKD.

**Methods:** Patients with estimated creatinine clearance below 60 ml/min/1.73 m² for more than three months, were included in the CKD group. Fifty-six patients and the propensity score-matched fifty-six control patients were followed-up at least 15 days or until death after diagnosis of COVID-19. All demographic data and diagnostic and therapeutic methods were evaluated. The endpoints were all-cause mortality and acute kidney injury (AKI).

**Results:** Patient and control groups were reviewed retrospectively over a median follow-up of 44 days (IQR, 36-52 days) after diagnosis of COVID-19. Patients in the CKD group had higher intensive care unit follow-up and mortality rates than the other group, but these results did not reach statistical significance (16 [28.6%] vs. 19 [33.3%]; p=0.54 and 11 [19.0%] vs. 16 [28.6%], p=0.269, respectively). The frequency of AKI was significantly higher in predialysis patients with CKD compared to the other group (8 [14.3%] vs. 5 [45.5%]; p<0.001), and there was no significant difference between the groups in terms of cytokine release syndrome and respiratory failure (8 [14.3%] vs. 8 [14.3%], p=0.226, 25 [44.4%] vs. 22 [39.3%], p=0.566, respectively). Multivariate logistic regression analysis revealed that respiratory failure (OR 2.83, 95% CI, 7.296 to 211.519; P<0.001) and AKI (10.961 [95% CI, 1.688 to 71.186; P=0.012) were independent risk factors for the mortality.

**Conclusions:** The prognosis of COVID-19 in patients with CKD is worse than non-uremic patients. Also, AKI and respiratory failure are independent risk factors for mortality.

Kidney and Clinical Outcomes of COVID-19 in the Mexican Population

Background: Coronavirus Disease 2019 (COVID-19) is a new disease of pandemic proportions. Currently, there are no reports about kidney involvement and the association with mortality in Mexico. Our aim was to describe the characteristics in our population, clinical, and renal outcomes.

Methods: Prospective, descriptive, single-center study in patients diagnosed with COVID-19 (positive RT-PCR tests), admitted to our hospital from April 2020 to date.

Results: 48 patients (60.41% men) with an average age of 54.33 years were included. 23 (47.92%) had a previous diagnosis of HTN, 11 (22.92%) had obesity (10%); 20% had neurologic diseases, 6 (13%) had heart disease, 3 (6.3%) had malignancies and 1 (2.1%) had liver disease. 9 (18.8%) patients with a history of smoking. At admission, the mean oxygen saturation was 85.76%. The main reason for consultation was dyspnea in 35 patients (72.9%). Regarding symptoms, 81.3% (39) had dyspnea, 87.5% (42) fever, 54.2% (26) headache, 72.9% (35) cough, and, to a lesser extent, odynophagia, myalgia and malaise in 33.3% (16), 45.8% (22) and 41.7% (20) respectively. The mean creatinine, urea and bicarbonate was 1.34 mg/dl, 56.69 mg/dl, and 18.49 mmol/l respectively. 25% of the patients required ICU admission and 27.1% mechanical ventilation. During the study period, 19 patients (39.6%) developed AKI, 20.8% classified as KDIGO stage 1 and 18.8% as stage 3. At the end of this study, 56.3% (27) had a complete recovery, 35.4% (16) died and 8.3% (5) are still admitted. Regarding the patients that had an AKI, 6 (31.57%) had a complete recovery, 1 (5.26%) required intermittent HD but eventually died and 8.3% (5) are still admitted. For a total of 13 deaths (68.4%). There was a statistically significant difference in mortality between patients with AKI vs patients with normal kidney function (p=0.002), with a RR of 3.47.

Conclusions: This study showed a higher prevalence of AKI in the Mexican population compared to reports from other countries, with a significantly higher risk for death. Special attention should be paid to this outcome and as nephrologists, we must take an active role in the care of these patients.

PO0781

Association Between Kidney Dysfunction at Admission and Outcomes in Hospitalized Patients with COVID-19

Imran Chaudhri,1 Farrukh M. Koraishy,1 Olена Bolotova,1 Jeawoon Yoo,1 Simrat Dhaliwal,2 Raji Reddy Annadi,2 Minh Hoai Nguyen,1 Sandeep K. Mallipattu,1 Stony Brook University Hospital, Stony Brook, NY,1 Stony Brook University, Stony Brook, NY,2 Northport VA Medical Center, Northport, NY.

Background: AKI is a major predictor of mortality in patients with coronavirus disease 2019 (COVID-19). Data regarding association of renal dysfunction (AKI, hematuria and proteinuria) at the time of admission with hospital outcomes is limited.

Methods: In this retrospective single-center study, we analyzed electronic medical records on 306 patients admitted with COVID-19 from 2019-2020. Data collection included history of comorbidities, medications, vital signs, and admission and peak laboratory values. Outcomes included inflammatory burden (calculated using composite scores for multiple markers of inflammation), AKI during hospitalization, admission to the intensive care unit (ICU), need for invasive and non-invasive ventilation, mortality and length of stay. For multivariate analysis, a generalized linear model (continuous outcomes) and logistic regression (dichotomous outcomes) were used. Machine learning algorithms (XGBoost classifier with 3-fold cross-validation) were performed to develop a predictive model for in-hospital AKI.

Results: No significant associations between admission AKI and hospital outcomes were observed. Admission proteinuria was associated with increases in in-hospital AKI, ICU admission, death, peak inflammation score, and length of stay on descriptive analysis; however, on multivariate analysis (after adjusting for multiple covariates), only in-hospital AKI remained statistically significant (OR=4.71, 1.28-17.38, p=0.02). Admission hematuria was associated with increases in hospital AKI, ICU admission, invasive mechanical ventilation, and death on descriptive analysis; and on multivariate analysis it still predicted increased rates of ICU admissions (OR=4.56, 1.12-18.64, p=0.03), invasive mechanical ventilation (OR=8.79, 8.09-37.00, p=0.003), and death (OR=18.03, 2.84-114.57, p<0.002). Using machine learning algorithms, an area under the receiver operating curve (AUC) of 0.77 with an accuracy of 87.6% was obtained for predicting in-hospital AKI using only admission data.

Conclusions: In patients with COVID-19, admission hematuria and proteinuria are associated with adverse hospital outcomes, and admission data can be used to predict AKI during hospitalization.

Funding: NIDDK Support, Veterans Affairs Support

PO0782

COVID-19 in CKD Patients: Lessons from 553 CKD Patients with Biopsy-Proven Kidney Disease

Juan León Román, Clara García-Carro, Nestor Toapanta, Irina Torres, Roxana Bury, Cinthia Baldaldo, Daniel Serón, María Jose Solet. Hospital Vall d’Hebron. Nephrology Department, Barcelona, Spain.

Background: COVID-19 is a novel coronavirus currently at the centre of a global pandemic, and patients with cardiovascular risk factors such as hypertension and diabetes are at risk of a serious complication such as hospitalization and death. Chronic kidney disease (CKD) increased cardiovascular risk and ~90% of CKD patients presented hospitalization. The prognosis and lebility of COVID-19 in patients with biopsy-proven kidney disease has not been previously studied.

Methods: Data included patients who underwent a kidney biopsy at the Vall d’Hebron Hospital between January 2013 and February 2020 with diagnostic confirmation and those with high clinical suspicion of SARS-CoV-2 infection during the period from March to May 2020.

Results: Of 553 patients, 39% were diagnosed with SARS-CoV-2 infection. The mean age was 63±14 years. 48.7% were male, 31 hypertension, 19 diabetics, 12 obese and 18 had long disease. The renal histological diagnosis of glomerulonephritis with extracapillary proliferation in 10.3%, allergic interstitial nephritis in 10.3%, secondary GSF in 8.5% and diabetic nephropathy in 10.3%. 4 patients were on hemodialysis and 6 had a kidney transplant. Creatinine before infection was 1.52mg/dl. Among the 283 patients who were under immunosupprese treatment (29% vs 0%, p=0.014). CKD patients under RAS blockade had less mortality than patients without RAS blockade treatment (29% vs 61%, p<0.001), and a higher rate of hospital admission (60% vs 33%, p<0.001).

Conclusions: COVID-19 was diagnosed in 7% of our CKD patients with kidney biopsy. The mortality was 15%, lower than the reported in hemodialysis patients. RAS blockade is not exerting a deleterious effect in our CKD patients with COVID-19 infection, suggesting that they should not be withdrawn.

Renal Dysfunction, COVID-19 Infection, and Mortality

Yanetês Villegas Aréncibia,1,2 Oscar A. García Valencia,1,2 Juan D. Salcedo Belloso,3 Gabriel Cervantes Maldonado,4 Alesia Forni,5 Subhra N. Talukder,6 Sayari Patel,6 Alexander R. Sands,6 Marie C. Desir,6 Samantha Spring,7 Staci J. Marbin,6 Anna K. Shah,6 Angela M. Meghan,6 Ciara G. Sanon,6 Jay-Shing Wang,6 Camille C. Baumrucker,6 Nidhi Patel,6 Samantha R. Greissman,6 Matthew J. Galau,6 Carlos A. Dallera,6 Sohil S. Desai,6 Marie A. Sosa,6,7 Jackson Memorial Hospital, Miami, FL;8 University of Miami, Coral Gables, FL.

Background: Critically ill patients with the SARS-CoV-2 virus (COVID-19) infection have diverse clinical manifestations including renal dysfunction which can determine their short-term outcomes. We assess if renal dysfunction on day one of hospital admission is associated with increased mortality risk of patients with severe COVID-19 infection.

Methods: We conducted a retrospective review of records of patients with severe COVID-19 infection admitted to the Intensive Care Unit between March 4 and April 11, 2020. Patients were divided into two groups based on serum creatinine level on day one of hospital admission. Group 1 included patients with normal serum creatinine (Scr) ≤1.10 mg/dl while group 2 included patients with high Scr > 1.10 mg/dl. The primary outcome was mortality. Secondary outcomes were the need for renal replacement therapy (RRT), duration of RRT, development of adult respiratory distress syndrome (ARDS) and need for mechanical ventilation. Comparisons between groups were done using Mann-Whitney U-tests for continuous variables and chi-square tests for categorical variables. Mortality was evaluated with a Kaplan-Meier Survival Analysis.

Results: A total of 77 in group 1 and 20 in group 2. Patients in group 2 compared to group 1 were older (67 vs. 56, p<0.04), more frequently African Americans (11% vs 45%, p<0.02), hypertenives (80% vs 52%, p<0.05) with chronic kidney disease (25% vs 0%, p<0.01), without significant differences sex, diabetes, smoking status or use of renin-angiotensin antagonists. 8 patients in group 2 and 3 patients in group 1 died, with significant difference in cumulative survival (Figure 1). Need for RRT (55% vs 41%, p<0.03), duration of RRT (6 vs 3 days, p=0.08), development of ARDS (85% vs 81%, p=0.75) and need for mechanical ventilation (65% vs 61%, p=0.89) were not significantly different between groups 2 and 1.

Conclusions: The presence of renal dysfunction on the day of hospital admission is associated with increased hospital mortality in patients with severe COVID-19 infection.

**Kidney Involvement and Outcome of COVID-19 Patients Admitted from a Federal Medical Facility**

Yahya R. Ahmed,1 Matthew Shea,1 Mohamed M. Abdalbari,2 Eljiah Kakani,1 Javier A. Neyra,2 Amr E. Mohamed.1 1University of Kentucky Medical Center; Lexington, KY; 2Mansoura University, Mansoura, Egypt.

**Background:** Correctional facilities face unique challenges with the COVID-19 pandemic. A COVID-19 outbreak was reported in the Federal Medical Center (FMC) in Lexington, Kentucky, a prison for inmates requiring medical and/or mental health care. We aimed to compare clinical characteristics and kidney related outcomes in inmates from this FMC to other COVID-19 hospitalized patients.

**Methods:** A total of 86 COVID-19 patients were admitted to our hospital between March 1st and June 1st, 2020. Among those, 37 patients were from the same FMC. We examined demographics, clinical and laboratory characteristics, along with the outcomes of this cohort and compared it to other COVID-19 non-prisoners. AKI was determined by KDIGO criteria.

**Results:** All inmates were men and their mean age was 59.8±10.6 years. The majority of them were white (60%) and required ICU admission (54%), while 39% of patients required mechanical ventilation. The prevalent comorbidities were hypertension (81%), obesity (62%), diabetes (41%) and coronary artery disease (CAD) (58%). Stage 3 CKD was present in 22% of inmates. The mean eGFR was 68±26 mL/min/1.73m² at time of admission. Significant hematuria and proteinuria were found in 17% and 25% of patients, respectively. Hypertension, heart failure, CAD, COPD, hepatitis C infection, and AKI were more prevalent in the FMC cohort (P = 0.030, 0.001, 0.024, 0.001, 0.011, and 0.011, respectively). The difference in mortality rates was not statistically significant between groups (12% for inmates vs. 13% for non-inmates, P=0.520). Incident AKI was higher in inmates vs. non-inmates (68% vs. 38%, P<0.001) and there was no difference in acute dialysis need (14% vs 12%, respectively). The overall mortality rates were higher in patients that required dialysis (80% vs. 6% for those who did not, P<0.001). The need for acute dialysis was independently associated with mortality in multivariable models.

**Conclusions:** Incidence of AKI was higher in hospitalized inmates with COVID-19 vs. non-inmates. The need for acute dialysis was strongly associated with mortality in overall COVID-19 hospitalized patients.

**Can Urine Biomarkers Predict Severity of COVID-19? A Preliminary Study**

Durkache Katagiri, Eisei Noiri, Masahiro Ishikane, Yusuke Asai, Noriko Kinoshita, Norio Ohmagara, Fumihiko Hinoshita. National Center for Global Health and Medicine, Shinjuku-ku, Japan.

**Background:** Early detection of coronavirus disease (COVID-19) in patients likely to develop severe manifestations enables appropriate interventions, including rapid intensive care unit admission. This study was conducted to determine whether non-invasive urine biomarkers can predict the clinical severity of COVID-19.

**Methods:** Design A retrospective case series. Setting Single-center study, national center hospital designated for infectious disease. Patients Fifty-eight patients who tested positive for SARS-CoV-2 in respiratory specimens through real-time reverse transcription-polymerase chain reaction (RT-PCR) were retrospectively studied. Measurements and main results Urinary β2-microglobulin (β2MG), liver-type fatty acid binding protein (L-FABP) were serially measured. Serum interferon γ and monoclonal chomatographic protein-1 were also evaluated.

**Results:** The 58 patients were assigned into three groups. Patients requiring intensive care were assigned to the severe group (N = 12). Patients treated with oxygen were assigned to the moderate group (N = 20). Other patients were assigned to the mild group (N = 33). Urine tests revealed that low β2MG and L-FABP levels on admission were associated with mild disease, whereas high levels were associated with severe disease. In severe cases, L-FABP tended to be persistently high. The resulting cutoff values were β2MG: Severe vs. Moderate+Mild: 2457 μg/dL (Specificity 76.9% and Sensitivity 90.0%, P=0.032) was the independent predictor for mortality.

**Conclusions:** Evaluating urinary biomarkers such as β2MG and L-FABP may allow determination of COVID-19 patients with active cytokines and recognition of patients likely to become critically ill and requiring careful observation and early intervention.

**Funding:** Government Support - Non-U.S.

**PO0786**

**Urinary Sediment Microscopy in COVID-19-Associated AKI**

Carlos F. Hernandez-Arroyo,1 Vinip Varghese,2 Muner Mohamed,1 Juan Carlos Q. Velaz.1,2 Ochsner Nephrology 1Department of Nephrology, Ochsner Health System, New Orleans, LA; 2Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.

**Background:** Acute kidney injury (AKI) is a complication of COVID-19 that is not fully understood. Microscopic examination of the urinary sediment (MicrExUrSed) is a valuable diagnostic tool in AKI. Thus far, there has been scant data about MicrExUrSed in COVID-19-associated AKI (CoV-AKI). We hypothesized that MicrExUrSed provides diagnostic clues in CoV-AKI.

**Methods:** We conducted a prospective observational study in patients seen for inpatient nephrology consultation with KDIGO AKI stage ≥1 and who were admitted to FMC for ≥1 month. Urine specimens were collected with personal protective equipment to perform MicrExUrSed. Slides were assessed for presence of white blood cells (WBC) [≥2+ dipstick, ≥6 per low power field (LPF)], red blood cells (RBC) (≥2+ dipstick, ≥8 per LPF), acanthocytes, granular casts (GC), renal tubular epithelial cell casts (RTECC) and waxy casts (WC). Slides were assigned to a category of acute tubular injury (ATI) based on either a Perazella cast score ≥2 or a ChaWla cast score ≥3.

**Results:** Among 161 cases of AKI, MicrExUrSed was performed in 20 (12.4%). Anemia and contact precautions were barriers to obtain specimens. GC were found in 17 (85%) of which 16 (80%) had “muddy” brown GC (MBGC). A median 5 MBGC per LPF (IQR, 1-20) were found in a median 40% (10-95%) of LPFs. WC were found in 10 (50%) cases with a median 2 (1-5) per LPF, all of whom had MBGC also present. RTECC were found in 3 (15%) cases with a median 1 (1-4) per LPF. Altogether, ATI score was assigned to 17 (85%) patients, of which 12 (60%) had AKI either after a hemodynamic/ischemic insult (9) or after a toxic insult (3) (rhabdomyolysis, vancomycin, contrast) and 3 (15) had biopsy-proven ATI along with collapsing glomerulopathy; for a total of 15 (75%) patients with either clinical or histological evidence on ATI matching the MicrExUrSed findings. Ten (50%) and 5 (25%) had WBCs and RBCs, respectively. Acanthocytes were found in 1 (5%) patient with presumptive proliferative endocapillary glomerulonephritis.

**Conclusions:** MicrExUrSed in most patients with CoV-AKI showed overt evidence of ATI with an abundance of MBGC and WC, including in cases of coexisting glomerulopathy. Pyuria was observed in half. The diagnostic utility of MicrExUrSed in CoV-AKI was comparable to that demonstrated in other forms of AKI.

**COVID-19: CKD and Transplant Patients**

**PO0787**

**COVID-19 Infection in Kidney Transplant Recipients: A Multicenter Experience in Istanbul**

Erol Demir,1 Murathan Uyar,1 Ergin Parmaksız,2 A. Sinangil,2 Bera Yelken,2 Ahmet B. Dirin,1 Ozgur Merhametsiz,1 Serap Yadigar,2 Zuhal Atan ucar,2 A. Ucar,2 Mehmet E. Demir,3 M. Mese,5 Emin Baris Akın,2 Nurana Guller,2 Sedan Safak,2 Ozgur A. Oto,2 Halil Yazici,2 Aydin Turkmen.3 1Istanbul Universitesi Tip Fakultesi, Istanbul, Turkey; 2Istanbul Bilim Universitesi Tip Fakultesi, Istanbul, Turkey; 3Koc Universiteleri, Istanbul, Turkey; 4Dr Lutfi Kirdar Kartal Egitim ve Arastirma Hastanesi, Istanbul, Turkey; 5Yeni Yazil Universiteleri, Istanbul, Turkey.

**Background:** Management of COVID-19 in kidney transplant recipients (KTR) should include treatment of infection and regulation of immunosuppression but there is no consensus on this issue yet. In this study, we aimed to describe our experience in KTR with COVID-19.

**Methods:** In this retrospective cohort study, we included KTR who diagnosed with COVID-19 from five centers. The patients were categorized into two groups for the analysis. Patients had respiratory failure and multiple organ dysfunctions were defined as severe pneumonia. All other cases were classified as moderate pneumonia. The primary outcome was all-cause mortality.

**Results:** 40 patients (20 female) were reviewed over a median follow-up of 32 days (IQR, 14-51 days) after COVID-19. 5 patients died during the follow-up. The frequency of graft dysfunction was similar between groups (n=12 and n=2; p=0.615, respectively). The frequency of previous induction (n=18 and n=7; p=0.016, respectively) and rejection therapy (n=4 and n=3; p=0.023, respectively) was significantly increased in the group with severe pneumonia compared to the moderate pneumonia group. None of the patients using cyclosporine A developed severe pneumonia. Also, multivariate logistic regression analysis revealed that previous anti-rejection therapy (9.75 [95% CI, 1.223 to 77.724; P=0.032]) was the independent predictor for mortality.

**Conclusions:** COVID-19 more commonly causes moderate or severe pneumonia in KTR. Immunosuppression should be carefully reduced in KTR. Induction therapy with lymphocyte depleting agents should be carefully avoided in KTR during the pandemic period.

**The demographic characteristics, treatment regimen, and outcomes of the patients**

**Abbreviations:** ALT, alanine aminotransferase; LDH, lactate dehydrogenase. P-values compared moderate pneumonia and severe pneumonia.
PO0788
COVID-19 and Kidney Transplant Outcomes

Background: Recent publications report great variations in the clinical course and mortality of COVID-19 in solid organ transplant (SOT) recipients. It is unclear whether these differences are related to study methods, treatment choices, or variables associated with patient populations.

Methods: We reviewed and summarized 9 published articles of COVID-19 in solid organ transplant recipients. We contrasted difference between study design and compared outcomes.

Results: All studies included kidney transplant recipients while study 6 and 8 included non-renal SOT. Four come from the United States. Results can be seen in the attached table. Most studies had a median age in the 50’s, with hypertension and diabetes being common comorbidities. Tacrolimus, mycophenolate analogs and prednisone was the most common immunosuppression regimen. Presenting symptoms were usually fever, cough, dyspnea, and diarrhea. Immunosuppression was either reduced or discontinued in all studies. The majority of patients received hydroxychloroquine. Azithromycin, remdesivir, letermovir, lopinavir-ritonavir, darunavir, oseltamivir, and tocilizumab were also used. Mortality ranged from 0% to 30%. All studies described hospitalised patients. A third of reports also included outpatients. The median follow up was approximately 3 weeks for most studies (range of 7 to 29 days). All but one series with reported patient deaths under 20% either did not include or had follow-up periods of less than 10 days.

Conclusions: Presentation of COVID-19 and immunosuppression strategies are similar among transplant centers. Differing outcomes may be related to small number of cases, potentially varying acuities of illness and follow up periods. Given that cytokine storm occurs late in the course of COVID-19, it is plausible that mortality may increase in studies with short follow up. When excluding short or missing follow up, mortality appears to be between 20-30%, which suggests that transplant recipients have a higher mortality than their non-immunocompromised peers.

PO0789
Thrombotic Microangiopathy (TMA) in a Patient with COVID-19
Bessy Susin Flores Chang, Rushang Parikh, Rinda Wanchao, Vanesha Bijol, Kenar D. Jhaveri. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: We describe a patient with COVID-19 and clinically significant kidney biopsy proven TMA

Case Description: A 69-year-old Caucasian female with medical history of asthma came to the ED with productive cough, fever and dyspnea for 2 weeks. She was afebrile, tachypneic and hypoxic. Initial laboratories showed a normal WBC, hemoglobin level and platelet count. Inflammatory markers were elevated. SARS-CoV-2 infection was confirmed by PCR assay. CXR showed bilateral diffuse patchy opacities. Treated with hydroxychloroquine, enoxaparin and oxygen was started. Patient received anakinra and hydroxychloroquine, azithromycin and convalescent plasma. Hospital course was complicated by septic shock and acute kidney injury with serum creatinine rising from a baseline of 0.8 mg/dl. Continuous veno-venous hemodialysis (CVVHD) without any complications except for heparin-induced thrombocytopenia. Heparin induced thrombocytopenia was not confirmed. Genetic testing was not done. Plasma exchange was not performed, but received a single dose of eculizumab on day 21. Unfortunately, she died on day 23.

Discussion: Coagulopathy associated with SARS-CoV-2 has been widely reported. Profound hypoxia, inflammation, disseminated intravascular coagulation(DIC) has all been implicated as potential causes, but were not present in our patient. To the best of our knowledge, we report the first case of TMA associated with SARS-CoV-2 with presence of diffuse cortical necrosis and widespread microthrombi in kidney biopsy. It is not clear if the virus played a direct pathogenic role or unmasked a latent complement defect leading to widespread endothelial damage and micro thrombi

PO0790
Renal Artery Thrombosis with Infarction in a Patient with Mild COVID-19
Ryan Mocerro, Neelja D. Kumar. Montefiore Medical Center, Bronx, NY.

Introduction: There has been increased focus on the microvascular and macrovascular complications of COVID-19. Here we present a case of renal arterial thrombosis in a woman with mild symptoms of COVID-19.

Case Description: A 69 year old female with diabetes, hypertension, coronary artery disease, and acute embolic cerebrovascular event post cardiac catheterization in 2016 presented to the emergency department with acute diffuse intermittent abdominal pain and nonbloody emesis. Prior to this, she had been evaluated for cough, shortness of breath and myalgias which were conservatively managed with improvement. Her medications included aspirin, clopidogrel, furosemide, and insulin. Examination was significant for diffuse nonspecific abdominal tenderness without rebound or guarding. Laboratory assessment revealed preserved renal function with creatinine of 1.10 mg/dL and PCR positive for SARS-CoV-2. A computed tomography of the abdomen and pelvis with intravenous contrast revealed a non-occlusive thrombus in the left renal artery with several large wedge-shaped areas of decreased enhancement consistent with multiple left renal infarctions. On interdisciplinary discussion, the patient was managed conservatively with anticoagulation without acute intervention and was discharged home on aspirin.

Discussion: To our knowledge, this is the first description of renal artery thrombosis with renal infarction in the setting of COVID-19 infection. Patients who present with a COVID-19 infection, regardless of disease severity, should be evaluated for coagulopathy and development of thrombosis as these may potentially contribute to infarction and end-organ damage. Although it requires a high index of suspicion, renal infarction should be considered part of the differential when evaluating a patient with COVID-19 infection presenting with abdominal pain or acute kidney injury. Initiation of anticoagulation should be considered with consideration of risks involved.

PO0791
A Case of Severe Thrombocytopenia in a Patient with COVID-19
Receiving Continuous Venovenous Hemodialysis
Huy Me, Zhong Zheng, Jennifer Griffiths, Anjani K. Dubey, Ravneek S. Chugh. Westchester Medical Center Westchester Medical Center, Valhalla, NY.

Introduction: Thrombocytopenia is a rare complication of renal replacement therapy with most of the cases reported in intermittent hemodialysis patients. There is limited data regarding the incidence of thrombocytopenia caused by continuous renal replacement therapy (CRRT). We report a case of thrombocytopenia in patient treated with CRRT for severe AKI from COVID-19 sepsis unrelated to heparin.

Case Description: A 73-year female with history of type 2 diabetes mellitus was admitted for Coronavirus Disease 2019 (COVID-19) pneumonia. Patient developed acute hypoxic respiratory failure requiring mechanical ventilation despite treatment with hydroxychloroquine, azithromycin and convalescent plasma. Hospital course was complicated by septic shock and acute kidney injury with serum creatinine rising from a baseline of 0.8 mg/dL. Continuous veno-venous hemodialysis (CVVHD) without any anticoagulation was initiated due to severe fluid overload. Significant thrombocytopenia below 50,000/mm3 was noted 2 days after CVVHD treatment. Patient received multiple antibiotics and heparin drip before CVVHD and platelet counts were above 150,000/mm3. Heparin induced thrombocytopenia (HIT) was ruled out with negative serotonin release assay and platelet counts remain low despite the discontinuation of all potential agents. Disseminated intravascular coagulopathy was excluded based on coagulation tests. Platelet counts finally went up to 160,000/mm3 on subsequent CVVHD holidays and again dropped to 70,000/mm3 after CVVHD was resumed.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

285
Discussion: The rate of rise in platelet count more than 150,000/mm³ in 2 days after commencement of CVVHD supports the diagnosis of thrombocytopenia caused by CVVHD. Although the exact mechanisms remain unclear, previous studies suggested that the mechanical destruction of platelets by the hemofilter or allergic reaction to dialyzer membrane as some of the reasons. Some studies have found that severe decline (more than 50% by platelet count was associated with increased mortality and decreased rate of renal recovery. Thrombocytopenia on CVVHD unrelated to HIT is an under-acknowledged complication. Understanding the multiple etiologies of thrombocytopenia will help prevent the excessive use of blood products, fluid overload state and the potential cloting issue of CVVHD due to transfusion.

Case Study: Kidney Transplant Patient with COVID-19: Impact of Viral Infection on Background Cell-Free DNA in a Donor-Derived Cell-Free DNA Reaction Assay

Introduction: Donor-derived cell-free DNA (dd-cfDNA) assays are clinically validated to detect kidney transplant injury, reporting the donor fraction as a percentage of the total, or background, cfDNA. Various clinical factors can cause a significant increase in recipient cfDNA, contributing to higher background cfDNA and lower donor fraction, which may result in a false negative test result.

Case Description: A 50+ year old woman with end-stage renal disease secondary to polycystic kidney disease presented with 4 days (d) of diffuse muscle pain at 11 months post-kidney transplant. In the emergency department she had a fever to 101°F, bilateral rales on chest auscultation, and a positive test for COVID-19 (SARS-CoV2) test. She remained febrile for 3d before developing acute respiratory distress requiring oxygen supplementation; her creatinine level was 3 mg/dL. Due to worsening of her respiratory status, she was intubated and started empirically on vancomycin, meropenem, and azithromycin. A mycopneucoccal meningitis was discontinued. She rapidly progressed to septic shock requiring vasopressor therapy. Her renal function deteriorated, and she was started on continuous renal replacement therapy on hospital d7. She received leunolimab on hospital d7 and d14 and convalescent plasma on hospital d11. Tacrolimus was discontinued on hospital d10 and she continued prednisone at 5 mg/d. dd-cfDNA testing to assess allograft injury and to rule out active rejection was performed. At hospital d20, her dd-cfDNA was 0.07% with an elevated background cfDNA of 28,569 arbitrary units (AU, ~57x median value). At the second blood draw at hospital d25, her dd-cfDNA was 0.25% with a background cfDNA level reduced to 7,503 AU (~15X median value).

Discussion: In this case, infection with the SARS-CoV-2 virus was associated with a very elevated background cfDNA level, likely due to cellular apoptosis due to the immune process and/or tissue ischemia due to sepsis-associated hyperperfusion. Although this patient was not known to have active rejection of her allograft, the very high background levels complicate the interpretation of results, especially when donor fraction was reported.

COVID-19 AKI to ESRD: A New Cohort of Dialysis-Dependent Patients

Introduction: The Covid-19 pandemic has resulted in a massive number of hospitalizations with widespread effects on the global healthcare system. More research is needed to understand the implications of the disease, particularly its effects on renal function. Although initial studies from China suggested otherwise, there is growing evidence for an association between Covid-19 and AKI.

Case Description: A 66-year old man with history of CKD IIIb presented to the ED with fever and dry cough for several days. On admission the patient was febrile and tachypneic. Labs were showed elevations in BUN, SCr and inflammatory markers. Chest CT revealed bilateral ground glass opacities and NP swab was positive for SARS-CoV-2. The patient was initially treated with hydroxychloroquine, levofloxacin, and IV fluids. Clinical status worsened, eventually requiring intubation and vasopressors. Renal function progressed to anuria. Bicarbonate, potassium binders and loop diuretics were attempted to treat renal failure. On hospital day 4 the patient was placed on CRRT however he remained anuric. CRRT was complicated by clotting episodes managed with circuit anticoagulation with unfractionated heparin. The patient slowly improved, was extubated 17 days later, and transitioned to IHD. The patient underwent tunneled catheter placement and was discharged 30 days after admission and remains in outpatient follow-up.

Discussion: It is theorized that renal impairment in Covid-19 is due to virus entry into host cells via the ACE-2 receptor present in lungs and kidneys. Post-mortem kidney biopsies suggest that renal damage in Covid-19 is mediated through multiple mechanisms including cytokine storm, hypoxic microvascular injury, and immunocomplex deposition, and microthrombs-related tubular damage. Although our patient recovered after a prolonged hospital course, he remained anuric requiring IHD far sooner than anticipated with natural progression of CKD.

PO0794

Rhabdomyolysis as a Complication of COVID-19: A Report of Five Cases

Miguel Maza Moreno,1 Vanessa C. Garcia Macas,1 Jose L. Herrera,1 Gandhy T. Fonseca,2 Jose H. Cano,1 Juvenal Torres Pastrana.1 CMN 20 de Noviembre 1Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; 2Medicine and Extracorporeal Membrane Therapy Department, Mexico City, Mexico.

Introduction: COVID-19 virus pandemic has caused more than 5million infected and 330,000 deaths worldwide. The incidence of acute kidney injury (AKI) is variable, from 0.5%-92.8%. Rhabdomyolysis(Rb) is a life-threatening emergency, usually manifesting as myalgia, fatigue, pigmenturia, and AKI. One of its leading non-traumatic causes are viral infections. We report 5cases of Rb associated with COVID-19.

Case Description: Of a total of 460 positive cases of COVID-19 infection (real-timePCR), at the NationalMedicalCenter20deNoviembre in MexicoCity, 5were diagnosed with Rb and associated AKI (SCr<5.000μmol/L and KDIGO AKIcriteria). Characteristics of patients are presented in(FIG.1). Age range was from 29to64 years, only one female, all withBMI<25 kg/m². time from admission-diagnosis of Rb was on average one week. Most common symptoms were fever, cough, and dyspnea (5/5), as well as abdominal pain (4/5). Only (1/5) was oliguric at diagnosis. Average Cr at diagnosis was 7845 (18-165 μg/L) and all cases had high levels of interleukin-6. They were managed with aggressive hydration, 2of them required renal replacement. At the time of this report, 2had been discharged, 2 remained hospitalised (one still on RRT), and one died.

Discussion: COVID-19 patients can develop AKI primarily due to low oral intake, sepsis, and cytokine storm. Patients with COVID-19 have multiple risk factors for Rb development: viral muscle cytoxicity, continuous hyperthermia, and cytokine storm among others. This results in a high risk of Rb via 3mechanisms: renal vasoconstriction, tubular obstruction and direct tubular toxicity. Of note, in the described cases, abdominal pain was a common symptom and only one was oliguric. Early identification allowed rapid diagnosis, which underscores the importance of having a high index of suspicion. Further observations will be needed to understand the full spectrum of association between COVID-19 and Rb, but is clear that these patients are at high risk for developing AKI by these mechanisms.
proteinuria despite an increase in GFR suggests that steroids played a role in the recovery. A randomized trial would be necessary to determine the safety and efficacy of steroids for COVID-19 related eFGSs.

PO0796
Remote Peritoneal Dialysis Training in a COVID-19-Positive Patient
Aditya V. Jain, Tina S. Samuel, Leslie A. Jansto, Erwin E. Morales, Cybele Ghosssein. Northwestern University Feinberg School of Medicine, Chicago, IL

Introduction: Training patients in peritoneal dialysis (PD) traditionally requires up to fourteen in-person clinic visits to cover all aspects of care. The COVID-19 crisis has created an unprecedented challenge in educating patients to perform PD safely while minimizing exposure to staff. Telemedicine has been well-received by staff and patients in other aspects of PD care. We present a case of a COVID-19 positive patient who was fully trained in PD using telemedicine.

Case Description: The patient is a 21-year-old man with VATER Syndrome who progressed to ESRD with uremic symptoms. He chose PD as his dialysis modality while awaiting a kidney transplant. Prior to his PD catheter insertion, he tested positive for COVID-19. He was deemed an ideal candidate for PD training via telemedicine and agreed to proceed. For the first two training sessions, he presented to the PD clinic and was placed in a designated isolation room with his personal computer. His PD nurse was in an adjoining room and trained him via video conferencing with the option to enter his room if needed. The patient quickly mastered the procedure in this monitored environment. He completed the remainder of the required education remotely in his home via telemedicine. Currently, he is fully trained and has initiated his full PD prescription.

Discussion: There are several advantages of telehealth in COVID-19 patients. The risk of viral exposure to healthcare staff and other patients is reduced by limiting trips to the PD clinic. Additionally, reducing the burden of travel saves time and expense for the patient. Patient selection for telehealth learning is critical: the ideal patient must be motivated and technologically savvy. The patient, PD nurse, and nephrologist must jointly determine whether proceeding with tele-learning is feasible and safe. Although remote videoconferencing is not the conventional or optimal method for PD education, it can be used successfully to train patients while minimizing exposure of COVID-19 to staff.

PO0797
Calciphylaxis and COVID-19-Associated Thrombotic Retiform Purpura in a Peritoneal Dialysis Patient
Elly Varma,1 Cynthia M. Magro,2 Jerry Nuovo,1 Frank Liu,1 Vesh Srivatana.2
1Weill Cornell Medicine, New York, NY; 2Rogosin Institute, New York, NY

Case Description: A 62-year-old female presented to the emergency room with leg pain and edema for 4 weeks. She had recently been started on peritoneal dialysis. Examination revealed tender, indurated retiform dusky plaques on thighs and bilateral lower legs (Figure 1). Laboratory findings are summarised in Table 1. Her SARS-CoV-2-RT-PCR was positive. Imaging revealed no evidence of thrombosis. Skin biopsy showed proliferation of visceral epithelial cells. (Right) Lab values: Admission to 2 weeks post discharge.

Discussion: In COVID-19 era, coagulation abnormalities are becoming increasingly evident. Management of calciphylaxis in PD patients is difficult under current circumstances due to limitations in the ability to provide regular infusions and multi-interventional care. We hypothesize that our patient had an underlying predisposition for calciphylaxis given risk factors of secondary hyperparathyroidism and an additional insult of COVID-19 due to a combination of procoagulant state, as well as any preexisting risk factors for calciphylaxis, must be kept in mind.

Table 1. Laboratory investigations

PO0798
Successful Recovery of COVID-19 Pneumonia in a Kidney Transplant Recipient with a Regimen Consisting of Favipiravir, Azithromycin, Nafamostat Mesylate (NM), and Intravenous Immunoglobulin (IV Ig)
Sumit Hidaka, Kunihiro Ishioka, Hidekazu Moriya, Yasuhito Mochida, Hiroaki Suzuki, Takayae Ohtake, Shuzo Kohayashi. Kidney Disease and Transplant Center, Shonan Kamakura General Hospital, Kamakura, Japan

Introduction: The SARS-CoV-2 virus has caused a worldwide pandemic of coronavirus disease 2019 (COVID-19) since end of 2019. Although COVID-19 has been widely reported, little is known about its impact on transplant recipients. We report a case of an interstitial pneumonia due to SARS-CoV-2 viral infection in a kidney transplant recipient. We also investigated how treatment of COVID-19 influenced the changes of lymphocyte subset and the number and activity of NK cells.

Case Description: This is a 49-year-old man who received kidney transplantation 13 months ago. His first clinical symptoms were of high fever, general fatigue, and myalgia. He had no complaints of cough nor shortness of breath, but his chest CT revealed interstitial pneumonia with SpO2 90 - 92 mmHg. Nasopharyngeal swab for SARS-CoV-2 RT-PCR assay was reported positive. He also showed acute kidney injury (AKI), whose serum creatinine level got elevated from 1.33 mg/dL to 1.67 mg/dL. We stopped tacrolimus and mycophenolate mofetil and continued low dose of methylprednisolone. The COVID-19 pneumonia and AKI were successfully treated with the regimen consisting of favipiravir, azithromycin, NM, and IVig. On the 14th hospital day, the SARS-CoV-2 RT-PCR had become negative and simultaneously we acquired IgG antibody against SARS-CoV-2 virus. Regarding lymphocyte subset, the percentage of CD19+ B lymphocytes has been extremely low level because of administration of rituximab 13 months ago due to ABO-incompatible living related-donor kidney transplantation. On the day of admission, the total number of lymphocytes was only 482 x 10^3 and most of them were CD4+ lymphocytes and the number of NK cells were very few (6.8%). As the symptoms improved, the number and activity of NK cells increased and the proportion of CD8+ lymphocytes decreased.

Discussion: We successfully treated the patients with 4 off-label drugs against COVID-19, consisting of favipiravir, azithromycin, NM, and IVg. Our current regimen seems to be successful, in particular, NM seems to block cytokine storm, thus preventing from serious illness, but a larger cohort of patients is required. Activation and expansion of NK cells are important in the treatment of COVID-19.
A 48 y/o Hispanic woman with history of HTN, hyperlipidemia and DM type 2 who presented to the ED complaining of shortness of breath, fever, cough, myalgia and shortness of breath for four days before presentation she had been diagnosed with COVID-19 and was self-isolating at home. Her symptoms worsened prompting her visit to the ED. Vital signs showed fever of 103.1 F, pulse 86, respirations 37 blood pressure 106/58 and O2 Sat 85% at room air, 95% with nasal cannula at 4 L. PE was normal except for tachycardia. She was febrile with tachypnea on lung auscultation. Admission labs were remarkable for AKI and rhabdomyolysis. Serum creatinine was 3.61, BUN, and total CK 106,193. UA with blood, 5-10 RBC, 5-10 WBC and many bacteria. FeNa was 0.3%. Toxicology panel was negative. Respiratory viral panel was negative. Influenza A and B and rhinovirus were initially identified in 2 L bowls of IV NS which then changed to excluded.

Discussion: Rhabdomyolysis can be seen associated with viral infections. We present a patient with COVID-19 and rhabdomyolysis. There are no studies establishing a mechanism for COVID-19 induced rhabdomyolysis. Patients with COVID-19 pneumonia are generally kept with negative fluid balance to avoid overload and worsening of ARDS. On the other hand, volume expansion is mainstay management for rhabdomyolysis. Clinicians should have a high suspicion for rhabdomyolysis in patients with COVID-19 presenting with myalgias and AKI. Early recognition of and appropriate treatment is crucial to improve outcomes.

PO0882
Plasma Exchange in Critically Ill COVID-19 Patients

Introduction: The spectrum of coronavirus disease 2019 (COVID-19) ranges from asymptomatic infection to respiratory failure and death of patients. Severely affected patients may develop a cytokine storm-like clinical syndrome with multi-organ failure and a mortality rate of up to 90%.

Case Description: We report on five COVID-19 patients with a median age of 67 years who were treated at the intensive care unit due to respiratory failure. Prophylactic antibiotics, immunosuppressive, and antiviral/immunomodulatory therapy was initiated in all patients upon admission. During the course of the disease, patients developed circulatory shock and persistent fever together with increased interleukin 6-levels compatible with the cytokine storm-like clinical syndrome. In addition, all patients had multi-organ failure with respiratory-distress syndrome (ARDS); 4 severe and 1 moderate COVID-19 injury of at least KDIGO stage 2. A single PE with a median of 3.39 L of fresh frozen plasma was initiated in all patients followed by one additional treatment in patients 1, 3, and 5. During the PE, striking reduction of inflammatory markers C-reactive protein (-47%, P=0.0078) and interleukin 6 (-74%, P=0.0078), as well as significant reduction of ferritin (-49%, P=0.0078), LDH (-41%, P=0.0078), and D-Dimer (-47%, P=0.016) were observed. Due to circulatory shock, four patients received vasopressor treatment at the start of the PE that could be substantially reduced during treatment (-71%, P<0.0031). Biochemical and clinical improvement continued over the following days together with an increase in the oxygenation index in 4 out of 5 patients. These improvements were achieved with only 1 to 2 PE, which might be a possible indication of a direct pathophysiological influence of PE on the COVID-19-associated cytokine storm-like clinical syndrome. Three of the four critically ill patients died in the hospital, a 71-year-old male and a 76-year-old female patient died after the therapy was limited due to persistent severe ARDS.

Discussion: PE improved inflammation, microcirculatory clot formation, and hypotension, thereby improving clinical outcomes. Further studies to test whether (repeated) PE can alter the course of critically ill COVID-19 patients are clearly indicated.
Rhabdomyolysis as a Late Complication of COVID-19 Infection

Benjamin Liggard, Ann M. O’Hare, Sarah F. Sanghavi, Bessie A. Young, University of Washington, Seattle, WA.

Introduction: The 2019 novel Coronavirus (COVID-19) is a betacoronavirus which typically presents with fever, cough, myalgia, and fatigue and can be associated with acute kidney injury (AKI). Recently, several cases of rhabdomyolysis (with and without AKI) have been reported with COVID-19 infection. We present a case of a patient with COVID-19 infection who developed rhabdomyolysis on hospital day 22.

Case Description: A 74-year-old man presented with several weeks of progressive malaise, dyspnea, fatigue, and nausea. He was hypoxic to 87%, febrile (38.8°C) and had diffuse bilateral infiltrates on chest x-ray [Figure 1]. He was intubated on hospital day 1. Testing for COVID-19 by PCR was positive. Creatinine improved from 1.6 to 0.9 mg/dL with 2L of IV fluids. He did not require vasopressors. On hospital day 22, while still intubated, his creatinine increased from 1.4 to 3.8 mg/dL. Laboratory evaluation revealed his serum creatinine peaked at 6.67 mg/dL on hospital day 26 and subsequently declined to 1.6 by hospital day 33.

Discussion: Rhabdomyolysis is an infrequent complication of COVID-19 infection. While observed, rhabdomyolysis is typically present on admission. This is, to our knowledge, the latest that rhabdomyolysis has been observed in COVID infection. The patient’s inflammatory markers were not re-checked at the time of this event, though worsening inflammation may have provoked this event. Their troponin was mildly elevated at 1.11 mg/dL. TE was not performed. No bed sores were observed, and the patient had no access to illicit substances. No medications known to cause rhabdomyolysis were given prior to this development. This case report suggests that rhabdomyolysis-related AKI may be a late complication of COVID-19 infection.

Attenuation of Circuit Longevity in COVID-19 Critical Illness with AKI on Continuous Venovenous Hemodiafiltration Despite the Use of Regional Citrate Anticoagulation (RCA) and Heparin-Bonded AN 69 (Oxiris®) Filter

Tung Lin Lee, Zhong Hong Liew, Manish Kaushik, Li Choo Michelle Ng, Jianghong, Hui-Lin Chooong, Han K. Tan. Singapore General Hospital, Singapore, Singapore.

Introduction: Critical illness in SARS-CoV-2 (COVID-19) infection can result in acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is part of the overall supportive ICU management.

Case Description: CRRT was delivered as Continuous Venovenous Haemodiafiltration (CVVHDF) using the Prismaflex (Baxter Inc.) system with heparin-bonded AN69 (Oxiris®). The filters were electronically changed every 12 hours for first 5 days to augment cytokine adsorptive capacity. Regional citrate anticoagulation (RCA) was used to ensure filter longevity. Initial citrate dose was prescribed at 3.0 mmol/L. All 3 consecutive patients were male aged 66.7 ± 6.02 years. APACHE II score was 32.7 ± 6.51 and predicted mortality was 71%. Mean initial creatinine was 264.7 μmol/L, and urine output was 6.7 mL/hour. All patients were on vasopressor support, broad spectrum antimicrobials and mechanical ventilation. 30 Oxiris filters were studied in the 3 patients.

6/30 (20%) filters clotted spontaneously before scheduled change. Mean filter lifespan (2430) was 689.6 ± 423.3 min before elective change. For the filters that clotted, mean circuit longevity was 515.7 ± 126.2 min. The observed difference was significant, p = 0.002. Importantly, filter clotting occurred despite adequate citrate dose of 3.0 mmol/L and mean post-filter ionized calcium of 0.34 ± 0.06 mmol/L. Vascular access issues were excluded by review of access, return pressures. Citrate dose was increased to 3.2 mmol/L for all patients and this reduced the frequency of filter clotting subsequently. Two patients were extubated and had full renal recovery - mean duration of CRRT dependence was 9.5 days. However, the third patient remained CRRT dependent until demise on the 28th day of ICU stay.

Discussion: Attenuation of circuit lifespan was observed despite adequately dosed RCA and heparin bonded Oxiris filters. We theorize that this could be due to a pro-coagulant state induced by the SARS-CoV-2 infection. Possibly, higher citrate dose to RCA and heparin bonded oxiris filters. We theorize that this could be due to a pro-coagulant state induced by the SARS-CoV-2 infection. Possibly, higher citrate dose to target even lower post-filter ionized calcium may be required to optimise anticoagulation and filter lifespan, thereby ensuring optimal effluent dose and solute clearance, for critically ill COVID-19 patients.

PO0808

SARS-CoV-2 Infection in the Early Post-Transplant Period After a Living Donor Kidney Transplant

Introduction: Coronavirus disease 2019 (COVID-19) pandemic presented multiple challenges for living and deceased donor kidney transplant programs with the likelihood of exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report the course of COVID-19 and immunosuppression within 3 months of living donor kidney transplantation (LDKT) which has not been described previously.

Case Description: Three LDKT recipients developed COVID-19 in the early post-transplant period and were detected positive for SARS-CoV-2 at day 7, day 19 and 2 days post-transplant. Patients 1 and 2 had received 1 mg/kg of anti-thymocyte globulin (ATG) as induction and patient 3 had received no induction at the time of transplant. Patients 1 and 2 had minimal symptoms at diagnosis, whereas patient 3 had high grade fever, cough and shortness of breath. All 3 patients had lymphopenia at diagnosis and none required supplemental oxygen or intensive care unit monitoring. All 3 patients received hydroxychloroquine and azithromycin. Mycophenolate mofetil dose was reduced in patient 1 and was stopped in patients 2 and 3. Patient 3 developed acute kidney injury with a peak serum creatinine of 2.4 mg/dL, whereas other 2 patients did not develop kidney allograft dysfunction. All 3 patients recovered from SARS-CoV-2 infection with normal renal function at discharge.

Discussion: Limited experience of SARS-CoV-2 infection in early post-transplant period is available in deceased donor kidney transplant (DDKT) with serious morbidity and mortality implications. Lymphopenia described in patients with severe illness due to SARS-CoV-2 can be aggravated by recently used higher doses of lymphocyte depleting agent, especially to cover for delayed graft function in DDKT. As compared to previously reported cases of DDKT, our relatively young recipients of LDKT had a period of exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report the course of COVID-19 and immunosuppression within 3 months of living donor kidney transplantation (LDKT) which has not been described previously.

PO0809

COVID-19-Related Collapsing Focal Segmental Glomerulosclerosis and Apolipoprotein L1: A Report of Two Cases

Sanddeep Magon,1 Varun Malhotra,1 Prasad B. Bichu.2 1Eastern Virginia Medical School, Norfolk, VA; 2Nephrology Associates of Tidewater, Norfolk, VA.

Introduction: Acute kidney injury has been seen in approximately 15% of the patient with COVID-19 infection. Acute tubular injury was presumed to be the most common cause of AKI, but it did not explain significant proteinuria and hematuria. We present the case report of 2 patients with collapsing focal segmental glomerulopathy with COVID-19.

Case Description: Case 1, a 28 years old African American female and Case 2, a 58 years old African American male with baseline CKD III, admitted with COVID-19 infection and had acute kidney injury with significant proteinuria with hypoaalbuminemia. Patients had kidney biopsies. Please see table for all the details.

Discussion: Possible etiologies of acute kidney injury in COVID 19 are tubular injury due to cytokine storm, direct cytopathic effect and immune mediated glomerulonephritis. Both the patients had collapsing FSGS in addition to tubular injury suggesting injury to the podocytes. Viral particles were not seen on both the biopsies, and hence direct cytopathic effect was not considered to be the mechanism of renal injury, although viral level below the detection threshold could not be excluded. Collapsing FSGS has been seen with other viral infections including Parvo-virus infection, Cytomegalovirus infection and HIV. Variant of apolipoprotein L1 (APOL1) gene in African Americans have been shown to be associated with FSGS. These two patients had genetic susceptibility due to APOL1 and COVID infection caused interferon surge leading to a second hit. Teaching Points: Renal biopsy should be considered in patients with COVID-19 and Nephrotic range proteinuria. APOL1 testing should be done in patients with African American descent.

PO0810

Diagnosing Vasculitis in the Era of COVID-19: A Diagnostic Dilemma for House Staff Officers

Kalyani L. Avya, Roberto L. Collazo-Maldonado, Christopher Farmakis. Methodist Health System, Dallas, TX.

Introduction: During our current pandemic, physicians must exclude COVID-19 in every patient presenting to the hospital with a febrile illness. However, every patient should have a complete work-up done to not miss other disease processes. Here we describe a case of microscopic polyangiitis with symptoms mimicking COVID-19 infection.

Case Description: The patient is a 69 yo female with history of HTN who presented with symptoms of 4-5 weeks of polyarthalgia and fevers; this was accompanied by a dry cough and morning stiffness in her shoulders and hips, for which she heavily used ibuprofen. Vital signs were within normal limits. Physical exam showed clear breath sounds with 2+ pitting edema in the lower legs and no rashes. Labs revealed a WBC of 20,000 cells/μl, with creatinine of 2.29 mg/dL, bicarbonate of 17 mmol/L, and C-reactive protein of 126.2 μg/L. The observed difference was significant, p = 0.002.

Possible etiologies of acute kidney injury in COVID 19 are tubular injury due to cytokine storm, direct cytopathic effect and immune mediated glomerulonephritis. Both the patients had collapsing FSGS in addition to tubular injury suggesting injury to the podocytes. Viral particles were not seen on both the biopsies, and hence direct cytopathic effect was not considered to be the mechanism of renal injury, although viral level below the detection threshold could not be excluded. Collapsing FSGS has been seen with other viral infections including Parvo-virus infection, Cytomegalovirus infection and HIV. Variant of apolipoprotein L1 (APOL1) gene in African Americans have been shown to be associated with FSGS. These two patients had genetic susceptibility due to APOL1 and COVID infection caused interferon surge leading to a second hit. Teaching Points: Renal biopsy should be considered in patients with COVID-19 and Nephrotic range proteinuria. APOL1 testing should be done in patients with African American descent.

Case Description: Case 1, a 28 years old African American female and Case 2, a 58 years old African American male with baseline CKD III, admitted with COVID-19 infection and had acute kidney injury with significant proteinuria with hypoaalbuminemia. Discussion: Systemic vasculitis remains to be a diagnostic challenge, especially in the era of COVID-19. The overlap in symptoms and the diagnosis is made on clinical history and histopathological findings coupled with positive ANCA. Despite treatment, almost a quarter of these patients will progress to ESRD. In the era of COVID-19, great care must be taken to diagnose the kidney manifestations of systemic vasculitis.

PO0811

Low-Sodium Disorders and the 2019 Novel Coronavirus Disease (COVID-19)

Jasmeet Gill,1 Xunxi S. Guo,2 Akinwande A. Akinfolarin,2 Ankit Mehta,1 1Baylor University Medical Center at Dallas, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX

Introduction: COVID-19 have been well characterized with hallmarks of pneumonia and respiratory failure. Hyponatremia is a well reported finding in patients with COVID-19. However, only few reports of sodium disorders have been directly attributable to the disease. We report three different presentations of hyponatremia in COVID19 patients.

Case Description 1: 70 year old man with hypertension, diabetes presented with dyspnea. He was clinically euolemic. Chest X-ray (CXR) showed bilateral interstitial and airspace opacities. Laboratory data revealed, serum sodium 122 meq/L, serum osmolality 264 mosm/kg, urine osmolality 579 mosm/kg and urine sodium 153 mmol/L. A diagnosis of hyponatremia secondary to the Syndrome of inappropriate Antidiuretic Hormone (SIADH) was made and the patient was treated with oral urea and fluid restriction. Sodium improved with normal saline infusion. 3. 69 year old female with hypertension admitted with vomiting and diarrhea. CXR showed diffuse pulmonary infiltrates. Initial laboratory data revealed serum sodium of 126 meq/L, serum osmolality 260 mosm/kg. Serum sodium recovered as diarrhea resolved. However, eight days after starting therapy with Selinexor, a nuclear transport inhibitor, serum Na declined to 128 meq/L, serum osmolality 275 mosm/kg, urine sodium 29 mmol/L, urine osmolality 372 mosm/Kg. ATN was suspected as urine microscopy showed granular casts and no dysmorphic RBC or cellular/WBC/RBC casts. After a repeat negative swab and improvement in respiratory symptoms yet worsening renal function requiring hemodialysis, a full serologic workup was performed. Positive results include p-ANCA (1:320), MPO (49), and ANA (1:160 homogenous) without hypocomplementemia. Other autoimmune markers including anti-GBM antibody were negative. A kidney biopsy was performed and showed pauci-immune crescentic glomerulonephritis (GN) with cellulosic crescents in more than 80% of the glomeruli with minimal interstitial fibrosis and tubular atrophy. Given the frailty of this patient, she was treated with oral prednisone and rituximab instead of cyclophosphamide. She remained on intermittent hemodialysis and tolerated the treatment well.

Discussion: This case emphasizes the importance of detecting pulmonary-renal syndrome in the time of COVID-19. Given the current global pandemic and a high volume of infected patients coupled with the lack of sensitivity of the SARS-CoV-2 assays, it is possible to miss this relatively rare ANCA-associated vasculitis. Patient with rapid proliferative GN feature and lung symptoms should be further worked up to avoid missing ANCA-associated vasculitis. COVID-19 may actually provoke ANCA-associated vasculitis and further testing is underway.

PO0813

ANCA-Associated Vasculitis Under a COVID-19 Mask

Rui Song, Srikanth Thiruvuruduothi, Jared Hassler, Ziauddin Ahmed, Serban Constantinescu, Avrum Gillespie. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Ground glass opacities (GGO) on CT scan are the hallmark of COVID-19. GGO can also be seen in ANCA-associated lung injury. Additionally, both can present with kidney injury. We report a case of presumed COVID-19 with AKI which was actually severe ANCA-associated vasculitis.

Case Description: A 74-year old female with a history of hypertension and diabetes, who presented with a week of chills, cough, dyspnea, and watery diarrhea, and a creatinine of 10.2 mg/dl (baseline creatinine 1.02 mg/dl). A month prior to admission, she was treated for presumed COVID-19 pneumonia with hydroxychloroquine, followed by ivermectin, and media, and then bacterial sinusitis with oral ciprofloxacin. Despite a negative swab, she was admitted with suspicion of COVID-19 given GGO seen on CT scan and an exposure history at her senior home. She was treated per the COVID-19 protocol IV methylprednisolone 125mg, azithromycin, and dexamethasone. Laboratory data revealed 24 hour urine analysis showed proteinuria, with a normal/ slightly elevated creatinine level at admission, normalizing after iv fluids, but significant proteinuria and hematuria, with a creatinine of 1.99 mg/dl. Hemodialysis was initiated due to refractory hyperkalemia. She was actually severe ANCA-associated vasculitis.

Discussion: ANCA-Associated Vasculitis remains to be a diagnostic challenge, especially in the era of COVID-19. Given the current global pandemic and a high volume of infected patients coupled with the lack of sensitivity of the SARS-CoV-2 assays, it is possible to miss this relatively rare ANCA-associated vasculitis. Patient with rapid proliferative GN feature and lung symptoms should be further worked up to avoid missing ANCA-associated vasculitis. COVID-19 may actually provoke ANCA-associated vasculitis and further testing is underway.
Case Description: 50-year-old African American male with past medical history of hypertension presented with cough, dyspnea and fever. On admission, he had a temperature of 104°F, BP of 149/90 mmHg, HR of 104 bpm, and oxygen saturation of 92%. Physical examination was remarkable for diminished and diffuse coarse breath sounds. Lab work-up showed serum creatinine of 2.99 mg/dl (baseline 1.19 mg/dl) with an estimated GFR of 26 ml/min. Urinalysis revealed protein > 500 mg/dl, RBC 25 and presence of coarse granular casts. Urine protein-creatinine ratio was 3.2. Serology was negative for ANA, ANCA, and anti-proteinase antibodies, as well as hepatitis and HIV panels. Serum C3 and C4 levels were within normal limits. Viral PCR of nasopharyngeal aspirate was positive for SARS-CoV-2. Home medications lisinopril and hydrochlorothiazide were held on admission, and he was started on intravenous fluids, azithromycin, and hydroxychloroquine. On day 4, serum creatinine trended up to 3.29 mg/dl and potassium was 4 mmol/L but since the patient was oliguric, hemodialysis (HD) was started. Serum creatinine then trended to a high of 15 mg/dl, urea nitrogen to 102 mg/dl and serum potassium level to 6.9 mmol/L despite multiple HD sessions. Meanwhile, his oxygen requirement also increased to 15L. After 10 days of daily HD sessions, serum potassium came down to 4.3 mmol/L but he ultimately required HD post discharge.

Discussion: Previous literature has discussed SARS-CoV-2 association with effects on ACE2 of RAS and proximal tubular cells causing hypokalemia. To the best of our knowledge this would be the first documented case of hemodialysis refractory hyperkalemia seen with SARS-CoV-2 infection. One of the mechanisms for kidney injury is a direct viral induced cytopathic effect, which we believe held true for our patient. As viremia cleared, the kidney function improved though it did not return to baseline. In our case, development of hyperkalemia despite hemodialysis makes it more interesting, but it remains unclear how.

Rhabdomyolysis in COVID-19 Patient Requiring RRT
Muhammad usama shah Hamdani, Jeremy Carlson, Hasan Zahid.
University of Florida College of Medicine, Gainesville, FL.

Introduction: Rhabdomyolysis is characterized by the release of intracellular muscle contents into the circulation. Of the 1099 patients affected by Covid-19 in China, only 0.2% had rhabdomyolysis.

Case Description: A 52 year old African American female with past medical history of Diabetes and hypertension presented to the ER with 7 days of worsening fever, chills, myalgia, nausea, vomiting, dyspnea, loss of sense of taste and smell. Her home medications included metformin and Candesartan-HCTZ, however, she had been off these medications for the last seven days. She was not on statins. She was a healthcare worker at a nursing home that had a recent outbreak of the novel Coronavirus with 51 0.2% had rhabdomyolysis.

Discussion: Previous literature has discussed SARS-CoV-2 association with effects on ACE2 of RAS and proximal tubular cells causing hypokalemia. To the best of our knowledge this would be the first documented case of hemodialysis refractory hyperkalemia seen with SARS-CoV-2 infection. One of the mechanisms for kidney injury is a direct viral induced cytopathic effect, which we believe held true for our patient. As viremia cleared, the kidney function improved though it did not return to baseline. In our case, development of hyperkalemia despite hemodialysis makes it more interesting, but it remains unclear how.

Severe AKI from Thrombotic Microangiopathy and Acute Tubular Necrosis in a Patient with COVID-19

Introduction: Thrombotic microangiopathy (TMA) is a known but rare complication of gemcitabine therapy. However, gemcitabine-associated TMA has not been reported in a patient with concurrent COVID-19. Here, we present an interesting patient with COVID-19 who developed severe acute kidney injury (AKI) from acute TMA and acute tubular necrosis (ATN) following gemcitabine therapy.

Case Description: 45-year-old AA female with history of recurrent metastatic cervical cancer, peritoneal carcinomatosis, small bowel resection, colo-vesical fistula, colostomy and bilateral nephrostomy tubes was hospitalized for severe symptomatic anemia, fever and AKI. A week prior to hospitalization, patient had received her third outpatient dose of gemcitabine. Four weeks prior to presentation, serum creatinine (Scr) was 0.77. On admission labs, Scr was elevated at 7.36 and hemoglobin was low at 4.8. Patient also tested positive for COVID-19 on admission labs. There was no evidence of hydrenephrosis on CT scan. Patient found to have clinical and labs findings of TMA (hypertension, thrombocytopenia, elevated lactate dehydrogenase and low haptoglobin) during hospital stay. Peripheral smear showed multiple schistocytes. Urinalysis was significant for microscopic hematuria and proteinuria. Spot urine total protein to creatinine ratio was 4.6. Complement C3 and C4 were not low. Patient was Coombs IgG positive and was initiated on high dose intravenous corticosteroids. Our patient also received one dose of rituximab therapy as per inpatient oncology team. Patient was initiated on hemodialysis for uremic symptoms. Kidney biopsy subsequently performed during hospital stay showed acute TMA and acute tubular injury with focal tubular necrosis.

Discussion: Our patient developed severe AKI in the setting of gemcitabine chemotherapy use and COVID-19. Kidney biopsy showed findings of both TMA and ATN. While the kidney biopsy findings are very interesting, it is unknown if either gemcitabine or COVID-19 or both were responsible for the severe AKI seen in our patient. Our patient remains oliguric and dialysis dependent.
Acute peritoneal dialysis (PD) remains a feasible RRT modality in patients on mechanical ventilations, making it a backup plan for fear of increasing intravascular pressures with PD and with dwellings due to altered respiratory mechanics. Our case demonstrates that acute PD has no adverse respiratory outcomes in a COVID-19 patient.

**Case Description:** A 42-year-old Hispanic male with end stage renal disease newly initiated on urgent start PD for 1 week (PD with acute hypoxemic respiratory failure secondary to ARDS from COVID-19). Upon presentation, he was intubated and initiated on lung protective ventilator strategies. Due to high ventilatory requirements (PEEP 15, FiO2 100%) with severe volume overload HD was selected in lieu of PD. He underwent 24 hours with no regain of his volume status and due to high daily intake. Due to limited availability of CRRT, he was transitioned to acute PD via cyclic (fill volume 2L, every 4hr). FiO2 reduced to 40%, peak and plateau pressures did not change, and he was able to maintain adequate ventilation with unchanged tidal volumes while on PD. He eventually received tracheostomy.

**Discussion:** COVID-19 has challenged providers with managing critically ill patients in the setting of limited resources. In our case of ARDS with ARF, we transitioned from HD to acute PD in order to facilitate fluid removal in lieu of CRRT. The ICU team feared increased IAP from PD would worsen lung compliance and hypoxemia from atelectasis. A prospective study by Almeida et al showed that acute PD in mechanically ventilated patients was associated with increased IAP, but lung compliance, oxygenation, and PatO2/FiO2 increased. Our case noted similar observations without adverse event. Acute PD was able to meet the demands on his daily intake without any compromise to ARDS lung protective ventilator strategies.

**Methemoglobinemia and AKI in Patients with COVID-19: Don’t Forget About G6PD Deficiency**

Samnia Nafees, Rouvick Gama, David Makanjula, Virginia A. Quan.

**Introduction:** Patients with COVID-19 can be asymptomatic or have severe illness. Oxidative stress may be a cause of increased severity and mortality in COVID-19 patients. Methaemoglobinemia (MetHb) and haemolysis can occur as a result of oxidative stress. MetHb is associated with sepsis, exposure to drugs and inborn errors of metabolism. Glucose-6-phosphate dehydrogenase (G6PD) deficiency may also manifest with MetHb and haemolysis.

**Case Description:** A 31-year old man, originally from West Africa, with no comorbidities, presented with dyspnoea, cough, anemia and oligo-anuria. He had type 1 respiratory failure and stage 3 AKI, which led to critical care admission for intubation, ventilation and haemorrhagia. COVID-19 pneumonia was confirmed by nasopharyngeal swab and radiological imaging. He developed haemolytic anaemia. The MetHb was 3.5% (normal <1.5%). It rose to a peak of 10.7% with persisting anaemia and fever. The MetHb in this patient was found to be due to increased G6PD degradation and haemolysis due to a combination of oxidative stress and the genetic defect.

**Discussion:** Triggers of G6PD deficiency include stress from infections, fava beans, or drugs e.g. Hydroxychloroquine. It typically presents as haemolytic anaemia, jaundice and AKI. Although MetHb is linked to severe illness including sepsis, little is known about the pathophysiological processes in this continuum. Our report highlights the importance of considering alternative diagnoses of very high MetHb levels such as G6PD deficiency in COVID-19 patients. This is of particular relevance as Hydroxychloroquine has been used as experimental treatment for COVID-19 and in the current climate, G6PD deficiency is being encountered with AKI in patients with haemolytic anaemia and significantly elevated MetHb, particularly in those from regions of high prevalence and those treated with known triggers such as Hydroxychloroquine.
excessive immune response and cytokine storms which often seen in COVID-19 can promote to high catecholamine and rhabdomyolysis and therefore it will contribute to rapid worsening on renal function. Early detection and promptly supportive treatment with RRT may help to improve the vital prognosis of COVID-19.

**Case Description:**

A 41-year-old male with severe obesity and T2DM presented to Rush Medical Center in Chicago, IL. He developed COVID-19 pneumonia and presented with acute kidney injury (AKI) and severe hypertriglyceridemia (SHT). The patient was intubated on presentation due to hypoxemic respiratory failure and admitted to the ICU. The patient presented with normal kidney function but peri-intubation had a rapid rise in creatinine to 4.00 mg/dL and was started on CRRT. It was noted that the CRRT circuit was continuously clotted within 30 minutes of initiation. The patient was also noted to have rising CPK levels and a concern for rhabdomyolysis due to CRRT issues and inadequate clearance a decision was made to perform lipopheresis to rapidly correct SHT. The patient underwent lipopheresis and the triglycerides dropped to 426 mg/dL. The heparin drip was continued and filter life greatly improved. The patient was continued on CRRT and adequate clearance was achieved.

**Discussion:**

This case highlights the importance of CRRT in critically ill patients and is of particular importance with COVID-19. We present a patient with COVID-19 on propofol for sedation with persistent filter clotting issues found to have severe hypertriglyceridemia (SHT) corrected with lipopheresis. This case highlights the importance of managing all aspects of CRRT, the highly inflammatory state of COVID-19 and supply chain management during high utilization periods.

**PO0824**

**Severe Hypertriglyceridemia Leading to CRRT Malfunction in a COVID-19 Patient**

Rahul Parikh, Richard L. Barnett. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

**Introduction:** Continuous renal replacement therapy (CRRT) is a therapy used in critically ill patients and is of particular importance with COVID-19. We present a patient with COVID-19 on propofol for sedation with persistent filter clotting issues found to have severe hypertriglyceridemia (SHT) corrected with lipopheresis. This case highlights the importance of managing all aspects of CRRT, the highly inflammatory state of COVID-19 and supply chain management during high utilization periods.

**Case Description:** A 41-year-old male with severe obesity and T2DM presented to the hospital with shortness of breath and fevers found to have COVID-19. The patient was intubated on presentation due to hypoxemic respiratory failure and admitted to the ICU. The patient was placed on Propofol for sedation. The patient presented with normal kidney function but peri-intubation had a rapid rise in creatinine to 4.00 mg/dL and was started on CRRT. It was noted that the CRRT circuit was continuously clotted within 30 minutes of initiation. The patient was also noted to have rising CPK levels and a concern for rhabdomyolysis due to CRRT issues and inadequate clearance a decision was made to perform lipopheresis to rapidly correct SHT. Patient underwent lipopheresis and the triglycerides dropped to 426 mg/dL. The heparin drip was continued and filter life greatly improved. The patient was continued on CRRT and adequate clearance was achieved.

**Discussion:** This case highlights important points for CRRT, COVID-19 and supply chain management. This patient was found to have PRIS however COVID-19.

**PO0825**

**COVAN, COVID-Associated Nephropathy: An Evolving Epidemic of Kidney Disease**

Aneessa A. Shetty, Ibrahim Tawhari, Maria L. Safar-Boueri, Nay Seif, Ameen S. Alahmadi, Vikram Aggarwal, Richard Gargiulo, Yashpal S. Kanwar, Susan E. Quagggin. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Introduction:** We highlight COVID-19 related renal characteristics in 6 African American patients with positive nasopharyngeal RT-PCR for SARS-COV-2 infection, presenting without severe respiratory symptoms but with acute kidney injury and nephritic range proteinuria.

**Case Description:**

One of the patients was a transplant recipient. None required mechanical ventilation and no COVID-19 specific therapy was prescribed. All underwent a renal biopsy that showed varying combinations of collapsing glomerulopathy, podocytopathy and protein over load tubulopathy (Fig 1A). Additionally, tubulo-arteric inclusions and virions (suspected to be SARS-COV-2 virions) were seen in electron micrographs (Fig 1B). APOL1 genotype was tested in 3 patients who were all found to carry high-risk genotypes, suggesting possible susceptibility of patients with high-risk APOL1 alleles to kidney involvement in SARS-COV-2 (Fig 1C).

**Discussion:** There was discordance between the high risk G1/G1 genotype of the transplant recipient and the low risk G1/G0 donor kidney genotype, suggesting the important possibility of a systemic APOL1-related mechanism in kidney injury. In conclusion, these 6 cases draw attention to proteinuric kidney disease in COVID-19 infection, possibly associated with a milder form of respiratory disease and high risk APOL1 genotype, emphasizing the need for ongoing vigilance and further investigation into this phenomenon.
PO0827

Kevin S. Hsu, Rasha Alawieh, Khaled Boubes. The Ohio State University, Columbus, OH.

Introduction: Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). With the evolution of COVID-19 pandemic, elective procedures were placed on hold. The American Society of Diagnostic and Interventional Nephrology (ASDIN) and Vascular Access Society of the Americas (VASA) issued a joint position statement on March 24, 2020, designating dialysis vascular access procedures to be “essential.” We present a case with a series of complications that could have been prevented had the patient undergone a timely thrombectomy procedure.

Case Description: A 62 year old woman with ESKD undergoing hemodialysis through an upper arm arteriovenous fistula (AVF) presented with a thrombosed AVF in early March 2020 (before the ASDIN statement was issued). She was evaluated by the surgical team; however, due to restrictions to surgical procedures at the time, she did not undergo a thrombectomy and had a right internal jugular tunneled dialysis catheter (TDC) inserted instead. This was complicated by a superior vena cava thrombosis a few weeks later. The TDC was then removed and she had a right femoral TDC placed. She was started on anticoagulation. Her right femoral TDC was complicated by tunnel infection, necessitating its removal and subsequent placement of a left femoral TDC.

Discussion: This case illustrates the complexity of dialysis vascular access and some of the potential complications that are associated with it. It also highlights the importance of timely action to rescue any failed access. As outlined by the statement of ASDIN and VASA, dialysis vascular access should always be treated as a priority, and procedures to salvage it ought to be considered essential. This should also be the case in any future unforeseen restrictions to surgical procedures, such as pandemics or natural disasters.

PO0828

Does Cyclophosphamide Exposure in Patients with Vasculitides Lead to Better COVID-19 Outcomes?
Syed Mohammed Fauzaan M. Zabiullah,1,2 Arie Gunarso,1 Ashok P. Chandhari.1 Metropolitan Hospital Center, New York, NY; 2 New York Medical College, Valhalla, NY.

Introduction: COVID 19 is a pandemic disease caused by novel coronavirus (SARS-CoV-2). End Stage Renal Disease patients are at high risk for developing severe manifestations of the disease often associated with high morbidity and mortality. Excessive and uncontrolled immune response is thought to be one of the important underlying mechanisms for severity of the disease. We present 3 ESRD patients with underlying vasculitides who were admitted with respiratory distress due to COVID 19.

Case Description: All 3 patients presented with shortness of breath and had typical features of COVID 19 including hypoxia, fever; extensive bilateral interstitial infiltrates on Chest X rays, lymphocytopenia, elevated LDH; and ferritin. The first patient was a 37-year-old Hispanic male with ANCA-PR3 related vasculitis resulting in ESRD, on hemodialysis. He had been treated with Cyclophosphamide and prednisone induction therapy and is on maintenance prednisone. The second patient is a 40-year-old male with ESRD secondary to crescentic IgA nephropathy. He had been treated with cyclophosphamide and prednisone induction. The third patient is a 43-year-old female with SLE; ESRD secondary to lupus nephritis. She had been treated with cyclophosphamide and prednisone induction and is on maintenance prednisone. All 3 patients recovered in the hospital with oxygen supplementation and did not require NIV or intubation.

Discussion: We hypothesize that due to residual immunosuppressive action of cyclophosphamide, the inflammatory response in these patients was probably blunted. And this could have led to better outcome in these patients. Due to lots of unknowns related to COVID 19, further prospective/retrospective studies should be done looking at outcomes of COVID 19 in patients who had received cyclophosphamide previously.

PO0829

Renal Biopsy Findings in Patients with COVID-19 Infection
Tuvet Hong Tran, Ming Wu. NYU Langone Health, New York, NY.

Introduction: COVID-19 infection is caused by severe acute respiratory syndrome-2 (SARS-CoV-2). SARS-CoV-2, using its Spike protein, interacts with angiotensin converting enzyme-II (ACE2) protein expressed in human kidneys. Upon internalization, host cells may go through pyroptosis, a process characterized by membranous pore formation, cytokine storm and cell death. We report light microscopy (LM), immunofluorescence microscopy (IF), and electron microscopy (EM) findings in renal biopsies of patients with COVID-19 to further understand the pathological process.

Case Description: 10 patients were biopsied, age range 25-63 years. 7 were confirmed by a positive RT-PCR test, 3 were suspected, but PCR-negative. Common comorbidities include hypertension, hyperlipidemia, and obesity. Patients had AKI with creatinine range 1.2 to 13.48 mg/dL. Kidney ultrasound showed enlargement and increased echogenicity. Biopsies were performed 9 to 71 days from symptom onset of such as fever, cough, and diarrhea. Tissue was fixed in formalin and processed for LM. Fresh frozen tissue was utilized for IF. Tissue was fixed in paraffin/oxide and processed for EM. All had acute tubular injury and viral particles on EM (Figure). Patients received supportive care. None required ventilation, but 4 required hemodialysis. Survival rate is 100% (8-12 weeks).

Discussion: Renal biopsies were evaluated in 7 confirmed and 3 suspected COVID-19 patients. Although PCR is the gold standard, it is known to have a 15% false negative rate. This may be due to low viral loads and antibody testing may be warranted in suspected PCR-negative patients. Coronavirus particles are reported to measure 50-200 nm, and SARS-CoV-2 50-140 nm. Viral particles were seen in all 10 patients. The particles are contained in vesicles or sags, and can be found in podocytes, endothelial, and tubular epithelial cells. This may contribute to intrinsic injury resulting in AKI seen in patients.

Serum Induces Major Transcriptional and Epigenetic Changes at COVID-19-Associated Gene Loci in Primary Renal Epithelial Cells

Kevin Lidberg, Selvaraj Muthusamy, Mohamed Adil, Jonathan Reichel, Jonathan Himmelfarb, Edward J. Kelly, Shreeram Akiles. University of Washington, Seattle, WA.

Background: Tubular epithelial cells express high levels of COVID-19 entry receptors ACE2 and the accessory protease TMPRSS2. High systemic levels of IL-6 and IL-8 may contribute to the “cytokine storm” associated with poor outcome with COVID-19 infection. We sought to understand the regulation of these key genes in a 3D microphysiological system (MPS) containing primary human tubular epithelial cells, to understand whether there is kidney histological data that KIM-1 may also serve as a receptor for SARS-CoV-2- virosomes suggests that KIM-1 confers efficient SARS-CoV-2 binding in kidney epithelial cells when these cells are expressing KIM-1. The KIM-1 dependent viromere uptake by 3D tubuloids indicates that this can be a valuable human kidney model for studying SARS-CoV-2 interactions and testing for inhibitors. KIM-1 inhibitors, such as JB-1, can be potential therapeutics SARS-CoV-2 for COVID-19. Kidney tubular intraluminal and systemic circulating levels of KIM-1 ectodomain may be protective by acting as decoy receptor for the virus.

Morphological Evidence Suggests That Kidney Injury Molecule 1 May Serve as a Proximal Tubule Receptor for SARS-CoV-2

Ping L. Zhang,1 Mustafa M. Desai,2 Joseph Fuller,3 Takaharu Ichimura,2 Mitul A. Amin,1 Joseph V. Bonventre2 Beaumont Health System, Royal Oak, MI; 1Brigham and Women’s Hospital, Boston, MA.

Background: Kidney injury molecule-1 (KIM-1), a type-I transmembrane glycoprotein, has been well studied as a specific injury marker for proximal tubules (PT). KIM-1 functions as a receptor for apoptotic fragments through a phagocytic process. KIM-1 (also called TIM-1) serves as a receptor for hepatitis A virus and Ebola virus, and possibly for severe respiratory syndrome-coronavirus (SARS-CoV-1). During the pandemic spread of coronavirus disease 2019 (COVID-19), many patients have suffered from acute kidney injury (AKI) as well as lung damage, Viral uptake has been attributed to interactions with ACE2, a receptor for the virus. The goal of this study was to investigate whether there is kidney histological data that KIM-1 may also serve as a receptor for SARS-CoV-2 to infect the PT.

Methods: Two patients (one adult and one child) who died of COVID-19 and 10 patients with AKI but no COVID19 (control group) were included in the study. All kidney tissue sections were stained for KIM-1 (monoclonal AKG7 antibody) and scored from 0 to 3. Electron microscopy was conducted using kidney tissue of the COVID19+ patients.

Results: Both COVID19+ patients had normal pre-mortem levels of serum creatinine (sCr) adult 0.63 and child 0.17 mg/dl, whereas the control cases all had elevated sCr (1.9 to 9.7 mg/dl). Control renal biopsies revealed positive KIM-1 staining ranging from 1+ to 3+ along the surface of PT in a patchy pattern involving 20% to 80% of the cortex; no cytoplasmic granular materials were identified. By contrast, the KIM-1 staining in COVID19+ kidneys revealed spoty granular staining in the cytoplasm and diffuse positive staining of the tubular lumina. The KIM-1 staining remained intense in the two COVID19+ patients, SARS-CoV-2 particles showed spiking-crown appearances with sizes ranging from 70 to 110 nm in the PT cytoplasm by ultrastructural studies.

Conclusions: Our initial evidence suggests there is an atypical staining pattern of KIM-1 in the PT of COVID19+ patients, raising a possibility that KIM-1 may serve as a receptor for SARS-CoV-2. KIM-1 may also serve to internalize the virus into the PT. In addition the two COVID19+ patients had normal sCr levels but positive KIM-1 staining, indicating that sCr overestimates renal injury caused by SARS-CoV-2 infection.

PO0834

Kidney and Lung ACE2 Expression After an ACE Inhibitor or an Angiotensin II Receptor Blocker: Implications for COVID-19

Enrique Lores,1 Jan Wysocki,2 Minghao Ye,3 Maria Jose Soler,2 Daniel Battle,1 Northwestern University Feinberg School of Medicine, Chicago, IL; 1Universitari Vall d’Hebron, Hospital Vall d’Hebron, Barcelona, Spain.

Background: There have been concerns that ACE inhibitors and Ang II receptor blockers may cause an increase in full length (FL) membrane bound ACE2, the main receptor for SARS-CoV-2, that could enhance the risk and worsen the clinical course of COVID-19. Information on the impact of ACE deficiency and AT1 blockade on ACE expression at target sites is required to understand this issue. To investigate whether ACE2 expression in COVID-19 kidneys from two genetic models of ACE deficiency and in mice treated with captopril or telmisartan were used to examine ACE2 in isolated kidney and lung membranes.

Methods: In global ACE KO mice and Ang II receptor blockers may cause an increase in full length (FL) membrane bound ACE2, the main receptor for SARS-CoV-2, that could enhance the risk and worsen the clinical course of COVID-19. Information on the impact of ACE deficiency and AT1 blockade on ACE expression at target sites is required to understand this issue. To investigate whether ACE2 expression in COVID-19 kidneys from two genetic models of ACE deficiency and in mice treated with captopril or telmisartan were used to examine ACE2 in isolated kidney and lung membranes.

Results: In global ACE KO mice, ACE2 protein abundance in kidney membranes was reduced to 42 % of wild type, p < 0.05. In ACE/8 mice that over-express cardiac ACE protein but has no kidney ACE expression, ACE2 protein in kidney membranes was reduced to 72 % of wild type, p < 0.05. In ACE/8 mice that over-express cardiac ACE protein but has no kidney ACE expression, ACE2 protein in kidney membranes was reduced to 72 % of wild type, p < 0.05.
also decreased (38% of the WT, p<0.01). In kidney membranes from mice that received captopril or telmisartan for 2 weeks there was a reduction in ACE2 protein to the level of 37%, p<0.01 and 76%, p<0.05 of that of vehicle control mice, respectively. In lung membranes the expression of ACE2 was very low and not detected by western blotting but no significant differences in terms of ACE2 activity could be detected in mice treated with captopril (115% of control) or telmisartan (93% of control).

Conclusions: Genetic kidney ACE deficiency, suppressed ACE2 enzyme activity by Captopril or blockage of the AT1 receptor with telmisartan are all associated with a decrease in ACE2 expression in kidney membranes. These findings altogether suggest that ACE2 protein abundance at two potential target sites for SARS-CoV-2 infection is decreased or unaffected by RAS blockers. Since these medications do not increase ACE2 expression in lung or kidney epithelia, we conclude that they likely would not pose a risk for increased susceptibility to COVID-19.

PO0835
Noninvasive Mapping of the Cellular Response to COVID-19 via Urine Single-Cell RNA Sequencing (scRNAseq)
Jennifer A. Schaub, Ryann Sohaney, Abhijit S. Naik, Rajasree Menon, Edgar A. Otto, Laura H. Mariani, Celine C. Berthier, Matthias Kretzler, University of Michigan Health System, Ann Arbor, MI.

Background: COVID-19 is associated with a high incidence of AKI. Mapping the transcriptional profiles of kidney and urinary track derived single cell populations can establish a framework to assess renal molecular response to COVID-19 and emerging treatment strategies.

Methods: Patients throughout the COVID-19 disease course were recruited to the study. A modification of the protocol (Arazzi et al. Nat Immunol) allowed for immediate isolation of urinary cell pellets followed by 10X Genomics Chromium based scRNAseq. Results: Urine scRNAseq data sets were generated from 13 COVID patients: age 50±17; 7 males; 7 African Americans; urine sampling 11 days post SARS-CoV-2 diagnosis (IQR 5-29) with 8 in AKI at time of sampling. 25,994 single cell profiles passed QC with a median of 433 cells per sample [IQR 271 to 718]. Cellular clusters were annotated to immune (9780 cells, Fig: cluster 3.-7.), renal epithelial (4364, cluster 1.) and bladder cells (4151, cluster 2.). The SARS-CoV-2 receptor ACE2 was found in epithelial cells and co-expressed with CD45. The COVID-19 therapeutic target IL-6 was robustly detected in both myeloid and epithelial cells with co-expression networks linking IL-6 expression in proximal tubular epithelial cells to HMGB1, VEGF and HIF signaling and to viral response networks in myeloid cells.

Conclusions: Urine derived single cells contain a spectrum of epithelial and immune cells expressing viral receptors of SARS-CoV-2 and therapeutic targets of emerging COVID-19 therapies offering a window to monitor renal cellular responses in COVID-19 trials.

PO0836
Stimulus and Cell-Specific Responses to Volume Depletion, Ischemia, and COVID-19
Katherine Xu, Tian Shen, Jacob Stauber, Krzysztof Kiylik, Vivette D. A’Agati, Jonathan M. Barasch. Columbia University Irving Medical Center, New York, NY.

Background: A stimulus-response map of the injured kidney might reflect a common stereotyped “final common pathway” or alternatively, a set of “stimulus-specific”, “cell-specific”, and “time-specific” read outs.

Methods: We expressed uracil phosphoribosyl transferase (Uprt) in specific segments of the kidney (Rosa-Uprf::Hoxb7Cre and Rosa-Uprf::Atapasev1hB6Cre) and identified nascent RNA by 4-thiouracil pulse labeling after initiating two clinically relevant injuries in utero. Thio-RNA was isolated from intact kidneys with thio-biotin beads. We examined human biopsies with RNAscope to confirm patterns of gene expression.

Results: Hierarchical clustering of z-score transformed normalized counts (padj)<0.05 and log, fold changes ≥3 demonstrated that 3180 genes distinguished volume depletion from arterial ischemia in Hoxb7Cre purified genes and 1405 genes in AtapaseCre purified genes, respectively. The vast majority of these stimulus specific genes (96% ischemia and 83% volume depletion) constituted cell specific responses as well (exclusive to Hoxb7Cre or AtapaseCre purified RNA). Pathway analyses demonstrated immune regulation complement and the coagulation pathways in ischemic disease, whereas volume depletion activated inhibitors of inflammatory pathways and metabolic Foxo signaling, clock genes, and lipid metabolism. Timed evaluation demonstrated distinct early and late responses. To confirm the unique responses to clinical injury, we examined the renal etiologic mouse genes responding to ischemia, Lcn2 (NGAL) and Haurc1 (KIM1) in human ATN kidneys (associated with NSAIA, 1, hypotension, 1, DGF, 1, neprectomy, 2, COVID-19 8, unknown etiology 1), together with segment specific anchor genes (Lrp2, ApoP2). Lcn2 and Haurc1 expression was cell specific (Haurc1: tubule, effete 2, Lcn2: Limboid and proximal tubule 1). Overall, Haurc1 was found in the majority of biopsies. Lcn2 and Haurc1 overlapped in the proximal tubule in a minority of severely affected kidneys.

Conclusions: KIDGO criteria for AKI imply that any elevation of serum creatinine needs referral to the nephrologist. Yet, without resorting to destructive methods of dissection or cell isolation, we identify snapshots of genes induced by different stimuli, expressed by different cells, specific in timing, constituting different sets of unrelated molecular responses.

PO9008
AKI and Collaborating Glomerulopathy Associated with COVID-19 and APOL1 High-Risk Genotype
Juan Carlos Q. Velazquez,1,3 Christopher P. Larsen,2 Huijuan Wu,1 Tiffany Caza,2 Cesar F. Hernandez-Arroyo,1 Muner Mohammad,3 Asim Chugh,1,4 Moh’d Sharshir,4 Liping Xie,7 Ellen Achampong,7 Ivy Rosales,7 Robert B. Colvin,2,5 Agnes B. Fogo,1 Ochsner Nephrology - Arkana - Vanderbilt 1Department of Nephrology, Ochsner Health System, New Orleans, LA; 2Arkana Laboratories, Little Rock, AR; 3Department of Pathology, Microbiology and Immunology, Vanderbilt University Medical Center, Nashville, TN; 4Division of Nephrology, Tulane University School of Medicine, New Orleans, LA; 5Department of Pathology, Massachusetts General Hospital, Boston, MA; 6Northwest Indiana Nephrology, Munster, IN; 7Ascension All Saints Hospital - Spring Street Campus, Racine, WI; Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.

Background: Acute kidney injury (AKI), with or without proteinuria, has been described in patients with Coronavirus disease 2019 (COVID-19). Kidney involvement in COVID-19 has been reported to be of greater severity in African Americans (AA). Here, we report genetic, histopathological and molecular findings in 6 AA patients with COVID-19 presenting with AKI and de novo nephrotic-range proteinuria.

Methods: Percutaneous kidney biopsies were performed in 6 patients with COVID-19 with respiratory manifestations and proteinuric AKI. Peripheral blood was obtained for APOL1 G1 (APOL1) risk allele assessment. Kidney tissue was also examined by in situ hybridization (ISH) for viral detection and by NanoString for COVID-19 associated genes and genes related to tubular injury.

Results: Six AA patients with COVID-19 (4 men, 2 women), mean age 55 years (37-65) were included in the series. At biopsy day, the mean serum creatinine was 6.5 mg/dL (2.9 – 11.4) and the mean urine protein to creatinine ratio was 11.5 g (3.6 – 25.0). Kidney biopsy specimen showed collapsing glomerulopathy, extensive foot process effacement, microcytsotic tubular dilatation and focal or diffuse acute tubular injury. Three patients had reticular endothelial aggregates. No viral particles were identified. ISH and NanoString showed absence of SARS-CoV-2 RNA. NanoString analysis showed genes related to acute tubular injury and an increase in chemkine gene expression. All 6 patients tested positive for 2 APOL1 risk alleles. Two patients died, 1 remained dialysis dependent, 2 partially recovered after transient need for dialysis and 1 partially recovered without dialysis findings.

Conclusions: Collapsing glomerulopathy in AA patients with COVID-19 was associated with high risk variants of APOL1. Direct viral infection in the kidneys was not observed, suggesting a possible “two-hit” phenomenon of genetic predisposition and cytokine-mediated host response to infection. Given the resemblance with HBV-associated nephropathy, we propose the term COVID-19-associated nephropathy (COVAN) to this new entity.

Funding: NIDDK Support

PO0838
Purva D. Sharma, Hitesh H. Shah, Kenar D. Jhaveri, Vanesa Bijol. On behalf of the Northwell Renal COVID 19 Consortium Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

Background: Acute kidney injury (AKI) has been recognized as a common complication of severe COVID-19 in hospitalized patients. Proteinuria and microscopic hematuria has also been observed. While a recent autopsy series of patients who died with severe COVID-19 in China found acute tubular necrosis (ATN) in the kidney, few case reports of collapsing glomerulopathy in COVID-19 have also been reported.

Methods: To better understand the clinical and histopathologic findings, we looked at 10 kidney biopsy cases in patients with COVID-19 along with clinical features of AKI with or without proteinuria or hematuria in our institution. We described their clinical features, pathologic findings and outcomes.

Results: The mean age of the patients who underwent kidney biopsy was 65 years. Five patients were Caucasian, three patients were Hispanic, and two were African American. Nine patients had varying degree of proteinuria. Eight patients had severe renal dysfunction, with or without proteinuria, meeting KDIGO criteria for AKI. Five patients had varying degree of proteinuria. Eight patients had severe renal dysfunction, with or without proteinuria, meeting KDIGO criteria for AKI.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
AKI necessitating renal replacement therapy. On kidney biopsy, all patients had varying degrees of ATN, with one patient having associated widespread myoglobin casts. In addition, two patients had findings of thrombotic microangiopathy (TMA), one patient had pauci-immune crescentic glomerulonephritis and another patient had global as well as segmental glomerulosclerosis with features of healed collapsing glomerulopathy. Importantly, all patients had negative immunohistochemistry staining for SARS-CoV-2 on their kidney biopsy material.

**Conclusions:** This biopsy series reveals ATN as the most common kidney biopsy finding with AKI in COVID-19 infection with no evidence of significant viral presence in the kidney tissue.

PO0839
Kidney Pathology Findings in Patients Dying with COVID-19
Meghan E. Kang,1 Jose E. Najul,2 Michael H. Hines,2 Brian P. Strollo,2 Jonathan L. Babin,3 Paiot Paueksakon,4 Mark鲈so,5 Agnes B. Fogo,1 Juan Carlos Q. Velez,6 1Vanderbilt University Medical Center, Nashville, TN; 2Ochsner Health System, New Orleans, LA.

**Background:** The global pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) leading to coronavirus disease 2019 (COVID-19) has predominantly resulted in a profound hypoxic respiratory disease with a significant subset of patients demonstrating fulminant multisystemic injury is unknown and our understanding of the pathologic findings is limited.

**Methods:** Kidney tissue from nine patients who died with COVID-19 was obtained at autopsy and evaluated by light, immunofluorescence, and electron microscopy. RNAscope technology was used to perform RNA in situ hybridization (RNA ISH) with probes to the SARS-CoV-2 virus (sense) and for human gene expression. RNAScope technology was used to perform RNA in situ hybridization (RNA ISH) with probes to the SARS-CoV-2 virus (sense) and for human gene expression. This was a retrospective case series of autopsy cases with confirmed SARSCoV-2 infection performed at the Mount Sinai Hospital in patients who died between 3/21/2020 to 4/23/2020. Patients who had a kidney transplant, were on dialysis, or if severe autolysis was present, or had no clinical data were excluded. To identify SARS-CoV-2, sections were examined by Transmission Electron Microscopy (TEM) and by In Situ Hybridization (RNAscope) in kidney sections.

**Results:** 32 patients had autopsies done, of which 17 patients fulfilled our inclusion criteria. The median age was 64 (interquartile range (IQR) 50, 79), 70% were male, 18% were black, 42% had diabetes and 59% had hypertension. Of the 17 patients, clinical evidence of AKI was present in 12 (71%) patients; 4/12 (33%) had Stage 1 AKI, 6/12 (50%) had Stage 2 AKI, and 2/12 (17%) had stage 3 AKI. Median peak creatinine was 0.86 mg/dL IQR 0.92-1.23 in those without AKI and 2.98 mg/dL IQR 2.11 – 5.99 in those with AKI. 3 patients had urine studies performed, only one of them had AKI and had hematuria, proteinuria, and leukocyturia. On histopathology, 9/17 (53%) had acute tubular injury (ATI) only (Fig 1A & B) and 1/17 (5%) had TMA and ATI (Fig 1C). ATI was present in 4/5 (80%) of patients without AKI. There was no TMA found in patients without AKI. Glomerular pathology included nodular sclerosis in diabetic nephropathy (Fig 1D) and glomerulosclerosis secondary to ischemic hypertension. Virus was found in 4 samples (Fig 1E & F).

**Conclusions:** There is direct involvement of kidney by SARS-CoV-2 supported by identification of viral particles by TEM, and by ISH RNAscope. The most common histopathologic finding in patients that died with COVID-19 was ATI, which was also present in patients who did not have AKI by serum creatinine criteria.
COVID-19: Clinical and Basic Science Characteristics
Poster

Diabetic kidney disease in 2. No immune deposits were localized by IS. By EM, varied glomerular changes were observed, including mild to moderate increase in the GFR (7), total foot process effacement (7), with hyperplastic and vacuolated epithelial cells having protein droplets are noted. The endothelial cells are variably swollen, with tubulo-reticular inclusions in 2. Viral particles are identified within cells of glomeruli and tubulo-interstitial, scattered or in clusters in the cytoplasm and endoplasmic reticulum vesicles, confirmed by IS.

Conclusions: The constellation of typical glomerular collapsing features with tubulo-interstitial findings and localization of virus by EM, suggests a distinct viral associated nephropathy, reminiscent of HIV associated nephropathy. A role for viral cytopathic effect, cytokines and altering APC gene variants could be considered.

COVID-19 Renal Pathology Protocols and Pathology Practice in Latin America: Analysis from GlomCon Latin America Working Group

Blanca Martinez-Chajoula, Denisse Arellano-Mendez, Diana Aguirre, Desiree Garcia Antônio, Julio A. Gutierrez-Prieto, Sonia Rodriguez Ramirez, Javier Soto-Vargas, Franco H. Cabeza Rivero, Carmen Avila-Casadó.

GlomCon Latin America Working Group

Background: A significant fraction of patients with COVID-19 display renal involvement (60%); however, the histological findings and pathology practice in Latin America (LA) have not been reported. The aim is to know how COVID-19 pandemic has affected the protocols for renal pathology and the main pathology findings in the kidney.

Methods: An online survey with 7 sections in 6 questions was distributed to pathologists, nephrologists, and other specialists from 16 Spanish speaking LA countries treating COVID-19 patients with kidney involvement. We are analyzing the impact of COVID-19 in renal pathology and pathology practice in LA.

Results: From 430 responses, 360 (84%) were considered for analysis. Only 13 participating from 16 LA countries were renal pathologists but the rest of responders also contributed to the response. Only 10% of the responders reported having renal biopsy protocols for COVID-19 patients. Acute kidney injury (AKI) (85%) was the most frequent indication for biopsies. 18 patients of the study had AKI (53%), 2 previously ESRD, and 5 required renal replacement therapy. Preserving Cr ranged from 0.7-9.6 mg/dl (mean 1.7). Renal pathology included diabetic nephropathy (14, 47%), with tubulointerstitial scarring ranging from <25% (60%), 25-50% (23%), to >50% (17%), and moderate (40%) or severe (40%) chronic vascular sclerosis. Other findings: obesity related glomerulosclerosis (2), atheroembolization (1), bilateral interstitial fibrosis (1), PIN/ARB (1), and thrombotic microangiopathy (2). No collapsing glomerulopathy was seen. Tubular atrophy prevents complete assessment of ATN. Platelet thrombi were seen by CD61 staining in 43% of cases involving <20% of glomeruli and peritubular capillaries. C3b 9 staining was positive in 2, 2-3 arteriolar in 67% and glomeruli in 20%, suggesting localized complement activation. By electron microscopy, viral particles were identified within cells of glomeruli and tubulo-interstitium.

Conclusions: Pathology in autopsy kidneys from 30 patients with COVID-19 display glomerulonephritic disease with co-morbidities in 60% associated with AKI or ESRD (59%). Despite varied tissue autolysis and the absence of significant proteinuria, the majority of AKI is presumed to be acute tubular injury due to ischemia and other causes. The viral particles in the renal glomerular and tubular cells may play a role in renal cytopathic injury.

RAAS Inhibition, Mortality, and Severity in COVID-19 Patients: A Systematic Review and Meta-Analysis

Mahmoud M. El-Damaty,1 Ahmed Daoud,1 Tibor Fulop,6 Maria Aurora C. Posadas,4 Michael Casey,1 Vinaya Rao,4 Karim M. Soliman;4 The University of Tennessee Health Science Center, Memphis, TN; University Hospitals of Birmingham, Birmingham, UK, Birmingham, United Kingdom; Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; Medical University of South Carolina, Charleston, SC; Ralph H. Johnson VA Medical Center, Charleston, SC, USA, Charleston, SC.

Background: The effect of angiotensin receptor blockers (ARBs) and angiotensin-converting enzyme inhibitors (ACEIs) on outcome and severity in COVID-19 patients has been postulated.

Methods: We performed a systematic review in different databases to identify studies and research work that assessed the association of ACEi/ARBs on the severity of illness and mortality in COVID-19 subjects. Inclusion criteria for our meta-analysis were all studies that included human subjects with COVID-19 infection, received rapamycin and severity of the disease, and described ACEi/ARB treatment. The data collected were the name of the first author, journal title, the country of the study, sample size, relative risk and confidence intervals for association of ACEi/ARB treatment and mortality and morbidity. We used the random-effects model for the meta-analysis and the funnel plot analysis to assess potential publication bias.

Results: Out of 4,702 records reviewed in different databases, 11 papers were included in our meta-analysis. Altogether, 8,643 patients were included in the final analysis. Random-effects model (REM) for the relationship between ACEi/ARB and disease and severity showed that ACEi/ARB are not related to disease severity (RR=0.90, CIR from 0.70 to 1.15). There was no evidence of heterogeneity with I-squared =53.5% and p=0.235. By applying Egger’s test, there was no evidence of small study bias with P=0.64. REM for the results of this meta-analysis. ACEi/ARB and survival showed that ACEi/ARB does not affect survival (relative risk [RR]=0.81, confidence interval ranges [CIR] from 0.53 to 1.23). There was no evidence of heterogeneity with I-squared =25.5% and p=0.235. By applying Egger’s test, there was no evidence of small study bias with P=0.64. REM for the results of this meta-analysis. ACEi/ARB and disease severity showed that ACEi/ARB are not related to disease severity (RR=0.90, CIR from 0.70 to 1.15). There was evidence of heterogeneity with I-squared =56.2% and p=0.01. By applying Egger’s test, there was no evidence of small studies effect with P=0.93.

Conclusion: Based on the results of this meta-analysis, ACEi/ARB are not associated with increased mortality or severity in COVID-19 subjects.
PO0846

The Use of ACE Inhibitors and ARBs in Patients Admitted for COVID-19

Background: Angiotensin converting enzyme (ACE) 2 receptor has been implicated as an entry point for severe acute respiratory syndrome coronavirus 2 (SARS-COV-2) causing pandemic coronavirus disease 2019 (COVID-19). Experts have postulated the potential benefits of using ACE/ARB to reduce the severity of acute lung injury and as the treatment of hypertension in COVID-19. However, there is limited data in showing the renal outcomes after the use of angiotensin converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) in COVID-19 patients.

Methods: This is a retrospective, single center study of 300 patients diagnosed with COVID-19 confirmed by real-time reverse transcription polymerase chain reaction. Four groups were divided based on ACE/ARB exposure. Group 1 (n=51 patients; 17%) were initiated on ACEIs/ARBs during hospitalization, group 2 (n=58 patients; 19%) were on ACEIs/ARBs at home and discontinued, group 3 (n=76 patients; 25%) were on ACEs/ARBS at home and continued during hospitalization and group 4 (n=116 patients; 38%) were never treated with ACEs/ARBs. The primary end points including the incidence of AKI using KDIGO definition, hyperkalemia, the necessity of dialysis and the secondary end points being the length of total hospital stays, the recovery rate, mortality rate were compared between group 1,2,3 with 4 using adjusted odd ratios (ORs).

Results: In group 1, the use of ACEI/ARB has 4 times higher risk of developing AKI than the control group 4 (P=0.001, 95% CI of 1.70-8.59) and is 4.6 times for stage 2 or above AKI (P=0.001; 95% CI of 1.8-11.5). OR for hyperkalemia is 5.7 (P=0.001, 95% CI of 2.09-15.5) and for hemodialysis is 3.7 (P=0.02, 95% CI of 1.2-11.2). Their mortality rate is increased 2.9 times (P=0.026, 95% CI of 1.23-7.44). In group 2, the incidence of AKI is 7.5 times higher (P<0.001, 95% CI of 3.3-17) and 3.5 times (P=0.001, 95% CI of 1.6-7.7) for stage 2 above AKI. OR for the initiation of hemodialysis and the mortality rate are not statistically significant after adjusted with variables. In group 3, no statistically significant data were found.

Conclusions: Our findings suggest that the initiation of ACE/ARB in COVID 19 patients have increased risk of AKI, hyperkalemia, necessity of dialysis and mortality rate.

Prospective Feasibility Study with the Use of Losartan in COVID-19
Jeanwoo Yoo, Olena Bolotova, Imran Chaudhri, Nisha Nataraj, Hasena Sahib, Farrukh M. Koraishy, Sahar Ahmad, Michelle E. Bloom, Sandeep K. Mallipattu. Stony Brook University Hospital, Stony Brook, NY.

Background: The risks of administering Angiotensin II Receptor Blockers for hypertension in hospitalized patients infected with SARS-CoV-2 remains debated. To date, there are no prospective studies evaluating outcomes with the use of ARBs in patients with hypertension and COVID 19.

Methods: We conducted a single-center prospective feasibility study to ascertain the safety and efficacy of losartan in patients with COVID-19 and HTN. Inclusion criteria are patients with age ≥18yr, PCR confirmed SARS-CoV-2, BP>130/80, and required supplemental oxygen.

Results: 250 patients were screened from April 22 to May 18, 2020, and 16 patients enrolled. Average time to enrollment was 5.5 days, with varying degrees of acuity. 6 patients were removed from the study (see Table 1). Eight patients completed the minimum 7 days of losartan while in the hospital 6/8 patients demonstrated no deterioration of SATO2/FiO2 ratio, SATO2/FiO2 compared on day 1 (201.1 ± 108.1) and day 7 (252.3 ± 148.4), and 2/8 patients improved to room air on day 7. Among all patients, inflammatory markers were not significantly changed from admission to peak values (Table 1).

Conclusions: This study has demonstrated that patients admitted with COVID 19 and hypertension who completed 7 days of Losartan showed no significant deterioration in oxygenation/worsening of inflammatory markers, thereby providing the rationale for a RCT with the use of losartan versus nonRAAS blockade in COVID-19.

Renin-Angiotensin-Aldosterone System Blocking Drugs in Patients with SARS-CoV-2: Systematic Review and Meta-Analysis
Chang Chu,1,2 Shufei Zeng,1,3 Ahmed A. Hasan,2,4 Carl-Friedrich Hocher,1 Bernhard K. Krämer,1 Berthold Hocher,1 ’ Charité – Universitätsmedizin Berlin, Berlin, Germany; 2Department of Nutritional Toxicology, Institute of Nutritional Science, University of Potsdam, Potsdam, Germany; 3Fifth Department of Medicine (Nephrology/Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Mannheim, Germany.

Background: COVID-19 patients requiring treatment with blockers of the renin-angiotensin-aldosterone system (RAAS) are at highest risk of developing pneumonia and dying. ACE2 is the functional receptor for SARS-CoV-2. Animal studies suggest that RAAS blocking agents might increase the expression of ACE2 and hence potentially increase the risk of SARS-CoV-2 infection.

Methods: We conducted a systematic review and meta-analysis of published studies on the association of RAAS blocking agents with lung disease related outcomes.

Results: The effect of ACE inhibitor treatment on the incidence of pneumonia in non-COVID-19 patients was analyzed in 25 studies (330,780 patients). ACE inhibitor use was associated with a 27% reduction of pneumonia risk (OR: 0.73, p<0.001). Pneumonia related death cases in ACE inhibitor treated non-COVID-19 patients were reduced by 27% (OR: 0.73, p=0.004). ARB treatment was analyzed in 10 studies (275,621 non-COVID-19 patients). The risk of pneumonia was not different between patients who did or did not use ARBs. Pooled result from 13 studies (27,704 COVID-19 patients) showed that COVID-19 related severe adverse clinical outcomes were not different between patients who did or did not use RAAS blocking agents (OR: 0.87, p=0.28).

Conclusions: Given the weak evidence coming from animal studies and the clear beneficial data of ACE inhibition in non-COVID-19 patients and the limited but promising data in COVID-19 patients, the use of RAAS blocking agents in patients with SARS-CoV-2 infection is justified. Further clinical studies analysing ARBs and ACE inhibitors separately in COVID-19 patients are needed.

Association of Prehospital RAAS Inhibitor Use with AKI and Death in a Cohort of Hospitalized COVID-19-Infected Patients
Ryan Mocerino, Emad Alahiri, Matthew K. Abramowitz, Ladan Goleetanesh. Montefiore Medical Center, Bronx, NY.

Background: The relationship of RAAS inhibitors (RAASi) and their purported role in increasing COVID-19 viral attachment and worse outcomes is controversial. In this study we examined the association of RAASi use with Acute Kidney Injury (AKI) and in-hospital death.

Methods: We assembled a cohort of all patients admitted to the 3 main Montefiore hospitals and diagnosed with COVID-19. RAASi use was defined by a prescription within 365 days prior to hospitalization. The association of RAASi use with COVID associated AKI incidence and mortality was evaluated using logistic regression models. Propensity score matching was then used to derive the odds ratio (OR) of AKI and death in those using RAASi compared with controls.

Results: Of 3345 hospitalized patients, 9.3% were prescribed a RAASi prior to hospitalization. Those prescribed RAASi were older (71.9 vs 63.6 years, p<0.001), more commonly Black or Hispanic (RAASi users 41.3% Black and 41.0% Hispanic vs non-RAASi 35.4% Black and 36.9% Hispanic) and had higher Charlson co-morbidity scores (median 4 (IQR 3-7) for RAASi users vs 2(1-3) for non-RAASi users). In unadjusted analysis, RAASi use was associated with a higher OR for AKI (OR 1.3295% CI 1.04-1.68)) and a higher OR for death (OR 1.53 (95% CI 1.18-1.98)). Multivariate adjustment for age, demographics, and clinical comorbidity attenuated associations of AKI and death towards the null (AKI: OR 1.00 (95% CI 0.76-1.31); Death: OR 0.92 (95% CI 0.86-1.24)). Similarly, in propensity score analysis there was no association between RAASi use and either AKI (OR 0.96 (95% CI 0.88-1.04)) or death (OR 0.96 (95% CI 0.89-1.05)).

Conclusions: RAASi use prior to hospitalization was not associated with AKI or in-hospital mortality in a cohort of patients hospitalized with COVID-19.

PO0850
Outcomes Associated with the Use of Angiotsin-Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers in Hospitalized Patients with SARS-CoV-2 Infection
Imran Chaudhri,1 Farrukh M. Kornishy,1 Olena Bolotova,1 Jeanwoon Yoo,1 Sandeep K. Mallipatii,12 Stony Brook University Hospital, Stony Brook, NY, 2Northport VA Medical Center, Northport, NY.

Background: SARS-CoV-2 uses the angiotensin converting enzyme (ACE) receptor for cell entry leading to COVID-19. The use of ACE Inhibitors (ACEIs) and Angiotensin II Receptor Blockers (ARBs) in hypertensive COVID-19 patients remains unclear. Since hypertension is a major comorbidity in COVID19, evaluating the efficacy versus adverse outcomes with the use of ACEI or ARB in patients with COVID-19 is essential.

Methods: In this retrospective single-center study, we analyzed electronic medical record data on 300 patients admitted with COVID-19 disease. Data collection included comorbidities, medications, vital signs, and laboratory values (on admission and during hospitalization). Outcomes included inflammatory burden (calculated using composite scores for multiple markers of inflammation), AKI, admission to the intensive care unit (ICU), need for mechanical ventilation, and mortality. For multivariate analyses, generalized linear model (continuous outcomes) and logistic regression (dichotomous outcomes) were used.

Results: Of the 300 patients, 80 patients (26.7%) had history of ACEI or ARB use prior to admission, with 61.3% (48/80) of these patients continuing the medications during hospitalization. Outpatient users of ACEI or ARB had a higher burden of comorbid disease and increased rates of admission and in-hospital AKI in the descriptive analysis, but not on multivariate analysis (after adjusting for multiple covariates). Continuation of ACEI or ARB in an inpatient was associated with lower peak C-reactive protein (CRP) levels, peak inflammation score, ICU admission and mortality in the univariate analysis. On multivariate analysis, continuation of these agents during hospitalization predicted lower ICU admissions (OR=0.25, 0.08-0.81, p=0.02), peak CRP (<6 ± 3.1 mg/dl, p=0.03) and peak inflammatory score (2.3 ± 1.1, p=0.04) as compared to their discontinuation.

Conclusions: In hospitalized patients with COVID-19, the use of ACEI or ARBs as an outpatient was not associated with adverse outcomes despite greater comorbid illness in users. The continued use of these medications during hospitalization was also not associated with adverse events, rather it predicted fewer ICU admissions and decreased inflammatory burden.

Glomerular Diseases and Immunosuppression Practices in Latin America During the COVID-19 Pandemic: Analysis from GlomCon Latin America Working Group (LGlomCon)
Julio A. Gutierrez-Prieto,A1 Franco H. Cabeza Rivera,B1 Sonia Rodriguez Ramirez,B2 Javier Soto-Vargas,B3 Denise Arellano-Mendez,B3 Desiree Garcia Anton,B1 Diana Aguirre,B1 Blanca Martinez-Chagolla,B1 Carmen Avila-Casado,B2 GlomCon Latin America Working GroupB1 Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; B2 Hospital General Regional 46, IMSS, Guadalajara, Mexico; B3 Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; B4 Hospital General de Morelia “Dr. Miguel Silva”, Morelia, Mexico; B5 Hospital General de Mexico, Mexico City, Mexico; B6 University of Michigan Medical Center, Jackson, MS; B7 Medstar-Organ Transplant Program, University Health Network, Toronto, ON, Canada; B8 Pathology Department, University Health Network, Toronto, ON, Canada.

Background: As COVID-19 spreads across the world, nephrologists are facing difficult decisions regarding the management of active glomerular diseases (GD). We aimed to report how COVID-19 pandemic may have changed the use of immunotherapies among nephrologists in Latin America (LA) for the treatment of glomerulopathies.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases among nephrologists in LA are already prescribing lower levels than usual and 6.7% continued the maintenance regimen. For patients already on maintenance immunosuppression, the same regimen was maintained by 74.2% of the respondents while 24.2% gave only a fraction of it and 21.7% deferred the induction treatment. For patients already on immunosuppression for GD treatment was not changed by 54.1% of the respondents. The participants were mainly nephrologists 276 (86%), renal pathologists 13 (4%) and physicians in training 11 (3%). 213 (59%) of the respondents treat patients in LA and 127 (38%) in the United States. The respondents were mainly from nephrologists 217 (68%), renal pathologists 11 (3%) and other health workers 50 (15%).

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. The participants were mainly nephrologists 276 (86%), renal pathologists and other health workers treating kidney diseases among nephrologists in LA are already prescribing lower levels than usual and 6.7% continued the maintenance regimen. For patients already on maintenance immunosuppression, the same regimen was maintained by 74.2% of the respondents, 24.3% decreased it and 1.5% suspended it completely. In case of relapse or flare, 53.6% used standard increase of immunosuppression, 39.7% increased it but at lower levels than usual and 6.7% continued the maintenance regimen. For patients already on immunosuppression diagnosed with COVID-19 infection, 42% would decrease immunosuppressive regimens for mild disease, 62.3% in case of moderate disease and 70.8% would consider completely discontinuing immunosuppression in case of severe disease.

Conclusions: Over 40% of the respondents in LA are already prescribing lower levels than recommended doses of immunosuppression for induction, relapses or flares as a preventive strategy in the context of COVID-19 pandemic. How this change in practice would affect the renal outcomes remains to be seen. The experiences in the treatment of GD in patients with concurrent COVID-19 infection remains limited.

Ramipril Decreases Lung and Kidney Angiotensin Converting Enzyme 2 (ACE2) in Diabetic Mice: Lessons for COVID-19 Infection
Ander Vergara,1,2 Conxita Jacobs Cach,2 Pamela Domínguez Báez,2 Mireia Molina Van den Bosch,2 Anna Giralt-López,2 Clara García-Carroy,1,2 Daniel Serrón,1,2 Maria Jose Soler,1,2 Nephrology Research Group 1Hospital Vall d’Hebron, Barcelona, Spain; 2Vall d’Hebron Institut de Recerca, Barcelona, Spain.

Background: ACE2 is a component of the renin-angiotensin system (RAS) that mainly degrades angiotensin II to angiotensin(1-7). It is expressed in renal tubular cells. Lung type 2 alveolar cells also express ACE2 where it acts as a receptor for SARS-CoV-2, which is responsible for the current coronavirus disease 2019 (COVID-19) pandemic. A controversy raised regarding the use of RAS blockers in COVID-19 patients despite its demonstrated efficacy in cardiovascular disease. We studied the effect of ramipril on ACE2 expression in experimental diabetes.

Methods: 12 weeks old diabetic db/db mice were given ramipril (8 mg/kg/day) or vehicle during 8 weeks. db/m mice were used as controls. ACE2 expression and enzymatic activity were studied in kidney, heart and lung.

Results: In non-treated db/db, ACE2 mRNA expression was increased in kidney (p<0.0001) and ramipril treatment reversed this effect. In heart, ACE2 expression decreased in db/db compared to db/m (p<0.028) and ramipril had no effect. We found no differences in lung. ACE2 enzymatic activity was increased 23% in kidney and 22% in lung of db/db mice when compared to db/m. Ramipril treatment decreased ACE2 activity 25% in the lung and 13% in the kidney when compared to untreated db/db. In the heart, ACE2 activity tended to decrease in db/db mice when compared to db/m, and increased with ramipril, but did not exceed the cardiac ACE2 activity of the db/m.

Conclusions: ACE2 is increased in the kidney and in the lung, and decreased in the heart of diabetic mice. Ramipril treatment restores ACE2. Our results suggest that diabetes and hypertension may per se be risk factors for COVID-19 and not the treatment with ACE inhibitors, which may exert a protective effect on COVID-19 infection.
